During and after the declaration of the state of emergency in the country, an extraordinary measure to stop the advance of the coronavirus (COVID-19), it was possible to verify the downward trend in air pollutants such as particulate matter smaller than 2.5  $\mu\text{m}$  diameter (PM 2.5), Lima. During the quarantine days, the environment had a respite and the improvement was evident, as demonstrated by the measurements taken by MINAM which indicated that the air quality in Lima reached the levels recommended by World Health Organization. In addition, there was a reduction in the average concentrations of other parameters, which meant a gradual improvement in air quality in the city, increased by the effect of the reduction in emissions due to the suppression of the flow of vehicles as a result of the mandatory social isolation.

Likewise, in the international context concerning air quality, there is evidence in research conducted in several countries, for example [3], analyzed the results of air quality monitoring and meteorological data recorded in Wuhan in the period from January to May 2020, finding that the Air Quality Index (AQI) reached 90.1% in January-April 2020 being significantly higher than the index recorded in 2017 of 71.9%, in 2018 of 70% and in 2019 of 72.5%, they also found that SO<sub>2</sub>, NO<sub>2</sub>, CO, PM<sub>10</sub> and PM<sub>2.5</sub> concentrations decreased by 6.95%, 38.23 %, 18.24%, 30.25% and 32.92% respectively from 2019 to 2020. Moreover [4], in Brazil, also evaluated the impact of the partial closure of activities such as shopping centers, restaurants, schools and universities on air quality in the state of São Paulo as a measure to stop the advance of COVID-19, for this they analyzed the monthly average concentrations of February, March and April from three air quality stations: Marginal Tietê, Marginal Pinheiros and Downtonwn from the period 2015-2019 for the registered in 2020, they observed significant reductions of NO up to 77.3%, NO<sub>2</sub> by up to 54.3%, CO by up to 64.8% and PM<sub>2.5</sub> by 29.8%.

For the development of the assessment, the Grey Clustering method, which is based on grey systems, specially, the Center-point Triangular Whitenization Weight Functions (CTWF) method and the Entropy weighting method, based on Shannon's entropy, to calculate objective weights for the evaluation criteria within the CTWF method, was used. In this sense, the objective of this study was to evaluate air quality using an artificial intelligence model based on the Grey

Clustering method and Shannon entropy in Lima, Peru before and during the period of total confinement due to the COVID-19 pandemic [5].

## II. MATERIALS AND METHODS

The impact of total confinement on air quality in the city of Metropolitan Lima was evaluated by analyzing the records of the monitoring stations of the National Meteorology and Hydrology Service (SENAMHI by its Spanish acronym) regarding the concentrations of PM10, PM2.5, NO2 and CO. from March 16 to June 30, 2021 (period of total confinement) and its similar in 2018 and 2019.

### A. Metropolitan Lima

Lima is the capital of Peru and the fifth most populous city in Latin America with a population of 9,485,405 people [5]. It is located on the shores of the Pacific Ocean on the Central Coast of Peru with an area of 2,819 km<sup>2</sup> as shown in Fig. 1.

Fig. 1. Geographical Location of Metropolitan Lima, Peru.

According to a study carried out by MINAM in 2014 on mortality and morbidity as a result of air pollution in Metropolitan Lima, 1220 cases of deaths associated with PM10 pollution were found, with respiratory diseases (468 cases) and cardiovascular diseases (165 cases) of higher incidence, being the vehicle fleet the main source of contamination characteristic of an old low-maintenance vehicle fleet [6] [7].

### B. Methodology

In this section, we describe the Grey Clustering method (GCM), which can be described as follows: first, suppose the area is set of  $m$  objects, a set of  $n$  criteria, and a set of  $s$  Grey classes, according to the sample value ( $i = 1, 2, \dots, m; j = 1, 2, \dots, n$ ). Then, the steps of the method can be developed with the following points according to different research.

#### Step 1: Determination of Center Points

The ranges of the criteria are divided into 4 Grey classes, and then their central points are  $\lambda_1, \lambda_2, \dots, \lambda_s$ , this is determined by the Air Quality Index (INCA).

#### Step 2: Dimension Removal

Dimension Removal of values of the Environmental Quality Index: For this second step we have the matrix "I" of

values of the Environmental Quality Index  $I = \{I_{ij}, i = 1, 2, 3, \dots, m; j = 1, 2, 3, \dots, n\}$ , in which "i" represents the central points of the air quality parameters: PM10 (ug / m<sup>3</sup>), PM 2.5 (ug / m<sup>3</sup>), NO<sub>2</sub> (ug / m<sup>3</sup>) and CO (ug / m<sup>3</sup>) and "j" are the quality levels according to INCA: Good, Moderate, Bad and Threshold of care. And we proceed to normalize said matrix into a new matrix "A<sub>ij</sub>", using (1).

$$A_{ij} = \left( \frac{I_{ij}}{\sum_{j=1}^n I_{ij}} \right) \quad (1)$$

Dimension Removal of Sampling data: In the same way as the dimension removal of standard data, it is performed for sampling data, whose matrix is  $M = \{M_{ij}, i = 1, 2, 3, \dots, m; j = 1, 2, 3, \dots, n\}$ , in which "i" represents the sampled air quality parameters and "j" are the sampling stations. Followed, we proceed to normalize the matrix M in a new matrix "B<sub>ij</sub>", using (2).

$$B_{ij} = \left( \frac{M_{ij}}{\sum_{j=1}^n M_{ij}} \right) \quad (2)$$

#### Step 3: Triangular Functions and their Values

The Grey classes are expanded according to the analyzed air quality parameters, this provides us with four quality levels for each parameter, so we will have 4 functions for each parameter or criterion used. These functions will have the form as shown in (3).

$$f_j^k(X_{ij}) \quad (3)$$

Then, we have the triangular functions as represented in (4) – (6).

$$f_j^2(X_{ij}) = \left\{ 0, x \notin [0, \lambda_j^2]; 1, x \in [0, \lambda_j^2]; \frac{\lambda_j^2 - x}{\lambda_j^2 - \lambda_j^1}, x \in [\lambda_j^1, \lambda_j^2] \right\} \quad (4)$$

$$f_j^k(X_{ij}) = \left\{ 0, x \notin [\lambda_j^{k-1}, \lambda_j^{k+1}]; \frac{\lambda_j^{k+2} - x}{\lambda_j^{k+1} - \lambda_j^k}, x \in [\lambda_j^k, \lambda_j^{k+1}]; \frac{x - \lambda_j^{k-1}}{\lambda_j^k - \lambda_j^{k-1}}, x \in [\lambda_j^{k-1}, \lambda_j^k] \right\} \quad (5)$$

$$f_j^4(X_{ij}) = \left\{ 0, x \notin [\lambda_j^3, +\infty]; \frac{x - \lambda_j^3}{\lambda_j^4 - \lambda_j^3}, x \in [\lambda_j^3, \lambda_j^4]; 1, x \in [\lambda_j^4, +\infty] \right\} \quad (6)$$

#### Step 4: Determination of the Weight for each Criteria

To eliminate the uncertainty regarding the calculation of the weight of the criteria, the Shannon entropy weighting method will be applied. Shannon developed measure H which satisfies the following properties for all  $p_i$  within an estimated joint probability distribution [7] [8].

- $H$  is a continuous positive function.
- $H$  should be a monotonic increasing function of  $n$  if all  $p_i$  is equivalent and  $p_i = 1/n$ .
- For all  $n \geq 2, H(p_1, p_2, \dots, p_n) = h(p_1, p_2, \dots, p_n) + (p_1 + p_2)H\left(\frac{p_1}{p_1+p_2}, \frac{p_2}{p_1+p_2}\right)$ .

Shannon showed that the only function which satisfies these properties is obtained by (7).

$$H_{Shannon} = -\sum_i^n p_i \log(p_i) \quad (7)$$

Where:  $0 \leq p_i \leq 1; \sum_{j=1}^n p_j = 1$ .

As shown above, it is assumed that there are  $m$  objects and  $n$  evaluation criteria, which form the following matrix  $X = \{x_{ij}, i = 1, 2, \dots, m; j = 1, 2, \dots, n\}$  [9]. After that, the steps to determine the weights under Shannon entropy are shown:

1) The matrix  $X = \{x_{ij}, i = 1, 2, \dots, m; j = 1, 2, \dots, n\}$  is normalized for each criterion  $C_j (j = 1, 2, \dots, n)$ . The normalization evaluates  $P_{ij}$  are calculated using (8).

$$f_j^1(x_{ij})P_{ij} = \frac{x_{ij}}{\sum_{i=1}^m x_{ij}} \quad (8)$$

2) The entropy of each criterion is calculated using (9).

$$H_j = -k \sum_{i=1}^m P_{ij} \ln(p_i) \quad (9)$$

Where  $k$  is a constant,  $k = (\ln(m))^{-1}$

3) The degree of divergence of the intrinsic information in each criterion  $C_j$  is calculated using (10).

$$div_j = 1 - H_j \quad (10)$$

4) In the weight entropy  $w_j$  of each criterion  $C_j$ , we have to use (11).

$$w_j = n_j = \frac{div_j}{\sum_{j=1}^n div_j} \quad (11)$$

Step 5: Determination of the Clustering coefficient

The classification coefficient "ik" for each sampling station "i = 1, 2, 3, ..., m", with respect to the grey classes "j = 1, 2, 3, ..., n", is calculated using (12).

$$\sigma_i^k = \sum_{j=1}^n f_j^k(X_{ij})n_j \quad (12)$$

Where the triangular function of each class of Grey with respect to each criterion is analyzed, while  $n_j$  are the weights of each criterion [9].

Step 6: Results using the highest Clustering coefficient

Finally, as the last step, the maximum value of the clustering coefficient is calculated [10]:

$$\max_{1 \leq k \leq s} \{\sigma_i^k\} = \sigma_i^k \quad (13)$$

In this way, it will be observed what kind of flock is found in each station studied.

### III. RESULTS AND DISCUSSION

#### A. Method Application

Step 1: Definition of Study Objects

Data from two air quality monitoring stations in Villa María del Triunfo and Carabayllo located south and north of Lima, respectively, were used; both stations managed by the National Meteorology and Hydrology Service (also known as

SENAMHI by its Spanish acronym) of Peru. The parameters analyzed were nitrogen dioxide (NO<sub>2</sub>), carbon monoxide (CO), particulate matter smaller than 10 μm in diameter (PM<sub>10</sub>) and smaller than 2.5 μm in diameter (PM<sub>2.5</sub>) during the period of mandatory social isolation, declared by the Peruvian State in the framework of the National Emergency because of the COVID-19 pandemic from March 16 to June 30, 2020 and what registered in the same period in 2018 and 2019. Table I details the location of the stations represented in Fig. 2.

TABLE I. AIR QUALITY MONITORING STATIONS IN METROPOLITAN LIMA

Station	Code	Coordinates (WGS84)		Sampling height
		East	North	
Villa Maria del Triunfo	VMT	291084	8654309	3m
Carabayllo	CAR	278498	8683451	6m

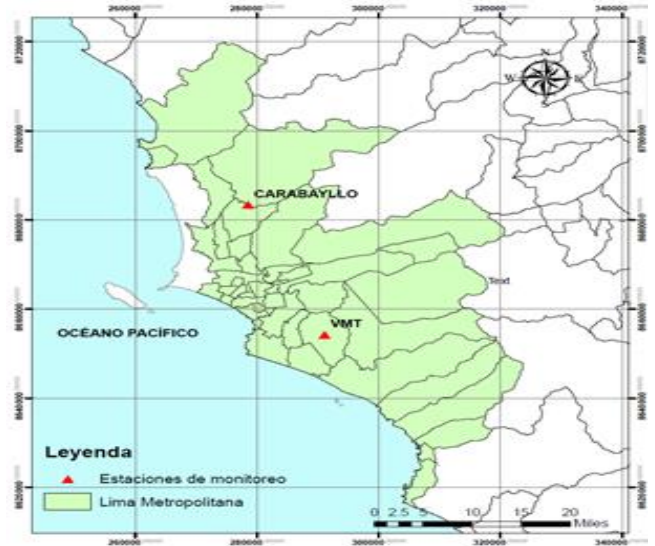

Fig. 2. Air Quality Monitoring Stations in Metropolitan Lima, Peru.

#### Step 2: Definition of Criteria

The evaluation criteria for the present study are determined by the air quality parameters presented in Table II.

TABLE II. CRITERIA FOR AIR QUALITY ASSESSMENT

Criteria	Units	Notation
PM <sub>10</sub>	ug/m <sup>3</sup>	C <sub>1</sub>
PM <sub>2.5</sub>	ug/m <sup>3</sup>	C <sub>2</sub>
NO <sub>2</sub>	ug/m <sup>3</sup>	C <sub>3</sub>
CO	ug/m <sup>3</sup>	C <sub>4</sub>

#### Step 3: Definition of the Grey classes

The classes for the evaluation are four and are based on the air quality levels according to the Air Quality index in Peru according to RM-N°-181-2016-MINAM and D.S. N° 003-2017-MINAM, which are presented in Table III.

TABLE III. AIR QUALITY INDEX STANDARD DATA FOR AIR QUALITY ASSESSMENT

Criteria	Grey Classes			
	Good	Moderate	Poor	Threshold of Care
PM <sub>10</sub>	0-50	51-100	101-200	>200
PM <sub>2.5</sub>	0-12.5	12.6-25	25.1-125	>125
NO <sub>2</sub>	0-100	101-200	201-300	>300
CO	0-5049	5050-10049	10050-15049	>15050

Step 4: Calculations using the CTWF Method

The calculations based on the Grey Clustering method are presented below:

1) Based on the air quality index in Peru, the central values of the parameters to be analysed are obtained. These values are shown in Table IV.

TABLE IV. CENTRAL VALUES OF THE AIR QUALITY INDEX IN PERU

Parameter	Good (λ <sub>1</sub> )	Moderate (λ <sub>2</sub> )	Poor (λ <sub>3</sub> )	Threshold of care (λ <sub>4</sub> )
PM <sub>10</sub>	37.5	113.0	200.5	288.0
PM <sub>2.5</sub>	6.3	18.8	75.0	131.3
NO <sub>2</sub>	50.0	150.5	250.5	350.5
CO	2524.5	7549.5	12549.5	17549.5

2) The non-dimensioned standard values for each parameter, according to the air quality index in Peru, were determined through (1). These values are presented in Table V.

TABLE V. NON-DIMENSIONAL STANDARD VALUE OF THE AIR QUALITY INDEX

Parameter	Good (λ <sub>1</sub> )	Moderate (λ <sub>2</sub> )	Poor (λ <sub>3</sub> )	Threshold of care (λ <sub>4</sub> )
C <sub>1</sub>	0.235	0.707	1.255	1.803
C <sub>2</sub>	0.108	0.325	1.297	2.270
C <sub>3</sub>	0.250	0.751	1.250	1.749
C <sub>4</sub>	0.251	0.752	1.250	1.747

Similarly, based on the results of the air quality monitoring stations in Metropolitan Lima, the values without dimension were obtained for each parameter of the 2 selected monitoring stations. These values are presented in Table VI.

TABLE VI. NON-DIMENSIONAL MONITORING DATA IN METROPOLITAN LIMA

Parameter	2018-2019 period		2020 period	
	VMT	CAR	VMT	CAR
C <sub>1</sub>	0.808	0.611	0.598	0.329
C <sub>2</sub>	0.487	0.428	0.353	0.235
C <sub>3</sub>	0.113	0.073	0.116	0.061
C <sub>4</sub>	0.082	0.117	0.066	0.105

Step 5: Triangular Whitenization Functions

With Table V, the triangular whitenization functions and the values for each parameter were determined as shown in Fig. 3.

Fig. 3. CTWF for the Parameter of Particles with a Diameter of Less than 10 μm Parameter (PM<sub>10</sub>).

Therefore, the expressions (14) – (17) were obtained.

$$f_1^1(x) = \begin{cases} 1, & x \in [0, 0.235] \\ \frac{0.707-x}{0.707-0.235} & x \in [0.235, 0.707] \\ 0 & x \in [0.707, \infty] \end{cases} \quad (14)$$

$$f_1^2(x) = \begin{cases} 0, & x \notin [0.235, 1.255] \\ \frac{x-0.235}{0.707-0.235} & x \in [0.235, 0.707] \\ \frac{1.255-x}{1.255-0.707} & x \in [0.707, 1.255] \end{cases} \quad (15)$$

$$f_1^3(x) = \begin{cases} 0, & x \notin [0.707, 1.803] \\ \frac{x-0.707}{1.255-0.707} & x \in [0.707, 1.255] \\ \frac{1.803-x}{1.803-1.255} & x \in [1.255, 1.803] \end{cases} \quad (16)$$

$$f_1^4(x) = \begin{cases} 1, & x \in [1.803, \infty] \\ \frac{x-1.255}{1.803-1.255} & x \in [1.255, 1.803] \\ 0 & x \in [0, 1.255] \end{cases} \quad (17)$$

Then, the values obtained for each period and location are displayed in Table VII and Table VIII.

TABLE VII. VALUES OF CTWF FOR VMT

Period of 2018-2019	f <sub>j(x)</sub> <sup>1</sup>	f <sub>j(x)</sub> <sup>2</sup>	f <sub>j(x)</sub> <sup>3</sup>	f <sub>j(x)</sub> <sup>4</sup>
C <sub>1</sub>	0.000	0.816	0.183	0.000
C <sub>2</sub>	0.000	0.833	0.167	0.000
C <sub>3</sub>	1.000	0.000	0.000	0.000
C <sub>4</sub>	1.000	0.000	0.000	0.000
Period of 2020	f <sub>j(x)</sub> <sup>1</sup>	f <sub>j(x)</sub> <sup>2</sup>	f <sub>j(x)</sub> <sup>3</sup>	f <sub>j(x)</sub> <sup>4</sup>
C <sub>1</sub>	0.232	0.768	0.000	0.000
C <sub>2</sub>	0.000	0.971	0.029	0.000
C <sub>3</sub>	1.000	0.000	0.000	0.000
C <sub>4</sub>	1.000	0.000	0.000	0.000

TABLE VIII. VALUES OF CTWF FOR CAR

Period of 2018-2019	$f_{j(x)}^1$	$f_{j(x)}^2$	$f_{j(x)}^3$	$f_{j(x)}^4$
$C_1$	0.203	0.797	0.000	0.000
$C_2$	0.000	0.894	0.106	0.000
$C_3$	1.000	0.000	0.000	0.000
$C_4$	1.000	0.000	0.000	0.000
Period of 2020	$f_{j(x)}^1$	$f_{j(x)}^2$	$f_{j(x)}^3$	$f_{j(x)}^4$
$C_1$	0.800	0.200	0.000	0.000
$C_2$	0.417	0.583	0.000	0.000
$C_3$	1.000	0.000	0.000	0.000
$C_4$	1.000	0.000	0.000	0.000

Step 6: Definition of the Clustering Weight

The clustering weight ( $\eta_i$ ) of each parameter was determined using Shannon entropy. For this, the following procedure:

1) The values of the parameters of the Air Quality index were normalized. These values are presented in Table IX.

TABLE IX. NORMALIZED VALUES OF EACH PARAMETER

Parameter	Good ( $\lambda_1$ )	Moderate ( $\lambda_2$ )	Poor ( $\lambda_3$ )	Threshold of care ( $\lambda_4$ )
$C_1$	0.059	0.177	0.314	0.451
$C_2$	0.027	0.081	0.324	0.568
$C_3$	0.063	0.188	0.313	0.437
$C_4$	0.063	0.188	0.313	0.437

2) The entropy  $H_j$  of each criterion  $C_j$  was calculated through (9). The results are presented in Table X.

TABLE X. VALUES FOR EACH PARAMETER

Entropy	$C_1$	$C_2$	$C_3$	$C_4$
$H_j$	0.863	0.713	0.875	0.875
Degree of divergence	$C_1$	$C_2$	$C_3$	$C_4$
$div_j$	0.137	0.287	0.125	0.125
Clustering Weight	$C_1$	$C_2$	$C_3$	$C_4$
$W_j = \eta_j$	0.204	0.426	0.186	0.185

Step 7: Definition of the Clustering Coefficients

The values of the clustering coefficients ( $\sigma_i^k$ ) were calculated using (12). Then, the results for each period and location are displayed in Table XI and Table XII.

TABLE XI. VALUES OF CLUSTERING COEFFICIENTS FOR VMT

Period of 2018-2019	$f_{j(x)}^1$	$f_{j(x)}^2$	$f_{j(x)}^3$	$f_{j(x)}^4$
$\sigma_j^k$	0.371	0.521	0.108	0.000
Period of 2020	$f_{j(x)}^1$	$f_{j(x)}^2$	$f_{j(x)}^3$	$f_{j(x)}^4$
$\sigma_j^k$	0.418	0.569	0.012	0.000

TABLE XII. VALUES OF CLUSTERING COEFFICIENTS FOR CAR

Period of 2018-2019	$f_{j(x)}^1$	$f_{j(x)}^2$	$f_{j(x)}^3$	$f_{j(x)}^4$
$\sigma_j^k$	0.412	0.543	0.045	0.000
Period of 2020	$f_{j(x)}^1$	$f_{j(x)}^2$	$f_{j(x)}^3$	$f_{j(x)}^4$
$\sigma_j^k$	0.711	0.289	0.000	0.000

Step 8: Definition of Maximum Clustering Coefficient

Finally, the condition was applied: if  $\max \{\sigma_i^k\} = \sigma_i^{k^*}$  it is decided that the object  $i$  belongs to the Grey class  $k^*$ ; for each monitoring station. Therefore, the maximum value obtained is presented in Table XIII.

TABLE XIII. VALUES OF MÁX  $\sigma_i^{k^*}$  AND AQI

Station	2018-2019 period		2020 period	
	Max $\sigma_j^k$	Air Quality Index	Max $\sigma_j^k$	Air Quality Index
VMT	0.521	Moderate	0.569	Moderate
CAR	0.543	Moderate	0.711	Good

B. Discussion about Results on the Case Study

On March 15, a state of emergency was decreed, making Peru the first country in South America to take strict measures to prevent an increase in positive cases of COVID 19. These measures include mandatory social isolation (through a national blockade) and a complete blockade of the border, starting on March 16. On March 18, a curfew was enacted to support mandatory social distancing measures because people did not adhere to lockdown restrictions, and the use of private vehicles was banned as of March 19. Despite all the health measures implemented, the number of confirmed cases in Peru exceeded 100,000 on May 20 [2]. The impact of the measures implemented during the state of emergency was to stop production activities, as reflected by electricity consumption [2].

The decrease in electricity demand reflects the freezing of production activities and possible sources of emissions of atmospheric pollutants. By June 30, 2020, air pollution in the two stations, in terms of PM10, PM2.5 and NO2 and CO2, had decreased (Table XIII), it is observed that there was an improvement in air quality in the station of CAR, being the index of good air quality, while in the VMT station it remains moderate. Likewise, compared to the historical period (the previous two years 2018-2019), it is show that the air quality index in the VMT and CAR stations is moderate [11].

Based on these results from the stations air quality it can be inferred that the northern part as well as the southern part of the territory of Metropolitan Lima has air quality problems, and with measures proposed by the state of emergency it has improved. This due to the fact that, as we can see in Fig. 4, the variation of the concentration of the four parameters during the years 2016 - 2020 for the period of March - June in CAR station, taking into account that the data from the years 2018 were used to perform the calculations of the study - 2019 (period without quarantine) and 2020 (period in quarantine), and show that during the years analyzed a reduction in concentration is observed for the four parameters. On the other hand, in the graph for the PM 2.5 parameter, no information is recorded for the year 2017, so only a trend line was drawn.

Followed, a summarize of the graphic representation is shown in Fig. 5 for a better understanding of the data obtained from the parameters studied in Carabayllo (CAR).

On the other hand, the variation of the concentration of the four parameters is shown in Fig. 6, during the years 2016 -

2020 for the months of March – June in VMT station, taking into account that the data from the years 2018 were used to perform the calculations of the study - 2019 (period without quarantine) and 2020 (period in quarantine). The values show that during the years analyzed a reduction in concentration is observed for the parameters of PM10, PM2.5 and CO, while NO2 shows an increase of around 2%, this can be explained because an average of the years 2018 - 2019, which present a considerable variation of the parameter.

Followed, a summarize of the graphic representation is shown in Fig. 7 for a better understanding of the data obtained from the parameters studied in Villa Maria del Triunfo (VMT).

The dispersion of pollutants in the atmosphere is subject to the meteorological and geographical conditions of the specific place for the city of Lima, the factors that influence the most is the atmospheric layer of thermal inversion and the action of the winds, the latter during March. In 2020, it presented a predominant direction from south to north of Lima with average daily velocity values of 2 to 4 m / s at a height of 10 m from the Surface [12], as shown in Fig. 8.

On the other hand, with respect to the atmospheric layer of thermal inversion, a lower height was evidenced in March 2020 in the southern area of Lima compared to the other areas. It is clear that in the VMT station the height is on average 300 m different from the Carabayllo station with a height above 400 m.

Fig. 6. Graphic Representation for the Four Parameters at Villa Maria del Triunfo (VMT).

Fig. 7. Graphic Representation Summarize for the Four Parameters at Villa Maria del Triunfo (VMT).

Fig. 4. Graphic Representation for the Four Parameters at Carabayllo (CAR).

Fig. 5. Graphic Representation Summarize for the Four Parameters at Carabayllo (CAR).

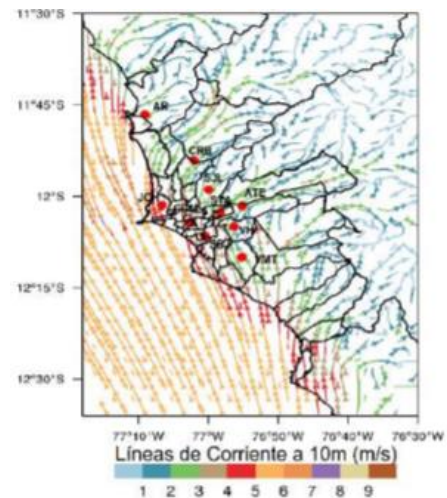

Fig. 8. Power Lines at 10m High during March 2020 in Lima.

Therefore, North Lima evidenced better dispersion conditions than South Lima during March 2020, based on the greater space available for the dispersion of pollutants (greater height of the planetary boundary layer) with respect to wind conditions; the conditions were similar in both areas, as shown in Fig. 9.

In this sense, the CAR station registered a more substantial improvement in air quality during the quarantine period compared to the VMT station because it is located in the north and south of Lima, respectively [13].

Fig. 9. Average Height of the Planetary Boundary Layer in Lima during March 2020.

### C. Discussion about the Methodology

Unlike the studies carried out in China and Brazil of air quality during the COVID-19 pandemic, the present work carried out a comprehensive methodology using the Grey Clustering method and the Shannon entropy for the same study.

The Grey Clustering method is the most appropriate in matters of high uncertainty [14], such as the evaluation of air quality, where each parameter varies according to environmental conditions.

On the other hand, the Shannon entropy method is very suitable for evaluating air quality after determining the grouping weights ( $\eta_j$ ) for each parameter objectively, without the need to consult an expert and that reduces evaluation costs. Furthermore, this method has multiple applications such as in studies of social conflicts or social impact evaluations [15], due to its great capacity to process information and reduce subjectivity in evaluations.

## IV. CONCLUSION

The air quality in Metropolitan Lima during the national closure in the framework of the state of emergency due to COVID-19 presented significant improvements compared to its similar in 2018-2019; specifically the north of Lima was also favored by the meteorological conditions. This allowed its classification as good quality, unlike the southern zone, which although it showed an improvement, the classification remains of moderate quality.

The Grey Clustering methodology made it possible to evaluate air quality in a comprehensive way based on the most relevant atmospheric pollutants in the study area, unlike conventional methodologies that evaluate individually with respect to each parameter, and also considers the uncertainty within the This analysis is therefore also applicable to problems with insufficient data, on the other hand, in reference to Shannon's entropy, it was possible to determine the weights

of the parameters in an objective manner, free of subjective assessments.

The work generates information of vital importance for future research on air quality using the Grey Clustering methodology as well as its integration into environmental regulatory bodies.

# Indonesia Sign Language Recognition using Convolutional Neural Network

Suci Dwijayanti\*, Hermawati, Sahirah Inas Taqiyyah, Hera Hikmarika, Bhakti Yudho Suprpto

Department of Electrical Engineering, Universitas Sriwijaya  
Indralaya, Indonesia

**Abstract**—In daily life, the deaf use sign language to communicate with others. However, the non-deaf experience difficulties in understanding this communication. To overcome this, sign recognition via human-machine interaction can be utilized. In Indonesia, the deaf use a specific language, referred to as Indonesia Sign Language (BISINDO). However, only a few studies have examined this language. Thus, this study proposes a deep learning approach, namely, a new convolutional neural network (CNN) to recognize BISINDO. There are 26 letters and 10 numbers to be recognized. A total of 39,455 data points were obtained from 10 respondents by considering the lighting and perspective of the person: specifically, bright and dim lightning, and from first and second-person perspectives. The architecture of the proposed network consisted of four convolutional layers, three pooling layers, and three fully connected layers. This model was tested against two common CNNs models, AlexNet and VGG-16. The results indicated that the proposed network is superior to a modified VGG-16, with a loss of 0.0201. The proposed network also had smaller number of parameters compared to a modified AlexNet, thereby reducing the computation time. Further, the model was tested using testing data with an accuracy of 98.3%, precision of 98.3%, recall of 98.4%, and F1-score of 99.3%. The proposed model could recognize BISINDO in both dim and bright lighting, as well as the signs from the first-and second-person perspectives.

**Keywords**—Indonesia sign language (BISINDO); recognition; CNN; lighting

## I. INTRODUCTION

Humans use language to communicate with others. However, a communication disorder may occur because of various factors that cause an impairment in understanding oral speech [1]. Such factors can arise from a hearing disorder or deafness. Thus, deaf people use sign language or hand gestures to communicate. However, most non-deaf people experience difficulties in understanding sign language. A computerized sign recognizer could be employed as an important tool to enable mutual understanding between deaf and non-deaf people.

Various studies have been proposed to recognize hand gestures or sign languages in different countries because each country has a different sign, such as the American sign language [2], Arabic sign language [3], Bengali sign language [4], Peruvian sign language [5], and Chinese sign language [6] using various methods.

Indonesia has two sign languages: Indonesia Sign Language System (SIBI) and Indonesia Sign Language

(BISINDO). In 1994, SIBI became the language used in formal schools for students with impairments. However, the deaf prefer to use BISINDO instead of SIBI in their daily lives.

Certain studies have been performed to recognize the SIBI. Hand gestures recognition approaches can be divided into vision based and sensor-based [7]. In vision-based approaches, images are acquired through a video camera. Meanwhile, sensor-based recognition needs an instrument to capture the motion, position, or velocity of the hands. Studies in Indonesian sign languages implemented the vision-based approach. A. Anwar et al. used a leap motion controller to recognize Indonesian sign language using feature extraction captured from hand movement [8]. In [9], a Myo Armband tool was used, which has five sensors, namely accelerator, gyroscope, orientation, orientation Euler, and electromyography (EMG). Both vision and sensor-based approaches need the data acquisition and classification stages. Various classification methods have been proposed to recognize patterns carried by input data. The k-nearest neighbor classification method was used to recognize the SIBI [10]. In this study, the distance between the coordinates of each bone distal to the position of the palm was measured using Euclidean distance. Meanwhile, Khotimah et al. implemented weighted k-nearest neighbor classification for dynamic sign language recognition [11]. Rosalina et al. used artificial intelligence to recognize SIBI [12]. Other studies utilized Hidden Markov Model [13] and Naïve Bayes [14] methods. Meanwhile, [15] used the generalized learning vector quantization model to recognize BISINDO and [16] utilized Scale Invariant Features Transform (SIFT) algorithm to recognize Indonesian Sign Language numbers. Iqbal et al. implemented a mobile device using a Discrete Time Warping for recognizing SIBI [17].

Most studies above discussed SIBI; however, BISINDO is the most common sign language used by the deaf in Indonesia. Thus, this study aims to convert hand gestures to text in BISINDO to improve communications between deaf and non-deaf people. In addition, the methods used in other studies depended on feature extraction. To improve performance, this study proposes a method to recognize BISINDO using a convolutional neural network (CNN) which uses the convolution layer as the feature extraction layer [18]. In other studies, a CNN was used by [2] to recognize American Sign Language. They employed a CNN to extract the features from the sign images, and the classifier used was a multiclass support vector machine. Hayani et al. also utilized a CNN coupled with an Adam optimizer to recognize Arabic sign

\*Corresponding Author.  
E-mail: sucidwijayanti@ft.unsri.ac.id

language [3]. Hossen et al. used a deep convolutional neural network to recognize Bengali sign language [4].

However, not many previous works have addressed converting BISINDO sign language to text. Furthermore, there is a need to develop CNN models that have lower computation costs for converting sign language to text. This study addressed both needs by developing a new CNN architecture to perform the BISINDO hand gesture to text, and reduced computation costs by using fewer parameters than the common CNN architectures. The experimental research objective of this study was to compare the BISINDO recognition performance of this simplified CNN model to AlexNet and VGG-16 which are other architectures commonly used in CNNs. We tested the performance using BISINDO standard hand signs recorded by a webcam under bright and dim lightning, and from first and second-person perspectives.

This paper is organized as follows: Section II provides a brief summary of BISINDO, followed by a description of the CNN architecture in Section III. The methods used in this study are described in Section IV. The results and discussion are presented in Section V. Finally, the paper is concluded in Section VI.

## II. INDONESIAN SIGN LANGUAGE

Sign language is a language that is expressed using body gestures and facial expressions as a symbol of the meaning of spoken language [19]. The sign languages of Indonesia can be categorized into two types: SIBI and BISINDO. SIBI was adopted from American Sign Language and is used as the formal sign language in schools for deaf students. However, the deaf prefer to use BISINDO instead of SIBI owing to its better applicability. The signs for the letters and numbers in the BISINDO language are shown in Fig. 1.

Fig. 2. Architecture of the CNN

The convolution layer extracts the features of images. This results in a linear transformation from the input, which is suitable for the spatial information of the filter. The weights in this layer determine the kernel convolution. Thus, kernel convolution can be trained based on the CNN input. The pooling layer comprises a filter with a stride and a certain size that passes through the path in the feature map. It aims to reduce image size. There are two types of pooling layers: max pooling and average pooling. In this study, max pooling was utilized by determining the maximum value in the vector dimension. After passing the convolution and pooling layers, the output of this process is used as the input to the fully connected layer. However, before this process, the input must be converted into one dimensional data. Finally, the process is performed using Softmax. Softmax calculates the probabilities

for all target classes to determine the classes based on the input [22].

## IV. METHODS

This section provides detailed descriptions of several steps used in our methods. This study was performed using primary data obtained from people who had no prior knowledge of sign language. Here is an overview of the steps. A webcam was used to gather sets of hand sign data from ten people to use as training data. The data were obtained by considering two conditions: lighting and perspective of the person. Then, a new CNN model was designed and trained, which was named model C. For comparison, we trained modified versions of AlexNet and VGG-16. Then, the three models were tested and evaluated against the test data.

Fig. 1. BISINDO Alphabets [20] and Numbers [21].

## III. CONVOLUTIONAL NEURAL NETWORK (CNN)

A CNN is typically used to detect or recognize images. It has an architecture that consists of a feature extraction layer and a fully connected layer. The feature extraction layer comprises a convolution layer and pooling layer. The general architecture of the CNN is illustrated in Fig. 2.

A. Data

The data used in this study were obtained using the webcam Logitech C922 with a resolution of 1080p and 30 fps. Ten respondents were asked to perform hand gestures, which consisted of 26 letters and numbers from 1 to 10, adhering to the BISINDO standard. Data were acquired 30 cm from the camera, as shown in Fig. 3. A green screen was placed as a background to minimize noise. Data were obtained by considering two conditions: lighting and perspective of the person.

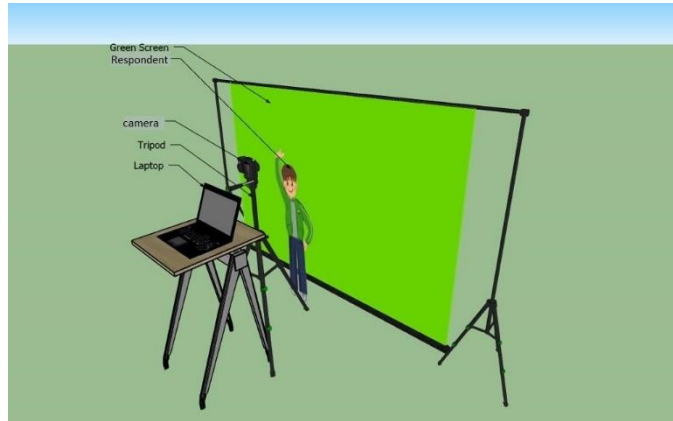

Fig. 3. Overview of the Data Retrieval Process.

B. Architecture of CNN

The CNN architecture used in this study consisted of three architectures, namely, models A, B, and C. Model A was a modified version of AlexNet [23]. The original AlexNet has 24,884,005 parameters, whereas the modified one has 1,432,261. Model B was a modified architecture of the VGG-16 [24]. It was modified to 2,140,405 parameters from its original value of 33,748,837. AlexNet and VGG-16 were chosen because they are the most common architectures used in CNNs. The architectures of models A and B are shown in Fig. 4 and 5, respectively.

This study proposed a new architecture, namely model C. Model C is a simpler architecture that consists of convolutional layer 1, max pooling 1, convolutional layer 2, convolutional layer 3, max pooling 2, convolutional layer 4, max pooling 3, flattened layer, and 3 fully connected layers. The visualization of model C is shown in Fig. 6.

C. Evaluation

This study utilized accuracy, precision, recall, and F1 scores to evaluate the performance of the three models. These parameters were calculated as follows:

$$accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

where True Positive (TP) is the number of positive data correctly predicted as positive, true negative (TN) is the number of negative data correctly predicted as negative, false positive (FP) is the number of negative data incorrectly predicted as positive, and false negative (FN) is the number of positive data incorrectly predicted as negative.

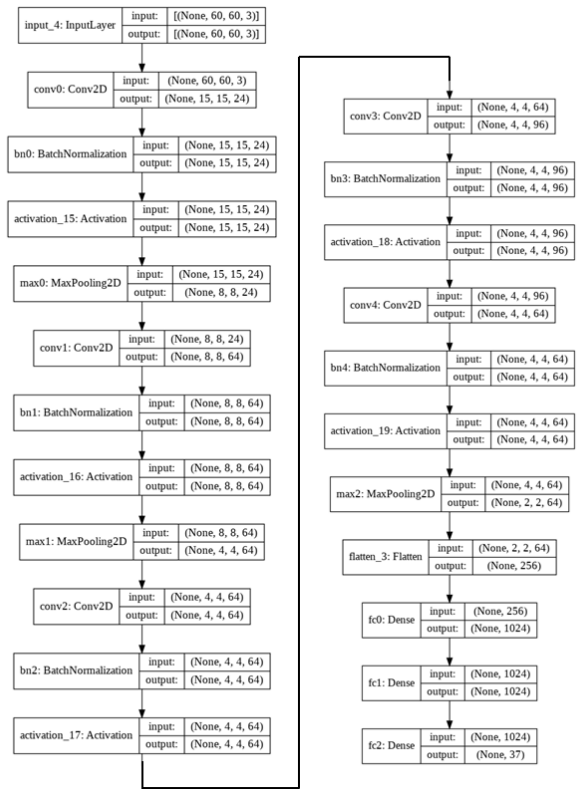

Fig. 4. Architecture of Model A.

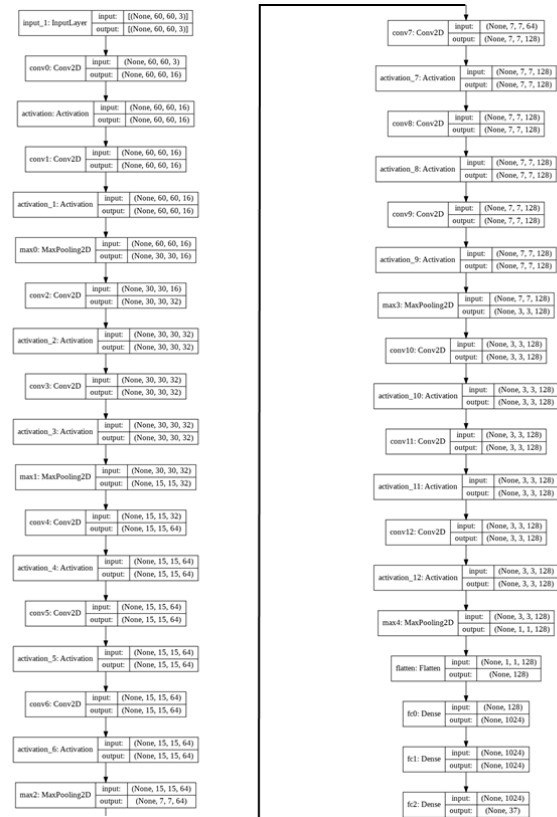

Fig. 5. Architecture of Model B.

Fig. 6. Architecture of the New Model C.

In addition, precision and recall are also utilized as evaluation parameters. These can be calculated as.

$$precision = \frac{TP}{TP+FP} \tag{2}$$

and

$$recall = \frac{TP}{TP+FN} \tag{3}$$

The balance between precision and recall is determined using the F1-Score, which is obtained as follows.

$$F1\ score = 2 \left( \frac{precision \times recall}{precision + recall} \right) \tag{4}$$

## V. RESULT AND DISCUSSION

### A. Image Dataset

The data used in this study were obtained from 10 respondents under two lighting conditions: dim and bright conditions. The position of the camera was also considered to be from the direction of the object considered (first-person perspective) and from the directions of others who observe the hand gesture (second-person perspective). Both lighting and viewpoints were considered in this study because illumination and viewpoints are challenges in gesture recognition [7]. Each respondent performed 37 hand gestures, consisting of 26 letters and 11 numbers (0–10). The data were recorded in a video format (.mp4) to obtain multiple data varieties. Subsequently, the data obtained were converted into images in the format of .jpg. The total data obtained through this process comprised 39,455 data points. Examples of the data are shown in Fig. 7.

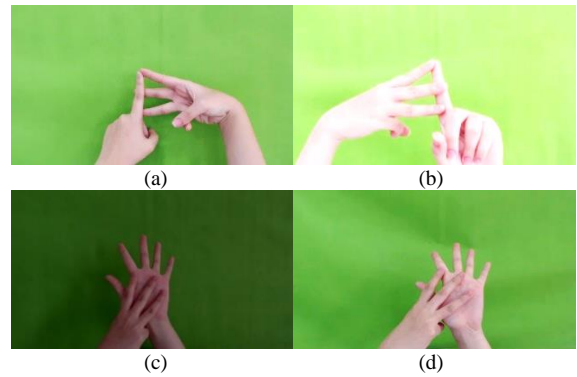

Fig. 7. Examples of Hand Gestures Obtained, (a) From the First-Person Perspective, (b) From the Second-Person Perspective, (c) Images Captured in Dim, and (d) Images Captured in Light.

### B. Data Preprocessing

Before using the data in the CNN, the image data were preprocessed. This stage was performed by resizing the image and scaling the features. The image was resized to the same size of 60 × 60 pixels. Thereafter, feature scaling was performed by dividing the values at each point in the image by 255 such that the data value interval in the image was 0–1. Fig. 8 shows the preprocessed results of the image data.

### C. Data Split

The preprocessed data were then fed as input to the CNN. In total 39,455 data were obtained, which was further divided using the stratified shuffle split method into three parts: training data, validation data, and test data. The division of the data was: 60 % training data, 20 % validation data, and 20 % test data, as shown in Fig. 9.

Fig. 8. Example of Preprocessed Result of Image Data.

Fig. 9. Data Splitting.

D. Training Process

The training process was conducted using the CNN algorithm. The training parameters for the three models are listed in Table I.

TABLE I. PARAMETERS OF TRAINING

Parameter	Value
Image size	60 x 60
Optimizer	Adam
Epoch	100
Learning Rate	0.001

The loss and accuracy of the training results using models A, B, and C are shown in Fig. 10, 11, and 12, respectively.

As shown in Fig. 10, model A exhibited training and validation losses of 0.011 and 0.096, respectively. Further, the training and validation accuracies were 0.997 and 0.984, respectively. As shown in the loss graph, the model tends to fluctuate, indicating instability. Nevertheless, the model can learn the patterns as shown by the loss values, which tend to zero in each epoch, and the accuracy is improved. In contrast, model B has a high loss value and low accuracy, as shown in Fig. 11. This implies that the model cannot learn the patterns given by hand gestures because the loss values are high. Fig. 12 shows that model C has training and validation losses of 0.020 and 0.079, respectively. In addition, the training and validation accuracies were 0.995 and 0.984, respectively. Thus, model C can learn the hand gestures given because the loss value goes to zero and the accuracy increases. A comparison of these models is shown in Table II.

Fig. 10. Loss Value and Accuracy of Model A.

Fig. 11. Loss Value and Accuracy of Model B.

Fig. 12. Loss Value and Accuracy of Model C.

TABLE II. COMPARISON OF TRAINING IN MODEL A, B, AND C

Parameter	Model A	Model B	Model C
Training Loss	0.0113	3.6049	0.0201
Validation Loss	0.0967	3.6045	0.0785
Training Accuracy	0.9972	0.0376	0.9948
Validation Accuracy	0.9839	0.0376	0.9839
Total Parameter	1,432,261	2,140,405	177,373

As shown in Table II, Models A and C have low loss values and high accuracy compared to Model B. Overall, Model A has the lowest training loss value, and high training and validation accuracy. Model C has the lowest validation loss, and high training and validation accuracy. In addition, the total number of parameters used in Model C was 177,383 while Model A had 1,432,261 parameters. Therefore, the computation time in Model C was the smallest compared to the other models. In addition, although Model C still exhibited a fluctuation in validation loss and validation accuracy (Fig. 12), it is lesser than that of Model A (Fig. 10). Thus, Model C has more stable validation loss. Based on these results, Model C exhibited the best performance compared to the other models. Consequently, these models were used to test whether the model is optimal and can generalize the testing data.

### E. Testing

Testing was performed after training to determine the ability of the model to predict the class of hand gestures. The test results are shown in Table III.

TABLE III. EVALUATION OF TESTING DATA

Model	Total Param.	Average prediction time per data (second)	Acc.	F1 Score	Precision	Recall
Model A	1,432,261	0.0002	0.986	0.996	0.987	0.987
Model B	2,140,405	0.0001	0.038	0.002	0.001	0.027
Model C	177,373	0.0001	0.983	0.993	0.983	0.984

As shown in Table III, model A has an accuracy of 0.986, F1 score of 0.996, precision of 0.987, and recall of 0.987. The results of testing using Model C are very similar to model A, with an accuracy of 0.983, F1 score of 0.993, precision of 0.983, and recall of 0.984. Since model B failed to learn, its

test results were very low. Thus, Models A and C obtained the best results. However, Model C has fewer parameters, thereby requiring less time to predict the data compared to Model A. The average prediction time per data for Model C was half the time for Model A: 0.0001 s for Model C and 0.0002 s for Model A. Therefore, Model C is twice as efficient as Model A while achieving near-equivalent performance levels.

1) *Test results by lighting*: This study used two lighting conditions: bright and dim. The performances for both conditions are shown in Table IV.

As shown in Table IV, both Models A and C could recognize the testing data in the two different lighting conditions, and they both had high performance. Meanwhile, Model B performed poorly in recognizing the signs.

2) *Test results by perspective*: This study used the first- and second-person perspectives. The position of the camera was considered to be from the direction of the object considered (first-person perspective) and from the directions of others who observe the hand gesture (second-person perspective). The performances for both conditions are shown in Table V.

Table V shows that Model A and C can recognize the signs in both the first and second-person perspectives with high performance levels. There was a slight improvement with the second-person perspective.

### F. Hand Gesture Prediction Results

The performance of the proposed model for predicting hand gestures was evaluated as well. Each class of hand gestures was performed, and the results obtained are shown in Fig. 13. The proposed model can recognize new data. Further, the hand gesture in the dim condition yielded a higher accuracy than in the light condition for the first-person perspective. In contrast, the second-person perspective exhibited the same performance under both dim and bright conditions. Certain samples of hand gesture recognition are listed in Table VI.

TABLE IV. TESTING RESULTS FOR DIFFERENT LIGHTING CONDITIONS

MODEL	Bright				Dim			
	Accuracy	F1 Score	Precision	Recall	Accuracy	F1 Score	Precision	Recall
A	0.985	0.985	0.986	0.984	0.987	0.987	0.988	0.987
B	0.038	0.002	0.001	0.027	0.038	0.002	0.001	0.027
C	0.979	0.980	0.981	0.981	0.987	0.987	0.987	0.988

TABLE V. TESTING RESULTS FOR DIFFERENT PERSPECTIVES

MODEL	First-person perspective				Second-person perspective			
	Accuracy	F1 Score	Precision	Recall	Accuracy	F1 Score	Precision	Recall
A	0.984	0.984	0.985	0.984	0.987	0.987	0.988	0.987
B	0.031	0.002	0.001	0.027	0.043	0.002	0.001	0.027
C	0.978	0.979	0.980	0.980	0.987	0.987	0.987	0.988

Fig. 13. Recognition Results using Proposed Model C.

TABLE VI. SAMPLE OF HAND GESTURES PREDICTION RESULTS

Data Test	Lighting Condition	Perspective	Actual Class	Result of Prediction
	Bright	First-person	4	4 (True)
	Dim	Second-person	H	H (True)
	Bright	Second-person	S	S (True)
	Dim	First-person	8	8 (True)
	Dim	First-person	B	B (True)
	Bright	Second-person	3	3 (True)
	Dim	First-person	2	V (False)
	Bright	First-person	M	M (False)
	Dim	First-person	N	M (False)
	Dim	Second-person	J	I (False)

As shown in Table VI, the proposed CNN model C works well in predicting hand gestures that were not included in the training data. This implies that the CNN can be implemented to recognize hand gestures. However, certain prediction errors occurred in certain classes, such as 2, M, N, V, and J. The

occurrence of prediction errors due to hand gestures from these classes is almost the same or similar to other classes. The numbers 2 and V have the same hand gesture, thus, an error occurred in the CNN while predicting the class. From the first-person perspective, no difference was observed between the letter M and N hand gestures, thereby resulting in an error in the prediction. Further, the hand gesture for the letter J is not static, thus a prediction error occurred wherein the letter I was predicted because the initial movement of the signal letter J resembles that for the letter I.

## VI. CONCLUSION

The results of this study demonstrated that our new simplified CNN model exhibited good performance in recognizing BISINDO hand gestures. The CNN architecture used was a simple architecture consisting of convolutional layer 1, max pooling 1, convolutional layer 2, convolutional layer 3, max pooling 2, convolutional layer 4, max pooling 3, flattened layer, and 3 fully connected layers. The parameters used were the Adam Optimizer, an iteration parameter of 100 epochs, and a learning rate of 0.001. During the training process, the last epoch resulted in a training loss value of 0.0201, validation loss value of 0.0785, and training accuracy value of 0.9948 with a validation accuracy value of 0.9839. The results of hand signal recognition testing using the CNN model on test data obtained performance results of 98.3%. Thus, this new simplified CNN model can recognize the BISINDO hand gestures well under dim and bright lighting and from the first- and the second-person perspective.

In the future, we will improve Model C to address those performance factors. We also expect to conduct the process of data retrieval with different backgrounds and do further research on real-time implementations of BISINDO hand gestures.

**Abstract**—Deoxyribonucleic acid (DNA) cryptography is becoming an emerging area in hiding messages, where DNA bases are used to encode binary data to enhance the randomness of the ciphertext. However, an extensive study on existing algorithms indicates that the encoded ciphertext has a low avalanche effect of providing a desirable confusion property of an encryption algorithm. This property is crucial to randomize the relationship between the plaintext and the ciphertext. Therefore, this research aims to reassess the security of the existing DNA cryptography by modifying the steps in the DNA encryption technique and utilizing an existing DNA encoding/decoding table at a selected step in the algorithm to enhance the overall security of the cipher. The modified and base DNA cryptography techniques are evaluated for frequency analysis, entropy, avalanche effect, and hamming weight using 100 different plaintexts with high density, low density, and random input data, respectively. The result introduces good performances to the frequency analysis, entropy, avalanche effect, and hamming weight, respectively. This work shows that the ciphertext generated from the modified model yields better randomization and can be adapted to transmit sensitive information.

**Keywords**—DNA cryptography; avalanche effect; frequency test; entropy; hamming weight

## I. INTRODUCTION

With the amazing development of Deoxyribonucleic Acid (DNA) computing, DNA cryptography is a new advancement in cryptography. DNA molecules are an integral part of a cell and act as genetic information carriers, but when applied in modern cryptography, it serves as a data manipulation tool [1].

The design of an encryption/decryption algorithm should be complex enough to stand for a long time against a security attacks. The best way to reach such complexity in a system is to work towards scalability because this will ultimately lead to large-scale complexity. The main idea to increase the complexity in the system by augmenting its size is to achieve the desired security that will require tremendous efforts to attack the system successfully. These desired properties can be achieved by DNA cryptography as it offers huge parallelism and storage capacity simultaneously [2]. The power of DNA encryption is not only in the molecules or encoding but in the positions where we want to save our data to protect it from attacks for a longer time [3]. Cryptography is the procedure to create such algorithms, whereas; cryptanalysis is the procedure where attackers or the algorithm developers validate the cipher

for its vulnerabilities and improve it by giving insight for future directions [4]. Randomness [5], avalanche effect [6], and entropy per bit [7] are some of the desired properties to evaluate the ciphertext. A cryptographic solution should satisfy this criterion, at least to ensure safety.

Avalanche effect [5] is a compelling test, whereby changing one bit in plaintext or key will change at least 50% of the bits in the ciphertext. This research work focuses on the change in ciphertext from a plaintext perspective. A detailed study of DNA cryptographic encryption algorithm as in [8] indicates that the avalanche effect is considerably less, leading to security vulnerabilities. Specifically, the conversion of the binary data into DNA bases (00 to A, 01 to G, 10 to C, 11 to T) exhibits poor avalanche effect or randomization of the ciphertext. This may cause an attacker to establish a relationship between plaintext and its ciphertext. In this paper, a modified DNA encryption technique with an existing DNA encoding table used in [9] are introduced to the existing algorithm to overcome the mentioned security vulnerability. The proposed encryption technique allows the user to send encrypted information with an extra fold of security. The experimental results have endorsed the effectiveness of the proposed technique by performing a statistical analysis between the base technique and the proposed technique.

The overall structure of the study takes the form of six sections, including this introductory section followed by a literature review in Section 2. Section 3 gives an insight on the encryption algorithm using base and the proposed technique. Section 4 explains the list of tests to measure the randomness in technique. Section 5 has a detailed analysis of results validating the effectiveness of the proposed technique. Section 6 discusses the concluding remarks considering improvements and limitations followed by cited references in a separate section.

## II. RELATED WORK

DNA computing is an increasingly important area in applied cryptography where the inherited property of storing huge data is adopted along with DNA replication to introduce randomness in the cipher. DNA computing can be applied in various forms during the encryption-decryption process; it can either be used as complement operation, digital coding, polymerase chain reaction, or as a security alternative [10]. A large volume of published studies describes the role of DNA in cryptography. This research focuses on DNA digital coding

only with detailed insight into its security impact in cryptographic techniques. In 2012, Noorul Hussain [9] introduced a new concept based on DNA digital coding, where a dynamic DNA encoding table was presented. This encoding table is a 24\*4 matrix of 96 American Standard Code for Information Interchange (ASCII) characters consisting of alphabets, numbers, and special characters. Later this table was used and extended by other researchers [11]-[13]. It is evident that the utilization of this table in an algorithm has improved the randomness of ciphertext and consequently enhanced the system security.

An extended version of the ASCII table was introduced with 256 ASCII character encoding [11]. For a dynamic sequence, table creation, all characters are initially allocated randomly to DNA base sequences followed by an iterative rearrangement using a mathematical pattern, whereas in the encryption process, the plaintext is first converted into DNA bases using the sequence table, followed by the creation of data chunks to encrypt them using an asymmetric cryptosystem and finally to merge the chunks as the ciphertext. The system of dynamic encoding coupled with asymmetric cryptosystem naturally raises the degree of data confidentiality. It is proved by comparison with existing techniques and a statistical suit of randomness defined by the National Institute of Standards and Technology (NIST).

In [12], a network traffic and intrusion detection system is proposed using DNA sequences, where DNA bases are used to encode the 41 attributes of the network. The next attributes have been analyzed for experimentation purposes, and the results indicate a 15% improvement in accuracy, whereby a more complex encoding can effectively improve the accuracy of the intrusion detection system. In [13] and [14], a Dynamic DNA sequence table is used in combination with OTP to improve data security. The attacker must execute all possible DNA sequence variations before getting original data, which is supposed to be very difficult. The proposed technique provides better security than other techniques, in particular against brute force attacks. The algorithm aims to transmit the One-time-pad (OTP) securely, but execution time has been increased as compared to other similar techniques.

Interestingly a cryptographic system is designed, where the authors in [8] apply a delayed Hopfield neural network to generate the cryptographic key before DNA encryption-decryption process. Specifically, the chaotic neural network generates a binary sequence, passed on to the permutation function yielding the first level key for encryption. The system's strength lies in the random selection of trajectories for neural networks, delay function, and DNA cryptography. The authors claim that changing one byte can change 32 out of 128 bits in the ciphertext, which is significantly less than the expected change, where changing one bit in plaintext or key should bring more than 50% change in the ciphertext.

All these research works endorse the fact that DNA encryption using DNA encoding can significantly improve the security of the cryptographic solution. A similar approach in [8] is extended with the existing DNA encoding table at a carefully selected location. The subsequent section explains the encryption process for the base technique followed by the

improved technique with an additional layer of the dynamic sequence table.

### III. METHODOLOGY

#### A. Base Technique

The Hybrid chaotic neural network as in [8] generates the key while the DNA cryptography algorithm encrypts/decrypts the original data. However, this paper only discusses the application of DNA cryptography, so it primarily discusses encryption/decryption without going into details of the key generation process. Plaintext, key, and ciphertext are of equal length, i.e., 128 bits. Following are the steps involved in the encryption process:

- 1) Take plaintext from the user and divide it into fixed-length sub-sequences  $R_j$ .
- 2) A random binary sequence  $S_j$  of equal length is produced using a key generation.
- 3)  $R_j$  is permuted using left cyclic shift yielding  $R'_j$  where the number of bits to be shifted  $V_j$  is pre-calculated by key generation part.
- 4)  $S_j$  is subjected to right cyclic shift producing  $S'_j$  using  $V_j$ .
- 5) To produce the 1st level encrypted text  $C'_j$ , an XOR operation is performed between  $R'_j$  and  $S'_j$  as given below:

$$C'_j = R'_j \oplus S'_j$$

- 6) The second level of encryption is performed on binaries obtained from  $C_j$ . Applying "00" to "A", "01" to "G", "10" to "C", and "11" to "T", yielding  $C_j$  is the DNA encoded ciphertext.

The decryption process is the reverse of the encryption process where DNA decoding produces  $D'_j$  and thus  $D'_j$  as below:

$$D'_j = D'_j \oplus S'_j$$

This  $D'_j$  undergoes permutation and cyclic shift to give the plaintext.

#### B. Proposed Technique

The proposed algorithm works the same way as far as the key generation is concerned in [8], but there is an improvement for encryption and decryption part as in Fig.1.

- 1) The user enters the plaintext, which goes directly to the DNA sequence table and gets encoded.
- 2) Then binary coding is applied as  $A = 00$ ,  $T = 01$ ,  $C = 10$ , and  $G = 11$ .
- 3) Conversion into corresponding decimal values.
- 4) Conversion of decimal values into ASCII characters.
- 5) Split each string into equal size blocks  $R_j$ .

The encryption process continues as the same steps, 3-6 in the base technique. Fig. 1 gives a pictorial representation of the system for the encryption-decryption process. The encryption process is illustrated in green, the key generation process in yellow, and the decryption process is in blue. These steps are similar to the original algorithm, and the improvements are

added as new layers (in red) and displayed distinctively in the encryption and decryption process. Table I indicates the DNA encoding/decoding table being introduced to the algorithm as applied in [9].

#### IV. EVALUATION PARAMETERS

In this section, several tests from the literature are performed to evaluate the randomness of the ciphertext produced by the proposed algorithm and the base technique [5], [7], [15]-[17]. These tests can only be performed on binary sequences. Thus, the ciphertext is then converted from DNA sequence into binary to complete the evaluation. Three different datasets have been used as inputs to these tests, categorizing them as low density, high density, and random [18]-[20]. Low and high density are the biased datasets, where plaintext has all zeros and only one 1 bit in string. A high density is an exact opposite with all ones but only 1 zero. The purpose of using biased data is to identify the exact randomness in the ciphertext. For an algorithm being provided with random plaintexts, there are high chances that the generated ciphertext will also be random. On the other hand, for a non-random (biased) dataset, the probability of obtaining a random ciphertext is relatively low. Therefore, the use of different categories of datasets can establish confidence in the improved scheme from security perspectives.

##### A. Frequency (Mono Bit) Test

The frequency test calculates the number of a binary string, 0's and 1's appear in the ciphertext. This test determines that either the number of zeros and ones are equal or not, as this is one of the desired properties of a ciphertext [5]. Value 0.01 is the level of significance for this test which means that only 1 sample out of 100 will be rejected. Ideally, the resultant value should be "1", which means a perfect balance of 0 and 1 in the string. This test assesses the closeness of these values to 1/2 of the total numbers of binary string appeared in the ciphertext, as it is ideal for these values to be equal. For this test, the preliminaries are:

$n$  the length of the bit string,

$\epsilon$  the sequence of bits in the string as  $\epsilon = \epsilon_1, \epsilon_2, \dots, \epsilon_n$

$S_{obs}$  the absolute value for summation of  $X_i$ .

$$X_i = 2\epsilon - 1 = \pm 1 \tag{1}$$

$$S_n = X_1 + X_2 + \dots + X_n \tag{2}$$

$$S_{obs} = \frac{|S_n|}{\sqrt{n}} \tag{3}$$

Finally, the tail probability, i.e., the p-value, is calculated in (4).

$$p\text{-value} = \text{erfc}\left(\frac{S_{obs}}{\sqrt{2}}\right) \tag{4}$$

*erfc* is a complementary error function. This test evaluates the p-value, whereas if the computed value of p is less than 0.01, it is concluded that the given sequence is not random [15], [16]. On the other hand, if the p-value is more than 0.01, the string passed the test and can be declared as a random string.

##### B. Avalanche Effect

A small change in plain text or key yielding a significant change in the ciphertext is called the avalanche effect (5). It's a highly desirable property for algorithm design, such as the higher the avalanche effect, the better the algorithm [21]-[27].

Avalanche > 50% of an exemplary algorithm makes the cipher more random and less predictable for attackers.

$$\text{Avalanche Effect} = \frac{\text{Number of flipped bits in cipher text}}{\text{Total number of bits in cipher text}} \quad (5)$$

### C. Entropy

Shannon introduced the concept of entropy in bits in 1948 [7] and is termed as uncertainty in the expected output bits. Uncertainty of the cipher is determined by the number of plaintext bits that can be recovered from scrambled ciphertext to get the original message [17] successfully. Moreover, entropy is the weighted average of optimal bit representation size, such as the average size of an encoded message. Mathematically, entropy can be defined as in (6).

$$H(X) = - \sum_{x \in X} (\text{Pr}[X] \log_2(\text{Pr}[X])) \quad (6)$$

Here we are calculating the entropy of X with  $X = \{0,1\}$ . Calculating for both bases as in (7).

$$H(X) = -[P(0) \log_2(P(0)) + P(1) \log_2(P(1))] \quad (7)$$

The highest uncertainty is only achieved when the values are equally distributed i.e.

$$H(X) = 1 \quad (8)$$

### D. Hamming Weight

Two strings of equal length having different symbols at some positions; the total number of those positions is called hamming weight [21], [26]. A higher value of the hamming weight represents the better randomness of the binary sequence.

$$\text{Hamming Weight} = \frac{\text{Total number of non zero bits}}{\text{Length of the cipher text}} \quad (9)$$

## V. RESULT AND DISCUSSION

Both techniques discussed in previous sections are implemented in Matlab 2019 to evaluate the randomness of the ciphertext. Tables II and III have results for all of the tests described in Section IV. The value of plaintext is changed by toggling bits across the string followed by a constant key. The plaintexts in Table II are 128 bits long. The key is set to "00011000100101010010010000101011100001101010010001100110000111111000110101100010111011100100100111110011011000001111100110010". The same key is used to produce the ciphertext for further evaluations. As the frequency is one of the tests by NIST [28] and the minimum required length of the string is 100 bits, the ciphertext bits are concatenated to apply this test. Here, we have 33 high density, 33 low density, and 34 random plain texts for evaluation, and, ultimately, the average value of all these observations is calculated.

### A. Frequency Test

As mentioned in the previous section, the frequency test calculates the number of 0's and 1's that appear in the ciphertext. If the p-value calculated on the ciphertext is more than 0.01, the ciphertext is concluded as a random string, or else it is a non-random. Thus, Table II shows the p-value of the ciphertext produced by the base and the improved algorithm using (1), (2), (3), and (4). High density, low density, and random plaintexts are used as inputs to both algorithms.

TABLE II. FREQUENCY ANALYSIS, AVALANCHE EFFECT AND HAMMING WEIGHT TEST FOR THE BASE AND THE IMPROVED TECHNIQUE

Plaintext	Frequency Test		Avalanche Effect		Hamming Weight	
	Base	Improved	Base	Improved	Base	Improved
High density	0.8227	0.9872	38.06 %	52.9 %	62.3	63.5
Low density	0.8953	0.987	40.6 %	55.33 %	63.9	64.2
Random	0.7625	0.9891	37.99%	55.7%	63.5	63.9
<b>Average</b>	<b>0.8268</b>	<b>0.9877</b>	<b>38.55%</b>	<b>54.64%</b>	<b>63.23</b>	<b>63.87</b>

Based on Table II, both techniques have passed the NIST frequency test successfully with the average p-values (y-axis) for three variants of plaintexts are greater than 0.01. Each p-value (y-axis) of the ciphertext generated from those variants of plaintexts is also depicted in Fig. 2 and 3. The ideal p-value for this test is 1, and all the ciphertexts should have a value close to 1. Based on Fig. 2 and 3, it can be seen that there are specific outputs that have successfully achieved a p-value of 1. However, this ratio is minimal in case of the base technique compared to the improved technique. It can be seen from Table II that the average p-value of the improved technique (0.9877) is very close to 1.

Fig. 2. Frequency Analysis of base Technique.

Fig. 3. Frequency Analysis of Improved Technique.

### B. Avalanche Effect

The avalanche effect is a very desirable property when it comes to randomness in the ciphertext. As mentioned earlier, the higher the avalanche effect, the better the security. Any given scenario where the attacker has access to ciphertext tries to establish a relationship between ciphertext and its plaintext.

If changing one bit results in a change of more than 50% bits, it becomes challenging for the attacker to retrieve the original message. In Table II, the base technique has the avalanche effect values, which range from 37.99% for random to 38.06% and 40.6% for high and low density plaintext, respectively. Meanwhile, the improved technique has values ranging from 52.9% to 55.7%, significantly higher than the base technique.

These values are calculated using (5) and presented in Fig. 4 and 5. As depicted in Fig. 4, changing 1 bit in plaintext has generally introduced a difference from 8% to 65%. Whereas by looking at Fig. 5, it is evident that observed values range between 40% and 70%. Row 5 in Table II has the average value of avalanche effect, and it can be observed that this value is 38.55% in the case of the base technique and has significantly improved to 54.64% for the improved technique.

Example scenarios of avalanche effect have been presented in Table III, where “CRYPTOGRAMMATIST” is the original plaintext, feed to the algorithm and the produced ciphertext is used as a reference to calculate the number of flipped bits. For example, changing one bit in the 40th location of the binary sequence in the plaintext yields 24 flipped bits in the ciphertext by the base technique. Thus, the avalanche effect is 18.755%, considering that the length of ciphertext is 128 bits. For the base algorithm, the result shows that the avalanche effects range from 12.5% to 32.0312%, with an average of 19.72% when changing one bit of the binary sequence in the plaintext at different locations (bold and underlined bit). Meanwhile, the improved technique has the avalanche effects range from 53.9% to 61.75%, with an average of 57.4175%. The average avalanche effect indicates a significant improvement of

37.69%. Thus, this new encryption/decryption technique can be used to improve security for an environment in which data sensitivity and randomness are essential.

Fig. 4. Avalanche Effect of base Technique.

Fig. 5. Avalanche Effect of Improved Technique.

TABLE III. AVALANCHE EFFECT AND ENTROPY FOR THE BASE AND IMPROVED TECHNIQUE

Average	-----	19.72%	0.9963	-----	57.4175%	0.9931

### C. Entropy

Equation (6) and (7) are applied to find the entropy of ciphertext. In Table III, the entropy of the ciphertext has been calculated for the base and the proposed technique. It can be seen that the entropy of ciphertext in both cases is nearly equal, with a value of 0.9963 for the base technique and 0.9931 for the proposed technique, which is the information content per bit. So it can be said that the information content per bit has not decreased even for the improved technique but has sustained some optimum value throughout the observations. The ideal entropy in the given case is 1, as depicted in (8), but the observed entropy for both techniques is very close to one.

### D. Hamming Weight

Hamming weight has been calculated using (9). In Table II, it is observed that hamming weight for base technique ranges from 62.3 to 63.9, whereas for improved technique, this value ranges from 63.5 to 64. The ideal expected value for hamming weight in a binary string of 128 bits should be 64. The average observed value of 100 plain texts for the base technique is 63.23, whereas, for the improved technique, it's 63.87.

In summary, Tables II and III confirm that the proposed technique performs better for frequency, avalanche effect, and hamming weight. The observed values are not only better than the base technique but are also nearly equal to ideal expected values. Whereas for entropy calculation, the value of the improved technique has not improved yet, the difference from the base technique is quite negligible. Hence, the improved technique is a better alternative to the proposed technique, where enhanced security is offered with all the security considerations of the base technique.

## VI. CONCLUSION

DNA cryptography has served as a better alternative to traditional systems in recent times. Advancement in the study helps to identify the security vulnerabilities in the existing systems. This research highlights that by carefully examining the ciphertext produced by the base technique, in terms of avalanche effect can be further improved. The average avalanche effect is 38.55% when flipping one bit of binary sequence in the plaintext for 100 different plaintexts ranging from high density, low density, and random data set. On the other hand, the average avalanche effect of the proposed technique has increased to 54.64% by introducing a DNA encoding table. The work also includes the frequency, entropy, and hamming weight to test the overall security of the improved system. The results show that the improved technique is better in terms of the frequency's p-value, avalanche effect, and hamming distance than the base technique. For entropy, the value produced by both algorithms is approximately equal. Hence, the improved technique is a better alternative to the proposed technique, and this research. A good future direction of this work can be defining new trajectories in key schedules and analyzing the impact of key changes to the ciphertext.

### ACKNOWLEDGMENT

The authors would like to thank all reviewers for their helpful comments. The authors would also like to thank the

Ministry of Higher Education Malaysia for supporting the research under Fundamental Research Grant Scheme Vot No. FRGS/1/2019/ICT03/UTHM/03/1 and partially sponsored by Universiti Tun Hussein Onn Malaysia.

# Multistage Sentiment Classification Model using Malaysia Political Ontology

Nur Farhana Ismail, Nur Atiqah Sia Abdullah\*, Zainura Idrus

Faculty of Computer and Mathematical Sciences  
Universiti Teknologi MARA  
40450 Shah Alam, Selangor, Malaysia

**Abstract**—Now-a-days, people use social media platforms such as Facebook, Twitter, and Instagram to share their opinions on particular entities or services. The sentiment analysis can get the polarity of these opinions, especially in the political domain. However, in Malaysia, current sentiment analysis can be inaccurate when the netizen tempts to use the combination of Malay words in their comments. It is due to the insufficient Malay corpus and sentiment analysis tools. Therefore, this study aims to construct a multistage sentiment classification model based on Malaysia Political Ontology and Malay Political Corpus. The reviews are carried out in sentiment analysis, classification techniques, Malay sentiment analysis, and sentiment analysis on politics. It starts with the data preparation for Malay tweets to produce tokenized Malay words and then, the construction of corpus using corpus filtering, web search, and filtering using linguistic patterns before enhancing with political lexicons. The process continues with the classifier construction. It started with a generic ontology with Malaysia's political context. Lastly, twelve features are identified. Then the extracted features are tested using different classifiers. As a result, Linear Support Vector Machine yields an accuracy of 86.4% for the classification. It proved that the multistage sentiment classification model improved the Malay tweets classification in the political domain.

**Keywords**—Malay corpus; political ontology; sentiment analysis; sentiment classification; social media

## I. INTRODUCTION

Social media is a common platform for internet users. Netizens can spread and viral issues quickly via social media like Facebook, Twitter, Blog, Instagram, and online platforms. Social media allows people to voice opinions freely on current matters. Their opinions are beneficial, especially for the business, marketing strategies, and policymakers include government. Sentiment analysis tools can analyze their comments into exploitable information.

The existing sentimental analysis classifiers manage to analyze different languages such as English, French, Indian, Arabic, and Chinese. However, it has yet insufficiently in analyzing the Malay language accurately. Each comment containing Malay words will be classified as neutral in most of the social media monitoring tools. It is one of the reasons for the Malay sentiment classifier to support the research on classifying the Malay language, which use lexicon and k-nearest neighbor [1], lexicon [2] and other classification

methods [3]. Besides, there is lacking Malay sentiment analysis that covers the political domain [4].

The author in [4] has conducted a study on the political inclination classifier model for Malay text in social media data. This study focuses on Malay sentiment analysis in the political domain. However, it needs to be improved to get a more accurate sentiment classification. Besides, some corpora are for the abbreviations [5] and hadith [6]. However, there is a need to create a corpus in the political domain.

Currently, most of the agencies use social media monitoring tools to extract comments for strategic planning in marketing, customer behavior, political inclination, and etc. However, the comments that contain Malay words are classified as neutral. This shortage motivates this research to improve the sentiment classification. It sets the interest to investigate the sentiment classification in the political domain due to the political scenario in Malaysia.

The main idea of this study is to propose a multistage sentiment classification model using Malaysia Political Ontology and Malay Political Corpus. This model aims to increase the sentiment classification by adding the entity classification to the existing process. Besides, new features are suggested based on the entity classification. By using this model, the analysis and monitoring process of social media can speed up. Besides, this research helps to expand the knowledge in this field to get better accuracy of sentiment. This paper continues with Section II explains the related works. Section III presents the methods and processes. Section IV and Section V contain the results and discussions. Finally, Section VI concludes the research.

## II. RELATED WORK

### A. Sentiment Analysis

Sentiment analysis is known as opinion mining where the purpose is to determine people's opinion towards certain entities such as an event, product, management, politician, and government issues [7]. Some studies on Malay sentiment analysis use different approaches to construct the Malay sentiment classifiers. Previous studies use the machine learning approaches for sentiment classification include machine learning [8-10], immune network [11], artificial immune network [12] and hybrid approaches [1, 6, 13].

TABLE I. MALAY SENTIMENT ANALYSIS

Author	Content of Article			
	Approach	Dataset	Politic	Ontology
[10]	Machine Learning	Newspaper	No	No
[11]	Machine Learning	Newspaper	No	No
[12]	Machine Learning	Newspaper	No	No
[8]	Machine Learning	Online Review	No	No
[9]	Machine Learning	Online Review	No	No
[2]	Lexicon based	Facebook Twitter	No	No
[1]	Hybrid	Online Review	No	No
[4]	Hybrid	Twitter	Yes	No
[13]	Hybrid	Article	No	Yes

Other than that, a lexicon-based approach is used to perform classification [2]. Although the machine learning approaches are used for Malay sentiment analysis, it does not mean this approach is the only one to perform Malay sentiment classification. Reference [13] proved that the hybrid approach gets the highest accuracy in the sentiment classification, which is better than previous studies.

Table I shows the Malay sentiment analysis in terms of approach, types of datasets, political domain, and application on ontology. Three major approaches are machine learning, lexicon-based, and hybrid approach used in Malay sentiment analysis.

From Table I, the study [13] improved the accuracy in sentiment analysis for the Malay language. It deals with informal language style and multilingualism that has become the norm of communication in social media. It used a hybrid approach, which is a combination of machine learning and a knowledge base. The ontology helps to get the more accurate sentiment with 94.34%. The polarities are positive, negative, neutral, and mixed. However, it is not in the political domain. Hence, it is a motivation for sentiment analysis on the political domain of other countries to find out the workflow in political sentiment classification.

### B. Sentiment Analysis in Political Domain

Some approaches that classify the sentiment in the political domain are the machine learning approach, lexicon-based approach, ensemble approach, and multistage classification approach. Table II shows the sentiment analysis in the political domain in various countries use mostly tweets as the dataset.

Two studies [14-15] performed sentiment classification using the machine learning approach. The researchers use tweets as the dataset in Egypt and Indonesia. The lexicon-based approaches in [16-17] used online news and tweets that related to Indonesia and Turkey political context. The research [4, 18] performed sentiment classification using a hybrid approach. These two researches used tweets and corpus-based approach in Malaysia and India. Lastly, the research [19] used a multistage classification approach to get higher accuracy. The study was carried out in United States by using hybrid approach.

TABLE II. SENTIMENT ANALYSIS IN POLITICAL DOMAIN

Author	Content of Article			
	Approach	Dataset	Corpus	Country
[14]	Machine Learning	Tweets	No	Egypt
[15]	Machine Learning	Tweets	No	Indonesia
[16]	Lexicon based	Online News	Yes	Indonesia
[17]	Lexicon based	Tweets	Yes	Turkey
[4]	Hybrid	Tweets	Yes	Malaysia
[18]	Hybrid	Tweets	Yes	India
[19]	Hybrid	Tweets	No	United States

From Table II, the researchers [19] predicted the presidential election of the United States using Twitter sentiment analysis. The multistage classification approach classified the tweets of Donald Trump and Hillary Clinton. The accuracy of sentiment classification for Donald Trump and Hillary Clinton is 0.99% and 0.98%. From the reviews on the sentiment analysis in political domain, the studies [16, 19] become the anchors to construct a Malay sentiment classifier in this study.

### C. Ontology

In [16], the ontology in a sentiment classifier helps to analyze social media content and gets an accurate sentiment. Ontology is a set of concepts related to entities, and the ontological hierarchy is constructed from the relations between concepts of entities.

There is still a lack of political ontology for the political domain in Malaysia. The construction of Malay political ontology (MPO) is adapted from [20]. Reference [20] constructed Australian politic ontology uses BBC politic ontology. There are four main concepts in BBC political ontology, which are person, place, organization, and event.

However, Australian politicians and parties are the main concepts in the ontology because it focuses on the election. These concepts with 53 instances for politicians, and 4 instances for parties. The Australian political structure is similar to Malaysian. Therefore, this study becomes another reference model to construct Malaysia Political Ontology (MPO).

### D. Multistage Classification

The study [19] identified the winner from the election of the United States. The study proposed a multistage classification to classify the entity and sentiment of the tweets. The first stage of classification, the classifier called as entity classifier that classifies a general stream data into the respective entities. The classifier is trained with the entire dataset labelled by the entities. For the next stage of classification, the classifier called a sentiment classifier that classifies the sentiment of the tweets written refer to that particular candidate. Therefore, each candidate has a classifier associated with him or her. The classifier is trained with a dataset that pertaining to only its candidate.

Hybrid approach is used to perform the multistage classification [19]. The hybrid approach combines the machine learning with knowledge-based approach to improve the accuracy of sentiment analysis. The postings are classified into positive, negative or neutral. The result from [19] shows the accuracy of 94.34%, which is better than Naïve Bayes (NB), k-nearest neighbor (kNN) and Support Vector Machine (SVM).

### III. METHODOLOGY

The dataset in this research is obtained from the Centre for Media and Information Warfare Studies (CMIWS) of Universiti Teknologi MARA (UiTM) Malaysia. There is a total of 1207 tweets in the political domain. There are six phases in this research, which are Preliminary Study, Data Pre-processing, Corpus Construction, Entity Construction, Multistage Classification Modelling, and lastly Evaluation.

#### A. Preliminary Study

In the preliminary study phase, literature reviews on articles to identify the research gap of sentiment analysis. It includes sentiment classification techniques, sentiment analysis in the Malay language, and political domain. Besides, it highlights the problem statement, research questions, objectives, scopes, and selected sentiment analysis techniques in the Malay language and political area.

#### B. Data Pre-Processing

This study focuses on Malay tweets. From the tweets collection, 752 Malay tweets are extracted. These tweets are the netizen comments related to political issues and selected politicians in Malaysia. The data pre-processing includes six processes to remove the noisy data. These processes begin with the removal of external links, symbols, and numbers. It continues with the lowercase conversion, abbreviation correction, stop words removal, word stemming, and then tokenization.

The external links, symbols, and numbers in a tweet are removed because these elements do not contain any meaning in classification. This process is similar to the previous studies [4, 15, 17-19]. Then, the remaining words are converted into lowercase to ease the word checking in the sentiment classification process. The abbreviations are converted into formal words as the abbreviations cannot be classified correctly [4].

Then, the process continues with removing the stop words as these words contain no meaning to analyze [14, 16]. The stemming process uses Fatimah stemmer [21] to get the seed words in the Malay language. The last process in the data pre-processing is word tokenization [4, 14] that split the words and store them in the database.

#### C. Corpus Construction

The corpus construction process from [22] is adapted in this research. It contains corpus filtering, web search, and filtering using linguistic patterns and domain-specific polarity lexicon. Our focus is building a Malay Political Corpus.

The corpus filtering contains two processes, which are word extraction and unique word selection. Firstly, 18 political words are extracted as the initial list. Next, the words that are

related to the election are selected. At the end of these processes, it produces a list of five political words that are related uniquely to the election.

After that, these election words are used together with a Linguistic pattern for web search to find more election-related words. There are two patterns in this searching process. In the first pattern, 'Pilihanraya' is used, which represents election in Malay. In the second pattern, it combines 'Pilihanraya' with 'seed words' related to the election.

- Pattern 1: Pilihanraya include(s)\*.
- Pattern 2: Pilihanraya + "seed word".

These unique seed words include 'calon' (candidate), 'kempen' (campaign), 'manifesto' (manifesto), 'parti politik' (political party), and 'pengundi' (voter). Table III contains Malay seed words and sample lexicon related to election. There are 182 lexicons after this searching process.

TABLE III. LIST OF LEXICON

Seed Word	Sample of Lexicon	Total Lexicon
Calon	Wakil, Tanding, Kredibiliti, Khidmat, Pilih	65
Kempen	Strategi, Demokrasi, Lawan, Provokasi, Taktik	48
Manifesto	Subsidi, Janji, Sistematis, Tawar, Bersih, Hapus	15
Parti Politik	Agenda, Bangkang, Kuasa, Propaganda	36
Pengundi	Pangkah, Protes, Daftar, Undi, Sokong, Tolak	18

Then, the process continues with setting the polarity and score for these lexicons. The lexicon is classified into positive, negative, or neutral polarity. The positive word has a score of 1 to 5 based on the meaning of the lexicon. The negative word has a score of -5 to -1, while the neutral word gets 0. At the point, the political corpus is successfully constructed.

#### D. Entity Construction

In this process, the political parties are classified into government or opposition. In the entity construction, the generic ontology construction and instances enrichment from [20] are adapted.

A generic ontology has a set of concepts related to an entity. The relations between these concepts are organized into an ontological hierarchy. The ontology is constructed using Protégé 5.5.0 tool and using OntoGraf for visualizing the relationship in the ontology.

Four main concepts in the ontology include Person, Place, Organization, and Event. The person concept is the class of people in Malaysian political environments like voters and politicians. The place concept is related to the electoral areas such as state and constituency. The organization concept in Malaysian politics includes political parties, government, and council. The event concept relates to Election Day and campaign.

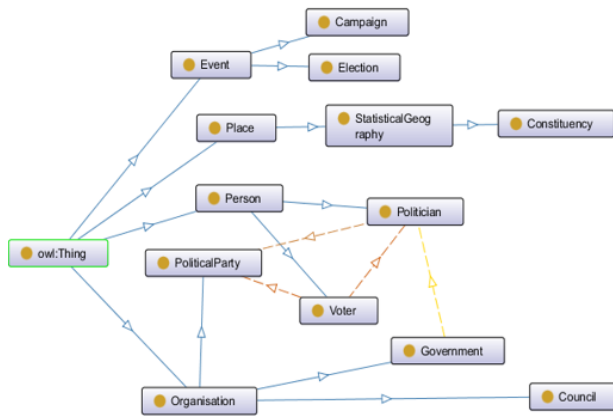

Fig. 1. Main Concept of Malaysian Politic Ontology.

This ontology is not sufficient to classify the entities in the tweets. Therefore, it needs to be enriched with instances before being fully utilized. The Parliament of Malaysia 2021 is referred to assign the instances for a political party and its candidates. We successfully construct the Malaysia Political Ontology (MPO) shown in Fig. 1.

The people and organization concept are used in this study to represent politicians and political parties. This ontology helps to classify the entity in the tweets. For example, with the instances of the political parties in Malaysia, the algorithm is developed to classify the entity into government or opposition. It helps to identify the sentiment towards the political parties in Malaysia. This information is valuable during the election.

E. Multistage Classification Modeling

The multistage classification from [19] is adapted in this model. There are two stages in multistage classification, which are entity classification and sentiment classification.

Entity classification is the classification based on the Malay Political Ontology (MPO). With MPO, the algorithm helps to classify the politicians and political parties into government or opposition. By this entity classification, it helps in the analysis of sentiment, especially during the pre-election. It speeds up the classification and sentiment analysis process based on the politicians and political parties.

TABLE IV. LIST OF ADAPTED FEATURES

Type	Description
F1	Presence of positive words
F2	Presence of negative words
F3	Presence of positive words in proportion to the presence of negative words
F4	Frequency of positive words in proportion to the frequency of negative words
F5	Weighted probabilities of a positive tweet
F6	Weighted probabilities of a negative tweet

Sentiment classification consists of the feature identification, feature extraction, training dataset, and testing dataset using Support Vector Machine (SVM) classifier. The trained dataset needs to be vectorized data. Therefore, it needs to vectorize data through feature extraction. There are twelve identified features in this research. Table IV shows six features adapted from [1].

From Table IV, the six features and descriptions are aimed to cater to the positive and negative words, proportion calculation, and weighted probabilities calculation.

There are six new features (see Table V) in this model that reflect the political domain in Malaysia. These features are used to cater the entity and words in political domain.

TABLE V. LIST OF NEW FEATURES

Type	Description
F7	Presence of domain specific positive words
F8	Presence of domain specific negative words
F9	Presence of domain specific positive words in proportion to the presence of domain specific negative words
F10	Frequency of domain specific positive words in proportion to the frequency of domain specific negative words
F11	Presence of a positive entity
F12	Presence of a negative entity

The feature extraction converts the words into vectors before training and testing. There are twelve sets of the formula, as stated in Table VI.

TABLE VI. FORMULA FOR FEATURES EXTRACTION

Type	Formula	Description
F1	$F1(T) = p$	T is referred to tweet; p is number of positive words in T
F2	$F2(T) = n$	n is number of negative words in T
F3	$F3(T) = p/n$	p is presence of positive words in T; n is presence of negative words in T
F4	$F4(T) = fp/fn$	fp is frequency of positive words in T; fn is frequency of negative words in T
F5	$F5(T) = p*(1-P+)*mp+$	p is number of positive words in T; P+ is probability of seeing positive words in a tweet; mp+ is manually assigned scores for positive score from lexicon
F6	$F6(T) = p*(1-N+)*mn$	n is number of negative words in T; N+ is probability of seeing negative words in a tweet; mn- is manually assigned scores for negative score from lexicon
F7	$F7(T) = dp$	dp is number of domain specific positive words in T
F8	$F8(T) = dn$	dn is number of domain specific positive words in T
F9	$F9(T) = dp/dn$	dp is presence of domain specific positive word in T; dn is presence of domain specific negative word in T
F10	$F10(T) = fdp/fdn$	fdp is frequency of domain specific positive word in T; fdn is frequency of domain specific negative word in T
F11	$F11(T) = pe$	pe is number of positive entities in T
F12	$F12(T) = pn$	pn is number of negative entities in T

After the extraction process, all data become vectorized data and assigned with sentiment polarity. The data is now ready to be trained and tested using MATLAB. 80% of vectorized data train using the Support Vector Machine classifier in MATLAB. The training dataset process runs eight times on different features for each technique in Support Vector Machine. This experiment aims to find the best features that can achieve high accuracy of sentiment.

After the experiments, the Linear Support Vector Machine classifier achieved high accuracy during the training process. A total of 20% of the remaining vectorized data test the Linear SVM classifier. The results are evaluated.

#### F. Evaluation

The result from the testing process was evaluated by the experts using the Delphi technique. Three experts in the political domain have cooperated in the evaluation phase. The experts are given the sample tweets to label the sentiment polarity separately in the first round of the evaluations. The anonymous responses are shared with the group after the first round. The experts are then allowed to adjust their answers in subsequent rounds. The final sentiments by the experts are collected to compare with the multistage sentiment classifier to measure the accuracy of the classifier.

### IV. RESULTS

The main result for this study is the multistage sentiment classification model. It is a combination of entity and sentiment classification. At the first stage, the politicians and political parties are classified into government or opposition using Malaysia Political Ontology (MPO). This knowledge-based technique helps to identify the entity in the tweets. This stage is crucial in sentiment analysis, especially during the pre-election. The data analysts have to analyze the netizens' opinions

quickly to ensure election candidates decide on the pledge to win the election.

The MPO is constructed using the ontology concept and reflect the political entities in Malaysia, which the political parties are classified into government or opposition. With the enrichment of instances from the Parliament of Malaysia 2021, the MPO can be used to classify the political entities into government (positive), and opposition (negative).

At the second stage, the data from the political corpus are used for sentiment classification. This political corpus is specifically constructed based on the election-related words in the Malay language. It follows the processes of corpus filtering, web search, and filtering using linguistic patterns and domain-specific polarity lexicon. At the end of this stage, the lexicons are classified into positive, negative, or neutral polarity with setting of the score. In this entity classification and political corpus, twelve features are identified and extracted using specific formulas to get the vectorized data. Next, the polarity of the data is set before it is classified using SVM. At the end of the processes, the tweets are classified into positive, negative, and neutral.

Fig. 2 shows the multistage sentiment classification model for Malaysia Political Ontology. It illustrates the whole processes for the multistage sentiment classification. The political tweets need to be pre-processed accordingly to form a political corpus. At the same time, the entity classification uses the MPO to classify the polarity of the political parties. Then, it continues with the final sentiment classification using SVM.

The model is executed in a prototype to prove the concept. The experiments are also carried out using MATLAB. The same dataset is used to compare the results with the previous study.

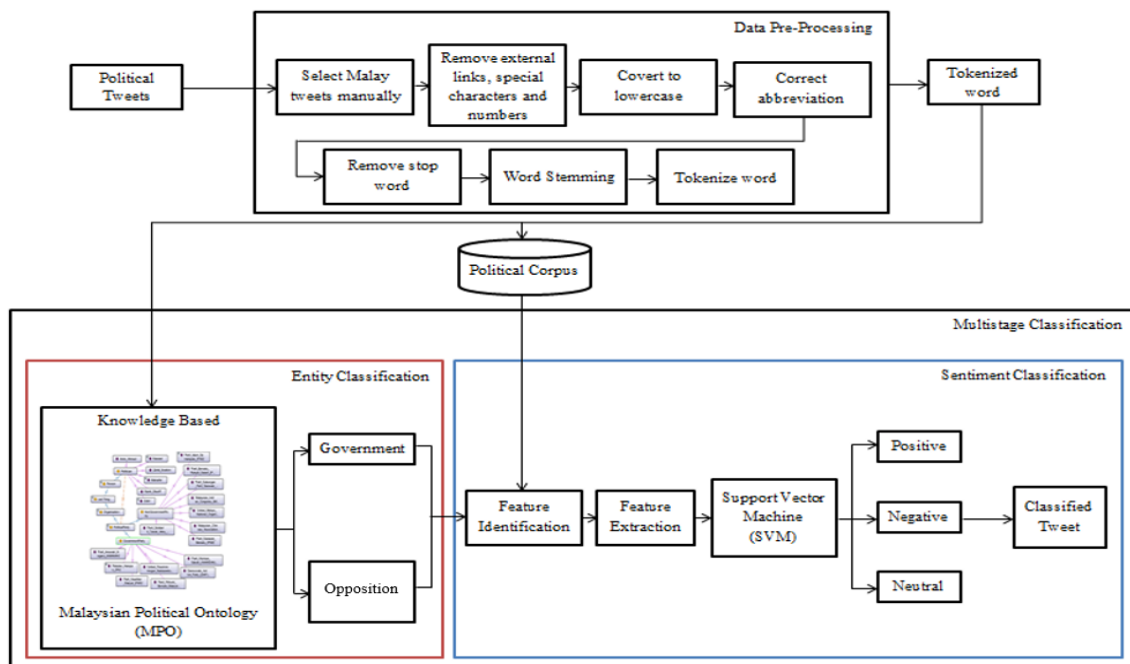

Fig. 2. Multistage Sentiment Classification Model using Malaysia Political Ontology and Malay Political Corpus.

Fig. 3. Accuracy of Classification.

There are five experiments conducted to find the highest accuracy. The classifiers include Linear SVM, Quadratic SVM, Cubic SVM, Fine Gaussian SVM, and Course Gaussian SVM (see Fig. 3).

From Fig. 3, F1-F6 are the features from the existing study. The best accuracy is 81.8% for the F1-F6. The additional features, F7-F12, have improved the accuracy to 86.4% for the classification. The evaluation results show that the 12 features improve the accuracy of the sentiment analysis.

The evaluation of the model is carried out using the Delphi technique. Then, the results between the political experts and the system are compared. We found that the expert results are similar to the results of the experiments.

## V. DISCUSSION

There are few points to discuss from this study. There are available Malay corpora include abbreviation corpus [5] and hadith corpus [6]. However, these corpora are used for the specific domain and are not suitable for the politic. In the political domain, there is a relation between the verb and the candidate or current situation. To ease the classification process, therefore there is a need for specific corpus construction. This study fills the gap by constructing Malay Political Corpus. The terminologies related to the election are the main focus of this study.

The multistage sentiment classification model is successfully constructed in this study. This classification has two stages to classify tweets, which are entity classification and sentiment classification. At the first stage, the politician and party entities are classified as government or opposition using Malaysia Political Ontology (MPO). By classifying the entity, it sentiments the opinions of the netizen towards the politicians and political parties. In the second stage, the classified entity and the political corpus are used for further classification. All data are vectorized using twelve features and finally classifying the polarity of the tweets. The vectorized data are trained and tested using the Support Vector Machine technique. The result

shows that the accuracy is increased by 4.6% compared to the previous study.

However, a few important challenges need to be highlighted in the study. Firstly, the pre-processing process is not covered for negation handling. This negation handling is important to keep the meaning of words. For instance, the word 'tak menang' gives a meaning for 'not winning, with means 'kalah' or lost in English. Thus, the polarity of this word is negative. If there is no negation handling process, the word 'tak' will denote as negative and 'menang' will denote as positive, then the polarity of this word will be neutral. This process affects the accuracy of sentiment.

Secondly, the political corpus in this study is still lacking in lexicon and needs to enrich more political words in future studies. The Malaysia Political Ontology (MPO) only covers person and organization concepts of the political domain. The event and place concepts are out of scope in the study. Therefore, there is a need to covers four main concepts to improve the sentiment analysis in the political domain.

## VI. CONCLUSION

Sentiment analysis tools help to analyze the social media comments into exploitable information for strategic planning in business, marketing, finance, entertainment and politic. The existing sentimental analysis classifiers manage to analyze different languages, but it has yet insufficiently in analyzing the Malay language accurately. Most of the comments that contain Malay words are classified as neutral. This shortage motivates this research to find a better solution for sentiment classification. This research sets the interest to investigate the sentiment classification in the political domain. It is one of the most popular areas due to the political scenario in Malaysia. From the literature, the existing Malay corpora such as abbreviation corpus and hadith corpus are not suitable for the political domain. In the political domain, there is a relation between the verb and the candidate or current politic situation. Therefore, this research constructs Malay Political Corpus, Malaysia Political Ontology, and proposes a multistage classification model. The experiments show the effect of twelve features on the performance of the sentiment classification. The multistage classification model proves that it improves the sentiment classification result by determining the entity in the political domain. The combination of entity classification and sentiment classification in the multistage classification can be a better solution in classifying the sentiments related to the political domain. Besides, the hybrid approach in multistage classification improves accuracy. With the political corpus and the linear SVM, the enhanced features selection increases the accuracy to 86.4%. In the future study, some improvements can be made to the pre-processing, enrich the list of words in the political corpus, and using a larger dataset.

## ACKNOWLEDGMENT

The authors gratefully acknowledge the use of service and facilities of the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA. This study receives funding from the Ministry of High Education (MOHE)

Malaysia, under the Fundamental Research Grant Scheme (FRGS/1/2018/ICT04/UITM/02/9).

# Factors Impacting Users' Compliance with Information Security Policies: An Empirical Study

Latifa Alzahrani

Department of Management Information Systems  
College of Business Administration, Taif University, Saudi Arabia

**Abstract**—One of the main concerns for organizations in today's connected world is to find out how employees follow the information security policy (ISP), as the internal employee has been identified as the weakest link in all breaches of the security policies. Several studies have examined ISP compliance from a dissuasive perspective; however, the results were mixed. This empirical study analyses the impact of organisational security factors and individual non-compliance on users' intentions toward information security policies. A research model and hypotheses have been developed in this quantitative study. Data from 352 participants was collected through a questionnaire, which then validated the measurement model. The findings revealed that while security system anxiety and non-compliant peer behaviours negatively impact users' compliance intentions, work impediments positively influence these intentions. Security visibility negatively influences users' non-compliance, and security education systems positively impact work impediments. This research will help information security managers address the problem of information security compliance because it provides them with an understanding of one of the many factors underlying employee compliance behaviors.

**Keywords**—Information security; users' compliance; compliance factors; security education systems; information security policies

## I. INTRODUCTION

The COVID-19 pandemic raised a crucial technical issue within many organisations due to a lack of relevant information security protocols [1]. Information security is the process and controls put in place to guarantee data access is protected for reading by authorized personnel only, writing by authorized personnel only, and its readiness is protected when needed by authorized parties, etc. According to Miller [2], even before the virus outbreak, IT threats against organisations increased by 35% in the fourth quarter of 2019 compared to the fourth quarter of 2018. The necessity to transfer IT, users, to remote workplaces opened up a new set of vulnerabilities quickly identified by hackers and scammers who took advantage of the situation [2]. Although the US's Cybersecurity and Infrastructure Security Agency advised preventing cyber-attacks, the need for effective and advanced information security measures remains. Information security is defined as a set of processes and policies that protect information from unauthorised access [3]. There is a significant requirement to analyse the actions of organisations related to higher information security standards (ISS) and protective measures. Now more than ever, during the COVID-19 pandemic, companies' most valuable assets consist of digital data, which

puts them at risk of a set of threats from both inside and outside actors [4]. Any organisation needs to implement strategies to prevent commercial data leaks to their competitors and protect their users' privacy [5]. With an ever-expanding set of information technologies, organisations must explore all possible ways to leak information. The COVID-19 pandemic has caused rapid transformation and increased IT in most organisations in many sectors, including education [6], healthcare [7, 8], business [9], and economics [10]. This recent development has considerably changed critical resources and assets. It is vital to ensure that no information is unintentionally disclosed or altered [11, 12]. To shield resources and safeguard organisations' important data from existing threats, progressive information security plans must be developed to list inappropriate and appropriate ISS activities for IT operators [13]. Information security is a complex issue due to its multidisciplinary nature involving organisational, behavioural, and technical aspects [5, 14, 15] and a holistic method is necessary for information security management (ISM) [16, 17]. Also, Siponen et al. [13] recommended that information security matters be regarded from a management perspective.

Existing studies have indicated that even though scholars in the computer science field have investigated the significant phenomenon of information security [18], most have evaluated the subject from an engineering viewpoint. These researchers have concentrated on expanding technical solutions with limited consideration of security from a behavioural perspective [19]. The existing literature has highlighted that many organisations fail to properly link information security with threats beyond outside IT-related breaches by not taking human error into account. According to Choi et al. [3], "organisations increasingly focus on implementing information security products such as anti-virus, intrusion detection, and prevention systems, total personal computer (PC) security, database/contents security, total security systems and public key infrastructure". It has also been noted that the concept of information security requires a strategy that focuses on different organisational aspects, including structured actions, policy, and governance, to protect organisations' information assets. Governance in an organizational context is the development of a management framework to strategically drive the business processes and support compliance with regulations. Governance is planning for effective management, where management is the application of operational decisions. Information security policies are a necessity for business survival in the new digital world; its main goals are to protect confidentiality, integrity and availability, and it has an essential role in today's organizations. Information security policies

standards are core fundamentals that control the arrangements of information systems. There are multiple standards for addressing information security policies in organizations (COBIT, ISO 27001/2, etc.), and combinations of multiple standards that can help organizations define roles and govern information security. However, the different aspects of information security, such as economic, financial and management are complements to the technical side and not substitutes.

Despite this apparent necessity, Pérez-González et al. [20] observed that the lack of internal protection results in more negative impacts and losses than the security threats posed by outsiders. Pérez-González et al. [20] also stated that “government programs and grants to help companies improve information security focus on supporting companies in purchasing hardware and software technology solutions, without paying attention to organisational issues”. Thus, this study aims to fill the gap between the technical measures of information security and companies’ information security policies for users. Recent research in information security has required the consideration of diverse perspectives by analysing both its technical characteristics and organisational variables and then examining issues linked to conformance with information security principles. It also entails developing systems and information security management models and scrutinising certification procedures [21, 22]. These actions are significant because they must focus on information security related to business procedures and the overall contemplation of information security. The development of information security procedures must begin from the strategic level before advancing to other aspects of an organisation [21-24]. Information Security management roles can be defined as follows:

- Defining security roles, responsibilities and applications: relevant when discussing the accountability of users to specific information security occurrences within organizations.
- Defining goals for security: goals should be built using the business model and defined needs. The classification of systems and data could also come into play when defining the security goals; different organizations with different data will have different security goals.
- Strategies for Security: strategies should comply with business needs. This comes to play when planning the future of business services and legal/regulatory compliance.
- Risk assessment and management: especially useful when policies are being developed, it helps in defining and taking ownership of risks to later define the controls to avoid, mitigate/control, accept or transfer the risks. Risk assessment and controls definition are also highly connected to the asset classification.
- Resource management for security: defining the ISG structure needed is important for running safe operations, achieve information security goals, monitor the security status and respond to threats.

- Compliance with regulations and rules: organizations need to comply with regulations to be able to run their business; compliance is needed to ensure the correct security measures and responsibilities are implemented. Investor relations and communications activity (in relation to security goals).

Consequently, it is particularly significant to recognise the organisational aspects that relate to information security. The mechanisms that categorise the organisational features that may impact information security are modern in their approach. These mechanisms differ in methodology and primarily use theoretical approaches, as well as case studies. They also differ in terms of units of inquiry and present an extensive diversity of elements; thus, it is critical to developing this topic by examining the impacts of these mechanisms on information security organisations.

## II. RELATED WORK

Information security policies are a prime component of almost every modern organization. Information security is a key component of such organizations, and the governance of information security enables organizations to add value to products and services, reduce costs and meet customer requirements. Information security products and technologies cannot defend an organization without the appropriate strategies and policies. Organizational aspects have a direct impact on the behaviour and efficiency of information security policies. However, it is confirmed, but repeatedly forgotten, that security is not principally a technical matter but a management or business issue. Different challenges for information security management are also detailed in von Solms and von Solms [25].

There are different organizational issues that challenge information security management in organizations. For example, Ashenden and Sasse [26] discuss the struggles that Chief Information Security Officers (CISO) face as representative of organizational information security management when dealing with organizational issues. The research focuses on management issues in the context of information security and investigates the factors that most influence CISO success in an organization: enabling or disabling a healthy information security management status through business strategy and compliance, marketing, employees’ engagement, CISO identity in the organization, lack of confidence, effectiveness evaluation, organizational structure, and social responsibility. They also emphasized organizational behaviour, where they prove that employee’s reaction to information security management is positive when well informed and educated; however, this cannot always be true because human behaviour cannot be controlled or predicted. They also indicated that autocratic attitude in an organization is highly damaging to the CISO role and is one of the biggest obstacles [27].

There are many other organizational issues that impact information security management in modern organizations that present serious challenges to the information security status. Information technology and information security’s strategic alignment with business objectives is one that is well documented in the literature. Chang et al. [28] established its

importance by stating that IT systems become more adopted for core modern enterprise activities. Doing so would stabilize systems and smooth operations, enabling better performance. The alignment of the business with IT is also important for external business changes and the introduction of new challenges and business opportunities. That is, rapid technological development can introduce new threats and vulnerabilities to data. The size of the organization is another factor that is documented in the literature to have an impact on the ISM status. Ghobakhloo et al., [29] discuss that organizational size has positive relationship to technological innovation and technology implementation, stating that larger organizations usually have better human, technological and financial resources to better utilize information systems; they are also able to handle information security better with better resources, expertise, and training. In addition, Horvath et al., [30] found that vendors are more willing to cooperate with larger organizations. Industry type has long been used by researchers to investigate quality assurance, information and change management, and using IT systems for competitive behaviour. Johnston et al., found large variations in information security related behaviour in organizations whose type of industry relied more on information security. Hasbini et al., [31] also concluded that financial organizations needed more information security to drive business, and therefore such would have an impact on ISM efforts. IT competencies enable an organization to plan, execute and invest in information security effectively. Various researchers have highlighted the importance of a shared management of IT and ISM between IT professionals and business managers in an organization. While there are a number of researchers who addressed the organizational factors that impact information security management in modern organizations and how these could be developed and maintained, there are few researches focusing on exploring these factors in information security policies. This is an important absence because information security policies are different from information security management. Therefore, such a gap needs to be filled for a better understanding of how organizations can (or should) plan to deal with future information security policies issues.

### III. RESEARCH METHODOLOGY

#### A. Data Collection and Sample

The data was gathered from an educational organisation in Saudi Arabia that had been transformed into an e-learning system during the COVID-19 pandemic. Our study used questionnaires to collect data because this method is appropriate for testing both reliability and validity. The study included approximately 400 respondents. Forty-eight incomplete questionnaires were rejected from the collected replies, leaving 352 fully completed questionnaires for analysis. Of these 352 responses, only usable responses were included and converted into an appropriate sample size. Analysis using AMOS was performed to conduct structural equation modelling (SEM), which assessed the proposed model and the final path prototype.

#### B. Study Instrument

The constructs used in the questionnaire. The survey included a total of 23 items to evaluate the six constructs. All the questions were obtained from preceding studies and incorporated into the research to make them more relatable and logical. Each question that the authors derived from previous studies were altered and attuned to the research framework .A five-point Likert scale has been employed to measure the constructs in the questionnaire, which ranged from “strongly agree” to “strongly disagree”. The respondents were required to select the level that most applied to them while considering each item. The respondents were also asked to provide demographic information.

#### C. Pre-testing the Questionnaire

A complex pilot phase and pre-tests of the procedure were initiated, during which particular e-learning experts and users were consulted. The authors employed 10% of the entire sample size for the pilot study. Selecting the sample size was undertaken with consideration of average research performance. All the questions used in the survey were pre-tested. Forty randomly identified students took part in the pre-testing exercise. The study’s dependability was established using Cronbach’s alpha; the alpha values of all variables surpassed 0.7. Consequently, this study’s questionnaire was highly reliable. The entire group of respondents conceptualised the final questionnaire to increase the overall survey quality and its reliability.

#### D. Students’ Demographic Data

Table I presents the survey respondents’ demographic information; most (approximately 83%) were aged 18–25 years old. The percentage of females (56%) was higher than that of males (44%). Lastly, in terms of internet experience, the highest percentage (52.4%) of respondents had 6–10 years’ experience, followed by 29.1% with 1–5 years.

TABLE I. DEMOGRAPHIC INFORMATION

Variable	Group	Percentage
Age	18–25 years old	83.0
	26–30 years old	14.0
	31–35 years old	3.0
	36–40 years old	0
	Total	100.0
Gender	Male	44.0
	Female	56.0
	Total	100.0
Years of Internet Experience	1–5 years	29.1%
	6–10 years	52.4%
	11–20 years	17.3%
	More than 20 years	1.2%
	Total	100.0

Based on a review of the extant literature, the proposed research model was developed considering both the organisational and individual security factors necessary to reduce the non-compliance of IT users. According to Hwang et al. [5], organisational factors comprise “security systems, security education, and security visibility”. In contrast, individual security factors include the impairment of workflow and peers' negative attitudes towards information security and security system anxiety. In addition, the non-compliance of IT users is an antecedent of increasing the intention to comply with security policy. Fig. 1 illustrates the proposed research model and hypotheses, and the following subsections provide further details on each construct.

### E. Security Education Systems

Organisational factors are major reasons for unintended data exposure due to inadequate security policies and technologies. Ideally, an educational institution should implement a security system that will prevent external attempts to gain unlawful access to information and simultaneously prevent employees from sharing this information [5, 32]. A recent study by Pérez-González et al. [20] demonstrated that students' lack of education about information security standards is a significant source of unintentional data leaks. Hwang et al. [5] also highlighted that it is the responsibility of educational organisations to educate their students about data security as any person with access to the organisation's internal network can be a potential threat. The integrity of a security education system affects all levels of individual compliance; an easy-to-use system reduces employees' anxiety when interacting with it. Based on this, the first hypotheses were developed as follows:

- H1. Security education systems negatively influence work impediments.
- H2. Security education systems negatively influence security system anxiety.
- H3 Security education systems negatively influence non-compliance behaviours.

### F. Information Security Visibility

Another major factor is the visibility of security measures, continuously advertised to remain at the top of students' priorities. Information security visibility refers to the degree that an organisation informs its members about its information security policies [5]. Given these factors, the efforts of each organisation play a crucial role in protecting itself against data breaches. Accordingly, this study proposed the following further hypotheses:

- H4. Security visibility negatively influences work impediments.
- H5. Security visibility negatively influences security system anxiety.
- H6. Security visibility negatively influences non-compliance behaviours.

### G. Work Impediments

In terms of individual non-compliance factors, users may ignore specific security policies when completing their tasks due to their unwieldiness. Work impediments are the adverse impacts of implemented security measures on task completion [5]. Other sources of work impediments can stem from insufficient training or data protection policies. As such, this study proposed the following hypothesis:

- H7: Work impediments negatively influence users' compliance intention.
- H8: Work impediments negatively influence system anxiety.

### H. Security System Anxiety

Security system anxiety may derive from a user's unwillingness to report security incidents due to the fear of punishment. Moreover, such anxiety can materialise due to the complexity of information security systems or users' lack of understanding of their functions [5]. Therefore, this led to the following hypothesis:

- H9: Security system anxiety negatively influences users' compliance intention.

Fig. 1. Proposed Research Model.

I. Non-Compliant Peer Behaviours

The third primary source of non-compliance behaviours is social pressure from others. According to Hwang et al. [5], users' behaviour is affected by peer pressure, including the collective attitude towards information security. Students feel more confident following security instructions when they observe their peers doing the same. Therefore, an institution needs to assess the organisational culture to identify such issues. Accordingly, the present study proposed the following hypothesis:

H10: The non-compliance of peers negatively influences user' compliance.

H11: The non-compliance of peers negatively influences work impediments.

IV. RESULTS

The data analysis was conducted in four steps. First, factor analysis of the collected data was conducted to determine the relationships between the variables. After that, confirmatory factor analysis was performed to confirm the findings. Reliability and validity testing were conducted on the model, followed by SEM. SPSS Statistics 25.0 software was used for factor analysis. SPSS AMOS 22.0 software was used to test the CFA model fit and SEM to estimate the relationships between the independent variables and the dependent variable to accept or reject the proposed hypotheses.

A. Exploratory Factor Analysis

The Kaiser-Meyer-Oklind (KMO) and Bartlett's tests were used to check the suitability of the data for factor analysis. The KMO value was 0.844, exceeding the recommended value of 0.70, and, thus, was considered adequate [33, 34]. Bartlett's test of sphericity reached statistical significance (approximate chi-square 5440.263, df 253 and Sig 0.000), signifying that the data was appropriate for factor analysis. The 23 items were subjected to principal component analysis (PCA), and Varimax Rotation with Kaiser Normalization was used for factor analysis. Any items with a factor loading less than 0.50 were eliminated; however, the factor loadings for each item in the present study's questionnaire were above 0.50, suggesting that the data set was appropriate [35, 36]. Consequently, all 23 items were accepted, and PCA revealed that they were grouped into six components with Eigenvalues exceeding 1 (Table II). The total percentage of variance was 76.825. The individual dimensions of the proposed instrument explained the total variance as exceeding 76%, suggesting the suitability of the process.

B. Confirmatory Factor Analysis

CFA explains the extent to which observed variables are linked to latent factors in a study. CFA postulates the relationships between variables based on theory, empirical research, or both and then statistically tests the hypothesised structure. The present study developed the model based on a priori knowledge, and CFA was used to confirm it, as shown in Fig. 2. The measurement model represents the pattern in which each measure loads on a particular factor. It demonstrates how the measured variables come together to represent the constructs and is used for validation and reliability testing. The

covariance between all the latent variables was significant as the P-value was less than 0.05 (Table III).

SEM showed that chi-square (CMIN) = 350.635, degree of freedom (DF) = 153, and the probability level was approximately 0.000, evidence that the null hypothesis was not significant at the 0.05 level. CMIN/DF represents the minimum discrepancy, which was 2.292; according to Wheaton et al. [37], a model has a reasonable fit if the minimum discrepancy is less than 5.

Table V shows the values found for each parameter to test the model's fit. In various studies conducted by Bentler and Bonett [38], Jöreskog and Sörbom [39], Bollen's and Bentler [38], it has been suggested that if the index value is greater than 0.9 and if the RMSEA value is less than 0.08, the model has a good fit.

TABLE V. PARAMETER VALUES FOR MODEL FIT

Parameter	Value
Goodness of Fit Index (GFI)	0.906
Comparative Fit Index (CFI)	0.955
Root Mean Square Error of Approximation (RMSEA)	0.064

### C. Reliability and Validity Tests

All the variables had composite reliability greater than 0.7 (Table VI), which indicated good reliability.

TABLE VI. COMPOSITE RELIABILITY TEST

	CR
Edusys	0.893
Int	0.943
Anx	0.839
Peer	0.888
Vis	0.892
Imp	0.761

All the variables had a convergent validity greater than 0.5 (Table VII), indicating good convergent validity.

TABLE VII. CONVERGENT VALIDITY

	AVE
Edusys	0.582
Int	0.805
Anx	0.635
Peer	0.725
Vis	0.805
Imp	0.624

The discriminant value was greater than the corresponding correlation between the variables, indicating good discrimination between the factors in the analysis (see Table VIII).

### D. Structural Equation Modelling

SPSS AMOS 22 software was used to perform CFA via SEM. The model was over-identified, which is a preferable situation for SEM. The path diagram in Fig. 3 specifies the relationship between the observed variables. The model's portion that specifies how the variables are related is

represented by the structural model; the estimates with the largest values represent the most important dimensions in terms of their influence on dependent variables. The findings of the regression weight estimates are summarised in Table IX. P-values demonstrate the significance of estimation: if the P-value is less than 0.05, then the independent variable has a significant effect on the dependent variable (P-values with \*\*\* indicate 0.000). All the impacts were significant except for information security visibility acting on security system anxiety, which did not significantly impact as the p-value was 0.036 (i.e. less than 0.05). Table X presents the results of standardised regression weight estimates.

Table X highlights that both the security education system and system visibility had a significant negative impact on peers' non-compliant behaviour. In addition, this study

highlights that both the security education system and peer' non-compliant behaviour had significant positive impacts on work impediments. In contrast, the system's visibility had a significant negative impact on it. Considering the factors influencing system anxiety, this study highlights that the security education system had a significant negative impact on security system anxiety. In contrast, the work impediments had a significant positive impact of 0.995 on security system anxiety. However, system visibility had no significant impact on security system anxiety. Finally, regarding the compliance intention, the findings of this research present that both security system anxiety and peer' non-compliant behaviour had a significant negative impact on compliance intention. In contrast, work impediments had a significant positive impact on compliance intention.

## V. DISCUSSION

This study analysed the relationship between organisational security factors and users' non-compliance behaviours in one higher education institution's transformation to online systems during the COVID-19 pandemic. A proposed model was developed based on a recent study by Hwang et al. [5]. In total, six constructs were selected for the model: two organisational security factors (security education systems and security visibility), three individual non-compliance causes (work impediments, security system anxiety and the non-compliance behaviours of peers) and compliance intention. The proposed model was tested using SEM. The negative link between study impediments and compliance was significant. This result is similar to previous findings, as work impairments diminish compliance [40, 41]. Users' compliance increases when they identify security actions as impediments to achieving the goals of a distinct task.

The hypothesis that security system anxiety exhibits a significant negative impact on compliance intent was

supported, an outcome that was similar to previous research demonstrating that employees' anxiety decreases their intent to comply [42, 43]. Users' anxiety regarding security systems, triggered by an institution's imprecise security guidelines, thus, has an undesirable effect on their compliance. The hypothesis that peers' non-compliance behaviours have an undesirable impact on compliance intent was also supported. Generally, people tend to follow the behaviours of others if they are in the same group. Consequently, as students working on an online system obey the same security guidelines, there is a higher chance that other individuals in the same group will embrace comparable behavioural patterns. Therefore, information security actions are necessary at a university's personal, departmental, and team levels. Meanwhile, the hypothesis is that security education negatively impacts users' non-compliance with information security policies. This demonstrates limited equivalency with previous findings that security education systems decrease the non-compliance of workforces [12]. Security education systems effectively lessened work impairments and were significant in decreasing non-compliance behaviours and security system anxiety. Lastly, the hypothesis suggesting the negative link between security discernibility and users' non-compliance. This outcome is similar to preceding studies that have demonstrated that security visibility augments employees' compliance intent at work [13]. Security visibility can be heightened by suggesting approaches for security actions and public relations packages, for example, visual advertisements regarding an organisation's information safety requirements.

We previously discussed the importance of users' compliance with information security policies and suggested methods to have that accomplished. Such measures are expected to be even more pressing as information security issues could be the cause of large-scale damage. Users' compliance with policies and regulations is an important matter and a major worry for modern organizations. A different number of challenges could be behind the lack of sufficient users' compliance, also going back to the literature around employee engagement part of an organizational culture. Hu et al. [44] emphasized the critical importance of top management's commitment and participation towards the influence on the organizational compliance culture and shaping the intention of employees to comply with information security policies. Puhakainen and Siponen [45] emphasized the need for the adoption of information security awareness training and continued communication processes to motivate the employees' systematic cognitive processing of the information they receive and achieve the best development of employees' compliance results. Another influencer of employees engagement is their perception of trainings and career development inside the organization, which highly reflect on smart cities requirements which demand smart people, though such cannot be achieved without strong skills development techniques employed in the workplace and presented in different forms of modern training methods like wargames or simulations [46].

## VI. RESEARCH IMPLICATIONS

This study's findings highlight some significant implications for both practitioners and academics. First, the

study confirmed that the intent to comply with an organisation's information security policy is undesirably impacted by the mediators of work impediments, the non-compliance of peers, and security system anxiety. A study impediment denotes the limitations on working processes and activities caused by conforming to established security guidelines. Education processes involve particular tasks, and completing these tasks is a more significant goal than complying with information security guidelines. Each time information security actions impede or conflict with their tasks, students can identify rational reasons for compliance but demonstrate non-compliance intents. Consequently, organisations should convince students that constructive security conduct is among the most important performance elements. Security system anxiety denotes an individual's hesitation or fear regarding information security guidelines. If these guidelines are severe and complex, users can experience anxiety regarding their security behaviours. In various cases, users may comply, although, in reality, they are more prone to non-compliance. Consequently, organisations should offer users support to better comprehend the systems and policies affecting information security. The non-compliance actions of peers encompass the belief that peers do not conform to the organisation's security procedure. Users exhibit tendencies to act like their peers. Comparable tendencies were demonstrated in this study, emphasising the need to promote a security atmosphere that stimulates peer compliance.

Secondly, the study's findings highlight that organisations' security efforts impact users' non-compliance. Security education systems increase work impairments, reducing peers' non-compliance and security system anxiety. Homogeneous security structures increase work impairments; for instance, organisations encourage users to use proficient USB drives and activate cloud-oriented security structures to systemise their safety configurations: security structures and security education system, anxiety, and non-compliant peer behaviour. Comprehensive education on matters linked to security procedures, performance, and behaviours may decrease users' system anxiety concerning required security actions, as well as peers' non-compliance tendencies. Moreover, security visibility was shown to decrease security system anxiety and peers' non-compliance behaviours; therefore, exhaustive promotion of security campaigns and guidelines may decrease these negative outcomes. Information security and protection controls should only be introduced when a risk is confirmed; they need to be cost-effective. Information security roles and responsibilities should be made public to all employees through the utilization of the information security policy. The information/asset owner is responsible for the monitoring and control of the information/asset usage in addition to the authorization of the users. They should also verify compliance with the information security policy and ensure that the system is appropriately secured. Information protection requires a comprehensive approach that follows a system development lifecycle. Information security should be periodically reassessed and verified, based on objectives and requirements. In

addition, information protection is directly impacted by the organizational culture. Information security management should be involved with business units to best understand their needs and determine the solutions that best protect assets.

This research expands the protection motivation model by suggesting discrete non-compliance causes and recommends organisational strategies for universities to help alleviate non-compliance with information security measures. The investigation recommends administrative variables for security improvement, including security education, security systems, and security visibility, as important constituents in reducing students' non-compliance with information security strategies. For establishments in which study impairments are a main cause of non-compliance, the institutions should invest primarily in security structures. In organisations with increased non-compliance levels and security system anxiety, an appropriate assortment of security systems, visibility, and education can result in satisfactory users' compliance.

## VII. CONCLUSION

This study aimed to establish a causal link between organisational security efforts and the reasons for users' non-compliance with information security policy during the COVID-19 pandemic. Specifically, the study scrutinised the influence of organisational countermeasures, including security education systems and security visibility, on the causes of users' non-compliance, including work impairments, security system anxiety, and peers' non-compliance behaviours. SEM was used to test the suggested hypotheses with data collected from students at a business college. The findings showed that users' compliance intent is negatively impacted by the mediators of security system anxiety and the non-compliance of peers, while it is also positively influenced by work impairments. Meanwhile, the independent variables of security education systems and security visibility negatively impact security system anxiety and the non-compliance behaviour of peers. Nevertheless, only security education systems were found to positively impact the work impairment of the identified independent variables. The study's outcomes indicate the significance of security visibility and education in decreasing non-compliance, although security education systems seem to increase it. This study has some limitations. First, it is restricted in that we measured students' reflections on the reasons for individuals' non-compliance and organisational security efforts without discerning real activities. Consequently, future research should observe real behaviours related to information security objectives via controlled research laboratory experiments. Second, this study used SEM to examine the reasons behind users' non-compliance and organisational efforts to alleviate these reasons. In the future, we plan to discover the theoretical factors behind compliance intent that are highlighted by education belief theory and safeguard the motivation model, which can impact the instigators of non-compliance with the data security policy and procedures employed in higher education. Lastly, this study was situated in a precise time and location. It may be reinforced by longitudinal studies that observe diverse nations for a more robust overview of information security outcomes.

# The Application of Image Processing in Liver Cancer Detection

Meenu Sharma\*, Rafat Parveen

Dept. of Computer Science, Jamia Millia Islamia  
New Delhi, India

**Abstract**—Hepatic cancer is caused by the uncontrolled growth of liver cells, an HCC is the most common form of malignant liver cancer, accounting for 75 percent of cases. This tumor is difficult to diagnose, and it is often discovered at an advanced stage, posing a life-threatening danger. As a result, early diagnosis of liver cancer increases life expectancy. So, using a digital image processing method, we suggest an automated computer-aided diagnosis of liver tumors from MRI images. Magnetic Resonance Imaging (MRI) images are used to identify liver tumors in this case. The image goes through image preprocessing, image segmentation, and feature extraction, all of which are done within the layers of an Artificial Neural Network, making it an automated operation. To make the edge continuous, this operation combines two processes: edge and manual labeling. On the basis of statistical characteristics, tumors are often divided into four categories: cyst, adenoma, hemangioma, and malignant liver tumor. The aim of this proposed technique is to automatically highlight and categorize tumor regions in Magnetic Resonance Imaging images without the need for a medical practitioner.

**Keywords**—Liver cancer; digital image processing; magnetic resonance imaging; early stage

## I. INTRODUCTION

Every day, billions of cells in our body multiply to create new cells. The newly created cells take up the area previously occupied by dead cells. Cells primarily combine to form tissues, which then combine to form organs [1]. As a result, in some abnormal cases, cells divide faster than the body requires, resulting in lumps or growths that are commonly referred to as tumors [2]. Tumors are irregular tissue growth caused by uncontrolled cell proliferation. They serve no physiological purpose and may be cancerous (malignant or metastases) or non-cancerous (benign) [3]. A benign tumor does not have the ability to spread to other areas of the body, while a malignant tumor does. Malignant tumor begins in the liver and grows on the surface or inside the liver. Primary cancer is described as cancer that begins in a tissue or organ, and primary liver cancer refers to tumors that occur from the liver itself. Hepatocellular Carcinomas is the most common form of malignant liver cancer [4]. We proposed a simple cancer detection approach based on digital image processing in this research paper.

Digital image processing is the method of processing images using computers and the necessary algorithms. Image processing is an evolving and growing industry of medical applications. The tumor area is detected using a computed tomography (CT) scan and a magnetic resonance imaging (MRI) scan image of liver cancer. Magnetic resonance imaging

(MRI) is a much safer technique than CT scan for avoiding ionizing radiation while still providing a better visualization picture of soft tissue. Detecting and analyzing tumors will assist doctors in providing better care to patients and reducing mortality rates [5]. There are three major stages in detecting liver cancer. Image preprocessing, image segmentation, and tumor area highlighting are all part of the process. Image resizing, image contrast enhancement, noise removal filters, and image imperfections are all examples of image preprocessing. This phase is critical in cancer detection because even a slight deviation caused by imperfections or noise can have a significant detection impact [2]. In a decision-oriented application for image segmentation, pixels of an image are correctly categorized. Image segmentation techniques include threshold-based, edge-based, clustering-based, neural network-based, and others. Image segmentation aims to make an image's representation more relevant and easier to analyze by simplifying or tuning it [6]. In conventional clinical practice, 3-D organ analysis is done manually, which takes a long time. Automated methods have a number of benefits over manual or interactive approaches. Automated methods are more efficient and do not necessitate the intervention of a person [3]. We used the Artificial Neural Network (ANN) algorithm to automate the tumor detection process in this study.

Artificial neural networks are a form of computation inspired by the human brain and nervous system (ANNs). ANNs have been used to perform cognitive tasks usually done by the brain, such as facial recognition, learning to speak and understand a language, recognizing handwritten characters, and determining if the same object is a target viewed from different angles. However, the number of applications for ANNs is the, and they have recently been used successfully in digital image processing [7].

In this analysis, we expect to segment a tumor into a liver, making it easier for the surgeon to see the tumor and treat it. The MRI images are taken in this analysis, and then the segmentation processes are applied to the liver image in order to locate, extract, and further identify liver disease [8]- [10]. We also show how to use image processing to automatically segment CT liver images and remove tumors, as well as categorize tumors into four groups: liver cancer (hepatoma), adenoma, cyst, and hemangioma, with analysis focused on statistical features without the intervention of humans, though keeping in mind that the manual method of testing data sets is time consuming and less accurate than computer-based analysis, and cost is also a consideration [11] – [20].

The following is how the paper is organized: Section 2 contains a detailed description of the proposed methodology. Section 3 discusses the findings and their discussion, and Section 4 concludes.

## II. MATERIALS AND METHOD

The aim of this study is to process and analyze MRI scan images in order to determine if they contain cancer cells or not, and if they do, which type of cancer cells they are. These images come from the Cancer Genome Atlas (TCGA) database, which is open to the public. To process the files, the experimentation procedure employs the MATLAB R2018 program. The segmentation and extraction process depicted in Fig 1 elucidates the overall methodology.

The dataset for this study includes MRI scan images of liver cancer, as well as five images of adenoma, cyst, and hemangioma. Image preprocessing was performed because the images framed by the MRI scan have some noise and discrepancy. The picture is normalized in this step by

minimizing noise, changing contrast and scale, and eliminating blurriness all at once. The image's noise and blurriness will slow down the process.

Since the cancer cell is now considered a region of concern, segmenting the liver alone from an abdominal MRI image is complicated since the image contains other organs such as the kidney, spleen, and pancreas that are very close to the liver and have similar intensities. The experiment uses image segmentation based on edge to collect only the liver component and examine the cancer cell. To make the edge continuous, manual labeling is performed. The segmented image, which depicts the extracted liver with cancer cell, is now used to detect cancer cells. The function is extracted by cropping the region of interest, and the k-means algorithm is used to evaluate and judge if the given image is cancer cell or not. Table 1 shows the clusters formed as a result of the above-mentioned procedure. The number of pixels must be calculated for statistical analysis of the affected portion, which is done using MATLAB software.

Artificial neural networks are used to automate cancer cell identification and further categorization in liver cancer, cyst, hemangioma, and adenoma. Artificial neural networks (ANNs), also known as neural networks (NNs), are computer structures that are loosely based on the biological neural networks that make up animal brains. The artificial neural network feedforward neural network was used in this study. It is made up of layers of neurons (nodes), such as input, hidden, and output layers. Nodes in neighboring layers have connections or edges connecting them. The input layer is made up of input nodes that provide information from the outside world to the network. This layer includes an MRI scan that is analyzed to determine if it contains cancerous cells and, if so, further categorization. There are no direct relations between the hidden nodes and the outside world.

They perform calculations and send data from the input nodes to the output nodes. While a feedforward network can

only have one input layer and one output layer, a hidden layer is formed by a group of hidden nodes. A feedforward network may have zero or several hidden layers. Different masks are saved as hidden nodes in different hidden layers, and the expected edge is compared to all the masks stored in hidden layers, with the highest matching being chosen. The output nodes, collectively known as the “output layer”, are in charge of computing and distributing network information to the outside world. As seen in Fig 2, this layer automatically generates the segmented liver.

Then, on a segmented liver, use the k-means clustering algorithm to predict the cancer-affected area. As shown in Fig 3, tumor analysis and categorization were performed on the basis of statistical features into four categories: cyst, liver cancer, adenoma, and hemangioma.

Fig. 2. Automate Segmentation.

### III. RESULTS AND DISCUSSION

One of the most difficult challenges confronting today's researchers is cancer detection. Despite extensive study, there is still a lack of an accurate model since detection is a multidisciplinary role that depends on a variety of parameters. The advancement of accurate cancer detection techniques at an earlier stage has been the subject of extensive research. This paper proposed a novel method for the early detection of cancer that is comparatively precise, less time consuming, and simple to calculate.

From the TCGA database, an MRI scan dataset was downloaded. After the liver segmentation preprocessing is completed, a mask for all images is generated. All of these masks are held in a hidden layer at various nodes. This mask was created using an edge, and since it is discontinuous, manual marking was used to make it continuous. To distinguish cancerous from non-cancerous regions, the Kmeans clustering algorithm was used, followed by statistical analysis. Skewness, Kurtosis, Energy, Entropy, Standard deviation, Eccentricity, and Circularity are used in statistical analysis.

When all of the image's textures were analyzed, the average value was determined for all cases of liver cancer, adenoma, hemangioma, and cyst, and then the calculation of the average was obvious by looking at the data in the form of tables. The Hemangioma has the highest values for Skewness, Entropy, and standard deviation, as can be seen in the table. Also, in the Hemangioma case, the energy and circularity are at their lowest levels as compared to other cases. The cancer of the liver has the highest energy value, indicating that it is mild and has less gray color. Since entropy is inversely proportional to energy, liver cancer has the highest energy value. As a result, it has the lowest entropy value.

The skewness gives a visual representation of the textural symmetry. As a result, the Adenoma has the smallest value, and the texture has the least symmetry. This means the texture is irregular and non-homogeneous, much like kurtosis. When it

comes to circularity, only a circle has a circularity of one, while every other form has different value than one. The cyst has the highest circularity value, because its form is more circular, while the Hemangioma has a lower circularity value. If the eccentricity value is one, the shape appears to be a line segment, and if it is less than one, the shape becomes more inclined toward a circle. Liver cancer has the highest Eccentricity value, indicating that its shape is more like a line section, while Adenoma has the lowest Eccentricity value, indicating that its shape is more like a circle.

The artificial neural network algorithm is used in the following research to do automatic tumor prediction in an image. Real-time MRI scans, used to determine whether a tumor area exists or not, were obtained from patients and fed into the first layer of an artificial neural network for liver segmentation after preprocessing. In addition, the mask is being prepared for real-time MRI. Then compare the masks saved in the hidden layer with the masks from the real-time MRI. After that, the liver is segmented using the mask with the best match. We get segmented liver in the output layer. To distinguish cancerous from non-cancerous regions, the K-means clustering algorithm was used.

The artificial neural network model is trained using all MRI scan images of liver cancer. A total of ten MRI scan images are used in the testing. The classification using an artificial neural network yielded an average result of 0.9 percent; the annotated result is shown in Fig 4.

The working of the proposed technique is depicted in this research paper on a single MRI scan, with measured attribute values of Eccentricity 0.7924, Circularity 0.7314, Skewness 0.3816, Kurtosis 1.9987, Energy 0.0049, Entropy 0.0415, and Standard deviation 0.0034 after study. When the computed attributes were compared to the average value of all the features (as shown in Table 2), this MRI scan was classified as Liver cancer, which it actually is. Figure 4 depicts the contrast of a real-time MRI scan's discontinuous mask with a mask stored in hidden layer.

Fig. 4. Shows the Working of our Proposed Method.

TABLE II. AVERAGE VALUE OF FEATURES FOR ALL CASES

Name	Skewness	Kurtosis	Energy	Entropy	Standard deviation	Eccentricity	Circularity
Liver Cancer	0.5149	3.3062	0.005583	0.0531	0.00454	0.7223	0.6545
Adenoma	0.4326	1.4709	0.000497	0.4588	0.05064	0.5867	0.5932
Hemangioma	0.6852	2.6214	0.000446	0.7261	0.05382	0.6932	0.3868
Cyst	0.4234	1.2686	0.000589	0.4413	0.0386	0.5945	0.6883

#### IV. CONCLUSION

Liver segmentation is a difficult task, and automating it is even more difficult, as it involves several steps such as preprocessing, segmentation, and classification. The analogous intensities of other organs such as the spleen, flesh, and muscles are all considered during preprocessing. The artificial neural network algorithm aids in the solution of this problem, automating it through the use of edge and manual marking to create a continuous edge system. The average accuracy rate of the whole liver segmentation using the artificial neural network algorithm is 0.9 percent. Furthermore, an automated method is being developed to identify tumors as benign or malignant, as well as a method to classify perpetual objects using features. It is self-evident that an automated method for classifying tumors as benign or malignant can be useful in object recognition, especially when dealing with medical imaging issues. In addition, a new classification for liver tumors is being considered, which includes more forms of benign liver lesions such as hemangioma, cyst, and adenoma.

#### ACKNOWLEDGEMENT

I am thankful to the Indian Council of Medical Research (ICMR), New Delhi, India for providing me funds for doing this research.

Bengaluru, India

**Abstract**—Criminal activities, be it violent or non-violent are major threats to the safety and security of people. Frequent Crimes are the extreme hindrance to the sustainable development of a nation and thus need to be controlled. Often Police personnel seek the computational solution and tools to realize impending crimes and to perform crime analytics. The developed and developing countries experimenting their trust with predictive policing in the recent times. With the advent of advanced machine and deep learning algorithms, Time series analysis and building a forecasting model on crime data sets has become feasible. Time series analysis is preferred on this data set as the crime events are recorded with respect to time as significant component. The objective of this paper is to mechanize and automate time series forecasting using a pure DL model. N-Beats Recurrent Neural Networks (RNN) are the proven ensemble models for time series forecasting. Herein, we had foreseen future trends with better accuracy by building a model using NBeats algorithm on Sacramento crime data set. This study applied detailed data pre-processing steps, presented an extensive set of visualizations and involved hyperparameter tuning. The current study has been compared with the other similar works and had been proved as a better forecasting model. This study varied from the other research studies in the data visualization with the enhanced accuracy.

**Keywords**—Time series analysis; deep learning; RNN; forecasting; crime data; predictive policing; machine learning

## I. INTRODUCTION

Time series analysis and forecasting[7][17] has always been crucial in the aspects of many research applications such as stock prediction, weather forecasting, supply chain management etc., So why not time series forecasting on crime data?

A time series [5] is a set of numerical values of the same entity taken at equally spaced intervals over time. A time series dataset can be collected yearly, monthly, quarterly and daily etc., any time series analysis can be explained with the help of three components such as

- Trend – Overall long-time direction of series (May be upward or downtrend trend).
- Seasonality – Repeated behaviour at fixed intervals of time.
- Cycles – Occurs when it follows up or down pattern that is not seasonal and can be of varying length.

Conventionally time series analysis has been implemented using linear methods such as AR models, ETS etc., and these methods are simple and effective in implementation for smaller datasets. Machine learning [8] and Deep learning algorithms on the other hand are able to learn the temporal dependencies among the features and do forecasting with more accuracies. Also, deep learning algorithms automatically learn features and build model whereas manual feature extraction is required. The major challenge of this research is to handle the growing volumes of crime data and to build a predictive model with improved accuracy.

This paper is intended to build a better performing forecasting model [4][6] on the crime data. The objective of the current study is to gage the forecasting capacity of the NBeats model [1] on crime data, which is a hybrid of RNN-LSTM [4]. This model will aid police personnel in optimal decision-making and resource management. This work has been compared with the previous works done in this domain and the results are tabulated.

The rest of the paper is organized into the following segments. Section II introduces the existing methodologies. Section III deliberates the proposed approach with flowchart to build a model, discusses the techniques to prepare the dataset suitable for time series analysis and also presents a wide array of data visualization. In Section IV, the outcomes of the forecasting model and measures to calculate its error percentage are presented.

## II. EXISTING METHODOLOGIES

Below is the detailed discussion of the existing methodologies used for forecasting. There are additive models, auto regression models[14][16], machine learning[8][15] and deep learning models[6][12] that are used to foretell about the trend or pattern of the crimes.

### A. Exponential Smoothing (ETS Models)

These ETS models[10] use weighted average of past observations. The components of the model are error, trend and seasonality. Each component can be applied either additively or multiplicatively. Additive methods are useful when the trend and seasonal variations remain constant over time whereas multiplicative methods are applicable when trend and seasonality decrease or increases in magnitude over time.

There are four ETS models:

- Simple exponential smoothing method - In simple exponential method, forecast has been measured as follows.  $Forecast = weight_t y_t + weight_{t-1} y_{t-1} + weight_{t-2} y_{t-2} + \dots + (1-\alpha)_n y_n$ , where  $t$  is the number of periods before the most recent period and  $y_t$  is the target value of time series in 't' and ' $\alpha$ ' is the smoothing parameter.
- Holt's linear trend method - The simple exponential method was expanded to include forecasting data with a trend known as double exponential method or Holt's linear trend methods. This method builds off simple exponential smoothing method not only the level but also trend in its calculation. Trend in this method is always applied in a linear or additive fashion and this method is great and suitable for non-seasonal data.
- Exponential trend method - A variation of Holt's linear trend method is the exponential trend method. It uses the same components (Level and trend) but they are applied multiplicatively. This method is great for non-seasonal time series analysis.
- Holt-winters seasonal method - This method models all the three components such as level, trend and seasonality of time series analysis. It can be either implemented as additive or multiplicative model. The additive method is used in which seasonal fluctuation does not change in time whereas in the multiplicative method, seasonal fluctuation changes in time.

### B. ARIMA Model

ARIMA[11] stands for auto regressive integrated moving average. It is of two types: Seasonal and Non-seasonal. Non seasonal models is built on three components: AR(p), I(d) and MA(q). (p,d,q) represents the amount of time periods to lag for in ARIMA calculation.

- p - refers to the previous periods or the number of lag observations.
- d - refers to differencing term and the number of transformations used in the process of transforming a series into non stationary one.
- q - refers to moving average.

### C. Recurrent Neural Networks(RNN)

Neural networks(NN)[6] in general are simple and great for classification problems by assigning labels and for regression problems in which a continuous value can be predicted. The disadvantage with this kind of NN is that its tendency to forget what it learned or what happened in the past. When it comes to sequential data or ordered data in which data points are interdependent, these NN are a greater disadvantage. Here RNN[4] come into picture which could be imagined as they have a sense of memory to remember what happened in the past. Hence RNN is best suited for time series analysis.

## III. PROPOSED APPROACH

This section introduces dataset and its attributes, data pre-processing steps, smoothing and normalization techniques,

proposed architecture, an algorithm to build a model and evaluation of a model using error accuracy measures such as MAE and Smape.

### A. Dataset

The data used in this paper are real time dataset which was collected from the Sacramento police Open Data portal <https://data.cityofsacramento.org/search> (2014-2021). The dataset contains attributes such as FID, RecordId, Offense Code, Offense\_Extension, Offense Category, Description, Police District, Beat, Grid, occurrence Timestamp. Each instance of the dataset is a crime record with date and timestamp. There are totally 66 unique crime categories. The data set is a collation of the past seven years data and contains a total of 2,72,333 records approximately.

The geographical locations[9] of city of Sacramento have been divided into six districts. Each district is divided into beats and there are a total of 21 prominent beats, beats further split in to grids for better patrolling and surveillance. The dataset reports 66 unique categories of offenses such as trespass, weapon offense, petty theft, burglary, DUI alcohol, owning or possessing ammuniton, conspired crime, vehicle theft, false personation etc.,

### B. Proposed Architecture

In Fig. 1, a flow chart is depicted that explains the proposed methodology step by step.

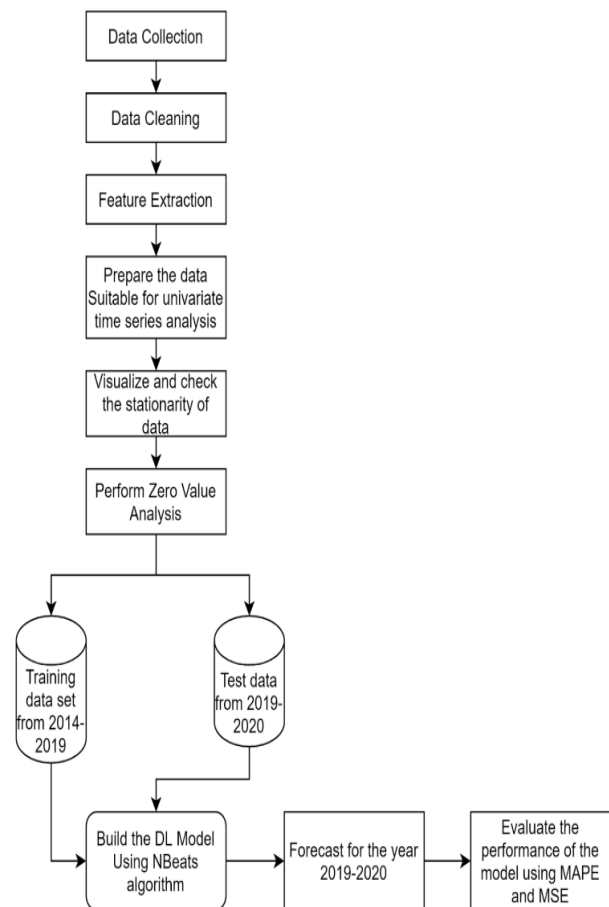

Fig. 1. Proposed Flow of this Work.

It begins with data collection, cleaning and extracting the appropriate features that suit to the requirement of time series analysis. Later, the dataset was tested to realize whether it is stationary or not. Smoothing and normalization techniques had been applied to understand their necessity. Then the dataset was divided into testing and training sets. The model had been trained on 2014 – 2020 data and was tested and forecasted on for the next year 2020-2021 data. The accuracy of the model was measured using MAE and sMAPE.

C. Data Preparation

The real time dataset has to be modified to suit Univariate time series analysis[13][17]. The dataset is cleaned by removing duplicate entries and the rows that contain null values. Less than 1% of rows are found dirty and removed. The instances in the dataset are grouped by Beat and the crime count is calculated for each day beat wise as given in Fig. 2. The zeroth row displays two crimes recorded on 01<sup>st</sup> January 2014, ten crimes recorded on 02<sup>nd</sup> January 2014 and so on in the beat ‘1A’.

For better performance of the model and to achieve uniformity in timeline across the Beats, the period from 2014-12-31 till 2020-12-31 have been considered and the rest of the days are ignored. To do forecasting, measurement of data should be sequential and equal with utmost one data point. For each day within the stipulated time period, the number of crimes is counted.

D. Checking the Stationerity of Series

To check the stationerity of time series, a histogram had been plotted for the 500 days from 1<sup>st</sup> of January 2014 against crime count. Since the distribution of data across the plot did not follow Gaussian distribution and it looked like the distribution is squashed as given in Fig. 3, it may be concluded that the mean and variance is not the same thereby, the given time series data is not stationery dataset.

E. Zero Value Analysis

Zero value analysis is one of the smoothing techniques. With respect to our time series forecasting, zero value analysis is finding the count of days within the given period for each Beat whose crime count is nil for the day. The sample result is given in Fig. 4.

	Beat	Occurence_Date	Record_ID
0	1A	2014-01-01	2
1	1A	2014-01-02	10
2	1A	2014-01-03	8
3	1A	2014-01-04	6
4	1A	2014-01-05	11
...	...	...	...
57625	UI	2021-02-10	2
57626	UI	2021-02-11	2

-----
for the beat : ( 4A ) of 1day interval with zero crimes: 17
-----
    
```

Fig. 4. Snapshot Displays Count of Days with Zero Crimes, Beatwise.

For a total of 2,192 days, a time series analysis[13][17] graph with the number of days on the X axis and the count of occurrences of crime on the Y-axis has been plotted for every Beat. Below are the snapshots starting from Fig. 5 till Fig. 13.

For each Beat, a time series graph has been plotted with the incrementing number of days on x-axis and count of crimes on y-axis. From the graphs, it is obvious that the given data set is not a stationary dataset as it exhibits strong seasonality and also there is no obvious upward or downward trend.

Fig. 5. Time Series Plot for Beat 1A.

Fig. 6. Time Series Plot for Beat 1B.

Fig. 7. Time Series Plot for Beat 1C.

Fig. 8. Time Series Plot for Beat 2A.

Fig. 9. Time Series Plot for Beat 2B.

Fig. 10. Time Series Plot for Beat 2C.

Fig. 11. Time Series Plot for Beat 3A.

Fig. 12. Time Series Plot for Beat 3B.

Fig. 13. Time Series Plot for Beat 3M.

Some Beats (geographical locations) recorded the highest number of crimes whereas some Beats such as Beat 3M as in Fig. 13 showed a smaller number of crimes reporting on a daily basis. Most of the Beats exhibited repeating patterns at fixed intervals of time is said to have seasonality. In most of the plots, there is a display for the presence of noise with extraordinary spikes in the growth of crimes.

A normalization technique has been applied to the feature ‘count of crimes’. The count of crimes for every day has been normalized in the range of 0 to 1. The rationale behind this normalization is that in general, deep Learning algorithms that suffer from vanishing and exploding gradient descent problems. In order to overcome these problems, data normalizing have been applied.

#### F. Algorithm

N-Beats – Neural basis expansion analysis for interpretable time series forecasting [1][2] is a block based deep neural architecture suitable for Univariate time series analysis. It is chosen to build a pure deep learning model for forecasting based on time series that can take non stationary data with long term trends and seasonality and excels the accuracy of existing models such as ETS, ARIMA and Holt Winters, etc.

NBeats[1][2] is a hybrid model of RNN and LSTM that takes an entire window of past values and computes many forecast time point values in a single pass. For doing so, the architecture uses fully connected layers containing several blocks connected in a residual way. The first block models the past data(backcast) and predicts the future, then the second block models only the residual error from the previous block and improves the forecast values based on this error and continues to repeat.

Hence it is a residual architecture wherein multiple blocks are stacked together to avoid the risk of gradient vanishing which is common in deep learning algorithms and also has the advantages of ensembling technique. Hence the forecast value is the sum of predictions of several blocks and keeps improving based on residual errors calculated in the other blocks.

Advantages of using N-BEATS RNN over several traditional approaches:

- As all operations are parallelized, it supports quicker training of networks.
- Stacked blocks are much configurable thereby light weight networks.
- Fully Configurable Backcast and Forecast.

This model in Fig. 14 takes time series data upto  $Y_t$ , where  $y = \text{datapoints upto time 't'}$  as its input and predict future  $Y_{t+l}$  where  $l = \text{length of forecast window}$ . Let us consider  $t = 90$  days and  $l = 30$  days. The size of the input is always  $x \cdot H$  where  $x$  refers to features and  $x = 1$ , also known as Lookback Period. During this period, our time series model learns the behavior in the past and tries to predict the behavior of  $H$  data points which is known as Forecast period. In our case, it is for one day.

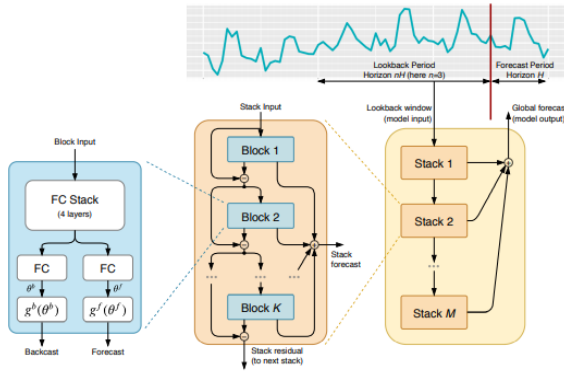

Fig. 14. NBeats Deep Layered Architecture [1].

NBeats architecture takes time series data for the lookback period of 90 days as input to stack 1, and each stack in turn is made up of multiple blocks and it is necessary to understand the structure of basic block as given below.

1) *Basic blocks*: A lookback period of 90 days is given as input to the stack that passes through every block and a forecast period is set for the next 30 days. The input passes through a set of 4 connected layered(FC + Relu) stack and then divided into two outputs. Each output is further passed through FC and finally we receive two outputs such as

- 90-dimension vector as backcast, (X).
- 30-dimension vector as forecast., (FC).

2) *Stacking of blocks*: Each stack consists of multiple basic blocks, arranged in a double residual manner. For each block,

- A vector  $X(x_1, x_2, x_3, \dots, x_{90})$  is given as input to the first block and every block.
- The first block gives two vectors as outputs ie. BC\_1(Backcast of block 1) and FC\_1
- The input of 2<sup>nd</sup>, 3<sup>rd</sup>, and so on blocks is calculated as  $(X - BC_1)$ .
- The backcast output (BC\_n) of nth block is the final stack output.
- The forecast output of stack is calculated as  $\sum_{k=1}^n FC_k$  where n is the number of blocks in a stack.

#### IV. RESULT AND DISCUSSION

Any deep learning neural network is trained using stochastic gradient descent algorithm. The purpose of this algorithm is to optimize the model by updating the weights

during training based on error gradient measures. The rate at which the weights are getting updated during training of a model are referred to as learning rate. A plot for tuning the hyperparameter ‘Learning rate’ is given in Fig. 15.

Training of any neural network involves the challenge of identifying the hyperparameter ‘learning rate’. Estimating the optimal training rate is crucial to train a neural network, since learning rate describes how quickly a model is adapted to the given dataset and problem. Learning rate is a highly tunable parameter that calculates the number of weights needed to be updated so that the loss is reduced each time. The calculated learning rate is 0.000562341325190349.

The error measure of this N-Beats baseline model has been measured using mean and SMape(Symmetric Mean absolute percentage error) [3] and displayed in Table I. There are many error metrics such as MAE, MAPE, sMAPE, etc. available.

Mean absolute Error (MAE) is defined as the average of forecast errors  $e_t$ , where  $e_t = F_t - A_t$ .

$$MAE = 1/n \sum_{t=1}^n |e_t| \tag{1}$$

Symmetric Mean absolute Percentage error(sMAPE) is chosen over MAPE for the reason that MAPE behaves extremely undefined for actual zero values. The prediction or the future values are calculated based on the recent known values. But the resulting SMAPE measure is disappointing and the error percentage is 0.5219. Hence the optimal learning rate to train the RNN is calculated as 10<sup>-4</sup> approximately. After training the model, the error in the model has been reduced and calculated as 0.2922. The smaller the sMAPE value, the greater is the prediction accuracy.

$$sMAPE = 1/v \sum_{i=1}^n |(F_i - A_i)| / (F_i + A_i) / 2 \tag{2}$$

#### A. Comparison with Previous Works

The novelty about our work is the in-depth statistical analysis on the data set and converting it into univariate time series data set suiting to model building, thereby pruning the other dimensions. Here is the tabulation of results of this paper with recently published works given in Table II.

Different data sets have been compared in the above table that are using RNN model and their performance measures have been tabulated.

Fig. 15. Plot for Hyperparameter Tuning.

TABLE I. ERROR ACCURACY MEASURES

Error Measures	Before training	After training with optimal learning rate	
		SMApe	MAE
Validation set	0.4314	-	0.1932
Test set	0.5219	0.3922	0.1407

TABLE II. COMPARITIVE ANALYSIS

References	Model	Accuracy Measures
Haseeb Tariq, Muhammad Kashif Hani, Muhammad Umer Sarwar, Sabeen Bari, Muhammad Shahzad Sarfraz, and Rozita Jamili Oskouei [4]	RNN-LSTM model	MAPE = 13.42
Wajiha Safat, Sohail Asghar, (Member, IEEE) and Saira Andleeb Gillani[6]	RNN	RNN-LSTM model for Chicago dataset, MAE = 11.6 RNN-LSTM model for Los Angeles dataset, MAE = 6.0
Current study	RNN-LSTM Model	MAE = 0.1407

## V. CONCLUSION

It is understood that RNN-LSTM model implemented on our univariate data set displayed better performance based on MAE measure(refer in Table II) than the other works in time series forecasting. In general, error accuracy measures vary depending on the context, size of training set and the number of features. In this table, we have used MAE as performance metric. The innovation of this work lies in the systematic way of statistical analysis thereby extracting and understanding the deep insights of the data and converting the dataset suitable for univariate analysis before building a model on the data compared to the other works.

## VI. FUTURE ENHANCEMENTS

In future, a hybrid model could be a better choice for building a forecasting model on this crime data and the accuracy of the mentioned model may be improved by exploring and tuning the other hyperparameters as well. This paper considered the features such as date and time and the number of occurrences of crime per day. In future, the attributes with respect to location that is geospatial coordinates can also be considered to build and improvise the model.

## AUTHORS' PROFILE

**J Vimala Devi** is a B.E graduate in Computer Science and Engineering from Bharathidasan University, M.Tech in Computer Science and Engineering from Satyabama University, Chennai and currently pursuing my Ph.D in Visveswrajs Technology University. She has 13 years of Experience in Teaching. She is a life member of CSI and ISTE. She published a paper titled "Fraud detection in Credit Card Transactions by using Classification Algorithms " in IEEE conference. She is doing a lot of projects on title "Descriptive analytics". She is currently working as Associate Professor, Department of CSE in Cambridge Institute of Technology, Bangalore.

**Dr Kavitha K S** completed BE computer science and Engineering from SIT Tumkur, MTECH from BMSCE Bangalore and PhD from Anna University, Chennai. She is having 22 years of experience in engineering colleges and has worked in various capacities. Around 40 research papers under her credit. Currently she is supervising 6 research scholars. Her areas of interest are Data mining, Machine Learning, Algorithms and Programming etc. Currently she is serving as Professor in the Department of CSE, Global Academy of Technology, Bangalore. She is a life time member of professional bodies such as CSI and IEEE.

# Level Transducer Circuit Implemented by Ultrasonic Sensor and Controlled with Arduino Nano for its Application in a Water Tank of a Fire System

**Abstract**—This article aims to describe the design of a circuit of a level transducer implemented by means of an ultrasonic sensor and controlled by Arduino Nano, applied to a water tank of a firefighting system. Initially, the integration of the Siemens 1212C programmable logic controller is described, in the connection between the sensor, the controller and the interfaces that allow to generate the monitoring, control and data recording, conditioned by a PWM pulse width modulated signal controlled by Arduino Nano. When developing the research and performing an analysis of the linear regression model, it is established that the behavior of the controlled variable with respect to time, generates a linear voltage response in the range of 0 to 10 volts; expressing in terms of correlational relationship a factor of R2 equal to 0.997, thus establishing that the designed transducer does not show susceptibility to noise or disturbances in the start-up of the firefighting system.

**Keywords**—Level transducer; ultrasonic sensor; Arduino Nano; control; pulse width

## I. INTRODUCTION

A control system essentially seeks to increase the efficiency of the entire process by maintaining the main variables of the system, within the pre-established range as optimal for the process [1]. Control systems seek to reduce the errors or margins of error typical of non-automated systems, reducing the risks of the plant or process working in unstable conditions [2], [3]. In the same line of opinion in [4], the author points out that control systems are implemented with the purpose of controlling the drive of machines or actuators, seeking to reduce the probability of failures and maintaining certain values of variables at determined intervals.

Under the above, and focusing on industrial systems that rely on fluid fill level control mechanisms. In [5], [6] the authors point out that in the industrial field there are several variables that intervene in the control of the altitude level of some type of fluid on tanks or reservoirs, which makes it essential to control with devices capable of monitoring and

controlling permanent variable tank fill level. Also in [7] the author points out that liquid level system represents a concrete example of control systems with wide diffusion in industrial settings. And it is that any process that needs to store substances in any of their states requires records on the level of deposit of the same in order to make timely and appropriate decisions in search of ensuring the sustainability of the production process [8].

In the search for quality in the production process, guaranteeing liquid level and flow control in tanks is a common problem in industrial processes [9]. Increasing globalization, quality standards and high production standards are the main foundations for specialists to intensify the study of automatic control strategies [10]. In this sense, the study and analysis of variables that intervene in the behavior of related systems in production processes is important and necessary [11]. In this regard in [12]-[14], the authors point out that taking into account technical aspects for the functioning and operation of the sensors and actuators on which the automation and control technology is based. The level control is intended to keep the level of the liquid or fluid within a predetermined value [15]. The inspection of the level height of a fluid by ultrasound encompasses a family of methods based on the transmission of a high frequency wave [16]-[18]. The level sensor detects the surface echo and sends it back to the microprocessor for a digital representation of the distance between the sensor and the surface level [19]-[21].

Low intensity ultrasound signals or, in other words, high frequency signals provide relevant and appropriate information regarding the characterization of liquids or fluids, being able to penetrate containers and chamber walls without significant degradation [22]-[24]. These signals are waves that can propagate through different media such as liquid, solid and gas [25]. In this regard, in [26], [27], the authors point out that the speed with which ultrasound signals propagate and its effects depend mainly on the density and viscosity of the medium

through which they travel, which is why they are They use these signals in industrial and measurement applications.

The electronic instrumentation used to measure the level of liquids works by measuring the height of liquids above a reference line on the one hand, or by measuring the hydrostatic pressure or by using other phenomena. This is the case of ultrasonic sensors, which incorporate an analog signal converter, a processor and input and output interfaces [28]. In this sense, the functionality of embedded systems built from Arduino technology is highlighted, which under its integrated environment seeks to facilitate the use of electronics in multidisciplinary projects [29]-[32].

In this sense, this article aims to describe the circuit of a level transducer implemented by means of an ultrasonic sensor and controlled by Arduino Nano, applied to a water tank of a firefighting system, for which i will initially proceed to specify the connection logic between the sensor, the controller and the interfaces that allow generating the monitoring, control and data recording of the variable under analysis. Finally, an analysis of the dispersion model of the collected data will be carried out in order to establish the behavior of the controlled variable with respect to time.

## II. RESEARCH METHODOLOGY

### A. Design and Research Level

The research method is quantitative, because the filling level of the tank of the firefighting system will be measured with respect to the voltage provided by the transducer output, likewise, the response of the controlled variable is evaluated, in this case the relationship that exists between the altitude measured by the sensor in response to the activation of the fire system.

The research level is descriptive-correlational; it is descriptive because the behavior of the collected data is detailed through statistics in relation to the indicators of the variable under analysis. In addition, it is correlational because it seeks to establish the level of association or relationship between the indicators under analysis in the firefighting system, in order to determine the dispersion model that best describes the data collected by the level transducer circuit.

### B. Data Collection Technique and Instrument

In this research, the technique used for data collection was observation, which was put into practice once the level transducer circuit was implemented and was used on the tank of the firefighting system. Likewise, the data collection technique used was the technical report, the same one that was validated in relation to the data collected through Cronbach's Alpha, and whose value turned out to be equal to 0.7349, evidencing a degree of reliability from moderate to optimal.

## III. DESCRIPTION AND DEVELOPMENT

### A. Description and Development of the Circuit

The control process responds to the use of a level transducer circuit implemented by means of an ultrasonic sensor and controlled with Arduino Nano to maintain the filling level of a tank of a firefighting system within the optimal parameters established for correct operation, as well as the sensors and actuators of the tank's water filling system, it is carried out through a Siemens 1212C programmable logic controller, which requires a conditioning circuit that represents the interface between the Arduino Nano controller and the logic controller programmable. In Fig. 1, the block diagram of the entire system is shown, in order to highlight the integration of the elements and the importance of the signal conditioning, to achieve optimal communication between the two controllers.

The level transducer is made up of an ultrasonic sensor plus an Arduino Nano controller, in which the controller has a PWM (pulse width modulation) output signal with a range of 0 to 5 volts, then we will amplify it with a TL081CP integrated circuit, so that the PWM signal converts it from 0 to 10 volts, Fig. 2 shows the connection architecture, highlighting the integration and synergy of the ultrasonic sensor and the Arduino Nano controller.

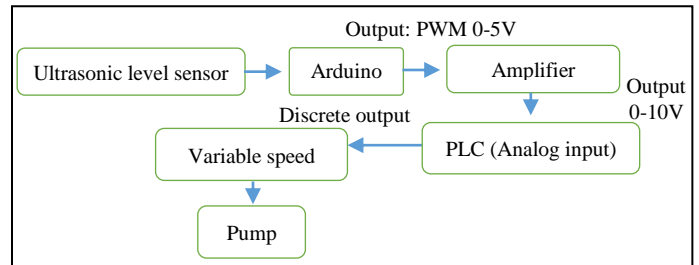

Fig. 1. Controllers Communication System Block Diagram.

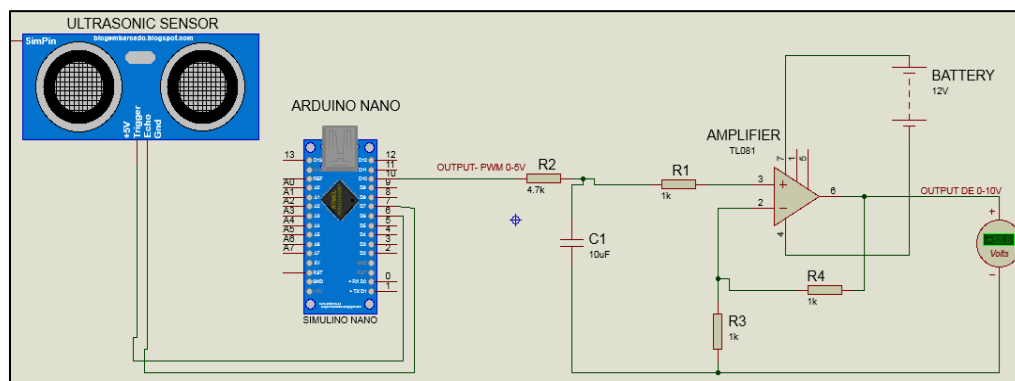

Fig. 2. Connection Architecture of the Arduino Nano and the Ultrasonic Sensor.

Once the connection architecture was defined, the Arduino Nano controller programming relationship was carried out, for which three real type variables (float) are declared, the same one that is linked to the input addresses of the Arduino Nano, these are: trigger (terminal 6), echo (terminal 7) and analog (terminal 10), these variables declared with floating point will be used to carry out the respective calculations in the programming, whose indicators to obtain will be time and distance. The setup function is used to declare the variables to know who will be the inputs and outputs on the Arduino Nano, likewise, the loop function is linked to the trigger variable, it is written in two states at a low level for two 2 seconds, then it is written at a high level for 10 seconds, the response time of the sensor is a function of the variable "echo" (when it is at high level) since it is part of the mathematical operation, thus also the variable "distance" of the sensor is the product of the variable "timeult" (which is the response of the variable echo at high level), between the two constants 2 and 29.15, (this constant is by default). It is important to bear in mind that the value of the variable "outputult" is obtained from the product of the variable "distance" by the constant, whose value is 7.5 (it is specified that how the value of the constant 7.5 is obtained, in the next paragraph).

As the purpose is to obtain an analog signal, it has to be converted to a PWM signal, the equivalent of 0 to 5 volts, but the Arduino Nano works with digitization's from 0 to 255 bits, since the test was carried out with a tank that has a distance of 32 cm, the following calculations are made. The analysis begins considering that 2 times the calibration constant of the distance variable (x) is equal to a digitization of 0 (zero), this due to a possible false alarm that the Arduino Nano controller may generate, thus, 32 is also considered by the calibration constant of the distance variable (x), this because it represents the register that the ultrasonic sensor provided to the tank with a digitization of 255 bits. From the conditions x is obtained, the same that is required, it will help to establish the calibration of the sensor with respect to the distance variable. Adding the two considerations, we have that "34x" is equal to 255, there it is obtained that the value of the calibration constant is 7.5. Adding the two equations, it is determined that the calibration constant of the variable distance (x) is equal to 7.5.

This constant is used to program the Arduino Nano controller. Thus, in Fig. 3, the programming code is shown, in which "analogwrite" is required depending on the operation obtained in the "outputult" variable, in this way we will obtain PWM from 0 to 5 volts.

Another aspect to consider is the amplification stage of the Arduino PWM output from 0 to 5 Volts and from 0 to 10 volts. To achieve such electronic conditioning, the PWM signal from the Arduino Nano was passed through the 4.7 KΩ resistor (R5) and through the 10 uF ceramic capacitor (C1), the sending time of the PWM signal was reduced, this conditioned signal then passes through the 1KΩ resistor (R2) and then connects to terminal 3 of the amplifier. Thus also in terminal 2 of the amplifier the 1KΩ resistor (R3) and the 1KΩ resistor (R4) are placed, in order to achieve a balance of the impedances. Terminals 4 and 7 with 12 volts power the amplifier, and terminals 1 and 5 for the intended purpose will not be used. Terminal 6 is the amplified PWM output of the Arduino Nano,

which is now 0-10 volts, in Fig. 4, the connection architecture of the TL081 operational amplifier is shown.

### B. Description of PLC Programming

To control the system, the system-M0.0 mark is created, which will be enabled by the start-I0.0 button, while the stop-I0.1 button is used to turn off the entire system (Fig. 5). Once the M0.0 mark is turned on, the level sensor programming is activated, for this a normalization is carried out with a digitization of 0-27648 of the Level sensor-IW0 (integer variable) so that a real variable is output with the name of level sensor norm-MD2, this real variable is scaled with a range of 0-35Liters to give us another real variable but already scaled (Level Sensor Output - MD6), as shown in Fig. 6.

```
ULTRASONIC_TRANSMITTER $
int trigger=6;
int echo=7;
int analog=10;
float timeult,distance;
float outputult;

void setup()
{
  Serial.begin(9600);
  pinMode(trigger,OUTPUT);
  pinMode(echo,INPUT);
}

void loop()
{
  digitalWrite(trigger,LOW);
  delayMicroseconds(2);
  digitalWrite(trigger,HIGH);
  delayMicroseconds(10);
  digitalWrite(trigger,LOW);

  timeult=pulseIn(echo,HIGH);
  distance=(timeult/2)/29.15;
  outputult=distance*7.5;
  analogWrite(analog,outputult);
  Serial.print(distance);
  Serial.println("cm");
  delay(100);
}
```

Fig. 3. Arduino Nano Controller Programming Code.

Fig. 4. TL081 op Amp Connection Architecture.

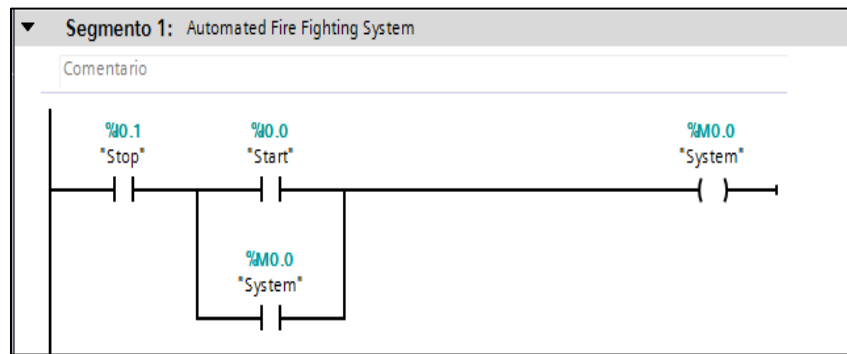

Fig. 5. Automated Fire Fighting System.

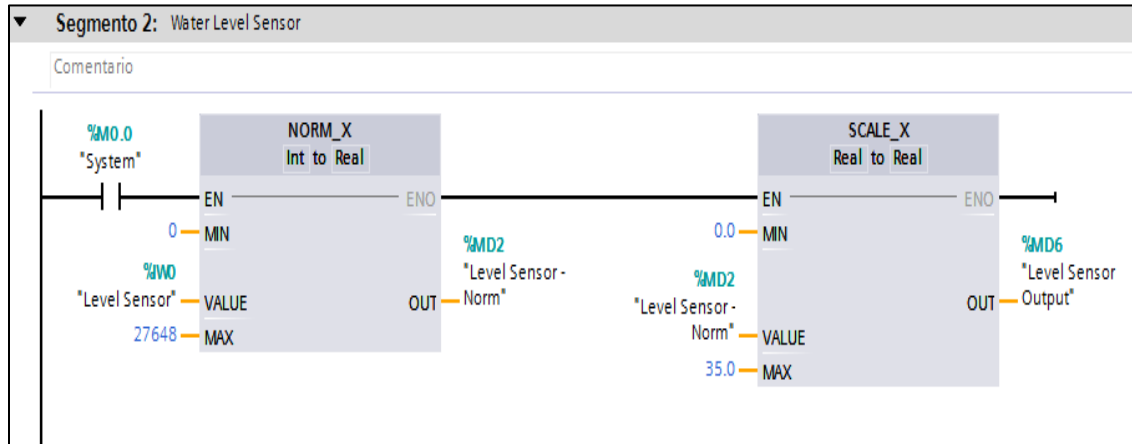

Fig. 6. Water Level Sensor.

Once the M0.0 mark is lit, the pressure sensor programming is activated. A normalization is carried out with a digitization of 0-27648 of the Pressure sensor-IW2 (integer variable) so that a real variable with the name of Pressure sensor norm-MD10 is output, this real variable is scaled with a range of 0-2 Bar which its value of the real variable but already scaled (Pressure Sensor Output - MD14) (Fig. 7).

Once the M0.0 mark is lit, the flow sensor programming is activated. A normalization is carried out with a digitization of 0-27648 of the Flow sensor-IW4 (integer variable) so that a real variable with the name of Flow Sensor Norm-MD18 is output, this real variable is scaled with a range of 0-4 L / min which its value of the real variable but already scaled (Flow Sensor Output - MD22).

When the system is on, the water pump works at a low speed Q0.0 (low speed output), the pump will stop working when the level sensor (Level Sensor output-MD6) reads less than 27L, at that point it will start other speed. The closed outputs Q0.2, Q0.1 and, Q.0.0 are security variables (that is, they are responsible for not letting work at another speed, other than the programmed one).

In the same way, when the level sensor (Level Sensor output-MD6) reads 26L the pump will work at an average speed Q0.1 (Average Speed output), the pump will stop working when the level sensor (Level Sensor output- MD6) dial less than 16L.

Finally, once the level sensor (Level Sensor output-MD6) reads 15L the pump will work at a high speed Q0.2 (Average Speed output), the pump will stop working when the level sensor (Level Sensor output-MD6) mark less than 2L (when it is at 1L), and in this way the process will be completed. In Fig. 8 the programming of the described is shown.

### C. Description of Programming in HMI

When the button I0.2 is pressed, the water pump starts with a low speed of 30 RPM, the level sensor shows a value of 30 liters, the pressure sensor will be at 0.7 Bar and the flow sensor will be at 2.5 L / min., the other speeds will be off. This speed will stop working when the level sensor comparator is less than 27L, which is where the average speed will begin. In Fig. 9 the HMI programming - Low speed is shown.

When the level sensor shows 26L, the water pump starts with an average speed of 45 RPM, the level sensor shows a value of 26 liters, pressure sensor 1 bar and flow rate 3.2 L / min. This speed will stop working when the level sensor comparator is less than 16 L, which will start the low speed. The described is visualized in Fig. 10.

Finally, when the level sensor reads 15L, the water pump turns on with a high speed of 45 RPM, the pressure sensor will read 1.2 bar and the flow rate 3.6 L / min. This speed will stop working when the level sensor comparator is less than 2 L, thereby causing the system to turn off.

#### IV. RESULTS AND DISCUSSION

##### A. Results

Likewise, the filling level of the tank of the firefighting system was measured with respect to the voltage provided by the transducer output. Using the curvilinear estimation analysis through the SPSS software, the determination factor  $R^2$  for a linear behavior was found to be 0.997, which shows that there is a level of linear scaling of the designed transducer; thus evidencing its optimal performance. It is necessary to indicate that the linear regression model was used because it is the one that provides us with a greater determining factor or  $R^2$ . In Fig. 11, the data dispersion model is shown, highlighting that it responds to a linear behavior.

Fig. 11. Curvilinear Estimation of the Response of Data Generated by the Transducer.

In Table I, a detail of the estimate that defines the behavior of the output data of the transducer is shown, with respect to the input voltages, the value of  $R^2$  and the constants that show the relationship between voltage and distance are observed.

TABLE I. RESULT OF THE  $R^2$  CURVILINEAR ESTIMATION TEST

Equation	Model Summary					Parameter estimates		
	$R^2$	$F$	$gl_1$	$gl_2$	Sig.	Constant	$b1$	$b2$
Lineal	0.997	10258.110	1	31	0.000	-0.053	0.320	0.000

##### B. Discussion

According to the findings obtained, it was possible to develop the level transducer, from the use of an Arduino controller and an ultrasonic sensor, guaranteeing the linearity of the results obtained, that is, the response of the sensor whose input signal is the filling level of water from the tank of the firefighting system, allows the conversion or transformation of the physical magnitude into an electrical signal in the range of 0 to 10 volts. In this regard, in [18], [8] and [15], they point out that the integration of the ultrasonic sensor, linked to an Arduino controller, turned out to work correctly in remote decision systems, although they emphasize that although they are susceptible to noise, these were not evidenced at the time of their operation. From my point of view, this scenario manifests itself due to the conditions and processes to which the ultrasonic sensor and the Arduino controller are being subjected, since it can change in other contexts.

Thus, in the analysis of the results, an almost linear behavior is obtained between the variables under analysis (tank filling level and transducer response voltage), in this regard, in [19], [28], [33] and [34] they point out that it is optimal to apply devices such as the Arduino controller to a filling level control system, because they show a linear behavior in their processed data. They do not specify the determining factor of the curvilinear estimate, however they do require that its implementation and assembly were optimal, and these appraisals coincide with the findings obtained in my research, since my determination factor turned out to be 0.997, for a curvilinear estimate.

As indicated in [35] the implementation of the pump alternators system was carried out without major inconvenience when performing the unification of a PLC and Arduino. Both solutions controlled the discrete event system according to the operating requirements set by GRAFCET. The main reasons for using Arduino in automation projects lie in the capabilities of the hardware and its costs. High-end Arduino are known to have superior processing capabilities than many nano PLCs, while PLCs have a high number of inputs and outputs sufficient to automate processes, as well as supporting a large number of open communication protocols.

## V. CONCLUSION

As part of the conclusions to be specified, in relation to the findings obtained, the following is specified:

It is concluded that the proposed integration between the ultrasonic sensor, the Arduino Nano controller and the Siemens 1212C programmable logic controller was viable, this thanks to the conditioning of the PWM modulated signals from 0 to 5 volts to 0 to 10 volts through the TL081 operational amplifier, thus achieving a synergy between all these devices, and achieving the purpose that is the capture of data on the tank filling level through the transducer designed and described in this article.

Finally, it is concluded that the process of converting the physical magnitude to the electrical signal was not affected by noise or external disturbances in the context of the process (tank used for firefighting systems), since when subjected to operations in the same process of detection and fire showed a linear behavior, that is to say, almost devoid of noise effects. This allows it to be concluded that its application to this type of process is useful.

Regarding future plans, remote monitoring, supervision and control strategies should be considered; as well as mechanisms for the detection of fire to be reported to a reception equipment in the 4G or 5G band, through a GPRS communication interface module.

**Abstract**—Human detection plays an important role in many applications of the intelligent surveillance system (ISS), such as person re-identification, human tracking, people counting, etc. On the other hand, the use of deep learning in human detection has provided excellent accuracy. Unfortunately, the deep-learning method is sometimes unable to detect objects that are too far from the camera. It is because the threshold selection for confidence value is statically determined at the decision stage. This paper proposes a new strategy for using dynamic thresholding based on geometry in the images. The proposed method is evaluated using the dataset we created. The experiment found that the use of dynamic thresholding provides an increase in F-measure of 0.11 while reducing false positives by 0.18. This shows that the proposed strategy effectively detects human objects, which is applied to the ISS.

**Keywords**—Human detection; YOLO; dynamic thresholding; intelligent surveillance system

## I. INTRODUCTION

Currently, the use of cameras as surveillance media is growing very fast. Usually, cameras are widely used for security purposes in public areas such as schools, offices, stations, airports, highways, and even private homes. Supported by artificial intelligence (AI) development, surveillance with cameras is no longer carried out manually by officers who have many drawbacks such as fatigue, limited staff, etc. Instead, camera-based surveillance allows it to be carried out automatically by utilizing AI-based modules, known as the Intelligent Surveillance System (ISS) [1].

Human detection plays an important role in many applications of ISS, such as person re-identification [2], human tracking [3], people counting [4], human action recognition [5], unattended baggage detection [1], etc. Even though many studies have been carried out for human detection, research on this topic still faces many challenges to overcome real problems constantly changing. One of the popular studies on human detection is the Histogram of Oriented Gradient (HOG), which was first proposed by Dalal [6]. In this study, the gradient in the image is extracted using the Sobel operator, and then histograms are formed. This method is straightforward but produces very good accuracy. Unfortunately, this method cannot handle various kinds of human poses and requires long processing times. Therefore, many new techniques have been

proposed to improve HOG, such as HOG+LBP [7] for handling occlusion, efficient HOG [8], SHOG [9], Rotation-Invariant HOG [10], etc.

The development of deep learning also has a good effect on human detection research. Because of this, many methods for human detection are based on deep learning [11][12]. Martinson and Yalla proposed to use CNN for human detection in mobile robots [11]. Kim and Moon proposed to use deep convolutional neural networks (DCNNs) for human detection on Doppler radar [12]. The use of deep learning provides a significant increase in accuracy compared to handcrafted methods such as HOG. If we assume humans as objects, then many deep-learning-based object detection methods can be used to detect humans. One of the popular deep learning-based methods is YOLO [13]. YOLO produces high accuracy in detecting various kinds of objects, one of which is human objects, and also won the Real-Time Object Detection on PASCAL VOC 2007 competition. Unfortunately, the deep-learning method is sometimes unable to detect objects that are too far from the camera. Thus, this paper proposes to solve this issue.

In many cases, human detection is used at an early stage and significantly affects the accuracy of ISS applications [1-5]. If the human detection accuracy is good, these applications will also produce a good performance and vice versa. Therefore, a reliable human detection module is needed. One method that produces good accuracy is based on deep learning, namely the YOLO Network. However, selecting the confidence value threshold produced by deep learning in the decision stage is very challenging. Using a large threshold will cause human objects far from the camera not to be detected correctly. Conversely, if we use a small threshold, it will result in a lot of false positives. In this study, we propose a new strategy using dynamic thresholding based on the location of potential objects that have been detected. Thus, it is expected to be able to detect small objects while reducing false positives.

Overall, this paper provides the following major contributions: (1) Utilize deep learning for the human detection method. (2) Propose a new strategy to use dynamic thresholding in the decision stage of human detection. (3) Provide a more detailed investigation regarding the effect of threshold selection.

## II. THE PROPOSED STRATEGY

### A. Data Collection

In this research, we use the open images dataset v4<sup>1</sup> for training purposes. This dataset contains more than 9 million images with unified annotations for image classification, object detection, and visual relationship detection [14]. We only used person images with object detection annotations. The example of the open images dataset is shown in Fig. 1. We used two CCTV videos from FMIPA Universitas Gadjah Mada, one CCTV video from traffic, and two random CCTV videos for testing purposes. The examples of a testing video are shown in Fig. 2. Table 1 shows the characteristics of video data for evaluation with the various scenario.

### B. Data Labeling and Preprocessing

For testing purposes, the ground truth labeling process starts automatically and then manually verifies using labeling software LabelImg<sup>2</sup>. The annotation process is carried out by following procedure:

- 1) The automatic labeling process is repeated until the best results are obtained subjectively assessed by the annotator.
- 2) The image and label, which is the output of the previous process, will be loaded on the labelImg application.
- 3) The validation process is conducted manually by the annotator.
- 4) If there are wrong or missing bounding boxes, the annotator can add them.

Every second of the video will be divided into twelve images then the coordinates of the bounding box of each image will be saved in a CSV file. The example of a saved bounding box is shown in Fig. 3.

Fig. 3. Saved Bounding Box for Testing Data.

### C. Detection Strategy using the Dynamic Thresholding

As shown in Fig. 4, the proposed method starts with extracting human candidate regions using a deep learning model and is then followed by the validation stage using thresholding. The basic method we use in detecting humans is by using YOLO. YOLO network will generate candidate regions of objects with certain confidence values. If the confidence value exceeds the threshold, we will classify this object as human and vice versa. However, selecting the threshold of confidence is very challenging. Using a large threshold will cause human objects far from the camera not to be detected properly. Conversely, if we use a small threshold, it will result in a lot of false positives. To solve this problem, we propose using dynamic thresholding for verifying the human region based on the object's position in the vertical direction, as shown in Fig. 5. The closer the object's position to the top, the smaller the object's threshold score will be and vice versa. This strategy is applied with the assumption that objects close to the top are far from the camera. Objects far from the camera will have faint details, so we use a small threshold so that the object can still be detected. However, if this small threshold is applied to objects close to the camera, it can be false positive.

<sup>1</sup> <https://opensource.google/projects/open-images-dataset>.

<sup>2</sup> <https://github.com/tzutalin/labelImg>.

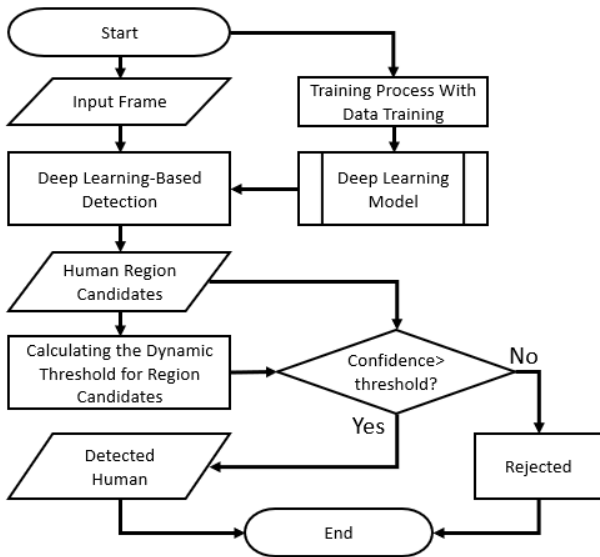

Fig. 4. The Flowchart of the Proposed Method.

Fig. 5. Illustration of Calculating the Object Vertical Position.

We determine the threshold with the following strategy. First, we scale the object's vertical position by dividing the object's vertical center point by the image height ( $H$ ). This value will be used to obtain a threshold on a scale of 0.5 to 1 using the following equation:

$$y' = \frac{y}{H} \quad (1)$$

$$t = y' \times (t_{max} - t_{min}) + t_{min} \quad (2)$$

### III. EXPERIMENT AND RESULTS

This section presents the evaluation protocol used in the experiment and the result of the proposed method with a comparison to the YOLO method. In addition, a discussion of the effectiveness of the proposed method is also presented.

#### A. Evaluation Protocol

We will compare performance and processing time between the basic YOLO method and the YOLO + dynamic threshold in the testing stage. Thus, it can be seen whether the

dynamic threshold process will significantly affect the accuracy and processing time. We use hardware with the following specifications: Processor AMD Ryzen 9 3900x, VGA Nvidia RTX 2080 Ti, RAM 64 Gb with Ubuntu 20.04 operating system.

There are seven videos from different CCTV as test objects. The evaluation process will calculate the IoU value between the detected bounding box and ground truth for each CCTV video frame. Intersection over Union (IoU) is the value based on the statistical similarity and diversity of the sample set whose purpose is to evaluate the area of overlap between the two bounding boxes, namely the predicted bounding box and the ground truth bounding box [15]. IoU can be found using the following equation:

$$IoU = \frac{A \cap B}{A \cup B} \quad (3)$$

We use 0.5 as a threshold for the IoU value. That means any detected object with an IoU value greater than the threshold will be considered true positives (TP). In contrast, if the IoU value is less than the threshold, it will be considered as false positive (FP), and any undetected object will be considered as false negative (FN). To evaluate the method's performance, we use precision, recall, and f-measure [16]. These metrics are used to evaluate the prediction of each frame. To evaluate the model, the precision, recall, and f-measure of all the frames are calculated.

$$Precision = \frac{TP}{TP+FP} \quad (4)$$

$$Recall = \frac{TP}{TP+FN} \quad (5)$$

$$FMeasure = \frac{2 \times precision \times recall}{precision + recall} \quad (6)$$

#### B. Comparison Results

Based on the testing results using seven different datasets, the following results were obtained in Table 2. It can be seen that in all datasets, the proposed strategy achieves 0.89, 0.95, and 0.91 in precision, recall, and f-measure, respectively, for detecting the human object on the video. These results are better than the YOLO method, which only archives 0.71, 0.94, and 0.80 in precision, recall, and f-measure, respectively. Furthermore, applying our strategy could increase the f-measure of human detection by around 0.11. Thus, it proved that the proposed approach is effective for increasing accuracy and reducing the false positive.

#### C. Discussion

In general, for each data test, it can be seen that the recall value tends to be higher than the precision value for both YOLO and the proposed method. This indicates that both methods are weak against false positives or often detect other objects as human objects. Some examples of test results for each datatest are shown in the image below. The blue box shows the results of YOLO detection, while the red boxes show the results of YOLO detection and the proposed method.

TABLE II. COMPARISON RESULTS THE PROPOSED METHOD AND YOLO

No	Datatest	Method					
		YOLO [13]			Proposed Method		
		Precision	Recall	F-Measure	Precision	Recall	F-Measure
1	MIPA 1	0.67	0.92	0.78	0.83	0.91	0.87
2	MIPA 2	0.73	0.97	0.83	0.95	0.99	0.97
3	MIPA 3	0.84	1.00	0.91	0.95	1.00	0.97
4	Office	0.56	0.92	0.70	0.81	0.88	0.84
5	Traffic	0.47	0.87	0.62	0.81	0.86	0.84
6	Kitchen	0.98	1.00	0.98	0.99	1.00	0.99
7	School	0.72	0.92	0.81	0.87	0.93	0.90

In video 1, the proposed method almost always succeeds in detecting human objects without errors. Still, there are false positives in the YOLO method by detecting the announcement box as a human object, as shown in Fig. 6(a). According to the YOLO network, the announcement box has a confidence value of 0.3, as it is close to the top area. The proposed dynamic thresholding process has eliminated the announcement box because it has a confidence value that does not meet the threshold. Same as in the first video, in video 2, the YOLO method is still wrong in detecting the announcement box as a human object, as shown in Fig. 6(b). However, it can be seen if the human object in front of the announcement box can be detected correctly by both methods.

In video 3, although the camera angle is the same as videos 1 and 2, there is a false positive for another object, namely the trash box, when detected using the YOLO method, as shown in Fig. 6(c). While in the proposed method, there are no errors. In video 4, there are false negatives if detected using the proposed method, as shown in Fig. 6(d). False negatives occur when there is an occlusion of a human object. Occlusion makes the object's confidence value low due to the lack of features that can be extracted due to some features covered by other objects. There were many false positives when testing on video 5 using the YOLO method by detecting road cones as humans, as shown in Fig. 6(e)-(g). At the same time, the proposed method is still able to detect well every human object.

Both YOLO and the proposed method can detect human objects well because the distance of the camera to the object is still quite ideal so that the details of the object are quite clear and there is no occlusion on the object. Therefore, it can be concluded that the proposed method has better performance than the YOLO method, as shown in Table 2. In the example of the detection results, it can also be seen that there are errors in the YOLO method in detecting objects. Overall, both YOLO and the proposed method can almost always detect human objects but still often detect other objects as human objects. This is indicated by the recall value, which is higher than the precision value.

Nevertheless, the proposed method fails to detect objects that are very far from the camera because the details of the object are not clear, so that there are not many features that can be extracted. It makes the object's confidence value below the threshold. To solve this problem, we may improve the selection of dynamic threshold by considering the distance between the candidate object and the vanishing point. In this case, we should integrate the vanishing point detection [17] [18]. Another solution is by utilizing the super-resolution method for very far objects [19]. However, this solution may require a long processing time.

(b) Detection Sample from video 2.

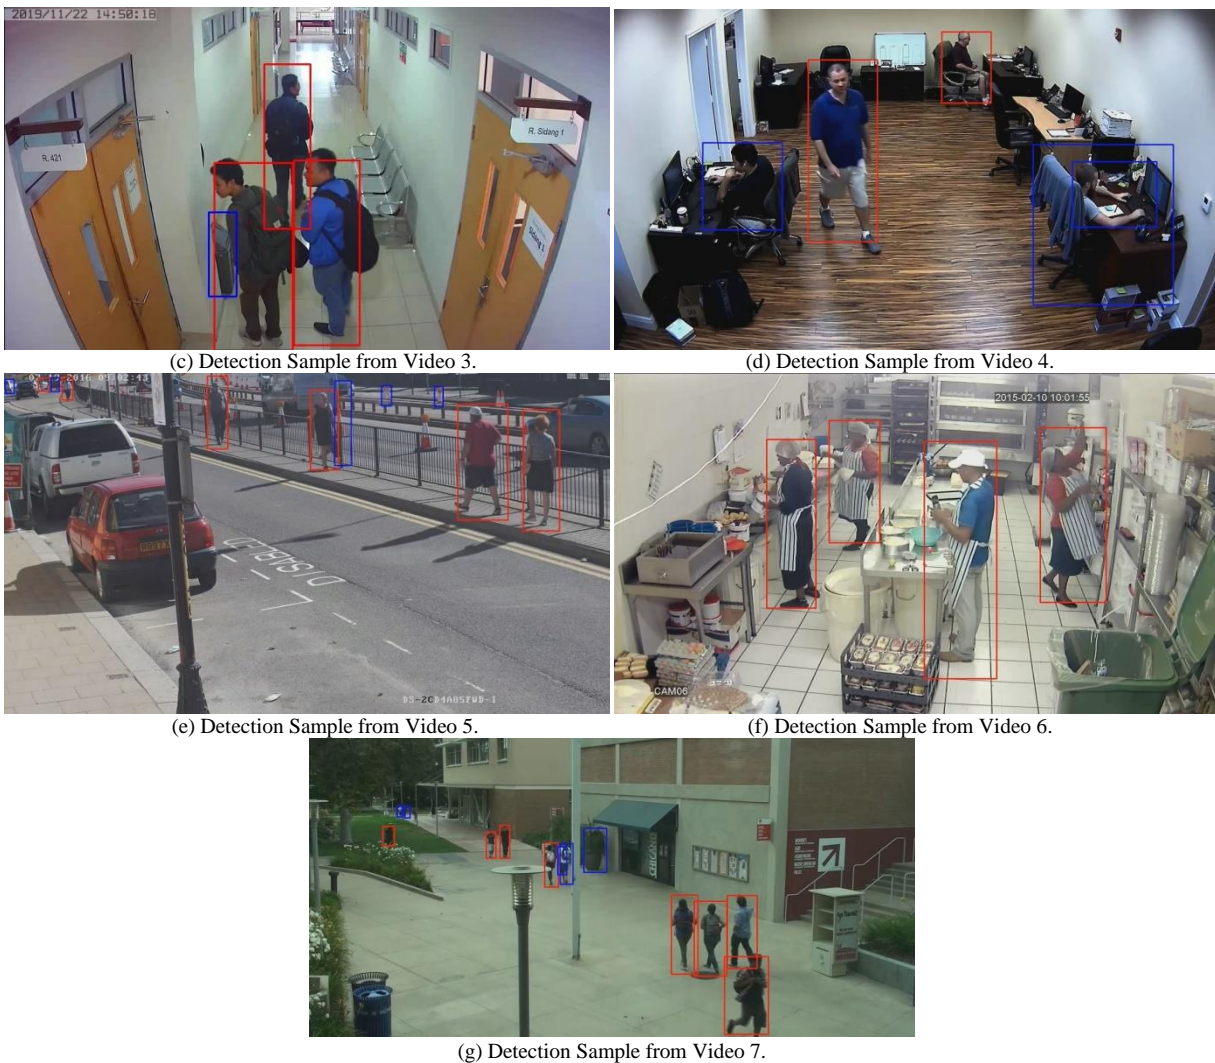

Fig. 6. Detected Sample for Video 1 until Video 7 with various conditions.

#### IV. CONCLUSION

The use of deep learning in human detection provides fairly good accuracy. However, this result is still influenced by selecting the threshold for the confidence value in the decision stage. The use of a static threshold is still not optimal in detecting objects that are far from the camera. This paper has succeeded in proposing the use of a dynamic threshold which is proven to provide a fairly good increase in f-measure, which is around 11% compared to the use of YOLO without a dynamic threshold. It should be noted that the use of dynamic thresholding can be used not only in YOLO but also in other deep-learning architectures. Even so, the dynamic threshold is still possible to be improved by considering the vanishing point in the image or super-resolution image [20].

**Abstract**—Now-a-days, breast cancer is the most crucial problem amongst men and women. A massive number of people are invaded with breast cancer all over the world. An early diagnosis can help to save lives with proper treatment. Recently, computer-aided diagnosis is becoming more popular in medical science as well as in cancer cell identification. Deep learning models achieve excessive attention because of their performance in identifying cancer cells. Mammography is a significant creation for detecting breast cancer. However, due to its complex structure, it is challenging for doctors to identify. This study provides a convolutional neural network (CNN) approach to detecting cancer cells early. Dividing benign and malignant mammography images can significantly improve detection and accuracy levels. The BreakHis 400X dataset is collected from Kaggle and DenseNet-201, NasNet-Large, Inception ResNet-V3, Big Transfer (M-r101x1x1); these architectures show impressive performance. Among them, M-r101x1x1 provides the highest accuracy of 90%. The main priority for this research work is to classify breast cancer with the highest accuracy with selected neural networks. This study can improve the systematic way of early-stage breast cancer detection and help physicians' decision-making.

**Keywords**—Convolutional neural network (CNN); breast cancer; Big Transfer (BiT); densenet-201; NasNet-Large; Inception-Resnet-v3; mammography

## I. INTRODUCTION

Breast cancer is the second crucial illness worldwide [1]. In 184 significant countries, breast cancer is most common in 140 (70%) countries and a frequent cause of cancer mortality in 101 (55%) countries. Compared to other diseases, the ratio of breast cancer in women is higher in more developed countries and increases rapidly. The swift advancement of new technology is helping the doctor to identify the breast cancer cells in the inflammation stage with the help of Artificial Intelligence. Deep learning models aided in the prognosis of cancer cells and took the necessary steps.

Almost every woman is fearful if they feel something abnormal in their breasts. Moreover, they become much seared when they lump their breast [2]. However, most of them are not aware of the thing that all lump is not cancer. Furthermore, there is a thing if a women lumps in her breast she cannot even ignore this. Because according to DRHC (STYLE YOUR HEALTH), one out of four women has a complaint about their

breast at one time, and one-quarter of those patients who complain about their breast has cancer. It is considered one of the most severe and petrified diseases in women.

There are many issues affecting breast cancer. A woman can be affected by breast cancer if she gets it from an inherited genetic mutation. The main risk factor for breast cancer is being women and getting older. According to the CDC (Centers for Disease Control and Prevention), most breast cancer patients are found in a woman whose age is 50 years or more than 50 years [3]. These factors cause breast cancer, but they also have other factors that can because breast cancer. Reproducing history is another serious risk factor. In this factor, a woman who has menstrual periods before age 12 and menopause after age 55. This risk factor raises the risk of getting breast cancer. Some other factors like having dense breasts, previous treatment using radiation therapy, women who took the drug diethylstilbestrol (DES) can cause breast cancer.

Breast cancer disease has two advanced primary detections: early detection and screening [4]. Detecting early age mammography is the best technique for doctors. For being a most sensitive technique, a significant fraction of patients are referred for biopsy. As a reason, mammography findings do not have a fatality. However, a specific biopsy is an expensive, presumptuous, emotionally disturbing procedure for women.

At present, researchers are mainly working on deep learning, which performs well in image processing. Out of all deep learning, artificial neural network is the most popular, whereas Convolutional neural network is an extended version of it [5]. CNN is a robust algorithm that can extract features from raw input. CNN performs better than any other in image segmentation and achieves better accuracy.

Cancer tumors generally happen when the cells of breast ducts are overgrown from normal cells. A study shows that when diagnosing breast cancer, microscopic images are ubiquitous. Breast tissue can provide important microscopic level images to the pathologist for access. From the analysis, a pathologist can identify the tissue as normal tissue, benign or malignant tissue. If a patient has a benign tumor, cells form a lump and grow abnormally, but it does not spread to other body parts [6].

\*Corresponding author.

# Both authors contributed equally.

On the other hand, an untreated malignant tumor can spear any part of the body. Here, it is crucial to identify types of tumors from the beginning. It can easily save a women's life as well as the precious time of the doctors.

This decade, machine learning algorithms have been proposed for cancer diagnosis from microscopic biopsy images [14]. Neural network algorithm-based intelligent systems are proposed to be a part of the systematic diagnosis process. Artificial intelligence (AI) can impact the ratio of early-stage cancer cell identification with its immense power and growing improvements.

## II. LITERATURE REVIEW

Cancer is currently a dire thread for women, especially for elders. Breast cancer is the second most cancerous disease in the world right now. As a result, many works have been done on breast cancer. Deep learning plays an essential role in medical science. With the help of deep learning algorithms, people can predict different diseases from very early stages, significantly reducing the suffering of patients and doctors.

Yadavendra discussed the detection of benign and malignant tumors in the breast using machine learning and deep learning algorithms [3]. They used almost 2lakhs color patches sized 50×50. For the library, the author implemented sci-kit, Keras, and tensor flow with CNN based classifier. For training, testing and validation, sigmoid activation provided output in malignant and benign classes. CNN-based classifier outperformed all other machine learning algorithms.

Preprocessing is very important for removing noises, artifacts, and muscle regions as they increase the probability of false-positive values. As a result, Luqman Ahmed proposed a method of fine-tuning and preprocessing to decrease the probability of false-positive rates [4]. The datasets were collected from mammographic image analysis society digital mammogram database (MIAS) and Curated Breast Imaging (Digital Database for Screening Mammography). The author said that for handling big data vast amount of memory resources is required; here, the author used a method of converting data in small patches for batch training. ResNet is 152 layer CNN. The limitation of this method is that the cancerous region is irregular in shape and border, affecting calculation and resulting in a drop in precision. Authors [7] apply machine learning-based classification to determine the risk factor and prognosis of the CKD disease.

ZHIWEN HUANG said a hybrid neural network is better than other CNN classifiers in accuracy, sensitivity, specificity [8]. The author here presents a hybrid model based on DenseNet and PCANet. For learning about the dataset, he used a kernel of modified PCANet. However, the DenseNet is used for high-level image classification and constructing dense blocks or transition blocks. The method uses the same number of feature map outputs in transition block input. The global pooling technique was implemented for blocking a large number of weights in the network.

Data augmentation increases the image dataset ten times with original quality with random geometric image transformations, flipping, rotating, scaling, and shifting. The

proposed models by Li-Qiang Zhou were trained with Keras 2.2.0 and Tensor Flow [2] and the weight of the pre-trained model on ImageNet. Feature visualization methods can increase the predictive ability of deep learning networks. The author also shows that his model performs better than the radiologist's inaccuracy.

Deep Convolutional Neural Network is a robust deep learning algorithm [9]. It is pretty used in breast cancer segmentation and detection. Author Md Zahangir Alom compared the existing algorithms concerning image, patch, image-level, and patient-level classification. For the implementation, he used Keras and Tensorflow frameworks. Here, the author mentioned the eight types of breast cancer with image level and patient-level performance classification. The image-wise and patch-wise classification was discussed for better understanding. Researchers [10] evaluated the papaya disease classification using a Convolutional Neural Network.

Convolutional Neural Network outperformed any other algorithms in image recognition [6]. The author gives an example of ResNet outperforming human participants with an error rate of 3.6%. Different dataset types were used in the proposed model, and it seemed like the performance was varying with different datasets. The model successfully predicts 12 types of skin tumors. For improving the performance, it is crucial to add standardized diagnostics images.

Vikas Chaurasia described the 10-fold cross-validation for measuring the performance of the models [11]. The author used prediction models for malignant and benign parameters, represented by "1" for malignant and "0" for benign.

The author presents a framework of unsupervised feature learning by integrating principal components [12]. DEJUN ZHANG aimed to merge feature selection and feature extraction in a deep learning algorithm. For tackling overfitting, he implemented some scarcity penalties in hidden layers. Elu was introduced for speeding up the training process in the deep neural network.

The study [13] proposed a deep learning model with Convolutional layers for breast cancer classification to extract visual features. First, the author implies a preprocessing method to transform images into common space or variances for improving detection performance. They discussed the effectiveness of data augmentation for increasing training data. Also, multiple deep Convolutional networks can improve the performance significantly with a tensor flow machine learning system. Extracted features were used to boost the framework.

The paper proposed an approach of DenseNet deep learning based on CNN for multiclass classification [14]. DenseNet uses a transition layer to reduce the size of the dataset. The author applied dropout and batch operation for optimization—transfer learning, fine-tuning pre-trained CNN models from natural to medical images. The advantage of using DenseNet is feature concatenation that helps to learn features without compression from any stages. Furthermore, the DenseNet model shows that the deep learning model can obtain good performance from natural images.

Author Angel Cruz-Roa said the main objective of their proposed work is to identify tumors from digital images with deep learning [15]. They show the experimental result of the method that can detect breast cancer regions. Five cohorts were used to train, test and validation. With the help of the dice coefficient, the performed evaluation shows positive predictive value, negative predictive value, true positive rate, true negative rate, and false positive and false negative rate all over the test slides.

The workflow of computer vision-based breast cancer cell detection primarily focused on the supervised learning-based system rather than the semi-supervised or unsupervised system. For the most part, the authors depend on hybrid neural network architectures like ResNet, DenseNet, and Inception. During the neural network-based models training and validation of the trained models, many different sources of public datasets took part as raw input data. Recent researches contain pre-trained weights from Keras deep learning models. Using pre-trained weights initiated by the ImageNet dataset has validated the models [26] [31]. To enrich the good prediction ability of models, researchers mainly focused on data preprocessing stages. Data augmentation has taken part for a smaller dataset, and a different cross-validation process follows through some research.

### III. PROPOSED SYSTEM

This study presents quantitative research on deep learning models based on Convolutional Neural Network (CNN). CNN is applying in the breast mammography dataset to prognosis the breast cancer disease in the human breast cell [16][17]. In this study, four deep learning algorithms (NasNet-Large, Inception ResNet-V3, DenseNet-201, and Big Transfer) are applied to achieve better accuracy from the prediction model [18][9][19]. In the beginning, data are acquisition and preprocessed with different parameters to split the dataset. Various preprocessing techniques such as zoom, rotation, rescaling, flip, shuffle are used to improve the data quality [20][18]. The preprocessed images go through the deep convolutional neural network. Convolutional blocks of the models extract the main features from the input images [21]. For training and testing the splits, the pre-trained model is customized with fully connected layers. The parameter of resizing is (224 x 224), (331 x 331), and the rescaling technique (0-1) is applied to split the data. In fine-tuning, selected convolutional layers are responsible for extracting feature extraction with fully connected layers [11]. This process changed the pre-trained model weights and evaluated the testing data for comparative analysis. Fig.1 visualizes the entire workflow of the proposed system.

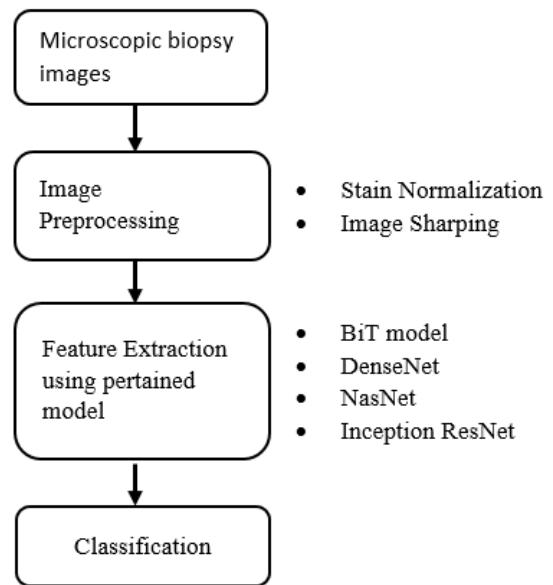

Fig. 1. Process Diagram of the Entire System.

### IV. DATASET DESCRIPTION

Benign and malignant breast cancer is microscopically imaged. Benign and malignant breast cancer is microscopically imaged. Table 1(I, II) provide general information about the dataset. The dataset is divided into two sections, Data for training and testing. In training data, benign and malignant directories contain 436 and 918 image data, respectively. On the other hand, test data is also divided into benign and malignant directories [22]. In testing, the benign directory has 111 files, and the malignant directory has 228 files.

TABLE I. (I): DATASET DESCRIPTION

Dataset features	Parameters
Total instance	1693
Total training data	1354
Total testing data	339
Number of classes	2

(II): DATASET DESCRIPTION

Breast Cancer classification	Number of Images	Number of Images Used for Train and Validation	Number of Images used for Test
Benign	547	436	111
Malignant	1146	918	228
<b>Total</b>	1693	1354	339

This breast cell microscopic biopsy patient's images were gathered from Kaggle [23]. Fig.2 visualize the microscopic images of a cluster of cells. The cluster of cells is called a tumor in medical science, and it is an abnormal growth of the cell. General tumors without invading the nearby area are categorized as benign, Fig.2 (a). A tumor with vast and uncontrollable speed is mentioned as malignant, as shown in Fig.2 (b).

Fig. 2. Microscopic Biopsy Images of a Cluster of Cells from the Selected Dataset [23]. Noncancerous and Cancerous Tumors are Mentioned as Benign (a) and Malignant (b), Respectively.

### A. Data Preprocessing

The dataset contains a variety of image types. The dimensions are as follows: 1500x750, 1254x836, 1024x768, 800x533, 220x230, 100x100, and 61x159. Due to the different image sizes, classification becomes difficult without a fixed image size. As a result, a proposed method used the 200x200 shape as an input shape function. This dataset must contain RGB images. Stain normalization and sharpening the edges of image contents taken part.

## V. MODEL DESCRIPTION

### A. Big Transfer

A BiT, also known as Big Transfer, is a recipe for an image classification model used for pre-training on large supervised datasets [19]. This algorithm has excellent fine-tuning efficiency on the given task. It can provide fantabulous performance on different tasks. R101x1 architecture is implemented in this model; as a result, it can execute multi-label classification on an ImageNet-21k dataset which can contain 14 million images. The output can detect the existence and lack of multiple classes of objects. There are two features in Big Transfer, one is the fine-tuning, and the second one is the BiT collection. Fine-tuning refers to the exact adjustment of parameters in a model. BiT uses a recipe, aka BiT Hyper Rule, for fine-tuning the parameters. This fine-tuning protocol is applied on many down-streaming tasks. BiT collections are used for performing multi-label classification on legit ImageNet-21k datasets. For classifying, it needs an imagenet21k\_classification model. For up streaming pre-trained data scale is essential because it can transfer to tasks with few data points. Residual block showed in Fig. 3 used in M r-101 model with minor changes in the normalization process.

**Residual Block:** Generally, the residual block is a layer stack where the preceding output feeds to the block's deeper layer [24]. For addressing the degradation problem of a complex function, a simpler function should be a subset which is the main idea of the residual block. I consider an input as  $x$  and desired mapping from input as  $g(x)$  then the simpler

function will be  $f(x) = g(x) - x$ . On the other hand, optimization of residual can compromise the dreaded identity mapping in a deep network. When the identity mapping is optimal, the optimization will carry out the weights of residual function to zero.

### B. NasNet Large

NasNet search space is known as Neural Architecture Search, which is used to find convolutional architecture from a dataset. In this search space, a Recurrent Neural Network controller is used to sample different architectures of a child network. Fig. 4 shows the neural architecture generation and selection process of the NasNet model. The child network is trained on a validation set to achieve some accuracy. These accuracies update the controller so that it can generate improved architecture with time. Policy gradient updates the weights of the controller. There are two types of cells named Normal cell and Reduction cell. The average cell returns the feature map's exact dimension, and the Reduction cell returns the reduced feature map (reduced by height and width by factor two). All convolutional cells have two striding for reducing the height width. NasNet can be forced as a hierarchical structure for asserting a well-designed network. For finding optimal architecture:

$$J(\theta_c) = E_{p(a_{1:T}; \theta_c)}[R] \quad (1)$$

Where  $\theta_c$  controller RNN,  $a_{1:T}$  list of actions.

For updating  $\theta_c$  policy gradient method of REINFORCE rule is:

$$\nabla J(\theta_c) = \sum_{t=1}^T E_{P(a_{1:T}; \theta_c)} [\nabla \theta \log P(a_t[a_{(t-1):1}; \theta_c]) R] \quad (2)$$

Where R is non-differentiable.

To overcome unbiased estimation and for reducing variance here need baseline function:

$$\frac{1}{m} \sum_{k=1}^m \sum_{t=1}^T \nabla \theta \log P(a_t[a_{(t-1):1}; \theta_c]) (R_k - b) \quad (3)$$

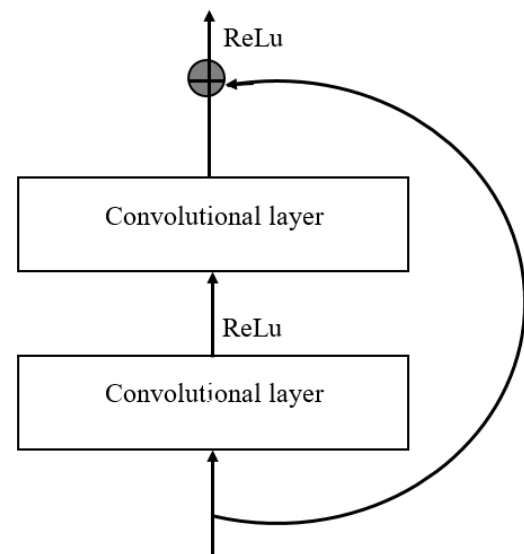

Fig. 3. Basic Residual Blocks of ResNet Architecture [27]. ResNet Architecture is at the Core of BiT Models.

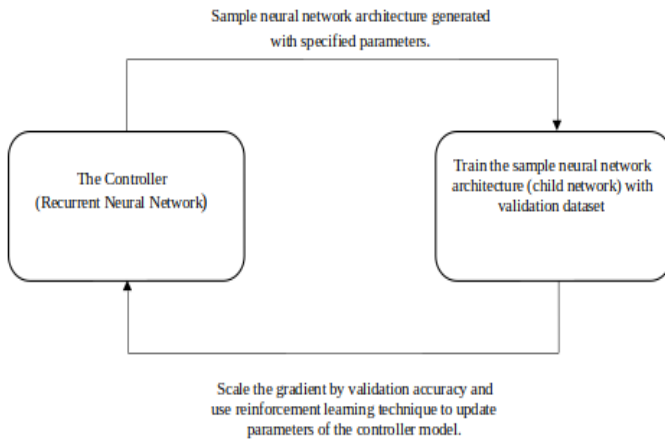

Fig. 4. NasNet Models Process Diagram [28]. The Controller Network is taken Part in Selecting the most efficient Neural Parameters for a Specific Dataset.

Here  $m$  is the number of various architectures,  $T$  is the number of hyper parameters. The validation accuracy of the  $k$ -th neural network after training a dataset is  $R_k$ . If  $b$  doesn't depend on current action then the function is unbiased gradient estimation.

**NasNet Controller Architecture:** On Neural Architecture Search, a controller is being used by us for creating architectural hyperparameters for neural networks [25]. The controller is mainly prepared as a recurrent neural network. Fig. 5 visualize the internal architecture of the NasNet controller. For predicting feed-forward neural networks with convolutional layers, the controller provides hyperparameters as tokens. The generating process of architecture is halted when the layer exceeds a particular value. For sampling convolutional network RNN anticipates filter height-width, stride height-width, and filter numbers for one or more layers. A Softmax classifier makes each prediction, and then the output is fed into the next step.

C. DenseNet-201

Considering CNN, DenseNet contains fewer perimeters than most conventional models [9]. A DenseNet architecture visualizes in Fig. 7. It contains sense built-in blocks with steam and transactional neural blocks. This architecture is not needed necessary to learn redundant feature maps. DenseNet can add a small set of new features because the layers it is narrow. To train intense networks, it has to face problems due to alluded flow of information and gradients. It can solve the problems by DenseNet. Cause each layer of this algorithm has direct access to gradients from the loss function.

Equations of DenseNet would be:

$$X_L = H_L(X_{L-1}) \tag{4}$$

For including skip connection ResNet extends the behavior by reformulating the equation:

$$X_L = H_L(X_{L-1}) + X_{L-1} \tag{5}$$

In this algorithm, the incoming feature maps don't sum up the output of the feature maps layer. So, the final equation is:

$$X_L = H_L([X_0, X_1, \dots, X_{L-1}]) \tag{6}$$

This thing makes the main difference between ResNet and DenseNet.

Using convolutional neural networks in a systematic flow for a specific task is known as blocks of CNN. Dense Block (showed in Fig. 6) is a benchmark model for specific feature extraction purposes. This module connects all matched feature maps (layers) with other available layers. For retraining from all feed forward quality each layer gets extra inputs from all foregoing and leaves them to subsequent layers. On DenseNet features are concatenated and the  $l^{th}$  layer has 1 input which consists of feature maps of previous convolutional blocks and its feature maps are left for  $L-l$  subsequent layers. For traditional dense connectivity, this layer implemented  $\frac{L(L+1)}{2}$  instead of doing  $L$ . The networks defined  $L$  as layers, and  $H_l(\cdot)$  is non-linear transformation,  $x_l$  is the output of the  $l^{th}$  layer.

The convolutional block is consists of two or more convolutional layers with essential activation functions. Fig. shows that every convolutional layer receives direct input from preceding layers. The transition layer mainly does the work of pooling and convolution, which is used in batch normalization with 1x1 convolution and 2x2 pooling. Input feature maps first go to batch normalization and standardize input data. After completing each convolution, the number of channels shows the growth rate of a block by remaining the same as before. After mapping out the feature, the output sends to all of the layer blocks. For extracting features from input data, activation function and convolutional layer are used. VGG-16 networks hold 16 convolutional layers with the same kernel.

D. Inception ResNet-V3

Inception networks interrupt the same filter size concept in a block [16][30]. A single built-in block searches for a different convolutional layer with different shapes shown in Fig. 8. Multiple layers subsist in parallel in a block and concatenate each sequence of layers. 1x1 convolutional layer at the beginning reduces the dimensionality of a sequence. Multilevel feature extraction is expedited by concatenating various filter-sized sequences. Res-Net passes the output of a convolutional layer typically.

## VI. SYSTEM OPERATION

Much work has been done on breast cancer using different types of machine learning and deep learning algorithms. This paper made a complete guideline to classify breast cancer-affected patients by following a flowchart given in Fig. 1. In this flowchart, after acquiring affected people's images, it needs to process those images. In this step, the machine takes the images from the dataset as input. In processing, the system split a dataset into two parts train data and test data. The system uses 80% of data for training and 20% of data for testing. This train data has to go through different processing techniques (rotates, room, flip and shuffle). This process improves the data quality by enhancing image features essential for the next training part of the process [22]. On the other side, in training data, the system applied resizing (224×224) and rescaling (0-1). Only the standard processes are applied between training and testing data.

Then these processed images have to go through the deep convolutional neural network. It is a feed-forward artificial neural network and has taken the role of feature extraction [12]. It is a fully connected layer containing multiple nodes, and every node is connected to the subsequent nodes with the next layer. Pre-trained weights can be changed by training procedure [15]. For comparative analysis, trained models are evaluated by testing data split.

## VII. RESULT ANALYSIS

This analysis was performed on four different types of deep learning algorithms. Table 2 contains the performance summary of selected models. The selected architecture's performance was promising. This study includes NasNet-Large, DenseNet-201, Inception-ResNet-V3, and Big Transfer, with a total of 1693 instances in the dataset. From here, 1354 were used in training and 339 instances in testing. The dataset contains two classes: Malignant and Benign. Out of 1693 selected datasets has 547 images in Benign and 1146 images in Malignant. Again 434 Benign images were used in training, and 111 were in testing.

On the other hand, 918 malignant images were used in the training phase and 228 in the testing phase. After analyzing the training and testing phase, Big Transfer achieved the highest accuracy of 90%, whereas DenseNet-201 has 89%, Inception-ResNet-V3 has 86%, and NasNet Large 81%. One of the great features of this study is that the applied algorithm will take the highest accuracy from 200 epochs intelligently, whereas other typical algorithms take values from predefined epochs [17] (Fig. 9). Table 3(I, II, III, IV) contains the performance measurement of the models with different classes of data. Here support is 111 for Benign and 228 for Malignant for each algorithm.

TABLE II. PERFORMANCES OF SELECTED MODELS

Models	Accuracy
NasNet Large	0.8183
DenseNet-201	0.8917
Inception-ResNet-V3	0.8642
Big Transfer	0.9000

NasNet Large: For Benign class NasNet has 0.31 precision with 0.29 Recall, 0.30 F1 Score. For Malignant class algorithm has 0.67 precision with 0.70 Recall, 0.68 F1 Score.

TABLE III (I): THE PERFORMANCE SCORE FOR EACH CLASS OF NASNET LARGE MODEL

Classes	Precision	Recall	F1 Score	Support
Benign	0.31	0.29	0.30	111
Malignant	0.67	0.70	0.68	228

DenseNet-201: For Benign class DenseNet has 0.28 precision, 0.27 Recall, 0.27 F1 Score and for Malignant class the precision is 0.66, Recall & F1 Score 0.67.

TABLE III (II): THE PERFORMANCE SCORE FOR EACH CLASS OF DENSENET-201 MODEL

Classes	Precision	Recall	F1 Score	Support
Benign	0.28	0.27	0.27	111
Malignant	0.66	0.67	0.67	230

Big Transfer: For the Benign class Big Transfer has 0.29 precision with 0.27 Recall, 0.28 F1 Score. For the Malignant class, the algorithm has 0.66 precision with 0.68 Recall, 0.67 F1 Score.

TABLE III (III): THE PERFORMANCE SCORE FOR EACH CLASS OF THE BIG TRANSFER MODEL

Classes	Precision	Recall	F1 Score	Support
Benign	0.29	0.27	0.28	111
Malignant	0.66	0.68	0.67	228

Inception-ResNet-V3: For Benign class Inception-ResNet-V3 has 0.31 precision, 0.31 Recall, 0.31 F1 Score and for Malignant class the precision, Recall & F1 Score is 0.67.

TABLE III (IV): THE PERFORMANCE SCORE FOR EACH CLASS OF THE INCEPTION-RESNET-V3 MODEL

Classes	Precision	Recall	F1 Score	Support
Benign	0.31	0.31	0.31	111
Malignant	0.67	0.67	0.67	228

Fig. 9. Best Epochs Selection between 20 and 200.

Training and validation are a significant part of deep learning. If the algorithm is well trained and validated, it can perform better in higher accuracy output. Fig. 10 shows that the dataset was well trained. The training accuracy was almost 0.98 with a standard deviation of 0.0258021, and the highest epoch generated was 120.

Fig. 10. Training & Validation Accuracy.

Fig. 11 shows that the number of accuracies repeated while performing accuracy with algorithms. Here 0.90 and 0.89 were achieved once. 0.86 accuracy was achieved two times, accuracy between 0.86 and 0.87 was achieved three times. 0.87 And 0.88 were achieved six times. The highest repeated number is 8. It was between 0.87 and 0.88.

Fig. 11. Multiple Test Accuracy Bar Chart.

Dropout is the method of removing random neurons from the network while training. As a result, the activity of the downstream neurons is temporarily removed from the forward pass, and weight changes do not apply to the backward pass [14]. L2 rate means that it will reduce overfitting with the small size of weight and biases. After analyzing Fig. 12, the best L2 rate was 1.47, and the best dropout was 0.45.

Fig. 12. Networks Dropout Rate Selection.

### VIII. DISCUSSION

Breast cancer is very deadly for women, especially older. Scientists are working very hard to find easy and practical solutions. With the help of modern technology, people are different types of deep learning or machine learning algorithms in medical science. This technology dramatically improves medical treatments as it is very effective, low on cost, and saves much time for doctors and patients.

This paper aims to identify breast cancer from images by using four deep learning algorithms. Those algorithms are NasNet Large, DenseNet-201, Inception-ResNet-V3, and Big Transfer. All of the experimented algorithms provide promising results. The dataset was collected from Kaggle. We worked with total 1693 instance divided into two classes named Malignant and Benign, from here 1354 was used in training, and 339 instances were used in testing. For all the algorithms, the total support instance was 339.

NasNet-Large is a convolutional neural network with more than 1 million images trained from the ImageNet database [28]. Input image size was 331\*331. This analysis shows it obtained 81% of accuracy, which is the lowest out of 4 algorithms.

DenseNet-201[29] is a convolutional neural network with 201 layers. It can add a pre-trained network trained on the ImageNet database. The input image size was 224\*224. This algorithm achieved 89% of accuracy, which is the 2nd highest.

Inception-ResNet-V3 is the descendant from the Inception family [30]. It has some improvements in Label Smoothing, 7\*7 factorized convolutions, and the use of an auxiliary classifier for propagating label information. Here input size was 299\*299. The algorithm provides the third-highest accuracy of 86%.

Significant Transfer is one of the newest in deep learning algorithms [19]. Although it is new, the performance of this algorithm is awe-inspiring. On current analysis, Big Transfer owned first place with 90% accuracy.

### IX. CONCLUSION

This study worked with deep learning methods to predict breast cancer. The proposed method goes through image data selection and preprocessing the data for focusing on the prime

features. DenseNet, NasNet Large, Inception ResNet (v3), m-r101x1x1 (BiT) neural architecture are selected for this study. The architecture selection process was based on their architectural variety and their efficiency in the computer vision sector. The selected public microscopic biopsy dataset is split into two parts for training and testing purposes, where 20% of the data is reserved for evaluating the trained neural network models. This study use pre-trained weights for the benchmark architectures from Keras. This study applies necessary modification in the tail order layers of benchmark models, customizes the neural models for forecasting breast cancer from histological images. Thirty evolution cases occurred for each trained model to finalize the reliable performance rate. The best accuracy of 90% was found once in the thirty evaluations from BiT based m-r101x1x1 architecture which contains 101 layers of neural network. The average accuracy of the Bit based model was found at 87.51%, which is higher than the average accuracy of comparative models. This inaugural work exhibit the probability and promise of working with large data set with more accuracy and larger multicenter studies for ulterior appraise the methods and findings.

**Abstract**—Education has taken a big turn due to the current health situation, and as a result the use of technology has become a great ally of education, achieving important benefits. Augmented reality is being used by teachers and students especially in distance and/or face-to-face learning through didactic learning, self-instruction and the promotion of research. This article shows the development and influence of a mobile application with augmented reality that serves as a reinforcement for the learning of Science and Technology in students of sixth grade of Primary and first year of Secondary School. The Mobile D methodology is used during the development process of the application, the research design is Pre-Experimental since the Pre-Test and Post-Test tests are performed to a single group of students being the total of 30, obtaining as final result the increase in the level of interest of the students to 100%, in the level of understanding there was an improvement of 50% and the level of satisfaction is maintained in a range of 40% satisfaction and very satisfied of 60%, which implies that the application helps them to improve their learning.

**Keywords**—Augmented reality; learning; mobile application; Mobile D methodology

## I. INTRODUCTION

In this sense, the Program for International Student Assessment (PISA) of the Organización para la Cooperación y el Desarrollo (OCDE), which is carried out every 3 years, evaluates 15-year-old students in the areas of reading, mathematics and science, contributing to systematically assess the knowledge of young people [1].

According to OECD results [2], the 10 countries evaluated in Latin America are below average in Reading and Mathematics, with Peru being one of the countries that is showing small growth. In 2018, Peru participated voluntarily with 342 schools and a total of 8028 students (6086 of whom took the cognitive competency and 1942 took the Financial Education competency) [3], 70% of which were state schools and 30% private schools. According to the results obtained by PISA in 2018, the average obtained by Peru were the following: reading comprehension of 401, mathematics of 400 and science of 404 placing it in 64th place out of 77 countries, although in some points a slight improvement has been achieved but it is still worrisome.

In the national evaluations of learning achievements carried out in 2019 [4], [5] where students at 1st secondary school were evaluated, to test if the learning obtained are those

expected by the National Curriculum of Basic Education (CNEB), the national results exposed in Table I were obtained, making a comparison of the national results of the year 2018 and 2019. It was identified that we remain in "Level in process", where the student managed to partially learn the expected learning, but still shows difficulties, since the academic performance that students are obtaining is very low compared to other countries.

One of the ways to establish improvements in the educational world is using technological tools [6], [7], these can be used by teachers and students especially in remote and/or face-to-face learning by combining traditional teaching with technology. One of them being Augmented Reality (AR), which consists of the overprinting of one or more virtual elements in real time [8], this is given thanks to the mobile camera being an appropriate means of entertainment for educational purposes.

What we want to achieve in this research is to provide a technological proposal, which will serve to improve the learning of students in the Science and Technology course, thus showing a significant increase in their level of interest in the course, their understanding of the information they are being taught and an increase in their level of satisfaction using the mobile application with reality, thus achieving a dynamic learning.

TABLE I. NATIONAL RESULTS BETWEEN 2018 AND 2019

Areas evaluated	Average Mean (MP)	
	2018	2019
Reading	571	567
Mathematics	560	567
Science and Technology	500	501

## II. BIBLIOGRAPHIC STUDY

The accelerated advance of technology together with mobile devices has led us to redefine current teaching and communication methods. A lot of research has conducted studies on the impact of Information and Communication Technologies (ICTs) both in everyday life and in specific areas such as education [9]-[11], aiming to demonstrate the results focused on the skills acquired by students. This technological development can use new technologies as an aid in the teaching and learning process for both teachers and students

[12]. Adolescents are during these changes and usually make use of the artifacts and technologies that are being incorporated into our daily lives [13], familiarizing themselves with them and allowing them to take advantage of them in a way that contributes to their intellectual development, aiming to achieve an education based on results.

This section presents a review of the latest research conducted regarding the topic in common, to show the benefits and effects achieved from AR implemented in education. Articles from academic journals and academic research databases between the years 2016-2021 were considered, presenting a summarized analysis of studies.

In the research [14], an application was proposed for learning the Quechua language with augmented reality in pre-school students, serving as support as teaching material inside and outside the classroom. The activities developed within the application were adapted by means of written and audiovisual comprehension, showing favorable results within the population. A 30% improvement in the students' performance was evidenced after being used in the classes as a support tool.

In the research work [15] proposes a mobile application called GEO+. The application would be used by elementary school students allowing them to have a better acquisition of knowledge based on the geometry course, making use of augmented reality, and generating a greater interest in the course. The effectiveness of learning was measured through post-test and pre-test evaluations, finally the results obtained were effective regarding the increase of satisfaction and learning before and after the implementation of the application, allowing them the ease of use of technology and achieving autonomous learning.

Finally, the present research [16], shows an application to demonstrate particle physics experiments using AR and the Kinest sensor to create an experience that immerses users in the subject. The results obtained were profitable, according to the qualitative analysis 85% of the participants were satisfied and recommended the application.

The studies shown allow us to identify how AR has made a great contribution to education.

### III. METHODOLOGY

The Mobile-D Methodology is used for a collaborative work to deliver a ready product within a maximum of ten weeks by a team of no more than ten developers, including test-driven development, continuous integration, and refactoring, as well as software process improvement tasks [17]. The Mobile-D methodology has 5 phases: Exploration, Initialization, Production, Stabilization and System Testing.

#### A. Exploration

At this stage the Stakeholders were established.

- Interest Group: Companies focused on the education sector.
- Application User: (30) Students of 6th Grade of Primary and 1st Grade of Secondary.

- Developers: Researchers/Developers of the present project.

#### B. Initialization

In this phase, the technological resources (hardware and software) for the development of the research project are established.

Hardware:

- 2 laptops with 4-core processor or more, 8 GB RAM.
- Samsung A20S mobile device.

Software:

- Unity: This is a video game development tool that also serves to create interactive experiences in Virtual or Augmented Reality [18], being processed, rendered, and displayed in real time.
- Blender: A software capable of creating new 3d visualizations [19] (still images, animations, video editions, etc.), it has a high-quality architecture, allowing an optimal workflow.
- Vuforia: Vuforia is an augmented and mixed reality application development tool, oriented for the Unity engine [20]. Offering text recognition, image recognition, tracking, target detection.
- Visual Studio: is an integrated development environment (IDE) being a program that has several features around software development [21].

#### C. Production

In this phase the ideas are organized, and the functions of the application are prototyped. Fig. 1 shows the general architecture of the application called ARST.

Through the mobile device captures the scene taken through the camera and the Vuforia SDK will create frames of the captured scene converting the image to a different resolution for the proper processing of the tracker. The Vuforia SDK will analyze the images through the tracker looking for similarities in the database that is composed of the targets, and then the application verifies the status of the targets to update the logic programmed in Unity, and finally present the virtual content on the screen of the device to be observed in augmented reality.

#### D. Stabilization

In this stage, the development of the components and the integration between them is carried out.

1) *Application prototypes*: Fig. 2 (a) shows the design of the main menu of the application, with its respective options where students can interact, then Fig. 2 (b) shows the initial interface of the presentation of the topic to be performed with its respective classification, in Fig. 2 (c), the interface of the ARST Application quiz is shown, finally in Fig. 2 (d), shows the application questionnaire where students interact by asking questions about the topic, giving a score.

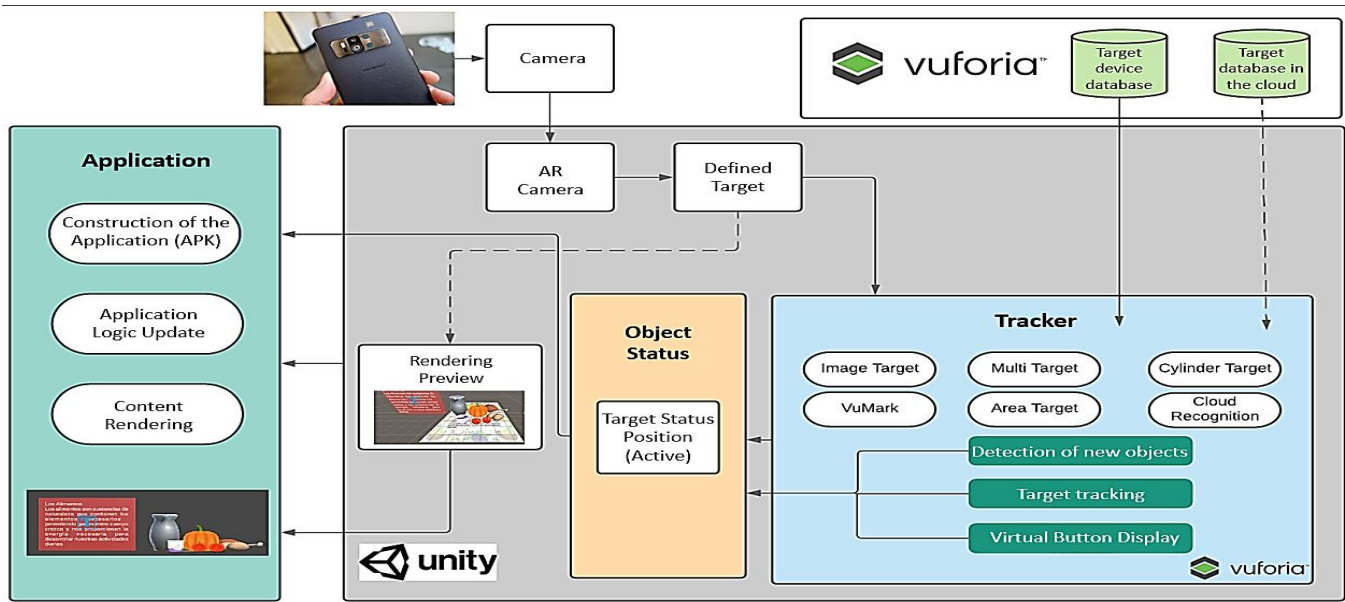

Fig. 1. Project Architecture.

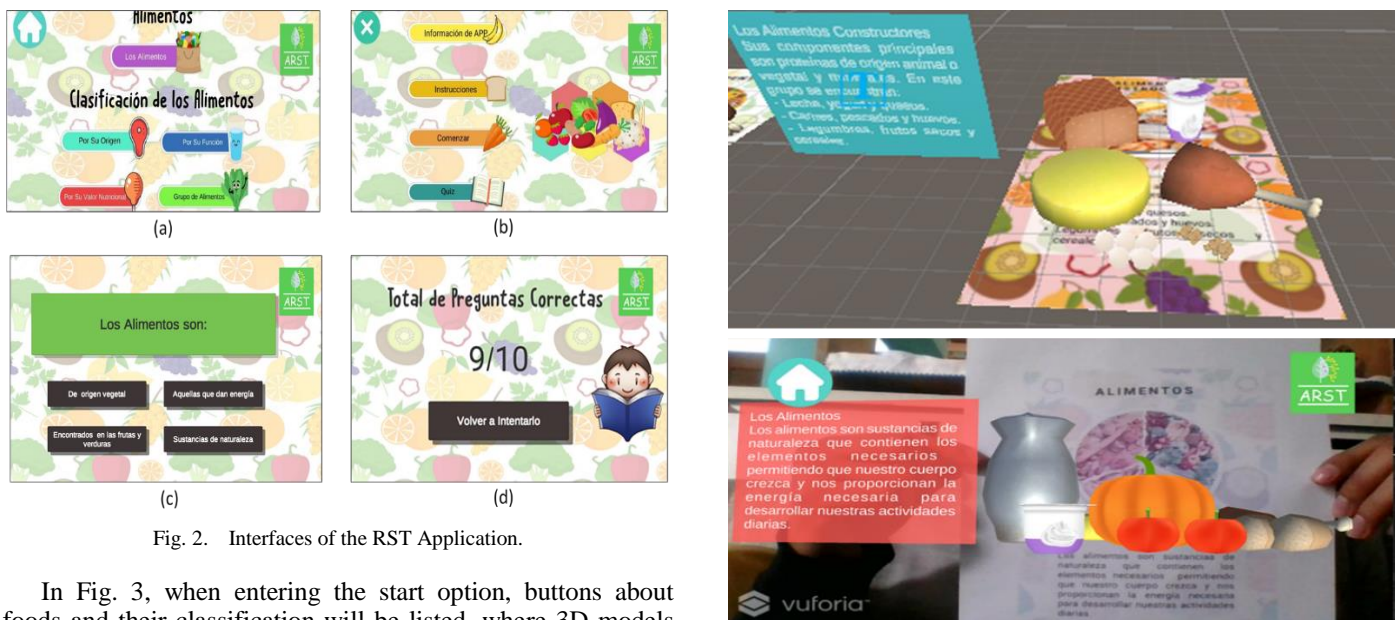

Fig. 2. Interfaces of the RST Application.

In Fig. 3, when entering the start option, buttons about foods and their classification will be listed, where 3D models of foods and their classification are visualized by means of targets. For example, the food with a brief information, the classification of food (by origin, by nutritional value).

E. Test

For this research, the population will be made up of 30 students from I.E.P. Magister in the city of Lima, district of Villa María del Triunfo. It is applied to students in 6th grade of Primary and 1st Grade of Secondary. The design used was pre-experimental, with a pre-test and a post-test since the online method was used (1). Table II shows the definition of the items.

$$Ge \ O_1 \ X \ O_2 \quad (1)$$

Fig. 3. Visualization of 3D Models of Foodstuffs by means of Targets.

TABLE II. DESCRIPTION OF PRE-EXPERIMENTAL ELEMENTS

Elements (I)	Description
Ge	Experimental Group
O1	Level of learning before applying the system. (Pre-test)
X	Mobile application with augmented reality
O2	Level of learning applied to the system (Post-test)

#### IV. RESULTS

The objective of this research is to determine to what extent the mobile application with augmented reality will improve learning in the Science and Technology course. For this purpose, the first tests were conducted on one of the most touched topics of the course "Food and its classification", considering the following criteria: The level of interest (KPI-1), the level of understanding (KPI-2) and the level of satisfaction (KPI-3). The information was collected by means of a survey through the Google Forms platform and the results were analyzed with the SPSS tool. The results are shown in Table III.

The first indicator of level of student interest is measured on a Yes/No scale, the second indicator of level of understanding is evaluated on a scale of Beginning to Outstanding Achievement, and the third indicator of level of satisfaction is evaluated on a scale of Very Dissatisfied to Very Satisfied.

1) *KPI-1*: Level of student interest: Fig. 4 shows the results obtained from the experimental group with respect to the Pre-Test and Post-Test, it is observed that the level of interest of the students increases by 30% over the interest they have during the development of the Science and Technology course.

In Fig. 5, the KPI-1 summary report on the level of interest after implementation of the application is shown, which obtained the following results: About 20% of students do not feel a level of interest and 80% do with respect to the science and technology course, also through a 95% confidence interval for the mean, 2 limits 0.61 and 0.99 were obtained.

TABLE III. TEST RESULTS: PRE AND POST

Indicators	Group	Pre-Test	Post-Test
Level of Interest	Experimental	78%	100%
Level of Understanding	Experimental	30%	50%
Satisfaction Level	Experimental	Very Satisfied	Satisfied

Fig. 4. Pre-Test and Post-Test of Students' Level of Interest.

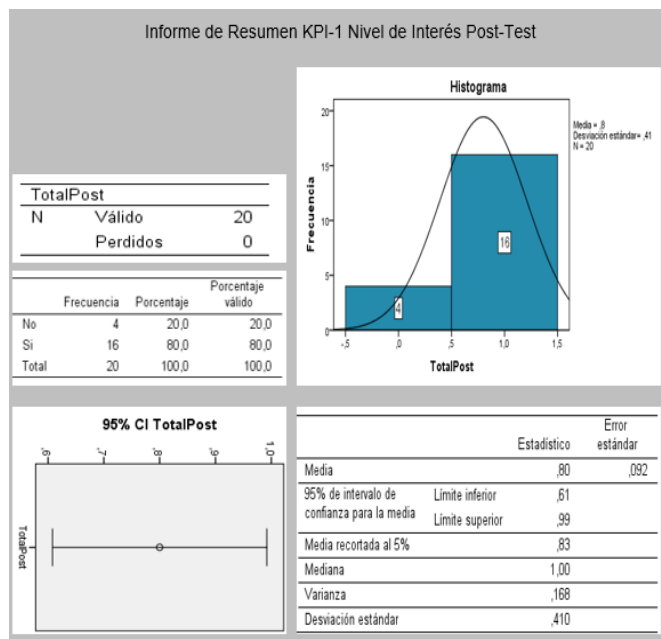

Fig. 5. KPI-1 Summary Report Post-Test Level of Interest.

2) *KPI-2*: Students' level of understanding: Fig. 6 shows the results obtained by the experimental group with respect to the Pre-Test and Post-Test, showing that the level of understanding of the students has increased by 50%, since half of the students have reached an achievement in their comprehension.

In Fig. 7, the KPI-2 Summary report on the level of understanding after implementation of the application is shown, which obtained the following results: Through the tabulation, 50% in process, 30% in Expected Achievement and 20% in Outstanding Achievement of the students with respect to their level of knowledge and understanding on the topic of Food and its classification of the Science and Technology course, with the use of the mobile application with augmented reality.

Fig. 6. Pre-test and Post-test of Students' Level of understanding.

Fig. 7. KPI-2 Post-Test Comprehension Level Summary Report.

3) **KPI-3: Student Satisfaction Level:** Fig. 8 shows the results obtained by the experimental group with respect to the Pre-Test and Post-Test, showing that the level of satisfaction has decreased, but is still maintained in a degree of satisfaction (Very Satisfied and Satisfied) by the students.

Fig. 8. Pre-test and Post-test of Student Satisfaction Levels.

Fig. 9. KPI-3 Post-Test Satisfaction Level Summary Report.

Fig. 9 shows the KPI-3 summary report on the level of satisfaction after implementation of the application, which obtained the following results: Through the tabulation, 40% of the students feel satisfied and 60% of the students feel very satisfied with respect to the application with augmented reality applied during the class with the topic of Food and its Classification in the Science and Technology course.

## V. CONCLUSION

This research article has presented a review of research in recent years regarding the benefits of AR in education, concluding that it contributes greatly to their academic performance, self-learning, and creativity, in addition to increasing their enthusiasm in courses by encouraging research.

An AR application was developed as a tool to improve learning in the science and technology course for regular elementary school students, providing additional didactic information together with questionnaires to measure learning.

It has been observed that the use of a mobile application with augmented reality significantly improves learning in the Science and Technology Course due to the 50% increase in the Comprehension Level (Fig. 4 and Fig. 5), applied in the questionnaire of students in 6th grade of primary education and 1st grade of secondary education (experimental group). There were not many changes in the students' satisfaction (Fig. 6 and Fig. 7), but it remains between the intervals of 40% of Satisfied Students and 60% of Very Satisfied Students. There was an increase of 30% of students who showed interest in the Science and Technology course (Fig. 8 and Fig. 9).

The results showed that the proposed ARST application has succeeded in promoting self-learning, didactic learning, and research. It is recommended for future research to develop more topics applying augmented reality focused on education.

# Learning Pick to Place Objects using Self-supervised Learning with Minimal Training Resources

## Pick-to-Place Objects with Self-supervised Learning

Marwan Qaid Mohammed, Lee Chung Kwek, Shing Chyi Chua

Faculty of Engineering and Technology  
Multimedia University (MMU)  
Melaka, Malaysia

**Abstract**—Grasping objects is a critical but challenging aspect of robotic manipulation. Recent studies have concentrated on complex architectures and large, well-labeled data sets that need extensive computing resources and time to achieve generalization capability. This paper proposes an effective grasp-to-place strategy for manipulating objects in sparse and chaotic environments. A deep Q-network, a model-free deep reinforcement learning method for robotic grasping, is employed in this paper. The proposed approach is remarkable in that it executes both fundamental object pickup and placement actions by utilizing raw RGB-D images through an explicit architecture. Therefore, it needs fewer computing processes, takes less time to complete simulation training, and generalizes effectively across different object types and scenarios. Our approach learns the policies to experience the optimal grasp point via trial-and-error. The fully convolutional network is utilized to map the visual input into pixel-wise Q-value, a motion agnostic representation that reflects the grasp's orientation and pose. In a simulation experiment, a UR5 robotic arm equipped with a Parallel-jaw gripper is used to assess the proposed approach by demonstrating its effectiveness. The experimental outcomes indicate that our approach successfully grasps objects with consuming minimal time and computer resources.

**Keywords**—Self-supervised; pick-to-place; robotics; deep q-network

### I. INTRODUCTION

Dexterous grasping is a crucial ability of robots that enables them to assist and substitute humans in accomplishing various tasks that might be too dangerous or tedious to do. Deep learning (DL) allows computational models composing multiple processing layers to learn data representation with multiple levels of abstraction [1]. On the other hand, Reinforcement learning (RL) relates how software agents learn to take actions in an environment such that some notion of cumulative reward is maximized via a trial-and-error approach [2]. A typical deep reinforcement learning (deep-RL) combines these two machine learning methods [3], which leverages the representation power of deep learning to solve the reinforcement learning problem. When applied to robotic grasping, the robot observes the environment through RGB-D data, and attempts an optimal action the predefined policy. Robotics can be used in nearly every circumstance, but particularly in cluttered environments, where the need for enhanced grasping efficiency demands. Object grasping is a

typical robotics challenge that has made substantial progress in recent years, which is an essential step in many robotic tasks [4]. Objects removal task has been extensively researched in many studies. yet it is a challenging task in robotic manipulation [5].

The process by which a robot learns to grab and remove objects from its workstation is called object removal. Although many studies have focused on learning to grasp a single or multiple objects, some of these studies have examined how to overcome the difficulty of grasping in crowded surroundings where things seem to be stuck together in a pile. The robot must be able to detect and interpret objects and their environment in this situation, as well as effectively remove the objects from the robot's workspace. Recently, a standard Deep-RL has been used in a variety of robotic applications [6], including placement [7], grasping deformable objects [8], and grasping in a cluttered environment [5]. Meanwhile, it has advanced technology by integrating visual and tactile input, particularly in robotic grasping [4]. Additionally, deep-RL has offered great solutions for difficult-to-perform and repeat tasks via the use of end-to-end training. Since robots are usually effective at grabbing a variety of objects, interest in robots with warehouse automation skills has steadily increased in recent years. RGB-D data is increasingly being used to enhance robotic vision-based grasping in cluttered environments. Zeng et al. [9] developed a method that utilizes multi-view RGB-D data in conjunction with self-supervised and data-driven learning.

In [10], the authors utilised a straightforward view-based rendering as a forward-prediction model. To generate reliable dense visualizations of objects from RGB-D data for robotic manipulation, Florence et al. [11] presented the Dense-Object Net using a ResNet architecture. Some studies used only RGB data, obviating the necessity of depth images. The use of depth images was not required in certain studies. For example, [12] proposed GANs that could use a single batch of RGB data to predict a hand's form and location for various object grasping. Kalashnikov et al. [13] employed RL to generate a grasp pose detection dataset from RGB data in cluttered settings. The learned policies were optimized utilizing the aforementioned methods' experience. However, learning typically takes days to acquire enough experience training iterations since it needs significant computing resources to calculate the large quantity of required data. Using a large dataset [14] (e.g., recognizing

graspable poses with RGB-D data [15], point clouds[16], semantic segmentation based grasp[17]) necessitates a large amount of memory and a powerful graphics processor unit (GPU), such as NVidia Drivers, which is currently one of the difficulties in Supervised learning. In this paper, we propose an explicit pick-to-place framework that is less sophisticated than others [18]–[22] and that can be trained with appropriate CPU-Memory or GPU-Memory while taking into account training time and sufficient data for adequate evaluation analysis.

We propose a pick-to-place approach in self-supervised learning, in which RGB-D images are mapped to grasping actions through a fully connected network (FCN). The executed action is evaluated via trial-and-error by maximizing the rewards. The paper's primary contributions are as follows:

- To create an all-inclusive explicit manipulation approach that incorporates both picking and placement activities.
- To minimize the complexity of the model architecture to do training with minimal GPU or CPU resources.
- To increase the chance of robotic grasping in cluttered environment.

The paper is organized as follow: Section 2 discusses related studies, while Section 3 discusses the proposed approach's methodology in detail, including an overview of the strategic approach. The simulation experiment is given in the next section. Section 5 summarizes the findings and discusses them. The conclusion of the paper is presented in Section 6.

## II. RELATED WORK

Several studies have focused on robotic grasping, especially in dense surroundings, and proposed solutions using deep-RL, an efficient method. This area requires further investigation and understanding of the problems. Taking everything from a robot's workplace is part of cleaning up a cluttered environment. The robot must be able to perceive, interpret, and act on its surroundings and objects. When objects are physically close together, the robot's gripper must locate a place for its fingers to grasp. Zeng et al. [9] proposed to train Q-learning on FCNs. The vision system takes RGB-D images from various angles. The robot's workspace collects RGB-D images from 15 to 18 angles. Each RGB image feeds an FCN for 2D object segmentation. The final product is 3D. This data is then combined with an existing 3D model to get the 6d posture. In [13], QT-Opt, an off-policy training technique based on Q-continuous learning's action extension, is proposed. Closed-loop vision-based control is enabled via dynamic manipulation and scalable RL. The robot constantly updates its grab tactic to improve long-horizon grasp success probability.

Florence et. al [11] used the idea of self-supervised learning. The Dense-Object Network is employed, which uses the ResNet model to learn dense visual representations of objects from RGB-D data for robotic grasping in cluttered surroundings. However, it only shows a dense descriptor for three object classes, but more object classes might complicate the descriptor space segregation. Furthermore, mask region-based convolutional neural network (R-CNN) incorporates pixel-wise multi-class instance mask prediction for visible and

occluded area mask segmentation. The [23] proposed learning instances and semantic segmentation for visible and occluded regions. Semantic segmentation utilizes Fully convolutional instance-aware semantic segmentation (FCIS) architecture to estimate position-sensitive masks using multi-class instance masks. It requires a dataset including all of the objects' possible occlusion states, labels, and masks; the amount of effort required to complete this task increases exponentially with the number of items. Those studies seem to be a time-consuming and complicated approach.

Active learning trained an RL framework on the intended neural network (NN) [24]. The grasp space is explored using a set of rules. Weighted retraining reduces the effect of measurement mistakes. The pixel-attentive policy gradient method proposed in [25] uses a single depth image and progressively zooms onto a specific area of the image to estimate the optimum grasp. Using Generative models to arrange multi-finger grasps is more difficult than using parallel-jaw grasps in a cluttered environment. In [26], a real-time deep convolutional encoder-decoder NN for open-loop robotic grasping has been proposed. In their method, UG-Net can estimate the quality and posture of a grip using a depth image. In [10], rendering or simulating future states concerning many possible actions is re-used. As a result, an end-to-end 6-DoF closed-loop grasping model using RL is shown employing a learned value function (Q-value). Also, an RL framework and 3D vision architectures were proposed [27] using hand-mounted RGB-D cameras. However, manipulation with more task-dependent representations must be learned from limited training data. Also, Yang and Shang [28] suggested an attention DQN for robotic grasping in clutter. Whereas, Assembly task to grasp the objects and place in stacking manner has been executed in [29].

In [12], generative adversarial networks (GANs) were introduced to estimate the hand shape and position for multiple item grasping. However, unstable training requires careful hyperparameter tuning. For 6-DoF grasping, the generative attention learning (GenerAL) method [30] has been provided, which uses deep RL to directly output the final position and configuration of the fingers. In another study, a generative grasping GG-CNN is provided [31] to extract the grip quality from a depth image. It also predicts the optimum grip based on the location, angle, and grasping breadth. However, an inaccurate grasp width estimate causes gripper collisions on large and small objects. In cluttered scenes, an end-to-end network (Contact-GraspNet) has been presented [32] to effectively and automatically distribute 6-DoF parallel-jaw grasps using depth data while preventing collisions. The limited grip breadth prevents it from grasping heavy objects. The discontinuous selection boundary makes predictions less trustworthy. Besides, The collision-aware reachability predictor (CARP) approach [33] has been proposed to learn to estimate the probabilities of a collision-free grasp position, thus substantially enhancing the grasping of objects in challenging situations. In addition, Generative deep dexterous grasping in clutters (DDGC) proposed to generate a set of collision-free multi-finger grasps in cluttered scenes. High-quality grasps produced by DDGC do not always give a successful grasp [34].

There are some challenges that arise as a consequence of the training requirements and the time required to complete grasping activities. Certain failure scenarios occur in clutter circumstances due to the clutter being so dense that there is no space for the robot to place its fingers. Additionally, it needs a simulation setup and, in most cases, an extensive parameter search to function well. As a result, it is computationally intensive, taking between tens of seconds and minutes to complete. Similarly, batch training may not be optimal for predictions involving dense clutter. Learning often involves computing a massive quantity of necessary data, which results in a high cost of training setup and a long amount of time required to acquire proficiency. As a result, the majority of studies used sophisticated architectural frameworks that need a powerful graphics processing unit (GPU) to accelerate the training process, which not every academic can afford. Additionally, they focused on executing grasp movements without regard for where the object should be placed after it was grasped. To overcome the aforementioned challenges, we propose a grasp action with a single FCN of posture estimation using an explicit approach that consumes less time while performing efficient grasping. The proposed approach's purpose is to avoid model architectural complexity to enable training to be done with minimal GPU or CPU resources. Additionally, it focuses not just on grasping but also on placing tasks. Accordingly, a complete manipulation system (pick-to-place) is developed, which is learned collaboratively via end-to-end learning.

### III. METHODOLOGY

This section will explain the system's architecture and functions in detail. Then, the grasp and placement actions will be described in terms of how they perform and how they grasp and place actions' rules-based coordination works. The reinforcement learning formula and associated rewards will be explained, as well as how this component contributes to the robot's task learning.

#### A. Approach Overview

The proposed approach is intended to minimize the demands of the computing process, which could have an impact on the cost of time used during operation (Figure 1). The approach architecture is designed to run in a reasonable amount of time on a moderate CPU or GPU. The purpose of this paper is also to create a self-supervised learning

manipulation approach that avoids the inherent complexity of approach architecture.

Firstly, the camera captures the RGB-D images, which then projected to generate the color ( $C_h$ ) and depth ( $D_h$ ) heightmaps. The  $C_h$  and  $D_h$  will be rotated ( $\cup \times N$ ) before being forwarded into the conventional layers (a 2-layer residual networks [35]). The residual networks will reduce the input parameters of DenseNet-121 to be 1024 instead 2048, which can effectively minimize the time-consuming, and run on moderate CPU and GPU. Then, the extracted features are then fed to a DenseNet-121 [36], a pre-trained model on ImageNet [37], to create motion agnostic features. Then, the motion agnostic features are used as inputs by the grasp net  $\phi_g$  followed by bilinear upsampling, which estimates the grasp Q-maps ( $Q_g(s_t, a_t) \in \phi_g$ ). A three-layer residual network is used in the  $\phi_g$ . Finally, the robot executes the predicted best grasp, corresponding to the highest Q-value. Rewards are then assigned automatically depending on the success of grasps. The experience replay [38] is employed, which used to store the agent's experiences at each time step in a data set  $e_t = (s_t, a_t, r_t, s_{t+1})$  that is pooled across many episodes to create a replay memory. Then, like with DQN, we randomly sample the memory for a minibatch of experience and utilize this to train off-policy.

#### B. Q-Learning and Reward Function

The representation image of the environment is viewed as a state ( $s_t$ ) in this article, which is the deep network's input. The output is the action with the highest action-value, and it results in an immediate reward. As a consequence, as demonstrated in Eq. (1) [2], the policy ( $\pi$ ) is reinforced by selecting the action with the highest state-action value. The agent's goal is to select the best action that maximizes the action-value function and the sum of future reward expectation returns. Maximization is accomplished by selecting the optimal value action (among all potential actions).

$$\pi^*(s) = \arg \max_a Q_\pi(s, a). \quad (1)$$

To estimate the optimal grasping action, the approach is trained via Q-learning on FCN. The Q-value is learned in association with the offline policy, as in Eq. (2).

$$Q_{new}(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha(r_t + \gamma \max_{a'} Q(a', s') - Q(s_t, a_t)) \quad (2)$$

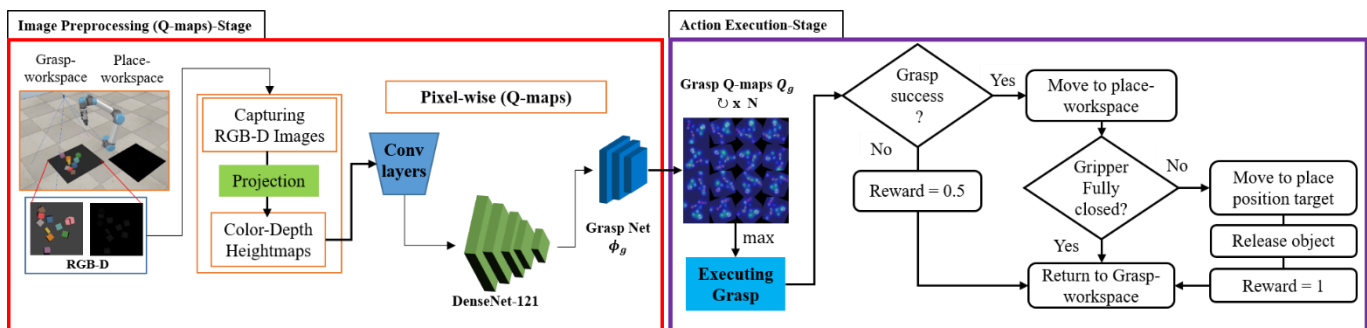

Fig. 1. The Workflow of Proposed Approach based Picking and Placing of Objects.

The  $Q(s_t, a_t)$  parameter represents the current Q-value, which is updated during the training, and the  $(\alpha)$  variable represents the assigned learning rate, which is between 0 and 1. Meanwhile, The discount factor  $(\gamma)$  is set to 0.5. The current reward  $(r_t)$  is received by transitioning from the present state  $(s_t)$  to the future state  $(s' = s_{t+1})$ . The reward is required to inform the robot about which state-action pairs are efficient and which are not. The initial value of  $r_t$  is 0, but it is increased throughout the training process to stimulate the robot to perform grasp tasks and reduce the loss value. The grasp prediction yields the future reward (e.g.  $\max_{a'} Q(a', s')$ ). Since Q-learning is trained on FCN, the learning rate is used in the stochastic gradient descent optimizer's back-propagation, it is no longer essential to include it in the Q-learning equation. After removing the learning rate, the two terms cancel out (as written in Eq. (3)).

$$r_t + \gamma \max_{a'} Q(a', s') \quad (3)$$

Accordingly, we set the reward function as follows:

- $r_g(s_t, s_{t+1}) = 0.0$  for grasp if it fails and gripper never come in contact with the objects,
- $r_g(s_t, s_{t+1}) = 0.5$  for grasp if it fails and gripper come in contact with the objects.
- $r_g(s_t, s_{t+1}) = 1.0$  for successful grasp and place the object.

### C. Grasp and Place Primitive Actions

Each action  $(a_t)$  is represented as a primitive motion  $(\Psi)$  at 3D position  $(P)$ , which is projected from the pixel  $(px)$  of the heightmap image that depicts the state  $(s_t)$ , as shown in Eq. (4).

$$a = (\Psi, P) \mid \Psi \in \{grasp\}, P \rightarrow px \in s_t \quad (4)$$

A gripping action is presented as primitive motion. In one of 16 positions, the grasping motion is executed utilizing the center point within the gripper's parallel-jaw of top-down grasp. The robot moves its gripper's fingers down 3 cm of the expected location before closing its fingers to ensure that it reaches the desired object. The difference between the location of the gripper before and after gripping attempts is compared to its threshold value to detect a grasp action. The distance between the gripper's fingers and the workspace, which is 300 cm, is used as the threshold value. A successful grabbing attempt, on the other hand, is recorded when the fingers are not entirely closed, indicating that the object stays intact within the gripper's fingers until the robot places the object down.

In the next stage, once the robot has gripped an object, the placing operation will be carried out, as shown in Figure 1. The robot arrives at the workplace. The gripper's state is then verified to make sure the object is still in position. The placement process will be interrupted if there is slippage. After then, the robot returns to its starting location for a new iteration. For example, the robot will then place the object into the pre-defined place-workspace if it has been successfully grabbed. If the robot's gripper is not fully closed during a placement job, it implies that the object is within the gripper's fingers, allowing the robot to continue placing the object;

otherwise, the robot will interrupt and resume grasping instead of placing the object.

## IV. SIMULATION EXPERIMENT

In this paper, V-REP [39] is used to simulate an experiment using a UR5 robot equipped with a parallel jaw gripper. The robot uses an RGB-D camera to observe its environment. The color and depth images are captured at a 640 by 480-pixel resolution. A 3.7 GHz Intel Core i7-8700HQ CPU and an NVIDIA 1660Ti GPU power the PyTorch-based prediction network.

### A. Training Session

Self-supervised learning using a simulation platform is used to train the proposed approach. A similar training procedure to that described in [40] is used. For training, a collection of ten objects of different shapes is randomly placed into the robot's workspace. By trial and error, the robot learns to perform picking and a placement action. After clearing the workspace of all objects, another set of 10 objects is dropped for additional training. Continuous data collection occurs until the robot has completed 3K training iterations.

### B. Testing Session

We conducted a series of experiments to determine if the proposed approach is successful at accomplishing the grasping-to-placing task. We validate our approach using scenarios involving randomly cluttered objects with varying degrees of clutter, namely sparsely, medium, and dense clutter levels, as shown in Figure 2.

Fig. 2. A Series of Randomly Sparsely, Medium, and Densely Cluttered Object Challenge Scenarios.

- Sparsely cluttered objects scenario (test-cases 1-3): the objects are randomly distributed on the workspace in groups of 6–7.
- Medium cluttered objects scenarios (test-cases 4-6): The objects disperse in a random order of 9–10 objects that are distributed in close contact with one another. They are more challenging to perform than the first type of scenario.

- Densely cluttered objects scenarios (test-cases 20-30): Three scenarios, including a random selection of 20–30 objects, conduct to assess the proposed approach, which implies more challenging than the previous two sorts of scenarios.

### C. Evaluation Metrics

The proposed approach is assessed using the test scenarios described before. The robot must retrieve and clean all objects from the workspace in order to place them into place-workspace. Five test runs (denoted by  $n$ ) are conducted for each test case. The workspace contains between 6 to 40 objects. Three assessment metrics are utilized to evaluate the models' performance. The greater the value for each of these metrics, the better. These are the metrics.

- The grasp success rate: Ratio of the success grasp attempts to the total of executed actions over  $n$  test runs per each test case, and
- The place success rate: ratio of the number of successful place over the number of successful grasp through whole run tests of each case test.
- The completion rate: It's the average of the total number of completed objects divided by the total number of objects. It is used to measure the capability of proposed approach to grasp all objects in each test case without failing for more than five actions consecutively.

## V. RESULT AND DISCUSSION

This section organizes the findings into training and testing sessions. The proposed method's results will be shown throughout the training session via graphs of grasp success rate, which illustrate how the proposed approach performed during the training stage and how fast and effectively it learned. The testing session consists of a sequence of test cases, each of which is conducted five times. The models' performance is assessed using their grasp success, place success and completion rates.

### A. Training Session Outcome

The proposed approach (PA) was trained alongside other baselines utilizing a different training procedure. The grasping performance is evaluated by the proportion of successful grasp attempts made within the last 200 tries ( $m = 200$ ). The percentage is scaled by a factor of  $i/m$  in the earlier training trials, i.e., trials  $i < m$ . Figure 3 illustrates the grasp success rate graphs for 4000 training iterations. In this section, we trained the suggested method using different variables to evaluate whether or not these aspects affect the grasping performance when taken into account.

1) *PA-nodepth*: the proposed approach is trained only on color image data, ignoring depth information. It can be shown that when depth is not included during training, it affects grasp performance, with a grasp rate of almost 73%. Additionally, it requires many trials at the beginning of learning to gain expertise with the environment to boost its performance.

2) *PA-nopretrain*: the proposed approach leverages the use of the DenseNet-121 model, which was pre-trained on

ImageNet. However, we need to evaluate our proposed approach's effectiveness in the absence of ImageNet pre-training. The training session findings show that pre-trained models assist the learning process by improving grasping performance with a minimum number of iterations, in comparison to grasping performance when no pre-training model was used, which struggled for the first 200 iterations of total training iterations, within the range of 65% to 70% grasp success rate.

3) *PA-noER*: In this portion, the proposed approach was trained without using experience replay (ER), which stores the agent's experiences at each time step for use as an off-line policy in subsequent training iterations. The success rate graph indicates that ER has an effect on learning, gradually improving grasping skill in comparison to other factors. The first 500 iterations of a training session achieve a success rate of almost 50%, indicating that the model could be significantly influenced by no experience replay.

Fig. 3. The Proposed Approach's Performance in Comparison to other Baseline Models in Terms of Grasp Success Rate throughout Training Sessions.

The proposed approach, when combined with pretrain, ER, and RGB-D data, has been demonstrated to significantly improve grasping performance with a success rate of almost 83% and steady learning throughout the training. In term of time-consuming, each iteration takes an average 4 second on the GeForce GTX-1660Ti (6GB) and GeForce GTX 1650 Ti (4GB). We also test the time consuming of the proposed approach on the CPU with RAM of DDR4 (16GB) with 30 seconds. The whole training session for each baseline it takes almost 4-4.5 hours.

### B. Testing Session Outcome

The grasp success, place success, and completion rate are the two evaluation metrics used to assess the performance of the proposed approach. The proposed approach is tested using three scenarios: 1) Sparsely clutter objects, 2) medium clutter objects and 3) densely clutter objects (Figure 2). These type of scenarios are varied in level of clutter challenge with range of objects 6-40 objects.

In Table 1, the results indicate that our approach performed well in more difficult tasks, especially in the first two types of

situations, namely sparsely and moderately cluttered objects, where it achieved a grasp success rate of 93.2 % and 86.1 %, respectively. However, performance degrades as the test scenario becomes more cluttered, with a grasp success rate of 71.7 %. In general, the proposed approach is capable of effectively performing grasping tasks, with a completion rate of about 95% in all scenarios. It implies that it is capable of efficiently moving objects from the robot's workspace to the place workspace.

When we compare our approach to others, many factors must be addressed, as shown in Table II. Interestingly, our approach is capable of grasping with a minimum of time and training resources. In comparison, other approaches need a minimum of ten seconds to complete one iteration. Similarly, if their approaches are carried out on the CPU, they may take

multiple minutes to finish a single iteration due to the complexity of the computing process. On the other hand, our approach is capable of performing grasping tasks on the CPU as well, with each iteration averaging 30 seconds.

TABLE I. ASSESSMENT OF RANDOMLY CLUTTERED OBJECT CHALLENGE SCENARIOS

Metrics (average %)	Test scenarios		
	<i>Sparsely Clutter</i>	<i>Medium Clutter</i>	<i>Densely Clutter</i>
Grasp Success Rate	93.2	86.1	71.7
Place Success Rate	100	95.7	93.8
Completion Rate	100	100	86.1

TABLE II. COMPARISON OF THE PROPOSED APPROACH WITH OTHERS

Method	Training Resources				Time-Consuming	Grasp Success %	Execution action	
	CPU		GPU				Grasp	Place
	RAM-16GB	4GB	6GB	≥ 8GB				
[9]	x	x	x	✓	8-15 seconds	66.7%	✓	x
[18]	x	x	x	✓	10-18 seconds	78%	✓	x
[29]	x	x	x	✓	15-20 Seconds	81.2%	✓	✓
[28]	x	x	x	✓	7-10 seconds	73.5%	✓	x
Ours	✓	✓	✓	✓	4-5 seconds	83.7	✓	✓

## VI. CONCLUSION AND FUTURE WORK

One of the difficulties faced by robots is performing grasping tasks in an unstructured environment. In this paper, the proposed approach, which is based on DQN, showed exceptional grasping performance in a range of test scenarios including randomly cluttered objects. The proposed method has been proven its capability of removing objects from a workspace efficiently. The approach achieves an 83.1 % grasp success rate in cluttered object settings, demonstrating that it is capable of successfully performing a grasping challenge. Additionally, even in challenging circumstances, the proposed approach obtains a high completion rate (96.1 % in all cluttered environment scenarios). In terms of time required, each iteration takes an average of four seconds on the GPU and 30 seconds on the CPU. Significantly, the proposed learning approach proved successful in addressing the aforementioned problems, namely the time and training resources requirements. On the other hand, the proposed approach becomes inefficient as the number of objects increases. This deficiency could well be addressed in the future via the potential merging of grasp and push. Similarly, simulations have been used to assess the proposed approach, which is another possible disadvantage to consider. However, the proposed approach has been evaluated only via simulations, which is a possible drawback to consider. The proposed approach will be implemented on hardware in a future study, giving strong validation for those interested in doing further research.

**Abstract**—Stratification of Blood Pressure is essential input in most of the cardiovascular diseases detection and prediction and is also a great aid to medical practitioners in dealing with Hypertension. Denoising based on spectral coding is developed based on frequency spectral decomposition and a spectral correlative approach based on wavelet transform. The existing approaches perform a standard deviation and mean of peak correlation in signal conditioning. The artifact filtrations were developed based on thresholding. Filtration of coefficients has an impact on accuracy of estimation and hence proper signal conditioning is a primal need. Wherein threshold is measured with discrete monitoring, time line observation could improve the accuracy of filtration efficiency under varying interference condition. Dynamic interference due to capturing or processing source results in jitter type noises which are short period deviations with varying frequency component. Hence a time-frequency analysis for filtration is adapted for filtration. This paper presents an approach of spectral correlation approach for signal condition in stratification of blood pressure under cuff less monitoring. This presented approach operates on the spectral distribution of finer resolution bands for monitoring signal in denoising and decision making. Existing approaches lacks the capability of loss-less denoising which is efficiently worked out in this paper.

**Keywords**—Stratification of blood pressure; discrete wavelet transform; spectral coding; and selective correlative approach

## I. INTRODUCTION

Monitoring of blood pressure is a vital monitoring for automated diagnosis in cardio vascular disease diagnosis. A deflected blood pressure (BP) has a high risk of heart disorderness or heart failure. An early detection and diagnosis is an optimal solution to the asserted risk. The present diagnosis is a cuff based monitoring where the device is interfaced to patient hand to read the mercury level for BP monitoring. The interfacing of such devices is limited to expert personals and not users friendly in handling. With advancement of technology new approaches has evolved in diagnosis, wherein BP monitoring is also improved towards cuff-less measurement. Pulse transient time (PTT) [1-4] is a majorly observed approach in this type of measurement. The analysis presents a good correlation in diagnosis of PTT with BP monitoring. In [5] author interfaced electrocardiograph (ECG) with photoplethysmography (PPG) signals to estimate

the BP level. A correlative approach in measuring mean error (ME) for the measured BP and the actual measurement is evaluated based on standard deviation for the magnitude values. In [6] boosting approach is presented in deriving a more calibrated monitoring of BP using ME. The impact of monitoring is however limited in such approach with the interference of external distortion.

This paper presents a novel Time line correlative spectral processing approach for efficient denoising of Vital Bio-Signals such as PPG, ECG and ABP. It utilizes an adaptive signal conditioning approach. The proposed method results in minimum loss in terms of Frequency components after wavelet computations and hence preserves the significant medical information in the signal.

To present the outlined approach this paper is outlined into seven sections. Section 2 presents the Background work citing the challenges and limitations of existing approaches. Section 3 outlined the existing approach of signal processing and analysis. Section 4 presents the approach of denoising signal in a nonlinear distortion approach. Section 5 outlines the simulation result for the developed approach. Section 6 presents Discussion and Future Work. The conclusion for the developed approach is presented in Section 7. Section 8 is about acknowledgment.

## II. BACKGROUND

The filtration of the distorted signal in BP monitoring were developed in past where a threshold based estimation approach is proposed in [4] for PLI noise elimination. The approach developed a correlative method in minimizing the distortion using spectral energy variation among the normal and effective signal. In [7,8] a wavelet based estimation is proposed based on threshold approach where the signal is processed based on wavelet coefficients and measured threshold value. The correlation performs an elimination of the distortion effect based compared threshold. However it has an elimination of required signal coefficient as well. To eliminate the effect a K-NN based approach was presented in [9]. Varying window of filtration for signal processing is outlined in [10]. The Hilbert transformation approach is developed in signal processing for varying interference. Feature detection based on normalized multi wavelet measure is outlined in [11]. The approach developed evaluate based on Euclidian distance. A simple

segmentation approach for signal processing is outlined in [12], where multiple features based on spectral representation is outlined. The approach works on the geographical feature is presented. A time based estimation where the time parameter of magnitude is outlined in [13, 14]. This approach is developed for a temporal sequence where time based features are used in deriving the observations for the determination of the peak parameter as feature values. The denoising based on DWT is developed based on frequency spectral decomposition and the range of frequency value is considered as the noised element wherein a standard deviation and mean of peak is considered for denoising. However, the decision is developed based on threshold value. The elimination of coefficient has an impact on accuracy of estimation hence threshold valuation is a critical issue. Wherein threshold is measured with discrete monitoring, time line observation could improve the accuracy of threshold detection and denoising efficiency. It is observed that sampling of signal for processing result in jitter [15-18] which are short period variation with different frequency component, which limits the DWT based denoising approach. The assumption of frequency range elimination for denoising leads to information loss and appropriate selection of coefficient could improve the accuracy. We propose to develop a new denoising approach to signal processing by developing time line processing and analysis for threshold computation. Secondly, we propose to integrate the DWT based approach with standard deviation and mean of peak over decomposed Time line (TL) to improve denoising performance. Towards developing a filtration of processing signal for distortion minimization in this work a time line approach for signal denoising using spectral decomposition and spectral correlation is outlined.

Machine Learning and Deep Learning is becoming increasingly popular in health informatics [21], [23-24], [27-29] [31]. Further Compute-Intensive Large Scale Servers and Cloud Storage could optimize the effectiveness in terms of storage and transmission which will be secure for such data systems in future development efforts [19], [20], [22], [25].

### III. PHOTOPLETHYSMOGRAPHY (PPG) SIGNAL ANALYSIS FOR BP STRATIFICATION

Blood pressure is an important physiological parameter in the human body and it is critical indicator of clinical condition in both emergency situations and daily health care basis. In modern society of rich living, high blood pressure is constantly increasing. At the same time, people are more cautious about their health. Blood pressure (BP) is a force in the bloodstream flowing in the blood vessels and chambers of the heart. It is measured as the amount of blood flow in the arterial arteries, which is the main blood vessel that transmits blood from the heart. BP of a person is usually measured as a systolic pressure due to contraction cycle of the heart and as a diastolic pressure during its relaxation state. Average values of healthy people at systole read 80 mm of Hg and 120 mm of Hg diastole at stable condition [1]. Some factors that affect a person's blood pressure are pumping rates, hypertension, immune suppression, and blocks in respiratory airways. Because of various reasons, the average blood pressure is different from each individual. Blood pressure is categorized into five main scope-based on measured values as shown in Table I.

TABLE I. CATEGORIES OF BLOOD PRESSURE [1]

Category	Systolic (mmHg)	Diastolic (mmHG)
Hypotension	<90	<60
Normal	90-120	60-80
Prehypertension	121-139	Or 81-89
Stage 1 Hypertension	140-159	Or 90-99
Stage 2 Hypertension	>160	Or =100

According to the Seventh Report of the Joint National Committee for Prevention, Detection, Evaluation, and High Blood Pressure, hypertension is an elevated blood pressure, which leads to vascular damages of internal organs. It is considered to be a critical issue, as most of the patients do not realize the symptoms of the elevated blood pressure. Hypotension refers to a state of low blood pressure due to inadequate supply of blood to other organs in the body. The drop in blood pressure consequently results in heart attacks, strokes, kidney failure and other more serious complications. The monitoring of cuff less blood pressure is hence a prime need in current health monitoring approach. Blood pressures are monitored via different bio-signals such as ECG, PPG, etc. In our previous work we have developed a Hybrid framework for BP estimation utilizing both ECG and PPG signals [30]. However, the approach of representative features and the quality of signal plays a vital role in making decision. The analysis of PPG is observed to be more effective in BP monitoring due to confined feature representation. In processing of PPG signal, the electrical distortions are the major concern. The distortion has a greater impact in the accuracy of decision and hence need to be removed to the finest level. In PPG signal processing, the 50-60 Hz power line noise are one major source of distortion. This noise is observed stationary and majorly observed in the signal processing. The baseline distortion is considered to be due to respiration artifact is observed to be of low-frequency and the component is effective in time domain due to saturation of analog component in the processing system. The high frequency components are observed to be due to muscular movement in the body. Filtration of such artifacts is of primal need in processing of bio-signal to highest accuracy. Wavelet based spectra coding were observed in recent past for the filtration of noise component and need a finer processing for filtration. The approach of DWT based processing decompose the signal into finer TLs where a low range frequency of 0-0.25 Hz referring to baseline and a higher frequency range of 20-500Hz reflect to power line harmonic and muscular based artifact where zero coefficient are removed. The decomposed coefficient is processed to denoising based on threshold approach. The deviation is measured based on mean peak value used for denoising. The representation of PPG signal is illustrated in "Fig. 1".

The process of Bio-signal processing for BP Stratification is developed in three steps of operations:

- 1) Preprocessing.
- 2) Feature extraction.
- 3) Learning and Decision system.

Fig. 1. PPG Signal Representation [3].

Preprocessing is developed for elimination of noise and artifacts in signal captured. In recent, DWT based approach was presented with a specified low and high frequency range for noise suppression. A standard deviation and mean peak based denoising is presented in [1]. Denoising is developed based on threshold limits. The limiting threshold is developed based on discrete magnitude monitoring, which is limited for usage for randomly varying time variant distortions. The sampling process adds jitter noise to the processing signal. The issue of discrete monitoring is focused and a new estimation approach based on time line observation is proposed. This approach develops a denoising threshold based on set of coefficients for a time interval. The process of denoising based on fixed cutoff approach is proposed to improve by a time line monitoring of standard deviation and peak (valley) for decomposed sub frequency bands. The noise parameter is developed for jitter analysis and harmonic content are observed in the processing signal. The decomposed signal is processed with a varying of frequency component is directly extracted and correlated using distortion minimization using spectral coding. The signal analysis is developed for the selection of a spectral power density using correlation approach. The derivative component of the filtration approach is processed for noise reduction in consider to lower magnitude value based on the deviation of the distortion in the signal processing. The processing of signal is divided into decomposed bands which eliminate the basic frequency for the process of no DC component. The process is developed based on the decomposition of processing signal into finer frequency bands and performs an extreme spectral selection. The process of decomposition for a given processing signal  $S(t)$  is represented by the spectral resolution ( $\varphi$ ) and the residual component  $res[i]$  is presented by,

$$S[t] = \sum_{i=1}^K \varphi_j[i] + res[i] \quad (1)$$

The processing bio-signal is recorded as a set of 3 channels data, where the 1st channel represents the PPG signal, 2nd signal represents the arterial blood pressure (ABP), and the 3rd channel represented the ECG signal of monitoring signal. Wherein channel 1 and 3 are the monitoring signal, channel 2

is taken as the baseline representation of the BP signal. In evaluation of the denoising process in this work, 2nd channel signal (ABP) is processed with varying noise levels to evaluate the efficiency of proposed approach. The baseline reference of ABP presents the level of analysis with the noised signal. The proposed approach of spectral correlation filtration approach for the Bio-signal in BP stratification is presented in next section. More noisy situations restricts the real time use of many such and similar systems [26].

#### IV. SELECTIVE TIME LINE SPECTRAL CORRELATIVE PROCESSING (TLSC)

This proposed approach focus in improving the denoising performance by minimizing the interference level and improving the details of representation. The spectral band extraction in time-frequency domain is proposed to represent physiological parameters and spectral parameters for denoising signal. A feature representation and classification process is used as an integral module for learning and decision making. The proposed processing system is for signal conditioning is illustrated in “Fig. 2”.

##### A. Spectral Decomposition Coding

The signal analysis of the processing signal is performed based on the spectral decomposition and correlation process where the following two process were performed,

- 1) Extreme bands decomposition is developed with the successive decomposition of signal using cascaded filters.
- 2) Selecting local minima parameter for noised component based on local maxima of spectral density in spectral bands.

The process of filtration is developed with the normalization of processing signal based on mean parameter given as,

$$m_1 = S(t) - mn_1 \quad (2)$$

The mean normalized signal set the processing signal to mean level, and random glitches are truncated to a mean reference. This normalized signal is then processed for spectral decomposition in denoising operation. The process of denoising is performed using a cascaded filter bank as shown in “Fig. 3”.

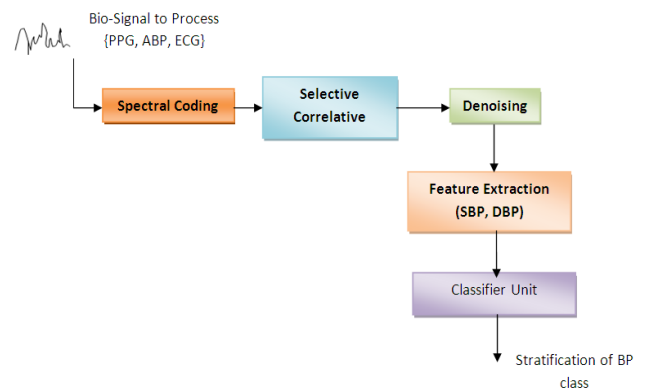

Fig. 2. Proposed Systems for Signal Analysis.

Fig. 3. Decomposition Filter Bank Structure.

The processing signal is represented as in “Fig. 4”,

Fig. 4. An ABP Signal Plot for Processing.

The monitoring input to the Decision system is given by the spectral feature developed by band decomposition. A successive integration of filter banks results in a decomposition of signal into finer frequency band. For the realization of such filtration a wavelet based filtration is used. In the process of spectral decomposition approach, successive filter bank architecture is used as shown in “Fig. 5”.

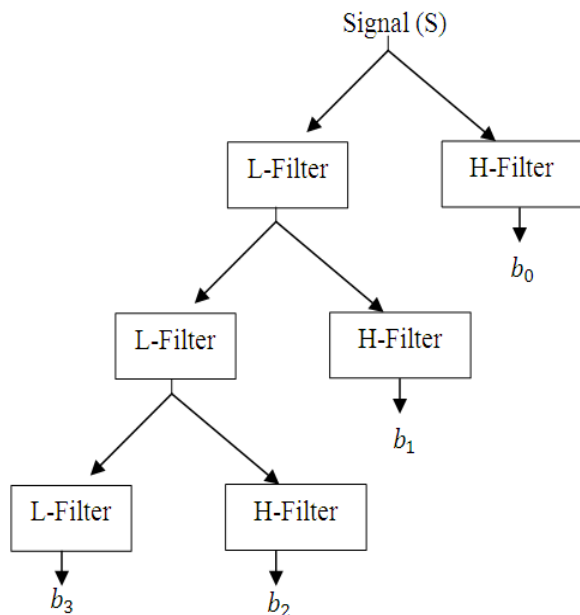

Fig. 5. Hierarchical Filtration Structure for Band Decomposition.

### B. Spectral Correlative Denoising Approach

For spectral denoising each of the signal (S) is processed for B-Bands decomposition which represent a set of decomposed bands  $\{b_0, b_1, b_3 \dots \dots b_n\}$  given as,

$$B = \{b_0, b_1, b_3 \dots \dots b_n\} \in S \tag{3}$$

The filtration of the noise component is developed by the convolution operation of given signal with the selected filtered signal F,

$$B = \text{conv} (S, F) \tag{4}$$

The High pass (HP) and low pass (LP) filter are developed as FIR filter giving the spectral variation of the observing parameter. Information's lower than the threshold is neglected. In this approach by the acquisition of vital parameter coding and normalization process is proposed. The acquisition process converts the vital parameter information into a 1-D plane. The resultant information is then processed for extracting the features based on Wavelet coding. This suggested method improves the selection of feature relevancy, in terms of selectivity. Since, now features are selected based on variation density rather than magnitudes. For the acquisition of the spectral coding curve, a linear sum of the entire vital parameter plane at different Gaussian smoothing factor is taken.

Each decompose band mean spectral density (MSD) is computed given by,

$$MSD = \frac{\sum_{i=1}^n |B^2|}{n} \tag{5}$$

B is the decomposed band for a signal S which reflect the measured parameter for a period 't'.

For each of the band decomposed is given by,

$$MSD (i), \text{for } i = 1 \text{ to } n. \tag{6}$$

Where n defines the number of decompositions.

For derived MSDi, the maximum MSD is given as,

$$MxPi = \max(MSDi) \tag{7}$$

For i=1 to n

if  $(MSDi \geq (MxPi / 2))$

$$\text{sel\_Bi} = Bi,$$

End

The selected SBSs, 'sel\_Bi' are only considered in processing where other bands are suppressed to zero. An inverse filtration operation with selected band and other band valued to zero is performed using convolution and successive addition process. This process results in de-noised signal with maximum information's suppressing noise distortion.

### V. SIMULATION RESULT

For the Stratification of Blood Pressure using signal processing, a correlative spectral approach is presented. Wherein the existing approach operates on discrete coordinates and a correlation with the threshold is used in decision, the discrete value can be biased due to miss-operation of sensor, or

measuring devices which effect the decision. Hence, a time line continuous monitoring in time-frequency domain result in more decision accuracy compared to discrete monitoring. It is observed that each of the observation has a systolic, Diastolic parameter which is time variant. In the developed approach the processing signal ABP is extracted from the 3 recorded channel and channel 2 is used for the noised component filtration analysis. The processing signal with Gaussian distortion have variance (var)=0.01 is shown in “Fig. 6”.

The noised signal is represented to decomposed sub band which is carried out using ‘db4’ wavelet decomposition to compute the spectral band (SBSs). The 5 sub bands extracted from the processing signal is shown in “Fig. 7”.

The MSD parameter for 4 detail SBSs and 1 residual SBS is illustrate in “Fig. 8”. The decomposed bands are processed for selection based on the magnitudes of these bands.

The representation of correlation of spectral bands with the decomposed band is illustrated in “Fig. 9”. The band with a maximum MSD is selected with other band suppressed to zero.

The inverse process of selected band with other zero suppressed in inverse filtered and successive added to produce de-noised signal. Obtained de-noised signal is shown in “Fig. 10”.

Fig. 6. Noised Signal with Variance (var=0.01).

Fig. 7. SBSs Extracted from Processing Signal for Analysis.

Fig. 8. MSD for the Spectral Bands Decomposed.

Fig. 9. (a) SBS for the Signal (b) MSD Correlation.

Fig. 10. De-noised Signal.

The de-noised signal is processed for feature extraction where the two extremes SBP and DBP is measured. The detected SBP and DBP detected for the de-noised signal is shown in “Fig. 11”.

The decision system process on the computed DBP and SBP for a period of observation and an average majority of the BP stratification as derived from the condition listed in Table I is made. The decision system generates an alert for the decision made as shown in “Fig. 12”.

A test of 10 iterations with varying Variance value from 0 to 10 is performed. The decision is monitored and an average accuracy is computed. The denoising efficiency is measured by an average Means square error (MSE), Peak signal to noise ratio (PSNR) and Root mean square error (RMSE) values.

Fig. 11. Detected Peak Points for Decision.

Fig. 12. Detected effect for Test Signal.

The average accuracy is computed given by,

$$Avg Acc = \frac{\text{majority of class detected}}{\text{Total Number of test conducted}} \quad (8)$$

The mean square error is given by,

$$MSE = \frac{\sum_{i=1}^n (x-x')^2}{n} \quad (9)$$

Where  $x$  is the actual signal processing and  $x'$  is the de-noised coefficient.

PSNR is given by,

$$PSNR = \log_{10} \frac{\text{peak}(x')}{\text{peak}(x)} \quad (10)$$

and RMSE is given by,

$$RMSE = \sqrt{MSE} \quad (11)$$

Observations for the developed approach TLSC is compared with the existing approach of temporal spectral coding (SR) [32], and multi information fusion with neural Network (MIF-NN) [1]. The observation of the developed approaches for denoising for different test samples is presented in Table II.

The test observations developed for different test sample illustrates an enhancement of PSNR by 16dB and 5.4dB in comparison to SR and MIF-NN method respectively. The time line coding of signal denoising eliminate distortion using a period of observation, wherein a discrete observation generate filtration for a observing coefficients only which has lower filtration performance; more effective denoising results into an

accurate signal representation. This result into improve the accuracy of detection. The performance of detection for the developed approaches is listed in Table III.

TABLE II. OBSERVATION FOR THE DEVELOPED APPROACH BASED ON TIME LINE SELECTIVE APPROACH

Test sample	Method	MSE	PSNR(dB)	RMSE	Time(Sec)
S1	SR	6.3076	34.9088	2.5115	0.156
	MIF-NN	1.3557	45.4041	1.1643	0.031
	TLSC	1.3821	50.8703	1.1756	0.015
S2	SR	6.2818	34.4641	2.5064	0.175
	MIF-NN	1.3553	45.4121	1.1642	0.029
	TLSC	1.3821	50.8703	1.1756	0.019
S3	SR	6.2378	34.7783	2.4976	0.168
	MIF-NN	1.3557	45.2999	1.1643	0.023
	TLSC	1.3821	50.8703	1.1756	0.011
S4	SR	6.2228	34.3509	2.4945	0.177
	MIF-NN	1.3560	45.4179	1.1645	0.029
	TLSC	1.3821	50.8703	1.1756	0.016

TABLE III. ACCURACY OF DETECTION FOR THE DEVELOPED SYSTEMS

Method of detection	Accuracy (%)
SR	83.25
MIF-NN	91.33
TLSC	94.34

The detection of BP parameters for the estimation accuracy is observed to 94.34% for the proposed time line processing, wherein the existing approach of SR [32] and MIF-NN [1] has 83.25 and 91.33% respectively. A more accurate signal denoising results to an improvement of detection of SBP and DBP parameters improve decision accuracy.

“Fig. 13” shows the Observation for MSE for the proposed method. It outperforms the SR method and is almost as good as MIF-NN method.

Fig. 13. Observation for MSE Plot.

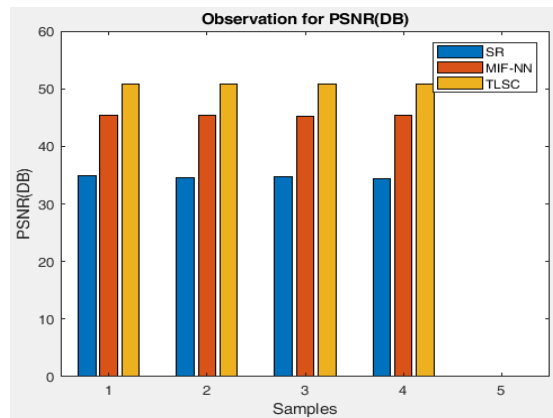

Fig. 14. Observation for PSNR(DB) Plot.

“Fig. 14” shows the Observation for PSNR(DB) plot for the proposed method. The proposed method demonstrates good PSNR values compared with the existing approaches.

“Fig. 15” shows the Observation for RMSE for the proposed method. It outperforms the SR method and is almost as good as MIF-NN method.

Fig. 15. Observation for RMSE Plot.

## VI. DISCUSSION AND FUTURE WORK

Cuff-Less BP Stratification has gained enormous attention in recent years due to its potential possibility of highly accurate, convenient to use and continuous nature of measurement. However, the accuracy of such measurements largely depends on the quality of captured Vital Bio-Signals used for stratification. Most of the signals are noisy and can lead to problems in BP Stratification. Existing signal denoising and normalization techniques are mostly discarding the wavelet coefficient values above a given threshold, discrete in nature and somewhat lossy. The proposed method in this paper namely Time line correlative spectral processing has demonstrated good results in terms of PSNR values as depicted in the results. It has outperformed the SR and MIF-NN techniques. This will in turn motivate to use this method in practical medical setups for Signal acquisition, filtering and for BP Stratification.

In future we will be using the Time line correlative spectral processing approach for more accurate BP Estimation by processing the PPG Signals by means of optimal feature

extraction, selection and application and invention of efficient machine learning algorithm; also to build a temporal dataset of continuous BP measurements and apply big data analytics for more scientific explorations of Cardiac diseases patterns and Hypertension.

## VII. CONCLUSION

A spectral coding approach based on correlative spectral density to implement cuff less Stratification of BP measurement is developed. The coefficients are represented as a continuous time series of measured parameter and the signals is decomposed using sub band coding. Each of the sub bands outlines a variation in frequency domain and is further processed for selection using mean spectral density (MSD). The proposed approach performs a selection for the required bands discarding less informative bands. Selected coefficients are processed for the detection of SBP and DBP parameter in Stratification of BP. The proposed approach shows an improvement of 11% in average classification accuracy and 16dB in PSNR for different tested samples.

## ACKNOWLEDGMENT

We would like to acknowledge Dr. Ramesh Pokale, Physician, Sidhhivinayak Clinic, Nira, Dist: Pune, India for providing the necessary medical support and required information from time to time.

# SMAD: Text Classification of Arabic Social Media Dataset for News Sources

Amira M. Gaber<sup>1</sup>, Mohamed Nour El-din<sup>2</sup>, Hanan Moussa<sup>3</sup>

Information System Department, Faculty of Computer and Artificial Intelligence, Cairo University, Giza, Egypt<sup>1, 2, 3</sup>  
Higher Institute of Computer Science and Information Systems, Culture and Science City Academy, 6 October-Giza-Egypt<sup>1</sup>

**Abstract**—Due to the advances in technology, social media has become the most popular means for the propagation of news. Many news items are published on social media like Facebook, Twitter, Instagram, etc. but are not categorized into various different domains, such as politics, education, finance, art, sports, and health. Thus, text classification is needed to classify the news into different domains to reduce the huge amount of news available over social media, reduce time and effort for recognizing the category or domain, and present data to improve the searching process. Most existing datasets don't follow pre-processing and filtering processes and aren't organized based on classification standards to be ready for use. Thus, the Arabic Natural Processing Language (ANLP) phases will be used to pre-process, normalize, and categorize the news into the right domain. This paper proposes an Arabic Social Media Dataset (SMAD) for text classification purposes over the social media using ANLP steps. The SMAD dataset consists of 15,240 Arabic news items categorized over the Facebook social network. The experimental results illustrate that the SMAD corpus gives accuracy of about 98% in five domains (Art, Education, Health, Politics, and Sport). The SMAD dataset has been trained tested and is ready for use.

**Keywords**—Text classification; Arabic text classification; Arabic Natural Language Processing (ANLP)

## I. INTRODUCTION

Recently, the news media has transformed from hardcopy like newspapers, radios, and magazines to digital forms integrated with the internet to organize social media platforms like Facebook, Twitter, blogs, channels, and other digital media formats. Online social media has become a great way to connect people with each other around the whole world. Users of social media share news, communicate with other people, and create more posts and tweets related to the news than they consume. Consequently, a huge amount of incredible news is created and propagated through social media, which has a serious impact on society and individuals. Various social media needed to categorize their news into different domains, like politics, education, finance, art, sports, and health. So text classification is used to reduce the huge amount of news available over the social media. It is useful for reducing time and effort for recognizing the category or domain, and the data will be pretreated to improve the searching process and performance of classification.

The online news published on social media propagates over the network in different languages and formats, such as texts, images, videos, and unstructured formats. It is difficult to detect and classify the news and check its veracity, especially in the Arabic language, where it needs human expertise.

However, Arabic Natural Language Processing (ANLP) are computational techniques that can be used for identifying the reality of text news based on facts and handling the Arabic language.

### A. Arabic Language

This work concentrates on Arabic language news. The Arabic language is one of the greatest languages in the world. As this language possesses special spelling, grammatical rules, and punctuation marks. However, the text classification for this language is a challenging task because its structural essentials are complex. In the Arabic language, the text consists of some features which can be classified into external or internal features. The external features do not relate to the content of the text document which includes the author name, publication date, publishing house, etc. In contrast, the internal features relate to the text content and its linguistics features including lexical words and grammatical characteristics [1]. As a result, the following is the characteristics of the Arabic language structure and should be treated and deal with them to classify the news into the correct domain:

- The direction of Arabic language reading and writing from right to left.
- This language possesses 28 letters and there aren't any upper-case letters
- Arabic pronouns can be a singular, dual, or plural; masculine or feminine pronoun.
- Has three grammatical cases: nominative, accusative, and genitive.
- Words are classified into three main parts of speech, nouns, verbs, and particles.
- Nouns include adjectives and adverbs.
- Arabic verbs can have suffixes that change the overall meaning or the tense of the word.
- All verbs and some nouns have morphological rules.
- Arabic sentence can be a noun phrase or verbose phrase in which the verb can be passive.
- The subject pronouns may be removed from the sentence [1] [4].

## B. Arabic Natural Processing Language (ANLP)

Most researchers tend to do and implement a set of tools that can be used in Arabic Natural Language Processing (ANLP) to help in the preparations for the processing structure for it. Because the Arabic language is the widest language due to the number of users using it and according to research introduced in 2015, it is the mother tongue of over 300 million people [2].

There are various developing tools and applications like tokenizers, Part of Speech (POS), Bag of Words (BOW), sentence segmentation, syntactic parsers, Matchers, etc. and various approaches are used for classification such as:

- Lexicon-based approach: The concerned data will be classified into a class or more based on linguistic rules (lexicon-based).
- Machine learning (ML) approach: The classification processes can be supervised, or unsupervised, or semi-supervised learnings. The seven stages of ML classification shown in Fig. 1.
- Hybrid approach: The classification integrates between the rule-based approaches besides the ML-based approach to achieve the optimum performance [3].

This paper presents SMAD dataset, a new Arabic social media dataset built across Facebook social media for news sources using the hybrid approach ANLP standard classification to cover five different domains (Sports, Arts, Health, Education and Political) domains. In addition, several algorithms in the ML approach will be used to help the classification with the principle of ANLP to reach high accuracy classification. The KNN algorithm will be used as a classifier. After the data was assembled and organized, the pre-processing methods and filtering are applied to make the data ready using ANLP.

This paper is organized as follows. Section II introduces the related work for the existing Arabic corpus. Section III presents the text classification methodology. Section IV presents the applied methodology that shows the formation of SMAD corpus, Section V displays the experiment results. Section VI will discuss the proposed methodology with others. Finally, Section VII concludes this work.

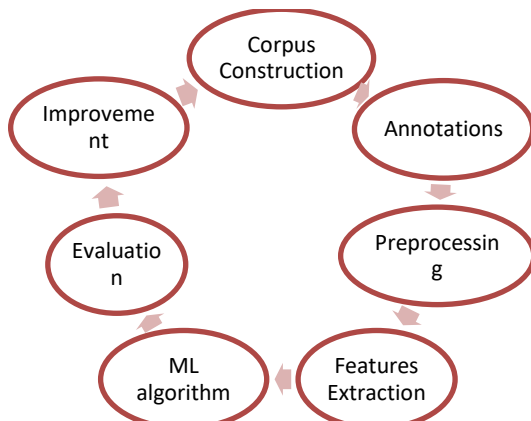

Fig. 1. Arabic Natural Language Processing (ANLP) Stages.

## II. RELATED WORK

There are several studies categorize the text and build datasets tested against the quality measurement metrics. Riyad et al. [4], proposed an Arabic text classifier based on the Document Frequency threshold (DF) besides the Support Vector Machines (SVM) algorithm with a precision of 0.95. The datasets were collected from various Arabic newspaper online websites like Al-Jazeera, Al-Hayat, Al-Ahram, Al-Nahar, and Al-Dostor.

Syiam et al. [5], proposed a new Arabic text classification depending on a Hybrid approach of document frequency. Egyptian newspapers like El-Ahram, El-Akhbar, and El-Gomhoria were used to collect datasets. The used classifiers are the Key Nearest Neighbor (KNN) and Rocchio the classifier performance accuracy was 0.98.

Harrag et al. [6], performed a classification in which data collected from the Arabian scientific encyclopedia. They used the decision tree algorithm with an accuracy of 0.93.

Chantar and Corne [7], applied the Particle Swarm Optimization (PSO) Algorithm with Support Vector Machin (SVM) classifier. Datasets were collected from specialized web sites as Al-Jazeera, Al-Hayat, and Al-Ahram. The result of the classification is more accurate and efficient.

In Saraç and Ayşe Özel [8], they concentrate on web documents they use a Firefly Algorithm and J48 classifier to test data from WebKB and Conference datasets. The applied algorithm returned an accuracy (between 0.56 and 0.93).

Rohaidah et al. [9], introduced a new Sentiment Analysis approach using the k-NN classifier. The dataset was collected from customer review datasets with maximum precision results equal to 0.892.

Guessoum et al. [10], performed a text classification on OSAC3 corpus (Open-Source Arabic Corpora) which was gathered from several different websites (BBC Arabic, CNN Arabic, etc.). It contains 22,429 textual records. Every text document is a part of one of ten separate categories (Economics, History, Religion, Health, Education and Family, Sports, Astronomy, Law, Stories, and Cooking Recipes).

There are number of Arabic datasets like, DAA [11] is a dataset in which nine categories have been processed and standardized with 400 documents for each category, Akhbar-Alkhaleej [12] is a popular Arabic Dataset with 5690 Arabic news documents gathered regularly from the online newspaper "Akhbar-Alkhaleej". It consists of five categories: Alwatan [13] is an Arabic Dataset with 20,291 Arabic news documents collected regularly from its online newspaper, Al-Jazeera-News [14] Arabic Dataset (Alj-News) is an Arabic dataset with 1500 documents. It consists of five categories (Sport, Economy, Science, Politics, and Art), NADA, [11] is an Arabic dataset consists of two corpora OSAC and DAA it used a s (Dewey Decimal Classification scheme (DDC) and Synthetic Minority Over-Sampling Technique (SMOKE) to reprocess and filtering to enhance the results to reach high accuracy.

All previous work concentrated on how to classify the articles using different classifiers which collected its precision and accuracy measurements. All Arabic datasets collected data

from web sources and didn't take into consideration the sources of the news collected from the social media sources. This paper will construct a new dataset collected from different news websites (BBC Arabic, Al-Watan, El-youm7, etc.) to classify the news over the Facebook social media because it is a widest mean for spreading news using the text classification methodology for the Arabic Natural Language Processing (ANLP).

### III. TEXT CLASSIFICATION METHODOLOGY

Text classification is a process of retrieving strong meaningful bulk of text [15] then segmenting them into meaningful sentence, topic, words or character for the text analysis [16]. There are many reasons for using text classification. One of the main reasons is the breaking down the text into smaller give more meaning and contrast than the whole document. Another one is the smaller text useful in accessing and analyzing the text.

#### A. Arabic Text Classification Steps

Fig. 2, shows the text classification process steps which are: 1) stemming, which returns back to the root of the word; 2) stop word removal: it removes unnecessary words, 3) Indexing is the process of creating an internal representation of the documents. It consists of three phases: a) Construction, which builds a vector consisting of all the words that appear in the document; b) Term Selection: choose the main words according to some criteria; c) Term Weighting: count how many occurrences the main word appears; 4) classifier construction, which learns the classifier for each category characteristics by training it on a set of documents to classify correctly; 5) Evaluate Classifier Which Apply a test set to check whether the classification process completed correctly or not [5].

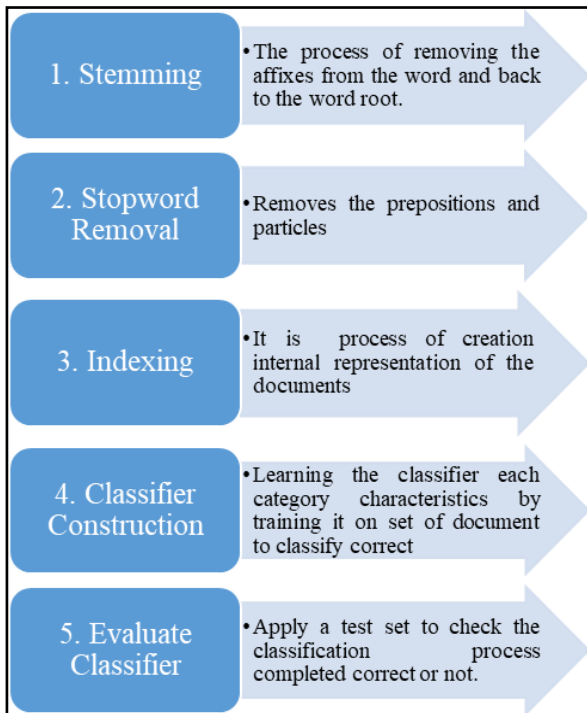

Fig. 2. The Arabic Text Categorization Steps.

### IV. SMAD METHODOLOGY

This work focused on classifying Arabic news into different domains for each news source that published news on Facebook. It can be considered as a new step in classification and detection of content targeted at the Arabic language over Facebook and social media. For this purpose, Arabic Natural Language Processing (ANLP) and machine learning are used, to achieve this purpose. Fig. 3 shows the phases of SMAD formation methodology.

Fig. 3. SMAD Methodology Phases.

#### A. Dataset Collection Phase

Data collection step it is a crucial step to gather the information of the research and it is accuracy depend it for all rest of steps [17]. In this step, the SMAD dataset will be collected. It is new corpora dataset consist of 15,240 textual topic of news collected from (BBC Arabic, Al-Watan, El-youm7, etc.) websites scrapped for five domains: Sports, Art, Education, Health and Political with size 2MB. For our study, the randomly train data about 2000 textual topics in different domain for training phase and about approximately 1000 textual topics news items extracted from Facebook social media for testing phase.

#### B. Dataset Construction Phase

This phase consists of two steps data preprocessing and indexing step.

1) *Data Pre-processing step using ANLP*: Data preprocessing considered as different transformations applied to the data (data gathered from various sources different in style which are not feasible for the analysis) before introducing it to the classification methodology. Data preprocessing is important to raise the efficiency of machine learning algorithms to put the data into a suitable form for the next processing steps [12] to facilitate the analysis of data. the SMAD methodology will follow steps of Arabic text classification explained in details in Section III:

- The Stemming and stop words removal steps, execute the stemming process which includes the stop word process by using the "Root-Based Stemmer" technique to remove the affixes from the word and back to the word root, matches the root word against a set of suggested 67 patterns that represent most of word forms to reduce the number of words used in the indexing step to get more accurate results and finally executes the stop word removal step which removes the prepositions and particles of the word. Fig. 4 will explain the steps applied in this step.
  - Remove all numbers exists in the text.
  - Splits text into words.

- Preprocess the content of the news like the header of the news.
  - Removes the stop words from the text like (من، إلى، عن، على) / (on, on, to, from).
  - Removes the punctuation letters or spaces Such as comma and semicolon, question marks and exclamation marks.
  - Removes the diacritics like (°, ´, ¨, ¨, ¨, ¨, ¨, ¨) which are signs above or below letters. used the grammatical case.
  - Removes the non-Arabic letters and special symbols in text.
  - Removes all words which have a small length (أنا (me) / oh (أه)).
- Deletes the repeated words and specifies the distinct terms from each news item and records the number of repetitions for each word.

Fig. 4. Data Pre-processing Phase.

2) *The Indexing step*: This step executes the indexing process which consists from two phases.

a) *Term selection*, tokenization technique will be used to split text into words, symbols, phrases as a token then construct a super vector which contains all most important terms.

b) *Term weighting*, there are four techniques to weight the terms: i) *Boolean weighting* it give the result 1 if the frequency word in the text greater than 0, otherwise give zero frequency, ii) *term Frequency weighting* it records the frequency of all words in the document, iii) *Term Frequency-inverse weighting (TF-IDF)* it is used to measure how many times an important word exists in a document, iv) *Normalized-TF-IDF weighting* : similar to TF-IDF but take into its consideration the different length of the text [5].

This phase implemented by using the TF-IDF technique because this technique constructs a vector contains the most important words and the less important ones as well, by using the scoring schema and take into consideration the rarity of words.

For a term T present in document D [18]. Eq. 1 specifies the TF-IDF formula.

$$TF\_IDF = TF \times IDF \quad (1)$$

The Term Frequency (TF) is used to measure that how many times a term exists in a document. It is calculated by Eq. (2) [19].

$$TF = \left[ \frac{\text{Number of times term appearance in text}}{\text{Number of all words in the text}} \right] \quad (2)$$

The IDF (Inverse Document Frequency) is an approach to measure the importance of a particular word that can be measured by taking the logarithm for the output of dividing the

number of all topics by the number of topics containing the text. Calculated by Eq. (3).

$$IDF = \text{LOG} \left[ \frac{\text{Number of all Terms}}{\text{Number of terms contain the text}} \right] \quad (3)$$

The following algorithm constructs a vector of the important words in each domain and then weights them.

The higher the TF-IDF weight value of the term, the stronger relationship to the text they appear in [18].

**Algorithm 1: Indexing Algorithm**

---

**Input:** News Titles Scrapped from multiples source  $s_1, s_2, \dots, s_i$

**Output:** News id, News Title, News Domain

1. **for** all articles  $A_0$  to  $A_i$
  2.  $tokens = \text{tokenize}(A_i)$
  3. **for** all  $t_i \in \text{tokens}$  **do**
  4. **if**  $t_i$  **not** a stop word **or** pun **or** small length
  5.  $\text{tokenlist}[] = t_i$
  6. **end if**
  7.  $\text{score} = \text{TF\_IDF}(t_i)$
  8.  $\text{tokenvector.put}(t_i, \text{score})$
  9. **write**  $t_i$  in the domain file
  10. **end for**
  11. **return** (News\_id, News\_title, domain)
- 

The following is the pie chart illustrates the number of training data used in each domain and testing data shown in Fig. 5.

Fig. 5. Training and Testing Data Pie Chart.

**C. Dataset Evaluation Phase**

This phase consists of two steps Build the classifier and Evaluate Classifier using the performance matrices.

1) *Build classifier*: In this step, the KNN algorithm used as a classifier, it is an efficient technique for text classification, it is used to test given text to be classified. This algorithm searches for the k nearest neighbors among the pre-classified training text based on similarity measure, and ranks these similarity scores, the prediction of the correct category of the test text decided by the weight of the candidate categories, if more than one neighbor belong to the same category then the sum of their scores is used as the weight of that category, the category with the highest score is assigned to the test text provided that it exceeds a predefined threshold, more than one category can be assigned to the test text [20]. For a similarity measure calculated by Eq. (4).

$$\text{Sim}(A,B) = \frac{\sum_{i=1}^r w_{ij} \times w_{ik}}{\sqrt{\sum_{i=1}^r w_{ij}^2} \sqrt{\sum_{i=1}^r w_{ik}^2}} \quad (4)$$

Where A and B are the two vectors constructed to get the similarity between them

,i,k are the text representing A and B.

, r is the number of terms in the feature space .

2) *Evaluate classifier*: All the news of the corpus is collected and handled using new corpus using TF-IDF technique, the number of trained texts used about 2000 news items for each domain and now it needs to input test data for the classifier to categorize news to the appropriate classes. The performance metrics are the best indicators to evaluate the classifier. There are four basic quality metrics of any classifier Precision (P), Recall (R), F-measure, and accuracy.

- Precision: it is the answer of the question; what are the of positive identifications were actually correct?
- Recall: it is the answer of the question, what are the actual positives of the data was identified correctly?
- F-score: is the harmonic mean of Precision and Recall, as precision and recall alone cannot provide the best evaluation of the model.
- Accuracy / classification error: is the performance measure, it is a ratio of correctly predicted observation to the total observations.

To calculate each of these measures, it's should define the following:

- TP (true positive) – the set of news that are in the correct category and are predicted truly.
- TN (true negative) – the set of news that are not in the correct category and are predicted to be in a different category.
- FP (false positive) – the set of news that are in a different category and are predicted to be in the correct category.
- FN (false negative) – the set of news that are in a different category and were predicted false category.

These four performance quality metrics are measured by the following equations [21].

- Precision (p) =  $\frac{T_p}{T_p+F_p}$
- Recall (R) =  $\frac{T_p}{T_p+F_n}$
- F-measure =  $\frac{2PR}{(R+P)}$
- accuracy =  $\frac{T_p+T_n}{T_p+T_p+f_p+f_n}$

## V. EXPERIMENTAL RESULTS

In this section, the evaluation and the performance of the proposed methodology is shown using six real datasets. Section A will present experimental setup details, including dataset construction by using the Arabic text categorization steps, and measure its performance by calculating its accuracy and quality metrics measurements. Section B will present the main results of the accuracy and quality metrics (Recall, precision, and F measure) of the SMAD dataset and then compares the performance improvement of the personalized model, with other similarity metrics for baseline datasets in different domains.

### A. Experimental Setup

Datasets: To evaluate our model, experiments were conducted on 15,240 news items collected from the (BBC Arabic, Al-Watan, El-youm7, etc.) website and Facebook in five domains, like sports, political health, art, politics, and education. The dataset was collected at a size of 2 MG with different files. Each file corresponds to one domain generated as a CSV file. The "SMAD" dataset trained on the 2000 news items and tested on a data benchmark of 1000 news item for each domain using the KNN classifier to classify the news into the correct domain at a specific time. Fig. 6 shows the performance of classifying SMAD through the recall, precision, and F1 measure quality metrics.

The proposed model will be compared with other baseline models on these six datasets compared with the previous Arabic datasets OSAC, DAA, Akhbar-Alkhalee, Aljezera, NADA, and Alwatan corpus used in categorizing domains in the Arabic language w.r.t. the recall, precision, and F1 measure quality metrics.

Fig. 7 shows the comparison of accuracy measurement for all datasets, SMAD corpus gives accuracy of about 98% in five domains while accuracy of 98% while the accuracy of NADA is 93.8792%, accuracy of OSAC is 98.1758%, accuracy of DAA is 80.9087%, accuracy of Alj-News is 93.1%, accuracy of Alwatan is 96.1% and the accuracy of AkhbarAlkhaleej is 88.7%.

### B. Main Results

The performance quality measurements of the proposed model will summarize the key observations and show a detailed comparison for the mentioned Arabic datasets with respect to recall, precision, and F-measures. These performance metrics are specialized in different domains and record the weighted average for each domain in each news source shown in Table I.

### C. Methodology Implementation Architecture

Fig. 8 illustrates the Data Flow Diagram (DFD) of the proposed methodology, which shows how the SMAD dataset implemented in the following steps:

- The news source will generate the news on its web page. Then, it publishes a sample of this news on the Facebook page for the interaction.

- The BOW Scrapper will pre-process posts and extract the bag of words (BOW) to train the classifier to choose the correct domain in the future. This step was completed by using Puppeteer library to scrap Facebook data.
- After the classifier extracted the data and is trained on the BOW, the dataset will be built as a Jason file then transform it into CSV files using unicodescv library.
- To evaluate the dataset, the sklearn.metrics library will be used to calculate the model confusion\_matrix (precision – recall – f-measure) and the accuracy\_score for this classifier.

Fig. 6. Performance Quality Metrics Measurements of different Datasets with SMAD Dataset.

Fig. 7. Accuracy Comparison between SMAD, NADA, OSAC, DAA, Alj-News, Alwatan and Akhbar-Alkhaleej Datasets.

## VI. DISCUSSION

All the pervious Arabic datasets [10-14] classify the articles using different classifiers for various purposes. All these Arabic datasets didn't take into consideration the fact that news spread rapidly over social media. Facebook is the widest means of social media as news plays an important role in spreading rapidly on it but is not classified into domains. Thus, the purpose of this paper is to classify the news that is widely spread on Facebook by constructing the SMAD dataset in order to save time and effort in recognizing domain news and to improve the search process for specific news at a specific time. The SMAD corpus was compared with other different datasets according to quality measurement metrics (precision, recall, F-measure, and accuracy). In the sports domain, its precision is 0.95, recall is 1 and the F-measure is 0.98. In the education domain, its precision is 0.98, recall is 1 and the F-measure is 0.99. In the arts domain, its precision is 1, recall is 0.96 and F-measure is 0.98. In the health domain, its precision is 0.99, recall is 0.97 and F-measure is 0.98. Finally, the political domain precision is 0.98, recall is 0.97, and F-measure is 0.98. The accuracy of the SMAD dataset is about 98% in five domains while the accuracy of NADA is 93.8792%, accuracy of OSAC is 98.1758 %, accuracy of DAA is 80.9087 %, accuracy of Alj-News is 93.1 %, accuracy of Alwatan is 96.1 % and the accuracy of Akhbar Alkhaleej is 88.7 %.

## VII. FURTHER WORK

For the future, a news benchmark will be needed for social media from the most credible news sources in a specific domain at a specific period of time to facilitate the searching process to reduce time, effort and checking the veracity of the news from the most credible sources.

## VIII. CONCLUSION

This study was done to construct a new Arabic Dataset corpus built from several websites to classify the news spreads over social media means. Facebook has become one of the

news sources. The Facebook social media's source news is not categorized into any domain; this corpus is composed of five domains (Art-Health-Education-Politics-Sports) and can be extended easily by adding new various domains which can be used for several purposes in the Arabic text classifications. This dataset goes through predefined stages of pre-processing and filtering to eliminate the anomalies of the data, then tested and validated using KNN classifier with four evaluation measures: precision, recall, F-measure, and accuracy for each domain. The experiment results deduced that the new corpus is an efficient dataset for the Arabic classification of news with an accuracy of 98%.

**Abstract**—Membrane computing is a computational framework that depends on the behavior and structure of living cells. P systems are arising from the biological processes which occur in the living cells' organelles in a non-deterministic and maximally parallel manner. This paper aims to build a powerful computational model that combines the rules of active and mobile membranes, called Mutual Dynamic Membranes (MDM). The proposed model will describe the biological mechanisms of the metabolic regulation of mitochondrial dynamics made by mitochondrial membranes. The behaviors of the proposed model regulate the mitochondrial fusion and fission processes based on the combination of P systems variants. The combination of different variants in our computational model and their high parallelism lead to provide the possibility for solving problems that belong to NP-complete classes in polynomial time in a more efficient way than other conventional methods. To evaluate this model, it was applied to solve the SAT problem and calculate a set of computational complexity results that approved the quality of our model. Another contribution of this paper, the biological models of mitochondrial is presented in the formal class relationship diagrams were designed and illustrated using Unified Modeling Language (UML). This mechanism will be used to define a new specification of membrane processes into Object-Oriented Programming (OOP) to add the functionality of a common programming methodology to solve a large category of NP-hard problems as an interesting initiative of future research.

**Keywords**—Computational biology; P systems; membranes fusion – fission; mitochondria; Mutual Dynamic Membranes (MDM); NP- complete problems

## I. INTRODUCTION

A lot of ideas in Bioinformatics have attracted the attention of researchers. These ideas have been inspired by living cells, their organics, and their membranes that have been used to

compute and model a large number of problems in computational science. Natural Computing is a wide field that describes computational methods and processes inspired by natural environments. The natural computing frameworks that are known to solve computational problems are, for example: DNA computing [1], automata computing [2], quantum computing [3], genetic algorithms [4], and neural networks [5]. Similarly, membrane computing is abstracted to solve hard problems in Artificial Intelligence (AI) [6].

Membrane computing is introduced by Păun in 1998 and was inspired by paradigmatic computation based on the structure, behavior, and functions of living cells [7]. One of such outcomes is the P systems, a category of various biological parallel computing models which can be considered as universal computing paradigms [8]. P systems projected efficient computational models by combining the structural and dynamic properties of biological systems [9]. As a result, many fields such as the formal languages [10], theory of computability [11], and theory of computational complexity [12] with intractable problems were solved by the biological model, called P systems [13].

Some of the biological phenomena of the living cells were incorporated into membrane computing as an influential kind of computational concepts, cell-like P systems. According to these phenomena, the framework of active membranes in polarizationless P systems [14] are developed and evaluated by using rewriting rules [7] which can be merged, divided, separated, or passed through membranes [15]. Another variant of cell-like P system was inspired by cells movement as exocytosis and endocytosis rules that are expressed of the outside and inside processes of neighboring membranes, this variant is called mobile membranes [16].

Fig. 1. P Systems Variants.

A general form of cell-like P systems variants is shown in Fig. 1. Each variant has a set of rules describing the basic structure of any model designed to solve computational problems. The main components used in the proposed model are represented by green arrows and compartments in Fig. 1.

The living cells have organelles called mitochondria; mitochondrion is a dynamic organelle capable of interacting with each other. It is responsible for producing energy molecules in the living cell, Adenosine Triphosphate, (ATP) [17]. The function of mitochondria depends on four processes, fusion, fission, motility, and Mitophagy [17]. In the current work, the focus is on the first two operations, fusion and fission that will be introduced in a powerful computational model. The influential division rule is cooperative with mutual exo and mutual endo rules in (MDM) model. All rules are applied in parallel and non-deterministically selecting the membranes, the rules, and the objects. In the case a set of rules can be executed in each step, but no other rules can be added to this set and no membranes and objects can be evolve at the same time; this is indicated to the parallelism mechanism is maximal for a final solution.

The basic idea is to develop a set of rules that will be the bases of a model to solve NP hard problems through the interactions of the objects, those set of rules are an abstraction of the natural biological generation of energy in human cells. From which conclusions can be achieved. The benefit is to develop a new set of AI models that do not need a priori knowledge nor learning, and moreover to model standardization in smart application development.

Our target is to represent the computability and complexity of an unconventional computing system as a theoretical solvent for NP-complete problems in Polynomial/ linear time. In the current work, the combination of variants of P systems in the model, using real operations, leads to solve a number of problems belonging to different classes further than NP in a more efficient manner than other classical computing systems. A semi-uniform linear time solution has been introduced to SAT problem using (MDM), with 3 membranes only as described in the initial configuration of the fission model.

Finally, another side is the need for alternative mechanisms and unconventional methods to describe and illustrate complex biomolecular processes which have actions, behaviors, and functions are vitality to the health of human. Accordingly, to

this aspect, our biological models are considered a computational method for the development of object relationship diagrams. Then the objects structure and their actions are represented by UML diagrams. These diagrams can be implemented using object-oriented programming to be used as an analysis tool for complex data of mitochondria neural diseases to extract the diseases' characteristics, causes, and insights as an initiation in huge applications of data science. The object relationship diagrams will be used to develop machine learning algorithms in the future work.

This paper is organized as follows: Section II introduces the concepts of active and mobile membranes, as well as their basic conceptions of P systems. The third section is dedicated to the elaboration of the related work. The proposed model, (MDM) is introduced and modeled in Section IV. Efficient Solutions to different classes of problems by the proposed model and a semi-uniform linear time solution have been introduced to SAT problem using the proposed model (MDM), with 3 membranes only as presented in the initial configuration of the fission model is explained in Section V. UML diagrams representations will be introduced in Section VI. A final conclusion and some future researches lines are given in Section VII.

## II. DEFINITIONS OF P SYSTEMS WITH ACTIVE AND MOBILE MEMBRANES

The distributed parallel computing models included P systems class arisen from the membrane computing framework. In the present work, the important processes in mitochondria are recruitment. The combination of two important classes of rules described in P systems models, active and mobile membranes are presented as a new model, (MDM).

The first class is the active membranes variant. It has evolution, merging, division, and communication rules. The second class is the mobile membranes variant, which is inspired by biological events such as cell membrane mobility, Endocytosis, and Exocytosis processes. It has four types: simple, enhanced, mutual mobile membranes and mutual mobile membranes with objects on the surface [18]. We will focus on the third type, mutual mobile membranes. It's worth noting that the rules permit a membrane to move independently of the other membranes involved. According to this property, the mutual mobile membrane is completely suitable for fusion and fission mitochondria.

The fundamental notions of P systems with active and mutual mobile membranes are constructed as follows:

$\Pi = (V, H, \mu, W, R, i)$ , where:

- 1)  $V$  is the alphabet (non-empty and finite) objects;
- 2)  $H$  is a finite set of labels for membranes, labeled  $h_1, h_2, \dots, h_n$ ; ( $n \geq 1$  the degree of the system);
- 3)  $\mu$  is the membrane structure, composed of  $n$  membranes;
- 4)  $W$  is string,  $w_1, w_2, \dots, w_n$  on  $V$  which represent the multisets of objects present in regions  $h_1, h_2, \dots, h_n$  of the membrane structure  $\mu$ ;

- 5)  $R$  is finite sets of evolutionary rules related to regions  $h_1, h_2, \dots, h_n$  of membrane structure, for the following forms;  
 6)  $i \in HU \{environment\}$ , is either one of the regions  $h_1, h_2, \dots, h_n$  and the respective region are the output range of the system, or it is  $\emptyset$ , where  $i = environment$ .

Fig. 2 presents the class of P systems with active and mobile membrane rules as follows:

a)  $[a \rightarrow v]_{h_1}$ , where  $a \in V; v \in V^*; h_1 \in H$ .

Object evolution rule; associated with the membrane and depending on the label, but not directly involving the membrane, in the sense that the membrane is neither taking part in the application of this rule nor modified by it [7, 19, and 20].

b)  $a[ ]_{h_1} \rightarrow [ ]_{h_2}$ , where  $a, b \in V; h_1, h_2 \in H$ .

In-Communication rule; an object is sent in the membrane  $h_2$  [7, 19, and 20].

c)  $[ ]_{h_2} \rightarrow a[ ]_{h_1}$ , where  $a, b \in V; h_1, h_2 \in H$ .

Out-Communication rule; an object is sent out of the membrane  $h_2$  [7, 19, and 20].

d)  $[a]_{h_1} \rightarrow [ ]_{h_2} [ ]_{h_3}$ , where  $a, b, c \in V; h_1, h_2, h_3 \in H$ .

Division rule for elementary membrane  $h_1$ ; in reaction with an object  $a$ , the membrane is divided into two new membranes with the different labels  $h_2$  and  $h_3$ , the object specified in the rule is replaced in the two new membranes by possibly new objects  $b$  and  $c$ ; the new objects may evolve in the same step [7, 20]. The object specified in this rule may be replaced in the two new membranes by possibly new objects or they are duplicated and may evolve in the same step by rule of type (a) [7].

e)  $[ ]_{h_2} [ ]_{h_3} \rightarrow [a]_{h_1}$ , where  $a, b, c \in V; h_1, h_2, h_3 \in H$ .

Merging rule for elementary membranes  $h_2$  and  $h_3$ ; in reaction with their objects  $b$  and  $c$ , they are merged into a single membrane  $h_1$ ; the object  $a$  is produced in the new membrane  $h_1$  [7, 20].

f)  $[ ]_{h_1} [a]_{h_2} \rightarrow [ ]_{h_1} [b]_{h_2}$ , where  $a, b \in V; h_1, h_2 \in H$ .

Mutual Endocytosis (mendo): Under the management of object  $a$ , an elementary region labeled  $h_2$  enters the next region named  $h_1$ ; the labels  $h_1$  and  $h_2$  stay the same during this process. But the object  $a$  may be adapted to  $b$  during the process;  $h_1$  isn't always seen as a fundamental region [7, 19].

g)  $[ ]_{h_2} [ ]_{h_1} \rightarrow [ ]_{h_1} [a]_{h_2}$ , where  $a, b \in V; h_1, h_2 \in H$ .

Mutual Exocytosis (mexo): an elementary region labeled  $h_2$  is sent out of a region labeled  $h_1$ , The labels  $h_1$  and  $h_2$  remain unchanged during this procedure, as they are under the control of object  $b$ , however, the object  $b$  may be changed to  $a$  during this operation; region  $h_1$  is not always an elementary region [7, 19].

In [21] one observed that the electrical charges (polarization) are not adapting to biological rules. In fact, using the polarization features with mobile rules as exo and endo rules were not common in membranes systems. Although of that, P systems with mobile membranes have given computational power and universality properties. Their efficiency and ability are used to solve NP-complete problems without using the polarization [22].

The rules of type (a) are applied in parallel (all objects that may be developed by such rules must evolve). However, the rules of types (b) through (g) are implemented in such a way that only one rule of these kinds may be utilized at a time on one membrane. Overall, the rules are applied in a non-deterministic, maximally parallel fashion; all objects and membranes that may evolve should do so. These rules modify the label of the membrane, but they must be implemented in a sequential manner to avoid label conflicts.

Rules (b) and (c) are considered as a simple form without polarization, those two powerful rules are used for in and out communication as illustrated in [23]. Even in the limited instance where no polarization is utilized, membrane labels are modified. While in rules (d) and (e), P systems are used without polarization and the membrane division and merging rules are allowed to change the label of a membrane (Theorem 2 in [21]). This condition is to accomplish P system efficiency and universality without polarization.

Finally, under the control of object  $a$ , the elementary membrane labeled  $h_2$  enters the next membrane named  $h_1$ ; the labels  $h_1$  and  $h_2$  stay unchanged during this operation. Hence, object  $a$  may be changed to  $b$  throughout the endocytosis process, rule (f). Similarly, under the control of object  $b$ , an elementary membrane labeled  $h_2$  is expelling from a membrane labeled  $h_1$ ; the two membranes labels stay the same. However, the object  $b$  from membrane  $h_2$  can be modified throughout the exocytosis process, rule (g).

In all of the variants, the number of membranes can only be reduced during computation by merging membranes as a result of applying evolution rules to the objects represented in the system. A natural possibility is to allow increases in the number of membranes also to increase during a computation. For example, by division, as it is well known in biology. Actually, the membranes from biochemical are not passive. Where, the majority of chemical compound passage across a

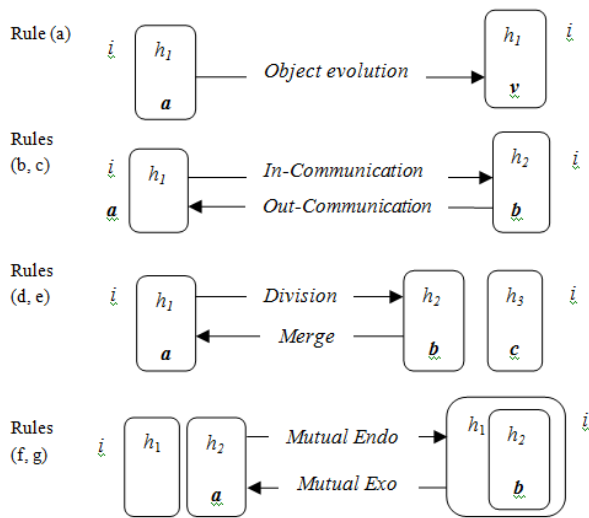

Fig. 2. Membranes Handling Operations.

membrane is accomplished by direct interaction with the membrane itself (through the membrane's so-called protein channels or protein gates). For the duration of this interaction, the chemical compounds that pass during membrane can be modified, while the membrane itself can in this way be modified at least locally.

### III. RELATED WORK

Researches of recent literature are well presented with grateful studies in P systems models that support the computing paradigm known as membrane computing. In addition to simulating the biomolecular processes as fusion and fission of mitochondria as we will introduce in this work the same behavior with P system variants to improve solutions for NP-complete problems. We mention a few reviews of the membrane computing concepts and their notions [24-29]. Membrane computing is similar to quantum computing, is a new unconventional computing model that is applied in linguistics, sociology, optimization design, and a large number of fields [30]. The researcher can read [27, 28, 31, 32, and 19] to cover widely part of P systems variants.

All of the studies are represented and developed to contribute to solving different kinds of problems from formal languages theory [24] to power systems blunder diagnosis [34], passing through a wide range of different research fields as in chemical engineering, scheduling of gasoline blending [35] by membrane computing with its application. Also, in the pattern recognition letters, an automatic clustering algorithm by P systems has been applied [36]. All of the mentioned applications used different P systems models; developed according to the problem nature whether it is theoretical or practical. Here, the focus is on the literary works that addressing computationally NP-complete problems using active and mobile membrane systems and their efficiency and computational power. The efficient variants of Membrane systems and the formal definitions of P systems are investigated from computational complexity theory [34]. Elegant works for NP-complete problems such as Boolean Satisfiability (SAT) problem, has been shown with the polynomial solutions with active membrane principles [26, 16], The Hamiltonian Cycle Problem (HCP) [37], and Travelling Salesman Problem (TSP) [38]. SAT solution is also set by P systems with active membranes by division rule for elementary membranes without dissolution rule. It's verified in [39]. Separation rules are utilized instead of division rules in [40], where it created two new membranes each of them has one new object and the rest of them are replicating. These rules had restrictions that created an exponential workspace in membranes terms in polynomial time, not in objects [41, 42]. The Turing completeness is achieved by using elementary division rules for nine membranes [16, 43].

Regarding the computational complexity of mobile membranes, four mobile membranes are obtained to prove a Turing machine power using evolution rules with exo and endo rules [44].

P automata variant is used to describe a mitochondrial fusion model [45]. It represented the procedure of specific protein production that is necessary for mitochondrial fusion [17]. In [33], Giannakis and Andronikos referred to use six

biological operations described in [46]. The most important process of them is the exocytosis operation used in the mitochondrial fusion model that concerns a mitochondrial fusion mechanism with communication orders and specific actions. The comparison between our model and their study [33] will be introduced in Table I.

TABLE I. COMPARISON BETWEEN OUR MODEL AND RELATED WORK [33]

Model in [33]	Our Model
Only one operation (fusion operation) is modeled.	Two operations (fusion and fission) are modeled.
Considered that the outer and inner membranes are two individuals in skin membranes; each of them has three nested elementary membranes. This is not matched with the structure of biological model.	Biological model is precisely designed to describe the operations occurred in the two nested mitochondria membranes and regulates the fusion and fission processes.
Depended on Bio Ambients rules with Mobile membranes to design the model.	Depended on combination of active membranes rules with mobile membranes to design the model.
Used an exo behavior to achieve the final configuration.	Used a combination of division, mexo and mendo behaviors to achieve the final configuration.
Proteins have been produced from the outer and inner membranes in the final configuration. This is not matched with mitochondria function and their membranes.	New mitochondria organelles have been produced from fusion and fission processes. These mitochondria organelles are capable to adapt its metabolic and produce ATP molecules.
	Rules of our model have been given computational efficiency for many NP complete problems.

Regarding the computational complexity of mobile membranes, four mobile membranes are obtained to prove a Turing machine power using evolution rules with exo and endo rules [44].

P automata variant is used to describe a mitochondrial fusion model [45]. It represented the procedure of specific protein production that is necessary for mitochondrial fusion [17]. In [33], Giannakis and Andronikos referred to use six biological operations described in [46]. The most important process of them is the exocytosis operation used in the mitochondrial fusion model that concerns a mitochondrial fusion mechanism with communication orders and specific actions. The comparison between our model and their study [33] will be introduced in Table I.

#### IV. PROPOSED MODEL

To present our model, firstly we describe the biological background for mitochondria actions (fusion and fission models), after that we will describe the biological actions by Mutual Dynamic Membranes (MDM) with P Systems.

##### A. Mitochondrial Fusion Model

A mitochondria fusion mechanism includes specific actions and communications motivated by the structure and the functioning of the distribution of mitochondrial fusion in the renewal of the mitochondrial population within an eukaryotic cell.

We will demonstrate the proposed scheme using an actual biochemical model of mitochondrial fusion processes. The proposed model consists of five actual membranes, the cell which acts as an “environment” in the P systems. The skin membrane has two non-elementary membranes called “Outer Membranes” with each one has one elementary membrane called “Inner Membranes”. Both inner and outer membranes have operations “rules” executed by proteins that are considered as “objects” in the P systems. Then, a new mitochondrion is produced in the environment.

1) *Fusion biological model:* As illustrated in Fig. 3, the biological description of a mitochondrial fusion model is designed by Cell Designer software. In the fusion model, the joining of two organelles into one was applied through two basic operations, Outer and Inner membrane fusion.

a) *First operation:* The fusion of outer membrane: There are several proteins involved in the fusion process of the outer membrane such as mitofusin 1 and 2 (MFN1& MFN2). Oxidative stress and the presence of high levels of oxidized glutathione (GSSG) are inducer signals for outer membrane fusion. These signals induced serial of constitutive steps as the following: oxidative stress and the excess formation of glutathione oxidized form (GSSG) induce mitofusins complexes in the outer membrane to act in trans. This induction of trans complexes of mitofusin proteins was mediated by disulfide bonds owing to the binding of organelle and causing fusion of the outer membranes [47].

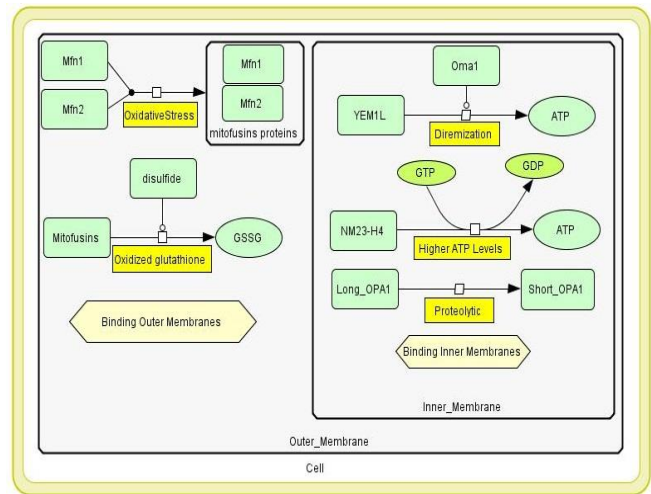

Fig. 3. Fusion Operations for Mitochondria Membranes.

b) *Second operation:* The fusion of inner membrane: A particular protein termed Optic Atrophy 1 (OPA1) has participated in the fusion of the inner membrane. The fusion was initiated by oxidative phosphorylation (OXPHOS) and advanced ATP levels as inducer signals. Concerning to OXPHOS signal these steps have occurred as follows:

- The presence of OXPHOS increases Yme1L metalloprotease. Yme1L and Oma1 activate the Proteolytic processing of Opa1 from the long-form to the soluble short form leading to inner membrane fusion.
- With regards to higher ATP levels, this signal was linked with GTP-loading and hydrolysis by the action of the kinase (NM23-H4) leading to conversion of OPA1 to short-form causing inner membrane fusion [47].

2) *Fusion membranes using Mutual Dynamic Membranes (MDM) with P Systems:* Active and mobile membranes with P systems are used to obtain the behavior of cooperation rules such that using more than one object on the left-hand side of the rule. The biochemical reactions in mitochondria organelles are usually created by the reaction of two or more proteins represented as normal objects that can improve through the computation to get the final configuration.

In the following configuration, proteins MFN1, MFN2, and OPA1 are used as “activators” of rules; these proteins are engaged in the fusion process and are important for the regulation of certain chemical processes. These proteins are also responsible for determining which rules apply in each phase leading to a final configuration.

$\Pi_I = (V, H, \mu, W, R, i_0)$  be a P system with the initial degree of the system is  $n = 5$ .

- The system can be viewed as a set of five membranes labeled by elements of  $H = \{s, 1, 2, 3, 4\}$  arranged in a hierarchical structure which including skin membrane ‘s’ contains two non-elementary membranes ‘1’ and ‘3’

each one of them has one elementary membrane, '2' in '1' and '4' in '3'.

- The initial configuration,  $\mu$  given by  $[[[[]_2]_1[[[]_4]_3]]_s$
- The finite multisets of objects are represented by  $w_1, w_2, w_3, w_4, w_s$  where  $w_s = \phi$ ,  $w_1=w_3$  have proteins of outer membranes, *MFN1* and *MFN2*. And  $w_2=w_4$  have proteins of inner membranes, *OPA1*. These are placed in membranes of the initial system. For simplicity, we will be considered  $MFN1=a$ ,  $MFN2=b$ ,  $OPA1=c$ ,  $new\_MFN1=a'$ ,  $new\_MFN2=b'$  and  $new\_OPA1=c'$ . Such that,  $a, b, c, a', b', c' \in V$
- $R$  is a finite set of the development rules over  $V$  of the following forms, (**R1**, **R2**, ..., **R6**).
- $i$  is 0, refer to the environment, "cell" in the system.

Initial Configuration

1) Apply mexo rule on membranes 2 and 1.

R1:  $[[ [ a b [ c ]_2 ]_1 [ a b [ c ]_4 ]_3 ]_s \rightarrow [ [ a b ]_1 [ c ]_2 [ a b [ c ]_4 ]_3 ]_s$ , where  $a, b, c \in V$ .

2) Apply mendo rule on membranes 2 and 3.

R2:  $[[ [ a b ]_1 [ c ]_2 [ a b [ c ]_4 ]_3 ]_s \rightarrow [ [ a b ]_1 [ a b [ c ]_4 [ c ]_2 ]_3 ]_s$ , where  $a, b, c \in V$ .

3) Apply merging rule on membranes 2 and 4 (the new membrane has label 4)

R3:  $[[ [ a b ]_1 [ a b [ c ]_4 [ c ]_2 ]_3 ]_s \rightarrow [ [ a b ]_1 [ a b [ c' ]_4 ]_3 ]_s$ , where  $a, b, c, c' \in V$ .

4) Apply mexo rule on membranes 4 and 3

R4:  $[[ [ a b ]_1 [ a b [ c' ]_4 ]_3 ]_s \rightarrow [ [ a b ]_1 [ a b ]_3 [ c' ]_4 ]_s$ , where  $a, b, c, c' \in V$ .

5) Apply merging rule on membranes 1 and 3 (the new membrane has label 1)

R5:  $[[ [ a b ]_1 [ a b ]_3 [ c' ]_4 ]_s \rightarrow [ [ a' b' ]_1 [ c' ]_4 ]_s$ , where  $a, b, a', b', c' \in V$ .

6) Apply mendo rule on membranes 4 and 1

R6:  $[[ [ a' b' ]_1 [ c' ]_4 ]_s \rightarrow [ [ a' b' [ c' ]_4 ]_1 ]_s$ , where  $a', b', c' \in V$ .

Final Configuration

### B. Mitochondrial Fission Model

A mitochondria fission mechanism is described by variants of active and mobile membranes using realistic biological operations. The proposed model consists of three actual membranes, the skin membrane which is a surface membrane, and the cell that acts as an "environment" in the P systems. The skin membrane has one non-elementary "Outer Membrane" that has one "Inner Membrane". Both inner and outer membranes have operations "rules" executed by proteins considered "objects" in the P systems. After that, two mitochondria are produced in the environment.

1) *Fission biological model*: Fig. 4 presented the biological description of mitochondrial fission regulation model. It designed by cell designer software. According to division operation, the fission model was included dividing one mitochondria organelle into two new ones. It should be taken in consideration that a dynamin-related protein 1 (Drp1) is the principal controller protein complicated in fission process. The Drp1 mobilization from cytosol onto the surface of mitochondria is essential and established via many proteins found on the outer membrane of mitochondria. They included

mitochondrial fission factor (Mff) and mitochondrial dynamics proteins 49 and 51 (MiD49 and MiD51). The regulation of fission process is completed by one of the following four basic modes [47]:

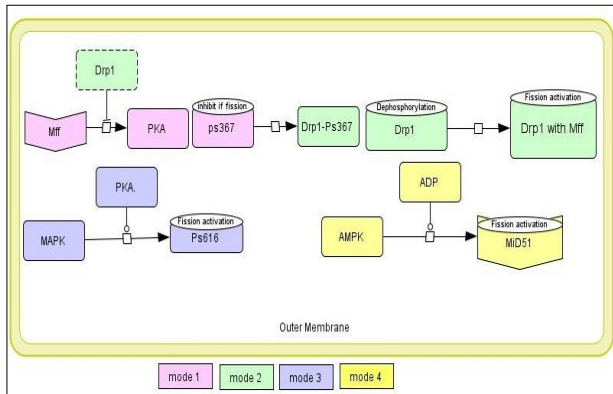

Fig. 4. Fission Operations for Mitochondria Membranes.

Mode (1): showed the inhibition of mitochondrial fission. It induced by signals included exercise and nitrogen starvation. The mode was done through the following sequencing steps:

- 1) Exercise and nitrogen starvation induce protein kinase A (PKA) activation.
- 2) The activated PKA causes phosphorylation of Drp1 at amino acid serine no. 637 (Ser637).
- 3) Phosphorylated Drp1 keep hold of Drp1 in cytosol preventing the fission process.

Mode (2): revealed the induction of mitochondrial fission. It initiated via signals such as metabolic uncoupling of the organelle and calcineurin.

The mode was done through the following sequencing steps:

- 1) Metabolic uncoupling of the organelle activates calcineurin.
- 2) The activated calcineurin dephosphorylates Drp1 at Ser637 (i.e. convert Drp1 from the phosphorylated to dephosphorylated form).
- 3) Dephosphorylated Drp1 allows mobilization of Drp1 to mitochondria resulted in activation of mitochondria fission.

Mode (3): exhibited the induction of mitochondrial fission. It began through signals such as cold exposure and oncogenic RasG12V. The mode was done through the following sequencing steps:

- 1) Cold exposure activates PKA, as well as oncogenic RasG12V activates mitogen-activated protein kinase (MAPK).
- 2) The activated PKA and MAPK phosphorylates Drp1 at Ser616.
- 3) The phosphorylated Drp1 links with both MiD51 and Mff leading to activation of mitochondrial fission.

Mode (4): illustrated the induction of the mitochondrial fission through high adenosine diphosphate (ADP) and adenosine monophosphate (AMP) levels as induction signals.

The following sequencing steps were included in the fission mode.

I- Steps regards to high ADP level signal:

- 1) The presence of high levels of ADP initiates the binding of ADP with MiD51 receptor.
- 2) The bounded ADP with receptor induces MiD51 activation.
- 3) The activated MiD51 associates with Drp1.
- 4) The activated and associated MiD51 with Drp1 causes Drp1 mobilization to mitochondria resulted in activation of mitochondria fission.

II-Steps regards to high AMP level signal:

- 1) The elevated AMP levels are detected by AMP-activated protein kinase (AMPK).
- 2) AMPK causes the phosphorylation of Mff protein receptor.
- 3) The phosphorylated Mff receptor binds to Drp1.
- 4) Drp1 bounded to phosphorylate Mff organizes Drp1 to mitochondria and activates mitochondria fission.

2) *Fission membranes using Mutual Dynamic Membranes (MDM) with P system:* The chemical reactions in mitochondria organelles are mainly caused by the reaction of two or more proteins. These are depicted as normal objects that can evolve by division computation, mexo, and mendo rules to get the final configuration.

In the following computation, proteins DRP1, MFF, MID51, PKA, Calcineurin, AMPK, and MAPK are used in P systems as “activators” of rules, where proteins are regulated certain biochemical reactions to the fission process occur.

$\Pi_2 = (V, H, \mu, W, R, i)$  be a P system with active and mobile membranes with the initial degree of the system is  $n = 3$ .

- The system can be viewed as a set of three membranes labeled by elements of  $H = \{s, 1, 2\}$  arranged in a hierarchical structure which including the skin membrane ‘s’ contains two nested membranes ‘1’ and ‘2’.
- The initial configuration  $\mu$  given by  $[[[2]1]1] s$ .
- The finite multisets of objects are represented by  $w_0, w_s, w_1, w_2$  where  $w_0$  has proteins of the environment,  $w_s$  has proteins of the surrounding of the outer membrane,  $w_1$  has proteins of an outer membrane and  $w_2$  has proteins of an inner membrane. These are placed in membranes of the initial system. For simplicity, we will be considered  $DRP1=a, DRP1-PS637 = as637, DRP1-PS616 = as616, MFF=b, Phospho-MFF=bp, MID51=c, PKA=d, Calcineurin=e, AMPK=f, MAPK=g$ . Then,  $w_0=d, f, g, w_s=a, e, w_1=b, c$  and  $w_2=\phi$ . Such that,  $a, as637, as616, b, bp, c, d, e, f, g \in V$ .
- $R$  is a finite set of the development rules in  $V$  of the following forms associated with the labels including

evolution, communication, division, mexo, and mendo rules, (R7, R8, ..., R33).

- $i$  is 0, refer to the environment, "cell" in the system.

Initial Configuration of Mode 1

- 1) Apply mexo rule on membranes 2 and 1.

R7:  $d [a [b c [ ]_2 ]_1]_s \rightarrow d [a [b c]_1 [ ]_2]_s$ , where  $a, b, c, d \in V$ .  
(mode1)

- 2) Apply object evolution rule in the same region [ $a \rightarrow a_{s367}$ ]

R8:  $d [a [b c]_1 [ ]_2]_s \rightarrow d [a_{s367} [b c]_1 [ ]_2]_s$ , where  $a, b, c, d, a_{s367} \in V$

Note:  $a_{s367}$  object leads to inhibition of mitochondrial fission, then it interaction with  $e$  object to activate fission process in mode.

Initial Configuration of Mode 2

- 3) Apply communication rule;  $a_{s367}$  object is sent out from the skin membrane  $s$ .

R9:  $e [a_{s367} [b c]_1 [ ]_2]_s \rightarrow e a_{s367} [ [b c]_1 [ ]_2]_s$ , where  $a, b, c, e, a_{s367} \in V$ . (mode2)

- 4) Apply object evolution rule [ $a_{s367} \rightarrow a$ ]

R10:  $e a_{s367} [ [b c]_1 [ ]_2]_s \rightarrow [a [b c]_1 [ ]_2]_s$ , where  $a, b, c, e, a_{s367} \in V$ .

- 5) Apply communication rule;  $a$  object is sent in the membrane 1

R11:  $[a [b c]_1 [ ]_2]_s \rightarrow [ [a b c]_1 [ ]_2]_s$ , where  $a, b, c, e \in V$ .  
(mode2)

- 6) Apply communication rule;  $c$  object is sent out from the membrane 1

R12:  $[ [a b c]_1 [ ]_2]_s \rightarrow [c [a b]_1 [ ]_2]_s$ , where  $a, b, c, e \in V$ .  
(mode2)

- 7) Apply division rule on membrane 1 (the different membranes labels 3, 4 are results)

R13:  $[c [a b]_1 [ ]_2]_s \rightarrow [c [a b]_3 [a b]_4 [ ]_2]_s$ , where  $a, b, c \in V$ .  
(mode2)

8) Apply division rule on membrane 2 (the different membranes labels 5, 6 are results).

R14:  $[c [a b]_3 [a b]_4 [ ]_2 ]_s \rightarrow [c [a b]_3 [a b]_4 [ ]_5 [ ]_6 ]_s$ , where  $a, b, c \in V$ . (mode2).

9) Apply mendo rule on membranes 5 and 3.

R15:  $[c [a b]_3 [a b]_4 [ ]_5 [ ]_6 ]_s \rightarrow [c [a b [ ]_3] [a b]_4 [ ]_6 ]_s$ , where  $a, b, c \in V$ . (mode2)

10) Apply mendo rule on membranes 6 and 4.

R16:  $[c [a b [ ]_5] [a b]_4 [ ]_6 ]_s \rightarrow [c [ab [ ]_5] [a b [ ]_6] ]_s$ , where  $a, b, c \in V$ . (mode2)

Rules of mode3:

1) Apply mexo rule on membranes 2 and 1

R17:  $d [g [b c [ ]_2] ]_1 ]_s \rightarrow d [g [b c]_1 [ ]_2 ]_s$ , where  $b, c, d, g \in V$ .

2) Apply object evolution rule in the same region,  $[g \rightarrow a_{s616}]$ .

R18:  $d [g [b c]_1 [ ]_2 ]_s \rightarrow d [a_{s616} [b c]_1 [ ]_2 ]_s$ , where  $b, c, d, g, a_{s616} \in V$ .

3) Apply communication rule;  $a_{s616}$  sent in the membrane 1,

R19:  $d [a_{s616} [b c]_1 [ ]_2 ]_s \rightarrow d [ [a_{s616} b c]_1 [ ]_2 ]_s$ , where  $b, c, d, a_{s616} \in V$ .

4) Apply division rule on membrane 1 (the different membranes labels 3, 4 are results).

R20:  $d [ [a_{s616} b c]_1 [ ]_2 ]_s \rightarrow d [ [a_{s616} b]_3 [a_{s616} c]_4 [ ]_2 ]_s$ , where  $b, c, d, a_{s616} \in V$ .

5) Apply division rule on membrane 2 (the different membranes labels 5, 6 are results).

R21:  $d [ [a_{s616} b]_3 [a_{s616} c]_4 [ ]_2 ]_s \rightarrow d [ [a_{s616} b]_3 [a_{s616} c]_4 [ ]_5 [ ]_6 ]_s$ , where  $b, c, d, a_{s616} \in V$ .

6) Apply mendo rule on membranes 5 and 3

R22:  $d [ [a_{s616} b]_3 [a_{s616} c]_4 [ ]_5 [ ]_6 ]_s \rightarrow d [ [a_{s616} b [ ]_3] [a_{s616} c]_4 [ ]_6 ]_s$ , where  $b, c, d, a_{s616} \in V$ .

7) Apply mendo rule on membranes 6 and 4

R23:  $d [ [a_{s616} b [ ]_3] [a_{s616} c]_4 [ ]_6 ]_s \rightarrow d [ [a_{s616} b [ ]_3] [a_{s616} c]_4 [ ]_6 ]_s$ , where  $b, c, d, a_{s616} \in V$ .

Final Configuration of Mode3

Rules of mode 4:

Initial Configuration of mode 4

1) Apply mexo rule on membranes 2 and 1.

R24:  $a [f [b c [ ]_2]_1]_s \rightarrow a [f [b c]_1 [ ]_2]_s$ , where  $a, b, c, f \in V$ .

2) Apply object evolution rule,  $[f \rightarrow b_p]$ .

R25:  $a [f [b c]_1 [ ]_2]_s \rightarrow a [b_p [b c]_1 [ ]_2]_s$ , where  $a, b, c, f, b_p \in V$ .

3) Apply communication rule;  $b_p$  object is sent in membrane 1.

R26:  $a [b_p [b c]_1 [ ]_2]_s \rightarrow a [[b_p b c]_1 [ ]_2]_s$ , where  $a, b, c, b_p \in V$ .

4) Apply communication rule;  $b$  object is sent out from membrane 1.

R27:  $a [[b_p b c]_1 [ ]_2]_s \rightarrow a [b [b_p c]_1 [ ]_2]_s$ , where  $a, b, c, b_p \in V$ .

5) Apply communication rule;  $a$  object is sent in skin membrane.

R28:  $a [b [b_p c]_1 [ ]_2]_s \rightarrow [a b [b_p c]_1 [ ]_2]_s$ , where  $a, b, c, b_p \in V$ .

6) Apply communication rule;  $a$  object is sent in membrane 1.

R29:  $[a b [b_p c]_1 [ ]_2]_s \rightarrow [b [a b_p c]_1 [ ]_2]_s$ , where  $a, b, c, b_p \in V$ .

7) Apply division rule on membrane 1 (the different membranes labels 3, 4 are results).

R30:  $[b [a b_p c]_1 [ ]_2]_s \rightarrow [b [a c]_3 [a b_p]_4 [ ]_2]_s$ , where  $a, b, c, b_p \in V$ .

8) Apply division rule on membrane 2 (the different membranes labels 5, 6 are results).

R31:  $[b [a c]_3 [a b_p]_4 [ ]_2]_s \rightarrow [b [a c]_3 [a b_p]_4 [ ]_5 [ ]_6]_s$ , where  $a, b, c, b_p \in V$ .

9) Apply mendo rule on membranes 5 and 3.

R32:  $[b [a c]_3 [a b_p]_4 [ ]_5 [ ]_6]_s \rightarrow [b [a c [ ]_5]_3 [a b_p]_4 [ ]_6]_s$ ,  
where  $a, b, c, b_p \in V$ .

10) Apply mendo rule on membranes 6 and 4.

R33:  $[b [a c [ ]_5]_3 [a b_p]_4 [ ]_6]_s \rightarrow [b [a c [ ]_5]_3 [a b_p]_6]_4]_s$ ,  
where  $a, c, b_p \in V$ .

Final Configuration of Mode 4

### C. Computational Properties of Proposed Model

There are several features of our model and are really appropriate for many problems (solvable) that will be discussed:

1) *Distribution*: the behavior of interactive systems in the mitochondrial model depends on nonlinearly results from protein composition to get a new configuration.

2) *Algorithmically*: Our computability model is defined by active and mobile variants, which deal with the Turing machine's computational power or other classic representations of algorithms, making full computational models as decidability devices and efficient algorithms to solve NP-complete problems in polynomial time easy to simulate (and exponential space).

3) *Transparency*: the rules applied in this model are nothing else than reaction equations as illustrated in the previous subsection, biological fusion, and fission models without any mysterious notation and mysterious behavior.

4) *Non-determinism*: our model is viewed as a collection of instructions/rules, with the sole structure being that imposed by membrane localization, but structure inside each membrane consisting of rigid sequences of instructions of programs written in common programming languages.

## V. EFFICIENT SOLUTIONS TO DIFFERENT CLASSES OF PROBLEMS USING PROPOSED MODEL

### A. Computational Complexity Classes with Proposed Model

The types of rules used in the proposed model are shown in the first column of Table II, while the applied rules for each type are listed in the second column. The basic classes of computational complexity problems have been shown in the second row are matched to the set of rules in the third column presenting solvability of each rule type.

TABLE II. COMPUTATIONAL POWER OF RULES RECOGNIZER IN PROPOSED MODEL

Rules Types	Rules Applied in our Models	Classes of Problems		
		P	NP	PSPACE
Evolution rule (a)	R8, R10, R18, R25	√	*	√
In-Communication rule (b)	R11, R19, R26, R28, R29	-	√	√
Out-Communication rule (c)	R9, R12, R27	-	√	√
Membranes Division rule (d)	R13, R14, R20, R21, R30, R31	*	√	√

√ denotes allowed types of rules; \* denotes disallowed types and - Rules with no impact on the computational power

Details of the notations P, NP, and PSPACE with definitions are presented in [48]. P is referred to Problems that had been solved in polynomial time with the evolution and rewriting rules for only one membrane [18, 49, and 50]. For instance, the ranking problem for three numbers had been solved by conventional computers. It has a computational power with P systems with an evolution rule. SUBSET SUM problem is belonging to a class of NP-complete problems that have been solved by division rule for elementary membranes with communication rules. In [51], the efficiency proof of its solution is demonstrated in uniform linear time. The QSAT problem is belonging to a class of PSPACE problems that are called "second class computers". QSAT has been solved by different families of active membranes. PSPACE class has been confirmed as an upper bound of the computations in polynomial time with P systems in [41].

Briefly, Table II is the summary of computational complexity power of rules that belong to active variant and used in this model. Presenting accepted classes of problems in polynomial time. The rules of types from (b, c, and d) can solve NP-complete problems in polynomial time as shown in the fifth column in Table II. Where the division rules for elementary membranes are unrestricted which leads to an increase of computational power [52, 53]. While the rules of types from (a) to (d) are suitable to address PSPACE problems in polynomial time. In [54] highlighted the role of different restrictions/extensions of evolution, communication rules.

### B. Solving SAT Problem using MDM

- The Satisfiability of a propositional logic formula in conjunctive normal form is known as the SAT problem. It is classified as a strong problem in categories of NP-complete problems.
  - For any instance of SAT, Consider the following expression:
 
$$\beta = C_1 \wedge C_2 \wedge \dots \wedge C_m$$
 over  $X = \{x_1, x_2, \dots, x_n\}$  such  $x_i$  where  $1 \leq i \leq n$ . In this case,  $(n = 3)$ .
  - For each  $C_i$ ,  $1 \leq i \leq m$ . In this case  $(m=3)$ , a disjunction of the form  $C_i = y_1 \vee y_2 \vee \dots \vee y_r$  ( $r \leq n$ ), where each  $y_j$  indicates to variable  $x_k$  or negation of  $x_k, \bar{x}_k$

- The working over the alphabet:  $V = \{z, \bar{z}, q, \bar{q}, g, g_0, \gamma, \bar{\gamma}, \text{yes}, \text{no}, b_i, t_i, f_i, \gamma_i, \bar{\gamma}_i \mid 1 \leq i \leq n\}$
- We construct the system by use the fission model configuration that has MDM rules to generate all potential variables assignments,  $\{x_1, \dots, x_n\}$ . By rules of MDM to solve the SAT problem as follows:

1)  $[b_i]_s \rightarrow [t_i b_{i+1}]_s [f_i b_{i+1}]_s$ , for  $1 \leq i \leq n - 1$  (division rule)

$[b_n]_s \rightarrow [t_n \gamma_1]_s [f_n \gamma_1]_s$  (division rule)

$[g]_1 \rightarrow [ ]_1 [ ]_1$  (division rule)

$[g_0]_1 \rightarrow [\bar{\gamma}_1]_1 [\bar{\gamma}_1]_1$  (division rule)

- $2^n$  membranes are created from the first two rules and labeled by  $s$  contain all potential variables assignments,  $\{x_1, \dots, x_n\}$ . Each membrane labeled by  $s$  is assigned by object  $\gamma_1$ .
- $2^n$  membranes labeled by 1 are created from the following two rules. Each one of them contains object  $\bar{\gamma}_1$ . The correct assignments for  $C_i$  are determined by using symbols  $\gamma_i$  and  $\bar{\gamma}_i$  in two steps.

2)  $[t_j \gamma_i]_s [\bar{\gamma}_i]_1 \rightarrow [[t_j \gamma_i]_s \bar{\gamma}_i]_1$  (mendo)

$[[t_j \gamma_i]_s \bar{\gamma}_i]_1 \rightarrow [t_j \gamma_{i+1}]_s [\bar{\gamma}_{i+1}]_1$  (mexo)

(in case  $C_i$  includes the literal  $x_j$ )

$[f_j \gamma_i]_s [\bar{\gamma}_i]_1 \rightarrow [[f_j \gamma_i]_s \bar{\gamma}_i]_1$  (mendo)

$[[f_j \gamma_i]_s \bar{\gamma}_i]_1 \rightarrow [f_j \gamma_{i+1}]_s [\bar{\gamma}_{i+1}]_1$  (mexo)

(in case  $C_i$  includes the literal  $\neg x_j$ )

$[t_j \gamma_m]_s [\bar{\gamma}_m]_1 \rightarrow [[t_j \gamma_m]_s \bar{\gamma}_m]_1$  (mendo)

$[[t_j \gamma_m]_s \bar{\gamma}_m]_1 \rightarrow [t_j z]_s [\bar{\gamma}_m]_1$  (mexo)

(in case  $C_m$  includes the literal  $x_j$ )

$[f_j \gamma_m]_s [\bar{\gamma}_m]_1 \rightarrow [[f_j \gamma_m]_s \bar{\gamma}_m]_1$  (mendo)

$[[f_j \gamma_m]_s \bar{\gamma}_m]_1 \rightarrow [f_j z]_s [\bar{\gamma}_m]_1$  (mexo)

(in case  $C_m$  includes the literal  $\neg x_j$ )

The objects  $\gamma_i$  from the identical membrane  $s$  are exchanged by  $\gamma_{i+1}$  if the assignments fulfilled the clause  $C_i$ . The assignments from the membranes which contain  $\gamma_{i+1}$  satisfy the clauses  $C_1, \dots, C_i$ , then, the object  $\gamma_{i+1}$  indicate the result in next step the clause  $C_{i+1}$  is checked. If all clauses are satisfied, then the membranes which have these assignments will be marked by object  $\bar{z}$ .

3)  $[c_i \gamma]_2 [\bar{\gamma}]_3 \rightarrow [[c_{i+1} \gamma]_2 \bar{\gamma}]_3$  (mendo)

$[[c_i \gamma]_2 \bar{\gamma}]_3 \rightarrow [c_{i+1} \gamma]_2 [\bar{\gamma}]_3$  (mexo)

$[[c_{n+2m+1} \gamma]_2 \bar{\gamma}]_3 \rightarrow [d \gamma]_2 [\bar{\gamma}]_3$  (mexo)

$[c_{n+2m+1} \gamma]_2 [\bar{\gamma}]_3 \rightarrow [[c_{n+2m+1} \gamma]_2 \bar{\gamma}]_3$  (mendo)

The mentioned rules in (iii) are used to determine the number of steps is applied in rules of type (ii). If the number of

steps is larger than  $n + 2m + 1$ , this is indicated to clauses are not satisfy. Then an object  $q$  is generated, that will create an object **no**. The number  $n + 2m + 1$  correspond to the following steps: generating space in  $n$  steps, validate assignments in  $2m$  steps, generating a **yes** object in one step. Additionally, step can be applied; membrane 2 including the object  $c_{n+2m+1}$  becomes sibling with membrane 3, thus increasing the number of steps needed to generate **d** object to  $n + 2m + 2$ .

4) iv.  $[\bar{z}]_s [z]_4 \rightarrow [[yes]_4]_s$  (mendo)

$[q]_3 [\bar{q}]_4 \rightarrow [[no]_3]_4$  (mendo).

- When membrane 4 enters membrane  $s$  in  $(2m+n+1)$  step, a yes object is created. But a no object is created when no membrane  $s$  contains an object  $q$ . When membrane 3 enters membrane 4, one of these two rules cannot be applied anymore. Finally, the computation result is either a yes or a no object in the system.
- The size of the working alphabet is  $4n+4m+13$ . The number of used rules is computed as follows: the number of rules from type (i) is  $n + 2$ , the number of rules from type (ii) is  $4nm$ , the number of rules from type (iii) is  $n + 2m + 3$  and the number of rules from type (iv) is 2 rules.
- As a result, the size of the computing system to solve SAT is  $O(mn)$ . Because  $n + 2m$  is an odd number, the computation ends in  $n + 2m + 3$ . As a result, we had to do an extra step before obtaining  $q$  object from  $c_{n+2m+1}$ . If  $n+2m$  is an even integer, then after  $n + 2m + 2$  steps,  $q$  object is generated.

## VI. REPRESENTATION MODEL USING UML

Different diagrams of UML are used to analyze the behavior of mitochondria fusion-fission models. The first diagram represents the modality of normal mitochondria organelles in the living cell using an object diagram as shown in Fig. 5.

Fig. 5 revealed that the object diagram is combined from a superclass titled cell that is considered as “environment” in P systems. The super class is consisting of many objects that represent components of a living cell that contains at least two mitochondria. Our proposed design is interested in mitochondria object which is a sub class from the superclass. The mitochondria object has some attributes such as DNA, RNA, and the mitochondria functional operations. The basic operations of mitochondria objects are fusion, fission, motility, and mitophagy, while in the current study, the authors focused on the fusion and fission operations. The outer and inner membranes objects are composited from mitochondria objects, where each mitochondrion has one outer membrane and one inner membrane, and all of them, have some attributes that are represented by proteins that involved in the fusion and fission processes.

Fig. 5 revealed that the object diagram is combined from a superclass titled cell that is considered as “environment” in P systems. The super class is consisting of many objects that represent components of a living cell that contains at least two mitochondria. Our proposed design is interested in

mitochondria object which is a sub class from the superclass. The mitochondria object has some attributes such as DNA, RNA, and the mitochondria functional operations. The basic operations of mitochondria objects are fusion, fission, motility, and mitophagy, while in the current study, the authors focused on the fusion and fission operations. The outer and inner membranes objects are composed from mitochondria objects, where each mitochondrion has one outer membrane and one inner membrane, and all of them, have some attributes that are represented by proteins that involved in the fusion and fission processes.

The diagram is illustrated in Fig. 6, the activity diagram and represents the interactions that occurred in two mitochondria objects to keep their metabolic regulation using fusion operations. The events that occurred to complete fusion operations of the two normal mitochondria organelles were

analyzed in Fig. 6. First, both outer membranes object with their contents such as proteins, enzymes, and ATP molecules are merged by chemical interactions to complete the binding process owing to the formation of a new outer membrane object. Second, both inner membranes object was merged using other chemical operations involved in the binding process followed by the production of a new inner membrane object. Lastly, both objects are joined producing new outer and new inner membranes leading to the production of new mitochondrion object which contains inherits behaviors from the original one. In Fig. 7, actions and events are analyzed to complete fission operations to the one normal mitochondrion organelle. First, the object of Drp1 protein is called to mitochondrion object to interact with proteins in the outer membrane, then one action from four actions will be activated the fission operation according to the required signal. Finally, the mitochondrion divided into two mitochondria organelles.

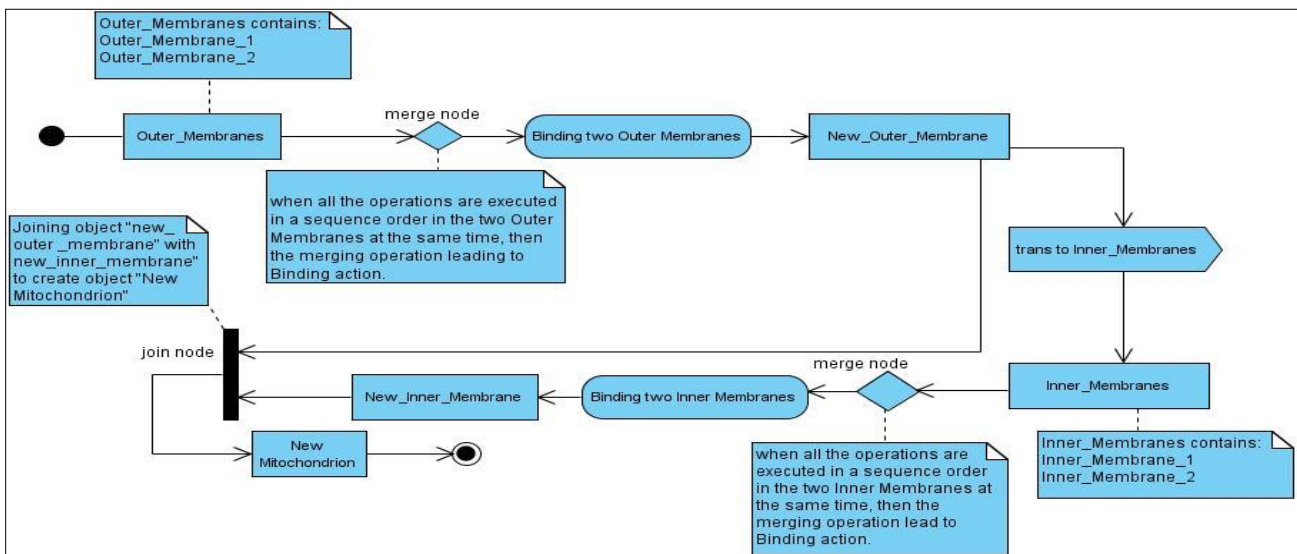

Fig. 7. Activity Diagram for Actions Fission Model.

## VII. CONCLUSION AND FUTURE WORK

P systems can be used to model biological and physiological processes. This paper proposed a model of two actual biological functions of important organelle in a living cell, mitochondria fusion, and fission. This model, MDM, combined a set of rules from different variants of P systems, division rule with mexo and mendo rules that provided higher efficiency in terms of space complexity rather than using rules of active membranes only. The conclusion of this work can be summarized in terms of three aspects. First, P is a computational power set of evolution rules in polynomial time. While a set of PSPACE problems are solved in polynomial time using polynomial uniform of active membranes families with the operation of elementary membrane division. This is one of the most well-studied methods for getting an exponential working space in order to exchange space for time and solve computationally difficult problems (commonly NP-complete problems) in a timely manner (typically polynomial or even linear). Second, this research introduced a semi-uniform linear time solution to SAT problem using MDM rules with 3 membranes. From the results, we proofed that only three membranes suffice in solving the SAT problem. MDM is faster than other models that used 9 membranes to obtain computational universality. Finally, using biological models and development of their object relationship diagrams have been implemented using object-oriented programming (OOP) to be used as an analysis tool for complex data of mitochondria neurodegenerative diseases.

Future research topics may include:

- 1) Understanding of the remaining two operations of mitochondrial regulation (motility and mitophagy) and simulated them by P systems variants.
- 2) Designing a complete model for metabolic regulation of mitochondrial dynamics.
- 3) By different kinds of cell-like P systems.

4) Complete understanding of physiological processes for studying different diseases and malfunctions involved in human neurodegenerative system mediated by irregular mitochondria.

5) Investigating and studying other biological operations for modeling other echo systems using different P systems variants.

6) We hope to define and develop a new strategy in OOP using P systems with active and dynamic rules to solve nondeterministic problems in polynomial time specifically in Machine Learning algorithms.

# Skin Lesions Classification and Segmentation: A Review

Marzuraikah Mohd Stofa, Mohd Asyraf Zulkifley, Muhammad Ammirul Atiqi Mohd Zainuri  
Department of Electrical, Electronic and Systems Engineering, Universiti Kebangsaan Malaysia, Bangi, Malaysia

**Abstract**—An automated intelligent system based on imaging input for unbiased diagnosis of skin-related diseases is an essential screening tool nowadays. This is because visual and manual analysis of skin lesion conditions based on images is a time-consuming process that puts a significant workload on health practitioners. Various machine learning and deep learning techniques have been researched to reduce and alleviate the workloads. In several early studies, the standard machine learning techniques are the more popular approach, which is in contrast to the recent studies that rely more on the deep learning approach. Although the recent deep learning approach, mainly based on convolutional neural networks has shown impressive results, some challenges remain open due to the complexity of the skin lesions. This paper presents a wide range of analyses that cover classification and segmentation phases of skin lesion detection using deep learning techniques. The review starts with the classification techniques used for skin lesion detection, followed by a concise review on lesions segmentation, also using the deep learning techniques. Finally, this paper examined and analyzed the performances of state-of-the-art methods that have been evaluated on various skin lesion datasets. This paper has utilized performance measures based on accuracy, mean specificity, mean sensitivity, and area under the curve of 12 different Convolutional Neural Network based classification models.

**Keywords**—Lesion segmentation; lesion classification; machine learning; deep learning; skin lesions

## I. INTRODUCTION

Skin cancer is one of the most dangerous types of cancer that infected humans regularly. In the field of dermatology, there are two types of skin cancers, which are melanocytic and non-melanocytic. For example, melanoma is a type of melanocytic cancer, which is found to be a riskier version of cancer compared to the non-melanocytic type. Therefore, diagnosis of the correct type of cancer at an early stage is important to reduce the mortality risk [1], [2]. Besides that, there are certain parts of the body that have a higher probability of infection such as the chest, back, and legs. Then, this paper observed that most research in recent years has focused on establishing an automated intelligent system for the unbiased diagnosis of pigmented skin lesions. The general framework of the system involves pre-processing, feature extraction, segmentation, and classification phases, which are necessary steps in obtaining accurate localization of the skin lesion map. Masood et al. [3] and Adeyinka et al. [4] is also found that diagnosis of skin cancer at an early stage using computer vision provides a significant improvement when machine learning techniques are implemented. First, the diagnosis process begins by removing unnecessary structures or artifacts

on the skin lesion image that might interfere during the segmentation process, such as air bubbles, hair, blood vessels, and oily surfaces. In general, skin lesions come in various colors, shapes, and sizes that limit the standard machine learning ability to obtain high levels of accuracy. This process involves complex annotations during manual screening even for dermatologists. Therefore, Al-Masni et al. [5] presented that an automated computerized diagnostic system is an important tool in skin lesion analysis that will be able to assist and support dermatologists in making timely decisions. Abdani et al. [6] show that deep learning has demonstrated its effectiveness in various applications, particularly in computer vision-related systems that use convolutional neural networks (CNN) as the base framework, even for a compact version. For example, a previous study in [7] has shown that the popular method in deep learning is through CNN utilization, which can process common and highly variable tasks in handling delicate objects. Krizhevsky et al. [8] and Lecun et al. [9] prove that this sophisticated and optimized model has better ability than handcrafted features in extracting outstanding features from the entire images of skin lesions.

The development of computer-aided algorithms is essential to address the increasing problem of global skin cancer cases where it is able to handle large amounts of data in real time and automatically. It is important to review the performance of deep learning algorithms in the classification and segmentation of skin lesions due to recent advances in deep learning paradigms, and particularly in medical imaging it shows excellent performance. So, in this study, an extensive investigation of the various approaches for analyzing skin lesions was conducted. In addition, the classification techniques are reviewed and compared in Section II, which is the process of categorizing the classes of skin lesions and other types of surfaces. A comparison between all the segmentation techniques is presented in the following Section III. In addition, a comparative analysis using deep learning methods for classification and segmentation of skin lesions was performed in Section IV to show the strengths and weaknesses of each method, and subsequently the conclusion section.

## II. CLASSIFICATION

The skin cancer detection system is made more accessible by categorizing images of lesions. This classification process can assist dermatologists in detecting the possibility of early skin cancer through visual-based sensing. According to the standard medical practice, skin lesions are often classified as benign or malignant cancer. Thence, each of the lesion types can be further classified into seborrheic keratosis, solar lentigo, squamous cell carcinoma, nevi, actinic keratosis, basal cell

carcinoma, melanoma, and others. In this paper, both the traditional and recent state-of-the-art methods were reviewed. Table I summarizes the differences between various general deep classification networks.

TABLE I. COMPARISON BETWEEN GENERAL CNN ARCHITECTURES FOR SKIN LESION CLASSIFICATION TASK

Techniques	Description	Advantages	Disadvantages
AlexNet [10]	Includes three fully connected layers and five convolutional layers. This model used various sizes of filter.	GPU are used as an accelerator to handle the complex architecture.	The probability of generating artifacts from feature maps is high because the filter's size is quite large.
VGGNet [11]	Uses only 3x3 of convolutional filters, placed on top of each other to increase the network depth.	Encouraging performance that uses up to 19 layers with significant improvement over the previous arrangements.	It is challenging to train the model, especially for the cases without transfer learning.
GoogleNet [12]	An architecture that has 22 layers of deep network.	There is no uncontrolled increment in computing complexity when more units are added at each level.	Difficulty in customizing the parameters due to the use of heterogeneous topology.
ResNet [13]	Applies feedforward neural network layers with skip connection by performing identity mapping and added them to the stacked-layer output.	Increase the network's depth and easier to optimize, while reducing zero diminishing gradient issues, which indirectly improves the accuracy.	Information on the features map is complicated and may be degraded throughout the feed-forward procedures.
Xception [14]	An "extreme" version of the Inception module that replaces the module with depth-wise separable convolution	Easy to define and modify with high accuracy performance.	High computational cost due to multiple layers of CNN with 728 filters.
DenseNet [15]	Have a complex connection to achieve maximum information flows between forward and backward layers.	Training is relatively easy due to the enhanced flows of gradient and information across the network.	The number of parameters increases a lot between shallow and deep configurations because of more feature maps in each layer.
EfficientNet [16]	The architecture model consists of eight configurations from B0 to B7, with each subsequent model refers to a variant with more parameters and higher accuracy.	Reduce computation cost and can produce faster classification inference.	In order to catch fine-grained patterns on huge images, the network requires additional layers that increase the receptive field size and uses more channels.

A. Recent Works on Conventional Classification Method

At the beginning of the study on skin lesion classification, the traditional machine learning approach was commonly used, whereby region-based or threshold-based approaches are utilized to extract the features. Some of the most popular conventional approaches nowadays are support vector machine (SVM), k-nearest neighbor, artificial neural network (ANN), and naive Bayesian algorithm [17], [18]. Then, the deep learning-based method was started to be developed to overcome the limitations of previously mentioned conventional approaches. Han et al. [19] presented the conventional methods require significant effort from humans to design the feature extractors, still they do not produce accurate multi-class skin lesions detection.

B. Recent Works on Deep Learning Classification Method

The deep learning method based on the CNN classifier has exceeded the general human capability in performing object classification tasks, whereby historically, it begins to gain popularity in 2012 [20]. Fig. 1 shows the general CNN architecture with standard major components such as CNN layers, activation function, and the trainable hyperparameters. Several previous studies have implemented CNN that was introduced in [7] to produce dermatologist-equivalent skin cancer classifiers [21], [22]. Compared to the traditional methods, the CNN-based methods proved to be more effective. Many CNN architectures are available for skin lesion classification such as AlexNet [10], GoogleNet/InceptionNet [12], VGG Net [11], ResNet [13], XceptionNet [14], DenseNet [15] or EfficientNet [16]. All these methods are discussed as follow:

Fig. 1. General Architecture of CNN.

1) AlexNet: AlexNet is a system developed over 10 years ago [10]. It utilizes two operators, the convolutional network and the pooling layer, which will be the main building blocks of the network. The network starts with several layers of convolutional layers, followed by the fully connected layers, which are aligned through flatten operator. AlexNet has also been developed for implementing deep neural networks (DNNs) methodology in speech recognition and computer vision. Such as in 2019, the work in [23] has applied AlexNet to classify skin lesions using various configurations. The proposed method managed to overcome the overfitting problem by adjusting the weight values and enriching the data set with synthetic data generated from different rotation angles. The final classification layer is then replaced with the softmax layer to categorize more than two types of skin lesion categories. The experiment results have exceeded the initial performance expectations, whereby this model is still being

used as the benchmark in classifying the skin lesions. This general architecture of this network is illustrated in Fig. 2.

Fig. 2. Diagram of AlexNet Architecture.

2) *VGGNet*: In comparison to AlexNet, VGGNet is a deeper and more complicated network. This model has been further improved by lowering the number of parameters [11]. In fact, it has been used as the building block for many compact applications [24], [25]. This model has been tested in large deep CNN configurations that consist of many convolutional layers followed by pooling layers for huge image classification tasks. Besides that, the pre-trained VGG network is also commonly utilized in various transfer domain applications. However, this model uses a significant amount of processing resources, and hence makes the application of the VGG model a tiresome task. Sun et al. [26] have recommended the usage of VGGNet to diagnose 198 types of skin lesions which were trained until they reached an optimal set of hyperparameters. They have utilized the DermQuest data set, which included 6,584 clinical pictures, whereby they have managed to obtain 50.27% average accuracy. Fig. 3. shows the general VGG 16 architecture, which is one of the biggest VGG network variants.

Fig. 3. Diagram of VGG 19 Architecture.

3) *GoogleNet*: GoogleNet is also popularly known as the InceptionNet [12]. It is composed of a 22-layer convolutional network structure. The primary goal of this design is to observe how the optimal local sparse structure can be handled and protected by the existing compact components. Most commonly, an Inception system is formed from modules that are stacked on top of one another. As Inception modules are stack on top of each other, their output correlation varies because deeper layers will capture better abstraction features, while the spatial concentration is expected to decrease accordingly. This reduction is done as such it will help the model to attain a faster training convergence. Thurnhofer-Hemsi et al. [27] have also used the CNN methodology to classify the skin lesion type based on the DermQuest database. The raw images were directly inserted into the CNN model to determine the presence of melanoma or not. They found out that GoogleNet and AlexNet produced the best results among the tested models. The authors have produced a highly accurate

system in terms of mean accuracy compared to the benchmarked models, even without utilizing any pre-processing step. The multiple inception modules are shown in Fig. 4.

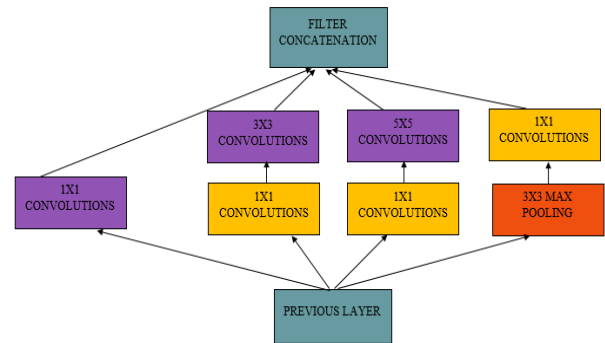

Fig. 4. Architecture of the GoogleNet Inception Module.

4) *ResNet*: As previously mentioned in [13], the residual modules in ResNet architecture can be used to train a very deep network effectively just by using the conventional stochastic gradient descent (SGD). He et al. [13] have shown that the residual networks with 152 layers can easily be trained and optimized to produce a model with good accuracy as its architecture becomes deeper. Moreover, they have also applied a feedforward neural network scheme with skip connection by performing identity mapping to combine the existing and skipped layers. This architecture is eight times deeper than VGGNet but it is still less complex and easier to train. Le et al. [28] have proposed a model that leverages the transfer learning method by using pre-trained models of ResNet 50, VGG 16, and MobileNet, coupled with weights and loss functions that focus on the classification process. Their results indicate that the ResNet 50 model produced the best performance with an average accuracy of 93% and total accuracy within the range [0.7, 0.94], which has surpassed the accuracy of dermatologists with an average accuracy of 84%.

5) *XceptionNet*: As an extension of the Inception design, Xception uses a stack of depth-separable convolution schemes to replace the Inception modules. In the newer versions of the Inception, some of the modules have replaced the different spatial dimensions ( $1 \times 1$ ,  $3 \times 3$ , and  $5 \times 5$ ) with a single dimension ( $3 \times 3$ ), followed by a pointwise convolution ( $1 \times 1$  convolution) to manage the computational complexity [14]. The feature extraction layer in the Xception architecture has a total of 36 convolutional layers with a large filter utilization of 728. Chaturvedi et al. [29] have suggested an automatic multiclass skin cancer disease classification system by conducting training procedures to obtain the optimal hyperparameter for five CNN models including Xception, ResNext 101, NasNetLarge, Inception V3, InceptionResNet V2, and the ensemble model. The best accuracy for the individual model was obtained by ResNext 101 and the best accuracy for the ensemble model was obtained by the combined network of InceptionResNet V2 and ResNetXt 101. However, the individual Xception model and the ensemble

model that contain Xception architecture also obtained good accuracy performances.

6) *DenseNet*: DenseNet is quite similar to ResNet from the architecture perspective, but the integration format of the two incoming networks is different, which leads to different network behaviors. Huang et al. [15] have developed an architecture with a simple connection pattern to ensure the maximal information flows between forward and backward layers to resolve the vanishing gradient problem. DenseNet accommodates the additional input from all previous layers by using cross-layer connectivity through the concatenation operator. Then, it transmits its feature maps to all subsequent layers, again via cross-layer connectivity. For image recognition, down-sampling layers divided the whole architecture into several densely connected blocks. Transition layers are also inserted between the convolution and pooling layers of various blocks. Hassan et al. [30] have implemented DenseNet-121 architecture to classify seven different types of skin lesions based on the HAM10000 dataset. Their model was trained by using supplemented augmentation data that managed to reach 92% of categorical accuracy and 97% of top2 accuracy which is much better than other models. The illustrated DenseNet architecture is shown in Fig. 5.

Fig. 5. Diagram of DenseNet Architecture.

7) *EfficientNet*: Recently, the EfficientNet model was introduced with a new up-and-down scaling strategy that scales uniformly the depth, width, and parameter resolution by using an effective compound coefficient [16]. One of the primary components of EfficientNet is MBConv or MobileNet, which follows an inverted bottleneck design. It is paired with an in-depth separable convolution by taking a shortcut between the bottlenecks, whereby it utilizes a considerably smaller number of channels. This model has achieved better classification accuracy compared to the existing models such as ResNet, DenseNet, Inception-V4, and NASNet when tested using a large ImageNet dataset. Gessert et al. [31] have implemented an ensemble of deep learning models to classify skin lesions using various EfficientNet architectures (B0-B6). They have boosted the training data by using meta information from ISIC 2019, whereby they have achieved the highest accuracy of 63.6% with AUC above 80% for the detection of skin lesions of eight different classes of skin.

### III. RECENT APPLICATION OF CNN MODELS FOR CLASSIFICATION TASKS

Many studies have indicated that CNN is a suitable method to be implemented for biomedical image applications, especially in the automated analysis of skin lesions. Esteva et

al. [7] have presented a method to classify malignant melanoma with significant accuracy by using a CNN architecture, which is through Google Inception V3 that has been pre-trained on 1.28 million images of general objects. Their automated system was then retrained with 129,450 clinical data of 2,032 different classes and managed to achieve 72.1% accuracy, whereas the two benchmark dermatologists only managed to obtain accuracy rates of 65.56% and 66%. Through the transfer learning scheme, the CNN classifier was able to achieve more or less a similar performance to those of 21 dermatologists in identifying malignant lesions, in which the CNN classifier produced an overall area under the curve (AUC) of >91%. Brinker et al. [32] then experimented on CNN deep learning architecture in categorizing skin lesions from 12,378 dermoscopic images, which were categorized into two classes of melanoma and atypical nevi. The findings were compared with the performances of dermatologists from various levels of competency and experience that also includes a few resident physicians from 12 German university hospitals. The CNN-based approach has managed to outperform the average accuracy of dermatologists.

Furthermore, Ratul et al. [33] have developed a computer-aided detection system for malignant skin lesions cases. Dilated convolution was used in four different architectures, namely InceptionV3, MobileNet, VGG16, and VGG19. The HAM10000 data set, which contains 10,015 dermoscopic images consisting of seven skin lesion classes were used to train, validate and test the algorithm with accuracy rates of 89.81%, 88.22%, 87.42%, and 85.02% for the previously mentioned models, respectively. Gessert et al. [34] researched further on the usage of patch-based techniques to extract fine-grain variations between different skin lesions using high image resolution input. Then, each image was divided into 5, 9, and 16 patches, which will be incorporated into a standard CNN architecture. Finally, three popular architectures were used to classify the skin lesions from high-resolution image patches, namely DenseNet, Inception V3, and SE-Resnext50.

Instead of using a fixed learning rate, Alqudah et al. [35] were integrated gradient descent with adaptive momentum learning rate and transfer learning approaches into two CNN architectures, which are AlexNet and GoogleNet for skin lesion classification tasks. Their method considered three types of skin lesions, which are benign, melanoma, and seborrheic keratosis, whereby the proposed classification approach was tested and evaluated using the International Skin Imaging Collaboration database. The system aimed to analyze input images to produce segmented and non-segmented skin lesions and reported accuracy rates of 92.2% and 89.8%, respectively. Contrary to the previous work, Akram et al. [36] developed a new framework for skin lesion classification that incorporates in-depth feature information to build the best discriminatory feature vectors while preserving the original feature space. To select discriminant features and reduce dimensionality, the authors have used the entropy-controlled neighborhood component analysis. The system employed several deep learning architectures, including Inception-V3, DenseNet 201, and Inception-ResNet-V2, as the classifiers. The proposed system was evaluated using different data sets, namely ISIC MSK, ISIC UDA, ISBI-2017, and PH2, with a common aim of

categorizing the skin lesions and obtained performance results of 98.8%, 99.2%, 97.1%, and 95.9%, respectively. The authors managed to cut off the features to less than 3% of the overall features, which resulted in improved classification accuracy by eliminating the redundancy and minimizing the computation time.

Researchers have also developed an integrated approach for skin lesion segmentation and multi-class lesion classification [37]. In this work, full-resolution convolutional network models have been applied for segmenting the lesion regions using popular CNN backbones of Inception, Densenet201, and ResNet-Inception to classify the segmented skin lesions. The Inception-ResNet model provided the most remarkable results out of the tested techniques. This model performed the best if it is trained with balanced data rather than imbalanced data. Using a similar approach, Purnama et al. [38] have tested two pre-trained CNN models, Inception V3 and MobileNet V1 for skin lesion classification. Then, they introduced an innovation through a web classifier. Their proposed method used a benchmark dataset of MNIST HAM 1000, where the results showed that Inception V3 had 72% accuracy, whereas MobileNet V1 only had 58% accuracy.

A unique multiple CNN models approach was proposed in [39] for solving challenging classification tasks due to the presence of artifacts, low-contrast images, and high intraclass differences in dermoscopic images. Multiple pre-trained CNN architectures were explored that include AlexNet, ResNet, GoogleNet, and VGG16 to speed up the training process using the dataset of ISIC 2016. This approach achieved an accuracy of 97.78% with an AUC of 0.98 for the training dataset and 85.22% with an AUC of 0.81 for the testing dataset. Instead of four models, Miglani and Bhatia [40] compared only two deep CNN models, ResNet-50 and EfficientNet-B0 for skin lesion classification purposes. The models were tested using the HAM10000 dataset, which resulted in the EfficientNet-B0 outperforming the ResNet-50 by achieving mean macro and micro AUC of 0.93 and 0.97, respectively. Their test has concluded that the recent CNN model is better in extracting richer, more complex, and fine-grain features of dermoscopic skin lesion images. Table II shows a comparison of the recent methods for skin lesion classification using the deep CNN methods.

#### IV. SEGMENTATION

Image segmentation is needed in a large-scale approach to diagnosing skin lesions automatically. It is an important step where the images will undergo pattern recognition or the utilization of a rule-based method to segment the region of interest (ROI). Al-Masni et al. [5] have defined ROI as the lesion areas that are separated from the non-lesion region. Generally, identifying the ROI requires a module to detect gaps in the images, before applying the similarity criteria to segment the lesions together [45]. The conventional approach involves handcrafted feature-based methods such as the edge [46], region [47], threshold [48], and intelligence-based methods [5]. The machine learning methods include both deep learning and conventional techniques, which will be discussed in the following section to examine and compare the segmentation performance. Table III shows the comparison between all segmentation techniques.

##### A. Recent Works on Skin Lesion Segmentation using Conventional Intelligence-Based Method

Conventional artificial intelligence allows rapid implementation of the skin lesion segmentation without much training requirement with a much lesser dataset compared to the deep learning approach. It can be easily implemented as such it allows a wider spread of the application to help with skin-related disease diagnosis. Researchers have analyzed the ability of artificial intelligence-based approaches by performing image analyses based on perception, reasoning, and learning using the existing medium-sized image datasets. The most recent popular artificial intelligence-based segmentation methods are ANN models [49], Fuzzy C-Means [52], and genetic algorithms [50], [51]. Artificial intelligence usually utilizing an analytical planning to make machine learn without program it especially using existing dataset while deep learning further with neural networks that imitate the neurons in human brain and enclose with multiple architecture layers. However, starting from 2015, the deep learning approach starts to be implemented due to the introduction U-Net, which changes the research direction in many bio-medical applications.

##### B. Recent Works on Deep Learning Approach to Skin Lesion Segmentation

The deep learning approach has been proven to be state-of-the-art in supervised image segmentation applications. Despite the heavy complexity of deep learning models, more information from the raw images can be learned optimally rather than being designed by a human designer. Researchers have utilized various deep learning models to segment skin lesions, including U-Net [64], fully CNN (FCNN) [65], deep fully convolutional residual network (FCRN), and SegNet [66].

1) *FCNN architecture*: FCNN is a segmentation module with deeper encoder parts compared to the decoder parts. This model has been used in [53] to segment the skin lesions automatically. Besides that, researchers have also developed multi-stage FCNN for skin lesion segmentation by using a parallel integration method. An evaluation of the suggested technique has been tested using the ISBI 2016 dataset, which has revealed a high segmentation performance with a dice coefficient score of 91.18% and an accuracy of 95.51%. Yuan

et al. [54] then presented a modified deep FCNN-based method for skin lesion segmentation, which was evaluated using two different databases; one is from the ISBI 2016 database and the other one is from the PH2 database. The modified method was found to outperform the previously mentioned techniques. Jafari et al. [55] then used a pre-processing approach to start the image analysis as such the pixels are smoothed so that the extracted edges will be larger with reduced noise artifacts such as hair. Then, each pixel of the pre-processed image is fed into the FCNN to obtain 98.5% accuracy and 95% sensitivity performance.

TABLE III. COMPARISON BETWEEN CONVENTIONAL METHODS AND INTELLIGENCE-BASED METHODS FOR SKIN LESION SEGMENTATION

Techniques	Description	Advantages	Disadvantages
Edge and region-based method [46], [47]	This method performs edge detection first, followed by detecting and linking the edge pixels to form connected contour. Then, region identification is done by comparing surrounding pixels that have comparable grey levels.	This method performs very well, whereby the algorithm rapidly converges when a massive number of dermoscopy images is used for training.	Requires extensive computational resources since this technique utilizes pixel level information with the presence of noises.
Threshold-based method [48]	The lesion will be removed from the background skin in the image using the thresholding approach, followed by analysis on blue channel image.	Easy to implement and extremely fast.	This method does not perform well since it is sensitive to noises.
Intelligence-based method: - ANN models [49] - Genetic Algorithms [50], [51] - Fuzzy C-Means (FCM) [52]	The system is based on artificial intelligence approach, which is the most popular approach in automated dermatology field. This approach can better inform the patients on the state of skin lesion by increasing the sensitivity and accuracy of skin lesion examination.	Less costly and fast computational time during inference stage.	Difficult to obtain prior information on the number of clusters due to skin lesions complexity.
Deep Learning: - Fully Convolutional Neural Network (FCN) [53]–[55] - U-Net [56]–[58] - Deep Residual Network [59]–[61] SegNet [62], [63]	Deep learning can learn optimal hierarchical features from the raw images directly rather than hand-crafted features by the network designer.	Perform end-to-end learning where raw data will be processed into network, whereby the network learns for optimal automation of the task.	Requires large memory storage and more expensive computation compared to other methods.

2) *U-Net architecture*: U-Net was inspired by the FCNN, which consisted of equal distribution of encoder and decoder paths, coupled with few feedforward layers. In addition, pooling layers are used to down-scale the encoder feature maps, while standard interpolation is used to up-scale the decoder parts. Moreover, in between the encoder and decoder paths, there are shortcut skip connections. U-Net has become a well-known architecture after it has achieved outstanding segmentation performances in various medical applications with limited training datasets. Many recent studies have also been conducted based on this architecture for skin lesion segmentation purposes. Skin lesion segmentation performance was improved by adding dilated convolution and batch normalization layers to the U-Net architecture as proposed in [56]. Moreover, Iranpoor et al. [57] have proven that the modified U-Net has significantly improved the architecture efficiency by utilizing a pre-trained ResNet model in the encoder path. According to [58], the SkinNet system is also based on a modified U-Net architecture but uses dilated convolution to improve the encoder branch. Fig. 6 shows the modified U-Net architecture for improved segmentation performance.

3) *Deep FCRN*: The deep residual network is a unique network invention that uses skip connections to jump over some convolutional layers to build a pyramid-like structure. Generally, it consists of multiple feedforward convolutional

layers. A fully convolutional residual network was developed in [59] to segment skin lesions in dermoscopic images. This method proposed a deep CNN model with an effective training process that can be used to evaluate complex medical images. Li and Shen [60] have used the fully convolutional residual network to develop the lesion index calculation unit in 2018 for skin lesions segmentation. Besides that, Nathan and Kansal [61] have suggested a base of U-Net architecture with deep residual units as the backbone of encoders and decoders. Each downsampling block consists of one convolutional layer and two deep residual units to improve skin lesion segmentation performance.

4) *SegNet architecture*: This architecture is based on a deep neural network with a straight flow of an encoder network followed by a corresponding decoder network, whereby the final layer is formed for pixel-wise classification tasks. The feature maps are produced by implementing convolution with a filter bank in each encoder network. Additionally, a recent study in [62] has proposed a modified SegNet for skin lesion segmentation. The authors have reduced the total learned parameter of the architecture by lowering the downsampling and upsampling layers of the original SegNet. Similarly, the work in [63] has utilized the SegNet architecture in skin lesion segmentation application and has been found to be accurate based on PH2 dataset testing.

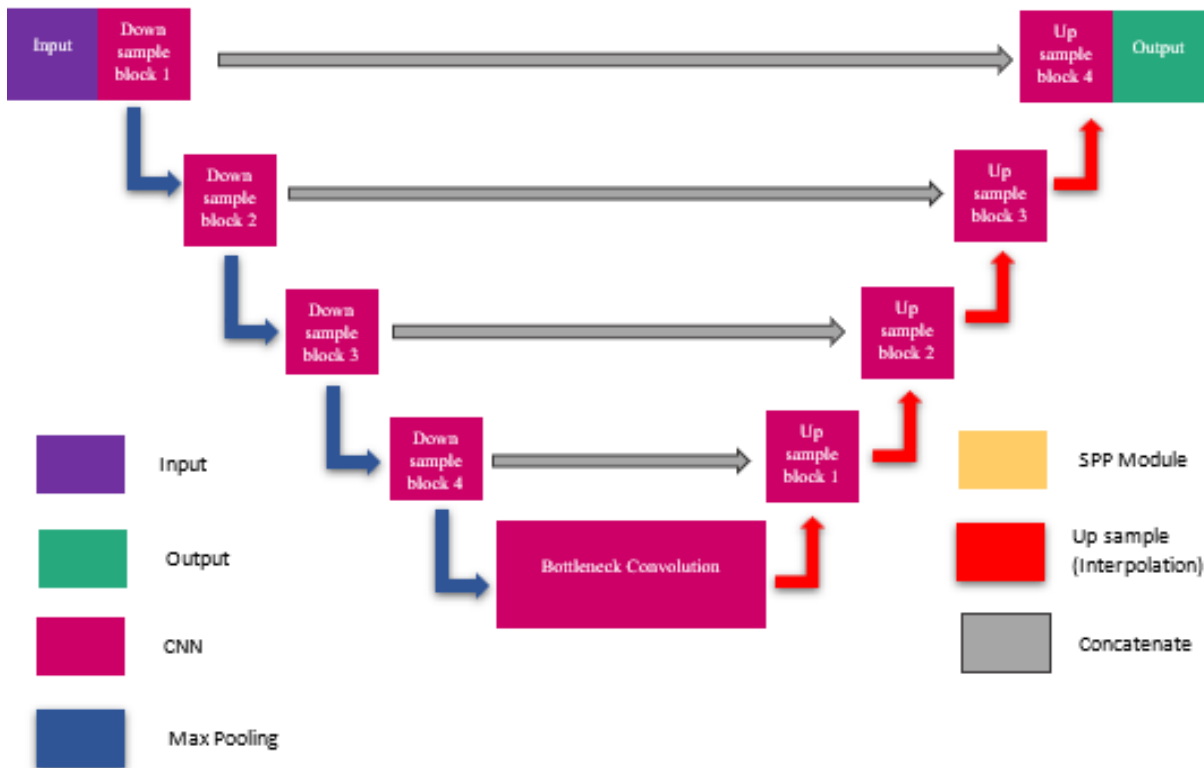

Fig. 6. Workflow Diagram of the U-Net Architecture.

## V. CONCLUSION

This paper presents a comparative study of state-of-the-art techniques, models, and methodologies for analyzing skin lesion images. This study has described the analysis process of skin lesions from segmentation to classification. Recently, researchers have paid more attention and effort into improving the accuracy of the diagnosis of skin lesions. However, some challenges remain difficult, especially in the interpretation of dermoscopic skin lesion images that contain noises such as bubbles, blood vessels, and hair. On the other hand, owing to the newest advancements in deep learning and its exceptional achievement in medical imaging, performance assessment of the deep learning approach for skin lesion segmentation and classification is worth to be reviewed. In this regard, state-of-the-art CNN models such as ResNet, Inception, Xception, DenseNet, and EfficientNet have generally shown excellent performances. However, these models require extensive computational resources with a long time to reach an optimal convergence state. This paper summarises the most important developments in this field and provides a complete discussion of the current approaches. Deep learning framework capabilities combined with pre and post-processing approaches are expected to improve future results and open the path for trustworthy screening and diagnostic systems.

Further research works should be tested using multiple open datasets to allow for better comparison. Besides that, more variations on the skin tone should be validated as most of the existing datasets are focusing on individuals with fair skin tones. Therefore, skin lesions with dark skin tone datasets also should be developed to produce a more robust testing platform that consists of all skin color types. A comprehensive analysis of various segmentation algorithms must be performed on the same dataset to achieve better accuracy, so that reliable results can be obtained. After that, a performance comparison of classification and segmentation models should also be tested on the same data set to produce a fair baseline model comparison.

## ACKNOWLEDGMENT

The authors would like to acknowledge funding from Universiti Kebangsaan Malaysia (Geran Universiti Penyelidikan: GUP-2019-008) and Ministry of Higher Education Malaysia (Fundamental Research Grant Scheme: FRGS/1/2019/ICT02/UKM/02/1).

**Abstract**—Games are a unique, interesting, and fun entertainment medium. Games can contain education, introduction to certain flora and fauna, work and daily life, intelligence and dexterity. The game built in this study aims to introduce the flora and fauna found in the forests of East Borneo (Kalimantan), Indonesia as the object of a platform game. Games are built using the Game Development Life Cycle method in order to make good and organized games. The GDLC method contain 6 stages, first is the initiation for the initial idea, second is to preproduction for the asset creation, third stage is production for the system creation, fourth is the testing for the trial, fifth is the beta for the external trial, and the sixth stage is to release for publication. The results of the study resulted in the Borneo Wildlife game platform. This game introduces the unique flora and fauna in East Borneo, Indonesia, such as Black Orchids, Ironwood trees, Proboscis monkeys, Mahakam dolphins and Hornbills, as well as how to protect and preserve their nature. The game received 46 downloads from March 1, 2021 to May 24, 2021.

**Keywords**—Game development; Kalimantan; Borneo; wildlife game

## I. INTRODUCTION

The island of Borneo (Kalimantan) is one of the five largest islands in Indonesia, in addition to the island of Sumatra, the island of Sulawesi, the island of Java and the island of Papua. The island of Kalimantan or internationally known as Borneo, is the third largest island in the world, with an area of 748,168 km<sup>2</sup>. The island of Borneo is surrounded by the South China Sea to the west and north-west, the Sulu Sea to the north-east, the Sulawesi Sea and Makassar Strait to the east and the Java Sea and the Karimata Strait to the south. On the island of Borneo there are 3 countries; Indonesia (73%), Malaysia (26%) and Brunei Darussalam (1%). The Indonesian provinces of North Kalimantan, South Kalimantan, East Kalimantan, West Kalimantan, and Central Kalimantan make up the southeastern part of the island [1-4].

The island of Borneo is dominated by tropical rain forests. In fact, in the midst of rampant deforestation, as much as 50% of the Kalimantan area is still a tropical rain forest area. Local problems that exist on the island of Kalimantan are illegal logging, forest fires and poaching of protected animals [3-4]. So in the design of this game, besides aiming to introduce flora and fauna, it also teaches the community how to protect the forest and protect the wildlife in it from damage and poachers. This is the map of Kalimantan shown in Fig. 1.

In this study, Game application was chosen to introduce the natural wealth on the island of Borneo. The game application was chosen because it is interesting, many users from the

younger generation like it, and it is a fun learning media to introduce the unique flora and fauna on the island of Borneo, for example hornbills, Mahakam dolphins, black orchid flowers, Ulin trees, orangutans and long nosed monkeys or proboscis monkeys [3-8]. All the uniqueness of the flora and fauna can be used as the object of the story, can be introduced to the world and can make local games more interesting. In the Fig. 2 we can see Hornbills, Proboscis monkeys, Black Orchid flowers, Ulin trees, and Mahakam dolphins as Gallery Item.

Fig. 1. The Map of Kalimantan (Borneo) [2].

Fig. 2. Hornbills, Proboscis Monkeys, Black Orchid, Ulin Trees, and Mahakam Dolphins.

The purpose of this research is to produce a game with the platform "Borneo Wildlife" with the theme of flora and fauna of Borneo and the application of the Game Development Life Cycle method (GDLC) method. This method is used to develop games with a standard flow of game development in general, starting from the planning process to the release process to

\*Corresponding Author

make it easier to produce or develop a game [9-12]. The details methodology steps to develop this game presented in Section II, which has 6 stages, namely initiation for the initial idea stage, preproduction for the asset creation, production for the system development, testing for the internal tester, beta for the external tester, and release for the game publication [9-12]. Section III focuses on result and discussion for this research. Furthermore, the game application testing explained in details in Section IV. The last Section is Section V is for conclusion and future works of this study.

## II. RESEARCH METHODOLOGY FOR GAME DEVELOPMENT

The method used in this study is the Game Development Life Cycle method which has 6 stages, namely 1) initiation for the initial idea stage, 2) preproduction for the asset creation stage, 3) production for the manufacturing stage system, 4) testing for the trial phase, 4) beta for the external trial phase, and 5) release for the publication phase [10-15]. We can see the stages of game development as shown in Fig. 3.

### A. Study of Literature

This stage searches and reads previous research literature related to develop the game, such as reading information about the flora and fauna typical of Kalimantan, system development methods, game engines used, and information about game platforms, stages of development and system testing method.

There was many research on the game development especially about the methodology for the game development [15-25]. From various existing research, we study, compare and try to analyze the suitable method to develop the game application for this work. The result from the literature review process, we found important stages to develop a game application and we use 6 general stages of the game development that already explained in the beginning of Section II.

Fig. 3. The Stages of Game Development.

### B. Initiation

In this research, a Game with the Platform genre is built where players pass obstacles and defeat existing poachers. The background of this game is to introduce the flora and fauna of Kalimantan Indonesia. The concept of this game is that the player will control a character where to move to the next level the player must find a way and defeat the existing poachers. For age restrictions, this game can be played at all ages. The game will have 6 levels, where there are 2 different levels, namely a special bonus level, and a special level against the last poachers.

This game is built using the Unity game engine with the target device being an Android smartphone device. Some of the features in this game are:

- 1) Single Player Games.
- 2) Game can save player progress
- 3) Game has touch control.
- 4) The game has a gallery feature where there is info on the flora and fauna of Indonesian Borneo.
- 5) Players can adjust the sound volume in the game.

### C. Pre-Production

At this stage, the initial game design stage will be carried out, such as creating stories, game rules, determining the software to be used, creating and finding assets, making level designs, game displays, in-game items, and in-game buttons [26-28].

- 1) The draft Story of Game Borneo WildLife is as follows:

The main character is a forest ranger named Agus, ordered by his superior named "Mr. Fery" to solve the problem of existing illegal loggers. Agus was then given 3 main orders by Mr. Fery, namely, destroy the wood machine, destroy the bulldozer, and defeat the leader of the illegal loggers. After that, Agus began to do his first task, namely destroying wood machines, while on his way Agus saw animals such as hornbills and dolphins. Then Agus saw a woodworking machine and smashed it. After destroying the woodworking machine, Agus continued his task of finding bulldozers and destroying them. Then Agus found the Bulldozer engine and then destroyed it. In the end, Agus' task reached the last one, which was to defeat the leader of the loggers, then Agus met the leader of the illegal loggers named Jono, and Agus defeated him. Finally, the forest was spared from the threat of illegal loggers and finished.

- 2) Game rules:

- a) If the player's HP runs out then the game ends.
- b) If the player falls into the water (not included in the bonus level) then the game is over.
- c) The player can go to the next level when the player defeats the boss or reaches the level finish point.
- d) Players will get 1 medkit to replenish HP when players collect 10 coins.

3) Software to be used:

- a) The Game Engine to be used is Unity 2020.01.b8.
- b) Software that will be used as asset creation is Aseprite and PS.

4) Image assets:

a) TileSet

This asset is an asset that will be used for making levels in this game shown in Fig. 4.

Fig. 4. TileSet.

b) Control User Interface (UI)

This asset is the asset that will be used for the creation of the player UI control buttons shown in Fig. 5.

Fig. 5. UI Control.

c) Status UI

This asset is an asset that will be used for making UI status of players and enemies in this game such as UI health of players and bosses shown in Fig. 6 and shown in Fig. 7.

Fig. 6. Icon Medkit, Health Effects and Player HealthBar.

Fig. 7. Boss HealthBar.

d) Menu UI

This asset is an asset that will be used for the creation of the main menu UI in this game shown in Fig. 8.

Fig. 8. UI Menu.

e) Gallery Icon UI

This asset is an asset that will be used for making the Gallery Menu in this game shown in Fig. 9.

Fig. 9. Icon Gallery Item.

f) Title UI

This asset is an asset that will be used for making the title and menu background in this game. The image of the dolphin used for the gallery description shown in Fig. 10 and shown in Fig. 11.

Fig. 10. Background Menu.

Fig. 11. Game Icon and Game Logo.

g) Animation Spritesheet

This asset is an asset that will be used to create animated characters, enemies, and entities in this game shown in Fig. 12 to 19.

Fig. 12. Player Spritesheet Animation.

Fig. 13. Enemy Spritesheet Animation.

Fig. 14. Lumbermachine Spritesheet Animation.

Fig. 15. Bulldozer Spritesheet Animation.

Fig. 16. Proboscis Monkey Spritesheet Animation.

Fig. 17. Pesut Spritesheet Animation.

Fig. 18. Spritesheet Animation.

Fig. 19. Coin Spritesheet Animation.

5) Audio assets are obtained from:

- a) Mixkit <https://mixkit.co/free-sound-effects/>
- b) RPG music pack <https://svl.itch.io/rpg-music-pack-svl>

6) *Display game design:* The main menu will display several options such as play to play the game from the beginning shown in Fig. 20, continue to continue the progress of the game, gallery to display the gallery menu shown in Fig. 21, settings to display the configuration menu, and exit to close the game application.

Fig. 20. Main Menu.

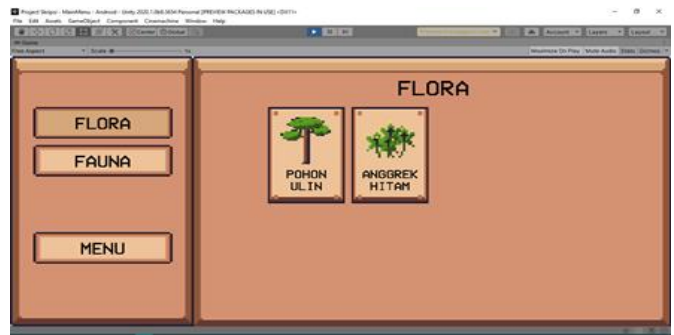

Fig. 21. Gallery Menu.

Fig. 22. Gallery Description.

In the gallery menu, players can see information on the flora and fauna in this game, such as descriptions and original pictures of the flora and fauna shown in Fig. 22.

Fig. 23. Settings Menu.

In the settings menu, players can adjust the volume and sound in the game shown in Fig. 23.

Fig. 24. The Gameplay Menu.

The gameplay view of the game shown in Fig. 24 includes several UIs such as player HP information, coins and medkits, and several UI control Mobile players such as left and right motion buttons, jump buttons, slingshot buttons, medkit buttons, pause buttons, and stick buttons to hit shown in Fig. 25.

Fig. 25. Pause Menu Display.

Pause display when the player presses the pause button.

Fig. 26. Gameover Menu.

Gameover display when the player's HP hits 0 or when the player falls into the water shown in Fig. 26.

7) Items inside the game shown in Table I.

TABLE I. ITEMS IN THE GAME

Name	Symbol	Function
Coin		If the player collects 10 coins, then the player will be given 1 medkit.
Medkit		Medkits can be used to restore blood to the player character.
Movement		To move the character right or left
Pause		To pause the game
Attack		Command the character to attack using the stick
Jump		Character command to jump
Ranged Attack		Command the character to attack using the catapult
Attack		Command the character to attack using the stick

#### D. Production

At this stage, the author begins to build a game system, such as creating a game plot, creating level designs, and creating a gameplay system shown in Fig. 27.

1) *Game system flowchart*: The game will display the main menu when it is first opened, there are several options on the menu such as play to start the game from the beginning, continue to continue the game based on player save data, gallery to display information on flora and fauna in the game, settings to display the settings menu games such as game volume settings, and exit to close game applications shown in Fig. 28.

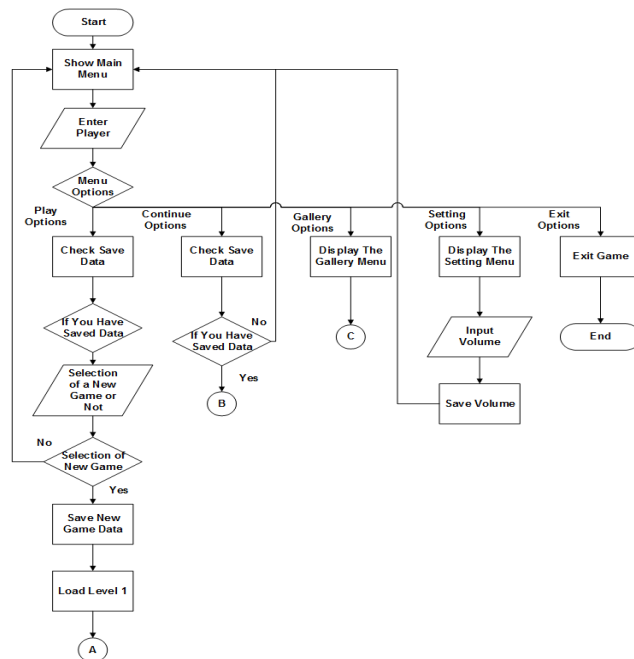

Fig. 27. Flowchart of the Game Menu.

Fig. 28. Flowchart of Gameplay Flow when Conditions Win

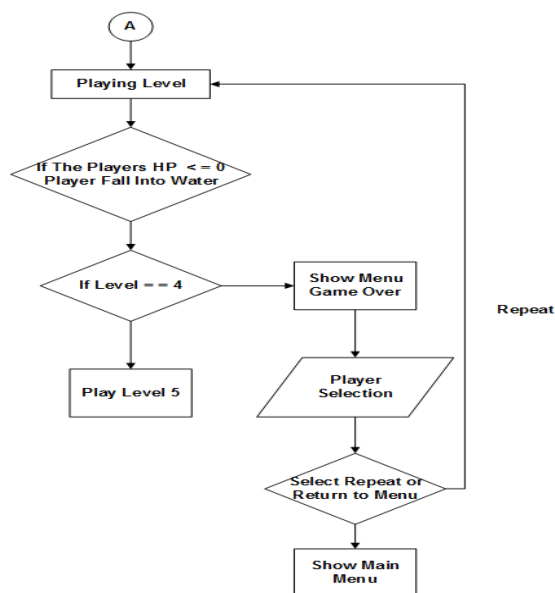

Fig. 29. Flowchart of Gameplay when Losing Conditions.

When loading a level, the game will check the existing save data and load the level based on the existing save data, players can complete the level by defeating the boss or reaching the end point of the level. By the time the player has completed level 6 then the game will be over and over shown in Fig. 29.

When the player's HP reaches 0 or falls into the water, the game will display a game over display with two options, namely to repeat or return to the initial menu, except for level 4 conditions where if the player falls into the water or HP reaches 0 then the player can continue to level next shown in Fig. 30.

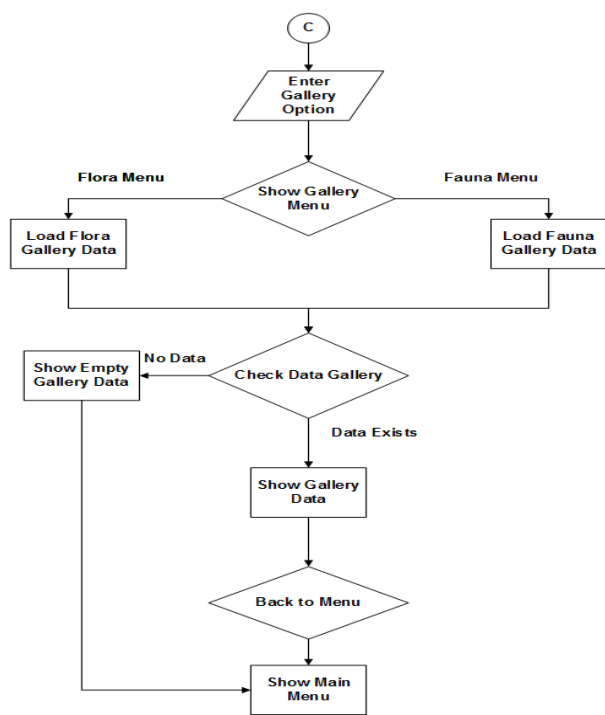

Fig. 30. Flowchart Gallery Menu.

### E. The Testing Stage

At this stage a trial is carried out from internal users who will test the game using the provided instruments, assessing the game's function and game balance. The results of these trials are bug reporting, change requests, and video game development decisions. The details explanation about the testing process will explain on the part IV Application Testing.

### F. Beta Stage

The beta stage requires external testers as game users and assesses the success rate of games that have been built before being released to the public. They tested whether changes to the features or gameplay were needed, whether there were still weaknesses in each level of the game. If there are still weaknesses, the GDLC cycle can be repeated. The details explanation about the Beta version will explain on the part IV Application Testing.

### G. Release Stage

This stage is the completion of the video game that has been built and is ready to be released. The details explanation about the release version will explain on the part IV Application Testing.

## III. RESULT AND DISCUSSION

When opening the gallery menu, the game will load the flora and fauna gallery save data that has been opened by the player's progress and display it.

1) *Design level*: Design Level 1 shown in Fig. 31 which is the first level, at this level there are new flora, namely ironwood trees and black orchids, there is a new fauna namely hornbills, at this level there are also 32 coins, 1 moving platform, 7 enemies, 1 boss which is a machine wood, and 5 dialogues which include 1 dialogue at the beginning of the conversation game between Agus and Pak Fery, 1 dialogue when seeing a hornbill for the first time and 3 dialogues for how to play this game.

Level 2 designs, at this level there are 39 coins, 4 moving platforms, 11 enemies, and 2 dialogues including 1 level 2 opening dialogue and 1 dialogue when level 2 is finished.

Level 3 design, at this level there is a new fauna, namely the Mahakam dolphin, at this level there are also 28 coins, 8 moving platforms, 12 enemies, 6 entities of which there are 4 dolphins and 2 hornbills, 1 boss, namely a bulldozer, and 2 dialogues including 1 dialogue when you see the Mahakam dolphin, and 1 dialogue when you meet the bulldozer boss.

Level 4 designs, this level is a bonus level where there are only 24 coins and 28 platforms that can fall. At this level there are no conditions that make the game over.

Fig. 31. Design Level 1.

Fig. 32. Design View Level 6.

Design Level 5, at this level there is a new fauna namely Proboscis monkeys, at this level there are also 27 coins, 36 enemies, 6 entities namely proboscis monkeys, and 3 dialogues including 1 dialogue when entering this level, 1 dialogue when viewing proboscis monkeys and 1 dialogue when this level is finished.

Design Level 6 shown in Fig. 32, which is the last level in this game, this level is specifically only against the last boss, namely Jono, the leader of the illegal loggers. At this level there are also 2 dialogues, namely when entering this level and at the time after defeating Jono.

2) *Game system creation*: The basic character behavior that can be done by players, namely hitting, jumping, using a slingshot, moving right and left, using a slingshot, reducing blood, saving character data is made in 3 scripts, namely Player Behaviour, Player Projectile Behaviour, and Player Scriptable shown in Fig. 33 and Fig. 34.

Fig. 33. Player Movement.

Fig. 34. Player Jump.

Fig. 35. Dialog System.

Fig. 36. Behavior of the Enemy Hitting.

In this game the story will be used in the dialog system shown in Fig. 35, while the dialogue system in this game has several parts, namely the speaker avatar, dialogue text, speaker name, dialogue control and dialogue trigger. This dialogue system is made using 3 scripts, namely Scriptable Dialog, Dialog Manager, and Trigger Dialog.

This game has enemies that can attack the player and can walk up to the player, for an enemy system like this is made using 4 scripts, namely EnemyAttribute, EnemyBehaviour, EnemyMovement\_1, PreventObjectOnPosition shown in Fig. 36.

The bosses in this game have their own uniqueness and behavior, where bosses such as wood machines cannot move but can remove wood, bulldozer bosses that can move quickly to the right and left, and the last boss Jono who can call for reinforcements. For making the boss, it is necessary to use enemy scripts and 5 additional scripts, namely 2 scripts for the wood machine boss, 2 scripts for the bulldozer boss, and 1 script for the last boss Jono shown in Fig. 37 and Fig. 38.

Fig. 37. Wood Machine Boss.

Fig. 38. Bulldozer Boss.

Fig. 39. Platform System.

Fig. 40. Dolphin.

The platform system shown in Fig. 39, can move as a player challenge which is made using 2 scripts, namely FallPlatform, and PlatformScript. For the next level system, game over, pause, save data, audio sound effect settings, gallery and UI related, 11 scripts are needed, namely, 3 scripts for UI which include GalleryMenu, HealthUiScript, UIControl, and 8 scripts for game manager including AddToGallery, AudioAmbienceSettings, AudioSettingsUI, GalleryScriptable, GameManager, SaveManager, SceneManagement, and SoundManager.

For AI entities, hornbills and dolphins need 2 scripts, respectively, namely hornbill behavior and dolphin behavior shown in Fig. 40.

#### IV. APPLICATION TESTING

##### A. Blackbox Testing

The game will be tested by the developer using the Blackbox testing method to see if the various scenarios and functions in the game are running properly. Testing is carried out using the blackbox testing method that focuses on the user's perspective and divided into testing Blackbox UI main menu (Table II), testing Blackbox UI gameplay (Table III), testing Blackbox gameplay scenario (Table IV), and testing for the device (Table V) [26-30].

TABLE II. TESTING BLACKBOX UI MAIN MENU

Scenarios	Success Indicator	Status
Play button on menu (When no save data)	level 1	Success
Play button on menu (When have save data)	Displays the display to create a new save data or not	Success
Continue button on menu (When having save data)	Loading game level according to save data Success	Success
Continue button on menu (When having save data)	level 1	Success
Gallery button on the menu	Displays a display to view fauna and flora gallery data from save data	Success
The flora button in the gallery	Displays a list of flora gallery items	Success
Fauna button in gallery	Displays a list of fauna gallery items	Success
Items in the gallery	Displays a description of the clicked gallery item	Success
Settings button on the menu	Displays the settings	Success
Volume slider in settings menu	Change game sound volume	Success
Toggle enable sound in settings menu	Turn game sound on or off	Success
Exit button on the menu	Exit the game application	Success

TABLE III. TESTING BLACKBOX UI GAMEPLAY

Scenarios	Success Indicator	Status
Move button to the right	Character goes to the right	Success
Move button to the left	Character goes to the left	Success
Jump button	Character jump	Success
Stick button	Character hit	Success
Slingshot button	Character attacks with slingshot	Success
medkit button (when having a medkit)	Replenish the character's HP	Success
Pause button	Pauses game	Success
Continue button on pause	Continue and stop pause in game	Success
Menu button on pause	Return to main menu	Success
Retry button on game over	Repeating the game at that level	Success
Menu button on game over	Return to main menu	Success

TABLE IV. TESTING BLACKBOX GAMEPLAY SCENARIOS

Scenarios	Success Indicator	Status
Fall into the water (except level 4)	Display game over	Success
Player's HP 0	Displays game over	Success
The player hits the enemy or the enemy's catapult.	The enemy takes damage	Success
Enemy hits player	Player takes damage	Success
Players take coins	Player coins increase	Success
Players take coins to 10	Players get medkits and coins return to 0	Success
Level completed	Checkpoint move to next level and save data	Success
Game over (level 6 completed)	Checkpoint move to level 1 and save data	Success
Player reaches the end of the level (level 2 and 5)	Displays the completed level display	Success
The player defeats the existing boss (level 1, level 3, and level 6)	Displays the completed level	Success
Dialog display appears	Character stops	Success
Screen is touched when dialog appears	Displays next dialog	Success
Touch screen when dialog ends	UI will disappear	Success

TABLE V. TESTING THE DEVICES USED BY THE GAME

Device	Specification	Status
Xiaomi redmi note 7	Android 10, Ram 4GB, Resolusi 1080x2340	Runs smoothly
Advan i5c plus	Android 7.0, Ram 2GB, Resolusi 1280x720	Runs smoothly
Nokia 5	Android 7.1, Ram 3GB, Resolusi 1280x720	Runs smoothly

##### B. BetaTesting

The game will be shared to itch.io using a link and with open beta conditions so that the beta version can be played and tested directly by players, in order to get input or bug reports that the developer did not find. The beta lasts for 2 months from March 11<sup>th</sup>, 2021 to May 20<sup>th</sup>, 2021. The target game tester is university friends or gamers from outside to get better

input. The minimum number of players is 10. The players will fill out a form, which contains suggestions and input that has been provided in the game description, through the 8 question tables that have been provided. Here are the results of the beta input from some players:

Fig. 41. The Results of the Level Input that have been Completed by the Tester.

Based on Fig. 41, it can be concluded that there are 5 testers who cannot even pass the first level and there are 3 testers who can finish this game.

TABLE VI. UI EXPERIENCE TESTER INPUT RESULTS

UI Experience	Number of Respondents
Great	8 people
Average	6 people
Bad	0
Terrible	0

Based on Fig. 41 and Table VI, it can be concluded that more than 50% of the testers were very satisfied with the UI display in the game.

TABLE VII. RESULTS OF INPUT CONTROL AND UI TESTER

No.	Feedback control and UI Tester
1.	Great, easy to understand, the function of each icon is clear.
2.	For people who have never played the game, it's fun and easy to use
3.	Sometimes it's a bit hard to control the character, UI is standard like other game
4.	Good
5.	Average, not good not so bad
6.	It's good because it works as it should
7.	There is a lack of control, namely when jumping, you can't shoot with a slingshot at the same time. It has a retro atmosphere. And the lack of in-game map instructions is still not available.
8.	the control feels great and the UI fits perfectly for mobile devices
9.	Safe and comfortable, fits well on the thumb.
10.	Reasonable
11.	The UI appearance is good, for control there are still touches that need to be improved again.
12.	Already good
13.	I like the UI design, it looks fresh and the colors chosen are good and match the theme (especially the trees and proboscis monkeys), but for some dialogs there are typos! The controls were a little less smooth as expected and therefore it was a bit difficult for me to complete the levels (especially at level 3, when I first encountered the Mahakam dolphin) and hopefully in the future I can punch or shoot enemies while walking! Because it's so hard to have to stop walking before you can hit! But overall it's a great UI and I love it! (P.S. hopefully in the future I can see my favorite animal (aka Crocodile) on there)
14.	UI controls can be replaced with analog or can choose between analog and buttons

Based on Table VII, it can be concluded that the tester likes the existing controls and UI and can be developed even better.

TABLE VIII. INPUT RESULTS ABOUT ENEMY AI BY TESTER

Enemy AI Experience	Number of Respondents
Great	8 people
Average	6 people
Bad	0
Terrible	0

Based on Table VIII, it can be concluded that the tester is quite satisfied with the existing enemy AI

TABLE IX. RESULTS OF INPUT CONTROL AND UI TESTER

No.	Feedback enemy AI Tester
1.	The enemy continues to follow the player even if he is not looking at the player (on the platform above or below the player)
2.	Pretty fun
3.	As expected, not too hard and not too easy
4.	Good
5.	Need more alive
6.	Here we cannot walk through the water but must be jumped and the enemy can be Diageo and stop when the enemy is too far from us
7.	The enemy is quite aggressive, the damage is also very strong.
8.	The AI for the enemy is great! but the difficulty for the bosses is too hard for the people who play it at first
9.	safe
10.	Can you give some coin after we killed the enemy?
11.	For the AI aspect, it's pretty good
12.	Already good
13.	I think the enemy is not bad (not easy and not too difficult), but for the boss level, it's really difficult and I think there's a bug when we accidentally jump over and get stuck with the boss, we can't help but quit the game and start over.
14.	But overall I enjoy preventing the enemy from destroying the forest to save our Kalimantan!
15.	Ordinary

Based on Table IX above, it can be concluded that the tester has various inputs about the AI in this game and the playing experience is quite different.

TABLE X. GALLERY MENU INPUT RESULTS BY TESTER

Knowing There's Gallery Menu	Number of Respondents
Yes	12 people
No	2 people

TABLE XI. GALLERY MENU INPUT RESULTS BY TESTER

No.	Gallery Information Tester Feedback
1.	Information for flora and fauna is quite complete and interesting.
2.	Very helpful
3.	Quite informative
4.	Good
5.	The gallery menu is quite interesting because we can see a pixelate version of the flora and fauna in Kalimantan and not only that, when the flora and fauna image is clicked it will display more info about the flora and fauna.
6.	it is informative, it has great description and picture to describe the flora and fauna in Kalimantan
7.	the information is complete enough
8.	In my opinion it is very informative but the number of flora and fauna is still small but it doesn't matter.
9.	I like it the design is great and hopefully in the future add more flora and fauna!
10.	The information provided is quite informative and accurate.

Based on Table X above, it can be concluded that more than 80% of testers know that this game has a gallery function to introduce flora and fauna on the Borneo Island.

Based on Table XI above, it can be concluded that the testers already liked the information about flora and fauna displayed on the gallery menu in the game.

TABLE XII. RESULTS OF INPUT, SUGGESTIONS, BUG REPORTS

No.	Tester suggestion, feedback, and bug report
1.	Sometimes when I'm on top of the enemy, the right and left directional buttons don't work, so I have to reset the level.
2.	Need a final look where animals are not scared, get stuck again while finishing the game
3.	Maybe a more minimized dialogue
4.	Sometimes I got stuck when jumping on enemy Other than that maybe you can add achievement system or time attack stage, and English version? Nice game
5.	Very good improve
6.	Bug when player jump above the enemy,
7.	I need a skip tutorial button
8.	A checkpoint needs to be made, so it's not too far to repeat it. Same controls shooting catapults while jumping are made.
9.	It is great! Only minor bug! other than that maybe the font in game seemed too "office" style, try to use more pixelated font for dialog.
10.	When stepping on the enemy (which is normal), there it stuck.
11.	Upgrade control. Get more coins by killing the enemies. Change agus's shirt colour. Tap twice for higher jumping. More damage weapon.
12.	Controls & bugs overhead
13.	I found a bug where people can get stuck and can be crushed if hit by wood that rotates up and down.
14.	add crocodile, thanks
15.	Bug: there is a bug when jumping and landing on the enemy's head Suggestion: -Information in the gallery can be added with information about why the animal/fauna is threatened with extinction, or the bad impact caused if the animal/fauna is threatened or extinct. -Level 4 gameplay is too repetitive, too many NPC Enemy which makes insufficient blood supply. -variation of animals/fauna can be added again

Based on Table XII above, it can be concluded that most of the testers had problems when players were at the head of the enemy causing bugs, this can be fixed in the next iteration of the GDLC cycle before it is released.

### C. Gameplay System Revision

Based on the bug report given by the tester, it was more inclined towards a problem where when the player was above the enemy's head causing a problem, then a fix was made for this problem in the game system changes and there was an iteration of the GDLC method, the developer then fixed this problem by making the player move. Penetrate past the enemy so that the previous problem will not occur again with duration of 5 days from May 20<sup>th</sup>, 2021 to May 24<sup>th</sup>, 2021.

### D. Release

After going through the cycle of making, repairing, and following input from several testers. Finally, the game enters the final stage, which is a release that is ready to be released on Itch.io by changing its status from in development to release on May 24<sup>th</sup>, 2021; the download link for this game will be shared to several social media such as Facebook and Instagram. The game received 46 downloads from March 1<sup>st</sup>, 2021 to May 24<sup>th</sup>, 2021 shown in Fig. 42.

Fig. 42. Borneo Wildlife Download Statistics.

The rating of this game refers to the ESRB at the following link <https://www.esrb.org/ratings-guide/>, namely with a rating of all ages, because it does not contain abusive language and violence.

Fig. 43. Rating Images for All Ages.

## V. CONCLUSION

Based on the results of research that has been carried out in the design and development of the game "Kalimantan Wild Life", the author draws several conclusions, namely the research produces a game platform "Borneo Wildlife" with the theme of flora and fauna on Borneo Island, Indonesia, the design and manufacture of the game "Borneo wildlife" has passed the stages of the GDLC method with the longest phase being the Beta test for 2 months, and the shortest phase being the release for 1 day. In the development of the game "Borneo Wildlife" a revision was made to provide a better playing experience from the considerations and inputs of the existing testers. The future work from this study is to analyze the impact of this educational game because of the main expectation of this game is to introduce the flora and fauna in the Borneo island to the world and give positive impact to the young generation.

**Abstract**—Content Delivery Network (CDN) offers faster transmission of massive content from content providers to users using servers that are distributed geographically to offer seamless relay of service. However, conventional CDN is not capable of catering to the larger scope of demand for data delivery, and hence cloud-based CDN evolves as a solution. In a real-world scenario, each requested content has different popularity for different users. The problem arises with deciding which content objects should be placed in each content server to minimize delivery delays and storage costs. A review of existing approaches in cloud-based CDN shows that yet the problem associated with content placement is not solved. In this regard, a precise strategy is required to select the contents objects to be placed in a content server to achieve higher efficiency without affecting the CCDN performance. Therefore, the proposed system introduces a novel architecture that addresses this practical problem of content placement. The study considers placement problem as optimization problem with the ultimate purpose of maximizing the user content requests served and reducing the overall cost associated with content and data delivery. With an inclusion of a bucket-based concept for cache proxy and content provider, a novel topology is constructed where an optimal algorithm for placement of content is implemented using matrix operation of row reduction and column reduction. Simulation outcome shows that the proposed system excels better performance in contrast to the existing content placement strategy for cloud-based CDN.

**Keywords**—Content delivery network; content placement; cloud; optimization; data delivery; cost

## I. INTRODUCTION

In the area of Content Delivery Network (CDN), the prime target is to offer a seamless relay of data and services associated with the delivery of contents by the content provider to a destined user [1]. There is various research being carried out towards this purpose while it was seen that it is challenging to offer this service of content delivery to large scale deployment regions by the conventional CDN [2]. Apart from constructing an appropriate CDN system and carrying out explicit maintenance of the distributed storage, followed by the delivery of appropriate content is heavily expensive from content providers' perspective. There is always a dependency of appropriate resources to perform maintenance of such servers [3]. To sort out this problem, the content providers are now seeking an alternative option of hosting the CDN over the cloud environment with much cost-effective solution [4]. Adopting the cloud environment is feasible to offer on-demand

delivery of an appropriate content in much reduced time and at a cheaper cost [5]. At present, data are evolving exponentially with respect to size and complexity, while processing such data is now feasible in cloud computing owing to its capability to offer distributed storage and analytical options more effectively [6]. Existing trends of research also showcase that cloud-based CDN has become a pivotal topic when it comes to content delivery [7]. It is also noticed that the majority of the research work is focused on performing optimization approaches towards solving the problems associated with effective placement of contents in the presence of low usage of resources [8]. Basically, the term resource in this domain of discussion pertains to the quantity of storage that is demanded to be used by the content providers for the Cloud. Out of this, the essential problem is to find out the mechanism of positioning the informative contents over the incorrect server location [9]. The idea is to accomplish the optimal cost of the content delivery system as well as to ensure the minimal consumption of cumulative cloud storage [10]. Irrespective of the availability of various forms of literature towards improving this issue, it is found that the majority of the existing approaches emphasize a specific set of problems with narrowed usage of parameters [11]. However, problems associated with optimizing the storage as the resource are not much addressed in the existing solution. Existing approaches also don't offer a discussion of the inclusion of any user or computing devices and its related connection with the cloud terminals. Therefore, there is a need to carry out an investigation in order to offer a cost-effective solution in terms of modelling content placement approach with a target to offer a higher degree of performance of content delivery in cloud-based CDN. It is also necessary to ensure that the modelling is carried out considering practical constraints that are normally connected to the incoming and outgoing stream of data. Therefore, this paper presents a novel architecture in the form of a framework that is meant for cloud-based CDN with a single target of achieving optimal cost of allocation of resources. The core goal of this study is to ensure optimal performance achievement. The significant contribution of this paper is highlighted as follows:

- A bucket concept is considered which have a caching proxy and content server, with specific storage capacity.
- A novel topology construction is performed using graph theory for the bucket placement that keeps the content server close to the users for faster content access and

cost-effective task allocation under peak traffic conditions. This not only reduces request latency, but also balances the load between content servers.

- The study utilizes node centrality and computes sparsity towards analyzing higher probability of the request and determining efficient localization of content servers hosted overcloud.
- Content placement is considered as optimal assignment problem, which is solved using an explicit function constructed based on the matrix operation with minimum cost.

The organization of the proposed manuscript is as follows: Section II discusses the explicit problem, and their corresponding solution evolved in present times. Briefing of identified issues in existing solutions towards content placement is carried out in Section III. The highlights of the proposed architecture are carried out in Section IV, followed by an elaborated discussion of adopted research methodology in Section V. Discussion of obtained simulation outcome is done in Section VI, while a conclusive summary of paper with respect to its contribution is carried out in Section VII.

## II. RELATED WORK

At present, there have been various works being carried out towards the content-delivery network. Existing approaches have addressed various forms of problems associated with the content delivery network. The most recent work of Qazi et al. [12] has addressed the problem associated with unnecessary caching, leading to cost maximization of various network resources in a content centric network. The work has introduced an optimization concept that minimizes network resources targeting to control the latency and channel capacity. Problems associated with excessive channel capacity usage are also one topic of investigation in existing schemes, which affects the content delivery process over cloud-hosted applications. Research in this direction has been carried out by Khabbiza et al. [13], where the case study of multimedia streaming has been considered. According to this solution, the traffic is directed towards the adjacent node instead of the central server, thereby controlling the servers' load.

The advanced variant of cloud usage, i.e., fog computing, was also used to enhance the content delivery network's operation. The problem associated with cost connected with the content server's placement has been discussed by Liu et al. [14]. According to the author, the existing scheme is not capable of better decision-making considering global dynamics. The authors have used the Q-learning approach to facilitate a significant decision for routing operation over a tree structure. The model performs a selection of paths based on the low cost associated with it for effective content delivery. However, this approach can still not offer much information about the topology, which will affect any form of the pricing scheme.

Moreover, such an approach is not suitable for small-scale content providers. This absence of topological information is discussed by Duan et al. [15] has used a software-defined network where the infrastructure provider hosts the cache

servers. This strategy maintains a balance between the content provider and infrastructure provider.

Further work towards content placement is carried out by Qu et al. [16], where problems associated with backhaul congestion are addressed. The study presented the solution to reduce the delay attribute associated with content delivery where mixed-integer linear programming has been used. Apart from content placement, existing studies were also carried out towards virtual network function, a part of the content delivery system. This completely depends upon the resource availability and its quantity. As per the discussion stated by Benkacem et al. [17], this problem is reported to be solved using their mathematical approach for cost minimization and upgrading quality of experience. The work carried out by Alghamdi et al. [18] has addressed the problem associated with the availability of content by using an improved version of the optimized link-state routing protocol. The study has a joint implementation of caching based on popularity and routing scheme over a cloud-based content delivery network. Similar problems of dedicated transmission of contents have been addressed by Asheralieva and Niyato [19] using game theory to model stochastic network control. The study has also used the Lyapunov optimization approach that emphasizes mobile nodes' activity connected with the operator. Another study carried out by Bosunia, and Jeong [20] addresses the challenges associated with the growing mobile internet market that affects seamless content delivery. The study has presented the usage of content-centric networking to carry out content delivery in the presence of a converged network. A case study of heterogeneous networks with radio access over Cloud is also seen in the literature concerning content delivery network investigation. The importance of using both qualities of wireless channels and their respective connection with the mobile station plays a significant role in improving the content delivery network's performance. The work carried out by Liu et al. [21] has addressed the problem associated with increasing the system's utilization using the belief propagation method. The study also presents a solution towards interference among the cells to resist the mobile station's overload at the remote radio unit. However, the adoption of a radio access network offers a significant issue over the delivery and caching of the contents and the capacity of processing. This problem has been considered in the work of Wang et al. [22], where a zone-based approach has been used for content caching cooperatively. The study has used a heuristic-based cooperation policy to better availability, and the transmission of more massive content is possible.

The existing content delivery network uses cloud radio access to support transmission in a faster network like 5G. However, the conventional caching principle offers degradation in network traffic. This problem is solved in a unique study carried out by Lau et al. [23] that has used content distribution based on humans' mobility patterns—the study aimed for the spatial allocation of radio resources and targets for resource efficiency. The resource provision methods always challenge balancing the war between the under and over-provisioning to handle the trade-off between an uncertain pattern of the user demand and their level of experiences as feedback. The authors, Haghghi et al., 2018, have designed an

optimization model for the resource assignment using Markov principles suitable for the C-CDN[24][25]. The problems associated with responsive factor in content-centric delivery are addressed in the work of Sinky et al. [26], which discusses the importance of using multiple cloudlets with contents and caching policies in a heterogeneous network.

Apart from the content mentioned above, placement approaches and existing schemes have reported various alternative schemes for content placement viz. Approaches for web content delivery for internet architecture of future (Siracusano et al. [27]), caching using the push-based strategy (Fan et al. [28]), hierarchical modelling (Papagianni et al. [29]), preemptive hierarchical approach (Salahuddin et al. [30]), bee-colony optimization algorithm (Ghalehtaki et al. [31]), cache placement approach (Ha and Kim [32]), and network-slicing (Retal et al. [33]). The next section discusses the problems associated with the existing content placement approaches, followed by a proposed solution to thwart this problem.

### III. PROBLEM STATEMENT

After reviewing the existing approaches, the following are the issues explored:

- Less emphasis on Quality of Experience (QoE): Existing studies have implemented a sophisticated mechanism of different types to address the content placement problem. However, these mechanisms do not consider the user's computing and communication device to exercise delivery services. Existing approaches do not offer much scalability concerning QoE regarding peak traffic conditions in both access and core networks.
- Impediment towards heavy file delivery: It is well known that CDN is mainly meant to handle more massive data delivery. However, theories in the paper differ from real-time demands owing to a lack of benchmarking approach. To deal with communication channels with inferior Quality of Service, the transmission rate is reduced to work at a specific limit. However, such approaches are not applicable when it comes to stream real-time multimedia content. Another practical problem is that users are usually considered connected with only one technology of access and hence, the issues shoot up.
- Scheduling of Resources: A specific amount of resources are required to carry out the problem of content placement. Management of resources can be optimized by using resource allocation for controlling cost factors. However, this is not a simplified form of the task as it demands precise information on the topology of the nodes and information by the content providers. Unfortunately, it is not there in the existing system and without which it cannot be deployed over a much complex environment of Cloud.
- Caching Related Issues: While transmitting more massive files or streaming content over the internet, it is essential to reduce the latency/delay. It is also known

that the conventional content delivery network offers varied caching algorithms; however, it is not much considered that this algorithm must be run over edges of the delivery network. This increases the complexity of multi-fold when it comes to cloud computing-based content delivery network. As the scale of deploying content servers extends exponentially when hosted over Cloud, developing an algorithm for caching management over edges is highly a complicated task.

- Ambiguity in cost modelling: There have been various models in existing approaches where cost-related modelling has been carried out. However, considered parameters in cost modelling and its relationship with the content placement problem have not yet been built. At present, the term cost is associated with the financial terms connected with the deployment of services. For effective cost modelling, it is necessary to consider all latent parameters that are the indicators of resource allocation and maintain a good streamline with user and content provider. Such consideration is missing in existing approaches.

All the problems mentioned above are addressed in the proposed system discussed in the next section.

### IV. PROPOSED SYSTEM

The proposed study's primary goal is to develop an analytical framework that could carry out a content placement in a cloud-based content delivery network. The secondary goal is to develop a cost-effective allocation of tasks from the user to the content servers over peak traffic conditions.

Fig. 1 highlights the proposed system's architecture, which shows that the model initiates by taking an input of several requests, bucket formation, and area of deployment. Each bucket is considered to possess a caching proxy and content server with an explicit storage capacity allocated for both of them. The proposed study uses graph modelling for constructing the topology by applying a directional graph where each vertex corresponds to a bucket. Geographical modelling is further carried out considering the domain-based CDN nodes where an orthogonal and symmetric directionality of the node placement is carried out. This directionality attribute plays a vital role in searching for optimal content placement over the buckets. The next step is to construct a proximity priority module where the node centrality is incorporated to understand the node's significance, considering the probability of the request. The traffic stream is judged based on the weight factor associated with the structure of in-degree and out degree nodes. The sparsity computation is carried out to find the best links out of many that lead to the efficient location of content servers hosted over cloud. After this process is carried out, the proximity priority model is executed further, followed by matrix-based operation development to carry out optimal placement using a function for performing allocation and cost estimation. This is based on the allocation of tasks to find an efficient node for content placement in cloud-based CDN. This process's outcome leads to the allocation of the task and the estimated cost of the evaluation. The next section discusses the adopted methodology.

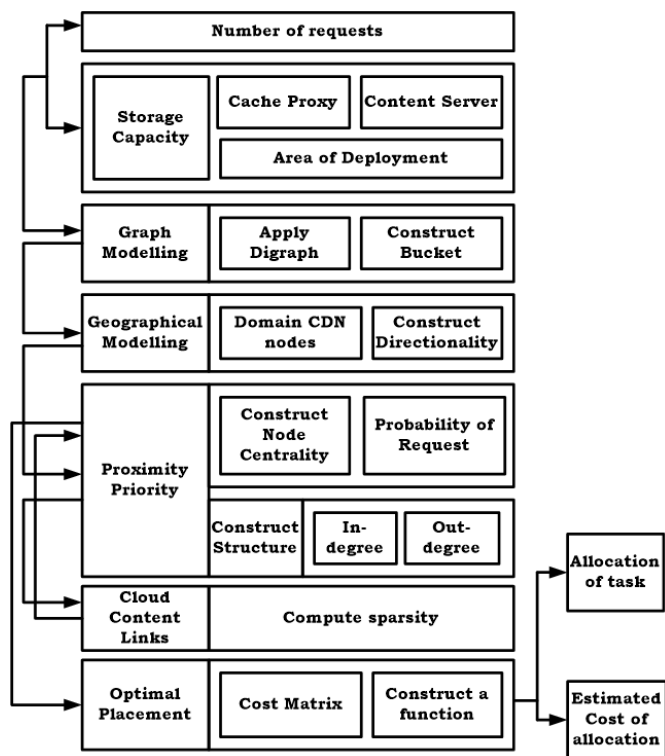

Fig. 1. Architecture of Proposed System.

### V. RESEARCH METHODOLOGY

The proposed research work's prime objective is to ensure that end user is facilitated with a higher degree of service quality using the cloud-based content delivery network's proposed model. The proposed system's solution is based on the appropriate placement of the distributed cloud environment's contents. The idea of the proposed logic is that if the content placement is done accurately in a shared manner, it is feasible to minimize the cost of content maintenance over a server. The proposed system applies a novel optimization approach that can facilitate a better form of content server update and dynamic updating of contents replication. Hence, an analytical research methodology is constructed for this purpose, which can finally ensure a better form of content delivery with a controlled reduction in latency in the content transmission process. This section offers details about the comprehensive process that is adopted for appropriate, cost-effective content placement.

#### A. Topology for Content Placement

According to the novel concept of content placement, the prime logic is to ensure a better symmetry in the node's geographical distribution. In existing times, the content placement is carried out based on the location of users, which is highly a dynamic event. Hence, toggling the location of contents based on user location (mobility) will demand more cost consumption owing to the non-symmetrical locus of the content server. Hence, better symmetric localization of content servers will lead to better delivery performance and better service availability. Therefore, the proposed topology considers the asymmetric distribution of buckets B, as shown in Fig. 2. Buckets are the nodes, which bear all the information

and are directly synched with the cache proxy and content server. The topology also considers a centralized server CN which is equidistant from all the buckets.

The study considers a test region R, which is further classified into *i* number of regions where the placement of the buckets is carried out. It can be empirically expressed as,

$$R_i = \{R_1, R_2, \dots, R_i\}$$

Each region is assumed to consist of buckets B, which will mean that  $B = B_1, B_2, \dots, B_N$ , where  $N=i$ . It is considered that each bucket B has cache proxy C1 and content server C2, which will mean that,

$$B_N = \{(C_{1N})_{ij} | (C_{2N})_{ik}\}$$

In the above expression, *N* represents the total number of buckets, *i* represents several regions, and *j* represents the maximum number of the proxy server while *k* represents the content server's highest capacity. The proposed concept of placement of content on multi-cloud architecture takes 'N' buckets (B) in geographically distributed Data Center (shown as CN in Fig. 1) acts both as Cache-Proxy as well as Content Server. Both of them are interconnected bi-directionally to each other under with a weight (w). The weight (w) is considered a set of the properties {caching, cost, latency, dynamicity/ambiguity, and interoperability}. The context of the  $N=4$  as  $\{B_1, B_2, B_3, B_4\}$  with the connectivity possibility of pair of  $:\{[(B_1-B_2), (B_1-B_3), (B_1-B_4)], [(B_2-B_4), (B_2-B_1)], [(B_3-B_2)], [(B_4-B_3), (B_4-B_1), (B_4-B_2)]\}$  as shown in the Fig. 2.

The respective weight for different capacities of the connection network,  $W = [B_1/3' B_1/3' B_1/3' B_2/2' B_2/2' B_3' B_4/3' B_4/3' B_4/3']$ . The proposed system performs modeling using graphical constructs, i.e.,  $G(V, E)$ , where the vertices 'V' represents the bucket  $B \rightarrow C1/C2$  and the edges 'E' represents connecting links among the respective nodes, is represented in Fig. 3. These associating weights mechanism assists in the proper identification of appropriate links connecting to various buckets that have reduced cost factors involved.

Fig. 2. Proposed Topology of Content Placement.

Fig. 3. Connectivity among the Buckets.

All these forms the shape of the matrix, and the entries of the adjacency matrix take either the complete or a sparse of the numeric data with the input elements of the connections of the network as edges among the nodes as a non-zero element. The value represents the weight of the edge connection and if it is a logical adjacency that results in an unweighted graph. If there are non-zero values in the diagonal representing a self-loop, the nodes are connected to themselves with an edge.

The standard topology consists of bucket placement in 4 different directions, which are the right angles. However, for better connectivity, more symmetrical placement is required for effective data transmission. The content bucket modeling for the consistency in the geographical distribution to achieve balanced latency is modeled as locational mapping with the placement of the proxy/content buckets in the location of the  $L = \{\text{North (N), South (S), East (E), West (W), North-East (NE), North-West (NW), South-East (SE), South-West (SW)}\}$  as shown the Fig. 4.

Fig. 5 highlights the 8 nodes placement of the bucket in a highly symmetric fashion. One of the advantages of this topology is that it offers complete supportability of sharing content in any of the buckets during the dynamic traffic scenario. Hence, the proposed topology is supportive of users with dynamic mobility. One case study of the data center CN's connectivity with all the 8 respective bucket positions is shown in Fig. 6. A graphical direction is given from the data center to the respective buckets.

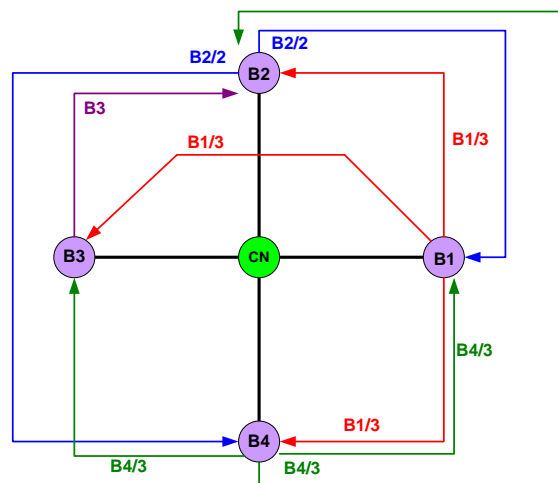

Fig. 4. Constructed Graph with Weights.

Fig. 5. Geographical Distribution of Cache/Content Server.

Fig. 6. Directed Graph for Optimal Connectivity.

The information associated with the degrees is captured from each node, assuming that the datacenter hosts a node with a domain `http://cdnserviceprovider.com/Central`. Therefore, the extracted features will be:

- CN: node `http://cdnserviceprovider.com/Central`
  - In-degree: 0, Out-degree: 8
- NW: node `http://cdnserviceprovider.com/NW`
  - In-degree: 2, Out-degree: 1
- NE: node `http://cdnserviceprovider.com/NE`
  - In-degree: 2, Out-degree: 1
- SE: node `http://cdnserviceprovider.com/SE`
  - In-degree: 3, Out-degree: 0
- SW: node `http://cdnserviceprovider.com/SW`
  - In-degree: 3, Out-degree: 0
- W: node `http://cdnserviceprovider.com/West`
  - In-degree: 2, Out-degree: 1
- N: node `http://cdnserviceprovider.com/North`
  - In-degree: 1, Out-degree: 2
- S: node `http://cdnserviceprovider.com/S`
  - In-degree: 1, Out-degree: 2
- E: node `http://cdnserviceprovider.com/East`
  - In-degree: 2, Out-degree: 1

All the above features are used for computing the cost factor involved in the proposed cloud-based content delivery network. The proposed system enables the connectivity with the cache proxy with the nearest bucket available in the topology. Apart from this, all the buckets are connected and synced with each other, as shown in Fig. 5. This interconnection of the graph edges facilitates the proposed cloud-based content delivery network to carry out the delivery of the contents in a dynamic pattern. The study also considers that datacenter CN consists of all the source content, and it is also directly linked with all the buckets in the proposed cloud-based content delivery network. In the conventional data delivery mechanism, the user-based contents required to be shared with users are duplicated over various variants of the cache proxies. However, this mechanism calls for a significant imbalance between content servers and the data transmission cost as there are a maximized number of increasing replicated files. The novelty of the proposed system is that it can eliminate the duplicated file from cache proxies and save them over different buckets in their respective buckets, unlike existing approaches. This mechanism can significantly minimize the quantity of the replicated file and potentially control the cost of content server placement. The algorithm developed for optimal cost computation is as follows:

---

#### Algorithm for Optimal Cost Computation

---

**Input:**  $s, t, B, N, D$

**Output:**  $c$

**Start**

1. Define  $s, t (B_N), D$
2. Apply graph,  $G(s, t)^D$
3.  $pr \rightarrow f_1(G)$
4. struct  $G=[pr, id, od]$
5. Apply  $f_2(G)$
6. obtain  $G_{sub}(G, sig_{p>p})$
7.  $c \rightarrow$  Apply  $f_3(pr)$

**End**

---

The above algorithm is responsible for computing the optimal cost in the proposed cloud-based content delivery network, which takes the input of  $s$  (source),  $t$  (destination),  $B$  (bucket),  $N$  (number of buckets), and  $D$  (domain hosted) that after processing yields an outcome of  $c$  (cost). The proposed algorithm's initial step is defining the particular  $N$  number of buckets concerning source and destination (Line-1). A digraph structure  $G$  is used for this purpose in order to give a shape of connected buckets in topology (Line-2). The next part of the implementation is about computing the centrality of graph  $G$  (Line-3). It is computed by dividing each bucket's value by one a smaller number of nodes that essentially represents the number of edges connected to the buckets. This operation results in a priority factor  $pr$  (Line-3). Once the priority factor is computed, the proposed system constructs a graphical structure  $G$ , which consists of priority factor  $pr$ , in-degree  $id$ , and outdegree  $od$  (Line-4). Finally, the proposed system constructs a sparsity pattern for the given buckets as variable test cases of different placement of the buckets. This is carried out to testify the sustainability of the algorithm towards lower latency over the various position of the bucket in a defined area. This operation is further followed by applying a digraph structure over  $G$  (Line-5). Finally, the sub-graph  $G_{sub}$  is obtained, and only those buckets are selected, whose priority factor is found to be statistically significant ( $>0.005$ ) (Line-6). Finally, the algorithm constructs an explicit function  $f_3(x)$ , which is responsible for obtaining the optimal cost of the content delivery placement. This mechanism is carried out using matrix-based operation where the buckets and their region-specific information are considered priority factor  $pr$ . The formation of this function is carried out in the following manner:

**Problem Formulation:** A case study using matrix-based operation is considered to understand the proposed study's problem formulation. As the proposed system uses information associated with buckets and priority factors associated with the content placement, it is easier to represent this fact using a matrix. The proposed system constructs a squared matrix of  $n \times n$ , which exhibits the associated cost for all  $n$  buckets to obtain buckets' optimal placement concerning the data center. The complete goal is to reduce the overall cost. As one bucket can be utilized for carrying out one set of job processing and all jobs should be allocated uniquely to each bucket in its respective position. Therefore, this allocation will formulate an independent set of matrix  $M$  as below:

$$M(i,j) = \begin{matrix} & \begin{matrix} a & b & c & d \end{matrix} \\ \begin{matrix} p \\ q \\ r \\ s \end{matrix} & \begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 6 & 8 \\ 3 & 6 & 9 & 12 \\ 4 & 8 & 12 & 16 \end{bmatrix} \end{matrix}$$

In such a situation, a random allocation is used where the bucket  $p$  is allocated job  $b$ , bucket  $q$  is allocated job  $d$ , and it goes on following such a pattern. The cost factor involved in such a case of job allocation will be 23, while the problem will be to search for allocating much minimal cost value. The constraint will be to perform all the individual allocation has to be relatively discrete and different overall the given rows and columns in matrix  $M$ . In order to find a solution to this problem, a brute-force approach can be used that can lead to a yield of a different independent set of  $M$  matrix. It should result in overall cost for all the content placements and explore the smaller set. However, it has to be noted that the complete computational complexity factor is associated with the size of the squared matrix and its associated allocation of buckets. It will mean that  $n$  choices will be the primary allocation while  $(n-1)$  will be the second allocation that finally leads to factorial  $n$  feasible sets of allocation. Hence, a significant complexity associated with computational run time is associated with this process. While selecting the assignment, the respective rows and columns must be eliminated; therefore, a problem will be to find the optimality of this reduction process. This leads to higher computational complexity. In this regard, the study presents optimal strategy based on cost matrix formulation as shown in Fig. 7.

Fig. 7. Visual Representation of Cost Matrix.

Solution: The solution to this problem is carried out by constructing a function  $f_3(x)$ . The matrix operation carried out in this function is showcased in Fig. 8. There are six steps of operation that are carried out to solve this problem viz. i) a non-squared matrix of  $n \times m$  is constructed where the elements depict cost factor associated with the allocation of one of  $n$  bucket to one unique  $m$  job. The matrix  $M$  is rotated in such a way that there is always a minimum number of rows and columns and considers  $k \rightarrow \text{argmin}(n, m)$ . ii) the next step is to search for the minimal element over all the rows in the  $M$  matrix and subtract it from all the elements present in the row, iii) the consecutive step is to look for the presence of zero in the outcome matrix. The absence of any zero in the row and the column calls for flagging that zero. It is iterated for all the matrix elements. iv) all the zero elements that are starred are covered concerning the column of its position. If  $K$  number of columns is covered, then the flagged zeros represent a cumulative set of non-repeating allocation. In such a case, the operation is completed, or else the next step is processed. v) All the zero elements that have not been covered up are identified and then are primed. In case of such primed zero, absence of any flagged zero over the row, the function performs next step, or else this particular row elements are covered, and all the columns consisting of flagged zero are uncovered. This process is repeated until and unless all the zero elements are covered. The minimal value of the uncovered element is saved, vi) a series of alternating flagged zero elements and primed zero elements is constructed, vii) the value of the result obtained in step 5 is added to all the elements over rows with covered elements, followed by subtracting it from all the values of a column that are uncovered. Without performing any alteration over covered lines, primes, and flags, the process returns to the 5th step. viii) The final step indicates the pairs of values to be allocated, considering the flagged zero elements' position over the  $M$  cost matrix. Therefore, if  $M(i,j)$  is flagged zero, then the values connected with this  $i$ th row are allocated to the  $j$ th column values.

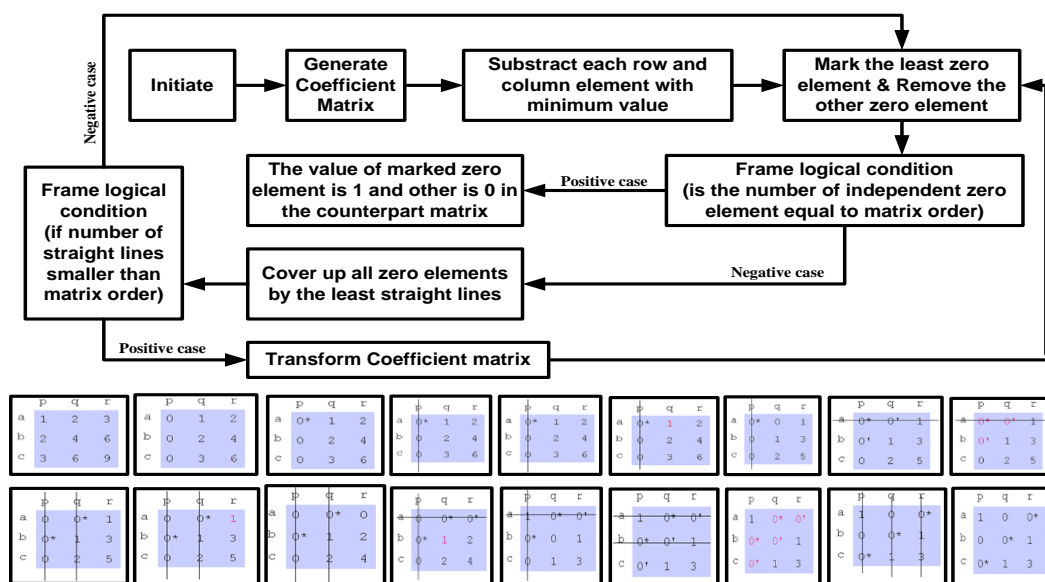

Fig. 8. Matrix Operation Carried Out in Function  $f_3(x)$ .

The function  $f_3(x)$  outcome is an optimal allocation with highly reduced cost based on the input argument cost matrix. The complete operation of  $f_3(x)$  is discussed concerning the proposed cloud-based CDN as follows:

Consider that there is  $\Phi$  number of jobs required to be accomplished based on the query generated by the  $\alpha$  number of computing devices of the user. Assuming that  $\Phi \leq \alpha$ , there is a possibility that any computing devices can be allocated in order to accomplish this task over a cloud environment, where each device incurs a cost in the form of resources as well as time to accomplish the task. Hence, the proposed cloud-based CDN system's objective function will be to carry out the complete task without the inclusion of maximized cost while performing a selection of the best resources and computing device for this purpose. Therefore, the objective function developed for this purpose is:

$$arg_{min} \sum_{i=1}^{\Phi} \sum_{j=1}^{\alpha} m_{ij} \cdot \beta_{ij} \mid \sum_{i=1}^{\Phi} \beta_{ij} = 1$$

$$0 \leq \sum_{j=1}^{\alpha} \beta_{ij} \leq 1, \beta_{ij} \in [0,1] \quad (1)$$

The expression (1) represents a cost matrix  $m_{ij}$  that essentially depicts the cost incurred by a computing device of user  $i$  to carry out the  $j^{\text{th}}$  task. The variable  $\beta$  represents a binary matrix whose value is considered 1 if a specific  $i^{\text{th}}$  computing device of the user is allocated a specific task of  $j$  or else it takes 0. The proposed algorithm of allocating the task offers by considering a bipartite graphical structure  $G=(V, E)$  where the vertices  $V$  is a union of all source node  $s$  and destination node  $d$ . All the vertex of the bipartite graph is labeled  $\gamma$ , and the condition for labeling is that all the labels are anticipated to map with the matching constraint in the distributed cloud environment. The system considers the possible labelling as a function that satisfies a criterion of  $\gamma(x)+\gamma(y) \geq \lambda(x,y)$ , where the variable  $\lambda$  represents the weight factor. The study considers that a vertex  $\alpha$  is only tagged as matching if this vertex is a part of the main vertex  $\alpha_m$ . The subgraph of  $G$  is represented by  $G_\lambda$  that consists of information about the edges. The study considers this subgraph  $G_\lambda$  to be a spanning tree of main graph bipartite  $G$ . Further; it amalgamates the complete available vertices from the main graph  $G$ . The feasibility of the allocation is ensured in this process by ensuring the inclusion of only those communication links (edges) from the core bipartite matched graph. Considering that  $\alpha'$  to be precisely matching with the spanning subgraph  $G_\lambda$  then  $\alpha'$  is considered to match with core graph  $G$  with the highest weight exhibiting the better allocation process and minimal cost. The implementation intends to exhibit that  $\alpha'$  is the only perfectly matching matrix where the weight computation for allocation is carried out as follows:

$$\lambda(\alpha) = \sum_{x,y \in \alpha} \lambda(x,y) \leq \sum_{x,y \in \alpha} \{g[\gamma(x,y)]\}$$

$$= \sum_x \gamma(x) + \sum_y \gamma(y) = \sum_{x,y \in \alpha} \{g[\gamma(x,y)]\}$$

$$= \sum_{x,y \in \alpha} \{\lambda(x,y)\}$$

$$= \lambda[\alpha'] \quad (2)$$

In the above mathematical expression (2), the variable  $g$  represents the summation operator while  $\alpha'$  signifies the highest form of matching for cost-effective allocation in cloud-based CDN, and thereby a global optimization is ensured. It should be noted that the complete process of cost-effective allocation in cloud-based CDN is applied over a dense matrix, which signifies that the proposed system is capable of withstanding peak traffic conditions. The study finds that such operation is capable of transforming the row and column by harnessing the potential advantage of the proposed data structure that is crossed linked. This structure is utilized to reposit the data while the links are manipulated to forward the data from the server to the users. There is another reason for the efficiency of allocation in the proposed cloud-based CDN. The proposed system uses the function  $f_3(x)$ , where the difference between the weight is reformulated in the form of a structure matrix. The structured matrix is then subjected to classification concerning its complete columnar elements into a specific number of blocks uniformly. A similar operation of classification is also carried out for row-wise elements. All the sub-problems are now solved in parallel fashion in the proposed system, ensuring the capability to perform job query processing from an incoming stream of traffic. All the tasks that are found to be unique are then checked. This ensures that if the same task resides within multiple computing devices of a user, then only the task with higher profit is only accepted and considered for allocation. With sparsity property aid, the proposed system offers better efficiency of allocation of job cost-effectively irrespective of the choice of operation either in a row or in column-wise. Therefore, the proposed system performs content in cloud-based CDN by formulating a novel topology using a bipartite graph. The solution offered by the.

## VI. RESULT ANALYSIS

The proposed system's implementation is carried out in an analytical fashion, where MATLAB was used for scripting. The analysis is carried out considering the graphical structures where cost and latency play a significant contributory role. Table I highlights the cost associated with each bucket in different position of North (N), East (E), West (W), South (S), North East (NE), North West (NW), South East (SE), South West (SW), and central node of the data center (CN). A bipartite graph is initially constructed for topology creation. The study assumes the simulation parameters as 25 cache proxy with 3000 MB of maximum capacity for each, 10 content servers with 5000 MB of maximum capacity for each, 9 areas of deployment of buckets. Table I shows the position of the buckets vertical wise while its respective cost is highlighted horizontally. The study's complete implementation has been carried out considering 9 buckets that have possession of both cache proxy and content server. The selection of the simulation parameters is highly flexible, and it is considered in such a way that there is an assignment of reduced capacity for the proxy server in contrast to the content server in the bucket. This is carried out in order to map with the practical environment of cloud-based CDN. Table I highlights the instance of the cost matrix for all location = { P/C-S-N (1), P/C-S-S (2), P/C-S-E (3), P/C-S-W (4), P/C-S-NE (5), P/C-S-NW (6), P/C-S-SE (7), P/C-S-SW(8), P/C-S-CN(9)}. Here, the variable P is an optimal position, and {S, N, W, E} represents 4 orthogonal directions

of south, north, west, and east for the considered topology. The variable Ct represents the cost of all 9 locations. The table highlights the nodes (buckets) under the different possible conditions of 4 orthogonal directions. Table II highlights the accomplished cost associated with all the nodes in 9 different positions in multiple nodes' directions. Table III represents the elements allocated in binary matrix  $\beta$  where the numerical

value of 0 will represent zero task allocation, while 1 will represent the allocated task from the user device to the bucket. Table IV highlights the estimated cost for all the nodes in 9 different positions. The estimation of cost is carried out by the proposed algorithm explicitly by applying the function for optimal placement  $f_3(x)$ .

At present, the content placement approaches are mainly of two types, i.e., deterministic and randomized. The deterministic approach selects a static topology and does not offer any changes in the user's due course of query processing. The randomized process involves selecting randomized buckets in due course of task processing query from the user. However, the proposed system is optimal in its approach as it can offer a dynamic update and dynamic change of topology by adapting the new cost associated with the link leading to the content matrix. All the calculations are carried out in a similar environment concerning increasing simulation rounds. Each simulation rounds are incorporated with random allocation of the task from the user towards the edge's bucket. The idea is to assess the performance of the proposed content placement approach concerning multiple performance parameters, e.g., Algorithm processing time, latency, cost of allocation, and the probability of resource allocation.

Fig. 9 shows that the proposed system offers a 20% improvement in faster processing than the existing one. The prime reason behind this is the faster update exchange within the topology, where it consumes less time to find the efficient bucket for content placement than the existing approach.

Fig. 10 highlights that the proposed system offers a significantly higher reduction in latency, approximately 60% compared to the existing system. A closer look at the graphical outcome shows no significant difference in randomized and deterministic approach much. The reason behind it is that, in the existing approach, the problem is solved from local problem space, which consumes more time and hence is not scalable for more massive and dense traffic conditions.

However, the proposed system focuses on the global problem space by constructing a crosslinked data structure with different buckers. This makes the process of algorithm execution faster and ensures that incoming queued jobs are faster processed. Each cost matrix keeps track of indegree and outdegree, which are always balanced if there is more indegree than outdegree, causing better control of latency performance.

Fig. 11 highlights that the proposed system's cost performance is approximately 40% better than the existing approach. The deterministic approach performs calculation of the efficient algorithms in advance and then fixed its topology to perform query processing towards buckets. This allocation's static nature often contradicts the allocated weight of the links with the incoming traffic, which causes an increased cost of allocation.

On the other hand, a randomized approach exhibits better performance in the prior set of simulation rounds; however, this approach requires additional effort to explore a greater number of network indicators for efficient content placement with increasing rounds. So, it is only slightly better than the deterministic approach. The proposed approach offers a better cost reduction capability as it can carry out all task processing and allocation using a parallel approach and hence same data structure is reused for parallel allocation of job over the buckets. This drastically reduces the cost associated with allocation in order to find a better content placement.

Fig. 9. Comparative Analysis of Processing Time.

Fig. 10. Comparative Analysis of Latency.

Fig. 11. Comparative Analysis of Cost.

Fig. 12. Comparative Analysis of Allocation.

Fig. 12 highlights that the probability of resource allocation of the proposed system is approximately 35% better than the existing approach for a similar cause. Hence, based on this outcome, it can be said that the proposed system is capable of offering cost-effective content placement with reduced computational complexity and at par with meeting the demands of practical networks over a cloud environment.

## VII. CONCLUSION

This paper has presented a novel framework where a unique architecture towards cost modelling is carried out for content placement. The overall contribution of this paper is as follows: i) the paper introduces a novel way of using cost matrix using crosslinking data structure which can minimize the dependencies of replica in order to optimize the cost of content delivery, ii) the study achieves faster processing time over a stream of continuous data (or request) from the user making it suitable for practical world application over Cloud-based CDN, iii) the applicability of proposed system will have a higher score of quality of experience as well as the quality of service due to the following reason: it offers reduced dependency of resources thereby making it resource optimized approach, it uses data sparsity and offers reduced allocation cost capable of processing multiple jobs at one instance. This makes the system support both parallel processing over a distributed storage environment over Cloud. The key novelty is that the scheme presented in this paper, jointly addresses multiple issues such as content server placement and optimal content placement on the content server to support maximum content request and content delivery with less delay and higher throughput. The proposed system can be viewed as a support system in CCDN to enhance the user experience. Our future work will be towards further optimizing the performance.

**Abstract**—Now-a-days, we are using modern locking system application to lock and unlock our vehicle. The most common method is by using key to unlock our car from outside, pressing unlock button inside our car to unlock the door and many vehicles are using keyless entry remote control for unlocking their vehicle. However, all of this locking system is not user friendly in impaired situation for example when the user hand is full, lost the key, did not bring the key or even conveniently suited for special case like disable driver. Hence, we are proposing a new way to unlock the vehicle by using face recognition. Face recognition is the one of the key components for future intelligent vehicle application in the Autonomous Vehicle (AV) and is very crucial for next generation of AV to promote user convenience. This paper proposes a locking system for AV by using face deep learning approach that adapt face recognition technique. This paper aims to design and implement face recognition procedural steps using image dataset that consist of training, validation and test dataset folder. The methodology used in this paper is Convolution Neural Network (CNN) and we were program it by using Python and Google Colab. We create two different folders to test either the methodology capable to recognize difference faces. Finally, after dataset training a testing was conducted and the works shows that the data trained was successful implemented. The models predict an accurate output result and give significant performance. The data set consist of every face angle from the front, right (30-45 degrees) and left (30-45 degrees).

**Keywords**—Face recognition; deep learning; internet of things; convolution neural networks

## I. INTRODUCTION

The Internet of Things (IoT) was first invented in 1999 by Kevin Ashton. The introduction of the term is mainly to promote Radio-Frequency Identification (RFID) technology until later in 2011, the IoT term started to spread widely. This IoT is rapidly expanding with the aim of developing a global infrastructure by embedded sensors and actuators in physical objects that connect to the Internet [1, 2]. IoT devices were supplied with unique identifiers and known as Smart Devices. The Smart Device can be in a range from ordinary household objects to sophisticated industrial tools [1] to enable the communication with the IoT platform.

Sensors, gateways or connection, cloud, analytics, and user interface are the five (5) essential components of IoT systems. Sensors and devices are the rudimentary components of an IoT system. Every hardware device, including embedded cell phones, household appliances, hardware devices, and nearly

everything else encountered in daily life, contains sensors. Sensors or devices in an IoT system collect and send data [3] from the surrounding environment on the state of the device's operation. As a data transmission channel, a gateway or link is necessary. The gateway's job is to make communication and data sharing between devices easier.

As a connectivity of physical objects, IoT works as a bridge to all devices by transferring their data using a common language to connect with various sensors or devices. Basically, sensors acting as the data's supplier to the IoT platform and the data are gained from multiple sources. Moreover, the raw data needs to be analyzed [3] before useful information can be extracted. In the end, the data, automate processes and the efficiency can be enhanced and improved further by integrating it with other devices.

Furthermore, the IoT platform such as storage, actuation, sensing, enhanced services, and communication technologies are very important to gather and analyses data [4] from smart infrastructure. On the other hand, the IoT is changing our way of life and transforming how we interact with technology[4], and it is driving the world to become a better place.

Human lifestyle has been impacted in certain ways [4] by how people react to the way humans behave with all gadgets (things) in synchronize with the increasing IoT revolution. This revolution, as described in [5] provided and guaranteed the capacity to have seamless interaction when transmitting and sharing data across a network without needing any human-to-computer communication.

The cloud, which functioned as a platform for collecting, storing, managing, and analyzing real-time data, was a major component of IoT. Analytics will play a role in transforming analogue data from billions of devices into meaningful information that can subsequently be utilized for thorough analysis once the cloud handles the data. Data from devices and sensors is converted into a format that is simple to read and process.

Artificial intelligence (AI) is becoming more prevalent in IoT applications and deployments [6]. John McCarthy was the first to present AI in 1956, and he felt that AI included developing a machine that could really mimic human intellect [6, 7]. Simply put, AI was designed in a way that a machine can simply replicate it and do the tasks from easiest to the hardest.

The idea of AI is to replicate human cognitive processes. The developer and researcher's expectation towards AI is up until imitating humans in simulating processes including perception, reasoning and learning [6]. In a number of situations, AI systems outperform humans by a large margin [8]. It demonstrated that AI can defeat numerous computer games, including a world champion chess program and the top professional poker players in the world [9].

There are two types of AI which are weak and strong [10]. Every system that always does a single task is known as weak AI, while the strong AI always refers to a sophisticated and difficult system. The example for the weak AI is like video games and personal assistants and the famous personal assistants in this world is like Apple's Siri [11].

Other than that, computer games also are one of the examples of weak AI. On the other hand, there are many examples of strong AI nowadays such as operating rooms in hospitals and self-driving automobiles. These technologies are capable of solving problems without human intervention [12] because they have been trained before to deal with the circumstances.

Previous AI standards are becoming obsolete as technology develops [12, 13]. Nowadays, machines that calculate fundamental operation or read text by applying optical character recognition are formerly regarded to contain AI because these operations are now inspected standard computer functions. AI is continuously being enhanced [13] to benefit a wide range of businesses.

Mathematics, psychology, linguistics, and computer science are examples of multidisciplinary methods that are always used to wire machines [14]. We can even lock and unlock Autonomous Vehicles (AV) with our own face utilizing a deep learning approach using facial recognition, thanks to the advancement of AI models [15] that connect with IoT.

Furthermore, the AV idea is now at the forefront of the automotive industry's future security [16]. With the progress of technology, AV have the potential to reduce accidents, increase accessibility to transportation, especially for elderly persons, provide stress-free parking, and provide high-end security, among other benefits [16, 17]. However, technological advancements might sometimes have downsides for AV users. Sensors, for example, may malfunction, attracting a hacker to steal personal data from an AV user [17]. In Section 2, we'll go into AV in further detail.

Fig. 1 shows a process on how the data gathered from AV devices or sensors and then the data go through an analysis process before being transferred to the cloud. Basically, the data is gathered in edge computing after receiving from the AV. This data needs to be gone through pre-processing and decision-making in the edge node. Thenceforth, the data will be transferred to the cloud by the edge node after analyses locally by the IoT sensor[18]. The aim of this process is for less time-sensitive decision-making and for offline global processing.

Based on the diagram shown above, the road accident can be prevented by using obstacle recognition as shown in the diagram above. These time-sensitive choices are capable of

avoiding crashes in a shorter amount of time as illustrated in the edge node above [18]. To improve a driving experience, the cloud provides a platform for the data to analyses about the traffic, roads and also the driving habits.

The edge node as illustrated above shows that the AI models will be actively changed in terms of consumer needs, regulations, policies and appropriate laws. Moreover, in this node the amount of data sent by the IoT is bigger than the generated data in AVs because the data needs to be pre-processed, filtered and cleaned before proceeding to the cloud and by using this method the amount of cost and bandwidth can be reduced.

When it comes to the locking security in AV, normally the most common method is by using key to unlock our car from outside, pressing unlock button inside our car to unlock the door and many vehicles are using keyless entry remote control for unlocking their vehicle. However, all of this locking system is not user friendly in impaired situation for example when the user hand is full, lost the key, did not bring the key or even conveniently suited for special case like disable driver. Hence, we are proposing a new way to unlock the vehicle by using face recognition. Face recognition is the one of the key components for future intelligent vehicle application in the Autonomous Vehicle (AV) and is very crucial for next generation of AV to promote user convenience. This paper proposes a locking system for AV by using face deep learning approach that adapt face recognition technique.

In the remainder of this paper, Section II contains a brief history of AV including the superiority of AV, challenges of AV and the solution of the challenges; Section III discuss the component of machine learning and in that section, we have discussed of 10 sub-component of machine learning; Section IV discuss the methodology that have been used in this research paper including the way we collect the data to the way we implement the research; Section V conclude the result and discussion in this paper ; Section VI is our conclusion part for this research; Section VII discuss the future work for this research paper and lastly Section VIII dedicated the acknowledgement for this paper.

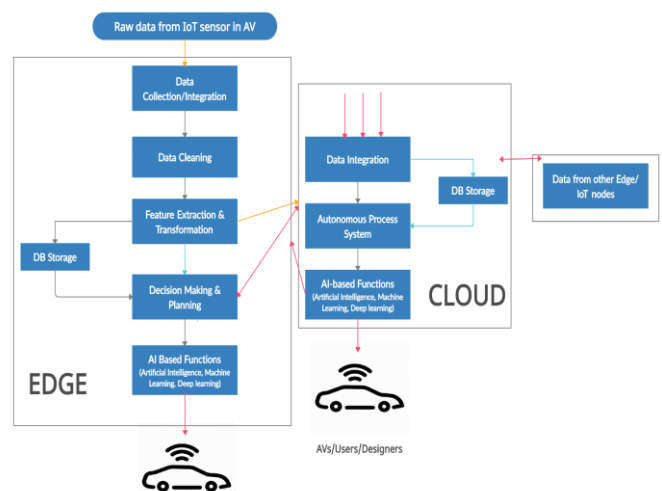

Fig. 1. The Basic Architecture for Artificial Intelligence and Internet of Things for Autonomous Vehicles.

## II. AUTONOMOUS VEHICLE

Autonomous Vehicle (AV) is one example of smart infrastructure [19]. A study from [16] had mentioned that AV was introduced in the 1980s and the research about AV was funded by Defense Advanced Research Projects Agency (DARPA) [16]. Thanks to AV because with the innovation of transport systems, combination of sensors and software to control, not only can reduce time, money and environmental impact yet can improve safety, increasing capacity, and minimizing traffic congestion [20].

Through the advancement of technologies in these modern days, the AV also known as driverless vehicles evolved by the ability to sense its surroundings, perform significance function, and operate by itself without interference by humans. An automation level generally divided into six levels which are from level 0 to level 5 and each level represents the operation control capabilities whichever the level 0 has the least automation control while the level 5 has the most control capabilities. The lowest level known as level 0 basically can't control all the operation and the whole process of driving needs to be done by humans [16]. On the other hand, the control process at the level 1 had been improved in terms of steering and braking control of the vehicle with the support of Advanced Driver Assistance System (ADAS).

As the level of automation increases, the vehicle becomes more advanced. As stated in [16], the level 2 automatics are capable of controlling the steering and braking by using the ADAS system. However, the drivers need to be focused and paying attention to the environment along the journey. At level 3 it becomes more advanced where the driver gives full control to the vehicle through Advanced Driving System (ADS). This system is capable of controlling all parts of the driving task with a few conditions. However, the human driver was allowed to control the vehicle when requested by ADS. In addition to that, the human driver executes the necessary tasks in the remaining conditions.

The ADS plays an important role in AV's system where at level 4 the system is capable to control and perform all tasks without any human intervention including supervision from the human. The last and the most advanced AV is at level 5, where in this level the AV is not only capable to perform all the driving tasks but also is capable to communicate with other devices [16] including traffic lights, signage and the environment of the roads and to perform this function this level requires 5G application.

Together with that, vehicle speed is also one of the important elements to the AV. To ensure the speed of AV kept at a safe distance, the Adaptive Cruise Control (ACC) is used. This system uses sensors to get the distance information and undertake the vehicle to perform tasks when the sensors send the signal to the vehicle such as perform brake when senses and predict any imminent and any vehicle ahead. These sensors give the information to the actuators in the vehicle and then proceed the control action activity in the vehicle such as braking, acceleration and steering [16]. Furthermore, the high level of AV is adept to control the automated speed in order to respond to the signals that come from the traffic lights and non-vehicular activities.

### A. Superiority of AV

Statistic states that usually vehicle crashes happen because of human error and it is proven when 90% of fatal vehicle accidents are due to human failure [21] hence, the AV's technologies got the potential to reduce the death statistics because of human error. Thus, driverless cars are a future technology that is needed by humans to scale down the deaths and injuries from car collisions. The reason for crashes comes from the driver's focus interruption [21]. On the other hand, there is a website called the house energy and commerce committee that claims that traffic deaths can be reduced up to 90% and can save up to 30,000 people yearly by using driverless vehicles or known as self-driving cars. Apart from that, there is a report from American Society of Civil Engineers (ASCE) that states that Americans can't avoid wasting their time in traffic every day [22] and surprisingly they used 6.9 billion hours for that purpose.

Furthermore, AV brings a lot of benefits to people, especially to senior citizens and for the disabilities drivers to handle vehicles safely. Other than reducing the numbers of accidents, the idea of AV is to help people in these groups to drive effortlessly. AV caters and provides more people to drive independently without worries about the safety issues [23]. Moreover, a study by [24] states that by accommodating AV technologies, will make life much easier and effortless to go to work, attend meetings with clients including going to the doctor especially for senior citizens and disability people.

Other than that, according to [23] Many benefits will be gained from the AV in terms of travel time, commuting and congestion time and also cut down the fuel consumption which is a good barrier to the citizen especially to the citizen who live in the city or town and crowded place and road. The country can save up to a trillion dollars when using AV and also can reduce manpower and law enforcers and save more money [25] to the country.

Safety and security issues are an important part of everyday life and are needed in many areas included in modern transportation. Moreover, these days AV concept is leading the future security of the vehicle industry [20]. AV has Light Detection and Ranging (LiDAR) sensor [16, 26, 27] It is capable of avoiding obstacles in an unknown environment and being able to classify dynamic objects in urban roads into cars, pedestrians, bicyclists and background [22]. LiDAR divides into two types which are non-scanning and also scanning LiDAR. In addition, scanning LiDAR comes with different features, other than single scanning, there is also one type called multi-line scanning LiDAR. In addition, LiDAR also has a non-scanning LiDAR type [23] that uses 3D-flash LiDAR.

The next feature in AV is Radio Detection and Ranging (Radar) [16, 26, 27]. Radars have proven effective for appearance on AV in the existence of fog and dust [25]. Besides that, radar is also designed to aid Off-road Light Autonomous Vehicle (OLAV) platforms in classification, map-reading, and detection [27]. Furthermore, Lidar and cameras are indeed very popular sensors, but radar gains much more advantage when compared to radar in terms of speed measurement capability and cost and target range [27]. AV also has an image sensor feature like rear-view cameras [27].

Rear-view cameras are used to detect obstacles behind the vehicle with aid of a fisheye lens [28]. The most important feature to AV is the locking system [29] when it comes to security factor.

Generally, a key of a vehicle is the most important thing to the vehicle to start the engine including to unlock the steering [26] such as by using pin tumblers lock, and then the lock changed to transponder key lock and after that an AV locking system became more advanced which can lock and unlock the vehicle by using Passive Keyless Entry and Start (PKES) system [29]. The PKES system is widely used in modern vehicles, the user can lock and unlock the vehicle whenever they are near to the vehicle without needing to take out the key from their pocket [29]. This system is very convenient to many users and makes life easier. Now, many manufacturers want to move to another level of vehicle locking security system by face recognition [30]. This paper invented the novel prototype of a safety system in AV, especially the locking system by using Keras, TensorFlow and Deep Learning (DL).

### B. Challenges of AV

The research done by [12] claims that though AV has been successfully programmed, an unpredicted flaw still may come after. On the other hand, the crazy advancement of technologies makes the older version equipment faced with the faulty code issues. With the many advanced technologies in the AV doesn't mean the vehicle can't be hacked by hackers. Hackers can hack AV systems easily because the system still has many vulnerabilities [16] as this is new to the world and the hackers definitely will steal the personal data through the AV.

The next drawback of AV is dysfunctional sensors [31]. Sensor failures often happened in AV [31], as an example the locking system. The locking system is a very crucial part in automated vehicles safety [32]. The AV user is very concerned about the locking system. AV provides the modern locking system to the user by maximizing the security and safety to the vehicle. Safety and vehicles cannot be apart. Safety is a very important element for the vehicle [16]. Basically, the common safety element in vehicles is like the lighting will turn on when the doors are unlocked, and the AV gives notification to the drivers by integrated control of the lighting.

However, AV locking systems also will have problems in the modern lifestyle, when the user's hand is full, lost the key, did not bring the key, the key can be duplicated by others or even conveniently suited for a special case like disable driver [33]. All of those factors demand a new locking system for AV users.

### C. Solution

As explained in the previous section, AI has been widely used in this world. Basically, AI is a technique that enables a machine to mimic human behavior. As example, an ability to sense, reason, engage and learn. AI operates autonomously and uses a variety of methods through data learning processes by machines [7]. By the recent advances in AI, many impacted areas have been affected by using AI techniques, as example voice recognition, Natural Language Processing (NLP),

computer vision algorithm, robotic and motion, planning and optimization, and knowledge capture [34, 35].

When we go deep in AI, we will find that AI is supported by an algorithm model known as Machine Learning (ML) and inside the ML there is another algorithm model called Deep Learning (DL) [36], [37]. Fig. 2 shows AI and the subfield.

ML is used to manage from the raw data, when ML gets the data, they need to be trained and this technique can be achieved by using specific algorithms. Basically, AI has a lot of methods that make machines operate autonomously through provided data [7], [37].

ML is created to be an independent computer program by learning itself from the data and ML algorithms is divided in a few categories [37], known as reinforcement, supervised, unsupervised and semi-supervised learning. This type of learning is illustrated in Fig. 3 below. Nowadays AI innovation is leads by ML techniques and nominal by Deep Neural Networks (DNN) [32, 33, 34, 37, 38] and this model widely used as black boxes.

Currently Deep Learning (DL) is a very popular algorithm and has been widely used by researchers and developers in various fields. The idea of DL is to imitate human brain function into machines. The most popular algorithms in DL are; a) Long Short-Term Memory Networks (LSTM), b) Convolutional Neural Network (CNN), c) Deep Belief Networks (DBN), d) Recurrent Neural Networks (RNN), e) Deep Boltzmann Machine (DBM) and f) Stacked Auto-Encoders. Moreover, the DL is focusing on the more complex and larger dataset [7, 11, 38] such as video, audio, text and image.

As mentioned above, the human brain acts as a major part for the evolution of DL. The design structure and frameworks of DL exactly look alike and function well as the human brain which is capable of differentiating patterns and can classify diverse types of data [38]. The evolution of DL makes the CNN become popular methods used in this field including Face Recognition (FR) technology based on CNN[39, 40]. FR is widely used nowadays in so many fields including to unlock mobile devices and the FR process includes the recognition task, feature extraction, alignment and detection [11]. On the other hand, the DL methods are able to support a huge dataset of faces and learn rich and compact representations of faces.

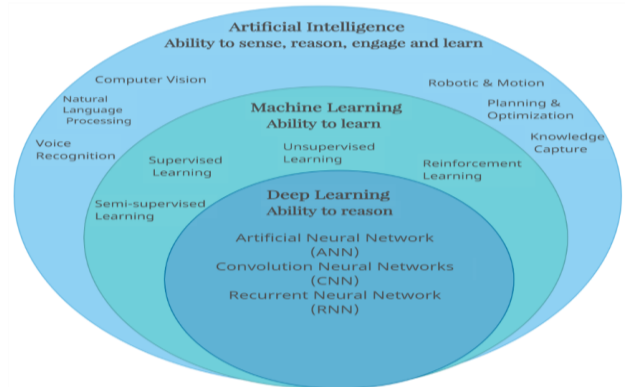

Fig. 2. Artificial Intelligent (AI) and the Subfield.

During 2012, a competition called ImageNet Large Scale Visual Recognition contesting became popular because of the CNN research that was initiated by Alex Krizhevsky [41]. After that competition the name of Alex became more popular. By using multiple processing layers and levels of features extraction, DL is capable of learning delegation of data [42]. On the other hand, fully connected layers, normalization layers, convolutional layers and pooling layers are a few examples of the layers that are hidden [38].in the CNN algorithm.

With DL, we can produce a new locking system for AV by using FR technique [43].The AI Researchers begin to use DL as a tool for training the face expression [44]. DL is knowingly an authoritative tool in the automation industry, and FR is part of the applications. FR is widely used in the military, finance industry, daily life and public security [45, 46], and FR is divided into two classes which are one to many augmentations and many to one normalization [46]. We will explain in detail about FR in Section 3 below. This method can solve the locking system problem. With the advancement of AI, the locking problem that was discussed in the previous section can be solved.

A survey done by [47] finds that FR technique will become a useful technique for AV users in terms of security, especially for locking systems. This technique requires a dataset to train before you can prove this technique meets the expected result. Moreover, with the help of IoT, the user will get notified [48] about the system failure.

In traditional methods, the system recognizes the human face by layers, which is one or two layers such as responses of filtering. With the emergence of DL, the landscape and framework of FR technique has been changed [49]and reshaped in all algorithm designs, evolution protocols, application scenarios including the dataset training.

FR needs three modules to run the system, the first one is a face detector. This module is needed to contain faces in images or videos. After that the next module is the face landmark detector and lastly is the FR module. This module is an anti-spoofing face [50]. There are two categories of FR [51], the first one is face verification and the other one is face identification.

In this study we are using ground truth research by using convolutional neural networks (CNN). This method is used for unlocking an AV by using our face. This model needs to be trained and validated in their own respective data. We will elaborate more in section 3 below about the methodology.

### III. MACHINE LEARNING

The advancement of ML was proven with minimal human interference and these methods are capable of analyzing the data before building an analytic model. Other than that, ML is intelligent in digesting information from raw data, analyzing the form of data and finding the decisions with least human supervision [52, 53]. Hence this new model of ML is definitely different from the traditional ML [54] which current ML was designed to learn from pattern recognition and can learn without being programmed to specific tasks but learn from data.

To be an independent model, ML’s interactive aspect is very crucial because ML works with the new data. The more ML learns about the data, the more ML will become smarter without any assistance from humans [55] and ML can produce reliable results and repeatable decisions.

Normally, to understand the data without human intervention, we need four kinds of algorithms that rely under ML, which are; a) semi-supervised learning, b) reinforcement, c) supervised, and d) unsupervised learning [36] Fig. 3 shows the ML types and the categories model in ML.

#### A. Supervised Learning

Supervised learning under the ML has been divided into two outcomes which are regression and classification. The regression outcome intention is to forecast based on the training sample set given, such as house pricing, weather forecast and market forecasting. Whereas the classification outcome’s goal is to identify pattern [36] such as identify fraud detection, image classification and diagnostics.

In supervised learning, there are three models [36], the first one is Classic Neural Networks or known as multilayer perceptron (MLP), the second one is Convolutional Neural Networks popular as CNN and the last model is Recurrent Neural Networks known as RNN.

Fig. 4 generally shows a normal workflow for classification in supervised learning algorithms. Above all, three steps are needed to classify data before generating the expectation output. The first step is to clean the raw data through the extraction process before gaining the quality or useful data. Secondly, the useful data including the labels are sent to the training stage by ML algorithm to analyze an excellent model.

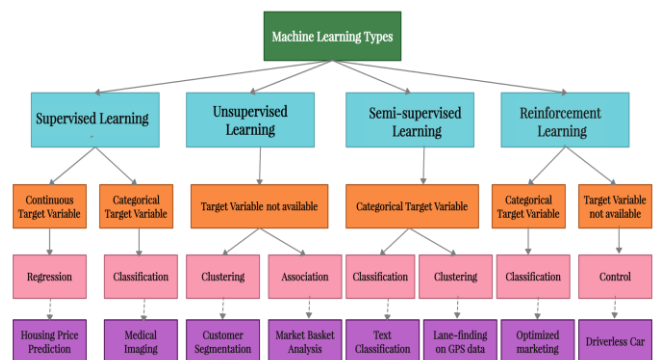

Fig. 3. Categories of Models in Machine Learning [49].

Fig. 4. A Flowchart of a Supervised Machine Learning Model [56].

To improve the accuracy of the model, the model needs adjustment from the evaluation step, because this step is capable of giving a point of view about the feature's extraction and learning stage. Before achieving the desired accuracy stage, the data needs to go through the training process [56] all over and over again. Once it done, the new data can be predicting easily.

### B. Multilayer Perceptron (MLP)

A simple algorithm that calculates the binary classification is called perceptron. Many real case's classified in this algorithm and this algorithm categorizes the input based on their own categories as an example cat or not cat and not fraud and fraud. While the MLP is composed of more than one perceptron [57].

A MLP involves a few layers and the layers have different types of uses. The common layers are known as output, hidden and input layers. Input layer task is to gain signal. Whereas core layer for MLP is the hidden layer, because this layer is the computational engine for MLP and lastly is the layer that functioning to predict the input and this layer known as output layer [58] Supervised learning technique is used in MLP for training purposes for every node and the technique called as back propagation and every node in this layer uses nonlinear activation function except the input node. The design of this layer is illustrated in Fig. 5.

To minimize the error the MLP's training does the altering parameters such as weights and biases. Then the MLP learns from the model's correlation between input and the output. Hence, not extraordinary when the MLP is capable of estimating the XOR operator and other nonlinear functions very well [58]. So, all of these are the advantages of MLP.

However, the parameters that are set by the MLP will become inefficient whenever the numbers of parameters become so high and it will cause redundancy in high dimensions. Moreover, it will disregard spatial information and make the flatter vectors as inputs [58].

### C. CNN

As discussed in the previous section, CNN play a paramount role in identifying and classifying images. Many researchers use CNN because of the magnificence of this algorithm in classifying images such as identifying objects, individuals, tumors, street signs, faces and many other data that are related to visuals. And these algorithms can perform the classification of images including photo search [34, 58].

Fig. 5. Multilayer Perceptron Model[49].

CNN came within three layers. And all the layers are very famous among the researchers and developers known as convolutional, fully-connected and pooling layers. The function of the first layer, which is convolutional layers, is to obtain many attributes and diversity of features that are gained from the input images. These input images are then filtered to a specific size by the mathematical operation. This layer is then followed by the other layer [34, 58] known as the pooling layer. Decreasing connections between layers capable to reduce the computational cost by decrease the convolved feature's size.

In the end, the last layer is called a full connection layer. This layer is located before the output layer and makes another layer in CNN architecture. This layer comes along with weights and biases and the neuron elements. All of these elements are used to connect with different layers [34]. Fig. 6 shows CNN architecture where that architecture consists of an output layer, an input layer, a full connection layer, 2 max-pooling layers and 2 convolutional layers.

Fig. 6. An Example of a CNN Model for Face Recognition.

All algorithms in ML have their own advantages. For CNN, the advantages for this algorithm are advances in Computer Vision (CV). CV algorithm diversity used in technologies nowadays including treatments for the visually impaired, security, drones, medical diagnoses and driverless vehicle [59]. Other than that, CNN is widely used in business-oriented tasks[58] such as making natural-language processing available on analogy and manuscript documents, whereby the images are symbols to be transcribed and to digitize text known as Optical Character Recognition (OCR).

However, the CNN are naturally slower because of the operation, like maxpool and in addition the training process will become slower when the CNNs have several layers because the computer doesn't consist of a good GPU. Other than that, based on [59] the author stated that to process and train the neural network CNN require a large Dataset.

### D. Recurrent Neural Network (RNN)

Artificial Neural Network (ANN) alongside internal loops is called RNN [60] and this is a powerful technique. The interesting part about RNN is this technique is being used every day such as image recognition that capable to tell the picture's content, speech recognition, language translation, stock prediction and also driverless vehicle RNN indeed a powerful algorithm for prediction purposes because this algorithm can divide text and words into sequences, especially on sequence data modelling and the sequence data appear in

many patterns like text and audio. RNN predicts the data by having a concept of sequential memory. For example, as a human we can easily mention the alphabet in sequence because we already memorized it. However, when we want to mention the alphabet backwards it's pretty hard for us because we have not memorized it. A human brain capable to recognize sequence of patterns [60] by using sequential memory mechanism.

RNN replicates the concept of sequential memory of the human brain by using 3 layers called as an output, hidden and an input layer. In RNN exists a looping mechanism that can pass the previous information forward. This looping performs as an expressway to flow information from one step to another [60]. The previous input information is kept in the hidden state. As an example, by using RNN we can build a chat box and the chat box capable to classify intentions from the user inputted text [60].

As mentioned in the previous sentence, the hidden layer representation of previous input and it will be modified. This modified hidden state contain data from all the earlier steps and continue to loop until no more words and then gives to the output to feed the board layer and it gives the forecast. Forward pass control flow of a RNN can be done by for loop [61].

The RNN architecture workflow quite simple to understand by many. Example of RNN such as previous information is taken by present cell before come out the output. Meanwhile, by referring the Fig. 7, it represents the processed word,  $t$  also will be the input after the word was processed. All the text available to process when the sequence dimensions are reduced to a certain value. The sequence needs to meet the size requirement, otherwise the sequences will be filled until the specified value. However, the excess will be barred if the sequence size is more than the specified value [62].

Training in neural network consists of three crucial steps. The first step is to make a prediction by forward pass, then by using loss function the networks can differentiate the output prediction to the ground truth. On the other hand, when the loss function gives an error value as their outputs, it means the network is performing badly. Finally, this network calculates the gradients for every node to do back propagation by using the error value [61]. In this case, gradients referred to a value that mainly used for allowing the network to learn by adjusting the network's internal weight and if more the gradient, hence the more the adjustment.

However, a short-term memory is inside the hidden state. This is common memory to other neural network architectures and exist because of the infamous problem which known as vanishing gradient. This problem appears on a one reason, which is the information that have been kept in the previous step have error[61], and basically during training and optimize neural network processes, this problem is normal nature to back propagation algorithms.

The computation of RNN model is slow, this drawback led to difficulty to train the data when the researchers using the activation functions because it will make a very exhausting process which makes the long sequences process [63]. Hence, the exploding or gradient vanishing will happen.

Fig. 7. An Example of RNNs Model.

### E. Unsupervised Learning

Supervised Learning is different from unsupervised learning in so many ways. This algorithm trains the samples without training the labels. The unsupervised learning is divided into two outcomes which are clustering and dimensionality reduction. Clustering outcome formulated using the algorithm to find consistent patterns become apparent, the similar data points can be clustered together, and different data points will be in different clusters in the data such as recommender system, targeting marketing and customer segmentation. While dimensional reduction outcomes are like finding suitable structure and pattern in the data [58, 61] such as big data visualization, structure discovery and feature elicitation.

The unsupervised Models also consist of three different models [58]. The first one is a self-organizing map or known as Self-Organizing Map (SOM), secondly is the Boltzmann Machines model and lastly is AutoEncoders model.

### F. SOM

A neural network based on dimensionality reduction algorithm is called as SOM commonly utilize two-dimensional discretized pattern to perform a high-dimensional dataset [58]. Dimensionality decreases will occur whenever to retaining the data's topology in the primary feature space.

The input space of the training samples will produce a low dimensional discrete on this type of neural network, called as map [34]. In addition, this technique capable to do reduction of the dimensionality.

The similarities in the data could be observed easily by using the dimensionality reduction and grid clustering, that makes this type of neural network is easily to understood and clearly explained [64]. However, cluster inputs need sufficient neuron weights. If the weights not sufficient the map will produce inaccurate results. The SOM model is illustrated in the Fig. 8.

Fig. 8. SOM Model [53].

### G. Boltzmann Machines Model

Unlike others neural network, Boltzmann model only have two kind of nodes called as visible and hidden nodes without an output node [63]. This situation makes this model known as non-deterministic features.

Two computational error can be fix by using this model. As example, optimization problem and search problem may happen and by fixing the weights on the connections the problem will solves and this method also is a cost function [63]. That is illustrated in the Fig. 9.

v - visible nodes, h - hidden nodes

Fig. 9. Boltzmann Machines Model [51].

The main disadvantage is that Boltzmann learning is significantly slower than backpropagation [63]. However, this model also has numerous problems in the use of algorithms. The example of the problems encountered are such as weight adjustment, the time needed to collect statistics in order to calculate probabilities, the times weights change at a time, the difficulties of adjust the temperature during simulated annealing and the difficulties to decide when the network has reached the equilibrium temperature [63].

### H. AutoEncoders Model

To learn an encoding data set, autoencoder model need to use training technique in unsupervised way. In order to learn an encoding data set focusing on dimensionality reduction, autoencoder need to training the network to overpass the signal noise [65].

Learning to encode a data set is the main focus for an autoencoder. Generally, autoencoder will reduce the dimensionality to neglect the noise's signal by network's training. In addition, autoencoders will provide a model to user by referring the data rather than predefined filters [65].

In general, the autoencoders provide the users a filter that may fit the user's data better [65]. However, Generative Adversarial Networks is much more efficient than autoencoders in term of recreate an image. In addition, images will start blurry whenever the complexity of the images increase [65]. That is illustrated in the Fig. 10.

### I. Semi-Supervised Learning

Semi-supervised learning falls in the middle of unsupervised and supervised learning. In reality, hiring an expertise worker needs a lot of money because we need to pay their skilled, because of that the cost of label is high [66].

Hence, semi-supervise algorithm became the best methods for the building the model especially for the less labels data. To put it clear, this data brings crucial information about the group parameters even from the unknown group of unlabeled data.

Fig. 10. Autoencoder's Model.

### J. Reinforcement Learning

Machine Learning that has a representative like robots that know how to behave in an environment by evaluate the results is called as Reinforcement Learning. In addition, the robot will get a reward through the points given to them based on their performance on gives correct response in every situation. This point will boost up the robot's confident to take more actions. This process is like Markov Decision Process also known as (MDP). On the other hand, data classification in reinforcement learning is useless [67] because the robot learns from trial and error and support by the concept reward and punishment by MDP.

## IV. METHODOLOGY

Based on those algorithms mentioned in the above sections, we chose the CNN algorithm. A study by found that the trendiest technique of neural network for working with image data is CNN. Other than that, CNN are very good in extract image features that makes this neural network became famous and our research paper is based on image data, so CNN is the best algorithm to build our model. On top of that as our research paper used image and pattern recognition, hence CNN is the best choice for our research as this network can solve our problems with using their technique whereas other neural network doesn't have this technique.

The interesting part in this paper is about our methodology stages. Firstly, pre-processing step is being used to haul the images of test data before predicting the classes for these images utilize the trained model. There are seven sequences to construct this model. Firstly, we need to set up Google colab, secondly, we need to import libraries, thirdly we need to load and pre-process data. This step took around three minutes, and then we needed to create a validation set. The next step is defining the model structure, this step took around one minute. Then we need to train the model. This step took around five minutes and the last step was to make a prediction and this step took around one minute. After that we may predict the pattern of the model and analyze its performance using model.predict().

In this study, we are using our own dataset to present the training set. To set up the structure of our image data, we prepared two folders for our data set, the first one is set A

which is named as known folder and the other one is set B which is named as unknown folder. Firstly, we create three folders in each set, the first folder is the train folder, the second folder is the test folder, and the last folder is the validation folder. These sets contain the images of all the test images but no labels. The reason is because the images set will be trained on our model and the testing set images will predict the data by label it.

After that we split the model building's process into four stages. The first one is loading and pre-processing data which takes 30% of all time, the second one is defining model architecture which takes 10% of all time. The third stage is training the model. This model took half of all time for this process. The last stage is estimation of performance. This stage took 10% of the time.

Validation set should be constructed before disclosing to the test set, these methods used to perform the unseen data. Train and validate the data should be done on their own data respectively by subdivide those data set. All the parameters applied in Table I. The model trained a few times using the list of parameters in the table and the results are shared in the next section of this paper.

#### A. Stage 1: Loading and Pre-processing Data

To begin with, we need a dataset to train on. Data is a new gold. ML and DL are not magic, they need data to train. As mentioned above, the first section is loading and pre-processing data. This is a very important step in any research. With having a good number in training set means it determine the better performance of the model and the architecture of the model determine the pattern of data in order to create the validation set.

In this study we are using our own dataset. As shown in Table II, our data consists of 255 images and the images represent two different datasets which are known face and unknown face folder. This process just needs a very little Pre-processing process because by considering the small size of the images, hence the dataset is very easy to upload. Firstly, we need to import the necessary libraries. We are using a matplotlib array and diverse modules correlate with TensorFlow and Keras.

TABLE I. THE PARAMETER USED DURING MODEL TRAINING

PARAMETERS	VALUES
Optimiser	Adaptive Moment Estimation (adam)
Learning Rate	0.0005
Batch Size	1, 20
Epochs	10, 20, 30, 40, 50, 60, 70, 80

TABLE II. THE SUMMARY OF THE IMAGES USED TO FEED THE MODEL

Input Image Size	378 x 378 pixels
Original Image Quantity	255 pieces belong to 2 classes
Training Images Quantity	72.5% of 255 images belong to 2 classes
Validation Images Quantity	69% of 255 images belong to 2 classes

In this research paper, the data images are shrunk to one similar size of training data images: 150 x 150 pixels during training.

Then we need to prepare the data. In this section we need to load and import our data In this section we can determine the data that we want to load by using load\_img() function. However, negative  $\text{impact}$  will happen if the amount is huge. On top of that, we set our data image to 150 wide and 150 heights. In this stage we need to normalize our input data.

Our research uses image as our input value. Its value is between 0 and 255. On the other hand, we need to normalize the data by divide the image value with 255. To predict the number of neurons that we need to compress in the last layer, firstly we need to declare the data type as an integer in the dataset and fix the number of classes. In our case, we utilize ImageDataGenerator (rescale = 1. /255) command because its currently an integers value.

#### B. Stage 2: Defining the Model's Architecture

Model architecture is very crucial step to define. CNN model was designed in this stage and estimate the number of convolutional layers and hidden layers that we need. After that we need to define the format that we will use for the model. We are choosing Keras because Keras has few different formats to create the models. In Keras sequential format is very popular because of those factors we import it from Keras.

A convolutional layer was used in our first model and this layer also will run in input nodes specifying the number of filters is very important to implement in Keras, the size of filters that we want, In our case we are using 64 filters of dimension 3 x 3, the input shape and the activation and padding that we need. So, the activation that we use is ReLU since it is the common activation in DL; however we can string the activation and pooling together.

Dropout layer were created to prevent overfitting. To do this, we need to eliminate some of the connections between the layers. We are using string dropout (0.5), so we can drop 50% of the existing connection. After that we are doing batch normalization where the input heads to the layer after and make sure that the network continuously provides activations with the similar circulation needed.

Then, to learn more complex presentation of network we need to increase the filter's size, hence another convolution layer will appear. Adding a convolution layer means the filter's numbers is increased too, hence, more complex images will be learnt. We also used a pooling layer. In the pooling layer, as discussed in the previous section this layer makes the image classifier more robust so it can learn relevant patterns. However, pooling layers discards some data, so we don't use many of those layers. Because of our data already in small size, we just twice the pool. After that we did over these layers to give our network look more representation. Then we used fully connected layers and sigmoid activation algorithms.

#### C. Stage 3: Training of the Model

After defining this architecture's model, then we do the training of the model stage. In this stage we need to compile it and need to detail up the epoch's number that we prefer to train

and the optimizer that we need to use. In order to reach the fewest point of loss, we need to use the right optimizer to tune the weights for the network and that why we choose Adam optimizer algorithm as it provides good output on most problem situations. In this stage we need to combine with our chosen model's parameter and also determine the metric to be implemented. We are using Adam optimizer as the optimizing function and binary\_crossentropy as the loss function while training the data.

Then, the model's summary can be print out to analyses the pattern. There is a lot of info inside the summary such as type of layer, the output shape and the parameter. To train the model we need to use the fit() functions on the model and pass in the chosen parameters. We will have the validation set which is different from the testing set. In this stage, we just want to make sure the test data is set aside but not to be trained.

For training models, we require two important data sets. The first one is the true labels and training images, and the other one is the validation images and true labels. The true labels in validation images are needed not for the training phase, but to validate the model.

D. Stage 4: Estimating the Model's Performance

Lastly is the estimating the model's performance stage. In this stage we can see the accuracy result, loss result, plot loss and plot accuracy for each validation and training epoch. Finally, we can test the model on the random train image for both sets; the flow of train image in our work is shown in the Fig. 11.

Fig. 11. The Flow of the Proposed Work.

To excellency support of the proposed approach, we compared the results of our approach with some other methods of face recognition in the literature based on existing methods including ANN, support vector machine (SVM) and Principal component analysis (PCA).

V. RESULT AND DISCUSSION

Few parameters are being adjusted on the validation and training process. The training was done repeatedly in eighty sets, and the Table III shown the experiment output. We also show our training and validation result in graph foam. The graph shows in Fig. 12 and 13.

TABLE III. THE PARAMETERS USED DURING MODEL TRAINING AND RESULTS, RESPECTIVELY

Step	Loss	Epoch	Learning Rate	Test Accuracy
355ms/step	0.5043	1	0.001	0.8889
350ms/step	0.0820	2	0.001	1.0000
340ms/step	0.0092	3	0.001	1.0000
346ms/step	0.5049	4	0.001	0.8750
349ms/step	0.0360	5	0.001	1.0000
362ms/step	0.5936	6	0.001	0.8889
363ms/step	0.0458	7	0.001	1.0000
347ms/step	0.2920	8	0.001	0.8889
361ms/step	0.1855	9	0.001	0.8889
350ms/step	0.0236	10	0.001	1.0000

Fig. 12. Training and Validation Accuracy Graph.

Fig. 13. Training and Validation Loss Graph.

Fig. 12 shows the training and validation accuracy graph for our research. The meaning of accuracy here is the number of correct predictions. The training accuracy is actually the accuracy that we get when we use the model on the training data; on the other hand, the validation accuracy is the accuracy on the validation data. As we can see in our graph below the training accuracy in our research achieves the 100-percentage accuracy before the 30 epochs.

Fig. 13 shows a training and validation loss graph for our research. As we can see the graph shows training which is the blue line against validation loss which is the orange line. Training loss means that is the error on the training set of data, while validation loss means that the trained data got error after running the validation, so when the epochs increase the both training and validation error drop. Our graph shows that the training error continues to drop, it also shows that the training error totally drops before the 30 epochs that means the network learns the data better and better.

Fig. 14 shows the testing model on a random train image from set A in our research. The figure shows the target size of the random image as shown in the figure.

Fig. 14. Testing Model on a Random Train Image from Set A.

Fig. 15 shows the testing model on a random train image from set B in our research. The figure shows the target size of the random image as shown in the figure.

Fig. 15. Testing Model on a Random Train Image from Set B.

Table III shows the parameters used during model training. In our research, we are using six parameters which are epoch, step per epoch which is calculated in second, loss, accuracy,

validation loss and validation accuracy. Epoch means the integer of the total number of repetitions on the data. In this research, we are using 80 epochs. While the step per epoch means the total number of steps that get from the generator before declaring one epoch finished and starting the next epoch. In our research the first step took around 53 seconds to finish before starting to the second epoch. For the epoch number 2 until 80 the range step per epoch took about 35 and 36 seconds for each step. The next parameter is loss that represents how much worst the model's prediction on one example.

Normally, the loss value will be reduced after each model training repetition. The model prediction is considered perfect if the loss is zero and vice versa. As we can see in the table IV below our loss value keeps reducing for every epoch, it means that our model prediction is perfect. The next parameter is accuracy; the accuracy of a model is defined as a percentage of correct predictions for the test data. In our research, the accuracy of the model increases in every epoch and achieves 100 percent accuracy before the epoch of 30. Next is the validation loss parameter, the validation loss means that the trained network has error after the data set have been run through the validation set, as we can see in table IV the validation loss of our research reduces in every epoch. That means the error is reduced in every epoch. The last parameter is validation accuracy parameter; validation accuracy is the accuracy on the validation data. As we can see in our table below the validation accuracy in our research achieves the 100-percentage accuracy before the 30 epochs.

TABLE IV. THE PARAMETERS USED DURING MODEL TRAINING AND RESULTS, RESPECTIVELY

Epoch	Step per epoch (second)	loss	accuracy	Validation Loss	Validation Accuracy
1	53s	0.4079	0.8486	0.2428	0.9429
5	36s	0.2305	0.9514	0.2325	0.9429
10	35s	0.2043	0.9514	0.1705	0.9571
15	36s	0.1192	0.9514	0.2591	0.9429
20	36s	0.0925	0.9784	0.0644	0.9571
25	36s	0.0757	0.9784	0.0236	0.9857
30	35s	9.3065e-04	1.0000	4.6639e-05	1.0000
35	35s	8.4819e-07	1.0000	2.2389e-06	1.0000
40	35s	2.2942e-06	1.0000	1.2312e-06	1.0000
45	35s	4.2259e-07	1.0000	5.8786e-07	1.0000
50	35s	7.4016e-07	1.0000	3.3890e-07	1.0000
55	36s	2.3546e-06	1.0000	9.1678e-08	1.0000
60	36s	4.8171e-07	1.0000	1.7699e-07	1.0000
65	36s	7.5054e-07	1.0000	3.6083e-08	1.0000
70	36s	1.0656e-07	1.0000	1.0284e-07	1.00001
75	35s	1.4218e-07	1.0000	4.9360e-08	1.0000
80	36s	2.7106e-07	1.0000	3.7226e-08	1.0000

When the research is completed, we will feed the tested images to the model that we have trained using known and unknown face's label. The predicted image in Fig. 16 and 17 is well identified by the model as we trained the model data, which is the Fig. 16 predicted to known faces and Fig. 17 is predicted unknown faces. The prediction images are shown in Fig. 16 and Fig. 17.

Fig. 16. The Prediction Image Result from Set A.

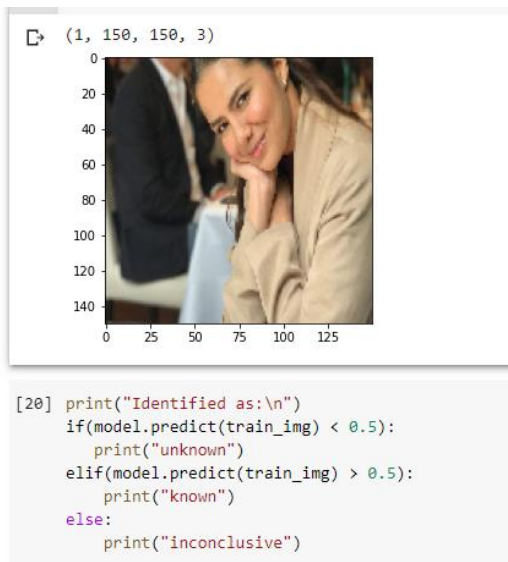

Fig. 17. The Prediction Image Results from Set B.

Based on the comparison of face recognition approach in the Table V, it is clear that the all mentions methods capable to recognize face recognition but the accuracy is differed. Author from [68] mention that the highest percentage by using ANN

approach is 80%. Meanwhile a study did by [69] had mentions that the experiment by using Multi-class SVM achieve until 96%. Other than that, a study did by [70], had mention their approach got the 77% similarities by using PCA integrated with Eigenface approach. From those comparisons, our proposed approach shows that the CNN can achieve a higher face recognition accuracy than others. As such, it can be concluded that the CNN can promote the performance of face recognition due to the availability of the many features.

TABLE V. COMPARISON OF FACE RECOGNITION ACCURACY

Method	Accuracy (%)
CNN	98.5
ANN	80%
Multi-class SVM	96%
PCA + Eigenface	77%

## VI. CONCLUSIONS

Convolution neural networks have become the main technique in the field of face recognition. In this research paper, implements a CNN, which automatically trained the given dataset to predict the classification of images. These models predict an accurate output result by using every face angle from the front, right (30-45 degrees) and left (30-45 degrees). and give significant performance. On the other hand, it will lead to further development for face recognition using deep learning. From the model training experiment point of view, we can conclude that our data set can produce good results and through the data set the model can differentiate between two different data in high accuracy prediction. Hence CNN is a good technique for face recognition technology.

However, we can have a better result if we divide our data set into 70: 20: 10 ratios. 70 % is for training folder data set, 20% is for validation folder data set and 10% for the test folder data set. We are using 255 images for this experiment. We can have a better prediction if we use the bigger data set.

## VII. FUTURE WORK

The research should be further developed in a large dataset to make sure this research can be implemented in real vehicles for safety purposes. Moreover, this paper aims to use face recognition technology in scientific and daily life applications for locking and unlocking autonomous vehicles. In the near future, face recognition technology will become a common approach in many applications. With the Covid-19 pandemic that happens in this world right now where all people are wearing mask wherever they go outside to public area, its hard to identify a person with a mask covering half of their face. The researcher should consider the user in pandemic situation. Furthermore, additional algorithms need to be used and conducted to improve user experience especially for disabled users.

## ACKNOWLEDGMENT

This research was supported by Ministry of Education (MOE) through Fundamental Research Grant Scheme (FRGS/1/2021/ICT10/UTM/02/3). We also want to thank to

the Government of Malaysia which provide MyBrain15 program for sponsoring this work under the self-fund research grant and L00022 from Ministry of Science, Technology and Innovation (MOSTI).

This research also was supported by UTM Encouragement Research Grant Q.J130000.3851.19J08.

# A Case Study on Social Media Analytics for Malaysia Budget

Ahmad Taufiq Mohamad, Nur Atiqah Sia Abdullah\*

Faculty of Computer and Mathematical Sciences  
Universiti Teknologi MARA, Shah Alam  
Selangor, Malaysia

**Abstract**—Malaysia citizen always looks forward to the budget announcement, which is presented by the government each year. Due to the direct effect on the economy, the citizens' opinions are crucial in understanding what they want and whether the budget satisfies them or not. Social media analytics can gather netizens' opinions on Twitter and conduct sentiment analysis. Most of the corpora in previous sentiment analysis research use English-based corpus. However, the current scenario of tweets in Malaysia uses a combination of English-Malay words. Therefore, this study uses a hybrid of the corpus-based and support vector machine approach. Semantic corpus-based combines the Malay and English words. Then, the domain-specific corpus on Malaysia Budget is constructed, which is budget corpus. Two separate analyses include category classification and sentiment analysis. Overall, most netizens have a positive sentiment about Malaysia's Budget with 56.28% of the tweets being positive sentiments. The majority of the netizens focus on social welfare and education that have the highest tweets. The discussion highlights the suggestion to improve the accuracy of this study.

**Keywords**—Malaysia budget; twitter; social media analytics; sentiment analysis; category classification; budget corpus

## I. INTRODUCTION

Social media platforms allow people to share content quickly, efficiently, and in real-time. There are numerous social networking services available to be utilized. Netizen intends to discuss current issues include politics, budget, products, and others using these social networking services. Budget is one of the important issues for a government. A government has annually presented the national budget plan for the next part of the year. The allocation and utilization of public funds in an efficient and prudent manner have always been a key concern in most of the budgets, including the Malaysia Budget. For this case study, the focus is on the Malaysia Budget 2020, which has been announced on 11 October 2019.

The budget consists of all aspects such as education, national defense, agriculture, transportation, and many more. This concern caused the government to reform its budget and finance to gain greater rationality and effectiveness in public financial management [1]. Therefore, the budget announcement is crucial for the ruling government.

Netizen shares their opinions through social media platforms about the budget before and after the budget presentation in Parliament. The government can use these

opinions as an evaluation of their budget allocation and citizens' satisfaction. Sentiment analysis can help in opinion mining. It makes use of natural language processing and text analytics to identify and quantify subjective information systematically. After the budget announcement, there is a need to conduct a social media analytic on these opinions to evaluate the peoples' sentiments towards the budget. It can be the guidelines for improving future budget analysis.

This paper aims to conduct a case study on social media analytics for the Malaysia Budget. The processes in the case study can be a guideline for future budget analysis. The paper continues with Section II that focuses on a literature review on social media analytics, sentiment analysis, and data visualization. Then, Section III shows the methodology for the study. It follows by the results and discussion in Section IV. It ends with the conclusion in Section V.

## II. RELATED WORK

### A. Twitter

Twitter has gained popularity among scholars, students, leaders, politicians, and the general public. It is one of the ideal public platforms for the rapid and comprehensive dissemination of political information and opinions [2], with an average of 330 million monthly active users and 500 million tweets. Retweeting is also a big part of Twitter, where people retweet or share other tweets with everyone else. The activity on Twitter involves the use of hashtags to aggregate tweets about the same subject.

### B. Social Media Analytics

The use of social media and the web creates a source of data that can be mined for new insights into how people communicate and behave, what they think and feel, and how they connect to each other [3]. Typically, retailers use social media in a few ways to promote their products. However, with people not only sharing content but also sharing their opinions, retailers or organizations find these opinions useful.

Gathering netizens' opinions about a topic or product or something in general, organizations can analyze their opinions and find ways to capitalize on them. If the netizens complain about a product of a rival company, organizations can use those opinions in creating a new product that will satisfy the netizens' needs. That is what social media analytics is all about; a practice of gathering data from social media websites and analyzing that data using social media analytical tools to make better decisions.

\*Corresponding Author.

### C. Data Preparation

Data preparation is crucial in social media analytics. It includes data scraping, data cleaning, data pre-processing, and stemming.

1) *Data scraping*: One of the ways to gather data from Twitter is through data scraping. The author in [4] describes scraping as getting the online data collection from social media and other websites in the form of unstructured data. Scraping has shown its capabilities in social media analytics, allowing new ways to collect and analyze social data [5].

2) *Data cleaning*: This process removes repeated data that are unrelated to the topic, removing typographical errors [4]. If there is incorrect or inconsistent data, it can lead to false conclusions, thus misdirecting the solutions. For example, this study analyzes the netizens' opinions if the data are incorrect, and the result could show netizens agrees with the budget allocation. However, the actual result could be the other way around.

3) *Data pre-processing*: Multiple steps of pre-processing [6] include removing stop words and stemming. However, it depends on the kind of analysis and expected output. Stop words are the most frequent words like articles (a, an, the), auxiliary verbs (be, am, is, are), prepositions (in, on, of, at), conjunctions (and, or, nor, when, while) that does not provide any information to the analysis. Therefore, stop words can be removed [7].

4) *Stemming*: In pre-processing, stemming is defined as coding multiple forms of a linguistic object into a 'rudimentary' shape with the same meaning [8] or obtaining the root, the stem of derived words [9]. Another part of data pre-processing is the categorization of data. It aims at classifying documents into a variety of pre-defined categories [10]. It is a process of assigning tags or categories to text according to its contents.

### D. Sentiment Analysis

Sentiment analysis is evolving rapidly as an automated linguistic relation and context review process [11] that involves a process of extracting attitudes, emotions, and feelings [4]. Social sentiment indicates how a person states his opinion and attitude towards an object [12]. The strength of sentiment or opinion is associated with the intensity of some emotions [13] such as joy and anger.

The evaluations can be based on consumer behavior research: rational evaluations and emotional evaluations. Rational evaluations are tangible beliefs and utilitarian attitudes, for example, "This house is worth the price". While emotional evaluations are based on non-tangible and emotional responses to events that go deep into the state of mind of individuals. For example, "This is the best house in the neighborhood". After evaluation, the polarity of the statements needs to be defined. Classification of polarity can be binary, ternary, or ordinal [11] depending on the aim of the sentiment analysis.

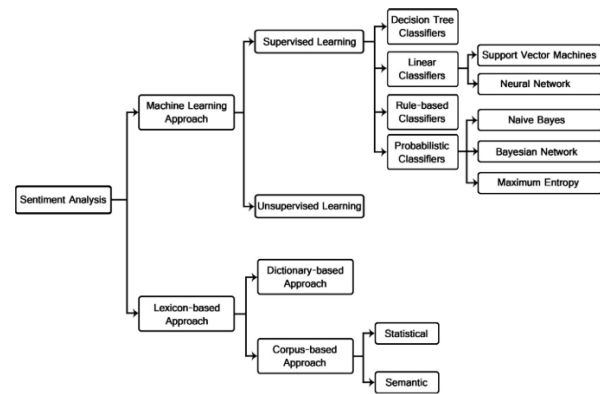

Fig. 1. Sentiment Analysis Techniques [15].

Fig. 1 shows the multiple techniques used for sentiment analysis. Sentiment detection approaches can be divided into the lexicon-based approach and the machine-learning approach [14]. The lexicon-based approach is divided into dictionary and corpus approaches. The machine learning approach (ML) uses popular algorithms such as Support Vector Machine (SVM) and Naïve Bayes (NB), which use linguistic features. ML approaches for sentiment analysis can be unsupervised or supervised machine learning.

Multiple articles on sentiment analysis are studied to gain knowledge on the performance of the classifiers mentioned. Table I shows numerous papers on sentiment analysis. The purpose of this comparison is to find the classifier that performs the best among others. From the review, SVM is the best as it performs better than other classifiers in terms of sentiment classification. There is a Malay Opinion Corpus [16] used as a data source. It is similar to this study, where the extracted tweets are Malay words with a combination of English words.

After a literature review of the sentiment analysis techniques, this study uses a hybrid of semantic corpus-based and machine learning SVM. The semantic corpus-based was chosen because it gives the sentiment values directly and suitable for domain/context-specific data. The SVM was chosen as the classifier as it is the best among others.

### E. Data Visualization

Data visualization can express data in a visual form that finds blind spots [27], which helps users acquire knowledge about the data. Data can be observed from different perspectives and used more in-depth observation and analysis. Because there are different degrees of data, the zoom feature should be implemented in data visualization [28].

Many researchers agree that data visualization can improve decision-making [29-31]. It helps an organization to view where they are and the process carried by an organization. An organization views and analyses the visualized data and can identify the problems for adjustments. Therefore, the organizations improve their decision-making through systematic data analysis to make changes to their process flow.

TABLE I. COMPARISON OF SENTIMENT ANALYSIS TECHNIQUES

Study	Technique	Feature Selection	Data Source/ Domain	Performance
[16]	SVM, Naïve Bayes, KNN	Information Gain (IG), Gini index, Chi-squared	Malay Opinion Corpus	IG-based performed best, SVM performed best (85.33%)
[17]	Naïve Bayes, KNN, and Decision Tree	Word tokens	Roman-Urdu opinions	Naïve Bayes highest accuracy (97.50%)
[18]	SVM, Naïve Bayes, Rocchio, C4.5, KNN	Word tokens	Reuters-21578, Ohsumed	SVM outperforms other classifiers
[19]	SVM, Artificial NN	Words, TF-IDF, IG	Amazon.com	ANN produce better or at least comparable results to SVM
[20]	Convolutional NN	Uses filters to produce features	Movie reviews, SST-1 SST-2, Subj, TREC, CR, MPQA	CNN achieve the highest accuracy for 4 out of 7 tests
[21]	Rule-based	Lexical features	Social media text	Performed as well as other techniques
[22]	Hybrid of Rule-based with supervised learning	N-gram, POS Tags, @USER, Hashtag, URL, Discourse	Twitter	Hybrid improve SVM Predictions
[23]	Bayesian Network	Chi-square	Twitter	Precision: 55.57%
[24]	KNN, Random Forest, Naïve Bayes, Bayesian Network	Words	Twitter	KNN highest accuracy for with stop words (99.65%) and without stop wards (96.64%)
[25]	Maximum Entropy	Words	Chinese online product reviews	Accuracy: 80.87%
[26]	Unsupervised learning	POS tagging	Korean language	F1 score: 71.8%

#### F. Types of Data Visualization

There are five data visualization categories, namely temporal, network, geospatial, hierarchical, and multidimensional.

1) *Temporal visualization*: It is one of the simplest and quickest ways to represent important time-series data. Temporary datasets usually include location and time datasets. Sometimes, these datasets may contain different characteristics [32], depending on the data sources. Temporal data have items that have a start and finish time with possibilities of data overlapping with each other.

2) *Network visualization*: A network dataset comprises an arrangement of a set of known connections among entities [33]. Network visualization shows complex relationships between several elements. A network visualization displays undirected and directed graph structures. This kind of visualization sheds light on the relationships between entities. Round nodes represent entities, while lines indicate their relationships. The vivid display of network nodes can reveal non-trivial data discrepancies.

3) *Geospatial visualization*: techniques supporting the analysis of geospatial data using interactive visualization. One of the earliest forms of information visualization is geospatial visualization. There exist a substantial number of applications these days, in which it is crucial to analyze relationships that include geographic location [34]. Geospatial visualization takes place in several real-world situations such as wildland fire fighting, forestry, archaeology, environmental studies, and urban planning that call for decision-making and processes for information formation.

4) *Hierarchical visualization*: Hierarchical visualization is suitable for numerous data types that are automatically hierarchical or ideal for a recursive grouping [35]. Hierarchical data are organized in a tree structure in which each data element identifies a node in the tree. At the same time, each

node can have child nodes. Hierarchical data visualization allows the user to drill down through multiple levels.

5) *Multidimensional visualization*: It manages datasets with several variables to correspond to the visual structure of one-dimension, two-dimension, or higher dimensions [36]. Usually, this technique can represent data depending on one or two variables [37].

### III. METHODOLOGY

There are several phases in the methodology include business understanding, data understanding, data preparation, modeling, evaluation, and deployment. The data preparation phase covers all activities to construct the final dataset from the initial raw data. After the data extraction, the data preparation phase focuses on cleaning the data before the modeling phase. The result of this phase produces a new dataset for the modeling phase.

#### A. Data Collection

RapidMiner software is used for data collection as it is easy to use and without coding. Using the “search Twitter” node in RapidMiner, an access token is needed from Twitter to gain access for extraction. After getting the access token, it sets the keywords for extracting tweets. The related keywords are Budget2020 and “Belanjawan 2020”, which obtain through Google Trends. The process of data extraction continues in 22 days (2 to 23 October 2019). The extraction happens at around 11.30 pm every single day and saves in separate excel files. At the end of data extraction, there are a collection of 9,638 tweets with 12 columns.

#### B. Data Cleaning

Dataset needs to be cleaned from unwanted data such as repetition of data and not related to the topic. Each data is scanned to remove noise, which is unrelated data. For the repetitive data, using the excel function of removing duplicates proves to be enough for removing repetitive data, keeping only the unique texts.

### C. Data Classification

As the budget covers various topics, netizens' tweets also diversify according to the categories in the budget. Therefore, there are nine budget categories with different keywords. The tweets are processed according to the words in the nine categories. Table II shows the sample of related terminologies for nine categories. The nine categories are selected because they are the most talked-about topic by netizens. After analyzing the tweets, the keywords used by the netizens are captured.

After thoroughly going through all the tweets and identifying the keywords, a corpus is created for category classification. The corpus is saved as a CSV file. Each row contains the words and the category. The related words are as follows: 26 words for agriculture, 151 words for the economy, 46 words for education, 41 words for general, 22 words for health, 45 words for others, 19 words for public services, 52 words for social welfare, and 36 related words for transportation. There are 438 words in the budget corpus.

Besides categorizing the words in the budget, the polarity of each tweet is assigned. There are three polarities in this study, positive, negative, and neutral. There are different words according to the polarity. Due to the multilingual comments by the netizen, the words are in Malay and English. Table III shows the related words for the three different polarities. The polarity represents the emotion and feeling of the netizen towards the budget categories. Positive words represent happiness and satisfaction in the budget category. The negative words show the dissatisfaction with the budget.

The processes of classification for the polarity are the same as the category classification. All the sentiment words are used to train the model to identify the sentiment of each tweet. After the classification processes, there are 114 words for the positive polarity, 90 words for neutral polarity, and 92 words for negative polarity. The corpus is used to train the model to classify the sentiment for each tweet.

### D. Modeling

For this modeling phase, there are a few steps to be taken. The first step is selecting a suitable model. For this study, the model focused on sentiment analysis. There are two approaches for sentiment analysis, which are machine learning and lexicon-based models. Machine learning models belong to supervised classification. Two sets of documents, training, and testing, are needed for classification purposes. The training set is used in an automatic classifier to differentiate the characteristics of tweets. The testing set is used to check the performance of the classifier.

For lexicon-based models, it employs dictionaries of words annotated with their semantic polarity and sentiment strength. It uses a corpus to help in the sentiment classification process. Then, the corpus is used to calculate a score for the polarity of the document or dataset. After comparing the techniques for sentiment analysis models, a hybrid of corpus-based and Support Vector Machine (SVM) is selected as the technique in this study. Fig. 2 shows the designed process of sentiment analysis for this study.

TABLE II. WORDS IN SELECTED CATEGORIES

Category	Related Words
Agriculture	Pertanian, sawit, getah, padi, peladang, pesawah, farmer
Economy	M40, B40, gst, tax, cukai, pekerjaan, gaji, ekonomi, epf
Education	Pendidikan, education, TVET, pendidikan tertiary, biasiswa
General	Menteri, Belanjawan, Budget, government, kerajaan, Malaysia
Health	Perubatan, patients, vaccines, medical, kesihatan, disease
Public Services	MINDEF, polis, tentera, kebombaam, pertahanan, TLDM, defence
Social Welfare	Bumiputra, disabled, OKU, wanita, children, orang asli
Transportation	Pengangkutan awam, tol, kereta, minyak, BSH, fuel, Petrol
Others	Persiaran, hiburan, seni, pelancongan, budaya, belia, sukan

TABLE III. SAMPLE WORDS IN THREE POLARITIES

Polarity	Related Words
Positive	best, sokong, satisfying, love, agree, baik, happy, excited, glad, uplifting
Negative	#pakatanhancing, malap, garbage, rugi, bodoh, worse, keburukan
Neutral	not sure, entah, unfortunately, why, but, cadangan, diharapkan

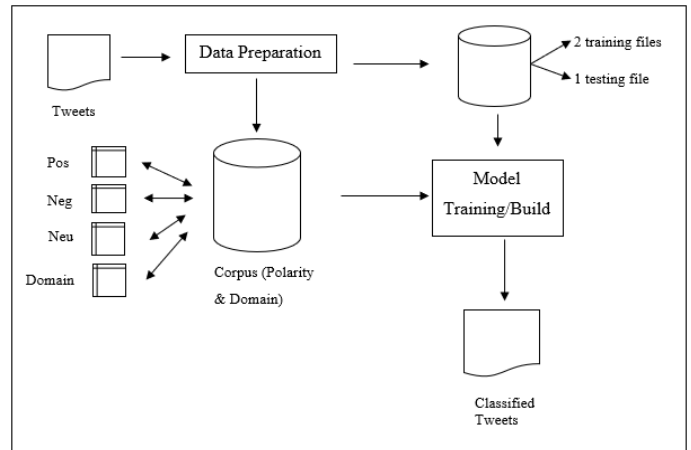

Fig. 2. Sentiment Analysis Techniques [15].

After pre-processing and the preparation of the data, the results of the classifications are set into a corpus. The corpus is used for modeling, where the extracted dataset is trained by two training files and tested using a single file using Support Vector Machine (SVM). The two training files are files containing the category keywords and sentiment keywords. The result of the testing is then compared with the benchmark sentiment dataset to check the accuracy.

The result of both analyses is visualized in a dashboard form. The visualization is presented using PowerBI software based on a dashboard approach where multiple charts are in a single view. As the visualizations have different techniques, multidimensional visualization is more suitable for this study due to the data types. Table IV shows the types of visualizations and data representations for the dashboard.

TABLE IV. DASHBOARD VISUALIZATION

Chart	Data Representation
Pie chart	Percentage and number of polarity
Column chart	Total of tweets in each category
Column chart	Total of tweets in each category with sentiment

The pie chart is used to show the percentage and amount of polarity. The column chart is used to show the total tweets in each category, and sentiments. As SVM has many parameters to experiment with, this study finds the best parameter that produces the best score. GridSearch function is used to find the best value for each parameter. To summarize, the best parameters for this SVM model are:

- Best C: 1000.
- Best Kernel: rbf.
- Best Gamma: 0.001.

These parameters are used for the category and sentiment classification as training files used in the GridSearch function yield the same result.

#### IV. RESULTS AND DISCUSSION

This study explains the processes of gathering and creating a budget corpus for analysis. A hybrid of SVM and corpus-based approaches is proposed for category classification and sentiment analysis. The modeling uses two training files and one testing file for both analyses. Based on the results, social welfare and education are the most popular category in Malaysia Budget 2020 (see Table V).

The netizen talked about the welfare of disabled people, natives, senior citizens, and people from different religions and races. On the topic of education, netizen comment about education issues ranging from kindergarten to university. The other categories in the tweets are agriculture, economy, health, and others. Table V shows the actual number of tweets in each category in the budget.

For sentiment classification, the result of the model training using the parameters achieved a score of 46.59%. The result of the testing model achieved an accuracy of 31.04%. Table VI shows the classification report of the sentiment classification.

Based on Table VI, the accuracy for the sentiment classification is 31.04%. Among the sentiments, neutral sentiment has the highest accuracy of 39.30%, f1-score of 32.54%, precision of 75.37% but the lowest recall score of 20.75%. For the negative sentiment, the model achieved 28.57% accuracy, 28.30% for f1-score, 19.79% in precision, and 49.60% for recall. Lastly, for positive sentiment, it achieved an accuracy of 27.53%, f1-score of 30.31%, precision of 19.48%, and recall of 68.21%.

Fig. 3 shows the noticeable gap between the actual and result of sentiment classification.

There are 843 actual positive tweets, but 2,951 tweets are predicted positive. For the negative sentiment, it is about 502 tweets, but 1,258 tweets are predicted negative. Lastly, neutral has the most sentiment tweets (n=3,952), but the model only

predicted 1,088 neutral tweets. The difference between the classification results is because of the lacking of words in the budget corpus.

With category and sentiment classification, the result is visualized in a dashboard. It helps the analysts in making a more in-depth critical analysis of the study.

Fig. 4 shows a dashboard for the social media analytics in Malaysia Budget 2020. There are three charts in the dashboard. A pie chart displays the tweets based on the sentiment. The column charts illustrate the tweets by time and category. A slicer function is also added to the dashboard to filter the visualization based on a specific category.

The dashboard is evaluated using convenience sampling. From the survey, the dashboard is understandable for the users. The majority of the users agreed that the dashboard is simple and useful for quick insight into the budget.

TABLE V. ACCURACY OF CATEGORY CLASSIFICATION

Category	Actual Number	Result
economy	856	746
education	261	3263
transportation	129	0
health	63	111
agriculture	89	1521
public services	532	0
social welfare	138	3284
general	1361	0
others	2206	94

TABLE VI. REPORT OF SENTIMENT CLASSIFICATION

Item	Accuracy (%)	f1-score (%)	Precision (%)	Recall (%)
negative	28.57	28.30	19.79	49.60
neutral	39.90	32.54	75.37	20.75
positive	27.53	30.31	19.48	68.21
accuracy		31.04	31.04	31.04
macro avg		30.38	38.22	46.19
weighted avg		31.78	61.21	31.04

Fig. 3. Bar Chart of Sentiment Classification.

Fig. 4. Social Media Analytics Dashboard for Malaysia Budget 2020.

With only 5,297 tweets used out of 9,638 raw tweets, the data collection for the analysis is insufficient. As the study focuses on Twitter for data collection, perhaps using other social media platforms like Facebook can increase the data collection related to the budget. Thus, it will lead to higher accuracy of category and sentiment classification of tweets. Furthermore, the study only explored a narrow range of possible parameters values. A recommendation is to explore the SVM parameters such as kernels, shrinking, tolerance for stopping criterion, and class weight. Moreover, a more complex model for analysis would be an opportunity to be explored.

## V. CONCLUSION

The budget presentation has a direct impact on the economy of the country. Therefore, the citizens' opinions are crucial in understanding the actual needs and their satisfaction. Social media analytics can process opinions with sentiment analysis. This study chose a corpus-based approach to extract the Malay and English words that focus on Malaysia's Budget. A hybrid of SVM and corpus-based approaches is used for category classification and sentiment analysis. Overall, the netizens are positive about Malaysia's Budget with 56.28% of the overall tweets. The netizens are more concerned about the social welfare and education aspect of the budget as both categories have the highest tweets. Further exploration of the SVM parameters and complex model for analysis is the potential area to be studied.

## ACKNOWLEDGMENT

The authors express their gratitude to the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA, Shah Alam, Selangor, Malaysia for supporting this study.

# A Pattern Language for Class Responsibility Assignment for Business Applications

Soojin Park

Graduate School of Management of Technology  
Sogang University  
Seoul, Korea

**Abstract**—Assigning class responsibility is a design decision to be made early in the design phase in software development, which bridges requirements and an analysis model. In general, assigning class responsibility relies heavily on the expertise and experience of the developer, and it is often ad-hoc. Class responsibility assignment rules are hard to be uniformly defined across the various domains of systems. Thus, the existing work describes general stepwise guidelines without concrete methods, which imposes the limit in deriving an analysis model from requirements specification without any loss of information and providing sufficient quality of the analysis model. This study tried to grasp the commonality and variations in analyzing the business application domain. By narrowing the subject of the solution, the presented patterns can help identify and assign class responsibilities for a system belonging to the business application domain. The presented pattern language consists of six segmented patterns, including 19 variations of relationship type among conceptual classes. Each sequence of a use case specification could be analyzed as the result of weaving a set of the six segmented patterns. A case study with a payroll system is presented to prove the patterns' feasibility, explaining how the proposed patterns can develop an analysis model. The coverage of the proposing CRA patterns and enhancement of implementation code quality is discussed as the benefit.

**Keywords**—Class responsibility assignment; analysis pattern; business application; sequence diagram

## I. INTRODUCTION

Developing an analysis model is the first phase in software development where abstract solutions are contrived. In the analysis model development, the task that is the most challenging and requires high creativity is assigning class responsibilities. Due to the nature of the task, responsibility assignment has heavily relied on the developer's experience and knowledge about the application domain. The class responsibility assignment (CRA) is hard to teach and apply [1]. On the other hand, it is hard to revise the wrong assignment of responsibilities to classes by adding other design patterns or architectural styles in successive phases.

The GRASP pattern [2] is remarkable and traditional among several approaches introduced to solve the CRA problem. However, it provides several fragmentary solutions and still requires lots of ad-hoc decision-makings to implement the patterns in a specific system. Since introducing the GRASP pattern, several approaches [3-5] that try to lessen the heuristic aspect of the CRA problem have been proposed. Nevertheless, their limitation is that they propose a way to evaluate the CRA

results rather than assign responsibility itself. The posterior evaluation cannot reduce developers' efforts which are already exerted for CRA.

This study presents a pattern-based approach for assigning responsibility, which bridges analysis modeling and design modeling. CRA problems for business applications can eventually be decomposed into a set of CRUD operations on information: creating (C), reading (R), updating (U), and deleting (D). Thus, a data transaction is decomposed into six fragments and designed a CRA pattern for each fragment. This study also provides a way to compose the six fragmented CRA patterns for realizing a sequence diagram for each scenario in use case specifications. According to the given scenario, the sequence diagram can be composed of 2~6 CRA patterns. The links and messages that appeared in sequence diagrams are reflected as relationships between classes and responsibilities of each class. Each CRA pattern is represented by a uniformed template similar to the Gang of Four (GoF) pattern template [6] and composed of predefined variables and constants. The information developers extract from use case specifications is used to substitute variables in the CRA pattern and decide which patterns compose a complete sequence diagram for a scenario. In other words, developers can make an analysis model from the requirements model by mapping the information from use case specifications into each CRA pattern in developing an analysis model from the requirements model.

Compared with other related studies, the differentiated point of the proposed CRA pattern is as follows: the most assignment result of class responsibility is not a set of the tentative candidates but a final decision itself. The limit of the other existing work on class responsibility problems is that developers must select one among multiple candidate responsibilities or revise the candidates even after applying proposed methods. The reason is that most methods do not have a limit on the scope of their application. A solution proposed by the approach to solving the CRA problem of all domains cannot embed the properties for each domain. As a result, even if it is a solution that automatically supports class responsibility assignment, developers must tailor it to fit the characteristics of the domain after applying the methods. This study limits the proposed CRA pattern's application scope to the business application domain to substantially reduce those kinds of developers' efforts. Instead, by embedding the inherent features of the business application domain into the patterns, most of the responsibilities extracted from the CRA pattern

application are included in the final version of an analysis model without any revise.

A case study is conducted to adopt a payroll management system to show the feasibility of using the proposed CRA patterns in developing an analysis model. The coverage of the responsibilities extracted from the CRA patterns is measured to show the benefit of the proposed patterns. The result explains that a considerable portion of the responsibilities can be systematically extracted by applying the CRA patterns and included in the final version of the analysis model. And, the enhancement of the code quality derived from the analysis model constructed by applying the CRA patterns is also evaluated.

The rest of the paper is organized as follows: Section 2 presents related works on the class responsibility assignment problem. Section 3 gives an overview of the presented CRA pattern language, and Section 4 introduces the representation of each CRA pattern. Section 5 demonstrates a case study using a payroll management system, and section 6 shows the evaluation result. Section 7 concludes the paper with future work.

## II. RELATED WORK

Most of the analysis patterns [7-12] tended to focus on providing a way to identify classes that abstract domain knowledge. The main objective of design patterns [7] published up to now is to solve specific problems for successive implementation steps or enhance specific software quality. Contrary to this trend, [2] designated designing objects with responsibilities step as the heart of developing an object-oriented system and introducing the GRASP pattern. GRASP presents nine design principles as patterns: information expert, creator, low coupling, protected variations, indirection, polymorphism, high cohesion, pure fabrication, and controller. The GRASP pattern addresses fundamental, common questions and fundamental design issues on assigning class responsibilities. However, the questions defined by the GRASP are too general, and some principles are more fundamental than others. Their solutions are rather guidelines than patterns that define constants and variables of a model.

Since the introduction of the GRASP, several studies have been dealt with the CRA problem. Bowman et al. introduced a solution for the CRA problem, which is based on a multi-objective genetic algorithm (MOGA) and uses class coupling and cohesion measurement [3][13]. The MOGA takes as input a class diagram to be optimized and suggests possible improvements to it. They implemented a case study that showed that the multi-objective genetic algorithm could fix various artificially seeded assignment problems. However, the result of the MOGA application is limited to fixing the information included in classes. It does not help to construct sequence diagrams that explain dynamic behaviors based on the fixed responsibilities.

In [4], another metaheuristic algorithm for detecting wrong assigned responsibilities and making an optimized CRA is introduced. The proposed four different algorithms (simply genetic algorithm, hill-climbing, simulated annealing, and particle swarm optimization) use the same class coupling and

cohesion metrics. They transformed the CRA problem into a search problem by encoding the problem and defining the fitness function. Like the MOGA, they chose a multi-objective approach, normalizing and combining three different coupling and cohesion measurements into a single aggregated fitness function and implemented a case study on the ATM Simulation domain model. Thus, their pros and cons are similar to MOGA's ones. Although they provide a way to evaluate already completed CRA results and enhance the quality of a design model, the contribution is limited to the conceptual model. Moreover, enhancement opportunities are given after the end of the developers' CRA step. Thus, it is hard to reduce the effort of developers on the responsibility assignment step itself.

Unlike the formerly described two approaches using some algorithm for detecting errors after the end of whole CRA steps, [5] proposed a technique to detect any error in every CRA step. For every step in CRA, the editor automatically detects bad smells of the current CRA and suggests refactored CRAs as alternatives. Designers can accept or reject the suggested CRAs. By repeating the steps of the responsibility assignment and refactoring, designers can construct the more appropriate CRA. This study's contribution is that they suggest formal representation for informal guidelines in GRASP and automatic detection rules for finding bad smells, which is violating the guidelines. However, like other approaches, the developers should create any CRA result before detecting the CRA errors and refactoring, and the application scope is limited on conceptual models.

Whereas the studies mentioned above mainly want to automatically detect errors as a follow-up to the developer's class responsibility identification results, the studies in [14-16] take an approach to automatically extract and present design elements from use case specification. [14] proposes an automated method that extracts domain classes from parsing use case specification using the Natural Language Processing (NLP) technique. [15], like [14], creates a parsed use case description (PUCD), an intermediate step product, from parsing the sentences of the use case specification, and then proposes candidates to construct a class model. The final decision to construct a class model remains to developers. [16] presents an automatic generation of a conceptual model from requirements written in a natural language, English, and proves the quality of the generated models against human works. However, their work has limited in that the coverage of the proposed method over all kinds of natural language is not comprehensive. And, the inherent ambiguity in the natural language occurs, hesitating the decision if a specific noun is an attribute, class, or association. Extracting a conceptual model from requirements needs an abstraction phase and heuristic insights for a specific domain area. Thus, it still requires experts' decisions on the details of the automatically generated conceptual model. Considering the effort of the experts' confirmation on the results, the benefit from the automatic generation of a conceptual model is skeptical. For this reason, this study does not include a conceptual model in the scope of automatically generated modeling artifacts. The conceptual model extracted by experts is used as input knowledge for automatic class responsibility assignments.

As mentioned above, although such NLP-based approaches have partial benefits, there is a limit to replacing the abstraction process that indicates the properties of the application domain, with only parsing the use case specification as a natural language sentence and interpreting it grammatically.

As the different approaches to solving class responsibility assignments, [17-18] attempt to determine responsibilities automatically between classes by using a class diagram as an input. [17] introduces a method that proposes an appropriate number of classes using three hierarchical agglomerative clustering algorithms and two criteria (aggregation metrics and CRA-Index) in the class diagram. And a comparison of the result applying their solution and the MOGA application result is presented. On the other hand, [18] presents a strategy for automatically generating a basic behavior schema from the static view represented by a class diagram. Through the analysis of the relationships between classes, the basic operations required for each class are identified. However, [17-18] has a limit in that the automatically generated operations are specified in too general terms, which requires the final decision of developers on every generated responsibility. Thus, the generated result can be utilized as a guide or reference to decide each responsibility of classes. Still, the automatically generated responsibility, i.e., operation, is hard to participate in an analysis model without a final update from developers.

Consequently, the existing studies on the CRA problem succeeded in enhancing the quality of a design model by providing various evaluation methods. However, most of the current work provides class responsibility assignments as a reference artifact or a candidate artifact for software developers. The result requires developers' final decision or update. It means that they still have a limit in relieving the developers of the CRA step's painful and challenging decision-making burden.

### III. A PATTERN LANGUAGE FOR CLASS RESPONSIBILITY ASSIGNMENT FOR BUSINESS APPLICATIONS

Most pattern-based approaches are subject to questions regarding the completeness of the patterns used. The answer to the question can be found in the definition of the business applications of [19]: "a business application is an application with structured logic and transaction-based database which supports simultaneous access by other applications." From the definition of a business application, an idea that a business flow can finally be disassembled into atomic CRUD(Create/Read/Update/Delete) operations can be captured. Most of the complex business services provided by the domain are readily broken down into a series of CRUD operations.

For example, Fig. 1 shows that the four different business flows from different systems can be decomposed to the identical combination of a read data pattern and an update data pattern. Besides the CRUD operations, interactions with the environment in which the system is driven are also needed to realize a business flow in the applications. In this study, the atomic collaboration between classes for realizing each CRUD operation and interaction with the environment is designed as each CRA pattern. The objective of the proposed CAR pattern language is to provide a way to build an analysis model by

generating a sequence diagram of the system belonging to the business application domain combining the atomically designed CRA patterns. In this study, the syntax to utilize the CRA patterns is also provided. So, for this reason, the proposed set of the CRA patterns is named a "CRA pattern language." First, this section presents an overview of the CRA pattern language.

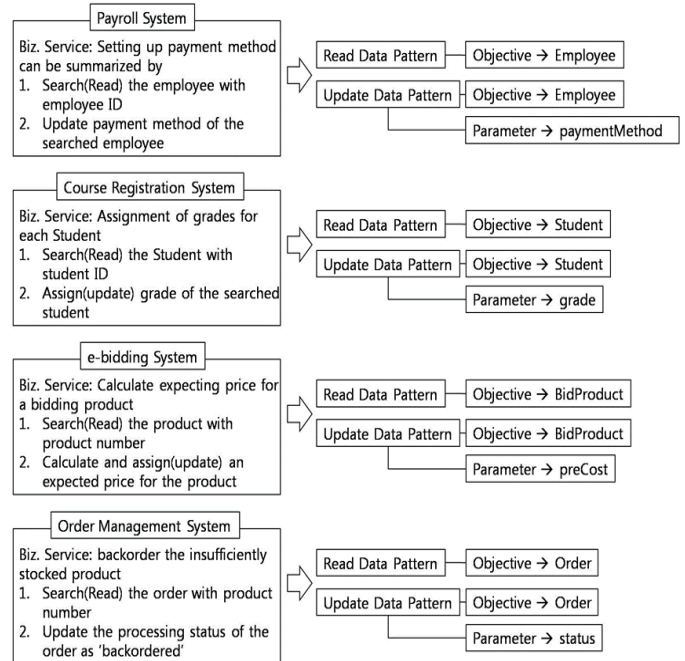

Fig. 1. Examples of Different Business Services Decomposed into the Same Atomic Collaboration Patterns.

#### A. Domain Model

A domain model for assigning class responsibilities for the business application contains all classes participating in the proposed pattern set. This study follows the Model-View-Controller (MVC) [20] pattern in identifying the role of participating classes in realizing a scenario of a use case specification. The participating classes that are divided into three analysis class stereotypes: << boundary >>, << control >> and << entity >>. These three stereotyped classes are arranged in separate packages that represent the basic three layers of business applications. The BizApplication package contains GUI form classes and <<boundary>> classes to interface with external systems. The BizProcess package contains <<control>> classes for managing flows in individual use cases. The BizLogic package contains <<entity>> classes to include actual business logic.

Fig. 2 depicts the whole class composing domain model for assigning class responsibilities of business applications. In Fig. 2, the question marks (?) in class names or operation names indicate pattern variables. The '+' mark, shown in class, operation, and parameter names, is an operator for concatenating two strings. Pattern variables are substituted with data values elicited from requirements documents to generate instantiated class or operation names during the pattern instantiation stage. For example, '?UCNm+ApprvlForm' is instantiated as RgstrCrSApprvlForm if the string value of

'?UCNm' is 'RgstrCrs.' Three classes in the BizApplication package are in charge of interfacing with external actors, including users and external systems. '?objective + ?DmType + Form' class is defined for user interfaces, and '?UCNm+AppvIForm' requests a specific approval from a supervisor role. '?Interface System' class is a boundary class for interfacing with other related systems. All of these three classes in the BizApplication package communicated with the control class, '?UCNm+Cntrl' in the BizProcess package, managing sequences of a flow. All messages from UI classes ('?UCNm+AppvIForm', '?objective+?DMType+Form' ) are blocked by '?UCNm+Cntrl' and all messages to the other system(s) go through the class. Except for the role of a proxy, the '?UCNm+Cntrl' class is responsible for calling appropriate messages to entity classes in the BizLogic package according to incoming requests.

The entity classes receiving messages from '?UCNm+Cntrl' are '?objective', '?AssociatingClass', '?AssociatedAttribute Class' and '?DependentClass'. '?objective+Container' classes are mainly generated by adopting one of the Read Data patterns. It plays as a container

for some entity classes when it is needed to display multi-row data. '?objective+Transaction' class is for only Transfer Data to Another System patterns. The role of the class is to specify data transactions by adding extra data (source system, destination system, length information, etc.) to the '?objective' class. The information of this class is passed when the system should propagate the data manipulation results to other external systems. In Fig. 2, attributes of each class are suppressed to highlight the core of the patterns to assign each responsibility to the proper classes.

### B. Idioms of Pattern Language for CRA Problems in Business Applications

In explaining an overview of the pattern language, this study follows the way of [21]. The pattern language application graph depicted in Fig. 3 shows how CRA patterns are applied during the modeling of applications. Still, it is not intended to show how the resulting system works, i.e., it is not a flowchart. In the original notation of [21], the main language patterns are split into mandatory patterns and optional patterns in the original notation. And, one entry point and several exit points are denoted to represent the pattern application flow.

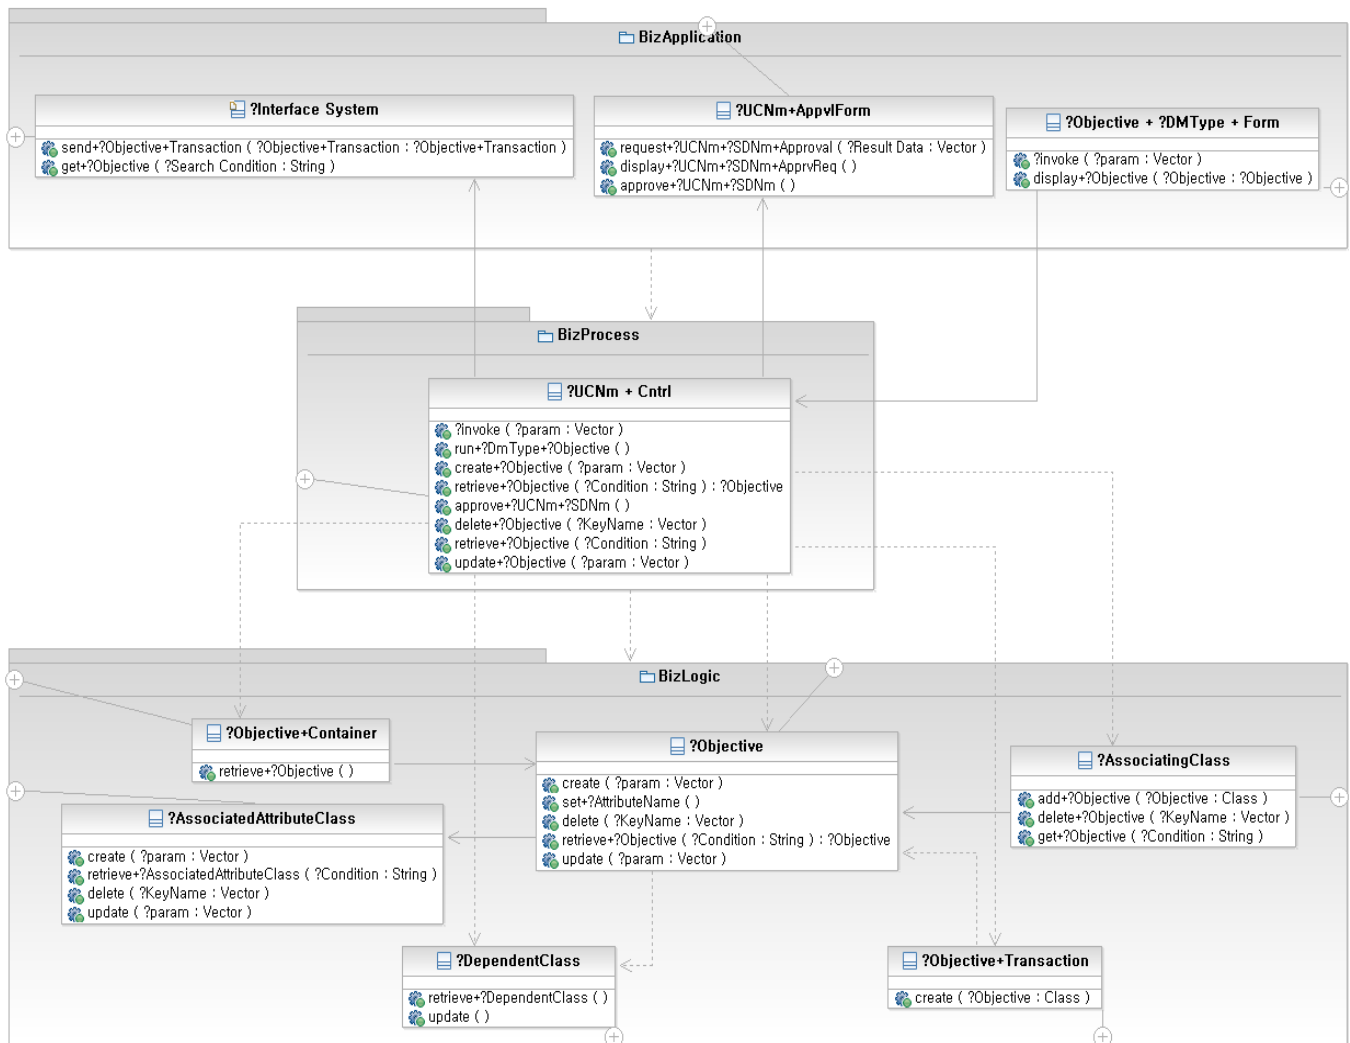

Fig. 2. Class Diagram for Domain Model of a Pattern Language for Class Responsibility Assignment.

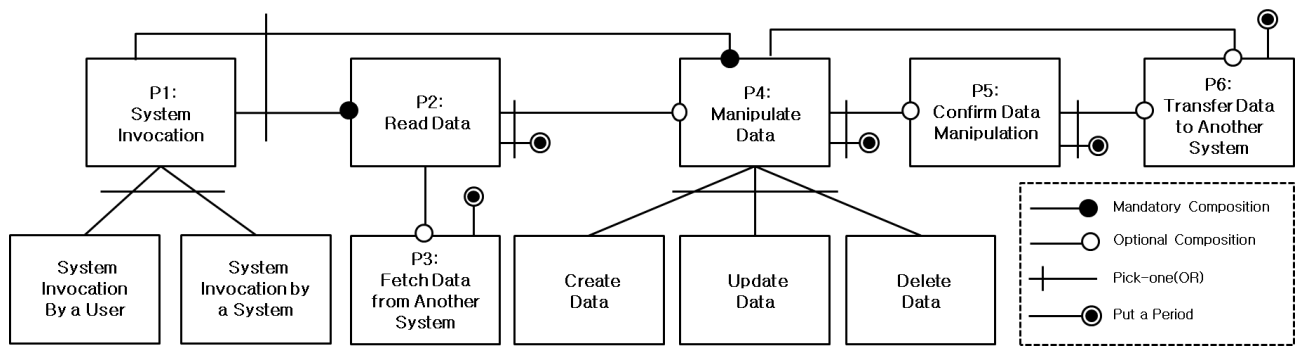

Fig. 3. Pattern Language Application Graph.

The firstly applicable pattern in order is the System Invocation pattern which gives a solution on how the system can be invoked. After applying the System Invocation pattern, the Read Data pattern can be successively applied as users usually check data before changing it. If the data is located in other systems, Fetch Data from Another System pattern can be applied. To be composed as a design fragment for reading some data, the possible pattern sequence is “System Invocation → Read Data” or “System Invocation → Read Data → Fetch Data from Another System.” If the data source to be read is the system itself, the first pattern sequence will be applied. Otherwise, the second option should be applied. So, a typical pattern application sequence is “System Invocation → Read Data → Manipulate Data” patterns. But users could manipulate data without reading anything in some cases, which is also a typical sequence. Thus, the Read Data pattern can be an optional pattern like Fetch Data from Another System pattern.

After applying a pattern belonging to the data manipulation pattern, Confirm Data Manipulation pattern could be optionally applied if it requires any specific actions to reflect the result of data manipulation on the system. The other applicable pattern is Transfer Data to Another System pattern, applied when the data manipulation result should be reflected to another related system.

To sum up, the proposed pattern language is composed of 2 required patterns (System Invocation, Manipulate Data) and four optional patterns (Read Data, Fetch Data from Another System(s), Confirm Data Manipulation, Transfer data to another system(s)). The Read Data pattern is an optional pattern when it is applied with other data manipulation patterns. However, it can be a mandatory pattern when it is used to implement a scenario to show some information to users without any change on data. The minimum number of the patterns composing a scenario is two as the shortest sequence is “System Invocation → Read Data” or “System Invocation → Manipulate (Create/Update/Delete) Data.” The maximum number of the applied patterns for realizing a scenario is six as the most extended pattern sequence is “System Invocation → Read Data → Fetch Data from Another System → Manipulate (Create/Update/Delete) → Confirm Data Manipulation → Transfer data to another system.”

### C. Process of Building an Analysis Model using CRA Pattern Language

With the CRA patterns, a sequence diagram to identify class responsibility from a scenario in a use case specification can be composed through three phases – use case analysis, CRA pattern weaving, CRA pattern instantiation. Fig. 4 shows each step of constructing an analysis model using the proposed CRA patterns, and the detail of each step is the following.

Use Case Analysis: (a) the reference artifacts are use case model and initially identified conceptual key classes. (b) The process starts with analyzing input use cases to identify the necessary information to populate CRA patterns through questions and answers. (c) A set of predefined questions is presented to the developer to decide patterns to be applied and elicit pattern variables to instantiate the chosen patterns.

CRA Pattern Weaving: Use case analysis results in a set of CRA patterns chosen to apply. Six patterns are presented in this study. Each selected pattern defines a segmented collaboration among participating classes, and the number of the selected patterns for a scenario is between two and six. (d) To realize a given scenario as an analysis model, the patterns to compose a complete sequence diagram should be weaved into a sequence diagram. The identically appeared lifeline between two CRA patterns becomes the connection point of the two patterns. From the P1 pattern to the P6 pattern, the required patterns are weaved step by step. At the end of CRA pattern weaving, we can get a skeleton of a complete sequence diagram for the target scenario.

CRA Pattern Instantiation: The skeleton of a sequence diagram resulting from the CRA pattern weaving step still has uninstantiated pattern variables. The value for each pattern variable is extracted in the previous use case analysis step. (e) From the answers to the questions, the values for pattern variables can be extracted. The instantiation of the composed pattern results in an analysis model with responsibilities of CRUD operations and other supporting operations for each analysis class. All of the responsibilities that appeared in the sequence diagram are registered as the operations of the key classes. Besides adding the operation to the existing key classes, new classes are also defined by applying CRA patterns.

The details of each phase will be explained with a tangible application case of a payroll management system in Section 5.

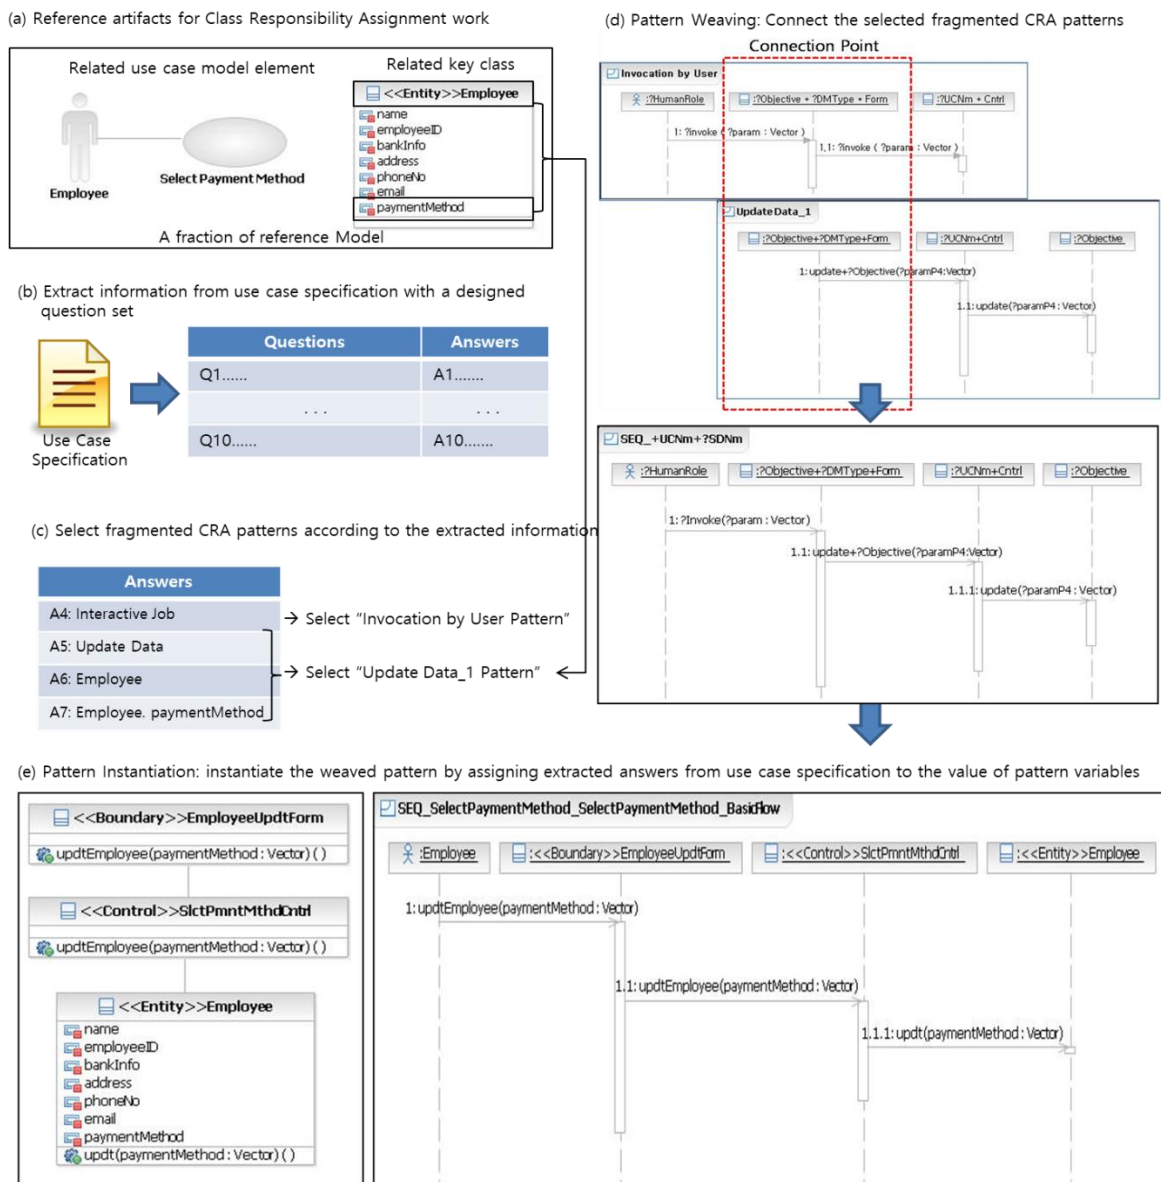

Fig. 4. Building an Analysis Model using CRA Pattern Language.

#### IV. REPRESENTATION OF A CRA PATTERN

The GoF pattern template [6] is utilized to represent each CRA pattern. However, all of the compartments of the GoF pattern template are not used. Also Known As, Motivation, Known Uses, and Sample Code sections are not used as they are out of the concern of the CRA pattern. The followings are the sections and their brief descriptions of the CRA pattern.

- 1) *Problem*: The question to be solved with the pattern regarding the class responsibility assignment aspect.
- 2) *Forces*: The conditions be satisfied by applying the pattern.
- 3) *Solution*
  - a) *Structure*: The static view of the newly defined classes or their properties (operations and relationships), which participate in the interactions in the pattern.

b) *Participants*: The specification of roles of the classes participating in the interactions in the pattern.

c) *Interaction*: The dynamic view showing the collaboration among the classes specified in section 3.2 Participants. More than one interaction could be defined according to the relationship format of the <<Target>> role class and other classes.

4) *Consequences*: The guaranteed benefit from the application of the pattern.

5) *Following patterns*: Another CRA pattern connected to the next to build a complete sequence diagram.

6) *Example*: Simple application example is presented. The finally generated sequence diagram and the corresponding class diagram are provided for understanding the pattern.

Fig. 5 shows the specification of the “Create Data” pattern documented according to the template above. The “Create Data”

pattern has three different interactions, and each sequence diagram defines the collaboration among the participating classes according to the given condition.

As specified in Fig. 5, the P4 patterns (Create/ Read/ Update/ Delete Data patterns) define several interaction

variants according to class relationships and attributes. Table I lists up all interactions embedded in each CRA pattern. There are a total of 19 interactions that can be used to construct a sequence diagram, as shown in Table I.

### Create Data Pattern

#### 1. Problem

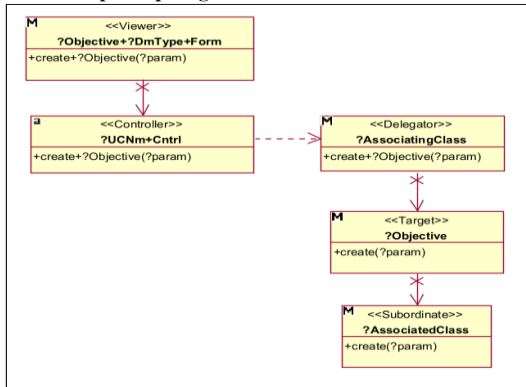

Who should be responsible for creating a new instance of some classes?

#### 2. Forces

- Input data from a user should be created as an instance of a class.
- Responsibility assignment with high cohesion and low coupling should be accomplished.

#### 3. Solution

##### 3.1 Structure: participating classes

##### 3.2 Participants

Role	Description
<b>Viewer</b>	A UI (User Interface) form class for accepting data required to be newly created.
<b>Controller</b>	A control class for conducting collaboration among classes for the realization of a given business flow.
<b>Target</b>	A newly created entity class as the result of the given business flow.
<b>Delegator</b>	An entity class including the <<Target>> class as a data member.
<b>Subordinate</b>	An entity class defined as a data member of <<Target>>.

##### 3.3 Interaction

###### Create Data 1: Simple Creation

Use WHEN a <<Target>> class does not exist in the current static view.

1. Input data from a viewer is passed to a controller
2. The controller creates a target object.

###### Create Data 2: Creation through an Associating Class

Use WHEN (a <<Target>> class exists in the current static view) AND (a <<Target>> is an associated attribute of other class(es))

1. Input data from a viewer is passed to a controller

2. The controller delegates create() responsibility to a delegator of the target object.
3. The delegator creates a target object.

###### Create Data 3: Successive creation of Associated Classes

Use WHEN (a <<Target>> class exists in the current static view) AND (a <<Target>> has (an) object(s) other class (es) as (an) associated attribute(s))

1. Input data from a viewer is passed to a controller
2. The controller creates a target object.
3. The controller delegates creation of subordinate to the target object.
4. The target creates subordinates object(s) as many as defined.

#### 4. Consequences

A fragment of sequence diagram which is instantiated by the pattern conforms to the guidelines of the GRASP pattern. Thus, the instantiated design model can guarantee high cohesion and low coupling.

#### 5. Following Patterns

Confirm Data Manipulation, Transfer Data to Another System

#### 6. Example

- The flow of Event: Create a Schedule

In the given conceptual model of a course registration system, Student class is associated with Schedule class. To compose a sequence diagram for the "creation of a schedule" flow, Create Data 3 is selected and applied. The values elicited from requirements are as the following:

Pattern Variable	Input Value
?Objective	"Schedule"
?AssociatingClass	"Student"
?UCNm	"RgstrfrCrss" (abbreviation of RegisterforCourses)
?DMType	"Crt"
?paramP4	"SID, Year, Semester"

The design model fragment resulting from applying to Create Data 3 is depicted in the following. The Student that is instantiated from ?AssociatingClass (Delegator) is the owner of createSchedule() responsibility and creates an instance of the Schedule which is instantiated from ?Objective(Target) class.

Instantiated Class Diagram for "Create a Schedule" Flow

Instantiated Sequence Diagram for "Create a Schedule" Flow

Fig. 5. CRA Pattern Specification: Create Data Pattern.

TABLE I. THE LIST OF THE CRA PATTERNS AND THEIR INTERACTIONS

Pattern	Interaction	Applicability
System Invocation (P1)	Invocation by User	Use when a user invokes a flow of events
	Invocation by System	Use when a software system periodically accomplishes a flow of events
Read Data (P2)	Read_Data_1	Use when all retrieved data items are attributes of ?objective class
	Read_Data_2	Use when(Retrieved data item(s) is(are) distributed into more than two classes) AND (there exist association relationships among the classes)
	Read_Data_3	Use when retrieved data item(s) which is(are) not attributes of ?objective class belong to the class(es) that has(have) no association relationship with ?objective class
	Read_Data_4	Use when retrieved data item(s) which is(are) not attributes of ?objective class belong to ?AssociatedClass class and the others belong to the class(es) that has(have) no association relationship with ?objective class
	Read_Data_5	Use when an ?objective class is an associated attribute of other class(es)
Transfer Data from Another System (P3)		Use when the reading data from another interface system is needed
Create Data (P4)	Create_Data_1	Use when an ?objective class does not exist in the current static view
	Create_Data_2	Use when (an ?objective class exists in the current static view) AND (an ?objective is an associated attribute of other class(es))
	Create_Data_3	Use when (an ?objective class exists in the current static view) AND (?objective has (an) object(s) other class (es) as (an) associated attribute(s) )
Update Data (P4)	Update_Data_1	Use when (an ?objective class does not exist in the current static view) OR ((an ?objective class exists in the current static view) AND (it is not the applicability of Update Data Pattern_2 and Update Data Pattern_3))
	Update_Data_2	Use when updated data item(s) that is(are) not an attribute(s) of ?objective class belong to ?AssociatedClass class
	Update_Data_3	Use when updated data item(s) which is(are) not an attribute(s) of ?objective class belong to the class(es) that has(have) no association relationship with ?objective class
Delete Data (P4)	Delete_Data_1	Use when (an ?objective class does not exist in the current static view) OR ((an ?objective class exists in the current static view) AND (it is not the applicability of Delete Data Pattern_2 and Delete Data Pattern_3))
	Delete_Data_2	Use when an ?objective class is an associated attribute of other class(es)
	Delete_Data_3	Use when (an ?objective class has another class as an associated attribute) AND (the relationship between the classes is an aggregation by value)
Confirm Data Manipulation(P5)		Use when an acquisition of higher leveled user for the reflection of data status changes is needed
Transfer Data to Another System(P6)		Use when the transformation of a data manipulation results to other system is needed

### V. CASE STUDY: BUILDING AN ANALYSIS MODEL USING CRA PATTERN LANGUAGE FOR A PAYROLL MANAGEMENT SYSTEM

The proposed CRA patterns impose many constants and parameters(variables) in participating classes' attributes and responsibilities, confusing unintimate readers. So, this paper will explain the details of each phase of adopting CRA patterns in building an analysis model from a scenario of a use case with a specific system, a payroll management system, rather than discuss with a set of general constants and variables. The chosen scenario of the payroll management system is the basic flow of "Select a payment method," as shown in Fig. 6.

#### A. Use Case Analysis

First, a set of generic questions is presented for applying the proposed CRA patterns, as shown in Table II. The developer answers the questions based on use case specifications and already defined key classes. Each question is used for the developer to select a set of appropriate fragmented patterns and identify parameter values in each CRA pattern.

- Q1~Q2: Questions for extracting the name of the target use case and flow of events.

This question is for composing the name of the sequence diagram from a flow of events in a use case specification. The blanks in the answer strings to Q1 and Q2 are excluded when used as values for pattern variables, '?UseCaseNm' and '?SeqNm'. For example, if the answer to Q1 is "Select Payment Method" and the answer to Q2 is "Basic Flow," the values for '?UseCaseNm' and '?SeqNm' are "SelectPaymentMethod" and "BasicFlow," respectively. Thus, the newly constructed sequence diagram name is "SelectPaymentMethod BasicFlow."

The value of variables, '?UCNm' and '?SDNm' are decided by excluding vowels from '?UseCaseNm' and '?SeqNm'. The values for '?UCNm' and '?SDNm' are used to name classes and operations.

- Q3: Question for selecting a type of the *System Invocation* patterns.

The available answers to the question Q3 are "Interactive Job" or "Batch Job." If the answer for Q3 is "Interactive Job," System Invocation by a user behavior is selected as the second segmented collaboration pattern. In that case, additional question Q3.1 is given to designate the active actor of the target flow of event. The answer to Q3.1 is denoted as an actor, as

described in Table II. If the answer to Q3 is “Batch Job,” System Invocation by a system behavior is selected, which describes a kind of automatic invocation of the target system according to predefined schedules. As it does not require an active actor, Q3.1 is skipped in this case.

The “Select payment method” flow is a kind of interactive job. Thus, the answer to Q3 is “Interactive Job.” According to the use case specification, the flow starts with an event from the Employee. The answer to Q3.1 is “Employee,” and it will be mapped to the active actor denoted as the pattern variable, ‘?humanRole’ of the sequence diagram.

- Q4~Q6: Questions to select proper *Manipulate Data* pattern and extract required values for pattern variables.

To realize a flow as a sequence diagram, not all of the CRUD operations are used. Depending on the event description of a use case, a different set of CRUD patterns are used. Questions Q4~Q6 are designed for developers to help determine the CRUD operations set and extract values of pattern variables.

### Use Case 5 : Select Payment Method

#### 1. Brief Description

This use case allows an Employee to select a payment method. The payment method controls how the Employee will be paid. The Employee may choose to either: pick up his check directly, receive it in the mail, or have it deposited directly into a specified bank account.

#### 2. Flow of Events

##### 2.1 Basic Flow

This use case starts when the Employee wishes to select a payment method.

1. The system requests that the Employee specify the payment method he would like (either : “pick up”, “mail”, or “direct deposit”).
2. The Employee selects the desired payment method.
3. If the Employee selects the “pick-up” payment method, no additional information is required.  
If the Employee selects the “mail” payment method, the system requests that the Employee specify the address that the paycheck will be mailed to.  
If the Employee selects the “direct deposit” method, the system requests that the Employee specify the bank name and account number.
4. Once the Employee provides the requested information, the system updates the Employee information to reflect the chosen payment method.

Fig. 6. Use Case Specification of “Select Payment Method.”

TABLE II. QUESTIONS AND ANSWERS FOR “SELECT PAYMENT METHOD” FLOW ANALYSIS

No	Generic Questions	Answer	Pattern Variable	Selected Pattern
FLOW LEVEL				
Q1	What is the Use Case Name?	“Select Payment Method”	?useCaseName	N/A
		“SlctPmntMthd”	?UCNm	
Q2	What is the name of the flow of events?	“BasicFlow”	?seqNm	N/A
		“SlctPmntMthdBsc”	?SDNm	
Q3	What is the job characteristic?	“Interactive Job”	invocationType	P1: Invocation by a User
Q3.1	If it is an interactive job, what is the name of the active actor?	“Employee”	?humanRole	N/A
DATA MANIPULATION LEVEL				
Q4	What is the data manipulation type? (select 1 among creation/read/update/deletion)	“Update Data”(Updt)	?DMType	P4: Update Data
Q5	What is the objective data of the data manipulation?	“Employee”	?objective	
Q6	What are the data items to be changed after this update?	“paymentMethod”	?paramP4	
Q7	Is there any other data for an <i>Employee</i> to retrieve for the update of the <i>paymentMethod</i> ?	“No”	needData	P2, P3 is not selected
Q8	Is the retrieved data located on another system? If it is, what is the system?	“No”	?interfaceSystem	P3 is not selected
Q9	To accomplish this flow of events, is it need to take any approval from someone?	“No”	NeedApproval	P5 is not selected
Q10	After completing this data manipulation, should the changed data be transformed to another system(s)?	“No”	NeedAnotherSystem	P6 is not selected

Q4 asks which data manipulation is needed to realize the target flow among creating/updating/deleting data. The abbreviation (Cr/Rd/Updt/Dlt) of the answer to Q4 is mapped to the value of the variable, '?DmType,' included in CRA patterns. After '?DmType' is designated, the next question, Q5, asks the objective of the designated data manipulation. The objective data of CRUD manipulation should be one of the key classes already given as an input artifact for building an analysis model. The next question, Q6, is applied only if the answer to Q4 is "Update Data." However, it does not mean that Q6 is differently designed according to the answer to Q4, in other words, the type of data manipulation. Q6 is designed to ask the property of the selected data manipulation. If the selected data manipulation type is "Delete Data," Q6 asks which property of the target class should be deleted. Therefore, while the answer of Q5 is one of the given key classes, the answer of Q6 should be one of the attributes in the selected class as the answer to Q5.

For example, in the case of the "Select payment method" flow of events, after all, the flow changes the value of the 'payment Method,' of the key class, 'Employee.' So, it is a kind of update manipulation. Thus, "Update Data" is the answer to Q4, and the abbreviation, 'updt,' is mapped as the value of '?DmType'. The objective data is the class, 'Employee.' The updated attribute is 'paymentMethod' as the answer to Q6, and it is mapped to the value of "?paramP4.'

- Q7: Questions to select *Read Data* pattern or not.

As depicted in Table II, for analyzing the "Select payment method" scenario, Q7 asks if an additional "Read Data(P2)" pattern is needed before the "Manipulate (Create/Update/Delete) Data" pattern. According to the given flow of events, the answer to Q7 is "No" as a user selects his preferred payment method without retrieving any additional data from the system. Consequently, the "Read Data(P2)" pattern is not selected to compose a sequence diagram.

However, in the case that require additional retrieving data before creating/updating/deleting data or the case that main flow is for retrieving data (answer to Q4 is "Read Data"), answering the additional questions Q7.1 and Q7.2 are needed for extracting data for the "Read Data" pattern. The additional questions Q7.1 and Q7.2 are specified in Table III. Those questions ask the name of retrieving data and the retrieval conditions.

- Q8: Questions to select *Fetch Data from Another System* pattern or not.

If the answer to Q7 is "Yes," the answer to Q8 is required. In applying Read Data(P2) pattern to compose a sequence diagram, one of the checkpoints is the location of the data to be retrieved. Suppose the data location is not the target system, message.

Sequences to request the data to the system that is the source of the retrieved data. The required collaboration with the other system is defined in Fetch Data from Another System(P3) pattern. Thus, in this case, the P3 pattern should be weaved with the already selected P2 pattern. For the given example scenario, selecting the P3 pattern is not considered

because it is not required to retrieve other data to update the payment method as the data resource is a user.

TABLE III. SUPPLEMENTAL QUESTIONS NOT APPLIED TO "SELECT PAYMENT METHOD" FLOW ANALYSIS

No	Generic Questions	Pattern Variable
Q7	Is there any other data for an '?humanRole' to retrieve to update the '?objective'?	?DmType
Q7.1	What is the name of the retrieving data?	?objective
Q7.2	What is the search condition for the retrieval of '?objective'?	?Condition
Q7.3	What are the retrieving attributes?	N/A
Q8	Is the retrieved data located on another system? If it is, what is the system?	?interface System
Q8.1	What data should be transferred from '?InterfaceSystem'?	?objective
Q8.2	What is the search condition for the retrieval of '?objective'?	?condition
Q9	To accomplish this flow of events, is it need to take any approval from someone?	NeedApproval
Q9.1	Who is responsible for the data confirmation?	?actorNm
Q10	After completing this data manipulation, should the changed data be transformed to another system(s)?	NeedAnotherSystem
Q10.1	What is the destination system of the data transfer?	?interface System
Q10.2	What is the additional data to be transferred except '?objective data'?	?addData

- Q9: Questions to select *Confirm Data Manipulation* pattern or not.

If the answer Q4 is one of the "create/ update/ delete data," the Manipulate Data(P4) pattern is selected, question Q9 should be considered. Q9 asks if any approval is needed to save data manipulation results or not. As the given example, if it is required to get a confirmation from any actor after updating the payment method of an employee, the answer to Q9 should be "Yes," and Confirm Data Manipulation(P5) pattern will be selected. P5 pattern defines the message sequences to request confirmation to an actor responsible for the approval of the data manipulation and to approve it into the target system.

In the case of payment method update, however, it is not required any other confirmation to select the payment method of own Employee. So, the answer to Q9 is "No," and the P5 pattern will not be selected.

- Q10: Questions to select *Transfer Data to Another System* pattern or not.

The other question to be considered when Manipulate Data(P4) pattern has been selected is Q10. In some cases, changes in data in the target system should be reflected in another system. The change should be propagated to the data source system when the changed data source is not the target system but the other system. In that case, the data source system should already have been identified as a passive actor in the given use case model. The transformation of the changed data to the passive actor is defined in Transfer Data to Another System(P6) pattern. Q10 asks if the changed data should be

transformed to another system after the completion of data manipulation. The P6 pattern will be selected and weaved with the P4 pattern to compose a sequence diagram when the answer to Q10 is "Yes."

In the given example case, the changed data, "payment Method" is an attribute of the class, "Employee," saved in the target system itself. The answer to Q10 is "No." Consequently, the P6 pattern will not be selected.

### B. CRA Pattern Weaving

A set of CRA patterns necessary to implement the given flow is selected from among the six segmented CRA patterns by analyzing the given flow of the use case specification and answering each predefined generic question introduced above. Most CRA patterns define several variations in the assignment of responsibilities. As the result of the use case analysis step, the needed collaboration variation in each CRA pattern is selected.

Among CRA patterns, the Manipulate Data(P4) patterns define several interaction variations in each pattern, as shown in Fig. 5. Once a specific pattern is selected from the use case analysis step, proper interaction variation should be selected in several variations. The factor determining a specific interaction variation is the class's relationship to the '?objective' variable in the use case analysis stage has with other classes. The relationship between classes can be grasped through the conceptual class model.

Fig. 7 shows that UpdateData\_1 is selected among the three interaction variations of the Update Data (P4) pattern according to the predefined rule. As shown in Fig. 8, the '?objective' class (Employee) has the updated item '?paramP4'(paymentMethod) as its attribute. So, the

relationship between '?objective' class and '?associatedClass' or '?AssociatingClass' is not required to be considered. Thus, the condition highlighted by the red square is satisfied with the given relationship between the 'objective' class and the updated item, '?paramP4'. For this reason, Update\_Data\_1 is finally selected.

In connecting two collaboration patterns, the most left one among the same lifelines in the two patterns is the connection point, and it is named as "weaving point." By overlapping the lifeline that becomes the weaving point, the two patterns are connected. While repeatedly weaving the selected patterns, the segmented CRA patterns are composed into a sequence diagram to realize the given flow of events.

Fig. 8 depicts the weaving of two patterns to compose a sequence diagram for the given example flow of events. The patterns selected according to the answers to each question described in Table II are Invocation by a User pattern in P1 pattern and Update Data\_1 collaboration pattern among P4 patterns. As shown in Fig. 8, the most left one among the object's lifeline commonly included in the two collaboration patterns is '?objective+?DMType+Form', which becomes a weaving point. The pattern variables marked with the prefix '?' still are denoted in the object names on the top of the diagram or the messages between lifelines as value assignment is not done in this step.

The 'invoke(param)'message in the Invocation by a User pattern is designed to be substituted by the first message in the firstly connected pattern to the Invocation by a User pattern. Therefore, the 'invoke(param)'message is substituted by 'update + ?objective (?paramP4)' in the weaved sequence diagram in the lower part of Fig. 8.

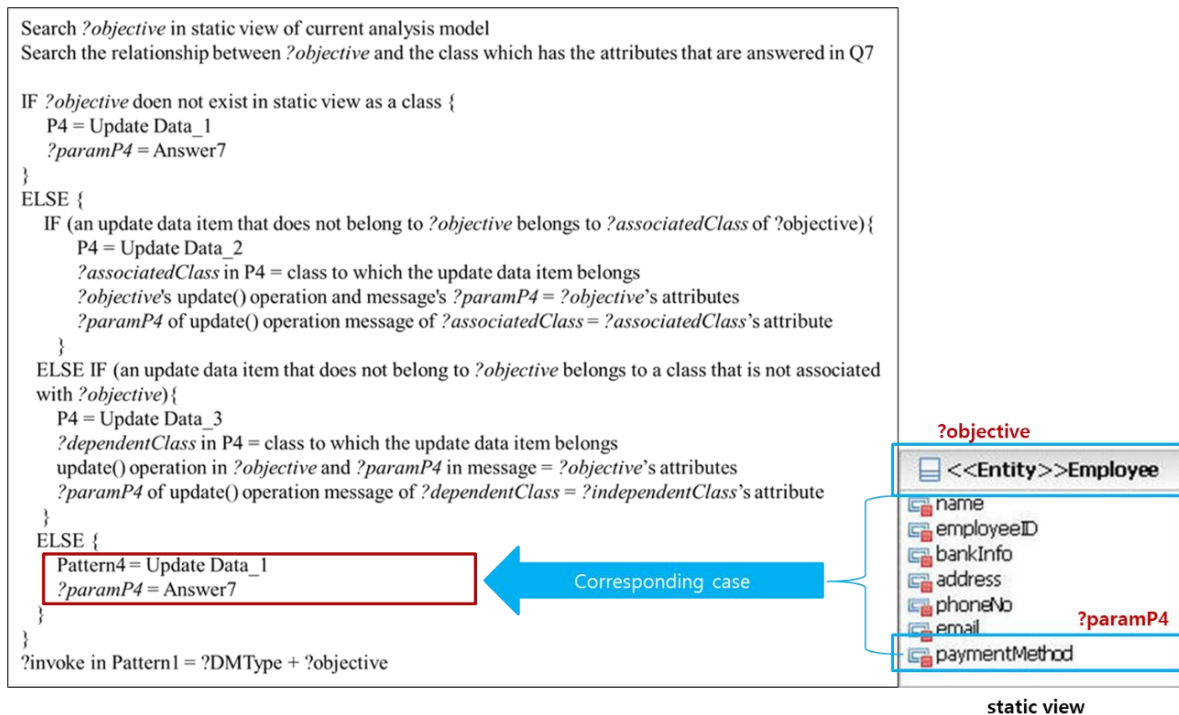

Fig. 7. Rule for Selecting an Interaction Variation in Update Data Pattern.

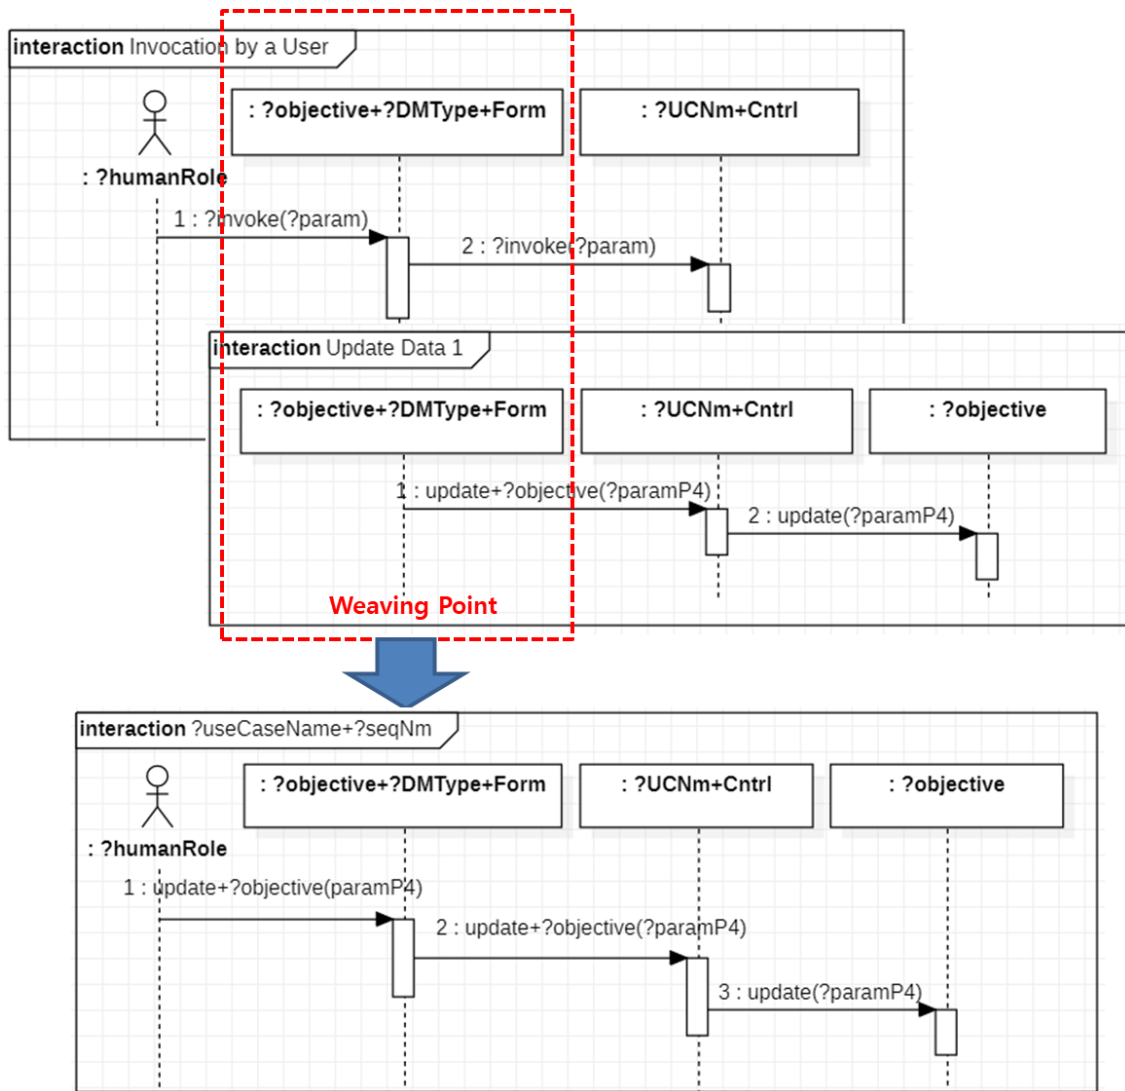

Fig. 8. An Example of CRA Pattern Weaving for Composing a Sequence Diagram for the “Select Payment Method” Flow.

### C. CRA Pattern Instantiation

The skeleton of the sequence diagram that realizes the given flow is completed through the CRA pattern weaving step. This step is called CRA pattern instantiation. The upper diagram in Fig. 9 is the weaved sequence diagram for the "Select payment method" flow. Although the sequence of messages is composed, uninstantiated variable patterns exist in the names of an actor, lifelines, and messages. The values to be substituted for the pattern variables included in the skeleton of the sequence diagram are the answers to each question identified in the previous use case analysis step. For example, the name of the control class of this sequence is '?UCNm+Cntrl' is instantiated to 'SlctPmntMthdCntrl' because the extracted value of '?UCNm' is 'SlctPmntMth' according to the values in the table of use case analysis. In the same way, all the pattern variables are instantiated with the values in the table. As a result, the lower diagram in Fig. 9 is completed, with no uninstantiated pattern variable.

The identified responsibility denoted on each message of the sequence diagram should be an operation of the class, which is the message's destination. The developer should keep the consistency between the static view represented by a class diagram and the dynamic view specified by a sequence diagram by adding the identified responsibilities to the proper classes as operations. Fig. 10 shows that the newly identified responsibilities in defining the sequence diagram for the "Select payment method" flow are added to the classes. In building the sequence diagrams with CRA patterns, the newly <<Boundary>>, and the <<Contoller>> stereotyped classes are additionally identified. Comparing the analysis model in Fig. 10 before and after the creation of the sequence diagram, it can be confirmed that the "<<Boundary>>EmployeeUpdtForm" class and the "<<Contoller>>SlctPmntMthdCntrl" extracted by the "Update Data" pattern are added to the analysis model.

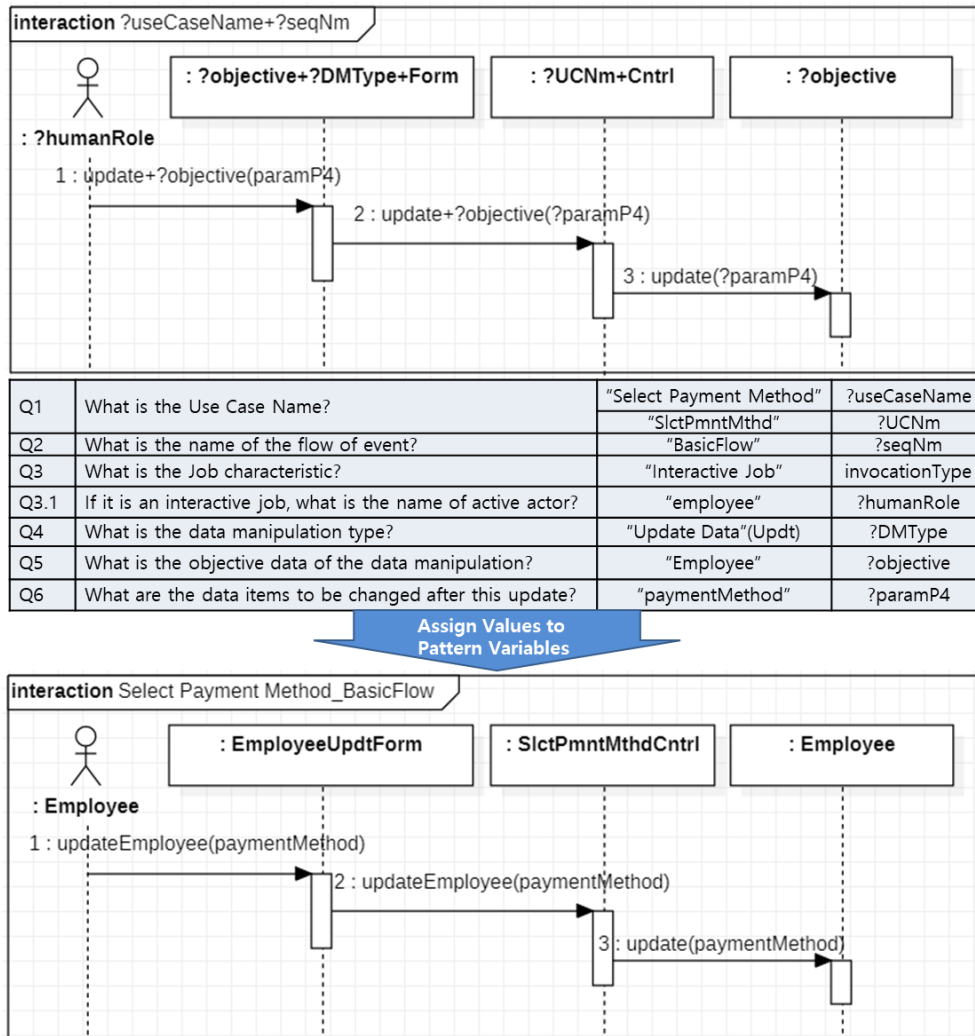

Fig. 9. An Example of CRA Pattern Instantiation to Build the Sequence Diagram for the "Select Payment Method" Flow.

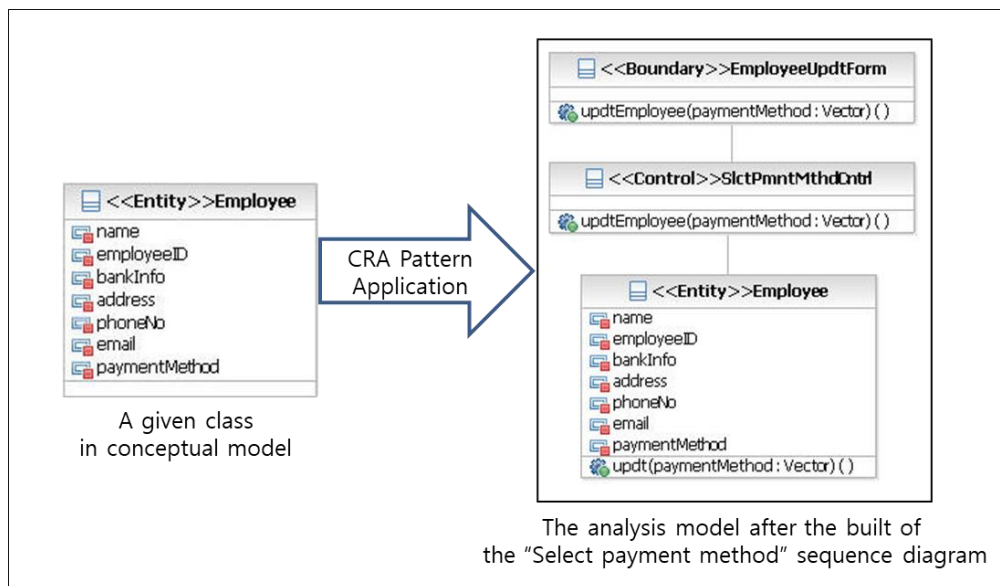

Fig. 10. The Changes of the Static View of the Payroll Management System.

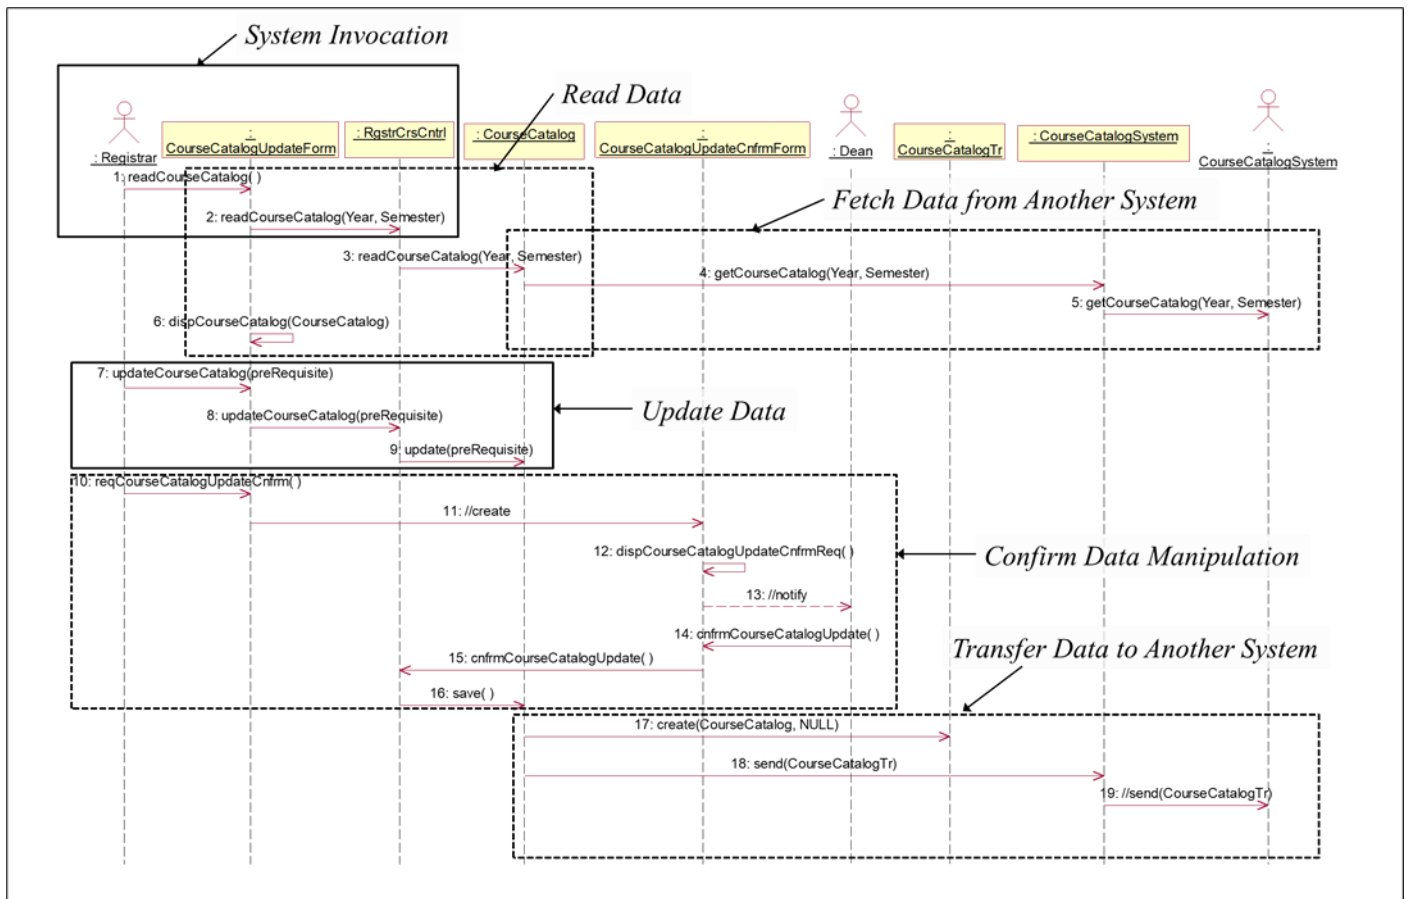

Fig. 11. Applying the six CRA Patterns in Building a Sequence Diagram: the Sequence Diagram for the "Register for Courses" Scenario of the Course Registration System.

D. An Example of Sequence Diagram Built by Applying All the Six CRA Patterns

In proving the feasibility of the proposed CRA patterns, it is necessary to show an example of the sequence diagram to apply all the six CRA patterns. However, unfortunately, in the payroll management system, the target system of this case study, there is no scenario to require all the six segmented CRA patterns. Thus, this study picked one of the scenarios of another system, the "Course Registration System," referenced as an example system in object-oriented analysis textbooks. The selected scenario is the basic flow of the "Register for courses" use case. By weaving the proper set of CRA patterns and instantiating pattern variables with the values from the use case analysis, the sequence diagram in Fig. 11 is built. Similar to the sequence diagram for "Select payment method", Fig. 11 is the sequence diagram with the two required CRA patterns: System Invocation pattern and Update Data pattern. However, in Fig. 11, all of the supporting CRA patterns are also participating. The responsibilities denoted on all messages have been identified from the application of the selected six CRA patterns. This example confirms that the flow composed of considerably long interactions can be realized by applying the proposed CRA pattern language.

VI. EVALUATION

Although the case study result shows the feasibility of the proposed CRA pattern language, it is needed to prove how much responsibilities could be extracted from system behaviors in use case specifications by utilizing it. First, this study applied the CRA pattern language to other scenarios in the use case specification of the payroll management system, besides the scenario presented as the case study in Section 5. Those scenarios realized by utilizing the CRA pattern language are: Select Payment Method / Maintain Timecard / Create Employee Report / Maintain Purchase Order / Create Administrative Report/ Maintain Employee Info / Run Payroll / Login.

TABLE IV. COMPARISON OF THE NUMBER OF ELEMENTS IN AN ANALYSIS MODEL

Elements #	Conceptual Model	Instantiated Model	Analysis Model
<b>Type</b>			
<b>Class</b>	7	35	38
<b>Operation</b>	0	44	51
<b>Attribute</b>	23	27	27
<b>Relationship</b>	6	37	42
<b>Total</b>	36	143	158

Fig. 12. Comparison of the Bad Symptoms Detected on the Implementation Code.

Table IV compares the number of identified operations (responsibilities) from the CRA pattern application on the scenarios above and the number of all operations in the finalized analysis model to prove the proposed CRA patterns' coverage. The number of design elements extracted purely by the CRA patterns is the value obtained by subtracting the # of elements of the conceptual model from the # of elements of the instantiated model in Table IV. The instantiated model refers to the model obtained as a result of pattern instantiation. The conceptual model is a model that is given as an input, including entity classes identified before applying the CRA patterns. The number of operations included in the conceptual model is 0. After that, the number of operations extracted through pattern application is 44, which is only seven less than 51 operations included in the model at the end of the analysis phase. It means that only seven operations that the developer additionally identified and added to the operation set. Other 86%  $((44-0)/51*100)$  of the class responsibilities of the entire analysis model were identified through CRA pattern application. Likewise, considering the number of whole elements, including classes and relationships, it can be confirmed that 67%  $((143-36)/158*100)$  of the elements are defined as the instantiation of the CRA pattern.

The fact that 67% of the elements of the entire analysis model can be extracted by applying uniform patterns means that, on another axis, 67% of the elements of the analysis model pose the same level of quality. Moreover, applying the proposed CRA patterns implies that GRASP guidelines like high cohesion and low coupling are assured. Thus, it implies that 67% of the analysis model built by the CRA patterns can provide a good and uniform quality even without a separate quality assurance task.

To confirm the effect of applying CRA patterns in the quality of the analysis model, we conducted a controlled experiment. The subjects who participated in the experiment were 4th-year undergraduate students who took the Object-Oriented Analysis and Design course. Students teamed up with 4-5 students to experience from identifying the requirements of the payroll management system to building the application. In constructing the analysis model, only 5 out of 10 teams (group A) provide only use case specifications. To the remaining five teams (group B), a questionnaire for identifying use case

specification, CRA pattern specifications, and pattern variables (Table II and Table III) was provided together. That is, in group A, students arbitrarily built an analysis model, and in group B, the CRA pattern language provided in this study was applied to build an analysis model. Both groups completed the development of their payroll management system for ten weeks.

For comparing the quality of the codes written by group B that applied the CRA pattern language to construct an analysis model and group A that did not apply the CRA pattern language, this study conducted static analysis on the implementation code using Understand [22]. As a result, as shown in Fig. 12, it can be confirmed that the number of detected bad symptoms of the source code is significantly smaller in group B than in group A. Among the bad symptom items, the notable result is the number of unused objects/variables and parameters, and those numbers of group B are close to 0. Since the analysis model is constructed by filling the pattern parameters defined in the given CRA patterns with the values extracted from the use case specification, there exists the effect of fundamentally preventing the inclusion of design elements that are not based on the requirements in the analysis model. It is the reason why the number of bad symptoms found in group B is minimal.

The benefits of the proposed CAR pattern language confirmed through the evaluation results can be summarized as follows. The CAR pattern language help that (1) a significant part of the analysis model can be completed by applying the CAR pattern language itself, and (2) developers with little design experience can also be expected to create an analysis model that guarantees consistent quality.

## VII. CONCLUSION AND FUTURE WORK

The assignment of responsibilities to classes is hard to teach and acquire in practice as many considerations should be taken. Several approaches are proposed to lessen heuristic factors and relieve the efforts to decide which responsibilities are required for a specific class. However, up to now, the existing works, regardless of the used technology, give too general assignment results or too many candidates for one responsibility for developers, which cannot reduce much effort in designing classes.

This study narrows the scope of the proposed CRA pattern language into the business application domain to solve the generality problems. It provides the responsibility assignments results not requiring further revision. The proposed CRA pattern language comprises the six segmented patterns, including several interaction variants according to the relationship format among the conceptual classes.

The six CRA patterns result from vertically decomposing one data transaction performed by a business application into one atomic sequence block. Manipulate Data patterns, which can be seen as the main pattern, contain several interaction variations that specify various collaboration aspects. While searching for the answer to the standardized question set for each flow described in the use case specification, the developers assign values to the variables existing in each pattern. The answers to the questions also determine the set of patterns needed to realize a given flow. The selected pattern

creates a sequence diagram while overlapping the lifeline corresponding to the predetermined weaving point, and this step is called pattern weaving. As a result of pattern weaving, the skeleton for one sequence diagram is completed, and instantiated sequence diagram can be obtained by substituting the values of pattern variables identified in advance.

This study shows the feasibility and the coverage of the proposed CRA pattern language in constructing an analysis model with a case study for constructing an analysis model of a payroll management system. In particular, the results showing that 67% of the operations identified in the final analysis model can be extracted only by applying the proposed CRA pattern proves the differentiation of this study. And, the enhancement of code quality shown through the designed experiment is another benefit of applying the proposed CRA patterns.

The questions for extracting information from use case specifications and the rules for selecting an interaction among the provided interaction variations in a CRA pattern are designed to consider the automation tool development. As for now, the development of the automation tool integrating with a UML authoring tool and Microsoft Word is under construction. With the automated tool, developers just select a proper word to answer a question from use case specifications written in Microsoft Word. And, then, automatically, a proper set of the CRA pattern will be selected, and each word selected by developers will substitute each pattern variable. Consequently, the sequence diagram will be created in a UML authoring tool automatically. Besides constructing the automated tool that supports the CRA patterns, we also plan to extend the case studies to more diverse applications.

# Implementing Flipped Classroom Strategy in Learning Programming

Rosnizam Eusoff, Syahanim Mohd Salleh, Abdullah Mohd Zin  
Center for Software Technology and Management  
Universiti Kebangsaan Malaysia  
Bangi, Malaysia

**Abstract**—Novice students encountered many difficulties and challenges when learning to program. They face problems in terms of high cognitive load in learning and lack of prior programming knowledge. Various strategies and approaches are implemented to overcome the difficulties and challenges in programming. A flipped classroom is an active learning strategy implemented in many subjects and courses, including programming. The flipped classroom strategy consists of three phases, namely, pre-class, in-class, and post-class. A focus group discussion is conducted involving 13 participants from various learning institutions. The purpose of the study is to discuss the implementation of flipped classroom strategy in programming. The study also identifies a technique for monitoring students' involvement in activities outside the classroom and proper motivation to engage students in programming. Related research questions are constructed as guidelines for the discussion. The deductive thematic analysis is performed on the transcripts of the discussion. As a result, four pre-determine codes and two codes were generated from the analysis. This study identifies suitable activities, tools, monitoring strategies, and motivation to support the implementation of a flipped classroom in programming. There is good potential through flipped classrooms in learning programming with a systematic and careful planned implementation.

**Keywords**—*Flipped classroom; learning programming; cognitive load; active learning; focus group discussion*

## I. INTRODUCTION

Programming is a complex subject that requires high concentration and focuses from the students. The process of learning programming requires a tremendous amount of exposure to understand the logic in each programming solution using the basic concepts despite the overwhelming syntax it might carry [1][2]. Novice students in learning the subject face difficulties and challenges. Challenges and difficulties are identified through studies in programming [3]–[7]. Among the challenges in programming are high cognitive workload [1][8], inappropriate learning strategies, time constraints, and lack of preparation before entering the classroom [2][9]. Novice students with limited knowledge need a strategy or method to help them in programming [10][11]. Active participation of the students in the learning process is one of the essential aspects of learning programming [12][13]. The difficulties experienced by students in learning can be attributed to the passive role played by them during traditional lectures [14].

Among the new strategies used in programming is flipped classroom (FC), where lecturers employ this strategy in the

learning session to enhance and improve the student learning experience [14]–[16]. The main advantages of FC are providing students with prior knowledge and preparing them before class; give extra learning time; experience active and collaborative learning in class, and strengthening the understanding of new knowledge and skills after class [17]–[19]. There are three phases of the learning process in the FC, namely pre-class, in-class, and post-class. Pre-class activities focus on theory, initial information, and preparation before entering the classroom. In-class sessions emphasize active learning activities for developing new knowledge and skills. Active learning requires students to engage in meaningful learning activities in class [20]. At the same time, post-class activities focus on strengthening knowledge and skills. Programming involves various cognitive activities and structures of multiple skills to learn [21]. FC can create a new learning environment with a practical session and enhance students' learning experience [22]. FC also enhances student satisfaction and their level of engagement in learning [23]. Besides, the implementation of FC also positively impacts students' self-efficacy and intrinsic motivation [24]. In a traditional classroom, educators allocate ample time to convey information to students to read and learn the information by themselves.

On the other hand, FC promotes pre-class activity whereby some knowledge is learned before class. This situation will give sufficient classroom time to lecturers as some of the topics are covered during the pre-class activity. Thus, lecturers can utilize the extra classroom time to focus more on impactful learning activities in programming [25]. The use of FC in programming strategy is reported to be more effective at the tertiary institution level than at the school level. Although more research on FC is increasingly conducted by researchers for various subjects [26], implementing FC in programming is not much discussed in the reports [27]. Instructors who want to use FC in their learning need to understand the implementation strategies to ensure the method's success and achieve its objectives [28]. In this regard, there is a need to conduct more research in FC [23], especially studies that describe the implementation of FC in programming.

## II. METHODOLOGY

Researchers have utilized a focus group discussion (FGD) technique to obtain qualitative data, which involved discussions in small groups [29]. FGD is a suitable technique for generating new ideas compared to individual interviews

because the participants can brainstorm ideas during the ongoing discussion [30]. Besides, the FGD method is an excellent option to understand the views and opinions of others regarding the discussed subject [31]. Further, FGD is a flexible method that can be performed in a variety of conditions. There are seven steps of FGD involved in this study, as listed in Fig. 1.

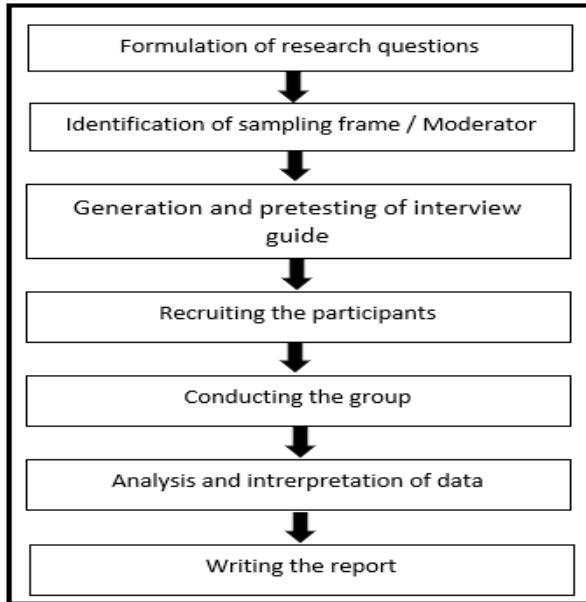

Fig. 1. Steps in Conducting a Focus Group Discussion Study. Adapted from [32], "Focus Groups Theory and Practice," p. 50.

#### A. Research Questions

A good research question (RQ) will guide the implementation of the study to be smoother and more efficient. Four research questions are posed in this study as follows:

RQ 1. What are the appropriate activities to implement FC strategy in programming?

RQ 2. What are the suitable tools that can support FC strategy in programming?

RQ 3. How to monitor students' participation in FC activities outside the classroom?

RQ 4. How to motivate students in learning programming?

#### B. Participants

The implementation of FGD requires two critical elements; the recruitment of participants and the design of the interview guide [32]. Research questions in the study are used as the design of the interview guide. Next, the researchers conducted a pilot test involving five participants. The purpose of the pilot test is to identify the weaknesses and provide improvements to the actual FGD. According to [33], the appropriate number of FGD is about six to twelve participants. The optimal time for each session is between one to two hours. Participants in the FGD are 13 senior lecturers who have been experienced in teaching programming at institutions of higher learning in Malaysia for about 12 to 32 years. According to [34], teachers with five to seven years of teaching experience can be considered expert teachers. FGD is conducted online by using

Zoom application. Participants were split into two groups to facilitate the online discussion effectively. The first group discussion was attended by six participants, and the second group was accompanied by seven participants.

#### C. Transcribing and Member Checking

The recording of the discussion is transcribed in a clean verbatim manner. Participants checked the transcript for the member checking process. Submission of the transcripts to the respective participants improves the accuracy of the data [35]. Furthermore, the checking process permits the participants to confirm or deny the interpretation made by the researchers on the views and suggestions of the participants during the discussion [36].

#### D. Coding and Analysis

Code is the smallest unit of analysis with exciting features about the data considered relevant to the research question. The data contained in the transcript is in the form of excerpts generated from the discussion. There are four predefined codes at the initial stage of the analysis process: Activity, Tools, Monitoring, and Motivation code. Two additional codes are produced when the analysis process is carried out, namely Learning Strategy and Evaluation. In total, there are 232 passages produced from the transcripts. Learning Strategy code has 91 passages which is the code that has the highest passages.

Meanwhile, the Activity code consists of 53 passages, and the Tools code consists of 36 passages. The Motivation code consists of 31 passages, while the Monitoring consists of 15 passages. Lastly, the Evaluation code consists of 6 passages. Thematic analysts are used to analyzing these coded passages. Thematic analysis analyses and translates qualitative data to form a specific theme [37].

### III. FINDINGS

#### A. Activities to Implement FC Strategy in Programming

In general, the findings in this section are made through passages grouped under the Learning Strategies, Activity and Motivation codes. As mentioned, FC comprises three phases, namely pre-class, in-class, and post-class. The learning activities involved can be regarded as the same or slightly different for each of these phases. However, students may encounter issues when learning to program in FC strategy. The problems are caused by students' failure to understand FC requirements. Hence, during the first face-to-face class meeting with the students, a sufficient explanation regarding the implementation of FC in learning should be given to the students. Students are informed about the three essential phases involved in FC: pre-class, in-class, and post-class. In the early stages of the course, students must participate in the learning session and eliminate their anxiety about programming. Lecturers can share exciting videos about programming with students in the class as a first insight for them. "The first topic is crucial to attracting students to programming. If students think that the first topic is difficult, most probably, students will have problems engaging with other topics. Students should not be addressed with difficult questions, but instead, the lecturer may opt for intermediate questions when asking questions to the respective students."

Ensuring students' participation in learning activities outside the classroom is the biggest challenge the educators face when implementing FC strategy [38]–[42]. A participant suggested that allocation of marks should be given to students who are actively involved in the pre-class and post-class activities. According to the participant, extra marks will motivate students to engage in activities outside the classroom actively. Thus, lecturers should consider allocating marks for students who show good involvement during the pre-class and post-class activities. This initiative will attract students' interest and boost their motivation in the learning process. "From my experience all this while, students will only do extra assignments outside class if there are only marks given for those assignments. I believe some extra marks will motivate them well."

Although students may view videos about programming online, lecturers need to guide their students on which video they should watch. A meaningful learning environment should be created as much as possible in learning activities. For example, the teacher should design the questions and problems based on students' daily life experiences, such as using ATMs and vending machines or developing a smartphone application's software. Most students have anxiety based on the information they have obtained about the difficulties of programming. "Lecturers need to create a meaningful learning environment for students. These novice students may have zero knowledge of programming. Most of them are worried about programming."

Programming is known as one of the subjects that has a high percentage of failures among students. The learning activities in programming should gradually develop students' skills from easy to challenging levels. The aim for each activity will focus only on one new skill so that students will not experience a high cognitive load. In the early stages of learning, students are exposed to videos from various sources to inform them about the importance of programming and its application in daily life. The video viewing activities can also be assigned to students as pre-class activities. Next, as in the class session, students are divided into several groups, and they are asked to discuss the videos they have watched and present the results of their discussions in class.

Lecturers can prepare several sets of questions for the students to discuss in their groups. Every two groups will receive a similar question for discussion. Then, each group should present the results of the meeting to all. Through this method, two different solutions can be generated from the same question. Based on this, students will be able to perceive that a problem that occurs in programming has various solutions. Post-class activities focus on exercises and tasks to strengthen students' new knowledge and skills. As a guide, the lecturer may provide students with examples of complete solutions to the assigned questions. Next, students will receive questions that are similar to the given example as post-class activity. Students can refer to the provided examples as a guide to answer the questions. These activities can be assigned as individual or group assignments. Thus, students will not feel burdened to carry out post-class activities through this method, especially for challenging problems.

### *B. Suitable Tools to Support FC in Programming*

The findings in the section are based on passages grouped under the Tools and Motivation codes. In supporting a learning process, lecturers can incorporate myriad choices of tools and supporting materials. Hence, to implement the FC strategy in the learning session, lecturers must prepare and choose suitable tools and learning materials for the class, especially for the pre-class and post-class activities, as the lecturer's supervision is absent. Video is the most widely used material in FC at the pre-class level [39]. The videos can be self-produced by lecturers or taken from various sources on the internet, such as YouTube. The optimum period for video viewing is between five to ten minutes [39] [43]. An appropriate video screening period will ensure that students are not burdened with such activity. Lecturers may assign quizzes or short questions to students while watching the video or after finishing the video. The task will ensure that students will pay attention to the details in the video as they need to answer the quiz or short questions. Besides that, lecturers can provide the students with a worksheet to record the pre-class and post-class activities. These worksheets can also be used to assess students' involvement in activities and class discussions. The worksheets are applicable in a lab, so students can use them to mark errors they have encountered while running a program.

Apart from providing students with questions, lecturers can ask students to look and solve the problems by themselves. The problem-solving tasks can be regarded as project work. For example, students are asked to identify the business needs of specific companies through the company's advertising catalogue. Students must identify the problem and suggest a solution using programming. In the early stages, lecturers can help students by providing ideas and input. Once students already have solid knowledge, they are encouraged to figure out their solutions without the intervention of the lecturer. The use of infographic notes should be given priority on technical topics in programming. The infographic form notes are easier to understand than text notes, especially in specialized topics such as control structures, arrays and method. "After the introduction topic, I think infographic notes are more suitable to be used because it will be easier for students to see the whole process in programming through infographics as compared to usual text-based notes."

### *C. Monitoring Students' Participation in FC*

The discussion of the findings in this section is based on the passages grouped under the Monitoring and Evaluation codes. Class management is a critical aspect of a physical classroom, while learning materials are essential online [44]. The biggest challenge in FC is to ensure that student engagement in activities outside the classroom [38][45]. The outside classroom's activities will occur without supervision from lecturers. In this situation, lecturers can measure students' involvement in the pre-class activities by judging students' responses in the class. Usually, students who have prepared before class will be more ready and able to answer questions while in-class compared to students who don't prepare. At the beginning of class, lecturers can ask some questions that are related to the pre-class activity. Students who have not completed their pre-class activities will be unable to answer the question. Monitoring students' involvement in activities is also

more accessible through a LMS platform such as Moodle. Log-in records into the LMS can be regarded as proof of students' participation outside of the classroom. A short quiz can be embedded in the video to ensure students will watch the entire video without skipping. In this way, students are required to watch the whole video to answer the quiz.

Besides, monitoring also can be done by students themselves in group activities. Every group has an appointed leader, and the leader is responsible for reminding the group members about the assigned task. Most of the students are more receptive to reprimands from their peers compared to lecturers. "From my experience, students have more of a sense of guilt towards their friends than lecturers. Most of their daily life is with their friends in the hostel. They would be embarrassed if they did not participate in the activities with their group."

Monitoring students' involvement in pre-class and post-class activities is vital in the implementation of the FC strategy. However, participants' opinion that students should be allowed to do activities outside the classroom at their convenience. In this regard, lecturers need to determine the appropriate monitoring method to be applied to the students accordingly. The most important thing is to make sure students carry out the activities they should do and complete outside the classroom.

#### D. Motivating Students in Learning Programming

The discussion of this section's findings is based on the passages grouped under the Motivation and Evaluation codes. Motivation is a crucial element in determining success in learning. Successful students are usually students who are highly motivated in their learning. Researchers have conducted various studies that show a connection between motivation and success in learning programming [5][46][47]. The different approaches and strategies introduced in the learning increase student motivation and make programming more exciting and relevant to real-life situations [48]. There are two types of motivation: intrinsic motivation from internal factors and extrinsic motivation from external factors [49]. Most of the motivational methods that are given to students are extrinsic forms of motivation. However, the best motivation is the intrinsic type of motivation, which comes from the students themselves. However, intrinsic motivation can also be developed from extrinsic motivation. For example, when students always achieve high marks in tests or quizzes, their interest in programming will subsequently increase, and this is where intrinsic motivation will indirectly appear. A study by [41], found that at the early stages of the implementation of FC in learning, students are more motivated to do assignments or quizzes as activities outside the classroom. These two activities are considered as extrinsic motivation for students. Gradually, intrinsic motivation will be formed when students are motivated to engage with any FC's activities outside the classroom. The success of new approaches in learning will occur if students are instilled with more intrinsic motivation. Lecturers also need to constantly motivate students about the importance of programming in student's daily lives. However, based on experience, most students will carry out activities directed by their extrinsic motivation. For example, students will only complete an assignment when they are informed that the marks will be awarded for the work. In this regard, it is

advisable if the allocation of marks is given for outside classroom activities. "My experience with students so far, if they knew there would be no marks for an activity, they would not do it."

As the most crucial factor in determining the success of flipped classroom strategies introduced to students, the motivational element needs attention in learning. Lecturers need to be creative in finding suitable methods to increase the motivation of their students.

#### IV. DISCUSSION

In general, FC is a technology-based strategy in providing early exposure to students outside the classroom. Students, in turn, will gain in-depth exposure during the classroom session [50][51]. Comparison of four learning strategies used in [52] study has found that FC strategy produced students with best performance achievement compared to other strategies. There are various methods of FC strategies that can be implemented in the learning process. The main goal of the FC strategy is to provide students with ample learning time and the opportunity to gain early exposure to the learning content before the class session [53]. The use of FC strategies does not mean eliminating the role of the instructor or any form of direct instruction that occurs in a learning process. Instead, this strategy maximizes meeting time between instructor and student with strategic activities that have a higher impact on learning programming. FC can also meet the individual needs of different students without having to reduce the material and filling in the learning [54]. According to [51], students who received FC exposure are more sensitive to their learning processes than students exposed to the traditional strategy. Several essential elements need to be presented in the FC implementation model for programming. The main elements are strategic planning of activities according to the FC phases, preparation of appropriate tools for learning activities, and an effective monitoring strategy for outside classroom activities. Student motivation is a key element in determining the success of the FC strategy used. Therefore, lecturers need to provide motivation to attract students to programming. Intrinsic motivation is best, although it is quite difficult to establish in the student. However, extrinsic motivation can turn into intrinsic motivation gradually as students begin to take an interest in programming. A flipped classroom model in programming is illustrated in Fig. 2.

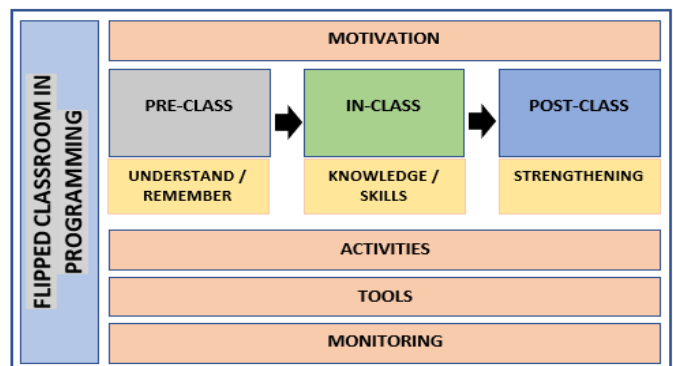

Fig. 2. A Flipped Classroom Model in Programming.

## V. CONCLUSION

There are myriad advantages gained through the implementation of FC in learning programming. Among the benefits are that students will be well prepared before entering the classroom as they must conduct a pre-class activity. This condition will aid the learning process in the classroom to be more efficient because students are equipped with basic knowledge. An extra-time earned can be used to conduct strategic active and collaborative learning in the classroom. The main goal of FC is to create a student-centred active learning environment. The lecturer only serves as a moderator who monitors the learning activities in the classroom. Post-class activities will focus on strengthening new knowledge that has been learned in class. However, the implementation of this FC strategy needs to be planned carefully and strategically to get the full advantage of this strategy.

**Abstract**—Removal of impulse noise from color images is a stringent job in the arena of image processing. Impulse noise is fundamental of two types: Salt and pepper noise (SAPN) and Random valued impulse noise (RVIN). The key challenge in impulse noise removal from color images lies in tackling out the randomness in the noise pattern and in handling multiple color channels efficiently. Over the years, several filters have been designed to remove impulse noise from color images, but still, the researchers face a stringent challenge in designing a filter effective at high noise densities. In this study, a combination of K-means clustering-based detection followed by a minimum distance-based approach for removal is taken for high-density impulse noise removal from color images. In the detection phase, K-means clustering is applied on combined data consisting of elements from designated  $5 \times 5$  windows of all the planes from RGB color images to segregate noisy and non-noisy elements. In the removal phase, noisy pixels are replaced by taking the average of medians of all non-noisy pixels and non-noisy pixels under  $7 \times 7$  windows residing at least Manhattan distance from the inspected noisy pixel. Performance of the proposed method is evaluated and compared up against the latest filters, on the basis of well-known metrics, such as Peak signal to noise ratio (PSNR) and Structural similarity index measurement (SSIM). Based on these comparisons, the proposed filter is found superior than the compared filters in removing impulse noise at high noise densities.

**Keywords**—Impulse noise; color image; salt and pepper noise; random valued impulse noise

## I. INTRODUCTION

Digital images are susceptible to be corrupted by noise while in transmission. There are certain procedures involved in image registering which captures the digital images by multi sensor imaging. During this type of image acquisition, transmission and recording events, different type's noise [1] can be incorporated into images. One of the noise types is impulse noise, which affects images by generating fixed or random changes in the pixel's intensities in the range of '0' to '255'. These sudden intensity changes not only degrade the images but also hamper the successive image processing

procedures like morphological processing, segmentation, object recognition etc. Impulse noise is of two types: salt and pepper noise (SAPN) [2] and random valued impulse noise (RVIN) [3]. Both the types of noises disturb the homogeneity of the pixel's intensities of images. Salt and pepper noise is categorized as fixed valued impulse noise, as it creates sudden dots in images by '0' (pepper noise) and '255' (salt noise) intensities. Due to these fixed but sudden fluctuations in pixel's intensities produces spikes in images. It may be possible that some '0' and '255', which are actual values may reside in the images. Those are either edge or texture pixels. On the other hand, random valued impulse noise degrades the images in arbitrary ways. RVIN can have any changed value in the range of 0 to 255. It is very tough to remove both the noise categories as it needs efficient detectors to find impulse-noise-like pixels and a removal mechanism to remove those noises without impeding the minute features of the images.

Fundamentally, a lot of filters [1 – 3] have been designed for removing impulse noise from grayscale images, but occasionally there are filters [1 - 23] designed for color images. The challenges in dealing with the multiple color panels and emulating a solution that integrates all those said channels have laid the way for further researches in this field. In this paper, an amalgamation of k-means clustering oriented detection trailed by least distance-based removal method is proposed for high density impulse noise removal from color images. The different clustering methods are found to be doing generously well in noise detection. It sorts out the noisy pixels effectively by applying K-Means clustering on each window of color images and the replacement of the noisy pixel is being performed by the combined average of non-noisy pixels at minimum distance from the designated noisy pixel and median of all detected non-noisy pixels within a certain window. Typically, the proposed work accentuated its superiority in producing excellent qualitative and quantitative outcome at high noise densities; however it yields moderate performance at low noise densities. Investigational results show the preeminence of the proposed method over the other recent methods.

The next section is oriented as follows. Section II exemplifies the literature review part. Section III illustrates the proposed methodology consisting of a detection algorithm followed by a removal algorithm. In Section IV, results of the proposed work are portrayed and discussed all over. The paper ends with a Section V on conclusion.

## II. LITERATURE REVIEW

Over the years, several linear and non-linear filters [1-24] were projected to remove impulse noise from grayscale and color images. The linear noise removal filters followed the convolution procedure with a window of coefficients. Later non-filters were proposed, out of which the median filter was the most popular one. The filter used median operation of surrounding pixels to restore every pixel which produced blurry outputs. But, in the restoration procedure, subtle features of images were lost. In the upcoming years adaptive median filters [4, 5] and weighted median filters [7, 8] were proposed. In those filters adaptive and weighted pixel-oriented approaches were taken respectively. Moreover, only the noisy pixels were restored leaving out the non-noisy ones. This approach created a revolution in image restoration. One of the established traditional switching filters among those, having the similar approach with boundary discriminative noise detection [4] created massive impact in the noise restoration arena. It was later reformed by amending with elimination tactics to form BDNDE [5]. Challenges came with designing noise restoration for color images as the complexity of the images increased with different color panels having diverse intensities. In a very recent approach, a switching filter [6] with fast processing speed was designed. The filter used the analogous neighborhood pixels in least distance as a measure of precipitateness and the replacement of noisy pixels were done by a practical fast processing switching algorithm.

Vector median filter (VMF) [7] was one of the most proven filters, having effective noise removal capability for color images by using vector median approach for reinstatement operation. It was improvised later, amalgamated with center weighted approach to form Center Weighted Vector Median Filter (CWVMF) [8]. With further research, an adaptive non-causal linear prediction-based vector median filter [9] was designed based on adaptive error prediction-oriented approach which was a further advancement of the VMF. Recently, another modification was performed on VMF where the researchers came up with an idea to integrate adaptive VMF with weighted median filter method [10]. This approach was equally effective at both low- and high-density noises. In vector median filtering approach [11] another used quaternion depiction to find out color distances based on which the filter classified noisy and non-noisy pixels using four directional criteria. That was followed by weighted median filter for removal operation. This approach was improvised with the previous filter's upgradation [12] by using a weighted adaptive approach in the quaternion depiction for finding out more justified color distances which, thereby vividly enhanced the outcomes. One more adaptive vector median filter (ANCLPVMF) [13] was proposed in the similar timeframe which used the concept of linear estimation to calculate error components and thereby compare it with a defined threshold to sort out noisy pixels. The removal phase used an adaptive

VMF for carrying out replacement of detected noisy pixels. Quaternion approach became popular as it combined three color planes into a single unit. Here, a rank-based approach [14] was proposed in recent times using quaternion theory which had segregated noisy pixels by rank criteria, along with edge detection mechanism and thereafter substituted those noisy pixels by weighted vector median filter. In the meantime, a relatively new filter [15] came up with a thought-provoking awareness by using statistical Moran's I (MI) index for noise detection operation, which was followed by VMF for carrying-out noise removal activity. In the same time, a support vector machine (SVM) oriented fuzzy filter [16] has been proposed. The approach used SVM in training phase and thereby, the testing phase segregated noisy and non-noisy pixels. Thereafter, fuzzy filtering was applied on the noisy pixel elements in removal operation. In the category of fuzzy filters, histogram fuzzy color (HFC) filter [17] was introduced where the association amid the planes was measured to estimate the original histogram and thereby rebuild the image by fuzzification. This approach was revised in Modified HFC [18] to scale up the performance for both RVIN and SPN. It was further restructured by using support vector machine-based approach to produce Multiclass support vector machine adaptive filter (MSVMAF) [19]. In the equivalent period an adaptive iterative fuzzy filter (AIFF) [20] was proposed that worked based on a trimming approach which created a new insight in fuzzy filtering. Among the recent approaches [21], a fuzzy averaging oriented noise detection and removal was carried out where detection was based on fuzzification of renowned ROD statistics and removal mechanism followed a thresholding based fuzzy oriented noise removal. In most recent times a method used deep convolution neural network for impulse noise removal. The method [22] first trained a classifier for noise detection and it was followed by putting the noise detected images into a denoiser for carrying out denoising operation. In current times a new filter [23] was designed which has used trimmed median filter, decision based median filter and unsymmetric trimmed mean filtering in circumstances based on the impulse values. The combined effect of those filters shaped virtuous outcome.

## III. PROPOSED METHODOLOGY

In this paper, it has been primarily concentrated on removal of high-density impulse noise from RGB color images. An amalgamation of k-means clustering based noise detection tactic followed by a minimum distance-oriented removal mechanism is portrayed here (see Fig. 1 and 2). A  $5 \times 5$  window is used here in the detection trailed by a  $7 \times 7$  window in removal method to process the whole image pixel wise. These local windows are formed by centering each designated pixels in the image. Let us define the center pixel as  $C_{m,n}$  and the window by  $WD_{5 \times 5}$ . Then the window criterion is outlined like below where:

$$WD_{5 \times 5} = [C_{row, col}], \text{ where } m - 2 \leq row \leq m + 2, n - 2 \leq col \leq n + 2$$

Here  $C_{row, col}$  denotes all the pixel elements under the local window where each of those pixels have corresponding red, green and blue components, well-defined in RGB color images.

### A. Detection Method

In the beginning of the detection procedure, red, green and blue planes are extracted from the input noisy RGB color image (CLIM). A binary flag matrix FCLIM of the same size as the RGB image CLIM is created and is filled by '0'. The center pixel of a window is denoted as CE and its intensity is denoted as  $PINT_{CE}$ . The proposed detection algorithm is applied on each  $5 \times 5$  window shaped surrounding the pixels obeying window criteria residing at each of the red, green and blue planes independently.

1) Primarily the designated local  $5 \times 5$  window elements are skimmed and put into an array. By this process, the respective  $5 \times 5$  window elements of each red, green and blue plane are stored in three independent arrays ARYRED, ARYGREEN, ARYBLUE.

2) The elements of each of the above defined three arrays are chronologically put into three successive columns to form a new  $3 \times 25$  matrix MATRGB. Thereby the 1st, 2nd and 3rd column of MATRGB represents ARYRED, ARYGREEN, ARYBLUE elements in unchanged order.

3) K-Means clustering method has been employed on MATRGB having combined data from each red, green and blue plane. K-Means clustering would engender four different clusters  $Cl_1, Cl_2, Cl_3, Cl_4$  and group the analogous elements having similar properties into an equivalent cluster. K-Means clustering is performed on combined data to get the overall impact of a particular pixel at identical position on the red, green, blue planes and thereby putting the designated pixel into a proper cluster. The work is primarily focused on detecting random valued impulse noise affected pixel elements from noisy images. This implies that the noisy pixel elements of despoiled images are having random or arbitrary intensity value, whereas the non-noisy pixel elements have non-arbitrary values. So, after the application of K-Means algorithm on the combined data there is more likelihood that the non-noisy pixels having similar properties are likely to fall in the same cluster, while the noisy pixels, having dissimilar properties will be falling in random clusters.

4) The cluster having maximum number of elements is marked as maximum cluster (MC). The maximum cluster is most likely to be formed by non-noisy elements, as the non-noisy pixels having homogenous properties are most likely to fall in a same cluster although the noisy pixels having heterogeneous properties are likely to be scattered in different clusters. So, there is a mere chance for the randomized noisy pixels to group together to form a superlative cluster that can surpass a non-noisy element-contained cluster based on the component count.

5) All the elements in the maximum cluster are marked as non-noisy and the corresponding marked pixels intensities in the flag image FCLIM is filled by '0' and others are filled by '1'.

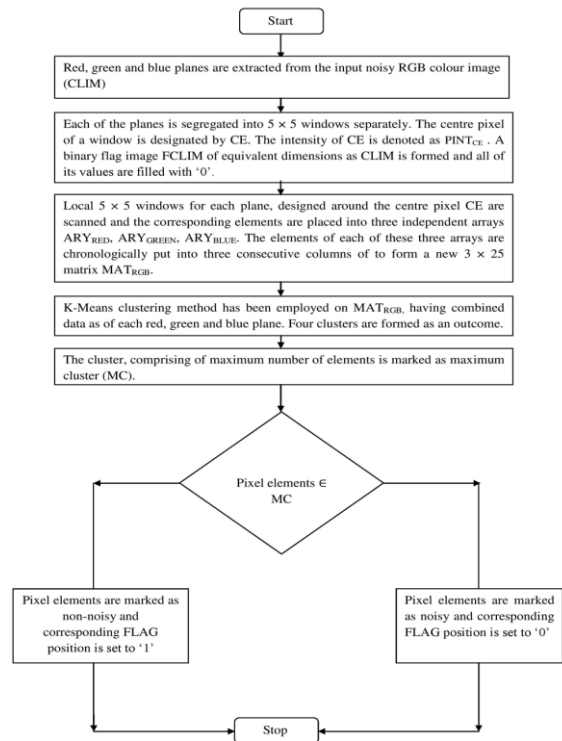

Fig. 1. Flowchart of Noise Detection Methodology.

### B. Removal Method

In the noise removal process, the output flag image FCLIM is segregated into  $7 \times 7$  windows, where each window's center element CE is noisy.

The following section portrays the removal algorithm for individual windows:

1) Primarily, for each  $7 \times 7$  window, the detected non-noisy pixels are kept on an array DRR. Instantaneously the array is sorted in ascending order to find out the median MD. The median value can effectively take part in the removal procedure as it brings out the overall impact of all of the non-noisy pixels in the DRR array. Furthermore, as the median value is a part of the non-noisy array, it can be more effective in removal.

2) Then, the non-noisy pixel or pixels in the DRR, partaking least Manhattan distance from the noisy center pixel CE is or are accumulated. Manhattan distance is calculated by taking the absolute difference between the center noisy pixel CE and the designated non-noisy pixel. If only such one-pixel value or multiple non-noisy values is or are present at minimum distance, then that value or those values are accrued in an array MDRR.

3) In a  $7 \times 7$  window, the maximum Manhattan distance possible is 6, whereas the minimum Manhattan distance possible is 1. Let DS be the Manhattan distance from CE. DS is initialized to 1. If any non-noisy pixel or pixels is or are found at DS from CE, then that or those non-noisy pixel or pixels are put in MDRR and we stop. If no non-noisy pixel is found at

DS, then DS is incremented and again non-noisy pixel or pixels is or are tried to be found. This process of finding non-noisy pixel at least distance is carried out up to the DS value of 6, until found. By this procedure, MDRR is formed with the non-noisy pixel or pixels at a least Manhattan distance of DS from CE.

4) Finally, the pixel intensity of center noisy pixel CE is replaced by using the equation below:

$$PINT_{CE} = \frac{(MD + \sum_{i=1}^n MDRR[i])}{1 + n}$$

Here, n is the number of elements in MDRR.

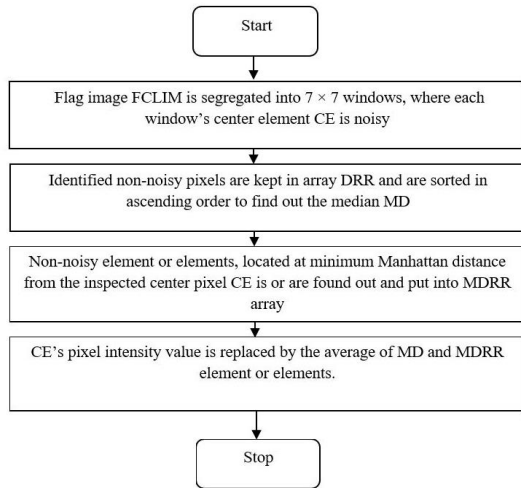

Fig. 2. Flowchart of Noise Removal Methodology.

MDRR[i] is the  $i^{th}$  element in MDRR.

#### IV. RESULT AND DISCUSSION

This section portrays the simulation results of the proposed method executed in MATLAB R2018a installed on a Windows PC having core i5 processor and 8 GB of RAM. Experiment has been carried out on 10 color test images at various noise densities for both salt and pepper and random valued impulse noise. Experimental results of 4 images: Lena, Baboon, Tower and Barbara, out of those 10 test images are shown in this paper. Seven different filters have been compared against the proposed filter at various noise densities. Qualitative results are portrayed by three figures. Two images: Lena and Baboon are used to show visual output and comparison of the proposed filters in contrast to different filters. Peak signal to noise ratio (PSNR) and Structural similarity index measurement is used to measure the quantitative performance of the proposed filter.

Visual performance of the proposed filter is portrayed by two established test images: Lena and Baboon. The filter has been tested on 20 images but only these two images are shown in this paper. Fig. 3 displayed the qualitative performance comparison of the proposed filter with the existing established recent filters in terms of Baboon image and from the said Fig. 3 it is pertinent that the proposed filter outpaced the compared state-of-the-art filters with respect to habitual human viewpoint. The performance variety of the proposed filter is

depicted in Fig. 4 and Fig. 5 using standard Lena image. The proposed filter is tested on both salt and pepper and random valued impulse noise effected images. Fig. 4 and Fig. 5 interpret the visual output of the proposed filter at diverse noise densities on the Lena image affected by RVIN and SAPN respectively. From the visual perspective, the proposed filter has shown notable result for both the types of impulse noise patterns. Quantitative performance of the proposed filter is judged by Peak signal to noise ratio and Structural similarity index measurement. Definition of Peak signal to noise ratio (PSNR) in 'dB' is demonstrated below:

$$PSNR = 10 \log_{10} \frac{255^2}{MSE} \quad (1)$$

$$MSE = \left( \sum_{A,B} \frac{\sum_{A,B} (Bi(a,b) - De(a,b))^2}{A \times B} \right) \quad (2)$$

Here, Bi = Base Image, De = De-noised image, A = Count of rows, and B = Count of Columns.

Fig. 3. Visual Performance Comparison of Proposed Filter Outcome against Recent Filters for Baboon Image in Terms of RVIN.

Fig. 4. Visual Performance of Proposed filter at Varied Noise Densities for Lena Image in Terms of RVIN.

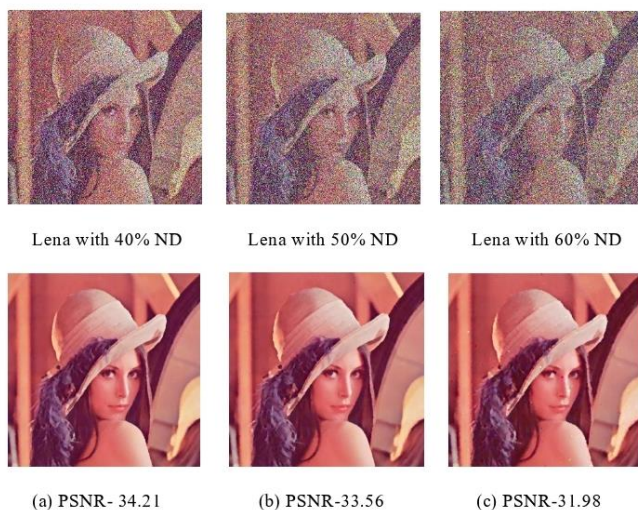

Fig. 5. Visual Performance of Proposed Filter at Varied Noise Densities for Lena Image in Terms of SAPN.

The structural semblance amid the base and restored image is quantified by Structural similarity index measurement (SSIM) and is defined as follows:

$$SSIM(i, j) = \frac{(2\Phi_i + \Phi_j + C_1)(2\beta_{ij} + C_2)}{(\Phi_i^2 + \Phi_j^2 + C_1)(\beta_i^2 + \beta_j^2 + C_2)} \quad (3)$$

Here,  $\Phi_i$  and  $\Phi_j$  are the mean of image  $i$  and image  $j$  correspondingly. The standard deviation of image  $i$  and image  $j$  is portrayed by  $\beta_i$  and  $\beta_j$  correspondingly.  $C_1, C_2$  are the defined constants.  $\beta_{ij}$  is the co-variance of  $i$  and  $j$ .

Table I assesses the proposed filter’s efficiency by means of PSNR for both RVIN and SAPN for standard Lena image. These two noise patterns create fixed and random dots on images thereby generating distorted images. The proposed algorithm takes care of both the noise patterns effectively as shown in Table I. Some recent filters are compared to the proposed filter to showcase its competence. It can be seen that at various noise densities, especially at higher noise densities the filter works superior to the recent reputable filters.

		80%	0.2215	0.8117	0.8137

Table II portrays the performance comparison of the proposed filter counter to some of the recent filters with respect to another metric SSIM, to judge the efficacy of the filter to embrace the shape and structure of the investigated images while going through the restoration procedure. Three different images Lena, Baboon and Tower are used to depict the result. As seen from the comparison, the proposed filter holds over

80% resemblances for all those images at a high noise density of 80% with respect to both SAPN and RVIN and also embraces 99% alikeness at a minimum 10% noise density. These results point toward the potential of the proposed algorithm to reinstate the structure of the images to a commendable extent post restoration.

One more imperative factor of the proposed filter was to choose the window size to be applied all over the image on both detection and removal stages. As the method is applicable for color image restoration, the same window size was applicable for all the red, green and blue color planes. Trial and error method was used to find the window size for the proposed method. After implementing the algorithm with different odd numbered window sizes,  $5 \times 5$  and  $7 \times 7$  size was found suitable for the proposed detection and correction method respectively. The PSNR outcome of the proposed filter using different odd numbered window sizes is demonstrated in Table III and it can be seen that, our method produced a superlative PSNR result for the selected window sizes.

It is intrinsic that, detection is the primary aspect for a filtering before applying a removal mechanism. While applying K-Means in the proposed method to cluster the least variant non-noisy elements, a cluster size has to be selected. As,  $5 \times 5$  window size is used in the detection procedure, we have 25 elements, which will be segregated into different clusters after applying the K-means method to the data. If higher cluster size is taken, that could invalidate the objective of clustering as several small cluster would be created and it will be hard to find a maximum cluster having non-noisy elements. So, smaller cluster sizes were taken and investigation was performed on a trial-and-error basis. From Table IV, it can be perceived that, cluster size 4 yielded maximum output for the proposed method after being tested on different images.

TABLE III. PERFORMANCE OF THE PROPOSED FILTER FOR VARIED WINDOW SIZES

Noise	Window Size		Noise Densities		
	Detection	Removal	40% ND	50% ND	60% ND
SAPN	3 * 3	3 * 3	34.06	33.19	31.64

TABLE IV. PERFORMANCE OF THE PROPOSED FILTER FOR VARIED CLUSTER SIZES

Noise	Images	Cluster Size		
		3	4	5
SAPN	Lena	31.75	31.98	31.61
	Baboon	29.51	29.68	29.30
	Barbara	25.01	25.69	24.46
RVIN	Lena	27.36	27.56	26.91
	Baboon	26.81	26.96	25.97
	Barbara	23.98	24.65	22.96

By all the results shown and analyzed above, the proposed emerged to be superior to all the compared state-of-art filters. In the work, the key aspect of the enhancement lies in the K-means clustering-oriented detection. K-means clustering of size 4 is used here on each of the  $5 \times 5$  kernels to generate four clusters having respective pixel intensities based on the randomized clustering method. As the non-noisy pixels have more propensity to have the least variant values within the defined small kernels, it is more likely that those pixels will be grouped by the clustering procedure and will belong to the same cluster. On the other hand, the noisy pixels are more probable to have scattered values and least possible to belong to the same cluster and also very occasional to form a cluster having the greatest number of elements. This creates the foundation of the proposed work followed by captivating the least Manhattan distance criteria in removal operation which has strengthened the proposed algorithm. Here, the non-noisy pixels, residing at least distance from the evaluated noisy pixel are taken as the key element in the removal operation. Because these non-noisy pixels at least distance are having the most influence on the assessed noisy pixel for each kernel. Altogether, these crucial facets of the proposed work justify its groundwork and showcase the reason behind the enhancement.

## V. CONCLUSION

This paper demonstrates a high-density noise removal scheme from color images. The proposed method is fabricated on K-means clustering based detection followed by least distance criteria-oriented removal. Applying K-means clustering on the collective data, formed by elements of each defined windows of a color image, extracts the mutual effect of all color planes for individual pixels, residing at identical positions in each plane and thereby categorizing each pixel into a specific cluster. Clustering is applied in the conjecture that, the non-noisy pixels from each window having similarity are categorized into a specific cluster while noisy elements having variations will be scattered into different clusters and thus can easily segregate non-noisy and noisy pixels effectively. Then the non-noisy pixels, found at least distance from the inspected noisy pixel, are used along with all over median criteria of segregated non-noisy pixels from each window, for the replacement operation. This removal scheme uses the impact of closest non-noisy pixels, because these pixels are having maximum influence on the inspected noisy pixel. The overall work is justified by the superior qualitative and quantitative results up against the recent reputable filters. It can be seen that; the proposed algorithm works brilliantly at high noise densities and effectively at lower middle noise densities. Our

future objective is to design a filter that is equally capable at both low and high noise densities.

#### ACKNOWLEDGMENT

We would like to express our heartfelt gratitude to Ms. Sonali Banerjee and Ms. Koyel Chakraborty for their relentless inspiration and motivation that abetted us to conduct this work in this tough time around.

**Abstract**—The adoption of cloud computing in different areas has shown benefits and given solutions to applications. The cloud provider offers virtualized platforms through virtual machines for the cloud users to store the data and perform computations. Due to the distributed nature of cloud, there are many challenges and security is one of the challenges. To address this challenge, verification method is implemented to achieve high level security in the cloud environment. Many researchers have provided different authentication mechanisms to safeguard virtual machines from attacks. In this paper, Multi Stage Authentication is proposed to overcome the threats from attackers towards virtual machines. In order to authorize and access the virtual machine, multistage authentication incorporating the factors like username, email id, password and OTP is carried out. Mealy Machine model is applied to analyze the state changes with factors supplied at multiple stages and trust built with each stage. Experimental results prove that system is safe achieving data integrity and privacy. The proposed work gives the protection against unauthorized users, provides secure environment to the cloud users accessing the virtual machines.

**Keywords**—Authentication; multi stage authentication; one time password; finite state machine; mealy machine

## I. INTRODUCTION

In cloud environment, many users deploy the applications. These applications are accessed by several users. Dependability of users on the cloud is increasing day to day[1] as the investment is lesser. Hence cloud environment is prone to security issues[2]. Illegal access, misuse of data and assets hacking by the malicious users are some of the threats that has to be addressed with more importance. Proper authentication has to be in place to safeguard against these attacks[3]. Traditional authentication mechanisms such as password-based login suffer with security problems. Password hijacking, stealing and phishing attacks[4] are some of the threats which create burden on cloud environment. Hence the resource access from the attackers has to be protected by good authentication.

Many well-known cloud computing environments such as Google, Amazon and Microsoft have already adopted the multifactor authentication. The major usage constraint is with respect to the users as they need to use the extra effort to login providing more factors. There is one more main concern to safeguard the user's credentials as they are shared with cloud environment to access the services from the cloud. Cloud users perform computations using virtual machines where they store the data and continue working till completion. Virtual

machines belonging to different users are stored in the same host. Hence security of the virtual machine (VM) has to be taken care with almost importance. Before the VM is granted or accessed by the cloud user, authentication has to be carried out. Authentication [5] helps in proving the trustworthiness of the cloud users. Single factor authentication suffered with the problems such as if the user forgets the password and losing of password will completely avoid the legitimate user to access the resources in the cloud. Multistage Authentication (MSA) gives an additional layer of security to access the resources in the cloud and cloud provider is sure of extra security along with service level agreement. First step for cloud users is signing the service level agreement with cloud provider, next step is multistage authentication to access the cloud. Hence using this multistage authentication avoids attacks by the compromised users. There are advantages of choosing multistage authentication when compared with normal authentication such as increased security in the cloud environment and prohibiting the unauthorized users in to the system.

### A. Motivation

The main objective of the paper is to protect the VMs in the cloud environment from illegal access and theft of data using MSA. MSA in cloud environment considers more than one factor from cloud users side credentials so that authentication is stronger. Even though the attacker tries with any one factor, gathering all the factors is not an easy measure to enter the system. MSA offers robust method of authentication cloud users and benefits with effective solution to the authentication. To provide high degree of security in the virtualized cloud environment and protect against several cyber-attacks that happen. Using multiple factors [6] provides an additional step towards accessing sensitive and confidential data stored in the cloud provider's domain. It is normally common that most of the users will accessing the virtual machines from the same host. Hence, it's the cloud provider's responsibility to meticulously provide the access to the virtual machines with appropriate authentication mechanism. Its observed number of incidents happening in the cloud regarding the data theft and DOS attacks.

Some of the research questions to be considered are:

- Access to the virtual machines in the cloud environment by the registered users without hassles.

- Will the MSA approach recognize the unauthorized users?
- The security features such as integrity, confidentiality and authenticity are achieved or not?

### B. Contribution

The paper starts with theoretical concept of authentication, state machine to provide strong model to overcome illegal access and protect the virtual machines from attacks. The paper includes

- Authentication requirement and different authentication approaches with pros and cons are explored in the paper.
- Mealy Machine is presented to analyze the authentication process performed by the legitimate user to build the trusted environment and prevent the unauthorized user at all states.
- The approach uses MSA to allow users to access VMs for completing the tasks assigned by their organization.
- To protect every user's credential in the cloud provider's domain, robust MSA approach is applied guaranteeing the integrity and privacy.

This paper is organized as Section 2 gives background, Section 3 describes the related work, Section 4 presents the proposed approach, Section 5 gives the evaluation of the algorithm, Section 6 explains the results and discussions and Section 7 concludes the paper.

## II. BACKGROUND

### A. Traditional Authentication

Authentication [7] is a technique of proving the identity of the user in accessing the system by providing the details such as password and username. Traditionally single factor authentication was used to enter the system with an access card. It is observed that every user obtaining any services from any provider normally uses password-based authentication [3]. This password-based approach is usually used across different applications on hosts. Password is a widely accepted mechanism as it does not involve any major complications, users have to memorise the password and apply whenever the authentication is required. Passwords can be plaintext, combination of various characters involving special characters, numbers and so on. Users have suffered with many attacks due to weak passwords. There are cases where random passwords are selected and attackers can crack passwords. The different types of password attacks are dictionary attack, brute force attack, session hijacking and so on. Attacks disrupt the normal functioning of the cloud environment. The usage scenario of any environment is the users register for the service with certain password, which gets stored in the cloud server. Claimant has to provide the password in order to prove that he is authorized user. If the password matches with the stored password, then the claimant users are authenticated. The systems usually advice to choose the strong password.

### B. Authentication

User has to prove that he is legitimate and this can be done using authentication. Usual methods are username and password to prove identity of the user. With the advancements in the security measures of any network, two factor and multifactor authentication [8] was applied to defend against illegal users.

Authentication avoids unauthorized access [5] to the sensitive information. There are all possibilities that the attacker gains access to virtual machines and tampers the information [9] stored, which leads to integrity threat.

There are five types of authentication mechanisms type [10] [11] [12].

- Password authentication: This method involves the password given by the users with a combination of characters, symbols and numbers. Users have to create strong passwords to avoid attacks. Many users keep simple passwords to avoid remembering long and cryptic passwords. Hence users are at the risk of password attacks.
- Certificate Authentication: User identity is confirmed by the digital certificate issued by the certification authority. The best example is Aadhar card to identify the user. Users provide the digital certificate when they are using the services or resources from the server. Once the server verifies digital certificate, user is decided as the legitimate.
- Biometric Authentication: User identification based on the biological characteristics of the user. Using the biometric factors, access doors or login to the system is granted in some of private firms. Biometric feature can be added as one of the factors with multifactor authentication.
- Token generated method: User credentials are maintained and users receive the tokens on one of the credentials. They provide the tokens to prove their identity.
- Multi factor authentication: Users add more than one factor to authenticate himself with server to access the resources. Multifactor authentication (MFA) can take more than one factor at the same time or multilevel. Due to this method of authentication, system is protected with various threats.

Among these different authentication [13] mechanisms multifactor authentication is applied as it is one of the most promising approaches. Multi factor authentication [6] mechanism defends against the attacks with extra care. Factor is the one which user provides to claim who he is. Suppose an employee enters the organization. He can enter the organization by swiping the card. How will the doors get to know that he is authorized person? It's because he has the smart access card which can be used for authentication. In this smart card, there is integrated chip which controls the access to the office environment. Normally chip stores the user

authentication data, user identification and data used by the users with respect to applications.

The different types of factors are collected [14] from the user to authenticate are:

- Knowledge factor: Aspects that users know like passwords. This factor is normally shared between the user and the provider. Once the user chooses the factor, it will be stored in the provider's database server and each time the user enters his factor, it has to be validated.
- Possession factor: Aspect that user has such as mobile phone or any other device. It can be the one-time password, smart cards or security tokens. If the user happens to lose the device, it is difficult to authenticate the legitimate user.
- Inherence factor: Feature that user is like biometric feature, voice or fingerprint. This factor is the one that the user is and the biometric factors are unique to each and every user.

Table I below represent the different factors which users are aware of to make use.

TABLE I. DIFFERENT FACTORS THAT ARE CONSIDERED FOR AUTHENTICATION

Knowledge factor	Possession factor	Inherence factor
User Knows- PIN, Password, security question related to his DOB or anything which user is aware of.	User possesses- Mobile phone, Smart card or tablet on which receives one time password(OTP), random password, etc	User is identified with biometric features: Iris, finger print or face recognition

The advantages of multi factor authentication [15] are:

- Improved Security: System security is enhanced by introducing the multifactor authentication. Additional Layers of authentication will add on to the security.
- Compliance: Necessary conditions of the organization are satisfied.
- Flexibility: Options for authentication is improved with more factors compared to traditional password authentication.

### III. RELATED WORK

Ometov et al [15]., has discussed about multifactor authentication right from single factor authentication. They have explored different authentication methods, applications and challenges involved in implementing the multifactor authentication. The authors have identified operational concerns such as usability, robustness, integration and security. They have provided the benefits of MFA towards security. The authors have proposed the reversed approach in which the factors obtained from the users have secrets such fingerprint or pin. Considering  $n$  as sum and  $I$  factors with  $S_e$  secrets provided to them.

Factors and correspondingly secrets can be written as

$$I_1: S_{e1}$$
$$I_2: S_{e2}$$
$$\dots$$
$$\dots$$
$$I_n: S_{en}$$

Secrets are provided by the user to authenticate so that they can enter the system. Assume there are four factors and user forget any one factor to enter, then there is a trusted cloud party, which will aid to recover factor so that the user will be able to enter the system. Some of the biometric factors such as fingerprint, face change over the time, for which there is support by trusted party to update the feature in the database. There is decision policy which helps in deciding whether the user is authenticated or not.

B. B.Gupta et al [16], have proposed a model for access control based on the identity and mutual authentication using smart cards. The approach has five different phases right from the registration to authentication including updation of credentials. Hash functions are used towards the data. The approach mitigates unauthorized access, eaves dropping and single sign on with smart cards. It also defends against DoS attacks, fake identity and illegal use of smart cards.

C. Singh and T. Deep Singh [17] have proposed MFA with three levels based on the three levels of authentication. At the first level the login and password are stored with double encryption such as SHA-1 and AES. Second level of authentication uses the out of band authentication technique. After the first level, server provides the OTP to registered mail. User has to prove that he is legitimate by providing the OTP to the server. Third level user has to click certain number of images and buttons on the screen to get authenticated. The approach provides the protection against various attacks like man-in middle, brute force and password guessing.

A. Bhanushali et al [18], have given a good input about different authentication algorithms with respect to security, usability, space and storage. They have described the algorithms such as draw a shape, grid selection and déjà vu authentication algorithm based on the images. In order draw a secret, technique user is provided with a drawing and user has to reproduce same by redrawing. In grid selection the user is provided with small grid and needs to draw the pattern for authentication. Déjà vu is based on the seed value generated by the trusted server towards the user and at the time of authentication, user has to prove using this value. The inference provided by the authors is graphical based approach is better than the textual approach with respect to security.

Multilevel authentication [19] is presented by the authors to enhance security for electronic devices. Three levels of security checks are performed to authenticate the legitimate user. First level of security check is done with normal password. Biometric authentication is carried out in the second level. Last level of security check is performed by the accelerometer.

The proposed approach in the paper does not need any trusted third party and the interaction is between the cloud

provider and cloud user. There is no need for the user to go through the sequence of images with MSA approach.

Some users might not be well versed with drawings and user has to go with stages and provide input. Hence the proposed work is friendly to the users and provides security with features such as confidentiality and privacy. The approaches implemented by the various researchers along with the security parameters are given in Table II.

TABLE II. IMPLEMENTED AUTHENTICATION APPROACHES WITH SECURITY PARAMETERS

Authors	Description	Security Parameters addressed
Ometov et al[15]	Multifactor Authentication	Highlighted the operational concerns robustness, security and integration.
B. B.Gupta et al[16]	Smart Cart Authentication	Protection against unauthorized access, eavesdropping and DoS attacks.
C. Singh and T. Deep Singh [17]	MFA based on three level authentications	Defends man-in- middle, brute force and password attacks.
A. Bhanushali et al[18]	Survey about authentication algorithms	Graphical based approach provides better security.
A.Dinakar et al[19]	Multilevel authentication	Three levels of security checks for authentication.

#### IV. PROPOSED APPROACH

The objective of the proposed work is to implement secure access to the virtual machines using Multistage Authentication. In Multistage Authentication more than one factor is considered. As per the authentication mechanisms, using multiple factors, system is less prone to attacks.

##### A. Adversary Scenario

Attacks are possible from the attackers to gather the information stored in the cloud server [20]. Attacker might also try to spoof and access the VMs from the cloud provider. In the Fig. 1 shown below, legitimate users are the authenticated users and attacker [21] is the one trying to intrude the system. In normal authentication, login and password are used to provide the VMs. The traditional approach will give opportunities for attackers to damage the security features such as data integrity, confidentiality and availability [22].

A formulation is obtained for the minimization of attacks on the virtual machines with automata theory. The model used to realize the approach is mealy machine. Given below are the details of the state machine and use case of mealy machine.

##### B. Introduction to State Machine

State Machine is the machine which works based on the behavior of the system. The output of the system depends on the user's input. The machine which has finite number of states is known as finite state machine. Let us consider the simple example of tube light. When the user switches on the button, the state changes to on and otherwise it is off. There are two states in this machine namely switch on and switch off which is depicted in the Fig. 2.

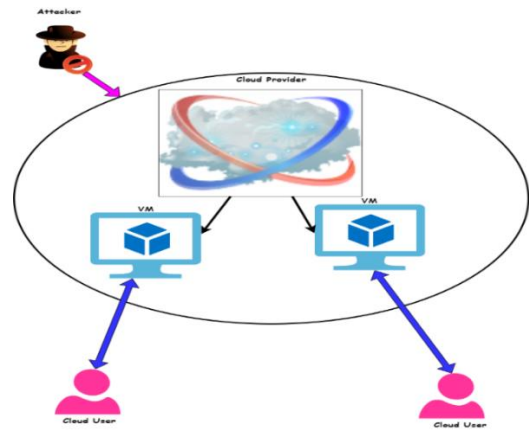

Fig. 1. Scenario of Risks.

Fig. 2. State Machine of Tube Light.

##### C. Finite State Machine

Finite State machine is a computational model [23] with defined number of states. States always present the status of the system at the given instance. Consider the example traffic signal. As per the light shown, pedestrians cross the road and vehicles navigate through the traffic. This is one of the classic examples of Finite State machine. Finite state machine contains starting state, accepting states and final state. The output is either accept or reject. With specific input transition of state takes place. All these input symbols are represented in the alphabet.

Formal definition of finite state machine: It is represented with set of three entities shown in the equation 1:

$$F = (V, I, t_r) \tag{1}$$

$V$  &  $I$  are non-empty finite groups

$t_r: V \times I \rightarrow V$  is a state transition function.

$v_0$ : Initial state where  $v_0 \in V$

$I$ : input alphabet contains input symbols

To summarize the concept of the FSM as

- Has finite number of states
- Either zero or more accepting states
- Has at least one state
- Set of symbols for transition
- Has alphabet which has the set of input symbols.

Next followed by this topic, mealy machine is FSM depending on the present state and input symbol. The system is modeled with Mealy machine.

D. Overview of Mealy Machine

Mealy Machine is a finite state machine [24][25] in which output state depends on the current input symbol and state.

Let us find out (V, v<sub>0</sub>, I, O, t<sub>r</sub>, F):

V: Finite Set of States

v<sub>0</sub>: Initial state

I: Set of symbols for transition

O: Output Symbol

t<sub>r</sub>: Function of transition mapping V x I → V

F: Output function mapping to V→O

Fig. 3. State Transition in Mealy Machine.

Mealy Machine [25] has simple one input upon which transition to the next state shown in Fig. 3. Only two states are presented Q<sub>0</sub>, Q<sub>1</sub>. Input symbols are 0 and 1. Output is represented as 0 and 1. Mealy machines have fewer states compared to that of Moore machine. Mealy machines are secure to use; response for the inputs with mealy machines are faster. Mealy machines are used so that each level the trust is increased and only legitimate users are granted with the VMs.

E. Use case with Mealy Machine

The factors considered for the authentication are Email-id, password, Phone Number and One Time Password. Using mealy machine trust chain can be seen. In any of the stage the input is wrong, trust is broken. When the trust is broken by any of the user, it is very clear that it is the attack performed by the intruder. These factors are provided as the input symbols to the system. As per the factor and present state, the user progresses to the next state shown in the Fig. 4.

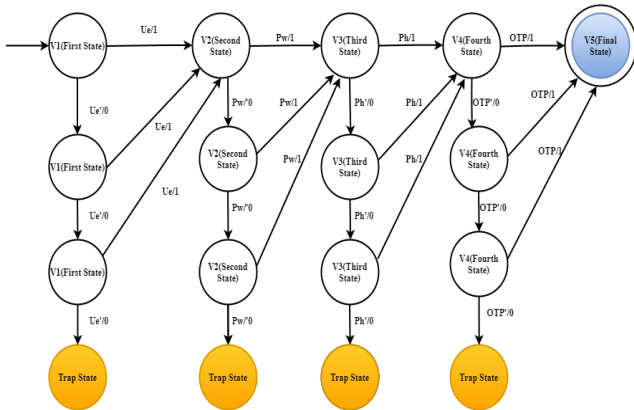

Fig. 4. Multistage Authentication System State Changes Depicted with Mealy Machine.

Here as per the input, the change in the state is seen. First user name and email id are the input symbol for state change. Next input symbol considered is password, followed by phone number and OTP. The system is multistage or multi-level where there are stages which legitimate user will be able to clear and succeed. Upon correct entry of email, password is generated to the valid email. User can login using the password generated. User has to go through the four stages in order to reach the final stage as shown in the Fig. 4. Every stage input and current stage important to advance to the next stage.

Let us represent the details of machine with the multifactor authentication

$$V = \{V_1, V_2, V_3, V_4, V_5\}$$

V<sub>1</sub>: Initial State or first state

I = { Ue, Pw, Ph, OTP }

O = { 0, 1 }

T<sub>r</sub> is the transition function.

Upon receipt of matching symbols like email id, phone number, password and OTP, transition takes place to the next level in the system. The output states are 0 and 1. 0 represents failure and no transition and 1 depicting success along with transition to next state. Three attempts are considered in the proposed approach. As shown in the Fig. 4 the intruder at any stage tries to perform attack, cannot advance further and access the virtual machine.

F. Security Analysis with Mealy Machine

Attacks can be viewed and analyzed based[26][27] on the automata theory. The proposed MSA approach protects against attacks[28] which are discussed below:

- **Replay Attack:** If an attacker somehow gathers the email id and user name, guessing the secret password and gathering the OTP is not possible. Attacker cannot penetrate the cloud environment and access the virtual machines. With the mealy machine, if at any stage input is wrong, state change will not happen. Between V<sub>1</sub> and V<sub>5</sub>, if the attacker tries to gather any factor and apply that in between randomly, successful authentication is not possible as mealy machine depends on current state also.
- **Spoofing Attack:** Attacker tries to impersonate in order to avail the virtual machines. Every time OTP is generated and it is not easy for attacker to get the OTP. There are multiple factors for attacker to guess, it is not just login and password compared to traditional systems. Intruder trying to capture Ue, Pw, User name and random password to authenticate himself is not accepted as password is received to legitimate user's email.
- **Data theft resistant:** The approach implemented overcomes the data theft as illegal access is not happening. If an attacker tries to intrude in any stage, there are only three attempts and third attempt being the last one, upon failure goes to trap state.

- Brute force attack: If any intruder tries to attack the system in any stage gathering some information, intruder cannot succeed in entering the system. As there are different levels and at each level if wrong input is raised, state change will not take place.
- Man in Middle attack: This system is resistant for man in middle attacks.

Intermediately in any state  $V_i \in V$  where  $i \rightarrow 1,2,3,4,5$  it is not possible enter the system. In order to validate the mealy machine model, simulation is performed and evaluated. The factors considered, algorithm steps and implementation details are presented below.

G. Methodology

Cloud user credentials are collected by the cloud provider during the registration phase. When users want to access the resources, authentication is performed. Here multistage authentication is used by the cloud provider. The factors considered for authentication in this approach are presented below.

- Email id: The user registers with his or her username and email ID. A unique hash code is created for each user using MD5 algorithm. MD5 algorithm [29] is used to encrypt the 4-digit random passwords generated for the user. The username and 4 digit non encrypted password are sent to the registered email ID. The user logs into his or her email account and must take note of the unique password provided in the body of the message. A link is sent to the registered email id. The user must click on the link included in the email to activate his account and get access to the login page.
- User name and password: Once the login page appears, the user enters the username and password sent via email. At this point they must also enter their contact number for the next level - OTP verification. If the username and password authenticate correctly, that is, if it matches with the information stored in cloud provider's database, the second factor is verified.
- One Time Password (OTP): Once the user clicks on the generate OTP button after providing the phone number, a random 5-digit OTP is generated and sent to the respective phone number. The user is required to enter the OTP. The entered OTP is verified with the temporarily stored OTP. If verification is successful, the user is granted access to the VM.

Multistage authentication shown in the Fig. 5 is explained step by step in the algorithm provided below. There are stages here in the approach. In the first stage, the email id and user name are provided. Cloud provider verifies in the database and sends the password to email. Using the password, user can login and provide the phone number for receiving OTP. This phone number is validated in the database and the OTP is sent. All these steps are shown in the Fig. 5.

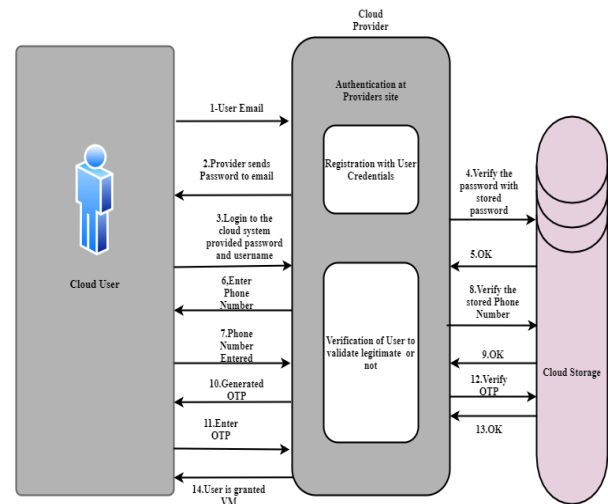

Fig. 5. Multistage Authentication Depicting Authentication Process.

Algorithm: Multi stage Authentication

Input: Username & Email-id

Output: Valid User is able to enter the cloud Environment

1. Begin
2. for each n users in the cloud provider Cp do
3. Enter Email-id Ue and User\_name Un
4. Cloud Server Generates 4-digit password PW4 and sent to user's email-id Ue
5. Enter the user\_name Un and Password PW4 in to the system
6. If (Un && PW4 with Cp server database)
7. Ask user to enter phone\_no Ph
8. Send OTP to Ph
9. If (entered OTP == Cp Server Value)
10. Grant the user request
11. Else
12. Generate Alert to the Cloud Provider about illegal access
13. End

Notations used in the MFA approach are described in the Table III.

TABLE III. NOMENCLATURE OF THE TERMS USED IN THE PROPOSED MFA APPROACH

Notation	Description
Cu	Cloud user
Un	User Name
Rn	Random Number
Act. link	Activation link
Cp	Cloud Provider
Ue	User email id
PW4	Four-digit password
Ph	Phone number
OTP	One time password
H(.)	One way hashing
X->Y: A	Send A from X to Y

The stages of authentication are login, authentication and verification phase in order to grant user with virtual machines requested. This is depicted in the Fig. 6.

1) Login Phase

Step 1: Cloud user requests to allocate the virtual machine to the cloud provider with whom he is signed the SLA. Cloud user sends user name and email id.

Step 2: Cloud Provider generates four-digit hash and sends to the cloud user. Along with this activation link is also sent to the cloud user's mail id.

Step 3: User clicks the link to activate his account in the cloud environment.

2) Authentication Phase

Step 1: User enters the password provided by the cloud provider in to the cloud system.

Step 2: Cloud Provider asks the user to enter the valid phone number.

Step 3: Cloud User Provides the phone number.

Step 4: Cloud Provider generates the randomly five-digit password as one time password valid for 60 seconds to the cloud user's phone.

Step 5: Cloud User has to enter the OTP to access the virtual machine allocated for him by the cloud provider.

3) Verification Phase

Step 1: OTP generated is stored in cloud provider's database.

Step 2: Cloud User entered OTP is compared with stored OTP.

Step 3: Both are same, cloud user is granted virtual machine.

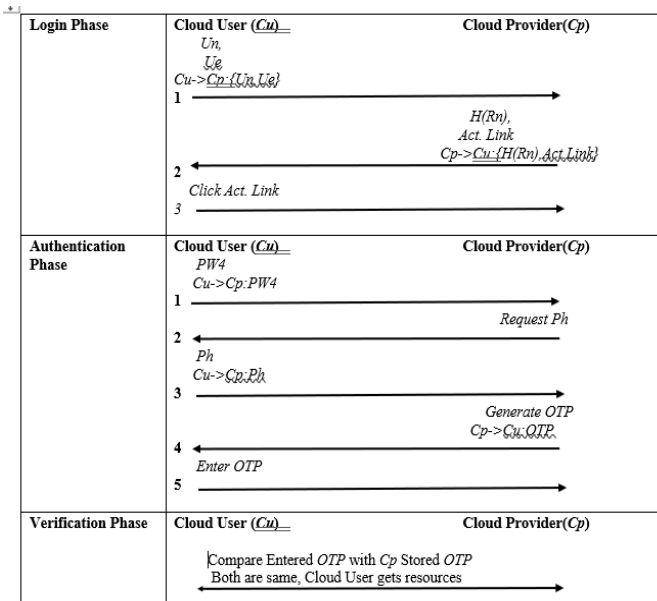

Fig. 6. Stages of Authentication.

V. EVALUATION OF ALGORITHM

Simulation is performed considering the many users and cloud provider. The authentication system is implemented using php, html and CSS at the front end, backend Mysql and XAMPP web server [30] solution stack. The backend database stores the user details. System has three modules viz. registering user credentials such as user name and email id, login page and OTP page. The algorithm has different factors for authentication. If the user is able to guess any of factor, it is not an easy mechanism for adversary to retrieve all factors. OTP is valid only for limited time and attacker breaking the OTP with in time duration is not easy. User has to sign up to access the cloud provider shown in the Fig. 7.

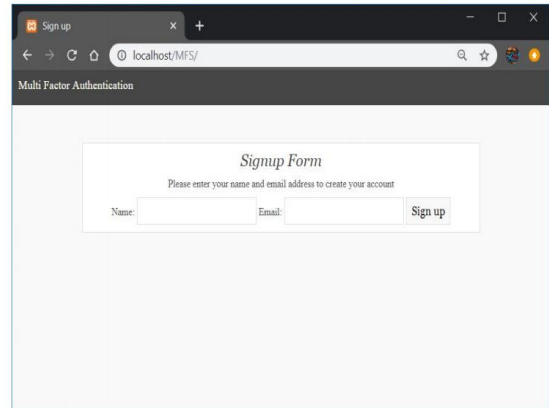

Fig. 7. User Sign up with cloud Server.

After the registration the username and unique password is sent to the user on his/her registered email id shown in Fig. 8.

Fig. 8. Reception of Username and Password by the user.

The user now knows his/her unique password and can access the login page, as shown in Fig. 9.

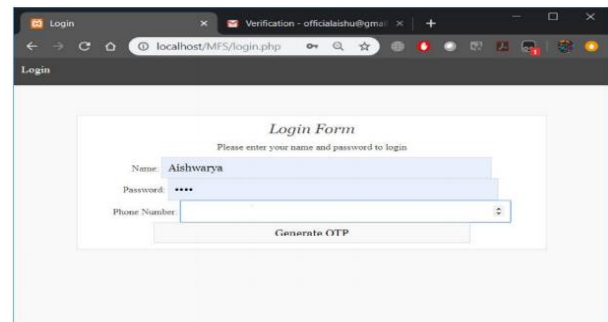

Fig. 9. Login Form.

Fig. 10. OTP Confirmation.

User receives the OTP on valid phone number and enters OTP as shown in Fig. 10.

When the user submits the OTP, it is verified with value stored in the cloud provider database and once it is confirmed the multistage authentication is complete. User has passed all authentication checks. Every time the OTP is generated and there is no chance of gaining the access to the cloud environment.

## VI. RESULT AND DISCUSSION

Multistage authentication is checked for different time slots and recorded the successful attempts and failure attempts. In these number of successful logins is legitimate users. Testing is carried out using JMeter [31]. Login analysis is performed using JMeter. JMeter is opensource java-based tool used to test load and performance. Failure attempts some of them are intruders trying with brute force method to enter the system. The system is tested for the varying number of users right from 10 to 100. It is found that the system has provided resistance towards the attacks. Accuracy of system is calculated using the formula given below.

$$Accuracy = \frac{Sl}{Tl}$$

Where *Sl* is successful logins and *Tl* specifies total logins. The graph representation is shown in the Fig. 11.

The experiment is run for one hour, three hours and six hours. Overall Login statistics of users are depicted in Table IV.

Fig. 11. Accuracy Depiction.

TABLE IV. OVERALL STATISTICS

Duration	60	180	360

The graph in Fig. 12 indicates that MSA approach provides the legal access to cloud environment. The cloud users after the SLA contract with cloud providers can request for resources using MSA. MSA adds one more layer of security after SLA. The system does not allow the unauthorized access; hence approach provides privacy and protection against intruders who are trying to access the resources illegally.

## VII. CONCLUSION

Cloud computing is technology which has lot of benefits to the cloud users in terms of cost, accessibility and scalability. In spite of these advantages, there are many challenges and security is one of the challenges to be addressed. In order to protect against the attacks launched by illegal users, MSA mechanism is used in the applied. Different authentication mechanisms are discussed. Adversary scenario is presented and how attacker gains access to cloud resources to disrupt the regular functioning of cloud environment. The approach is validated with mealy machine theory. Mealy machine representation provides the stage changes along with trust flow from one stage to another to evaluate if any unauthorized access is carried out. MSA uses the factors viz user name, email id, phone number and OTP. Though user is registered, authentication mechanism has to be carried out every time user wants to access the virtual machines. The proposed approach protects against the attacks such as spoofing, replay and data theft. The results clearly depict how strong the authentication mechanism with respect to number of authenticated logins and time duration. With the observation of the approach implemented, it is quite unlikely to get the access by unauthorized users to the virtual machine which is meant for legitimate users. With the benefit of security, there is an overhead experienced by the user in passing through multiple stages to authenticate and access the VM whenever it is required.

In future, it is planned to consider the roles and grant the access to the virtual machines in cloud environment.

**Abstract**—Recycling plays a vital role in saving the planet for future generations as it allows keeping a clean environment, reducing energy consumption, and saving materials. Of special interest is the plastic material which may take centuries to decompose. In particular, the Polyethylene Terephthalate (PET) is a widely used plastic for packaging various products that can be recycled. Sorting PET can be performed, either manually or automatically, at recycling facilities where the post-consumed objects are moving on the conveyor belt. In particular, automated sorting can process a large amount of PET objects without human intervention. In this paper, we propose a computer vision system for recognizing PET objects placed on a conveyor belt. Specifically, DeepLabv3+ is deployed to segment PET objects semantically. Such system can be exploited using an autonomous robot to compensate for human intervention and supervision. The conducted experiments showed that the proposed system outperforms the state of the art semantic segmentation approaches with weighted IoU equals to 97% and Mean BFscore equals to 89%.

**Keywords**—PET; recycling; computer vision; machine learning

## I. INTRODUCTION

Over the last decade, people around the world have a rising concern about efficient waste management due to the yearly waste increase. In fact, according to the World Bank Group 2020 statistics, 2.01 billion tons of solid municipal waste are engendered every year worldwide [1]. Furthermore, according to the same source, it is predicted that this amount would increase to 3.4 billion tons by 2050. One way of processing this huge amount of waste is by incineration. However, it can be harmful to the environment because of greenhouse gas emissions. Another commonly used way to process waste is landfill. Nevertheless, it is not appropriate for certain materials that need a very long time to biodegrade. In particular, plastic material, which constitutes 14% of the total waste amount [2], takes over 100 years to biodegrade. Therefore, recycling, which consists of processing and reusing the waste, emerged as an alternative method suitable for waste processing. Since the way of processing the waste depends on its type, the waste needs to be sorted. To make the sorting process easier, there are sometimes specific waste bins for the most common waste types such as plastic, glass, and paper. Even though different types of plastic require specific methods of treatment. Therefore, plastic materials must be sorted according to their type since the quality of waste separation highly affects the quality of the recycled plastic. One of the most valuable types of plastic for recycling is Polyethylene Terephthalate (PET). It is widely used for plastic bottles. It is

recognized by the symbol “PET” or “PETE” imprinted in the container.

The wide use of PET is due to the fact that it is environmentally friendly and inexpensive. For that reason, recycling centers sort plastic waste into PET and non-PET plastics. It is even further sorted into transparent, blue and green, and mixed color PET since they do not have the same sale price. In fact, transparent PET is the most valuable one and the mixed color is the least valuable [3]. Manual waste sorting is exhaustive and time consuming. Moreover, it may be affected by the worker’s condition. On the other hand, the PET chemical sorting process is very delicate, dangerous, and generates chemical residue [4]. Electrostatic systems that disperse plastics according to their types are alternative solutions for plastic sorting [5]. Nevertheless, they are not cost effective. Thus, mechanical approaches have been used instead, as they are safe and less costly [6]. They mainly use visual sensors to localize the PET materials that would be moved to the appropriate waste bin. Typically, mechanical sorting systems use a conveyor belt to carry the waste. When the waste reaches the camera position, an image of the waste scene is captured. Then, a computer vision system localizes the PET object in the captured image and categorizes it using image processing and machine learning techniques. More specifically, the image is segmented into objects. Then, these objects are conveyed as input to a recognition system in order to categorize it as PET or non-PET. Nevertheless, suitable visual descriptors need to be extracted from the image in order to discriminate PET objects effectively. In this respect, considering the diversity of PET waste and the background clutter, the determination of such features is arduous and constitutes a hindrance for computer vision systems [7]. One way of alleviating the problem of choosing the appropriate visual features is through the use of deep learning techniques ability to semantically segment the waste image.

In this paper, we propose to localize and categorize PET plastics on the conveyor belt. The proposed approach will semantically segment the PET material. To achieve this, DeepLabv3+ deep neural network architecture [8] will be trained to learn PET containers’ visual characteristics.

## II. SEMANTIC SEGMENTATION

In the field of computer vision, image segmentation is the task of dividing the image into sets of pixels called segments. It is considered as a one of the most difficult and challenging problems in the computer vision field [9]. Image segmentation aims to represent the image at a higher level in a way that

facilitates its analysis by localizing objects and edges. Over the last decades, image segmentation has been used in several applications such as medical image analysis, scene understanding, robotic vision, and self-driving cars [10]. The image segmentation process can be supervised or unsupervised. Unsupervised image segmentation does not require a training phase, and thus previous knowledge of the object is not needed [11]. Alternatively, supervised segmentation requires a training phase that uses a set of labeled pixels. It can be perceived as a classification of the pixels that constitute the image [12]. While instance segmentation treats multiple instances of the same object as distinct objects [13], semantic segmentation treats multiple instances of the same object as a single one. It does not differentiate between two or more instances referring to the same object in the same image. In the last decade, semantic segmentation approaches were mainly based on the extraction of suitable engineered features fed to a classifier. However, the efficiency of these approaches depends heavily on the extracted features. This is considered a critical factor for the progress of semantic segmentation [14]. Recently, the boost of Deep Learning in the context of computer vision has also affected semantic segmentation [14].

The development of Deep Convolutional Neural Net (DCNN) led to a significant improvement in semantic segmentation [15]. One of the main characteristics that led to the success of DCNN is its ability to learn abstract data representation [16]. However, while the special abstraction is recommended for classification tasks, it impedes semantic segmentation. In fact, semantic segmentation approaches based on DCNN face three main problems. The first one is related to the repeated combination of the max-pooling layer and striding that yields a feature map with decreased feature resolution [17]. The second obstacle concerns the multi-scale challenge, where the objects may have different scales [18]. This induces increasing the number of computations since it requires training the network with different scale versions of the image. The third hindrance is due to the discard of the location information [19]. DCNN, designed for image classification and object detection, is invariant to special transformation. This results in inconsistent segmentation outcomes. Furthermore, as semantic segmentation implicates segmentation and classification processes, the key point is then how to adjoin the two processes. We distinguish three types of deep learning approaches for semantic segmentation. The first type starts by learning the object regions [20] [21]. These regions, integrating the shape information, are then conveyed to a DCNN classifier [22] [23]. This type of approach depends on the results of the segmentation phase which in its turn depends on the engineered features. Alternatively, the second type of approach uses the convolution layers of DCNN to extract the features to use them for the segmentation phase [19] [24] [25]. However, segmentation and classification tasks are still performed in cascade. Therefore, classification still depends on the segmentation phase and consequently, any segmentation error cannot be recovered by the classification task. The third type employs DCNN directly on the images to learn the pixels' categories [17] [26]. This eliminates the segmentation phase. In order to enhance the segmentation performance along the

edges, the Conditional Random Fields (CRFs) approach [23] has been integrated into the DCNN based approaches [24] [27]. In fact, by taking into consideration the neighboring pixels, the object boundaries are better localized. CRF has been used as a post-processing step [8]. It has also been integrated to the DCNN architecture in [23], [24], [25], [26] and [27].

### III. RELATED WORK

In the literature, several PET sorting approaches have been reported. Among the reported works, some works designed a handcrafted feature suitable for PET categorization [28] [29] [30]. Other works used available generic handcrafted features [31] [32].

#### A. PET Sorting Approaches based on Application Dedicated Handcrafted Features

The approach in [28] extracts the foreground object (the waste object) by employing background subtraction. After connecting the obtained objects and enhancing the border using morphological operations, small blobs are discarded according to a pre-defined size threshold. For the remaining blobs called "white strips", a contour box is determined along its eight surrounding boxes of the same size called "grey strips". After the detection of the plastic blobs, a visual descriptor is extracted. The authors in [28] designed a new handcrafted feature. It is based on modeling the color distribution of the "grey strips". Alternatively, the authors in [29] propose the "white pixel" approach. They first start by preprocessing the image by performing noise removal, background subtraction, and grey level transformation. Then, they employ the MATLAB function "regionprops" [33] to split the image into a set of disconnected objects. This results in reducing the problem to a classification problem where only one object is present in the image. From the obtained grey level image, the authors designed two handcrafted features. The first one is extracted from the whole image by computing the average of the last 106 entries of the 256-bin normalized color histogram. Assuming that the bottom of the container is not covered by a label and is transparent showing the black color of the conveyer belt, the second proposed feature divides the image into five parts and extracts the center of the fifth one. From the extracted Region of Interest, ROI, the mean and standard deviation of the first 100 entries of the normalized 256-bin color histogram are computed. The resulting two features are then fed to the Linear Discriminant Analysis (LDA) classifier [34]. On the other hand, the reported approach in [30] assumes that only one object is present in the scene. It starts by converting the RGB image to a greyscale one. Then, the Canny edge detector [35] is employed to detect the object in the image. The 256-bin histogram is computed from the detected object based on which the authors in [30] designed a new handcrafted feature. The proposed feature consists of two values. The first one is the sum of the first one hundred entries of the 256-bin histogram,  $v_1$ , and the second one is the sum of the last one hundred entries,  $v_2$ . Similar to the proposed approach in [29], the authors in [30] assume that PET objects are transparent. Thus, they will be perceived as black, like the color of the conveyer belt. Considering this assumption, they design a rule to classify PET and non-PET

objects. More specifically, an object is considered PET if  $v_1$  is greater than  $v_2$ .

### B. PET Sorting Approaches based on Generic Handcrafted Features

The authors in [31] proposed a PET sorting system. They assume that there is only one object in the captured image and propose to classify plastic bottles carried on a conveyor belt as PET or non-PET. Moreover, they propose to further classify non-PET plastic bottles as High Density Polyethylene (HDPE) or Polypropylene (PP). The preprocessing step starts by segmenting the image using Otsu's thresholding method [36] in order to locate the object. It is followed by background subtraction and segmentation enhancement using morphological operators. The authors suggest working directly on the pixels of the considered object. However, due to the image's size, the obtained feature has a high dimension and the system would then be prone to the curse of dimensionality. That is why they propose to reduce the dimensionality using five techniques. Namely, they used Principal Component Analysis (PCA) [[37] [38], Kernel PCA [39], Fisher's Linear Discriminant Analysis (FLDA) [40], Singular Value Decomposition (SVD) [41], and Laplacian Eigenmaps (LEMAP) [42]. The resulting feature vectors are fed separately to the Support Vector Machine (SVM) classifier [43]. Then, the classification results obtained using each feature are combined using the majority vote approach. Alternatively, the system proposed in [32] treats each object present in the image separately. First, edges are detected. Then, standard shape features are extracted. These are the length, the width, the area, the aspect ratio, and the filling fraction. The Cartesian and polar coordinates of the 90 equally spaced points of the perimeter are also considered. The authors in [32] considered three classifiers. Namely, the K-Nearest Neighbor (KNN) [34] with  $K=1$ , Kohonen map [44], and Artificial Neural Net (ANN) [45]. For the KNN classifier they used the geometric feature, the Cartesian coordinates of the perimeter, and its polar coordinates separately. On the other hand, the geometric feature is used with Kohonen map, and the polar coordinate of the perimeter is used with ANN. Moreover, the authors designed a "factor-of-merit" measure to decide on the final category of the object. In fact, the "factor-of-merit" is computed for the different considered system results in order to combine them. The system is assessed in a 50-instance dataset.

### C. Convolutional Neural Net based Approaches

In [46], the authors developed a system that sorts four kinds of waste: glass, paper, plastic, and metal, based on a pre-trained ResNet-50 architecture [47]. ResNet was pre-trained using ImageNet dataset [48]. It is used to extract the feature automatically from the whole image. In fact, a single object is considered per image. A multi-class soft kernel SVM [43] is used instead of softmax for the classification task. In [49], the authors proposed a waste management system using ResNet-34 deep learning architecture. The system assumes the presence of a single object in the captured image. The work in [49] classifies the waste into six categories which are cardboard, glass, metal, plastic, paper, and trash. Nevertheless, the proposed system aims to classify the waste as digestible and indigestible. In fact, cardboard, glass, metal, plastic, and

paper categories are considered indigestible while the remaining waste is considered digestible. A computer vision waste sorting approach is proposed in [50]. It considers a single object per image. The authors adopted AlexNet [51] deep learning architecture to categorize various types of waste material. However, this system performed poorly compared to the system based on extracting Scale Invariant Feature (SIFT) [52] and feeding it to the SVM classifier [43]. The authors in [53] proposed a waste sorting system for all types of materials. It is based on DenseNet-121 [54] deep learning architecture. The choice of DenseNet was motivated by the small size of the dataset [53]. In an attempt to improve the performance, data augmentation is employed by considering vertical, horizontal, and random 25° rotations. To further improve the system's performance, a genetic algorithm is utilized to optimize the hyper-parameters of the fully connected layers.

As stated above, various vision-based recognition approaches have been proposed in the literature. The extracted features differ between these approaches. Some papers focus on designing handcrafted features suitable for the PET sorting application [28] [29] [30]. However, these approaches assumed that PET materials are transparent. The designed features are based on the fact that PET containers appear black like the conveyor belt color. Nevertheless, this is not the case. PET containers can be transparent, blue and green, and mixed colors. This infers that these approaches addressed only the problem of sorting transparent PET materials. Other approaches used existing generic features [31] [32]. One of them used dimensionality reduction on the image pixels as a feature. The other one employed the shape feature. However, in addition to using only 50 instances as a dataset, the shape feature would not be able to recognize crashed containers. These feature-based approaches face the challenge of feature choice or feature design. Moreover, the images need to be preprocessed and segmented in order to separate the object from the background. This makes the system performance sensitive to the performance of these preprocessing and segmentation techniques. Convolutional Neural Nets, CNN, would alleviate these problems by learning the appropriate feature without the need of preprocessing and segmentation techniques. However, the only approach that used deep learning to classify PET bottles did not classify plastic as PET or non-PET [55]. Rather, only PET bottles are fed to their system, which identifies the state of the PET bottles. Namely, it checks if the PET bottle has a cap, a seal, or content. Thus, to the best of our knowledge, no reported work addressed the problem of PET sorting using CNN. Alternatively, sorting all kinds of waste approaches based on various Deep CNN have been reported [46] [49] [50] [53]. Among these approaches, two are based on ResNet architecture [46] [49]. Another is based on AlexNet [50] and performed poorly. While the other is based on DenseNet [53] and would be practical only for small datasets.

## IV. PROPOSED APPROACH

We propose to segment the images captured from the conveyor belt semantically. Three categories need to be localized and identified. These are transparent PET, blue and green PET, and mixed color PET. For this purpose, we employ DeepLabv3+ [8]. Fig. 1 displays the architecture of

the proposed system. DeepLabv3+ [8] is designed to overcome the limitations of existing semantic segmentation approaches based on DCNN. More specifically, DeepLabv3+ [8] adopts an encoder-decoder architecture and uses Resnet as a backbone for the encoder. Nevertheless, as shown in Fig. 2, it introduces modifications to the Resnet through the use of atrous convolution. Moreover, Atrous Spatial Pyramid Pooling (ASPP) and fully connected Conditional Random Fields (CRF) are incorporated.

Fig. 2 shows a simplified structure of DeepLabv3+ model. As shown, the Resnet model reduces the size of the input image by a factor of 16. Nevertheless, DeepLabv3+ discards the striding of the last convolutional layer and replaces it by atrous convolution with rate equal to 2, and appends it by the Atrous Spatial Pyramid Pooling (ASPP) module. The output of ASPP is then up-sampled by 4 in the decoder module. The obtained feature map is concatenated with a feature map from the encoder module that has the same size, specifically the one down-sampling the input by a factor of 4. Next, it is convoluted using a set of 3X3 filters, and then up-sampled by 4 to engender an output of the same size of the input. Recurrent pooling and convolution layers decrease the resolution of the obtained feature. To remedy that, atrous convolution is introduced. Its idea comes from the wavelet decomposition. It up-samples the filter by inserting holes that are filled with zeroes to enlarge the receptive field. This is called Atrous convolution, or dilated convolution. Moreover, DCNNs are able to handle objects with different scales by using the Atrous Spatial Pyramid Pooling (ASPP) method.

The latter performs four parallel operations. These are one convolution with kernel 1X1 and three atrous convolutions with kernel 3X3 and rates equal to 6, 12 and 18, respectively. This results in extracting 4 features at different scales. The feature map learned at the end of the encoder is a stack of the obtained 4 features. To alleviate the localization problem, fully connected Conditional Random Field (CRF) [23] is employed. It is a statistical approach that models the relation between pixels by estimating the cost of assigning a pair of labels to a pair of pixels (pairwise cost). Its main function is to clear out invalid predictions by coupling neighbor pixels and privileging same label assignment for nearby pixels.

This leads to refining the segmentation result. Furthermore, DeepLabv3+ adopts the encoder-decoder architecture. It aims to refine the edges obtained by the segmentation. More specifically, the encoder is responsible for extracting the features and the decoder allows retrieving the spatial resolution. The encoder consists of two modules which are ResNet with atrous convolution component and the ASPP. The decoder merges and up-samples the learned features and the result of the encoder after up-sampling. We train DeepLabv3+ using labeled captured images. Images captured from the conveyor belt are fed to DeepLabv3+ [8]. The corresponding mask images are provided at the output. Mask images indicate the label of each pixel of the input image. The label could be transparent, blue and green, mixed color, or others.

## V. EXPERIMENTS

In order to evaluate the performance of the proposed approach, a dataset is collected. It includes images of size 720X960X3 pixels captured from 420X594 mm scene using a camera. The scene contains PET and non-PET materials on a black background representing the conveyor belt. The waste materials can be overlapped or not. Three types of PET are considered. These are transparent, blue and green, and mixed color PET. The dataset is labeled manually accordingly. The performance of the proposed approach is assessed using five performance measures. These are the standard performance measures used for semantic segmentation that take into consideration both the categorization and localization performances [57]. Namely, we will use the Global Accuracy [58], Mean Accuracy [58], Mean Intersection over Union (Mean IoU) [10], Weighted Intersection over Union (Weighted IoU) [58], and Mean BFscore [59]. In order to assess the performance of the proposed system, we intend to conduct three experiments.

### A. Experiment 1

In this experiment, we try to empirically figure out the best hyperparameter configuration for both Resnet-50 and Resnet-18 [47] when they are used as backbone models for the DeepLabv3+ in the context of PET sorting. In this regard, we train two DeepLabv3+ models. Precisely, Resnet-50 and ResNet-18 are trained using 60% of the data, validated on 20%, and tested on the remaining 20%. For each considered model, various configurations were tested. In particular, the optimizer, the learning rate, and the L2 regularization parameter were tuned. This results in 6 configurations for each model. Table I and Table III report the details of each

Fig. 1. Proposed System Architecture.

Fig. 2. Simplified Structure of DeepLabv3+ [56].

considered configuration with respect to Resnet-50 and Resnet-18 [47], respectively. Moreover, for this experiment the size of batch is set to 2 and the number of epochs is set to 30. In order to determine the best model, the testing performance results of each configuration are reported. These are Global Accuracy, Mean Accuracy, Mean IoU, Weighted IoU, and Mean BFscore.

TABLE I. THE CONSIDERED CONFIGURATIONS FOR RESNET-50

	Optimizer	Learning rate	L2 regularization
Configuration 1	SGDM	1e-3	0.005
Configuration 2	ADAM	1e-3	0.05
Configuration 3	SGDM	Initially:1e-3 Learn Rate Drop Period: 5 Learn Rate Drop Factor: 0.2	0.001
Configuration 4	SGDM	Initially:1e-3 Learn Rate Drop Period: 6 Learn Rate Drop Factor: 0.5	0.001
Configuration 5	SGDM	Initially:1e-3 Learn Rate Drop Period: 4 Learn Rate Drop Factor: 0.05	0.001
Configuration 6	SGDM	Initially:5e-2 Learn Rate Drop Period: 5 Learn Rate Drop Factor: 0.2	0.001

TABLE II. WEIGHTED IOU AND MEAN BFSCORE WHEN USING RESNET-50

	Weighted IoU	Mean BFscore
Configuration 1	0.9476	0.8744
Configuration 2	0.7539	0.7084
Configuration 3	0.9687	0.8933
Configuration 4	0.9233	0.8420
Configuration 5	0.9268	0.8146
Configuration 6	0.6333	0.6591

TABLE III. THE CONSIDERED CONFIGURATIONS FOR RESNET-18

	Optimizer	Learning rate	L2 regularization
Configuration 1	SGDM	1e-3	0.005
Configuration 2	SGDM	1e-4	0.001
Configuration 3	SGDM	Initially:5e-3 Learn Rate Drop Period: 5 Learn Rate Drop Factor: 0.2	0.001
Configuration 4	SGDM	Initially:1e-2 Learn Rate Drop Period: 6 Learn Rate Drop Factor: 0.03	0.001
Configuration 5	SGDM	5e-3	0.01
Configuration 6	SGDM	Initially:2e-2 Learn Rate Drop Period: 1 Learn Rate Drop Factor: 0.3	0.1

TABLE IV. WEIGHTED IOU AND MEAN BFSCORE WHEN USING RESNET-18

	Weighted IoU	Mean BFscore
Configuration 1	0.9252	0.8337
Configuration 2	0.9165	0.7698
Configuration 3	0.7863	0.6905
Configuration 4	0.8002	0.7077
Configuration 5	0.8122	0.7328
Configuration 6	0.7978	0.7012

Fig. 3. Proposed System Performance when using Resnet-50 as Backbone.

Fig. 4. Proposed System Performance when using ResNet-18 as Backbone.

Fig. 3 displays the performance measures of the system when using Resnet-50 as backbone for the DeepLabv3+ semantic segmentation approach. Similarly, Fig. 4 shows these performances when using Resnet-18. Table II and Table IV report Weighted IoU and Mean BFscore for Resnet-50 and Resnet-18, respectively.

Fig. 5. Resnet-50 and Resnet-18 Models.

As shown in Fig. 3 and Fig. 4, configuration 3 allowed obtaining the best performance for Resnet-50. Actually, since the data is unbalanced Weighted IoU and Mean BFscore reflect better the performance of the system. Thus, configuration 3 outperformed the other configurations with a Weighted IoU of 0.9687, and Mean BFscore of 0.8933. This is confirmed by the results reported in Table II. More specifically, configuration 3 uses stochastic gradient descent (SGDM) as optimizer, a learning rate initially set to 0.001, and increasing by a factor of 0.2 every 5 epochs, and an L2 regularization of 0.001. According to [60], SGDM is expected to give better results. Moreover, the considered learning rate gave better result by avoiding missing the optimal weights while training the network. Furthermore, the L2 regularization of 0.001 avoided both over-fitting and under-fitting situations. In fact, in case of a large value, the model doesn't fit well, while in case of a small value, the training time is too long. Concerning Resnet-18, the best performances in terms of Weighted IoU and Mean BFscore were obtained when adopting configuration 1 which consists of a constant learning rate of 0.001, and a L2 regularization of 0.005. In fact, by avoiding missing optimal values for the model, and not over-fitting it, these two hyperparameters yielded a Weighted IoU equal to 0.9252, and a Mean BFscore equal to 0.8337. This result is confirmed by Table IV where configuration 1 yielded better results.

### B. Experiment 2

In this experiment, we try to empirically determine which Deep Learning model, Resnet-50 or Resnet-18 [47] is more effective as backbone model for the DeepLabv3+ when used for PET sorting. In this regard, we take into consideration the best obtained results for both models according to experiment 1. Namely, we consider the results lead by configuration 3 for Resnet-50 and the one lead by configuration 1 for Resnet-18. Fig. 5 displays the performance measures of Resnet-50 and

Resnet-18 on the testing sets, respectively. As mentioned previously, since the data is unbalanced, Weighted IoU and Mean BFscore are more suitable to assess the performance of the system. Thus, in Table V, we report Resnet-50 and Resnet-18 performances in terms of Weighted IoU and Mean BFscore. To further investigate the obtained results, Fig. 6 shows the comparison between Resnet-50 and Resnet-18 in terms of Weighted IoU with respect to each considered class. Similarly, Fig. 7 displays the comparison between Resnet-50 and Resnet-18 in terms of Mean BFscore with respect to each considered class. Finally, Fig. 8 displays sample semantic segmentation results obtained using Resnet-18 and Resnet-50. Taking into account, the best obtained results for both Resnet-50 (configuration 3), and Resnet-18 (configuration 1), we compare the two models when used as backbone for deepLabv3+ semantic segmentation approach.

Fig. 6. Comparison between Resnet-50 and Resnet-18 in Terms of Weighted IoU with respect to each Considered Class.

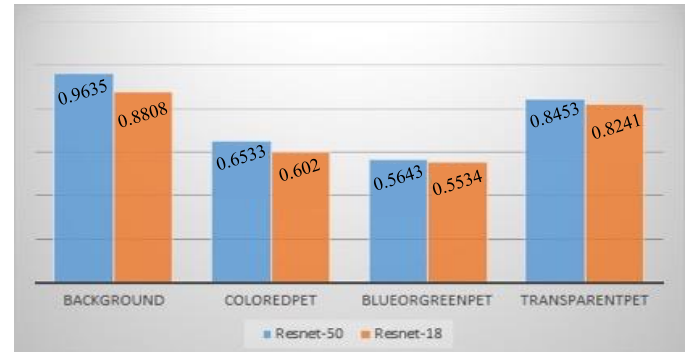

Fig. 7. Comparison between Resnet-50 and Resnet-18 in Terms of Mean BFscore with respect to each Considered Class.

TABLE V. TESTING WEIGHTED IOU AND MEAN BFSCORE COMPARISON BETWEEN RESNET-50 AND RESNET-18

	Resnet-50	Resnet-18
Weighted IoU	0.9687	0.9252
Mean BFscore	0.8933	0.8337

As shown, in Table V, Resnet-50 outperforms Resnet-18 with Weighted IoU equal to 0.97 and Mean BFscore equal to 0.89 for the testing results. The reason that Resnet-50 performs better than Resnet-18 can be explained by the fact that a deeper network learns more abstract features which yields better segmentation results.

Fig. 8. Sample Semantic Segmentation Results Obtained using Resnet-18 and Resnet- 50. (a), (d), and (g) are the Original Images, (b),(e),and (h) The Segmentation Results Obtained when using Resnet-18, and (c), (f) and (i) The Segmentation Results Obtained when using Resnet-50.

As shown from Fig. 6 and Fig. 7, the performance is not the same for all considered categories. In fact, the background and Transparent PET classes have the higher performances. This is explained by the fact that background consists of black homogeneous color corresponding to the conveyor belt. Obviously, this is an easy segmentation problem. Concerning Transparent PET category, the obtained result can be attributed to the fact that this category is represented by a larger number of pixels in the dataset. In fact, if the model is trained with larger training set, the classification results are expected to be better. Alternatively, Blue or Green PET, and Colored PET are less represented in the training data. Furthermore, these two categories have large intra-class variance. In fact, in addition to the container shape variance, they are characterized by the color variance, whereas the background and the transparent PET categories have the same color per category. To better illustrate the obtained results, we can see from Fig. 8 (e) and Fig. 8 (f) that some blue or Green PET pixels are segmented as Mixed color PET or transparent PET. Similarly, from Fig. 8 (h) and Fig. 8 (i), we observe that some parts of the background are segmented as mixed color PET.

### C. Experiment 3

In this experiment, we intend to compare DeepLabv3+ semantic segmentation model to the state-of-the-art approaches on the waste sorting dataset. Namely, Fully Connected Network (FCN) [61], Unet [62], and Segnet [63] semantic segmentation approaches are considered. In this experiment, we consider Resnet-50 as backbone for DeepLabv3+ since it achieved better performance than Resnet-18. For the-state-of-the-art approaches, several hyperparameter configurations are considered. Moreover, in this experiment, the batch size is set to 2 for Unet [62], and Segnet [63]. It is the largest possible value due to the

memory size constraint. Alternatively, since FCN [61] uses a smaller size of the images (lower resolution), it is possible to increase the batch size 3. After considering the above mentioned configuration, the best obtained performance with respect to each approach is considered for the purpose of comparison with DeepLabv3+. Fig. 9 displays the performance comparison between DeepLabv3+ [47], FCN [61], Unet [62], and Segnet [63]. As depicted in Fig. 9, DeepLabv3+ outperforms the other deep learning segmentation approaches with weighted IoU equal to 0.9687 and a Mean BFscore of 0.8933. The second best is FCN, whereas Unet and Segnet perform poorly in terms of Mean BFscore.

Fig. 9. Performance Comparison of DeepLabv3+ [47], FCN [61], Unet [62], and Segnet [63].

In order to better analyze the obtained results, a comparison of the four considered semantic segmentation approaches with respect to each category in terms of IoU and Mean BFscore is displayed in Fig. 10 and Fig. 11, respectively. As it can be seen from Fig. 10, DeepLabv3+ gives the best IoU performance with respect to all categories. This means that it is able to localize the PET container with respect to all categories better than the other approaches. Moreover, we can observe from Fig. 11 that DeepLabv3+ has the highest Mean BFscore with respect to most categories. However, the semantic segmentation performance is not the same with respect to all categories. This is the case for all considered segmentation approaches. For a better illustration of the results, we show sample segmentation results of DeepLabv3+ [47], FCN [61], Unet [62], and Segnet [63]. As shown in Fig. 12, Deeplabv3+ outperforms the other semantic segmentation approaches for the sample image representing the transparent PET. In fact, it localizes and identifies better the boundaries of the containers. This can be accredited to fully connected Conditional Random Field (CRF) module. Similar result can be observed from Fig. 13. In fact, although DeepLabv3+ miss - segmented some Blue and Green PET pixels as Mixed Color PET (Fig. 13(b)), it performs better than the other segmentation approaches. FCN is the second best (Fig. 13(c)). However, Unet (Fig. 13(d)) and Segnet (Fig. 13(e)) are not able to segment the Blue and Green PET image

shown in Fig. 13 (a). Actually, these two approaches classified the corresponding pixels as transparent PET. It means they were not able to capture the visual characteristics of the Blue or Green category.

Fig. 10. Performance Comparison of the Four Considered Semantic Segmentation Approaches with respect to each Category in Terms of IoU.

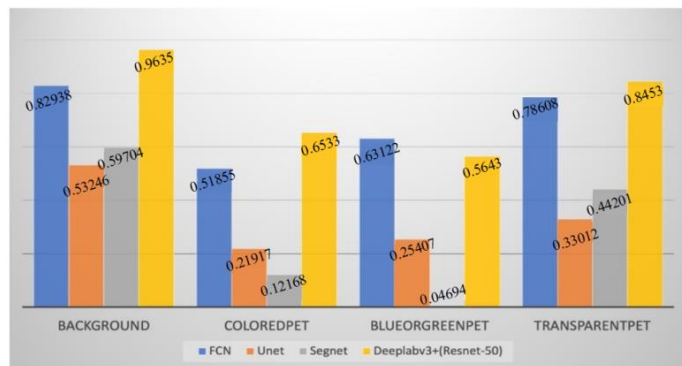

Fig. 11. Performance Comparison of the Four Considered Semantic Segmentation Approaches with respect to each Category in Terms of Mean BfScore.

FCN miss-segmented some pixels as transparent PET, and Unet and Segnet miss-segmented a large number of pixels as transparent PET. Actually, the confusion between the conveyor belt and the transparent PET can be explained by the fact that the transparency of this material makes them appear as black. Nevertheless, DeepLabv3+ is able to learn the appropriate visual feature that in engendered good segmentation result.

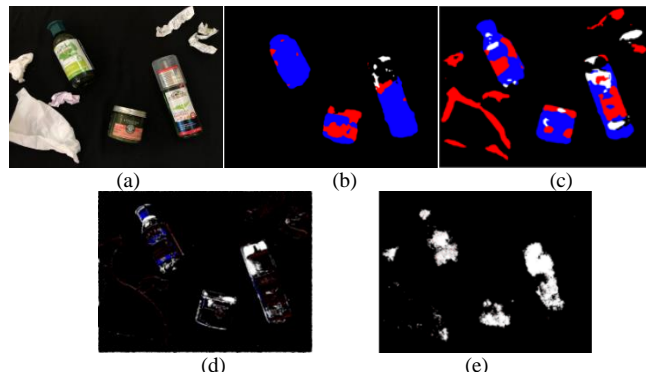

Fig. 13. Blue or Green PET Sample Image (a) Segmentation Results of (b) DeepLabv3+, (c) FCN (d) Unet, and (e) Segnet.

Legend: Transparent PET (white), Blue and Green PET (blue), Mixed Color PET (red), Background (black)

Fig. 14. Colored PET Sample Image (a) Segmentation Results of (b) DeepLab v3+, (c) FCN (d) Unet, and (e) Segnet.

Legend: Transparent PET (white), Blue and Green PET (blue), Mixed Color PET (red), Background (black)

Fig. 15. Non-PET Sample Image (a) Segmentation Results of (b) DeepLab v3+, (c) FCN (d) Unet, and (e) Segnet.

Legend: Transparent PET (white), Blue and Green PET (blue), Mixed Color PET (red), Background (black)

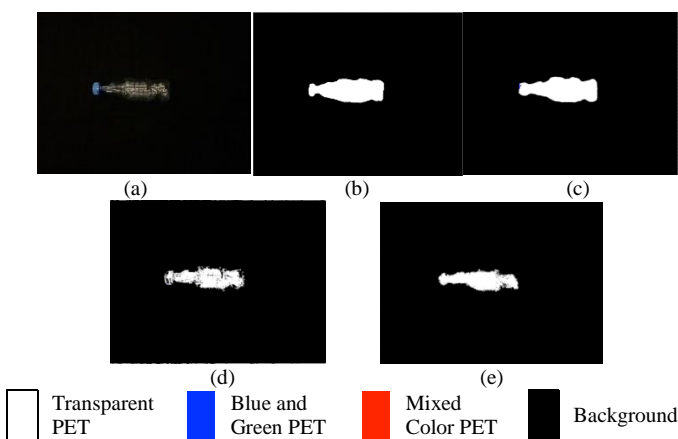

Fig. 12. Transparent PET Sample Image (a) Segmentation Results of (b) DeepLabv3+, (c) FCN (d) Unet, and (e) Segnet.

As showcased in Fig. 14, DeepLabv3+ yields better segmentation results than the other approaches. For this case too, FCN is the second best, and Unet and Segnet perform poorly. Similar analysis can be conducted on Fig. 15. Although the background (the black conveyor belt and other non-PET materials) is correctly segmented by DeepLabv3+,

## VI. CONCLUSION AND FUTURE WORK

Plastic containers are one of the most common types of waste. In order to be recycled, they need to be sorted according to their type since the quality of recycled plastic depends on the quality of waste separation. Of particular interest is Polyethylene Terephthalate (PET). In fact, recycling centers sort plastic waste into PET and non-PET, and further sort PET into transparent PET, blue and green PET, and mixed color PET. For this purpose, mechanical systems have been used. They need to recognize and localize PET materials in order to move them to the appropriate waste bin. In this context, we proposed to design a computer vision system to locate and recognize PET waste materials in a captured waste image using a deep learning network architecture called DeepLabv3+. The conducted experiments showed that increasing the number of layers of Resnet from 18 to 50 yields better semantic segmentation results. Furthermore, DeepLabv3+ outperformed the other considered approaches on the PET sorting dataset. As future works, we suggest to use Resnet with even larger number of layers, and to investigate ways to decrease the frame processing time.

# A New Approach for Training Cobots from Small Amount of Data in Industry 5.0

Khalid Jabrane, Mohammed Bousmah  
LTI Laboratory, National School of Applied Sciences  
Chouaib Doukkali University  
El Jadida, Morocco

**Abstract**—Machine learning is a vital part of today's world. Although the current Machine Learning slogan is “big data is required for a smarter AI”. All Artificial Intelligence learning techniques require the training of algorithms with huge data. Collecting and storing this data takes time and requires increasing computer memory. In Industry 5.0, human-robot collaboration is a challenge for artificial intelligence (AI) and its subdomains. Indeed, integration of its domains is required. Many AI techniques are needed, ranging from visual processing to symbolic reasoning, task planning to mind building theory, reactive control to action recognition and learning. Otherwise, the main two obstacles to this natural workflow interaction are big data memorization and time Learning that grows exponentially with the problem complexity especially. In this article, we propose a new approach for training Cobots from Small Amount of Data in the context of industry 5.0 based on common-sense capability inspired by human learning.

**Keywords**—Small data; industry 5.0; common-sense capability; machine learning

## I. INTRODUCTION

Despite its economic progress, all industrial revolutions had an impact on the labor market with the goal of replacing human labor with machines. The first industrial revolution replaced manual work with the invention of a steam engine and the second industrial revolution enabled mass production using electric energy. The tertiary industrial revolution started the automation era with informatization based on computers and the Internet. In the fourth industrial, the super intelligence revolution based on the Internet of things, cyber-physical system, and artificial intelligence (AI) will greatly change human intellectual labor. Fig. 1 depicts the five industrial revolutions.

Industry 5.0 will transform the labor market by emphasizing the central role of humans and encouraging collaboration between humans and a new generation of robots known as "collaborative robots" or "cobots". These cobots are designed to work alongside their human counterparts and, more importantly, help them accomplish common tasks in real world. They are user-friendly and their key function is to provide physical assistance to operators by performing unpleasant and risky activities. With the introduction of Cobots there should be no fear of losing the production line due to automation which has been a major concern of Industry 4.0, as a result better agility will be added to the smart factory.

In the context of Industry 5.0, AI and cobotics must play a central role to improve the capabilities of Cobot. The cobotics is a major discipline that focuses on collaborative robots and their uses as technical agents. Moreover, Cobotics seeks to extend beyond the isolated faculties of humans and robots. Synergy is an essential factor in increasing the respective capacities of man and machine.

However, this promising vision of cobot, driven by AI and cobotics, requires significant R&D progress. Many technical challenges remain in all subfields of AI application. The neural networks of deep learning models require exposure to huge amounts of data to learn a task. Training a neural network to recognize an object, for example, could require feeding it as many as 15 million images. Acquiring relevant datasets of this size can be costly and time-consuming, which slows the pace of training, testing and refining AI systems. Furthermore, some fields suffer from a lack of data to feed a starving deep learning model.

Researchers are working hard to find ways to train systems with less data and are optimistic that they will find a viable answer. As a result, AI specialists anticipate that the "big-data" variable's tendency will be reversed in the AI growth equation. Small data will supplant Big Data as fresh and innovative AI drivers in Industry 5.0.

The goal of this study is to present a novel approach for training cobots with small amounts of data. We place a premium on a framework built on common sense and on-the-fly multitasking techniques. As a result, this article presents a summary of current cobotics research. We define cobotics and provide a brief classification of cobotic systems. The second segment discusses the main challenges of artificial intelligence, while the third section looks for potential solutions. Finally, we'll present our model.

Fig. 1. The Five Industrial Revolutions.

## II. RELATED WORK

Cobotics is a transdisciplinary technology and is the intersection of three main fields such as robotics, ergonomics and cognitive. This new discipline focuses on studying the interaction of human and cobot.

Cobotics is not included in robotics because certain aspects, such as the human representation of the robot, ergonomics of the workstation, or operator acceptance, are the result of ergonomic and cognitive engineering studies.

At the end of the 1990s, the term "cobot" was describe as a passive effort-assistance device controlled directly by an operator [1]. Since then, the meaning of the term has evolved. It was only popularized in the 2010s. Current cobotics allow the extension of human gesture or behavior and is distinguished from simple robotics by the real, direct or remote interaction between a human operator and a controlled or pseudo-autonomous robotic system. This cooperative robotics is more "user-centric" [2].

While is still conceived today as a cooperative augmentative robotics, cobotics corresponds generically to the use of mechanical or artificial sensorimotor support systems developed specifically for a given task or relationship. It then becomes a form of parallel robotics or extension robotics, allowing an increase in performance, in strength, speed or precision [3].

Given the novelty of the theme, the majority of articles in the literature treat this new industrial revolution as being the era where Man and cobots will have to work side by side. Although this observation is part of our daily life in some pioneering industries in this field, this cooperation takes place for very specific and low-level tasks.

For some authors, Artificial Intelligence needs a theory based on the tasks [4], others think that to design new factories in Industry 5.0 with a human-centered perspective, technological engineering should be centered on values and ethics [5].

Other authors have even proposed probabilistic models to infer intention in human-robot interaction [6]. In this context, intention inference has been the subject of several studies and research based on the Markov model which predicts and models human behavior by a series of discrete states and actions.

Also, some studies explain an inspiring technique based on Reverse Reinforcement Learning (IRL) [7] [8]. Ordinary reinforcement learning involves the use of rewards and punishments to teach a behavior to an intelligent agent, in IRL the process is reversed, the robot observes a person's behavior to determine the goal that behavior appears to be aiming for. The problem in IRL is to determine the optimized reward function, by the agent, which best and in a transferable way defines the intended task. This approach has enabled state-of-the-art advances in several areas of robotics.

Although some articles suggest possible research avenues, finding a relevant issue linking artificial intelligence and Industry 5.0 seems philosophical if we move away from technical reflections based on the adoption of a stochastic

modeling approach, which also remain restrictive given the input hypotheses and the cases treated, which do not promise generalization.

In short, according to scientists and industry, the trend in the era of industry 5.0 is converging on the search for tools and technologies that propel the advancement of symbiotic interaction in the workplace.

In this context, recent advances in reinforcement learning have successfully combined deep learning to make significant improvements in the formation of an agent. Despite the impressive performance of Deep Reinforcement Learning (DRL) techniques on individual tasks, training a single DRL agent to perform multiple tasks remains difficult [9]. Traditional learning algorithms that consist of directly training a DRL agent for multiple tasks one by one have been shown to offer poor performance and may even fail on some tasks.

Unlike DRL which teaches an agent to perform a single task, the new multitasking DRL techniques advocate that the agent learns a single control policy that could work well on several different tasks.

The current AI approach is to train agents using as much data as possible while also blending real and synthetic data. Big data alone will not be able to overcome the difficulties of human-machine collaboration in real-world interactions.

We typically think of "big data" when we hear "artificial intelligence," because the most notable advancements in AI have been built on massive data sets. Image classification, for example, has made significant progress in the construction of ImageNet, while the GPT-3 language model has been trained on hundreds of billions of words of online text using deep learning techniques to produce human-like writing. It is therefore not surprising to see AI being closely linked to "big data" in the popular imagination. But AI is not just about big data sets, research on 'small data' approaches is being developed nowadays.

The common sense is the natural ability to make good judgment to behave in a practical and sensible way.

Common sense is the unconsciously acquired knowledge that all humans have since birth. This common-sense knowledge is gained through experience and curiosity, sometimes without the learner's knowledge.

According to John McCarthy, father of AI, Common sense knowledge includes the basic facts about events and their effects, facts about knowledge and how it is gained, facts about beliefs and desires. It includes the basic facts about material objects and their properties [10].

Common sense is the ability to interpret a situation in light of its context, based on millions of interconnected elements of common knowledge. The capacity to use this knowledge wisely qualifies the ability to perform common sense reasoning. Common sense reasoning is a central part of intelligent behavior.

In 1959, John McCarthy proposed common sense reasoning in the form of a theoretical program named Advice Taker. However, despite recent advances in machine learning,

there has been no progress in terms of true common sense reasoning skills. The recent surge in popularity of the subject can be attributed to recent advances in NLP and the importance of the task.

Since John McCarthy's hypothesis, proposed in the 1950's, that common sense programs could be developed using formal logic, Today's primary approaches to common sense reasoning in AI, as well as their taxonomies, are depicted in Fig. 2.

McCarthy's hypothetical proposition has sparked a flurry of research into logic-based approaches to commonsense reasoning. There are several research efforts; here are a few of them: situation calculus, naïve physics, default reasoning, non-monotonic logics, description logics, and qualitative reasoning, less formal knowledge-based approaches.

The 'Cyc' Project remains the most notable effort adopting the knowledge-based approach. The 'Cyc' Project spent 35 years codifying common sense into an integrated logic-based system. This awesome effort covers vast areas of common-sense knowledge and incorporates sophisticated logical reasoning techniques.

For a variety of reasons, including the fragility of symbolic logic, 'Cyc' was unable to realize its goal of delivering a generally useful common-sense service.

Artificial intelligence (AI) systems lack common sense knowledge. Furthermore, despite years of effort, developing common sense reasoning AI systems has always been a tedious task. Today's AI researchers agree that the most difficult problem in AI research is developing programs with common sense capabilities.

Formalizing common sense knowledge for any reasoning problem, no matter how simple, is a huge task. This is because common sense knowledge is implicit, whereas expert/specialist knowledge is usually explicit. As a result, developing an AI common sense reasoning system will necessitate explicitly expressing this knowledge.

An intelligent system lacking in common sense will struggle to understand its surroundings, interact naturally with people, respond appropriately in unexpected situations, or learn new experiences.

The concept of common-sense reasoning is still challenging for AI specially in the context of Human-Cobot collaboration in the industry 5.0 era. Progress in common sense applications for AI is insufficient. The difficulty lies in explicit formulations of what is common sense because it is an unstructured and very confused field.

### III. STATE OF THE ART AND TECHNICAL CHALLENGES OF AI IN THE ERA OF COBOT IN INDUSTRY 5.0

#### A. Classification of Cobot System

Cobotic systems are very diversified and their applications are numerous. Their classification is based on various and dispersed criteria. Many authors have tried to classify these cobotic systems to well structure this field.

First, the social-based classification of robot properties includes form, modality, social norms, autonomy, and interactivity [11]. Then safety-based classification of robot which was a major concern since the beginning of industrial robotics, standards and norms were established to regulate this field [12].

Moreover, Robots can be classified according to their architecture, degree of autonomy, mobility, transport capacity, handling, size, and distance from the operator. This approach disregards the human component of the cobotic system. Jean Scholtz proposes a role-based classification to more clarify the role and the nature of the Human-Robot Interaction (HRI) as described below [13]:

- Supervisor Interaction: The supervisor's role is to monitor and control the overall situation.
- Operator Interaction: The operator intervenes to change the internal model or to parameterize the software when the robot behavior is altered.
- Coworker: It works in the same environment as the robot, in parallel, and sometimes has some interactions with him, for example taking the piece he just processed.
- BYSTANDER: Present in the same environment as the robot and sometimes enters its working area, it has no real interaction with it. The robot is equipped with a presence sensor, as soon as a human enters its zone, it automatically switches to a slower mode or stops temporarily. Collaboration is reduced to a minimum.

#### B. Type of Human-cobot Industrial Collaboration

Human-robot collaboration in the industrial field can take several forms. Collaboration takes place either in a shared workspace without direct contact or in a shared workspace with direct contact. Tasks are executed with or without synchronization. The robot adapts its movement to meet the human workers, and in some cases, adjusting the movement is recommended in real time.

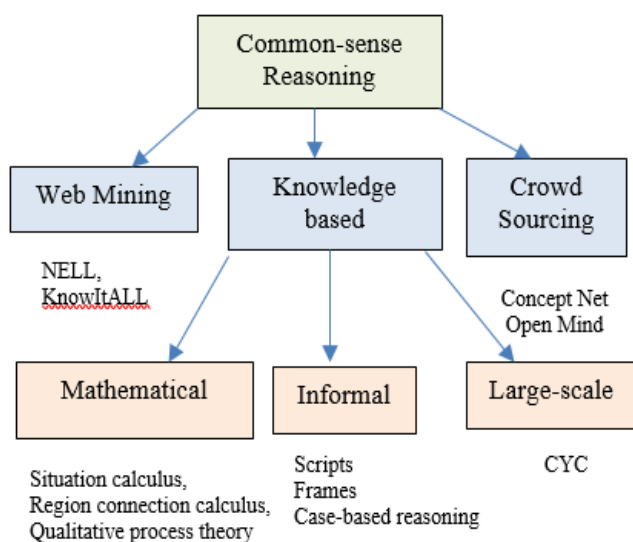

Fig. 2. Taxonomy of Approaches to Common Sense Reasoning.

According to the International Federation of Robotics (IFR), collaborative robotics today is characterized by applications where tasks run sequentially in shared workspaces, in which the robot and the employee work side by side.

Fig. 3 from IFR web site shows different types of industrial robots collaboration.

Fig. 3. Type of Collaboration with Robots Industry.

The robot frequently performs tedious or impractical tasks, such as lifting heavy parts or tightening screws. Otherwise, real-time applications in which the robot must react and expertly modify its actions to those of a worker are more technically challenging. However, robot movements are completely unpredictable; the user must ensure that the robot's potential setting meets safety requirements.

In fact, reactive human-robot collaboration will not be reachable so early in most manufacturing sectors where precision and repeatability are required to increase productivity. Otherwise, the most advanced research projects are all categorized as “sequential” or “support” collaboration scenarios [14]. Interdependent and collaborative scenarios between humans and machines require more sophisticated systems and solutions. Indeed, Cobots need a stronger semantic knowledge of the task's goal, as well as the behaviors and intentions of their human coworkers. Humans must also be able to communicate intuitively with the cobot.

### C. Technical Challenges of AI in the Era of Cobot in Industry 5.0

Today's researchers are trying to push the boundaries in order to create more advanced or complex forms of interaction by arming cobots with comprehension and anticipation skills aided by Artificial Intelligence.

Future cobots should be able to recognize human signals, movements and intentions, as well as distinguish between intentional and unintentional gestures related to the collaborative work. The natural collaboration between humans and cobots requires that cobot be able to capture, process and understand human demands with precision and robustness.

However, the technical challenges of AI lie in the interaction modalities such as speech, gaze or gesture planning

as well as motion control that must be performed in real time to ensure a natural workflow interaction. This natural workflow interaction will not be achieved only with both the classical sense-plan-act architectures and Reinforcement learning models that constitute the current state of the art in applied robotics.

Human-robot collaboration is a challenge for artificial intelligence (AI) and its subdomains. Indeed, AI's methods need to be further strengthened for a better integration of many techniques such as visual processing, symbolic reasoning, task planning, reactive control, recognition of actions and learning.

Otherwise, the main two obstacles to this natural workflow interaction are big data memorization and time learning that grows exponentially with the problem complexity especially.

1) *AI and big data:* The future of cobotics depends on artificial neural networks and deep learning which are designed to acquire advanced learning skills without the need for any type of programming. The goal of this extremely complex discipline is to enable robots to mimic the ability of humans to smoothly integrate inputs with motor responses, even as they undergo changes in their environment.

All Artificial intelligence learning techniques require the training of algorithms with huge data. Collecting and storing this data takes time and requires increasing computer memory. However, for cobotics, deep learning is a future goal rather than immediately achievable given that it requires truly massive amounts of processing power and data.

For example, deterministic problem optimization methods, including Q-learning, require recording important statistical data. Research has established that the convergence of the Q-Learning function has been proven for an infinite time. That's why it's inconceivable to teach a machine in 10 years what humanity has learned over millions of years.

One of the biggest problems of artificial intelligence is acquisition and storage. In the industry the input data comes from sensors. To validate the AI system, a mountain of sensor data must be collected. Irrelevant and noisy data sets can cause obstructions because they are difficult to store and analyze.

In addition, the AI algorithm becomes stronger and more powerful as the data collected is of good quality, relevant, and increases during its processing. The AI system fails badly when it is not fed with sufficient and good quality data; however, small variations in data quality have large consequences for results and predictions. Again, adoption of AI systems is limited for some industry sectors where data availability is insufficient.

2) *AI and multitask:* Deep reinforcement learning (DRL) has significantly improved the performance of intelligent agents. Although DRL approaches can improve agent performance to a greater extent, they were limited to systems that learned a specific task primarily through reinforcement learning algorithms.

DRL is a type of reinforcement learning and deep learning and can be defined as a crossroads between traditional and true

artificial intelligence, as illustrated in Fig. 4. The DRL combines action-based reward techniques from reinforcement learning with the concept of using a neural network to learn feature representation from deep learning.

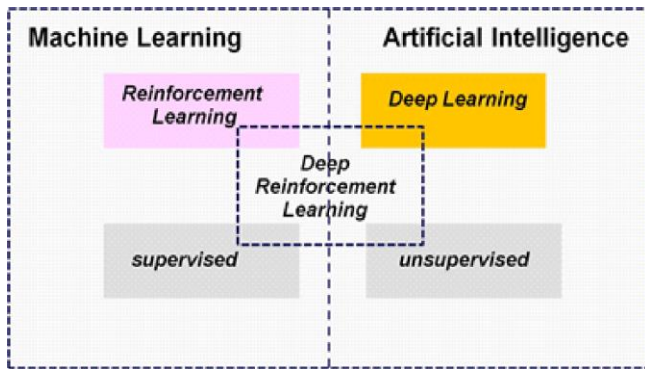

Fig. 4. Deep Reinforcement Learning.

Simultaneously, this method has proven to be inefficient in terms of data, particularly when reinforcement learning agents should interact with more sophisticated and rich data environments. This challenge emanates mostly from the limitations of deep reinforcement learning algorithm to deal with multiple scenarios of related tasks in the same environment.

Training reinforcement learning algorithms is typically time consuming, and processing requires high number of data samples to achieve an acceptable result. Second, reinforcement learning is a task-specific. Learning generalization to other tasks is practically impossible. The trained agent is deployed only on the task for which it was trained.

The section that follows provides an overview of the various challenges associated with multitasking learning in the context of deep reinforcement learning environment.

- Scalability

Scalability is a major issue in artificial intelligence when implementing multi-task learning via deep reinforcement learning [15].

One of the main shortcomings of traditional RL algorithms is their inability to extend their learning to other scenarios.

To converge to an acceptable result, RL algorithms often demand a larger number of training data samples and a longer training time [16]. There should be continuity and scalability in multitask learning by transferring the acquired knowledge to other tasks or processes. It should not take  $N$  times more samples or training time to learn  $N$  different tasks.

- The distraction problem

Balancing the demands of several tasks for the limited resources of a single learning system in a particular environment is one of the most challenging aspects of multitasking deep reinforcement learning.

Therefore, learning algorithms are often distracted to solve only a few tasks among others (a phenomenon known as the distraction dilemma) [17].

- Fractional observability

Observations made by an RL agent in many real-world scenarios are partial. Capturers only reflect a small part of the complete state of the environment [15]. When the state-action space is large, this challenge includes learning and remembering a compact representation of the environment with the most pertinent details from the environment.

- Real-world exploration

Continuous Reinforcement learning is generally based on trial and error. Exploration and exploitation are methods used by RL agents to learn by experimenting numerous possible actions from a given state in order to find the best action that delivers the best overall future reward [15]. When applying reinforcement learning to real-world problems, it is frequently difficult to achieve a higher level of exploration.

- Catastrophic interference

The goal of multitasking deep reinforcement learning (DRLM) is to train agents to learn a series of tasks with the ability to transfer knowledge from previous tasks to new tasks in order to improve the convergence speed [18]. This is a lifelong learning situation in which deep neural networks unexpectedly lose knowledge learnt in a previous task that is applicable to a new task.

The fundamental cause of this problem is changes in network parameters (weight) associated with a task that are overwritten to accomplish the goals of the following task [18]. This phenomenon is considered as a crucial obstacle to the development of a General Artificial Intelligence (AGI), as it has a negative impact on the ability to continual learning.

3) *AI and Human-Robot Interface (HRI)*: Human-Robot Interaction (HRI) is a field that studies, designs, and evaluates robotic devices for use by or with humans. The Human-robot interface (HRI) is related to the interaction modalities between the user and the robot. The sub-domains more concerned by AI research in robotics is the cognitive HRI (cHRI) that analyzes the information flow between the user and the robot and focuses mainly on multimodal interactions including textual, vocal and gestural interfaces.

Despite the advances of the AI, Human-Robot Interaction (HRI) continues to be a challenge for artificial intelligence (AI) and its subdomains. Human-robot interaction involves many technical challenges both on the technical level as well as human-centered aspects. The latter includes issues such as expectations, attitudes and perceptions.

HRI research deals with a wide range of issues, including the direct usage of robot systems that interact with humans in specific situations. The main research challenges in the field of HRI concern multimodal sensing and perception, design and human factors, and those related to developmental robotics:

- Multimodal perception

Real-time perception and management of uncertainty in detection are two of the most difficult challenges in robotics.

The need to perceive, understand, and respond to human activity in real time makes sensing and perception more complex and challenging in the field of HMI.

Human interaction sensors are far more diverse than those used in most other robotic fields today. The processing of real-time data from HRI inputs such as vision and speech poses significant challenges. Face expressions [19] and gestures [20] are examples of possible inputs that computer vision algorithms must be able to process. Correspondingly Language understanding and human-robot communication systems are still unsolved research difficulties [21, 22]. Understanding the relationship linking visual and linguistic inputs [23] then combining them to improve detection [24] and expression [25] is even more difficult. The Fig. 5 below illustrates the information processing of cobot.

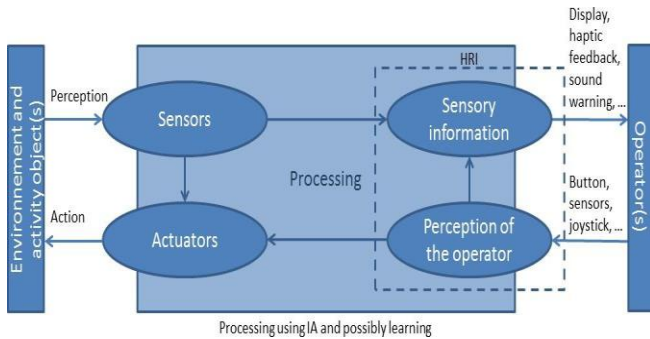

Fig. 5. Information Processing for the Cobot.

- Developmental Robotics

Developmental robotics is not a direct subset of the HRI field, but the two fields overlap significantly in their goals and have a lot in common when it comes to information acquisition techniques and multimodal perception.

The robot learns to model its environment, the objects that surround it, its own body, it learns elements of language, all this in strong interaction with the physical world but also through social interactions with humans or even other robots. The model that preoccupies the artificial intelligence researcher is no longer the chess player, but being able to learn and develop cognitively.

Developmental robotics, proposes to focus not on reproducing an immediately intelligent robot, but a robot that will be able to learn, starting with a reduced amount of innate knowledge.

#### D. Overview of Existing Solutions

DeepMind and OpenAI as research organizations have contributed significantly to the field of multi-task deep reinforcement learning (MTDRL). Their research efforts have resulted in three major MTDRL solutions, namely DISTRAL (DIStill & TRAnsfEr Learning), IMPALA (Importance Weighted Actor-Learner Architecture), and PopArt, which should be briefly mentioned in this paper as potential solutions to the issues listed in this part.

- DISTRAL (DIStill & TRAnsfEr Learning)

According to authors Nelson Vithayathil Varghese and Qusay H. Mahmoud [26]. The transfer-oriented method consists in sharing neural network parameters across related tasks in a given environment. This method has been considered as the reference for multitasking in reinforcement learning [27]. This approach encounters issues that have an impact on the learning process, such as negative knowledge transfer and ambiguity when designing a reward system for various tasks. [28]. The rewards system, in a multitasking context, should be built so that no task has to control or monopolize the shared model's learning.

DISTRAL was created as a framework for learning multiple tasks at once. DISTRAL is a novel approach to multitasking training that addresses the issues raised above.

The design's primary goal was to develop a general framework for distilling centroid policy and then transferring common behaviors into reinforcement learning across multitaskers rather than sharing parameters among the various workers in the environment [29].

Fig. 6 illustrates the Distill structure which provides a high-level view involving four tasks. The method is founded on the concept of shared policy (shown in the center), which distills common behaviors or representations from task-specific policies [30, 31]. The distilled policy is then regulated in order to direct the task-specific policies.

The knowledge gained in one task is distilled into the shared policy, which is then applied to other tasks.

The DISTRAL approach has proven to be very effective compared to the traditional method, transfer learning in multitasking therefore consists in sharing parameters over the neural networks.

DISTRAL algorithms learn faster and achieve better asymptotic performance. They are much more robust to the settings of the hyperparameters. Learning is more stable than with multi-tasking A3C baselines.

A3C was originally conceived as an extension of the actor-critic approach whose model is illustrated in Fig. 7. Two distinct neural network components are used: the actor and the critic, each having its own loss function. According to RL approaches such as Q-learning or REINFORCE, an actor can be considered as a function approximator that guides the way to act.

Fig. 6. Illustration of the DISTRAL Framework.

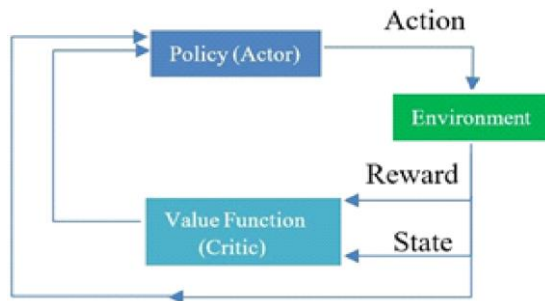

Fig. 7. Actor-Critic Model.

- Asynchronous Actor-Critic Advantage (A3C).

A3C (asynchronous actor-critical advantage) is an algorithm introduced by DeepMind. A3C offers a parallel training approach where multiple agents (called workers) run on multiple instances of the same environment [32].

Global value function is updated asynchronously by multiple workers operating in parallel environments. During the training, each parallel agents will experience a variety of different states at any time step  $t$ . The agents learning becomes nearly unique. This A3C uniqueness factor provides an effective and efficient way for agents to explore the complete state space in a given environment [33].

The role of the critic consists in evaluating the effectiveness of the policy put in place by the actor and contributes to its improvement [32].

Fig. 8 is the representation of a typical actor-critical model on which A3C is based.

Fig. 8. Actor-Critic Model.

- IMPALA (Importance Weighted Actor-Learner Architecture).

Dealing with the increased amount of data an agent must handle, as well as the training time required, is one of the major issues in achieving functionality with a single reinforcement learning agent.

DeepMind has proposed an architecture called IMPALA to solve the abovementioned aspects of multitasking in the field of reinforcement learning. The IMPALA distributed agent architecture is based on a single reinforcement learning agent with a single set of parameters [30]. The main feature of the IMPALA approach is the ability to efficiently use resources in a single machine learning environment while scaling to many machines.

DeepMind also introduced a new correction policy based on a method known as V-trace, which enables relatively stable and fast learning by combining action and learning without compromising data efficiency or resource usage [30].

Generally, the architecture of a deep reinforcement learning model includes a single (critical) learner who is linked to several actors. Each individual actor in this ecosystem generates learning cycle parameters (also known as trajectories), which are sent as knowledge to the (critical) learner through a queue.

The learner collects the trajectories from all the other environmental actors to prepare a central policy. The policy parameters are updated with the learner (critical) and transmitted for each actor who retrieves them before the start of the new learning cycle (trajectory).

The IMPALA topology connects multiple actors and learners who should work together to build knowledge. Fig. 9 and Fig. 10 dropped from [34] depict, respectively the configurations of an IMPALA ecosystem architecture with a single learner and multiple learners.

- PopArt

Recent advancements have shown that reinforcement learning can outperform human performance in specific tasks. A specific aspect of reinforcement learning is training agents for one task at a time, learning an additional task requires instantiation of the agent [17].

Fig. 9. IMPALA Single Learner Model.

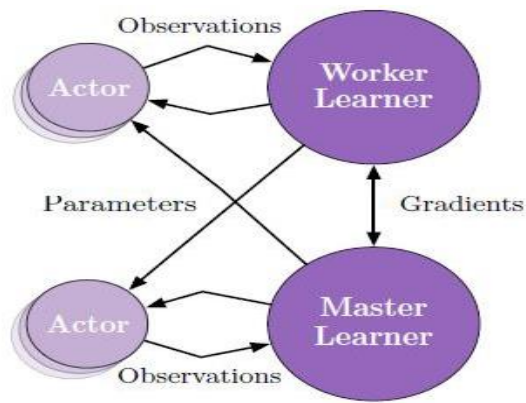

Fig. 10. IMPALA Multiple Synchronous Learners Model.

In order to overcome this limitation, much research has been carried out to improve RL algorithms by giving them the ability to carry out multiple sequential decision tasks at the same time. These research attempts that aim to support multitasking learning have often been faced with various challenges.

In general, this situation requires the establishment of a multitasking reinforcement learning (MTRL) system with strong immunity to the dilemma of distraction. Balancing the mastery of individual tasks is also important in order to achieve the ultimate goal of better generalization of learning [17]. The primary cause of the distraction scenario is that some tasks appear to be more important to the learning process due to the density or magnitude of the rewards given to them (rewards in the task).

As a result, the algorithm prioritizes these important tasks over others, sacrificing generality in the process [17].

PopArt is a new method proposed by DeepMind to improve reinforcement learning in multi-task environments. PopArt aims to reduce distractions and thus stabilize learning in order to facilitate the use of multitasking reinforcement learning (MTRL) techniques.

The PopArt method's main feature is the modification of the neural network's weights based on the results of all tasks in the environment. PopArt estimates mean and distribution of the ultimate targets for all tasks considered in the initial phase. The estimated values are then used to normalize the targets before updating the network weights. This method improves the stability and robustness of the learning process.

#### IV. PROPOSED MODEL

Artificial systems with common sense are generating a lot of interest in various fields of cognitive science and artificial intelligence to engineer common-sense reasoning into artificial agents in ways inspired by human reasoning.

Despite recent advances in many areas, artificial systems are still unable to comprehend and act on the world in a human-like manner, and are incapable of performing basic common sense thinking at the level of even young children.

So, how to concept a structure made of sense and common-sense blocks that allows cobots to understand, interact,

distinguish, and make decisions in order to overcome the challenges of the world around them. How to give cobots the intelligence and common sense they need to learn from raw and optimal representations of the scenes that fill the workplace with its objects, agents, events, and their properties.

So far, no approach has succeeded in implementing an intelligent, common-sense system. Isn't it time to reverse the trend and employ techniques and tools based on small data sets and the integration of a common-sense computational model tailored to each area of interest?

#### A. Small DATA is the Future of AI

Human intelligence has always been able to innovate and discover even before the advent of big data. All scientific discoveries throughout human history have been fueled by small amounts of data. It is estimated that 65% of these discoveries were the result of compiling a small amount of data in the form of rules, hypotheses and theories that were sophisticated and successful.

Today's biggest obstacle facing companies in developing AI systems is the lack of big data. These companies do not have the capacity of giants like Google or Facebook that rely on billions of data resources. Google, for example, benefits greatly from its massive amount of data. It can develop algorithms by processing over 130 trillion web pages, but a corporation may only have 30 relevant instances to automate an internal operation. The gap in AI adoption by companies is due in part to disparities in data resources.

Furthermore, developing a big data initiative within a company necessitates time, money, and expertise. The principles for implementing such a process include creating a data-driven program with architecture and infrastructure appropriate for the initiative's overall lifespan. The cost of this process is prohibitively expensive, and it grows in proportion to the scale of the issue and the complexity of the data.

Although it appears that current AI developments rely primarily on big data, we forget the value of observing small samples. AI becomes even smarter and more powerful if it can be trained with small amounts of data. The ultimate purpose of AI should be mastering knowledge rather than processing data. It is all about teaching a machine the knowledge it needs to complete a task.

In fact, small data mastery is essential to advance AI especially for specific industrial domains where man and robot have to collaborate by exchanging information although they are small quantities but relevant for the accomplishment of common tasks. As a result, the development of new AI techniques that do not rely on the well-known "big data" variable as input becomes critical.

The genesis of AI was to create machines capable of imitating human intelligence. However, Humans can learn from small amounts of information, they do not need to observe millions of examples of cars to learn to detect them correctly.

On the other hand, specialized learners have the ability to learn from small data because they have adequate inductive biases. Inductive biases represent knowledge of the world in

which learning will take place and are present in the model even before training begins. In other words, the model must already be capable of extracting meaning from a particular dataset. A In fact, machine learning model will learn successfully from small data only if it has a sufficient amount of this knowledge.

To summarize, small data has the advantage of being easy to collect, simple to process, ubiquitous and quickly exploitable by machine learning models. Furthermore, when applied to deep learning methods, the model can predict and converge rapidly towards an expected result even more in a narrow area, due to the ability to assign weights and rewards that will become less complex.

Investing in small data appears to provide a significant benefit because it increases the possibility of implementing alternative learning techniques.

To argue this point of view, we highlight some emerging AI tools techniques that rely only on small data and perform better than those that work with big data. These techniques appear to reinforce traditional machine learning modeling approaches and they include:

- Collaborative Machine Learning (CML).

As a distributed learning technology, collaborative machine learning (CML) trains multiple agents in a network to build a common and robust machine learning model without sharing data.

Similarly, to the synergy of heterogeneous human teams, task offloading allows agents to hold different, complementary and private representations of the training environment. The peripheral agents' joint learning is then achieved by parallelization and co-inference of distributed model learning.

The goal of collective machine learning is to create a unique predictive model that is more accurate than the sum of its parts.

- Few-Shot Learning

Few-Shot Learning is a technique that consists of performing supervised classification or regression based on a very small number of samples. Few-Shot Learning (FSL), also known as low intensity learning or spot learning, is a machine learning model that serves primarily as a tool for training machine learning algorithms with data relevant to the training context, even if it is small in number.

Else, Few-Shot Learning is different from standard supervised learning, which trains a model to recognize images in the training set and then generalize to the test set. In contrast, the goal of this technique is to distinguish similarities and differences between objects.

The idea of this approach is humans inspired; man can learn quickly by using what has been learned in the past. For example, a child can easily recognize the same person or animal in a large number of pictures.

Most approaches characterize few-shot learning as a meta-learning problem. To overcome the lack of data, a possible solution is to gain experience from other similar problems.

Meta-learning is a subfield of machine learning that is also known as learning to learn. In meta-learning, machine learning algorithms are applied to metadata related to machine learning experiments.

The main objective is to understand how machine learning can become flexible in solving learning problems and aims to improve the performance of existing learning algorithms or to learn (induce) the learning algorithm itself.

The small collection of labeled images used in meta-learning is called a support set as shown in Fig. 11. In contrast, the training set for conventional machine learning algorithms is large enough to learn a deep neural network, for example. Each class in the training set contains many samples.

The basic idea behind few-shot learning is that the support set has a limited number of classes and samples and can only provide additional information during the test. However, with a training set, if each class only has one sample, it is impossible to train a deep neural network.

The algorithm will be trained through a series of training tasks, each of which includes a support set with three different classes and two examples. The issue is a three-way-two-shot classification.

During training, the cost function will evaluate in turn for each task the performance on the query set taking into account the respective support set (Fig. 12). At test time, a completely different set of tasks is used to evaluate performance on the query set, given the support set.

As shown in Fig. 13, no overlap is existing between the classes in the two training tasks {cat, lamb, pig}, {dog, shark, lion} and between those in the test task {duck, dolphin, hen}. The algorithm will have to learn to classify image classes in general rather than focusing on classifying a particular set.

Support Set

Fig. 11. Support Set Example.

Query

Fig. 12. Query Set Example.

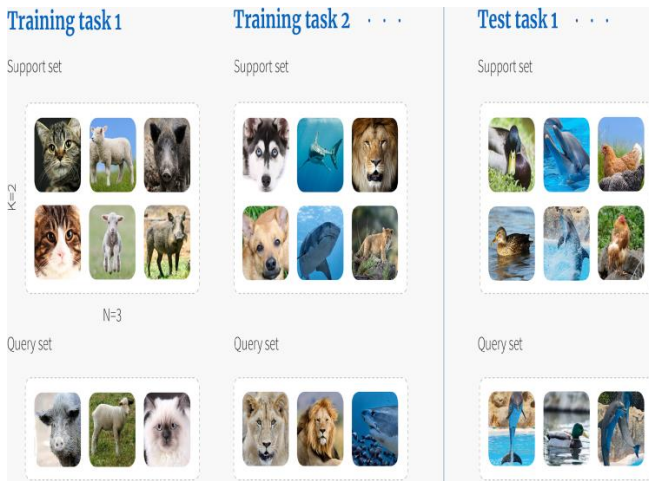

Fig. 13. Meta-Learning Framework.

The emphasis in FSL learning is on the quality of training data rather than the quantity. Furthermore, there is interest in designing and building AI machines or computer programs that improve automatically with experience.

The human-like learning allows FSL models to naturally advance robotics by improving robots capabilities that can at one-shot replicate or imitate human actions as well as enhancing their visual navigation.

- Zero-Shot Learning (ZSL)

Zero-shot learning is a learning model in which a machine is trained with an optimal minimum of labeled data during the learning phase. The machine learns to recognize a class of objects without having seen any previously labeled examples of that class. This method is also called on-the-fly learning.

Zero-shot learning relies on inference in order to reduce the requirement of the training phase for slightly different permutation masses.

The inference step in zero-shot learning is crucial: in this step, the algorithm attempts to predict and categorize classes of unseen data by analyzing its labeled data predictions to map the underlying attributes that have the highest probability of describing the data in general.

To solve Zero-Shot recognition problems, there are two popular ways. Fig. 14 depicts the anatomy of the first common method called “Embedding-Based Zero-Shot Learning”.

The input image is first processed by a feature extractor network (deep neural network (DNN)) to generate an N-dimensional feature vector for the image. This vector is fed into the main network, which produces a D-dimensional output vector.

The ultimate goal is to compute the weights of the projection network so that the N-dimensional input can be mapped to a D-dimensional output. Then, the loss compatibility module assesses the D-dimensional output's compatibility with the ground truth semantic attribute. The network's weights are tuned so that the D-dimensional output is as near as possible to the ground truth data.

The training seeks to develop a projection function from visual space to semantic space (word vectors or semantic embedding).

The Generative Model-Based Approach is the second Zero-shot Learning method. The generative method's goal is to use semantic attributes to generate image features for unobserved categories. At training time, the zero-shot classification model is trained on both seen and non-observed category images.

A general generative model-based zero-shot learning diagram is shown in Fig. 15.

The feature extractor network (deep neural network (DNN)) generates an N-dimensional feature vector for the image. The attribute vector is first fed into the generative model, as shown in the diagram. Based on the attribute vector, the generator creates an N-dimensional output vector. The generative model is trained in such a way that the synthesized feature vector resembles the original N-dimensional feature vector.

The generator's weights are fixed by the generative model, and the class attributes are used as input to generate non-observed category image features.

A basic image classifier is then trained by taking class image features (the training dataset) and non-observed category image features as the input and outputs the respective category label as shown in the Fig. 16.

**B. Proposed Model**

Our research aims to contribute to the growing literature on the new and novel theme that promises industrial revolution 5.0 in terms of collaboration between man and cobot. Our primary goal is to generate new ideas that will stimulate the interest of scholars in this subject.

According to our literature review, we have raised many challenges to overcome, especially when it comes to achieving effective collaboration between humans and machines. In this sense, the main problems that slow down the achievement of this goal largely concern big data.

Our approach consists of training a cobot by small amount of data using techniques discussed in this paper notably FSL and ZSL and MTDRL. An optimal common sense knowledge representation will be modeled and covers areas relating to human-machine collaboration in the context of Industry 5.0. These areas mainly concern actions and tasks, object recognition in the workplace and spatial navigation.

To compensate for the lack of the big data variable, research is continuing and focusing on strategies that rely simply on small data and allow for learning through collaboration or knowledge transfer.

In this order of thoughts, learning a cobot should be done as close to the human way as possible.

The cobot can collaborate and interact with its human counterpart only if it has a minimum of knowledge and common-sense background that allow it. The model will be able to learn at three levels: predictions against common-sense, human expectations and workers collaboration.

The cobot can act or accomplish a task in accordance with what has been pre-established in the model while remaining in permanent multimodal communication with the human collaborator who can correct it instantly to achieve the desired performance.

Like human learning, the cobot will be trained gradually from early stages of task completion, interaction, communication or decision making.

The model will be built around memory, computational units and three neural networks serving as training and correlating tools. The policies, rules and an optimal common-sense-knowledge repository will be stored at the memory level.

As shown in Fig. 17 our proposed model will be developed on three functions in order to calculate the action value, the policy and common-sense repository compliance value and finally the correlation function to assess the completion of multitasking based on the established policies and the repository of common-sense.

These functions will be implemented by three Deep Neural Network called:

- ZSL-DNN (Zero-Shot Learning Deep Neural Network).
- FSL-DNN (Few-Shot Learning Deep Neural Network).
- MTDRL-DNN (Multi-Task Deep Reinforcement Learning Deep Neural Network).

The Cobot's computational system will perform correlations between the objectives targeted by an action and what has been achieved by taking as reference the common-sense-knowledge repository, Human expectations and workers collaboration according to the algorithm illustrated in Fig. 18.

The algorithm's instructions will be carried out in the following sequence:

- Step 1: start of action;
- Step 2: correlation against common-sense;
- Step 3: return to step 2 if the outcome is unsatisfactory;
- Step 4: correlation against Human expectations;
- Step 5: return to step 4 if the outcome is unsatisfactory;
- Step 6: correlation against co-workers collaboration & correction;
- Step 7: return to step 6 if the outcome is unsatisfactory;
- Step 8: calculation of the action-value;
- Step 9: return to step 1 if the outcome is unsatisfactory;
- Step 10: reaction on the environment.

## V. CONCLUSION AND FUTURE WORK

The current trend in industry 5.0 is to be human-centered, the human and the cobot can interact safely and cooperate to accomplish the assigned tasks. The great progress of these systems is convincing, but the performance in this field is still far from being efficient. Artificial intelligence, while making great steps in many areas will have to overcome difficulties inherent to real-world environments.

Big data is critical to intelligence's success. On the other hand, the most significant constraint of deep learning is the requirement for enormous volumes of data; nevertheless, isn't it time to develop machines that can learn from little amounts of data?

In this paper, we have identified some of the technical challenges faced by researchers working on human-cobot collaboration. Current models of reinforcement learning for multi-tasking have many shortcomings that need to be addressed.

This study also highlights some of the existing solutions for addressing the key difficulties in the reinforcement area, such as DISTRAL, A3C, IMPALA, and PopArt.

Similarly, human-robot interaction has been briefly discussed given its importance in achieving Industry 5.0 goals. Human-robot interaction implies many technical challenges both in technical and human-centered aspects. Human-robot interaction is an open multidisciplinary field where current research is alive and growing.

Finally, we have proposed a new model and algorithm for training Cobots from small amount of data. Our model is based on three Deep Learning Neural Networks such as ZSL, FSL and MTDRL. The Cobot training will be gradually from early stages of task completion, interaction, communication or decision making.

In future work, we will try to deploy and experiment our model in a real industrial 5.0 context, in order to establish an appropriate Cobot collaboration.

**Abstract**—Machine learning prediction algorithms are considered powerful tools that could provide accurate insights about the spread and mortality of the novel Covid-19 disease. In this paper, a comparative study is introduced to evaluate the use of several parametric and non-parametric machine learning methods to model the total number of Covid-19 cases (TC) and total deaths (TD). A number of input features from the available Covid-19 time sequence are investigated to select the most significant model predictors. The impact of using the number of PCR tests as a model predictor is uniquely investigated in this study. The parametric regression including the Linear, Log, Polynomial, Generative Additive Regression, and Spline Regression and the non-parametric K-Nearest Neighborhood (KNN), Support Vector machine (SVM) and the Decision Tree (DT) have been utilized for building the models. The findings show that, for the used dataset, the linear regression is more accurate than the non-parametric models in predicting TC & TD. It is also found that including the total number of tests in the mortality model significantly increases its prediction accuracy.

**Keywords**—Covid-19; parametric regression; non-parametric regression; linear regression; log regression; polynomial regression; generative additive regression; spline regression; k-nearest neighborhood; KNN; support vector machine; SVM; decision trees; DT

## I. INTRODUCTION

Once the coronavirus pandemic, Covid-19, broke out at the late of December 2019, in Wuhan, China, the virus has been spread all over the world by the Spring of 2020. The coronavirus pandemic has so far followed a wave pattern, with increases in new cases followed by reductions [1]. SARS-CoV-2, the coronavirus that causes Covid-19, has mutated since the beginning of the pandemic, resulting in variations of the disease symptoms [2]. The delta variation is one of these mutations. The delta coronavirus is one of the most contagious coronavirus strains to date [3]. Presently, some countries are suffering from the fourth wave of the pandemic with the severest mutated version of the virus, delta variant. The current total number of confirmed cases of Covid-19 approaches 245 million persons worldwide with nearly five million total deaths [4]. The unpredictable rapid spread of the pandemic all over the world has caused unprecedented global lockdowns and overwhelmed the healthcare systems. As no medicine has been

approved yet for this virus, the World Health Organization (WHO) has guaranteed the availability of Covid-19 clinical data for the majority of countries and encouraged the research community to provide support in this pandemic to “fight panic with information” [5][6]. This would certainly aid in directing governments toward proper crisis management and effective resource utilization to contain the pandemic.

Many recent studies have tackled the problem of forecasting the spread and mortality of the new coronavirus disease using various machine learning prediction methods. Based on the survey done in [7], most studies focused only on addressing the relationship between the numbers of confirmed and recovered cases and deaths to build models for predicting the spread of the coronavirus disease. However, there are other features that would significantly affect the prediction accuracy of these models.

In this paper, we propose a comparative study to evaluate the use of several parametric & non-parametric machine learning regression methods to model the two main folds of Covid-19 spread: the total number of confirmed cases and the total number of deaths. Within the study framework, we seek for the most significant input features of the models and investigate the impact of the number of tests on the prediction performance. The proposed framework has two phases: The Data Analytics & Modeling Phase and the Future Prediction Phase. In the first phase, Covid-19 time sequence dataset is preprocessed, and several significant predictors are selected according to a correlation criterion. These predictors are then used to build several regression models using several parametric & non-parametric methods using the training subset of the data. The model that shows the best prediction performance in terms of the least RMSE value will be considered for making the future predictions in the following phase. In the Future Prediction Phase, the values of the total deaths & the number of the total cases are to be predicted at future dates. In order to do so, the selected predictors should be estimated at the required future dates as well. Therefore, in this phase, each predictor is modeled individually against time (the day count referenced to an origin date) using a set of parametric & non-parametric methods. The best model is then used to estimate the value of the corresponding predictor at the required future date and predictor value is then substituted in

\*Corresponding Author

the total cases model as well as the total death model. The proposed framework has been applied on the Covid-19 dataset of Saudi Arabia over 116 days from April 25 till August 8, 2020 for training & testing the prediction models and these models have been used for estimating the future values of the total number of cases and total number of deaths.

## II. LITERATURE REVIEW

Several factors have influenced whether new Covid-19 cases are increasing or decreasing in specific locations during the pandemic. Some of these factors include the efficiency of vaccination, adhering the precautionary measures, the virus mutations, and the PCR tests. For instance, there was a huge surge in the number of Covid-19 confirmed cases during the winter of 2021 in the United States as a result of people not adhering to the COVID-19 precautions and regulations. Additionally, in many countries, vaccinating the citizens has aided in bringing new infection levels down until the spring season of 2021.

The number of PCR tests is one of the most important features that could significantly contribute to the prediction accuracy of the spread/ mortality models as it is explicitly affecting the number of confirmed cases. Nonetheless, no studies, to the best of our knowledge, have included the number of tests as an input feature to the Covid-related prediction models, nor have they examined its impact on the prediction accuracy of those models. For instance, the study of Yuanyuan et al. The work done in [8] utilized a linear regression analysis to create a model between the number of Wuhan roaming people and the cumulative number of Covid-19 cases in Henan province, China. Another study by Sansa et al. [9] conducted a correlation analysis and built a simple linear regression model between the numbers of confirmed cases and recovered cases in China over one month period. In another study [10], the epidemic peak in Saudi Arabia was predicted using the (Susceptible-Infected-Recovered) model [11], and the Logistic Growth model [12]. In that study, four variables were considered in the prediction models which are the number of daily confirmed, accumulated confirmed, recovered and deaths cases. Other studies utilized a number of non-parametric machine learning approaches to forecast the worldwide spread & death rate of Covid-19 and other pandemic-related variables as in [13][14][15]. The Naïve method, averaging, and Holt linear/winters method have been used in [14] to predict the value of the number of deaths in the next day based on the value of the present day. Another work in [16] has presented the application of linear and logistic regression for the prediction of the risk periods and survival of Covid-19 in different ages. However, the Decision Tree (DT) [17], K-Nearest Neighborhood (KNN) [18], and Support Vector Machine (SVM) [19] have been employed for the classification of patients (risk/mild) and hence the significant features have been extracted to distinguish between the classes of patients. In addition, DT, SVM, Random Forest, KNN, Naïve Bayes, and logistic regression were employed in [20] to predict the number of days needed to recover from Covid-19 and the age of patient that may result in risky outcomes of the disease.

## III. MATERIALS

In this work, a data set of COVID-19 records for Saudi Arabia [3] is used for building and evaluating the regression models. This dataset is published in the upstream repository at Johns Hopkins University Center for Systems Science and Engineering website [17]. The Covid-19 data set records the number of new confirmed cases, new deaths and recovered cases daily along with the corresponding accumulated total numbers. Other auxiliary entries like the median patient age, population, diabetes prevalence and others are also included in the data [2]. These auxiliary entries have constant values across the days. The number of new tests and total tests were recorded as well starting May 13th, 2020 for the Saudi Arabia data [2]. In this work, the entries with variable values are only used to model the number of the total confirmed cases and the total deaths using regression while the auxiliary entries were ignored as they do not contribute significantly to the models. There were four missing entries for the total tests and their values were estimated using the average of its two adjacent values. Day counts have been created to be used in reference to the required date. Day counts start from April 25th, 2020; i.e. Day 1 corresponds to April 25th, Day 2 to April 26th and so on. The available records are divided randomly into a training data set and a testing data set with a ratio of 8:2. The training data is used to estimate the regression coefficients of the prediction models while the testing set is used to evaluate the prediction accuracy of the proposed models. In order to unify the range of the input observations, the min-max normalization [18] is used to normalize the input features before building the models. All the codes of this work are created using the R programming language. For convenience, the following notations are used for the variables throughout the paper. TC, TR, ND, TD, TT, and DC denotes the number of the Total Confirmed Cases, the number of the Recovered Cases, the number of the New Deaths, the number of the Total Deaths, the number of the Total Tests, the Day Count.

## IV. METHODS

Regression is a supervised machine learning technique that is used for the prediction of a continuous quantitative outcome. For this purpose, the relationship between a dependent (response) variable and one or more independent variables (predictors) in a labeled dataset is estimated during the regression analysis process. Regression can be implemented using parametric and non-parametric algorithms. If a dataset is collected about a response variable  $Y$ , and predictor variables  $(x_1, x_2, x_3, \dots, x_m)$ , the relationship between  $Y$  and  $X$  can be modeled as in Eq. (1) [21].

$$Y = f(X, C) + C_0 \quad (1)$$

Where,  $C$  is a vector of  $m$  parameters,  $C_0$  is an error term that shows the deviation of the actual values from the model predictions and  $f(\cdot)$  is some function that maps the relationship between  $Y$  and  $X$ . The selection to use the parametric, semi-parametric or nonparametric method to implement the regression model depends mainly on the prior knowledge about the form of the function  $f(\cdot)$ . If  $f(\cdot)$  is known a priori, parametric methods is to be used; otherwise, non-parametric methods should be used. Semi-parametric methods can be used if  $f(\cdot)$  is known partially [21]. The function  $f(\cdot)$  could be

linear or non-linear function in the model parameters and accordingly the model becomes a linear or non-linear parametric model respectively. Parametric models require the estimation of the model parameters  $C$  and  $C_0$ . It is noteworthy mentioning that parametric models perform the best when the relational function is known and correct. In contrast, using the wrong function would result in larger bias when compared to the other competitive models [21] and would make inaccurate predictions. The most common parametric regression is the linear regression in which a linear model is composed of linear combination of the input predictors. Non-parametric regression methods do not require pre-knowing the form of  $f(\cdot)$  and consequently, they provide more flexibility in analyzing the relationship between the variables [21]. Many machine learning algorithms that are used for classification can be used as non-parametric regressors with some structural amendments when the response variable is continuous rather than discrete. The K-Nearest Neighborhood (KNN), Support Vector Machine (SVM) and Decision Tree (DT) algorithms are examples of such non-parametric regression methods.

**A. Parametric Machine Learning Regression**

To get sense of the relation between the dependent variable and each of the predictors, a set of scatter plots are provided in Fig. 1 for the total number of deaths and in Fig. 2 for the total number of confirmed cases. The scatter plots show that the

relationship between the response variables and all predictors, individually, are increasing and could be linearly modeled using the multivariate parametric linear regression.

**TD Linear Regression Models**

As the TD is highly correlated with the TC, TR & TT, the proposed prediction model of the TD in Experiment 1 is given in Eq. (2) while that of Experiment 2 after excluding TT, is given in Eq. (3) :

$$TD = C_0 + C_1 * TC + C_2 * TR + C_3 * TT \tag{2}$$

$$TD = C_0 + C_1 * TC + C_2 * TR \tag{3}$$

Where  $C_0, C_1, C_2, C_3$  are the regression coefficients of the model which represent the association of the model predictors to the dependent variable.

**TC Linear Regression Models**

The proposed prediction model of (TC, TT&TR) is given as in Eq. (4) and that of the (TC,TR) is given in Eq. (5):

$$TC = B_0 + B_1 * TR + B_2 * TT \tag{4}$$

$$TC = B_0 + B_1 * TR \tag{5}$$

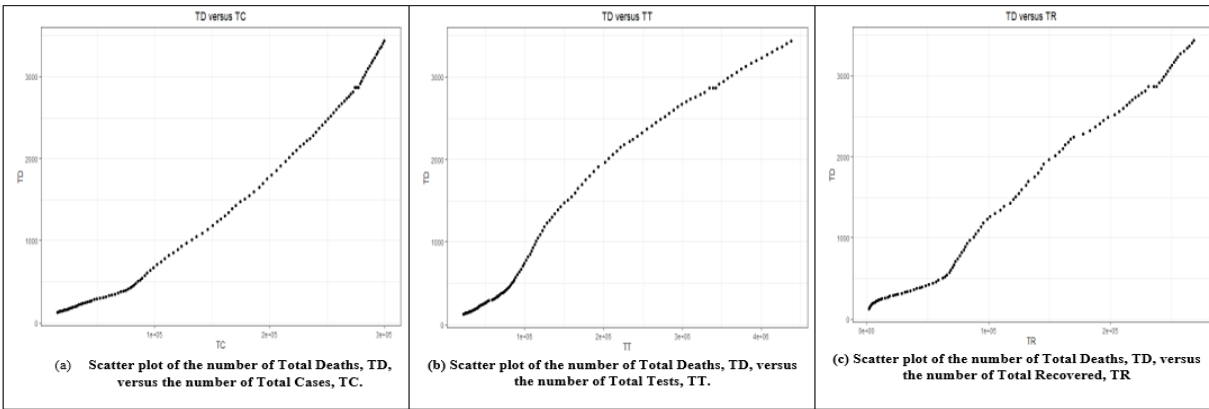

Fig. 1. Scatter Plot of the Total Deaths (TD) Versus Total Cases (TC), Total Tests (TT), and Total Recovered (TR).

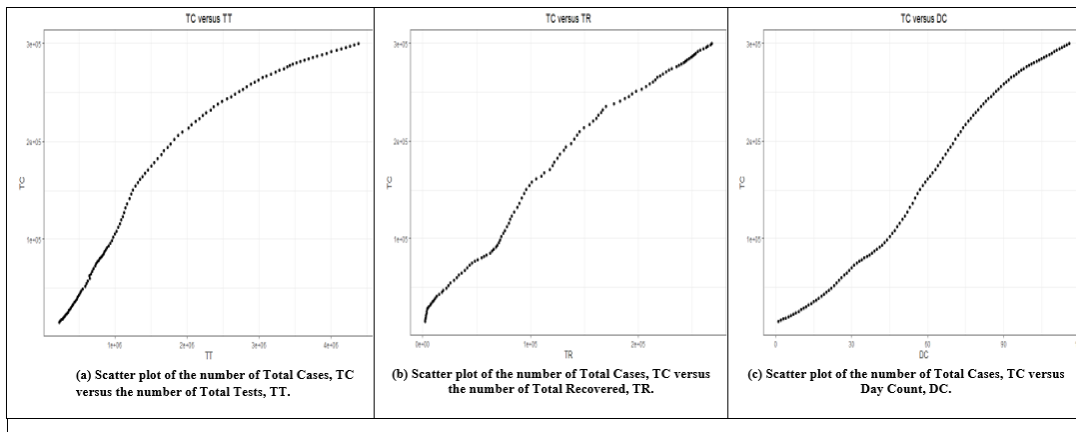

Fig. 2. Scatter Plot of the TC Versus Total Tests (TT), Total Recovered (TR), and Day Count (DC).

Where  $B_0, B_1, B_2$  are the regression coefficients of the model. The model coefficients for all of the linear models built in this study are estimated using the Least Squares Estimation algorithm.

### B. Non-Parametric Machine Learning Regression

In this part, the TC and the TD are modeled using a number of supervised learning non-parametric algorithms. Non-parametric algorithms do not make an assumption about the relationship between the response and predictors or the underlying distribution of the data and the model structure is configured from the data itself. In this study, the KNN, SVR and the DT algorithms are used for manipulating the regression problem.

KNN is a non-parametric supervised machine learning algorithm that is used for classification and regression. KNN approximates the association between the input features and the response variable using feature similarity[22]. In classification, KNN finds the majority votes of a number of neighbors (called k) of an input instance to select the appropriate class. However, in regression, the response variable is estimated by averaging the observations in the nearest neighborhood of the input instance based on a similarity measure. The similarity measure employed herein is the Euclidian Distance [23]. In order to select the optimal value of k, we run the KNN algorithm on the training dataset with k values starts from 3 up to 8 and calculate the RMSE at each k value then select the value that minimizes the root mean-squared error. k values of 1 & 2 are excluded as they cause unstable predictions. Also, k values greater than 8 are excluded as it has been observed that the RMSE values keep increasing as k increases.

Support Vector Machine (SVM) is a supervised machine learning algorithm that is used for classification and regression tasks. In a classification problem, SVM tries to find a hyperplane in the input feature space to distinctly classify the input data points[24]. Finding the hyperplane is an optimization problem to select the plane that achieves the maximum margin between the data points of two classes using the aid of kernel functions[25]. For a regression problem, SVM is known as SVR (Support Vector Regressor) and the problem then is to find a function that approximates input features to real numbers instead of discrete classes. This function itself defines the hyperplane in the regression problem and is used for the prediction of the response variable. This is again an optimization problem that aims to find the best hyperplane that passes through the maximum number of points within a given decision boundary at distance “ $\epsilon$ ” from the hyperplane. Let’s consider that the hyperplane is a straight line as in Eq. (6) [24]:

$$y = wx + b \quad (6)$$

Where  $w, b$  are the parameters of the line. Then the decision boundary can be defined as in Eq. (7), and Eq. (8):

$$wx + b = +\epsilon \quad (7)$$

$$wx + b = -\epsilon \quad (8)$$

So, any hyperplane that satisfies our SVR should satisfy Eq. (9) [24]:

$$-\epsilon < y - wx + b < +\epsilon \quad (9)$$

In this part of study, as no assumptions are made about the multivariate input or their relationships to the response variable, therefore, multiple kernel functions are used to adapt to the patterns in the data. The linear, polynomial, Gaussian radial basis and the sigmoid kernel functions [25] have been employed to non-linearly map the data from the original space into a higher dimensional space.

Decision Tree (DT) is a well-established supervised machine learning algorithm that can be used for classification and regression [26]. A decision tree makes decisions by splitting nodes into sub-nodes using the “if, then” condition multiple times until reaching the terminal homogeneous nodes. In this work, the Recursive partitioning has been employed to build the regression models of the response variables. The models are built against the predictors that show very high correlation with the response as depicted in Table I. As we are tackling a regression problem, we used the ANOVA splitting rule as the partitioning method of the tree. ANOVA rule is based on the Reduction of Variance concept to split the nodes. For each split, ANOVA calculates the variance of each node and then the variance of the split and then selects the split with the lowest variance. This process is repeated until all nodes with zero variance are reached and marked as the terminal nodes. At this end, no further splits are needed[26]. The ANOVA splitting rule is used as the partitioning methods of the tree. To pre-prune the Decision Tree, three hyperparameters are tuned and optimized. That is, the Complexity Parameter (CP), the Maximum Depth (MD) and the Minimum Split (MS). Complexity Parameter is used to save computing time by pruning off splits that does not improve the fit’s R-squared value by the value of (CP). The Maximum Depth indicates how deep the tree can be. The Minimum Split of the parent node which is the minimum number of observations in the parent node that can be split further[27]. To optimize the values of these hyperparameters, the R function “Rpart.tune” is used.

### C. The Study Framework

In this study, two models are to be built for the prediction of two response variables separately: the total number of confirmed cases (TC) and the total number of deaths (TD). Several parametric and non-parametric machine learning regression methods are utilized to build the models. The models will be evaluated based on some performance metrics and the best performing model will be considered for the future predictions of the response variables. The framework, shown in Fig. 3, is composed of two phases:

#### Phase 1: Data Analytics and Modelling

As a first step in this phase, data is explored to determine the significant predictors (the independent variables) to be used in building the models. A correlation analysis between all the input variables in the data has been conducted and the Pearson Correlation Coefficients (PCC)[28] are depicted in the correlation matrix in Table I. Only highly correlated variables (PCC>0.9) with the response variable are considered significant and used as predictors of the corresponding model. In Table I, highly correlated variables with the total confirmed

cases are highlighted in light grey while those highly correlated with the total deaths, are highlighted in dark grey.

After selecting the significant predictors, several parametric & non-parametric regression methods are used to model the total number of confirmed cases and the total number of deaths. At last, the model that shows the best prediction performance is selected for the future prediction in phase 2 of the framework.

The prediction model of the total number of deaths are built using the predictors that show high correlation with it which are the total number of tests, the total number of recovered cases and the total number of confirmed cases as shown in Table I. However, it was noted that the effect of the total number of tests on the Covid-19 prediction models is not investigated widely in the literature. Most probably this is because recording the TT on a daily basis was started late in most countries. Therefore, it has been decided in this study to figure out the impact of the total number of tests on the prediction accuracy of the proposed regression models. This is achieved by conducting two experiments for modeling the TD. In Experiment 1, all predictors that are highly correlated with the TD (which are TT, TR and TC) are used to build the model using the multivariate regression paradigm. On the other, the TT is excluded in Experiment 2 and the model is constructed using only TR and TC.

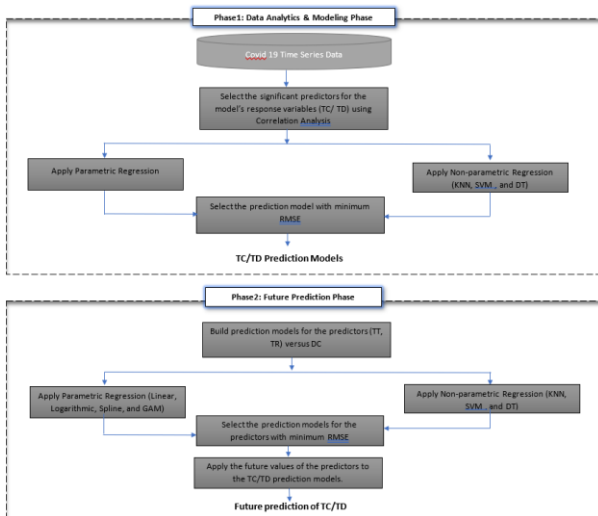

Fig. 3. The Study Framework for Predicting the Total Number of Cases & Total Number of Deaths of Covid-19 Outbreak.

TABLE I. CORRELATION MATRIX OF ALL VARIABLES INCLUDED IN THE STUDY

	DC	TR	TC	TT	TD	ND	NC
DC	1	0.99	0.994	0.969	0.982	0.658	0.032
TR	0.992	1	0.992	0.988	0.995	0.592	0.072
TC	0.994	0.992	1	0.965	0.989	0.658	0.034
TT	0.969	0.988	0.965	1	0.988	0.498	0.186
TD	0.981	0.994	0.989	0.988	1	0.580	0.083
ND	0.657	0.592	0.658	0.497	0.580	1	0.590
NC	0.033	0.072	0.034	0.186	0.083	0.59	1

The prediction of the total number of confirmed cases is one main fold in tracing the spread of a pandemic. Therefore, an accurate model should be developed for the prediction of the total number of confirmed cases. In this study, two approaches are used to build and select the suitable TC model. In the first approach, a univariate prediction model is built for the TC using the day count as will be described later in this section. In the second approach, the multivariate regression is used to model the TC against the most significant predictors according to the high correlation criterion following the two experiments as in the TD model. In Experiment 1, according to the correlation criterion and as depicted in Table I, the TR and the TT achieve the highest correlation with the TC with  $PCC > 0.9$  and hence are used as the model predictors in this approach. Although, the TD shows high correlation with the TC, the former has been excluded while building the TC model. This has been decided to avoid any inaccuracy due to duplication as the TD model is considered the primary model and has already taken the TR and the TT in the prediction of TD. In Experiment 2, the TT is excluded from the model and the TR is the only predictor of the model.

After the TD & TC models from the two approaches are built by a set of parametric and non-parametric regressors, some performance metrics are then applied to evaluate the performance of the prediction models on the testing data set. The model that achieves the highest performance measures on the testing dataset are selected to be used for the prediction of the TC.

Phase 2: Future Prediction

As it is one of our objectives in this study to track the spread of Covid-19, values of the total number of confirmed cases and the total number of deaths are to be calculated at future dates. Given that the prediction models require the future values of their correspondent predictors, the values of these predictors are unknown apriori and need to be estimated beforehand at the required dates. Therefore, in this phase, each of the selected predictors is modeled individually against the day count. After that, the predictors' future values are substituted in the TC/TD forecasting models to find their corresponding future predictions. A number of parametric & non-parametric regressors are used to model the univariate predictors against the day count and the model with the least RMSE value is considered.

V. RESULT AND DISCUSSION

In this section, the results related to the TC model are presented first followed by the results of the TD model. Within this arrangement, we present the models built using the parametric linear regression then those built using the non-parametric methods. To evaluate the performance of the regression models developed in this study, a number of well-known performance metrics are utilized. The Min-Max accuracy, MAPE, the Root Mean Squared Error (RMSE), the R-Squared, Error rate of the RMSE referenced to the mean of the actual values and the correlation accuracy are used to evaluate the accuracy of predictions on the testing data[29][30][31]. The model that achieves the highest significance and prediction accuracy will be used for making the future prediction of the total cases and deaths.

A. The Total Number of Confirmed Cases Prediction Model (TC Model)

Within the proposed framework for TC prediction, two approaches are used to model the total number of confirmed cases. In one approach, a univariate model that relates the TC with the DC is constructed. However, in the other approach, the highly correlated predictors with the TC (which are the TT & TR) are used to build the model. Under this approach, two experiments are conducted to investigate the effect of the TT on the TC prediction model. In Experiment 1, a model that relates the TC to both the TT & TR is built while in Experiment 2, the TT is excluded, and a univariate regression model is constructed using the TC & TR training data. Several regression models are built using the parametric linear regression and the KNN, SVR & DT non-parametric methods. The performance of each of the proposed models is assessed using the measures described in the Methods Section. The model that best fit the training data and that provides the highest prediction accuracy on the testing data is selected to be used in estimating the future value of the TC predictor required in the TD model.

1) Parametric Linear Regression

In this part, the relation between the predictors (TR, TT, DC) and the dependent variable (TC) is assumed to be linear. We have used two approaches in modeling TC. In the First Approach, TC is modeled versus predictors with high correlation with the response variable. And in the second approach TC is modeled only versus DC. In the first experiment under the first approach, we model TC versus TR & TT. To check the statistical significance of the estimated model coefficients, the standard error, p-value and the t-value are calculated after building the model using the training dataset as shown in Table II. The low values of these metrics reveal that the estimated coefficients are significant.

The accuracy of the TC model on the testing data has been evaluated using the Min-Max accuracy, the Mean Absolute Percentage Error (MAPE) and the R-Squared metrics. An average value between the maximum and minimum predictions has been retrieved as 94 % with a MAPE value of 0.063 which show a good accuracy of the prediction model over the testing data. The RMSE value of 6826 implies that there is an average alteration between the actual and the predicted values in the testing subset with an error rate of 5.27%. The value of the 0.99 for the R-squared reveals the high correlation between the actual and predicted values. This is consistent with the correlation accuracy of 0.9973 computed after predicting the TC for the test data. This implies that the actual and the predicted values have analogous directional movement in which the actuals values increase as the predicted values increase and vice-versa.

TABLE II. SUMMARY OF THE STATISTICAL SIGNIFICANCE OF THE ESTIMATED COEFFICIENTS OF THE (TC- TT& TR) PREDICTION MODEL

	Estimated Coefficient	STD Error	t-value	p-value
B <sub>0</sub>	25520	1560	16.36	< 2e-16
B <sub>1</sub>	-194135	18922	-10.26	< 2e-16
B <sub>2</sub>	464305	17319	26.81	< 2e-16

TABLE III. SUMMARY OF THE STATISTICAL SIGNIFICANCE OF THE ESTIMATED COEFFICIENTS OF THE (TC- TR) PREDICTION MODEL

	Estimated coefficient	STD Error	t.value	p-value
B <sub>0</sub>	1.084e+00	1.426e-02	75.98	<2e-16
B <sub>1</sub>	2.884e+04	2.091e+03	13.79	<2e-16

In the second experiment under this approach, the first approach, we model TC versus TR only. Like what has been done in Experiment 1, the statistical significance of the (TC, TR) model (given in Equation 4) are calculated and shown in Table III. The retrieved results of Min-Max accuracy, MAPE, RMSE, and R-squared are 91%, 0.1, 12812, and 0.98 respectively which are worse than the values for the (TC, TT&TR) model. The values of the performance measures depict that excluding the TT from the model reduces its statistical significance and reduces the prediction accuracy as well.

In the Second Approach, TC versus DC Model, the training dataset of the day count and the total number of cases (DC, TC) is used to fit a model for the TC. Five models have been built using the Linear, Logarithmic, Spline, Polynomial and the Generative Additive Regression. Scatter plots of these models are shown in Fig. 4. The R-squared values of these models vary from 0.8 to nearly 1. The Logarithmic regression provides the worst fit with the lowest R-squared value of (0.79) followed by the Linear regression model. The Spline regression and the Polynomial regression provide comparable R-squared values while the Generative Additive Model (GAM) provides the best fit in terms of the highest R-squared value. Therefore, the GAM model is considered here for further statistical significance analysis.

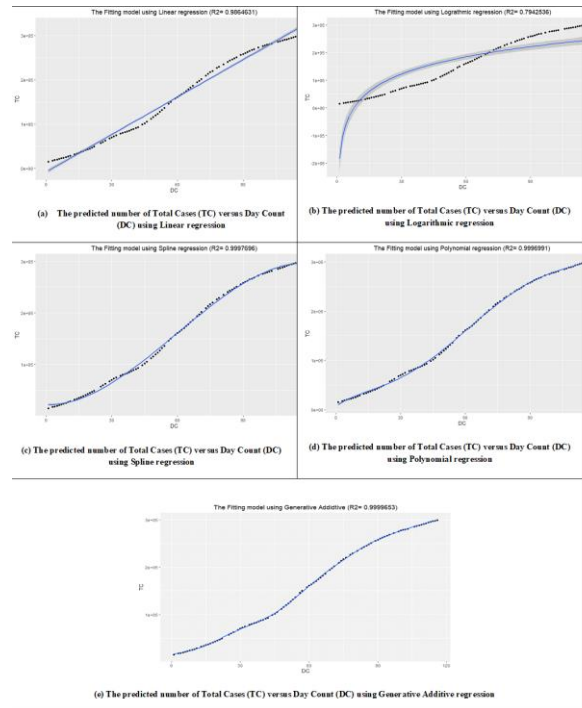

Fig. 4. The Predicted Total Cases (TC) Versus Day Count (DC) using: a) Linear Regression b) Logarithmic Regression c) Spline Regression d) Polynomial Regression e) Generative Additive Regression.

In an assessment of the prediction accuracy of the GAM model on the training data, the Adjusted and Multiple R-squared and the F-statistics are computed. The values of all R-squared measures are 1 which indicate that the variability in the TC is captured perfectly by the prediction model. This is supported by the very large value of the F-statistic (124906) and the very low p-value which reflect the high significance of the model. Therefore, this model was used to predict the TC values for the testing data and the performance metrics were computed to evaluate the prediction accuracy of the model. A Min-Max accuracy of 98.9% and a MAPE value of 0.011 were obtained for the model. The RMSE value of 1018 implies that there is a low average alteration between the actual and the predicted values in the testing subset with an error rate of 0.63%. The value of the 0.9999 for the R-squared reveals the high correlation between the actual and predicted values. This is consistent with the correlation accuracy of 0.9999 computed after predicting the TC for the test data.

2) *Non-parametric Machine Learning Regression*

In this part, no assumptions about the relation between the predictors (TR, TT, DC) and the dependent variable (TC) are made and the TC model is estimated from the data using the KNN, SVM and the DT regression methods. The performance measures calculated for all non-parametric methods are depicted in a table for each model and the model with the lowest RMSE is highlighted in light grey to facilitate the visual interpretation of the results. At the end, a comparison is conducted between the parametric and non-parametric models based on the RMSE measure to select the model that will be used for future predictions. Also, we have used two approaches in modeling TC as done in the Parametric regression.

In the First Approach, TC is modeled versus predictors with high correlation with the response variable. In the first experiment under this approach, we model TC versus TR & TT non-parametrically. Table IV shows the summary of the accuracy metrics for the models built by the KNN, SVM and the Decision Tree Regression. For the KNN, it is obvious that as the K increases, the larger the RMSE values are. Among all K values, the lowest RMSE & MAPE are achieved when the number of neighbor points equals 3. This k value also corresponds to the highest R-squared & Min-Max accuracy. For the SVM regression, the optimization tuning function “tune.svm” in the R language is used to deliver the best Gamma & cost parameters values for the Polynomial, Sigmoid & the Radial bases kernels for the SVM model. Values of the retrieved parameters are given in the caption of the table. It is noticed that the Radial kernel offers the least RMSE among the other kernels, yet still performing worse than the KNN. The Decision Tree Regressor has the worst performance over all non-parametric methods while the opposite is true for the KNN.

TABLE IV. SUMMARY OF THE ACCURACY OF THE (TC- TT & TR) PREDICTION MODEL ON THE TESTING DATASET USING THE KNN, SVM (GAMMA = 0.001, COST = 10 FOR POLYNOMIAL, RADIAL, SIGMOID KERNEL FUNCTION), AND DECISION TREE (BEST PARAMETERS: MAX DEPTH=3, CP=0.002, AND MINI SPLIT=10)

	Learning Parameters	RMS E	R2	Min-Max Accuracy	MAP E
KNN	k=3	1907.4	0.999	0.976	0.026
	k=4	2356.3	0.999	0.974	0.029
	k=5	2085.1	0.999	0.970	0.034
	k=6	2501	0.999	0.970	0.036
	k=7	2969.6	0.999	0.964	0.043
	k=8	3099	0.999	0.961	0.048
SVM	Linear Kernel	9349	0.991	0.907	0.118
	Polynomial Kernel	36644	0.85	0.77	0.29
	Radial Kernel	6326.7	0.996	0.927	0.099
	Sigmoid kernel	12713	0.649	0.38	0.778
DT	Anova Partitioning Method	11388.9	0.98	0.894	0.142

In the Second Approach, TC is modeled versus DC. Table V shows that the KNN with k=3 achieves the lowest error and the highest accuracy over all KNNs. Also, it has been found that the Radial kernel SVM is the best performer over all SVRs followed by the linear kernel. Decision tree performs comparably with the linear SVM and better than the Sigmoid SUM. However, again, the KNN with k = 3 is the best regressor over the other non-parametric algorithms and is highlighted in grey in Table V.

TABLE V. SUMMARY OF THE ACCURACY OF THE (TC-DC) PREDICTION MODEL USING KNN, SVM (GAMMA = 0.1, COST = 10 FOR POLYNOMIAL, RADIAL, SIGMOID KERNEL FUNCTION), AND DECISION TREE (BEST PARAMETERS: MAX DEPTH=3, CP=0.002, AND MINI SPLIT=10)

	Learning Parameters	RMSE	R2	Min-Max Accuracy	MAPE

DT	Anova Partitioning Method	12087	0.98	0.89	0.12

**B. The Total Number of Deaths Prediction Model (TD Model)**

In order to build the TD model, two experiments were conducted as aforementioned in Sec 3 in which the impact of the total number of tests on the prediction accuracy of the TD model is investigated. Several models are built using the parametric linear regression and the KNN, SVR & Decision Tree Non-parametric methods. The performance of each of the proposed models is assessed and the best fit will be used to estimate the total number of deaths.

**1) Parametric Linear Regression**

As a first Experiment, the TT, TR and the TC are used to model the TD using linear regression given in Equation 1. These predictors show very high correlation with the TD as illustrated in the scatter plots of Fig. 1. Table VI shows that the TC & TT coefficients have highest significance followed by the TR.

The accuracy of the TD model on the testing data has been evaluated. A Min-Max accuracy of 86% with a MAPE value of 0.13 is obtained for this model. The RMSE value of about 72 implies that there is very low average alteration between the actual and the predicted values in the testing data with an error rate of 4.25 %. A value of 0.995 for the R-squared and a correlation accuracy of 0.998 show that the actual and predicted values are highly correlated.

In the second Experiment, the TT is excluded, and the TR and the TC are used to model the TD using linear regression given in Equation 2. Table VII demonstrates the model significance over the training data. This table shows that the model coefficients have higher STD error, p-value & t-value than those obtained in Table VI for Experiment 1 using the TT as a model predictor. The accuracy of the TD model on the testing data has been computed. It has been found that the retrieved results of the Min-Max accuracy, MAPE, RMSE, and R-squared are 82%, 0.19, 97, 0.992 correspondingly which are worse than the values for the (TC, TT&TR) model.

TABLE VI. SUMMARY OF THE STATISTICAL SIGNIFICANCE OF THE ESTIMATED COEFFICIENTS OF THE (TD- TC& TR& TT) PREDICTION MODEL

	Estimated coefficient	STD Error	t-value	p-value
C0	-75.43	13.99	-12.378	5.32e-07

C2	592.64	267.18	2.218	0.029

**2) Non-parametric Regression**

In the first Experiment, TD is modeled versus (TT-TR-TC). And as depicted in Table VIII, we can notice that the RMSE values for all KNN regressors used to build the (TD- TC& TR& TT) model is less than all other non-parametric models. Specifically, the least RSME is achieved by the KNN regressor with k =3 which is highlighted in grey in Table VIII. In contrast, it has been noticed that the Decision Tree has the worst performance metrics. For the SVMs, the radial kernel outperforms the linear & the sigmoid kernels.

TABLE VIII. SUMMARY OF THE ACCURACY OF THE (TD- TC& TR& TT) PREDICTION MODEL USING KNN, SVM (GAMMA = 0.01, COST = 10 FOR POLYNOMIAL, RADIAL, SIGMOID KERNEL FUNCTION), AND DECISION TREE (BEST PARAMETERS: MAX DEPTH=3, CP=0.015, AND MINI SPLIT=40)

	k=7	55.58	0.99	0.96	0.03
	k=8	53.15	0.99	0.97	0.03
SVM	Linear Kernel	117.7	0.99	0.78	0.23
	Polynomial Kernel	1188	0.87	0.44	1.75
	Radial Kernel	73.64	0.99	0.83	0.16
	Sigmoid kernel	125.2	0.98	0.75	0.25
DT	Anova Partitioning Method	269	0.94	0.83	0.22

In the second Experiment 2, TD is modeled versus (TR-TC). Table IX shows that the (TD- TR& TC) model also behaves like the (TD- TC& TR& TT) model in terms of the RMSE values but with larger values. It has been noticed that all KNN regressors has less RMSE values than all other non-parametric models. However, unlike the (TD- TC& TR& TT) model, the least RSME & MAPE and the highest accuracy & R-squared values are achieved by the KNN with  $k=6$  (highlighted in grey in Table IX). Moreover, it has been found that the Decision Tree has the worst performance metrics. For the SVMs, the radial kernel performs better than the linear & the sigmoid kernels.

### C. Selecting the basic Models

In order to select the basic models that will be considered for the future prediction of the total number of confirmed cases & the total number of deaths, we compared the performance metrics for all the models created to the TC & TD variables using the parametric & non-parametric regression methods. The RMSE is selected to be used as the reference for the comparison as the R-squared values are convergent between most models, the Min-Max accuracy behaves consistently with it and the MAPE behaves consistently with the RMSE. The Bar graphs of Figures 5 & 6 are bar charts that show the lowest RMSE values for the parametric & non-parametric regression models built for the TC & the TD models respectively in this study. For the TC models, the RMSE values of only the KNN with  $k=3$  and the Gaussian radial kernel SVM along with the Decision Tree are depicted in Fig. 5. However, for the TD models, the records of the KNN with  $k=6$ , radial kernel SVM & the Decision Tree are shown in Fig. 6.

Fig. 5. Bar Chart for the Minimum RMSE retrieved for the TC Fitting Models.

Fig. 6. Bar Chart for the Minimum RMSE retrieved for the TD Fitting Models.

For the TC, it is obvious that the (TC-DC) models have the best performance over all other models when estimated by both the parametric & non-parametric methods. Conversely, the (TC-TR) models are the worst consistently over all methods. Also, it has been observed that adding the TT as a predictor to the (TC-TR) model apparently improves the performance of the model but yet the (TC-TD) model outperforms the (TC-TR&TT) model. In order to select the best (TC-DC) model, we select the modeling method that provides the least RMSE. It has been found that the parametric linear regression model outperforms the KNN, SVM & DT non-parametric regressors. Therefore, it has been decided in this study to consider the linear regression model of the (TC-DC) model as the basic model for tracking the TC growth and for estimating the future values of the TC predictor in the TD model.

For the TD, we can see that adding the TT to the TC& TR reduces the RMSE for all parametric & non-parametric models. Although the reduction in RMSE is slight for almost all regression methods, for the KNN ( $k=6$ ), the presence of TT in the model reduces the RMSE by nearly 50%. However, we can see that TT has negligible effect for the SVM (Radial) Regressor. It is also noticed that the non-parametric KNN ( $k=6$ ) performs the best over the other non-parametric models and the parametric linear model followed by the SVM regressor. It is clear also that the linear regression & the SVM performs comparably for the (TD-TC&TR&TT) Nevertheless, it is decided in this study to consider the (TD-TC& TR&TT) build by the Radial Kernel SVM to be used for predicting the future values of the TD instead of the KNN. By finding the future prediction for the unseen data at multiple future dates, we found that all TD predictions have the same values. This could be explained in the light of knowing the nature of the KNN algorithm in associating the unseen data to its neighbors. That is, all upcoming future values appear in the neighborhood of the last training example (Day 116) in the training dataset which always uses this neighborhood to find the future prediction which will give surely the same value for the predictions for all days after Day 116.

### D. Prediction of the Predictor's Future Values

The future predictions of the TD are estimated using the (TD-TC&TR& TT) model. However, the future values of the predictors TC, TR and TT are yet to be predicted against the Day Count. The (TC-DC) model has been previously built and its linear regression model will be used for predicting the future TC value. However, in this part, we model each of the predictors (TT and TR) with respect to the DC using parametric & non-parametric regression methods. Five parametric models have been built using the Linear, Logarithmic, Spline, Polynomial and the Generative Additive Regression [32][33][34]. However, the non-parametric models have been built using the KNN, SVM & DT regression. Afterward, we select the model that has the least RMSE value for the future prediction of the corresponding predictor. Fig. 7 & 8 show the parametric models of the predictors while Fig. 9 & 10 show the non-parametric models. The values of the RMSE corresponding to each model are depicted in Table X. It is clear from this table that the GAM models have the least RMSE over all other models therefore, they have been selected to find the future values of the predictors.

TABLE X. THE VALUES OF THE RMSE & R-SQUARED VALUES FOR THE (TT/TR VERSUS DC) MODELS BUILT USING SEVERAL PARAMETRIC AND NON-PARAMETRIC REGRESSION METHODS. LEAST RMSE VALUES ARE HIGHLIGHTED IN GREY

Predictor	Method	RMSE	R2
TT	linear	275906	0.94
	log	720572.8	0.59
	Splines	15480.06	0.99

## VI. CONCLUSION

The main objective of this work is to investigate the power of the parametric and non-parametric machine learning methods in the accurate prediction of the spread and mortality of Covid-19 pandemic. Different features in the used Covid-19 dataset have been examined. Very high correlation between the models' response variable and the input predictors is used as the feature selection criterion. The significance of using the number of PCR tests as a model predictor has been investigated. Within the framework of this study, the data is preprocessed, and the most significant predictors are selected to build a number of regression models for the TC & TD separately. The parametric linear regression and the non-parametric KNN, SVM and DT are used for individually modeling the response variables against the selected predictors. The models that show the best prediction performance are considered the basic models to be used for the future prediction of the response variables. The predictors are modeled individually against a time variable using a variety set of parametric & non-parametric methods. The best model is then used to estimate the value of the corresponding predictor at the required future date. The findings show that, for the given dataset, the linear regression performs better than the non-parametric models for predicting TC & TD. It is also found that including of the total number of tests in the mortality model significantly increases its prediction accuracy.

# Comparison of Machine Learning Algorithms for Sentiment Classification on Fake News Detection

Yuzy Mahmud, Noor Sakinah Shaeali, Sofianita Mutalib  
Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA  
40450, Shah Alam, Selangor, Malaysia

**Abstract**—With the wide usage of World Wide Web (WWW) and social media platforms, fake news could become rampant among the users. They tend to create and share the news without knowing the authenticity of it. This would become the most critical issues among the societies due to the dissemination of false information. In that regard, fake news needs to be detected as early as possible to avoid negative influences on people who may rely on such information while making important decisions. The aim of this paper is to develop an automation of sentiment classifier model that could help individuals, or readers to understand the sentiment of the fake news immediately. The Cross-Industry Standard Process for Data Mining (CRISP-DM) process model has been applied for the research methodology. The dataset on fake news detection were collected from Kaggle website. The dataset was trained, tested, and validated with cross-validation and sampling methods. Then, comparison model performance using four machine learning algorithms which are Naïve Bayes, Logistic Regression, Support Vector Machine and Random Forest was constructed to investigate which algorithms has the most efficiency towards sentiment text classification performance. A comparison between 1000 and 2500 instances from the fake news dataset was analyzed using 200 and 500 tokens. The result showed that Random Forest (RF) achieved the highest accuracy compared to other machine learning algorithms.

**Keywords**—Data mining; fake news; sentiment classification; supervised machine learning; text mining

## I. INTRODUCTION

Fake news is now viewed as one of the greatest threats to democracy, journalism, and freedom of expression. Fake news is typically produced by people, the so-called “fakesters”, who generate an article with fake content often injected to an original real and trusted news content [1]. Although fake or satirical news can be less deceptive, intentional readers may still be deceived. Satirical news may deliberately establish a false expectation in the minds of readers through traditional meanings of dissatisfaction, taken as a face value. The untruthfulness is badly dissimulated and demand to be known [2]. According to Parikh and Atrey [3], researchers around the world have been very involved in the issue of fake news detection. Their studies have been carried out on the impact of fake news and how people react to it by viewing the title of the story, and cover image of the story. These factors might convince the readers about the content in the story or in news is realistic. Thus, the headline and image should be given more attention and take a step back and analyze the story or news after reading it so that readers might not believe the news fast enough. The fake news issues have become more popular after

the Presidential election of U.S. which makes many researchers trying to find out better solutions for machine learning classification [4].

Sentiment analysis study has taken a long time. Sentiment analysis in science and development has been the main problem of today’s world. As the number of users on social networking websites increases daily, enormous quantities of data are produced in text, audio, video, and images. Sentiment analysis as messages or posts must be carried out to decide if the sentiment is positive, negative, or neutral. Many automated classifiers are introduced to identify the text in the basic phrases, but new informal terms are applied to the current environment in the minimal spheres, which implies everything in the social realm [5].

This research focuses on filling the research gap between the machine learning algorithm and fake news challenges and assessments. Therefore, the research aims to perform research for automated prediction on fake news detection and investigate the performance of the machine learning technique to predict the fake news using text classification of the data. Manual analysis of the textual review can be frustrated and tedious. Some of data contains a lot of textual unrelated and unimportant message and this would be some challenges to define the best text representation for the textual classification.

In this research work, the textual classification and prediction can help an organization, a group of teams, or the other people to understand and expose more to the efficiently and effectively of fake news detection. Despite that, the automated natural language processing concept will be proposed and implemented that can be adaptive by the business or some organization to handle the hugely massive fake news textual data that show the genuinely comes from the truth sources. The remainder of this work is structured as follows: Section 2 presents the literature review. Section 3 explains the methodology of the research. Section 4 describes the result and discussions, and Section 5 explains the conclusion and future work that can be made to improve the research.

## II. LITERATURE REVIEW

Sentiment analysis or opinion mining, as it is often called, is indeed one of the computational studies that discuss the analysis of opinion-oriented natural languages [6, 7]. These opinion-oriented work comprises, along with other aspects, gender disparities, emotion, and attitude detection, ranks, evaluations of significance, textual perspective, description of source documents, and descriptive opinion [8]. The sentiment

analysis puts together several fields of research, such as natural language processing, data mining and text mining. The purpose is to use artificial intelligence tools in the activities, and to simplify and develop their goods and services which are becoming extremely essential for the enterprises. The goal is to discover views of people articulated in the written language (text) in sentiment analysis or opinion mining [9].

Machine learning techniques are particularly effective for classifying sentiments in positive, negative, or neutral types for classified document [10]. Training and testing datasets are needed in machine learning techniques. A testing data collection is used to study the documents and to verify the accuracy of the evaluation dataset. To classify and evaluate the performance of fake news data, some machine learning techniques were utilized and modelled. Based on the literature findings, there are four common classification machine learning models that have been used in many research to build the model which are Support Vector Machine, Naïve Bayes, Logistic Regression and Random Forest classifier [e.g: 11, 12, 13].

Few studies on comparing the machine learning classification algorithms on fake news have been conducted. For example, Hasan, et al. [11] has performed lexicon-based sentiment analysis (W-WSD, SentiWordNet and TextBlob) with two machine learning algorithms, Naïve Bayes and Support Vector Machine. The finding shows that W-WSD has a better result when analyzing the Tweets. Another research was by Aphiwongsophon and Chongstitvatana [12] who have conducted the experiments using Naïve Bayes, Neural Network and Support Vector Machine classification algorithms to detect fake news. The result shows that Naïve Bayes has the accuracy of 96.08%, and Neural Network and SVM provide the accuracy of 99.09%. Next, Hiramath and Deshpande [13] proposed fake news detection system based on classification using Logistic Regression, Naïve Bayes, Support Vector Machine, Random Forest, and Deep Neural Network for detecting fake news. The result shows that deep neural network is more crucial in detecting the fake news.

### III. RESEARCH METHODOLOGY

This research is conducted using CRISP-DM methodology. CRISP-DM is a modelling process which provides a data mining framework that could be used in technology and industry sectors to improve cost-effectiveness, reliability, repeatability, and speed for large data mining projects [14]. Fig. 1 shows the six phases of CRISP-DM methodology namely business understanding, data understanding, data preparation, modelling, evaluation, and deployment. The explanation of each phase will be explained in the next subsections.

#### A. Phase 1: Business Understanding

Business understanding is the first place of this research area. In this phase, the main area that will be examined is issues that are related with fake or real news and the representation of text and the lexicon-based method [15] to preprocess the textual data that are consider the point and significant phase in this text mining project. The initial business understanding phases emphasis on understanding the

business objective from business point of view, then changing over this knowledge into a research question, and after that create a research plan to accomplish the research objectives. This phase involves two activities. The first activity focuses on delivering research title, problem statement, research objectives, and research significance. While the second activity focuses on delivering the literature review to understand how previous scholars conduct the research in this area, for example what techniques have been used, what are the research findings, and what are the limitation of their research.

#### B. Phase 2: Data Understanding

This phase requires the researchers to obtain the required data and transformed it into a format that could be mined using data mining tools. Two activities are involved in this phase. The first activity is conducting data gathering. In this study, we used dataset from Kaggle website. However, this dataset might occur data incompleteness and data redundancy. Hence, several alternatives need to be applied to solve the problems, such as replace with alternative data source, gather new data, or narrow down the research scope. For this research, the dataset of Fake News Prediction consists of 12999 instances news with 20 attributes included the news title, authors, and others in year 2016 when the US President Election was happened. The second activity is to verify the quality of data. Up to this phase, data has been examined and studied, hence, it is crucial to confirm whether the data is good enough to support the objective of this research. Any missing value or error need to be identified and come out with the lists of action that can be taken to overcome this issue.

#### C. Phase 3: Data Preparation

Data preparation refers to preprocess the dataset for the modelling phase. This activity needs to perform multiple times to ensure the quality of the data. Fig. 2 illustrates the five stages of data preparation process which consists of data selection, data cleaning, data construction, data integration and data formatting. However, for this text mining research, the process is slightly different from the data mining process where some of the stages will happen in the middle of the modelling phases and not before. This is the flexibility of adapting CRISP-DM framework for textual mining research.

Fig. 1. Life Cycle of CRISP-DM [14].

Fig. 2. Data Preparation Process.

#### D. Phase 4: Textual Data Labelling

Before the sentiment text classification performance can be compared, the model of the sentiment text classification must be constructed first. Fig. 3 shows the work flows of textual representation process.

The process starts with preprocessing the raw text data from the Fake News Dataset. Then, the data is transformed into a tokens and tags formation in Data Selection, which has been filtered and cleaned. When the data is ready, the preprocessed text will be sent to the sentiment analysis to label the sentiment from the review text data. Hu and Liu [16] sentiment analysis widget is based on the lexicon has been chosen for these activities. Unlike Vader method [17], Liu Hu method is simpler, which generate a single output of sentiment integer. However, the sentiment integer label is not represented as sentiment classification. The comparison result between the use of Liu Hu and Vader methods will be shown later in the results and discussions section. Therefore, the unsupervised label integer sentiment needs to classify using the hierarchical clustering technique. The purpose of this technique is to cluster integer sentiment that has close relations to classify into three groups of sentiment classification. Thus, the negative integer sentiment label will cluster under the negative values, the positive sentiment label will cluster under the positive values and the neutral sentiment label will cluster between -1 and 1 values.

#### E. Phase 5: Modelling

Orange data mining toolkit has been used in this phase to show the relationships between data in an understandable figure. The modelling method in this study is divided into three tasks, which consist of textual representation using a sentiment rating model, a content comparative model, and a predictive model. The process flow of architecture design in this research is shown in Fig. 4. The cleaned dataset derived from this phase was fed into the Designing Test task. There is one process occurred here, which is training process. To train the models, four machine learning algorithms are selected namely Naïve Bayes, Logistic Regression, Support Vector Machine and Random Forest. The selection of a best classification model is based on the highest coefficient accuracy result. The prediction model will use the same dataset during the model building phase. This is to produce the best classification model in predicting the fake news dataset.

A predictive model will be developed during this process. The Orange data mining prediction model is transparent and simple. Fig. 5 shows the prediction model process workflow. The prediction analysis uses the same data sets for classification model as the data set. The model is therefore nearly similar to the one for the performance analysis, in which the beginning component before the word bag is the same. The data sampler module is then used to separate the datasets into training and test results. The method of sampling is the one-on-

10-fold testing of the selected fold. One-fold will select 2000 instances from 6525 instances of datasets of input. The data sample serves as the test data and connects to the prediction module. In the meantime, the rest of the data acts as training data and connects to the learning algorithms.

Fig. 3. Textual Representation Process Workflow.

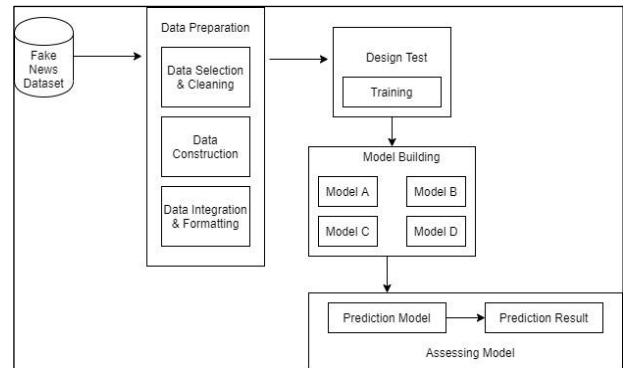

Fig. 4. The Process Flow of Architecture Design .

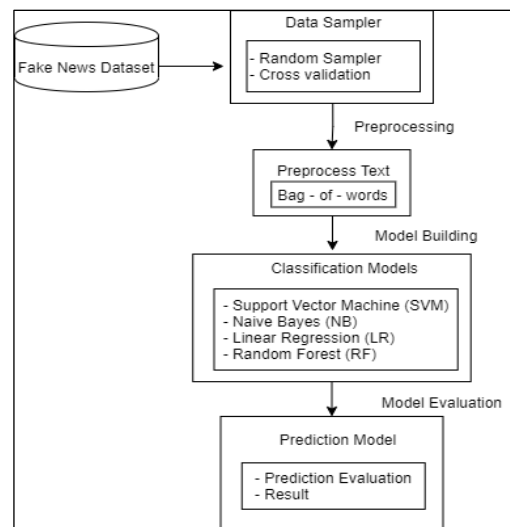

Fig. 5. Prediction Model Process Workflow.

Then, performance of each model is compared for sentiment classification. The process begins with the Data Sampler where the random sampler and ten-fold cross-validation will be done in this process using the same dataset. Then, the preprocess text activity and bag-of-words activity is combined to produce the clean data. For classification models, four accessible machine learning algorithms in the literature [18] has been determining to assess the performance of machine learning on sentiment classification. The selected machine learning algorithms are Support Vector Machine, Naive Bayes, Logistic Regression, and Random Forest. Each of classification model was developed through the training and testing process, following the supervised method. For that training and testing process, both the cross-validation approach was applied with 10 folds and hold out method through random data sampler, with 66% of dataset as training set and 34% of dataset as testing set.

#### F. Phase 5: Evaluation

In the evaluation phase, the performance of the predictive model is evaluated. The model is assessed in terms of precision, accuracy, recall and value of F1 classification. Error rates are used by supervised classification tasks to assess the consistency of data mining process. The dataset is also measured by the difference in the value of fixed data and the most common tokens for determining whether the data set size may affect the machine performance. If the process is failed, it is necessary to identify any possible reasons why the model did not satisfy the requirement. The data mining process also need to check thoroughly if there is existing additional process of iterations that can be made. The evaluation on the results from the comparison of the classification algorithms is performed on the dataset. In comparison, the assessment of datasets involves 10 cross validation directories and 10 random samples containing 60 per cent training results. This is an important experiment to determine how well the model can predict based on the data sets of training. There are two categories of performance measure that comprises of accuracy measures, as in (1) and error measures, as in (2). These performance measures will be discussed in the results and findings section.

$$\text{accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$\text{error rate} = \frac{FP+FN}{TP+TN+FP+FN} \quad (2)$$

#### G. Phase 6: Deployment

Deployment is the final phase of the CRISP-DM approach. This phase requires all the process involves in this research are documented properly. Every part of the experimental results and comparative textual analysis from findings of this research are discusses and presents.

### IV. RESULT AND DISCUSSION

This section discusses the results and findings of the applied classification methods that had been chosen. It also provides the analysis on the trained and testing results based on

ten folds cross-validation and sampling methods of 66% training set and 34% testing set. The first experiment is performed to determine the label of each record in the Kaggle fake new dataset. This is a crucial process for textual classification using supervised method. The second experiment is focused on evaluating the performance of machine learning algorithms, which are Naïve Bayes, Logistic Regression, Support Vector Machine and Random Forest, for textual classification problems in the fake news data set. The third experiment is to compare the four machine learning algorithms with top frequent tokens. To compare the quality of the machine learning algorithms, the researchers used different performance measures such as accuracy score, precision, recall, and F-Score.

#### A. Experiment 1: Labelling of Textual Data using Lexicon Scores

Textual representation model experiment is more likely to a sentiment classification model where it has been conducted to prove the effective way to automated sentiment analysis through textual representation. Initially, the textual data and type of data is selected using select columns and corpus. Then, the raw data will be sent to preprocess text module which need to go through several stages to prepare the data for the sentiment analysis process. The text preprocessed activities generate 673862 based on the tokenization and uni-gram with bi-grams technique. Among all the token generated, 45183 types were identified as unique tokens. All the generated tokens will be feed into sentiment analysis widget to predict and label the sentiment on each news text. The sentiment classification labelling is conducted using lexicon-based dictionary approach by Liu Hu and Vader [16, 17] which produces the sentiment value. The sample of two lexicon-based sentiment is shown in Table I. Based on the sample of bias type, the first news text sentiment is bias with a negative value of sentiment. The second news text sentiment is also bias but with a positive value of sentiment.

The next process is to group the sentiment values to represent textual labels. Hierarchical clustering has used with distances to produce ten clusters contains positive sentiment values, negative sentiment values and lastly neutral sentiment values. A result of hierarchical clustering with Top-N = 10 selections for the three textual representation models for (a) Liu Hu [16] and (b) Vader [17] methods using ‘ward’ as the linkage between the attributes and 10 levels of pruning were compared. The 10 Top-N was chosen for this experiment because of the sentiment values show the random and mixture values of sentiments, so to make the next process easier, and an “Edit Domain” widget is used to group the 10-clusters into the three categories which is positive, negative, and neutral groups. Fig. 6 shows how the 10 Top-N cluster was categorized and labelled into three clusters group of positive, negative, and neutral sentiment according to sentiment values produced in hierarchical clustering chart in Fig. 7 (Liu Hu method) and Fig. 8 (Vader method).

TABLE I. SAMPLE OF LEXICON-BASED SENTIMENT

News Text	Type	Sentiment
Print They should pay all the back all the money plus interest. The entire family and everyone who came in with them need to be deported asap. Why did it take two years to bust them? Here we go again ...another group stealing from the government and taxpayers!	Bias	-1.961
Share on Facebook You've got to hand it to this guy for such an ingenious, yet simple design. The how-to example in the video below is made from approximately 12 feet of copper tubing plus a few fittings (the stainless steel tube option is shown too). Follow the instructions in the video below to learn how to build it yourself. If a torch isn't something you have in your tool kit you can find "push on" fittings from a hardware store that you won't need to solder.	Bias	1.786
Today Dr. Duke and Dr. Slattery talked about Hillary's clear acts of treason against the United States by providing massive shipments of weapons to Saudi Arabia at a time that she knew they were providing support to ISIS. Dr. Duke, if elected to the Senate, would be in a position to expose Hillary and push for her impeachment should she win (steal) the election. BLOOD ON THE TRAITOR'S HANDS!	Hate	0.784
Today Dr. Duke discussed the state of his campaign, including television commercials that he was preparing. He will be in a televised debate with the other leading candidates, which should be critical in putting him in the run off. Pastor Mark Dankof took over the show at the break. He took calls from listeners. One call asked about Jesus's warning about the Synagogue of Satan. Pastor Dankof ended the show with a passionate warning about the risk of World War III should Hillary be elections. This is another great show that you won't want to miss.	Hate	-1.370
COLUMBUS, OH (AP) — History was made today in Columbus, Ohio when more than 3 million Amish poured into the city to see the American Amish Brotherhood (AAB), an organization which acts as an informal governing body for the Amish community, endorse Donald Trump for president. That number represents a significant portion of the total Amish population, which the United States Census Bureau says numbers more than 20 million men and women nationwide all pledging their vote to Trump for President. Fig. 6. Edit Domain Widget Process.

The comparison results of hierarchical clustering between Liu Hu [16] and Vader [17] methods does not show a lot of differences, but from other perception, Liu Hu method shows the most useful information that needed in this experiment as it uses lexicon-based sentiment analysis to classify each data in the dataset. Liu Hu method is easier because it shows the result of the sentiment directly and the values of sentiment for each cluster using the 'edit domain' widget. While for Vader method, the result from the hierarchical clustering shows a 'pos', 'neg', 'neu' and 'compound' values. The result from Vader method makes this experiment confusing because there is too much value of sentiment with the compound values that we define it was not useful for this experiment. So, for the next experiment Liu Hu's method will be chosen.

By referring to the text reviews in Table I for the bias texts, the negative and positive value sentiments are due to hierarchical clusters of Ward linkage combine with Euclidean on distances widget. The probability of correcting the precise opinion would evaluate the distance between two points in the line and then measure the number of squared differences within

each of the clusters. This means that most of the result is close to the average neutral sentiment. The findings of the output sentiment can be acknowledged therefore by analyzing the dispersal plot between the output sentiment and the text types ranking scale.

**B. Experiment 2: Classification Model Construction**

In the evaluation of prediction models, the same dataset was used to compare the output sentiment result of the automated sentiment classification based on the lexicon-based approach in Experiment 1, and the result of the prediction model using LR supervised machine learning in Experiment 3. The only different in dataset for Experiment 2 is the dataset will be split into two subsets of data using ‘data sampler’ widget for the training dataset and the testing dataset. Based on the confusion matrix for prediction model in Fig. 9, negative prediction on sentiment text classification is 100%, which shows that the accuracy is perfect. However, the percentage results for this dataset are likely to change after inserting more data. The highest value of misclassified is through neutral sentiment, which is 5.1%. However, the misclassified sentiment cannot assume as wrongly predicted. For example, in Table II, it shows the differences value of misclassified for Naïve Bayes is quite high but for correctly prediction, Naïve Bayes provides the highest accuracy among the other classifiers. Based on the situation, the researchers conclude that by using machine learning algorithms, the automated sentiment text classification can be improved.

	negative	positive	neutral	Σ
Actual negative	100.0 %	0.0 %	1.4 %	366
Actual positive	0.0 %	100.0 %	3.7 %	83
Actual neutral	0.0 %	0.0 %	94.9 %	801
Σ	354	52	844	1250

Fig. 9. Sample of Confusion Matrix of Prediction Model.

TABLE II. DATA AND PREDICTION USING MACHINE LEARNING CLASSIFIERS

Classifier	Support Vector Machine (SVM)	Random Forest (RF)	Naïve Bayes (NB)	Logistic Regression (LR)
Correctly Classified	99.8%	99.9%	84.0%	96.7%
Correctly prediction	99.6%	99.3%	99.7%	92.8%
Misclassified	12.0%	8.4%	56.4%	7.4%

**C. Experiment 3: Comparison Performance Model with Top Frequent Tokens**

The third experiment was conducted to compare four machine learning strategies for sentiment text classification with selected terms. The models are developed using a bag of words and four supervised machine learning technology, which includes Support Vector Machine, Naïve Bayes, Logistic Regression and Random Forest. The news text will be pre-processed by text and sent to bag-of-words to count the number of words occurring in the news text. Then two setups for experiments using four machine learning techniques of supervision are carried out. To assess the efficiency of this machine learning, four main efficiency indicators (KPI) will be evaluated which are classification accuracy, F-1 Score, Precision and Recall.

Table III shows the machine learning classification accuracy based on fixed proportion data and the number of tokens that are most common, as the first set up. The effect based on the number of tokens can be seen by comparing Set A for 1000 instances with 250 most frequent token, Set B for 1000 instances with 500 most frequent token, Set C for 2500 instances with 250 most frequent token and Set D for 2500 instances with 500 most frequent token.

TABLE III. CLASSIFICATION ACCURACY BASED ON SIZE DATA AND THE AMOUNT OF TOKENS

Label	Classifier	SVM	NB	LR	RF
Set A	50% proportion of data (1000 instances) with 250 most frequent tokens	96.2%	87.6%	94.9%	<b>98.7%</b>
Set B	50% proportion of data (1000 instances) with 500 most frequent tokens	<b>99.4%</b>	86.3%	93.4%	97.8%
Set C	50% proportion of data (2500 instances) with 250 most frequent tokens	55.6%	48.9%	45.1%	<b>58.4%</b>
Set D	50% proportion of data (2500 instances) with 500 most frequent tokens	49.2%	35.8%	54.6%	<b>60.2%</b>

The results show that the amount of the most frequent tokens (Set B and Set D) does not affect the classification accuracy, while the lowest number of tokens show a higher classification accuracy (Set A and Set C). By contrast, the effect based on the size of proportion data can be seen by comparing Set A with Set C and Set B with Set D. The

different of classification accuracy for comparing these set is quite high. Thus, this can conclude that the size of proportion data is affecting the classification accuracy but not heavy. One unanticipated finding was that all the classification accuracy of A is higher when the size proportion of data is bigger for Set A with Random Forest accuracy 98.7% except Set B for Naive Bayes, Set C for Logistic Regression and Set D for Naive Bayes. Surprisingly, Support Vector Machine has the highest achievable classification accuracy of 99.4% with a variable of high proportion data and high frequent token in Set B. However, with 2500 instances for 250 and 500 most frequent tokens in Set C and Set D show that the classification accuracy for all four methods was unsatisfied, whereby the classification accuracy for Set C shows that Random Forest with highest accuracy of 58.4% and the highest accuracy for Set D is 60.2% for Random Forest. In conclusion, variable Set B shows the best option for creating classification accuracy with the highest result and can be considered to adopt for the next experiment.

In the second set up of experiment, the machine learning performance were evaluated based on the sampling approach, which are ten folds cross-validation and ten repeat train or test random sampling with 60% training set size. The same data for the four KPIs will be analyzed in these experiments to studies the performance of a machine learning technique for textual sentiment classification. Later, the confusion matrix will be applied to observe the proportion between the actual and predicted class. With the confusion matrix, a misclassified instance can use to review the textual data in detail to discover the reason behind it. Table IV and Table V show the KPI of machine learning algorithms for textual sentiment classification using 1000 instances and 2500 instances. The results for show that the highest classification accuracy is 98.5% for 1000 instances and 99.9% for 2500 instances using Random Forest algorithm. By comparing between sampling type, the different of KPI for all algorithms are not much except for Naïve Bayes algorithm. All algorithms have slightly higher KPI result for using ten folds cross-validation sampling except for Naïve Bayes, which KPI result is better on ten folds cross-validation. As the conclusion from this experiment, both

sampling approaches give almost the same value of classification accuracy results and do not contribute to classification performance.

For further analysis, the confusion matrix in Fig. 10 and Fig. 11 shows the comparison of the proportion of the predicted sentiment on the text datasets with 1000 instances and 2500 instances. The results show that most predicted correctly is positive sentiment of fake news for 1000 instances is 82.1%, while for 2500 instances is 98.8% of positive sentiment for fake news. However, neutral sentiment for fake news in Fig. 10 archived 100% accuracy, while Fig. 11 shows the highest accuracy of neutral sentiment is 99.7%. In contrast, negative sentiment for fake news in both result shows lower accuracy compared to the rest. In conclusion, the bigger proportion of data to be tested, the bigger accuracy can be classified and evaluated, compare to the small proportion of data that predicted as positive, negative, and neutral sentiment.

Fig. 10. Confusion Matrix of Predicted Sentiment using 1000 Instances.

Random Forest (RF)	99.9%	99.9%	99.9%	99.9%	99.8%	99.8%	99.8%	99.8%

## V. CONCLUSION AND RECOMMENDATION

The study includes the comparison of four classification algorithms to evaluate the performance of classification accuracy in sentiment text classification. The evaluation process includes several aspects such as the size of data, amount of token, and test sampling approach. A 1000 instances dataset and 2500 instances dataset with different values of 250 and 500 most frequent tokens were applied in this experiment. The four classification algorithms used in this experiment are Support Vector Machine, Naïve Bayes, Random Forest and Logistic Regression. By that, a model was evaluated to measure the accurateness and the exactness of the model to make a prediction on a new dataset. Prior to the model evaluation, the model was able to predict all the fake news correctly, which makes the model reliable and trustworthy to be used to predict the fake news detection status.

However, there are some limitations in this research that need to be highlighted. Firstly, Orange toolkits have some technological weakness and limitation when managing massive databases. This work will therefore process randomly 1,000 fake news and 2500 fake news from the initial data sets out 12999 total of fake news during US Presidential Election in 2016. Secondly, this research focuses on the Fake News Detection dataset, which focused on a single objective. The research can be applied to another dataset such as from twitter or social media to mine the knowledge from the text deeper to understand its sentiment. Lastly, in the case of model validation using a cross-validation and/or an individual validation method, Orange Toolkits provide the facilities but cannot save the model and need to rebuild the model each time for the next data set.

For some future work, there is another feature and word representation approach that can be used for text mining project. Nevertheless, in this research there is only focuses on bag-of-words feature approach. There is a possibility that another feature approach can increase classification accuracy performance. Based on literary research, the sentiment analysis may be carried out with the modification of lexicon-based dictionary using a specific language. For more study, an automatic sentiment analysis multi-classification is also can be done for future work.

**Abstract**—Previous studies have considered scheduling schemes for Internet of Things (IoT)-based healthcare systems like First Come First Served (FCFS), and Shortest Job First (SJF). However, these scheduling schemes have limitations that range from large requests starving short requests, process starvation that results in long time to complete if short processes are continuously added, and performing poorly under overloaded conditions. To address the mentioned challenges, this paper proposes an analytical model of a prioritized scheme that provides service differentiation in terms of delay sensitive packets receiving service before delay tolerant packets and also in terms of packet size with the short packets being serviced before large packets. The numerical results obtained from the derived models show that the prioritized scheme offers better performance than FCFS and SJF scheduling schemes for both short and large packets, except the shortest short packets that perform better under SJF than the prioritized scheme in terms of mean slowdown metric. It is also observed that the prioritized scheme performs better than FCFS and SJF for all considered large packets and the difference in performance is more pronounced for the shortest large packets. It is further observed that reduction in packet thresholds leads to decrease in mean slowdown and the decrease is more pronounced for the short packets with larger sizes and large packets with shorter sizes.

**Keywords**—Delay tolerant; delay sensitive; internet of things; mean slowdown; prioritized scheme

## I. INTRODUCTION

The recent advances in technologies have led to the emergence of Internet of Things (IoT) [1], [2] that interconnects everything around us, including sensors, devices and systems and also supports a range of applications. IoT has been applied in several domains including but not limited to remote health monitoring [3]. IoT-enabled remote health monitoring systems have huge advantages over traditional health monitoring systems and are likely to improve the future of healthcare monitoring and emergency management.

In remote health monitoring, the IoT-based physical monitoring devices need to transmit collected data in real time, with low latency and in a highly reliable way so as to ensure accurate monitoring of patients. This is because healthcare systems are highly time-sensitive and require minimal delay.

Specifically, it is required that medical emergencies are given precedence in reporting over other regular services [4]. Further to this, transmission services for medical signals should be classified based on the different signal requirements. Besides, low latency is important for healthcare environments such that in cases of emergencies timely notification allows the medical personnel responsible to respond accordingly [5],[6].

The traditional computing server scheduling schemes are not ripe enough to provide services to IoT based healthcare services due to the heterogeneity of IoT applications and traffic which require different levels of service guarantees [7].

Healthcare IoTs may tolerate delays ranging from milliseconds to microseconds [8], [9]. Increase in the data size leads to increase in delay for the healthcare IoT applications and for time-sensitive applications the delay may vary from milliseconds to minutes [8], [10], and this worsens the performance of real time healthcare IoTs [11], [12].

While, scheduling traffic in healthcare systems, the following issues need to be addressed [13]:

1) *Emergent medical situations* should be given precedence in reporting than those with regular importance. This is because excessive delays in the transmission of emergent medical situations may deteriorate health services to patients. To address this issue, this study prioritizes delay sensitive packets over delay tolerant packets.

2) *Transmission services* for non-emergent medical situations should be differentiated by their heterogeneous delay sensitivities with regards to different application purposes. Applying absolute priority rule can maintain the transmission priorities among different medical levels, but may lead to tremendously large waiting delays for “less important” packets and yet the “less important” medical packets are also critical components of patients’ health profiles. To address this issue, service differentiation is implemented, in this study, to differentiate the traffic based on the delay sensitivity of the traffic and also based on the size of each packet, with the short packets being serviced before large packets in order to improve on the number of requests served per unit time.

3) *Healthcare IoT* devices generate huge volumes of healthcare data which results in high data traffic that causes network congestion and high latency [18]. By servicing short packets before the large packets, the number of packets served will increase hence reducing the congestion.

Recent developments within the research community provide numerous scheduling schemes for IoT-based healthcare systems namely: First Come First Served (FCFS) [19], Shortest Job First (SJF) [24], [25], preemptive resume service priority [20]. Unfortunately, these schemes have limitations that range from large requests starving short requests [19], process starvation that results in a long time to complete if short processes are continuously added [24], to high priority requests starving lower priority requests [6].

To address the above limitations, this study formulates an analytical framework for the performance evaluation of IoT-based healthcare heterogeneous delay-sensitive multi-server priority queuing system based on the formulated packet transmission scheduling.

The contribution of this paper is two-fold. Firstly, the study developed models of mean slowdown for the prioritized scheduling scheme for IoT-based healthcare monitoring systems. Secondly, the performance of the proposed models is evaluated against the FCFS and SJF scheduling schemes. The rest of the paper is organized as follows: Section II is related work. The analytical models are presented in Section III, while Section IV presents the performance evaluation, discussions are presented in Section V, conclusion in Section VI and future work is presented in Section VII.

## II. RELATED WORK

First-Come-First-Served (FCFS) scheduling scheme applied in [19] is the simplest scheduling policy where requests are served according to their order of arrival. As a non-preemptive scheduling discipline, once a request has a server, it runs to completion. One of the major drawbacks of FCFS scheme is that the emergent healthcare packets are completely starved of service and this increases the average waiting time of emergent healthcare packets which may result into serious issues in healthcare including death.

Therefore, scheduling techniques that provide fairness to all competing packets is required in the allocation of resources to prevent starvation of some packets.

Preemptive resume service priority introduced in [20] is a scheduling scheme where incoming traffic are prioritized into normal and emergency traffic, where normal traffic has low priority and emergency traffic has high priority. This scheduling is based on preemptive priority mechanism where a higher priority traffic is serviced before a low priority traffic but each category of traffic is served in a FCFS order. A lower priority traffic is preempted on arrival of emergent traffic and the lower priority traffic could be dropped if the buffer is full so as not to cause data loss or delay of sensitive traffic. However, the weakness of preemptive resume service priority is that when high priority rate exhibits high arrival rate, the low priority traffic is starved. Hence, there is need to place a threshold on the amount of high priority traffic to be serviced

during high arrival rate of high priority traffic so as not to starve the low priority traffic.

A priority-aware truthful mechanism for scheduling delay constrained medical packet transmissions in IoT-based healthcare networks is proposed in [13]. The study considered multiclass health packets from the biosensors arriving randomly at each gateway and their delay-constrained transmission requests are immediately reported to the base station. The base station schedules the transmissions by including the priority and the delay constraints of medical packet transmissions. However, the limitation of this scheme is that; the absolute prioritized transmission used naturally results in a non-preemptive priority queueing, where under high arrival rates of higher priority medical packets, the lower priority medical packets are starved. In addition, the servers (channels) are taken to be homogeneous implying same characteristics, which in reality is not the case being that different channels have different characteristic and can be modeled as heterogeneous servers.

In [22], a dynamic scheduling of beyond-WBAN medical packet transmissions is modeled by  $M/G/K$  queues with a Poisson packet arrival, generally distributed service (transmission) time and priority disciplines. The system consists of a gateway, a number of heterogeneous biosensors worn on different parts of the human body and the Base Station (BS). The BS serves the packets in a priority order with emergent medical packets being given a higher priority over those with regular importance. In scheduling, some channels are completely reserved for emergent medical packets and the balance of the channels are reserved for non-emergent channels. However, when channels are completely partitioned for each packet class, the use of the un-utilized channels of one class of packets cannot be used by other classes of users and therefore the capacity is wasted.

T. Aladwani [23] proposed to use fog computing between sensors and cloud computing to reduce the amount of data that is transported between the cloud and the sensors. In addition, the authors improved task scheduling algorithm by making the main factor in giving priority to tasks their importance regardless of their length. The authors proposed a new method of scheduling called Tasks Classification and Virtual Machines Categorization (TCVC) based on tasks importance. Tasks that are received by IoT are classified based on their importance into three classes: high importance, medium importance, and low importance tasks based on the patient's health status. In scheduling, critical tasks take high importance, important tasks take medium importance, and general tasks take low importance. The limitation of this scheme is matching the virtual machine's capability to the important of tasks, and also under high arrival rate of higher priority tasks, the lower priority tasks are starved of service.

SJF scheduling policy has been used in scheduling tasks in healthcare systems, for example, an innovative IoT based remote healthcare monitoring system by using Free RTOS with priority scheduling based on SJF is proposed in [24]. The proposed system provides vital health information and live video of a patient who is located in a rural area. A framework that utilizes the 5G network's low-latency, high bandwidth

functionality to detect COVID-19 using chest X-ray or CT scan images, and to develop a mass surveillance system to monitor social distancing, mask wearing, and body temperature using the SJF policy is proposed in [25]. The weakness of the SJF scheduling algorithm is that it gives priority to tasks based only on their length. This leads to unfairness, as the large tasks must be waiting in the tasks list until the smallest tasks finish execution even if it is important.

In summary, the limitations of the existing studies include; lack of a fair scheduling scheme that prioritizes traffic in the system without penalizing other classes of traffic, lack of scheme that caters for the dynamic changes in the periods, starvation of emergent healthcare packets, and lack of optimized frameworks and algorithms in allocation of system resources.

In contrast to the existing work reported in the literature, this study proposes an analytical model that will aid in studying and analyzing performance of healthcare monitoring systems considering different packet sizes and packet thresholds.

### III. SYSTEM MODEL

The healthcare monitoring system consists of heterogeneous healthcare monitoring data packets from different independent sensors mounted on the body to monitor different health situations. In the considered system model as shown in Fig. 1, the heterogeneous data packets generated by the different sensors arrive randomly to the network gateway following a Poisson process, the Poisson distribution has been found to approximate well the arrival patterns of healthcare data packets [26], [27].

Fig. 1 shows the queue system model with healthcare data packets generated from different sensor nodes mounted on the body.

The gateway is required to immediately declare a transmission packet along with the corresponding packet priority based on the time sensitivity of the packets, this is done at classifier 1, where requests are classified into delay sensitive and delay tolerant based on their delay requirements, for example EEG/ECG/EMG has delay requirement of less than 250ms, Glucose monitoring less than 20ms, Blood pressure less than 750ms, Endoscope imaging less than 500ms [13]. Examples of delay tolerant traffic include access to a patient’s Electronic Health Records; home tele-monitoring, medication dispenser data, etc. [14].

Fig. 1. Queue System Model.

A major requirement in scheduling transmissions of multiclass healthcare packets with different criticality is the priority awareness [28]. For each queue of the delay sensitive or delay tolerant classes, packets are queued in the buffers assumed to be infinite. For each of the delay sensitive and delay tolerant classes, the data packets are further classified as short or large based a threshold. Short packets are chosen for the next execution before the large packets, the idea being to reduce the average waiting time for other packets awaiting execution. After classifying the packets by their sizes, the packets are forwarded to the scheduler which allocates the packets to the different servers. This scheduling scheme considers shared servers for each priority class. Considering the diversities in terms of packet sizes, the transmission time of healthcare packets can be represented by a generic random variable, that is, follows the general service distribution [13]. In particular, the service rate of packets will follow the exponential distribution [21]. The probability density function of an exponential distribution is given as [13]:

$$f(x) = \mu e^{-\mu x}, x \geq 0, \mu \geq 0 \quad (1)$$

where  $\mu$  is the service rate and  $x$  is the size of the packet. The proposed policy is a delay sensitive non-preemptive size-based scheduling policy where packets are classified as delay sensitive or delay tolerant at the first priority level and also on their sizes, namely  $(x_s)$  and large  $(x_l)$ . For each delay sensitive or delay tolerant classes, short packets are served before large packets. Within each class, packets are served in a FCFS order using multiple servers. The system model can be represented as a multi-server queue. For each queue of the delay sensitive or delay tolerant classes, packets are queued in the buffers assumed to be infinite. The queue model can be formulated under the following assumptions:

The arrival rate follows the Poisson process with parameter  $\lambda_i, i = 1, 2$ , where  $\lambda_1$  is the arrival rate of delay sensitive packets and  $\lambda_2$  is the arrival rate of delay tolerant packets.

The service times of each server is independent and identically distributed exponential random variable with

parameter  $\mu_i, i = 1, 2$ , where  $\mu_1$  is the service rate of delay sensitive packets and  $\mu_2$  is the service rate of delay tolerant packets.

There are  $m$  servers through which the service is provided.

The capacity of each server is finite,  $N$ .

The above system can be represented as an  $M/M/m/N$  queue system, where the first  $M$  represents random arrivals of packets following the Poisson process, the second  $M$  represents exponentially distributed service time, with  $m$  servers each of finite capacity  $N$ .

#### A. Mathematical Background

Denote the probability density function of a packet of size  $x$  as  $f(x)$  defined in equation 1. The cumulative distribution function is then given as:  $F(x) = \int_0^x f(t)dx$ .

Using a naive definition of packet size based on threshold  $x_t$  which may be dynamic, all packets that have sizes less than or equal to  $x_t$  are said to be short, whereas packets that are larger than  $x_t$  are said to be large.

The load due to packets with sizes less than or equal to  $x_t$  is given as  $\rho_{x_t} = \lambda \int_0^{x_t} tf(t)dt = \frac{\lambda}{\mu}(1 - e^{-\mu x_t}) - x_t e^{-\mu x_t}$  [15], where  $\mu$  is the service rate of packets, while the load due to packets with sizes greater than  $x_t$  is given as.

$$\rho_{x_l} = \lambda \int_{x_t}^{\infty} tf(t)dt = \lambda e^{-\mu x_t} \left( x_t + \frac{1}{\mu} \right)$$

The steady state equations of the  $M/M/m/N$  queue model are derived as follows:

The probability that there are packets in the system is given as [17]:

$$P_n = \begin{cases} \frac{\rho^n}{n!} P_0, & 1 \leq n \leq m \\ \frac{\rho^n}{m!} \left( \frac{\rho}{m} \right)^{n-m} P_0, & m < n \leq N-1 \end{cases} \quad (2)$$

where  $P_0$  is the probability that the system is empty and is given by;

$$P_0 = \left[ \sum_{n=0}^m \frac{\rho^n}{n!} + \sum_{n=m+1}^N \frac{\rho^n}{m!} \left( \frac{\rho}{m} \right)^{n-m} \right]^{-1} \quad (3)$$

The expected waiting time in the queue can be deduced as

$$W_q = \frac{1}{\lambda} \sum_{n=m}^N (n-m) P_n \quad (4)$$

Hence,

$$W_q = \sum_{n=m}^N (n-m) \frac{\rho^n}{\lambda m!} \left( \frac{\rho}{m} \right)^{n-m} P_0 \quad (5)$$

We next define the expressions for the mean response time under FCFS and SJF, which will be used to compare with the prioritized scheduling scheme. An arriving packet to the FCFS queue has to wait for all packets it finds in the queue upon arrival. The mean response time of a packet of size  $x_s$  in an  $M/G/m/FCFS$  system is given as [15].

$$T^{FCFS}(x_s) = x_s + W^{FCFS}(x_s) \quad (6)$$

where  $W^{FCFS}(x_s) = \frac{\overline{\lambda x_s^2}}{2(1-\rho_{x_s})}$  and  $\rho_{x_s} = \frac{\lambda}{m\mu}$

Under SJF, the shortest packet in the queue is given priority. Therefore, at every instant, the next packet to be serviced is the smallest one in the queue. A packet of size  $x_s$  is then delayed by packets in the system that is less or equal than its size. The mean response time of the packet of size  $x_s$  under SJF is given as [15].

$$T^{SJF}(x_s) = x_s + W^{SJF}(x_s) \quad (7)$$

where  $W^{SJF}(x_s) = \frac{\overline{\lambda x_s^2}}{2(1-\rho_{x_s})^2}$  and  $\rho_{x_s} = \frac{\lambda}{m\mu}$ ,  $m$  being the number of servers.

### B. Model for Delay Sensitive Packets

Consider a tagged packet arriving to a delay sensitive queue, two scenarios arise, the first scenario is when the tagged

packet finds in the queue short delay sensitive packets being serviced, including at least one delay sensitive large packet, the second scenario includes the tagged packet arriving to a delay sensitive queue with only short packets. We consider scenario one where at least one delay sensitive large packet is found in service.

Assuming the tagged delay sensitive short packet, its service will be delayed by all delay sensitive short packets it finds in the queue and the remaining service of the large packets it finds in the servers when it arrived. The mean response time for the delay sensitive short packet of size  $x_s$  is given as [15]:

$$T(x_{ts}) = x_{ts} + W(x_{ts}) + W_r(x_{ts}) \quad (8)$$

where

$$W(x_{ts}) = \sum_{n=m}^N (n-m) \frac{\rho_{x_{ts}}^n}{\lambda_1 n!} \left( \frac{\rho_{x_{ts}}}{m} \right)^{n-m} P_0^{x_{ts}} \quad (9)$$

and

$$P_0^{x_{ts}} = \left[ \sum_{n=0}^m \frac{\rho_{x_{ts}}^n}{n!} + \sum_{n=m+1}^N \frac{\rho_{x_{ts}}^n}{m!} \left( \frac{\rho_{x_{ts}}}{m} \right)^{n-m} \right]^{-1} \quad (10)$$

$$\rho_{x_{ts}} = \lambda_1 \int_0^{x_{ts}} tf(t)dt$$

$$W_r(x_{ts}) = \sum_{n=m}^N (n-m) \frac{\rho_{x_{ts}}^n}{\lambda_1 n!} P_0^{x_{ts}} \quad (11)$$

Where

$$P_0^{x_{ts}} = \left[ \sum_{n=0}^m \frac{\rho_{x_{ts}}^n}{n!} + \sum_{n=m+1}^N \frac{\rho_{x_{ts}}^n}{m!} \left( \frac{\rho_{x_{ts}}}{m} \right)^{n-m} \right]^{-1} \quad (12)$$

and  $\rho_{x_{ts}} = \lambda_1 \int_{x_{ts}}^{\infty} tf(t)dt$

On the other hand, the delay sensitive large packet is delayed by all delay sensitive short packets found in the queue plus all delay sensitive large packets found in the queue, and the mean service time of the large packets the tagged large packet finds in the servers when it arrived. In addition, all delay sensitive short packets that arrive after the tagged large packet is in the queue will be served before the tagged large packet. The mean response time for the delay sensitive large packet of size  $x_l$  is given as:

$$T(x_{ls}) = x_{ls} + 2W(x_{ts}) + W(x_{ls}) + W_r(x_{ls}) \quad (13)$$

The term  $2W(x_{ts})$  is the contribution from delay sensitive short packets found in the queue and the delay due to the delay sensitive short packets that arrive after the tagged large packet is in the queue,  $W(x_{ts})$  and  $W_r(x_{ls})$  are as given in equations 9 and 11 respectively and.

$$W(x_{ls}) = \sum_{n=m}^N (n-m) \frac{\rho_{x_{ls}}^n}{\lambda_1 n!} \left( \frac{\rho_{x_{ls}}}{m} \right)^{n-m} P_0^{x_{ls}} \quad (14)$$

where,

$$P_0^{x_{ls}} = \left[ \sum_{n=0}^m \frac{\rho_{x_{ls}}^n}{n!} + \sum_{n=m+1}^N \frac{\rho_{x_{ls}}^n}{m!} \left( \frac{\rho_{x_{ls}}}{m} \right)^{n-m} \right]^{-1} \quad (15)$$

### C. Model for Delay Tolerant Packets

Consider a tagged packet arriving to a delay tolerant queue. In case the tagged packet is a short delay tolerant packet its service will be delayed by all delay sensitive short packets, all delay sensitive large packets and all delay tolerant short packets found in the queue. In addition, the short delay tolerant packet will be delayed by all delay sensitive short and large packets that arrive after the tagged delay sensitive short packet is in the queue will be served before the tagged delay tolerant short packet is serviced. The mean response time for the delay tolerant short packet of size  $x_{sd}$  is given as:

$$T(x_{sd}) = x_{sd} + 2W(x_{ts}) + 2W(x_{ls}) + W(x_{td}) \quad (16)$$

where,

$$W(x_{td}) = \sum_{n=m}^N (n-m) \frac{\rho_{x_{td}}^n}{\lambda_2 n!} \left(\frac{\rho_{x_{td}}}{m}\right)^{n-m} P_o^{x_{td}} \quad (17)$$

and

$$P_o^{x_{td}} = \left[ \sum_{n=0}^m \frac{\rho_{x_{td}}^n}{n!} + \sum_{n=m+1}^N \frac{\rho_{x_{td}}^n}{m!} \left(\frac{\rho_{x_{td}}}{m}\right)^{n-m} \right]^{-1} \quad (18)$$

$$\rho_{x_{td}} = \lambda_2 \int_0^{x_{td}} tf(t) dt$$

The term  $2W(x_{ts})$  is as explained for equation 13.

For the case of the tagged large delay tolerant packet its service will be delayed by all delay sensitive short packets, all delay sensitive large packets, all delay tolerant short packets and all delay tolerant large packets found in the queue. In addition, the tagged large delay tolerant packet will be delayed by short and large delay sensitive packets that arrive after the tagged delay tolerant large packet is in the queue will be served before the tagged delay tolerant large packet. The mean response time for the delay tolerant large packet of size  $x_{ld}$  is given as:

$$T(x_{ld}) = x_{ld} + 2W(x_{ts}) + 2W(x_{ls}) + W(x_{ld}) \quad (19)$$

where

$$W(x_{ld}) = \sum_{n=m}^N (n-m) \frac{\rho_{x_{ld}}^n}{\lambda_2 n!} \left(\frac{\rho_{x_{ld}}}{m}\right)^{n-m} P_o^{x_{ld}} \quad (20)$$

and

$$P_o^{x_{ld}} = \left[ \sum_{n=0}^m \frac{\rho_{x_{ld}}^n}{n!} + \sum_{n=m+1}^N \frac{\rho_{x_{ld}}^n}{m!} \left(\frac{\rho_{x_{ld}}}{m}\right)^{n-m} \right]^{-1} \quad (21)$$

$$\text{and } \rho_{x_{ld}} = \lambda_2 \int_{x_{td}}^{\infty} tf(t) dt$$

The term  $2W(x_{ts})$  is the contribution from delay sensitive short packets found in the queue and the delay due to the delay sensitive short packets that arrive after the tagged large packet is in the queue,  $2W(x_{ls})$  is the contribution from delay sensitive large packets and delay sensitive large packets that arrive after the tagged delay tolerant large packet is in the queue.

In the next section, we present the performance evaluation of the derived models in terms of mean slowdown.

## IV. PERFORMANCE EVALUATION

In order to evaluate the performance of the proposed IoT-based healthcare monitoring system, the derived models are used to plot graphs using MATLAB and in particular Simulink package was used [16]. Simulink provides a graphical editor, customizable block libraries, and solvers for modeling and simulating dynamic systems. It is integrated with MATLAB, enabling one to incorporate MATLAB algorithms into models and exporting simulation results to MATLAB for further analysis.

The performance of the proposed system is evaluated using mean slowdown as the performance metrics. Mean slowdown is the normalized response time, i.e., the ratio of the response time of a packet to the size of that packet. Unlike mean response time which tends to be representative of the performance of just a few big packets since they count the most in the mean because their response times tend to be highest [32], slowdown is a useful metric to analyze fairness of a scheduling scheme.

The paper investigates how the prioritized scheduling (PS) scheme performs compared to the FCFS and SJF scheduling schemes for short and large packets. The effect of key parameters such as packet sizes on mean slowdown is investigated.

### A. Model Parameters

Table I shows the hypothetical parameters used in the analysis which is consistent with parameters used in literature [29], [30]. The packet arrival rate and service rate follow Poisson distribution [15].

TABLE I. IMPLEMENTATION PARAMETERS

Parameter	Value
Number of servers, $m$	10 [29]
The maximum number of health data packets in the queue $N$	150 [30]
Packets arrival rate $\lambda$	6.549 packets/second [31]
Packets service rate $\mu$	8.8 packets/second [31]
The average packet size $x_r$	100 Kb [13]
Threshold size of the packet size $x_{ts}$	75 Kb [13]

### B. Evaluation of the mean Slowdown with Packet Sizes for Delay Sensitive Packets

This section presents the performance of the packets in terms of mean slowdown while varying packet sizes for delay sensitive packets.

Fig. 2 shows the mean slowdown of delay sensitive short packets under FCFS, SJF, and PS schemes where short packets are packets with sizes less or equal to  $x_s = 75Kb$ . It is also observed that some shorter packets experience lower mean slowdown under SJF than under the PS scheme. The situation is however very different as the sizes of packets increase, the PS scheme performs better than FCFS and SJF by offering lower mean slowdown. It is shown that the difference in performance between the PS scheme and SJF and FCFS is more pronounced as the packet sizes increase for short packets. It can be observed that in all cases, the FCFS scheme performs

worse than SJF and PS scheme for all packet sizes for short packets. We can also see from Fig. 2 that the PS scheme performs much more closely with FCFS and SJF for small packet sizes for short packets.

Fig. 2. Mean Slowdown for Delay Sensitive Short Packets under PS, SJF and FCFS Schemes.

Fig. 3. Mean Slowdown for Delay Sensitive Large Packets under PS, SJF and FCFS Schemes.

Fig. 3 shows the mean slowdown of delay sensitive large packets under FCFS, SJF, and PS schemes where large packets are packets with sizes greater than  $x_s = 75$  bytes. It can be observed from the figure that the PS scheme performs better than FCFS and SJF scheduling policies regardless of the packet size for large packets. In turn, FCFS also performs better than the SJF scheme for all large packet sizes considered. This is because under FCFS, there is a mix of short and large packets resulting into lower mean slowdown, whereas under SJF, large packets are serviced last and will always experience higher mean slowdown. The difference in performance is much more pronounced for shorter packet sizes, however as the packet sizes increase, the performance becomes closer as the mean slowdown values are closer.

### C. Evaluation of the Mean Slowdown with Packet Sizes for Delay Tolerant Packets

This section presents the performance of the packets in terms of mean slowdown for the PS scheme in comparison with the FCFS and SJF scheduling schemes for delay tolerant packets.

Fig. 4 shows results of PS scheme in comparison with FCFS and SJF scheduling schemes for delay tolerant short packets. It can be seen that the SJF scheme performs better than the PS scheme for shorter packet sizes, this is because delay tolerant short packets are delayed by delay sensitive large packets which is not the case under SJF where there are only short packets, however as the packet sizes increase, the PS scheme performs better than SJF by offering lower mean slowdown. Similar to Fig. 2, it can be observed that in all

cases, the FCFS scheme performs worse than SJF and PS scheme for all packet sizes for short packets. It is observed that the difference in performance between the PS scheme, SJF and FCFS is more pronounced as the packet sizes increase for short packets. In general, the PS scheme performs better than SJF and FCFS as the packet sizes increase for short packets.

Fig. 4. Mean Slowdown for Delay Tolerant Short Packets under Prioritized, SJF and FCFS Schemes.

Fig. 5 shows results of PS scheme in comparison with FCFS and SJF scheduling schemes for delay tolerant large packets. It is observed that for the considered packet sizes, the PS scheme performs better than FCFS and SJF schemes by offering lower mean slowdown; the FCFS in turn is observed to offer lower mean slowdown than SJF scheme. It is further observed that the difference in mean slowdown is higher for shorter packet sizes and closer when the packet sizes increase. The performance between PS, FCFS and SJF schemes differ specifically for shorter packets where SJF performs worse than FCFS which in turn performs worse than the PS scheme.

Fig. 5. Mean Slowdown for Delay Tolerant Large Packets under Prioritized, SJF and FCFS Schemes.

### D. Evaluation of the Effect of Packet Threshold on Mean Slowdown for the PS Scheme for Delay Sensitive Packets

This section presents the performance of the packets in terms of mean slowdown for the PS scheduling scheme for different thresholds for delay sensitive packets. In doing this, the effect of the variation of the packet threshold in terms of size is investigated.

The results of the effect of varying the packet threshold on the mean slowdown for delay sensitive short packets are shown in Fig. 6. It can be observed that the decrease in the packet threshold leads to a reduction in the mean slowdown of delay sensitive short packets. The reduction in mean slowdown is observed to be more pronounced as the packet sizes increase, however for smaller packet sizes, the packet threshold has very

little effect. When the packet thresholds are reduced, it means the number of shorter packets are reduced hence the reduction in the mean slowdown.

Fig. 7 shows the variation of mean slowdown for delay sensitive large packets under the PS scheme for different packet thresholds. It can be observed that the decrease in the packet threshold reduces the mean slowdown of delay sensitive large packets. The reduction in mean slowdown is observed to be more pronounced for large packets with smaller sizes, however as the sizes of the delay sensitive packets increase, the packet threshold has very little effect. When the packet thresholds are reduced, the large packets with shorter sizes experience a more reduced mean slowdown due to the reason presented in Fig. 6.

### E. Evaluation of the Effect of Packet Threshold on Mean Slowdown for the PS Scheme for Delay Tolerant Packets

This section presents the performance of the packets in terms of mean slowdown for PS scheduling scheme for different packet thresholds for delay tolerant packets as shown in Fig. 8 and 9.

Fig. 8 shows the variation of mean slowdown for delay tolerant short packets under the PS scheme for different packet thresholds. It can be observed that when the packet thresholds are reduced, the mean slowdown of delay tolerant short packets is reduced. The reduction in mean slowdown is observed to be more pronounced as the packet sizes increase, however for smaller packet sizes, the packet threshold has minimal effect and this is similar to the observation noted for delay sensitive short packets in Fig. 6. When the packet thresholds are reduced, the number of shorter packets is reduced hence the reduction in the mean slowdown.

Fig. 6. Mean Slowdown for Delay Sensitive Short Packets under Prioritized Scheme for different Thresholds.

Fig. 7. Mean Slowdown for Delay Sensitive Large Packets under PS Scheme for different Thresholds.

Fig. 8. Mean Slowdown for Delay Tolerant Short Packets under PS Scheme for different Thresholds.

Fig. 9. Mean Slowdown for Delay Tolerant Large Packets under PS Scheme for different Thresholds.

Fig. 9 shows the variation of mean slowdown for delay tolerant large packets under the PS scheme for different packet thresholds. It can be observed that the decrease in the packet threshold reduces the mean slowdown of delay tolerant large packets. The reduction in mean slowdown is noted to be more pronounced for large packets with smaller sizes, however as the sizes of the delay tolerant packets increase, and the packet threshold has minimal effect on the mean slowdown. When the packet thresholds are reduced, the large packets with shorter sizes experience a more reduced mean slowdown due to increased number of large packets with shorter packet sizes.

## V. DISCUSSION

This study developed analytical models of mean slowdown for the PS scheme where incoming packets are prioritized based on the delay requirement and size of the packets and serviced using multiple servers. The effect of varying packet sizes on the mean slowdown under the PS is investigated in comparison with the FCFS and SJF scheduling policies. Results from the derived models show that the largest short packets perform better under the PS scheme than under the SJF and FCFS schemes. Similar observation has been noted by SWAP policy which also favors short packets to the expense of delaying large ones within the queue [15]. On the other hand, all large packets perform better under the PS scheme compared to the FCFS and SJF schemes. By giving priority to short packets under the PS scheme, more packets are served and hence large packets do not have to wait for so long for service. Large packets perform worse under FCFS scheme because their services are interrupted by large packets whose sizes may be larger. Similar explanations hold for the SJF scheme where large packets remain in the queue for a long time and may even lead to starvation.

## VI. CONCLUSION

The PS scheduling scheme has been modeled and evaluated for varying packet sizes and thresholds. The numerical results

obtained from the derived models show the PS scheme generally reduces the mean slow down for most of the packet sizes considered. The comparison of the PS scheme with FCFS and SJF show that the PS scheme is superior in reducing the mean slowdown except for the few shortest short packets under SJF. The performance difference is more pronounced for the large packets with shorter sizes. It is also observed that short packets which are much shorter perform better under SJF than under the Prioritized scheme, however as the packet sizes increase, the PS scheme offers better performance than FCFS and SJF. It is further observed that when the packet threshold is reduced, the mean slowdown packets are reduced and the reduction is more pronounced for the short packets with larger sizes and large packets with shorter sizes.

## VII. FUTURE WORK

In this paper, numerical results for the PS scheduling scheme using multiple homogeneous servers are presented. In the future, it will be interesting to investigate the effect of using heterogeneous servers on the performance, and also the effect of varying arrival and service rates.

# A Survey on Sentiment Analysis Approaches in e-Commerce

Thilageswari a/p Sinnasamy, Nilam Nur Amir Sjaif  
Razak Faculty of Technology and Informatics  
Universiti Teknologi Malaysia  
Kuala Lumpur, Malaysia

**Abstract**—Sentiment analysis represents the process of judging customers' behavior expression and feeling as either positive, negative or neutral. Hence, a tangle of different approaches for sentiment analysis is being used, reflecting analysis of unstructured customers' reviews dataset to guide and generate insightful and helpful information. The aim of this paper is to highlight research design of sentiment analysis and choice of methodological by other researchers in E-Commerce customers' reviews to guide future development. This paper presents a study of sentiment analysis approaches, process challenges and trends to give researchers a review and survey in existing literature. Next, this study will discuss on feature extraction and classification method of sentiment analysis of customers' reviews to have an exhaustive view of their methods. The knowledge on challenges of sentiment analysis underpins to clarify future directions.

**Keywords**—Sentiment analysis; e-Commerce; feature extraction; classification; customers' reviews

## I. INTRODUCTION

Since COVID-19 is a pandemic globally and causing companies to not be able to operate normally due to locked-down with business operators to doing e-Commerce to survive [1]. e-Commerce is a safe way for consumers who make purchases for essentials and non-essentials goods and services online while staying home during the lock-down phase. E-Commerce is made possible via different online platforms. Online platform is known as e-commerce or Electronic commerce which is online transaction business used in buying and selling products through internet [2] [3]. Examples of e-Commerce are Shopee, Lazada, Zalora and eBay. These are world famous platforms selling goods, necessary products or services over the internet. However, people are doubtful of buying products from online platforms [4]. According to USA survey, there are 81% internet users who are buying products from online platform [5]. These customers express their feedback on their purchased items or services by writing reviews online at the comments section. Hence, reading other customers' feedback, comments or reviews is important to understand more about the products or services. Customers' reviews also known as Word of mouth (WOM) [3] [6] help other customers or clients to understand about the products, services and retailers. The more convincing the reviews are, the more confident the potential customers or clients will feel toward the products or services and be convinced to select and purchase them. Though customers' reviews are vital to effective customers' decision to make the right choices, the

increasing number of reviews will require a potential customer to spend more time and effort to go through each review thus affecting the decision making process to be quite tedious as the potential customer has to read each review and analyze the product or service involved before making the final decision [1] [2]. Thus, to assist customers to improve making purchase decisions, many reviews analysis methods are employed to extract useful information for customers. Sentiment analysis helps to identify and analyze customers' or clients' sentiments in their text reviews to extract and present specific information necessary to make better purchase decisions on products or services in E-Commerce. This paper contributes survey analysis results by other researchers on sentiment analysis methods future development.

The paper is organized as follows: after this introduction, level of sentiment analysis, method for identification and basic requirement of sentiment analysis is discussed in Section 2. Section 3 outlines sentiment analysis process presented with supporting examples. Section 4 reviews studies on related works from other researchers in different backgrounds and E-Commerce customers' reviews using sentiment analysis. Section 5 discusses comparative analysis table of sentiment analysis with different methods in e-Commerce. Section 6 present discussion on comparative analysis table. Finally in Section 6, the paper ends with conclusions and acknowledgements.

## II. SENTIMENT ANALYSIS LEVEL

Nowadays, the huge number of reviews requires efficient method for analyzing [4]. Customers and retailers reading thousands of reviews manually take plenty of time to classify the reviews in e-commerce using sentiment analysis method. The volume of reviews stored like mountain which requires some effective classifier to identify valuable information from text. Sentiment analysis or opinion mining is useful to extract customer's behavior by analyzing and exploring customer's reviews in E-commerce [7] [8] [9]. Customers express their emotions by writing subjective judgement about the products in E-commerce [40]. Sentiment analysis also helps to categorize the unstructured text as positive, negative and neutral whereby summarizes judgement by customers in order to understand other customer's expression and strength better about product and retailer [7] [10] [11]. Unstructured sentiments refer to detailed opinion by customer about the product [8]. Some information is explicit and others are implicit features. There are three levels of sentiment analysis:

Document-level Sentiment Analysis (DSA), Sentence-level Sentiment Analysis (SSA) and Aspect-level Sentiment Analysis (ASA).

#### A. Document-Level Sentiment Analysis (DSA)

A document talk about negative or positive sentiment is called DSA. It is extracting sentiments from whole document [8] [12] [13]. The scenario has applied the sentiment analysis of air purifier based on coarse-grained reviews whereby the researcher presented neural network model to identify semantics of sentences classification [14].

#### B. Sentence-Level Sentiment Analysis (SSA)

SSA means sentiment expressed in sentences which decide whether negative or positive. Whereby it is simple sentiment analysis for extracting sentiments or customer's experiences from sentences [8] [12] [13]. At sentence level, the researchers present phrase recursive autoencoder (PRAE) model to identify sentiment in sentences for analysis of coarse-grained reviews [14]. However, according to [14] document and sentences level sentiment analysis unable to fine-grained features from the words.

#### C. Aspect-Level Sentiment Analysis (ASA)

ASA is opinion that classifies by identifying entities and their properties by classification and extraction [13] [15]. Whereby, it is interested on opinion words only from the reviews such as "Love the Amazon show", it is clearly mentioned using the word love [12]. The aspect 'love' from the text is important feature extraction phase that needed for sentiment analysis method. At aspect level classification, researcher presents hybrid model for the analysis of fine-grained product's features [14]. It also expressed out sentiment polarity for further prediction process [16].

### III. SENTIMENT ANALYSIS PROCESS

Fig. 1 shows process flow of sentiment analysis where by divided three main stages: product feature extraction, sentiment classification and ranking alternative products [2].

Fig. 1. Sentiment Analysis Process Flow [2] [4] [15].

#### A. Preprocessed Texts

As first step, data cleaning exhibit to clean unnecessary reviews from selected dataset [17] [18]. Data preprocessing perform to remove all missing values, remove stop words, tokenization, unwanted symbols, digits and URL tags [31]. Tokenization helps divide sentences into words, phrase or symbol and remove all stop words such as 'the', 'is', 'are' and 'a' [9]. The words required to convert to lower case as preparation for next step.

#### B. Feature Extraction

Aspect extraction from unstructured data helps extract all relevant information from dataset, reduces or removes irrelevant features of data for sentiment classification whereby the method is known as feature extraction [2] [19]. Feature extraction also helps extract implicit information from reviews other than explicit opinion to give more effective and better performance. There are few methods used for feature extraction :- frequent pattern mining with association rule mining, term document matrix (TDM), parts-of-speech (POS) tagging, Maximum entropy (ME), N-gram and lexicon [2] [8] [10] [16]. Those methods have advantages and disadvantages while applying for extract features in reviews. Frequent pattern mining is itemset, subsequence or substructures which helps find sequence database [20]. Apriori algorithm with association rules is one of the approach is in many fields. Other than that, according to U.A.Chauhan with other researchers has implemented Part-of-speech to find differences between noun, adjective, verb and adverb [5]. By extracting the term, in sentences reveals the hidden story and emotions of customers to be classified positive or negative. Furthermore, TDM is implemented to compute frequency of each word using method like bag of words and term frequency-inverse document frequency (TF-IDF) [5] [21] [22] [23]. TF-IDF helps to calculate number of times the word occurs and focuses on the importance term. By extracting most frequent words, researchers can ignore words with least scores. Some implement N-gram features for extracting the features as unigram (One word), bigram (2 words) and trigram (3 words) whereby N represent number of words [22] [24]. Based on researchers, unigrams features commit to increase accuracy result in classification method. N-grams helps to avoid semantic scores, the score calculation creates domain independent sentiment dictionary and computes to eliminate human annotators. These are some options by researchers for extract features from dataset before classifying the sentiment into positive, negative or neutral.

#### C. Sentiment Classification

Sentiment refers to feeling, emotions or responses of an individual by words for expressing human behavior and character [11] [25]. Hence, in this area explicit and implicit features that extract and identify hidden sentiment in measurable format. Whereby there are few methods to polarize the aspect in review theoretically: lexicon and machine learning classifier [2] [11] [13]. There are dictionary-based and corpus-based approaches for lexicon based such as Senti, HowNet, and Wordnet [8]. It is WorldNet dictionary which is stored with polarity positive, negative and neutral. Whereby automatically it is able to score the words in documents by

counting number of positive and negative words in review [21]. If the review has more positive words than negative words, it is polarized as positive reviews. Some machine learning classifier for supervised learning are Naïve Bayes, Support vector machines (SVM), Maximum Entropy and Random forest [2] [9] [10] [26] [27] [31]. Fig. 2 shows summary overall sentiment classification based machine learning and lexicon approaches. Supervised learning required training labeled data to process output result based on input data [21], whereas unsupervised learning requires unlabeled training data to identify pattern of data output. Many researches used Naïve Bayes and SVM machine learning method for sentiment classification [15] [21].

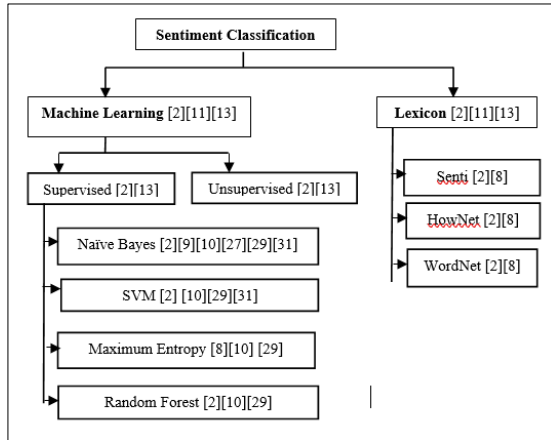

Fig. 2. Sentiment Classification Methods [2] [8] [9] [10] [11] [13] [26] [27] [31].

#### D. Evaluation Score

Based on feature extraction and sentiment classification on online reviews is rank the result using statical method [2]. The overall evaluation result is very important to judge subjective online reviews for customers. The result can predict or measure with mean squared error (MSA), confusion matrix, accuracy, precision, recall and F1-score [9] [15] [28] [29].

Equation of precision is presented as true positive (high quality reviews) divide by true positive (high positive reviews) + false positive (low quality reviews) [5] [18] [29].

$$\text{Precision} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} \quad (1)$$

Recall represented as true positive (high quality reviews) divide by true positive (high quality reviews) + False negative (low quality reviews) [5] [18] [29].

$$\text{Recall} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}} \quad (2)$$

F-score is calculated based on recall and precision as) [5] [18] [29]:-

$$F_{\text{Score}} = \frac{2 * \text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

Mean absolute error (MAE) and Root Mean Square Error (RMSE) measure the closeness between fitted line to the data points [18] [29] [30].

$$\text{MAE} = \frac{1}{n} \sum_{i=1}^n |d_i - d_i^{\wedge}| \quad (4)$$

Confusion matrix helps to show data difference between two classes [29]. Here, example of confusion matrix sketch with values True positive (TP), False positive (FP), False negative (FN) and True Negative (TN) as refer Fig. 3 [9] [15] [31].

TP: The output where correctly predicts the positive class.

FN: The output where incorrectly predicts the negative class whereby mislabeled as negative.

FP: The output incorrectly predicts the positive class whereby mislabeled as positive.

TN: The output where correctly predicts the negative class.

		ACTUAL VALUES	
		Positive	Negative
PREDICTED VALUES	Positive	TP	FP
	Negative	FN	TN

Fig. 3. Confusion Matrix for Amazon Dataset [9] [15] [31].

#### IV. RELATED WORK

This section presents related studies of sentiment analysis on customer's reviews which conducted by researchers on E-Commerce and different background of studies.

##### A. Previous Work from Different Background

Sentiment analysis is applied in different background of study. In Indonesia, Twitter status analyze with sentiment analysis method using SentiWordNet [32]. The emotion in tweet describes sentiment of user in Indonesian language whereby each sentences can polarize to positive, negative and neutral. Researcher used SentiWordNet which contains set of words score between 0 (negative) to 1(positive). After scoring of sentiment, final result identified by sentiment classification method by calculating accuracy positive score 0.77, neutral score 0.60, negative score 0.78 and average score is 0.74. Hence, emotions that express in words transform to meaning information. Other than that, sentiment analysis is also applied to extract Arabic opinions from text which is collected from twitter posts. In this research, Machine learning (ML) and Lexicon based (LB) approach with respect sentiment orientation is applied. The data collected and query using Tweepy Application Programming Interface (API) whereby positive and negative tweets are selected. N-gram features applied to divide the letter as Unigram (one word), bigram (two words) or trigram (three words). ML classifiers such as Naïve Bayes (NB), BNB, Multinomial NB (MNB), Maximum Entropy (ME), Support Vector Machine (SVM), Logistic Regression (LR), Stochastic Gradient Decent (SGD), RR, Adaptive Boosting (Ada-boost) and PA. To evaluate the performance of classifier accuracy, precision, recall and F-score is used. Based on final result, single fold SVM 99.31 with unigram feature shows highest accuracy and 10 fold PA 99.96% with unigram feature shows highest accuracy. The

classifier helps to extract and discover the polarity of the given tweet. On other hand, movies' reviews and score in Rotten Tomatoes website predict with sentiment analysis method [33]. In this research, lexical based approach and supervised machine learning approach were used to predict sentiment polarity in movies' reviews. This researcher also has polarized the sentiment in review using SentiWordNet whereby it classified into two classes rotten (negative) and fresh (positive). The result evaluate by comparing proposed method and baseline method by calculating average precision, recall and F measure whereby proposed method shows highest result 0.97. Hence, it is able to show better judgement on movies' reviews from rotten tomatoes website.

### B. Theory of Sentiments Analysis in E-Commerce

This section discussed previous work related sentiment analysis in customers' reviews e-commerce. Amazon dataset on product's reviews has been selected by few writers for sentiment analysis. Sentiment analysis of unstructured data in Amazon dataset helps to measure and evaluate information in sentiment in reviews using natural language processing techniques [4] [7] [34]. Sentiment analysis was implemented for analysis of e-commerce product reviews to categorize negative and positive comments and visualize it in charts [4]. The model is developed with unigram and bigram and evaluate with classifier such as linear support vector machine,

Multinomial Naïve Bayes, Stochastic Gradient, Random Forest, Logistic regression and Decision tree by product category cellphone, musical and electronics [4] [27]. The result measure using accuracy, precision, recall and F-measure whereby linear support machine shows highest accuracy 93.57 better results compared to other papers. Text mining techniques Apriori and Term Frequency-Inverse Document Frequency (TF-IDF) were applied for identifying text features in proper way [23] [34].

### V. COMPARATIVE ANALYSIS

Table I shows implementation of sentiment analysis on review by some researchers based on Amazon dataset. The table presents many research and different sentiment analysis approaches toward resolving problems in e-commerce customers' reviews. Process of identifying sentiment from unstructured dataset provides different results as different methods are applied. The challenging part of sentiment analysis is to discover what customers like and dislike as written expression [15] [27]. The researchers used sentiment analysis method for identifying sentiment scores in online reviews and overall result as presented in Table I. Different researchers have conducted different approaches for feature extraction and sentiment classification, hence, some future improvement in method application is needed to attain greater accuracy.

TABLE I. RELATED STUDIES BASED ON FEATURE EXTRACTION IN SENTIMENT ANALYSIS

Paper Title	Year	Dataset	Feature Extraction	Sentiment classification	Result
Amazon Reviews business analytics with sentiment analysis [35]	2016	Review of Cellphone & accessories	N/A	MNB	Accuracy:- 72.95%
				SVM	Accuracy:- 80.11%
Comparison of classification techniques for Feature Oriented Sentiment Analysis of Product Review Data [27]	2016	Amazon fine foods:-214 reviews [36]	POS tagging, Bigram	Naïve Bayes	Accuracy:- 74.76% Precision:- 79.54% Recall:-75.89% F-Measure:- 73.75%
				SVM	Accuracy:- 82.85% Precision:- 84.45% Recall:-82.13% F-Measure:- 82.38%
				Maximum Entropy	Accuracy:- 79.04% Precision:- 81.75% Recall:-79.99% F-Measure:- 78.59%
Sentiment Analysis on Large Scale Amazon Product Reviews [4]	2018	Review of cellphone & accessories :- 21600 reviews [37]	TF-IDF	Linear support vector machine	Accuracy:- 93.57%
		Review of electronics:- 24352 reviews [37]			Accuracy:- 93.52%
		Reviews of music instruments :- 2548 reviews [37]			Accuracy:- 94.02%
Sentiment classification on Amazon reviews using machine learning approaches [21]	2018	Amazon dataset :- 252000 reviews from snap dataset	Bag of words model	Naïve Bayes	Accuracy:- 92.72%
				SVM	Accuracy:- 93.20%
Classification of Amazon Book Reviews Based on Sentiment Analysis [23]	2018	Amazon Book reviews [38]	TF-IDF	Random Forest	Accuracy:- 90.15%
Aspect-Level Sentiment Analysis on E-Commerce Data [13]	2018	Customer reviews from Amazon products	Apriori algorithm	Naïve Bayes	Accuracy:- 90.423%
				SVM	Accuracy :- 83.423%
Machine learning based aspect level sentiment analysis for Amazon products [15]	2020	Amazon Products :- [39]	N/A	SVM classifier (RBF Kernel, BP-ALSA)	Accuracy:- 97%
A comprehensive analysis of adverb types for mining user sentiments on amazon product reviews [5]	2020	Amazon DVD musical product :- .Net Crawler, 9555 reviews	POS Tagging (Constituent Likelihood Automatic Word-tagging System (CLAWS))	Hybrid approaches	Precision :- 0.89, Recall:- 0.84, F-Measure:-0.86

## VI. DISCUSSION

The survey table presents comparison result for years from 2016 till 2020 in sentiment analysis E-Commerce from various categories of Amazon dataset. Based on Table I, most of the method in sentiment analysis implement feature extraction and sentiment classification in their process flow for get better accuracy results. Many researchers have implemented text mining method for extract most frequent information from dataset like TF-IDF and Apriori algorithm. Machine learning supervised method is used in most of the papers for classification of information. The experimental results from frequent pattern mining and supervised machine learning methods are able to provide more than 90% accuracy result. For future investigation, lexicon method and result analysis needed for compare accuracy result with machine learning method in sentiment analysis of customers' reviews.

## VII. CONCLUSION

In this paper, we have presented methodology of sentiment analysis and approaches based on previous studies in E-commerce. Research studies results are to address customer satisfaction on online shopping platform based on other's reviews. Data analysis approach presents statical result for predicting and building strong confidence among customers who purchase product from online. Most researches have looked into many approaches and challenges, toward judging customers' behavior as discussed in different methods. The approaches are further applied in other field like Airline, Tourism, Hotel industry, hospitality and others. Sentiment analysis methodology and interpretation using analytic tools perform accurate result to customers. Hence, there are many challenges and ongoing more research in this area have to be discussed and improved to produce more efficient and reliable sentiment analysis approaches.

## ACKNOWLEDGMENT

The authors would like to thank Ministry of Higher Education (MOHE) and Universiti Teknologi Malaysia (UTM) for their educational and financial support. This work is conducted at Razak Faculty of Technology and Informatics, under Cyber Physical Systems Research Group and funded by MOHE (FRGS: R.K130000.7856.5F026) and (UTM GUP: Q.K130000.2538.18H42).

# Assessment Framework for Defining the Maturity of Information Technology within Enterprise Risk Management (ERM)

Rokhman Fauzi, Muharman Lubis

Department of Information System, Telkom University, Bandung, Indonesia

**Abstract**—The process of reviewing, assessing and improving the organization's IT risk management requires some basic information summarized in a process maturity profile. In general, IT risk management standards or frameworks do not include a mechanism for assessing the maturity level of process implementations. This study was conducted to develop a framework, which can be applied to assess the maturity level of IT risk management under ISO / IEC 27005. A standards-based management system implementation can be represented as a model cycle of planning, implementation, validation and also action plan. The proposed evaluation framework consists of templates, methods, and working papers. Therefore, the template focus on the evaluation areas, which are planning, execution, validation, and execution, then evaluation area details (8 domains, 35 subdomains, 82 items), and evaluation metrics and criteria. Meanwhile, a working paper has been created to assist in conducting the evaluation. Actually, by using this evaluation framework, it can provide a representation of the maturity level from the entire process in managing IT risk, based on the provisions of ISO/IEC 27005. This framework complements the existing model with the representation of (1) providing a single-cycle planning, establishment, validation, and execution, (2) evaluation tools, (3) more comprehensive data collection methods, and (4) priority list of elements to be reformed and/or improved.

**Keywords**—Risk management; assessment framework; maturity level; PDCA cycles; ISO/IEC 27005

## I. INTRODUCTION

In the process of forecasting, minimizing, monitoring, and controlling the likelihood or impact of unfortunate events, also in maximizing the realization of opportunities; organizations utilize enterprise risk management (ERM) frameworks in particular to manage every potential loss, problem or damage towards company. This framework needs to provide a structured process that integrates risk management activities into the systems development life cycle (SDLC) or agile management project to enable risk managers in making the informed decisions. In general, this process should involve determining the accuracy of risk decisions and the possible accepted risks. On the other hand, good prescriptions for making risk decisions include a mixture of objective data, pass or fail test results, mitigation measures, qualitative analysis, subjective data, and a healthy bit of intuition [1]. In actual, a description of the enterprise's risk management maturity level should provide the benefit of identifying the actual strengths and weaknesses of risk management in the enterprise. Then get

measurement results that will help organization to increase its maturity level and ladder. It also integrates organizational risk management documents to enhance its contribution to be more effective organizational governance and to improve the quality of risk management and risk mitigation processes. Thus, the company's leadership must define expectations for the company's risk management programs on how to measure them, especially the security assessment stage of the risk management framework. Asking the right questions is important for auditors to discover how risk management software works and the true state of program integration. Moreover, audit teams need to focus and concentrate on a more in-depth review of a broader set of systems and integrity testing.

Each year, the public sector provides indicators and metrics to support government compliance and reporting requirements. Some of these many metrics include the number of systems that company operates in their viability to execute and risk of acceptability. Therefore, the accuracy in measuring the effectiveness of risk management programs depends on whether safety controls are regularly tested as well retested, and whether there is a record of test results related to five primary sources of risk namely production, marketing, financial, legal and human [2]. Risk is a necessary part of doing business and in a world where massive amounts of data are processed at an ever-increasing rate, identifying and mitigating risks is a challenge for any company. Actually, little wonder that many contracts and insurance policies require strong evidence of good risk management practices [3]. In addition, it is imperative that the framework provides guidance for companies to integrate risk-based decision-making into organizational governance, planning, management, reporting, policies, values and culture. It is an open principles-based system that allows organizations to apply standard principles in their context.

Every International Standard Organization (ISO) are reviewed every five years and revised as needed. This allows them to remain a useful and relevant tool in the market. Therefore, in this case, the study focuses on old versions and emphasize about ownership that many organizations face obstacles and barriers directly to further modernizing technology and infrastructure, while at the same time needing the guidance to be as simple as possible so the older versions provide benefit in term of contextual more compare to the latest version developed. In particular, this framework helps provide the basis for a comprehensive risk management

methodology for assessing and improving program risk management practices. The risk management framework can be applied to all stages of the system development life cycle, including acquisition, development and operations. In addition, the framework can be used to guide the management of various types of risks, including acquisition program risks, software development risks, operational risks, and information security risks [4]. In short, risks are of paramount importance to organizations that need to identify, assess, manage and the process to report many types of risks for the company is extremely important to improve external and internal decision-making. Interestingly, risks can be viewed as threats or called as a negative event to the organization. Managing risk in this context means using management techniques to reduce the likelihood and impact of adverse events without incurring excessive costs. On the other hand, risk also can be defined as uncertainty as the danger related to the distribution of all possible outcomes, positive and negative. Thus, managing risk means minimizing the difference between expected and actual results. Finally, risk can be described contextually as an opportunity that can be viewed as a source of business opportunities [5], [6]. Thus, it is recommended to utilize the popular and older version of ISO/IEC 27005 with the modified version to bring simplification to the organization that have been used in certain period of time without the burden in the transition process or adopting the new method regularly every five year while at same time creating flexibility and improvement to the business process as a whole, which, this study want to offer the ERM template.

## II. LITERATURE REVIEW

Processes in risk management besides functioning to reduce negative impacts can also be used to identify and optimizing the positive and potential aspect of the organization. Meanwhile, ISO/IEC Guide 73 defines risk as a combination of an opportunity (likelihood) and its impact (implication). Information Technology (IT) Risk is a business risk related to the use, ownership, operation, involvement, influence, and application of IT in a company [7], [8]. It is also defined as something that is wrong with IT and has a negative impact on business [9], [10]. The types of risks that affect and/or become a direct result of IT activities have a broad scope. In short, risks can be grouped into several categories that help providing an overview of the organization's risk profile. The IT risk portfolio is one approach in identifying and grouping IT risks, which can be grouped into 7 (seven) categories, namely: projects, continuity of IT services, information assets, service providers, applications, infrastructure, and strategic matters [11], [12]. The IT risk portfolio provides an overview of things that should be the main concern of the organization in managing the risks associated with IT, which Symantec [13] classifies IT risk into 4 categories, namely: security risk, availability risk, performance risk, and compliance risk. In addition, the common threads that serve as for the various IT risk rating models are confidentiality, integrity, and availability [14].

In general, PDCA (Plan, Do, Check, Act) is included in an endless cycle of risk management where all executed and implemented solutions can be seen as indicators of further improvement activities. This knowledge is used as a basis and

fundamental organizational resource that provides an ongoing competitive advantage in a relevant and dynamic environment and market by identifying gap between strategic planning and potential knowledge [12]. National Institute of Standards and Technology [15] defines IT Risk Management as a process that allows IT managers to balance operational and economic costs from the protection of IT and benefit from such protection. This definition compromises between classical definitions in business and definitions in the context of the organization's IT operations. Risk management also must be carried out continuously and have sustainability to be developed in order to overcome the risks of the organization at present and in the future. Thus, every manager and staff must understand their roles and responsibilities in risk management. In addition, risk management must also be integrated with organizational culture through policies and programs led directly by senior management [16]. In fact, IT Risk Management is the foundation of the implementation of the Information Security Management System [17]. ISO/IEC 27001 stipulates that the controls implemented within the scope, limits, and context of the Information Security Management System (ISMS) must be risk-based. The PDCA has been engaged as an impressive and essential tool for quality and continuous improvement with both simple and powerful to implement the strategy and policy in the organization. The application of the PDCA cycle has been found more effective than adopting "the right first time" approach. By using of the PDCA cycle means continuously looking for better methods of improvement and enhancement [18].

Implementing a risk management process is not always easy, and some organizations give up without achieving the desired results. This may be due to the inability to implement the risk management process in a consistent and predictable manner in the long term. On the other hand, a maturity model is a tool that represents the pathway to an increasingly structured and systematic way of doing business, usually involving people, organizations, and processes. Over the past few years, these tools have become very popular, using models of maturity in many areas, such as data management, information security, and project management. In a maturity model, the evolutionary path is described through separate stages. To reach the next level, the organization must achieve the objectives of the required level and all previous levels [19], [20]. To enable the measurement of maturity levels and identify gaps between current levels and follow-up to enable planning efforts; priorities and objectives should be formulated to achieve proposed goals. It allows the assessment process run smoothly and building the achievement compliance. Ultimately, this approach provides organizations with an understanding of strengths, weaknesses, and opportunities that can support audits, benchmarks, and progress assessments against goals, strategic decisions, and project portfolio management [21], [22].

The difference between organizations whose systems are more or less mature is not only related to the results of the indicators used, but also to the fact that dominantly mature organizations measure differently using various indicators when compared to immature organizations. The concept of maturity is related to one or more of the elements identified as

being related but the concept of function is only appropriate for each of these elements [23], [24]. It appears very important for non-financial companies to promote and discuss on how to implement and manage risk management efforts. One of the key issues is how to effectively evaluate the quality of a company's risk management performance. The most important factor is the growth of a consistent risk culture and the independence of the board of director in determining the decision for integration process within the organization [25], [26], [27]. Therefore, it is also important to understand the role of individual, institutional and environmental within the organization as the primary prerequisites for improvement in raising awareness of the strategies used in each business process within the framework of a particular project or service [28].

### III. FRAMEWORK DESIGN

This study was conducted using several phases: literature review, framework design, and case studies (see Fig. 1). The evaluation framework, on the other hand, consists of evaluation forms, methods, and a worksheet of descriptive structure (see Fig. 3). Evaluation forms are a key component of this framework, which this model consists of 8 domains, 35 subdomains, and 4 evaluation domains (PDCA) detailing 82 items with the detail area is a set of provisions of the ISO / IEC 27005 standard. The domains are taken from the main blocks in the standard process model. Meanwhile, subdomains and elements refer to clauses of the standard in each domain. Interestingly, the presence of a Chief Risk Officer (CRO) does not clarify the level of support and leadership from the CEO and the Board of Directors in relation to the creation and distribution of risk information throughout the organization, which dedicated to mitigate and manage major risks [29], [30]. Most importantly, create a portfolio of company risks and opportunity events: finance, strategy, compliance, operations, and reputation can influence the achievement of strategic goals.

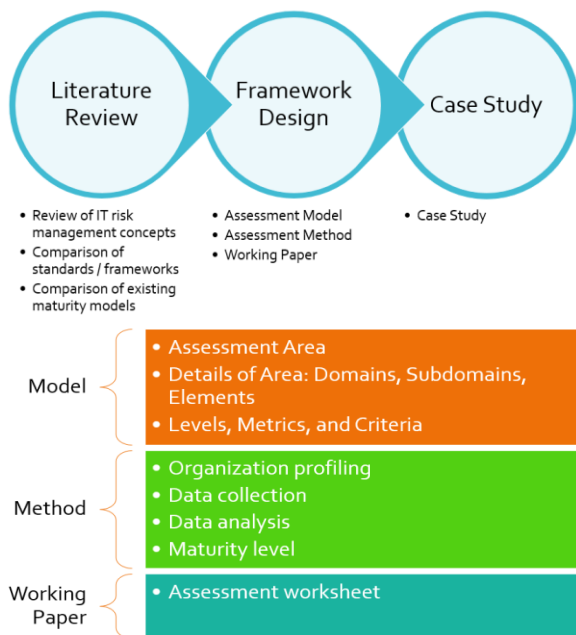

Fig. 1. Methodology and Assessment Framework.

### IV. ASSESSMENT AREA

In fact, this study divided the process into five groups related to the plan in implementing ERM: full implementation, partial execution, implementation planning process, feasibility study or evaluation, and level of ERM implementation. On the other hand, traditional risk management approaches utilize segmented methods to face different risks across different organizations. In contrast, ERM is a relatively new paradigm that enhances a company's ability to predict the set of risks it faces [31], [32], [33]. ERM is a top-down approach that includes identifying, assessing and addressing strategic, operational and financial risks to achieve the following four objectives: (1) high-level strategic objectives aligned with the corporate mission, (2) effective and efficient use of resources, (3) reliability of reporting, and (4) compliance - enforcement of legal and regulatory compliance [34]. As can be seen in Fig. 2, the process is started and ended with context establishment to risk identification, estimation and evaluation, the once again context become the consideration to determine risk treatment as well risk acceptance.

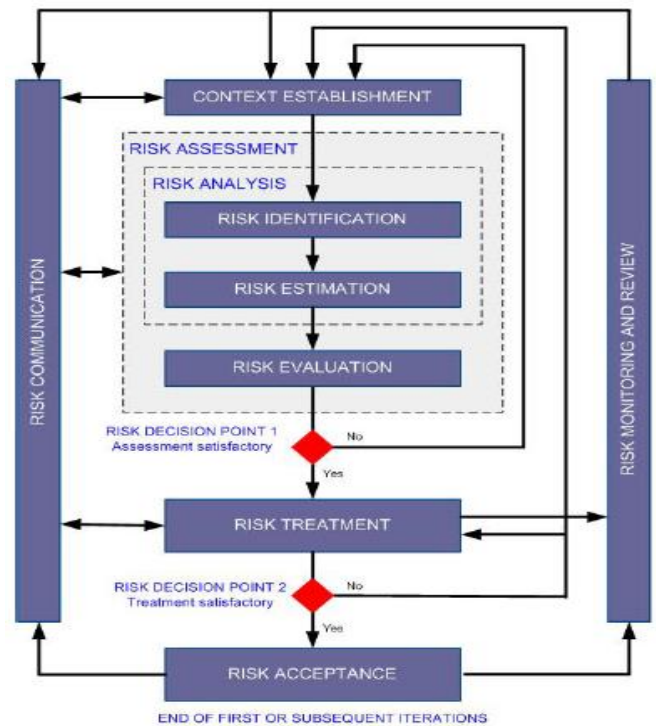

Fig. 2. Process Model of ISO/IEC 270005.

The main purpose of placing this evaluation form is to provide a structured description of the improvement stages of the PDCA cycle process. The following table defines levels using the Business Risk Management Maturity Model and the Business Process Maturity Model. Providing metrics is essential because the lack of process measurement affects the determination of performance levels and further disrupts the organization's business and activity improvement processes. Measurements are an approach of the evaluation process and organizational performance, and in this model the standard is defined as a metric of the elements score level and a list of conditions that indicate the determination of requirements. In

addition, referring to the standard paragraph, each domain is divided into several subdomains and elements. The result was 35 subdomains and 82 items (Table I). In addition, PDCA code elements are assigned to classify needs based on several specifications to increase the sustainability of the activity process (Table II).

TABLE I. SUBDOMAINS AND ELEMENTS

Domains	Number of subdomains	Number of elements
Context Establishment	6	16
Risk Communication	4	13
Risk Identification	5	15
Risk Estimation	4	6
Risk Evaluation	3	4
Risk Treatment	7	7
Risk Acceptance	2	2
Risk Monitoring and Review	4	19
	35	82

TABLE II. MAPPING OF AREA: PLAN, DO, CHECK AND ACT

Area	Code of elements
PLAN	1.1.1, 1.2.1, 1.3.1, 1.4.1, 1.4.2, 1.4.3, 1.4.4, 1.4.5, 1.4.6, 1.4.7, 1.4.8, 1.4.9, 1.4.10, 1.4.11, 1.5.1, 1.6.1
	2.1.1, 2.2.2, 2.3.1, 2.3.2, 2.3.3, 2.3.7, 2.3.8, 2.3.9
	3.1.1, 3.1.2, 3.1.3, 3.1.4, 3.2.1, 3.2.2, 3.2.3, 3.3.1, 3.3.2, 3.4.1, 3.4.2, 3.4.3, 3.5.1, 3.5.2, 3.5.3
	4.1.1, 4.1.2, 4.2.1, 4.2.2, 4.3.1, 4.4.1
	5.1.1, 5.2.1, 5.2.2, 5.3.1
	6.1.1, 6.2.1, 6.7.1
	7.1.1, 7.1.2
DO	2.4.1
	6.3.1, 6.4.1, 6.5.1
CHECK	2.2.1, 2.3.5
	6.6.1
	8.1.1, 8.1.2, 8.1.3, 8.1.4, 8.1.5, 8.1.6, 8.1.7, 8.2.1
ACT	2.3.4, 2.3.6
	8.3.1, 8.3.2, 8.3.3, 8.3.4, 8.3.5, 8.3.6, 8.3.7, 8.3.8, 8.3.9, 8.4.1, 8.4.2

The life cycle of an innovation project is a series of interrelated processes and stages of novelty. Innovation projects generally include the following life cycle rule with well-defined stages: innovation development, production readiness, market entry, growth, maturity, recovery, or decline. In order to maintain the competitiveness of innovation projects at all stages, it is necessary to develop and implement specific type of innovations (incremental, responsive, disruptive or radical) that are included in the portfolio of innovation projects and which are implemented in a specific order with different levels of innovation content and research intensity [35]. Entirety was used then to map the component into each Assessment Area, in which each element is also mapped into

them respectively (Fig. 3-7). The level and criteria should be defined to set the indicators that can be looked at and matching for the purpose of improvement in the process (Table III). Meanwhile, the metrics is also essential to simplify the process maturity to be recognized in every type of risk domain respectively (Table IV). Risks are localized in implementing innovation projects in the process of analyzing and modeling a set of innovations. Choosing the best combination of risk management techniques as part of a particular innovation project requires assessing a range of factors, such as the complexity and specificity of innovation activities and the level of profitability of the innovation at a given time. Time periods, insurance service costs, likelihood of risk, size and quality, predictability of risk, legal limits and provisions, and project implementation phases are several aspects that become primary considerations [36].

TABLE III. LEVEL AND CRITERIA

Level	Criteria
Level 5	Organizational focus is the ongoing improvement process. The whole process was in accordance with the reference standard.
Level 4	Organizational focus is the evaluation and optimization of existing resources. Much of the process followed a reference standard.
Level 3	Organizational focus is to build a standard managerial processes to achieve organizational goals. A small part of the process followed the reference standard.
Level 2	Organizational focus is to build managerial foundation in every program or project. Some processes are standardized, without a reference standard.
Level 1	No specific targets. Achievement of the organization depends on the competence and hard work of a handful of personnel. There is no standard process.

TABLE IV. METRIC COMPONENTS

Domain	M1	M2	M3	M4	M5	M6
Context Establishment	P	P	P	P		
Risk Communication	P		P	P		P
Risk Identification	P		P	P	P	P
Risk Estimation	P		P	P	P	P
Risk Evaluation	P		P	P	P	P
Risk Treatment	P		P	P	P	P
Risk Acceptance	P		P	P		
Risk Monitoring and Review	P		P	P	P	P

\*P: Primary related; metric component used in the domain assessment

Metrics and Assessment Criteria are determined per domain because each has its input, process and output characteristics. In this case, it used various assessments namely [M1] policy, plans and procedures, [M2] goals and success measurements, [M3] roles and responsibilities, [M4] communications, [M5] skills and trainings, as well as [M6] tools. Furthermore, the metric components used in the domain context of establishment; the assessment are [M1], [M2], [M3] and [M4] communications. On the other hand, the metric components used in the domain of risk communication; the assessment are [M1], [M3], [M4] and [M6]. Nonetheless, the

metric components used in the domain risk identification; the assessment are [M1], [M3], [M4], [M5] and [M6]. Then, the metric components used in the domain of risk estimation; the assessment are [M1], [M3], [M4], [M5] and [M6].

The ERM template can be seen in Table V is designed for use as a self-assessment for the tool to be effective; it must be conducted in such a way that the process is as objective as possible to avoid bias or group thinking. From experience using the model, the self-evaluation discussion includes the following important considerations such as project duration and role responsibility. According to the government comments, it could take hours to a day or more, depending on the amount of preparation before the group discussion and the level of detail of the discussion itself take place. Ideally, there should be a diverse group of employees responsible for managing ERM involved in the self-assessment across the ranks. Thus, caring must be taken to ensure that the

conversation is open and transparent, which people should be encouraged to express their opinions. It may be helpful to ask someone outside of the management chain to manage ERM to facilitate discussion. That person should read specific note and understand on how to handle the self-evaluation of the form [37]. In addition to facilitating discussions, a person should be able to challenge the opinions of the self-assessment group, including looking for supporting evidence as needed. The metric components used in the domain risk evaluation, the assessment are [M1], [M3], [M4], [M5] and [M6]. Meanwhile, the metric components used in the domain risk treatment; the assessment are [M1], [M3], [M4], [M5] and [M6]. Nevertheless, the metric components used in the domain risk acceptance; the assessment are [M1], [M3] and [M4]. At last, the metric components used in the domain risk monitoring and review; the assessments are [M1], [M3], [M4], [M5] and [M6]. All of them can be seen in Table VI, respectively based on each separated criteria level.

TABLE V. LEVELS, METRICS AND CRITERIA FOR DOMAIN CONTEXT ESTABLISHMENT, RISK COMMUNICATION, RISK IDENTIFICATION AND RISK ESTIMATION

Level	Criteria	Criteria	Criteria	Criteria
Domain	Context Establishment	Risk Communication	Risk Identification	Risk Estimation
Level 5	All items in this clause already exist in the Policy, Planning and/or Procedure documents. Defining goals and measures of success is clearly given. All roles and responsibilities are clearly described and there is no overlap. Socialization is carried out on all stakeholders.	Senior management and all stakeholders understand and care about key aspects of IT risk management; IT risk is part of the main consideration of decision making. All roles and responsibilities are clearly described and there is no overlap. There are procedures for all forms of risk communication needed. There are communication aids that support normal and emergency conditions.	Risk identification activities are regulated in Policies, Planning and/or Procedures. Risk identification details are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Risk identification involves all parties involved. Implementing risk identification is an internal team of organizations (who have received special training) and experts from outside the organization. Risk identification is carried out with tools that are in accordance with the Standards and conditions of the Organization.	Risk estimation activities are regulated in Policies, Planning and/or Procedures. Details of risk estimates are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Risk estimates involve all parties involved. The executor of risk estimation is the internal team of the organization (who has received special training) and experts from outside the organization. Risk estimates are carried out with tools that are in accordance with the Standards and conditions of the Organization.
Level 4	All items in this clause already exist in the Policy, Planning and/or Procedure documents. Defining goals and measures of success is clearly given. All roles and responsibilities are clearly described and there is no overlap. The socialization was carried out for some stakeholders.	Senior management and all stakeholders understand and care for key aspects of IT risk management. All roles and responsibilities are clearly described and there is no overlap. There are procedures for all forms of risk communication needed. There are communication aids that support normal and emergency conditions.	Risk identification activities are regulated in Policies, Planning and/or Procedures. Risk identification details are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Risk identification involves all parties involved. Implementers of risk identification are internal organization teams (who have received special training) or experts from outside the organization. Risk identification is carried out with tools that are in accordance with the Standards and conditions of the Organization.	Risk estimation activities are regulated in Policies, Planning and/or Procedures. Details of risk estimates are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Risk estimates involve all parties involved. Implementers of risk estimation are internal organization teams (who have received special training) or experts from outside the organization. Risk estimates are carried out with tools that are in accordance with the Standards and conditions of the Organization.
Level 3	All items in this clause already exist in the Policy, Planning and/or Procedure documents. Defining goals and measures of success is clearly given. All roles and responsibilities are clearly described, but	IT and Management staff related to IT understand and care for key aspects of IT risk management. All roles and responsibilities are clearly described, but there are still overlaps. There are procedures for some form of risk communication that is needed.	Risk identification activities are regulated in Policies, Planning and/or Procedures. Risk identification details are in accordance with some clauses in the Standard. All roles and responsibilities are clearly described, but there are still overlaps. Risk identification involves all parties involved. Implementers of risk identification are	Risk estimation activities are regulated in Policies, Planning and/or Procedures. Details of risk estimates are in accordance with some clauses in the Standard. All roles and responsibilities are clearly described, but there are overlaps. Risk estimates involve all parties involved. The executor of risk estimation is an

	there are still overlaps.	There are communication aids that support normal conditions.	internal organization teams (who have not received special training) or experts from outside the organization. Risk identification is carried out with tools that are in accordance with the Standards and conditions of the Organization.	internal team of organizations (who have not received special training) or experts from outside the organization. Risk estimates are carried out with tools that are in accordance with the Standards and conditions of the Organization.
Level 2	Some items in this clause already exist in the Policy, Planning and/or Procedure documents. Defining goals and measures of success is not clearly stated. All roles and responsibilities have been described, but are still unclear and there are overlaps.	IT and Management staff related to IT understand and care for key aspects of IT risk management. All roles and responsibilities are described, but still unclear and there are overlaps. There is no procedure; risk communication is carried out informally.	Risk identification activities are regulated in Policies, Planning and/or Procedures. Risk identification details are in accordance with some clauses in the Standard. All roles and responsibilities are described, but still unclear and there are overlaps. Risk identification does not involve all parties involved. Implementing risk identification is an internal team of organizations (who have not received special training)	Risk estimation activities are regulated in Policies, Planning and/or Procedures. Details of risk estimates are in accordance with some clauses in the Standard. All roles and responsibilities are described, but still unclear and there are overlaps. Risk estimates do not involve all parties involved. Implementing risk estimates is an internal team of organizations (who have not received special training)
Level 1	This clause does not yet exist in the Policy, Planning and/or Procedure document. Defining goals and measures of success is not clear.	There is still IT staff who do not understand and care for the key aspects of IT risk management.	Risk identification activities are not regulated in Policies, Planning and/or Procedures. Risk identification does not involve all parties involved. Implementing risk identification is an internal team of organizations (who have not received special training).	Risk estimation activities are not regulated in Policies, Planning and/or Procedures. Risk estimates do not involve all parties involved. Implementing risk estimates is an internal team of organizations (who have not received special training).

TABLE VI. LEVELS, METRICS AND CRITERIA FOR DOMAIN RISK EVALUATION, RISK TREATMENT, RISK ACCEPTANCE AND RISK MONITORING & REVIEW

Level	Criteria	Criteria	Criteria	Criteria
Domain	Risk Evaluation	Risk Treatment	Risk Acceptance	Risk Monitoring and Review
Level 5	Risk evaluation activities are regulated in Policies, Planning and/or Procedures. Details of risk evaluation are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap by involving all parties involved. Risk evaluation implementers are internal organizational teams (who have received special training) and experts from outside the organization. Risk evaluation is carried out with tools that are in accordance with the Standards and conditions of the Organization.	Risk handling activities are regulated in Policies, Planning and / or Procedures. Risk handling details are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Risk management involves all parties involved. Risk management executors are internal organization teams (who have received special training) and experts from outside the organization. ERM is carried out with tools that are in accordance with the Standards and conditions of the Organization.	Risk acceptance activities are regulated in Policies, Planning and/or Procedures. Roles and responsibilities are clearly defined. Acceptance of risk in accordance with all risk acceptance criteria. Justification, communication and monitoring of risk acceptance are carried out in accordance with the clause in the Standard	Monitoring and risk checking activities are regulated in Policies, Planning and / or Procedures. Details of monitoring and risk checking are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Justification, communication and monitoring are carried out on the entire list of risk acceptance that does not meet the criteria.	Monitoring and risk checking activities are regulated in Policies, Planning and / or Procedures. Details of monitoring and risk checking are in accordance with all clauses in the Standard. All roles and responsibilities are clearly described and there is no overlap. Risk monitoring and inspection involves all parties involved. Implementers of monitoring and risk checking are internal organization teams (who have received special training) or experts from outside the organization. Risk monitoring and inspection is carried out with tools that are in accordance with the Organization's Standards and conditions.

	Standards and conditions of the Organization.	Standards and conditions of the Organization		
Level 3	Risk evaluation activities are regulated in Policies, Planning and/or Procedures. Details of risk evaluation are in accordance with some clauses in the Standard. All roles and responsibilities are clearly described, but there are overlaps. Risk evaluation involves all parties involved. The risk evaluation implementer is an internal team of organizations (who have not received special training) or experts from outside the organization. Risk evaluation is carried out with tools that are in accordance with the Standards and conditions of the Organization.	Risk handling activities are regulated in Policies, Planning and/or Procedures. Risk handling details are in accordance with some clauses in the Standard. All roles and responsibilities are clearly described, but there are still overlaps. Risk management involves all parties involved. Risk management implementers are internal organization teams (who have not received special training) or experts from outside the organization. Risk management is carried out with tools that are in accordance with the Standards and conditions of the Organization.	Risk acceptance activities are regulated in Policies, Planning and/or Procedures. Roles and responsibilities are clearly defined. Acceptance of risk is in accordance with some risk acceptance criteria. Justification, communication and monitoring are carried out on part of the risk acceptance list that does not meet the criteria.	Monitoring and risk checking activities are regulated in Policies, Planning and / or Procedures. Details of monitoring and risk checking are in accordance with some clauses in the Standard. All roles and responsibilities are clearly described, but there are overlaps. Risk monitoring and inspection involves all parties involved. Implementers of monitoring and risk checking are internal organization teams (who have not received special training) or experts from outside the organization. Risk monitoring and inspection is carried out with tools that are in accordance with the Organization's Standards and conditions.
Level 2	Risk evaluation activities are regulated in Policies, Planning and/or Procedures. Details of risk evaluation are in accordance with some clauses in the Standard. All roles and responsibilities are described, but still unclear and there are overlaps. Risk evaluation does not involve all parties involved. Risk evaluation implementers are internal organization teams (who have not received special training)	Risk handling activities are regulated in Policies, Planning and/or Procedures. Risk handling details are in accordance with some clauses in the Standard. All roles and responsibilities are described, but still unclear and there are overlaps. Risk management does not involve all parties involved. Risk management executors are internal organization teams (who have not received special training)	Risk acceptance activities are regulated in Policies, Planning and / or Procedures. Roles and responsibilities are not clearly defined.	Monitoring and risk checking activities are regulated in Policies, Planning and / or Procedures. Details of monitoring and risk checking are in accordance with some clauses in the Standard. All roles and responsibilities are described, but still unclear and there are overlaps. Risk monitoring and inspection do not involve all parties involved. Implementers of risk monitoring and inspection are internal organizational teams (who have not received special training)
Level 1	Risk evaluation activities are not regulated in Policies, Planning and/or Procedures. Risk evaluation does not involve all parties involved. The risk evaluator is an internal team of organizations (who have not received special training).	Risk handling activities are not regulated in the Policy, Planning and/or Procedure. Risk management does not involve all parties involved. Risk management implementers are internal organization teams (who have not received special training).	Risk acceptance activities are not regulated in the Policy, Planning and / or Procedure.	Monitoring and risk checking activities are not regulated in Policies, Planning and / or Procedures. Risk monitoring and inspection do not involve all parties involved. Implementers of risk monitoring and inspection are internal organization teams (who have not received special training).

In general, the framework evaluation process consists of four steps, starting with the definition of an organizational profile, the collection and analysis of data, and finally the maturity profile of the presentation. In the early stages of defining an organization's profile, it helps determine the most suitable data collection method for targeted application. The next step is data collection, which the methods are: (1) Document analysis, (2) Interview, (3) Questionnaire, or (4) Material review [19, 20]. Methods (1) and (2) are the two main data collection methods for obtaining evidence. Methods (3) and (4) are necessary when the organization is highly complex and high risks are expected in the IT arena. The resulting data is processed into a worksheet that contains the results of data evaluation, data manipulation and data processing in the basic form as shown graphically in the Fig. 3.

$$\text{Maturity Level} = (\sum \text{Area Score}) \times 1.25 \quad (1)$$

$$\text{Area Score} = (\sum \text{Actual Score}) / (\text{Maximum Score})$$

$$\text{Maximum Score} = (\sum \text{Elements}) \times 5$$

The result at this phase is related to the maturity of the PDCA cycle. These values also indicate the plane position (1-5) and its properties. In addition to the PDCA cycle maturity model, data processing can also explain the status of each component in each region. These results form the basis of the merit assessment of each component. The final step is to prepare a PDCA cycle maturity profile for the organization. This profile consists of at least: (1) Maturity model, (2) Maturity evaluation of each component, (3) Evaluation of conclusions and recommendations.

V. CASE STUDY

The organization's overview involves services with offices in multiple cities with more than 1000 employees, information technology (IT) helps supporting basic business and IT departments with the employees at around 30 to 60 people. The data was collected using interviews and document analysis, which is obtained through storage process using the analytical methods described in the previous section. The interview was conducted with an IT risk manager with the material used was the material described in the worksheet and clarified with the reference document for evaluation. The analysis performed on the referenced document was directly related to IT risk management as they are complementary methods. A list of included documents can be stated such as MRTI/20xx policy, MRTI/20xx appendix policy, asset registration software, hardware asset registration, movable property registration, asset data or information record. The evaluation results consist of (a) PDCA cycle maturity, (2) maturity evaluation of each component, and (3) conclusions and recommendations. Organizational policies are forward-looking policies, based on strong evidence of what the organization can achieve, and that promote a consistent approach to health and safety at all levels of the organization. Therefore, organizational leaders promote a consistent approach to health and safety and setting the transition or transmitting the clear directives that shape daily activities. It also works continuously at all levels of the organization, promotes the values, ethics and culture needed to achieve the goals of the organization, and transforms the leadership style for the entire organization rather than transactional [38]. The result for case study can be seen in Table VII for the maturity assessment.

ERM should be viewed as an evolutionary process within an organization. This is often considered a compliance driven exercise that is achieved, documented and presented while it is doubtful at certain situation whether much value can be extracted from this type of effort [39]. Solving cost and skill problems in the evaluation process also motivates the organization to provide correct answers, and to show robust results in all real-world ways [40]. Aligning the IT investments with ever-changing business goals and priorities remains a major challenge for IT managers. Despite management's efforts to improve project success, an unacceptable number of IT initiatives cannot reach specific goals and target, or simply do not reach the objective in full. There is no end to the various factors that can contribute to the failure of the project. As a result, IT organizations have invested significantly in improving output predictability, productivity, and quality. Techniques such as estimation, risk assessment, process management, delivery management, and project management improve project implementation, but they cannot address the more important issues of investment selection and improving IT performance [41].

As can be seen in Fig. 4 to 7, each code of element and heatmap are distributed to plan, do, check and act realm. The resulting heat map can also be used to inform senior management, audit committees and councils of risk assessment. By having iterative design and management methods used in the business, it can support for continuous control and improvement of processes and products. Basically,

the two frameworks in this study cannot be compared with the difference in maturity model for reference. However, the framework proposed in this study includes several aspects that may complement the missing aspects of the current model such as the representation, measurement, method, and presentation of evaluation results as the conclusion. It is important to keep the results anonymous in certain timeframe to ensure that community or governments are not influenced by the use of the maturity model due to concerns about outside perceptions, and its primary purpose as a self-assessment tool to inform the future strategies as well as to promote the attempt to assess the process quality within the organization [37]. Historically, organizations have sought to improve project visibility by compiling schedules, budgets, progress, and spending information from detail-oriented project management tools or enterprise risk management systems.

To be successful, all projects must be planned in detail and updated in a consistent and reliable manner. This is a rare case, and the resulting collected data is often inaccurate, outdated and misleading [41]. It should be noted that PDCA cycle in IT Risk Management (ISO/IEC 27005) could not be separated from the company's overall risk management [42]. In addition, clients and organizations often misunderstand responsibilities and rights in business functions, processes, and levels. Thus, it is necessary for professionals to think about how to formulate the rules governing the collection and distribution of information; also, information system specifications and requirements for developers and administrators. Therefore, to improve the effectiveness of stakeholder interactions and communication, many related factors such as human beings, environment, culture, language, literacy, and organization have to be taken into account [43], [44], [45]. Interestingly, by leveraging the creativity and entrepreneurial spirit of employees and managers, it should depend on the ability of the organization to create favorable conditions for potential entrepreneurial to emerge in the proper way that align with context and trend within the environment [46], [47], [48]. In the end, the most effective risk functions have gained strategic influence within the organization and are empowered to invest in the overall development of task and role responsibilities [49], [50].

## VI. CONCLUSION

The unexpected framework recommends establishing the appropriate alignment between the ERM design parameters called ERM Mix or Modified with contingent variables in order to achieve organizational effectiveness. These type of ERM includes specific roles for risk identification processes, frequency of risk meetings, risk tools, risk functions, then, contingent variables as the types of risks that refer to preventable organizational and industry variables, parameters, strategy or external domain. Finally, it must also be understood that it is impractical to expect an ERM process to develop into this mature state in a relatively short period of time. Interestingly, it can be implemented shortly if the organization want to concentrate or focusing in assessing certain aspects only such as risk treatment and risk acceptance by utilizing

context establishment. Several sample companies have integrated ERM software for some time and the process still ongoing especially to improve the quality. On the other hand, the ERM process should continually update existing risk inventories and reviewing probability and impact assessments to ensure that significant and potentially catastrophic risks are not overlooked. To ensure that this ERM approach becomes dominant within the company, both the Board of Directors and the CEO explicitly agree on the ERM efforts, and elements of the mature ERM process described by the framework reported with the ERM staff as it is also essential to have sufficient resources available to fully achieve the implementation. As this modified framework has been used in case study, it is expected to be evaluated further in different context and perspective of diverse case study to strengthen and advance the proposed framework.

# Using Eye Tracking Approach in Analyzing Social Network Site Area of Interest for Consumers' Decision Making in Social Commerce

Suaini Binti Sura<sup>1</sup>, Nona M. Nistah<sup>2</sup>, Sungwon Lee<sup>3</sup>, Daimler Benz Alebaba<sup>4</sup>

Faculty of Computing and Informatics, Universiti Malaysia Sabah, Sabah, Malaysia<sup>1,2,4</sup>  
Department of Convergence Software, Kyungmin University, Gyeonggi-do, South Korea<sup>3</sup>

**Abstract**—The growing popularity of social network site (SNS) in social commerce (s-commerce) has intensified interest in understanding consumers decision making based on the SNS seller generated content (SGC) and user generated content (UGC). This study examines consumers' decision making while doing online shopping by analyzing both SNS's seller-user generated content on SNS utilizing eye tracking approach. Based on eye tracking experimental with 50 participants, gaze map in term of fixation time were collected and analyzed to measure the order of identified Area of interest (AOI) by which consumer viewed and heat map to measure the consumer intensity when looking at the identified AOIs. The results identify that SCG is most important AOI compare to UGC and that product image and description receive the greatest attention from consumers when making decision. Furthermore, seller information serves as a key entry point for SNS-based commerce based on fixation time. The analysis result shows that there is no significant influence of AOIs order based on consumers' viewed on the intensity which consumers look at the AOIs. The comparison between Facebook and Instagram reveals some substantial differences in mean between AOIs based on fixation time and intensity. The findings suggest several AOIs should be addressed and emphasized for sellers and companies who interested in utilizing SNS for their s-commerce strategy.

**Keywords**—Eye tracking; SNS-based commerce; seller generated content; user generated content; social commerce

## I. INTRODUCTION

The emergence of social media has facilitated the new way of conducting online commerce, whereby rather than doing commerce (sell and buy), it allows users to socialize and build virtual community to generate better information in order to support their decision on commerce activities [1, 2]. This new way of conducting online commerce is known as social commerce (s-commerce). In other words, s-commerce refers to any commerce activities conducted through web 2.0 tools and social media in consumers' online shopping process includes the interaction between business with their customers (B2C), and customer with other customers (C2C) [2]. The concept of interaction and socialization among s-commerce's consumers empowers the e-WOM creates user generated data (UGC), another source of information required both business and consumer in doing their social commerce decision [2, 3, 4].

Social network site (SNS) (i.e. Facebook, and Instagram) is the most popular platform among social media user. Initially

SNS was created to build virtual network communities so that user can communicate and share experience, idea, information and common interest as in real-life connection [5]. The increase users of SNS, has boosted the use of SNS as s-commerce platform. In the context of s-commerce, SNSs a widely support both B2C and C2C commerce model. For B2C, a company creates it's an own SNS account or page to promote and sell their products or services and usually it is linked to company's website. Company has also taken an opportunity to join SNS marketplace and commerce or retail group. As for C2C, SNS marketplace and group (based on common interest) is the best choice to sell and promote the products and services. This kind of SNS is assisting consumer by offering seller or marketer or produce generated content (SGC) such as product or service and seller information, consumer experience and other s-commerce constructs generated from e-WOM based on reviews, ratings, likes, shares, comments and recommendations [5, 6, 7]. The widely use of SNS for online commerce can be seen through the report by [8] claiming that, in case of Malaysia, 26 million Internet users access to SNS and 41% of Malaysian use SNS as source of new brand discovery and inspiration for their purchases decision. Therefore in this study, we refer SNS based-commerce as the use of SNS platform for online commerce activities in order to support s-commerce activities.

The increase use of SNS as s-commerce platform has motivated researchers to investigate this phenomenon, particularly the SNS consumers' behavior toward s-commerce decision. Understanding customers' behavior is essential for both business and customer. SNS as source for commercial information and social exchange enrich consumer s-commerce decision that lead to higher positive perception of the consumers to the SNS, products and services, resulting increase in volumes of sales, customer loyalty and decreased costs [6, 9]. In another words, it helps business to plan its s-commerce strategy as well as marketing strategy [1, 9].

Previous studies indicated the website consumers' behavior is not only affected by the content itself but also the design of website, and position on screen is a critical, particularly in influencing consumer decision-making [7, 9, 10]. In studying of consumers' behavior related to website design and position on screen, eye tracking is one of the methods used by researchers. Eye tracking tool is used to collect the fixation data based on consumers' gaze on certain area known of area of interest (AOI) [11, 12]. Eye-tracking technique is always

This work was supported by Universiti Malaysia Sabah (SLB0160)

used because researchers believe what a person looking at indicates that a person currently is thinking about or attending to and it leads to purchase decision [13, 14]. Thus, investigating purchase decision related to website design gain mass attentions from researchers. For example, Hwang & Lee [15], Chae & Lee [16], Huddleston et al.[17], Maslowska et al [18], and Cortins et al. [19] conducted eye tracking study on AOIs of SGC e-commerce website. Huang & Kuo [20], Wang et al. [21] and Pavani et al [22] conducted eye tracking study on information presentation, navigation and complexity level and task of e-commerce website. Menon et al. [23], Mikalef et al. [24, 25] and Kumar et al. [26] conducted eye tracking study on the s-commerce context. All studies showed the significant finding of eye-tracking data associate with consumers' purchase decision.

In the context of s-commerce website, the design and position highlight two main components: SGC and UGC from e-WOM among consumers, and these explain the main difference between e-commerce and s-commerce. S-commerce focuses on support of social connection during commerce activity, meanwhile e-commerce focuses on product information and features by seller, and personalized shopping experience [6]. The emergence of Web 2.0 technology has triggered the evolution of s-commerce platforms and each platform has its own unique function and design to support s-commerce. For instant, SNS mainly known for its' social connection, with more unstructured data sources, limited design for information space and features in facilitating s-commerce activities, is difference from s-commerce website which is primarily created for the aim business goal, therefore has less unstructured data source and more business features (i.e. shopping cart, ordering) [3, 6].

Despite of significant finding of eye-tracking study related to consumers' purchase decision in the context of e-commerce, there are limited study using eye-tracking approach in the context s-commerce particularly the SNS platform. To date, limited studies related to s-commerce can be found especially on SNS platform. In addition, majority of studies gave most focus on UGC components and less on SGC components as well as the combination of the components. Given 1) the increase popularity of eye tracking method in research related to decision making, 2) the limited amount of empirical researches that has employed eye tracking to examine SNS consumer decision making especially examining both SGC and UGC, and 3) the differences between s-commerce website and SNS, have motivated us to conduct this study. Our purpose of conducting this study is to investigate s-commerce consumers' decision making by analyzing SNS (i.e., Facebook and Instagram) AOIs using eye tracking approach, so that we could propose the most important AOI for SNS based-commerce which has ability to affect consumers' decision making. Therefore, we pose these research questions:

- What are the most important AOI for SNS-based commerce based on gaze maps and heat maps?
- Is there any difference on how SNS consumers perceived AOIs based on the gaze maps and heat maps?
- Is there any different of gaze maps and heat maps between Facebook and Instagram?

In this study, we divide the Facebook and Instagram page to targeted AOIs by considering the SNS layout. We used gaze map of fixation time to investigate the order by which SNS consumers viewed the AOIs and heat map to investigate the intensity of SNS consumers look at the each AOI [11, 12].

This rest of the paper is organized as follows: Section 2 discusses background and related literature on s-commerce decision and the use of eye-tracking in analyzing SNS. Section 3 details the research methodological design. Section 4 presents the results. Section 5 discusses the finding and implication of the finding on theory and practice. Last, Section 6 is conclusion emphasizes the purpose of the research and explains the limitation and recommendation of further study.

## II. BACKGROUND AND RELATED LITERATURE

### A. S-commerce Decision

S-commerce refers to commerce activities conducted using the social media platform that support social interaction activities and formation of UGC through consumers participations in the buying and selling products or services in online environment settings [4, 10]. Thus, social platform supports reviews, ratings, online communities and recommendations) about the products/services enhance the s-commerce [7]. The increase popularity of social media usage in s-commerce has attracted many researchers to discover how the social platform shaping the consumer behavior due to the fact understanding consumer behavior particularly, consumer decision making in s-commerce is important for planning a new marketing strategy as well as revise the existing strategy, so that it is oriented to particular market audience directly increase the sale [9]. The five stages model of consumer decision making highlights purchase decision is one of the important process and it is commonly accepted and the decision is not only supported by the content offered by the seller but also UGC formation by customers participation [10, 27].

In the s-commerce, seller quality and product quality play important role in determining consumer purchase decision quality, and product type can moderate almost all the association [28]. Social constructs consist of forum and communities, reviews and rating, and recommendations, which are the source of UGC were found out have significant influence on consumers' purchase decision making [28, 29]. In addition, SNS platform influences consumers' decision making in s-commerce [27]. Huang and Benyoucef [10] investigated the effect of social commerce design factors on the consumer decision and claimed that website or webpage design has considerable effect on consumer behavior. Specifically, web design includes the layout and content are significantly influence consumer purchase decision. Nevertheless, for SNS, the essence of the content design is its UGC [23, 26]. These contents are organized in specific area in SNS page and eye tracking approach always used in order to examine the area [11, 12] because eye tracking is one of the process tracking method to determine consumer decision making due to the fact eye movement and gaze can reflect human thought in decision making [20,21].

### B. Eye Tracking and SNS based- commerce AOI

In recent years, eye tracking approach is widely used in website design studies. Eye tracking used to observe consumer cognitive process to investigate how specific visual features in webpage influence the eye gaze and movement which directly indicate that a person is currently thinking or attending to can lead to a better understand of decision making process [13, 18]. This suggest eye movement and gaze patterns are consistent with pattern predict by the decision adopted [12, 20]. Researchers have adopted eye-tracking approach to examine website design because of the two advantages. First, compare to other approaches particularly, questionnaire and interview, eye tracking eliminates the subjectivity of self-reporting data. Second, eye tracking capability captures user reaction to webpage and show the page part that captured most user attentions [21].

In process tracking study, eye movements capture the gaze maps and heat maps which are composed of fixation and saccades [11, 12, 30]. Gaze maps capture sequence of fixation in term of fixation i) duration which captures the duration of AOIs looked at, ii) frequency which measures how many time AOIs visited, and iii) time which tells the order by which users viewed the AOIs [12, 30]. However, heat maps measure the intensity of people look at the objects recognized as fixation intensities telling us the attention key point of website design [11, 31]. In the context of web design study, webpage grouped in to regions called AOI in various ways depend on website and research purpose. AOIs are categorized based on certain area (e.g., top, middle or bottom) or specific elements (e.g., logo, picture, description) [11, 20]. Eye-tracking tool is used in collecting fixation data based on the AOIs to measure user interest [12, 13]. In the s-commerce context, especially SNS-based commerce, AOIs specific elements are divided into two main parts, SGC consist areas which information provided by the seller, and UGC consist areas which information provided and supported by SNS-based commerce consumers [24, 25].

Eye-tracking studies in the e-commerce context focusing on SGC have shown SGC areas received significant higher attention. The higher level attention on SGC areas associate with human brand has significant influence with perceived purchase decision [16]. Based on fixation count, more attention on product image and description indicate consumers more likely to buy [17]. Based on Cortinas [19], heat maps data showed that product area consist of product name, image, price is likely grab more attention from consumers. For s-commerce platform, some eye tracking studies have investigated the consumer purchase decision based on both SGC and UGC AOIs have been conducted and yielded significant finding. The study found out that UGC areas moderate the effect fixation for SCG area based on fixation duration [15]. Nevertheless, fixation duration and heat maps showed that both UGC and SCG especially, image and description captures more consumers' attention. [18, 24], and fixation duration confirmed that consumer spend more attention to positive review [25]. However, lack studies have been undertaken through SNS-based commerce. Menon et al [23] and Kumar [26] have conducted eye tracking study by examining targeted area of Facebook but solely focusing on SGC AOIs. The results indicated fixation duration higher on price placement near

image [23] and heat maps showed the placement of the image of human face gets more consumers' intensity and attention [26].

From these literatures, we can conclude examining both SGC and UGC AOI using eye-tracking offered researchers a new unique insight to understand consumer's decision making. However, existing studies have not fully explored the impact both SGC and UGC on consumers' decision making in the context SNS-based commerce. Most studies either using eye tracking to analyze SGC or UGC areas. Thus, we took an opportunity to utilize eye tracking approach in examine both SCG and UGC area in the context SNS-based commerce. Our main challenge is to choose the measurement for our eye tracking assessment. Despite fixation duration has been used widely as a measurement, we used fixation time to capture the order by which users viewed the AOIs because we believe the visual hierarchies are important guide for consumer to find the entry point to the SNS page [11, 12]. Furthermore, longer duration fixation doesn't mean always positive attention, it may cause of confusion, for example consumers need time to digest the information that difficult to understand [11,30]. In addition we used heat maps to measure consumer intensity toward AOIs because it is efficiently more effective for web design [11,31].

## III. RESEARCH METHOD

### A. Subject and Design

50 participants consisted of staffs and students of Universiti Malaysia Sabah Labuan International Campus (UMSLIC) participated in the lab experiment. The participants were divided into two groups: Facebook and Instagram (25 participants for each group). The respondents' range was in age from 24 – 36 years old. All of the respondents have experience using SNS for online shopping. The selection of UMSLIC students and staffs as a sample is related to the research material whereby the material for the research is based on the existing Facebook page "*Jualan Borong Barang Terpakai UMSKAL 2012*" as SNS-based commerce platform. The main purpose of this page is to facilitate selling and buying of second hand product targeting UMSLIC community. For this research, a new Facebook and Instagram page as stimuli were created based on the existing page and calibrated it with eye-tracking device. Fixation time and intensity data were collected for further analysis.

### B. Material

The experimental design was based on two simulated SNS: Facebook and Instagram. To retain the nature looking of the existing SNS and the degree of realism, the primary traits and components are kept by retaining the seven AOIs' locations. The AOIs were divided into two main parts. The first part, SGC, consists of Seller profile and product information. Seller profile, which is AOI reflected the seller information, includes the SNS seller's account photo, profile, and name. By clicking the seller's photo and name, the SNS consumers are linked to the seller's SNS page. Product information comprises four AOIs: the product name, image, price, and description. The second part, UGC includes two AOIs, Likes and Comments, which allow the SNS consumers to express their thought and

feeling about the product or services. The arrangement of the AOIs follows the layout provided by the SNS itself. We included only three products from the same category for each SNS to limit time spent on the assignment and prejudice in product selection. The product was chosen based on the most popular searches in the existing SNS, which are printers and stationeries. As a result, we designated a printer for Facebook and stationery for Instagram.

### C. Procedure and Task

The study was conducted within two days, 50 UMSLIC staffs and students were participated in the lab experiment. The first day was for Facebook group consisted with 25 participants and the second day was for Instagram participant with 25 participants. Two days were required in conducting this experiment due to the size of computer lab. The experiment was conducted following three phases:

1) *Phase 1* – Respondents were needed to complete a basic questionnaire in order to obtain demographic information, online purchasing experience, and familiarity with SNS for online shopping. We give the respondent 5 minutes to complete the task.

2) *Phase 2* – Experiment execution: Respondents were briefed on the experiment prior to its execution. Respondents were informed that their browsing activity is recorded. Respondents were given 5 minutes to browse the SNS page without any intervention from the researcher. In this task, respondents were required to browse to search the product that they intended to buy.

3) *Phase 3* – Post-test questioning. Following the experiment, a basic interview was conducted to capture the respondent's answer to the product they intended to purchase.

### D. Method and Measurement

The experiment allowed the researcher to obtain eye tracking data. The data were based on gaze maps in term of fixation time and heat maps. For the analysis, the gaze maps and heat maps within the selected AOIs were counted in, therefore fixation outside AOIs treated as outliers [19]. The heat maps in term of fixation intensity were represented using the color. The dark color represented the highest level of fixation and light color represented the lowest level of fixation [21]. For analysis purpose, the heat maps color was coded to 5 scales from the scale 1 represented by the blue light color means the lowest level of fixation to scale 5 represented dark red representing the highest level degree of fixation.

Fixation time was used to measure the AOI order based on consumers' viewed. The fixation sequence was ordered from 1 to 7, with 1 being the AOI that the consumers viewed at first and 7 representing the AOIs that the consumers viewed at last. Descriptive statistic was used to analyze the fixation intensity and fixation time. The Independent Sample T-Test was used to compare the differences in mean of the fixation time and fixation intensity between Facebook and Instagram. The SPSS v21 programme was used to analyze the data.

## IV. RESULT

The eye tracking data from 44 participants were used for further data analysis, with 6 participants' eye-tracking data being omitted due to calibration issues. As a result, the total number of participants was 24 for Facebook and 20 for Instagram. The findings were organized in accordance with the research questions.

RQ1: What is the most important AOI for SNS-based commerce based on gaze maps and heat maps?

Table I and Table II present the descriptive statistic mean and standard deviation of heat maps and gaze maps fixation time. Table I, descriptive statistic mean and standard deviation measure the intensity of consumer look at the AOIs meaning that the highest number of mean implies the AOI receives the most intensity from the consumers and the lower number of mean implies the AOI receives the less intensity from the consumers. Therefor heat maps results indicate product image (Mean=4.59, SD =0.726) received most intensity, product description (Mean 3.18, SD= 1.514) received acceptable intensity, and both likes (Mean = 1.77, SD = .985) and comments (Mean = 1.77, SD = .459) received less intensity.

As shown in Table II, the descriptive statistic mean and standard deviation represent the fixation time, which measures the order of AOIs viewed by the consumers, beginning with the AOI viewed first and ending with the AOI viewed last. The AOI viewed first by the consumer is indicated by the lowest number of means, while the AOI viewed last by the consumer is shown by the largest number of means. Therefore the results indicate seller profile (Mean=1.59, SD =1.317) is the AOI the consumers viewed first and comments (Mean=6.55, SD= 1.130) is the AOI the consumers viewed last.

RQ2: Is there any difference on how SNS consumers perceived AOIs based on the gaze maps and heat maps?

TABLE I. HEAT MAP (FIXATION INTENSITY) ON AOIS RESULT

AOI	Mean	Std. Deviation
Seller profile	2.41	1.436
Product name	2.68	1.410
Product price	2.43	1.437
Product image	4.59	0.724
Product description	3.28	1.514
Like	1.77	0.985
Comment	1.77	0.459

TABLE II. GAZE MAP (FIXATION TIME) ON AOIS RESULT

AOI	Mean	Std. Deviation
Seller profile	1.59	1.317
Product name	3.30	1.193
Product price	4.05	1.099
Product image	3.16	1.817
Product description	4.91	1.309
Like	4.50	1.798
Comment	6.55	1.130

V. DISCUSSION

Table III shows the ranking of AOI from most important to least important for both heat maps and gaze maps (fixation time). It implies a significant difference in how SNS consumers perceive the seller profile. Based on heat maps, consumers regard the seller profile as a less important AOI (rank = 5), yet in the fixation time, the seller profiles (rank = 1) is the first AOI viewed by consumers, indicating that it is the most important AOI. The same is true for comments, which both the heat maps and the fixation time suggest as the less important AOIs.

We further investigated the relationship between gaze maps (fixation time) and heat maps, whether the order of viewed AOIs by consumers has an influence on the intensity which they look at the AOIs. Thus, result in Table IV, the regression coefficient results ( $\beta = -0.163$ ,  $t = -1.075$ ,  $p > 0.05$ ) show there is no significant influence of the gaze maps (fixation time) (AOI rank – viewed by consumer) on heat maps (the intensity of consumer look at AOIs).

RQ3: Is there any different of gaze maps fixation time and heat maps between Facebook and Instagram?

T-Test for equality of mean is used to compare the differences in gaze maps (fixation time) and heat maps between Facebook and Instagram. Based on heat maps data, Table V shows the differences between Facebook and Instagram. The results show there are significant difference on fixation intensity between Facebook and Instagram for product name ( $t = -4.581$ ,  $p < 0.001$ ), product price ( $t = -9.334$ ,  $p < 0.001$ ) product image ( $t = 10.870$ ,  $p < 0.001$ ), product description ( $t = -8.452$ ,  $p < 0.001$ ) and likes ( $t = 9.314$ ,  $p < 0.001$ ). But there is no significant difference for seller profile ( $t = -0.726$ ,  $p > 0.05$ ) and comments ( $t = -1.792$ ,  $p > 0.05$ ).

Table VI presents how Facebook and Instagram differ in terms of gaze maps (fixation time). The findings demonstrate that there is a substantial variation in the order in which SNS consumers viewed AOI on Facebook and Instagram for product description ( $t = 4.926$ ,  $p < 0.001$ ), but there is no statistically significant difference for others AOIs.

TABLE III. AOI RANK MOST CRUCIAL TO LESS CRUCIAL

AOI	Rank	
	Heat map	Gaze map (Fixation time)
Seller profile	5	1
Product name	3	3
Product price	4	4
Product image	1	2
Product description	2	6
Likes	6	5
Comments	6	7

TABLE IV. AOI RANK MOST CRUCIAL TO LESS CRUCIAL

AOI	Heat map		
	$\beta$	t	Sig.
Gaze map (Fixation time)	-.164	-1.075	.289

The findings reveal that SGC areas, particularly product image and description attracted greater attention from SNS-based commerce consumers as compare to UGC area in making purchase decision. This result is in accordance with the previous studies finding, largely have confirmed that SCG in term of product information namely, product name, image, price and description have significant influence on consumer decision making [16, 17, 19]. The most significant aspects of product information are the product image and description, which have the capacity to increase consumers’ trust and confident in the product [7, 17]. The results from gaze maps (fixation time) indicate that SCG of seller information is the first area visited by the consumers. We believe this result is related to SNS (i.e., Facebook and Instagram) page design specifically, the layout, in which seller information, including seller photo, profile, and name, is displayed at the top of the post. According to Huang and Benyoucef [10] website design is one of the consumers purchase decision determinants. However, the heat maps results show that seller information is the least important area among SCG, meaning that consumers place more emphasis on product information during the product search and purchasing process.

Although previous studies [24, 25] have argued SNS consumers give more focus and attention to UGC areas in making purchase decision, but it contradicts with our findings. This phenomenon can be explained based on (1) the role of UGC itself. In this study, SNS UGC comprises of likes and comments, which are considered as supplementary information that the seller does not supply. SNS consumers prioritize product information; but, if they are dissatisfied or uncertain with the information provided by the seller, or if they require extra clarification, they search it form of likes and comments as claimed by Hwang & Lee [15] and Maslowska et al. [18] UGC supports and moderates the product information for consumer conducting their decision making. (2) Limitation of SNS page design. SNS page design is different from s-commerce webpage. More social constructs for UGC to promote selling and buying activities can be found on s-commerce websites. S-commerce websites typically include rating and product recommendations features and these features are not available on SNS. Although the likes feature is accessible in SNS, it does not imply purchasing when compared to the rating function, which is generated after the purchase done.

TABLE V. T-TEST EQUALITY OF MEAN RESULT FOR HEAT MAP

AOI	t	df	Sig. (2-tailed)	Mean difference	Std. Error difference
Seller profile	0.726	40.41224.586	0.472	.292	0.402

Likes	0.475	41.753	0.637	1.142	0.298
Comments	0.828	41.971	.0413	0.308	0.373

We analyzed whether the order of consumers viewed AOIs has significant effect on the intensity of consumer look at the AOIs. Our findings show that there is no significant effect of the order in which consumers viewed AOIs on the intensity with which they looked at the AOIs, suggesting that consumers' attention on SNS AOIs stems from their own context related to purchasing decision. Purchasing decision making is usually more linked to the material's content and the information consolidation of the products or services [19].

The results of the comparison between Facebook and Instagram show that there are some significant difference in mean on the intensity with which consumers look at product information namely, product name, price, image and description, and likes. We argue that the differences in the goals and features served by each SNS, as well as the manner in which sellers utilize the both SNS to provide information, are the main contributors to this findings. Facebook is mainly used to associate with individuals and brands, helping in enhancing brand by leveraging eWom [32]; however Instagram mainly used to share picture, video or other kind of media, and for each media usually followed by story [32]. Additionally, fixation time results which used to measure the order of AOIs indicate the significant different solely for product description. We believe that the differences in the layout of both SNS's webpages contribute to these findings. On Facebook, the product description displays first, followed by the product image, but it is other way round for Instagram.

The results of this study have important implications for both theory and practices. From a theoretical standpoint, most prior research in s-commerce [15, 23, 24, 25, and 26] adopted eye tracking approached to investigate consumers' decision making in utilization of both SGC and UGC. Despite of significant results of those studies, lack of research was undertaken through SNS platform in particularly examining the UGC components. Therefore, this study attempted to fill this gap by extending Mikalef et al [24] with adaption of SGC and UGC through SNS platform. Our findings pinpoint SGC receives more attention from consumers compare to UGC during performing their decision making. Surprisingly, it contradicts the purpose of the SNS which is promoting sociability, indicating while doing online shopping consumers generally focus on their goal which is to purchase. In addition, UGC which is most important to determine consumers' decision making in s-commerce does not in line with our findings. Thus, our study provides the enrichment to existing literature concerning consumers' decision making in s-commerce by highlighting both SGC and UGC in a new related setting called SNS-based commerce. From our findings, we

argue (1) the difference of s-commerce platform contributes to different features of UGC and indirectly viewed and perceived differently by consumers and (2) UGC plays a role as supportive, additional or alternative information will be referred by consumers if they unsatisfied or uncertain with product information provided by seller. Further study is needed to acquire better understanding of this occurrence.

From a practical viewpoint, the important of our findings generates insights for who are interested to utilize SNS-based commerce as individual sellers or as a company for s-commerce strategy. The results reveal product information especially image and description, grab the most of consumers' intensity and attention, indicating product image as key point of the SNS page. It suggests seller and company should focus on how to present their product image and description in order to grab consumers' attention. Company and seller should utilize any method or technique to highlight the product image. Providing additional support to highlight product image include zoom function, close-up or use of human (model) has proven to attract consumers' attention [16, 33]. The way in which product descriptions are presented should be emphasized so that they are able to attract consumers' attention; failure to do so will result in consumers diverting their attention to gain additional or alternative information from other sources such as product reviews, which is quite risky and may cause consumers to refrain from making purchases. Therefore, seller and company should provide detail information about the product because it has been proven from previous research asserted the good quality of product description means consumers more likely to buy. [17,18, 25] Although UGC (i.e., likes and comments) component is less important, it is not insignificant. Seller and company should continually monitor and response wisely. Furthermore, seller information is discovered as a critical key entry point for both Facebook and Instagram. As a result, clear and exact seller information is required in order to obtain consumer trust and confidence [17].

## VI. CONCLUSION

In summary, we present a study to investigate s-commerce consumers' decision making by analyzing SNS (i.e., Facebook and Instagram) AOIs using eye tracking approach. We used gaze maps (fixation time) to measure the order by which consumers viewed the AOIs and heat maps (fixation intensity) to measure the intensity of people look at the AOIs. In addition, we compared consumer decision-making on Facebook and Instagram based on gaze maps and heat maps data. The findings revealed that both fixation time and intensity suggest that the most important AOI for consumers during their decision making process is product image and the least important is comments. Our investigation showed that the gaze maps (fixation time) (the rank of AOI viewed by the consumer) has no significant effect on heat maps (the intensity of consumer look at AOIs). Furthermore, a comparison of Facebook and Instagram revealed there is significant difference in consumers' intensity on SCG of product information and UGC of like, as well as a significant difference in gaze maps (fixation time) on product description.

The first limitation is the generalizability of the research mainly sample respondents and SNS applications. The sample

responders consist only UMSLIC students and staffs, age between 22- 34 years old, do not overall picture the SNS user population particularly Malaysia. Therefore the future research, with more samples represents SNS-based commerce consumers population must be adopted to obtain better understanding on subject matters. Because of the popularity of these applications in Malaysia, this study focused mostly on Facebook and Instagram; however, with the advancement of technology and globalization, certain SNS, such as Tiktok and Pinterest, have begun to gain awareness. Each SNS has its own set of primary function criteria. Therefore, in future research, adopting this research to examine the AOIs of the identified SNS to highlight its' function and criteria. Second, current study focuses on gaze maps (fixation time) and heat maps. In the future study, the use of fixation count, frequency and duration will be needed to measure the degree of attention and focus on AOIs. Thus, comparison study can be conducted to provide deep understanding of SNS consumers' attention. Third, for each SNS, we placed three products in the same category, with the goal of making it easier for consumer to search within a limited time frame. However, this is not really represent the real setting of SNS consists more products from variety categories. For the future research, we explicitly recommend different products from different categories should be included to obtain deep understanding on how SNS user make decision based on product and category differentiation. Despite its limitation, we believe this study is still beneficial for company, business organization, and individuals who are interested in utilizing SNS as one of their s-commerce marketing strategies. For other researchers, this study offers fundamental understanding of consumers' attention on SNS page in context s-commerce as a foundation for future research in this field.

# Chatbot Design for a Healthy Life to Celiac Patients: A Study According to a New Behavior Change Model

Eythar Alghamdi<sup>1</sup>, Reem Alnanih<sup>2</sup>

Computer Sciences Department, Faculty of Computing and Information Technology<sup>1,2</sup>  
King Abdulaziz University, Jeddah, Saudi Arabia<sup>1,2</sup>  
University of Bisha, Bisha, Saudi Arabia<sup>1</sup>

**Abstract**—There is an absolute need for technology in our daily life that makes people busy with their smartphones all day long. In the healthcare field, mobile apps have been widely used for the treatment of many diseases. Most of these apps were designed without considering health behavior change models. Celiac disease is a significant public health problem worldwide. In Saudi Arabia, the incidence of celiac disease is 1.5%. Celiac patients have a natural demand for resources to facilitate care and research; however, they have not received much attention in the field of healthcare apps. This study introduced a new health behavior change model based on the existing common models and adapted it to the use of technology for the changing behavior of celiac patients towards healthy suitable food. As proof of concept, the new model was applied to the WhatsApp chatbot for patients with celiac disease. To test the impact of the chatbot, 60 Saudi celiac patients participated in three steps. First, they completed a pre-test questionnaire. Then, the participants were divided into two groups: the control group, which was left without any intervention, and the test group, who used the chatbot for 90 days. Finally, all participants completed the post-test questionnaire. The results confirmed a significant statistical difference between both groups, and the test group improved their healthy life in terms of eating habits, reduced celiac symptoms, and commitment to the treatment plan.

**Keywords**—Celiac disease; health behavior changes models; healthcare apps; user-centered design; experiment test; WhatsApp chatbot

## I. INTRODUCTION

There is an absolute need for technology in daily life. Everyone is dependent on technology to the point that we cannot stay without it; starting from communicating with others and ending monitoring of health. One of the most popular technologies worldwide is mobile, and the number of people around the world who use mobile in 2021 is 5.27 billion users, accounting for 66.85% of the total global population, every one of them spends an average of 145 minutes daily online [1][2]. In addition, statistics show that mobile users in the United State rely on their mobile devices to make decisions about many things, such as making decisions about purchasing a product, choosing a place to live, or choosing daily activities [3].

In the healthcare field, mobile apps have been used widely for many diseases, such as atrial fibrillation and diabetes. It has

also been used to control or change unhealthy behaviors, such as smoking and alcohol drinking [4-7]. Most healthcare apps aim to monitor patients' behaviors and follow their improvement [8]. On one hand, most of these apps were designed without considering the health behavior change models such as the health belief model (HBM), theory of planned behavior (TPB), diffusion of innovation theory (DOI), social norms theory (SNT), and transtheoretical model (TTM) [8]. This cast doubts their effectiveness in controlling user behavior or changing it [9]. On the other hand, a few apps are based on one of the health behavior change models, but some studies have proven that they are ineffective in avoiding relapse and because there are many flaws in these models [9].

Health apps depend on the user to enter most of the data, and if the user does not commit to using them daily by entering the required data, it may become useless. A study has proven that the more apps on the mobile device, the less the user uses them [10]. This means that if a mobile user has 20 apps on his mobile device, he uses approximately 8-10 of them actually. In addition, some statistics showed that mobile users use social networks more than other apps, spend half of the mobile use time on it, and they use it daily and for extended hours.

A social network service is an online platform that people use to build social relations with other people by sharing their interests. WhatsApp is the most used social network globally, with 1.5 billion monthly active users [10]. WhatsApp allows the user to communicate with other users using writing messages, voice notes, voice calls, and video calls through simple encrypted interfaces. WhatsApp also supports the conversational system, which is a computer system intended to converse with a human in a manner similar to a human using writing, speaking, or gesturing. The conversational system actions are based on user inputs using both short-and long-term user knowledge [11]. The chatbot is a conversational system supported by WhatsApp. Chatbots have been widely used in customer service. In the field of health, chatbots are used on a small scale to spread health information, deny rumors, and correct false information [12, 13].

Celiac disease is a significant public health problem worldwide. It is an autoimmune enteropathy resulting from the interplay between environmental and genetic factors, which is affected by eating gluten-containing grains [14]. The current worldwide prevalence of celiac disease is between 0.7% and

1.4%, and it affects women more than men and children more than adults [15]. In Saudi Arabia, the incidence of celiac disease in adults and children is 1.5%, which is at least twice the average prevalence rate in Europe and North America [16, 17]. Although it is a high rate, there is a study that confirmed that the incidence of celiac disease in Saudi Arabia is higher than 1.5% and reaches 2.7% [18]. However, celiac patients have not received much attention in the field of healthcare apps; rather, they rely heavily on nutrition apps, and only 5% of specialists use social networks, websites, and nutrition apps to educate celiac patients [19, 20]. In contrast, celiac patients have a natural demand for web-based resources to facilitate care and research, especially on mobile devices [21].

Therefore, this paper aims to take the benefit of user experience toward using social media but, instead of taking this user experience randomly, we take it based on a scientific model. All this is motivated by the human sense to improve the life quality of celiac patients since the potential benefits of the proposed solution are painless and easy life for them. This paper focuses on the problem from two perspectives, as follows:

- The user's perspective: The user uses many apps in order to change his/her health behavior, but a large number of apps on the mobile cause him to become distracted, which makes him gradually tend to quit using those apps. In addition, healthcare apps built based on one of the common health behaviors change models are negatively affected by their limitations. Therefore, it would be better to design a model that avoids the limitations of common models and benefits from the apps that the user already uses to change behavior.
- Developer's perspective: The developer wants to develop an app that achieves widespread and supports the sustainability of continuous use by users, especially if its target changes behavior. It has been noticed that social networks are the most used mobile apps. Therefore, it would be better to use social networks to change healthy behaviors rather than developing a new mobile app.

In this paper, the authors proposed a new health behavior change model that can be adapted to the technology. The proposed model is based on common health behavior change models in terms of the defined criteria of objectives for using each one, method of implementation, duration of implementation, advantages, and disadvantages. As a proof of concept, the proposed model was applied to the chatbot through WhatsApp. The chatbot is designed for celiac patients as a scope of the research, and gamification is used as an engagement boost tool. This study's main contributions are the new health behavior change model and the benefit of social media in behavior change. The implications of these contributions are to the creation of a health behavior change model that avoids the shortcomings of existing models. Also, taking advantage of the long hours that users spend using social media.

The proposed design was empirically tested with 60 celiac patients divided into two groups for three months (90 days)

based on a study that proved that celiac patients' condition could improve from one month to six months [22, 23].

The rest of the paper is organized as follows: The second section contains the literature review, and the third section provides the data collection and analysis. The fourth section explains the proposed model, and the fifth section shows the prototyping and design phases. The sixth section presents the details of the experimental design, the seventh section discusses the results, and the eighth section concludes the paper.

## II. LITERATURE REVIEW

This section divides the literature review into several subsections in terms of the health behaviors change models, their applications in the healthcare field, mobile health apps, WhatsApp and chatbot, and the methods used to collect and analyze the data.

### A. Health Behavior Change Models

Social and behavioral sciences researchers have invented different models to change people's behavior in the health field. The most common models are the HBM, TPB, DOI, TTM, and SNT [24-28].

Although these models have some advantages, they have many disadvantages: for example, HBM works only with a fatal disease [24], TPB is based on motivation and ability [25], DOI works better with the adoption of behaviors rather than cessation or prevention of behaviors [26], SNT focuses only on social influences and their impact on an individual's behavior [28], while TTM operates on the assumption that taking years to change behaviors [27]. In addition, many of these models do not consider the maintenance of behavior, but rather focus on initiating behavior.

### B. Health Behavior Change Models Applications

To the best of our knowledge, no studies have explored the impact of the application of health behavior change models on celiac patients. One study [29] found that TPB was used to measure celiac patients' beliefs about a gluten-free diet. However, it did not measure the effect of TPB on patients with celiac disease in terms of health behavior change.

The authors in [30-33] used HBM in their studies. The authors in [30] targeted the asymptomatic hyperuricemia patients, but measured 5 of HBM constructs only, the follow-up was short, and participants were from one community. The authors in [31] targeted the obesity patients, but the sample was small because of the low response rate and data collection was from a single campus. The authors in [32] targeted the gestational diabetes patients, but there was a lack of related works on which the study relied, and they used self-reporting. The authors in [33] targeted the smokers, but gathering information was by self-reporting, the study relied on people's ability to remember past behaviors accurately, which cannot be trusted, and due to some legal, ethical, and social reasons in the study community, it is not possible to trust that the answers obtained were accurate.

The authors in [34-36] used TPB in their studies. The authors in [34] targeted the smokers, but the implementation

was in the tobacco belt, which may affect the reactions of the participants, and the study measured the smoking behaviors before the campaign only, it did not measure it after the campaign. The authors in [35] targeted the type two diabetes patients, but the study did not take the patient's diversity into account and the social desirability bias might affect the accuracy of the data. The authors in [36] targeted the cervical cancer patients, but the study did not employ an experimental design to establish the causal effect relations among variables.

The authors in [37-38] used DOI in their studies. The authors in [37] targeted the smokers, but the implementation relied mainly on community awareness in a community that accepts smoking and there was no monitor of participants to ensure adherence. Authors in [38] targeted the maternal and neonatal health, but the health systems problems, Infrastructure problems, and cultural constraints affected the study result.

The authors in [39-41] used TTM in their studies. The authors in [39] targeted the smokers, but the study did not use the blood tests to measure nicotine before and after the experiment, the study did not include all TTM stages, the sample was small, and the follow-up was short. Authors in [40] targeted the cardiovascular patients, but the intervention was based on individuals' readiness for behavioral changes, and it had not part in making them ready, and the post-test was not applied. Authors in [41] targeted the obesity patients, but gender was not considered as a mediating variable, and there was the sample loss during the study.

Finally, the authors in [42-44] used SNT in their studies. The authors in [42] targeted the smokers, but the study linked social norms and the use of tobacco products with a temporal relationship, which in turn changes and therefore it is not possible to establish the relationships between them. Authors in [43] targeted the type two diabetes patients, but there was a lack of real behavioral measurements, which limits the

generalization of these results. Authors in [44] targeted the people who eat junk food, but the follow-up was very short.

From our review and analysis of the methodologies that were used in previous studies, the aim of each model and the most appropriate case for its use became clear. Also, the shortcomings of each model were discovered. Table I describes the proposed new model compared to the other common models in terms of a set of criteria such as the number of processes, the healthcare domain, problem-solving issues, applying the technology, using social networks, taking advantage of social influences, and the ability of the model to work with behavior adoption, behavior prevention, and behavior maintenance.

C. Healthcare Mobile Apps

Based on the studies published in the field of health apps, it was noticed that many of those apps work based on one or more of the health behavior change models in order to track behavior [8]. The authors in [4] used SNT in their app and targeted the atrial Fibrillation disease patients, but a very small sample used the app (only 2 patients). Authors in [5] used TTM in their app and targeted the Type two diabetes patients, but it was limited to patients with high motivation to use a mobile app for self-management. Authors in [7] used SNT in their app and targeted the alcohol drinkers, but the sample was from rural and urban without consider the digital divide between them. Authors in [45] used TPB in their app and targeted the hospitalized smokers, but the sample size was relatively small, and the follow-up was short. Authors in [46] used DOI in their app and targeted the gestational diabetes mellitus patients, but the number of interviews was limited. Authors in [47] used TTM in their app and targeted the children with diabetes, but the app did not include all TTM stages.

TABLE I. THE COMPARISON CRITERIA BETWEEN MODELS

Model	Process	Problem	Healthcare Domain	Technology	Social Networks	Social Influences	Behavior Adoption	Behavior Prevention	Behavior Maintenance
HBM	Six constructs	Diabetes, Hyperuricemia, Obesity Smoking.	√	√	√	X	√	√	X
TPB	Six constructs	Cancer, Diabetes, Smoking.	√	X	X	X	√	X	X
DOI	Five categories	Maternal & Neonatal health, Smoking.	√	X	X	X	√	X	X
TTM	Six stages	Cardiovascular, Obesity, Smoking.	√	X	X	X	√	√	√
SNT	Six phases	Diabetes, junk food eating, Smoking.	√	X	X	√	√	X	X
The new model	Four stages	Celiac, Chronic disease.	√	√	√	√	√	√	√

#### D. WhatsApp and Chatbot

WhatsApp is the most widely used social and communication app globally. User engagement owing to its features, such as free calls and messages, the user interfaces are simple, easy to use, and messaging encryption [10]. The chatbot is a conversational agent that interacts with users using natural language [48]. Chatbot inhabits platforms such as Facebook, Messenger, WhatsApp, Telegram, iMessage, and even websites. Users communicate with a chatbot via the chat interface, such as talking to a real person, chatbot interprets, and processes the user's words and provides an instant answer.

Different chatbots have been developed using text communication, and they have been used in various domains such as customer service, education, and website help [48]. Chatbots have been used in the healthcare field for many reasons, like:

- Change behavior as in food consumption chatbot [11] on Facebook Messenger and smoking cessation chatbot [49] on Telegram.
- Sharing health information as in COVID-19 chatbot [12] on WhatsApp and Saudi health ministry chatbot [13] on Telegram.
- Monitoring Patients as in chronic conditions' teenagers chatbot [50] by Text Message.

As a summary for this section, the common existing models for health behavior change have critical limitations that effect of their applications negatively. Therefore, this paper intends build a new model to avoid those limitations. Also, it's notice that the use of social media to change health behavior is an idea that was previously applied, but not applied to change the behavior of patients with chronic diseases. Therefore, this paper intends to take advantages and use social media to change behavior of chronic diseases patients.

### III. DATA COLLECTIONS AND ANALYSIS

Three different collection methods were used in this study: 1) Interview with celiac expert users. 2) Questionnaire distributed to patients with celiac disease. 3) Studying exciting changing behavior models in the literature review. The reason is to collect the information data from different angles and draw a complete picture of the existing problem. The following subsections describe each method and their results.

#### A. Existing Health Behavior Models

Five common existing health behavior models were explored, examined, and analyzed. The existing health behavior models were HBM, TPB, TTM, DOI, and SNT. The goal was to determine the similarity, differences, necessary stages, and unnecessary stages to build a new health behavior change model that is compatible with the needs of patients with celiac disease. To analyze the five-existing model, three steps were followed:

- 1) Finding similarities between the three models (HBM, TPB, TTM).
- 2) Dispense with unnecessary stages in the three models (HBM, TPB, and TTM).

3) SNT and DOI were added to the three models (HBM, TPB, and TTM).

#### B. Interviews

Interviews were conducted with celiac experts to find out the following:

- The most common celiac symptoms.
- The most common treatment plan for celiac.
- The difficulties that celiac patients face in treatment plan commitment.

The celiac experts were divided into four categories as follows:

- Group 1: A patient diagnose with celiac four years ago or more.
- Group 2: A patient's parent who was diagnosed with celiac four years ago or more.
- Group 3: A dietitian who has supervised the diet of celiac patients for four years or more.
- Group 4: A gastroenterologist who has treated celiac patients for four years or more.

The reason of chosen four years or more as a criterion are:

- 1) The period required to change behavior.
- 2) The period required for a person to become an expert in a field.

It has been proven that any behavior can be changed within 18 days and not more than 254 days (less than a year) [51, 52]. It has also been proven that a person can become an expert in a field by practicing for not less than 10,000 hours [53], which can be considered as 3.9 years if the practice is daily, as in the case of chronic diseases, for 7 hours.

Ten questions were designed and prepared for the interviews. Before the interviews were conducted, a pilot test was conducted with an expert to test the suitability of the questions. The expert is a female celiac patient since 2015 and lives in Madinah, Saudi Arabia. She helps new patients adhere to their treatment plan by providing educational lectures about celiac and how to cope with it. After expert-approval, the interviews were conducted by phone, due to the social distancing measures that were imposed in the summer of 2020–the time of the interviews conducted- due to the spread of COVID-19. The interviews were conducted with four celiac patients, two celiac patients' parents, two dietitians, and three gastroenterology consultants. 54.5% of the interviewees were females, 45.5% were males. 36.4% of the interviewees had Ph.D. degree, 27.3% had bachelor's degree, 18.2% had master's degree, 9.1% had degree less than a bachelor's degree, and 9.1% prefer not to answer the question. 100% of the interviewees believed that the best treatment way for celiac is Gluten-free diet. The celiac symptoms -based on the interviewees' opinions- were stomachache, bloating, diarrhea, nausea, headache, and fatigue. 100% of the interviewees confirmed that the patients never experience the same symptoms after commit the treatment way. Difficulties that the

patients meet -based on the interviewees' opinions- were lack of alternatives, the need to sessions with a dietitian, and lack of support groups.

### C. Questionnaire

The questionnaire was distributed among different celiac patients' communities targeting the celiac patients and their relatives to answer the following questions:

- How are patients ranked as the most common physical and psychological symptoms based on the fastest appearance when they eat gluten?
- How are patients ranked as the most common physical and psychological symptoms based on the fastest disappearance when they stop eating gluten?
- What are the patients' preferences regarding the use of technology?

A total of 137 responses were received. The questionnaire was divided into five sections, and each section contained several questions. Before the questionnaire was distributed, an expert tested content validity and face validity. Many comments were received and considered before being distributed.

For reliability, one week after the questionnaire was administered. Sixty-nine participants agreed to retake the questionnaire (50.36% of the total participants). The questions' results were tested by finding the correlation between the results of the first time the questionnaire was submitted and the results of the second time. The overall correlation was 0.9749042904, which indicates a very high positive correlation.

When finding the correlation for each question separately, the results ranged between 0.7967715443 and 1, which made the correlation moderate, and reliability was acceptable. The above results proved the following:

- 83.8% of patients are female.
- 87.6% of patients are Saudi.
- 46% of the patients are 29 years old or less.
- 83.2% of the patients lived in three regions: Riyadh (34.3%), Makkah (29.2%), and Eastern (19.7%) regions.
- 75.18 of the patients lived in six cities: Riyadh (30.7%), Jeddah (22.63%), Madinah (8.03%), Dammam (5.11%), Dhahran (5.11%), and Makkah (3.6%).
- When patients eat gluten, they suffer from stomachache, bloating, diarrhea, nausea, headache, and fatigue.
- When patients suffer from eating gluten symptoms, they feel a desire to isolate themselves, worry that symptoms get worse, fear of what others think about them, that they are a burden to others, shame about their illness, depression, and the desire to cry.
- 67.9% of patients think that having a health application will benefit them.

- All patients can read Arabic.
- 82.5% of patients prefer WhatsApp over any other social media apps.
- Patients want the mobile application to provide alternative products, gluten-free recipes, medical and psychological follow-up, gluten-free diet suggestions, and periodic reports.

## IV. PROPOSED MODEL

To build a new health behavior change model, the focus has been on, in the first hand, the users and their needs, and, in the second hand, the software development life cycle. Therefore, user-centered design (UCD) has been used as a model that focuses on the users' needs and the waterfall model as a software development life cycle model. In the following subsection, details about the proposed model and its phases, phase duration, and phase quiz.

### A. The Chronic Diseases Extended Model

Since the new model extends from five old models, it was decided to name the new model "The Chronic-Disease Extended Model," or "CDEM" in short form. This section provides an overview of CDEM and its phases.

The CDEM involves progress through a series of phases, but progression occurs in a nonlinear fashion. This means that patients can progress from the earlier phase to later ones, regress from the later phase to the earlier one, and recycle through the phases from the last phase to the first one. As shown in Fig. 1, the model consists of the following four phases.

- Phase 1: Preparedness: the phase in which the patient knows what to feel about the disease.
- Phase 2: Readiness: the phase where the patient is ready to deal with the disease.
- Phase 3: Confidence: the phase in which the patient can find solutions for every barrier that faces.
- Phase 4: Continuance: The phase where the patient commits to the treatment plan.

Every phase has its own actions that help reach the phase goal. In addition, a patient is assigned to one of the phases based on his answers on the phase quiz, which is conducted every two weeks.

Fig. 1. Chatbot Processes.

TABLE II. THE PHASES AND THE WAY TO PROGRESS THROUGH THEM

The phase level	Phase character	Progressing status
<b>Preparedness</b>	Person knows what to feel about his disease and be conscious of the need for innovation.	Motivation to start treatment
<b>Readiness</b>	Person feels the seriousness of leaving the disease untreated and knowing treatment ways.	deciding to change behavior
<b>Confidence</b>	Person believes that social norms approve the new behavior and starting the new behavior.	feeling confident in the ability to perform a behavior.
<b>Continuance</b>	Person's perception of the obstacles to performing the behavior and knowing the factors that facilitate the performance of a behavior.	-

Table II presents the phases and ways of progressing through them. The first column in the table shows the phases' level, the second column shows the patient attributes in the different phases, and the last column shows the attribute that makes the patient ready to move to the next phase.

**B. Phases Duration**

Each phase differs from another in its goals and actions, and each patient differs from the other in his personality and needs. Therefore, it is difficult to predict how long each patient needs at each phase because of the large number of variables. This model suggests that the duration of each phase is a minimum of two weeks and a maximum of three months, based on the duration average of the five models that have been studied. To determine if the patient is ready to move to the next stage, a test called the phase quiz.

**C. Phases Quiz**

A phase quiz was developed based on the TTM instrument. The TTM instrument was created by Prochaska and DiClemente and validated in different intervention studies, which have focused on multiple health problems. Furthermore, phase quizzes develop based on the short version of the instrument, and its validation has been proven [54]. The reason for this choice is that the short version contains only one question, and the patient never feels bored when he takes the test every two weeks. The phase quiz consists of one question with four clauses that detriment whether patients stay, progress, or regress in the phases based on the sentence the patient's choice. Table III presents the question, its clauses, and action when choosing every clause.

TABLE III. PHASE QUIZ QUESTION AND ITS CLAUSES

Question	Clauses	The action when choosing the clause
Did you do the habit that was recommended to stay away from it in the last two weeks?	Yes, and I feel no bad about it.	The patient is in phase 1: <b>Preparedness</b>
	Yes, but I regret it.	The patient is in phase 2: <b>Readiness</b>
	No, But I still face some obstacles with no solutions.	The patient is in phase 3: <b>Confidence</b>
	No, and I totally committed to the treatment plan.	The patient is in phase 4: <b>Continuance</b>

**V. PROTOTYPING AND DESIGNING**

For proof of concept, the proposed model was applied to the chatbot. This section presents the chatbot analysis and chatbot design.

**A. Chatbot Analyzing**

To analyze the chatbot, the flowchart diagram as shown in Fig. 2 starts with a welcome message that explains the chatbot's goal and how to interact with it. Then, the pre-processing step, which is a pre-questionnaire to collect demographic information about the participants and their health behaviors and eating habits. After that, the processing includes the phase quiz to determine each participant's phase and interact with them with different actions based on their phase.

For example, in some phases, participants learn about celiac and its complications; in other phases, participants can find a place to order a gluten-free meal. The participants took the quiz phases every two weeks to reassign them to a suitable phase. Finally, after the experiment period was completed, the participants took post-processing, which is a post-questionnaire to collect information about their health behaviors and eating habits.

**B. Chatbot Design**

This section presents the chatbot prototype, tool used for development, pilot test feedback, and final chatbot design layout.

1) *Chatbot prototype*: To ensure the correctness of the information provided by the chatbot, information about celiac was collected from the website of the Saudi Ministry of Health. The chatbot prototype was designed using a chatbot design tool called "Botsociety".

2) *Deployment service provider*: To deploy the chatbot on WhatsApp, based on WhatsApp policy, it is necessary to deal with a licensed company. A search was conducted to identify different licensed companies that work as chatbot deployment service providers. The "Widebot" platform was used for chatbot design after strict comparison between five different companies based on the target customers, supporting WhatsApp, supporting Arabic, having an AI engine, and supporting natural language processing (NLP). For AI, "Widebot" uses its own classifier that combination between exact matching, fuzzy matching, and Naive Bayes classifier. For NLP, "Widebot" uses BERT model.

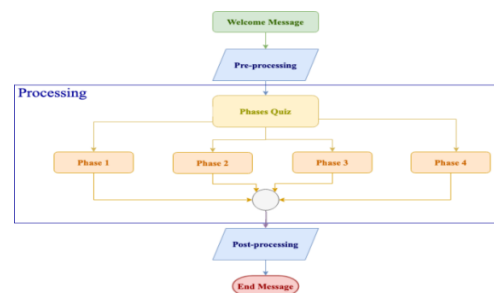

Fig. 2. The Chatbot Flowchart.

## VI. EXPERIMENT

This section presents the details of the experimental design, including, participants, materials and testing procedure.

### A. The Participants

The experiment was conducted on 60 Saudi participants diagnosed with celiac disease. Sixty participants were recruited through online virtual communities of celiac patients in Saudi Arabia. Many patients expressed their desire to participate in the experiment (137 patients). Only 60 participants met the experimental criteria. The criteria were:

- The participants lived in Jeddah. Jeddah city was chosen because it can suggest places that provide gluten-free meals only in Jeddah.
- Participants read and wrote Arabic fluently. Arabic was chosen because Arabic is the language of the chatbot.
- The participant approves to participate in the experiment and commits to it until the experiment ends by signing the consent form.

The 60 celiac patients who participated in the study experiment were split randomly into two groups: the control group and the test group. The control group was left without any intervention, which means that the proposed chatbot was not used, while the test group used the proposed chatbot.

### B. The Materials

An empirical study was planned and executed through three steps to determine whether the new model helps patients improve their health and adhere to the treatment plan. In addition, determining whether the idea of benefiting from the user experience of WhatsApp may be beneficial in the health field. The three steps are:

- Step 1: Pre-test questionnaire to collect the participants' data on eating habits, celiac symptoms, and treatment plan commitment.
- Step 2: Formal test to collect the data attributes during the test and record it in the log-in form to evaluate the participants interacting with the chatbot and their time of use.
- Step 3: Post-test questionnaire to collect the participants' data about eating habits, celiac symptoms, and treatment plan commitment to evaluate the participants' experience in using the proposed design as a tool to improve their health.

### C. Testing Procedure

The participants in the test group only used the proposed chatbot for three months (90 days) since the improvement in celiac patient health could show in a week to 6 months [22, 23]. The experiment was conducted from December 20, 2020, to March 19, 2021. During this process, the researcher observed the WhatsApp conversations with the participants and collected the data daily. The "Widebot" platform is dedicated for collecting the data. This allows the observer to read the conversations and extract data from them. It also gives him an analysis of the chatbot performance and the users' use of it.

## VII. RESULTS AND DISCUSSION

This section analyzes the pre-test and post-test questionnaire results.

### A. Pre-Test Result

First, the control and test groups answered the pre-test questionnaire on December 19, 2020, and the test group started using the proposed chatbot on December 21, 2020. The pre-test questionnaire consisted of the following four questions:

- 1) When was the last symptoms date?
- 2) Do you face difficulties in finding gluten-free products?
- 3) Do you face difficulties committing to the treatment plan?
- 4) Did you eat any food that contains gluten in the last two weeks? (Phase quiz)

From the result, it was noticed that 6.67% of the participants in the control group and 6.67% of the participants in the test group felt celiac symptoms last time on the same day they answered the pre-questionnaire. In addition, 30% of the participants in the control group and 30% of the participants in the test group always had difficulty finding gluten-free products. Additionally, 20% of the participants in the control group and 16.67% of the participants in the test group always had difficulties committing to the treatment plan. Finally, 30% of the participants in the control group and 30% of the participants in the test group were in phase one, based on the CDEM.

### B. Formal Test

The test group started to use the chatbot only. This step provided a clear picture of the number of chatbot times of use, the chatbot features that user tend to use, and the participants' progress in the CDEM phases. Analyzing the result of this step is useful in improving the chatbot for future research and does not affect the outcome of the experiment.

### C. Post-Test Result

After the experiment was completed, both groups of participants answered the post-test questionnaire on March 20, 2021. The post-test consists of the following four questions:

- 1) When was the last symptoms date?
- 2) Do you face difficulties in finding gluten-free products?
- 3) Do you face difficulties committing to the treatment plan?
- 4) Did you eat any food that contains gluten in the last two weeks? (Phase quiz)

From the result, it was noticed that 0.33% of the participants in the control group felt celiac symptoms last time on the same day they answered the post-questionnaire, but none of the participants in the test group felt celiac symptoms on the same day. In addition, 20% of the participants in the control group always had difficulties finding gluten-free products, but only 0.33% of the participants in the test group always had difficulties finding gluten-free products. Additionally, 6.67% of the participants in the control group

never had difficulties committing to the treatment plan, but 46.67% of the participants in the test group never had difficulties committing to the treatment plan. Finally, 26.67% of the participants in the control group were in phase one based on the CDEM, while none of them were in phase four. However, none of the participants in the test group were in phase one, while 43.33% of them were in phase four.

In general, and based on the previous comparison, it is clear that the status of participants in the control group, who were left without any intervention, did not improve; on the contrary, it regressed in many cases. However, the status of the participants in the test group, who used the proposed chatbot, improved, except concerning difficulty committing to the treatment plan.

**D. Discussion**

This section discusses the results statistically to reach the results of this study. The first two subsections compare the results of the two groups in the pre-test and post-test by finding the correlation, and ANOVA test.

1) *Correlation between the two groups:* After obtaining the results, Pearson’s correlation analysis between the two groups’ results for each question was applied, as it is the most used measure of correlation to show the degree of the linear relationship between variables. Table IV presents the results.

As Table IV shows the correlations between the two groups’ answers on the pre-test four questions were large positive correlations between 0.88 and 0.99. The correlations between the two groups’ answers to the post-test questions were as follows:

- Medium positive correlation in one out of four questions, equal to 0.76,
- Medium negative correlation in two out four questions between -0.73 and -0.60,
- No correlation in one out of four questions, equal to -0.06.

This means that the two groups were close in their answers in the pre-test. Still, after the test group participants conducted the experiment, the answers differed greatly, which made some correlation results appear negative, which can be said that the intervention applied to the test group (the experiment) affected the results of the group. Therefore, this intervention can help to reach the goal of changing health behaviors using social media.

However, the "no correlation" result for the second question, which was related to facing difficulties in finding gluten-free products, in the post-test was noticed. This result can be attributed to the fact that the 60 participants were reached through some virtual celiac patient communities, in which patients share experiences about gluten-free products, including the free-gluten products’ companies, and where those products are available. Therefore, it may be difficult to establish a relationship between the status of the participants in the two groups regarding this question.

2) *ANOVA Test between the two groups:* An ANOVA test was applied to determine which hypotheses are listed below:

- H0: There is no difference between the behavior of the Celiac patients before and after using the Chatbot based behavior change.
- H1: There is a difference between the behavior of the Celiac patients before and after using the Chatbot based behavior change:

The ANOVA test finds the p-value, a value that determines whether a significant statistical difference exists between the groups.

Table V shows the ANOVA test results of the pre-test for the groups, while Table VI shows the ANOVA test results of the post-test for the groups.

A P-value < 0.05, indicating a significant statistical difference between the groups. In the two tables above, the P-value for the pre-test was 0.77, which is more than 0.05, which means there is no significant statistical difference, but the P-value for the post-test was 0.0, which means there is a statistically significant difference between the groups. Therefore, we can confirm that the proposed chatbot helped celiac patients improve their eating habits.

TABLE IV. THE PRE-TEST AND POST-TEST CORRELATION BETWEEN THE CONTROL GROUP AND TEST GROUP

The list of questions	Pre-test correlation	Post-test correlation
When was the last symptoms date?	0.96	0.76
Do you face difficulties in finding gluten-free products?	0.88	-0.06
Do you face difficulties committing to the treatment plan?	0.98	-0.73
Did you eat any food that contains gluten in the last two weeks? (Phase quiz)	0.99	-0.60

TABLE V. ANOVA TEST RESULT OF THE PRE-TEST FOR THE CONTROL GROUP AND TEST GROUP

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Square	F-statistic value	P-value
Between Groups	0.066666666667	1	0.066666666667	0.08618127786	0.7701371105
Within Groups	44.866666667	58	0.7735632184		
Total	44.933333333	59			

TABLE VI. ANOVA TEST RESULT OF THE POST-TEST FOR THE CONTROL GROUP AND TEST GROUP

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Square	F-statistic value	P-value
Between Groups	28.03333333	1	28.033333333	50.61574074	0.000000003250293
Within Groups	28.8	52	0.5538461538		
Total	56.83333333	53			

It can be generalized that the chatbot intervention based on the proposed model had a positive effect on the results of the test group compared to the control group that did not use the chatbot, in terms of eating habits, finding alternatives, and progressing in the phases of the new model. However, patients still have difficulties committing to the treatment plan, which may be caused by the difficulty of the treatment plan itself, which includes stopping eating many of the common meals consumed in daily life and social occasions. Also, the reason for the decrease in chatbot usage rate from month to month may be due to the fact that the communication with the chatbot is by using writing, which allows reading the messages again and again that makes the user benefit from the chatbot message history without making a new chat with the chatbot.

### VIII. CONCLUSION

This study built a new health behavior change model based on the common existing models. Then, it used that model to design and test a chatbot for celiac patients in order to find out the answers to the research questions: Does the proposed behavior-changing model-based design of WhatsApp chatbot help celiac patients improve their eating habits?

In order to do that, the data were collected using three methods: studying the most common health behavior change models (HBM, TPB, DOI, TTM, and SNT), interviews with patients, their parents, dietitians, and gastroenterologists, and questionnaires for celiac patients and their relatives. Using these data, the new model was built (called CDEM) and adapted for use in technology. As a proof of concept, the CDEM was applied to WhatsApp chatbot for patients with celiac disease.

Two groups participated in the experiment: the control group and the test group. The control group was left without any intervention, whereas the test group used the chatbot. The results showed improvement in the eating habits of patients with celiac disease after using the chatbot in the test group compared to the control group. Therefore, it can be said that the proposed behavior-changing model-based design of WhatsApp chatbot can help celiac patients improve their eating habits.

This study faced many challenges because the timing of this study coincided during the Covid-19 pandemic, which led to limited communication with the target group, as well as limiting the pre-test and post-test to electronic tests. The study was conducted in the Kingdom of Saudi Arabia and on a Saudi sample from Jeddah only. The same study may provide different results with a different demographic sample or a diverse demographic group.

Our future direction is to conduct more experiments on the CDEM and use it in different social networks, since the experiment was applied in WhatsApp only. In the future work, the authors will study another social network apps' ability to change behavior, as we believe that some apps will give better results than others in achieving the goal. Also, may be carried out on other categories of society to improve the quality of life for sustainability factors.

# Design of Optimal Control of DFIG-based Wind Turbine System through Linear Quadratic Regulator

Ines Zgarni, Lilia ElAmraoui

Research Laboratory Smart Electricity & ICT, SE&ICT Lab., LR18ES44  
National School of Engineers of Carthage  
University of Carthage, Tunisia

**Abstract**—This paper is devoted to implement an optimal control approach applying Linear Quadratic Regulator (LQR) to control a DFIG based Wind Turbine. The main goal of proposed LQR Controller is to achieve the active and reactive power and the DC-link voltage control of DFIG system in order to extract the maximum power from the wind turbine. In fact, the linearized state-space model of studied system in the d-q rotating reference frame is established. However, the overall system is controlled using MPPT strategy. The simulation results are obtained with Sim-Power-System and Simulink of MATLAB in terms of steady-state values, Peak amplitude, settling time and rise-time. Finally, the eigenvalue analysis and the simulation results are rated to ensure studied system robustness and stability, and the effectiveness of the control strategy.

**Keywords**—Wind turbine system; doubly fed induction generator; DFIG; optimal control; linear quadratic regulator; LQR

## I. INTRODUCTION

The main renewable energy sources are Hydro Energy, Wind Energy (onshore or offshore), Solar Energy (PV or thermal), Biomass, Geothermal Energy, Wave Energy, Tidal Energy, and other alternative sources [1].

In 2020, according to IRENA (International Renewable Energy Agency), the share of renewable energy of global electricity production reached 36.6% which 9.58% produced by Wind energy [2][3].

Nowadays, due to the importance that takes the energy, which is at the core of all economic activity, the massive integration of wind turbine systems on power grids has created an effervescence in the world of scientific research, thus making it possible to improve the performance of wind turbines in terms of efficiency, reduced overall costs and maximum extraction energy [4].

In fact, many research works have been established studying the development of new design and control approaches for wind power system.

The most common combination for wind turbines is that with variable speed (with wide range of operation) and based on Doubly Fed Induction Generator (DFIG) which offers 10-15% higher wind energy capture and holds flexible control [5].

In the literature, Vector control is generally applied to control active and reactive powers of DFIG [6]. Even if, over the last three decades, the PI controller is the most successful controllers mostly in the 1st order SISO model of DFIG.

Nevertheless, facing variation of DFIG's parameters (MIMO system), PI becomes vulnerable. [7].

This research work stands out an LQR regulator, as a feedforward controller, using a linearized state-space model of the DFIG wind turbine. This approach reaches zero error between the desired magnitudes and the measured ones for the active and reactive powers and the DC-link voltage within a considerable time delay.

This paper is structured as follows. Section II presents related works. Section III describes the equivalent circuit of wind turbine based on DFIG and the modeling of the wind turbine, the DFIG, the grid side filter and the DC-link in d-q rotating reference frame. Section IV presents the linearized system around a point of equilibrium. In Section V, an LQR control strategy for studied system is discussed. Section VI is devoted to the implementation by creating a block diagram by MATLAB Simulink. Section VII details the simulation of studied system and the obtained results. Section VIII concludes the paper. Finally, Section IX details system parameters.

## II. LITERATURE REVIEW

In recent years, many works have been established on linear control of DFIG Based wind energy conversion system.

A direct control power output for DFIG wind turbine using LQR regulator for rotor side and grid side converters is evoked and discussed in [8].

A LQR Robust static state tracking control, described in [9], is designed to ensure tracking of the active and reactive power of the WECS over the wind speed range employing a polytopic LPV DFIG model.

In [10] they opted to use two control loops; from the reference power, the outer loop determines the reference rotor current and the interloop regulates the rotor current according to the outer loop output using LQR.

In this respect, in this paper, LQR Controller approach is proposed to improve the stability and robustness of the linearized DFIG system.

## III. DFIG-WIND TURBINE SYSTEM MODELING

The aim of this section is to present the Overall system which explains the configuration of the doubly fed induction generator (DFIG) wind turbine.

At first sight, Gearbox establishes the connection between wind generator (DFIG) and wind turbine [11]. Then, the stator is directly connected to the grid, whereas the rotor is connected to the grid via back-to-back converter (RSC and GSC) [12].

Rotor-side-Converter (RSC) represents a rectifier which transforms AC currents and voltages delivered by the rotor into DC currents and voltages, thus allowing a decoupled control of the active and reactive powers [13].

However, GSC stands for a PWM controlled inverter that recuperates DC current and voltage at the output of RSC to generate a three phase AC current and voltage system with the same frequency as the grid given that the variation of the speed of the rotor according to the speed of the wind generates a current with variable frequency.

This configuration allows variable speed operation of wind turbines [14].

Fig. 1 shows general configuration of Wind Turbine system based on DFIG. At the beginning, each part is modeled separately.

### A. The Model of Wind Turbine

Given that the static characteristics of a wind turbine rotor are derived from the relationships between the total wind power and the mechanical power of the wind turbine.

Some parameters of the variable speed wind turbine are taken into consideration in order to modeling DFIG.

In this study, turbine angular speed is considered equal to generator angular speed. Thus, system analysis and modeling have been done as a one-mass.

In Addition, the pitch angle controller dynamics is not taken into consideration on account of the fact that its slower response compared to the electrical control dynamics. Then, differential equation 1 reveals the rotation equation.

$$\frac{d\omega_r}{dt} = \frac{1}{2H} T_m - \frac{1}{2H} T_e \quad (1)$$

Where,  $\omega_r$  : Generator angular speed; H: total equivalent inertia (the equivalent inertia reduced to the shaft);  $T_m$ : Mechanical torque and  $T_e$ : Electromagnetic torque.

The mechanical power captured by the WT is described as follows: [16]

$$P_m(t) = \frac{1}{2} \rho_{air} \pi R^2 C_p(\lambda, \beta) V_w^3(t) \quad (2)$$

Where  $\rho_{air}$  identifies the air density, R is the blade radius,  $C_p$  denotes Power coefficient, and  $V_w$  represents the wind speed.

The power coefficient  $C_p$  depends essentially on two parameters which are  $\beta$  (Pitch angle of the blade) and  $\lambda$  (Tip speed ratio).

$\lambda$  is defined by the following expression: [17]

$$\lambda = \frac{R\omega_r}{V_w} \quad (3)$$

Thus, the curve describing the Power coefficient  $C_p$  as a function of the Tip speed ratio  $\lambda$  by taking a fixed value of pitch angle of the blades  $\beta$  is given by Fig. 2.

As shown in Fig. 2,  $C_p$  has a maximum point to a specific value of  $\lambda$  equal to  $\lambda_{opt}$ .

Fig. 1. General Configuration of Wind Turbine System based on DFIG. [15].

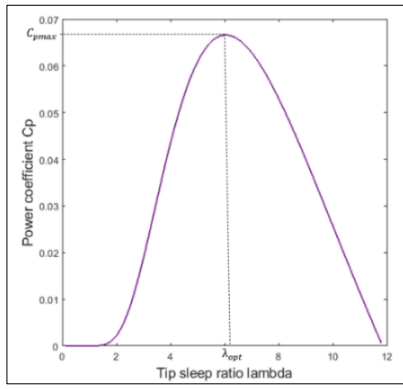

Fig. 2. Power Coefficient as a Function of the Tip Sleep Ratio.

Therefore, the expression of maximum mechanical power  $P_{max}$  is determined by equation 4. [18].

$$P_{max}(t) = \frac{1}{2} \rho_{air} \pi R^2 C_{pmax} V_w^3(t) \quad (4)$$

Furthermore, the range of the optimal power control for WT is obtained when:  $\omega_r \in [\omega_{rmin}, \omega_{rated}]$  and  $V_w \in [V_{wmin}, V_{wrated}]$ .

The control system for wind turbines is generally operates according to the technique of MPPT (Maximum Power Point Tracking). Then, the equation 5 represents the turbine power and the mechanical torque [19], [20].

$$P_{MPPT} = K_{opt} \omega_r^3 \text{ and } T_m = K_{opt} \omega_r^2 \quad (5)$$

$$\text{With: } K_{opt} = \frac{1}{2} \rho \pi R^5 \frac{C_{pmax}}{\lambda_{opt}^3} \quad [21]$$

In fact, the electromagnetic torque is obtained by making the ratio of air gap power to the DFIG mechanical speed. it is then written in the form:

$$T_e = L_m i_{qs} i_{dr} - L_m i_{ds} i_{qr} \quad (6)$$

To sum up, the rate of change of the generator angular speed is obtained from equations 1, 5 and 6.

$$\frac{d\omega_r}{dt} = \frac{K_{opt}}{2H} \omega_r^2 - \frac{L_m}{2H} i_{qs} i_{dr} + \frac{L_m}{2H} i_{ds} i_{qr} \quad (7)$$

### B. DFIG Model

The DFIG is described in the dq frame as follows: the equations describing DFIG in dq frame are as follows: [22]

$$V_{ds} = -R_s i_{ds} - \omega_s \Psi_{qs} - \frac{1}{\omega_B} \frac{d(\psi_{ds})}{dt} \quad (8)$$

$$V_{qs} = -R_s i_{qs} + \omega_s \Psi_{ds} - \frac{1}{\omega_B} \frac{d(\psi_{qs})}{dt} \quad (9)$$

$$V_{dr} = -R_r i_{dr} - (\omega_s - \omega_r) \Psi_{qr} - \frac{1}{\omega_B} \frac{d(\psi_{dr})}{dt} \quad (10)$$

$$V_{qr} = -R_r i_{qr} + (\omega_s - \omega_r) \Psi_{dr} - \frac{1}{\omega_B} \frac{d(\psi_{qr})}{dt} \quad (11)$$

With:

$$\psi_{ds} = L_{ss} i_{ds} + L_m i_{dr} \quad (12)$$

$$\psi_{qs} = L_{ss} i_{qs} + L_m i_{qr} \quad (13)$$

$$\psi_{dr} = L_m i_{ds} + L_{rr} i_{dr} \quad (14)$$

$$\psi_{qr} = L_m i_{qs} + L_{rr} i_{qr} \quad (15)$$

And

$$L_{ss} = L_s + L_m \quad (16)$$

$$L_{rr} = L_r + L_m \quad (17)$$

Where  $(V_{ds}, V_{qs})$  and  $(V_{dr}, V_{qr})$  represents stator and rotor voltages in dq frame, respectively;  $(i_{ds}, i_{qs})$  and  $(i_{dr}, i_{qr})$  denotes stator and rotor currents in dq frame, respectively;  $(\psi_{ds}, \psi_{qs})$  and  $(\psi_{dr}, \psi_{qr})$  identifies stator and rotor flux in dq frame, respectively;  $L_{ss}$  and  $L_{rr}$  stands for stator and rotor self-inductance, respectively;  $(L_s, R_s)$  represents stator leakage inductance and resistance;  $(L_r, R_r)$  represents rotor leakage inductance and resistance;  $L_m$  is an abbreviation for mutual inductance; at last,  $\omega_s$  identifies synchronous angular speed.

Moreover, the base speed is taken equal to  $\omega_B = 2\pi f$  with  $f = 50$  Hz which represents nominal frequency. [23]

The rotor slip is determined as follows:

$$s = 1 - \frac{\omega_r}{\omega_s} \quad (18)$$

Section 8.1 includes all constant parameters of studied system.

From the equations 8 to 17, the rate change of rotor and stator current in dq frame is established [24].

$$\begin{aligned} \frac{di_{qs}}{dt} = & \left( \frac{\omega_B R_s L_{rr}}{L_m^2 - L_{ss} L_{rr}} \right) i_{qs} + \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [(\omega_s - \omega_r) L_m^2 - \\ & \omega_s L_{ss} L_{rr}] i_{ds} - \left( \frac{\omega_B R_r L_m}{L_m^2 - L_{ss} L_{rr}} \right) i_{qr} + \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [(\omega_s - \\ & \omega_r) L_m L_{rr} - \omega_s L_m L_{rr}] i_{dr} - \left( \frac{\omega_B L_m}{L_m^2 - L_{ss} L_{rr}} \right) V_{qr} + \\ & \left( \frac{\omega_B L_{rr}}{L_m^2 - L_{ss} L_{rr}} \right) V_{qs} \end{aligned} \quad (19)$$

$$\begin{aligned} \frac{di_{ds}}{dt} = & \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [\omega_s L_{ss} L_{rr} - (\omega_s - \omega_r) L_m^2] i_{qs} + \\ & \left( \frac{\omega_B R_s L_{rr}}{L_m^2 - L_{ss} L_{rr}} \right) i_{ds} - \left( \frac{\omega_B R_r L_m}{L_m^2 - L_{ss} L_{rr}} \right) i_{dr} + \\ & \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [\omega_s L_m L_{rr} - (\omega_s - \omega_r) L_m L_{rr}] i_{qr} - \\ & \left( \frac{\omega_B L_m}{L_m^2 - L_{ss} L_{rr}} \right) V_{dr} + \left( \frac{\omega_B L_{rr}}{L_m^2 - L_{ss} L_{rr}} \right) V_{ds} \end{aligned} \quad (20)$$

$$\begin{aligned} \frac{di_{qr}}{dt} = & - \left( \frac{\omega_B R_s L_m}{L_m^2 - L_{ss} L_{rr}} \right) i_{qs} + \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [\omega_s L_m L_{ss} - \\ & (\omega_s - \omega_r) L_m L_{ss}] i_{ds} + \left( \frac{\omega_B R_r L_{ss}}{L_m^2 - L_{ss} L_{rr}} \right) i_{qr} + \\ & \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [\omega_s L_m^2 - (\omega_s - \omega_r) L_{ss} L_{rr}] i_{dr} + \\ & \left( \frac{\omega_B L_{ss}}{L_m^2 - L_{ss} L_{rr}} \right) V_{qr} + \left( \frac{\omega_B L_m}{L_m^2 - L_{ss} L_{rr}} \right) V_{qs} \end{aligned} \quad (21)$$

$$\begin{aligned} \frac{di_{dr}}{dt} = & \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [(\omega_s - \omega_r) L_m L_{ss} - \omega_s L_m L_{ss}] i_{qs} - \\ & \left( \frac{\omega_B R_s L_m}{L_m^2 - L_{ss} L_{rr}} \right) i_{ds} + \left( \frac{\omega_B R_r L_{ss}}{L_m^2 - L_{ss} L_{rr}} \right) i_{dr} + \left( \frac{\omega_B}{L_m^2 - L_{ss} L_{rr}} \right) [(\omega_s - \\ & \omega_r) L_{ss} L_{rr} - \omega_s L_m^2] i_{qr} + \left( \frac{\omega_B L_{ss}}{L_m^2 - L_{ss} L_{rr}} \right) V_{dr} - \\ & \left( \frac{\omega_B L_m}{L_m^2 - L_{ss} L_{rr}} \right) V_{ds} \end{aligned} \quad (22)$$

### C. The Model of the Grid-side Filter

As it is known that the GSC serves to stabilize DC voltage by supervising the power transition in the grid, whereas the GSC filter is employed to minimize the system harmonics as well as to adjust the phase and amplitude of the voltage in the output of the GSC [25].

The circuit corresponding to the GSC Filter is given by Fig. 3.

Fig. 3. GSC Filter Equivalent Circuit.

Where  $R_g$  and  $L_g$  identifies the resistance and the inductance of the Grid side filter, respectively, and  $(i_{dg}, i_{qg})$  and  $(V_{dg}, V_{qg})$  stands for the GSC current and voltage components, respectively. [26].

Furthermore, the GSC current are given as follows:

$$\frac{di_{qg}}{dt} = -\frac{\omega_B R_g}{L_g} i_{qg} + \omega_B \omega_s i_{dg} + \frac{\omega_B}{L_g} V_{qg} - \frac{\omega_B}{L_g} V_{qs} \quad (23)$$

$$\frac{di_{dg}}{dt} = -\omega_B \omega_s i_{qg} - \frac{\omega_B R_g}{L_g} i_{dg} + \frac{\omega_B}{L_g} V_{dg} - \frac{\omega_B}{L_g} V_{ds} \quad (24)$$

### D. The Model of DC-Link

The two converters of the wind energy conversion system (RSC and GSC) are interconnected via a DC-link capacitor which allows energy storage.

Acting as a reactive power source, the rotor-side magnetizing current is supplied by DC-link. Otherwise, the control of the stator-side power factor can be established.

In this study, supposing that the losses of the converter are neglected, the active power of DC-link  $P_{DC}$  is determinate as follows:

$$P_{DC} = P_r - P_g \quad (25)$$

Where  $P_g$  and  $P_r$  identifies the active power at the RSC and GSC AC terminal, respectively.

It is also written in this form:

$$P_{DC} = V_{DC} i_{DC} = V_{DC} C_{DC} \frac{dV_{DC}}{dt} \quad (26)$$

Where  $V_{DC}$  and  $i_{DC}$  are the voltage across DC-link capacitor and the current flowing through the capacitor, respectively.

The derivative of  $V_{DC}$  is, thus, obtained as a function of  $P_g$  and  $P_r$ .

$$\frac{dV_{DC}}{dt} = \frac{1}{C_{DC} V_{DC}} (P_r - P_g) \quad (27)$$

Moreover, by calculating the apparent power, the stator active power  $P_s$  represents real part of equation 28. As for the stator reactive power  $Q_s$ , it denotes the imaginary part.

$$P_s + jQ_s = V_{dqs} i_{dqs}^* = (V_{qs} + jV_{ds})(i_{qs} + ji_{ds})^* \quad (28)$$

Accordingly, the expressions of  $P_s$  and  $Q_s$  are given by equations 29 and 30. [27].

$$P_s = [V_{qs} i_{qs} + V_{ds} i_{ds}] \quad (29)$$

$$Q_s = [V_{ds} i_{qs} - V_{qs} i_{ds}] \quad (30)$$

Based on the same principle, the rotor active and reactive powers can be obtained as follows: [28].

$$P_r = [V_{qr} i_{qr} + V_{dr} i_{dr}] \quad (31)$$

$$Q_r = [V_{dr} i_{qr} - V_{qr} i_{dr}] \quad (32)$$

Similarly, the active and reactive power, on the Grid-side converter, is given by equations 33 and 34.

$$P_g = [V_{qg} i_{qg} + V_{dg} i_{dg}] \quad (33)$$

$$Q_g = [V_{dg} i_{qg} - V_{qg} i_{dg}] \quad (34)$$

Then, by exploiting the equations 27 to 34, the expression of  $\frac{dV_{DC}}{dt}$  becomes as follows:

$$\frac{dV_{DC}}{dt} = \frac{1}{C_{DC} V_{DC}} (V_{qr} i_{qr} + V_{dr} i_{dr} - V_{qg} i_{qg} - V_{dg} i_{dg}) \quad (35)$$

## IV. STUDIED SYSTEM LINEARIZATION

The dynamic characteristics of the studied system will be analyzed by studying the different linearization techniques and eigenvalues.

The modeling of the whole of the studied system comprising DFIG, GSC filter, and the subsystem of drive train is obtained by combining the models of the above-mentioned subsystems.

The small-signal model is established revealing linearization around operating point:

$$(i_{qs0}, i_{ds0}, i_{qr0}, i_{dr0}, i_{qg0}, i_{dg0}, \omega_{r0}, V_{DC0})$$

Moreover, q axis of the machine is set in such a way that it coincides with stator voltage  $V_s$ . Consequently, the total voltage corresponds to q-axis stator voltage ( $V_s = V_{qs}$ ) and d-axis stator voltage is taken zero ( $V_{ds} = 0$ ).

The generalized equations are written as follows: [29]

$$\dot{x} = f(x, y) \quad (36)$$

$$y = g(x, y) \quad (37)$$

Vectors  $x$ ,  $y$  and  $u$  represent the state vector, the output vector, and the control vector respectively.  $f$  and  $g$  denote nonlinear functions.

The equations of the state-space are as follows: [30]

$$\Delta \dot{x} = A \Delta x + B \Delta u \quad (38)$$

$$\Delta y = C \Delta x + D \Delta u \quad (39)$$

With  $\Delta$  stands for the deviation. Thus, the deviations of the state, input and output variables are given by equations 40, 41, and 42.

$$\Delta x = [\Delta i_{qs} \ \Delta i_{ds} \ \Delta i_{qr} \ \Delta i_{dr} \ \Delta i_{qg} \ \Delta i_{dg} \ \Delta \omega_r \ \Delta V_{DC}]^T \quad (40)$$

$$\Delta u = [\Delta V_{qr} \ \Delta V_{dr} \ \Delta V_{qg} \ \Delta V_{dg}]^T \quad (41)$$

$$\Delta y = [\Delta P_s \ \Delta Q_s \ \Delta P_r \ \Delta Q_r \ \Delta P_g \ \Delta Q_g \ \Delta V_{DC}]^T \quad (42)$$

The matrices A, B, C and D which stand for respectively the state matrix, the control matrix, output matrix and feedforward matrix are computed and shown in equations 43, 46.

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} & A_{14} & A_{15} & A_{16} & A_{17} & A_{18} \\ A_{21} & A_{22} & A_{23} & A_{24} & A_{25} & A_{26} & A_{27} & A_{28} \\ A_{31} & A_{32} & A_{33} & A_{34} & A_{35} & A_{36} & A_{37} & A_{38} \\ A_{41} & A_{42} & A_{43} & A_{44} & A_{45} & A_{46} & A_{47} & A_{48} \\ A_{51} & A_{52} & A_{53} & A_{54} & A_{55} & A_{56} & A_{57} & A_{58} \\ A_{61} & A_{62} & A_{63} & A_{64} & A_{65} & A_{66} & A_{67} & A_{68} \\ A_{71} & A_{72} & A_{73} & A_{74} & A_{75} & A_{76} & A_{77} & A_{78} \\ A_{81} & A_{82} & A_{83} & A_{84} & A_{85} & A_{86} & A_{87} & A_{88} \end{bmatrix} \quad (43)$$

All the elements of matrix A are given in section 8.2.

$$B = \begin{bmatrix} \frac{-\omega B L_m}{L_m^2 - L_{SS} L_{rr}} & 0 & 0 & 0 \\ 0 & \frac{-\omega B L_m}{L_m^2 - L_{SS} L_{rr}} & 0 & 0 \\ \frac{\omega B L_{SS}}{L_m^2 - L_{SS} L_{rr}} & 0 & 0 & 0 \\ 0 & \frac{\omega B L_{SS}}{L_m^2 - L_{SS} L_{rr}} & 0 & 0 \\ 0 & 0 & \frac{\omega B}{L_g} & 0 \\ 0 & 0 & 0 & \frac{\omega B}{L_g} \\ 0 & 0 & 0 & 0 \\ \frac{i_{qr0}}{C_{DC} V_{DC0}} & \frac{i_{dr0}}{C_{DC} V_{DC0}} & \frac{-i_{qg0}}{C_{DC} V_{DC0}} & \frac{-i_{dg0}}{C_{DC} V_{DC0}} \end{bmatrix} \quad (44)$$

$$C = \begin{bmatrix} V_{qs0} & V_{ds0} & 0 & 0 & 0 & 0 & 0 & 0 \\ V_{ds0} & -V_{qs0} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & V_{qr0} & V_{dr0} & 0 & 0 & 0 & 0 \\ 0 & 0 & V_{dr0} & -V_{qr0} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & V_{qg0} & V_{dg0} & 0 & 0 \\ 0 & 0 & 0 & 0 & V_{dg0} & -V_{qg0} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad (45)$$

$$D = \begin{bmatrix} 0 & 0 & 0 & 0 & i_{qs0} & i_{ds0} \\ 0 & 0 & 0 & 0 & -i_{ds0} & i_{qs0} \\ i_{qr0} & i_{dr0} & 0 & 0 & 0 & 0 \\ -i_{dr0} & i_{qr0} & 0 & 0 & 0 & 0 \\ 0 & 0 & i_{qg0} & i_{dg0} & 0 & 0 \\ 0 & 0 & -i_{dg0} & i_{qg0} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (46)$$

### V. LQR CONTROLLER DESIGN

Modeling the small signal is set in order to apply the control law:  $u = -K_{LQR}x$ . The control law is determined by minimizing the LQR cost function given by equation 47. [31].

$$J = \int_0^{\infty} (x^T Q x + u^T R u) dt \quad (47)$$

Where Q ( $8 \times 8$ ) and R ( $4 \times 4$ ) denotes the state and control weighting matrices. They are symmetric and square.

Besides, in this study, Q and R are chosen as identity matrices.

As a result of the theory of linear control, matrix gain  $K_{LQR}$  is obtained as follows:

$$K_{LQR} = R^{-1} B^T P \quad (48)$$

Where P (positive-definite matrix) is spotted by solving the following continuous Riccati equation: [32].

$$A^T P + P A - P B R^{-1} B^T P + Q = 0 \quad (49)$$

Fig. 4. Block Diagram of Studied System Simulation.

In fact,  $K_{LQR}$  is determined by ensuring the stability of the system. The checks carried out are as follows:

The controllability of (A, B) and the observability of (Q, A),

$(A - BK_{LQR})$  which represents the closed-loop system must be asymptotically stable, that is, accomplished by checking the matrix eigenvalues that they must have a negative real part.

The step response of studied system is detailed in Section 5 after identifying the feedback LQR gain  $K_{LQR}$  which is detailed in Section 8.3.

Given that the cost function J represent the integral summing of the control effort  $J_u$  and the criterion of performance  $J_x$  illustrated by equations 50 and 51.

$$J_u = (V_{qr})^2 + (V_{dr})^2 + (V_{qg})^2 + (V_{dg})^2 \quad (50)$$

$$J_x = (i_{qs})^2 + (i_{ds})^2 + (i_{qr})^2 + (i_{dr})^2 + (i_{qg})^2 + (i_{dg})^2 + (\omega_r)^2 + (V_{DC})^2 \quad (51)$$

### VI. IMPLEMENTATION OF STUDIED SYSTEM

The Fig. 4 shows the block diagram of studied system simulation, which is accomplished using Simulink of MATLAB, the help of Sim power System and the built-in LQR function of MATLAB.

According to Fig. 4, the overall operational diagram of studied system is described as follows: the blue box presents the proposed LQR controller algorithm, the pink box indicates the wind turbine model, and the green box encompasses the DFIG model, the GSC Filter model and the DC-Link model.

### VII. SIMULATION AND RESULTS

The studied system's response as achieved using previously detailed and discussed control algorithm, are described in this section.

The DFIG's overall characteristics and the location of the poles have been obtained in such a way that ensures the stability of the system.

Table I illustrate the DFIG's eigenvalues without and with proposed controller.

Without controller, the positive real part was identified for one eigenvalue that is providing the instability of the initial system. As shown in Table I, in case of proposed controller, all eigenvalues dispose negative real part.

TABLE I. DFIG'S EIGENVALUES WITHOUT AND WITH PROPOSED CONTROLLER

Without LQR controller	With LQR Controller
$-16.2 \pm 313.5i$	$-13963.6 \pm 314i$
-4.8	$-4429 \pm 94.25i$
$-14.4 \pm 120i$	$-1.4 + 314i$
$-167.5 \pm 314i$	-9.2
+0.00000071	-1.3

Fig. 5. Output Variables Errors with Proposed Control Approach.

From the simulation, the active and reactive powers, the DC-Link voltage, and the generator angular speed have been determined.

To sum up, the following specifications of time-domain, given by Table II, have been obtained from Fig. 5.

TABLE II. (A) SPECIFICATIONS OF TIME-DOMAIN

Output variables	$P_s$	$Q_s$	$P_r$	$Q_r$
Peak-value	-0.161pu	0.218pu	-0.186pu	-0.102pu
Rise-time	7.39e-04s	0.001 s	1.1e-04 s	1.6e-04 s
Settling time	2.37s	2.77 s	0.112 s	2.77 s
Steady-state-value	-0.078pu	0.0193pu	-0.021pu	0.004 pu

(B) SPECIFICATIONS OF TIME-DOMAIN

Output variables	$P_g$	$Q_g$	$V_{DC}$
Peak-value	0.09 pu	0.01 pu	-0.131 pu
Rise-time	0.403 s	2.19e-04 s	0.238 s
Settling time	0.576 s	0.54e-04 s	0.52 s
Steady-state-value	-0.002 pu	0.01 pu	-0.131 pu

Previously, the simulation results described are satisfactory in terms of Peak-value, rise-time and settling time.

Given that the evaluation of optimization problems without constraints is a primary objective of an LQR controller.

However, the proposed controller ensures a systematic computation of the state feedback gain matrix as well as a regulation of all the states to zero which is validated by the values of steady-state found for the active and reactive powers and the DC-Link voltage.

### VIII. CONCLUSION

In this paper, the design, and the implementation of LQR controller as a feedforward controller employing a linearized state-space model of the DFIG wind turbine in the rotating dq reference frames, is achieved in order to control the active and reactive powers and the DC-link voltage.

Further, the choice of the weighting matrices R and Q is focused on the investigation of a satisfactory response of the simulation.

According to the simulation results, with proposed controller, errors between the actual and desired values converged to zero and the response of the system shows good performance.

Finally, given that the LQR criterion can be perceived as a compromise between performance (described by the state weighting matrix Q) and consumption (denoted by the control weighting matrix R), the choice of the matrices R and Q (other than identity matrices) will be investigated in the forthcoming studies. Furthermore, comfortable stability margins will be determined to guarantee the robustness of the control.

### IX. SYSTEM PARAMETERS

Simulations are obtained with a 7.5kW generator connected to a 220V/50Hz grid.

#### A. Parameters of Studied System and Steady State

The machine and steady-state parameters are illustrated in Table III.

TABLE III. PARAMETERS OF STUDIED SYSTEM AND STEADY STATE

Parameter	Designation	Value
$\omega_B$	Base speed	314.16 rad/s
$\omega_s$	Synchronous angular speed	1 pu
s	Rotor slip	-0.03
$R_s$	Stator resistance	0.005 pu
$R_r$	Rotor resistance	0.0055 pu
H	Total inertia (Wind turbine + generator)	3.5s
$L_m$	Mutual inductance	2.25 pu
$L_{ss}$	Stator self-inductance	2.2725 pu
$L_{rr}$	Rotor self-inductance	2.2839 pu
$L_g$	GSC filter inductance	0.0225 pu
$R_g$	GSC filter resistance	0.012 pu
$X_t$	Transmission line resistance and reactance	0.0225 pu
$k_{opt}$	Constant corresponding to the maximum power coefficient	0.5787
$C_{dc}$	DC-link capacitor	0.0001 pu
$V_{dc0}$	Initial DC-link voltage	1200 V
$P_{total}$	Total active power	1 pu
$V_s$	Stator voltage	1 pu
$V_r$	Rotor voltage	$V_s/n$ pu
$V_B$	Slack bus voltage	1 pu
n	Stator to rotor turns ratio	1.5

**Abstract**—Teeth are very important for humans to eat food. However, teeth do get damaged for several reasons, like poor maintenance. Damaged teeth can cause severe pain and make it difficult to eat food. To safeguard the tooth from minor damages, an inert material is used to close the gap between the live part of the teeth or sometimes even the nerve and enamel. Although, long-time ignorance can increase the damage and inevitably result in root canal or tooth replacement. In the case of root canal, the gap between nerve and enamel is filled with an inert material. To check if the filling has been done properly, an X-ray is taken and verify. As technology is developing, robots are being introduced into many fields. In the medical field, there are instances where robots do surgery. For dental treatment, as an X-ray is taken to determine the filing, this work introduces a model to analyze the X-ray taken and estimate the level of filing done. The model is constructed using Mask RCNN with ResNet50 architecture. A dataset of different kinds of filings is taken and trained using the model. This model can be used to enable machines to perform dental operations as it works on pixel-level classification.

**Keywords**—Dental x-rays; deep learning; mask RCNN; RESNET50

## I. INTRODUCTION

Humans need food to survive. For eating food, teeth are essential and healthy teeth indicate healthy life. As medical sciences have advanced, dental research and learning also have advanced. People of the present generation have the most common issues related to teeth. As teeth are one of the most important parts of the body, which does most of the work helping in grinding the food consumed and supporting the digestive system, they need to be safeguarded from damage [28]. Not taking proper care of teeth may lead to some issues like cavities, swelling of gums, broken teeth, etc. When an issue arises, there are dentists who can attend the issue, and different problems need a different kind of treatment. Many issues may arise in teeth, and multiple solutions might be there to cure them. This project focuses on the external material that a dentist uses to fill, do the treatment, or close the gaps in teeth. This work mainly focuses on three things, namely “Endodontic”, “Restoration” and “Implant” [9], [13]. “Endodontic” refers to the stick-like tools that a dentist generally uses to clean the inner part of teeth. “Restoration” refers to the filing that a dentist does on some break, some cavities, and then caps that are used after a root canal. “Implant” is a screw-like structure used to provide rigidity and structure to the teeth. Many studies were also conducted

regarding identification of human using dental X-rays [7], [14], [16]. The aim of their work was to identify teeth as a unique bio metric system [21], [22], [23]. Their studies help this work by providing ways in which the uniqueness of teeth was identified by using computer vision.

This work aims at helping dentists identify the objects in a dental radiograph. This work benefits dentists, but it also helps common people read their own dental radiograph and understand the treatment being done [1], [2], [3], [4], [5]. The model focuses on detecting the filings in dental x-rays, which have been generalized to three classes. Assuming a case of many cases arising, there will be many x-rays taken to identify the teeth damage. Automating the detection helps reduce time and improve efficiency [6],[8].

Also, as robotics is being advanced and are brought into different fields, the medical field has also conducted experiments. There are works demonstrating robots doing and assisting in surgeries. In the future dental operations can also be automated, and robots can perform minor operations. By identifying objects at pixel level, this work can help robots in real-time identification of objects in radiographs. The models trained in this work use the concept of transfer learning where “COCO” (Common Objects in Context) dataset trained weights are imported, and the new dataset updates those weights for results [9]. A Mask RCNN (regional convolutional neural network) model is used with RESNET50 (residual neural network) as its backbone architecture.

The dataset for this project has been collected from different dental clinics in Hyderabad, Telangana, India. The dataset consists of several dental radiographs in “JPG” format containing RGBA (red, green, blue, alpha) channels. The images were processed and converted to RGB (red, green, blue) format with fixed dimensions of 416\*416. Then the images were annotated using the “Labelme” tool with three classes. After annotations, the model was trained with 100 images, 250 images, 500 images, 750 images, 1000 images, and 1755 images to see the improvement in results as the dataset size increases [27].

In this work, the medical radiographs are collected, which is the dataset required, annotated the images obtained. Then trained a MASK RCNN model with RESNET50 architecture with increasing dataset sizes, epochs in two variants. Also, the model is tested with increasing validation sets and considering the average as the final result.

## II. LITERATURE REVIEW

Chen H, et al, (2019) [6], have taken a dataset of 1250 dental X-ray films of periapical view and have trained a Faster RCNN model. They have done some post-processing to reduce the complexity of data for faster training of the model. Also, they suggest a filtering algorithm to delete overlapping boxes detected by their model. They have computed their results using IoU (Intersection over Union) score to calculate average recall. However, their work is limited to bounding boxes only which cannot be used for treatment with precision. The current work strives to improve the detection at pixel level to enable computer understand the exact position and region of treatment.

Jie Yang, et al, (2018) [27], have used a small dataset of 196 dental radiographs. They have said in their work that dental radiographs are important for clinical diagnosis and treatment. They have taken two classes for the condition of teeth. A CNN (convolutional neural network) model was constructed, and the F1 score was the measure of evaluation. Although, the author demonstrates results with a small dataset the accuracy is not satisfactory in terms of real time treatment. Taking the model into consideration, the current work intends to obtain the results which are more accurate and required for real time operations.

Kim J, et al, (2019) [19], have used a huge dataset of 12,179 panoramic dental radiographs to train a deep convolutional neural network. They have suggested a different measuring system where they have considered an increasing validation set count and finally computed the average F1 score. The mechanism to calculate results proposed by the author is unique. As such a similar way of validation system is implemented to summarize the end results of the current work.

## III. PROPOSED MODEL

As shown in Fig. 1, the project has four steps:

- Data Collection and processing
- Data Annotations
- Model Training
- Testing

In this work, data is collected, i.e., dental periapical view radiographs from different dental clinics in Hyderabad, Telangana, India [10]. After the collecting step, the data is processed, as shown by Chen H, et al, (2019) [6]. The dimensionality of images has to be reduced for less computational complexity, and also resizing images is a must for a model to accept them as training input. Then proceed to the data annotations step, where annotations are done for required objects in an image. An image can contain more than one object. After the annotations are done, the corresponding files are passed to the model for training. The model is trained with certain parameters and is passed to the testing stage. The IoU threshold in the testing phase is set to 50% and AP50 (average precision) score is obtained.

Fig. 1. Proposed Model Workflow.

### A. Data Collection

In this work, 1000 dental radiographs of periapical view have been collected from different dental clinics in Hyderabad, Telangana, India. The dental radiographs collected are images of “JPG” format with four channels RGBA. The images are processed by resizing to 416x416 dimensions to reduce the dimensional complexity. Also, the alpha channel is being eliminated, i.e., the images are converted from RGBA to RGB data. The images have a total of three classes: “endodontic”, “restoration” and “implant”.

### B. Data Annotations

The images collected have to be annotated. Annotation indicates creating a mask around the desired object for the algorithm to identify and train on. Image annotations are done using “Labelme” tool. “Labelme” tool, as shown in Fig 2, is an open-source manual annotation creator. It provides us with the “create polygons option” that is used to create a mask around desired objects. A single image can have more than one desired object and of different class. A json file is generated containing the mask coordinates and the class identity name for every image annotated.

Fig. 2. Labelme Tool Interface.

### C. Model Training

After the annotations have been completed, combine all the json files to a single json file for the model to train on. A python script is used for the conversion. All the images along its corresponding json file are uploaded into google drive. The main model used to train is Mask RCNN which is capable of instance segmentation [11], [15]. The model was trained with base learning rate of 0.002, with 600 epochs and 10 images per batch. The model weights are the “COCO” instance model weights which are updated through transfer learning [24], [25].

## IV. MODELS

### A. Mask RCNN

Mask RCNN is a deep neural built to process instance segmentation i.e., it can identify objects at pixel level. Mask RCNN does both object detection and instance segmentation. As the work is aimed at identifying objects in real time at pixel level, the algorithm implemented is Mask RCNN. Mask RCNN has two stages of training. Initially, region proposals are generated where objects might be present in an input image. Now, in the second stage, these proposals are used to predict the object class and construct a bounding box around the object detected. The bounding box is refined and a mask is generated

at pixel level for the proposal in the first stage. Both these stages are connected to the backbone architecture.

The backbone architecture used in this project is “RESNET50” [17], [18]. A backbone architecture is a feature pyramid network-style deep neural network. “RESNET50” architecture is a bottom-up pathway that extracts features from the input raw images. Fig. 3 shows the architecture of Mask RCNN algorithm.

In the first stage, use a region proposal network to propose the regions where objects are expected. Now a feature map is generated through the proposals to bind the features to their locations in raw images. Now, use anchors, a set of boxes with predefined locations that are scaled with respect to the images. Use anchors of different size to bind the different levels of feature map, the region proposal network uses these anchors to Fig out the region of the feature map that should get an object and what dimension the bounding box should be. Convolution, down sampling and up sampling of feature map would retain the relative positions of objects in the original image.

In the second stage, take another neural network that takes proposed regions as input which is generated by the region proposal network in stage one [26]. The pixel level classification is done by fully connected network (FCN) as shown in Fig. 4. These proposals are now taken by a new neural network and assigned to several specific areas of a feature map level. These areas are scanned and object classes are generated with bounding boxes and masks. The main trick used here is the “ROI align” (Region of interest) used to locate the relevant areas of the feature map. A branch of “ROI align” is used to generate masks at pixel level for an image.

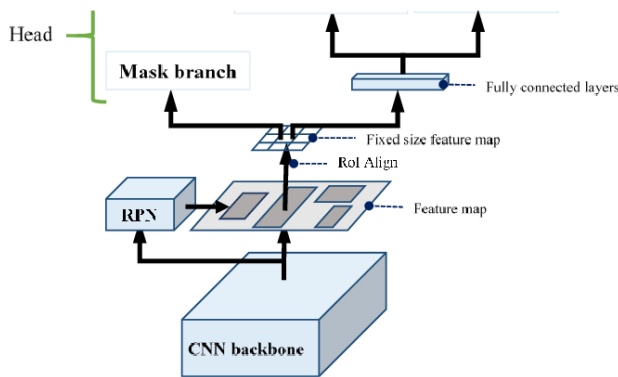

Fig. 3. Mask RCNN Architecture.

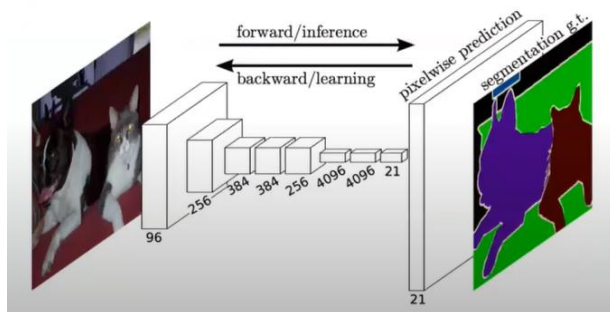

Fig. 4. FCN Showing Pixel Level Classification.

In “Faster RCNN” it uses “ROI pooling” for the case quantization where the bounding box dimensions become the desired dimensions [12]. In case of “ROI align” there is no necessity for quantization for data pooling [6]. As shown in Fig. 5 the dimensionality has to be changed in mapping or pooling process requiring the use of bilinear interpolation.

Fig. 5. ROI Align in RESNET50 Architecture.

### B. RESNET50

Resnet50 algorithm was made with the aim of solving vanishing gradient problem [20]. Vanishing gradient problem is a case in neural networks where the loss when sent back to update weights of the nodes, the differential value calculated becomes so small that the weights no longer get updated. In such a case the loss of the model does not decrease and the model is not capable of learning anymore. In case of RESNET models the input and processed input are both sent to the next stage of layers and the same happens when loss is propagated through the model. This concept is known as “skip connection”.

If ‘x’ is the input and f(x) is the function output. As neural networks are good function approximators, they should be capable to identify a function where the output becomes input itself.

$$f(x) = x \tag{1}$$

Assuming this if the input of the first layer of model is bypassed to be the output of the last layer of the model, the network should be able to predict the function it was learning before with the input added to it.

$$f(x) + x = h(x) \tag{2}$$

With RESNET one can pass the gradients through skip connections to the next layers of a model and from end layers to initial layers. Resnet50 deals with 48 convolutional layers along with 1 “MaxPool” and 1 “Average Pool”. It all starts with a convolutional layer with kernel size 7\*7\*3 with dimension of 64 and then stride 2. Then “MaxPooling” is done where for each feature map the maximum number is extracted to reduce the dimension of the image, which also reduces noise and then enter into the main Resnet layers in which they perform the convolutions with kernel size of 3\*3\*3 with the dimension set of 64, 128, 256 and 512. For every 2 convolutional blocks the skip connection takes place where the input and output value doesn’t change.

The dimension changes with stride 2 during the skip connection, like from 64 to 128 then dimension change causes

problem at that particular time. In any case one convolutional block is added to the skip connection process for dimension change to take place without mismatch and errors. After all the RESNET layers are traversed, “Average pooling” is done where the average value is taken from a particular feature map and gives the output. This helps in smoothening of the image but this method cannot be used for sharp images. Fig. 6 showcases the concept of “skip connection”.

Fig. 6. RESNET Model Skip Connection.

After that, the obtained feature map is flattened and then passed to an artificial neural network. The process continues where certain weights are assigned with the inputs and sent to the successive layers, known as forward propagation. Loss is calculated at the output layer which is back propagated to the previous layers to update weights for improving the model. Fig. 7 shows a demonstration of RESNET50 architecture.

Fig. 7. RESNET50 Architecture.

### V. RESULTS

The results for the instance segmentation problems are measured using the average precision scores. For measuring any classification object, preliminarily calculate “True Positive” (TP), “True Negative” (TN), “False Positive” (FP) and “False Negative” (FN). In instance segmentation, calculate them by using Intersection over Union (IoU) score as shown in Fig. 8. As a mask is being generated around the objects in the input image and have the ground truth of the object, try to find the area of intersection of the two masks and calculate the area union of the two masks. These values are divided to get Intersection over Union score.

The Intersection over Union score is now used as along with a threshold where if the IoU score is greater than threshold then it is considered as “True Positive” and if the IoU score is less than threshold then it is considered as “False Positive”. If an object is not being recognized, it is a “False Negative” and a wrong classification is considered “False Positive”. Fig. 9 is a sample of area covered by bounding boxes and ground truth to calculate IoU score for classification.

Using these values, the precision values are calculated. Precision is the measure of true positive detections.

$$Precision = \frac{TP}{TP+FP} \tag{3}$$

$$IoU = \frac{\text{area of overlap}}{\text{area of union}}$$

Fig. 8. Intersection over Union Calculation.

Fig. 9. IoU Score Classification.

In evaluations, 50% threshold is being considered. AP50 means the average precision at 50% IoU threshold.

The dataset has been split into parts of increasing order to observe the change in results as the dataset used for training is being improved. Taking the data sizes of 100, 250, 500, 750 and 1000 into consideration and testing over validations sets of 20, 50, 100, 150 and 200 [27], [29]. After calculating the results, the average value was calculated and was considered the final AP50 score. Starting with dataset of 100 the results obtained for bounding boxes are: 55.963, 54.636, 54.12, 46.881, 63.141 and for mask segmentation are: 58.186, 51.193, 51.649, 37.723, 56.268 respectively as shown in Fig. 10. The dataset was trained for 600 epochs as the loss was minimum and stable at that point.

Moving on to the dataset with 250 images; the results for bounding box AP50 scores are: 59.571, 55.252, 54.14, 51.654, 55.503 and for mask segmentation are: 59.571, 50.282, 49.546, 40.736, 46.59 as shown in Fig. 11. The dataset was trained for 600 epochs as well.

Fig. 10. AP50 Scores Obtained for Dataset of 100 Images.

Fig. 11. AP50 Scores Obtained for Dataset of 250 Images.

Moving on to the dataset with 500 images; the results for bounding box AP50 scores are: 75.596, 71.929, 76.32, 60.471, 76.283 and for mask segmentation are: 69.166, 64.899, 72.075, 47.209, 66.472 as shown in Fig. 12. The dataset was trained for 600 epochs as well.

Fig. 12. AP50 Scores Obtained for Dataset of 500 Images.

Moving on to the dataset with 750 images; the results for bounding box AP50 scores are: 83.168, 81.3, 79.203, 68.126, 80.022 and for mask segmentation are: 85.269, 78.019, 75.605, 57.17, 71.194 as shown in Fig. 13. The dataset was trained for 600 epochs as well.

Fig. 13. AP50 Scores Obtained for Dataset of 750 Images.

Finally, the dataset with 1000 images; the results for bounding box AP50 scores are: 84.334, 82.489, 78.091, 84.083, 83.28 and for mask segmentation are: 86.883, 76.708, 75.186, 72.115, 76.029 as shown in Fig. 14. Although, the dataset was trained for 600 epochs there was still trainable parameters.

Fig. 14. AP50 Scores Obtained for Dataset of 1000 Images for 600 Epochs.

The model trained utilized the transfer learning concepts and the weights were imported from the “COCO dataset” model. Transfer learning is the concept where the weights are imported by training a model on a different dataset. This should help the new model update weights in less epochs. For the model trained with 600 epochs, observations seen were best bounding box and mask segmentation average AP50 score with 1000 images dataset.

Fig. 15. Comparing AP50 Score of different Dataset Sizes with respect to Bounding Boxes.

As continuing with observations, the 1000 images dataset has obtained AP50 score of 82.4554 for bounding boxes and 77.3842 for mask segmentation at 600 epochs. Fig. 15 compares the AP50 scores of different datasets and it is observed that 1000 images dataset has the best results yet, however it is also inferred that improvement in results with respect to dataset size declines exponentially.

Further, the 1000 images dataset was in two variations:

- With transfer learning (1200 epochs).
- Without transfer learning (1600 epochs).

When trained with transfer learning for 1200 epochs on 1000 images dataset the model gave AP50 scores of 88.4248 and 84.2662, respectively for bounding boxes and mask segmentation as shown in Fig. 16.

Also, for training without transfer learning, the weights are initiated and updated from scratch. Due to which the model needed to be trained for 1600 epochs where the loss stabilizes. The results obtained at this stage are 76.1696 and 72.123 for bounding boxes and mask segmentation as shown in Fig. 17.

In Fig. 18, the results of “with transfer learning” and “without transfer learning” are compared and it is observed that “with transfer learning” model gives better results. Additionally, as observed that with an increase in the dataset size, the results also improve. So, another dataset consisting of 1755 images is considered.

The 1755 images dataset was trained for 1200 epochs with transfer learning and obtained an AP50 score of 88.2416 and 82.1224 respectively for bounding boxes and mask segmentation as shown in Fig. 19.

Fig. 18. Comparing Results of 1000 Images with and without Transfer Learning.

Fig. 16. AP50 Scores Obtained for Dataset of 1000 Images at 1200 Epochs.

Fig. 19. AP50 Scores Obtained for Dataset of 1755 Images at 1200 Epochs.

Also, the 1755 images dataset is trained without transfer learning for 1600 epochs and obtained 82.3398 and 62.7846 AP50 scores respectively for bounding boxes and mask segmentation as shown in Fig. 20.

Fig. 17. AP50 Scores Obtained for Dataset of 1000 Images at 1600 Epochs without Transfer Learning.

Fig. 20. AP50 Scores Obtained for Dataset of 1755 Images at 1600 Epochs without Transfer Learning.

Although the results obtained seem stable and do not alter much, the size of the dataset showed that the model could be trained further and improved. The 1755 images dataset was trained further for 2400 epochs, and results obtained showed improvement. It obtained AP50 scores of 87.9548 and 76.1272 for bounding box and mask segmentation, respectively as shown in Fig. 21.

Fig. 21. AP50 Scores Obtained for Dataset of 1755 Images at 2400 Epochs without Transfer Learning.

As observed, the results have improved and altered less, showing that the complexity change in images will not affect the model much. Also, as the 1000 images dataset has obtained better results for mask segmentation, the results may vary depending on the complexity of images but with less intensity.

Fig. 22. Comparing AP50 Scores of 1000 and 1755 Images Datasets.

From Fig. 22, one can observe that the bounding box AP50 was highest for the 1755 images dataset trained without transfer learning for 2400 epochs but the mask segmentation AP50 score was highest for the 1000 images dataset with transfer learning at 1200 epochs. One can still observe that results are stable and vary less when there is an increase in dataset size with increased epochs.

## VI. CONCLUSION

The need for expertise in dental clinics is a must. Making the process of taking and reading radiograph must be improved. Also, robotic treatment in dental science needs a system to understand and identify dental objects at the pixel level. This work provides a model that can identify the dental objects at pixel level and has obtained an Average Precision-50 score of 84 and 88 for mask segmentation and bounding boxes respectively for 1000 images dataset at 1200 epochs. The model used in this work is Mask RCNN with RESNET50 architecture. The training was done in two variants of with transfer learning and without transfer learning and with increasing dataset sizes and epochs.

The work demonstrates the mask generated around a tooth with pixel level accuracy which can be further developed for robotic treatment in the future. The model showcases results which are considerable to further explore with more resources for better results that are satisfactory for medical treatment. The AP50 scores of 1000 images dataset prove to be good when trained for 1200 epochs. While the 1755 dataset at 1200 epochs give AP50 scores of 88 and 82 for bounding boxes and mask segmentation. Increasing the number of epochs without transfer learning give similar results for bounding boxes but mask segmentation has reduced by a lot. The results of 1755 dataset trained without transfer learning for 1600 and 2400 epochs give 82 and 87 AP50 scores respectively but the mask segmentation scores have declined to 62 and 76. Further training of model may improve the scores but for more better and practical results it is suggested to increase the dataset size.

The work can be further improved by taking a larger dataset, as observed there is an improvement in results with an increase in dataset size. Also, in this work, the classes of objects have been generalized to three. More specific classes can also be taken for object detection with the help of a dentist or a person with good knowledge in dental science, and work can be improved further.

**Abstract**—Reusability is necessary for developing advance software. Aspect Oriented programming is an emerging approach which understand the problem of arrangement of scattered software modules and tangled code. The aim of this paper is to explore the AOP approach with implementation of real life projects in AspectJ language and its impact on software quality in form of reusability. In this paper, experimental results are evaluated of 11 projects (Java and AspectJ) using proposed Quality Evaluation Model for Software Reuse (QEMSR) and existing Aspect Oriented Software Quality Model (AOSQ). To evaluate AOP quality model QEMSR based on developers AOP projects by using Analytic Hierarchy Process (AHP) tools. Paper provides the evaluation of software reusability and positive impact on software quality. QEMSR model is used to assess Aspect Oriented reusability quality issues, which helps developers to adapt for software development. The overall quality of three models QEMSR, existing AOSQ and PAOSQMO are 0.62552223, 0.5283693, and 0.505815 calculated. According to this, QEMSR model is best in form of quality in same characteristics and sub-characteristics.

**Keyword**—Reusability; AspectJ; software quality metrics; analytic hierarchy process

## I. INTRODUCTION

Various software quality models described the assessment of software quality in software engineering. Quality assessment of software is an interesting research area in software engineering. Several AOSD seminars, workshops and research conferences had considered evaluation of quality of software model is emerging sector in traditional software engineering journals and conferences. According to IEEE/ACM “Software Engineering Curriculum Guidelines list software engineering education” in 2004 as one of the ten specific areas of software engineering education[5][20]. Various international network groups and research communities are working on software evolution. Software evolution concerned issues are very complex because it engages with various dimensions.

This paper focuses performance evaluation of proposed Qualitative Evaluation Model for Software Reuse (QEMSR) by experimentation method using characteristics and its sub-characteristics. We describe some metrics such as WMC, DIT, NOC, LCOM, and CBO for statistical value [10]. We also analyze the existing model such as Aspect Oriented Software Quality Model (AOSQ) and Proposed AO Software Quality Model (PAOSQMO) to examined performance evaluation. The negative impact on software quality is duplication of code.

Crosscutting concerns reduced to have negative effect on understandability, maintainability, operability, modularity because understanding and changing crosscutting concerns requires touched various place in source code.

In existing system, firstly crosscutting concerns are derived after that distinguishes into aspects. Main traditional software reveals crosscutting concern that is called “tyranny of the dominant decomposition.” In existing system, exploration helps to find out aspect. Aspects will help the software developers to examine where and how these tangling and scattering codes are implemented and its effect on quality of software [9]. This process is called aspect mining which is used to examine crosscutting concerns in existing model codes.

Contribution of the paper:

- To examine area of evolution of traditional programming (OOPs) different form evolution of Aspect Oriented Programming (AOP).
- To promote evolution of Object-oriented Programming (OOPs) be implemented to Aspect-oriented Programming (AOP).
- To improve performance evaluation of software quality models in software engineering.

This paper divides into eight sections. First section describe introduction about Aspect-oriented Programming. Related work has been done by the researcher explain in section two. Third section defines the framework or method to achieve research goal and motivation to do that work. Section four and five describe the platform used for practical work and design and result of experiment. Section six describes the analysis of experimental result and qualitative evaluation of 11 research case studies and its impact on quality. Examine performance evaluation of QEMSR model and existing model is described in section seven. In section eight, we discussed major finding of proposed quality model as conclusion and area for future research work for researcher point of view.

## II. LITERATURE REVIEW

In late 1990s, Aspect-oriented Programming (AOP) is an emerging area in evolution of software and it declares the positive impact on software quality; simultaneously, various risks, challenges and paradoxes for AOP adoption for development of software. In 2006, Steimann stated the question:

“Does aspect orientation really have the substance necessary to found a new software development paradigm or is it just another term to feed the old buzzword permutation based research proposal and PhD thesis generator?”

In 1997, Kiczales explore the idea of AOP pattern to modularize the crosscutting concerns in existing system. Table I shows last ten years quality models which is described time to time by researchers. Kumar et. al. extends the ISO/IEC 9126[11] quality model by adding some extra characteristics and sub-characteristics in 2009, called Aspect Oriented Software Quality Model (AOSQUAMO). AOSQUAMO model is first purely based on Aspect Oriented Software Development (AOSD). In 2010 another quality model REASQ is derived by Castillo et.al. REASQ quality model is the combination of ISO/IEC 9126 and ISO/IEC 25030 define by UML.

Simultaneously, Kumar et. al. adds evolvability as an attribute in software quality model for AOP application in 2012 named Aspect-oriented Software Quality (AOSQ) model [1] [18]. This model described four sub-characteristics such as sustainability, design stability, extensibility and configurability [4] [16]. AOSQ model is based on AOSQUAMO and ISO/IEC9126 quality model [23].

G. Suryanarayana et.al. described MIDAS [13] model to analyze design quality assessment method for industrial software in 2013. T. Alrawashdeh and M.I. Muhairat were exploring the quantitative evaluation of enterprise resource planning systems proposing ERPSQM model in 2014[3] [12] [17]. In 2016, Pardeep Kumar Singh and Yugal Kumar assess the empirical evaluation of Aspect-oriented software quality model using multi-criteria decision making approach using PAOSQMO model.

Pankaj Kumar and S.k. Singh also measure a comprehensive evaluation of Aspect-oriented software quality model (AOSQ) using Analytic Hierarchical Process (AHP) [26] [28]. In 2018, Petrus Mursanto and Dameria Christina Pasaribu define software quality rank using AHP and Object-oriented metrics which is used to perform evaluation of quality of QEMSR model[14][24][30].

Sufia Nadeem Chishti explores the quality improvement in small scale projects using Aspect Oriented design in 2019[2] [19]. S. Dixit explores the performance of quality modeling using artificial neural network technique in Aspect Oriented Programming [7]. P. Kumar analyzes the metrics of Aspect Oriented and Object oriented using AspectJ and Java programming languages [8].

Hamed Fawareh proposed the software quality model for maintenance software purposes [6]. Bharti Bisht describes the metric approach to anticipate reusability of object oriented software systems [21].

K. Chitra measures the performance merits of software component using CK metrics [27]. We evaluate quality of QEMSR model using Analytic Hierarchical Process (AHP) that is based on AOS Quality Model (AOSQ) and PAOSQMO [25].

### III. MOTIVATION AND METHODOLOGY

Last few years, various researcher working on different software quality model in software engineering. All researcher derived own quality model using some characteristics and metrics. These researchers also evaluate only derived model and not compared other researcher model in respect of quality. Every researcher use different technique to evaluate own quality model like Analytic Hierarchy Process, fuzzy logic, Gang of Four design pattern, etc. No anyone researcher can perform quality evaluation with same parameter with different quality model which is identify best model. So, we decide or motivate that we perform or derive a quality model in respect of reusability and its characteristics and metrics and compare with other model with same parameter. We also extend the qualitative evaluation of a model in more informative form, which helps for software developers to take decision to implement software or applications.

We can assume research methodology for this paper is software reengineering which is comparison analysis technique. Firstly, we can divide our objective into two parts like goals and sub-goals as shown in Fig. 1. In goals part, we define performance evaluation as purpose and concept use reusability. In sub-goals, internal characteristics and metrics are defined which measure the statistical data to evaluate quality. We can re-engineer concept that involve forward and reverse engineering principles. For experimentation purpose, we use quasi-controlled experimentation.

According to QEMSR model, research manipulates one or more independent variables to examine their impact on one or more dependent variables, set of metrics and validation of metrics [15]. We also describe the experimental part using 11 real world projects. We implement these projects in AspectJ and Java language and assign weight of methods and calculate average mean value for qualitative evaluation. All the 11 projects implement to assess contemporary phenomena within its real world situation.

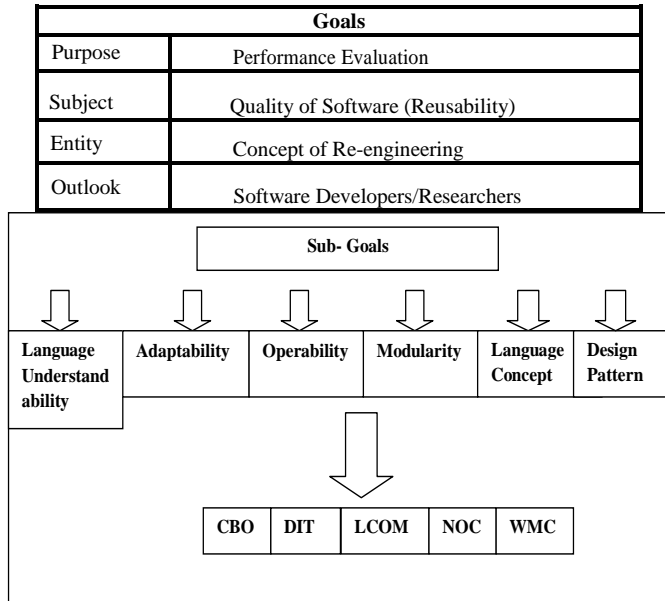

Fig. 1. Framework of QEMSR Model.

Fig. 2. Methodology for Performance Evaluation of QEMSR.

To achieve goals and sub-goals, we also use R. Marti, Henry and Li, Garcia et. al. and C & K metrics definition and these metrics associated for quality measurement in AOP [29]. QEMSR model proposed to validate metrics and analysis of qualitative evaluation and its impact on quality for AOP. To validate metrics we use experimental results of 11 projects implementations (Java & AspectJ). Experimental result gives intuitive information for the analysis of evolutionary aspects during Aspect-oriented software evolution. Fig. 2 describes the methodology for performance evaluation of QEMSR.

#### IV. EXPERIMENTAL SET-UP

Set-up for experimentation is for 11 projects (AspectJ and Java) to collect descriptive value (metrics) for the analysis of quality of software using AOP metric tools; a common AOP metric tool for both Aspect-oriented and Object-oriented metrics, such as R. Martin, Henry and Li and C & K. For doing experiment operating system required MS Windows XP/7/8, AspectJ 1.6, Java JDK 1.6v and AOP metrics 0.3 binary<sup>20</sup>. Ms-excel sheet generated for manipulation of descriptive data after successful execution of set of list files in a command line for a given source running compile.bat,(.1<sup>st</sup>)(projects) and metrics.bat files. All these descriptive data used for analysis for several AOP characteristics by impact tests and statistical tests.

#### V. EXPERIMENTAL DESIGN AND RESULTS

We can design procedure for 11 projects (AspectJ and Java) implementation for analysis of quality of AOP software consist five steps:

- Description of 11 projects which is used for experimentation or implementation (Java and AspectJ) as shows in Table II.
- Collection of data for experimental results and descriptive data used for AOP metric tools shown in Table IV.
- QEMSR framework which shown in Fig. 1.
- Methodology for performance evaluation of QEMSR shows in Fig. 2.

Ms-excel sheet generated for manipulation of descriptive data after successful execution of set of list files in a command line for a given source running compile.bat, (.1<sup>st</sup>)(projects) and metrics.bat files. All these descriptive data used for analysis for several AOP characteristics by impact tests and statistical tests.

The main goal to provide qualitative evaluation using 11 real world projects implementation (AspectJ and Java) using metric and statistical data with regard to reusability characteristics and sub-characteristics from the software developers view point. Only interesting metrics for this evaluation is DIT, NOC, CBO, LCOM, WMC of reusability characteristics and sub-characteristics. In this paper 11 projects real world system from different size and domain is shown in Table II. Table III shows the description of metrics adapted for QEMSR. Table IV shows the absolute mean values of 11 projects (AspectJ and Java).Using measurement of metrics we evaluate the experimental results on 11 projects and correlation among reusability characteristics and sub-characteristics. Table V shows the difference of average mean value of all 11

projects metrics and also calculate the impact of every metrics as graphically shown in Fig. 3. Table V contains the average mean value of metrics calculated as sum of different module divide by number of module taken for analysis. AHP is applied on these mean values to get corresponding weights of characteristics and sub-characteristics in which total quality weight has been taken as 1.000. These weights used for

comparing for Aspect –oriented projects. Aspect-oriented version of 11 projects shows an improvement in all structured complexity metrics. So for performance evaluation we compare existing AOSQ model and PAOSQMO model to select best suitable model for implementation in Aspect-oriented technology based projects.

TABLE II. DESCRIPTION OF 11 PROJECTS ( ASPECTJ & JAVA)

Name of projects	Description
AJHotDraw	Framework for structured and technical 2D graphics. <a href="http://ajhotdraw.sourceforge.net">http://ajhotdraw.sourceforge.net</a>
AspectTetris	Implementation of Tetris game in AspectJ. <a href="http://www.guzzt.com/coding/aspecttetris.shtml">http://www.guzzt.com/coding/aspecttetris.shtml</a>
PetStore	Demo for the J2EE platform which represent existing applications of E-commerce. <a href="http://java.sun.com/developer/releases/petstore/">http://java.sun.com/developer/releases/petstore/</a>
Eimp	Eclipse plug-in which support collaborative software developments for distributed teams. <a href="http://eimp.sourceforge.net">http://eimp.sourceforge.net</a>
HSQldb	Used for a relational database management system implementation. <a href="http://vrwxv.hsqldb.org">http://vrwxv.hsqldb.org</a>
Hypercast	Software for developing application programs and protocols for overlay network, application layer.
CVS Core	Eclipse plug-in which implements the basic functionalities of a CVS client such as check out and check in system stored in a remote repository. <a href="http://www.eclipse.org/eclipse/platform-cvs/">http://www.eclipse.org/eclipse/platform-cvs/</a>
AJFTPd-Server	Crosscutting concern implementation for security. Application level Server for BLP access control. <a href="http://homepages.wmich.edu/plbijjam/cs555/Projects/">http://homepages.wmich.edu/plbijjam/cs555/Projects/</a>
Telecom AspectJ	Examples of AspectJ <a href="http://www.eclipse.org/aspectJ/">http://www.eclipse.org/aspectJ/</a>
Spacewar Game AspectJ	Examples of AspectJ <a href="http://www.eclipse.org/aspectJ/">http://www.eclipse.org/aspectJ/</a>
Observer Pattern AspectJ	Examples of AspectJ <a href="http://www.eclipse.org/aspectJ/">http://www.eclipse.org/aspectJ/</a>

TABLE III. DESCRIPTION OF METRICS ADAPTED FOR QEMSR

Name of Metrics	Description
WMC	Total number of weighted operation in a class
CBO	Total number of interfaces declaring class or number of class or fields which can be called by a given class
LCOM	Total pairs of operation working on common fields minus total number of pairs of operation working on different
DIT	Longest path length From aspect/ class to the given class hierarchy root
NOC	It measures the total number of class, immediate descendants.

Fig. 3. Qualitative Evaluation based on Impact Analysis for QEMSR.

TABLE IV. ARITHMETIC MEAN VALUES OF QEMSR METRICS OF 11 PROJECTS

Projects /Metrics	Reusability and its Sub-characteristics

## VI. EVALUATION OF RESULTS

The collection of data for every module (interface, class, aspect) of every system use the extended version of Aspect-oriented metric tools. For every real life project experimental result are represented independent. Crosscutting concerns investigated intensively for all 11 projects which show in Table II. For all project system represent common software problems and solution of those problems. Table IV define the average mean value of Aspect-oriented and Object-oriented implementations of 11 projects. The measurements of metrics have been computed but experimental results of 11 projects. The evaluation of quality of QEMSR model using characteristics and sub-characteristics and metrics adopted from C & K metric suite such as NOC, DIT, LCOM, WMC, and CBO. A smaller average value of lack of cohesion and coupling is between object taken for AOP AspectJ projects. Remaining metrics take same trends variation between values.

We can compare calculated percentage of all 11 project using matrices and determine difference of both AspectJ and Java implementation. 07 (64%) DIT metrics have higher value through Java implementation. 04 (36%) DIT metrics have higher value through AspectJ implementation. 04 (36%) LCO metrics have higher value through Java implementation. 06 (54%) LCO metrics have higher value through AspectJ implementation. 01 (10%) LCO have the same value. 07 (64%) NOC metrics have higher value through Java implementation. 04 (36%) NOC metrics have higher value through AspectJ implementation. 03 (27%) CBO metrics have higher value through Java implementation. 08 (73%) CBO metrics have higher value through AspectJ implementation. 03 (27%) WMC metrics have higher value through Java implementation. 07 (63%) WMC metrics have higher value through AspectJ implementation. 01 (10%) WMC have the same value. CBO and WMC have higher value as compared to NOC and DIT using AspectJ implementation. According to this, coupling is high in AspectJ implementation due to high value of WMC and CBO than the Java implementation. Limited numbers of projects are implemented in this paper, so we can't generalize the experimental results. Experimental results improve the validation of metrics for Aspect Oriented Programming and impact on quality of metrics. QEMSR model supports to take decision or choose the best quality for the applications software.

## VII. PERFORMANCE ANALYSIS OF QEMSR MODEL USING AHP

In this paper, we used two approaches to appraise the AOP and its impact on quality.

1) Qualitative evaluation of Aspect-oriented programming using QEMSR model and Analytic Hierarchy Process technique, similar approach used by Kumar A adapted in this paper [18]. Developer's projects used to determine impact of quality using Aspect-oriented programming (AspectJ) and Object-oriented programming (Java).

2) Describe performance evaluation of QEMSR model using Analytic Hierarchy Process (AHP) with existing model

Aspect-oriented Software Quality (AOSQ) model and Proposed Aspect-oriented Software Quality Model.

Saaty proposed Analytic Hierarchy Process technique uses the pair wise matrix to analyze ambiguity in multi-criterion decision-making problems. In this paper, n elements have main characteristics such as  $mC_1, mC_2, mC_3, \dots, mC_n$  considered, which have compared related weight of  $mC_i$  with respect to  $mC_i$  denoted as  $a_{ij}$ . A square matrix  $A = [a_{ij}]$  of order n as given in equation (1).

$$A = [a_{ij}] = \begin{matrix} & mC_1 & mC_2 & \dots & mC_n \\ mC_1 & \begin{pmatrix} 1 & a_{12} & \dots & a_{1n} \\ 1/a_{12} & 1 & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots \\ mC_n & 1/a_{1n} & 1/a_{2n} & \dots & n \end{pmatrix} & & & \end{matrix} \quad (1)$$

Where  $a_{ij} = 1/a_{ji}$ , for i is not equal to j and  $a_{ij} = 1$  for all i.

Matrix is said to be reciprocal metric.

$$A \cdot \omega = \lambda_{\max} \cdot \omega, \lambda_{\max} \geq n \quad (2)$$

Matrix involving human decision making, decision are inconsistent to a lesser or greater degree, in such a case find vector  $\omega$  satisfy the equation (2).

Here  $\omega$  is Eigen Vector and  $\lambda_{\max}$  define Eigen value. The dissimilarity between  $\lambda_{\max}$  and n if any is an indicator of inconsistency of decision. Saaty (1980) describe a consistency Index (CI) and Consistency Ratio (CR) to validate the consistency of the comparison matrix. Following equation is defined for validation:-

$$\text{Consistency Index (CI)} = (\lambda_{\max} - n) / (n - 1) \quad (5)$$

$$\text{Consistency Ratio (CR)} = \text{CI} / \text{RI} \quad (4)$$

Here RI is the average consistency Index over several random entries of same order reciprocal matrix. Saaty (1980) suggested that if the Consistency Ratio exceeds 0.1, set of decision or judgment may be too inconsistent to be reliable. In that condition, a new comparison matrix is required to prepare until Consistency Ratio (CR) is less than equal to 0.1.

In this sequence to determine the sub-characteristics and characteristic for software in Aspect-oriented, we manage a survey from programmer's expert or software developers working in industry and academic experts who have completed their projects and worked in AOP domain. We can identify the weight value of characteristics and sub-characteristics. A table is used to fill the pair wise relative weight value of eight characteristics from  $mC_1$  to  $mC_6$ . The mean of all gathered samples of pair wise relative weight are given in square matrix  $A = [a_{ij}]$  of order eight in equation, which is derived using equation(1) to apply Analytic Hierarchy Process. We have calculated Eigen vector and Eigen value to find the corresponding weight of  $mC_1, mC_2, mC_3, mC_4, mC_5, mC_6$  and CR. We also create a reciprocal matrix after that to calculate Eigen value and Eigen vector for CR and CI.

We assign value it to a square matrix taken from survey. We also assign pair wise relative weight value to all six characteristics using equation (1). Further step to calculate Eigen value and Eigen vector of get corresponding weights and CR. We calculate Eigen vector to multiply all the entries in every row of matrix A and take  $n^{th}$  root (i.e.  $6^{th}$  root) of the product helps in getting Eigen vector. Sum of the  $n^{th}$  root and used to normalize the Eigen vector element.

$$A=[a_{ij}] =$$

$$\begin{bmatrix} 1 & 2.00 & 4.00 & 2.00 & 3.00 & 7.00 \\ 0.50 & 1 & 0.25 & 1.00 & 1.00 & 4.00 \\ 0.25 & 0.33 & 3 & 2.00 & 2.00 & 4.00 \\ 0.50 & 0.33 & 0.5 & 0.33 & 0.05 & 1.00 \\ 0.33 & 2.00 & 1.0 & 2.00 & 1 & 3.00 \\ 0.14 & 0.25 & 0.25 & 0.33 & 0.3 & 1 \end{bmatrix} \quad (5)$$

Table VI shows all calculations and clearly show that  $A_n$ . We calculate  $A \cdot \omega$  and multiply the matrix ( $A_1$  to  $A_6$ ) from Eigen vector. Calculation of first row in Table V shown below:

$$(1 * 0.3499) + (2 * 0.1069) + (4 * 0.2189) + (2 * 0.0695) + (3 * 0.144) + (7 * 0.0342) = 2.2497.$$

The values for remaining five rows are calculated similarly. As per equation (2),  $\lambda_{max} \geq 6$ , to determine product of  $A \cdot \omega$  Eigen value also determined by using  $\lambda_{max} = (A \cdot \omega) / \omega$ . All values are greater than six which satisfy the condition  $\lambda_{max} \geq n$  we calculate Consistency Index using equation (3):

$$CI = (6.46792 - 6) / (6 - 1) = 0.093584$$

After that we calculated CR for set of judgment using CI for considered samples. RI value can be taken from Saaty a scale that is 1.24[22].

$$CR = (0.093584 / 1.24) = 0.07547$$

The calculated value of Consistency Ratio (CR) is 0.1 which indicates estimate is acceptable. The assessment of overall quality of any AOP projects evaluated using below mentioned formula:-

$$AO \text{ Project Quality} =$$

$$\sum_{i=0}^n \text{Comparative value of Sub characteristics (SC}_i) \times \text{weight value of SC}_i$$

Where n is the number of sub-characteristics,  $SC_i$  is sub-characteristic  $i$ . We are determining quality of our QEMSR model and existing Aspect-oriented Software Quality (AOSQ) model and existing Proposed Aspect-oriented Software Quality Model (PAOSQMO) as shown in Table VII. The overall quality of three models QEMSR, AOSQ and PAOSQMO are 0.62552223, 0.5283693, 0.505815. According to this, QEMSR model is best in form of quality in same characteristics and sub-characteristics. This calculation shows that overall quality of QEMSR is defined positive impact on software quality. This paper also extends the methodology adapted by Kumar A and based on random choice and decision of experts on AOP technology. Fig. 4 shows the analysis of quality values of all internal characteristics of QEMSR, AOSQ and PAOSQMO model graphically.

Fig. 4. Performance Evaluation of Quality of QEMSR, AOSQ, PAOSQMO.

### VIII. CONCLUSION AND FUTURE RESEARCH

In AOP, AspectJ is a popular language which provides a support to the software developers to achieve improved quality. AOP is a standard that is trusted for quality improvement. AOP quality measurement has been trusted by evaluation of experimental results using a new QEMSR method and set of metrics for reusability and its sub characteristics. The set of AOP metrics (Coupling, Cohesion, size metrics such as DIT, NOC, CBO, LCOM, WMC, RFC) have authorized to support AspectJ and Java and an authentication of these existing metrics for quality assessment instead of new metrics proposed for AOP. Comparisons of projects are not industrial projects. Nevertheless, this paper provides the evaluation of quality and methodology of comparison as a single unit.

For future research perspective, to validate the quality metrics for large and more complex (commercial) system empirical study require in AOP research. Experimentation on large industrial projects for this domain is very difficult. This paper assessment provides some intuition about AOP and its quality which can't be generalized and it needs supplementary study. The focus of future research is on native programming languages, which is extension of AOP.

# Analysis of the Asynchronous Motor Controlled by Frequency Inverter Applied to Fatigue Test System

Nel Yuri Huaita Ccallo, Omar Chamorro-Atalaya

Faculty of Engineering and Management  
National Technological University of Lima Sur  
Lima, Peru

**Abstract**—This research focuses on analyzing the functional and operational parameters of the three-phase induction motor, squirrel cage type; Where the experimental model consists of a fatigue test system operated by two types of control: Control by Frequency Inverter and Classic star-delta control, where the engine load consists of a standard specimen, corresponding to 61.9% of the nominal load of the object of study. Experimental evaluations of this rotary machine are at regular operating conditions. Managing to Record electrical, mechanical, thermal variables; in a database where they were classified, developed, analyzed and interpreted; Highlighting from the graphs, the quasi-constant behavior of the  $\text{Cos}(\varphi)$  at 0.754 at different regulated frequency values which lead to a low energy consumption of current 1.88 Ampere with variator with respect to the weighted of 2.04 Ampere without inverter; even with improvements in torque when you are opting to use the drive from a 0.71 N-m to a 0.94 N-m. Likewise, the operation of this machine at low frequencies manifests some damages to normal operation, such as the rate of increase in the operating temperature of 78.76 °C in a short time and with projection to increase. Similarly, the injection of harmonic distortion into the network as a result of using electronic equipment, contributes to the detriment of energy quality.

**Keywords**—Induction; torque; frequency inverter (VDF); current; harmonic; temperature

## I. INTRODUCTION

The constitution of an asynchronous electric motor based on the squirrel cage model, presents the condition of gradual variation of speed by controlling the frequency of the stator, and the particularity of modifying the pole numbers in the inductor winding with the automatic adaptation of the same pair of poles in the rotor [1].

According to the constructive differences of electric motors, the types of lower operating speeds require greater torque-motor to deliver the same rotoric power of motors of higher revolutions; this is reflected in the sizing of this type of machine due to the assembly of more solid components for operability [2]. Since, these induction motors are described as a non-linear system because the speed and load condition present sudden jumps [3], so the presence of a special controller that provides vector or scalar control, is useful depending on the application area [4].

Among the different methods of electrical drive of these machines, the establishment of a variable frequency drive (VDF), based on microprocessors and power electronics

components[5, 6, 7]; Of which this operation of speed control in Alternating Current (AC) motors, consequently implies the reduction of wear of electro-mechanical components, such as the rotor conductive bars, which lead to one of the probabilities of failures; and a decrease between 20% and 60% of electrical energy consumption under the same load conditions[8]. The most recurrent VDF model for this application, works under the principle of Power Weight Modulation PWM [9] and this operating mechanism lies explicitly in the reduction or increase of the duration of the series of pulses that allow the control mode depending on the adjustment of the voltage and frequency of the power supply network [10].

Given the significant reduction in energy due to the use of this device, the presence or origin of the harmonic content generated by the grid expressed in the Total Harmonic Distortion (THD) is negligible, although this concept is specified according to the operating conditions and nominal load of the electric motor [11], given that, the VDF is used in specific sectors where they require a negligible THD, it should be noted that these optimal values are exclusive for quasi-stable frequency values; That is, not for applications of continuous velocity variations [12].

It should be noted that this presence of the harmonic spectrum influences the emission of thermal energy, about an additional 5%, in the engine that is operating at nominal load. On the other hand, the rectification of the power factor (f.p.) is developed based on the reduction of the phase angle between the current and voltage established by the VDF [13, 14].

In this sense, this article aims to determine the operational behavior of asynchronous motor controlled by frequency inverter applied in a fatigue test system for analysis of standardized specimens subjected to conditioned tension-compression. Therefore, the purpose of this is to analyze the benefits and particularities caused by the use of controllers such as the frequency inverter.

## II. LITERATURE REVIEW

If we assume that the excessive electronic control equipment consequently generates electrical noises, deformations and harmonics these can be evaluated to counteract them by power electronics, after analysis of the particular, but it is possible when it comes to a line of several motors, the cost is contemplated; Likewise, also ensuring [15].

Electric machines necessarily require reliable protection systems that involve additional expenses; however, among the

advantages of VDF, in addition to speed control, are the safety functionalities where the VDF presents algorithms that guarantee an instant response before possible failure scenarios, as reaffirmed [16] in his case study. These unfavorable scenarios can be: low starting current (ramp), dynamic braking (under reverse magnetic shock), reversal of rotation, absence of phase, imbalance of phases, among others; supplying mechanisms for starting, safety and braking of the electric motor.

### III. RESEARCH METHOD

#### A. Data Logging Processes

The model under study is composed of elements: mechanical, electrical, electronic, among others. Which we can show in Fig. 1, arranged according to their function, being able to be static and/or dynamic. Which we can classify into three systems: Control (command), Actuator (force) and Monitoring; All these are listed in Fig. 2 and Fig. 3 This composition consists of:

- 1) A three-phase network called L1, L2, L3, (220V 60Hz), where only two phases (L1 L2) are used to power the VDF.
- 2) A Siemens Micromaster 440 frequency inverter (attach tab as required), which was preconfigured with the plate data "Parameters"; In addition, peripherals were connected as an external control system composed of: Switch type switch (digital input), which enables the entire external control panel; Switch 1 - 0 - 2 (digital input), makes the so-called rotation inversion; Potentiometer (analog input), Performs the increase or decrease in speed as needed.

Fig. 1. A Three-phase Network VDF Connection Diagram.

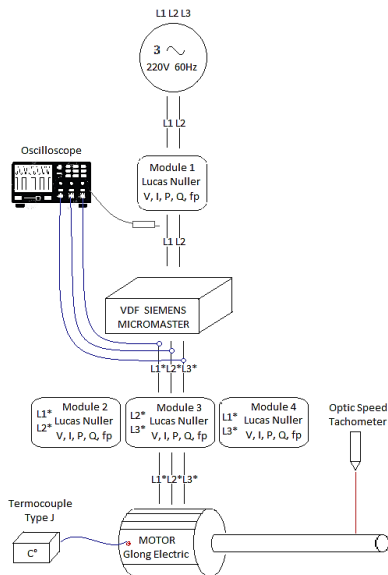

Fig. 2. A Siemens Micromaster 440 frequency inverter (VDF Connection Diagram).

Fig. 3. Direct Boot Connection Diagram.

- 3) A fatigue test machine where a class A-36 specimen was analyzed during the study, see Fig 5; Which consisted of a 61.9% nominal load for the induction motor.
- 4) An optical light tachometer (Standard ST6236B Tachometer) (see Fig. 5).
- 5) A digital oscilloscope (Instek GDS-2064) which registers an admission signal to the drive (L1 L2); drive output signal (L1\* L2\* L3\*)
- 6) Lucas Nuller measurement modules, obtaining (V, I, P, Q, f,p), which were located as follows: Red section – VDF input; VDF – Motor section, one module for each pair of phases (L1-L2/L2-L3/L1-L3); That is, in general it consisted of four modules (see Fig. 4).

#### B. Theoretical Bases

A theoretical part of the subject of the study is based on the behavior of the asynchronous or induction electric motor according to its operability-configuration, which obey laws of electrostatics.

In induction motors the variation of the simultaneous speed developed by the rotating rotor and rotary magnetic field is generated, this behavior of asynchronism is called slippage [17].

The rotor velocity Equation 1 ( $n_r$ ) of these electrical machines is given by the following expression:

$$n_r = \left[ 120 \times f \times \frac{(1-s)}{P} \right] \text{ (r/min)} \quad (1)$$

Where (f) is the wave frequency in units of Hz, (s) is the slippage expressed in percentage value and (P) is the number of magnetic poles.

The difference of this speed with respect to the speed of synchronism is represented according to Equation 2.

$$n_d = n_s - n_r \text{ (r/min)} \quad (2)$$

Where ( $n_d$ ) is the sliding velocity and ( $n_s$ ) is considered precisely the velocity of the magnetic field of the stator.

The description of these motors is similar to a rotary transformer; According to the secondary windings constituted

in the rotor design of the motor, they generate a power flow output mechanically due to the short-circuited system of the coupled windings [18].

This useful power is directly related to the torque induced in the machine, such torque is the result of the difference of the actual torque at the engine terminals and the torque produced by friction and friction with air in this equipment [19]; therefore, the developed mechanical power ( $P_{mec}$ ) is expressed by the following Equation 3:

$$P_{mec} = \frac{\tau_{ind} \times n \times \pi}{30} \text{ (W)} \quad (3)$$

Where ( $\tau_{ind}$ ) is also called motor torque expressed in N-m, and ( $n_r$ ) the rotational speed expressed in RPM.

In asynchronous motors the slip mainly influences the performance result, since the lower the slip value an acceptable efficiency is obtained [1, 17], specifically interpreted in the rotor performance Equation 4 ( $\eta_r$ ):

$$\eta_r = 1 - s = \frac{P_{EM}}{P_S} \quad (4)$$

Where ( $P_{EM}$ ) is the internal mechanical power and ( $P_S$ ) is the interlocking power that reaches the rotor. From the power supply, the motor is supplied with electrical power which is classified as ( $P_{Absorbed}$ ) recorded in the input conductors of the machine, in full operation mechanical power expressed as ( $P_{Util}$ ) is released, this variable differs with the input power due to iron losses, copper and thermally dissipated mechanics.

$$\eta = \frac{P_{util}}{P_{absorbed}} = \frac{P_{output}}{P_{input}} = \frac{P_{Mechanical}}{P_{Electrical}} = \frac{HP \times 746}{\sqrt{3} \times V \times I \times \cos\phi} \quad (5)$$

It is considered that the increase in the feeding frequency influences the decrease in reactive power of magnetization. Since, the reactive energy is consumed when the asynchronous motor performs an operation in vacuum, according to the impedance of the motor, it causes a high angle of lag between voltage and current, consequently, a low  $\cos(\phi)$  [20].

In the mechanism of drive of asynchronous motors, the transient stage is taken into consideration when the change of state is developed by increase or variation of speed where there are various methods of analysis, of which emphasis is taken to the frequency inverter VDF used to control the mechanical speed of rotation of the induction motor.

### C. Basic Concepts

Our model under study is a three-phase squirrel cage type motor in the brand "Glong Electric", asynchronous classification, denomination due to the difference in speed between the magnetic field with respect to the rotational speed, also related to sliding, has an F classification insulation whose working ranges around 155 °C (IEC 60085); Also, a degree of protection with respect to solids and fluids. IP 54 (IEC 60529).

In the Table I, relevant parameters of this electric machine for the present study are detailed, which are collected according to plate data and technical sheet provided by the manufacturer.

TABLE I. ENGINE TECHNICAL SPECIFICATIONS

MODEL - GLONG	
TYPE	MS7132
HP	1
(D) V	220
(Y) V	380
(D) I	3.3
(Y) I	1.93
POLES	2
KW	0.75
HZ	60
RPM	3300
Cos(φ)	0.82
NO.	1111103
η	0.727

Likewise in Table II, the machine would be considered at full load if the consumption was the nominal intensity, but for our case the applied load only represents 61.9%.

### D. Overview of Experimental Analysis

During the experimentation, the most relevant electrical parameters were analyzed and documented, which were synthesized in Excel calculation tables, which consist of two analyses, where the Tables III, IV and V correspond to the first analysis; also, for the second analysis consist of two Tables VI and VII. However, these parameters were obtained through different methodologies.

Fig. 4. Experimental Instrumentation System.

Fig. 5. Fatigue Analysis System.

So, we have in Fig. 4: Lucas Nuller modules (V-1Ø, I, f, p (Cos(φ)); Oscilloscope (amplitude, frequency); Tachometer (RPM); parameters obtained through national electrical portals COES SEIN (frequency); Parameters obtained by calculations, using the equations described in the theoretical bases section. powers 3Ø "P-Q-S", Angle(φ°), mechanical power (Equation 3), torque (Equation 3), magnetic field speed, slippage (Equation 2).

In this Fig. 5 we have a partial view of the driving part of the modular fatigue stress analysis system, where in: on the right side, rotating mechanical parts corresponding to the load of the electric machine are observed (rowlocks, specimen, dynamometer, etc.); Similarly, we have on the left side the electric machine, which is the object of study in this article.

IV. ANALYSIS

A. First Analysis

Tables corresponding to those obtained during the operation of the asynchronous motor by means of a VDF, where Table III corresponds to the supply with two live phases; Also, Table IV corresponds to the output of three quasi-alternating live phases of the VDF which are directed to the terminal box of the three-phase motor.

The Table V, presents six variables under analysis, where the only one obtained experimentally is the Cos(φ); Otherwise with the other variables which are a consequence of the calculations made, based on theoretical bases described above.

Once the values obtained by instrumentation (Table III, Table IV) and calculations in Table V have been admitted and synthesized, we proceed to make graphical representations of the most relevant electrical parameters, including those that are the object of analysis.

In all cases the representations correspond to figures obtained by Module 1 and Module (2, 3 and 4) nomenclature specified in Fig. 1, Fig. 2 and Fig. 3. Parameters represented by IBM SPSS interfaces, corresponding to V, I, P, Q, S and f.p.

For Fig. 6, the intake voltage at all analysis points is within the maximum permissible ranges of +/- 5%. However, at the output of the VDF in all cases it presents a stable increase, corresponding to the directly proportional increase of the frequency in selected analysis.

Fig. 6. Analysis of 1Ø (V) and 3Ø (V).

Fig. 7. Analysis of 1Ø (A) and 3Ø (A).

The output intensity of the VDF presents an increase in peak value, due to the low starting frequency, in addition to the natural inertial load of the rotor and including the load; however, this peak is temporary, since it presents a beneficial decrease in time, in inverse relation to the frequency. However, in the admission of the VDF presents a quasi-constant proportional increase.

Likewise; Regarding the Fig. 7, we can affirm that the use of VDF is profitable at low frequencies, since the consumption of the network is lower than the output of the VDF. Where the point of non-profitability would be around 12 where the frequency is around 30.21 HZ.

Given this representation Fig. 8, we can reaffirm one of the greatest virtues of the VDF, which consists in the reduction of energy consumption of the electricity grid. Where according to the graph at all times the active power of the network is lower, than that of the output of the VDF.

Fig. 8. Analysis of 1Ø (W) and 3Ø (W).

Fig. 9. Analysis of 1Ø (VAR) and 3Ø (VAR).

Given the interpretation of the graph (Fig. 9), we can affirm that the reactive power in the output of the VDF is greater than that of the network for all the frequencies analyzed, which has similitude to a circuit with a reactive energy compensation system.

Apparent powers are also considered one of the most important parameters of a power triangle. This is a consequence of vector considerations of the f.p, active and reactive powers that is why we can affirm through its graph (Fig. 10), that the use of a VDF reduces energy consumption, without affecting the electrical or mechanical power of the induction motor.

Having simulated several representative waves of ideal waves using software PSIM, we make available the waveforms obtained by the function generator, which we show in Fig. 11. Being able to show the distortions caused in the fundamental wave by the use of a VDF.

Similarly in Fig 12, the waveforms generated by a frequency inverter; That is, the one we make available to the cargo.

Fig. 10. Analysis of 1Ø (VA) and 3Ø (VA).

Fig. 11. Harmonic Distortion Caused by the use of a Variable Frequency Drive.

Fig. 12. Quasi-Sine Waveform Generated by the Variable Frequency Drive to make the Load Available.

B. Second Analysis

From now on we start a new analysis; where we compare the rotary machine, operating on a regular basis with a direct starting system using contactors Fig. 3 and a second using a VDF with ramp starting system Fig. 2; but, both with delta connection. The electrical parameters obtained were arranged in tables, respectively (Table VI and Table VII).

In the Table VII, we make the comparison under similar operating conditions with the exception of considering in the installation a VDF "C/VDF" (see Fig. 2) or not using it "S / VDF" (see Fig. 3).

From now on we proceed to perform the validation of the results obtained by Power Simulation Software (PSIM), for this we start by making the representative equivalent diagrams in the software interfaces, where we also declare the nomenclatures and denominations of the instruments, to analyze subsequent representations that preserve the same nomenclatures.

We can deduce the following diagram as the electrical interpretation of Fig. 2. Where modules (2, 3 and 4) are presented as a composition of instruments specific to each parameter. In addition to performing the electrical representation of a rotating electric machine by its equivalent impedance (resistance "r" and inductive reactance "xl") Of similar characteristics to the previous wing, the present representation corresponds to the electrical interpretation of Fig. 3 with similar contemplations with respect to instruments and equivalent electrical circuits described in Fig. 13.

Fig. 18. Effective Parameters c/s VDF.

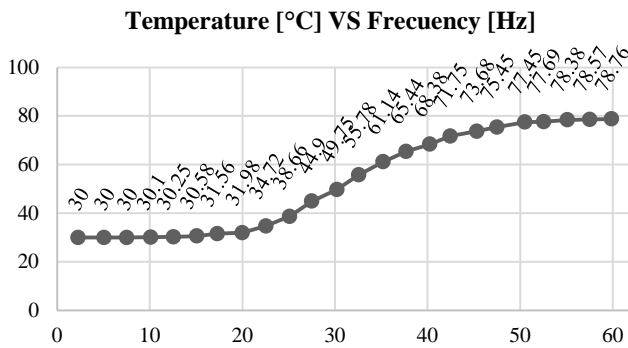

Fig. 19. Temperature Values of the Induction Motor with VDF.

One of the parameters considered of high importance in the useful life of electrical machines is the working temperature, since this is responsible for the physical state of the insulation (windings, rotoric core, statoric core, etc.). This parameter has an impact on efficiency. Which relates the power that is absorbed from the electrical network, materializing it in losses per joule effect and minimizing the useful power; also, with respect to this we can deduce given Equation 5.

That said, in this table data collected during experimentation were synthesized, where they are in units of S.I. [°C], these were collected by ammeter Prasek (PR-103), in the temperature function with connection of external receiver peripheral called thermocouple type J, where the thermocouple was fixed to motor housing (see Fig. 2 and Fig. 3)

#### V. DISCUSSION

If we consider between the option of controlling the speed of a rotating machine and we opt for only 2 possibilities such as changing the number of poles or installing a vdf according to a Cost-benefit analysis, the second option would be the most convenient for the benefits of varying any RPM value with only the variation of frequencies, in addition to having protection algorithms. Likewise, it states in [7], in addition to other options that are not the subject of study.

There are control systems based on fuzzy logic in which they focus directly on the torque of the engine in the condition of operation or of certain regimes [21]; however, these would only be applicable to machines of regular work regime, the exception being those of intermittent work or irregular periods. Since these would necessarily have the phenomenon of vibrations of high torque and of different magnitudes in this regard, in [22], they point out that the claims were even higher, but for regular work regimes.

The asynchronous rotary machines have a self-coupled cooling system by constitution and composition, where the first refers to the fins of the housing, whose function is to dissipate the temperature by conduction, the temperature increases produced by the core and winding of the stator; Also, the second refers to the fan coupled to the rotary axis which directs the flow of cold air to the fins by means of the principle of forced convection; However, this fan is conditioned to the rotational speed of the rotor, where the nominal speed guarantees its efficiency; Also in [23] it is sated in regard. In the case of speed variations, they strongly impair the efficiency

of this. Therefore, according to the machine dimensions, power, environmental factors, programmed rotational speeds, external ventilation systems must be chosen, guaranteeing the working temperature. Avoiding exceeding these recommended values even of “F” insulation which guarantees us a maximum optimal work at the temperature of 155 °C (IEC 60085); in this regard in [24] they also assure the same.

#### VI. CONCLUSION

Electric machines have as a fundamental purpose to transform electrical energy into mechanics. So, in this article, two analyses were performed: The first, using a VDF, the torque was evaluated at different speeds (Table V); the second, making a functional comparison of the engine with and without VDF (Table VII), in both situations, only operating at nominal speeds. consequently, we can assert that, in the first case, under any frequency value assigned in the VDF the mechanical torque of the electrical machine is preserved almost constant, oscillating between 0.88 (N-m); However, in the second case the electric machine has a higher torque when using the VDF; that is, with VDF 0.94 N-m and without VDF 0.71N-m.

Rotary electric machines have standardized operating temperatures, which meet criteria of rotational speed, mechanical load, type of bearings, insulation class, among others; Given the importance of this parameter, in our experimentation with VDF, it was determined that the working temperature increased drastically in shorter operating time, and with possibilities of increase, establishing itself at 78.76 °C (see Fig. 19); However, when the use of VDF is ignored, the engine is set to a temperature of 40 °C, during any operating time. For both cases: First, the evaluation period was similar, corresponding to approximately 30 minutes, until stability was evident; Second, the percentage of mechanical load is less than the nominal, see Table II.

The power factor is directly related to the powers (P, Q, S), arranged in a triangle, in relation to their nominal parameters. lower load corresponds to lower f.p. consequently greater unnecessary energy consumption, making possible alternatives such as reactive energy compensation. however, among the advantages of a VDF drive is to preserve a Cos(φ) as high as possible, but at the cost of injecting harmonics into the network. Likewise, we can see the manifestation of this event in Table VII in the electrical current apparatuses (I[Ampere]).obtaining a Cos(φ) of 0.754 despite reducing energy consumption, against a Cos(φ) of 0.782 with higher consumption. Both in equal operating conditions at 61.9% load. This value is optimal if we consider that such a machine is not operating at nominals.

The slippage is increased directly proportional to the rotational and statoric velocities (magnetic field); Then, according to the analysis carried out in Tables IV and V. We can affirm that this increase is very small, but it is preserved over time; that is, the use of a VDF does not alter its main characteristic of this type of electrical machines asynchronous. However, this slide has an average of approximately 30 rpm.

Given the analysis to Fig. 7 we can affirm, that despite the configuration of acceleration ramp, the electrical intensity presents a visible peak, because the engine starts its march in

zero frequency; In addition to including the inertia of the natural rotor axis with load included; However, this peak will be settling as the speed increases; Likewise, the machine has optimal energy efficiency at low frequencies, where the breaking point is approximately 12 and the corresponding frequency is around 30.21 HZ. This energy reduction can be evidenced as the curve of the intensity admitted in the VDF is lower, regarding the one supplied to the engine.

The injection of harmonics into the network is directly related to the operating frequencies of the rotating machine Fig. 12, even more so at low frequencies, the manifestation of this phenomenon is reflected in the waveform obtained by the function generator; so, we have in Fig. 11, which shows the distortion caused in the fundamental wave.

According to the analysis in Table VI we can deduce that the dependence on reactive energy is much higher when you choose to use a VDF; however, this variable is relatively debatable, only for specific sectors where energy regulations consider in addition to active energy, reactive energy. Current regulations that contemplate tariffs and penalties, regarding consumption or injection into the interconnected electricity grid depending on whether the sector is used, distributed or transmitted.

**Abstract**—Spreadsheets are contained critical information on various topics and were most broadly utilized in numerous spaces. There are a huge amount of spreadsheet clients everywhere in the world. Spreadsheets provide considerable flexibility for data structure organization. As well as it gives their makers an enormous level of opportunity to encode their data as it is simple to utilize and easy to store the data in a table format. Because of this flexibility, tables with very complex and hierarchical data structures could be generated. Thusly, such complexity makes table processing and reusing this data is a difficult task. Therefore, the expansion in volume and complexity of these tables has prompted the necessity to preserve this data and reuse it. As a result, this paper implemented a novel algorithm-based heuristic technique and cell classification strategy to automate relational data extraction from spreadsheet hierarchical tables and without need any programming language experience. Finally, the paper does experiments on 2 different real public datasets. The percentage of average accuracy using the proposed approach on the two datasets is 95 % and 94.2% respectively.

**Keywords**—*Spreadsheet table analysis; hierarchal table structure; cell classification; heuristic algorithm; relational data extraction*

## I. INTRODUCTION

A spreadsheet is an interactive application tool for organization charts, storage, and analysis of data. It contains data that is viewed in a tabular form. It consists of information orchestrated during a two-dimensional (2-D) cell. Normally, fragments during a table address the table name, and each line addresses the attributes or the values. The primary line or lines may contain segment attributes or variable names. Cells may contain numbers, text, dates, and other data types. Past this fundamental model, Spreadsheets are utilized by an enormous number of clients as a typical generally useful data management tool. Because of this flexibility, tables with very complex data structures could be generated. Thusly, such complexity makes automatic table processing and data extraction a difficult task. Therefore, the table pre-processing step is regularly needed in the data extraction pipeline [1].

Unfortunately, an enormous amount of spreadsheet tables are unstructured tabular data with simple or hierarchical and

sophisticated table structures. The attributes or the header of simple tables [2] acts in only the first line or only in the left column (rule). The hierarchical table structures [3] act in hierarchical attributes at the top lines (highest rows) of spreadsheet tables or multi-dimensional levels of left attributes (left columns). As shown in “Fig. 1”, the complex table structure [4] acts within the top and left attributes together. These attributes of complex table structures could also be hierarchical or simple (top and left) without hierarchy. They are intended to be explicitly understood by humans but not by a machine which makes it implicit to understand and process these hierarchal and unstructured data. Nowadays, there is an explosion of computation intelligence vision that requires the data to be understood by machine and extracted in a structured form like an electronic database. The automatic extraction of hierarchical table header structure is the initial step of converting unstructured data to structure data form.

The data stored in spreadsheets is unstructured, inconsistent, has low quality, and lacks data integration operations. Spreadsheets do not observe a standard data model (definite structure or schema), thus it is difficult to integrate with other data sources. The spreadsheet tables contain a huge amount of high value that needs to convert to a relational form to reuse and integrate. The first logical step to make such data relational is to extract the relational table structure from a spreadsheet.

According the literature, there are three main types of approaches that are responsible for extracting relational data from the spreadsheets:

1) *Schema-based approach*: It is a traditional schema mapping system used to extract or convert from spreadsheets to relational data by specifying the source and target attributes mapping.

2) *Rule-based approach*: It requires explicit user-provided conversion rules.

3) *Visualization-based approach*: It provides the users with an interactive visualization interface to extract or manage the underlying data that exist in the spreadsheets.

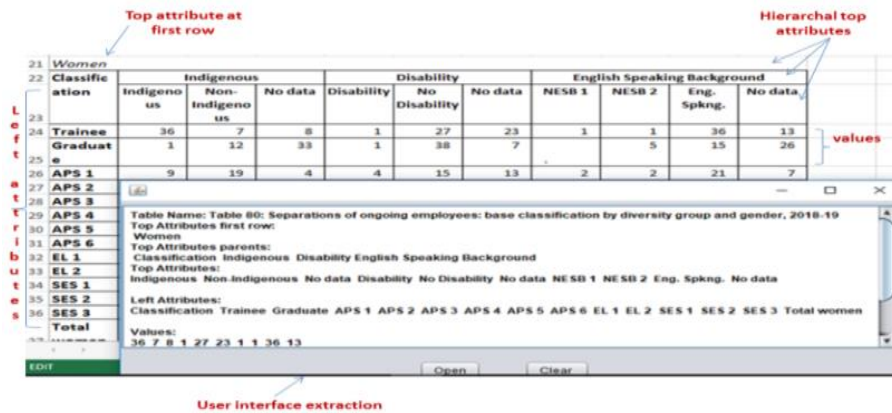

Fig. 1. A Running Example of Complex Table Structure with user Interface Extraction.

However, there are three common draw-backs of these three main approaches:

- a) Challenges to handle hierarchal spreadsheet tables.
- b) The extraction process cannot be accomplished automatically.
- c) Most of the approaches require the users to learn a new language or pre-defined operators to describe the extraction rules.

Therefore, the paper used an automatic approach based-heuristic algorithms and cell classification strategy to accurately extract relational data from hierarchal and complex spreadsheet tables.

The importance of this research lies in the future vision of the relational data extracted from a spreadsheet includes computer agents searching for information, making decisions, and taking actions on behalf of human users. Thus, it is needed to automate extracts for collected complex table header structure in the spreadsheet (semi-structured format) to improve spreadsheet quality as it is the precondition for investigating and utilizing information and for ensuring the estimation of the information.

The main contribution of this research is developing variant techniques and algorithms that allow discovering tables in spreadsheets to infer their layout and their relational data. However, most of the existing approaches and techniques cannot achieve the extraction process automatically for hierarchal table structure extraction. It often required some user efforts to accomplish this process. As a result, this paper developed an automatic approach that is accompanied by some heuristic rules and cell classification features.

As extension of our previous work [5, 6], a new method was developed to extract multiple tables from the Excel sheets. Also, extended to extracts implicit and relational data from complex and hierarchy structure tables not only from simple table structure based on:

Proposed an algorithm based on heuristic rules and classification cell features for selecting complex and hierarchal section header lines and data values. This methodology provides a way to extract a more and more organized structure data from spreadsheets.

This paper is organized as follows. Section 2 discusses the related work as well as the relational data extraction. Whereas Section 3 introduces the proposed approaches with the process extraction of relational data from spreadsheet tables, Section 4 presents the proposed algorithms. Section 5 presents the results and analysis of the experiment of the accuracy of complex table structure. Finally, the paper is concluded in Section 6.

## II. RELATED WORK

Spreadsheet table discovery is the assignment of identifying all tables on a given sheet and finding their reaches. Table detection header is the stage of detection mechanism that achieves state-of-the-art results in computer vision [7, 8] based on the convolutional neural networks approach. On the other hand, [9] presented a multi-task learning method to extract a semantic structure of a table. [10] Includes heuristics on the structure and textual content of a table that is designed for three model table types. [11] Combines various heuristic-based algorithms that classify spreadsheet cells into four functional groups (roles; headings or data values). [12] Used rules-based language for table analysis and interpretation. [13] Assumes that all content in one cell is either a label or an entry. [14] Proposed a classification approach and training the data to discover only the layout of tables in spreadsheets above cell level structure. [15] Presented a predictive synthesis algorithm to helpfully automating the data wrangling process. [16] Used the heuristic approach for table header to correct and achieve matching between the physical and visual presentation of the table structure. However, authors in [17] used programming by examples for hierarchal data conversion to a relational table. The authors of [18] applied the cell features algorithm to classify and identify the table spatial in the spreadsheet. The authors of [19] generate a flash relate algorithm and the user must use the input-output examples for the relational data required. In addition, the authors in [20] used a heuristic method to correct a physical structure to the table header by merging the empty cell with the neighboring ones that are not empty. Most of these algorithms require user efforts for relational data extraction or conversion.

Through reviewing previous work, the research has covered this point from different angles, including automation like the proposed work [21], which does not need any user intervention. However, they automatically infer some

spreadsheet structure, but they cannot process hierarchical spreadsheets. Semi-automation [22,23] who needs user intervention, and sometimes needs to understand the user to a specific programming language, and what needs to be programming language [24,25]. The current study is consistent with past investigations in its principle subject and the general objective, yet it differs from it in the application strategy.

### III. RESEARCH METHOD

As depicted in “Fig. 2”, the initial phase for the extraction process of research approach is to detect the tables found in the Excel sheet. The spreadsheet may contain only one table or multiple tables. After that, the algorithm starts to detect the tables' names if found. Then the algorithm begins to distinguish between tables' headers and their values. Finally, the proposed algorithm extracts tables found in the spreadsheet with their names and their attributes besides their values. The detailed process of each phase can be described in the next sub-section as the following steps:

#### A. Table Detection and Extraction Phases

Spreadsheet table detection and discovery is the first step needed to complete the process of changing over information put away in spreadsheets into organized information in a database that can be questioned and handled to applied decision making and knowledge discovery rules. Table detection is the errand of recognizing all tables on a given sheet and finding their separate reaches as shown in “Fig. 3”.

Fig. 2. The Research Methodology.

```
1- Iterate upon all sheets
for (int i = 0; i < workbook.getNumberOfSheets(); i++) {XSSFSheet
sheet = workbook.getSheetAt(i);
2- Detect rows [max-written rows number].
sheet.getPhysicalNumberOfRows()
3-Read number of merge region and detect it's address.
CellRangeAddress address = new CellRangeAddress(first column ,last column
,first row , last row);
address = sheet.getMergedRegion(region number);
4-Iterate on all rows
Iterator<Row> rowIterator = sheet.iterator();
while (rowIterator.hasNext())
Row row = rowIterator.next();
5-Iterate on every cell in all rows.
Iterator<Cell> cell iterator = row.cellIterator();
while (cellIterator.hasNext())
Cell cell = cellIterator.next();
6-Read cell value and detect which it value or attribute.
7-Get last row number at every sheet int lastRow =
sheet.getLastRowNum();
```

Fig. 3. Table Detection Process.

After detecting the table in the spreadsheet, the algorithm starts to extract table name, attributes, and values based on the heuristic rules and cell features as shown in “Fig. 4”, “Fig. 5”, and “Fig. 6”.

1. If this cell Attribute cell
2. Only one cell at this row
3. Next row is empty blankRow == null
4. No table name yet TablNm == false
5. Cell value contains substring "Table"  
CelValue.contains("Table")

Fig. 4. Extract Table Name.

1. If this cell Attribute cell
2. Extract table name before TablNm == true
3. There are other attribute cells at the same row
4. Check if this merged region and get its address (parent attribute)
5. sheet.getNumMergedRegions() \\  
calculate NUMBER of merged region
6. CellRangeAddress address = new  
CellRangeAddress(firstRow,endow,firstColumn,endCo  
lumn) \\  
return address of merged region
7. There is an empty cell in the same row
8. If the next row has an attribute cell, this is a hierarchal  
attribute
9. Every cell in the next row has the same address of  
merged cell be a child of parent Attribute

Fig. 5. Extract Top Attributes.

1. If this cell Attribute cell
2. First cell at row columnIndex == 0
3. There are not any attribute cells at the same row  
phNumOfCell == 1
4. If the rest of the row blank is parent left Attribute
5. If there are other data at the same row value left  
attribute

Fig. 6. Extract Left Attributes.

#### B. Extract more than One Table from One Datasheet

In the case of the existence of more than one table in the same datasheet, there are two possible causes for the positioning of them. Case (A), if these tables were placed side by side separated by one or more empty columns. Case (B), if these tables were placed over each other separated by one or more empty rows.

### IV. HORIZONTAL SYNCHRONIZATION

In this case, if the algorithm found an empty column before the maximum number of the filled data columns, that means there is another table in the same rows. The algorithm will implement a new matrix to store the new table.

### V. VERTICAL SYNCHRONIZATION

In this case, if the algorithm found an empty row before the maximum number of the filled data rows, that mean there is another table below. The algorithm will finalize and send the current table then starts to explore the new one.

## VI. ALGORITHMS USED

### A. Header Inference Algorithm based on Heuristic Rules and Cell Classification Features

1) The spreadsheet table has its exceptional trait of being a structure of vertically on a level plane extended segments, which are table name, attributes, and values. The paper displays a calculation for table identification in spreadsheets. The calculation utilizes three kinds of cells as its premise: table name cell, attribute cell, and value cell. As shown in "Fig. 7", the cell classification identification proof was based on its heuristic features and the number of cells, one cell or more than one cell.

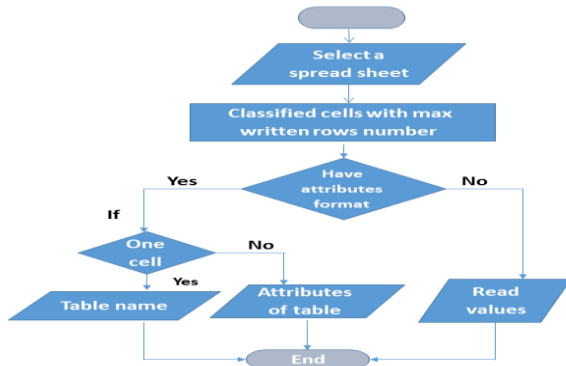

Fig. 7. Cell Classification Flow Chart.

Once the user opened the selected spreadsheet, the algorithm begins to detect all tables found in the spreadsheet using the method of cell classification based on detect max written rows number. This method detects the first row that contains data and the last row that contains data which makes a table frame. After that, the algorithm will check the cell formats for example if it is bold, italic, justified, capitalized, or colored to detect if this cell has an attribute's format or not. The attribute's format detects based on the cell classification numbers as well as one cell and has attributes format, it will be table name. However, if there is more than one cell and contains the format of the attributes, it will be attributes or headers of the detected table. However, table attributes detection is divided into two phases, top and left attributes. Top attributes are the first row that is not empty and contains data with attributes format and the left attributes are in the first left column within attributes format. The Top and Left attributes may be extended in a multi-level of rows or columns respectively which makes it a hierarchal attribute. Otherwise, the algorithm detects and extracts table values based on a cell type if it is the numeric type which means the cell contains numbers or the string cell is not an attribute cell.

Heuristic rules for complex and hierarchal table structures are found in the top first row and first left column. Also, Heuristic rules for hierarchal table attributes extended for multi-level rows or columns. Excel relational data extraction for table structure can be summarized as shown in Algorithm 1.

Physical layout features (the cell has right border, the cell has bottom border, the row has bottom border, if there is a table, the table has outside border, the table has a bottom

double border, the table has thick bottom border, the table has top and double bottom border, the row has a top and double border, the cell has all borders, the column has a right border if there are merged cells).

---

#### Algorithm 1. Excel relational data extraction

---

```
Input: Exc
el workbook with multiple sheets  $A = \{S_1, S_2, \dots, S_n\}$  and contains
complex and hierarchal tables structure
Output: Separate tables each include TBL: Table name as a variable
TblNm and Attributes as an array list  $Att = \{att_1, att_2, \dots, att_n\}$ , values
as  $Val_{[m,n]} = \{val_{m1n1}, val_{m1n2}, \dots, val_{mnn}\}$ 

Begin A
  For every sheet in A Do
    Begin new TBL // row 3
    For every filled row Do
      For every filled column Do
        For every cell Do
          If the cell has attributes format and no other data in
this row or column // one cell
            TblNm <- cell data
          Else if a cell has attributes format and there is other
data in this row or column // more than one cell contains the same
format // top or left attribute
            Att <- cell data
          Else if the cell in the next line have Attributes format
// next line column or row
            Att <- cell data // Hierarchal attributes
          If a cell does not have attributes format or it is a numeric
value
            Val[m,n] <- cell data
          Else if an empty row or an empty column go to row 3
        End if
      End if
    End for
  End for
End for
End for
```

Semantic content features for cells ( bold, italic, underline, different font or content style, different background cells color ( fill color or cell format), alignment ( top, middle, bottom, left, center, right), attribute contains keyword such as: "Total", "Name", "ID", "Average", "Avg", "Date", Year...etc., attribute letters are all capitalized, attribute contains a colon, attributes font size is bigger than values font size, the attribute has blank cells in the middle( blank row or column inside the detected frame), child's row index is greater than parents, parent row index is smaller than children, in left attributes the child's indentation is greater than parents, attribute cell is long width, if there are the same features on multiple rows or column until finding deferent features, etc.

## VII. RESULTS AND DISCUSSION

The evaluations of the accuracy of the approach are used and illustrate it by utilizing the gov.au.data dataset [26]. The paper downloaded two different public datasets with Excel (.xlsx) Formats. The datasets contain multiple sheets (61 and 82 sheets, respectively) and every sheet may contain only one table or multiple tables as illustrated in Table I. The evaluation supported relational data detected and extraction from the spreadsheet tables.

TABLE I. EXPERIMENTAL RESULTS

Datasets	Number of sheets	Number of randomly selected sheets, tables	Number of successfully identified relational data	Percentage of successfully extracted relational data %
1- Australian Public Service Statistical Bulletin - December 31, 2016	61 sheets	20 sheets with 20 tables	Table name: 20 Top attributes: 19 Left attributes: 18	Table name: 100% Top attributes: 95% Left attributes: 90%
2- APS Employment Data 30 June 2019 release	82 sheet	20 sheets with 29 tables	Table name: 29 Top attributes: 27 Left attributes: 26	Table name: 100% Top attributes: 93.1% Left attributes: 89.6%

REFERENCES

The experimental results showed that the percentage of accuracy to the first dataset of table name detection and extraction is 100%, top attributes are 95%, and left attributes are 90%. However, the second dataset results accuracy is 100% for the table name detected and extraction, 93.1% of top attributes, and 89.6% of left attributes. In summary, It is important to need to understand the nature of the Excel sheet that will be working on because each excel sheet has a different structure from the other one, and therefore the difficulty of extracting data from it comes from here. Therefore, it needs to know the structure of the Excel sheet that will be work on, and if there is any structure other than this, the extraction algorithm will be stopped working, or it will not work correctly to extract the data from it. Thus, to extract a large corrected number of relational tables successfully from spreadsheets, you have to identify a variety and of heuristic tables' cells features and rules.

The algorithms are written in JAVA as a programming language, connected with SQL server as an analysis tool, and Windows 7 as an operating system. To test it, an executable jar file is created. The hardware specifications for the system are, Intel® Core™ 2 Duo CPU with 4 GB of RAM. The version of Microsoft Excel installed on the machine is 2013. However, the proposed tool works only with new version of Excel (.xlsx' format).

VIII. CONCLUSION AND FUTURE WORK

This paper presents a detailed algorithmic data processing method for automatically extracting relational data in complex and hierarchal table structures from spreadsheets. The automatic approach is accompanied by some heuristic rules, features, and cell classification categories. The experimental results showed that the accuracy of relational data detected and extracted from the spreadsheet tables for the tested two datasets are 95% and 94.2% respectively. In the future work, the proposed method can be extended to integrate the extracted data into an existing relational database.

IX. CONFLICTS OF INTEREST

The paper declares that it has no conflict of interest and no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

ACKNOWLEDGMENT

We would like to thank the "Future University in Egypt" for its continuous support and efforts to improve the scientific research results for publication.

# Effective Controlling Scheme to Mitigate Flood Attack in Delay Tolerant Network

Hanane ZEKKORI, Saïd AGOUJIL, Youssef QARAAI

Dept. of Computer Science of Faculty of Sciences and Techniques, University of Moulay Ismail  
Errachidia, Morocco

**Abstract**—Conventional routing protocols breaks down in opportunistic networks due to long delays, frequent disconnectivity and resource scarcity. Delay Tolerant Network (DTN) has been developed to cope with these mentioned features. In the absence of connected link between the sender and the receiver, in DTN mobile nodes replicate bundles and work cooperatively to improve the delivery probability. Malicious nodes may flood the network as possible by a huge number of unwanted bundles (messages) or bundle replicas which waste the limited resources. DOS (Denial of Service) attack especially Flooding attack attempt to compromise the availability service of the network. Traditional congestion control strategies are not suitable for DTN, so developing new mechanisms to detect and to control flooding attack is a major challenge in DTN network. In this paper, we presented a comprehensive overview of the existing solutions for dealing with flooding attack in delay tolerant network, and we proposed an effective controlling mechanism to mitigate this threat. The main goal of this mechanism is first to detect malicious nodes that flood the network by unwanted messages, and then to limit the damage caused by this attack. We also ran a large number of simulations with the ONE simulator to investigate how changing buffer capacity, message lifetime, message size, and message replicas affect DTN network performance metrics.

**Keywords**—DTN; flooding attack; DOS; congestion; buffer capacity; bundle; ONE

## I. INTRODUCTION

Nowadays, the use of wireless technology has invaded the mobile network market. MANET (Mobile Ad hoc Network) [1] is a wireless network that does not rely on a pre-existing infrastructure. This traditional mobile network, on the other hand, does not support packet transfer in an environment characterized by an intermittent connectivity between the transmitter and the receiver. Which results in the birth of the DTN (Delay tolerant network) [2], that comes to cope with these challenges by the help of a Bundle layer added on top of lower-layer protocols (see Fig. 1). The bundle layer ensures interoperability between network regions and the transfer of bundles (messages) via a technique known as store carry and forward [2], in which network mobile nodes collaborate with each other to increase the message delivery rate.

Contacts in the DTN network are opportunistic [3]; nodes meet with no prior knowledge about the movement and the mobility of the other nodes in the network. So, flooding based routing strategy can be opted to improve the probability of delivery and to reduce the average latency. This routing strategy consists of flooding the network with multiple copies

or replicas for each single bundle to increase the likelihood that one of these copies will reach its destination. This strategy, however, consumes more network resources.

DTN uses the store-carry and forward paradigm [2] to avoid data loss if the upstream path is interrupted. When a source node creates a bundle, it stores it in its persistent buffer until a contact opportunity with an intermediate node occurs. The mobile nodes exchange bundles in a hop-by-hop manner, and the process is repeated until each bundle arrives at its final destination. Each node has a persistent buffer B in which it stores the received bundles, and it is defined by its limited capacity C.

Fig. 1. Illustration of DTN Layered Architecture.

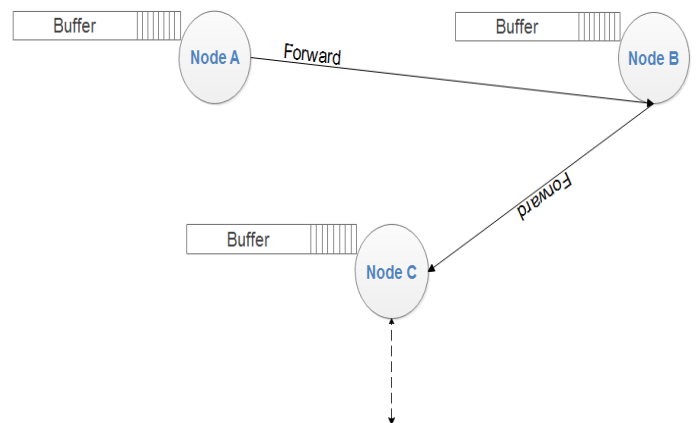

Fig. 2. Illustration of the Store Carry and Forward Transport Technique.

We have schematized the technique Store and Forward in the Fig. 2: to deal with the DTN network's intermittent connectivity, each node keeps the bundle in its buffer (store phase) while waiting for a future communication opportunity with a relay node to transmit that bundle (forward phase).

#### A. Security Requirements

The fundamental security requirements for DTN [4] are similar to those for wired and wireless networks with infrastructure. Security services are based on five fundamental concepts: Authentication, confidentiality, data and network traffic integrity, availability, and non-repudiation (see the Fig. 3 below) [5] [6].

Fig. 3. The Five Fundamental Security Requirements.

#### B. The Five Fundamental Security Requirements

- Authentication

Authentication verifies the identity of network entities or nodes. This is a crucial step in controlling network resource access. Without authentication, a malicious node can easily spoof another node in order to gain the privileges assigned to that node, or attack using that node's identity in order to harm its reputation. The authentication process in wired or wireless networks with infrastructure is based on a trusted third party which has been approved by all network entities. The trusted third party is simply the certificate authority, which distributes certificates to nodes with access to specific network services. This centralized authentication scheme is known as Public Key Infrastructure (PKI) [7]. It is nearly impossible to apply the PKI model directly to the DTN network because the DTN network topology changes frequently and dynamically and the connectivity is intermittent, the nodes are autonomous, and their capabilities (energy, computation, buffer space, etc.) are limited.

- Confidentiality

The fundamental service for ensuring private communication between nodes is confidentiality. It is about protecting against threats that could lead to unauthorized disclosure or viewing of private information. It is fundamentally based on cryptography, specifically encryption algorithms. Encryption algorithms, whether symmetric or asymmetric, require an encryption key to encrypt a message

before it is sent to its destination. However, in order to decrypt the message, the destination must have a decryption key. As a result, a key management and sharing mechanism tailored to the DTN network is required, however due to the DTN network's unique characteristics (intermittent connectivity...), it is a significant challenge to implement these traditional encryption algorithms.

- Integrity

This service ensures that traffic from the source to the destination has not been altered or modified without prior authorization during transmission. The risk that a malicious node modifies a message is always present in the DTN network. The goal of integrity service is to ensure that resources are working properly. This service protects information from unauthorized modification (ensure data integrity). Indeed, this service can be used in conjunction with security protocols that provide confidentiality and authentication.

- Availability

Availability refers to ensuring the continuity of a node's services even in the face of an attack. In other words, nodes must ensure network services continuity (such as routing, data access, and so on) in the event of a flooding attack. To accomplish this, it is necessary to protect against threats that may disrupt network functions to ensure that all nodes have access to network resources without any restriction.

- Non-Repudiation

The ability to verify that the sender and the receiver are the parties claiming to send or receive messages is referred to as non-repudiation security requirement. In other words, the undeniable source demonstrates that data was sent, and the undeniable destination demonstrates that data was received. Non-repudiation, in other words, ensures that the transaction (transmission/reception) cannot be denied. This is extremely helpful to detect and isolate infected nodes. Any node that receives an incorrect message can use evidence to accuse the sender, which helps other nodes believe in the sending node's compromise.

Because of long delays [5], frequent disconnections, and resource scarcity, traditional routing protocols fail in opportunistic networks. To address these issues, the Delay Tolerant Network (DTN) was created. In the absence of a connected link between the sender and the receiver, DTN mobile nodes replicate bundles and collaborate to improve the probability of delivery. Malicious nodes may flood the network with as many unwanted bundles or bundle replicas as possible, wasting the network's limited resources. A flood attack attempts to compromise the network's availability service. Because of the unique characteristics of DTN networks, traditional mechanisms are ineffective for detecting and controlling flooding attacks, so developing new mechanisms to detect and control flooding attacks is a major challenge in DTN.

In this paper we examined the impact of changing buffer capacity, message lifetime, message size, and message replicas on flooding-based routing protocols in terms of the following

performance metrics: delivery probability, overhead ratio, and latency average, and we proposed an effective controlling mechanism to mitigate the flooding attack. The primary goal of the proposed mechanism is to detect malicious nodes that flood the network with unwanted messages and then limit the damage caused.

This paper is structured as follows: Section 2 discusses related work on the existing security solutions against selfish behavior in Delay Tolerant network and presents flooding attack in DTN. Section 3 gives our proposed work whereas section 4 focuses on the simulation setting used to discuss the performance of routing protocols in DTN, also this section emphasizes and analyzes the obtained results. Finally, Section 5 concludes the paper providing a final summary of the study and suggests additional research topics for the future.

## II. RELATED WORK

### A. Flooding Routing Protocols

To improve the delivery probability and to reduce the average latency, flooding-based routing protocols can be used (see the Table I). Flooding-based routing strategy [8] involves flooding the network with multiple copies or replicas of each single bundle (message) in order to increase the likelihood that one of these copies will reach its destination. This, however, consumes more network resources.

TABLE I. DESCRIPTION OF THE FLOODING BASED-ROUTING PROTOCOLS

Routing Algorithm	Description
Epidemic[9]	In the epidemic routing protocol, each mobile node stores a copy of each message in the network in its buffer. When it makes a contact with another node, all its messages are routed to that node, and so on. Each bundle is labeled with a unique identifier (ID) and listed in a list known as a "state vector." When two nodes communicate, the list of bundle IDs is exchanged; at the end of this operation, both nodes should have the same bundles in their buffers. There is no prior network knowledge required for the epidemic routing protocol. This protocol, on the other hand, necessitates a substantial amount of buffer space, bandwidth, and energy.
Spray and Wait[10]	Spyropoulos et al proposed the Spray and Wait routing protocol, which works on the principle of starting the transmission with a limited number of copies L (with $L > 1$ ) in order to preserve the DTN network's limited resources. For each bundle in the network, the Spray and Wait protocol algorithm consists of two phases: <ul style="list-style-type: none"><li>• The spray phase: The source node sends L copies of each bundle to the L relay nodes during the spray phase.</li><li>• The wait phase: When each bundle has a single copy, each node will wait for a direct meeting with the destination node before sending the bundle copy to its destination.</li></ul>
Binary-Spray and Wait[10]	The spray phase here differs from the one described above (the spray phase of Spray & Wait protocol); in Binary-Spray & Wait protocol, the source node sends L/2 copies to the neighboring nodes, and when there is only one copy left in each node's buffer, it enters in the wait phase, as described above in the wait phase of Spray & Wait protocol.

### B. The Queue Management

When the DTN runs out of storage space, it discards old bundles because they are likely to have arrived at their destinations. When storage resource becomes insufficient, the Bundle layer has only a certain amount of freedom in managing the situation, so it can drop older ( $TTL \approx 0$ ) bundles in order to receive new bundles.

There are several service disciplines (Buffer management policies) to manage a queue, the simplest way to manage a queue is the FiFo (First in First out) discipline[11].

- DLR (Drop Least Received): is identical to FiFo, the first message to arrive will be the first served.
- DOA (Drop Oldest Arrive): deletes the oldest message because there is a high probability that this message has reached its destination.
- DLE (Drop Last Encountered): drops the message that has the smallest predictability.

### C. Problem Statement: Flooding Attack

A Denial-of-Service (DOS) [12] attack is an active attack that aims to make a network's services unavailable for an extended period of time. The purpose of this type of attack is not to modify or drop bundles. But the goal is to disrupt or harm the reputation of a network service. This attack consumes resources such as bandwidth, energy, and storage space.

The basic idea behind this attack is to send bundles in an unusual pattern, causing saturation or instability in the victim nodes and preventing them from providing the network services that they are supposed to provide. When several nodes cause a Denial-of-Service attack. This is referred to as a "Distributed Denial of Service (DDOS)". A DDOS attack has the same goal as a DOS attack, except that the attack is launched from more than one node at the same time.

Such attacks are classified into two types [13]:

- a) Denial of service by saturating a node's buffer to the point where it can no longer receive other bundles.
- b) Denial of service by exploiting vulnerabilities, which involves exploiting a network flaw to render it inoperable.

### D. Overview of the Existing Solutions for Detecting the Flooding Attack in Delay Tolerant Network

Table II summarizes the fundamental three techniques used in the literature to detect and prevent the flooding attack in DTN.

TABLE II. SURVEY OF THE EXISTING SECURITY SCHEMES USED FOR MITIGATING THE FLOODING ATTACK IN DTN

Scheme	Its process	Its limitation
Claim-Carry and Check scheme[14]	A rate limiting was proposed, each node has a limit on the number of messages that it can generate in each time interval and a limit on the number of replicas that it can generate for each message. When a node violates its rate limiting, a claim is generated as an alarm, and each node receiving the alarm must check for the inconsistency between the received claims.	False claims and inconsistency of the received claims.
Encounter Records (History of encounters) (ERs) scheme[14]	This scheme is based on recording the history of encounters. In order to record the messages sent during previous contacts, nodes must exchange their ER (Encounter Record) history. Malicious nodes will be identified, resulting in a flooding attack.	Removing favorable ERs. ERs falsification and modification.
Stream-Check scheme[14]	The streaming node is used in this scheme to monitor the network environment. Three tables must be maintained by the monitor node. The first contains the rate limits of all nodes in the network, the second contains the delivery probability of each node in the network, and the third contains the blacklisted nodes. The streaming node compares estimated probability of delivery to actual probability of delivery; if the difference is greater than the assigned limit value, the node is added to the blacklist by the streaming node.	A large number of resources are required by the streaming node.

### III. THE PROPOSED MECHANISM TO CONTROL THE DISTRIBUTED FLOODING ATTACK

In this paper we are interested in the first type of DOS [12] (saturation of a node's buffer) in the DTN network because it appears to be more severe than the second due to DTN's scarcity of resources. Consider the scenario in which the attack is launched from multiple DTN nodes. In a brief, we are interested in a distributed flooding attack. This attack is carried out by several network nodes with the goal of disrupting the availability service of the nodes. The figure below (Fig. 4) depicts a node's inability to transmit messages due to the saturation of its buffer by unwanted bundles (bundles mean messages in DTN network).

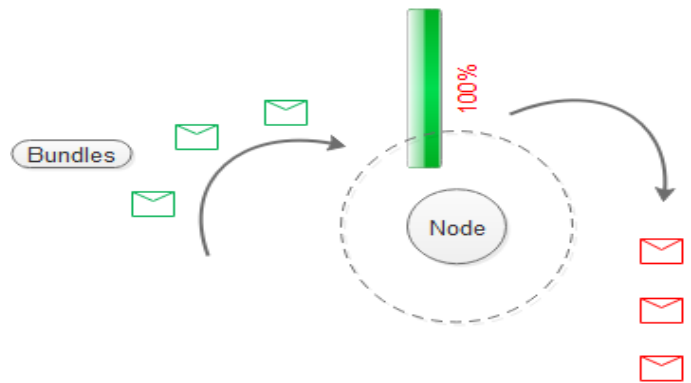

Fig. 4. Unwanted Bundles Saturating a DTN Node's Buffer.

Fig. 5. Classification of the Flooding Attack.

The flooding attack [15] [16] can be classified into three types based on the type of bundles, as shown in the figure below (Fig. 5):

- Bundle-Flood Attack: when the attacker nodes flood the network by normal messages.
- Replica-Flood Attack: when the attacker nodes flood the network by replicas of each message.
- Forged Bundle-Flood Attack: when the attacker nodes flood the network by fake messages.

#### A. Our Assumptions

- A partition of the network is affected all by distributed flooding attack.
- Malicious nodes flood the network by bogus bundles, so we need to filter the traffic by filters.
- There are three groups of bundles which circulate into the network: Normal Bundles, Replica Bundles and Forged Bundles.
- Nodes are classified into three main groups, Nodes that are nearer to their destinations, they transfer very important (urgent) bundles, Nodes that are partially near to their destinations, they transfer important but not urgent bundles and finally, nodes that are far to their destinations, they transfer unimportant bundles.
- According to the priority of each bundle into the network, bundles are classified into three main groups: Urgent bundles, important bundles, and unimportant bundles.

TABLE III. TABLE OF THE USED NOTATIONS FOR OUR PROPOSED WORK

Notation	Signification
N	The total number of nodes in the network
TTL (Time To Live)	Bundle lifetime
$d_i, i = \{1,2,3\}$	Node classes based on their proximity to the destination with ( $d_1 < d_2 < d_3$ ).
$P_i, i = \{1,2,3\}$	Priority classes of bundles.

**B. Our basic Idea**

Each DTN node generates different bundles and then commits to prioritizing them as follows (More information about the notations used can be found in Table III):

- It classifies messages that are very important (urgent) in the set P1.
- It classifies the messages that are important but not urgent in the set P2.
- It classifies the messages that are less important than P2 in the set P3.

Nodes are classified into three categories based on their distances from the destination nodes:  $d_1$ ,  $d_2$  and  $d_3$  with ( $d_1 < d_2 < d_3$ ).

- Nodes that are closer to the destination, their distance to the destination is  $d_1$ .
- Nodes that are partially close to the destination, their distance to the destination is  $d_2$ .
- Nodes that are far away from the destination, their distance to the destination is  $d_3$ .

The priority of each message is determined according to its lifetime (messages with a short TTL have a high priority because they must be transmitted before their TTL expires), its size (messages with a smaller size have a high priority than large messages because the latter may saturate the limited storage space) and its number of replicas (Messages with a small number of replicas have a higher priority than messages with a large number of replicas).

The distance of each node from its destination is determined by referring to the movement history of the DTN nodes (the hop-by-hop count taken before arriving at the destination). The value of this distance is predictive because DTN nodes are mobile.

Our basic idea is first to distribute the bundles to the various nodes based on their priorities in the following manner:

- The nodes whose distance to the destination is  $d_1$  agree to receive only messages with priority P1 and agree to forward them to their destinations.
- The nodes whose distance to the destination is  $d_2$  accept to receive only the messages of priority P2 and agree to transfer them to their destinations.
- The nodes whose distance to the destination is  $d_3$  accept to receive only the messages of priority P3 and agree to forward them to their destinations.

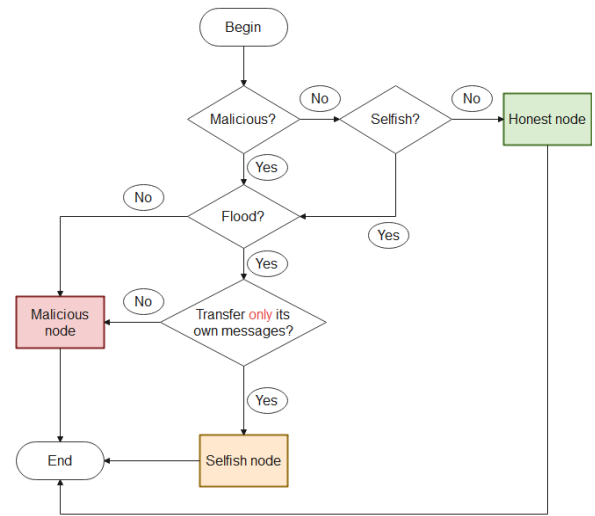

Fig. 6. Overall Flowchart.

Then, to identify malicious nodes that flood the network by unwanted bundles, we have proposed an effective scheme (see the below flowchart, Fig. 6).

**C. The Objectives of our Proposed Work**

- 1) Identify the nodes that flood the network with unwanted messages so that the other nodes in the network do not accept their messages the next time they contact them.
- 2) Reduce and optimize the network load by categorizing nodes and messages (as explained above in section 3). When exchanging messages between two neighboring nodes, it is not necessary for the receiver node to accept all the messages from the sender node; instead, it must accept a subset of these messages based on its type (close to the destination or not) and based on the priority class of the messages (P1, P2 or P3).

**IV. SIMULATION AND ANALYSIS**

The ONE (Opportunistic Network Environment Simulator) simulator [17] is an opportunistic networking simulator that provides several tools for creating complex mobility scenarios that are more realistic than many other synthetic mobility models. ONE supports various node movement models and simulates a variety of DTN routing algorithms. The ONE simulator is written in Java, and it allows to add routing algorithms by extending the built-in routing classes.

**A. Simulation Environment Setup**

The ONE simulator (Opportunistic Network Environment Simulator) [17] was used, as shown in Fig. 7. Our scenario includes a network of 140 DTN nodes (an average density): 120 pedestrians and 20 trams. The simulation time was 12 hours, with a 0.1 second update interval. The effect of changing the buffer capacity, bundle lifetime, bundle size and bundle replicas on flooding protocols was investigated. To make our simulation more realistic, we used a cluster-based mobility model with three clusters or regions (each cluster can be a remote village) spread across an area of  $4.5 \times 3.4$  Km. The pedestrians within each cluster were moving at a speed ranging from 0.5 to 1.5 m/s. See the table below (Table IV) for more information on the simulation parameters that were used.

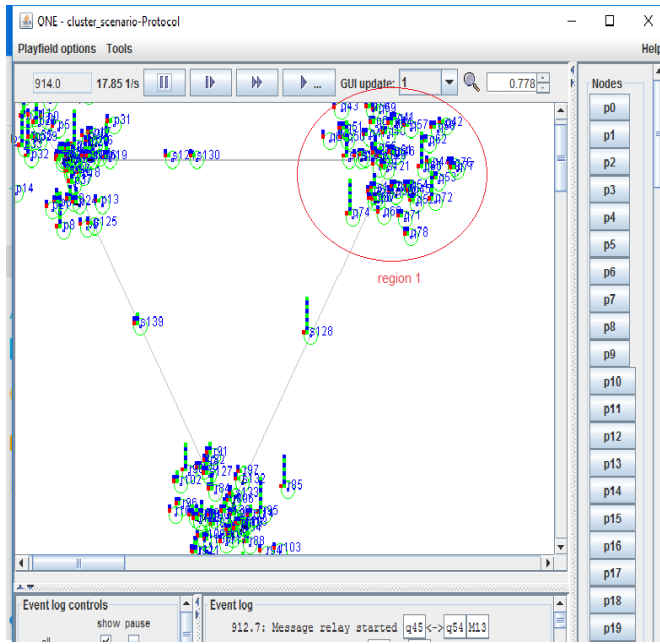

Fig. 7. The Screenshot of our Scenario on the ONE Simulator's GUI.

TABLE IV. SIMULATION PARAMETERS

Parameter name	Value(s)
Simulation time	43200s
Number of Nodes	140
TTL	60Min-300Min (step 60)
BufferSize	20MB-180MB (step 20)
MsgSize	50kB-550kB
NBOOfReplicas	20-100 (step 20)
movementModel	ClusterMovement
RoutingProtocols	Epidemic, Spray & Wait, Binary-Spray & Wait

The following performance metrics are considered in analyzing the effect of changing buffer capacity, bundle lifetime, bundle size, and number of replicas on the flooding protocols:

- **Delivery\_prob**: this metric describes the probability of message delivery at the end of the simulation. It is also known as the delivery ratio because it is the ratio of delivered messages to created messages. One of the primary goals of the DTN network is to maximize the value of this parameter. This metric's value is scaled in

[0,1]. It is computed using the following formula:  $(\text{NumberOfDeliveredMessages}/\text{NumberOfCreatedMessages})$ .

- **Overhead\_ratio**: it denotes a bandwidth efficiency evaluation during the simulation. The primary goal of the DTN network is to reduce the value of this metric. It is computed using the following formula:  $((\text{NumberOfRelayedMessages}-\text{NumberOfDeliveredMessages})/\text{NumberOfDeliveredMessages})$ .
- **Latency\_avg**: it is the average message delay from the time a message is created at the source to the time it is delivered to the destination. In a DTN network, the terms delay and latency are used interchangeably. The DTN network's primary goal is to reduce the value of this metric.

### B. Simulation Results and Discussions

#### a) The impact of BufferSize on flooding-based routing protocols

Fig. 8 (a) depicts the delivery probability obtained by using the flooding-based routing protocols: Epidemic, Spray & Wait (S&W), and Binary-Spray & Wait (B-S&W) in terms of BufferSize (MB). When the Epidemic routing protocol is used, the delivery probability increases with the increase of the BufferSize (MB) since buffer space means more nodes can carry more copies of messages, as opposed to the B-S&W and S&W routing protocols, which have approximately similar invariant values. This is because the Epidemic protocol's message transmission logic necessitates a large buffer size as compared to the B-S&W and S&W routing protocols. While the overhead-ratio falls (Fig. 8 (b)) particularly when using the Epidemic protocol. This is due to an increase in buffer size, which means more free space is available to transmit and to carry more messages. Fig. 8 (c) shows that when using the Epidemic protocol, the average latency decreases as the buffer size increases thanks to the multiple-copy nature of this protocol, which spreads replicas blindly, as opposed to the spraying protocols (S&W and B-S&W), which spread limited replicas into the network. Briefly, the Epidemic protocol benefits the most because its process of exchanging messages is quick, lowering average latency, thereby improving performance.

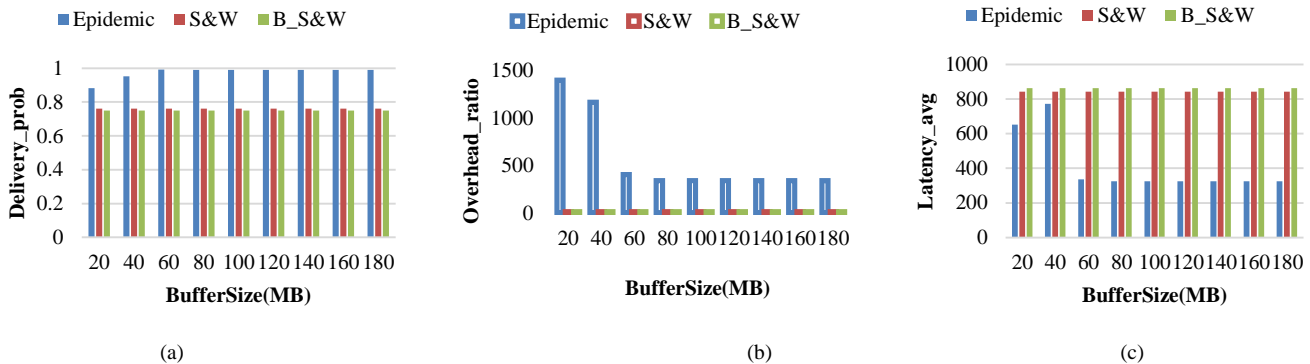

Fig. 8. The Effect of Changing the Buffer Size on Three Performance Parameters, (a) Delivery Probability, (b) Overhead Ratio, and (c) Average Latency, when using Flooding-based Routing Protocols (Epidemic, Spray&Wait and Binary-Spray&Wait).

Fig. 9. The Effect of Changing the Message TTL on Three Performance Parameters, (a) Delivery Probability, (b) Overhead Ratio, and (c) Average Latency, when using Flooding-based Routing Protocols (Epidemic, Spray&Wait and Binary-Spray&Wait).

b) The impact of MsgTTL on flooding-based routing protocols (with BufferSize=5M)

Fig. 9 (a) shows that there is some progress in delivery probability as message TTL improves but the value of Delivery probability does not exceed 0.2 for the three protocols because messages with high MsgTTL values are classified as P3 Priority class (not important messages for transmission, see the third section) which lowering the delivery ratio. Furthermore, messages with a high MsgTTL value have a high chance of being delivered because these messages tolerate long RTT (Round Trip Time). However, increasing MsgTTL leads to an improvement in the network's overhead ratio, as shown in Fig. 9 (b). The epidemic protocol has higher values than the other protocols because it is possible that the replicas of each delivered message are still circling in the network, which increase the overhead ratio. Fig. 9 (c) depicts the effect of message TTL on average latency. The average latency for the three protocols has higher values. When the message lifetime is long, the average latency increases significantly. This behavior is easily explained by the fact that when a message has a large TTL value, it means that the transmission of this message is not a critical or urgent task. According to the third section, the priority class of the message is P3, and the nodes whose distance to their destinations is d3 are the nodes who accept to receive and transmit that category of messages. Because these nodes are so far away from their destinations, the average latency rises, which conform to our assumptions (see the third section).

c) The impact of MsgSize on flooding-based routing protocols (with BufferSize=5M)

Fig. 10 (a) shows the effect of varying Message size on the delivery probability for flooding-based routing protocols. When the message size increases, it seems that the delivery probability significantly decreases especially in the case of

using Epidemic as a routing protocol, but it does not have much effect on the other protocols (S&W and B-S&W). Increase message size, reduce the limited buffer size, and make congestion and cause continuous buffer space occupation. Which force relay nodes to accept to store only a small number of messages in their buffers, lowering the delivery rate. According to our assumptions, messages with a small size have a higher priority than messages with a large size. As a result, the delivery ratio has low values when large messages circulate in the network (as Fig. 10 (a) depicts). The priority class of messages with large sizes is P3, and the nodes transmitting these messages are far from their destination nodes (with distance d3), which explains the decrease in the delivery probability (see the third section). Fig. 10 (b) shows how changing the size affects the overhead ratio. As we can see, increasing the message size reduces the overhead ratio, especially when using Epidemic routing protocol. The overhead ratio is defined as  $(\text{NumberOfRelayedMessages} - \text{NumberOfDeliveredMessages}) / \text{NumberOfDeliveredMessages}$ , and as shown in Fig. 10 (a), the delivery ratio decreases as message size increases, implying that the number of relayed messages decreases as MsgSize increases. This behavior can be explained by the loss of large messages. Therefore, to avoid saturating their buffers, nodes rarely accept large messages (these large messages have a low priority class P3), resulting in a decrease in the delivery rate and a decrease in the network overhead ratio that can only be explained by the loss of large data. However, because large-sized messages are considered to have the lowest priority class (P3) according to our assumptions, and the nodes whose distance to their destinations is d3 are the nodes who accept to receive and transmit this category of messages, and because these nodes are so far away from their destinations that their transmission will take a long time, the average latency increases which conform to our assumptions see Fig. 10 (c)).

Fig. 10. The Effect of Changing the Message Size on Three Performance Parameters, (a) Delivery Probability, (b) Overhead Ratio, and (c) Average Latency, when using Flooding-based Routing Protocols (Epidemic, Spray&Wait and Binary-Spray&Wait).

d) The impact of NBOfReplicas on flooding-based routing protocols (with BufferSize=5M)

Fig. 11 depicts the message delivery, network overhead, and latency ratios when flooding-based routing protocols were used with different replica number values. The delivery rate, overhead ratio, and latency average for the Epidemic protocol are invariant to the number of replicas, which is due to the nature of this protocol, which floods the network with an unbounded number of copies (replicas); in comparison to the spraying protocols (Spray & wait protocol and Binary-spray & wait protocol), it has a higher value of the overhead ratio because it floods the network with unlimited replicas and the buffer space is limited in size (5M). As a result, we will concentrate on the comparison between Spray & Wait protocol and Binary-Spray & Wait protocol. For S&W and B-S&W the delivery rate shows an increasing trend up to a certain extent beyond which it saturated but B-S&W has higher values of delivery probability compared to S&W, see Fig. 11 (a). Fig. 11 (b) shows that the overhead ratio for S&W is invariant to the number of replicas, whereas the overhead ratio for B-S&W always increases continuously with the increase of the number of replicas. Messages with a small number of replicas have a higher priority than messages with a large number of replicas, according to our assumptions, and nodes whose distance to their destination is d1 (close to the destination) agree to receive

and to forward only messages with priority P1 (highest priority class). This means that as the number of replicas increases, the delivery probability must decrease (because messages are transmitted by nodes located far from their destinations) and the overhead must increase. Fig. 11 (a) shows, however, that the increase of the number of replicas leads to the increase in the probability of delivery, which contradicts our assumption. Fig. 11 (b), on the other hand, depicts the increase in overhead as the number of replicas increases, which is a natural result of the increase in delivery probability (as shown in Fig. 11 (a)). Fig. 11 (c) shows that as the number of replicas increases, the average latency decreases, particularly when using the B-S&W, implying that nodes have a short Round Trip Time (RTT) before being delivered to their destinations.

e) Message Graphs by using graphviz (with MsgTTL=60min)

The graphs below (Fig. 12, Fig. 13, Fig. 14) depict the node connections as well as the network paths that the delivered messages took. The MessageGraphviz [18] report module creates directed graphs of delivered message paths. The figures below show three examples of delivered messages graphs that contain all the messages sent from one network node to another during the simulation (Fig. 12, Fig. 13, Fig. 14). The figures show an example of a message graph, which contains all the messages sent from node to node during the simulation.

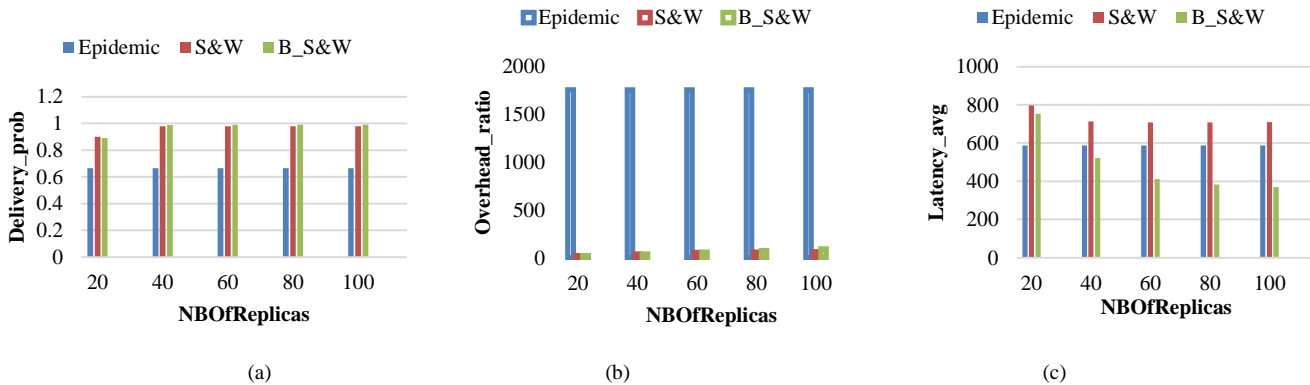

Fig. 11. The Effect of Changing the Number of Replicas on Three Performance Parameters, (a) Delivery Probability, (b) Overhead Ratio, and (c) Average Latency, when using Flooding-based Routing Protocols (Epidemic, Spray&Wait and Binary-Spray&Wait).

Fig. 12. Graph of the Messages that were sent from r113 to s128 for Epidemic Routing Protocol (173 Messages Delivered).

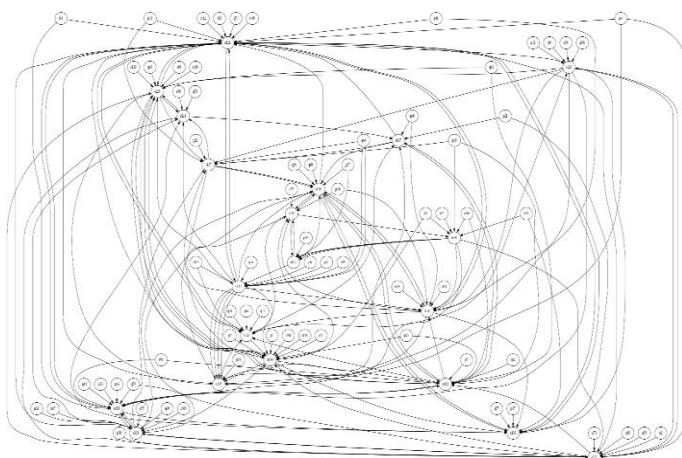

Fig. 13. Graph of the Messages that were sent from r112 to s121 for Spray and Wait Routing Protocol (109 Messages Delivered).

Fig. 14. Graph of the Messages that were sent from r113 to s128 for Binary-Spray and Wait Routing Protocol (149 Messages Delivered).

The graphs show that the Epidemic routing protocol's delivered message graph (Fig. 12) has more edges than the other graphs (when using the S&W and B-S&W protocols), resulting in an increase in delivered messages when using the

Epidemic protocol, as evidenced by the way Epidemic protocol messages are transmitted.

## V. CONCLUSION

Security is still a major concern in the Delay Tolerant Network. The DTN network lacks a centralized authority in charge of network filtering, and each mobile network node functions as both a router and a host. Malicious nodes can quickly flood the network with unwanted messages. Flooding attacks, in particular, disrupt the availability of network services. In this paper, we have proposed a security mechanism for controlling the distributed flooding attack, as well as a security scheme for detecting malicious nodes that flood the network. Then, in terms of three important metrics: delivery probability, overhead ratio, and latency average, a comprehensive study of the impact of changing buffer capacity, message lifetime, message size, and message replicas on flooding-based routing was presented. The simulations validate our most important hypotheses. In future work, we intend to improve our mechanism for dealing with flooding attack in order to improve the network performance in DTN, and we intend to design and implement a collaborative trust management protocol with an integrated buffer management scheme for dealing with flooding attack.

# Efficient DNN Ensemble for Pneumonia Detection in Chest X-ray Images

V S Suryaa, Arockia Xavier Annie R, Aiswarya M S

Department of Computer Science and Engineering  
College of Engineering, Guindy Anna University, Chennai, India

**Abstract**—Pneumonia is a disease caused by a variety of organisms, including bacteria, viruses, and fungi, which could be fatal if timely medical care is not provided. According to the World Health Organization (WHO) report, the most common diagnosis for severe COVID-19 is severe pneumonia. The most common method of detecting Pneumonia is through chest X-ray which is a very time intensive process and requires a skilled expert. The rapid development in the field of deep learning and neural networks in recent years has led to drastic improvement in automation of pneumonia detection from analysing chest x-rays. In this paper, a pre-trained Convolutional Neural Networks (CNN) on chest x-ray images is used as feature extractors which are then further processed to classify the images in order to predict whether a person has pneumonia or not. The different pre-trained Convolutional Neural Networks used are assessed with various parameters regarding their predictions on the images. The results of pre-trained neural networks were examined, and an ensemble model was proposed that combines the predictions of the best pre-trained models to produce better results than individual models.

**Keywords**—Deep neural networks; ensemble learning; pneumonia detection using x-ray images; transfer learning

## I. INTRODUCTION

Pneumonia is an infection in one or both lungs. Bacteria, viruses, and fungi cause it. The infection causes inflammation in the alveoli. The alveoli fill with fluid or pus, causing difficulty in breathing. Pneumonia and lower respiratory tract infections like influenza and respiratory syncytial virus are the leading cause of death worldwide. WHO Child Health Epidemiology Reference Group reported that the median global incidence of clinical pneumonia is 0.28 episodes per child- year. This statistic converts to an annual incidence of 150.7 million new cases, of which 11-20 million (7-13%) are severe enough to require hospital admission [1]. Majority of the episodes of clinical pneumonia in young children worldwide occur in developing countries due to lack of proper timely diagnosis. In 2015, More than half of all global pneumonia cases were from India, Nigeria, Indonesia, Pakistan, and China alone [2]. Chest X-rays are used by radiologists to identify pneumonia among patients. They look for white spots in the lungs (called infiltrates) that identify an infection. Medical imaging accounts for more than 90% of the entire available medical. Radiologists are required to analyse large quantities of medical images which is a time-consuming and exhaustive process. With the development of deep learning methods, it would be possible to sift through the data and analyse medical exams more efficiently.

Machine learning algorithms like Logistic Regression, Support Vector Machines (SVM) do not learn any hidden representation in the images and directly use the image data provided. On the contrary, deep learning in computer vision has shown great success in decoding hidden representations and extracting features from them with the help of Convolutional Neural Networks. Convolutional Neural Networks (CNN) can extract and process data at very high speeds. The recent advancement in deep learning frameworks [3] have enabled faster and more accurate detection, while the increased CPU and GPU processing power available allows radiologists to improve their diagnostic efficiency.

In this work, pre-trained CNN architectures proposed in the past few years taken into consideration and try to assess their prediction on various parameters to identify the ideal one. All architectures used in the paper are CNNs which were pre-trained on ImageNet dataset previously. The CNNs were fine-tuned with the pneumonia chest x-ray dataset which was then used for feature extraction. The CNNs were connected with a common fully connected layer to assess their predictions from extracted features.

Lower image resolution helps lower training time on very large dataset and also decreases computational needs and device capacities due to relatively lesser number of parameters. With the advent of technology, it is easier to transfer image files over the phones which could be taken to advantage if the image is of lower resolution as it decreases the file size drastically. This also helps storing a large database of X-ray images over a device without much hassle.

The related works section discusses the various pre-trained networks. The third section discusses the strategies and hyper parameters considered for the comparison of these deep neural networks. The proposed ensemble model is discussed in the fifth section and it is followed by result analysis in the next section and finally the sixth section concludes.

## II. RELATED WORK

In recent years, there has been significant research in automation of Pneumonia detection through deep learning and neural networks which has yielded impressive results.

The study in [4] contributed a voting ensemble (AlexNet, ResNet18, InceptionV3, DenseNet-121 and GoogleNet) classification approach to Pneumonia detection. In [5] proposes a customized VGG16 model for the detection with an accuracy of 96.2%. The work done in [6] asserts that DenseNet201

architecture outperforms AlexNet, ResNet18 and SqueezeNet with an accuracy of 98% and AUC score of 0.98.

Kernany et al. (2018) in [7] used InceptionV3 pre-trained model for classification. They have also worked on bacterial and viral pneumonia classification in addition to normal and pneumonia. Saraiva et al. (2019) in [8] used cross validation technique in a customized 4 fully connected layer neural network to obtain an accuracy of 94.4% and compared it with MLP network.

D.Varshini et al (2019) [9] used different pre-trained CNN feature extractors combined with classifiers SVM with RBF kernel, Naive Bayes, k-nearest neighbours and Random Forests. They conclude that DenseNet-169 for the feature extraction stage and SVM for the classification stage provide statistically better results. Quan et al (2021) [10] proposed DenseCapsNet, a capsule network for detection of Covid-19 from X-ray images. DenseCapsNet reached 90.7 % accuracy and 96% sensitivity in test set results.

#### A. Transfer Learning

Transfer learning is a machine learning method that involves using an already developed model on a new problem task as the initial model in [11]. It is a popular approach used in computer vision and other arduous deep learning tasks.

When transfer learning is used, the model parameters start with good initial values due to the previous training and do not require huge modifications to be better adapted to the new task. The pre-trained model weights are treated as the initial values for the new task in hand, and updates are performed on that during training [12].

In proposed work, due to limited availability a new classifier is fitted on the top layers and fine tune only the last few convolutional layers in the model and use that for feature extraction purposes. The performance of some famous pretrained networks such as ResNet-50, ResNet-101 ResNet-152, VGG- 16, VGG-19, MobileNetV2 and DenseNet-201 also evaluated.

#### B. VGG Architecture

VGG16 is a convolutional neural network model proposed in the paper “Very Deep Convolutional Networks for Large-Scale Image Recognition” in [13]. The model achieves 92.7% top-5 test accuracy in ImageNet dataset. The model was submitted to ILSVRC-2014 and gained huge popularity. It makes improvements over its previous works by replacing large kernel-sized filters with multiple 3×3 kernel-sized filters one after another. The network is characterized by stacking 3×3 convolutional layers on top of each other to increase network depth. The convolution layers increase the volume size which is handled by max-pooling. Max-pooling is performed over a 2×2-pixel window, with stride 2.

The VGG-19 Neural Network is defined as that type of neural network which is also specifically trained on more than a million images from the ImageNet database, but the difference between the VGG-19 Neural Network and the VGG-16 Neural Network is its network layer depth level as 19 and 16, respectively.

#### C. ResNet Architecture

The main idea behind ResNet is adding more layers without degrading the performance of the whole network due to vanishing gradient problems. Vanishing gradient problem was caused due to repeated application of chain rule during back propagation which made the gradient too small and eventually disappears. This led to no actual learning in the networks.

ResNet introduced, “Identity Shortcut Connection” that skips one or more layers [14]. It stacks up identity mappings which are initially skipped and the activations from the previous layers are used instead. This enables faster learning in the compressed network. Later when the network trains again, the skipped layers are included to understand the feature space. The main difference between ResNet-50, ResNet-101 and ResNet-152 are the number of layers in them. ResNet-50 has  $3.8 \times 10^9$  floating point operations in total compared to  $7.6 \times 10^9$  in ResNet-101 and  $11.3 \times 10^9$  in ResNet-152.

#### D. DenseNet Architecture

The increasing depth of convolutional neural networks caused a problem of vanishing information about the input or gradient when passing through many layers. In order to solve this, authors introduced architecture [15] with a simple connectivity pattern to ensure the maximum flow of information between layers both in forward computation as well as in backward gradients computation. Each layer in the network adds its own feature-maps to the input received from its previous layers, which are then passed on to the subsequent layers in the network.

In DenseNet,  $H_i$  ( $i$  refers to the layer index) is a composite function of operations like ReLU, pooling, convolution and batch normalization. Each layer implements  $H_i(x_0, x_1, x_2, \dots, x_{i-1})$  where,  $[x_0, x_1, x_2, \dots, x_{i-1}]$  refers to concatenation of the feature-maps produced in layers 0 to  $i-1$ . Variable size of feature-maps does not allow concatenation operation. Down-sampling layers are the most important aspect of convolutional neural network. To facilitate the downsampling in the architecture, the complete architecture has been divided into multiple densely connected dense blocks. The layers between dense blocks are transition layers which perform convolution and pooling. Convolution and pooling operations are performed in transition layers between the dense blocks.

The main advantages of DenseNet are decreasing vanishing gradient issue, improving feature propagation, both forward and backward, increase feature reuse and reducing the number of parameters.

#### E. MobileNetV2 Architecture

MobileNetV2 has three convolutional layers in a block: the first is a 1x1 convolution called the expansion layer. The main purpose of the expansion layer is to increase the number of channels in the data before it is passed on to the next layer. The expansion factor is 6 by default. The next layer is the depth wise convolution which is used to filter inputs. Finally, a 1x1 projection layer is used which projects data with higher dimension into a tensor with lower dimension and it reduces the amount of data that flows through the network.

Fig. 1. MobileNetV2 Architecture Description.

As observed in Fig. 1, the architecture introduces residual connection which helps the flow of gradients through the networks. All the layers have batch normalization and ReLU6 activation function (except for projection layer). The authors in [16] report that due to low dimensional data produced in the layer, using a non-linearity affects the information obtained.

The dataset used is from Labeled Optical Coherence Tomography (OCT) and Chest X-Ray Images for Classification” released by Daniel et al. in 2018 published on the Kaggle platform [17], which consists of 5,863 X-Ray images. Chest X-ray images (anterior-posterior) were selected from retrospective cohorts of pediatric patients of one to five years old from Guangzhou Women and Children’s Medical Center, Guangzhou.

For this work, following the approaches from the past, the labels are treated as ground truth for the purpose of pneumonia detection. Out of the complete Radiographic image dataset, 4608 images were used as a training set which contains 1115 normal X-ray images and 3493 images labeled as Pneumonia. The test data and validation data both contains 624 X-ray images with 234 normal X-ray images and 390 images labeled as Pneumonia. The images were downscaled to 184 x 184 size for computational purposes before using it for analysis.

The training of all the models was done using a computer with 16 GB RAM and Nvidia Tesla P100 GPU. The figures shows sample chest X-ray images taken from dataset used for training, where, Fig. 2 is a chest X-ray of a normal patient and Fig. 3 is a chest X-ray of a patient affected by Pneumonia.

#### F. Pre-processing Stage

The images were scaled down to 3 channel 184 x 184 resolution and data normalization techniques were deployed to improve computational efficiency. The values were scaled

between 0 and 1 with random zooming on the images for image augmentation [18].

#### G. Feature Extraction and Classification

The pre-trained neural networks considered for feature extraction in the experiment are ResNet-50, ResNet-101, ResNet-152, VGG-16, VGG-19, MobileNetV2 and DenseNet-201.

Further on the features extracted are classified using a fully connected layer fitted to the network. All the networks were fine-tuned by freezing earlier layers and unfreezing the rest for the network to adapt well to the dataset considered for the experiment.

1) *Resnet pre-trained networks:* All the Resnet networks considered for the experiment- ResNet50, ResNet101 and Resnet152 were networks pre-trained on the ImageNet dataset and were fed in with input of 184 x 184 x 3 chest x-ray images. All three had been fit with a fully connected layer for classification. The fully connected layer consists of a dense layer of 2048 units and another dense layer of 64 units with ReLU activation function, dropouts and batch-normalization.

2) *VGG pre-trained networks:* Both VGG-16 and VGG-19 taken for consideration were pre-trained networks on the ImageNet dataset. The output of the network without top layers was further classified with a fully connected layer containing two dense layers of 4096 units with ReLU activation. Then the fine-tuned network shown in Fig. 4, was later trained on the dataset to obtain the results on the test data

3) *DenseNet201 pre-trained network:* The feature extracted from the ImageNet pre-trained network was subjected to global average-pooling and fed into a fully connected layer consisting of 1024 unit dense layer and 512 units dense layer with ReLU activation function which was then classified with a Softmax function.

4) *MobileNetV2 pre-trained network:* The ImageNet pre-trained network was used for feature extraction which was then fed into a fully connected layer after global average-pooling with dense layers of 4096 units and 512 units and ReLU activation function. The output of that was classified with a Softmax function.

### III. STRATEGIES AND HYPER-PARAMETERS OF THE NETWORK

#### A. Learning Rate

The learning rate controls the ease of the model to adapt to the problem [19]. Smaller learning rates require more epochs during training given the smaller changes made to the weights each update as mentioned in Equation 1, whereas larger learning rates result in rapid changes and require fewer training epochs.

Large learning rates can cause the model to converge too quickly to a non-optimal solution or might lead to exploding gradient, whereas a small learning rate can cause the training to get stuck or lead to vanishing gradient issue.

$$w'_i = w_i - \gamma \frac{\partial L}{\partial w} \quad (1)$$

where

$\gamma$  - Learning rate.

L - Loss function.

$w_i$  - weights.

The equation shows as to how the weight gets updated. The learning rate used in training is 0.001, generally the learning rate ranges from 0.00001 to 1.

#### B. Optimization Algorithm

Batch gradient descent recomputes gradients for similar samples before each parameter update which leads to drastic increase in redundant computations for large datasets. Stochastic Gradient Descent [20] does away with this redundancy. Stochastic Gradient Descent frequently updates with a high variance that cause the objective function to

fluctuate heavily, on the other hand, it allows it to find better local minima. With SGD estimating loss function using a small batch it potentially may not lead us in an optimal direction. Hence, usage of exponentially weighted averages can help us with a better estimate which is closer to the actual derivative. This explains the better performance of SGD with momentum than the classic SGD. SGD tends to find it difficult to find the optimum in cases of ravines (area where surface curves much more steeply in one dimension than other) and oscillates around them. This issue is overcome with momentum as it accelerates gradients [21] in the optimal direction. Hence, Stochastic Gradient Descent is used with momentum. This is shown in Equation 2 and 3.

$$V_t = \beta V_{t-1} + (1 - \beta) \nabla_w L(w, x, y) \quad (2)$$

$$w = w - \alpha V_t \quad (3)$$

where,

$\beta$  - Coefficient of momentum.

L - Loss function.

V - Retrained gradient.

$\nabla$  - Learning rate.

w - weight.

x - Feature vector.

y - Output.

Using lower values of momentum implies averaging over much lesser values and more than 0.9 averages over a large data previously encountered. Hence, 0.9 is generally said to be a good estimate and is used in the experiments.

#### C. Dropout

Dropout involves removing some nodes so that the neural network does not overfit and can be implemented during the training process [22]. This enables the network to understand and distinguish redundant features. For each training stage, each node can be selected with probability P or drop it with probability (1-P). A dropout of 0.3 is applied on both the hidden layer units in the fully connected layers.

#### D. Batch Size

The batch size defines the number of samples that will be propagated through the network in one forward and backward propagation. Networks train faster with mini batches because the weights get updated after each propagation. It requires less memory. Since, the network is trained using fewer samples, the overall training procedure requires less memory. That's especially important when using large image datasets for training. A batch size of 32 is used for this work.

#### E. Activation Function

An activation function is a function that is added into an artificial neural network in order to help the network learn complex patterns in the data, it takes in the output signal from the previous cell and converts it into some form that can be taken as input to the next cell. It is like adding non-linear layers in between linear layers because non-linearity is required for

the network to understand complex data. In the fully connected layers, ReLU activation [23] is applied for the hidden dense layers and softmax function [24] in the prediction layer. Softmax is used in multiclass classification problems, as in equation 4.

$$\sigma(\vec{z}_i) = \frac{e^{z_j}}{\sum_{j=1}^K e^{z_i}} \quad (4)$$

where,

$\sigma$  - softmax.

$e^{z_j}$  - standard exponential function for output vector.

$z$  - input vector.

$K$  - no. of classes in multi-class classifier.

$z_i$  values are the elements of the input vector and can take any real value. The denominator is the normalization term used so that the summation of the output values results in 1 and a valid probability distribution is maintained. ReLU (Rectified Linear Unit) is a type of activation function. ReLU is defined as  $y = \max(0, x)$  in mathematical terms and the graphical representation is provided in Fig. 5. It is most commonly used activation function in convolutional neural network.

### F. Loss Function

The loss function used in the experiment is sparse categorical cross-entropy. Cross-entropy is defined as the measure of the difference between two probability distributions for a given random variable or set of events.

A skewed probability distribution has lower entropy than a balanced probability distribution. In this work, sparse

categorical cross-entropy is considered because the classes are mutually exclusive from each other unlike the categorical cross-entropy which is used in the case of samples having multiple classes or soft probabilities.

### G. Inference from Individual Models

The classification accuracy for each model has been plotted on a graph with respect to the number of epochs used for training. Both validation and training set accuracy has been plotted for each epoch. This helps us to see how the model has been fitting input data. The model loss for each of the models has been plotted for both validation and training set for every epoch.

Loss and Accuracy from the various Network models are tested and depicted as graphs in Fig. 6(a – g). The network models evaluated are ResNet-50, ResNet-101, ResNet-152, VGG-16, VGG-19, DenseNet-201 and MobileNet-V, respectively.

Fig. 5. ReLU Function.

Fig. 6. Loss and Accuracy from the Various Network Models (a) ResNet-50 (b) Resnet-101 (c) Resnet-152 (d) VGG-16 (e) VGG-19. (f) DenseNet-201 (g) MobileNet V2.

#### IV. ENSEMBLE NETWORK MODEL

The ensemble model works on combining predictions and decisions of different models to augment the overall performance and generalization of the models. The main idea is to reduce noise, bias and variance in different models. The ensemble model can employ simple methods like mode and weighted average or resort to advanced techniques like bagging and boosting depending on the requirements and constraints for the task in hand. Although it drastically increases the complexity of the model and the design time, it generally improves on the accuracy, stability and robustness of the model.

Weighted average predictions involving the multiple models are employed to obtain an ensemble model in the experiment. Ensemble model of which is proposed has the following models:

- a) VGG-16
- b) ResNet-50
- c) ResNet-101
- d) ResNet-152
- e) VGG-19

- f) DenseNet-201
- g) MobileNet-V2

As shown in Fig. 7, the trained models are loaded with their respective weights and the prediction on the test set is obtained for all the models.

Then the model predictions are combined through weighted average, with 30% weightage VGG16 and 20% for VGG19 as they have a relatively higher accuracy and AUC score compared to others. All other models are given 10% weightage for computation of ensemble prediction value.

The proposed model has an accuracy of 95.03% and an AUC score of 0.9441 which is higher than any model considered by a good margin. The ROC curves used to compute the AUC scores have been compiled in Fig. 8. ROC graph [25] is a plot with the false positive rate on the X axis and the true positive rate on the Y axis. It is a visual approach for analysing the trade-off between the ability of a classifier to correctly identify positive cases and the number of negative cases that are incorrectly classified. ROC graph captures all information contained in the confusion matrix, since, FN is the complement of TP and TN is the complement of FP. Fig. 8 shows the different ROC curves for all the models.

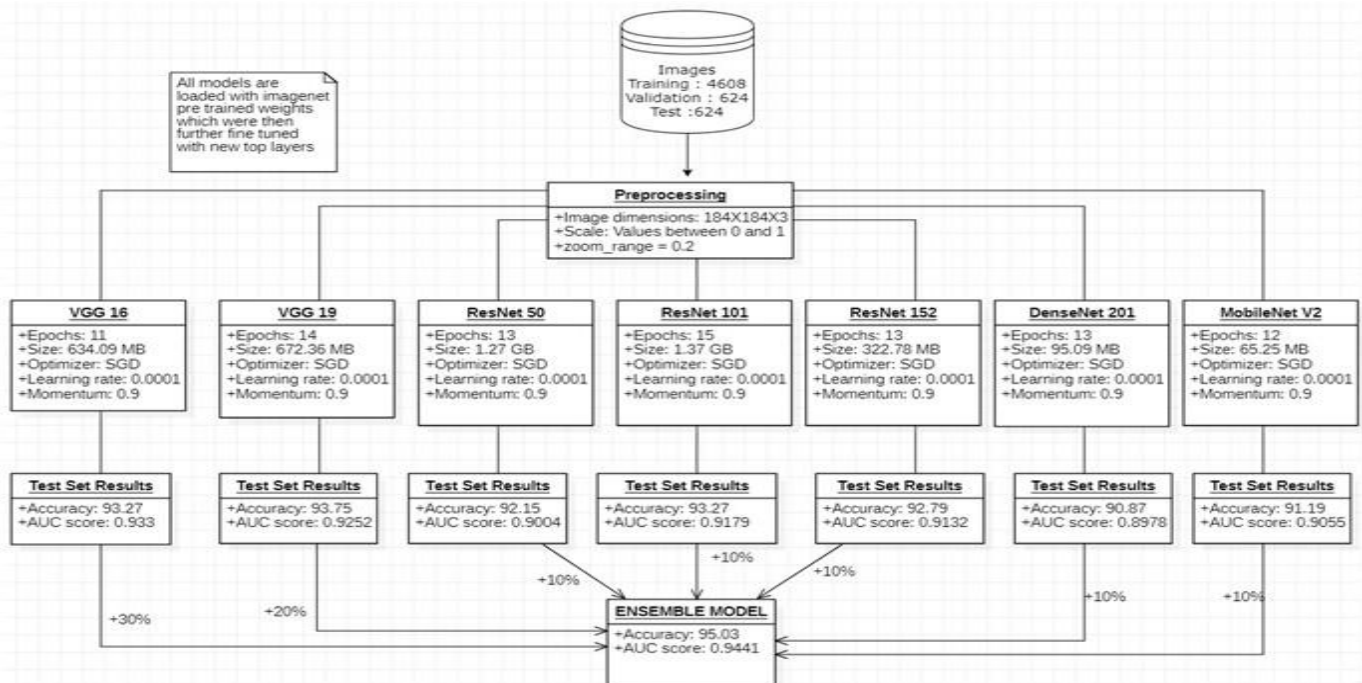

Fig. 7. Proposed Ensemble Model.

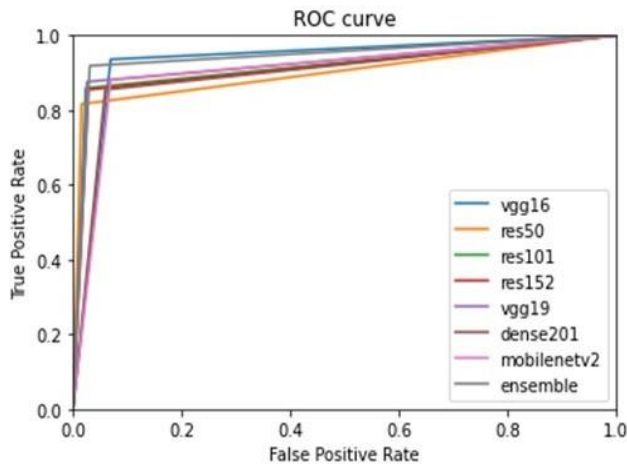

Fig. 8. ROC Curve Comparison of all the Individual Models with Ensemble Model.

## V. RESULT ANALYSIS

In this section, a comparison of the ensemble model and other models are done with different metrics. The following sections gives the performance metrics used, and provides discuss on how the Ensemble model provides better results than other models.

### A. Performance Metrics for Evaluation

The Results have the study on Accuracy impact with various models as described in [26]. The various metrics used are as follows:

Confusion matrix, Classification accuracy, Precision, Sensitivity and Specificity, F1-Score and Area Under Curve AUC - ROC curve.

### B. Result and Discussion

Table I shows that the ensemble model does better than all the models considering the different metrics of evaluation used and the ensemble network has an accuracy of 95.03 and AUC score of 94.41. The ensemble model is based on weighted voting, with each model's output being assigned a different weightage. The results assert that the combination of different results with appropriate weightage improves the overall prediction significantly. This can be attributed to the tendency of a particular model being biased towards a particular region of interest or feature. The bias can be avoided in an ensemble model. Moreover, it aids the evaluation by accounting different niche aspects of the image.

Different models have been trained in accordance to the validation result analysis using early stopping technique as observed in Fig. 6. Among individual models, VGG-16 and VGG-19 have comparatively better results with accuracy of 93.27% and 93.75%, respectively, and with an AUC score of 93.30 and 92.52 for VGG16 and VGG19. AUC score is generally used for binary classification models and is taken as the main parameter to assess the models because of the class imbalance between normal and pneumonia affected X-ray images. AUC score is not in consistent with the accuracy which avoids evaluating the model from a narrow perspective.

TABLE I. COMPARISON OF METRICS OF ENSEMBLE MODEL WITH OTHER INDIVIDUAL NETWORK

Model	Accuracy	Sensitivity	Specificity	Precision	F1score	AUC
DenseNet-201	90.87	91.52	89.69	94.1	0.927	89.78
ResNet-50	92.15	89.93	96.95	98.46	0.94	90.04
MobileNet-V2	91.19	92.84	88.41	93.08	0.929	90.55
ResNet-152	92.79	91.77	94.79	97.18	0.944	91.32
ResNet-101	93.27	92.03	95.71	97.69	0.947	91.79
VGG-19	93.75	92.91	95.35	97.44	0.951	92.52
VGG-16	93.27	96.03	89.02	93.08	0.946	93.3
<b>Ensemble</b>	<b>95.03</b>	<b>95.21</b>	<b>94.71</b>	<b>96.92</b>	<b>0.961</b>	<b>94.41</b>

TABLE II. COMPARISON OF ENSEMBLE MODEL WITH BASELINE MODELS

Models from Literature	Accuracy	Precision	Sensitivity	AUC
Rajaraman et al. [5]	96.2	97.7	96.2	99.3
Rahman et al. [6]	98	97	99	98
Chouhan et al. [4]	96.39	93.28	99.62	99.34
Enes Ayan et al. [27]	84.5	91.3	89.1	87
Saraiva et al. [8]	94.4	94.3	94.5	94.5
Kermany et al. [7]	92.8	-	93.2	-
<b>Ensemble Model - Proposed</b>	<b>95.1</b>	<b>96.92</b>	<b>95.21</b>	<b>94.5</b>

On the comparison study for previous works in Table II, the works of Kermany et al. in [7], Rajaraman et al. in [5] and Rahman et al. in [6] have been significant in automation of pneumonia detection. They have also compared their works with other authors who have published their results in the same problem. Rahman reported 98% classification accuracy and AUC score of 98 for an input image size of 224 x 224 for ResNet18 and DenseNet201 and 227 x 227 for AlexNet and SqueezeNet architectures. Rajaraman et al. [5], provided a study of the better results of cropped ROI (Region of Interest) data when compared to baseline data and proposed a customized VGG 16 model for the problem. Vikash et al proposed an ensemble model with an AUC score of 99.34 and 96.39 accuracy. Saraiva et al. in [8] evaluated a CNN network with an input image size of 150 x 150 pixels and reported 94.4% accuracy and 94.5 AUC score.

The slight dip in both [8] and proposed Ensemble results can be attributed to low training image resolution which affects the classification performance of the CNN. This has been supported and reasoned in the works of Sarkar et al. in [28], Kozierski et al. in [29], Dodge et al. in [30] and Kannoja et al. in [31]. The work in [29], reports that models that achieved high accuracy on the original, undistorted images were also more resilient to low image resolution and the pattern was observed across almost all the architectures. In our work, the relative dip in performance on testing with images of lower resolution would be less compared to the previous works due to the lower training set image resolution. This is also confirmed by the works of [31] in the reported values for MNIST and CIFAR-10 datasets where we could observe the drastic lowering of performance in models when the resolution of training and testing images vary vastly. They also state that improved results on low quality images need models trained with lower quality images which is the core idea behind our work.

For a 224 x 224-pixel image of 8-bit depth, file size is 6.125 KB whereas a 184 x 184-pixel image of 8-bit depth is 4.132 KB, which is nearly 150% increase in file size. In addition to it, it adds on to the computation time due to the increased number of parameters in the CNN leading to poor efficiency. With COVID-19 pandemic causing damages on a global scale, deep learning solutions using X-ray images are being actively proposed by researchers. Sridhar et al. in [32] evaluated a ResNet model to identify the similar regions between the X-rays of different lung disease and reported Atelectasis, Consolidation, Emphysema, and Pneumonia are most similar in nature to COVID-19. The result augments the need for more extensive research in Pneumonia detection to help distinguish the disease from COVID-19 which would help provide timely and appropriate treatment.

## VI. CONCLUSION

The study presents a transfer-learning based ensemble model to automate Pneumonia detection using Chest X-rays. Different CNN architectures were fine-tuned, trained and the results analyzed to finally propose an ensemble model. The other core idea focused on the work is to lower the resolution and size of the images used while balancing the trade-off with the performance of the model. The final ensemble model

evaluated had an accuracy of 95.03 and AUC score of 94.5 with a precision of 96.92. With significant research in the problem yielding promising results, such models can be deployed in real life to reduce the workload on physicians and bring down human error levels. With lower storage capacity and computing device needs, the implementation can be taken to remote rural areas globally that lack proper diagnoses and treatment for such illness due to lack of skilled doctors and radiologists, poor connectivity and lack of infrastructure. Although it cannot replace a physician, it can aid the diagnosis process and reduce the crucial time taken.

## ACKNOWLEDGMENT

Acknowledge Dr. T.V.Geetha Prof (retd.), Department of Computer Science and Engineering, CEG, Anna University, for motivating us to carry out this work during 2020, COVID'19 pandemic.

## FUNDING STATEMENT

Not received any financial support from any sources.

## CONFLICTS OF INTEREST

All the authors declare that they have no conflicts of interest to report regarding this study.

**Abstract**—Recent research discovers that delivering user intentionality for authentication resolves a random authentication problem in a proximity-based authentication. However, they still have limitations – energy issue, inaccurate data consistency, and vulnerability to shoulder surfing. To resolve them, this paper proposes a new method for user intent delivery and a new proximity-based bilateral authentication system by adopting it. The proposed system designs a protocol for authentication to reduce energy consumption in a power-constrained wearable, applies a Needleman-Wunsch algorithm to the matching of time values as well, and introduces randomness to a user behavior that a user must perform for authentication. We developed a prototype of our authentication system on which a list of experiments was conducted. Experimental results show that the proposed method results in more accurate data consistency than conventional methods for user authentication intent delivery. Eventually, our system reduces authentication failure rate by 66.7% compared to conventional ones.

**Keywords**—Security; authentication; internet of things; user intentionality; proximity-based authentication; bilateral

## I. INTRODUCTION

An ID-password authentication has enjoyed a variety of applications for a long time. While it is simple to use, it requires mental efforts to remember IDs and passwords as well as physical efforts to input them directly. It is recommended to use different passwords for different IDs. However, people in real life use the same password for multiple IDs because it is easy to remember one password. Once the password is exposed, however, user's accounts can be exposed to security risks.

With advancement of Internet of Things (IoT) technologies and pervasive computing, recent proximity-based authentication performs without requiring both mental and physical from users. The proximity-based authentication initiates authentication when a wearable user approaches a certain distance from the authentication device (say, a computer). We note that once the user is within the distance, the authentication automatically proceeds regardless of the user's intention to authenticate. That is, the user proceeds with authentication that she does not know, named a random authentication problem. Moreover, the user's lack of understanding of authentication intent leads to the problem of continuing authentication; an authentication process starts whenever the user passes a certain distance of the computer that she wanted to authenticate.

A user authentication intent delivery solves the problems. It proceeds with authentication via a user's specific behavior, enabling proximity-based authentication to work with the sensor values in the wearable and data collected from the computer for this behavior. Conventional methods for user authentication intent delivery use a mouse in the computer to calculate acceleration values using mouse position values and distance traveled values to collect them with time values and use a keyboard to press the keyboard and time to press the time. The wearable collects acceleration sensor values and the time values and transmit them to the computer. The computer checks the consistency of these data to determine whether to authenticate.

However, the conventional methods have limitations as follow. First, they require the wearable device to keep running built-in sensors and recording data, which consumes energy faster in the small, power-constrained device. Next, they predefine the type of behavior that a user must perform for authentication and the number of actions that the user repeats the behavior, which could be vulnerable to external attackers. Last, the conventional methods do not make use of time values when checking data consistency, which may result in less accurate matching.

This paper proposes a new method that delivers user intentionality for authentication and resolves the limitations and eventually proposes a new proximity-based bilateral authentication system by adopting the new method. To address the energy concern, the proposed system designs a new protocol for authentication where an authentication process is initially detected by the wearable. The system resolves the second limitation by applying randomness to the number of actions; that is, it changes the number each time a user proceeds with authentication. Last, our system enhances accuracy of data consistency by applying a Needleman-Wunsch algorithm to the matching of time values as well as acceleration sensor data.

A prototype is developed where we use a Galaxy Watch as a wearable, and experiments are conducted to evaluate performance of the proposed system. Experimental results show that the proposed system reduces error in data consistency by 46.6% on average (from 0.3593 to 0.1918). The improved accuracy affects performance of authentication; our system reduces authentication failure rate by 66.7% compared to the conventional method.

\*Corresponding Author.

The rest of the paper is composed as follows. Section II reviews two popular authentication methods and their limitations. Section III describes a conventional method for a user authentication intent delivery in detail. Section IV proposes a new proximity-based authentication system that delivers user's intentionality for authentication in an accurate manner. Experiments and performance evaluation of the proposed system are discussed in Section V. The last section concludes the paper.

## II. RESEARCH BACKGROUND

This section reviews a widely used authentication method, an ID-Password authentication, and discusses limitations. It also describes a proximity-based authentication method that can resolve the limitations.

### A. ID-Password Authentication

The most popular user authentication method has been an ID-password authentication [1]. It determines whether these data are equivalent to the values stored in the database by the user entering their own ID and password. Recently, authentication security through secondary authentication has been strengthened. The security of authentication is increasing with the addition of various secondary authentication methods, including authentication methods using existing ID passwords [2], sending messages using smartphones to enter additional code of messages [3], and user verification methods using specific applications.

**Limitations:** The ID-Password authentication method has limitations; it requires mental and physical efforts from users. In the case of mental effort, it is likely to be resolved if the passwords and IDs of all accounts are unified, but if passwords and IDs are exposed, all accounts may be at risk. On the contrary, if all IDs and passwords are set differently, mental efforts are needed too much because one should remember the whole thing. In the case of physical effort, the process of entering an ID and password is more mobile than expected because it uses a mouse and keyboard to enter characters. Recently, additional authentication methods using secondary passwords and QR codes [5] have been utilized by utilizing smartphones [4] to increase security. This method is certainly highly reliable in security, but there is a hassle of unlocking a smartphone, using an application, or checking a message and entering it back into the computer.

### B. Proximity-based Authentication

Proximity-based authentication is a technology that logs in or out users from applications, devices, websites, etc. using the distance between users and authentication devices as a key value [6]. To be successful in authentication, it is necessary to have auxiliary devices such as smartwatches and wearables near devices that users want to authenticate. Proximity-based authentication automatically initiates authentication when a user approaches a certain distance of the authentication device. At this time, authentication devices and users use wireless communications such as Bluetooth and Wi-Fi. The proximity-based authentication system is shown in Fig. 1. A computer and a user proceed with authentication by exchanging authentication tokens with each other [7] when the user is within a certain distance of the server.

Fig. 1. Proximity-based Authentication Initiates as a user Approaches a Computer.

**Limitations:** Proximity-based authentication automatically begins a process when a user approaches a certain distance of the authentication device. The authentication that occurs at this time proceeds regardless of the user's intention to authenticate. In other words, authentication proceeds even if a user approaches a device within a certain distance without any intention of authentication, so the user proceeds with authentication that he or she does not know [8]. Authentication fails if the user deviates from the effective distance for authentication with the authentication device while the authentication is in progress. This is an important part of the authentication process that is irrelevant to the user's intentions described earlier. Authentication is attempted if the user passes the effective distance of the authentication device, at which point authentication attempts-authentication failures [9] are repeated because authentication fails if it is outside the effective distance. If this process is repeated, certain devices lock down the authentication and cause problems that prevent users from proceeding with authentication in the situation they want to authenticate. The following section describes how one can communicate users' authentication intent in proximity-based authentication in detail.

## III. DELIVERY OF USER INTENTIONALITY FOR AUTHENTICATION: CONVENTIONAL APPROACH

In proximity-based authentication, a user authentication intent delivery allows accurate authentication to proceed by delivering authentication intention from assistive devices (e.g., wearables and smartwatches) or authentication devices (e.g., computers). Two typical technologies for user authentication intent delivery include wristband-based authentication for desktop computers (SAW) [10] and proximity-based user authentication on voice-powered Internet-of-Things devices (PIANO) [11]. This section describes a conventional approach that accurately conveys users' authentication intent in proximity-based authentication. Since our scenario sees authentication between a wearable and a computer, a review in this section is mainly based on the former.

### A. User Authentication Intent Delivery

A user authentication intent delivery is generally based on near-field based authentication, where wearable users and computers are paired over wireless communication within a certain distance, then double-click a specific button on the computer keyboard to confirm the user's intention to authenticate. Afterwards, values for a user's specific behavior are collected from wearable and computer, and authentication is carried out by matching these data [12].

1) *System architecture*: After wearing a wearable device, the user double-taps the computer's keyboard to verify the computer's authentication intent. When the computer confirms the authentication intent, it requests data about the acceleration sensor of the wearable. Users take certain actions, using a mouse or keyboard. On wearable devices, the acceleration sensor value and the gravitational sensor value are calculated and sent to the server using a specific program to calculate the value of the mouse and keyboard movement. When transmitting, it is carried out through wireless connections such as Bluetooth and Wi-Fi. The matching of the sensor value of the wearable device sent to the server is verified using a mouse or keyboard, and user authentication is performed on the computer with an authentication completion message. Request to measure again if authentication fails.

Unlike traditional proximity-based authentication, the user authentication intent delivery conveys the user's authentication intent, which allows the user to approach within a certain distance, verify the authentication intent, and authenticate. Differences from proximity-based authentication methods are shown in Table I [13].

2) *Operation*: In a conventional method for user authentication intent delivery, a computer and a wearable is paired via Bluetooth communication [14]. After pairing, authentication starts by pressing the computer's keyboard specific key twice, and the computer requests acceleration sensor values and time data from the wearable. The worm transmits the requested acceleration sensor data [15] to the computer. When the data is transferred, the computer checks data consistency; it successfully authenticates upon successful data matching or fails to authenticate upon data matching failure. In the event of a data matching failure, the sensor data transfer request is re-requested. If the data is not sent within 5 seconds of pairing, the pairing is canceled and then the pairing is requested again.

3) *Detection of user intent on computer*: The computer uses data values for wrist movements of wearable users to check the consistency with acceleration sensor data of wearable [16]. To collect data on the user's wrist movement from a computer, conventional methods use a mouse-wiggle [17] and/or a TAP [18]. Fig. 2 illustrates these two ways.

Fig. 2. Mouse-Wiggle (Left) and Keyboard Tab (Right) Methods.

When authentication begins, a user in the mouse-wiggle method moves the mouse from side to side on the screen, which is recorded. The computer measures the mouse's position values and time values with which it computes acceleration values. Finally, the acceleration value is calculated by dividing the time value by the distance traveled previously obtained. The TAP method makes use of the time value when the keyboard was pressed a certain number of times and difference between the current time value and the time value when the keyboard was first pressed. This value indicates the time when the user's hand presses and releases the keyboard. The computer uses this time value to verify that the value of the highest point of the acceleration sensor value in the wearable matches the recorded time.

4) *Detection of user intent on wearable*: After pairing with a computer, a wearable is asked to send sensor data. When a user performs a mouse-wiggle and keyboard-TAP method, the wearable transmits the value of the acceleration sensor of the device itself to the computer [19].

*B. Limitations of User Authentication Intent Delivery*

A delivery of explicit user intentionality for authentication solves the random authentication problem [20] that can occur in proximity-based authentication methods, thus enabling more accurate authentication. However, conventional methods for user authentication intent delivery have limitations that hinder optimal authentication operations. First, the methods make a computer to detect a user intent for authentication initially. Once detected, the computer tries to communicate with a wearable device on the user side to obtain sensor records. This implies that the device remains on a ready state all the time, which makes it hard to save energy consumption on the device. Next, conventional methods use fixed forms of user behaviors as intent. For instance, the TAP-5X method pushes a computer's keyboard five times to collect data for matching data between computers and wearables. Because TAP-5X performs exactly five actions by the user, it is possible for an external attacker to observe and analyze the user's behavior and authenticate by taking the same action [24]. Wearable devices may not be problematic because they are usually worn by the user, but if the user is away for a while or if the wearable is stolen 15 times, the computer cannot verify whether the user is a user or an attacker, making the TAP-5X vulnerable to external attackers. Last, conventional methods prioritize the matching of acceleration sensor values in data matching for authentication between computers and wearables for authentication. Data obtained from computers and wearables include time values and acceleration sensor values. A Needleman-Wunsch algorithm [21] has been used to match the

TABLE I. DIFFERENCES BETWEEN TRADITIONAL AUTHENTICATION METHODS AND USER AUTHENTICATION INTENT DELIVERY BASED METHODS

<i>Proximity-based authentication</i>		<i>User authentication intent delivery</i>	
Advantages	Authentication system operation when user approaches within a certain distance	Characteristics	Complement the absence of a user authentication intent verification method of traditional proximity-based authentication by identifying the intent through specific actions.
Weakness	Continuously operates the authentication system when accessing within a certain distance without identifying the user's authentication intent.		

acceleration sensor values, increasing the accuracy of the acceleration sensor data values. However, algorithms for data matching were not used for time values while time values have been used as one of the most significant metrics in previous research on user authentication intent delivery [22, 23]. This can cause problems in the process of identifying data matching.

#### IV. PROPOSED SYSTEM: USER-INTENDED PROXIMITY AUTHENTICATION

This section proposes a new proximity-based authentication system that explicitly delivers user intentionality for authentication. To resolve the first limitation, an authentication process in the proposed system is initially detected on a user side instead of on a computer. To this end, the user is required to touch her wearable twice first. The next limitation is resolved by applying a one-time password concept that proposes a new criterion for the number of actions that a user must perform each time he or she proceeds with authentication. To resolve the last limitation, our system improves accuracy in the data matching process by applying the Needleman-Wunsch algorithm to time values as well.

##### A. System Architecture

The proposed system consists of two entities, a user and a computer, as shown in Fig. 3. The user is with a wearable that is paired with the computer via Bluetooth communication. The user starts behaving an intent action, and her behavior is detected both on the wearable and on the computer and processed. Fig. 4 helps us describe how accurately the system measures data on the behavior and determines that the measured values on both sides are matched.

The computer in Fig. 4 opens a Bluetooth server and connects it to Intelligent Unit that calculates data matching and Action Detector that is responsible for detecting the movement of a keyboard and a mouse on the computer and for measuring corresponding data. The wearable uses Bluetooth Server on the computer and a Bluetooth socket to make a UUID connection. Sensor Manager keeps monitoring values from built-in sensors. Once an authentication process is triggered, Sensor Manager transmits the sensor records to the computer via the Bluetooth communication. At the same time, Action Detector measures the movement of the computer's mouse and keyboard and records related data. Upon collecting data from both Sensor Manager and Action Detector, Intelligence Unit checks the match between the two data. Authentication is completed if the data is matched, or retransmission is requested if authentication fails due to data mismatch.

##### B. Protocol

The proposed system designs a protocol for authentication between the computer and the wearable, and Fig. 5 depicts flows and processes of the protocol.

The computer makes a pairing request to the wearable by transmitting its UUID. The wearable checks the validity of the UUID received and transmits its own UUID to the computer to proceed further with pairing. Once they are paired, a user is allowed to request authentication to the computer.

An authentication process in the proposed system is initially detected by the wearable unlike conventional methods

for user authentication intent delivery. The user double-touches the wearable to communicate her authentication intent to the computer. Then, authentication begins when the computer confirms the intent. The computer requests the wearable to transmit sensor records. At the same time, it generates a random number (a nonce) and piggybacks the nonce on the request message.

Upon receiving the message, the user takes an action; she moves a mouse or pushes a key in a keyboard connected to the computer. The nonce received guides her behaviors; that is, she repeats the movement or the push multiple times corresponding to the nonce value. When the user performs an action, Sensor Manager in the wearable records acceleration values and corresponding time values and transmits them to the computer. After sending the request message to the wearable, Action Detector in the computer starts collecting data of mouse movement (changes of the pointer's positions and corresponding timestamps) and/or data of keyboard (numbers of key presses and timestamps of pressing and releasing).

Fig. 3. The Proposed Authentication System Consists of Two Entities, a user and a Computer. They do Authentication by Delivering the user's Authentication Intent.

Fig. 4. Two Entities in the Proposed System Include a List of Components, and they are Responsible for Exchanging Data Regarding user's behavior and Processing it for Data Matching.

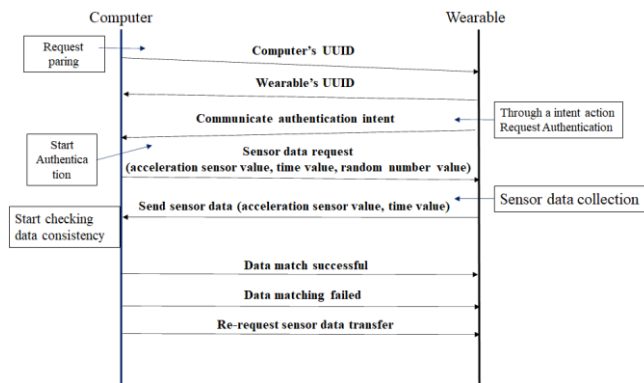

Fig. 5. The Proposed System Designs a Protocol for Authentication between Computer and user, where user's Intentionality for Authentication is Delivered Explicitly.

Intelligence Unit in the computer collects data from both Sensor Manager and Action Detector. These data are supposed to represent the user's behavior for authentication intent commonly but recorded by two different devices. It then checks the consistency of the data using the Needleman-Wunsch algorithm. If two data are matched, the user is authenticated. If they are not matched or the collected data is not received, the computer retransmits the request message. If there is no response within timeout period, authentication fails.

### C. Accuracy of Data Consistency

Conventional methods for user authentication intent delivery, like our system, apply the Needleman-Wunsch algorithm to the data consistency check; it matches data from user-worn wearables with data measured on the computer. It is observed that the methods use the matching algorithm only to determine the matching of sensor values and do not care for corresponding time values. However, time values in general authentication have played an important role especially when computing data consistency and data matching [25]. Matching of sensor data may result in failure of authentication unless corresponding time values are matched. To resolve the limitation, this paper proposes applying the Needleman-Wunsch algorithm to the matching of time values as well as acceleration sensor data, enhancing accuracy of data consistency.

### D. Randomness of user behavior

In a behavior-based authentication, data consistency is verified using data obtained by a user taking an action. Conventional methods for user authentication intent delivery define criteria in their specific behaviors [26]. This criterion is an essential part of users' behavior but can be abused for attacks. An external attacker can observe certain behaviors that a user performs when authenticating to a computer and then mimic the same action with a wearable device to carry out an authentication attack [27]. The criteria for users' behavior serve as fixed ID-Password values in a popular authentication. Thus, if data is leaked, constant data can be analyzed and attacked with authentication using fake data.

To tackle the challenge, the proposed system adopts the concept of OTP in the existing ID-Password authentication method [29]. The computer in our system sends a random number together when requesting data for authentication to a wearable [28]; this changes the required number of criteria for each authentication of a user's specific behavior. More technically, the computer sends two random values that are applied separately to the mouse and keyboard actions. To reduce the time required for certification as much as possible, a random number for the mouse is between 3 and 5 and that for the keyboard is between 3 and 7, which is based on numbers of existing authentication methods. This allows users to defend against authentication attacks because each authentication requires different numbers of certain behaviors. Even if external attackers observe and analyze users' behavior, they are inconsistent. We note that an optimal range of random values could be an interesting topic for further research.

## V. DEVELOPMENT AND PERFORMANCE EVALUATION

This section develops a prototype of the proposed system, runs experiments, and evaluates its performance. To assess accuracy of data consistency, we compare error values both in a traditional (conventional) method reviewed in Section III and in the proposed system that applies the matching algorithm to the time values additionally. Regarding randomness of user behavior, we measure data on how much user behaviors are matched when using randomized criteria. The initial result is then used to see whether an external attacker is authenticated when he imitates a particular behavior in both systems.

### A. Development

The test environment was modeled on the way that a user performs authentication at a personal computer, and a wearable was worn on the user's right wrist. We use a computer running Linux Ubuntu 16.04.04 LTS on a system of Intel® Core™ i5-9600KF CPU @ 3.70GHz and 16GB of memory. When recording mouse movements, the computer calculates the acceleration value using the position change value and the time change value [30]. When recording keyboard input, the time when the keyboard is inputted and the time when it is inputted is recorded. We use a Galaxy Watch (smartwatch) as a wearable, and Table II shows its technical specification. The smartwatch samples the accelerometer sensor at 200 Hz and transmits the data to the Bluetooth server in real time.

### B. Experiments on Traditional Method

For traditional methods, we use a mouse and keyboard to collect data about a user's specific behavior. Participants wear smartwatches on their right wrist to conduct experiments. In the smartwatch, acceleration sensors are used to collect acceleration values for wrist movements, and in the computer, mouse and keyboard are selected sequentially from Python-based programs. When selecting a mouse, the mouse moves from side to side on the screen to collect the mouse's location data and time data and calculate the acceleration. We then collect the time when the keyboard button is pressed once the keyboard is selected, or the time when the keyboard button is pressed [31]. The computer uses the matching algorithm to determine the data match for the acceleration value of the collected data.

For accurate verification of consistency of the data collected via the mouse-keyboard method of the participants, the data values are graphically represented to confirm the consistency of the values directly. This section compares the two graphs with the largest error in the experimental results as representatives, and the overall experimental results are tabulated.

TABLE II. SPECIFICATIONS OF SMARTWATCH

	Spec OF Galaxy Watch
<b>O.S</b>	Tizen-based wearable OS 4.0
<b>CPU</b>	Dual-core 1.15 GHz Cortex-A53
<b>Memory</b>	4GB 768MB RAM, 4GB 1.5GB RAM
<b>SENSOR</b>	Accelerometer, gyro, heart rate, barometer
<b>BATTERY</b>	Up to 72 h (mixed usage)

Fig. 6 shows the mouse experiment results of participant 1. The x-axis of the graph is the time in seconds, and the y-axis uses the acceleration value ( $m/s^2$ ). The graph for acceleration values in computers and smartwatches shows a similar graph in the peak, but in the last peak in the computer, the computer shows an acceleration value of 0.47264 and 0.168671 in the smartwatch, with an error value of 0.303969. In the SAW paper, the criterion for the error value of the data is 0.3. Existing systems determine that certification failed for the current participant.

Fig. 7 shows the results of a keyboard experiment for the same participant. In the figure, the part marked in red squares takes time for the keyboard to press and hit. The data consistency check on the keyboard first determines whether the acceleration value on the smartwatch is the value of the peak point at the time the keyboard is pressed on the computer. The keyboard checks the pressed and hit time and determines that it is the same if there are no other pick points within this time interval. However, the above graph shows that the value is peak at the time the keyboard was pressed on the second computer, but the exact data matching was not achieved because another pick point was displayed in the red square section, which represents the interval where the keyboard was pressed and hit. For the first experimental participant, neither mouse-keyboard nor mouse-keyboard matched the data.

Fig. 8 shows a graph of the mouse results of participant 6. The graph on the mouse results of the 6th experimental participant shows significantly similar appearance and matching values in computers and smartwatches than the graph of the first participant in the preceding one. However, the maximum value on a computer at 2.5 seconds in the graph is 1.62745, and the minimum value for a smartwatch is 1.10937. In this experiment, the error value at the peak point has a maximum value of 0.51808. This value is also determined to be an authentication failure because it does not match the data with more than twice the error tolerance value of 0.3 in [10].

Fig. 9 shows the results of the same participant's keyboard experiment. By checking the graph above, the sixth experimental participant was able to see the matching of the data in the keyboard experiment because the time the keyboard was pressed on the computer was all peak value of the smartwatch's acceleration value and no other peak value was included in the red square section.

Fig. 6. An Experimental Result of Mouse Movement on Participant 1.

Fig. 7. An Experimental Result of Keyboard Press on Participant 1.

Fig. 8. An Experimental Result of Mouse Movement on Participant 6.

Fig. 9. An Experimental Result of Keyboard Press on Participant 6.

Table III summarizes mouse experiment results of a total of eight experimental participants in the traditional method. Five of the eight participants in the experiment are close to the tolerance value of 0.3, of which three are accurately included in the tolerance value, with one exceeding some.

Table IV shows eight participants are certified through the results of a keyboard experiment. There were five successful participants in the experiment, and three unsuccessful participants. Authentication via keyboard rather than mouse is the main method. All participants matched the time the keyboard was pressed on the computer with the peak point of the acceleration value on the smartwatch, but three failed to authenticate, including the other peak value in the keyboard's pressing and hitting interval. These results confirm that when the matching algorithm for time values is not applied during the authentication process through the user authentication intent transfer method.

TABLE III. EXPERIMENTAL RESULTS OF EIGHT PARTICIPANTS USING TRADITIONAL METHODS

	Computer	Smartwatch	Error value
Participant 1	0.47264	0.16867	0.30396
Participant 2	0.25175	-0.18172	0.43347
Participant 3	0.84264	0.28839	0.55425
Participant 4	-0.02481	-0.39514	0.37033
Participant 5	0.64428	0.41439	0.22989
Participant 6	1.62745	1.10937	0.51808
Participant 7	0.75613	0.52571	0.23042
Participant 8	0.40917	0.17514	0.23403

TABLE IV. KEYBOARD EXPERIMENT RESULTS FROM EIGHT PARTICIPANTS USING TRADITIONAL METHODS

Participant Number	2, 3, 6, 7, 8	1, 4, 5

C. Experiments on Proposed System

Unlike traditional methods, a smartwatch in the proposed system verifies the user's authentication intent, sends it to the computer, and verifies this intention on the computer to proceed with authentication. In this case, random values are transferred to the smartwatch together to provide a baseline for a specific behavior for the user's authentication, and experimental participants take a specific behavior through the mouse and keyboard according to this number.

With these data values, the computer applies the Needleman-Wunsch algorithm to verify the consistency of the data, and then applies the algorithm to the time value to perform authentication with more accurate data matching. Experiments conducted by experiment participants are the same as previous experiments, and only new parts are added that initiate authentication by touching the smartwatch twice. The graph also displayed the results of the experimenter with the largest error value and the experimenter with the smallest error value, just like the previous experiment, and the results for the entire experiment were tabulated.

Fig. 10 shows a graph of the acceleration sensor values of participant 5. The random number of mouse experiments occurred was 4, and the user moved the mouse left and right for 4 seconds to measure acceleration sensor data, time data, and acceleration and time values through the computer's mouse movement. In the above graph, the graphs for acceleration values of computers and smartwatches are not completely consistent, but we can confirm that the two data are much more consistent than those of conventional methods. At this point, a peak value of 0.33762 was recorded on the 1.2-second computer, while the smartwatch recorded a value of 0.25983. At this point, the error of the two values is 0.07779, showing a significantly lower value than 0.3 which was represented by the error value in the existing user authentication scheme.

Fig. 11 shows the results of a keyboard experiment of the same participant. At this point, the displayed random numbers represent the same 5 as the existing experiments, and the user conducted an experiment of pressing the keyboard five times.

In the graph above, the time when the keyboard was pressed on the computer and the peak point of the acceleration value of the smartwatch are the same, and the red section for the time when the keyboard was pressed and hit does not include other peak points. In the case of keyboard experiments, there was no problem with data matching, unlike previous conventional methods experiments among participants. In other words, authentication was carried out by applying the need only-one algorithm to the time value, matching the section where the keyboard was pressed and hit to the time when the peak point of the smartwatch was stamped.

Fig. 12 is a mouse experimental graph of participant 1 in the proposed method. Unlike the results of one previous experiment, graphs for acceleration values of smartwatches and computers show more consistency. The computer's acceleration value is 0.50388 and the smartwatch recorded acceleration sensor value is 0.25983. The error value for this is 0.22284, which is lower than the error range of 0.3. However, the values shown this time showed similar values in previous experiments.

Fig. 10. An Experimental Result of Mouse Movement on Participant 5 in the Proposed Method.

Fig. 11. An Experimental Result of Keyboard Press on Participant 5 in the Proposed Method.

Fig. 12. An Experimental Result of Mouse Movement on Participant 1 in the Proposed Method.

The results of the overall participants in the proposed scheme are presented in Table V. There were seven participants who did not correspond to the error value of 0.3, and only one failed to authenticate beyond the error value. It shows higher accuracy than data matching experiments in which three people in the previous existing method succeeded and five failed. This is the result of applying the need-one-value algorithm to the time value, which makes the comparison between computers and smartwatch data more accurate. It shows a lower error value than the error value shown in the experiments of the existing method, and is reliably successful in data matching, enabling authentication.

TABLE V. EXPERIMENTAL RESULTS OF 8 PARTICIPANTS IN THE PROPOSED SYSTEM

	Computer	Smartwatch	Error value
Participant 1	0.50388	0.28104	0.22284
Participant 2	-0.02944	0.09978	0.12922
Participant 3	0.27756	0.23265	0.04491
Participant 4	0.98824	1.09113	0.10289
Participant 5	0.33762	0.25983	0.07779
Participant 6	0.8537	1.3054	0.4517
Participant 7	1.2084	0.98841	0.21999
Participant 8	0.74269	1.02772	0.28503

#### D. Performance of Data Consistency

We confirm the experimental results of the existing and proposed methods in the previous subsection. In mouse authentication, we show that the existing method succeeds in 3 out of 8 and 5 fails, and that the proposed method fails only 1 out of 7 people. Furthermore, we show that the error value of the proposed scheme is also significantly lower, and we can confirm that it is a more suitable method for data matching. This can be confirmed through the graph in Fig. 13.

Fig. 13. Comparison of Error Values between Existing and Proposed Methods.

By checking the graph in the figure, the maximum value of the error in the existing scheme is 0.55425 and the minimum value is 0.21989 and the maximum value of the error in the proposed scheme is 0.4517, with a minimum value of 0.04491.

The mean of each error value shows a significantly lower value of 0.359304 in the existing method, 0.191796 in the proposed method, and since the data error value for successful authentication must be less than 0.3 it is appropriate to use the proposed method focusing on matching time values over the existing method.

Keyboard-experiments also showed results of five successful and three unsuccessful using conventional methods, but the proposed method showed results of seven successful and one failure. However, because the proposed method can only authenticate when both the mouse and keyboard have a data match, one failed to authenticate through a match at the mouse value. Comparing only keyboard values, all eight showed accurate data matching.

#### E. Comparison of Behavioral Matching with Randomness

Traditional methods operate by setting criteria for specific behaviors of users. For instance, SAW in [10] used the TAP-5X, a five-press keyboard method. However, as previously stated, certain behaviors with these criteria can allow an external attacker to observe the user's movements and take the same action to make an authentication attack [32-34]. In this paper, random numbers are transferred from the computer to the smartwatch to perform the mouse-keyboard behavior at different times per authentication, rather than the criteria set for a particular number of actions. To confirm this, eight participants observed other people's experiments and examined whether they could perform the same behavior.

In experiments with existing methods, all eight participants answered that all users could do the same because they used the same authentication method of mouse movement and keyboard No. 5 tab. However, the experimental participants failed to take the same action because the proposed authentication method applied different random numbers to the mouse-keyboard method. Through this, authentication methods through randomness have an advantage in attacks through the observation of external attackers than when there is a set standard for a specific number of actions for authentication of existing users.

## VI. CONCLUSION

This paper proposed a new proximity-based authentication system that delivered user's intentionality for authentication in an accurate manner. Conventional methods for user authentication intent delivery solve a random authentication problem that can occur in proximity-based authentication. But, they still have limitations; (i) a wearable device may consume energy much faster, (ii) conventional methods proceed based on the number of actions fixed to a specific behavior for user authentication, which could be vulnerable to external attackers, and (iii) the methods do not match time values, which results in less accurate data consistency process.

To overcome the limitations, the proposed system designs a new protocol for authentication where an authentication process is initially detected on a user side instead of on a computer. The system adopts a randomness that changes the number of actions that a user should perform each time she proceeds with authentication. It increases the accuracy of the matching of the data by applying a Needleman-Wunsch

REFERENCES

algorithm to time values when verifying data consistency. Experimental results showed that authentication was succeeded 5 times and failed 3 times with conventional methods, but the proposed system showed 7 successes and 1 failure. Results in the mouse experiments showed that the maximum error value in the conventional methods was 0.55425 and the minimum value was 0.21989, while the proposed system showed the maximum of 0.4517 and the minimum of 0.04491, which was much lower.

A. Discussion

Verifying user intentionality is one of the most important goals in authentication process. In traditional patterns of authentication interaction (human-machine, human-human, and machine-human authentication), human beings have been involved directly in authentication and delivered authentication intent explicitly [35]. Examples include password-based methods and biometric-based methods. By touching on a finger scanner, a user presents her intent for authentication in a fingerprint authentication. With increasing development of IoT technologies and pervasive computing, however, a new pattern of a machine-machine authentication becomes popular [22, 36-37]. For instance, a user carrying a wireless authentication token approaches a target computer that authenticates the user whenever the token is within a certain distance. In such a new pattern of the proximity-based authentication, the user intentionality is often omitted or not verified explicitly.

Delivering the intent and verifying it on both sides of authentication entities may delay processing and degrade convenience of the machine-machine authentication [38]. That is, a new authentication method is on between accurate verification and user convenience. The proposed authentication system is somewhat intended to high accuracy and high protection level. It diminishes risks from external attackers by randomizing user behaviors in authentication, increases accuracy of data consistency process by handling time values, and takes care of energy consumption of a power-constrained IoT device by designing a new authentication protocol.

The proposed system may not provide an excellent benefit of user convenience. Our authentication may be recognized as an interruptive step in a user's normal workflow. That is, a user should start explicitly authentication after stopping what she is doing. Once authentication done, she gets back to her normal work that she was on before authentication. A future work may include development of an advance authentication that blends seamlessly into users' workflow. One possible approach is to make use of the workflow for authentication [26]. It would be optimal if she is being authenticated while she is doing her work; that is, seam between authentication and workflow are blurred.

Delivery of users' authentication intent is expected to enable faster and safer authentication through user behavior analysis if machine learning, which has recently been utilized in various fields, is applied. Furthermore, as the demand for wearable devices such as smartwatches is increasing, further research is required to analyze user behavior patterns in more detail and to quickly authenticate based on them.

**Abstract**—The pre-operative planning process for High Tibial Osteotomy (HTO) is vital to correct the deformity of the long bones. The most important process is needed to find the Centre Of Rotation of Angulation (CORA) and display the forecast result based on the value of the correction angles simultaneously. Presently, these practices should be done manually because current software only can define either CORA's point or correction angle at one time. This paper proposed to use computer-aided software to make the fully digitized process of pre-operative planning for HTO to be done. For this purpose, we introduced OsteoAid software. This software enables the user to define the mechanical or anatomical axes and define the CORA's point and the angle at one time. For testing purposes, we compared the reliability of osteotomy's correction angle between this two software (MedWeb and OsteoAid) in preoperative planning open-wedge high tibial osteotomy. This is to ensure that the new software is reliable for the correction. Thirteen digital long leg radiographs with long-standing positions from the frontal axis showing patients with both tibia deformities were examined using intra-class correlation. Those images are accessed from the picture archiving and communication system (PACS). Three medical officers (raters) who were involved in an osteotomy used the same medical image format twice with a two-week interval. Using the MedWeb software, the mean correction angle score of each rater is at excellent level: 0.989 (intra-rater1), 0.982 (intra-rater2) and 0.972 (intra-rater3). Scores of each rater for OsteoAid are also excellent: 0.949, 0.987 and 0.986 respectively. The inter-rater reliabilities of the correction angle were 0.820 and 0.979 ( $p < 0.001$ ) respectively for each software. The principal finding of this study was that the new software (OsteoAid) showed excellent reliabilities and good consistency in preoperative planning in finding CORA and correction angle.

**Keywords**—Center of rotation of angulation; CORA; HTO; software; digital; medical image

## I. INTRODUCTION

The High Tibial Osteotomy (HTO) is one of the trusted methods and an effective medical treatment option for correction in ensuring the success of HTO surgical procedures [1], [2]. HTO is an acceptable and common procedure to treat symptomatic osteoarthritis of the medial compartment of the

knee with varus alignment. HTO is considered a very successful surgical procedure with low complication rates. The goal of surgical treatment is to shift the weight-bearing axis from the medial compartment to the lateral compartment [3]. It is becoming increasingly important nowadays in the treatment of cartilage pain or central osteoarthritis with varus deformity [4].

Proper planning, especially the height of the wedge base and osteotomy correction angle, is also a crucial aspect of effective HTO. Usually, preoperative planning of HTO will be done before the real surgery to ensure optimum correction and to avoid malalignment that can lead to under-correction or over-correction, even with navigation systems [5]. Inaccurate preoperative planning will produce inadequate correction during surgery and loss of correction in the postoperative period [6].

Previously, conventional preoperative planning for HTO was done by tracing out the x-ray film on paper. When the technology was replaced from X-ray film to digital, the full digital procedure for preoperative planning should also be produced. Current software is reliable for preoperative planning for HTO in a part of procedure such as finding CORA's point or angle at one time only, it does not visualise the forecast result as needed by surgeon. This motivates researchers to develop a new software that can fulfil all the requirements needed by surgeon.

Computer-assisted planning gives the advantages to the higher accuracy and reliability in many ways such as digital storage, infrastructure and technology [7], digital planning [3], better result [8], real-time feedback [9] and possible to display future results [10]. In optimizing a digital radiographic image in the orthopaedic department, the researcher developed digital preoperative planning for high tibial osteotomy software.

A previous study from Awang et al [11] shows five different specification software namely TraumaCad, MediCad, Sectra, MedWeb, and Photoshop applied to implement preoperative planning for an osteotomy. However, certain software is usually equipped with advanced equipment

\*Corresponding Author

(computer navigation) and exorbitantly costly and it is difficult for developing countries such as Malaysia to purchase. On the other hand, current software implemented in Universiti Kebangsaan Malaysia Medical Center (UKMMC), as an example, has limited functions and does not provide a forecast image for postoperative.

OsteoAid software was developed to overcome the current limitation that occurred during the planning process, such as, the current software does not provide a centre of rotation of angulation and it does not provide visualisation for correction. The new software enables the user to easily find out an angle for correction and rotate a part of the image and visualise it. This paper aims to determine the CORA and correction angle at one time. It also aims to compare the accuracy of new software, in order to ensure the reliability of the new software in doing preoperative planning for HTO.

Meanwhile, the CORA is the point of intersection between two straight lines at the proximal and distal [12]. According to Kim et al., [3] CORA is determined by the intersection of the transverse dividing line between the proximal and distal tibial anatomical axes and the posterior tibial cortex. Moreover, it allows accurate analysis of lower limb angular defects [13].

CORA is the most important assessment for angular defect correction. The line that crosses the CORA and divides the lateral and medial angles formed by the proximal and distal axes of the bone is called the transverse bisector line (tBL).

The intersection of these straight lines involves mechanical [14], [15] or anatomical axes [16] It is also influenced by the need or regulation of the osteotomy itself i.e. varus gene defect [14], valgus [17] or recurvatum [18]. This selection also depends on the selection of wedges to be used that is whether open wedge, closed, dome and also a combination.

Thus, this study is focusing on the requirements needed to develop the digital planning for HTO. CORA as the main requirement in this study is needed to guide the surgeon to cut the proximal tibia with dedicated correction angle. Then the correction angles founded from the same images using two different software were then tested and compare their ICC to prove that it is also equivalent among MedWeb and OsteoAid. This section also contains the background of the current research. Section II discussed the materials and methods needed in this study. Section III discussed the evaluation followed by the results, discussion and conclusion.

## II. MATERIALS AND METHODS

This new software was developed based on the user requirements. The main focus of this development is on the defining CORA's location and correction angles' value. Besides, this software enables end user to see a picture based on the previous result of CORA point and the angle of the correction.

A retrospective case series was conducted between 2016 and early 2018, 26 tibia's radiographic images from 13 patients have already undergone osteotomy surgery. The patients were five men and eight women with aged between two to 15 years old. To ensure good quality results, two identical tests will be

conducted by the same three evaluators for all two tests, within a two-week interval at the PPUKM Orthopaedic Clinic by medical officers in specialist training in the osteotomy field.

The three medical officers (evaluators) will test the Medweb software and also OsteoAid using medical images (Dicom). All of the images were tested to compare CORA's angle finding from two different software; MedWeb which is the current software used in that hospital and OsteoAid, new proposed software that was developed to overcome MedWeb's deficiency.

### A. Preoperative planning

Since this study focused only on the genu varum and valgus, all radiographic images were from the coronal plane which required a long lower limb. The aim is in preoperative planning for high tibial osteotomy by realigning the deformity leg to the normal weight-bearing line. This study only focuses on comparing results in finding CORA based on two different softwares. Here, CORA was defined based on two intersections of lines produced from proximal and diaphyseal anatomical axis to produced lateral open wedge for high tibial osteotomy. Fig. 1 shows how to produce CORA and the correction angle.

### B. Radiographic Evaluation

There are many records of patients who had undergone osteotomy, but to ensure that the testing can be done fairly and transparently, several things need to be concentrated. Those requirements are long leg radiograph with long-standing position from the frontal axis and using the same Movement Reference Number (MRN) of each patient from picture archiving and communication system (PACS).

### C. Correction Angle

A correction angle is an angle produces based on the percentage of anatomy or mechanical axis. An example, based on [19], the target mechanical axis were calculated as much as 62.5% using radiographs in the standing and supine positions based on Fujisawa technique. The author in [17] defines correction angle based on the drawn line from the hinge point to the line connecting the center of the femoral head and 55, 60, and 65% weight-bearing line.

In this study, two straight lines of T-shaped and T-downward which are known as T1 and T2's markers were used to produce the angles. T1 as by default is at a zero angle of degrees while T2 is at an angle of 180 degrees. If the user clicks on the right arrow key for any marker, the current value of the marker will be added to five degrees, while if the user clicks on the left arrow key, the current value of the marker will be subtracted to negative five degrees. Those markers are shown in Fig. 1.

Similarly, if the user clicks on the up-arrow key, the current value of the marker will be added to one degree, while if the user clicks on the down arrow key, the current value of the marker will be subtracted to negative one degree. The two markers will then be continuously updated with the value of their respective findings. Fig. 2 shows the programming language used to calculate the angles.

Fig. 1. CORA's Location and Correction Angle.

```
if DeltaTheta ~= 0 || dAlpha ~= 0
    handles.data.Alpha = handles.data.Alpha + dAlpha;
    if ID == 1
        handles.data.Theta1 = handles.data.Theta1 +
DeltaTheta;
        handles.data.Marker1 =
imrotate(imresize(handles.data.MarkerRef,handles.data.Alpha,
'bicubic'),-handles.data.Theta1,'bicubic');
        handles.data.bMarker1 =
any(handles.data.Marker1>0.1,3);

set(handles.Theta1,'String',num2str(handles.data.Theta1));
    else
        handles.data.Theta2 = handles.data.Theta2 +
DeltaTheta;
        handles.data.Marker2 =
imresize(imrotate(handles.data.MarkerRef,-
handles.data.Theta2,'bicubic'),handles.data.Alpha,'bicubic')
;
        handles.data.bMarker2 =
any(handles.data.Marker2>0.1,3);

set(handles.Theta2,'String',num2str(handles.data.Theta2));
```

Fig. 2. Algorithm of the Selection and Rotation a Part of Image.

#### D. Rotating a Part of Image

As the correction angle is produced, they want to display the prediction of correction. Based on the CORA correction's angle obtained, the next task is to mark an area of the image of the tibia to be rotated and visualize the expected result of the rotation. This is done to get the satisfaction of the surgeon in obtaining the best picture of point and angle results before the operation. In addition, it is also important to provide an initial overview to patients and family members about the treatment methods that the patient will receive.

Fig. 3. (a) Process of Selection a Part of the Area, (b) Result Displayed based on the Correction Angle.

Fig. 3(a) shows an example where a part of the area was selected for cropping and rotation. Here, the user needs to mark four corners of the part of the image to be rotated and it must cross the line at the CORA point. In the last corner, which is the fourth corner, the user has to click the mouse twice to finish the process of selection. Then the result will display as shown in Fig. 3(b).

#### E. Statistical Analysis

Normality tests were performed using Kolmogorov – Smirnov on all variables before determining parametric statistics. This test is made to determine the compatibility between the two methods is also tested by comparing the mean of the correction angle obtained. Kolmogorov – Smirnov testing was performed to confirm the normal distribution. This test was chosen to test the normality of the data when the data were in small numbers and less than 50.

If the data is normal, then the researcher can use a T-test to run a further test. Else, Wilcoxon signed-rank test can be used. Then, the intra-class correlation was used to test the reliability of the results (ICC). Inter- and intra-rater reliabilities using the IntraClass Correlation Coefficient method were accessed. For statistical analysis, the IBM SPSS software for Windows version 17 was employed to determine if statistically significant similarities were present between the group studied. A p-value of 0.05 or less was considered to be a significant difference.

### III. EVALUATION

After the development of the system was completed, one simple test will be done to evaluate the accuracy of the system. Testing has been conducted on 13 patients with impairment on both legs who had undergone osteotomy treatment from 2016 to early 2018 at Universiti Kebangsaan Malaysia Medical Center (UKMMC). The respondents comprised of three medical officers who practice osteotomy correction planning and the tests were conducted at UKMMC. They tested on this system themselves in conducting osteotomy preoperative planning procedures and obtained the results based on the given patient. To determine the sample size, an a priori power analysis was performed using the null hypothesis test at  $\alpha$  level

of .05. It had been hypothesized that the reliability of intra- and inter-rater for the dedicated software was zero.

As the study involves the field of medicine that leads to orthopaedic, the test is based on the guidelines obtained from the International Society of Arthroscopy, Knee Surgery and Orthopaedic Sports Medicine (ISAKOS), in which the results lead to the reliability of new techniques based on existing techniques.

The reliability of this new software will be evaluated. The current software is regarded as a gold standard, and consistency was evaluated for the examination of the accuracy of the new system PACS-OsteoAid method. Coronal alignment and posterior tibia slope were evaluated and excluded to sagittal alignment. The reliability of the measurement was accessed, by examining the intra-rater and inter-rater reliability, using intra-class correlation coefficient (ICC) to determine each component score [20]. Three medical officers, who were involved in osteotomy, measured the correction angle twice with a two-weeks interval.

#### IV. RESULTS

A few standards on the development that have been done were listed to be followed before testing could be executed as followed:

- 1) the software can use the medical image in Dicom format.
- 2) surgeons are free to define CORA.
- 3) the software can visualise CORA for correction.
- 4) software is tested by the medical officer who is involved in osteotomy.

Based on the standard proposed, one evaluation was done to accept the level of accuracy achieved from the usage of OsteoAid. The demographic data based on thirteen patients with both tibia's patients underwent preoperative planning in finding CORA angle are in age 2-15 based on the data available in the PACS is shown in Table I.

Table II shows the two tests (Test1 and Test2) that need to be performed by all evaluators. Result shows that all of the significant value is 0.00. This indicates that Test1 and Test2 are not significantly different from the normal distribution based on statistics. Thus, non-parametric testing such as Wilcoxon Rank-Marked Test will be conducted.

The Wilcoxon Signed-Rank Test was chosen to make a comparison between Test1 and Test2. If a pair of scores has the same value, then it is considered bound and dropped from the analysis and the sample size will be reduced taking into account the value of  $P < 0.05$  is considered significant. For this study, the Wilcoxon Rank-Marked Test was used to compare scores from two tests performed at two different time points.

The finding of MedWeb's for Rater1 and Rater2 from two weeks apart for Rater1 did not show a statistically significant change ( $p = .444, 0.71$ ) compared with alpha value = 0.05. For Rater3, it shows a statistically significant change ( $p = .036$ ) compared with alpha value = 0.05. For the OsteoAid, all raters did not show a statistically significant change ( $p = .545, .224, .932$ ) compared with alpha value = 0.05.

TABLE I. DEMOGRAPHIC RESULT

Item	Number
Total tibia examined	26
Total number of patients	13
Right tibia	13
Left tibia	13
Age	2-15
Gender (M/F)	5/8

TABLE II. NORMALITY TEST BY KOLMOGOROV-SMIRNOV

	Kolmogorov-Smirnov		
	Statistic	df	Sig
Test1	.111	234	.000
Test2	.090	234	.000

As shown in Table III, the finding of MedWeb's for Rater1 and Rater2 is there is no difference between Testing1 and Testing2 whereas for Rater3, there is a difference between Testing1 and Testing2. For the OsteoAid, the findings for each rater are there was no difference between Test1 and Test2. The factor that contributes to the difference between Testing1 and Testing2 for Rater3 was due to the factor of variability between users where this factor is out of control. Thus, the number of evaluators of three people has helped to reduce the biased results.

TABLE III. WILCOXON SIGNED-RANK TEST

Rater	MedWeb		OsteoAid	
	z value	p Value	z value	p Value
Rater1	-.765	.444	-.605	.545
Rater2	-1.806	.071	-1.217	.224
Rater3	-2.102	.036	-.086	.932

Z Asymp. Sig (2-tailed) at 0.05

Table IV shows the intra-rater result for each rater towards each software. For intra-raters, three raters would test two different software which is (a) MedWeb and (b) OsteoAid. Every rater had done the testing twice every fortnight. Meanwhile, the inter-rater testing was done by all three raters towards the two software. Through the statistics software package SPSS version 21 (SPSS Inc.), an estimation of ICC and Confidence interval (CI) of 95%, absolute-agreement and two-way mixed-method model were chosen.

Each rater scored excellent level: 0.989 (0.975-0.995), 0.982 (0.961-0.992) and 0.972 (0.938-0.987) respectively for MedWeb. As for OsteoAid, the scores were also excellent: 0.949 (0.882-.0978), 0.987 (0.970-0.994) and 0.986 (0.969-0.994) respectively. The finding from the usage of each software to get the CORA angles of the preoperative planning for osteotomy by all three raters is excellent.

The statistics for the inter-rater reliability between MedWeb and OsteoAid showed that the ICC of the latter is higher compared to the former. The ICC for OsteoAid is 0.979 while the ICC for MedWeb is at 0.820. Therefore, both figures can be accepted. OsteoAid method is in the range of good and acceptable reliability for preoperative planning of high tibial osteotomy.

TABLE IV. INTRA-CLASS CORRELATION FOR INTRA-RATERS

Rater	Correction Angle
Intra-rater 1(a)	0.989 (0.975-0.995)
Intra-rater 2(a)	0.982 (0.961-0.992)
Intra-rater 3(a)	0.972 (0.938-0.987)
Intra-rater 1(b)	0.949 (0.882-0.978)
Intra-rater 2(b)	0.987 (0.970-0.994)
Intra-rater 3(b)	0.986 (0.969-0.994)
Inter-rater (a)	0.820 (0.663-0.901)
Inter-rater (b)	0.979 (0.967-0.987)

Intra-rater 1 means ICC of rater 1 for first and second measurements. Intra-rater 2 means ICC of rater 2 for first and second measurements. Intra-rater 3 means ICC of rater 3 for first and second measurements. (a) refers to MedWeb, while (b) refer to OsteoAid. Inter-rater (a) means the ICC using MedWeb, between rater 1, 2 and 3. Inter-rater (b) means the ICC using OsteoAid between rater 1, 2 and 3.

## V. DISCUSSION

The most important finding of this study was that new software (OsteoAid) had a significant reliability in finding CORA's angle rather than current software (MedWeb). This study successfully compares measurement angles of digital radiographic images among two softwares. In addition, there was excellent intra- and inter-rater correlation.

Planning techniques need to be reliable [21]. This study was done because existing software can only perform one of the procedures at a time. It is difficult for surgeons to define the CORA and propose the correction angle at one time. Fig. 4 shows the CORA that was produced based on the intersection of two lines, and the correction angle is automatically displayed when the user rotates the line based on the desired location.

Other studies have discussed the preliminary planning of high tibial osteotomy [14], [22]. Based on different osteotomy problems, the need for planning also varies. For example, based on the difference of deformity whether genu varum, valgus or recurvatum, selection of frontal and sagittal planes, selection of mechanical or anatomical axis [22] in planning, open or close wedge, as well as CORA cuts are also different is based on the needs and determined by the surgeon himself. This study is reassuring concerning the reliability of preoperative planning, but it does not cover the reliability of intra- and post-operative.

Fig. 4. Finding CORA and Automatically Software will Define Correction Angle.

The outcome was that both current and newly developed software had outstanding reliabilities and consistency in finding CORA for preoperative planning open wedge high tibial osteotomy. In addition, the finding of this paper are comparable to that of Sivertsen [23] in their study comparing the correction angle between Dugdale and Miniaci method found that both Intra- and inter-rater reliability was excellent for the correction angle with 0.992 and 0.991 and 0.988 and 0.987 respectively. So et al [24] ICC for medial proximal tibial angle MPTA is 0.844 (0.774–0.892).

Schroter et al [25] conducted an ICC comparison between two software, namely PreOPlan and mediCAD with ICC values of 0.993 (0.990-0.995) and 0.995 (0.992-0.996) respectively on the wedge angle. Elson et al. [19] in turn compared the results obtained on digital planning using the Miniaci method where the ICC values for interrater 0.980–0.986 and intra-rater 0.968–0.985, respectively.

## VI. CONCLUSION

Preoperative planning for HTO has proven useful in producing the best decision needs to be taken in the surgery. However, manual procedures become obsolete and take time. We have developed a new digital preoperative planning for HTO to assist the developer to assist surgeon in their task. The digital method undertakes the manual procedure hence to reduce the time for decision making and giving the more effective way to provide a solution.

Based on the testing that has been done shows that the existing software also has similar results to the new software. This makes the new software can be adopted to conduct testing for future osteotomy prenatal planning as well as provide added value such as post-surgical expectation display and planning that can be repeated using fully digital. This finding also contributes in medical field especially in the digital preoperative planning of HTO.

The principal finding of this study is that, the new software OsteoAid method showed excellent reliabilities and good consistency in preoperative planning. This proves that all hypotheses have failed to reject the null hypothesis meaning to accept the hypotheses. Consequently, it shows the reliability of each rater for all tested software is zero. Thus, the use of the OsteoAid enables direct measurement of the angle measurement with high reliability.

There were various flaws in this study. The clinical results of patients after surgery were not studied, but that was not the study's major goal. The other limitation was this software is focusing on the HTO only. The future study should expand to other practices in orthopedics. It also should enhance 3D medical images in future.

## ACKNOWLEDGMENT

This research project was conducted in collaboration with Prof Dr Abdul Halim Abdul Rashid from the Department of Orthopaedic and Traumatology, Medical Centre of University Kebangsaan Malaysia. University Grants GP-2019-K007341.

Engineering, BNMIT, Bengaluru, Karnataka, India

**Abstract**—Plants need nutrients to develop normally. The essential nutrients like carbon, oxygen, and hydrogen are obtained from sunlight, air, and water to prepare food and plant growth. For healthy growth, plants also need macronutrients such as Potassium, Calcium, Nitrogen, Sulphur, Magnesium, and Phosphorus in relatively great quantities. When a plant doesn't find necessary nutrients for its growth inadequate amount, deficiency of plant nutrients occur. Plants exhibit various symptoms to indicate the deficiency. Automatic identification and differentiation of these deficiencies are very important in the greenhouse environment. Deep Neural Networks are extremely efficient in image categorization problems. In this work, we used the part of the pre-trained deep learning model i.e. Transfer Learning model to detect the nutrient stress in the plant. We compared three different architectures including Inception-V3, ResNet50, and VGG16 with two classifiers: RF and SVM to improve, classification accuracy. A total of 880 images of Calcium and Magnesium deficiencies in the Tomato plant from the greenhouse were collected to form a dataset. For training, 704(80%) images are used and for testing, 176(20%) images are used to examine the model performance. Experimental results demonstrated that the largest accuracy of 99.14% has resulted for the VGG16 model with SVM classifier and 98.71% for Inception-V3 with Random Forest Classifier. For a batch size of 8 and epochs equal to 10, the Inception -V3 architecture attained the highest validation accuracy of 99.99% and the least validation loss of 0.0000384 on an average.

**Keywords**—Nutrient deficiency; plant nutrients; deep neural networks; transfer learning; random forest (RF); support vector machine (SVM)

## I. INTRODUCTION

A proper combination of nutrients is required for plants to live, develop and reproduce. So, plant analysis is a necessary tool that assists farmers by providing significant information about the nutritional description of the growing plant to obtain a better yield. Generally, plant analysis indicates the analysis of magnesium (Mg), sulphur (S), phosphorous (P), calcium (Ca), nitrogen (N), potassium (K), etc. Normally, plants show signs of being unhealthy when they suffer from undernutrition. For example, yellow around the edges of its leaves are a sign of magnesium deficiency. Yellow spots between the leaf veins and Blossom End Root denote the absence of calcium. Brown edges along the plant leaves indicate a deficiency of potassium. Yellow or pale green leaves imply the need for nitrogen [1]. These nutrient deficiency symptoms will help growers to identify the nutrient status of plants for a better crop yield. Manually diagnosing these deficiencies is a difficult task. So,

the key objective of this work is to automate the identification of nutrient deficiencies in plants using Convolutional Neural Networks (CNN).

Artificial Intelligence has numerous applications in multiple industries, healthcare, environment, finance, education, agriculture, etc. to solve complex problems and make our daily life more secure and fast.

G. Madhulatha et al. [2] proposed an automatic plant disease detection on the plant leaves to decrease crop loss and increase productivity. Plant diseases are predicted and classified with 96.50% accuracy based on visual symptoms using deep CNN. The authors used a dataset from the "Plant-Village" dataset for plant leaf diseases. The model was pre-trained using AlexNet. Muhammad Hammad Saleem et al. [3] developed three Deep Learning meta-architectures namely; Faster Region-based Convolutional Neural Network (RCNN), Single Shot MultiBoX Detector (SSD), and Region-based Fully Convolutional Networks (RFCN) to recognize plant disease and healthy leaves. All three models include a feature extractor and a base network. This research used Gradient Descent with its Momentum version, Adaptive Moment Estimation (Adam), and Root Mean Square Propagation (RMSProp) optimization algorithms to increase the performance of the Deep Learning meta-architectures. The authors examined that all the Deep Learning meta-architectures needed 126 epochs (200,000 iterations) for training convergence. When the SSD model was trained using Adam optimizer, the maximum means Average Precision (mAP) of 73.07% was obtained. Guan Wang et al. [4] suggested a deep learning model for control plant disease application. The authors used the apple leaf black rot images produced by the fungus Botryosphaeria obtuse from the PlantVillage dataset for disease severity classification. The highest overall accuracy of 90.4% was obtained for the VGG16 model. Sharada P. Mohanty et al. [5] established a smartphone-assisted application to detect the disease using a deep convolutional neural network. In this research, GoogLeNet architecture performs better and provides 99.35% accuracy as compared to AlexNet architecture. The presently available deep learning methods to identify the plant disease were reviewed by M. Nagaraju and Priyanka Chawla [6].

Many previous works have considered Image Recognition and Machine Learning models to classify the images into healthy and unhealthy images. However, most of these algorithms require image segmentation and feature extraction. But, from the many extracted features, it is difficult to judge

the important and dominant features for plant disease detection. Moreover, under difficult background circumstances, many techniques fail to successfully segment the leaf and will lead to unreliable deficiency recognition. So, image segmentation and feature extraction are still challenging tasks. Therefore, automatic plant disease detection and nutrient deficiency recognition are still challenging tasks. Recently, Convolutional Neural Network (CNN) is becoming the preferred scheme to overcome few challenges.

The main objective of this research is to diagnose nutrient deficiency in plants and take several measures like adjusting the pH value of water to achieve a quality yield, providing the right amount of fertilizer, etc. using deep learning models. For nutrient deficiency classification, we employed the Transfer Learning method, where pre-trained models are used as the entry point to develop the neural network models. In this research, we have used these models to predict Calcium (Ca) and Magnesium (Mg) deficiency in tomato crops grown under a greenhouse environment.

The key advantage of transfer learning is that instead of beginning the learning process from the scratch, the model commences from the characteristics that have been educated when resolving other problems which are analogous to the one being resolved. We have used three pre-trained models- InceptionV3, VGG16, and ResNet50 as a base model and SVM or Random Forest classifier on top of it to attain better results.

The rest of this paper is structured in the following fashion. Section II introduces the images collected to form the dataset of Ca and Mg deficiencies followed by related concepts. This section also presents Inception V3, ResNet50, and VGG16 architectures, and the proposed model to identify and classify the deficiencies. Section III dedicated to the evaluation, and the comparative analysis of results obtained in this experiment. In Section IV, the paper is summarized and future work is mentioned.

## II. MATERIALS AND METHODS

### A. Data Acquisition

Tomato plants were grown in a greenhouse of a size 10x4 sq.ft. to study and gather the dataset for lack of nutrients in tomato leaves and fruits. The calcium and magnesium deficiencies were induced for the plants in different stages and their images were captured from the camera for training and testing the performance of the model. The dataset was developed with two classes for classification and prediction: Calcium and Magnesium. Altogether, there are 880 images in the dataset. Out of 880 images, 704 (80%) images are for training the model, and 176 (20%) images are for testing the model. There are 374 calcium deficiency and 330 magnesium deficiency images in the training dataset. Further, out of 176 testing images, 94 images are of calcium, and the remaining 82 images are of magnesium deficiency images. To enhance the dataset, the data augmentation methods including image resizing, flipping, random rotation, shearing, etc., are applied. The details of calcium and magnesium nutrient deficiency symptoms in tomatoes are presented in Table I. 256 x 256

pixels is the size of all the resized images. These sample images are input to the convolutional neural network for training the model. The trained model is applied for the class prediction of unseen images. These phases are explained in detail in the following sections. Machine learning algorithms including SVM, Decision-Tree and, RF are excellent in resolving classification problems [10]. However, they go wrong in extracting the proper features from the image. Alternatively, Convolutional Neural Networks receives the raw pixel of the images directly as inputs instead of extracting certain features manually [12-14]. CNN learns how to take out these features from the actual image.

### B. Convolutional Neural Networks

CNN's are a class of Deep Neural Networks that can identify and categorize specific features in images and are generally used for examining visual images. Significantly, CNN can yield good results than the traditional feature extraction algorithms in plant disease diagnosis [15-18]. In CNN, the filters are learnable. A classic CNN consists of two components: The Convolution Block and the Fully Connected block, which are detailed as follows.

TABLE I. CALCIUM AND MAGNESIUM NUTRIENT DEFICIENCY SYMPTOMS IN TOMATO

Nutrients	Description	Deficiency Symptoms on Leaf/ Fruit
Calcium (Ca)	Young leaves curl inwards and cause dry decaying areas at Blossom End of the fruit (BER) in Tomatoes.	
Magnesium (Mg)	Interveinal chlorosis (Veins of Leaf remains green whereas the areas between the leaves go yellow). Elder leaves drip their color excluding in the veins. It does not affect the fruit.	

### C. Convolutional Neural Networks

CNN's are a class of Deep Neural Networks that can identify and categorize specific features in images and are generally used for examining visual images. Significantly, CNN can yield good results than the traditional feature extraction algorithms in plant disease diagnosis [9, 11]. In CNN, the filters are learnable. A classic CNN consists of two components: The Convolution Block and the Fully Connected block, which are detailed as follows.

1) *Convolution block*: The convolution block contains the Convolution Layer and the Pooling Layer. In this block, the task of feature extraction is accomplished. The convolutional layer produces the feature maps or activation maps by applying filters to input images using the ReLU activation function. The ReLU function returns  $x$  for all the values of  $x > 0$ , and returns 0 for all values of  $x \leq 0$  and is given in equation 1.

$$F(x) = \max(0, x) \quad (1)$$

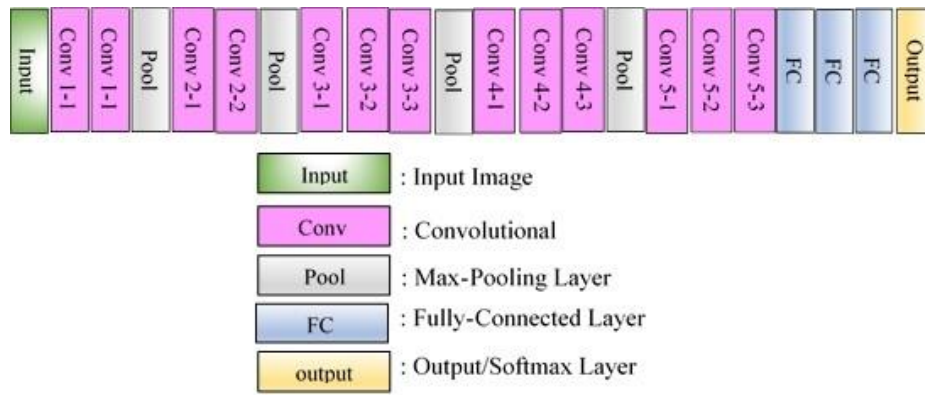

Fig. 1. VGG16 Architecture

Fig. 1. VGG16 Architecture.

The convolutional layer uses filters kernels to recognize various features like edges, horizontal lines, vertical lines, etc., in an image. To extract more composite and thoughtful features, the same size convolution kernel is used again and again multiple times. The pooling layer is enforced next to a convolution layer in which a down sampling operation is performed on a convolved feature to scale down the number of dimensions of the feature map. Commonly, the average and maximum values are selected by the pooling layer for this task.

2) *Fully connected block*: The Fully Connected block comprises of fully connected simple neural network design which does classification depending on convolutional block inputs. Convolutional Neural Network has one or more fully connected layers at the end of it. At the end of the fully connected layer, there is a softmax activation function whose output is a probability (from 0 to 1) for every classification label.

#### D. VGG16 Model Architecture

VGG is a pre-trained model and has 138 Million parameters. VGG is trained over 14 million images belonging to 1000 classes and learned to detect generic features from images. There are 16 and 19 weight layers in the network for VGG-16 and VGG-19 respectively.

This research work uses VGG-16 as the base model and altered it to create a different network. As VGG16 attains 92.7% test accuracy in ImageNet, and because of its high performance, the pre-trained weights are retained and only the top three Fully Connected Layers or Dense Layers are modified to fine-tune the neural network. In this work, the features extracted from VGG16 are given as input to RF or SVM Classifiers to reduce the training time and increase the classification accuracy. Fig. 1 describes the VGG16 scheme. All the resized images in this model are of fixed size 244x244.

The VGG16 model used NVIDIA Titan Black GPUs and was trained for weeks. The VGG16 model can categorise the images into 1000 classes. The VGG model handles the input image and yields the vector of 2 values.  $y^\wedge$  denotes the probability of classification for the corresponding class and is given by equation 2.

$$y^\wedge = \begin{bmatrix} y_0^\wedge \\ y_1^\wedge \end{bmatrix} \quad (2)$$

Where,  $y_0^\wedge$  represents the probability with which class 0 (Ca) is predicted and  $y_1^\wedge$  represents the probability with which class 1(Mg) is predicted. The RGB image of constant size 224x224 is the input to the conv1 layer. The image is moved through several convolutional layers. Each layer uses a small 3x3 or 1x1 filter. Five max-pooling layers perform spatial pooling. A 2x2 pixel window with a stride of 2 is used to implement max-pooling. There are three Fully-Connected (FC) layers where there are 4096 channels in each of the first two layers and the third layer comprises 1000 channels. The softmax layer is the terminating layer. All networks have a similar configuration of the fully connected layers. A non-linear ReLU activation function is used by all hidden layers.

#### E. Inception-V3 Model Architecture

Inception-V3 is the most generally used CNN architecture and achieved more than 78.1% accuracy for image prediction on the ImageNet dataset. The model comprises Convolution Layers, Max pooling Layers, Average pooling Layers, Concat Layers, Dropout Layers, and Fully Connected Layers. In Inception V3, the resized images are of size 299x299x3 pixels. The structure of Inception-V3 is analogous to Inception-V2 with few modifications including Label Smoothing Regularization, Batch normalization, Auxiliary Classifier. Use of Factorized 7x7 convolutions. Inception-V3 is a CNN with 48 layers in depth. The inception model is a concatenation of parallel convolution layers with 1x1, 3x3, 5x5, etc. sized filters and a max pooling layers of 3x3 matrix. The error rate improved to 0.2 % by adding label smoothing in Inception-V3 architecture. Fig. 2 describes the Inception-V3 scheme.

Inception-V3 model used RMSProp optimizer that offered significant results in connection with accuracy and time to achieve it. RMSProp is fixed as a default optimizer. The update dynamics in the Inception-V3 model are given by equation 2 and equation 3.

$$g_{k+1}^{-2} = \alpha g_k^{-2} + (1 - \alpha) g_k^2 \quad (3)$$

$$w_{k+1} = \beta w_k + \frac{\eta}{\sqrt{g_{k+1}^{-2} + \epsilon}} \nabla f(w_k) \quad (4)$$

Fig. 2. Inception V3 Architecture.

Where,  $g_k$  is gradient descent at time  $k$ ,  $g_{k+1}$  is gradient descent at time  $k+1$ ,  $w_k$  is the weight at time  $k$ ,  $w_{k+1}$  is the updated weight at the time  $k+1$ , ' $\alpha$ ' is the step size, ' $\beta$ ' is known as momentum and ' $\epsilon$ ' is small positive constant to avoid division by zero in implementation, ' $\nabla$ ' is the gradient, which is taken of  $f$ , ' $\eta$ ' is learning rate.

In RMSProp, the parameters ' $\alpha$ ', ' $\beta$ ', and ' $\epsilon$ ' are set as decay  $\alpha = 0.9$ , momentum  $\beta = 0.9$ , and  $\epsilon = 1.0$

#### F. ResNet50 Model Architecture

ResNet (Residual Network) is presented by Kaiming He, Xiangyu Zhang, Shaoqing Ren, and Jian Sun in 2015 in their paper "Deep Residual Learning for Image Recognition". The development of ResNet improved the problem of training deep neural networks. The simple element in ResNet is as depicted in Fig. 3. In the Residual network, there is a straight connection called 'skip connection' which skips some in between layers.

The 'skip connection' is used to resolve the vanishing gradient problem and to learn the identity functions. The output  $H(X)$  with the introduction of skip connection is given by the equation  $H(X) = F(X) + X$ . Table III shows the elements of the ResNet50 model. The ResNet model was tested on the ImageNet set and attained a 20.47% top-1 error rate also 5.25% top-5 error rate.

The proposed model used these transfer learning techniques for feature extraction and altered their basic structures by adding Random Forest or SVM classifiers to improve the classification ability of the models as illustrated in Fig. 4.

Fig. 3. A Basic Residual Network.

Fig. 4. Proposed Model.

### III. EXPERIMENTAL RESULTS AND ANALYSIS

In this work, image pre-processing techniques, data augmentation, and implementation of Convolutional Neural Network algorithms were conducted using Jupyter notebook(Python 3.9), Keras API, OpenCV library, Matplotlib visualization library, OS module, glob module, and so on. The hardware specifications in this experiment to train and test our model includes Intel(R) Core (TM) i7-4210U CPU, 4.00 GB RAM. In this experiment, the CNN is developed using InceptionV3, ResNet50, and VGG16 Transfer Learning Models.

All three models used pre-trained weights from the ImageNet dataset by eliminating the upper layer and redefining a fresh fully connected Softmax layer with 2 classes for classification [7, 8]. In this experiment, the batch size was fixed to 8 and the number of epochs was set to 10 with Adam optimizer. The features extracted from the Transfer Learning technique were used by SVM and Random-Forest classifiers. 80% of the total images were used to form a training dataset to train the model and 20% were used to form a testing dataset. For the Inception-V3 model, all the images were resized to 299x299x3, the input image size for ResNet-50 and VGG16 was 224x224. Inception V3 attained the validation accuracy of 99.99 % and the validation loss of 0.0000384 as depicted in Table II out of the three models.

The accuracy and loss obtained from three different Transfer Learning models are presented in Fig. 5 to 7.

TABLE II. ACCURACY AND LOSS OF DIFFERENT TRANSFER LEARNING MODELS AFTER 5 AND 10 EPOCHS

Transfer Learning Model	Training Accuracy (%)		Validation Accuracy (%)		Training Loss		Validation Loss	
	5 Epochs	10 Epochs	5 Epochs	10 Epochs	5 Epochs	10 Epochs	5 Epochs	10 Epochs
Inception V3	99.23	100	98	99.99	0.1364	0.000264	0.3685	0.0000384
ResNet-50	89.40	82.28	87.00	82.10	0.2632	0.5541	0.2568	0.4783
VGG16	100	100	98.86	98.86	0.000001	0	0.3572	0.2220

Fig. 5. Inception V3: Accuracy and Loss Model.

Fig. 6. ResNet50: Accuracy and Loss Model.

Fig. 7. VGG16: Accuracy and Loss Model.

Fig. 8 to 10 represents the confusion matrix of plant nutrient deficiencies identification using three Transfer Learning models with RF and SVM classifiers. The classification accuracy chart of plant nutrient deficiency identification in tomato plants using Transfer Learning models with Random Forest and SVM classifiers is presented in Fig. 11. It is noticed from the chart that the largest accuracy of 99.14% has resulted using the VGG16 model with SVM classifier and 98.71% for Inception-V3 with Random Forest Classifier.

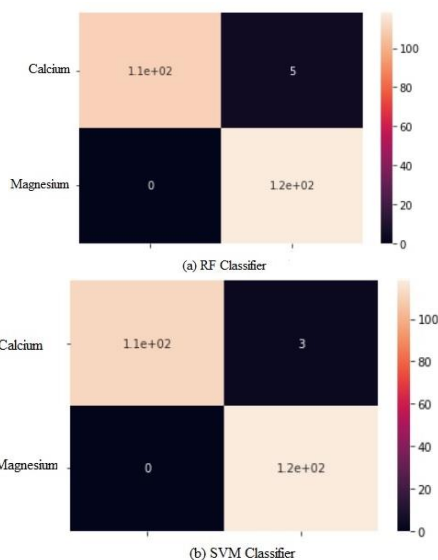

Fig. 8. Confusion Matrix using Inception V3.

Fig. 9. Confusion Matrix using ResNet50.

Fig. 10. Confusion Matrix using VGG16.

The results of lack of nutrients predicted from three different models with RF and SVM classifiers on few samples are displayed in Fig. 12. From Table II, it can be observed that almost calcium and magnesium deficiencies were detected properly by all three Transfer Learning models with RF and SVM classifiers. The average classification accuracy is high for InceptionV3 and VGG16 models in various experiments. These models could be extended for the identification of other nutrient deficiencies.

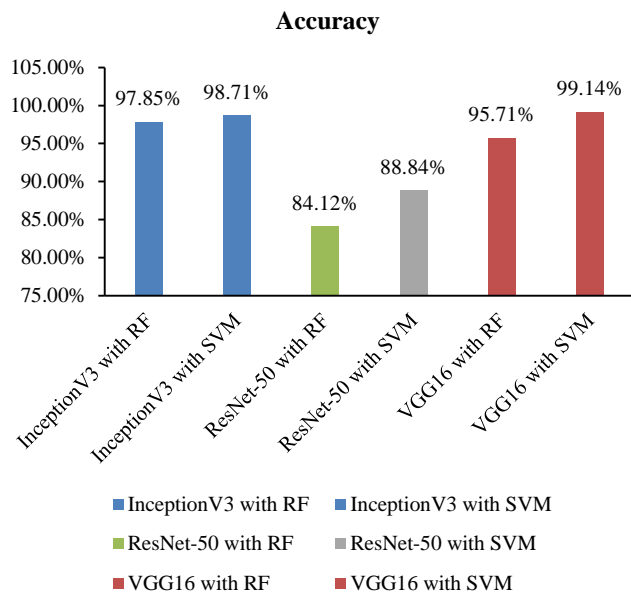

Fig. 11. Comparison Efficiency for Transfer Learning Models with RF and SVM Classifiers.

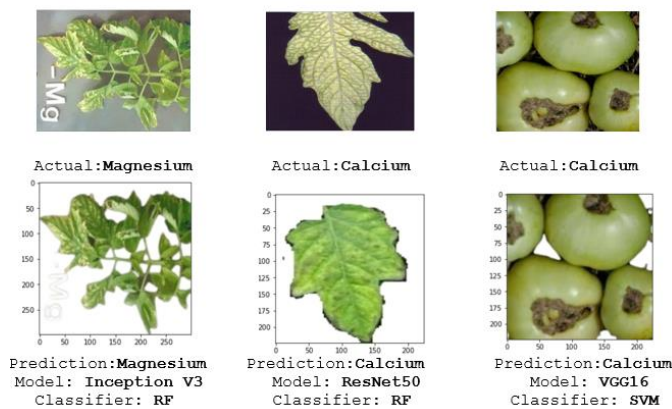

Fig. 12. The Predicted Samples of Plant Nutrient Deficiency Images.

#### IV. CONCLUSION

Quick identification of plant nutrient deficiency is necessary for a greenhouse environment. Manual inspection of these deficiency symptoms in a large greenhouse requires more effort. Consequently, automated plant nutrient deficiency diagnosis is required in greenhouse technology. With technology growth, a CNN using Transfer Learning models such as Inception V3, ResNet50, and VGG16 were proposed along with Random Forest (RF) and SVM classifiers to improve the efficiency. These models are pre-trained on ImageNet dataset and are modified for our tomato dataset with images of calcium and magnesium deficiencies in this research. On average, out of all the three Transfer Learning techniques, Inception V3 attained the highest validation accuracy of 99.99 % and the least validation loss of 0.0000384 for 10 epochs. Further, when the experiment was conducted for Random Forest (RF) and SVM classifiers, results show that the largest accuracy of 99.14% has resulted using the VGG16 model with

SVM classifier and 98.71% for InceptionV3 with Random Forest Classifier.

To control these plant nutrient deficiencies, the tomato greenhouse environmental factors such as humidity, temperature, pH, and soil moisture need to be monitored to find out the right quantity of fertilizer to be applied. Hence, in the future, this work can be improved by monitoring the greenhouse parameters by Wireless Sensor Network (WSN) to apply fertilizer precisely in a greenhouse.

#### ACKNOWLEDGMENT

We extend our heartfelt gratitude to the management of the BNM Institute of Technology, Bengaluru for providing us with all the necessary sources to accomplish this work and all the support to do the subsequent publications. We are also grateful to Visvesvaraya Technological University for giving us an appropriate platform to complete this research.

**Abstract**—Although biometric technologies have revolutionized the world of communication and dematerialized exchanges, authentication by biometrics still has many limitations, particularly in terms of privacy concerns, due to the various potential threats to which biometric templates are subject. The existence of these vulnerabilities has created an enormous need for biometric data protection. Indeed, several protection schemes have been proposed, which are normally supposed to offer certain guarantees, including the confidentiality of the collected personal data and the reliability of the recognition system. The challenge for all these techniques is to achieve a trade-off between performance accuracy and robustness against vulnerabilities, which is not always obvious. In this paper, we propose a theoretical protection model dedicated to biometric authentication systems. The objective is to ensure a high level of security for the stored reference data in such a way that it complies with the non-invertibility and revocability properties. The main idea is to incorporate a discretization tool, namely the spread spectrum technology and in particular the Code Division Multiple Access (CDMA), into a biometric system based on Random Projection. We introduce and demonstrate the proposed scheme as a non-invertible transform, while proving its effectiveness and ability to meet the requirements of revocability and unlinkability.

**Keywords**—Biometric template; security; authentication; CDMA; random projection

## I. INTRODUCTION

In a society where the risk of fraud continues to increase, the security of individuals within authentication systems has become a major concern. Despite the development in this sector, which has experienced a qualitative leap in terms of surveillance and access control, the traditional authentication systems, namely those based on knowledge (use of passwords) or possession (use of badges and keys) are ineffective against attacks of fraud and identity theft. Over the years, this kind of system has shown great weaknesses because of its inability to differentiate between an authorized person and an impostor who fraudulently acquires knowledge of the authorized person. Thus, the use of an authentication system that was both efficient and secure was essential, hence the emergence of biometric authentication.

In just a few years, biometrics has become the only way for authentication to guarantee rigorous access control since it is based primarily on the morphological and behavioral aspects specific to each person. Indeed, biometric systems exploit the physical characteristics (such as fingerprints, face, iris, etc.) or the behavioral aspects (such as voice, writing, the rhythm of typing on a keyboard, etc.) to construct an identity representing

an individual. Commonly called modalities, these biometric identifiers are often universal, unique to each person, and permanent in time [1]. Moreover, they ensure great robustness since it is very difficult for them to be lost, forgotten, stolen, copied, or falsified. The main objective of biometrics is to provide a more secure alternative to traditional access control systems, in the sense that it avoids the use of a large number of complex passwords, concerns about loss, theft and other falsifications of keys [2].

Although biometric authentication systems provide a much higher level of security compared to traditional systems, they are not safe from tampering. The use of this kind of system has given rise to new challenges related to the protection of biometric data [3]. Biometric information is generally considered sensitive since it is specific to each individual, and through which it can identify the owner. The inappropriate use of biometrics may involve risks to respect for fundamental rights and freedoms. Some risks of privacy violation are presented as follows:

- **Absence of secrecy:** Biometric data can expose very sensitive information, simply because the data are publicly available, so they can serve as a basis for unjustified discrimination.
- **Traceability:** the tracking and monitoring of an individual identified by the same biometric data across different databases, to perform profiling of the user.
- **Irrevocability:** In case of a compromise of the reference biometric template, it is impossible to revoke it because of its uniqueness.
- **Function creep / Misuse:** extending a specific use of the biometric identifier for another unintended or unauthorized use.

The issue of preserving biometric data deserves special attention to ensure respect for privacy when using biometric data. It should be noted that despite the advantage of biometric features being virtually impossible to steal, and difficult to guess by a tier, biometric systems are still vulnerable to attacks that target this kind of system [4]. Indeed, any component of the biometric system may be susceptible to a specific attack: the sensor, the feature extractor, the biometric reference templates stored and the final decision [5, 6]. The storage and security of reference data remain among the most crucial issues for a biometric system, as it can lead to serious security and invasion problems compared to other modules such as:

- The handling sensitive information.
- The regeneration of the original biometrics from the stored template.
- The construction of a falsified biometric sample.
- The secondary use of biometric information (surveillance, discrimination, etc.).
- The inability to revoke the biometric identifier when identity theft occurred.

These tasks require imperative attention, especially in the absence and necessity of an effective protection mechanism based on biometric templates. This has undoubtedly motivated us to multiply our thoughts on this point. The challenge is to design, implement and use a cancellable biometric system that improves authentication services without unduly compromising privacy.

Each protection approach for biometric templates must be designed with strong security analysis while taking into account the scenarios where the risk of fraud threatens the stored templates, and must also offer the possibility of revoking a biometric data set in the case of interception [7]. As specified by Jain et al. [3], template protection techniques are generally divided into two families: (i) Feature Transformation and (ii) Biometric Cryptosystem. The common feature of these methods is that they do not directly store the raw biometric data in databases, but rather they are either stored on an external medium or stored after an alteration due to a transformation function.

The principle of feature transformation approach [3, 8] consists in transforming the original biometric template  $X$  by using a function  $\mathfrak{F}$  which depends on a random data  $K$ . This specific information that should normally be secret is assigned to each legitimate user of the system. Thereafter, only the transformed template  $\mathfrak{F}(X, K)$  will be stored. At authentication, the query features  $X'$  will be transformed in the same way using the same transformation function  $\mathfrak{F}$ , then is directly matched with the reference template. Authentication will succeed if  $\mathfrak{F}(X', K)$  is sufficiently close to  $\mathfrak{F}(X, K)$  using some measures of similarity. To guarantee the notion of revocability in case of compromise of the transformed data, it is sufficient to change the parameters of the transformation function, and this is done by directly replacing the user key  $K$ , the reason for which biometric transformations generally use secret data in addition to the original biometric data [9, 10]. The choice of the transformation function remains the paramount element in the design of a protection approach belonging to this category. The function used can be either invertible in case of *Salting*, where security is relative to the knowledge of the transformation parameters [11], or is non-invertible when a one-way function is applied to the template [12, 13], in this case, it is computationally infeasible to reconstruct the original template, even if the transformation parameters are known.

Biometric cryptosystems [14, 15] provide the means to adapt cryptographic protocols to biometric data which are very sensitive and intrinsically noisy. The use of this kind of system consists either in securing the cryptographic keys using the biometric features or else indirectly generating cryptographic

keys from biometric features. They are also based on user-linked help data extracted from the biometric feature vector, which is needed during matching to extract the cryptographic key from the query biometric features. The helper data is public information that should not, in any case, reveal any significant information about the original biometric template. Biometric cryptosystems in their turns can be classified into key generation schemes, where binary keys are directly created from the acquired biometrics, and key binding schemes, which store information obtained by combining biometric data with randomly generated keys.

All evoked protection schemes have their advantages and limitations in terms of performance, accuracy, and robustness, but generally do not yet respond effectively to all desired requirements. The difficulty is that the transformation is in most cases entirely or partially invertible. Moreover, the desired criterion of revocability is not obvious to achieve without creating other risks. This is why we are motivated to design a generic transformation, in which the protected reference templates will be easy to revoke, difficult to reverse, and will not degrade performance. In this paper, we present a demonstration of a new protection model for reference templates by adapting the security aspect of a multiplexing technique defined as spread spectrum called *Code Division Multiple Access (CDMA)* within a system based on random projection. The proposal aims to verify and prove the identity of an individual only through its provided identifier while ensuring agreement with the properties of revocability, unlinkability, and non-invertibility. This paper is organized as follows. Section 2 presents related works. Section 3 is devoted to preliminary knowledge. Section 4 describes in detail the steps required to build the templates. Analysis and discussion of the revocability, diversity, and non-invertibility requirements produced by our proposal are given in Section 5. Finally, Section 6 is dedicated to the conclusion and future work.

## II. RELATED WORK

In biometric protection schemes, privacy preservation is related to the protection of the biometric templates. Ideally, as defined in several references [16], these schemes are designed to meet the requirements of non-invertibility, unlinkability, and revocability. Among the solutions that have been proposed by the research community to further protect the biometric templates, we can quote:

Ratha et al. [17] have proposed an interesting solution. The main idea is to apply geometric transformations on the fingerprint minutiae representation. Three types of transformations have been tested: Cartesian, polar and functional. This solution offers great security, as it is difficult to recover the original minutiae representation from the transformed template. However, these transformations increase the rate of intra-class variations in the protected representation, which considerably degrades the performance.

Tulyakov et al. [18] made use of symmetric hash functions as means of protecting fingerprint templates. The hash functions were constructed from the minutiae locations, considering the random shifting of the minutiae during the acquisition phase. The security of the generated templates is improved in [19] using a combination of various hash functions. How-

ever, it seems that the enhanced approach also suffered from computational complexity.

Wang and Hu [20], proposed a non-invertible transformation that can be applied to vectors derived from pair-minutiae. The proposal is an infinite-to-one mapping approach which is able to generate revocable templates. The performance of the system is very promising except that the consistency of the user key matrix leads to certain storage problems.

Moujahdi et al. [21] have developed a protected fingerprint representation that relies on the distances between fingerprint global features (Singular points) and all other fingerprint minutiae. The principal is to build special spiral curves, which will represent the final protected template rather than the features of minutiae. The accuracy performance is supposed to be maintained, however, The risk is that when a fingerprint template is compromised, it may reveal the distances used to generate the protected template.

There are a variety of other methods in this context, many of which are recent [22, 23].

### III. PRELIMINARY KNOWLEDGE

In this section, we focus on the main pillars on which our approach is based. For this, we will detail both *Random projection* and *CDMA*.

#### A. Random Projection

*Random Projection* is a technique that allows in a way to hide data in a certain space, it is considered in several works [24, 25, 26] as one of the most secure transformations concerning biometric template protection [27], as it ensures unlinkability and revocability. The principle of *Random projection* is to project a data vector  $X \in \mathbb{R}^n$  onto a random matrix  $R$ , to generate a vector  $M \in \mathbb{R}^m$  of reduced dimension  $m < n$  (from the product  $M = RX$ ). In biometry, the utility of such a projection depends on whether the distances between the different feature vectors of the same user will be preserved or not. For that purpose, S. Kaski [28] has proved that if the matrix  $R$  is orthonormal then the similarity between vectors is preserved, and therefore the matrix  $R$  becomes a basis of projection. To get an orthonormal matrix, we have to go through the Gram-Schmidt process [29], which requires that the set of randomly generated vectors must be linearly independent.

According to the literature, the *Random projection* was always a basis for many approaches that deal with biometric template protection, specifically *BioHashing* [11] and *BioPhasor* [12] approaches. The use of such a technique was to produce transformed biometric data that may be used for authentication purposes, given that it provides an impressive diversification effect for biometric templates protection. Moreover, through the *Random projection*, we can also reinforce the property of non-invertibility using quantization. This step consists in transforming the result of the projection  $W = (w_1, \dots, w_m)$  to a vector with binary values, by using a one-way transformation such that the resulting transformed biometric data cannot be used to reveal the original biometric data. However, the quantization requires the definition of a threshold  $\tau_b$  for the

computation of the resulting vector  $B = (b_1, \dots, b_m)$ , from the following formula:

$$b_i = \begin{cases} 0 & \text{if } w_i \leq \tau_b \\ 1 & \text{if } w_i > \tau_b \end{cases} \quad (1)$$

Generally, the threshold  $\tau_b$  is chosen equal to zero as the results of the projection have the same probability of being negative or positive.

#### B. Code Division Multiple Access (CDMA)

*CDMA* is a multiplexing technique that is widely used in the radiofrequency domain, where it provides multiple access and resource sharing that is both flexible and secure [30]. This method of access is derived from the spread transmissions used in the context of military transmissions for many years, where their objective was to resist at best narrow-band interferers and to carry out discrete transmissions. Subsequently, this technique has seen a surprising emergence and a great evolution over the following years [31].

The principle of *CDMA* consists in transmitting a set of messages coming from several transmitters simultaneously on the same physical medium. On receiving, each recipient collects the received data and then tries to retrieve only the message originating from his corresponding transmitter, notably through a code that was allocated to him at the beginning of the communication. The use of spreading sequences as codes provides a way of distinguishing between the different given users. This makes the transmission less vulnerable to selective fluctuations in frequencies, and as well as a secure transmission [32]. This results in better management of available resources. It was thus stressed that the *CDMA* technique based on the use of orthogonal spreading sequences, was theoretically very satisfactory so that the different trains emitted by the users do not interfere with one another [30]. The generation of orthogonal codes is such a crucial step for resistance against interferences with multiple users. According to [33], there are two important properties of spreading sequences that must be respected: autocorrelation and cross-correlation. The autocorrelation property refers to the correlation between time-shifted versions of the same code while cross-correlation concerns if the codes which are used are completely orthogonal or not, if it was not the case, the different users are interferers to each other, hence the near-far problem appears. There are several code expansion techniques to generate orthogonal codes. Probably Hadamard transform [34] is the best-known technique. According to our reflection, we will adopt the same strategy as the *CDMA* by multiplexing all the reference templates in the same instance. During the authentication, the code corresponding to the user is calculated and then used to extract the specific reference template to perform the matching. We discuss the approach in detail in the following section.

### IV. THE PROPOSED APPROACH

In this section, we introduce a new protection scheme for the biometric template, which consists of applying a non-invertible transformation on the biometric features in order to generate a unique compact binary code. The secure transformation is based essentially on the principle of multiplexing provided by *CDMA* and the principle of *Random projection*.

Furthermore, we made sure during the design phase, that our approach meets the requirements of revocability, unlinkability, and non-invertibility. Generally, cancellable biometrics [35] is mainly based on two factors that must be presented at each authentication [36], namely the biometric trait and the seed (which can be seen as a secret key). The seed is a user-specific component through which the transformation of the original template is carried out, this element must indeed be secret and out of the way of impostors. For this reason, we have made sure that the transformation only relies on the biometric modality as [13] to avoid any vulnerabilities that may arise in case of seed theft [37]. So, to keep the seed secure and unknown to adversaries, we integrated its generation intuitively during template generation as shown in Fig. 1. In general, biometric systems consist of two main phases: 1) enrollment and 2) authentication (which can take the form of either identity verification or identification [20]). During Enrollment, the user biometric trait is captured (acquisition) and the features are extracted and stored in a database as a reference template. At authentication, the same biometric trait is captured again, the features are extracted and compared with those previously stored in the database for an eventual matching and then produce a decision (match/no match). In the following, we outline the stages that make up our processes.

#### A. Enrollment Stage

Our proposed protection scheme consists of two main steps:

- 1) Associate for each enrolled user a unique seed, through which we can always access the same projection space.
- 2) Projection of the extracted original biometric features onto a secure domain generated from the seed used in the previous step.

During processing, we used *CDMA* to discretize the seed associated with each user. As mentioned above, *CDMA* is a mechanism that requires the use of spreading sequences to avoid interferences. For this reason, our thinking has led us to apply the *QR decomposition*, which decomposes a matrix into two components  $Q$  and  $R$ , where  $R$  is an upper triangular matrix and  $Q$  is orthogonal with orthonormal columns  $Q^T \cdot Q = I$  (where  $I$  is the identity matrix). When the decomposed matrix is square, then firstly it will always have a decomposition and secondly  $Q$  will be orthogonal  $Q^T \cdot Q = Q \cdot Q^T = I$ . In our approach, this decomposition assumes an important part, not only in the generation of orthogonal sequences but also in linking each identity to a unique orthogonal code. All steps of the proposed revocable approach are described in the Algorithm 1.

The enrollment phase involves the storage of three elements, namely the matrix  $R$  from which the orthogonal code is recovered, the sum  $S$  relative to the *CDMA* technique, and finally the protected templates.

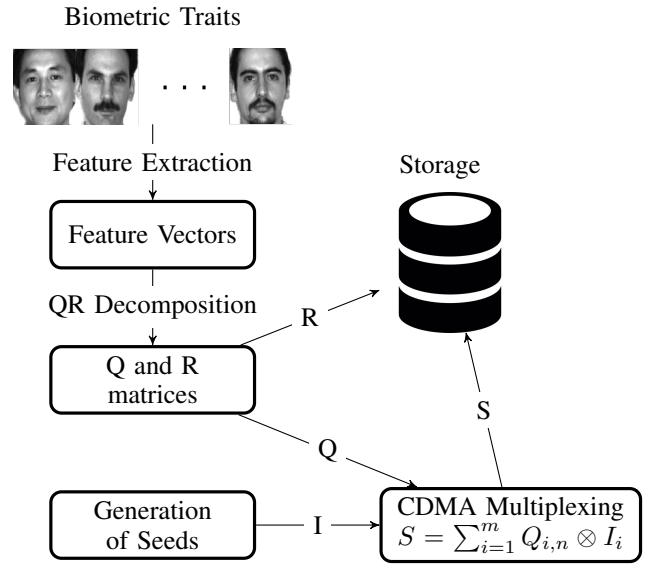

Fig. 1. Binding and Discretization of Seeds.

#### B. Authentication Stage

During the authentication phase, the system scans the biometric trait of the enrolled user  $k$ , hence the extraction of the feature vector  $V_k$ . Thereafter, the orthogonal code  $Q_k$  is recovered using the stored triangular matrix  $R$  according to the following formula:

$$Q_k = R^{-1} \cdot V_k \quad (4)$$

(It should be noted that making the matrix  $M$  squared during the enrollment phase, was very useful when selecting orthogonal sequences residing at the rows of the orthogonal matrix  $Q$ ). Then, the sum  $S$  is multiplied by the recovered orthogonal code  $Q_k$  to separate the seed  $I_k$  corresponding to the user  $k$ . Applying the same process of random projection during the enrollment phase, the protected template will thus be obtained. The system computes then the Hamming distance between the resulting template and the reference one stored in the database to either accept or reject the claimer. Concerning the determination of the threshold, it depends on the system design, and it is chosen such that the desired false rejection rate (FRR) and false acceptance rate (FAR) are satisfied.

#### V. ANALYSIS AND DISCUSSION

Our scheme is considered as a one-way function since it is computationally infeasible to reconstruct the original template starting from the stored elements. It is true that the sum  $S$  contains all the orthogonal codes and their associated seeds, but it is almost impossible to extract them in case of compromise. Even the knowledge of the triangular matrix  $R$  can not reveal the orthogonal codes  $Q_i$ , especially with the absence of the feature vectors, knowing that  $M = QR$ . So the security of our scheme is ensured as long as it is difficult to reverse the transformation to obtain the original biometric template. Furthermore, the scheme meets also the requirements of revocability and unlinkability, properties for which an ideal biometric template protection technique is founded. Thus, if a

---

**Algorithm 1** Stages of the enrollment phase

---

**Step 1.** Extraction of the biometric features vector  $x \in \mathbb{R}^n$  from a raw biometric image where  $n$  is the feature vector dimension.

**Step 2.** Assemble the set of feature vectors on a matrix  $M_{m \times n}$ , where  $m$  represents the user index during enrollment phase and  $n > m$ .

$$M_{m \times n} = \begin{pmatrix} x_{1,1} & x_{1,2} & \cdots & x_{1,n} \\ x_{2,1} & \ddots & & \vdots \\ \vdots & & \ddots & x_{m-1,n} \\ x_{m,1} & \cdots & x_{m,n-1} & x_{m,n} \end{pmatrix}$$

**Step 3.** Make  $M$  a square matrix by complementing it with random numbers in a way to avoid the case where  $\det(M) = 0$  (the order of the new matrix becomes  $n \times n$ ).

**Step 4.** Apply the *QR Decomposition* on the matrix  $M$ , which it can be expressed as  $M_{n \times n} = Q_{n \times n} R_{n \times n}$

**Step 5.** Generate for each identity a random vector representing the seed,  $\{I_k \mid k = 1, \dots, m\}$ .

**Step 6.** Application of *CDMA* combining all the generated seeds  $\{I_k \mid k = 1, \dots, m\}$  with the first  $m$  orthogonal sequences residing at the first  $m$  rows of the orthogonal matrix  $Q$  into a single data as :

$$S = \sum_{i=1}^m Q_{i,m} \otimes I_i \quad (2)$$

**Step 7.** Generate a set of pseudo-random vector,  $\{r_i \in \mathbb{R}^n \mid i = 1, \dots, m\}$  from each seed  $I_k$ , through a random number generator (RNG), in our case we used Blum-Blum-Shub [38].

**Step 8.** Apply the Gram-Schmidt process on the previous set of random vectors to get an orthonormal set of  $r$ ,  $\{or_i \in \mathbb{R}^n \mid i = 1, \dots, m\}$  thereby forming a projection base.

**Step 9.** Project each acquired biometric vector on its associated projection base, by computing the inner product of feature vecteur  $x \in \mathbb{R}^n$  and each orthonormal vector  $or_i$ , such that  $\langle x, or_i \rangle$ .

**Step 10.** Quantify the transformed template as follow:

$$b_i = \begin{cases} 0 & \text{if } \langle x, or_i \rangle \leq \tau \\ 1 & \text{if } \langle x, or_i \rangle > \tau \end{cases} \quad (3)$$

where  $\tau$  is a predefined threshold, and  $m$  is the dimension of the protected template.

---

stored template is compromised, it can be protected by using a new seed instead of the one corresponding to the identity of the compromised template. The revocation requires both the storage of a new protected template resulting from the use of the new seed and also the update of the stored sum  $S$  as:

$$S_{new} = S_{stored} - (Q_{identity} \otimes I_{old}) + (Q_{identity} \otimes I_{new}) \quad (5)$$

That is how we will be able to generate multiple protected templates for the same biometric identity by using different seeds, which ensures the unlinkability or diversity property. The advantage of the proposed technique lies not only in the fact that it is perfectly secure but also in that the scheme does

not require the repetition of the enrollment phase in case of a compromise of a protected biometric template.

On another hand, it should be noted that biometric identifiers are very sensitive and are affected by the variations that can occur during acquisition thus leading to a considerable degradation in accuracy performance [39]. This lack of accuracy is due to several factors: variability during capture (i.e. acquisition noise, use of multiple acquisition sensors, etc.), intra-class variability (variability of biometric data for an individual), and inter-class similarity (i.e., the similarity of biometric data for multiple individuals). The work we have proposed at this stage is dedicated to biometrics that represents high stability during the acquisition phase or non-biometric digital data to demonstrate the effectiveness of the provided discretization mechanism.

## VI. CONCLUSION AND FUTURE WORK

In this paper, we have proposed a new scheme for biometric template protection. We have indeed exploited the multiplexing property provided by the Code Division Multiple Access (CDMA) to generate a certain discretization for biometric templates as a non-invertible transformation in a system based on random projection. Our proposal is a kind of biometric protection approach, which only requires the user biometric identifier to perform the authentication of individuals. We have demonstrated that it meets the requirements of a revocable biometric system, namely, the properties of revocability, unlinkability, and non-invertibility. It must be mentioned that the nature and sensitivity of the biometrics have a crucial impact on performance preservation after the application of the non-invertible transformation. Through this work, our proposal has been proven to be effective for stable digital data. In this perspective, future work will focus on adapting sensitive biometrics and then evaluating them through experiments using public biometric databases, as well as a comparative study with some classical protection schemes in terms of revocability, unlinkability, non-invertibility, and accuracy performance.

**Abstract**—Cloud computing is becoming an essential part of computing, especially for enterprises. As the need for cloud computing increases, the need for cloud data privacy, confidentiality, and integrity are also becoming essential. Among potential solutions, homomorphic encryption can provide the needed privacy and confidentiality. Unlike traditional cryptosystem, homomorphic encryption allows computation delegation to the cloud provider while the data is in its encrypted form. Unfortunately, the solution is still lacking in data integrity. While on the cloud, there is a possibility that valid homomorphically encrypted data beings swapped with other valid homomorphically encrypted data. This paper proposes a verification scheme based on the modular residue to validate homomorphic encryption computation over integer finite field to be used in cloud computing so that data confidentiality, privacy, and data integrity can be enforced during an outsourced computation. The performance of the proposed scheme varied based on the underlying cryptosystems used. However, based on the tested cryptosystems, the scheme has 1.5% storage overhead and a computational overhead that can be configured to work below 1%. Such overhead is an acceptable trade-off for verifying cloud computation which is highly needed in cloud computing.

**Keywords**—Cloud computing; computation verification; data confidentiality; data integrity; data privacy; distributed processing; homomorphic encryption

## I. INTRODUCTION

The demanding needs of modern computing have prompted many enterprises to outsource their data solution to cloud service providers (CSP). CSP provides services that improve performance efficiency and ease of maintenance to the adopters. On top of the improvements, adopting cloud services also offers savings in information technology infrastructure costs, in which most of the infrastructure cost is transferred to the CSPs, and clients only pay for what are used. Thus, enterprises can conveniently store, maintain, and manage data files remotely with reduced operation costs [1]. The CSP market is currently brimming with CSPs and their innovative and competitive products. In general, the current success of cloud services is mostly on cloud storage. However, the market for cloud computing is also building up in momentum. Implementing cloud computing empowers enterprises to become more competitive by having computing platforms that are scalable, agile, and reliable. As a result, the growth in the cloud computing market is projected to reach US 623.3 billion by 2023 [2].

A typical cloud computing ecosystem consists of cloud users (client), CSP, and the network infrastructure that connects the client and the CSP. Models of CSP architecture consist of

software as a service, infrastructure as a service, and platform as a service. In addition, there are a few CSP designs that include private, public, hybrid, and community clouds [3].

Even though the outlook for cloud computing is positive, this technology is always being plagued with the trade-offs between cost and security. The issue lies in the principle of cloud computing, where enterprises need to delegate the task of protecting their data to CSP [4]. Subsequently, data sovereignty is lost once the data is stored in a remote CSP. This absence of control for data security presents data protection problems. According to the Cloud Security Alliance (CSA) analysis, for the third time in a row [5], [6], [7], data breaches topped the list of threats in the cloud. Data is considered breached once its information is disclosed, manipulated, or used by unauthorized parties. A data breach may be the primary goal of a targeted attack or merely the result of human error. However, the management of CSP is central, and it cannot guarantee the reliability of its employees [8]. [9] found that the occurrence of internal breaches is more serious and costly than foreign attacks. The reason behind this result is that insiders know the system and attack valuable information, while outsiders steal what they have access to [10].

As part of the security risk assessment, data privacy, confidentiality, and integrity must be considered to mitigate potential risks. Privacy refers to the access control that the clients have over their data. Confidentiality means only authorized parties can access the data. In comparison, data integrity refers to the assurance of data consistency over its entire life-cycle [11].

In order to ensure privacy and confidentiality in cloud computing, researchers have indicated that homomorphic encryption (HE) is one of the promising methods for remote manipulations over encrypted data [12], [13]. However, although HE makes computation delegation possible, it has security flaws that can affect the validity of outsourced calculations. Specifically, HE is malleable in nature, which makes it non-compliance to the indistinguishability under adaptive chosen-ciphertext attack (IND-CCA2) security notation [14]. Therefore, data integrity is at stake with only HE itself versus centralized cloud data management. For cloud computing, the threats to data integrity can be numerous and varied. This paper addresses the problem of data integrity verification (DIV) of CSP computations over homomorphically encrypted data. The focus of this paper is on the CSP behavior that stores and computes sensitive data. Specifically, the threats from the CSP can be enumerated as follows:

- 1) An attacker (CSP) violates the data integrity by directly substituting the given ciphertext with another valid ciphertext.
- 2) An attacker (CSP) maliciously substitutes a given computation query with another valid query.

Integer-based HE has been extensively researched and used. Therefore, this research aims to achieve the computational integrity of HE over an integer finite field. That contributes to strengthening the security of HE against data tampering and thus achieving privacy, confidentiality and integrity of the processed data.

The rest of the paper is organized as follows. Section II presents the current DIV methods with their limitations. Section III illustrates the candidate HE cryptosystems and presents the proposal scheme. The results and discussion are shown in Section IV. Finally, Section V provides the conclusion.

## II. RELATED WORK

Researchers are still looking for a comprehensive security solution that can bring cloud computing to the mainstream. HE with different approaches have been utilized to address the DIV problem. Classical auditing methods on single data copy had a broad resonance in addressing this problem, which represented by provable data possession (PDP) techniques [15], [16], [17], [18], [19], [20] and proving the possibility of retrieval (POR) techniques [21], [22], [23], [24], [25], [26], [27]. However, these methods are ineffective in the case of data loss or corruption on the servers. Another alternative is to archive multiple replicas of each file to use if the original copy has compromised, this model is known as data integrity auditing under distributed such as [28], [29], [30], [31].

As the previous schemes by their nature allow for a limited number of queries, there are proposing solutions [32], [33], [34], [35] that assign auditing tasks to a single third-party auditor (TPA) that independently manages the data audits. There are also works [36], [37], [38] where the auditing task is assigned to multiple TPAs to benefit from simultaneous synchronous audit sessions. Nevertheless, all the aforementioned schemes focus on checking the data integrity stored in cloud computing servers without verifying the validity and efficiency of CSP computations over the data.

In the field of verifiable computing, a variety of methods, including such [39], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50], [51]. [52] the basic of many variants of the verifiable computing proposal afterward, that developed based on fully homomorphic encryption (FHE). Although FHE appears theoretically ideal, it is inefficient for practical implementations due to the difficulty of the requirements of high storage usage and heavy overhead computing, therefore it is not very powerful for use in many power-limited devices. Likewise, these schemes [53], [51], [54], [55], [56], [57] proposed impractical methods based on FHE.

Otherwise, [46] presented a verifiable scheme that implements a commitment utilizing probabilistically checkable proofs. At the same time, [44] extended the scope of verifiable computation in two essential directions: public delegation and public verifiability. While [47] used a quadratic arithmetic

program and Elliptic curve encryption to obtain public verification commitment with a constant size however the number of executed operations. Also, [40] suggested a verifiable method of computations of quadratic polynomials over a large number of variables. Meanwhile, [45] tried to solve possible collusion attacks in the El-gamal scheme by re-encrypting the ciphertext using the receiver's public key. After that, [41] present a general Incremental verifiable database system by integrating the primitive vector commitment and the encrypted-then-incremental MAC encryption mode. And [48] suggested a framework using a hash function over ciphertext and dual-CSPs to check data duplication. [43] scheme promised an improved deduplication system in a hybrid cloud architecture. Furthermore [58] introduced the IKGSR scheme to improve the RSA key generation function based on the use of four giant prime numbers to generate encryption and decryption keys. In short, all of these proposals have the same framework idea of bounding the CSP generate a commitment, and accordingly, the client used this commitment to verify the CSP performance over his ciphertexts.

Whereas [50] proposed a public evaluation verification scheme over ciphertexts by interacting with the trusted authenticator (TA) and a public auditor proxy (PAP). Although they reduce the overload of both the cloud users and the verifier, it inefficient for practical applications due to using FHE's complicated scheme.

While numerous attempts have been made to overcome the CSP's computation cheating attack problems, they remain subject to certain fundamental flaws. First of all, most of the previous works are constructed for particular structures and cannot be included in other environments. This means that even a minor alteration can cause the schemes to fail due to their particular layouts. Furthermore, all the proposed models believe in the centralization of the CSP's authority or any third party over the data. As CSP can manipulate the computations applied to the data, it can generate the commitment value to match the applied computations. Thus, the client still receives an adequate commitment to computed ciphertexts, while the CSP perform the computation fraud attack.

In different ways, some researchers, such as [11] and [4], sought to use blockchain technology to prove the work of cloud service providers on cloud data. [11] relied on fiat cryptocurrencies such as Bitcoin and Ethereum to store the hash of the database issued by at least four cloud service providers and compare all the issued results. [4] used the proof of work consensus to delay the creation of a new record in the database to 6 minutes to create a single record as a minimum.

Despite the security effectiveness of the proposed schemes, they are pretty expensive; i.e. in addition to the cost of the required computations, blockchain implementation costs will be added as additional costs that clients will have to pay. Moreover, adopting the Byzantines Fault Tolerance consensus for both proposals would at least quadruple both costs. Also, using proof of work consensus in scheme [4] will impact cloud computing business performance. Therefore, our proposal will be based on modular arithmetic to provide a verification mechanism for the processes applied to the data at the lowest costs. Furthermore, the use of modular arithmetic dramatically increases digital signal processing performance in algorithms with extensive use of addition and multiplication. Thus, it

provides speed and low energy consumption and promises high reliability and fault tolerance [59], [60], [61]. The analysis of the latest scientific papers [62], [63], [64], [65], [66] confirms that the use of modular computation is continuously expanding. They ascribe that to the modular arithmetic's ability to increase the reliability of monitoring systems and their tolerance of errors significantly by increasing the resources used while preserving the operating time. As a result, many major companies such as Cisco and Kabushiki Kaisha Toshiba are rushing to research and apply modular arithmetic [67].

### III. VERIFICATION SCHEME DESIGN

The migration of sensitive data into CSP is a source of security issues. If sensitive data are migrated into CSP, the client must be assured that proper data security measurements are in place. In order to ensure data privacy and confidentiality, this paper assumes the use of HE. Subsequently, this section presents the proposed scheme which enables the client to verify the integrity of the applied computations over the encrypted data. Fig. 1 shows the flow diagram of the proposed scheme.

#### A. Scheme Preliminaries

This paper proposes the use of HE over  $\mathbb{Z}_p^*$  in encrypting the data before sending them to CSP, thus allows CSP to perform operations on the encrypted data at the client's request, without disclosing its content. In the context of this paper, the HE is briefly defined as follows. An HE over operation ' $\diamond$ ' in a finite field  $\mathbb{Z}_p^*$  is an encryption scheme that supports the following equation:

$$Enc_{k_e}(m_1) \diamond Enc_{k_e}(m_2) = Enc_{k_e}(m_1 \diamond m_2), \quad \forall m_1, m_2 \in \mathbb{Z}_p^*, \quad (1)$$

where  $Enc(\cdot)$  is an encryption algorithm,  $k_e$  is the encryption key and  $(m_1, m_2)$  are plaintexts. An HE scheme is primarily characterized by four operations: KeyGen, Enc, Dec, and Eval. Eval is an HE-specific operation, which takes ciphertexts as input and outputs a ciphertext corresponding to the plaintexts [68]. The Eval function in this paper supports both addition and multiplication operations over  $\mathbb{Z}_p^*$ . Table I summarizes the math notations used in this article. Depending on the supported homomorphism features, HE schemes can perform different type of operations. At any given time, the Partial Homomorphic Encryption (PHE) scheme can only perform one type of computation operation. It can be either a multiplicative homomorphism; e.g. RSA [69], and ElGamal [70], or additive homomorphism; e.g. Benaloh [71], Paillier [72], and Okamoto-Uchiyama (OU) [73]. While Somewhat Homomorphic Encryption (SWHE) scheme is a cryptosystem which supports both properties but for limited number of operations. Such as Boneh-Goh-Nissim (BGN) [74] which allowing unlimited number of additions, but only one multiplication. In this paper six HE schemes over  $\mathbb{Z}_p$  are benchmarks against the propose scheme. The following subsections introduce the six cryptosystems.

1) *RSA Cryptosystem*: RSA is a block cipher algorithm over integer finite field which support evaluation function for only homomorphic multiplication computations over ciphertext [69]. In RSA, the plaintext and the ciphertext (which are

TABLE I. MATHEMATICAL NOTATION

Notation	Explanation
$c_i$	a ciphertext
$m_i$	a plaintext
$p$	a large prime number
$q$	a large prime number
$n$	a modulus
$\lambda$	an encryption security parameter
$\mathbb{Z}_n^*$	a set of integer modulo $n$
$\mathbb{Z}_p^*$	a set of integers modulo $p$
$\mathbb{Z}_r^*$	a set of integer modulo $r$
$\mathbb{Z}_T^*$	a set of integer modulo $T$
$Prk$	a private key
$Puk$	a public key
<i>KeyGen</i>	a homomorphic $Prk$ and $Puk$ generation
$Dec_{Prk}(c_i)$	a homomorphic decryption of $c_i$ using $Prk$
$Enc_{Puk}(m_i)$	a homomorphic encryption of $m_i$ using $Puk$
<i>Eval</i>	a homomorphic function of $m$
$\diamond$	a computation function
$c_r$	a homomorphic computed result in ciphertext
$G$	a cyclic group
$\mathbb{G}$	a multiplicative group

represented as positive integers) are bounded by  $n$ , where  $n$  is defined as  $n < 2^{4096}$  for practical purposes. Following are the four main operations governing the RSA multiplicative-PHE cryptosystem:

- **KeyGen**: The public key  $Pk = \{e, n\}$  and the private key  $Prk = \{d, n\}$  are built upon two large prime numbers  $p, q$  such that  $p \neq q$ , and  $n = p \times q$ . The integer  $e$  is randomly selected such that  $\gcd(\phi(n), e) = 1$ ,  $1 < e < \phi(n)$  and  $d \equiv e^{-1} \pmod{\phi(n)}$ , where  $\phi(n) = (p-1)(q-1)$ .

- **Enc**: The public key  $Pk = \{e, n\}$  is used to encrypt plaintext  $m \in \{0, 1\}^*$  as shown by Equation (2).

$$c = Enc_{Pk}(m) = m^e \pmod{n}. \quad (2)$$

- **Dec**: The ciphertext  $c$  can be decrypted by using private key  $Prk = \{d, n\}$  as shown in Equation (3).

$$m = Dec_{Prk}(c) = c^d \pmod{n}. \quad (3)$$

- **Eval**: RSA cryptosystem satisfies multiplicative homomorphism as shown in Equation (4).

$$\begin{aligned} Enc(m_1) \times Enc(m_2) &= (m_1^e \pmod{n}) \times (m_2^e \pmod{n}), \\ &= (m_1 \times m_2)^e \pmod{n}, \\ &= Enc(m_1 \times m_2). \end{aligned} \quad (4)$$

2) *ElGamal Cryptosystem*: ElGamal proposed a probabilistic cryptography scheme based on public key cryptosystem in 1985 [70]. The scheme is based on Diffie-Hellman key exchange. The security of the scheme is based on the security of the discrete logarithm problem. A simple ElGamal's scheme is as follows:

- **KeyGen**: Key generation process required a cyclic group  $G$  with order  $n$  using generator  $g$ . ( $h = g^y$ ) is calculated based on a randomly chosen  $y \in \mathbb{Z}_n^*$ . The public key and the private keys are defined as  $Pk = \{G, n, g, h\}$  and  $Prk = \{y, n\}$ , respectively.

Fig. 1. Proposed Scheme Flow Diagram.

- **Enc:** The encryption of plaintext  $m$  requires a random integer  $r$  to be selected and kept hidden. The result of encrypting plaintext  $m$  is a ciphertext pair  $c = (c_1, c_2)$  which is defined as follows:

$$(c_1, c_2) = Enc_{Pk}(m) = (g^x, mh^x) = (g^x, mg^{xy}) \quad (5)$$

- **Dec:** The decryption is performed by using the private key  $\{y, n\}$  to compute  $s = c_1^y$ , followed by the decryption process itself as shown in the following equation:

$$Dec(c) = c_1 \times s^{-1} = mg^{xy} \times g^{-xy} = m. \quad (6)$$

- **Eval:** ElGamal cryptosystem satisfies multiplicative homomorphism as shown in Equation (7).

$$\begin{aligned} Enc(m_1) \times Enc(m_2) &= (g^{x_1}, m_1 h^{x_1}) \times (g^{x_2}, m_2 h^{x_2}) \\ &= (g^{x_1+x_2}, m_1 \times m_2 h^{x_1+x_2}) \\ &= E(m_1 \times m_2). \end{aligned} \quad (7)$$

3) **Benaloh Cryptosystem:** Benaloh scheme is based on the Goldwasser-Micali (GM) public key cryptosystem [71]. Benaloh scheme enhances the GM scheme by encrypting in blocks of bits rather than encrypting bit by bit. Security assumption of Benaloh scheme is based on the higher residuosity problem which is the generalization of quadratic residuosity problems ( $x^2$ ). Following is the description of the Benaloh additive-PHE cryptosystem:

- **KeyGen:** For a given block size  $r$ , two large primes  $p$  and  $q$  are selected such that  $\gcd(r, (p-1)/r) = 1$  and  $\gcd(r, (q-1)) = 1$ . Subsequently  $n$  and  $\phi(n)$  are calculated as  $n = pq$  and  $\phi(n) = (p-1)(q-1)$ , respectively.  $y \in \mathbb{Z}_n^*$  is selected such that  $(y^{\frac{\phi}{r}}) \equiv 1 \pmod n$ , where  $\mathbb{Z}_n^*$  is the multiplicative subgroup of integers modulo  $n$  which includes all the numbers smaller than  $r$  and relatively prime to  $r$ . The public key is published as  $(y, n)$ , while  $(p, q)$  represents the private key.

- **Enc:** To encrypt a plaintext  $m \in \mathbb{Z}_r$ , where  $\mathbb{Z}_r = \{0, 1, \dots, r-1\}$ , a random  $u \in \mathbb{Z}_r^*$  is selected. The encryption equation is as shown below:

$$c = Enc_{Pk}(m) = (y^m u^r) \pmod n. \quad (8)$$

- **Dec:** The decryption process is done through an exhaustive search for  $i \in \mathbb{Z}_r$ , in which the plaintext  $m$  can be recovered by using Equation (9).

$$m = (y^{-i} c)^{\phi/r} \pmod n. \quad (9)$$

- **Eval:** Benaloh cryptosystem satisfies additive homomorphism as shown in Equation (10).

$$\begin{aligned} Enc(m_1) \times Enc(m_2) &= ((y^{m_1} u_1^r) \pmod n) \\ &\quad \times ((y^{m_2} u_2^r) \pmod n), \\ &= (y^{m_1+m_2} (u_1 \times u_2)^r) \pmod n, \\ &= E((m_1 + m_2) \pmod n). \end{aligned} \quad (10)$$

4) *Okamoto-Uchiyama Cryptosystem*: [73] proposed a new additive cryptosystem which improve the computational performance by defining  $n = p^2q$  within the same domain of  $\mathbb{Z}_n^*$ . The security assumption of OU cryptosystem is based on the  $p$ -subgroup that makes it equivalent to the factorization of  $n$ . Following is the OU cryptosystem:

- **KeyGen**: After determining the value of  $n$ , a random number  $g \in \{2, \dots, n-1\}$  is selected such that  $g^{p-1} \not\equiv 1 \pmod{p^2}$ . Subsequently  $h$  can be calculated as  $h = g^n \pmod{n}$ . The public key and the private key are  $\{n, g, h\}$  and  $\{p, q\}$ , respectively.
- **Enc**: A plaintext  $m < p$  can be encrypted with the public key  $Pk = \{n, g, h\}$  as shown in Equation (11).  $r \in \{1, \dots, n-1\}$  is randomly selected.

$$c = Enc_{Pk}(m) = g^m h^r \pmod{n}. \quad (11)$$

- **Dec**: To recover the plaintext, the private key  $Prk = \{p, q\}$  is used with Equation (12).

$$a = \frac{(c^{p-1} \pmod{p^2}) - 1}{p},$$

$$b = \frac{(g^{p-1} \pmod{p^2}) - 1}{p}, \quad (12)$$

$$b' = b^{-1} \pmod{p},$$

$$Dec_{Prk}(c) = ab' \pmod{p}.$$

- **Eval**: OU cryptosystem satisfies additive homomorphism as shown in Equation (18).

$$Enc(m_1) \times Enc(m_2) = ((g^{m_1} h^{r_1}) \pmod{n})$$

$$\times ((g^{m_2} h^{r_2}) \pmod{n}),$$

$$= (g^{m_1+m_2} h^{r_1+r_2}) \pmod{n},$$

$$= Enc(m_1 + m_2). \quad (13)$$

5) *Paillier Cryptosystem*: Paillier cryptosystem is a probabilistic public key cryptosystem based on higher-order residual classes which support only additive homomorphism computations [72]. Following are the four main operations governing the Paillier additive-PHE cryptosystem:

- **KeyGen**: Paillier cryptosystem has a set of keys.  $p \in \mathbb{Z}_n^*$ ,  $q \in \mathbb{Z}_n^*$ ,  $g \in \mathbb{Z}_{n^2}^*$  are randomly selected such that  $\gcd(L(g^\lambda \pmod{n^2}), n) = 1$ , where  $p, q$  are two large primes,  $n = p \times q$  and functions  $L$  and  $\lambda$  are defined as follows:

$$L(u) = (u-1)/n. \quad (14)$$

$$\lambda = lcm((p-1)(q-1)). \quad (15)$$

- **Enc**: The encryption process utilizes the public key  $Pk = \{n, g\}$  to encrypt an arbitrary plaintext  $m \in \mathbb{Z}_n^*$  with a randomly selected integer  $r \in \mathbb{Z}_n^*$  to produce ciphertext  $c$ .

$$c = Enc_{Pk}(m) = g^m r^n \pmod{n^2}. \quad (16)$$

- **Dec**: The decryption process uses the private key  $Prk = \lambda$  in the decrypting process as shown by Equation (17).

$$Dec_{Prk}(c) = \left( \frac{L(c^\lambda \pmod{n^2})}{L(g^\lambda \pmod{n^2})} \right) \pmod{n} = m. \quad (17)$$

- **Eval**: Paillier cryptosystem satisfies additive homomorphism as shown in Equation (18).

$$Enc(m_1) \times Enc(m_2) = (g^{m_1} r_1^n \pmod{n^2})$$

$$\times (g^{m_2} r_2^n \pmod{n^2}),$$

$$= (g^{(m_1+m_2)} (r_1 \times r_2)^n) \pmod{n^2},$$

$$= Enc(m_1 + m_2). \quad (18)$$

6) *Boneh-Goh-Nissim Cryptosystem*: BGN defined a Paillier-like cryptosystem with an unlimited number of homomorphic additions and a single multiplication on the plaintext [74]. BGN cryptosystem is described as follows:

- **KeyGen**: A two large prime numbers  $q$  and  $r$  are chosen to produce the value of  $n = qr$  and a positive integer  $T < q$  which is selected randomly. Subsequently, two multiplicative groups  $\mathbb{G}, \mathbb{G}_1$  of order  $n$  that support a bilinear pairing  $e: (\mathbb{G} \times \mathbb{G}) \rightarrow \mathbb{G}_1$  are selected. Random generators  $g, u$  are chosen where  $g, u \in \mathbb{G}$ , and  $h = uq$  where  $h$  is a generator of the subgroup of order  $p$ . The public key is composed of  $Pk = \{n, g, h, \mathbb{G}, \mathbb{G}_1, e\}$ , and the private key is  $Prk = \{p, n\}$ .

- **Enc**: For a plaintext  $m \in \mathbb{Z}_T$  a random  $r \in \mathbb{Z}_n$  is selected. The encryption process is as shown by Equation (19).

$$Enc_{Pk}(m) = c = g^m h^r \pmod{n} \quad (19)$$

- **Dec**: Decrypting ciphertext  $c \in \mathbb{G}$  by using private key  $Prk = \{p, n\}$  is shown in Equation (20). Message  $m$  can be recovered in time  $O(\sqrt{T})$  since the message is bounded by  $T$ .

$$c^p \equiv (g^m h^r)^p \pmod{n}$$

$$\equiv (g^m)^p \pmod{n} \quad (20)$$

$$\equiv (g^p)^m \pmod{n}$$

- **Eval**: BGN satisfies unlimited additive homomorphism as shown in Equation (21) and a single multiplicative homomorphism as represented in Equation (22).

$$Enc(m_1) \times Enc(m_2) = ((g^{m_1} h^{r_1}) \pmod{n})$$

$$\times ((g^{m_2} h^{r_2}) \pmod{n})$$

$$= (g^{m_1+m_2} h^{r_1+r_2}) \pmod{n}$$

$$= E(m_1 + m_2) \quad (21)$$

$$Enc(m_1) \times k = c_1^k \pmod{n}$$

$$= (g^{m_1} h^{r_1})^k \pmod{n} \quad (22)$$

$$= (g^{km_1} h^{kr_1}) \pmod{n}$$

$$= E(m_1) \times k$$

HE cryptosystem is malleable, and therefore it is not IND-CCA2 secured by design. Data integrity can still be compromised by CSP and can go undetected. For example, the CSP

can implicitly substitute given ciphertext or the cumulative result with other valid ciphertext without the need to know the content of those substituted data. Different from confidentiality and privacy, once integrity is compromised there is no way to restore the original data. Therefore, data integrity needs to be enforced on such outsource computations.

### B. Proposed Scheme

The verification scheme has three phases: environment setup, computation outsourcing to the CSP by the client, and computation validation of CSP's work by the client, in which the last two phases can be repeated as required (see Table II). The three phases are thoroughly discussed in the subsequent context.

**Phase 1 (Setup):** The client initiates the initialization phase by defining system parameters. The propose scheme consists of two different number systems. The first number system is the finite field  $\mathbb{Z}_p^*$  where the HE calculations take place. The second number system is an  $n$ -bit binary number system, where  $n$  is a positive integer such that  $2^n$  is much smaller than the prime  $p$ . The HE encryption function takes as input a public key  $k_e$  and message  $m$  of index  $i$  and produces a ciphertext  $c_i$  as an output, as shown in Equation (23).

$$c_i = Enc_{k_e}(m_i); m_i, c_i \in \mathbb{Z}_p^*. \quad (23)$$

Subsequently, the client identifies a positive integer  $v < L$  as the secret value, where  $L$  is the largest integer allowed in the implemented system.  $v$  will also serves as the verification parameter.

**Phase 2 (Outsource):** In this phase, the client sends its outsource calculations in a form of an arithmetic equation to the CSP. In return the CSP executes the requested calculations and returns the corresponding result back to the client. From the client's repository, the client sends the arithmetic expression,  $\langle expr \rangle$ , to CSP for evaluation. The expression,  $\langle expr \rangle$ , consists of ciphertexts that had been encrypted by using HE with the corresponding arithmetic operators (e.g. “(101 + 202) × 303”). The syntax of the  $\langle expr \rangle$  follows the following grammar:

$$\begin{aligned} \langle expr \rangle &::= \langle term \rangle \text{ '+' } \langle expr \rangle \mid \langle term \rangle \\ \langle term \rangle &::= \langle factor \rangle \text{ 'x' } \langle term \rangle \mid \langle factor \rangle \\ \langle factor \rangle &::= \text{ '(' } \langle expr \rangle \text{ ')' } \mid \langle const \rangle \\ \langle const \rangle &::= \text{ integer} \end{aligned} \quad (24)$$

In return, CSP calculates the requested arithmetic expression before sending the corresponding result,  $c_r$  (e.g. “91809”), back to the client.

**Phase 3 (Validation):** To verify CSP's calculation(s), the client needs to assure that the value received from CSP,  $c_r$ , is the result of the arithmetic expression outsourced earlier,  $\langle expr \rangle$ .

The equality of a basic arithmetic expression can be validated by evaluating its modular residue. Let  $\langle expr \rangle$  be the outsourced arithmetic expression send by the client to the CSP

and let  $c_r$  be the calculation result received by the client from CSP. Subsequently, the client can validate  $c_r$  by comparing the modular residues of both  $c_r$  and  $\langle expr \rangle$ , as depicted by Equation (25).

$$\begin{aligned} c_r &= \langle expr \rangle. \\ c_r \bmod v &= \langle expr \rangle \bmod v. \end{aligned} \quad (25)$$

To simplify the calculation of the right-hand-side of Equation (25), the expression,  $\langle expr \rangle$ , is further expanded by using the following grammar based on modular arithmetic properties.

$$\begin{aligned} \langle expr \rangle &::= \langle term \rangle \text{ '+' } \langle expr \rangle \mid \langle term \rangle \\ \langle term \rangle &::= \langle factor \rangle \text{ 'x' } \langle term \rangle \mid \langle factor \rangle \\ \langle factor \rangle &::= \text{ '(' } \langle expr \rangle \text{ ')' } \bmod v \mid \\ &\quad \langle const \rangle \bmod v \\ \langle const \rangle &::= \text{ integer} \end{aligned} \quad (26)$$

TABLE II. WORKING EXAMPLES OF THE PROPOSE VERIFIED SCHEME BASED ON THE ARITHMETIC EXPRESSION  $c_r = ((c_1 + c_2) \times c_3)$ : (A) SETUP, (B) OUTSOURCING, (C) VALIDATION

(a) Setup: client determines modulus and identifies ciphertexts.

## IV. RESULT AND DISCUSSION

In this section, the data storage requirement and computation performance are analyzed when implementing the proposed scheme. The client and the CSP are simulated with different machines capacity to reflect the actual setting of the two domains. Cloud computing enterprises offer different computing instances with different performances as shown in Table III. To reflect such capabilities, an Intel® Core(TM) i7-3770 CPU, 3.40GHz CPU, 12GB RAM machine was used

to emulate the CSP computation environment. On the other hand, the client computations are simulated on a machine with Intel® Core(TM) i5-7500U, 2.70GHz CPU, and 4GB RAM.

On the software side, the proposed verified scheme that is running at CSP was implemented using Numpy [75], a compiled library which is efficient in manipulating big integer calculations for Python. For the client implementation which does not require big integer calculations, a basic C++ compiler was used when implementing the proposed scheme. This paper further assumes the use of the two HE properties; PHE represented by multiplicative homomorphic (RSA, ElGamal) and additive homomorphic (Benaloh, OU, Paillier) and SWHE represented by the BGN's method.

TABLE III. GENERIC CLOUD SERVICE PROVIDER CONFIGURATIONS

In the following subsections, we present the results of applying the verification scheme to the different ciphertext sizes generated from candidate cryptosystems. The purpose of these calculations is to assess the implementation costs and performance of the proposed scheme for all candidate cryptosystems.

#### A. Storage Analysis

For the storage analysis, it is important to analyze the storage requirement to store the residues of all the encrypted data at the client side against the actual encrypted data stored at the CSP. Storing the residues at the client side is an overhead to the proposed verified scheme, which does not exist in a normal HE implementation. To gauge the CSP's storage requirement, a few assumptions are made. Among the assumptions is the modulus size. NIST recommends 2048-bit as the minimum size for the factoring modulus. While for a more secured applications, factoring modulus of at least 3072-bit is recommended [79]. To simplify calculation while adopting highest modulus value, this paper assumes 4096-bit as the factoring modulus.

Another assumption is the machine word-size. Current CPUs typically operate on 32- or 64-bit data, stacked of 4-bits or 8-bits based on ISO/IEC 2382:2015 standard [80]. The storage requirement for the verified scheme depends on the size of the verifying parameter,  $v$ . In order to simulate primitive encryption, we assume the client operates on 64-bit data which is typical in most modern desktop computers. Thus, the storage requirement at the client side is less than 1.5% of the CSP full storage. To put this result into perspective, for a client who owns petabytes of data stored at the CSP, this scheme will require the client to store only terabytes of the corresponding

TABLE IV. MULTIPLICATIVE HOMOMORPHIC CALCULATIONS: VERIFICATION COST AGAINST THE COST OF PERFORMING THE ACTUAL HOMOMORPHIC CALCULATION

Number of Operations per Verification	CSP: RSA	Client: RSA-Verified Method	
	Actual Multiplicative Homomorphic Calculation* (μsec)	Verification Calculation* (μsec)	Overhead (%)
1	63.83332	0.477777	0.748
10	745.9444	0.833333	0.111

data at the client side which is feasible on current modern desktop.

#### B. Performance Analysis

It is crucial to analyze the calculation overhead of the proposed verification scheme, that is, it is important to gauge the acceptable number of calculations per verification in order to reduce the calculation overhead in the proposed scheme. The analysis in this section is therefore qualitative in nature and based on how the proposed scheme works in terms of homomorphic operations. In general, the computations performed by the client's machine is slightly faster than the computations performed by the CSP when processing single outsource expression (one expression, one verification). However, a series of expressions (many expressions per verification) can reduce the calculation overhead extremely.

In case of multiplicative-PHE, on verifying one RSA multiplication calculation the client is required to perform one 64-bit multiplication and two 64-bit modular operations on the residues of the two corresponding ciphertexts, while the CSP homomorphically performs one big integer multiplication (4096-bit) operation on the two ciphertexts. Whereas ElGamal cryptosystem needs to double up the RSA computations for one multiplication operation because the nature of the scheme in producing ciphertext pair for each single plaintext. Table IV shows the simulation results in multiplicative-PHE over  $x$  operations. Where Fig. 2 and Fig. 3 show the application of the proposed scheme to RSA and ElGamal cryptosystems, respectively. Both figures demonstrate the requested time variance between the client verification process and the CSP processing the data. Fig. 4 illustrates the corresponding overhead in processing multiplicative-PHE expressions per verification. Both encryption systems converge in the overhead percentage. In which a performing of one verification process per each computation process is less than 0.01%, but it quickly drops further to less than  $1.00E^{-7}\%$  in one verification process per 10000 computations.

Fig. 2. Verified Scheme over RSA.

Fig. 3. Verified Scheme over ElGamal.

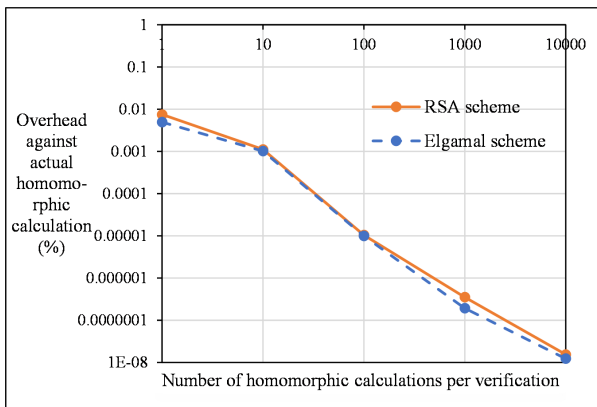

Fig. 4. Cost Overhead for Verifying Multiplicative-PHE Calculation.

The schematic for additive-PHE verification is similar to the multiplicative-PHE. For verifying  $x$  additive Benaloh or OU calculations, the client performs  $x$  multiplications and two modular operations. Whereas in verifying  $x$  additive Paillier calculations, the client performs  $x$  multiplications and two modular  $n^2$  operations, as seen in Section III-A. On the other hand, the CSP homomorphically performs  $x$  big integer multiplications (4096-bit). Table V shows the CSP and client average execution time for the verified scheme in additive-PHE. Fig. 5, Fig. 6 and Fig. 7 display the results of

TABLE V. ADDITIVE HOMOMORPHIC CALCULATIONS: VERIFICATION COST AGAINST THE COST OF PERFORMING THE ACTUAL HOMOMORPHIC CALCULATION

Number of Operations per Verification	CSP: Benaloh		Client: Benaloh-Verified Scheme	
	Actual Additive Homomorphic Calculation* (μsec)	Verification Calculation* (μsec)	Overhead (%)	
1	70.2354	0.5324	0.75802	
10	821.267	0.9924	0.12083	
100	96514.354	1.352	< 0.000	
1000	8075412.25	3.1231	< 0.000	
10000	175000000	27.564	< 0.000	

Number of Operations per Verification	CSP: OU		Client: OU-Verified Scheme	
	Actual Additive Homomorphic Calculation* (μsec)	Verification Calculation* (μsec)	Overhead (%)	
1	121.733	0.78889	0.6480	
10	1663.42	1.02222	0.06145

Fig. 5. Verified Scheme over Benaloh.

applying the verification scheme over the selected additive-PHE cryptosystems. Also, Fig. 8 shows the overhead results in processing additive-PHE expressions per verification for the selected cryptosystems. They are at rates less than 0.01% and rapidly decline to be approximately  $1.00E^{-5}\%$  in only 100 applied computations.

The verification for a BGN calculation consists of verifying additive homomorphic and multiplicative homomorphic at the same time. For  $x$  BGN computation, the verification process at the client side involves  $x$  64-bit addition, one 64-bit multiplication and two 64-bit binary operations on the residues of the two respective ciphertexts, while the CSP homomorphically conducts  $x$  big integer addition and one

Fig. 7. Verified Scheme over Pailler.

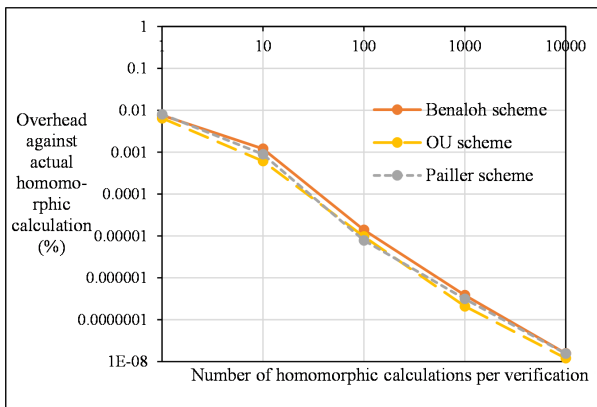

Fig. 8. Cost Overhead for Verifying Additive-PHE Calculation.

big integer multiplication (4096-bit) operations on the two ciphertexts. Simulation result shown in Table VI and Fig. 9. Where Fig. 10 indicates that the verification overhead which is performed by the client is about 2.9% of the computation time needed by the CSP to process the real BGN calculation, moreover, it shows the overhead at the client side decreasing fast, as the number of calculations per verification increases.

TABLE VI. SOMEWHAT HOMOMORPHIC CALCULATIONS: VERIFICATION COST AGAINST THE COST OF PERFORMING THE ACTUAL HOMOMORPHIC CALCULATION

### C. Security Analysis

The proposed verification mechanism enhances the security of HE against data tampering. That is, HE cryptosystems with this mechanism are able to provide data integrity, not only confidentiality and privacy. Now the client can infer if any data breach occurred from substitution in ciphertext or change in the query process. In which the verification result does not match the results sent to the client.

### D. Discussion

In general, the overhead of the propose scheme does not varied too much against the homomorphic cryptosystems.

This is because all the mentioned cryptosystems are based on the integer finite field, in which both the multiplicative-PHE and additive-PHE are being designed by manipulating only the multiplication operation on the ciphertexts. Across the board, the overhead is high since the proposed scheme is verifying by invoking calculations within the integer finite field. However, as shown in the previous section, amortization plays an important role in reducing the overhead, that is, one verification calculation is used to verify a batch of outsourced calculations. This is attributed to the increase in the execution time discrepancy between the CSP and the client; that is, the increase in the number of multiplications that CSP applies to the encrypted data against the execution time for verification which changes very slightly on the client machine.

It is also important to note that the increase in the ciphertext size due to the different cryptosystems and the size of the finite field do affect the overall performance of the proposed scheme. It is also important to note that the proposed scheme is less efficient on BGN with SWHE feature. This is due, partly to the high cost of exponential operation that was used to represent a single multiplication operation.

## V. CONCLUSION

This paper addresses the problem of DIV of outsource computation. In the context of outsourcing computation to CSP, HE over  $\mathbb{Z}_p^*$  does provide data confidentiality but lacks in data integrity. This paper presents an efficient DIV scheme for HE over  $\mathbb{Z}_p^*$  by evaluating the modular residue of the outsource calculation. The proposed scheme is flexible and extensible in design, in which the number of modulus that can be used is limited only by the word size of the client's machine. With a 64-bit machine, there are technically  $2^{64}$  possible modules. Subsequently, based on a 64-bit machine the storage requirement on the client's machine is less than 1.5% of the data size stored at the CSP. Across different cryptosystems tested, the worst computational overhead performed by the client is less than 3% of the actual homomorphic calculation performed by the CSP, that is, if one verification is applied to one homomorphic calculation. The worst computational overhead reduces to less than 0.1%, if one verification is performed for every 10 homomorphic calculations. It is also worth noting that the cryptosystems tested are slightly varied in their performances. In general, the proposed verified scheme can be implemented on any homomorphic cryptosystem that operates over the integer finite field  $\mathbb{Z}_p^*$  without much restriction. Although the scheme solves the problem of verifying the integrity of the data computations, it may constitute a burden on the client to provide storage and extra work to achieve the verification phase. Therefore, we aim to shift the verification process to decentralized fog nodes, which communicate through a consensus in future work.

**Abstract**—In the internet era, Intelligent Transportation System (ITS) for smart cities is gaining tremendous attention since it offers intelligent smart services for traffic monitoring and management with the help of different technologies such as micro-electronics, sensors and IoT. However, in the existing literature, very few attempts are made towards effective traffic monitoring at road junctions in terms of providing faster decision making so that the traffic present in heavily congested urban environments can be dynamically rerouted. In order to tackle this issue, this article proposes a new Controller framework that can be applied at junction-points in order to control the traffic movement. Specifically, the proposed framework utilizes a multi-logic ruleset database to estimate the traffic density dynamically at the first stage followed by the usage of signal-time computation algorithm at the second stage in order to streamline the traffic and achieve faster clearance at the junction-points. The experimental results conducted with the help of test environment using MEMSIC nodes clearly demonstrate the improved efficiency of the proposed framework in terms various performance metrics including move command frequency, ruleset score and fluctuation score.

**Keywords**—Intelligent transportation systems; junction-point traffic monitoring; ruleset database; traffic density estimation

## I. INTRODUCTION

Nowadays, Intelligent Transportation System (ITS) for smart cities is gaining huge attention, which offers smart as well as intelligent services towards traffic management and monitoring with the help of technologies including electronic sensing, data communication, and advanced information management systems [1],[2]. Further, the transportation efficiency can be significantly enhanced with the aid of the proximity cooperation of the user over the road and vehicle targeting towards reducing the congestion of the traffic [3]. Precisely, the prime idea of ITS is to address the all sorts of problems associated with traffic density over the network of the road [4]. In general, ITS system consists of the different sophisticated components such as Advanced Traffic Information Service System (ATIS), Emergency Rescue System (ERS), Freight Management System (FMS), Electronic Public Transport System (EPTS), Advanced Public Transportation System (APTS), Advanced Vehicle Control System (AVCS) and Advanced Traffic Management System (ATMs) and so on [5].

Though enormous amount of research efforts are made towards ITS research domain, yet several serious issues of traffic density control are however remaining unresolved till

now in almost all the major cities in every part of the world. In addition to that, an increase in traffic density gives rise to severe congestion problems and induces pollution and thereby adversely affects economic losses. In the current scenario, the successful deployment of ITS for facilitating effective traffic monitoring is significantly affected by these two limitations: a) To standardize the elementary factors in order to compute and predict the state of deadlock condition of traffic over larger traffic density and b) To ensure the reliability associated with the predictive concept in traffic management along with higher accuracy [6]. The former limitation is addressed up to a certain extent, in the existing literature by means of Vehicular Ad-hoc Networks using forecasting approaches [7]. The latter issue is addressed using infra-structure based approaches by employing GPS data [8]. However, the state-of-the art techniques in both the cases, fail to provide effective performance, due to problems such as inaccurate estimates of traffic, delay and inadequate accuracy in dynamic and large-scale urban traffic environment.

From setup perspective, the existing literature towards ITS traffic monitoring can be broadly classified into two categories namely, infrastructure Vs non-infrastructure-based techniques. The infrastructure-based techniques primarily focus on essential functionalities such as traffic light management, route suggestion, congestion detection, re-routing and speed adjustment whereas non-infrastructure-based approaches primarily concentrate on cooperative congestion identification, congestion avoidance accident detection and warning. However, one of the significant research challenges in the existing literature is, the complexity in design framework due to which only normal classification over test environments can be performed. Further, the traffic density computations are assessed using certain formulated theories without suitable validations with real-world traffic systems, which results in significantly poor performances [9],[10]. Due to these aspects, promising techniques are needed for traffic monitoring in ITS which can effectively make faster decisions for rerouting traffic in heavily congested urban environments. In this article, a novel controller design framework is proposed, which can be deployed at junction-points in order perform effective traffic monitoring and management by formulating a unique multi-logic ruleset. The organization of the article is described as follow: Section 2 discusses the existing literature, Section 3 describes the proposed along with detailed discussion of

system design as well as algorithm. Section 4 details result analysis followed by the illustration of conclusion in Section 5.

## II. RELATED WORK

In the existing literature, a lot of research attempts are made towards incorporating novel features in ITS so that different sorts of traffic monitoring issues can be addressing. For instance, Calabuig et al. [11] presented a novel techniques which is responsible for managing alert message for the remotely positioned vehicle by means of utilizing cluster-head selection strategies of VANETs in ITS. However, it suffers due to huge requirement of resources for unicast communication as well as non-availability of potential broadcasting features incellular networks. Also, recently, Derrouz et al. [12] developed a vehicle type classification framework using both the 3D parameters and 2D features in order to control traffic as well as violations of road code. Specifically, 3D parameters are used to reconstruct complete dimension of given vehicle in terms of height, width and length whereas 2D features are utilized for dimensionality reduction. Though the proposed classification system can accurately detect vehicles from different view angles, yet the performance may get seriously affected due to the errors calibration process used for estimating 3D parameters.

Recently in 2019, Blazek et al. [13] addressed the communication latency problem by presenting a burst-error performance modelling, which utilizes the formulation of the maximum likelihood function to measure the various extensive records based on channel-based parameters. Though, the authors successfully employed the fading information from the target channel and signal noise to investigate the degree of burstiness, yet few of fault-tolerance aspects such as burstiness for stress testing may degrade the performance of the system.

Very recently in 2020, Chavhan et al. [14] proposed a context-aware public transport system based on IoT, which uses both the context information and emergent intelligence, in order to enable public transport services in metropolitan areas. Though, the proposed system provides better results, yet it fails to address towards security issues. Javed et al. [15] addressed the security problems in ITS by developing a mechanism that can detect outliers and un-authenticate the false data and thereby enhance the decision of the traffic. A study towards safety standards in ITS is carried out by Naufal et al. [16], where a control and supervision system is designed for autonomously transport systems. Dotoli et al. [17] introduced have used multi-objective optimization framework in order to perform routing of vehicles by evaluating the user's preference. A similar kind of case study is considered by the adoption of blockchain technology in ITS by the authors in [18]. Szymanski et al. [19] presented a vehicle positioning framework using spatio-temporal features of the delay caused in public transportation systems with the help of GPS. The work carried out by Zhao et al. [20] includes a probabilistic framework in order to study the pattern of flows of passengers over different trains and routes. Calvillo et al. [21] have investigated connecting bridges between all the connected devices in smart cities. The study hypothesizes on distributed energy system, which plays an important role in performance improvement in smart cities.

Recently, Tian et al. [22] developed a recurrent attention framework for identifying the traffic signs by making use of deep neural networks, which suffers due to its computational complexity. Cai et al. [23] introduced a vector-based query processing system, which carries out query processing of ITS. Very recently in 2020, Choy et al. [24] proposed a low power speed monitoring framework with the help of radio frequency as well as neural network architectures. However, the performance of the proposed framework primarily depends on the estimation accuracy and antenna design. Rafter et al. [25] developed an adaptive traffic signal system with multiple modes that integrates position data of linked vehicles with data extracted from a network in a decentralized manner over a single intersection of the road.

To summarize, in the existing literature, huge efforts are made towards introducing the usage of sophisticated mechanisms to perform traffic monitoring, which are not much explored towards compatibility issues. Specifically, every vehicle's practical scenario over the road is given least preference, which on the other way plays a vital role in the realistic traffic situations. More specifically, in most of the existing traffic monitoring systems fail to include the practical constraints such as bi-directional traffic, routing viewpoint and directionality and so on in their decision making process, which may result in slightly less realistic estimations. In addition to that, in existing literature, very few attempts are carried out towards embedding automated decision-making or intelligence within the system to perform traffic monitoring. On the other hand, the adoption of the Global Positioning System (GPS) and sensors are widely popular in the existing literature for controlling navigation and traffic monitoring. However, GPS suffers from outages many times, and they are not always accurate. Usage of the sensor is a good idea, but the sensors are used in a very simplified manner which cannot capture dynamic information about the mobility of the vehicles based on direction in a two-lane system. Furthermore, generally the bottleneck condition of the traffic density is witnessed in intersection points or junctions. When one junction has multiple routes connected, it becomes the most challenging scenario to provide the command for vehicle clearance by executing different commands of the signal light. Unfortunately, most of the existing traffic monitoring systems perform slightly less effective due to manual process in traffic monitoring. Based on these aspects, promising traffic monitoring systems are needed, which can carry out faster decision-making as well as streamlining the traffic based on dynamic traffic events over the peak density conditions on the road.

### A. Motivation and Contributions

In this article, a novel *Junction-point Movement Controller framework, named as JMC Framework* is presented, which makes use of multi-logic ruleset database, in order to estimate the traffic density dynamically and also perform faster clearance at the junction-points. More precisely, the main contributions of the proposed JMC framework are given by,

- ★ *Construction of a new Ruleset Database* consisting of multi-value logic rulesets, which are used to generate aggregated traffic density inferences in the form of vehicle statistics and thereby effectively control the traffic movement.

- ★ Introducing a *novel Traffic Density Estimation and Signal-time Computation Algorithm*, named as *TDM-SC Algorithm*, in order to achieve consistent traffic density estimation followed by effective path determination, so that faster clearance of the vehicles can be ensured at the specified junction-points.

The proposed JMC framework along with construction of rule-set database and TDM-SC algorithm along with the detailed design is illustrated in Section 3.

### III. PROPOSED FRAMEWORK

Fig. 1 describes the overview of proposed JMC framework architecture consists of two stages. In the first stage, the number of inbound and outbound vehicles over the specific route are first inputted into the system. Precisely, the inbound and outbound vehicles are tracked with the help of sensors, which are placed on both the entry as well as exit points of routes, assuming that the multi-routes meet at the junction points. In the second stage, the entire aggregated vehicle movement data is then passed to a controller system hosted over the junction point. The controller processes the aggregated vehicular information and applies a multi-value logic system where different possibilities of ruleset are constructed based on traffic density. The resultant information helps the controller node to understand the degree of traffic density in different routes meeting at the junction. Based on the inferences derived from the ruleset, the controller decides for clearing the vehicles from their routes, by providing three different forms of commands including *MOVE* command, *WAIT FOR* command and *STOP* command, whereas *MOVE* command plays a vital role in clearing the traffic. In this way, the proposed system provides a solution in order to handle the variable traffic density on different routes by means of introducing a faster decision-making system for facilitating traffic monitoring and management in the urban environment. The complete system design including the analytical modelling of the proposed framework is detailed in the forthcoming section.

### IV. SYSTEM DESIGN

In this section, the main concept of the proposed JMC framework design is illustrated in detail, which in turn can be fully automated to optimize the traffic system, especially for any level of traffic density, so that smart traffic monitoring and controlling can be achieved. Specifically, system design modules including assumptions considered, Ruleset Database Formation followed by algorithm design are illustrated.

#### A. Assumptions

The implementation of the proposed JMC system is carried out by considering the following assumptions given by:

- Each vehicle V1 is equipped with a sensing device, which is having the unique identity of the vehicle.
- Every entry and exit points of a road are equipped with a transceiver which performs identification of the vehicles and aggregates the information about several inbound and outbound vehicles.
- A controller system with specific traffic commands tc is assumed to be present in every junction point

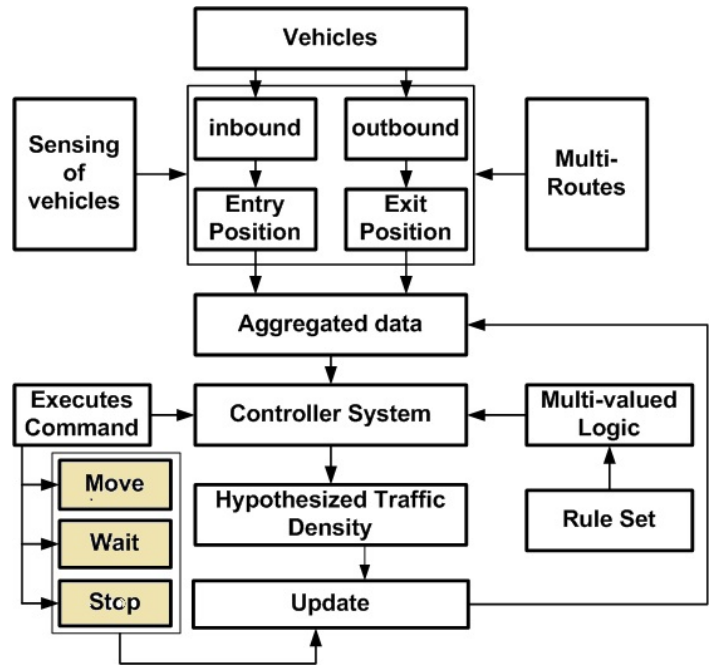

Fig. 1. Overview of the Proposed JMC Framework.

which performs execution of the ruleset in order to implement the automated and intelligent traffic management in the urban region.

- Apart from this, the proposed JMC design also assumes that, any street with a higher capacity is capable of introducing larger number of vehicles within it.
- The proposed framework also assumes that all the sensory devices are powered with a battery of finite lifetime.

#### B. Formation of Ruleset Database

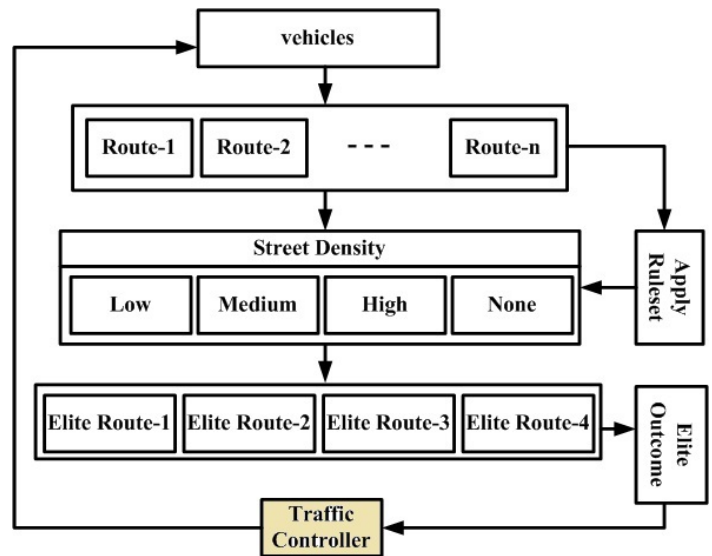

Fig. 2. Formation of Ruleset Database.

The proposed JMC framework, utilizes a Ruleset Database

using which it controls the movement of the traffic by means of employing multi-values logic systems in the form of vehicle statistics from four sample streets. Precisely, Fig. 2 describes the concept of Ruleset Database formation based on the traffic density over the street. More precisely, in the first step, the proposed system uses two primary logical operators, namely, “and” and “then” in order to check the density of all streets and thereby derives the inferences about the traffic density as shown in the top portion of figure. Specifically, a simplified version of a rule in the given ruleset database is given as follows:

$IF(cond1)\&(cond2)\&(Cond3)\&(Cond4)--THEN--Inf1$   
(1)

In the above rule expression, cond1 to Cond4 represent four different street conditions corresponding to its respective traffic density in terms of low, medium, and high traffic. More specifically, cond1 includes {low,medium,high} which represents various combination of street 1 traffic to be low, medium, and high. The similar type of rules are constructed for all combinations of traffic conditions. The inference is the outcome of the combination of these conditions resulting in selection of specific direction of a vehicle to move by choosing an outbound street, and thereby the inferences represent the outbound street. Precisely, in the proposed JMC framework, a complete Ruleset Database consisting of 80+ combinations of rulesets is constructed in order to generate the aggregated traffic density inferences and a snapshot of this database is shown in Fig. 3. After this step, the resultant traffic density

58. If (street1 is high) and (street2 is low) and (street3 is medim) and (street4 is low) then (witch-street is Lstreet1) (1)  
59. If (street1 is high) and (street2 is low) and (street3 is medim) and (street4 is medium) then (witch-street is Lstreet1) (1)  
60. If (street1 is high) and (street2 is low) and (street3 is medim) and (street4 is high) then (witch-street is no-differ) (1)  
61. If (street1 is high) and (street2 is low) and (street3 is high) and (street4 is low) then (witch-street is no-differ) (1)  
62. If (street1 is high) and (street2 is low) and (street3 is high) and (street4 is medium) then (witch-street is no-differ) (1)  
63. If (street1 is high) and (street2 is low) and (street3 is high) and (street4 is high) then (witch-street is no-differ) (1)  
64. If (street1 is high) and (street2 is medium) and (street3 is low) and (street4 is low) then (witch-street is Lstreet1) (1)  
65. If (street1 is high) and (street2 is medium) and (street3 is low) and (street4 is medium) then (witch-street is Lstreet1) (1)  
66. If (street1 is high) and (street2 is medium) and (street3 is low) and (street4 is high) then (witch-street is no-differ) (1)  
67. If (street1 is high) and (street2 is medium) and (street3 is medim) and (street4 is low) then (witch-street is Lstreet1) (1)  
68. If (street1 is high) and (street2 is medium) and (street3 is medim) and (street4 is medium) then (witch-street is Lstreet1) (1)  
69. If (street1 is high) and (street2 is medium) and (street3 is medim) and (street4 is high) then (witch-street is no-differ) (1)  
70. If (street1 is high) and (street2 is medium) and (street3 is high) and (street4 is low) then (witch-street is no-differ) (1)  
71. If (street1 is high) and (street2 is medium) and (street3 is high) and (street4 is medium) then (witch-street is no-differ) (1)  
72. If (street1 is high) and (street2 is medium) and (street3 is high) and (street4 is high) then (witch-street is no-differ) (1)  
73. If (street1 is high) and (street2 is high) and (street3 is low) and (street4 is low) then (witch-street is no-differ) (1)  
74. If (street1 is high) and (street2 is high) and (street3 is low) and (street4 is medium) then (witch-street is no-differ) (1)  
75. If (street1 is high) and (street2 is high) and (street3 is low) and (street4 is high) then (witch-street is no-differ) (1)  
76. If (street1 is high) and (street2 is high) and (street3 is medim) and (street4 is low) then (witch-street is no-differ) (1)

Fig. 3. Snapshot of Ruleset Database.

inferences are fed to the controller, so that it can understand the current traffic data aggregation. Followed by this step, the controller uses similar ruleset to compute the result of go time algorithm based on the traffic density and thereby performs decision-making.

### C. Algorithm Design

The proposed JMC framework presents an algorithm named as, Traffic Density Estimation and Signal-time Computation Algorithm (TDM-SC), which is in short indicated as TDM-SC algorithm for optimizing the traffic density monitoring efficiency in the urban traffic environment. Specifically, in the proposed JMC framework, first traffic density information is calculated with the help of execution of rules in Ruleset database followed by the classification of the traffic density. Then the resultant density estimations are further employed by the Controller in order to compute signal passing time allowed for every vehicle in the specified route. More specifically, the

proposed TDM-SC algorithmic with step-by-step procedure is detailed as given below.

Input: V (vehicles), tc (traffic command), iv (inbound vehicle)

Output:  $\alpha$  (execution of traffic command)

Start

```

1:  For i∈(1: V)
2:      init V, tc, iv
3:      sim→f1(V, tc)
4:      vrand→f2(iv)
5:      V→V + vrand
6:      If V < [max(Vden)]
7:          logrule = f3(V, ruleset)
8:          For m ∈ {(i + 1), mmax}
9:              If logrule ≤ m
10:                 mc(i) = k
11:             End
12:         [denmc(i)] = argmax(v)
13:         gotime(i) = f4(V, mc, iv, et, durcom)
14:         For j = 1 : gotime(i) + 1
15:             v(mc(i)) = v(mc(i)) - ov
16:             V = v + f5(rand, iv, χ)
17:             If v(mc(i)) < 0
18:                 α=simulate traffic command(V, tc)
19:             End
20:         End
21:     End
22: End
23: End

```

### a) The working of TDM-SC algorithm is illustrated as follows::

The first initialization step of TDM-SC algorithm is to turn on the controller system for computation of the vehicle’s signal-time calculations. Then, the proposed algorithm takes the inputs namely, input of V (vehicles), tc (traffic command), and iv (inbound vehicle), which after processing yields an outcome of  $\alpha$  (execution of traffic command). Precisely, the algorithm initially considers all the vehicular nodes v as specified in step-1 of Fig. 4 (Line-1). The variable tc (traffic control) represents a controller system that directs the vehicle’s movement using standard signal lights. The variable iv and ov represent the total number of vehicles sensed by sensors over the streets entry and exit points respectively. The proposed study considers four entry points that meet at the junction where the controller system resides. An explicit function f1(x) is implemented which is responsible for simulating the vehicles V and traffic command tc over the junction point as shown in step-3(Line-3). The proposed system considers the junction point as a prominent bottleneck condition of routing within the junction itself in the urban traffic system.

The next part of the implementation focuses on generating the random number of vehicles  $v_{rand}$  by considering the function f2(x), which in turn takes a random number of incoming vehicles iv in step-4 (Line-4). Therefore, the total number of vehicles on each route is the addition of vehicles V and a random number of vehicle  $v_{rand}$  as specified in step-5 (Line-5). In order to depict a realistic traffic scenario, the proposed algorithm takes a fixed number of maximum vehicle density  $v_{den}$  on all of four considered routes as given in step-6 (Line-6). A logical ruleset  $log_{rule}$  is computed by applying a function f3(x) considering the input argument of vehicles

V and ruleset created earlier as specified in step-7 (Line-7). After this step, the function  $f3(x)$  performs the logical ruleset's evaluation by considering the four membership functions of 4 constituent routes meeting at the junction point.

Depending on the deployed environment of vehicular movement on the four test routes, the algorithm compares the value of the ruleset  $log_{rule}$  with the  $m$  variable, representing the output degree of density of the road as shown in step-8 (Line-8). Depending on the degree of road density encountered  $m$ , the algorithm assigns  $k$  to the move command  $mc$  as given in step-9(Line-9).It should be noted that  $k \ll m$ , which means that if the vehicles density is found higher, the number of move command towards every 4 points of streets, is  $k=1, 2, 3, 4$  (Line-10). For example, if the value of the  $log_{rule}$  is found less than 3, it will signal move command  $mc$  to 1st route ( $k=1$ ). If the value of  $log_{rule}$  is found less than 6, it will signal move command  $mc$  to 2nd route ( $k=2$ ). Similarly, if  $log_{rule}$  is found less than 9, it signals move command  $mc$  to 3rd route ( $k=3$ ), and so on as shown in Fig. 4.

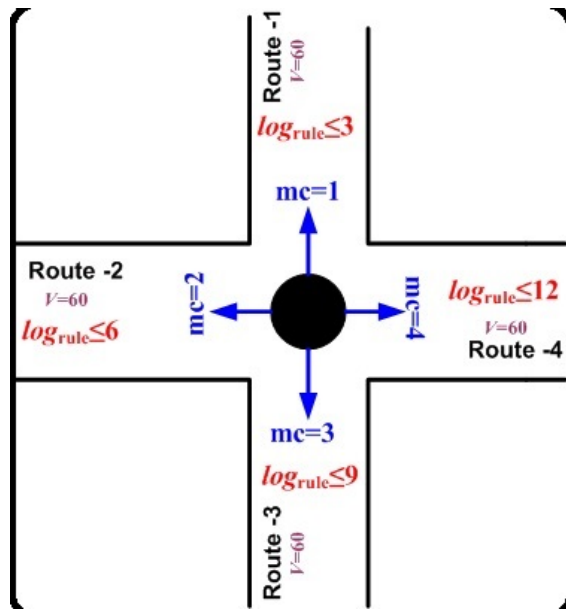

Fig. 4. Signal-Time Computation for Directing Vehicles Through Signals.

## V. RESULT AND DISCUSSION

### A. Experimental Setup:

The experimental setup of the proposed JMC framework including the test environment, deployment scenario as well as simulation nodes are detailed in this section as follows. Precisely, the deployment scenario including the urban traffic for the proposed JMC framework is shown in Fig. 5, in which the simulation environment consisting of inbound and outbound vehicles are visible on the assigned routes connected to respective junction points. More precisely, simulations are carried out with the help of MATLAB and the primary details considered in this setup are illustrated as follow:

- Urban traffic scenario is created by the deployment of Junction-points, that are constructed with 4 orthogonally joined routes.

- All the routes have both inbound and outbound vehicles in terms of 2-lane system with bidirectional traffic is considered.
- The entry and exit point are simulated with standard MEMSIC nodes which are responsible for estimating both inbound and outbound vehicles. Specifically, with one MEMSIC node in each route, the setup is implemented by 4 MEMSIC nodes which can capture from 5 to up to 3000 vehicles in entire simulation rounds.
- The junction point is equipped with the proposed centralized JMC system, which accepts the aggregated data from all the routes and performs the traffic density estimation followed by the signal-time computations by making use of TDM-SC algorithm, as described in the previous section in order to control the traffic density.
- Further, the duration of individual outbound cars is considered as 0.3 seconds. Also, the average number of inbound cars are set as 2 whereas for outbound cars it is 12.
- The simulations are carried out from a lower bound of 50 iterations to 500 iterations, in order to test the efficiency of the proposed framework.
- The simulation is also carried out for sample traffic conditions, where same number of vehicles are allocated in all streets at same time. For an example, all streets have 60 vehicles to be cleared in one signal. This sample scenario is also considered and proposed framework utilizes suitable rulesets in order to make appropriate decisions.

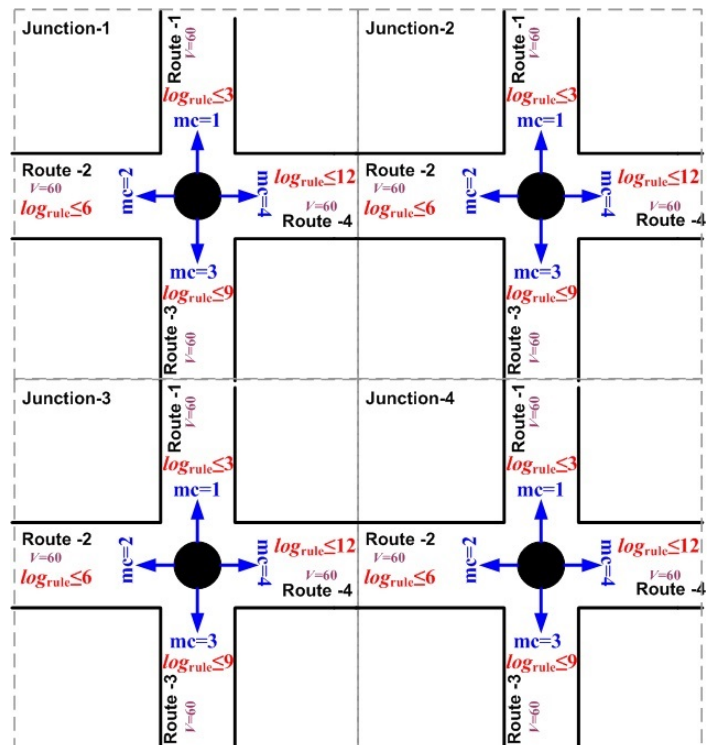

Fig. 5. Simulation Environment for Proposed JMC Framework.

## B. Results and Discussion

The performance of the proposed JMC framework is evaluated in terms of analyzing different parameters, such as no. of vehicles passed and effectiveness multi-value logic set and so on. More specifically, the efficiency of the proposed framework is demonstrated in terms of analyzing the four important parameters as given by,

- Analysis of Frequency of MOVE Command and number of vehicles passed.
- Analysis of Fluctuation Score.
- Analysis of Ruleset score and
- Analysis of Command Transition duration.

1) *Analysis of MOVE Command Frequency and number of vehicles passed:* Fig. 6(a) and (b) show the simulation results of move command frequency as well as vehicles passed in terms of bar graphs with respect to the corresponding routes, which are inbound to junction points. Precisely, *move* command frequency is defined as the number of times the controller executes signal for moving the vehicles in order to facilitate clearance to move, which is similar to green light signal. The simulations are carried out up to 500 iterations, in which it exhibits increasing occurrence of vehicle clearance for all four sample routes as shown in Fig. 6(a). Similarly, a number of vehicles that are allowed to pass also exhibit an incremental curve as indicated in Fig. 6(b), which in turn proves the efficiency of the proposed framework.

Fig. 6. (a) Analysis of Move Command Frequency (b) No. of Vehicle Passed.

2) *Analysis of Fluctuation Score:* Fig. 7 shows the results of second performance parameter -fluctuation score, which is a dimensionless unit, for a maximum of 500 simulation rounds. Specifically, Fluctuation score is defined as, the degree of execution of the logical ruleset considering three scenarios including lower, medium and higher traffic along with the time for move command is computed. More specifically, the goal is to find differences in the duration of the move command which is needed for vehicle clearance in every defined route. Using ruleset, if the time duration of the move command is found

less than 2 seconds or 5 seconds or more than 5 seconds, then the system automatically allocates scores of value of 0.8, 0.9, and 1 respectively in order to calculate the rate of fluctuation. Fig. 7 clearly indicates that, though different fluctuation rates are shown in the various routes inbound to the junction points, however the fluctuation score is restricted within the maximum of 1-2 units only. In this way, Fig. 7 demonstrates the improved consistency of the proposed JMC framework in terms of lower degree of fluctuations, by means of balancing the complete traffic system without any occurrences of deadlock situations.

Fig. 7. Analysis of Fluctuation Score.

Fig. 8. Analysis of Ruleset Score.

3) *Analysis of Ruleset score:* Fig. 8 illustrates the results of Ruleset score, which is an essential parameter, since it plays a significant role in predicting performance of the proposed JMC framework. Precisely, ruleset score responsible for finding out the actual need of the ruleset on 4 test routes. It is to be noted that, in the proposed system, ruleset database consisting of 81

Fig. 9. Analysis of Duration of Command Transition.

rulesets covering all possible cases of traffic density is utilized as described in Section 3. Fig. 8 graph indicates that the rulesets are capable of dynamically controlling the variable rate of traffic density with higher consistency for all four sample routes. It is also observed in Fig. 8 that, though there is an increase in number of simulation rounds, yet there is not much significant divergences in the ruleset scores. Therefore, Fig. 8 results demonstrate the better consistency of ruleset scores and thereby prove the scalability feature support of the proposed JMC framework, even in case of heavy traffic environments.

4) *Analysis of Duration of Command Transition:* Fig. 9. highlights the result graphs of fourth performance parameter - duration of command transition, in terms of simulation rounds vs command transition durations. Precisely, this parameter specifies the duration of command release performed by a controller with respect to move, stop, and wait for signals. From Fig. 9, it can be observed that, a consistent outcome is indicated for all the respective routes, which in turn demonstrates the efficiency of the proposed system in monitoring and managing the traffic system. Though, the number of inbound entries over the junction increase, yet a consistent performance is indicated in the Fig. 9 graphs, which clearly proves the efficiency of the proposed framework.

## VI. CONCLUSION

In this article, a novel junction-point movement controller framework is presented, which can efficiently perform traffic monitoring and management by means of employing multi-logic rulesets. Precisely, the significant features of the proposed system are: i) usage of non-complex mechanism to carry out decision making for the elite route to be selected, ii) inclusion of routes connected at junction point with faster clearance of the vehicles, iii) system capable of counting the both inbound and outbound vehicles and thereby effective path determination and traffic density estimation becomes easier, iv) usage of the non-iterative process to offer cost-effective solution. In future, the proposed framework can be enhanced for inclusion of

security features, adaptive properties and so on, so that it can be reasonably applied in real-world urban traffic situations.

## ACKNOWLEDGMENT

**Abstract**—Mining approaches based on video data can serve in identifying stores' performance by gaining insight into what needs to be proceeded to further enhance customers' experience, leading to increased business profits. To this end, this paper proposes an association rule mining approach, depending on video analytic techniques, for detecting store-items that are likely to be out of demand. Our approach is developed upon motion-tracking and facial emotion expression methods. We used a motion-tracking technique to record information related to customers' regions of interest inside the store and customers' interactions with the on-shelf products. Besides, we have implemented an emotion classification model, trained on recorded video data, to identify customers' emotions towards items. Results of our conducted experiments yielded several scenarios representing customer behavior towards out-of-demand stores' items.

**Keywords**—Shopper Behavior; motion tracking; emotion classification; machine learning; association rule learning

## I. INTRODUCTION

The advancement of Internet retailers and online stores for over two decades has empowered and facilitated consumer experiences. Unlike visiting physical stores, online shoppers can comfortably search for their needs, place them at competitive prices, and then request a home delivery service with ease. To a considerable extent, Internet retailers are highly lucrative as they offer customers the facility to order a universal variety of products from all over the world. However, traditional retail stores necessitate being more competitive with offering services that guarantee customer satisfaction and loyalty. Consequently, marketing specialists and store owners are perpetually attempting to find any intelligent solution that could enhance the customer's shopping experience, using, e.g. sensors equipped with computer vision technologies [1]. Such technologies can aid retail stores in staying competitive and offer the best desirable services [2].

Understanding customer behaviors on one hand and business requirements to success, on the other hand, is essential for the sustainability of e-shopping. There are many traditional methods used by businesses to collect information about the needs of their customers (such as feedback questionnaires). These methods can provide good insight, but they have some significant drawbacks. Therefore, with the advancement of data collection and processing technologies as well as the use of highly accurate sensors, one can collect vast amounts of data about the customers and get many valuable insights [1].

Depending on video analytics, data mining approaches can serve in identifying a store's performance by gaining insight

into what needs to be carried out to further enhance customers' experience, leading to increased business profits [2]. Some helpful information that is obtainable through the use of Big Data analytics such as customers' regions of interest, customer count during a particular time, customer's emotion recognition, general information about the customer like their age and gender, interactions with on-shelf products, purchasing patterns and products that are likely to be bought together. Business owners can leverage this information to achieve great results that help in keeping customers returning to their stores and increase their financial returns.

This paper studies a learning-based solution for predicting the sales of items in retail chains and/or physical stores. In particular, we propose an association rule mining approach, depending on video analytic techniques, for detecting items that are likely to be out of demand. The association rule is a data mining technique that we apply to a store's transactional database to extract information about items (mainly about explicit features). Relying on available video analytic tools, we use a motion-tracking technique to record information related to customers' regions of interest inside the store and customers' interactions with the on-shelf products. Besides, we implement an emotion classification model, trained on recorded video data, to identify customers' emotions towards items. In a nutshell, this paper makes three contributions as follows:

- We propose an association rule-mining approach compounded with video analytic techniques for predicting the sales of items in physical stores, including out-of-demand items.
- We report on seven different scenarios representing customer behavior towards items that are out-of-demand.
- We conclude the paper by giving broad recommendations to tackle the symptoms of out-of-demand items.

The remainder of this paper is organized as follows: Section II represents the related works, shedding light on data analysis, motion-tracking, and emotion detection techniques. In Section III, we introduce a high-level design of our proposed predictor, and then we give a brief description concerning the technical tools used for implementation. Section IV presents and discusses the conducted experiments for assessing our proposal. Last but not least, Section V concludes the paper with suggestions for future research to consider.

## II. RELATED WORK

This section reviews different sorts of related work, described into three aspects: data analysis, motion tracking, and

emotion detection aspects. The original contribution of this paper lies in mixing these three aspects in our proposed solution.

#### A. Literature Related to Data Analysis

The system suggested in [3] mines data from a transaction database of a retail market. It is supposed to be similar to popular mining tools such as Weka and RapidMiner. The data is stored in a MySQL database which is later accessed by simple Java and Python programs to apply a classification algorithm (C4.5) and an association rule mining algorithm (Apriori). Advantages of this system include being simple, user-friendly, and lightweight. In addition, information can be drawn directly from the operational database. The main goal of [4] is to discover the association between items to help store owners figure out the best layout for their stores. A simple Apriori algorithm is used to find the frequent itemsets and then apply the Lift measure for the association between sets to discover the rules between items. Before mining the association rules, the items of the store are divided and then grouped into sub-categories. This is useful because, in many cases, some items are considered substitutes.

Association rule mining in [5] is based on quantitative correlation coefficient (Pearson's correlation coefficient). It allows us to extract linear relations between two item sets. The suggested method starts by grouping transactions by the desired criteria (specific periods, for example), making it worthwhile to discover relevant rules within a given time frame. After the data has been grouped, a quantitative correlation analyzer is used to derive relations between item sets. Results of this implementation show more patterns detected in comparison to traditional association rule mining. In addition to discovering periodic customer demand which helps owners introduce offers and balance the supply and demand for products.

A study described in [6] proposes a model for finding periodically repeated patterns in a database. A pattern-growth algorithm (GPF-growth) was proposed to detect these patterns. A given pattern is considered frequent when it occurs within a defined maximum period, and its support exceeds the user-defined minimum. Thus, when it comes to analyzing data from the customers' transactions finding repeated patterns yields information related to regularly purchased products. The works described in [7], [8] apply the principles of association rule mining algorithms such as Apriori and FP-growth. Nevertheless, unlike these algorithms, the proposed approach focuses on the time of transactions. As a result, a new type of pattern is defined, which is called transitional patterns. The frequency of such patterns changes noticeably over a period of time. First, frequent patterns in the database are discovered by the use of an association rule mining algorithm such as Apriori or FP-growth. After that, an algorithm called TP-mine is introduced for the purpose of transitional mining patterns. With the use of this algorithm, it is possible to extract points in time where a frequency of an item-set has changed negatively or positively.

The aim of a study described in [9] is to introduce a method for analyzing a customer's basket data and deriving relevant association rules between its items. The approach relies on minimum spanning trees (MSTs). Using a minimum spanning tree for representing relations between items allows us to consider those strongly correlated items, which limits the search

space for the association rule mining. Another advantage of this approach is that not only can we extract strong association rules, but also, we can find items that tie other items together. In the study described in [10], an algorithm is proposed for detecting changes and trends in transactions data. It relies on association rule mining and the prediction of rules that may change at a later time. The algorithm works by tracking rules with high confidence, and the result of this algorithm is rules that will have higher confidence in the next period and rules which will have lower confidence. Apriori algorithm is used to mine rules over many time frames, and later each of the rules is given a score for each time frame to help track changes in confidence level over time. The approach provides great insight that could help prepare for upcoming association rules changes and find outlier rules that may apply in few time frames. However, the main disadvantage of this method is that it is heavily skewed based on the manually selected threshold values.

The main point of a study described in [11] is to understand the purpose behind customers' visits to a store. This is done through data mining transactions data and identifies the products in each transaction, and based on these products, the customers' purpose can be understood. The approach uses clustering techniques to segment different visit types, and the purpose behind these visits is later identified based on the types of products they contain. K-means clustering is used to segment visits in this research. The contribution of a study described in [12] is a framework that helps in predicting sales changes based on weather data. Two models are deployed to help with the prediction of the change in product demand. One of them is short-term, and the other is for long-term predictions. A LASSO Poisson regression model was used for predicting the impact of weather on customer demands.

A method for recommending the next purchase for customers is detailed in [13]. They have named the Co-Factorization model over sequential and historical purchase data (CFSH). Transactions data is mined to discover sequential purchasing patterns. From these patterns, two matrices are constructed. One for sequential and one for historical customer behaviors, these two matrices are both factorized to predict the best recommendation for the next customer visit. A study described in [14] suggests a method for segmenting customers based on their lifestyle. The segmentation is done with the help of analyzing a retailer's transactional database. The approach relies on a variable clustering algorithm (VARCLUS), resulting in clusters of related items. The lifestyles for each cluster are identified by looking into the type of items in each cluster. Each customer is then assigned to a lifestyle based on which cluster's item types did they purchase the most.

The contribution of [15] is a framework for product feature characterization and predicting the customer's most preferred specifications by analyzing purchase history data. A trained neural network model was used with the input as a matrix of all possible combinations of a product specification. The output is the predicted customer satisfaction rate. Predicting the customers' preferred characteristics in a product can guide a manufacturer to develop a product based on the customers' needs. A study described in [16] introduces a recommendation system that's based on collaborative filtering and data mining techniques. Customers are segmented based on their values

using the RFM analysis. The used clustering algorithm is K-means. To discover the best recommendation for a customer, the cluster that they belong to is identified first. Then, the Apriori algorithm is applied to transactions that belong to customers in the same cluster to extract the top associated items.

Another study described in [17] proposed a method to discover frequent itemsets with high value to the sellers. Association rule mining is applied on transactional databases considering the FM (frequency, monetary) values for the transactions. The result is association rules which have high revenue potential. These works highlight many important algorithms and techniques in the field of data analysis in order to find helpful information from the customer's transaction data such as products that have more or less sold, compatible products, time statistics, and more information, which we will mention it in the coming sections.

The main advantage of the proposed method in this paper is that it considers user-centric and item-centric recommendations to discover the correlation between customers and products, allowing for better recommendations.

### *B. Literature Related to Motion Tracking*

Work described in [18] describes a computer vision system in real-time; this system is designed for an electronic billboard and recognition and track customers, the provide a piece of demographic information about these people. This information is used to update the current advertisement on current products to fit customer needs. The information provided by this system about customers includes age, the number of customers, how much time customers sets in front of the billboard. Another study described in [19] introduced a new system for monitoring and tracking the number of customers in some open places like a shopping center and museums hall. Two main techniques are used to develop this work first one is the laser scanner, and the second one is a single camera. To combine the information that extracts from these two tracking devices, Bayesian methods are used. The advantage of this approach is that it combines two techniques and uses them in one field of tracking people. However, the disadvantage of this approach is that it is inaccurate information is from the laser scanner. Work described in [20] provides an integrated system based on an RGB-D camera. This system can monitor customer behavior inside the shop environment. In addition, discover the interaction between customer and products through analysis of the recorded videos and classify this interaction into three types: pick up the product, pick up the product, and bring it back to the shelf and no interaction between customer and product.

The study described in [21] provides a system which distinguishes a variety of customer behavior opposite the products: incurious, taking a look, passing the body near shelf, touch the product, take product then return it to a shelf and take it and put into shopping cart, which gives us a hint that the customer has an interest in products. The given system is dependent on the orientation of head and body and arm action, which divided those into eight directions to estimate whether the customer searches to products or looking to the shelf. Then, a semi-supervised learning method was applied to

improve the training dataset and generate the file that contains accurate data. Work described in [22] showcases a system for tracking and identifying customers' interactions with on-shelf products inside a retail store. To accomplish the tasks of this system, an RGB-D camera is installed in a vertical position to capture the area of a store shelf. The Water Filling algorithm is used to recognize customers' interactions. Interactions such as a customer picking up a product off the shelf, putting a product back on the shelf, and customers grouping formation can be evaluated. The data collected from these interactions makes it possible to construct an intensity map on a shelf to show where interactions happened. Some of the most prevalent obstacles that a system like this might face are camera position, person's clothing, occlusion, body pose changes, diversity in product shapes, and constantly changing background. Some key factors make the implementation of this system viable, such as its affordable cost and ease of installation and maintenance. A study described in [23] proposes a framework for people detection in a store environment with the help of essential CCTV (Closed-circuit Television Camera) security cameras. The approach aims to achieve accurate customer detection from video recorded by the store's security cameras. An SVM (Support Vector Machine) binary classifier is used to classify each frame, where it returns positive if a person is detected or negative if not. Detected data is then recorded and mapped with coordinates to signify a customer's location within the video frame. This data is later mapped into a heat map to show the highest traffic areas within the store. The heat map visualization is based on Kernel Density Estimation (KDE). Advantages of this approach are the availability of CCTV cameras in many stores and an unambiguous visual representation of the exciting store regions.

Work described in [24] suggested CREEN system, which is an intelligent mechatronic system for help customers to search or to get the products which they want within the retail environment. This system works to reduce the needing to put helping icons or maps within the storing center. This system's primary function helps people move within the store by forecasting the probability that customers will attract positions that are analyzed in front of a shelf of products. There are installed tools on the cart that include information about the location of elements and a location map for elements, which in turn leads the customer to the product he wants to pick. This system aims to develop a robot that searches for the best location to put the product within the store. Also, it can be used for blind and older adults. A study described in [25] presents the VMBA problem, which is based on set up cameras on store carts and considers three main stages, which include: the interaction, location, and the scene that is taken from the camera. Which in result goal to inference the behavior of customers within the retail environment. Furthermore, by merging these behaviors with information exported from the analysis, the market cart-like (transactions) gives retail store owners the management of areas and shopping strategies. Work described in [25] provides a new methodology for tracking, which is based on the visual attention focusing for customers WVFAO for many persons and which is used on understanding human behavior. This approach is based on capturing the attention of wandering to external ads and considers Bayesian network (HDBN) to discover the number of people in scene, body, head location (Direction), the interactions, and WVFAO

their own. In addition, this research includes the way to design the model WVFOA.

As a result of previous research, we can list many techniques in the field of tracking the motion of people and the study of their behavior. These techniques will provide our work the complete information about customers' behavior within the store, such as information about customers' (age, gender), customer count and region of gathering people, etc. In addition to that, the interactions between customers and products like how much time customers spend in front of a product, if interested or not. This information considers the main thing in our work which we will mention this necessary in the following steps.

### C. Literature Related to Emotion Detection

A study described in [26] explains that a strong structure is a design to recognize the three-dimensional position and local emotional expressions of the face, such as eyelid movements and mouth movements, which given a significant role in explaining the face emotion expression, by using RGB-D camera and the Kalman Extended filters. Advantages of this method include high 3D data with the information of color and density, high accuracy, and full automation. Disadvantages include that it is sensitive to light cases and gets confused by shadows. Another study described in [27] study the face recognition depending on FTFA-DLF. FTFA-DLF can merge deep learning features and handcraft features extracted from the nose, eye, and mouth regions. It used to help deep learning features by adding deep learning and handcraft features to the objective function layer to get better facial recognition performance based on the LFW dataset. Advantages include color information, and the descriptor computation strategy does not affect performance, high accuracy, and is fully automated. Disadvantages include missing pixels and brightness have a harmful effect and data storage.

Work described in [28] study an emotion recognition system depending on a MATLAB environment into a MATLAB Simulink environment that is able to recognize facial expression automatically in real-time. The label and the dataset used in this study build-up from the videos. The facial recognition system built on the programmable array and the camera sensor uses through this study can recognize facial emotion in actual time at a frame rate of 30. Advantages include FPGA devices being updatable, fully automated, high-performance, and FPGA no need cost compared to ASLCs. Disadvantages include Data storage and camera angle. Work described in [29] presents some algorithms for facial expression recognition grin detection. The algorithms depend on deep machine learning a [CNN], the main goal of this network is to select one of the six types of emotions using the [CMN] MultiPie database, by training through this database parallel on a large number of independent flows on [GPU]. Advantages include accuracy in image detection problems and being fully automated. Disadvantages include being very slow to train and needing to use a lot of data and data storage and camera angle training.

A study described in [30] suggests a way for emotion recognition-based facial components. It is complete in extracting the local features of the mouth and eye from each frame using GW with selected orientations and scales. The

express that features on to classifier for detecting of the face scope. From detection, each pixel on through the face. Finally, select and recognize the emotion of the face by using the Adboost algorithm. Advantages include improved performance compared to the current techniques because of its new features and not affected by changes in colors lighting. Work described in [31] applies the concepts of deep learning for detecting facial expression, so they proposed a facial expression monitoring system [PFEMS] in addition to design a convolutional neural network model using TensorFlow into two parts: a) Validation tools and b) Training model for data training after extracts the facial images from the video frames into the facial detector then detecting this image by using CNN to monitor the emotion state from the six universal emotions [angry, disgust, happy, surprise, sad and fear].

A study described in [32] introduces a method for the classification of facial expressions, which is based on a fuzzy logic model. The approach relies on a supervised machine learning method, which uses pre-existing databases that contain images of faces labeled with their respective emotions. A set of fuzzy logic rules are generated from the given data using the FURIA algorithm. These rules are generated based on the cosine values of the essential triangles plotted on the most critical points on a face. Each generated fuzzy rule presents some conditions, which are then used to classify different emotion types. To start the emotion recognition, first, a face must be detected. For this task, the DLIB toolkit was used for real-time face tracking and provide a set of 68 landmarks from the face detected. Some triangles are then overlaid over these points, and the cosine value is calculated for all the vertices of the triangles. The values are later passed to the generated fuzzy rules to recognize the emotions expressed in the image. The main advantages of the proposed method include working with image files, pre-recorded video, and live webcam, and it can classify emotions in real-time and detect multiple faces simultaneously. Limitations of this study include it can only classify six basic emotions, the model used is influenced by the quality of the data used in training it, and the model detects most intensive emotions better than less intensive emotions.

While Cisco has afforded different and promising solutions towards improving the shopper experience using IoT and big data analytical approaches [33], [34] (i.e. depending on monitoring and analyzing the shopping path and their movements), their focus stayed on studying horizontally a massive set of data without paying much attention to specific products. Nevertheless, this paper differs in that our approach focuses on detecting a particular product (i.e. out-of-demand store-items) based on the shopper's interaction with a product vertically.

## III. APPROACH

This section presents our proposed association rule-mining approach, which consists of three main components (i.e., data analysis, motion detection, and emotion detection), illustrated in Figure 1. We explain these components in some detail in the following subsections.

### A. Data Analysis

This component is concerned with analyzing data collected from stores' transactional databases using association rule

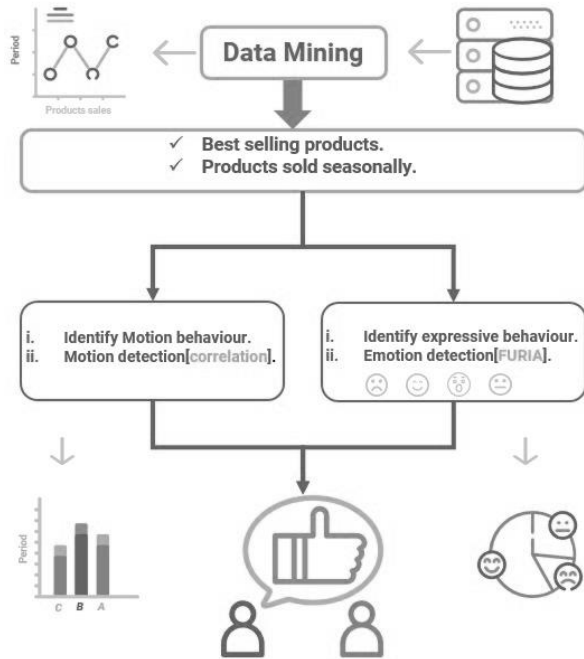

Fig. 1. The Top Level Workflow of our Proposed Approach, Illustrating the Interaction between the three Main Components (i.e. Data Analysis, Motion Detection, and Emotion Detection).

mining. Through this analysis, business owners can discover knowledge pertaining to associated store items that could be bought together, customers’ periodic purchasing patterns, product performance, and other sound patterns. In addition to analyzing the data from the customers’ transactions, this component supports analyzing video data collected from motion and emotion observation tools.

There are different algorithms for association rule mining, but the two widely used are Apriori and FP-Growth. We choose to implement the FP-Growth algorithm as it performs better with larger datasets. In addition, the FP-Growth algorithm relies on the divide-and-conquer approach and only performs two full I/O scans of the database, making it more suitable for more large databases. Concerning the tool used, we have implemented the FP-Growth algorithm using PyFpgrowth<sup>1</sup>.

More in detail, to use PyFpgrowth, one needs to encode data from transactional structures into a 2-dimensional list object, where each sub-list contains the items of a single transaction. To generate the association rules, one also needs to specify the minimum values for support, confidence, and lift. By specifying these values, the best rules can be generated while controlling their size. The output from this algorithm is a set of association rules, each with its specific values for support, confidence, and lift.

Figure 2 describes the results generated from the association rules from a sample dataset used in our experiments using

<sup>1</sup>A Python implementation of the Frequent Pattern Growth algorithm <https://pypi.org/project/pyfpgrowth/>

Fig. 2. Examples of Association Rules Generated by FP-Growth Algorithm.

the FP-Growth algorithm with the configurations (Minimum support = 0.05, minimum confidence = 0.2, minimum lift = 0.4). The aim here is to infer the total sales of a selected product in specific periods (weekly, monthly). This is essential to detect the change in customer behavior and their inclination towards some products. By using the same previous dataset of bakery sales, we can view a list of unique products present in the transactions. The next step is to select one of the products from the list and the period steps to show the total sales. The output of choosing the product 'cookies' and choosing the monthly steps shows the total sales of the product for each month recorded in the dataset.

The ability to discover relations between items and to show the change in customer inclination to buy a particular product is helpful for this project as they provide us with critical information about the customers’ behavior. Although sometimes the reasons behind these changes in customer behavior may not be apparent to the business owners. Hence, we suggest that business owners need to further inspect the reasons behind the ambiguous changes using the proposed methods for customer tracking and emotion classification, discussed in the next subsections.

### B. Motion Detection

Store video analytics is an essential technique to understand the customers’ behavior accurately. With the help of this component, we can collect information related to customers’ region of interests (ROIs), customer count, density maps, customer’s interaction with on-shelf products, and general information about the customer such as their age and gender. The system

Fig. 3. Classification of Customers' Interest based on Hand Movement.

Fig. 4. Result of the Interaction Per Section between the Customer and the Selected Product.

also records data related to the customers' interactions with the products on the shelf; this is done by applying a motion detection algorithm that we implemented. We concluded that the best way to capture the customers' interactions is through a camera that is installed above the shelf. The camera shall only record the area which is very close to the shelf.

The used algorithm works with the real-time video that is captured from the camera and divides every captured video frame into three equal sections, as shown in Fig. 3. The main reason behind this separation is to provide us with a way to classify the customers' interactions based on how close they are to the shelf. The algorithm will then detect the interactions (motion) that happen at each section separately and record the section number and the time when the interaction happened.

This data can help business owners understand the types of interactions that their products get. For example, if we compare the total number of interactions recorded in Section 1 (closest section to the product) and the total sales of that product, we could detect cases where products might get a lot of interaction/interest from customers but a low number of those customers purchasing the product. Thus, we can conclude that there might be something we can improve with that product.

The main goal of the algorithm is to detect and record motion-captured from real-time video. The execution starts by defining a list that contains three objects of the Frame class. The Frame class has a constructor that defines two main properties for each frame. First is the content property, which will be assigned the image captured from a video source. Second is the stoppage frames property that will start as 0

initially but should later be incremented accordingly. Finally, we create a second list that should hold the three corresponding reference frames (background frames) during execution. These frames are only initialized once.

Execution continues by reading the first frame from the video source (camera). The frame will then be split into three equal (in height) frames. Each one of these subframes will be assigned to the three previously declared frame objects. We then iterate over each of the frame objects to detect movement separately for each section. The iteration over a frame object starts by processing the frame to be ready for movement detection. Frame processing includes: (1) converting the frame to grayscale and (2) applying Gaussian blur on the frame.

The next step is to check if the corresponding reference frame is initialized. To determine if there is a movement that occurred between our current frame and its reference frame, we need to:

- 1) Calculate the absolute difference between them and assign it to a new frame.
- 2) Apply threshold on the subtracted image with a chosen threshold value.
- 3) Dilate the threshold image.
- 4) Find contours in the dilated image.
- 5) Calculate the total area of the contours found.

Next, check if the total area of contours exceeds the set minimum. Setting the minimum value depends on how large the object one needs to track (hand in this case). If the minimum is exceeded, we check if the stoppage frames for the current frame if it exceeds a set value (15) that means that an object has entered the frame, and we can record the current time and the section related to the movement and we have to reset the stoppage frames back to 0 because the frame currently has movement.

If the total area of contours did not exceed the minimum value, we could increment the stoppage frames for the object. The execution will then continue for the remaining two frames. After that we begin executing the same steps for the next frame of the video source. Fig. 4 displays the interaction per section between the customer and the selected product.

### C. Emotion Detection

Advancement in the field of deep learning and computer vision allows to capture the facial expressions of a customer and accurately predict their displayed feeling. This can be helpful for getting information about the customers' feelings toward certain products. Understanding how the customer feels opens up many questions about why they feel a certain way in a given moment. Through understanding how the customers feel, we can propose solutions to enhance their shopping experience further. The system analyzes video recordings of people and detects their facial expressions, then record and store that data. The emotions detected from peoples' faces can be helpful in trying to understand their behavior and to evaluate their satisfaction rate. A business must keep the customers' satisfaction to retain their loyalty.

The input is taken from a video camera. At the start, the algorithm splits the video into a list of frames, and each frame constructs an image frame. Then a face must be detected within

the image frame. This is done with the DLIB toolkit. Then cover the face that is discovered with a rectangular shape. The toolkit will also plot some points and form triangles on significant areas in the face (eyes, nose, and mouth) detected and calculate the cosine values for all vertices. Values are then passed to some fuzzy rules to determine the emotion detected from the frame. Testing was done using a video recording of one person. The length of the video was 42 seconds, and the recorded instances in the results were 450. The result is recorded in an Excel file with their respective time stamps and emotion classifications. Then Represent the results in a byte chart to make them more understandable by the client. The recorded result contains 450 instances where each one has a precise time stamp and a value for each emotion recorded as shown in Figure 5.

Data on peoples' expressions could be further analyzed to understand the meaning behind them. For this paper, we found a reliable way to collect such data, but this information is handy to business owners because they need to know the customers' feelings and understand their causes to adapt their business to improve the customers' satisfaction. In our case, we consider that the customer needs to touch the product to know the price.

Time	Msec	Stamp	Happy	Sad	Surprise	Fear	Disgust	Anger	Neutral

#### IV. EXPERIMENT AND DISCUSSION

##### A. Questionnaire

We prepared a questionnaire<sup>2</sup> to identify customers' emotional reactions against the items with exorbitant prices, out-of-date products, and so on. 150 people took the questionnaire

<sup>2</sup>[https://docs.google.com/forms/d/e/1FAIpQLSdSRhmV9esbHdCSZQ6n\CvDMm2e-JK4Q-M\\_FyYQ89VEC7J5xJg/viewform](https://docs.google.com/forms/d/e/1FAIpQLSdSRhmV9esbHdCSZQ6n\CvDMm2e-JK4Q-M_FyYQ89VEC7J5xJg/viewform)

(90 males and 60 females). The mean age of the participants was 22 years. The responses were statistically analyzed to find the customers' emotions against the design and price of the items. Based on the results of the questionnaire, we classified emotions into six categories, which include Happy, Sad, Surprise, Fear, Disgust, and Anger.

##### B. Experimental Setup

We experimented with a grocery store in which some products were facing sales problems, as reasoned from the transaction database of the store. We picked these products for our experiment. We set up the proposed system for 30 days to analyze the behavior of customers towards the product. During the experiment, 3000 customers visited the store in total, with an average 100 customers per day. Out of these, 2500 customers interacted with the products monitored with an average of 83 customers per day.

##### C. Results

TABLE I. SUMMARY OF RESULTS DEPENDING ON BOTH THE PROPOSED PREDICTOR AS WELL AS THE QUESTIONNAIRE RESULTS.

Emotion	Motion		
	Excited (>50%)	Hesitant (>50%)	Careless (>50%)
Happy	Price/Placement	Design	Placement
Sad	Placement	Placement	
Surprise	Price	Design	
Fear	Price	Design	
Disgust	Design	Placement	
Anger	Placement	Placement	

Table I summaries our findings based on the measures from both prediction tasks by our proposal as well as from questionnaires. Moreover, we report on seven different scenarios representing customer behavior towards items that are out-of-demand, as follows:

*Case 1:* This case is an intersection between Excited and Careless. If no motion is recorded, then no emotion can be predicted, and the problem can be addressed by correcting the placement.

*Case 2:* This case represents the emotional happiness for more than 50% of customers towards the selected product and the interaction between customer and product (i.e. excited, hesitant, careless). If the customer feels happy and there is an interaction between the customer and product, but the product's sales are still low, then the problem is in the product price, which needs to be improved.

*Case 3:* This case represents the emotional happiness for more than 50% of customers towards the selected product and the interaction between customer and product (i.e. excited, hesitant, careless). If the customer feels happy and there is no interaction between customer and product, but there are movements in front of the product, the problem is in the product design, which needs to be improved.

*Case 4:* This case represents the emotional sadness for more than 50% of customers towards the selected product and the interaction between customer and product (i.e. excited, hesitant, careless). If the customer feels sad and there is an interaction between customer and product, then the problem is in the product placement, which needs to be corrected.

*Case 5:* This case represents the emotional sadness for more than 50% of customers towards the selected product and the interaction between customer and product (i.e. excited, hesitant, careless). If the customer feels sad and there is no interaction between customer and product, but there are movements in front of the product, then the problem is in the product placement and needs to be corrected.

*Case 6:* This case represents the emotional surprise for more than 50% of customers towards the selected product and the interaction between customer and product (i.e. excited, hesitant, careless). If the customer feels surprised and there is an interaction between customer and product, but the product's sales are still low, then the problem is in the product price, which needs to be improved.

*Case 7:* This case represents the emotional surprise for more than 50% of customers towards the selected product and the interaction between customer and product (i.e. excited, hesitant, careless). If the customer feels surprised and there is no interaction between customer and product, but there are movements in front of the product, then the product design problem needs to be corrected.

## V. CONCLUSION AND FUTURE SCOPE

Mining approaches based on video data can serve in identifying a store's performance and production by gaining insight into what needs to be proceeded to further enhance customers' experience, leading to increased business profits. To this end, we have proposed an association rule mining approach, depending on video analytic techniques, for detecting store-items that are likely to be out of demand. Our approach is developed upon motion-tracking and facial emotion expression methods. Results of our conducted experiments yielded seven different scenarios representing customer behavior towards out-of-demand stores' items.

Regardless of the high computational costs associated with the mining process, challenges to ideally apply our approach require overcoming: illumination conditions, complex people activities, crowded areas, constantly changing backgrounds, occlusion, and ineffective camera placements. We plan to tackle these challenges in the future besides conducting other experiments on a more comprehensive real-world dataset to validate the concept of our approach.

## ACKNOWLEDGMENT

We are grateful to Wasim Ahmad  for his advice on motion-tracking and emotion analysis methods, and their use in association rule-mining..

# Hybrid Model of Quantum Transfer Learning to Classify Face Images with a COVID-19 Mask

Christian Soto-Paredes, Jose Sulla-Torres  
Escuela de Ingeniería de Sistemas  
Universidad Nacional de San Agustín de Arequipa  
Arequipa, Perú

**Abstract**—The problem of the COVID-19 disease has determined that about 219 million people have contracted it, of which 4.55 million died. This importance has led to the implementation of security protocols to prevent the spread of this disease. One of the main protocols is to use protective masks that properly cover the nose and mouth. The objective of this paper was to classify images of faces using protective masks of COVID-19, in the classes identified as correct mask, incorrect mask, and no mask, with a Hybrid model of Quantum Transfer Learning. To do this, the method used has made it possible to gather a data set of 660 people of both sexes (man and woman), with ages ranging from 18 to 86 years old. The classic transfer learning model chosen was ResNet-18; the variational layers of the proposed model were built with the Basic Entangler Layers template for four qubits, and the optimization of the training was carried out with the Stochastic Gradient Descent with Nesterov Momentum. The main finding was the 99.05% accuracy in classifying the correct Protective Masks using the PennyLane quantum simulator in the tests performed. The conclusion reached is that the proposed hybrid model is an excellent option to detect the correct position of the protective mask for COVID-19.

**Keywords**—*hybrid; quantum; classify; face; COVID-19; mask*

## I. INTRODUCTION

According to the COVID-19 Data Repository by the Center for Systems Science and Engineering (CSSE) at Johns Hopkins University [1], which consolidates online information from the World Health Organization, the Chinese Center for Disease Control and Prevention, and the Johns Hopkins University as of September 2021, an estimated 219 million cases of people affected by COVID-19 [2] of which 4.55 million led to death. For this reason, security protocols have been implemented to prevent the spread of this disease. One of the main protocols consists of using protective masks that correctly cover the nose and mouth; even following safety protocols help reduce the incidence of other infectious diseases such as influenza, pneumonia, and mycobacterium tuberculosis [3]. Thus, this research contributes to compliance with the security protocol that establishes the use of protective masks in public places, the global impact is noted since it is not only a requirement demanded in all the cities of Peru, but it is also required in the rest of the countries around the world, in addition, reducing the number of people who dedicate themselves to the task of inspection and monitoring of compliance with this regulation has an impact on reducing costs and increasing the number of people verified. The literature presents Transfer Learning studies that try to solve this problem. A greater incidence in the use of ResNet-18 as a residual network is noted, with

significant results and accuracy greater than or equal to 90%, respectively.

Under this juncture, it was decided to classify the use that people give to masks in 3 classes: correct mask, incorrect mask, and no mask; it was decided to use Transfer Learning with ResNet-18 and enhance it with the use of quantum computing. An innovative hybrid model is born that represents an alternative for improvement to the classical methods of recognition, classification and/or prediction implemented in the literature. It is known that quantum computing helps in the simulation of quantum systems; it is in this subject that it is about simulating objects such as small molecules or macromolecules; quantum computing also supports the field of quantum optimization, helping to solve problems that have a cost that is intended to be minimized; also in stochastic physics, it helps to simulate random processes; It also supports risk analysis or simulation of probability distributions; even in cryptography; and finally in machine learning it allows machines to learn in a faster way since it allows representing multiple states at the same time. An additional motivation for proposing the hybrid model in question is that to date, there have been no Hybrid Quantum Transfer Learning investigations that seek to solve the problem of classifying face images using a COVID-19 protective mask.

A sample of 660 images in resolution of  $1024 \times 1024$  pixels, of people facing the front wearing a protective mask, of both sexes (male and female), aged between 18 to 86 years, was considered, 68% of these images were used for training and the rest 32% for testing, for their use the images were transformed to  $(3 \times 224 \times 224)$ , in the training a resizing and cropping of the images was carried out, to improve the training cases; regarding the quantum simulator, PennyLane was used with four qubits, with an exact number of shots. Regarding the construction of quantum neural networks, these were made up of the embedding layer, the variational layers and the measurement layer; in this sense, 3 types of quantum variational layers were contemplated, those made with the Basic Entangler Layers template, the Strongly Entangling Layers template and a custom construction called Custom Layers, with Basic Entangler Layers being the one that provides the best results; for the optimization tasks of the training of the model as a whole, the performance was compared with the Adam optimizer and with the SGD with Nesterov Momentum, being SGD who provides the best results; to finalize an accuracy of 99.05% in the tests was obtained, which is satisfactory compared to the similar problems of Hybrid Quantum Transfer Learning reviewed in the literature, although it is true that

the accuracy, together with the precision, the recall and the f1-score are essential metrics to validate the relevance of the research, it should be noted that this study focuses on illustrating the innovative proposed method and the particular adaptation of the method by the authors, not on exceeding all existing methods in accuracy, it is in this sense that the development of the research and the techniques used are the most significant contribution left by this study.

After this introduction, this article is organized as follows: The works related to this article are explained in Section II the methodology used in this research in Section III, the experimental results in Section IV, discussions in Section V, conclusions in Section VI, and finally, future works in Section VII.

## II. RELATED WORK

The bibliographic review contemplated various aspects such as Transfer Learning, ResNet, Hybrid Quantum Transfer Learning, and Datasets of images of faces with a mask.

### A. Transfer Learning

Solving a problem involves gathering a large amount of information related to the solution of that problem; Transfer Learning is based on taking advantage of a large amount of data acquired and using it to solve another type of problem that shares certain characteristics. Thus, the author Yadav in [4] proposes a video surveillance system implemented in raspberry pi4, which is developed by Transfer Learning, with MobileNetV2 [5] as a pre-trained neural network and a single Shot Detector (SSD), which provides an 85% to 95% accuracy in detecting people using a protective mask.

There are Transfer Learning researchers that create their own datasets. This is how the authors Wang, Zhao, and Chen [6], propose a two-stage method that uses a Faster RCNN framework with Inception v2; your created dataset consists of 26,403 images of faces using masks; With their proposed model, they achieved 97.32% accuracy in simple scenes and 91.13% in complex scenes.

Transfer Learning modifies patterns already trained in specific characteristics and uses them to recognize similar patterns. Thus, using Inception v3 [7] in Face Mask Detection, the authors Jignesh Chowdary, Punn, Sonbhadra, and Agarwal [8], propose a model of Transfer Learning with the Simulated Masked Face Dataset (SMFD), achieving 99.9% during training and 100% during testing.

### B. ResNet

ResNet [9] is known to allow deep training networks of more than 100 layers; In essence, it is a residual network which is based on the fact that some neurons connect with others in layers that are not necessarily contiguous, that is, jumping intermediate layers, considering this, the authors Loey, Manogaran, Taha and Khalifa [10] propose to use video object recognition to recognize people who use a protective mask, using for this purpose YOLO v2, here a feature extraction process is developed with ResNet-50 [9], achieving an accuracy of 81%.

The authors Addagarla, Kalyan Chakravarthi, and Anitha [11] proposed two models, FMY3 and FMNMobile; the latter uses Resnet SSD300 to tackle the task of recognizing people using masks, obtaining 98% accuracy and 99% recall rate.

The fundamental component of ResNet is the residual blocks; in a residual block, the input  $x$  is added directly to the output of the network by means of the jump connection; thus, the authors Jiang, Fan, and Yan [12], propose a one-stage detector called RetinaFaceMask which implements a Feature Pyramid Network, achieving a prediction in the detection of people with a mask of 82.3% with MobileNet [5] and 93.4% with ResNet-18 [9].

To conclude, the authors Sethi, Kathuria, and Kaushik [13] present a two-stage detector that compares the ResNet-50, AlexNet, and MobileNet models, concluding that ResNet gives better results in the task of classifying faces with a mask in video surveillance, achieving an accuracy of 98.2%.

### C. Hybrid Quantum Transfer Learning

Hybrid neural networks are made up of classical and quantum elements. There is the paradigm by which a pre-trained classical neural network is augmented with a variational quantum circuit [14]; this is how the paradigm called Hybrid Quantum Transfer Learning was born. Based on this approach is that the authors Mari, Bromley, Izaac, Schuld, and Killoran [15], propose to use this method for image recognition and quantum state classification; in their study, they are given the task of classifying images of bees and ants, among their The results obtained are 96.7% accuracy in the Pennylane simulator [16], 95% accuracy in IBM's ibmqx4 quantum hardware [17] and 0.80% in Rigetti's Aspen-4-4Q-A [18]. There are thus four ways to develop Transfer Learning, which are: classical to classical, classical to quantum, quantum to classical, and quantum to quantum; the classical to quantum approach is the one chosen for this research.

The authors Umer, Amin, Sharif, Anjum, Azam, and Shah [19], use Hybrid Quantum Transfer Learning with ResNet-18 and a 4-qubit quantum circuit to classify radiographic images of lungs of 3 types: COVID-19, Normal and Viral Pneumonia, with an accuracy of 99.7% in a quantum computer.

To run a Hybrid Quantum Transfer Learning model with ResNet-18, you can use simulators such as Pennylane [16], Qiskit-Aer [17], and Cirq [20]; you can also use real quantum hardware like the one provided by IBM: ibmq london, ibmq rome, among others, is how the authors Acar and Yilmaz [21] made their proposal in the devices mentioned above; They also used CT images of the lungs of 126 people with COVID and 100 ordinary people, achieving an accuracy of 90% in the simulator and 94% to 100% in quantum computers.

### D. Dataset

The datasets contribute to the task of classifying images of people's faces using masks; so authors such as Cabani, Hammoudi, Benhabiles, and Melkemi [22] created a dataset that they called MaskedFace-Net, which consists of 137,016 images in resolution of 1024x1024 pixels, to which they added masks utilizing image editing [23], that is how they created two groups which they called:

- Correctly Masked Face Dataset (CMFD).
- Incorrectly Masked Face Dataset (IMFD).

To end, in [24], a dataset of more than 250,000 images of faces using masks is provided, it consists of high-quality images 1024x1024 pixels, these images were not edited by computer, so real people are shown as is using masks of 4 different ways, which can be interpreted as follows:

- Correct use of the mask, the one that covers the nose and mouth.
- Incorrect use, which does not cover the nose.
- Incorrect use, which does not cover the nose or mouth.
- Incorrect use, which does not have any mask.

### III. METHODOLOGY

The objective of the study was to classify faces using protective masks from COVID-19 with a hybrid model of Quantum Transfer Learning; taking for this purpose a dataset of 660 people of both sexes (male and female), with ages between 18 to 86 years; in a diverse set of mask types and facial features. The classes identified for classification were 3: correct mask, incorrect mask, and no mask. The methodology used for the classification consists of 4 stages, elaborated under the approach of the Business Process Model and Notation (BPMN) [25] as shown in Fig. 1.

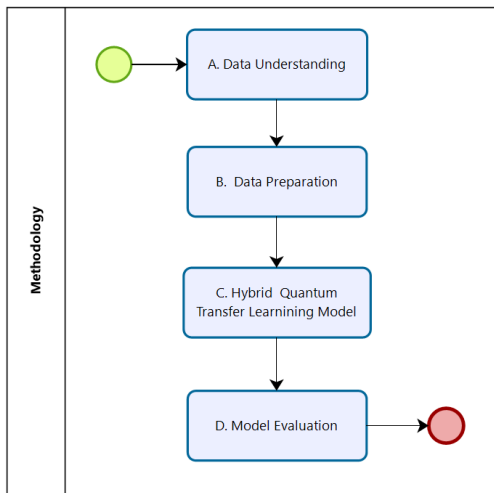

Fig. 1. Proposed Methodology for Classification (BPMN).

#### A. Data Understanding

The original dataset in [24] consists of more than 250,000 images divided into several parts; for the study, only part 2 of this dataset was taken, which consists of 40,000 images. This dataset is accompanied by a .csv file, which contains the detailed list of all the images; this is constituted as shown in Table I; this list is essential because it helped in the identification, understanding, and preparation tasks. Such as the subsequent processing of the sample images.

Explanation of the fields:

TABLE I. STRUCTURE OF THE DATASET LIST

<b>Id</b>	<b>Type</b>	<b>User Id</b>	<b>Gender</b>	<b>Age</b>	<b>Name</b>
Incremental	1-4	Numeric	M—F—N	Numeric	Text

- **Type:** Represents the four ways in which a person uses a mask, 1-correct mask, 2-incorrect mask (does not cover the nose), 3-incorrect mask (does not cover the nose or mouth), 4-incorrect mask (The person is not wearing the mask).
- **User Id:** Numerical value with which a person is identified.
- **Gender:** Male, female, or none.
- **Age:** Numerical value that is between 18 to 86 years old.
- **Name:** Sequence of alphanumeric characters with which the .jpg image is labeled.

The dataset organized by gender is shown in Table II, “None” corresponds to people whose gender was not registered; in addition, there is a predominance of people of the male gender 59.58%.

TABLE II. DATASET ORGANIZED BY GENDER

<b>Gender</b>	<b>Number</b>	<b>Percentage (%)</b>
Male	23832	59.58
Female	7012	17.53
None	9156	22.89

The dataset organized by age ranges is shown in Table III. From this, it is observed that the most significant population range is in the range of 18 to 30 years of age and that there are 1,948 people whose age was not registered, approximately 4.87%.

TABLE III. DATASET ORGANIZED BY AGE RANGES

<b>Age</b>	<b>Number</b>	<b>Percentage (%)</b>
18-30	27844	69.61
31-40	7732	19.33
41-50	2416	6.04
51-60	12	0.03
61-70	0	0.00
71-80	44	0.11
81-90	4	0.01
others	1948	4.87

#### B. Data Preparation

As a first step, the number of classes was reduced from 4 to 3, that is, to 30,000 images; since there is no significant difference between not bringing a mask and bringing a mask that does not cover the nose or mouth, the new output classes are:

- **Correct Mask:** This represents a correct use of the protective mask, which covers the nose and mouth (Fig. 2).

- Incorrect Mask: Representing an incorrect use of the protective mask, which does not cover the nose (Fig. 3).
- No Mask: This represents the absence of a mask that protects the individual (Fig. 4).

Fig. 2. Correct Mask.

Fig. 3. Incorrect Mask.

Second, a representative sample was taken, which is defined in (1), where:

- $n$  Sample size.
- $N$  Population size.
- $p$  Probability of occurrence of the event studied.
- $q$  Probability of non-occurrence of the event studied.
- $Z$  Parameter that depends on the confidence level.
- $e$  Estimation error.

$$n = \frac{N \times Z^2 \times p \times q}{e^2 \times (N - 1) + Z^2 \times p \times q} \quad (1)$$

The 30,000 images considered became the initial population  $N = 30,000$ , in addition, a confidence level of 90% was estimated, that is, a  $Z = 1,645$ , an estimated error of 5.52%,

Fig. 4. No Mask.

and the values of  $p$  and  $q$  are calculated to have the same probability of occurrence 50% each. Executing the calculations with (1), it was obtained the selected sample was  $n = 660$  in total, then, the next step was to randomly retrieve the images, considering 68% for training and 32% for testing as well as it's shown in Table IV.

TABLE IV. QUANTITIES FOR TRAINING AND TESTING

Phase	Percentage (%)	Total images	Total per class
training	68	450	150
testing	32	210	70

Then, transformations were made to the sample images; initially, these had a resolution of  $1024 \times 1024$  pixels, but since it was the residual network ResNet-18 it required that they be transformed to the form  $(3 \times 224 \times 224)$ , it was also carry out a normalization with the mean and the standard deviation to  $[0.485, 0.456, 0.406]$  and  $[0.229, 0.224, 0.225]$  respectively, both for training and testing. Additional tasks such as random resizing and clipping were also performed on the training dataset, as well as a random horizontal rotation to improve the training cases. To finish, the data was loaded into a dictionary with the help of the Pytorch DataLoader [26], with a batch size of eight as shown in Fig. 5. and two workers to speed up the loading.

### C. Hybrid Quantum Transfer Learning Model

Here the most critical topics in constructing the proposed hybrid model and its variants are detailed in 9 parts, which give rise to comparisons that trigger the final results.

1) *Number of Qubits*: It took four qubits, a qubit is the basic unit of quantum computers, just like a bit can take the value 0 or 1, however by the superposition principle, it could have a part of 0 and a part of 1, when measuring said qubit it will collapse towards one value or another; in definition, a qubit is a unit modulus vector in a complex two-dimensional vector space, the quantum states are  $|0\rangle$  in (2) and  $|1\rangle$  in (3).

Fig. 5. Transformations Made for Training in a Batch of Images of Size Eight.

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad (2)$$

$$|1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad (3)$$

In addition, the state of a qubit can be represented by the “Bloch Sphere”, this shows in the extreme north the state  $|0\rangle$  and in the extreme south the  $|1\rangle$  the rest of possible states would be represented along the surface of the sphere by  $|\psi\rangle$ , which is a linear combination of the states  $|0\rangle$  and  $|1\rangle$  as in (4), the state of a qubit is more likely to collapse towards  $|0\rangle$  when it is further north and to collapse towards  $|1\rangle$  when it is further south Fig. 6.

Fig. 6. Graphical Representation of a Qubit as a Bloch Sphere, shows the General States  $|0\rangle$  and  $|1\rangle$  and Arbitrary General States Represented by  $|\psi\rangle$ , where  $\theta$  and  $\phi$  are Real Numbers Such that  $0 \leq \theta \leq \pi$  and  $0 \leq \phi \leq 2\pi$ , any  $|\psi\rangle$  can be Expressed as in (5).

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle \quad (4)$$

$$|\psi\rangle = \cos\left(\frac{\theta}{2}\right)|0\rangle + e^{i\phi} \sin\left(\frac{\theta}{2}\right)|1\rangle \quad (5)$$

2) *Quantum Node and Differentiation Method:* In pennylane [16], quantum computing is represented by objects composed of quantum nodes; a quantum node is used to declare a quantum circuit and relate it to a device that executes said circuit. Regarding the differentiation methods, for the simulation in pennylane [16], they are available: backprop,

adjoint, and reversible, and for real quantum computers: parameter-shift and finite-diff are available. For the present study, “reversible” was chosen because the quantum network will run in a simulator and give better results than the others.

3) *Device and the Number of Shots:* A “device” is the one that allows indicating in which hardware to execute the quantum circuit, for the given case “default.qubit” was chosen, the default local simulator of pennylane [16]; the number of “shots” was established as “exact,” this is only possible because they are simulators, in real quantum computers the number of “shots” is determined by the equation proposed in (6), where:

- $c$  Confidence level.
- $Z$  Parameter that depends on the confidence level.
- $e$  Estimation error.

$$shots = \left(\frac{Z_{1-c}}{2 \times e}\right)^2 \quad (6)$$

For a confidence level of 95%, we have that  $Z = -1.96$ , and if an approximate error of 5% is taken, it is obtained that 384.16 is needed, which rounding would give rise to  $shots = 384$ .

4) *Quantum Neural Network with Basic Entangler Layers:* The proposed quantum neural network is similar to a classical fully connected neural network; it receives a vector of 512 features and has three outputs associated with the correct-mask and incorrect-mask and no-mask classes. The structure is composed of a preprocessing layer of type Linear, an activation function of type hyperbolic tangent, a layered architecture of Basic Entangler layers, and a post-processing layer. The layer mentioned above architecture is built with a variational quantum circuit or variational circuit [27]; this hybrid algorithm combines quantum and classical computing and is designed to be executed in quantum computers. To implement this type of variational circuit, you must first define a node with a quantum function that receives as parameters the number of features and the selected weights; we must resize the weights to the form: number of quantum layers x number of qubits. Then for each wire, you have to place a Hadamard gate ( $H$ ) Fig.7, which operates on a single qubit, this is in charge of transforming the state  $|0\rangle$  in  $|+\rangle$  and the state  $|1\rangle$  in  $|-\rangle$ , its matrix representation is observed in (7) as well as the representations of the  $|+\rangle$  and  $|-\rangle$  in (8) and (9) respectively.

$$H = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \quad (7)$$

$$|+\rangle = \frac{|0\rangle + |1\rangle}{\sqrt{2}} \quad (8)$$

$$|-\rangle = \frac{|0\rangle - |1\rangle}{\sqrt{2}} \quad (9)$$

Then three types of quantum layers are added, as detailed:

- Embedding layer: Here a layer consisting of single-qubit rotations was inserted, with rotation gates such

as RX (10), RY (11), and RZ (12), where  $\phi$  is the angle of rotation, for this the template “Angle Embedding” was used, The graphic representation of this layer is shown in Fig. 7.

$$R_x(\phi) = \epsilon^{-\frac{i\phi\sigma_x}{2}} = \begin{bmatrix} \cos(\frac{\phi}{2}) & -i \sin(\frac{\phi}{2}) \\ -i \sin(\frac{\phi}{2}) & \cos(\frac{\phi}{2}) \end{bmatrix} \quad (10)$$

$$R_y(\phi) = \epsilon^{-\frac{i\phi\sigma_y}{2}} = \begin{bmatrix} \cos(\frac{\phi}{2}) & -i \sin(\frac{\phi}{2}) \\ \sin(\frac{\phi}{2}) & \cos(\frac{\phi}{2}) \end{bmatrix} \quad (11)$$

$$R_z(\phi) = \epsilon^{-\frac{i\phi\sigma_z}{2}} = \begin{bmatrix} \epsilon^{-\frac{i\phi}{2}} & 0 \\ 0 & \epsilon^{\frac{i\phi}{2}} \end{bmatrix} \quad (12)$$

Fig. 7. Embedding Layer for 4 Qubits, with Hadamard Gates and Single Rotation Gates RZ (Graphic Generated with ibm Qiskit).

- Variational layers: Built with the Basic Entangler Layers template, which receives as parameters the weights, a vector of wires, and the axis on which to rotate, this is in charge of building the number of layers specified in the shape of the weights; This template inserts *CNOT* gates (13) and single-qubit rotations (10), (11), and (12), as shown in Fig. 8.

$$CNOT = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix} \quad (13)$$

Fig. 8. Variational Layers with Basic Entangler Layers for four Qubits and a Depth of 2 Layers, with CNOT Gates and Single Qubit Rotations Gates RZ, as an Example, only Two Layers are Shown because, for the Evaluation of the Study, a Depth of 10 Variational Layers was Considered (Graphic Generated with ibm Qiskit).

- Measurement layer: This layer contains 4 Pauli *Z* operators (Fig. 9), which allow measuring the state of

the four qubits, which, when observed, will collapse towards one state or another; the matrix that represents it is shown in (14).

$$\sigma_z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \quad (14)$$

Fig. 9. Measurement Layer with 4 Pauli Z Operators (Graph Generated with ibm Qiskit).

5) *Quantum Neural Network with Strongly Entangling Layers*: In a similar way as in the previous section III-C4, the quantum neural network receives a vector of 512 features and provides three outputs corresponding to correct-mask, incorrect-mask, and no-mask, of Likewise, it consists of a processing layer, a post-processing layer and has a *tanh* activation function, the difference lies in the architecture of the variational circuit that is built with the “Strongly Entangling Layers” template [28], so the embedding layer and the measurement layer are the same as seen in the previous section, Fig. 7 and Fig. 9 respectively, with the same operators seen in (10), (11), (12), (13), and (14).

The “Strongly Entangling Layers” template [28] is based on the circuit-centric classifier design, which is composed of single-qubit rotations interlaced with *CNOT* gates; each single qubit *G* is a  $2 \times 2$  unitary, as shown in (15).

$$G(\alpha, \beta, \gamma, \phi) = \epsilon^{i\phi} \begin{pmatrix} \epsilon^{i\beta} \cos \alpha & \epsilon^{i\gamma} \sin \alpha \\ -\epsilon^{-i\gamma} \sin \alpha & \epsilon^{-i\beta} \cos \alpha \end{pmatrix} \quad (15)$$

“Strongly Entangling Layers” does not support the “reversible” differentiation method, so pennylane [16] automatically selects the best possible method. In Fig. 10, this type of variational circuit is shown with a depth of 2 layers.

6) *Quantum Neural Network with Custom Layers*: Also in a similar way to section III-C4, the quantum neural network is completely connected as described in that section, the difference is that the architecture of the variational layers is based on the examples detailed in [15], this latest layer design proposal is based on interlacing of *CNOT* gates and single-qubit rotations as seen in Fig. 11, the embedding layer is seen in Fig. 7 and the measurement layer in Fig. 9 respectively, also makes use of the operators seen in (10), (11), (12), (13) and (14).

Fig. 10. Variational Layers with the use of the “Strongly Entangling Layers” Template for four Qubits and a Depth of 2 Layers, with CNOT Gates and U<sub>3</sub> Rotations Gates that Represent Three Single-Qubit Rotations R<sub>Z</sub>, R<sub>Y</sub>, and R<sub>Z</sub> Respectively, as an Example only Two are shown Layers because for the Evaluation of the Study a Depth of 10 Variational Layers was Considered (Graph Generated with ibm Qiskit).

Fig. 11. Variational Layers with Basic Entangler Layers for four Qubits and a Depth of 2 Layers, with CNOT Gates and Single Qubit Rotations Gates R<sub>Z</sub>, as an Example, only Two Layers are shown because, for the Evaluation of the Study, a Depth of 10 Variational Layers was Considered (Graphic Generated with ibm Qiskit).

TABLE V. RESNET-18 ARCHITECTURE

7) Hybrid Transfer Learning: About classic transfer learning, two types are considered: finetuning and feature extraction. In “finetuning,” you start from a pre-trained model and update all the parameters for a new task; essentially, the entire model is completely re-trained. In “feature extraction,” we start from a pre-trained model and only update the final layer’s weights, with which we can now make predictions. Both transfer learning methods follow the following steps:

- Step 1: Initialize the pre-trained model with the selected parameters.
- Step 2: Reshape the final layer.
- Step 3: Define an optimization algorithm.
- Step 4: Carry out the training.

In addition to the above, it should be clarified that hybrid quantum computing receives its name for combining classical computing approaches with quantum computing. So to do hybrid quantum transfer learning, a classical pre-trained network must be taken, for this case, ResNet-18 (Table V), to which the final layer is reshaped to connect it with a quantum neural network whose architecture is based on a variational circuit that will be executed in a quantum computer.

In the present study, “feature extraction” was carried out, and the final layer of ResNet-18 is linked to the quantum neural network with 512 features in the manner described in section III-C4. Furthermore, let  $L$  be a layer,  $n_0 \rightarrow n_1$  represents  $n_0$  inputs and  $n_1$  outputs,  $x$  an input vector and  $y$  an output vector as in (16).

$$L_{n_0 \rightarrow n_1} : x \rightarrow y \tag{16}$$

Then it is known that  $Q$  is a variational quantum circuit with  $E$  embedding layer and  $M$  measurement layer (17).

$$Q = M \circ Q' \circ E \tag{17}$$

Finally, to apply hybrid quantum transfer learning, the quantum neural network  $\bar{Q}$  [15] has to be created as shown in (18), based on what is formulated in (16) and (17) .

$$\bar{Q} = L_{n_q \rightarrow n_{out}} \circ Q \circ L_{n_{in} \rightarrow n_q} \tag{18}$$

From all the above, it is possible to graphically observe the proposed hybrid quantum transfer learning model Fig. 12.

8) Optimization: The optimization process consists of the task of finding the best weights, minimizing the error in each iteration. For this, two methods were used: Adam [29] with a learning rate of 0.0004 and Stochastic Gradient Descent with Nesterov Momentum [30], the implementation of momentum

Fig. 12. The Proposed Hybrid Quantum Transfer Learning Model Receives an Image of a Person Wearing a COVID-19 Protective Mask, as Input and as Output a Classification (Correct Mask, Incorrect Mask, and no Mask) is Provided; on the Side of Classical Computing, it is Found ResNet-18 and on the Side of Quantum Computing is the Quantum Neural Network with 512 Features, four Qubits, and Three Outputs, this Quantum Neural Network is based on what is Formulated in (18).

is described in (19) and (20), with a learning rate of 0.001 and a momentum of 0.9.

$$v_{t+1} = \mu * v_t + g_{t+1} \quad (19)$$

$$p_{t+1} = p_t - lr * v_{t+1} \quad (20)$$

Where  $p$  represents the parameters,  $g$  the gradient,  $v$  the velocity and  $\mu$  the momentum.

9) *Training*: Is performed by first defining a training function that receives input parameters such as a model, a dictionary with the information of the loaded images, a loss function, in this case, “cross-validation”, an Adam or SGD optimizer, several epochs to train, and an “is inception” flag which is used to prepare the function to work with Inception v3. It is worth mentioning that this training function was tested in transfer learning with the following classic models: resnet, alexnet, vgg, squeezenet, densenet, inception, and on the quantum side resnet-18 and densenet were implemented. This training function performs 2 phases: one of training itself and another that tests the time in question; with the optimizer, the best weights are chosen to allow the resulting model to classify between correct-mask, incorrect-mask, and no-mask. Finally, the results obtained by executing 10, 20, and 30 epochs were recovered, and each model was tested with the images intended for testing; a sample can be seen in Fig. 13.

#### D. Model Evaluation

To evaluate the model [31], the Precision (21), the Recall (22), and the F1-score (23) were used. For many classes  $C_i$ ,  $fp_i$  represents false positive,  $tp_i$  true positive,  $fn_i$  false-negative, and  $tn_i$  true negative.

$$Precision = \frac{\sum_{i=1}^l \frac{tp_i}{tp_i + fp_i}}{l} \quad (21)$$

$$Recall = \frac{\sum_{i=1}^l \frac{tp_i}{tp_i + fn_i}}{l} \quad (22)$$

$$F1 - score = \frac{(\beta^2 + 1)(Precision)(Recall)}{(\beta^2)(Precision) + Recall} \quad (23)$$

Fig. 13. Composite Model Predictions with Strongly Entangling Layers for 30 Epochs, Optimized with SGD.

The repository where the source code is available, developed by the authors of this research, which allows to recreate the study and obtain the results presented, is available at [32].

#### IV. RESULTS

Tables VI and VII show the results of the classification, taking Accuracy and Training time as relevant factors; for 10, 20, and 30 epochs, considering a dataset of 660 images, 450 for training and 150 for testing, on the quantum side, there are four qubits, the number of shots was “exact,” the depth of the variational layers was 10, The differentiation method was “reversible,” and the processor used was the GPU provided by Google Colab [33], the selected simulator was “PennyLane” [16]. From now on, “Basic Entangler Layers” will be used interchangeably as “BEL,” “Strongly Entangling Layers” as “SEL,” and “Custom Layers” as “CL”. The residual network selected for transfer learning was ResNet-18. From now on, all other results tables will work with the same hyperparameters previously described. The results of Tables VI and VII are divided by the type of optimizer used, “Stochastic Gradient Descent with Nesterov Momentum” and “Adam” respectively.

TABLE VI. RESULTS WITH THE STOCHASTIC GRADIENT DESCENT OPTIMIZER WITH NESTEROV MOMENTUM

Variational Layers	Epochs	Testing	
		Accuracy (%)	Training Time (min)
BEL	10	97.14	48
BEL	20	98.57	97
<b>BEL</b>	<b>30</b>	<b>99.05</b>	<b>142</b>
SEL	10	95.71	105
<b>SEL</b>	<b>20</b>	<b>99.05</b>	<b>211</b>
SEL	30	98.57	309
CL	10	97.14	43
<b>CL</b>	<b>20</b>	<b>99.05</b>	<b>85</b>
CL	30	68.10	129

Tables VI and VII show that the best results were for “BEL” at 30 epochs, “SEL” at 20 epochs and “CL” at 20 epochs, the 3 with 99.05% accuracy and the 3 used the SGD as the optimization method. Once the three models with the best accuracy were identified, an analysis was performed based on the Precision, the Recall, and the F1-score to determine the

TABLE VII. RESULTS WITH THE ADAM OPTIMIZER

Variational Layers	Epochs	Testing	Training
		Accuracy (%)	Time (min)
BEL	10	83.81	49
BEL	20	93.33	98
BEL	30	97.14	144
SEL	10	95.24	104
SEL	20	92.38	221
SEL	30	94.29	313
CL	10	87.62	42
CL	20	88.10	80
CL	30	98.57	127

model with the best classification. Tables VIII, IX, and X show the classification reports for the three best models mentioned above.

TABLE VIII. CLASSIFICATION REPORT FOR BASIC ENTANGLER LAYERS WITH STOCHASTIC GRADIENT DESCENT WITH NESTEROV MOMENTUM AT 30 EPOCHS

Class	Precision	Recall	F1-score
Correct Mask	0.96	0.99	<b>0.97</b>
Incorrect Mask	0.97	0.94	<b>0.96</b>
No Mask	0.99	0.99	<b>0.99</b>

TABLE IX. CLASSIFICATION REPORT FOR STRONGLY ENTANGLING LAYERS WITH STOCHASTIC GRADIENT DESCENT WITH NESTEROV MOMENTUM AT 20 EPOCHS

Class	Precision	Recall	F1-score
Correct Mask	0.91	0.87	0.89
Incorrect Mask	0.88	0.84	0.86
No Mask	0.89	0.97	0.93

TABLE X. CLASSIFICATION REPORT FOR CUSTOM LAYERS WITH STOCHASTIC GRADIENT DESCENT WITH NESTEROV MOMENTUM AT 20 EPOCHS

Class	Precision	Recall	F1-score
Correct Mask	0.84	1.00	0.92
Incorrect Mask	0.97	0.80	0.88
No Mask	0.99	0.97	0.98

Still, among the three, it is observed that the best result was for the model that uses variational layers built with the “Basic Entangler Layers” template and whose training optimizer was “Stochastic Gradient Descent with Nesterov Momentum” at 30 epochs, given its accuracy of 99.05% and its F1-score of 97% to classify “Correct Mask,” 96% for “Incorrect Mask” and 99% to rate “No Mask” respectively. Similarly, the confusion matrices Fig. 14, Fig. 15, and Fig. 16 confirm the analysis results mentioned above.

### V. DISCUSSION

Table XI shows a comparison of image classification problems using Hybrid Quantum Transfer Learning models with ResNet-18 and four qubits; it can be seen that the proposed model shows the best accuracy with 99.05% when executed in a simulator, and also it is an encouraging result when compared

Fig. 14. Confusion Matrix for Basic Entangler Layers with Stochastic Gradient Descent with Nesterov Momentum at 30 Epochs.

Fig. 15. Confusion Matrix for Strongly Entangling Layers with Stochastic Gradient Descent with Nesterov Momentum at 20 Epochs.

with the other results of real quantum computers. Although indeed, the accuracy, together with the precision, the recall, and the f1-score are essential metrics to validate the relevance of the research, it should be noted that the present study focuses on illustrating the innovative proposed method and the particular adaptation of the method on the part of the authors, not in surpassing in accuracy to all the existing methods, it is in this sense that the development of the investigation and the techniques used are the most significant contribution that the present study leaves.

TABLE XI. COMPARISON OF IMAGE CLASSIFICATION PROBLEMS USING HYBRID MODELS OF QUANTUM TRANSFER LEARNING WITH RESNET-18 AND 4 QUBITS

Autor	Classes	Images	Simulator Acc (%)	QC Acc (%)
[15]	2	ants, bees	96.7	95
[19]	3	lung covid-19	-	98
[21]	2	lung covid-19	90	94 - 100
Proposed	3	masked face covid-19	99.05	-

### VI. CONCLUSION

A hybrid Quantum Transfer Learning model was developed with ResNet-18. Thanks to the inclusion in its quantum neural network of variational layers developed with the Basic Entangler Layers template and Stochastic Gradient Descent with Nesterov Momentum in its optimization, this is how it manages to enhance its performance.

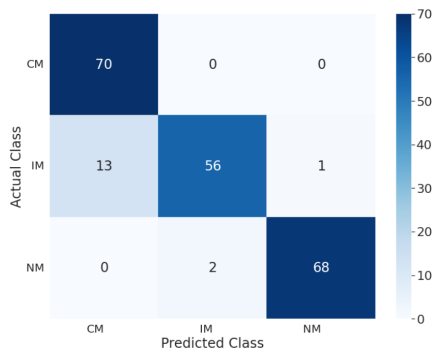

Fig. 16. Confusion Matrix for Custom Class Layers with Stochastic Gradient Descent with Nesterov Momentum at 20 Epochs.

The evaluations carried out in classifying the use of a protective mask (correct mask, incorrect mask, and no mask) of images of 660 people of both sexes between 18 and 86 years old obtained an accuracy of 99.05%. These results are satisfactory when compared with similar hybrid quantum classification problems with ResNet-18 and four qubits in its implementation.

## VII. FUTURE WORK

The models trained with Strongly Entangling Layers at 20 epochs and Custom Layers at 20 epochs also obtained 99.05% in accuracy but decreased in the levels of precision, recall and f1-score, so it is proposed to improve the hyperparameters to enhance their performance and future use. From the consulted literature, it is known that there are other quantum templates that could be more adaptable to the problem of image classification, “CV Neural Net Layers” is one of them, its research and the future proposal are recommended.

**Abstract**—In a Parallelizing Compiler, code transformations help to reduce the data dependencies and identify parallelism in a code. In our earlier paper, we proposed a model Data Dependence Identifier (DDI), in which a program  $P$  is represented as graph  $G_P$ . Using  $G_P$ , we could identify data dependencies in a program and also perform transformations like dead code elimination and constant propagation. In this paper, we present algorithms for loop invariant code motion, live range analysis, node splitting and loop fusion code transformations using DDI in polynomial time.

**Keywords**—Automatic parallelization; parallelizing compilers; code optimizations; data dependence; loop invariant code motion; node splitting; live range analysis; loop fusion

## I. INTRODUCTION

Multicore processors have completely replaced single core processors, as a result general purpose computers became parallel systems, this change has thrown lot of challenges to software community in the effective utilization of the former. Though multiprocessing capability of operating systems improves the overall throughput of new hardware still performance of serial programs remains the same even on multicore systems. To enhance the performance of serial programs on multicore systems, instructions in the serial code has to be broken into groups such that each group can be run in parallel. One way to accomplish this task is by manual conversion which is a tedious job. One more way is to use a tool that converts serial program to parallel.

Automating the process of serial to parallel conversion is called as Automatic Parallelization and the compiler which can perform automatic parallelization is typically referred as Parallelizing Compiler. The general process of serial to parallel program conversion is a three step one: 1) perform code transformations in order to detect potential parallelism; 2) check for data dependencies in the code; 3) generate parallel code.

Two instructions  $I_1$  and  $I_2$  in a program are said to be *data dependent* if both the instructions access same memory location. Presence of data dependencies makes parallelism an impossible task. Code transformations help to eliminate some of the data dependencies thereby giving a scope to detect potential parallelism.

In our earlier paper [1], we proposed a model called Data Dependence Identifier(DDI) which can identify data dependencies in scalars, arrays, and pointers in a program. We also

discussed how code optimizations like dead code elimination, constant propagation can be performed using DDI. In this paper, we discussed how code optimizations like loop invariant code motion, live range analysis and node splitting, loop fusion are performed using our model DDI.

## II. RELATED WORKS

Compiler converts source code to Intermediate Representation (IR) to perform code optimizations. This IR may differ from compiler to compiler. Generally, in traditional compilers for uniprocessor systems, instructions in source code are intermediately represented in three address code format and Directed Acyclic Graph (DAG), code optimizations are performed using this Intermediate Representation [3].

Intermediate Representation is crucial for a parallelizing compiler. Here, we will discuss in brief about some of the parallelizing compilers and their Intermediate Representations.

- SUIF (Stanford University Intermediate Format): SUIF is a source to source parallelizing compiler that takes C or FORTRAN serial code as input and produces parallelized code to be run on a multi-processor machine. SUIF intermediate representation is a language-independent abstract syntax tree. Data flow analysis, data dependence analysis, scalar and array privatization, reduction variable analysis are performed using IR [4], [5], [6].
- Cetus: Cetus converts serial program written in C to parallel C program by inserting OpenMP annotations to be run on a multicore system. Cetus intermediate representation is a hierarchical tree based structure implemented in Java. Cetus IR includes a set of iterators that traverses through the IR to get the required information about loops, conditional statements, etc. Data dependence analysis - GCD Test [7] and Range Test [8] are used to identify data dependencies in arrays. Transformation techniques like scalar and array privatization, induction variable substitution, reduction variable recognition are performed using IR to eliminate some of the dependencies [9].
- Pluto: Pluto is a source to source compiler that transforms serial C program to OpenMP C [10]. Intermediate Representation of Pluto is based on polyhedral model. Dependence analysis, loop transformations for parallelism and optimized data locality are performed

using IR [11]. Optimizations based on polyhedral model are integrated in compilers like GCC and LLVM. State-of-art in Pluto includes loop fusion transformation using Fusion Conflict Graphs (FCG) [12] and verified code generation [13].

- Intel compiler [16] automatically identify the loops that can be parallelized and partitions the data accordingly.

Using our proposed model DDI, we have shown how data dependence analysis can be performed. We are broadening the scope of our model by showing how code transformations like loop invariant code motion, live range analysis and node splitting, loop fusion can be applied on DDI.

### III. DATA DEPENDENCE IDENTIFIER

In this section we discuss in brief about our model Data Dependence Identifier(DDI) which we have proposed in our earlier paper [1]. The main objective of DDI model is to represent a program as graph to identify data dependencies in a program. Though many graphical representation of program exists [14], [15], our representation takes a completely different perspective, we consider variables in the program as nodes and the edges between these variables are drawn based on the mode of access of variables from memory. For this purpose, we have categorized the instructions in a program and parameterized program as discussed in sections A and B.

#### A. Categorization of Instructions based on Memory Accessibility

We categorized the instructions in a program broadly into **Memory Access Instruction (MAI)** and **Non Memory Access Instruction (NMAI)** based on the way they access the memory. In MAI, instructions access the memory to perform the required operation. Instructions like arithmetic, conditional fall under this category. In NMAI, instructions do not access the memory at all i.e., instructions like jump, break come under this category.

MA Instructions are further classified into three categories: MA-READ, MA-WRITE, MA-READWRITE. In **MA-READWRITE(MARW)**, instructions access the memory for both read as well as write operations. For example, in Arithmetic instruction: ' $c = a + b$ ', data is read from memory locations  $a$  and  $b$  and written to a memory location  $c$ . In **MA-READ(MAR)**, instructions perform only read operation but no write operation. For example, in conditional instruction: ' $if(a > b)$ ' data is only read from memory locations  $a$  and  $b$  but the output is not written to any variable. Generally in these instructions data is read from memory and send to other Hardware Units(HU) in the computer system like processor or output devices. In **MA-WRITE(MAW)**, instructions perform only write operation but no read operation. For example, in assignment instruction ' $a = 5$ ', a constant value is written to a memory location  $a$ . Here we assume,  $a = 5$  means that the constant 5 is read from the programmer(PR) and written to the location  $a$ .

#### B. Parameterization of Program

A program  $P$  is parameterized with  $I, V, W, HU, PR$ , where:

- Set  $I$ , finite set of instructions  $\{i_1, i_2, \dots, i_n\}$
- Set  $V$ , finite set of memory allocations or variables  $\{v_1, v_2, \dots, v_p\}$
- Set  $MAI$ , finite set of MA instructions where  $MAI \subseteq I$ .  
An instruction  $i \in MAI$  is represented as ordered pair  $[R, W]$  where  $R, W \subseteq V$ .  $R$  is a set that contains all the variables from which the instruction  $i$  reads the data and  $W$  is a set with a single variable to which  $i$  writes the data. For example, instruction ' $c = a + b$ ' is written as pair  $[\{a, b\}, \{c\}]$  where data is read from variables  $a, b$  and output is written to  $c$ .
- $HU$  represents the set of hardware units i.e. input devices, output devices, processor and any other hardware unit in the computer system.
- $PR$  is the set of constant values initialized in the program  $P$  by the programmer.

Therefore, we write  $P$  as  $P(I, V \cup \{HU, PR\}, MAI)$ .

#### C. Directed Graph Representation of a Program

In DDI model, we represent a program as graph. Here, we discuss how a program  $P$  is transformed to an equivalent directed graph called graph of  $P$  written as  $G_P$ .

All instructions in a given program  $P$  are indexed sequentially with the positive integers  $1, 2, \dots, n$ . First instruction in a program is indexed as 1, second instruction as 2 and so on. For  $i_n \in I$ , we call index of  $i_n = n$ . Every instruction  $i_n$  is written as the pair  $[R, W]$ . In other words,  $index[i_n] = index([R, W]) = n$ .

A program  $P = (I, V \cup \{PR, HU\}, MAI)$  is transformed into a directed labeled graph  $G_P = (V \cup \{PR, HU\}, E, L)$  as follows:

- Set of nodes of  $G_P$  are the set of variables  $V \cup \{PR, HU\}$ .
- For every ordered pair of sets  $(R, W) \in MAI$ , we include the edges  $\{(r, w) | \forall r \in R, w \in W\}$ .
- Every edge in  $G_P$  is labeled with elements from label set  $S$  which contains indices of instructions in  $I$ .  $L : E \rightarrow \{1, 2, \dots, n\}$  such that  $L((r, w)) = k$  if  $index([R, W]) = k$  such that  $(r, w) \in E, r \in R, w \in W$ .

We use the notation  $(., .)$  to represent the edges of the graph and  $[\cdot, \cdot]$  indicates the pair of sets  $R, W$  for representing memory access instructions.

In example 1,  $I = \{i_1, i_2, i_3, i_4\}$ ,  $V = \{a, b, c, d\}$  and  $MAI=I$  as all instructions in program  $P$  are memory access instructions. To construct  $G_P$ ,  $V$  acts as nodes  $N$ . For instruction 1 :  $[\{a, b\}, \{c\}]$ , we include the edges  $(a, c)$  and  $(b, c)$  with labels  $L((a, c)) = 1$  and  $L((b, c)) = 1$  are added to  $G_P$ . For instruction 2 :  $[\{a, PR\}, \{d\}]$ , edges  $(a, d)$  and

$(PR, d)$  with labels  $L((a, d)) = 2$  and  $L((PR, d)) = 2$  are added. For instruction 3 :  $\{c, d\}, \{HU\}$ , edges with label  $L((a, HU)) = 3$  and  $L((d, HU)) = 3$  are added. For instruction 4 :  $\{a, PR\}, \{b\}$ , edges with label  $L((a, b)) = 4$  and  $L((PR, b)) = 4$  are added to  $G_P$ . The adjacency matrix

of graph  $G_P$  is shown in example 1(c), rows gives the **read** information about the variables and columns gives the **write** information. Scanning column  $c$  of the matrix tells that variable  $c$  is accessed for 'write' in instruction 1 and row of  $c$  shows variable  $c$  is accessed for 'Read' in instruction 3.

The procedure by which we convert  $P(I, V \cup \{PR, HU\}, W)$  into a simple edge labeled graph  $G_P(N \cup \{PR, HU\}, E, L)$  is discussed in algorithm 1.

**Algorithm 1** Convert Program  $P$  to Directed edge-labeled graph  $G_P$

```

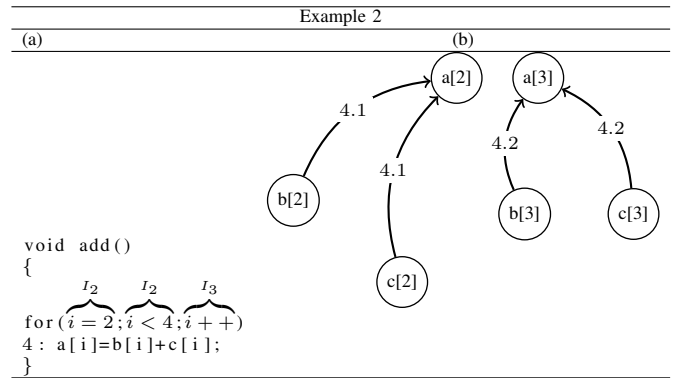

1: procedure PROGRAM TO GRAPH
   Input: Program  $P(I, V \cup \{PR, HU\})$ 
   Output: Graph  $G_P(N \cup \{PR, HU\}, E, L)$ 
2: for each instruction  $[R, W] \in I, index[R, W] = k$  do
3:   if MAI-verification() then
4:     for every  $r \in R$  and  $w \in W$  do
5:        $E = E \cup \{(r, w)\}$ 
6:        $L([r, w]) = k$ 
                
```

**Loop representation in DDI:**

The statements within the loop are denoted as  $i.k$ , where  $i.k$  represents instruction  $i$  when the loop is executed  $k^{th}$  time.

**Nested loop representation in DDI:**

Consider nested loops  $L_1$  and  $L_2$ , where  $L_1$  is the outer loop and  $L_2$  is the inner loop. The statements within the nested loop are denoted as  $m.x.p$ , where  $m.x.p$  represents  $m^{th}$  instruction when the loop is executed  $x^{th}$  iteration in  $L_1$  loop and  $p^{th}$  iteration in  $L_2$  loop.

Consider the nested sequence of loops  $L_1, L_2, L_3, \dots, L_n$ , where  $L_1$  is the outermost loop and  $L_n$  is the innermost loop. The statements within this nested loop are denoted as  $m.x_1.x_2 \dots x_n$ , where  $m$  represents the instruction number and  $x_1$  represents the instance of iteration of outermost loop  $L_1$ ,  $x_2$  represents the instance of iteration of loop  $L_2$ , and  $x_n$  represents the instance of execution of innermost loop  $L_n$ .

**IV. APPLICATIONS OF DDI**

In our earlier paper [1], we proposed how compiler optimizations like constant propagation, dead code elimination and induction variable detection can be performed using our DDI model. In this section, we will discuss how optimizations like loop invariant code motion, live range analysis, loop fusion, scalar privatization can be performed using our DDI model.

**A. Loop Invariant Code Motion**

A set of statement(s) within a loop is called as Loop Invariant Code if the semantics of the program is not affected when the statements are moved out of the loop. Identifying and removing invariant code loop reduces the number of statements within the loop, thereby enhancing the performance of the parallel loop. Code Motion is the process of moving the loop invariant code outside the loop. In the program given in example 3(a), value of  $x$  in instruction 5 remains unchanged through out the execution of loop. Even if instruction 5 is moved above the loop, value of  $x$  remains the same.

Following observation is made to identify loop invariant code:

- For an instruction  $i : [R, W]$ , the value of the variable 'W' will get updated during the loop iteration if atleast one of the values of variables in 'R' is changing during the execution of the loop. In example 3(a), in instruction 5 :  $\{t, PR\}, \{x\}$ , input variables are  $\{t, PR\}$ ,  $t$  is the only input variable here as  $PR$  is a constant value and variable  $t$  never gets updated in the loop. As  $t$  value never changes during the execution of the loop, consequently there is no change in  $x$ . We call statement 5 as 'Loop Invariant Code'.

**Theorem 1.** Given a loop  $l$  with statements  $\{i_1, i_2, \dots, i_s\}$  and  $G_l$  be the graph that corresponds to the loop  $l$ . A statement  $l_k \in l$  is said to be **Loop Invariant Code** if

1. There exists a node  $u \in N.G_l$  such that  $L((u', u)) = [i_k.1, i_k.2, \dots, i_k.m]$  where  $m$  is the number of iterations of the loop.

2. There is no edge  $(v, u')$  for every  $u \in N.G_l$ .

*Proof:*  $i_k$  is 'Loop Invariant Code'

$\implies$  If  $i_k : [R, W]$ , then  $\exists u \in W$  where the value of  $u$  does not change through out the loop.

$\implies u \in W$  implies that there exists  $u_k \in R$  such that value of  $u_k$  is written in  $u$  and there is no change in  $u_k$  through out the loop.

$\implies$  By algorithm,  $G_l$  will have the edges  $(u_k, u)$  and there will not be any edge of the form  $(v, u_k)$  where  $u, u_k \in N.G_l$ , since the nodes of  $G_l$  pertains to the variable inside the loop. ■

Algorithm illustrates the process of loop invariant code detection. Line 3-6 of the algorithm examines if node  $u$  have

**Algorithm 2** Loop invariant code detection

```

1: procedure LOOP INVARIANT CODE DETECTION
   Input: Graph  $G_p(N, E, L)$ 
2:   edgelabels=FALSE, invariant=TRUE
3:   LS={ $i_1, i_2, \dots, i_s$ }
4:   for every  $u \in N.G$  do
5:     if  $L((u_i, u)) == [n.1, n.2, \dots, n.m]$  then
6:       if  $L((v_i, u_i)) \in LS$  then
7:         invariant=FALSE
8:       if invariant==TRUE then  $\triangleright$  perform Code Motion
9:         delete edges  $L((u_i, u)) = [n.1, n.2, \dots, n.m]$ 
10:        add edge  $L((u_i, u)) = p, p < l_1$ 

```

any incoming edges from nodes  $u, u_1, u_2, \dots, u_k$  with labels matching the pattern  $[n.1, n.2, \dots, n.m]$ . If so, then line 8-10 checks if there are any incoming edges to nodes  $u, u_1, u_2, \dots, u_k$  with label  $l$  where  $l \in LS$ , LS contains loop statement labels. If no such edges exist, instruction  $n$  is considered as loop invariant code, move instruction  $n$  above the loop in the program. Line 8-10, perform code motion. Example 3(b) shows the program and graph after code motion.

**B. Live Range Analysis**

For parallelizing a program, statements in the program has to be grouped in such a way that the statements in these groups can be executed in parallel and gives the same output as sequential execution. one way to accomplish this task is using the live range information of variables in the program. We define the *live range* of a variable in a program as follows:

**Definition IV.1.** A variable  $u$  is said to *live* in statement  $k$  of program  $P$  if either *Read* or *Write* operation is performed on  $u$ .

Consider the program in example 5,  $y$  is *live* in statement 2 and *not live* in statements 1,3,4.

**Definition IV.2.** Live Range Analysis of a program  $P$  is a description which provides an information on the nature of the variable, whether live or not, in each of the instruction of program  $P$ .

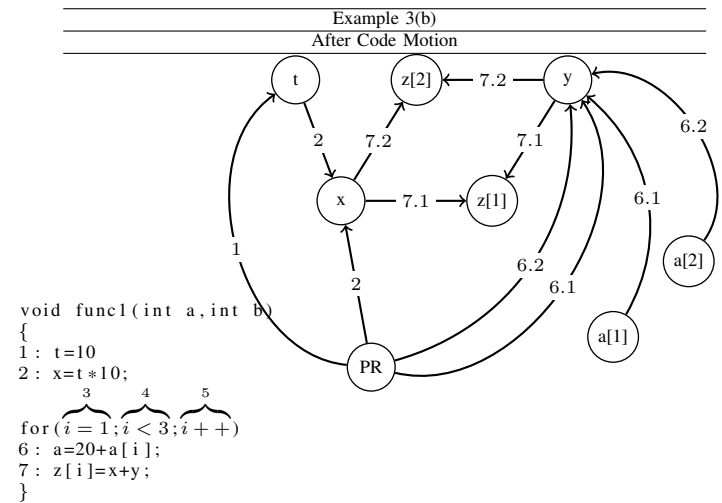

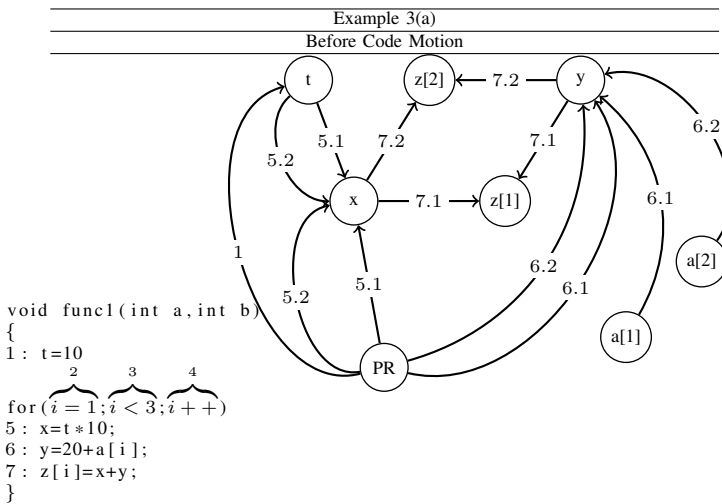

In example 4(a),  $x$  is live in statements 1,2,3,4.  $y$  is live in statement 2.  $k$  is live in statement 1.  $a$  is live in statement 4. This information is represented in the form:  $x : \{1, 2, 3, 4\}$ ,  $y : \{2\}$ ,  $k : \{1\}$ ,  $z : \{3\}$ ,  $a : \{4\}$ , which is usually referred as live range analysis of P.

Now, we propose a method to compute live range of variables in a program using our DDI model.

**Theorem 2.** Given a program  $P$  and the corresponding graph  $G_p$ . If node  $u \in G_p$  have either incoming and outgoing edges with labels  $i_k$  then variable  $u$  is said to be *live* in statements  $i_k$  of program  $P$ .

*Proof:*  $u$  is live in instruction  $i_k$ .

$\implies$  By definition IV.1, either *Read* or *Write* operation is performed on  $u$  in  $i_k$ .  $\implies$  By algorithm 1, there will be

In example 4(a), Loop Statements(LS)={5,6,7} for node  $x$ ,  $L((t, x)) = [5.1, 5.2]$  and  $L((PR, x)) = [5.1, 5.2]$ , there exists no other edges to node  $x$  with label 5. Only source of input to node  $x$  with label 5 is from nodes  $t$  and  $PR$ . As  $PR$  is constant value, only input is node  $t$ . Incoming edge to node  $t$  is  $L((PR, t)) = 1, 1 \notin LS$ . Therefore, we conclude statement 5 is loop invariant code.

an outgoing edge with label  $i_k$  from  $u$  (if Write operation is performed over  $u$  in  $i_k$ ) or there will be an incoming edge with label  $i_k$  to  $u$  (if Read operation is performed over  $u$  in  $i_k$ ).

⇒ There is an edge incident on  $u$  with label  $i_k$ . ■

Based on the above theorem, we propose an algorithm to compute live range of variables in a program.

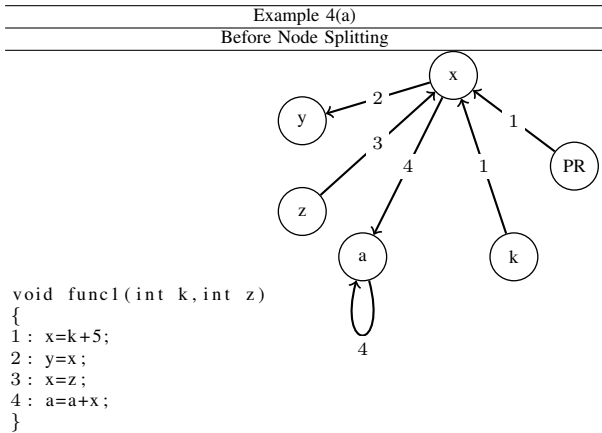

In Line 2 of algorithm 3, A is initialized as an empty two

**Algorithm 3** Live Range Analysis

```

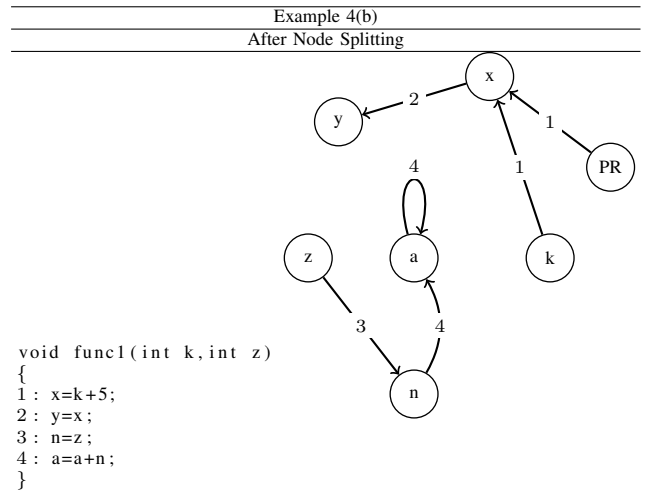

1: procedure LIVE RANGE ANALYSIS
   Input: Graph  $G_p(N, E, L)$ 
2:   A=[ ]
3:   i=0
4:   for every  $u \in N.G$  do
5:     A[i].append( $u, L((v, u)), L((u, u'))$ )
6:     i=i+1
7:   return A
    
```

dimensional array. The for loop in lines 4-6 examines all the incoming and outgoing edge labels of each node and assigns this information to A. Each row of array A have node label  $u$ , the incoming and outgoing edge labels of node  $u$ . With assumption the graph is represented using adjacency matrix, the running time of this algorithm is  $O(n^2)$ , where  $n$  is the number of nodes in the graph. The for loop requires scanning the row and column of each and every node, therefore the complexity  $O(n^2)$ .

**C. Node Splitting**

If a variable is *live* through out the program means there exists data dependence among the statements. The data dependence has to be broken in order to group the statements such that each group can execute in parallel. One approach to break the data dependence cycle is using **Node Splitting**. Node splitting creates one more copy of a node(duplicate node) in the graph and divides the edges between two nodes to produce an analogous graph. This transformation limits the live range of a variable to a section in the code hence producing a code more feasible for parallelization. Consider the program in example 4, variable  $x$  is live in instructions  $\{1, 2, 3, 4\}$ , after splitting  $x$  as  $x$  and  $n$ ,  $x$  is live in instructions  $\{1, 2\}$  and  $n$  in  $\{3, 4\}$ .

Given a variable  $v$ , the possible sequence of *Read(R)* and *Write(W)* operations on  $v$  are 1.  $\{W, R, R, R..R\}$  - value assigned to  $v$  is only *Read* through out the program. 2.  $\{W, R, W, R..R\}$  - variable  $v$  is updated multiple times in the program. Based on this observation, we define the scope of node splitting as follows:

**Definition IV.3.** A node  $u \in V.G_P$  is said to be a splitting node if the sub-graph that involves  $u$  can be split into two sub-graphs  $G_{P_1}$  and  $G_{P_2}$  such that functionality of both the programs  $P_1$  and  $P_2$  is equivalent to the functionality of  $P$ .

**Theorem 3.** Let  $P$  be a program,  $G_P$  be the graph that corresponds to  $P$ . A node  $u \in V.G_P$  is a splitting node of  $G_P$  if and only if  $\exists$  a sub-graph  $G_P^u$  that involves the node  $u$  as follows.

Fig. 1.  $u$  is Splitting Node of  $G_P$ .

*Proof:*  
Hypothesis:  $u$  is a splitting node of  $G_P$ .

Claim:  $\exists$  a sub-graph  $G_P^u$  of  $G_P$  as shown in fig1.

Hypothesis:  $G_P^u$  can be split into two sub-graphs  $G_{P_1}^u$  and  $G_{P_2}^u$  such that the functionality of  $P_1$  and  $P_2$  is equivalent to  $P$ .

$\implies \exists$  a program  $P$  in which variable  $u$  is used more than once ( $t_1$  times) for writing and  $u$  is used more than once ( $t_2$  times) such that  $t_1 \geq t_2$ .

without loosing any generality, assume  $t_1 = t_2 = t$

$\implies u$  is used  $t$  times for writing and  $u$  is used  $t$  times for reading purpose.

$\implies$  Again, without loss of any generality, for every writing to  $u$ , we have a reading from  $u$ .

$\implies$  Since  $u$  is a splitting node, we have a sequence of  $t$  blocks in  $P$  such that in each block,  $u$  is written first and then  $u$  is read.

$\implies$  A snippet of  $P$  that involves  $u$  will look as follows:

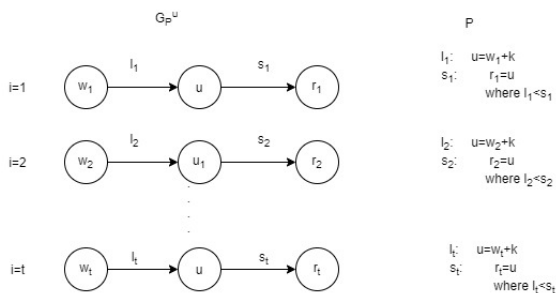

Corresponding  $G_P$  will be as shown in fig.1, hence the claim.

Claim:  $u$  is a splitting node.

Hypothesis:  $P$  has a sequence of  $t$  blocks and in each block, value is read from  $u$  after a value is written to  $u$ .

$\implies G_P^u$  can be split as follows

In each  $P_i$ , a value is written to  $u$  first and then  $u$  is read.

$\implies$  From  $G_P^u$ , we infer that in  $P$ , value is written first and then read next.

$\implies$  By sheer observations, we infer that the total functionality of the snippets  $P_i (i = 1 \text{ to } t)$  is same as

the functionality of  $P$ . The functionality of other statements (which does not involve  $u$ ) in  $P$  remains as such in  $P_i$  also.

$\implies$  We have a node  $u$  in  $G_P^u$  which can be split into a sequence of sub-graphs  $G_P^u, i = 1, 2, \dots, t$  such that the total functionality of  $P_i, i = 1, 2, \dots, t$  is equivalent to the functionality of  $P$ .

$\implies u$  is a splitting node of  $G_P$ . ■

**Corollary 3.1.** Let  $P$  be a program. Let  $G_P$  be the graph that corresponds to  $P$ .  $P$  is parallelizable if and only if  $G_P$  has atleast one splitting node.

**Algorithm 4** Node Splitting

```

1: procedure NODE SPLITTING
   Input: Graph  $G_P(N, E, L)$ 
2: for every  $u \in N.G$  do
3:   if  $L((u', u)) = m$  and  $L((u', u)) = n$  and  $n > m$ 
      then
4:     add node  $w$ 
5:     delete edge  $L((u', u)) = n$ 
6:     add edge  $L((u', w)) = n$ 
7:   for every edge  $(L((u, v)) > n)$  do
8:     delete  $L((u, v))$  and add  $L((w, v))$ 

```

Let  $M$  be the adjacency matrix representation of  $G_P$ . In algorithm, line 2 requires scanning each and every column of  $M$  to check if there exists any node  $u$  which satisfies the condition in line 3. Lines 4-6 i.e. adding a new node and edges takes constant time. In line 3, if a node  $u$  meet the condition then in lines 7-8 the entire row of the node  $u$  has to be examined. Let's say if there are  $n$  nodes among which  $m$  nodes satisfy the condition in line 3, then the complexity is  $O(mn)$ .

**D. Loop Fusion**

Loop fusion is a technique in which two loops are merged or fused to form a single loop. Generally, a loop iterates through the same set of instructions to perform a task. Two loops  $L1$  and  $L2$  can be fused if number of iterations, terminating conditions of both the loops match and the semantics of the code be intact after merging. Fusing of loops reduces the number of loops present in a program thereby mitigating the overhead involved in parallelization of many loops.

**Definition IV.4. Loop Fusion:** is a technique by which statements of multiple loops are merged into a single loop such that semantics of the code is intact.

Consider  $L1$  be the first loop and  $L2$  be the second loop in sequence, then  $L1$  and  $L2$  can be fused if the following conditions are satisfied:

- Loops  $L1$  and  $L2$  should have same looping conditions and should iterate for same number of times.
- Dependencies that exist between statements of loop  $L1$  and  $L2$  does not change the semantics of the code.

So, concept of fusion depends on the dependencies that exist between the loops. Hence, first we discuss different dependencies that exist between the loops. Two loops  $L1$  and  $L2$

are said to be data dependent if dependence exists between any statement of  $L1$  and any statement of  $L2$ . Let statements  $S_i \in L1$  and  $S_j \in L2$ . The following dependencies may exist between  $S_i$  and  $S_j$ :

**Definition IV.5. No dependence:**  $L1$  and  $L2$  are said to have no dependence if the statements  $S_i$  and  $S_j$  do not access any common memory location.

**Definition IV.6. Flow dependence:** If memory location  $M$  is accessed for 'Write' operation in statement  $S_i$  and the same location  $M$  is accessed for 'Read' in statement  $S_j$ . Then, flow dependence exist between statements  $S_i$  and  $S_j$ .

In example 6(case i), 'Write' operation is performed on an index location in array  $A$  in first loop and is 'Read' from the same index location in array  $A$  in second loop. So, there exist flow dependence between loops  $L1$  and  $L2$ .

**Definition IV.7. Anti dependence:** If memory location  $M$  is accessed for 'Read' operation in statement  $S_i$  and the same location  $M$  is accessed for 'Write' in statement  $S_j$ . Then, anti dependence exist between statements  $S_i$  and  $S_j$ .

In example 7(case i), 'Read' operation is performed on an index location in array  $x$  in first loop and 'Write' operation on the same index location of array  $x$  in second loop, there exist Anti dependence between loops  $L1$  and  $L2$ .

**Definition IV.8. Loop carried forward dependence:** If memory location  $M$  is accessed by an iteration of statement  $S_i$  and then the same location  $M$  is accessed in later iterations of statement  $S_j$ . Then, loop carried forward dependence exists between statements  $S_i$  and  $S_j$ .

In example 8,  $A[1]$  value computed in first iteration of first loop is read in the second iteration of second loop, shows existence of loop carried forward dependence between  $L1$  and  $L2$ .

**Definition IV.9. Loop carried backward dependence:** If memory location  $M$  is accessed in an iteration of statement  $S_j$  and then the same location  $M$  is accessed in later iterations of statement  $S_i$ . Then, loop carried backward dependence exists between statements  $S_i$  and  $S_j$ . In example 9,  $A[2]$  value computed in second iteration of first loop is read in the first iteration of second loop, shows presence of loop carried backward dependence.

#### Identification of data dependencies using DDI and feasibility of fusion

So far we have discussed the dependencies that exist between the loops. Here, we will discuss the type of dependencies between  $L1$  and  $L2$  which does not affect the fusion of  $L1$  and  $L2$ . We propose four theorems with which we can identify the type of dependence that exist between  $L1$  and  $L2$  using our DDI and the feasibility of fusing them.

**Theorem 4.** Given program  $P$  with loops  $L1$  with statements  $\{i_{r_1}, i_{r_2}, \dots, i_{r_n}\}$  and loop  $L2$  with statements  $\{i_{s_1}, i_{s_2}, \dots, i_{s_m}\}$ . Let  $G_P$  be the corresponding graph of  $P$ , with  $G_{L1}$  and  $G_{L2}$  as the sub-graphs of  $G_P$  that corresponds to loops  $L1$  and  $L2$  respectively.  $L1$  and  $L2$  is said to have **no dependence** if there exists no edge  $(u, v)$ ,  $\forall u \in G_{L1}$  and  $\forall v \in G_{L2}$ . Such

loops  $L1$  and  $L2$  can be fused.

*Proof:* Assume that there exists an edge  $(u, v)$  where  $u \in V(G_{L1})$ ,  $v \in V(G_{L2})$ .

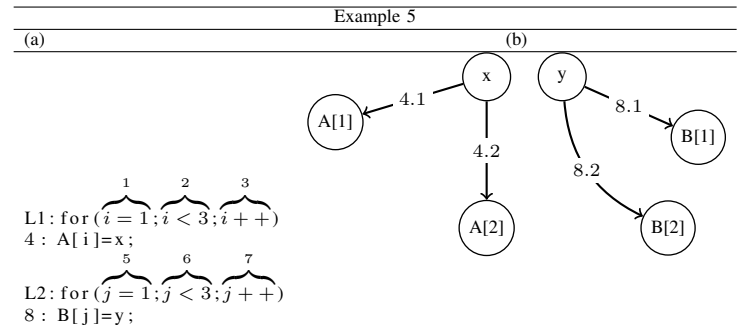

$\implies$  An edge  $(u, v)$  in  $G_{L1}$  means that a value is Read from variable  $u$  in some statement  $i_{r_j}$  (say) and Written to variable  $v$ . As  $v \in G_{L2}$ ,  $v$  is accessed by some statement  $i_{s_k}$  (say) in  $L2$ .

$\implies$  By Algorithm 1, there exists a statement  $i_{r_j}$  in  $L1$  which Read's a value from variable  $u$  and that value is Written to a variable  $v$  in statement  $i_{s_k}$  in  $L2$ .

$\implies$  Thus, we have proved that if there exists an edge  $(u, v)$  with label  $i_{r_j}$  then there exists a statement  $i_{r_j}$  which accesses the variables  $u$  and  $v$ .

$\implies$  By considering contrapositive statement of above proposition i.e, if there does not exist a statement  $i_{r_j}$  which accesses the variables  $u$  and  $v$  then there does not exist edge  $(u, v)$ .  $\implies$  There exists no common variable accessed by statements of  $L1$  and  $L2$ . Therefore, by Definition 4.5, if statements of  $L1$  and  $L2$  do not access common memory location then there exists no dependence between statement of loops  $L1$  and  $L2$ .

■

In Example 5, nodes  $\{x, A[1], A[2]\} \in L1$  and nodes  $\{y, B[1], B[2]\} \in L2$ , there exists no common nodes among  $L1$  and  $L2$ , no edges between nodes of  $L1$  and  $L2$ . Therefore, no dependence exist between the two loops, in which case merging of loops is possible.

**Theorem 5.** Given program  $P$  with loops  $L1$  with statements  $\{i_{r_1}, i_{r_2}, \dots, i_{r_n}\}$  and  $L2$  with statements  $\{i_{s_1}, i_{s_2}, \dots, i_{s_m}\}$ .  $G_P$  be the corresponding graph of  $P$ ,  $G_{L1}$  and  $G_{L2}$  are the sub-graphs of  $G_P$  that corresponds to loops  $L1$  and  $L2$  respectively. Let there exist edges  $L((u, v)) = i_{r_j}.n$  and  $L((v, w)) = i_{s_k}.m$  such that  $i_{r_j} \in L1$ ,  $i_{s_k} \in L2$ . i

- 1)  $L1$  and  $L2$  is said to have **flow dependence** if  $i_{s_k} > i_{r_j}$ .
- 2)  $L1$  and  $L2$  can be fused if  $m \geq n$  and  $i_{s_k} > i_{r_j}$ .
- 3)  $L1$  and  $L2$  can not be fused if  $n > m$ .

*Proof:* Let  $G_{L1}$  and  $G_{L2}$  be the sub-graphs of  $G_P$  that corresponds to loops  $L1$  and  $L2$  in  $P$  and there exist edges  $L((u, v)) = i_{r_j}.n$  and  $L((v, w)) = i_{s_k}.m$  in  $G_P$ .

Hypothesis 1: There is a flow dependence if  $i_{s_k} > i_{r_j}$ .

⇒ An incoming edge with label  $i_{r_j}.n$  to node  $v$  means variable  $v$  is Written in  $n$ th iteration of instruction  $i_{r_j}$ . An outgoing edge with label  $i_{s_k}.m$  to node  $v$  means variable  $v$  is Read in  $m$ th iteration of instruction  $i_{s_k}$ .

⇒ The condition  $i_{s_k} > i_{r_j}$  means that first a value is Written to  $v$  in  $n$ th iteration of instruction  $i_{r_j}$  and then Read from  $v$  in  $m$ th iteration of instruction  $i_{s_k}$ .

⇒ By Definition IV.6, there exists flow dependence between statements  $i_{s_k}$  and  $i_{r_j}$  if Read operation succeeds Write operation.

Hypothesis 2:  $L1$  and  $L2$  can be fused if  $m \geq n$  and  $i_{s_k} > i_{r_j}$ .

⇒ As  $m \geq n$  and  $i_{s_k} > i_{r_j}$ , even after fusing the statements  $i_{s_k}$  and  $i_{r_j}$  as Read operation succeeds Write operation on variable  $v$ , semantics of code is unchanged.

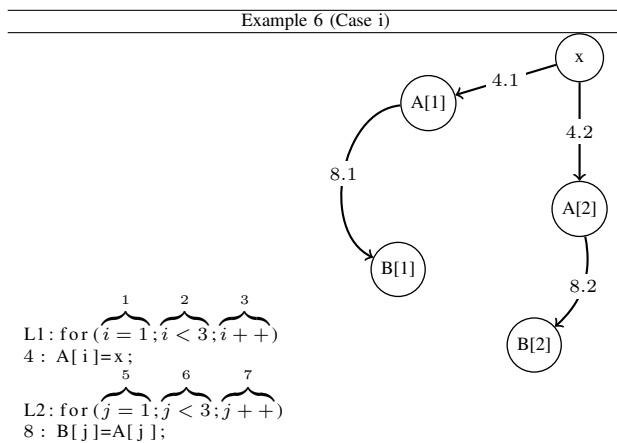

⇒ By definition IV.4, statements of loops  $L1$  and  $L2$  can be fused if the semantics of the code is intact.

Hypothesis 3:  $L1$  and  $L2$  can not be fused if  $n > m$ .

⇒ Before fusing, in loop  $L1$  write operation is performed on variable  $v$  in  $n$ th iteration of instruction  $i_{r_j}$ . In loop  $L2$  variable  $v$  is Read in  $m$ th iteration of instruction  $i_{s_k}$ .

⇒ If  $L1$  and  $L2$  are fused, as  $n > m$ , variable  $v$  is read in  $m$ th iteration of instruction  $i_{s_k}$  even before  $v$  is written in  $n$ th iteration of instruction  $i_{r_j}$  i.e., older value of variable  $v$  is read not the updated.

⇒ As semantics of code changes, loop fusion is not possible if  $n > m$ . ■

If flow dependence exists between loops  $L1$  and  $L2$  i.e., if an instruction in  $L1$  access a memory location  $M$  for ‘Write’ and the same location is accessed by an instruction in loop  $L2$  for ‘Read’ then merging of loops is possible if  $M$  is accessed for ‘Write’ and then for ‘Read’ even after fusion. In example 6(case i),  $L((x, A[1])) = 4.1$  and  $L((A[1], B[1])) = 8.1$  says  $A[1]$  is updated in iteration 1 of instruction 4 and read in iteration 1 of instruction 8. As a value is updated in first loop and read in second loop in the same iteration, merging of loops will not change the semantics of code. Therefore edges  $L((u, v)) = n.i$  and  $L((v, w)) = m.j$  where  $n \in L1$ ,  $m \in L2$

and  $j \geq i$  in the graph represents flow dependence where merging of loops is possible.

If flow dependence exists between loops  $L1$  and  $L2$  merging of loops is *not* possible if on fusing of loops ‘Write’ operation succeeds ‘Read’ on memory location  $M$ , which changes the semantics of the code. In example 6(case ii),  $x$  is accessed for ‘Write’ in first loop and for ‘Read’ in second loop, which shows flow dependence.  $L((A[2], x)) = 4.2$  and  $L((x, B[1])) = 8.1$  says, value of variable  $x$  to be written in iteration 2 of instruction 4 is read in iteration 1 of instruction 8 i.e., value of  $x$  is read even before write operation. Therefore, merging of loops  $L1$  and  $L2$  changes the semantics of the code.

**Theorem 6.** Given program  $P$  with loops  $L1$  with statements  $\{i_{r_1}, i_{r_2}, \dots, i_{r_n}\}$  and loop  $L2$  with statements  $\{i_{s_1}, i_{s_2}, \dots, i_{s_m}\}$ .  $G_P$  be the corresponding graph of  $P$ ,  $G_{L1}$  and  $G_{L2}$  are the sub-graphs of  $G_P$  that corresponds to loops  $L1$  and  $L2$  respectively. Let there exist edges  $L((u, v)) = i_{r_j}.n$  and  $L((w, u)) = i_{s_k}.m$  such that  $i_{r_j} \in L1$ ,  $i_{s_k} \in L2$ . i

- 1)  $L1$  and  $L2$  is said to have **Anti dependence** if  $i_{s_k} > i_{r_j}$ .
- 2)  $L1$  and  $L2$  can be fused if  $m \geq n$  and  $i_{s_k} > i_{r_j}$ .
- 3)  $L1$  and  $L2$  can not be fused if  $n \geq m$ , i.e., an outgoing edge from  $u$  of  $L1$  have iteration number greater than an incoming edge to  $u$ .

*Proof:* Let  $G_{L1}$  and  $G_{L2}$  be the sub-graphs of  $G_P$  that corresponds to loops  $L1$  and  $L2$  in  $P$  and there exist edges  $L((u, v)) = i_{r_j}.n$  and  $L((w, u)) = i_{s_k}.m$  in  $G_P$ .

Hypothesis 1: There is an anti dependence if  $i_{s_k} > i_{r_j}$ .

⇒ An incoming edge with label  $i_{r_j}.n$  to node  $v$  means variable  $v$  is Written in  $n$ th iteration of instruction  $i_{r_j}$ . An outgoing edge with label  $i_{s_k}.m$  from node  $w$  to node  $u$  means variable  $u$  is Written in  $m$ th iteration of instruction  $i_{s_k}$ .

⇒ The condition  $i_{s_k} > i_{r_j}$  means that first a value is Read from  $u$  in  $n$ th iteration of instruction  $i_{r_j}$  and then Written from  $w$  to  $u$  in  $m$ th iteration of instruction  $i_{s_k}$ .

⇒ By Definition IV.7, there exists anti dependence between statements  $i_{s_k}$  and  $i_{r_j}$  if Write operation succeeds Read operation.

Hypothesis 2:  $L1$  and  $L2$  can be fused if  $m \geq n$  and  $i_{s_k} > i_{r_j}$ .

⇒ As  $m \geq n$  and  $i_{s_k} > i_{r_j}$ , even after fusing the statements  $i_{s_k}$  and  $i_{r_j}$  as Write operation succeeds Read operation on variable  $u$ , semantics of code is unchanged.

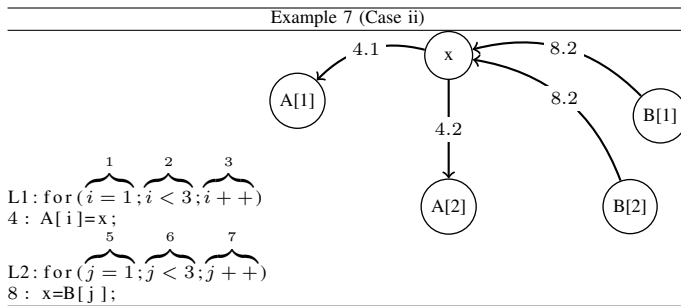

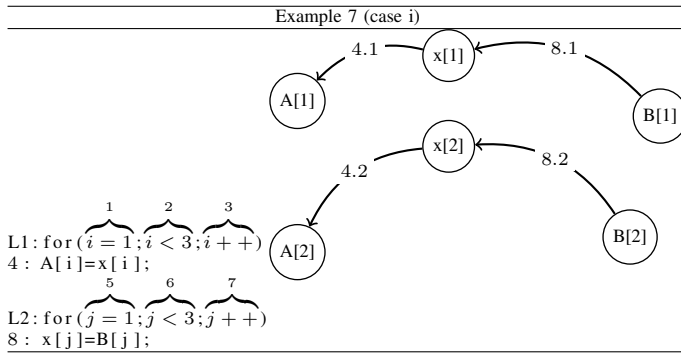

⇒ By definition IV.4, statements of loops  $L1$  and  $L2$  can be fused if the semantics of the code is intact.

Hypothesis 3:  $L1$  and  $L2$  can not be fused if  $n > m$ .

⇒ Before fusing, in loop  $L1$  Read operation is performed on variable  $u$  in  $n$ th iteration of instruction  $i_{r_j}$ . In loop  $L2$  variable  $u$  is Written in  $m$ th iteration of instruction  $i_{s_k}$ .

⇒ If  $L1$  and  $L2$  are fused, as  $n > m$ , variable  $u$  is Written in  $m$ th iteration of instruction  $i_{s_k}$  even before  $u$  is Read in  $n$ th iteration of instruction  $i_{r_j}$  i.e., a new value is written to  $u$  even before older value is Read.

⇒ As semantics of code changes, loop fusion is not possible if  $n > m$ . ■

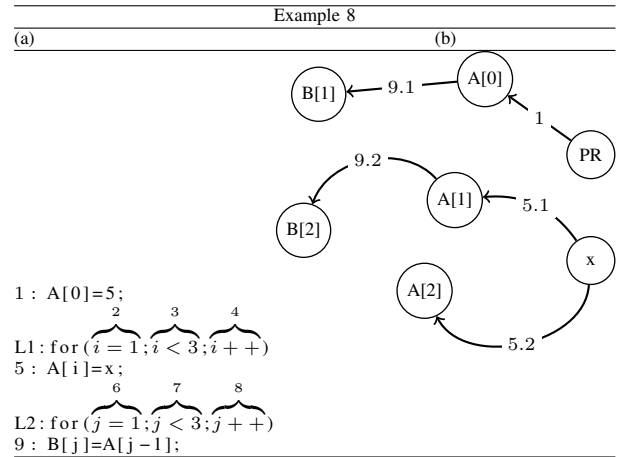

If anti dependence exists between loops  $L1$  and  $L2$  i.e. if an instruction in  $L1$  access an memory location  $M$  for Read and the same location is accessed by an instruction in loop  $L2$  for Write, merging of loops is possible if  $M$  is accessed for Read first and then for Write even after fusing. In example 7(case i),  $L((x[2], A[4])) = 4.2$  and  $L((B[2], x[2])) = 8.2$  says  $x[2]$  is read in iteration 2 of instruction 4 and written in iteration 1 of instruction 8. As the value is ‘Read’ in first loop and ‘written’ in second loop in the same iteration, merging of loops will not change the semantics of code. Therefore edges  $L((u, v)) = n.i$  and  $L((w, u)) = m.j$  where  $n \in L1$ ,  $m \in L2$  and  $j \geq i$  in the graph represents anti dependence where merging is possible.

If anti dependence exists between loops  $L1$  and  $L2$  merging of loops is not possible if a memory location  $M$  which is accessed for ‘Read’ in  $L1$  and then for ‘Write’ in  $L2$  is not preserved after fusing. Example 7(case ii) shows the anti

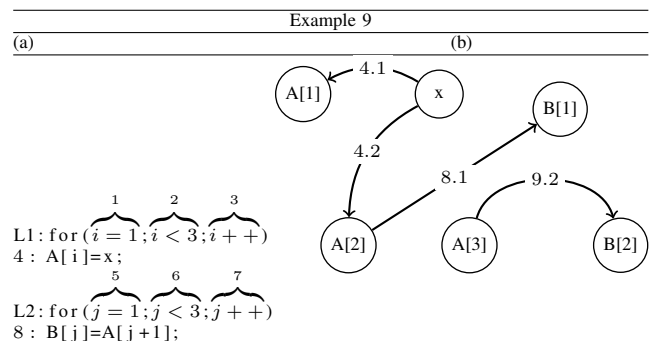

dependence where memory location  $x$  is accessed for ‘Write’ many times in first loop and for ‘Read’ in second loop, merging of loops is not possible.

If **Loop carried forward dependence** exists between loops  $L1$  and  $L2$  merging of loops is possible. In Example 8,  $L((x, A[1])) = 5.1$  and  $L((A[1], B[2])) = 9.2$  says memory location  $A[1]$  is written in iteration 1 of instruction 5 and is read in iteration 2 of instruction 9. As a value computed in iteration  $i$  of first loop is accessed in iteration  $j$  of second loop where  $j \geq i$ , merging of loops will not change the semantics of the code.

If **Loop carried backward dependence** exists between loops  $L1$  and  $L2$  merging of loops is not possible. If a memory location is accessed by an iteration of a statement  $S_i$  in loop  $L1$  and the same location is accessed by previous iterations of statement  $S_j$  in loop  $L2$ , when such statements are merged  $S_j$  in  $L2$  will access the memory location first and then  $S_i$  which will change the order of execution. As semantics of code will change, fusing of loops is not possible if *loop carried backward dependence* is present between  $L1$  and  $L2$ .

In Example 9,  $L((x, A[2])) = 4.2$  and  $L((A[2], B[1])) = 8.1$  says memory location  $A[2]$  is written in iteration 2 of instruction 4 and is read in iteration 1 of instruction 8 i.e., memory location  $A[2]$  is read even before it is updated. As a value computed in iteration  $i$  of first loop is accessed in iteration  $j$  of second loop where  $j < i$ , merging of loops can change the semantics of the code.

Thus, we conclude that fusion of two loops  $L1$  and  $L2$  is possible though the above discussed dependencies such

as flow dependence(case i), loop carried dependence, anti dependence(case i) exists between the statements of the loops.

## V. CONCLUSION AND FUTURE WORK

In this paper, we have introduced a model to perform various optimizations like loop invariant code motion, live range analysis, node splitting and loop fusion through a graphical representation of the program called as Data Dependence Identifier (DDI). For each of the optimization we have investigated on the condition that has to be satisfied by DDI (graphical representation of the program  $P$ ) so that optimizations can be performed which leads to an effective parallelization of  $P$ .

All the optimizations that were discussed are justified as well as validated conceptually with a sequence of rigorous theorems. These theoretical proofs also serve the purpose of the *correctness of proposed algorithms* with which one could easily perform the optimizations of a program.

**Salient Features:** Though there are many graphical representations for a program, our graphical representation referred as DDI is a unique graphical representation in the state that the variables of  $P$  are used as nodes and the edges between the nodes reflect the nature of access (read/write) of the variables from the memory.

Thus, salient features of our work are:

- a novel graphical representation of a program.
- performing almost all the optimizations with one model DDI.

**Future Work:** The optimization procedures are the main components of parallelization process. With our DDI model, in this paper we have just established the performance of various optimization procedures. Validating the optimization procedures with the benchmarked programs may not yield any significant insight on the performance of optimization procedures with DDI. The reason being that, performance of the various components of a machine may not yield any useful information on the performance of the machine built with those components. For this reason, experimental validation of a full DDI based parallelizer is proposed as future work and to be taken as separate work.

Further, one can initiate investigating DDI for extending the DDI as an optimizer, to as parallelizer. Extension of the DDI as a full fledged parallelizer and the empirical comparison of

the DDI based parallelizer with the contemporary parallelizers are the two major works worthful to be considered as future works in the direction of the present paper.

**Abstract**—Distance and online learning (or e-learning) has become a norm in training and education due to a variety of benefits such as efficiency, flexibility, affordability, and usability. Moreover, the COVID-19 pandemic has made online learning the only option due to its physical isolation requirements. However, monitoring of attendees and students during classes, particularly during exams, is a major challenge for online systems due to the lack of physical presence. There is a need to develop methods and technologies that provide robust instruments to detect unfair, unethical, and illegal behaviour during classes and exams. We propose in this paper a novel online proctoring system that uses deep learning to continually proctor physical places without the need for a physical proctor. The system employs biometric approaches such as face recognition using the HOG (Histogram of Oriented Gradients) face detector and the OpenCV face recognition algorithm. Also, the system incorporates eye blinking detection to detect stationary pictures. Moreover, to enforce fairness during exams, the system is able to detect gadgets including mobile phones, laptops, iPads, and books. The system is implemented as a software system and evaluated using the Fddb and LFW datasets. We achieved up to 97% and 99.3% accuracies for face detection and face recognition, respectively.

**Keywords**—Online learning; online proctor; student authentication; face detection; face recognition; eye blinking detection; object detection; distance learning; e-learning

## I. INTRODUCTION

Most schools and universities provide educational courses and training physically, i.e., requiring the attendance of lectures, entrance examinations, semester exams, and other activities in physical classrooms and spaces. Teaching and learning in physical spaces have many disadvantages such as inflexibility for students, teachers, and other staff, requiring physical spaces with stringent requirements, accessibility-related challenges for the students and staff in terms of space and time, challenges related to human disabilities, higher financial costs, transportation-related challenges and harms to people and environment, and many more. Online teaching and learning have been known to have many advantages including the flexibility and accessibility for people to attend classes from homes, at their convenience both in time and space, lower costs, a much smaller impact on the planet environment, and many more. Indeed, all the disadvantages of in-class teaching mentioned above could be overcome or abated by online learning.

Despite the many benefits of online learning, in-class learning has remained the mainstream choice for teaching and learning. Massive open online courses (MOOCs) that are offered online have motivated many to attend and complete courses and degrees online [1]. Many of the top schools and universities worldwide provide students with online courses as well as certificates upon completion of the courses. However, these MOOCs are mainly used to upskill knowledge rather than replace school and university education. This trend of moving towards MOOCs had been on the rise and is expected to take an increasingly larger share of in-class education.

The COVID-19 pandemic has caused disruption in many spheres of our lives. Physical interaction for education, work, and leisure has been regulated by governments around the world to minimise human infection rates [2]. This situation has forced education and many other physical activities and businesses to move from physical to online spaces [3]. School, university, and other education and training around the world have moved to online learning. However, many challenges are prohibiting its wide adoption by the governments and public. For example, monitoring of attendees and students during classes, particularly during exams, is a major challenge for online systems due to the lack of physical presence. There is a need to develop methods and technologies that provide robust instruments to detect unfair, unethical, and illegal behaviour during classes and exams. Current literature in this respect is limited with most of the software available from commercial entities that provide limited and “non-open” software tools. Many open-source tools and efforts are needed to bring innovation, variety, and richness to this online learning software systems domain.

Artificial intelligence (AI) has revolutionized our world and environments by providing smartness to many of our daily life activities [4], [5], [6], albeit with several challenges [7], [8]. Particularly, machine and deep learning has accelerated innovation in many fields such as education [1], healthcare [9], [10], transportation [11], [12], communication networks [13], disaster management [14], smart cities [15], and many more. With no exception, AI has the capacity to revolutionise online learning and proctoring.

This paper proposes a novel online proctoring system that uses deep learning to continually proctor physical places without the need for the presence of a physical proctor.

The system employs biometric approaches including face recognition using the HOG face detector and the OpenCV face recognition algorithm. Also, the system incorporates an eye blinking detection method to detect stationary pictures. Moreover, to enforce fairness during exams, the system is able to detect gadgets including mobile phones, laptops, iPads, and books. The system is implemented as a software system and evaluated using the Fddb (Face Detection Data Set and Benchmark) and LFW (Labeled Faces in the Wild) datasets.

The rest of the paper is structured as follows. Section II discusses the research related to online proctoring systems. Section III describes the methodology and design of the proposed system. Section IV provides system evaluation. Section V concludes and discusses future work.

## II. LITERATURE REVIEW

An overview of the relevant research is presented in this section. In the online proctoring system, Section II-A analyzes the literature in the academic realm, and Section II-B reviews the literature in the commercial sector.

### A. Academic Research

The online exam is facing immense challenges throughout the exam. Sarrayrih et al. [16] discussed the several challenges presented by the online exam, as well as providing a solution by grouping the hostnames or IPs of clients for a specific location and time, with a biometric solution like face recognition and fingerprints. In [17], a profile-based authentication framework is proposed for the online exam based on different challenging questions, including the favourite questions, personal questions, and an academic question. Fenu et al. [18] proposed a multi bio-metric continuous authentication system including face recognition, voice recognition, touch recognition, mouse, and keystroke in 2018. Selvi et al. [19] designs and implements a firewall security system using different firewall technologies, including Network Address Translation, Demilitarized Zone, and Virtual Protocol Network, which are used for intrusion detection. Wei et al. [20] proposed fingerprint-based solution. Garg et al. [21] proposed a face recognition and detection solution for the secured online exam using deep learning. Another online proctoring system was proposed by Atoum et al. [22], which continuously estimates six components, including voice, phone, text, and active window detection, gaze estimation, and user verification. A fingerprint and eye tracker-based online test management system was proposed by Bawarith et al. [23]. Cheating and not cheating are used as student status to evaluate their proposed methodology.

### B. Commercial Systems

Recently, the online proctoring system has become a challenge for researchers and developers. Due to the coronavirus situation, the demand and challenges for the online proctoring system are enormously increasing day by day. Several industrial companies developed the proctoring system commercially with the paid version. For example, Mettl [24], Proctortrack [25], Proctoredu [26], Proctoru [27], Comprobo [28], and so on.

**Mettl:** Mettl created web-based online proctoring software that divides their system into four major components: candidate authentication using a picture, OTP and ID affirmation, human-based proctoring using real-time recording in the classroom, secure browser-based proctoring using disables the following features: opening new browsers and data transferring media, and AI-based proctoring using facial, mobile phone, candidate distraction, and multiple person detection. To use this software, the examiners have to pay.

**Proctortrack:** Proctortrack built a web-based multi-level proctoring system through four levels of security. Level 1 is called ProctorLock, and it has automated identity verification, including audio, video, and desktop data recording. The real-time video data is available up to 2-3 hours for the proctor. Level 2 is named ProctorAuto, and it includes level 1 features with automated data analysis. Level 3 is called ProctorTrackQA, which is a robust version of level 2. It analyzes the results from level-2 using a manual QA review process. Finally, level 4, called ProctorLive AI, includes AI-based auto proctoring intervention capabilities in cases of suspicious reactions, cheating, or aiding a student. Testing sincerity results are additionally analyzed with AI.

**Proctoredu:** Proctoredu is a web-based online proctoring system which includes features like online supervision and video recording, additional camera, face and voice detection, passport recognition, face bio-metric, focus, and online status tracking, locking a parallel login, content copy protection, screen recording, and determining a second monitor. For PC Chrome and Firefox, all features are available. For Android, Chrome and IOS Safari supported all the features except screen recording and second monitor determination.

**Proctoru:** Proctoru promoted a web-based online proctoring system including live proctor monitoring, flagging, and intervention. Admins can observe the session in real-time and perform AI-based behavior analysis.

**Comprobo:** Comprobo solutions developed an online automated invigilation system on the web-based platform including features such as capturing the user's photographic ID against each assignment and verifying the reference photo, substitution check, restriction of using other applications or browsers, recording the IP address of the device, remote ID verification, biometric monitoring, and recording the full working environment.

Motivated by the challenges in the area of online learning systems, we propose and implement an online proctoring system that provides solutions to mitigate problems including fraud and multiple student attendance, cheating using still images, and unauthorised use of devices during class or exam time.

## III. METHODOLOGY AND DESIGN

### A. The Proposed Framework

The proposed web-based online proctoring system is distributed into two modules. Firstly, the online registration part, and secondly, the online proctoring part. Fig. 1 describes the proposed architecture for the online proctoring system.

1) *Online Registration:* For registering students' faces, we accessed the student's web-camera through HTTPS protocol

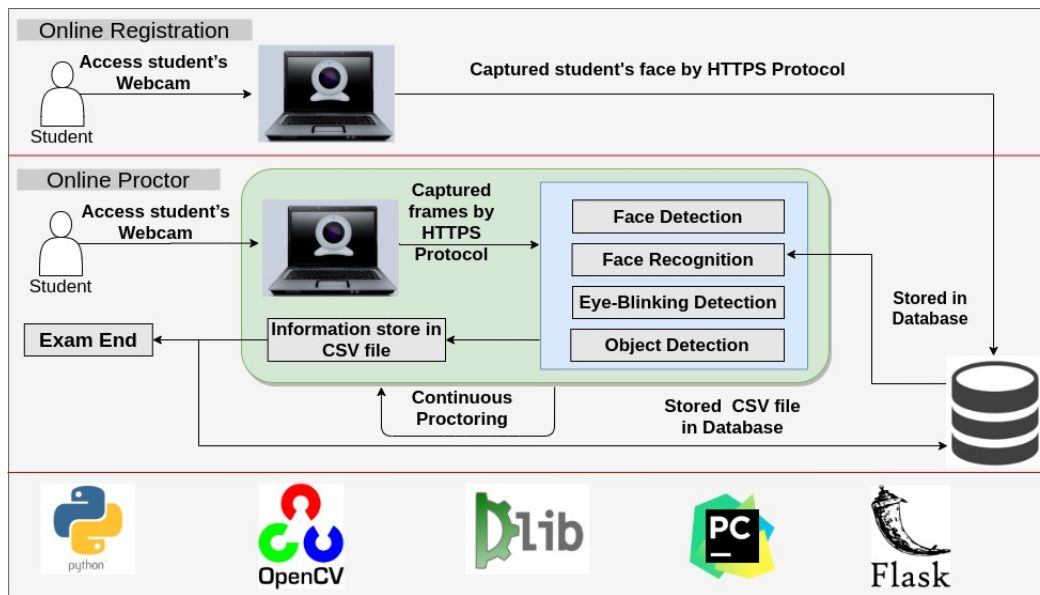

Fig. 1. Proposed Architecture.

during registration and captured the students' faces, storing the face information in the database. We used a flask micro-framework for web development.

The primary challenge in this module was accessing the client-side camera to capture the students' faces. To get around this, we utilized the HTTPS (HyperText Transfer Protocol Secure) protocol to access the students' webcams, which encrypts all conversations between the browser and the server. When using the HTTPS protocol to host a website, SSL certificates are also required. We used a self-signed SSL certificate to run the server.

2) *Online Proctoring*: During online exam sessions, there are some challenges to conducting the exam. Challenges are:

- An unauthorized student may participate in the exam.
- Multiple students may participate together for the exam.
- The student may use his still picture for face recognition.
- The student may use a device such as a mobile, laptop, or iPad to run a video for face recognition.
- The student may use books during the exam.

Our main goal is to mitigate those challenges. In the online proctoring module, we use biometric methods like face detection and recognition with eye-blinking detection. The suggested system's algorithm is detailed in Algorithm 1. In the face-recognition part, we detect and recognize students' faces and detect multiple faces in front of the camera. There is a chance that students can use their still pictures in front of the web-camera. As a result, the face-recognition algorithm recognizes the student as a real face. To avoid the recognition of still pictures, we use eye-blinking methods. If the number of eye-blinking is not more than 30, then we can confirm that the picture in front of the camera is still. There is another possibility that students can hold a device in front of the

web camera by playing his face video. In this case, face recognition and eye-blinking algorithms will detect the image as real and authenticate. So, we use object detection methods like YOLOv3, which also serve to prevent cheating in the exam using devices. We also detected the book using the same YOLOv3 model as the fare and secure exam.

**Algorithm 1** Master Algorithm

```

1: procedure onlineProctor
2:   while True do
3:     frame ← captureFrameFromWebCamera
4:     faceDetect ← faceDetection(method = "HOG")
5:     faceCount ← detectFaceCountForCurrentFrame
6:     if faceCount == 0 then
7:       Exam cancel: no face found
8:     else if facecount == 1 then
9:       Exam continue
10:    else if facecount > 1 then
11:      Exam cancel: multiple face found
12:    end if
13:    faceMatch ← faceRecognition()
14:    if faceMatch == False then
15:      Exam cancel: Unauthorized face found
16:    end if
17:    blinkingRatio ← eyeBlinkingDetection()
18:    if blinkingRatio > 4.5 then
19:      noBlinking ← noBlinking + 1
20:    end if
21:    if noBlinking > 30 then
22:      Exam cancel: still image found
23:    end if
24:    object ← objectDetection()
25:    if object == list of target objects then
26:      Exam cancel: object found
27:    end if
28:  end while
29: end procedure

```

## B. Datasets

We have used FDDB data sets for face detection which contain 5171 face annotation from 2845 images collected from Faces in the wild data sets. We divide the data sets into two parts, including faces and without faces, and implement face detection algorithms to evaluate our proposed system. The resolution of each image in the data set is 86 x 86 pixels. To evaluate face recognition algorithms, we used LFW dataset which contain 5749 people's 13233 images, where 1680 people's had two or more images. As our face recognition algorithm needs a single image for face recognition, we divided the data sets into ten sections based on the number of images available of the people in each data set. In the data set, every 3180 people have one image, every 775 and 290 people have two and three images consecutively, and so on. Each of the image resolutions is 250 x 250 pixels.

## C. Face Detection

In our proposed system, we used the HOG (Histograms of Oriented Gradients) method to detect the faces that were proposed by Navneet and Dalal [29]. In the initial stage of face detection, we convert our input image into grayscale because we don't need an RGB image to find faces. After that, we process every single pixel and the directly surrounding pixels of the image at a moment. We would like to determine the darkness of the current pixel is in contrast to the pixels around it. To show in which direction the image is becoming darker, we draw an arrow. If we replicate such a method for each and every pixel in the image, then we discover that every pixel is followed by an arrow. Gradients are the arrows, which determine the overall image's movement from brightness to darkness. Following that, we can see the image's fundamental pattern. To conduct the function, we divided all of the images into 16x16 pixel squares. Then we count gradient points in each major direction of each square and replace the square image with the strongest single gradient direction. The process's output will convert the original picture into the face's fundamental structure, which seems to be the most similar to the HOG pattern derived from training images. We used the HOG frontal face detector using dlib and the OpenCV library for face detection.

## D. Face Recognition

Face recognition is the most popular biometric solution for the online authentication system. OpenCV is a famous computer vision library that was started by Intel in 1999. OpenCV implements three face recognition algorithms, including Eigenface, Fisherface, and LBPH (Local Binary Patterns Histograms) face recognition. To detect faces, these algorithms employ the Haar cascade classifier technique, introduced by Paul and Michael [30].

In our proposed methodology, we snap a picture of a student as input and use HOG techniques to recognize faces in the image. Then, for the identified picture, estimate the 68 landmarks. Faces that are oriented differently and seem differently to a computer may all belong to the same person, and these signs can be used to easily identify them. Finally, the identified photos are directly compared to previously learnt and saved faces in our database. The pseudo code for facial recognition is shown in the Algorithm 2.

We match a known face from our database to unknown faces using a deep neural network. We train a classifier to determine which known student is the closest match based on measures from a new test image. The classifier's output would be the name of a student. The number of faces in the photograph is also counted.

---

### Algorithm 2 Face Recognition

---

```
1: procedure Face Recognition (studentId, studentName)
2:   while True do
3:     Grab current frame from student's Webcam
4:     frame ← currentFrame
5:     faceLocations ← get all faces on frame
6:     faceEncoding ← get all faceEncodings on frame
7:     faceMatch ← compare studentFace with all faces
8:     if faceMatch == True then
9:       Face Recognized
10:    else
11:      Face Unrecognized
12:    end if
13:  end while
14: end procedure
```

---

1) *Facial Landmark Estimation:* To a computer, the split faces rotated in various orientations appear to be different. To address this issue, we apply the face landmark estimation algorithm [31], which aids in the localization and representation of important facial features including the right and left eye, nose, jawline, mouth, and right and left eyebrow. The HELEN dataset is being utilized to find 194 landmarks on the face from a single image in a millisecond using this approach, which gives an ensemble of randomized regression trees. The method below can help determine whether two faces facing different directions and appearing differently from a computer's perspective are actually the same person.

Based on the fundamental concept of 68 distinct places on an image, we will train the system to recognize any 68 specific landmarks from the target image. We can center the eyes and lips no matter how the faces are rotated after using this method. The landmark boundary of the face is shown in Fig. 3(a), and the face landmark with 64 points is shown in Fig. 3(b).

2) *Encode the Faces:* The most basic concept in facial recognition is matching a recognized face to an unknown one. We identify a previously tagged face that appears to be frighteningly similar to an unknown face as belonging to the same individual. If there are thousands of students, it will take a long time to recognize everyone. As a result, we will need a technique for extracting a few basic measures from each face so that we can measure our unknown face and find the closest known face. We may, for example, measure the distance between the eyes and eyebrows, the length of the nose and mouth, and the size of each ear.

## E. Eye Blinking Detection

To identify a still image, the eye blinking method is utilized. Each eye is represented by 6 (x, y)-coordinates, which begin in the upper left corner and work clockwise around the rest of the area.

---

**Algorithm 3** Eye Blinking Detection

---

```

1: procedure Blinking Detection(studentId, studentName)
2:   eyeModel ← load shape-predictor-68-face-landmarks
3:   while True do
4:     frame ← Grab current frame from Webcam
5:     # get Blinking Ratio
6:     function bRatio( EyePoint, landmark)
7:       leftPoint ← left eye point
8:       rightPoint ← right eye point
9:       centerTop ← center top eye point
10:      centerBottom ← center bottom eye point
11:      horLineLenght ← horizontal line of eye point
12:      verLineLenght ← vertical line of eye point
13:      ratio ← horLineLenght / verLineLenght
14:      return ratio
15:   end function
16:   faces ← dlibFrontalFaceDetector (Frame)
17:   for face ← faces do
18:     # facial landmark (lm)
19:     lm ← eyeModel(grayFrame, faces)
20:     # Left Eye Ratio
21:     ler ← bRatio ([37,38,39,40, 41,42], lm)
22:     # Right Eye Ratio
23:     rer ← bRatio([43,44,45,46, 47,48], lm)
24:     bliningRatio ← (ler + rer)/2
25:   end for
26: end while
27: end procedure

```

---

From Fig. 2 image, we can get the key point to find the relation between height and width.

Fig. 2. Eye Blink Detection Landmarks.

In 2016, soukuter and cechj[32] proposed a method for real-time eye detection using facial landmarks. According to their research, we use an eye aspect ratio (EAR) equation that represents this connection, where 2D facial landmark positions are p1,..., p6. We utilize dlib and OpenCV to create eye blinking detection using facial landmarks and a frontal face detector.

#### F. Object Detection

Object recognition refers to identifying objects from digital images. Object classification can be divided into three tasks: object localization, image classification, and object detection. Object segmentation is the final task for object recognition. R-CNN, YOLO, SSD, RetinaNet, and ImageNet are popular deep learning-based object recognition models. The improved versions of the R-CNN model are Faster R-CNN, and Fast R-CNN, which are demonstrated and designed

for object recognition, and object localization. The acronym YOLO stands for ‘You Only Look Once’. YOLO model versions are YOLOv2 and YOLOv3 [33].

The R-CNN family of models delivers excellent object identification accuracy, but its processing speed is a key drawback. The processing speed is just 5 frames per second on a GPU, but the YOLO model is significantly quicker than R-CNN since a single-layer neural network is applied to the entire image. The YOLOv3 model is 100 times quicker than fast R-CNN, and 1000 times quicker than R-CNN. For training, the YOLO model is linked to a single neural network. It takes pictures and divides them into a grid of cells, with the cells anticipating bounding boxes and class labels. The predicted accuracy rate for this model is lower. “YOLO9000: better, faster, stronger” is how YOLOv2 is known. This model can predict 9000 object classes after being trained on two object identification datasets in parallel. The model is trained using high-resolution input pictures and batch normalization. Darknet-19, a proprietary deep architecture with a 19-layer neural network augmented with an additional 11 layers to identify the objects, was utilized by YOLOv2. YOLOv2’s 30-layer design made it difficult to detect tiny objects, but it’s primarily utilized in real-time object identification when precision isn’t required.

YOLOv3 is better than YOLOv2 in terms of speed and strength. It implements the darknet-53 proprietary deep architecture, which includes a 53 network and additional layers for object identification trained on ImageNet. As a result, it has a fully convolutional underlying architecture with 106 layers. The YOLOv3 model was employed in our suggested approach. This model was trained on pictures from the COCO dataset with different sizes: 608 x 608 (less speed, high accuracy), 416 x 416 (moderate speed, moderate accuracy), and 320 x 320 (high speed, low accuracy), and includes 80 labels such as laptop, mobile phone, and book.

---

**Algorithm 4** Object Detection Algorithm

---

```

1: procedure ObjectDetection (studentId, studentName)
2:   while True do
3:     Grab current frame from student’s Webcam
4:     frame ← currentFrame
5:     height, width, channels ← frame.shape
6:     blob ← blobFromImage(frame, scale)
7:     set the blob in network as input
8:     outputs ← forward pass to get Outputlayer
9:     for out ← outputs do
10:      for detection ← output do
11:        #scan outputs to get max confidence score
12:        confidence ← max scores
13:        if confidence > 0.7 then
14:          Object detected
15:        end if
16:      end for
17:    end for
18:  end while
19: end procedure

```

---

## IV. SYSTEM EVALUATION

To implement our proposed system, we use OpenCV for image processing, the dlib package for machine learning and

(a) Face landmark boundary

(b) Face landmark with 64 points

Fig. 3. Facial Landmarks.

Python, etc. We continuously proctor the exam system and concurrently implement each of the methods. Several experiments have been carried out to determine its efficiency, and the results are presented below.

We used the confusion matrix, which is a technique for summarizing the performance of a classification algorithm. There are some key terms for evaluating the confusion matrix, including TP, TN, FP, FN, accuracy, precision, recall, etc.

**True Positive (TP):** The number of positive samples that are accurately labelled.

**True Negative (TN):** The number of negative samples that are accurately labelled.

**False Positive (FP):** The number of negative samples that are mislabelled as positive.

**False Negative (FN):** The number of positive samples that are mislabelled as negative.

**Accuracy:** The percentage of classes are properly anticipated across all classes.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \times 100$$

**Precision:** The percentage of positive classes that are accurately predicted and truly positive.

$$Precision = \frac{TP}{TP + FP} \times 100$$

**Recall:** The percentage of classes are properly anticipated across all positive classes.

$$Recall = \frac{TP}{TP + FN} \times 100$$

### A. Face Detection

The face detection results are shown in Fig. 4 and 5. We have used the “HOG” method for face detection. In our test image dataset, we have a total of 4305 images with faces from the Fddb dataset. After implementing the face detection method, we got 97.21% accuracy, 100% precision, 97.18% recall, and 98.57% F1-score. Additionally, we obtained 4141, 0, 44, and 120 TP, FP, TN, and FN from the confusion matrix, correspondingly.

Fig. 4. Face Detection Result (TP, TN, FP, FN).

### B. Face Recognition

The experimental result for face recognition is shown in Table I, and II. We used the LFW face dataset to experiment with the results of the face recognition algorithm. In our proposed system, we need a single image per person for the proposed algorithm. So, we use one image per person in the training image, whereas in the test image set, we use the corresponding person images in identical or different backgrounds or poses, as well as unknown person mages. Table I shows the confusion matrix number of correctly and

Fig. 5. Face Detection Results (Accuracy, Precision, Recall, F1-Score).

incorrectly predicted images for several users and test images using TP, TN, FP, and FN. We achieved reasonable results with the proposed algorithm.

TABLE I. FACE RECOGNITION RESULT (TP, TN, FP, AND FN)

No. of Users	No. of Test Cases	TP	TN	FP	FN
3810	5256	3808	0	1410	38
143	3897	3824	0	52	21
775	1431	1401	0	28	2
290	808	779	0	24	5
187	695	675	0	11	9
112	525	508	0	12	5
55	304	298	0	3	3
39	253	249	0	2	2
33	247	245	0	2	0
26	221	212	0	7	2
15	144	143	0	1	0

We perceive from Table II that the accuracy of the algorithm is almost near to 99% for around 1000 people, but if the number of people is increased, then the accuracy decreases slowly. For example, if we train 15 to 775 people’s faces, then the accuracy is near to 99% and for 143 people’s faces, we used a large image set for testing where we achieved a better accuracy of about 98%. For training 3810 people’s faces, we got a low accuracy result of about 72%. Based on the aforementioned findings, we may conclude that the suggested algorithm performs significantly better with a smaller number of students.

TABLE II. FACE RECOGNITION RESULTS

No. of Users	No. of Test Cases	Accuracy	Precision	Recall	F1 Score	Time (S)
3810	5256	72.45	72.98	99.01	84.02	2373.03
143	3897	98.12	98.66	99.45	99.05	1096.74
775	1431	97.90	98.04	99.86	98.94	587.42
290	808	96.41	97.01	99.36	98.17	304.15
187	695	97.12	98.39	98.68	98.54	268.46
112	525	96.76	97.69	99.02	98.35	173.27
55	304	98.03	99.00	99.00	99.00	97.44
39	253	98.42	99.20	99.20	99.20	76.49
33	247	99.19	99.19	100.0	99.59	83.38
26	221	95.93	96.80	99.07	97.92	67.48
15	144	99.30	99.30	100.0	99.65	41.06

### C. Object Detection

As we mentioned earlier, we implemented the Yolov3 object detection model for our proposed system that was proposed by Joseph and Ali [33], and the model was assessed on the COCO dataset. They compared YOLOv3 with RetinaNet and found that YOLOv3 has a similar mean average precision (mAP) with a considerably quicker inference time. For example, YOLOv3-608 achieved 57.9% mAP in 51 milliseconds, while RetinaNet-101-800 achieved 57.5% mAP in 198 milliseconds, a 3.8 milliseconds faster.

## V. CONCLUSION AND FUTURE WORK

Face recognition and object identification techniques are utilized in this study to give comprehensive knowledge for online tests. Our proposed method will aid in reducing inequity during the online exam. Human-induced detection is very important when conducting an online proctoring system, as it will aid in detecting students’ suspicious behavior throughout the test. We do not incorporate human activity detection in our suggested model, instead of relying on a single biometric solution and object recognition approaches for the online proctoring system.

In the future, we hope to apply and investigate various human behaviors such as gazing out the window, conversing with people, focusing on other directions, moving about, and so on. We only utilize the YOLOv3 model because of its quicker object detection algorithms, although there are several other object detection approaches available. In the next study, we will focus on such approaches and compare them to our current suggested system.

We have evaluated our proposed system using two datasets. However, the system has not been tested in a real-life deployment with a large number of users. Future work will look into further testing and development of the system in real-life environments. The current proctoring systems are commercial and their designs and sources are not available openly. This work is an effort to develop open systems so the community can learn from each other leading to faster innovations in the field under open-source developments.

### ACKNOWLEDGMENT

The work reported in this paper is supported by the High Performance Computing Centre at King Abdulaziz University, Saudi Arabia. The experiments reported in this paper were performed on the Aziz supercomputer at King Abdulaziz University.

Shaqra University, Saudi Arabia

**Abstract**—e-Learning can generally be applied by employing learning management system (LMS) platforms designed to support an instructor to develop, manage, and provide online courses to learners. During the COVID-19 pandemic, several LMS platforms were adopted in Saudi Arabian institutions, such as Moodle and Blackboard. However, in order to adopt e-learning and operate LMS platforms, there is a need to investigate factors that influence the capability of faculty to utilize e-learning and its perceived benefits on students. This paper examines how training support and LMS readiness factors influence the capability of faculty to adopt e-learning and student perceived benefits. A quantitative research method was conducted using an online questionnaire survey method. Research data was collected from 274 faculty members, who used Moodle as a main LMS platform, at Shaqra University in the Kingdom of Saudi Arabia (KSA). The results reveal that training support and LMS readiness have a positive influence on the faculty's capability to adopt e-learning, which leads to enhancing students' perceived benefits. By identifying the factors that influence e-learning adoption, universities can provide enhanced e-learning services to students and support faculty through providing adequate training and powerful e-learning platform.

**Keywords**—e-Learning; Learning Management System (LMS); distance learning; LMS readiness; training

## I. INTRODUCTION

The COVID-19 pandemic has affected education worldwide [1]. Universities have adopted e-learning as an alternative to conventional ways of learning as its relevance have never been as significant as during this pandemic. E-learning can generally be implemented by using a learning management system (LMS), which is a web platform to manage all online e-learning processes and course materials for students and faculty [2]. Most of the Saudi universities provide Blackboard LMS for their teaching and learning activities [3], [4], while several other Saudi universities, such as Shaqra University, use open source LMS like Moodle platform.

Given LMS' enormous benefits in education during the COVID-19 pandemic, many researchers have examined the adoption of e-learning systems and investigated the key factors that can increase its adoption at their institutions. These studies focus on varied e-learning perspectives such as student adoption's evaluation. Reference [5] explores a small interpretive case study that finds students realistic and social perceptions. That have impacted positively by habitual activities. It recommends that faculty should engage informal social platforms such as Facebook and WhatsApp in e-learning approaches. Meanwhile, Reference [6] evaluates the student academic performance using organizational aspects and finds

that there are positive relationships between organizational aspects and student's performance during the emergent remote teaching. Reference [7] propose a new adoption framework for e-learning, grouping various characteristics from information system success and diffusion of innovation (DOI). Applying the framework on students' data results in a significant relationship of these characteristics with e-learning adoption. Reference [8] examines four factors from the perspective of students such as ease of use and technical usage of LMS in order to investigate the student's behavior toward using the LMS.

To reach success factors that can affect the e-learning activities, various approaches were used. Theoretical frameworks can be used to analyze the challenges facing e-learning adoption. For example, unified theory of acceptance and use of technology (UTAUT) and diffusion of innovation theory (DOI) are employed to rationalize challenges in e-learning activities [9]. Researchers extend the technology acceptance model (TAM) with factors of knowledge sharing and acquisition, building a new model to assess e-learning adoption [10]. Advanced techniques in artificial intelligence (AI) have also been used to examine the significance of selected factors [11]. Nevertheless, there is limited research investigating several factors, e.g. technical support, relevant to increase the faculty productivity of the LMS benefits [12].

In order to adopt e-learning and operate LMS platforms, it is important to realize the user's perspective toward e-learning adoption [13], so faculty members certainly have major roles in the execution of e-learning activities. There is a need to examine factors that influence the capability of faculty to adopt e-learning and its perceived benefits on students. Thus, this study fills the literature gap by investigating the relationship among faculty training support, LMS readiness, the capability of faculty to adopt e-learning, and students' perceived benefits in the context of one university in Saudi Arabia: Shaqra University.

This paper is organized as follows. Section II provides a literature review, Section III describes a research model, Section IV presents the research methodology, Section V shows the research results, Section VI offers a discussion, and, finally, Section VII concludes the paper.

## II. LITERATURE REVIEW

This research reviews four key research areas: training support, readiness of the LMS, capability to adopt e-learning, and students' perceived benefits. These research areas are used

to develop the theoretical base for the research's hypotheses and model in the following subsections.

#### A. Training Support

Training support that is provided by institutions, such as readable guides and training videos, definitely enhance faculty's capability to interact with e-learning tools and apply course design standards. Researchers have found the importance of supporting faculty in teaching online by, for example, providing online education resources and training, especially on ICT skills, e-learning tools, and course design abilities.

Authors in [14] identify the lack of technical support systems as one of the main barriers an instructor may experience. Teo and others [15] also show that the quality and the accessibility of online education resources have shaped the effectiveness of e-learning, which encourage users to adopt and utilize e-learning systems. Furthermore, researchers on [12] found that the more the institution provides support, the higher the confidence and capability of faculty is in using LMS to accomplish their work. March and Lee in [16] find that a university faculty have gained technical knowledge after going through a training program. The LMS capability test, for instance, shows that post-test correct responses have increased nearly 160% than pre-test. Adequate training from institution as well as institutional encouragement and support have been suggested in [17] as a factor to raise faculty motivation towards the use of e-learning systems.

#### B. Readiness of the LMS

The LMS readiness presents the readiness of all aspects that are part of the e-learning environment. There are number of factors might affect the readiness of LMS adoption in various dimensions e.g. technology, user proficiency, motivations, organization support. Factors can be based on behavioral patterns studying multiple constructors of readiness to accept changes, to change beliefs and to resist changing [18]. Successfully preparing the technological requirements of LMS is essential in increasing its adoption [19]. Researchers have discussed the technical factors from different perspectives. A theoretical base based on the technology acceptance model (TAM) in [20], [21], where others from analyzing perceptible such as [19] focusing on the importance of user-support technical. Several characteristics can be considered to measure the quality of readiness software systems, especially in open-source systems such as the LMS Moodle system used for this case study [22]. However, we found that the usability characteristic as defined by [22] covers several important factors such as learnability, operability, accessibility, and user interface. Thus, we tailored our survey specifically to the usability factors that match our requirements.

#### C. Capability to Adopt e-Learning

Many studies discuss how the desire and technical capability of faculty members impact their successful adoption of e-learning. [14] identified faculty resistance to change, lack of time to develop e-courses, lack of e-learning knowledge, and lack of motivation as main barriers in adopting e-learning. Also, the acceptance to change and the adoption of Blackboard platform in [18] is affected by various variable, such as

resistance to change and individual differences. Moreover, [12] identified the ability to use LMS for teaching as LMS self-efficacy. The paper showed that the higher LMS self-efficacy the higher faculty perceived benefits. [23] also reveal that unwillingness, disinterest, and demotivation are main internal challenges that hinder e-learning uptake.

Adopting LMS and e-learning tools has a positive influence on students' perceived benefits and satisfaction. Engaging students with e-learning tools has a positive impact on their performance and score [24], [25]. [26] revealed the positive impact of adopting blogs for learning on students perceived satisfaction. Also, providing students with supported e-learning apps through their own tablet devices found to be useful for students in the learning scenario [27].

The level of development of e-learning in an educational institution helps overcome faculty challenges in adopting e-learning. Al Gamdi and Samarji [28] found that the most-cited barriers in adopting e-learning is the external barriers such as lack of technical support in the university, training on e-learning, institutional policy for e-learning, and Internet access in universities. The author in [29] evaluated e-learning readiness and showed that improvement in the field of e-learning, like arranging workshops and resetting the infrastructure of the organization create a positive attitude towards adopting e-learning.

#### D. Students' Perceived Benefits

1) *Cognitive Skills*: Cognitive skills (CS) is an important concept, which refers to the level of the knowledge a student gains [30]. The level of the gained knowledge indicates the improvement of a student's skills and the effectiveness of the teaching methods used. Researchers have considered a number of factors affecting CN. These factors varied from basic factors e.g. student's learning behaviors [31], students' duties [32] to advance factors, e.g. travel schedule and outing schedule [30]. Current research in the field of CN that studies e-learning adoption shows adequate contributions. However, we believe that there are more CN factors to be investigated. In our research, we focus on four CN factors: student's IT skills, student's self-learning, student's effective communication with faculty, and student's effective communication with classmates.

Relative research has defined the concept of student's IT skills and self-learning under the term self-efficacy, which refers broadly to the efforts and capabilities of a student toward executing and organizing successfully required course tasks [12], [33], [34], [35]. In this research, student's IT skills (SITS) factor refers to the student's technical ability to use the LMS software effectively. The student's self-learning (SSL) factor represents the motivation of the student in using the course 's learning resource' to learn from the faculty's perspective. Effective communication is the volume of two-way electronic communication between one or more parties. Lastly, student's effective communication with faculty (SECF) refers to announcements, audio/video message and comments, online discussions, and e-mail exchanged between students and faculty [36].

There are several studies in the field of exploring students' adoption of e-learning systems. These studies have investigated

Fig. 1. Research Model.

students' adoption from different perspectives such as knowledge sharing [10], [37], [19] qualitative [19], and quantitative [36], [38]. [10] studies the results of acquisition and sharing of the knowledge on the students' behavioral intention to adopt e-learning systems. It employs the acquisition and sharing of the knowledge as extensions of the technology acceptance model (TAM). The results show that the factors considered on the studies have significant effects on the student's e-learning adoption. [38] focus on studying students' intention to use LMS and the element of attitude strength.

These studies have applied their experiments and surveys on data sets that have been collected from students' feedback. In contrast, in this research, we have evaluated the students based on specific factors collected from faculty's perspective.

2) *Academic Achievements*: The factors that might measure the student academic achievements (SAA) are classified into three domains: traditional, psychological, and students' demographic characteristics [31]. In this research, we define three traditional and two psychological factors: student's remote attendance (SRA), student's completed assignments (SCA), student's grade-average (SGA), student's e-interactions with lectures (SEIL), and student's e-interactions with resources (SEIR). This research has derived these factors as the most frequently used factors in recent literature [39], [40]. Although the traditional factors are numerically accurate, we adopt a scale-base in order to unify measurements.

The SRA presents actual attendance of registered students in a course from the point of view of the faculty at scale base. The SCA is the total of completed assignments in a specific due date for all registered students in a course. The SGA refers to the average final grade achieved by students in a course. The SEIL is the communications among registered students and course's faculty, while the SEIR is registered students' utilization of the online resources of a course.

### III. RESEARCH MODEL

The proposed research model examines the impact of training support and faculty LMS readiness on the capability of faculty to adopt LMS. It also examines students' perceived benefits, as described in Fig. 1.

Training support is defined as the training provided to faculty by organization, which includes technical, instructional, and pedagogical training. Many educational institutions provide various training programs, digital guides, and awareness publications to, for example, support the capability of faculty to deal with e-learning tools, course design, and teaching strategies.

Although LMS is widely considered in institutions, some educational institutions, especially before the COVID-19 pandemic, did not offer enough training programs and instructions on using LMS tools and course design. However, faculty members who utilize e-learning tools depend significantly on the support from technicians in employing different e-learning tools and course design [12], [16]. The faculty's capability to adopt e-learning is defined as the extent to which faculty members believe that they have enough efficiency and intention to adopt e-learning and its technical tools in education. Accordingly, a sufficient training support provided by an organization can better aid the faculty members capability and aspiration to adopt e-learning in education. Thus, the following hypothesis is proposed:

**Hypothesis 1 (H1).** Training support provided by an institution has a positive effect on faculty capability to adopt e-learning.

LMS readiness is defined as the extent to which faculty members believe that the LMS in their institution is sufficiently prepared, accessible, effective, and has a friendly interface to support future use. In other words, the higher quality of LMS in terms of availability, system efficiency, and ease of use is a main motivation for faculty to adopt e-learning. It has been identified that quality of system services have a positive influence on users perceived value, which also has a positive influence on users intention and adoption of e-learning [41]. This study is intended to examine the effect of LMS readiness on the capability of faculty members to adopt e-learning. Thus, the following hypothesis is proposed:

**Hypothesis 2 (H2).** The LMS readiness has a positive effect on faculty capability to adopt e-learning.

Authors in [42] have found that engaging students in the e-learning process with developed e-learning teaching strategies is has a statistically significant impact on students' performance and satisfaction by comparing with traditional learning. Students' perceived benefits is defined as the extent to which a student is expected to benefit from the faculty's capability to apply e-learning regarding academic achievement and cognitive skills. This study is intended to examine the capability of faculty members to adopt e-learning on students' perceived benefits from the point of view of faculty members. Thus, the following hypothesis is proposed:

**Hypothesis 3 (H3).** The faculty capability to adopt e-learning has a positive effect on students' perceived benefits from the point of view of faculty members.

### IV. RESEARCH METHODOLOGY

This paper shows how training support and LMS readiness influence the capability of faculty to adopt e-learning, which influence the students' perceived benefits. This study was carried out to measure the variables and test the hypothesis. The survey structure and its constructs will be presented in Section IV-A, then data collection and the demographic factors of the survey respondents will be discussed in Section IV-B.

TABLE I. RESULTS OF THE DESCRIPTIVE STATISTICS OF ALL ITEMS IN THE CONSTRUCTS (N = 274).

Construct	Item	Mean	Std.Dev
Training Support (TS)	What is your assessment of training support in terms of:		
	- TS1: Your knowledge of accessing it	3.34	1.09
	- TS2: Your Knowledge of it	3.61	1.08
	- TS3: Its Quality	3.37	1.10
	- TS4: Its Diversity	3.38	1.16
LMS Readiness (LMS-R)	How do you evaluate LMS in terms of:		
	- LMS-R1: Accessibility	3.79	1.05
	- LMS-R2: Efficiency	3.85	0.98
	- LMS-R3: Friendly interface	3.62	1.06
	- LMS-R4: Continuous use	3.61	1.02
Capability to adopt e-learning (CA-EL)	How do you rate e-learning in terms of your:		
	- CA-EL1: Satisfaction level	3.53	0.99
	- CA-EL2: Desire to use	3.87	1.08
	- CA-EL3: Technical capability	4.09	0.92
	- CA-EL4: Level of development	3.78	1.05
Students' Perceived Benefits (SPB)	How would you evaluate e-learning in terms of supporting students in the following:		
	- SPB1: Self-learning	3.38	1.04
	- SPB2: Communication with classmates	3.62	1.03
	- SPB3: Communication with faculty	3.68	1.04
	- SPB4: Technical capability	3.18	1.09
	How do you rate students' discipline when applying e-learning in terms of:		
	- SPB5: Commitment to attend	3.70	0.94
	- SPB6: Interaction in lectures	3.14	0.99
	- SPB7: Interaction with e-resources	3.15	1.04
	- SPB8: Completion of assignments	3.66	0.90
- SPB9: Students' grade	3.80	0.91	

### A. Survey Structure

An online questionnaire survey has been prepared and distributed among Shaqra University faculty members. The first part of the survey collected some personal data from the participants, such as their gender, department, and college. The second section of the online survey contains four constructs that are broken down by items and is shown in Table I.

The first construct has four items to assess the level of training support from the university to faculty. The second construct has four items that allow faculty to evaluate LMS readiness. The third structure also contains four components that give the opportunity for faculty members to assess e-learning. Finally, the fourth construct has four items that faculty members answer to assess the extent to which a student is expected to benefit from the faculty's capability to adopt e-learning. The survey consists of a five-point Likert scale with very satisfied (5), satisfied (4), moderately satisfied (3), dissatisfied (2), and very dissatisfied (1).

### B. Data Collection

The questionnaire was administered to faculty members of Shaqra University. First, a cross-sectional online questionnaire was distributed among all faculty members of Shaqra University on January 2021 through their formal emails. Shaqra University has only provided Moodle as the main LMS since the beginning of 2019 and did not provide any other LMS, such as blackboard, before it. The study was conducted on faculty members who completed the online questionnaire also on January 2021. The faculty members officially used Moodle as the main LMS during the first year of the COVID-19 pandemic. They used it to manage virtual classes, discussions, assignments, and exams among others. The Moodle LMS has

been used at Shaqra University limitedly before the COVID-19 pandemic, but the number of users increased remarkably right when the COVID-19 pandemic started. As a result, the questionnaire was distributed after a year of using e-learning in the university. All survey respondents were considered because they were able to finish the questionnaire successfully.

## V. RESULTS

In this section, the frequency of respondents and a descriptive statistics is explained to show if variables are normally distributed and have adequate reliability.

The study collected data from faculty members of Shaqra University. The collected data was analyzed and examined using statistical analysis system (SAS) program. Among 274 faculty members that participated, 151 (55.1%) were males and 123 (44.9%) were females. Table II shows the demographic for respondents based on their professional fields. The table shows that most of the respondents, 98 (35.8%), were from science and engineering fields, and among respondents in these fields, 53 (54.1%) were males and 45 (45.9%) were females.

Table I shows the mean and standard deviation of all constructs' items. Among the four items of the training support assessments, faculty knowledge about training support materials gained the highest mean among assessment items of training support (3.61  $\pm$ 1.08), while the knowledge of how to access materials gained the lowest mean (3.34  $\pm$  1.09). The last three items have very close means. Among items related to LMS readiness, efficiency of LMS Moodle (3.85  $\pm$ 0.98) and accessibility (3.79  $\pm$ 1.05) rated as the most important factors determining LMS readiness, according to faculty members, while the friendly interface (3.62  $\pm$ 1.06) and continues use items(3.61  $\pm$ 1.02) were rated as the lowest

TABLE II. DEMOGRAPHIC DATA OF RESPONDENTS' PROFESSIONAL FIELDS

Fields	Female	Male	Total
Science and Engineering	45 45.9%	53 54.1%	98 35.8%
Humanities	27 48.2%	29 51.8%	56 20.4%
Business Administration	21 38.2%	34 61.8%	55 20.1%
Medicine and Applied Medicine	11 33.3%	22 66.7%	33 12%
Others	19 59.4%	13 40.6%	32 11.7%
Total	123 44.9%	151 55.1%	274 100%

Fig. 2. The Research Model with Significant Results.

factors for LMS readiness. The technical capability item within the faculty capability to adopt e-learning construct was rated as the highest value among all items in the survey (3.09 ±0.92), while satisfaction level is the lowest within the construct (3.53 ±0.99). Finally, the students' grade items of the students' perceived benefits construct had the highest mean value from the faculty's point of view (3.80 ±0.91) in the academic achievement category, while communication with faculty had the highest mean value in the cognitive skills category (3.68 ±1.04).

The results of the descriptive analysis of the four constructs, including the constructs' mean and standard deviation, are shown in Table III. The mean values of the four variables are from 3.42 to 3.82, where the highest value is the mean of the capability to adopt e-learning. Also, the standard deviations of the four variables range from 0.76 to 0.95, where the highest value is the standard deviations of training support. The statistics together indicate that all variables are normally distributed.

The reliability and validity test in Table III reports the values of Cronbach Alpha  $\alpha$  and Pearson's correlation coefficient (Corr). A Cronbach Alpha value of 0.70 or higher suggests that the measurement scale performs consistently when it is tested repeatedly [43]. Thus, the measurement scale is viewed as reliable. The  $\alpha$  value of all four variables ranged from 0.81 and 0.83, implying that their measurement scales have suitable reliability. Pearson correlation showed a positive correlation among all variables[44]. These correlations were separated into strong and moderate correlations. The strong positive correlations were found between training support and LMS readiness and between capability to adopt e-learning and student perceived benefits (> 0.70). While moderate positive correlation was found between all the remaining variables (>0.5).

Table IV showed the result of the study logistic regression analysis, which examined the study hypothesis. First, the logistic regression significantly rejects the first null hypothesis and conclude there was a statistically significant association between an exogenous variable training support and an endogenous variable capability to adopt e-learning ( $\chi^2 = 24.60$  and  $p < .0001$  as shown in Fig. 2). As the score of training support increased by one unit, the odds ratio of faculty capability to adopt e-learning increased by 7.87 (OR = 7.87, 95% CI = 3.36 – 18.42,  $p < 0.0001$ ), supporting hypothesis H1 (Training support provided by institution has a positive effect on faculty capability to adopt e-learning).

Next, the logistic regression significantly rejects the second null hypothesis and concludes that there was a statistically significant association between LMS readiness and the faculty's capability to adopt e-learning ( $\chi^2 = 31.36$  and  $p < .0001$  as shown in Fig. 2). The score for LMS readiness increased by one unit and the odds of faculty's capability to adopt e-learning increased by 11.78 (OR = 11.78, 95% CI = 5.01 – 27.72,  $p < 0.0001$ ), suggesting that hypothesis H2 (The LMS readiness has a positive effect on faculty capability to adopt e-learning) is supported.

Finally, the logistic regression significantly rejects the third null hypothesis and conclude that there was a statistically significant association between an endogenous variable capability to adopt e-learning and another endogenous variable students' perceived benefits ( $\chi^2 = 65.47$  and  $p < .0001$  as shown in Fig. 2). The score for faculty capability to adopt e-learning increased by one unit and the odds of students' perceived benefits increased by 41.61 (OR = 41.61, 95% CI = 13.53 – 127.98,  $p < 0.0001$ ), which supports hypothesis H3 (The faculty capability to adopt e-learning has a positive effect on Students' Perceived Benefits from faculty point of view).

## VI. DISCUSSION

This research examined factors influencing the adoption of e-learning and student perceived benefits from the perspective of faculty members at Shaqra University, Saudi Arabia. By applying simple and multivariate logistic regression analyses, the findings indicate that the proposed research model demonstrates the significance of selected factors on e-learning adoption. The results evidently support positive effects for our hypotheses (H1, H2, and H3).

The study size is similar to comparable studies, but the study sample socio-demographics are slightly different. The proportion of female to male participants was approximately half the proportion of female to male participants in a similar study [12] and different from what was found in earlier Saudi studies [28], [14], [45]. More than third of the participants in our survey were from science and engineering fields, most likely because of their strong e-learning knowledge and ICT background. Also, the fewest respondents in the survey came from the Other category, such as Arabic language sciences and Islamic studies sciences, most likely because of their lack of e-learning knowledge and ICT backgrounds [14], [45], [46].

The findings of this study show a positive association between training support and the faculty's capability to adopt e-learning. Previous studies validated our results by finding that a lack of e-learning knowledge and skills will impact its

TABLE III. DESCRIPTIVE STATISTICS, RELIABILITY, AND DISCRIMINANT VALIDITY TEST (N = 274)

Construct	Mean	Std.Dev	Cronbach's Alpha ( $\alpha$ )	Pearson correlation coefficient (Corr)			
				1	2	3	4
Training Support (TS)	3.42	0.95	0.84	1	0.71565	0.63197	0.54697
LMS Readiness (LMS-R)	3.72	0.92	0.83	0.71565	1	0.60942	0.57849
Capability to Adopt e-learning (CA-EL)	3.82	0.87	0.82	0.63197	0.60942	1	0.70880
Students' Perceived Benefits (SPB)	3.48	0.77	0.81	0.54697	0.57849	0.70880	1

TABLE IV. RESULTS OF RESEARCH MODEL

Independent Variables	P-Value <sup>a</sup>	Odds Ratio (OR)	95% Confidence Interval (CI)

Training Support (TS)	<0.0001	7.87	3.36 – 18.42
Second Hypothesis (Dependent variable = Capability to Adopt E-learning (CA-EL)) <sup>c</sup>			
LMS Readiness (LMS-R)	<0.0001	11.79	5.01 -27.72
Third Hypothesis (Dependent variable = Students' Perceived Benefits (SPB)) <sup>d</sup>			
Capability to Adopt E-learning (CA-EL)	<0.0001	41.61	13.53-127.98

<sup>a</sup> Significant at  $p < 0.05$

<sup>b</sup> Model  $\chi^2 = 24.60$ ,  $df = 1$ ,  $p < 0.001$

<sup>c</sup> Model  $\chi^2 = 31.36$ ,  $df = 1$ ,  $p < 0.001$

<sup>d</sup> Model  $\chi^2 = 65.47$ ,  $df = 1$ ,  $p < 0.001$

successful implementation in Saudi Arabia, Iraq, and Libya [14], [23], [46]. Shaqra University is an emerging university in Saudi Arabia that had limited training support before the COVID-19 pandemic and intense training support after it. Training support is a necessary factor for all universities regardless of their rank, size, or country. [23], who conducted a survey on four medium-size universities in the United States, found that the higher the organizational support, through training programs, the higher the faculty member's confidence in adopting LMS, which is also emphasizes the importance of the training support factor.

As shown in Table IV, the faculty's capability to adopt e-learning has the strongest association with the e-learning adoption (OR = 41.61) as compared to the association between training support and capability to adopt e-learning (OR = 7.87) and between LMS readiness and capability to adopt e-learning (OR = 11.787). Interestingly, this association is uncertain with a wider interval (13.53-172.98), which might indicate the need to study further the capability to adopt the e-learning factor and consider more sub-factors. Unlike some previous studies, such as [10], [19], [38], this study was conducted in the context of a pandemic, traditional learning was necessarily replaced by e-learning methods. Therefore, it is recommended to reconduct this study in more regular circumstances and compare results to better comprehend e-learning adoption.

It is worth mentioning that Shaqra University is only providing Moodle system, unlike most other Saudi government universities that use officially Blackboard system. As result, the LMS readiness findings could be slightly different if they are applied in other universities that use different LMS platforms, such as Blackboard or Canvas. It is advisable to apply our research model with faculty from different universities who use different LMS platforms. This will help in revealing the suitable LMS platform and e-learning tools that fit e-learning environment. Also, it might consequently change the significant association with other factors such as the capability to adapt e-learning.

## VII. CONCLUSION

In the current study, the proposed research model describes a set of constructors that could impact e-learning adoption from faculty's perspective. The selected constructors are defined from four relevant factors based on the available literature, i.e. training support, readiness of the LMS, capability to Adopt e-learning, and students perceived benefits. These factors basically present the essential dimensions of the e-learning processes.

The findings demonstrate the statistical significance association among the selected constructs in the space problem, supporting our hypotheses. The results reveal the importance of providing the adequate training to faculty and LMS readiness in order to increase e-learning adoption. It confirms that the faculty's capabilities play a major role not only in provoking students' perceived benefits but also in overcoming challenges in LMS readiness. Although faculty members' capabilities were an essential factor that significantly affects all e-learning processes, some statistical uncertainties were found that might affect the reliability of the results. Indeed, the results of this study can be used to increase e-learning adoption specifically in Shaqra University and other universities in the region. For future work, further detailed and reliable analysis, such as sensitive analysis, is required to understand faculty's capabilities.

## VIII. ACKNOWLEDGMENT

The authors are grateful and thankful for Shaqra University for all the support. They would also like to thank all participants in this research for their valuable comments.

# Joint Deep Clustering: Classification and Review

Arwa Alturki, Ouiem Bchir, Mohamed Maher Ben Ismail  
Department of Computer Science  
King Saud University, Riyadh  
Saudi Arabia

**Abstract**—Clustering is a fundamental problem in machine learning. To address this, a large number of algorithms have been developed. Some of these algorithms, such as K-means, handle the original data directly, while others, such as spectral clustering, apply linear transformation to the data. Still others, such as kernel-based algorithms, use nonlinear transformation. Since the performance of the clustering depends strongly on the quality of the data representation, representation learning approaches have been extensively researched. With the recent advances in deep learning, deep neural networks are being increasingly utilized to learn clustering-friendly representation. We provide here a review of existing algorithms that are being used to jointly optimize deep neural networks and clustering methods.

**Keywords**—Clustering; deep learning; deep neural network; representation learning; clustering loss; reconstruction loss

## I. INTRODUCTION

Clustering is a challenging problem in machine learning, as its purpose is to categorize objects into groups according to similarity measures. To achieve this, many clustering algorithms have been published in the literature [1]. These algorithms can be classified into two groups: hierarchical and partitional approaches. In hierarchical clustering, the data are organized into nested clusters that are merged into larger ones or divided into smaller ones. This yields a hierarchy of clusters called a dendrogram. Conversely, partitional clustering is based on the optimization of a specific cost function that allows separation between clusters. The performance of these different clustering algorithms depends on their accurate representation of the data. Hence, data representation learning is a critical step in the clustering process.

Over the past several decades, many traditional representation learning techniques have been proposed. Some of these techniques are designed to learn low-dimensional data representation with linear projections, such as unsupervised principal component analysis (PCA) [2], supervised linear discriminant analysis (LDA) [3], kernel-based PCA [4], and generalized discriminant analysis (GDA) [5]. To discover the intrinsic structure of high-dimensional data, manifold learning algorithms that are based on locality were introduced, such as isometric feature mapping (Isomap) [6] and locally linear embedding (LLE) [7]. In 2006, Hinton et al. [8, 9] introduced the concept of deep learning by utilizing artificial neural networks (ANNs) for dimensionality reduction. Specifically, they introduced a greedy layer-wise pretraining process and a finetuning framework for deep neural network (DNN) learning. The resulting performance was better than that of state-of-the-art algorithms on MNIST [9] handwritten digit recognition and

document retrieval tasks. Following this groundbreaking work, a considerable number of deep representation learning algorithms were developed.

Recently, frameworks that perform deep representation learning and clustering procedures have attracted much attention. These frameworks are referred to as deep clustering algorithms, and they can be divided into (1) separated deep clustering and (2) combined deep clustering methods. In separated deep clustering, the deep representation is learned first, and then fed into a clustering algorithm. However, because these two tasks are optimized separately, the learned representation may not be suitable or sufficient for the clustering. In combined deep clustering, the deep representation learning and clustering are jointly optimized. This implies that the clustering assignments and network parameters are reciprocally affected in every learning iteration. Such an approach yields a representation that is more suitable for clustering. Two approaches to achieve combined optimization exist: the pretraining and finetuning approach, and the joint training approach. In the pretraining and finetuning approach, the DNN is pre-trained with nonclustering loss (network loss) to initialize the network parameters and learn initial representation. Then, the clustering loss is used to train (finetune) the initialized network and output clusters. In contrast, in the joint training approach, the network is trained with a joint loss function that integrates the clustering loss with a nonclustering loss (network loss). In this review, we survey joint deep clustering algorithms by examining different network structures and analyzing the building blocks of these algorithms.

In Section 2, we introduce deep representation learning techniques. In Section 3, we will describe the clustering algorithms that are utilized in joint deep clustering. In Section 4, we provide a survey of the joint deep clustering approaches, and in Section 5, we present the conclusions from the results of this survey.

## II. DEEP REPRESENTATION LEARNING

Deep representation learning techniques generate multiple levels or a hierarchy of representations. In this hierarchy, the high-level representations are constructed from multiple low-level ones. These techniques are based on deep ANNs. A typical (single-layer) neural network consists of input, hidden, and output layers. The input layer receives the raw input data, whereas the output layer produces the task results, such as object classification or clustering. The hidden layer applies nonlinear transformation to extract more abstract and composite representations from the input data. DNNs contain

more than one hidden layer, to apply multiple nonlinear transformations and create the representation hierarchy. The word “deep” refers to the multiple hidden layers in the neural network.

DNNs apply a supervised learning process, where a set of input–output pairs is provided for training. This learning process is composed of two passes: a forward pass (forward propagation) and a backward pass (backpropagation). The forward pass first randomly initializes the network parameters, that is, the connections, weights, and biases. Then, the input data are passed through the network layers, in the forward direction, to calculate the predicted output. Next, the predicted output is compared with the actual output through a task-specific loss function. An optimization technique, namely, stochastic gradient descent (SGD), is then applied to minimize the loss function. Conversely, the backpropagation process is initiated by updating the network weights so that the predicted output is closer to the actual output. This can be achieved by minimizing the error of each output neuron in the entire network.

In the following subsections, we discuss three DNN types that have been used as representation learning techniques for clustering tasks. The first is feedforward neural networks (FNNs), which fall into two categories: completely connected networks (FCNs) [10] and convolutional neural networks (CNNs) [11]; the second is deep belief network (DBNs), which are composed of a stochastic probabilistic component called a restricted Boltzmann machine (RBM); and the third is the autoencoder (AE), which comes in two types: the stacked AE (SAE) and convolutional AE (CAE).

#### A. Feedforward Neural Networks

The FNN [12] is the simplest type of neural network, where the connection between neurons does not form a cycle. The information in this type of network moves forward (in one direction) from the input neurons to the output neurons. In this case, there is no feedback from the output toward the input neurons. FNNs are arranged in the form of layers, as are all neural networks. Depending on the number of layers, an FNN can be a single- or a multilayer network. As mentioned above, FNNs fall into two types: FCNs and CNNs.

An FCN, also known as a multilayer perceptron (MLP) [13], consists of multiple completely connected (FC) layers, where each neuron in one layer is connected to every neuron in the previous layer. In addition, every one of these connections has its own weight. FCNs are composed of an input layer, an output layer, and an arbitrary number of hidden layers. This type of feedforward network is tailored for supervised learning.

Inspired by biological process, the neuron connectivity pattern in CNNs mimics the organization of the animal visual cortex. The first and core building block of a CNN is the convolutional layer, where each neuron is connected to only a few neurons in the previous layer. The same set of weights is used for every neuron. The second layer is the rectified linear unit (ReLU) layer, which applies an elementwise nonlinear activation function to retain the positive parts of the inputs and remove the negative ones by replacing them with zero. The reason for applying ReLU layers in a CNN is to increase the

nonlinearity of the inputs. A pooling layer is frequently inserted between two consecutive convolutional layers. The pooling layer applies a function to reduce the spatial size of the representation by combining the output of the set of neurons in one layer into a single neuron in the next layer. As a consequence, the number of parameters and computations throughout the network is reduced and overfitting is controlled. The final layer of a CNN is an FC layer to classify the input. Similar to FCNs, CNNs are designed for supervised learning, and specifically to classify image datasets.

Deep clustering algorithms that employ feedforward networks for unsupervised representation learning use clustering loss only to train the network. Hence, these algorithms aim to optimize the objective function,

$$L = L_c \quad (1)$$

where  $L$  is the algorithm loss function and  $L_c$  is the clustering loss function. In the absence of other measures and depending completely on the clustering loss, such deep clustering algorithms may lead to a distorted representation space, wherein all data points are assigned to tight clusters. Such a trivial solution results in a small amount of meaningless clustering loss. To alleviate this problem, and in addition to the careful design of the clustering loss function, suitable network parameter initialization is required to enhance the performance.

#### B. Deep Belief Network

DBNs [14] are a branch of DNNs, and are composed of a stack of RBMs [15] followed by a softmax layer that applies a softmax activation function to the input. An RBM is a two-layer neural network, where the first is the visible (input) layer and the second is the hidden layer. A DBN is trained by greedy layer-wise unsupervised learning with RBMs as the building blocks for each layer. Then, the parameters of the DBN are finetuned according to a task-specific loss function. DBN-based deep clustering algorithms finetune the network parameters using the clustering loss function only, and thus optimize an objective function similar to the feedforward network loss function in equation (1). Hence, careful clustering loss selection and good network parameter initialization affect the performance of the deep clustering algorithm.

#### C. Autoencoder

An AE [16] is a special type of neural network designed for unsupervised representation learning. It consists of three building blocks: an encoder, a bottleneck layer, and a decoder. The encoder maps the input  $x_i$  to its hidden representation  $z_i$  through a nonlinear function  $f_{W_1}(\cdot)$ , as in equation (2), and the decoder reconstructs the input  $x_i$  from its hidden representation  $z_i$  by using a transformation function  $g_{W_2}(\cdot)$  as in equation (3).

$$z_i = f_{W_1}(x_i) \quad (2)$$

$$y_i = g_{W_2}(z_i) \quad (3)$$

Here,  $W_1$  represents the encoding weight, and  $W_2$  the decoding weight. The encoder and decoder can comprise an FC network to construct an SAE [17], or a CNN to form a CAE [18]. The bottleneck layer controls the amount of information that traverses the network by learning a compressed representation of the input data. The learning problem can be

formulated as a supervised one that is aimed to output the reconstruction image  $y_i$  from the input  $x_i$ . The entire network can be trained by minimizing the reconstruction loss  $L_{r\_AE}$ , which measures the differences between the original input  $x_i$  and the reconstructed image  $y_i$ :

$$L_r = \frac{1}{n} \sum_{i=1}^n \|x_i - y_i\|^2 \quad (4)$$

AE-based deep clustering algorithms seek to optimize an objective function that combines clustering and reconstruction losses:

$$L = L_r + \gamma L_c \quad (5)$$

where  $\gamma$  is a coefficient to control the distortion of the representation embedding space. The existence of the reconstruction loss forces the algorithm to avoid trivial solutions and learn more feasible representations.

#### D. Variational Autoencoder

VAE [19] is a generative variant of AE that enforces the latent code to follow a predefined distribution. This goal is achieved by encoding the input data into two vectors instead of one: mean value and standard deviation. Unlike the output of the standard AEs that points directly to the encoded value in the latent space, VAE outputs point to the area where the encoded value can be. To be more specific, VAE initializes a probability distribution where the mean value controls the location point of the encoding center, and the standard deviation defines the area in which encoding can vary from the mean. As a consequence, VAE allows interpolation and generation of new samples. Mathematically, VAE measures the Kullback–Leibler (KL) divergence [20] from a prior distribution to approximate the variational posterior distribution. The objective function can be formulated as the following:

$$L_{r\_VAE} = E_{q(z|x_i)} [\log p(x_i|z)] \quad (6)$$

$$L_{VAE} = L_{r\_VAE} - \sum_{i=1}^n \text{KL}(q(z|x_i)||p(z)) \quad (7)$$

where  $L_{r\_VAE}$  represents the reconstruction loss of the VAE,  $p(z)$  is the prior over the latent variables,  $q(z|x_i)$  is the variational posterior to approximate the true posterior  $p(z|x_i)$ , and  $p(x_i|z)$  is the likelihood function. Gaussian distribution is the common choice as prior; however, VAE-based clustering algorithms should choose a distribution which can describe the structure of the clusters.

#### E. Adversarial Autoencoder

Similar to VAE, AAE [21] utilizes a prior distribution to control the encoding of the input data. Hence, the decoder learns only the mapping from the prior distribution to the data distribution. The output of the AAE encoder, i.e. the encoded value, is fed as input to the decoder and to a special generative adversarial network (GAN) [19]. In AAE, the encoder and decoder together form the generator model ( $G$ ), while the GAN is known as discriminator ( $D$ ). Through the learning process, AAE establishes a min–max adversarial game between its generator and the discriminator. While the generator tries to map a generated sample from a prior distribution to the data space, the discriminator computes the probability to detect whether its input a real sample from the data distribution or a

fake sample from the generator. The training process of AAE is handled through two phases: (1) a reconstruction phase and (2) a regulation phase. During the reconstruction phase, the generator is trained to minimize the reconstruction loss of the generated sample and produce a reconstructed image of it. In the regulation phase, the discriminator parameters are updated to distinguish the real samples generated by the prior from the fake samples generated by the encoder. The discriminator network  $D$  is updated by the following discriminative loss ( $L_d$ ):

$$L_d = \frac{1}{n} \sum_{i=1}^n [\log D(\hat{z}_i) + \log(1 - D(z_i))] \quad (8)$$

where  $\hat{z}_i$  and  $z_i$  are the sample from prior distribution and input sample, respectively. Then, the discriminator is fixed, and the encoder is updated to confuse the discriminator by increasing the classification error of  $D$  on the input latent representation with generation loss  $L_g$ , as in the following equation:

$$L_g = \frac{1}{n} \sum_{i=1}^n \log(1 - D(z_i)) \quad (9)$$

AAE-based deep clustering algorithms optimize a loss function that combines reconstruction loss, generation loss, and clustering loss:

$$L_{AAE} = L_r + \alpha L_g + \beta L_c \quad (10)$$

where  $L_r$ ,  $L_g$ , and  $L_c$  represent the reconstruction loss defined in equation (4), the generation loss in equation (9), and a clustering loss, respectively.  $\alpha$  and  $\beta$  are hyperparameters to balance the importance of the generation loss and the clustering loss, respectively.

### III. CLUSTERING TECHNIQUES

As stated previously, clustering techniques can be divided into two types: hierarchical and partitional clustering. Hierarchical clustering methods iteratively merge smaller clusters into larger ones, or split large clusters into smaller ones. The difference between hierarchical algorithms includes the similarity measures that are used to determine which clusters should be merged or split. The results of hierarchical clustering are organized in a tree called a dendrogram, which shows the relationships between clusters. Conversely, partitional clustering seeks to decompose data into a set of disjointed groups. This decomposition is achieved based on the minimization of a specific objective loss function. Centroid-based algorithms, such as K-means [22, 23] and KL-divergence [20] clustering, distribution-based algorithms such as Gaussian mixture clustering [24], graph-based clustering algorithms such as spectral clustering [25] and RCC [26], and density-based algorithms such as DBSCAN [27] are all subtypes of partitional clustering algorithms. As existing joint deep clustering utilizes only centroid- and graph-based clustering, these two techniques are explained in the following subsections. Finally, we introduce some auxiliary clustering losses that are used in conjunction with other losses to guide deep representation learning.

#### A. Centroid-Based Clustering

Given a dataset  $X = \{x_1, \dots, x_n\}$  of  $n$  points together with its extracted representation  $Z = \{z_1, \dots, z_n\}$ , centroid-based clustering partitions the data points into clusters with central

representatives called centroids. These cluster centroids, denoted by  $\mathcal{M} = \{\mu_1, \dots, \mu_k\}$ , where  $k$  is a predefined number of clusters, do not necessarily belong to the dataset. In joint deep clustering algorithms, two centroid-based algorithms are utilized: K-means and KL-divergence clustering.

1) *K-means Clustering*: K-means clustering first randomly selects  $k$  centroids from the input data representations, each of which represents a cluster. A K-means algorithm minimizes the total mean squared error between the input data and cluster centroids according to the loss function:

$$L_{KM} = \sum_{j=1}^k \sum_{i=1}^n \|z_i - \mu_j\|_2^2 \quad (11)$$

An additional variation of the K-means loss function is the weighted least squares error, referred to as weighted K-means. It optimizes the cost function as:

$$L_{WKM} = \sum_{j=1}^k \sum_{i=1}^n S_{ij} \|z_i - \mu_j\|_2^2 \quad (12)$$

where  $S_{ij}$  is a similarity weight that encodes the closeness of a data point to a cluster centroid; i.e.,  $S_{ij}$  will be larger if the data point  $z_i$  is close to the centroid  $\mu_j$ . In the K-means learning process, the following two steps are repeated until convergence is reached:

- Point assignment update, which is accomplished by (i) calculating the mean distance from the data point to every cluster centroid, and (ii) assigning points to the cluster with the minimum mean among all clusters.
- Centroid update, which is computed according to the following equation, where  $m_j$  is the number of points in the  $j^{th}$  cluster:

$$\mu_j = \left(\frac{1}{m_j}\right) \sum_{i=1}^{m_j} z_i \quad (13)$$

K-means perform well when the distribution of the points is in circular form. Otherwise, K-means will attempt to group the points in circular form, which will affect the clustering result. To remedy this issue, K-means should be updated to employ a distribution-based model instead of a distance-based model.

Gaussian Mixture Model (GMM) [24] is a probabilistic soft clustering technique which tends to group points with the same distribution together. The clustering process starts by initializing the means and covariances of the Gaussian distribution for  $k$  clusters. Then, the expectations of all points assignments are calculated for all clusters. Furthermore, the distribution parameters are re-estimated, and the log-likelihood function is computed. This process continues until a predefined convergence criterion is reached.

2) *KL-divergence Clustering*: KL-divergence clustering is a soft assignment clustering technique, in which each data point is assigned to all clusters with varying probabilities. This algorithm is initiated using K-means to obtain  $k$  initial centroids. Next, the learning process is executed to optimize the following Kullback–Leibler (KL) divergence loss function:

$$L_{KLD} = KL(P||Q) = \sum_i \sum_j p_{ij} \log \left(\frac{p_{ij}}{q_{ij}}\right) \quad (14)$$

where  $P$  is an auxiliary target distribution and  $Q$  represents the data point soft assignments. The KL-divergence clustering algorithm refines the point assignments by learning from higher confidence points utilizing the auxiliary target distribution  $p_{ij}$ . Specifically, the algorithm matches the soft assignments  $q_{ij}$  with the target distribution  $p_{ij}$  by computing the KL divergence. The clustering algorithm iteratively performs the following steps until convergence is obtained or the maximum iteration is reached:

1) *Calculation of  $q_{ij}$* , the probability that a data point  $i$  belongs to cluster  $j$ . Two means of calculating  $q_{ij}$  exist: (1) student's t-distribution [28], as in equation (15), and (2) a multinomial regression [28] function, as in equation (16).

$$q_{ij} = \frac{(1 + \|z_i - \mu_j\|_2^2)^{-1}}{\sum_j (1 + \|z_i - \mu_j\|_2^2)^{-1}} \quad (15)$$

$$= \frac{\exp(\mu_j^T z_i)}{\sum_j \exp(\mu_j^T z_i)} \quad (16)$$

2) *Computing  $p_{ij}$* , a higher confidence distribution that can be obtained by calculating the soft cluster frequencies by considering the formula:

$$p_{ij} = \frac{q_{ij}^2 / \sum_i q_{ij}}{\sum_j (q_{ij}^2 / \sum_i q_{ij})} \quad (17)$$

3) Updating clusters centroids according to:

$$\mu_j = \mu_j - \frac{\lambda}{n} \sum_{i=1}^n \frac{\partial L_{KLD}}{\partial \mu_j} \quad (18)$$

## B. Graph-Based Clustering

Given a dataset  $X = \{x_1, \dots, x_n\}$  of  $n$  points together with their corresponding representation  $Z = \{z, \dots, z_n\}$ , graph clustering techniques first construct an undirected similarity graph  $G = (V, E)$ , where  $V = \{v_1, \dots, v_n\}$  denotes a set of vertices to represent the input data, and  $E$  is the set of edges between vertices. Several approaches for building a similarity graph [1] exist, two of which are specifically used in joint deep clustering. These approaches are the following:

- K-nearest neighbor (KNN) graph: this graph connects vertex  $v_i$  with vertex  $v_j$ , if  $v_j$  is within K-nearest neighbors of  $v_i$ . One problem common to KNN is that the graph is asymmetric, which means that if  $v_j$  is among the KNNs of  $v_i$ , then  $v_i$  is not necessarily among the KNNs of  $v_j$ . Hence, the constructed graph is a directed one. To alleviate this problem, there are two solutions; first, to insert an undirected edge between the two vertices  $v_i$  and  $v_j$ , if one of them is within the KNNs of the other; second, to restricts the edges, two vertices  $v_i$  and  $v_j$  are connected by an undirected edge only if they are both among the KNNs of each other. The resultant graph in the latter solution is called a mutual KNN graph.
- Completely connected graph: this graph simply connects all vertices with each other by weighted edges.

The weight of an edge  $w_{ij}$  between two vertices  $v_i$  and  $v_j$  represents the similarity between them. Because the graph should express the local neighborhood relationship, a Gaussian similarity function is usually utilized.

The graph is represented by an adjacency matrix, in which the similarity  $w_{ij}$  between every two vertices is included. Two graph-based clustering algorithms are utilized in joint deep clustering techniques: spectral clustering [25] and robust continuous clustering (RCC) [26]. We briefly explain these two approaches.

1) *Spectral clustering*: After the construction of the similarity graph and the extraction of the adjacency matrix, the spectral algorithm transforms the data into a low-dimensional space. To achieve this, another graph representation matrix is computed, the Laplacian matrix. The graph Laplacian matrix  $\mathcal{L}$  is computed as:

$$\mathcal{L}_{ij} = \begin{cases} d_i, & \text{if } i = j \\ w_{ij}, & \text{if } (i, j) \in E \\ 0, & \text{if } (i, j) \notin E \end{cases} \quad (19)$$

where  $d_i$  is the degree of the vertex  $v_i$ , which can be computed as:

$$d_i = \sum_{\{j|(i,j) \in E\}} w_{ij} \quad (20)$$

Then, the Laplacian matrix is utilized to find the eigenvalues  $\lambda$  and eigenvectors  $v$ , such that.

$$\lambda \mathcal{L} = \lambda v \quad (21)$$

Once the eigenvectors have been obtained, the low-dimensional data transformation is completed. Finally, a K-means clustering algorithm, explained in section 3.1, is applied to the transformed data (eigenvectors) to create clusters.

2) *Robust Continuous Clustering (RCC)*: This approach operates on a set of representations  $U = \{u_1, \dots, u_n\}$  for the original dataset  $X$ , where  $X$  and  $U$  have the same dimensionality. This algorithm minimizes the loss function.

$$L_{RCC} = L_{data} + \lambda L_{pairwise} \quad (22)$$

where  $\lambda$  is a coefficient that balances the two objective terms. The first term  $L_{data}$  is the data loss that constrains the representations to remain near the corresponding data points. The data loss can be computed as:

$$L_{data} = \sum_{i=1}^n \|z_i - u_i\|_2^2 \quad (23)$$

The second term, which is the pairwise loss  $L_{pairwise}$ , is designed to encourage the representations to merge, and pulls them together according to.

$$L_{pairwise} = \sum_{(p,q) \in E} w_{pq} \rho(\|u_p - u_q\|_2; \mu) \quad (24)$$

where  $\{w_{pq}\}$  represents appropriately defined weights,  $\mu$  is a scale parameter, and  $\rho$  is a redescending M-estimator that can be calculated according to a scaled Geman–McClure function [29]:

$$\rho(x; \mu) = \frac{\mu x^2}{\mu + x^2} \quad (25)$$

The first stage in the RCC learning procedure is initialization, which includes the following steps:

1) Construction of the similarity graph  $G_1 = (V, E)$  using mutual KNN.

2) Initialization of the data representation with  $u_i = z_i$ .

3) Initialization of the line process  $\mathbb{L} = \{\ell_{pq}\}$ , where  $\ell_{pq}$  is an auxiliary variable between two connected vertices  $v_p$  and  $v_q$  with  $\ell_{pq} = 1$ .

4) Initialization of a scale parameter  $\mu$  with  $\mu \gg \max\|z_p - z_q\|_2^2$ .

The optimization is aimed to reveal the cluster structure latent in the data; thus, the number of clusters does not need to be known in advance. The following optimization steps are recursively repeated until a maximum iteration number is reached, or the difference between the clustering loss in two consecutive iterations is less than a predetermined threshold.

1) Update  $\ell_{pq}$  according to the following formula.

$$\ell_{pq} = \left( \frac{\mu}{\mu + \|u_p - u_q\|_2^2} \right)^2 \quad (26)$$

2) Update the representations  $U = \{u_1, \dots, u_n\}$  using the following equation:

$$UM = Z \quad (27)$$

where

$$M = I + \lambda A \quad (28)$$

$I$  is the identity matrix,  $e_i$  is an indicator vector with the  $i^{th}$  element set to 1, and  $A$  is computed as the following:

$$A = \sum_{(p,q) \in E} w_{pq} \ell_{pq} (e_p - e_q)(e_p - e_q)^T \quad (29)$$

Update the value of  $\lambda$  as.

$$\lambda = \frac{\|Z\|_2}{\|A\|_2} \quad (30)$$

Update the value of  $\mu$  as.

$$\mu = \max\left(\frac{\mu}{2}, \frac{\delta}{2}\right) \quad (31)$$

where  $\delta$  is a threshold set to be the mean of the lengths of the shortest 1% of the edges in  $E$ . Then, RCC constructs a new graph  $G_2 = (V, E)$  with  $\varepsilon_{pq} = 1$  if  $\|u_p^* - u_q^*\|_2 > \delta$ . Finally, the algorithm outputs the clusters given by the connected vertices of  $G_2$ .

### C. Auxiliary Clustering Losses

Some clustering loss functions are designed to guide deep representation learning techniques to extract feasible clustering-oriented representations; they cannot, however, output clusters. These functions are known as auxiliary clustering losses. Considering a dataset  $X = \{x_1, \dots, x_n\}$  of

$n$  points together with its extracted representations  $Z = \{z_1, \dots, z_n\}$ , we present the auxiliary clustering losses that have been used in joint deep representation clustering algorithms.

1) *Balanced assignment loss*: Balanced assignment loss is used in conjunction with other clustering loss to enforce balanced clustering assignments. The difference between two distributions,  $f$  and  $u$ , is measured based on KL divergence as follows:

$$L_{BA} = KL(f||u) = \frac{1}{n} \sum_i \sum_j p_{ij} \log \left( \frac{f_j}{u_j} \right) \quad (32)$$

where  $P$  is the target distribution proposed in equation (17)  $u$  is the uniform distribution, and  $f$  is the probability distribution, which can be calculated as.

$$f_j = \frac{1}{n} \sum_i p_{ij} \quad (33)$$

2) *Locality-preserving loss*: Locality-preserving loss preserves the local structure property of the original data by pushing the nearby points together as.

$$L_{LP} = \sum_{i,j \in N_k(i)} S_{ij} \|z_i - z_j\|_2^2 \quad (34)$$

where  $N_k(i)$  is the set of  $k$  nearest neighbors of the data point  $x_i$  and  $S_{ij}$  is a similarity measure between  $x_i$  and  $x_j$ .

3) *Group sparsity loss*: Group sparsity loss was inspired by spectral clustering, where a block-diagonal similarity matrix is utilized for representation learning. Specifically, the hidden units are divided into  $k$  groups, where  $k$  is the number of clusters. For each data point  $x_i$ , after its representation  $z_i$  has been extracted, a  $k$  group unit  $\{f^j(x_i)\}_{j=1}^k$  is obtained. Then, the group sparsity is computed as.

$$L_{GS} = \sum_{i=1}^n \sum_{j=1}^k \lambda \sqrt{n_g} \|f^j(x_i)\|_2 \quad (35)$$

where  $f(x_i)$  is the representation encoding function,  $\lambda$  is a constant, and  $n_g$  is the group size.

4) *Self-expressiveness loss*: Self-expressiveness loss is a property where a point in a subspace can be expressed as a linear combination of other points in the same subspace. Let  $X$  be a column matrix of all data points; the self-expressiveness can then be represented as  $X = XC$ , where  $C$  is the self-representation coefficient matrix. By minimizing a certain norm of  $C$ , and under the assumption that the subspaces are independent,  $C$  is guaranteed to have a block-diagonal structure. This ensures that  $c_{ij} \neq 0$ , where  $x_i$  and  $x_j$  are two data points lying in the same subspace. The matrix  $C$  can then be leveraged by spectral clustering to construct the affinity matrix. Given this fact, each data representation  $z_i$  in a latent subspace is approximated by a weighted linear combination of other points  $\{z_j\}_{j=1}^n$  with weights  $c_{ij}$ . To encode self-expressiveness, the following auxiliary clustering loss function is introduced:

$$L_{SE} = \lambda_1 \|C\|_p + \frac{\lambda_2}{2} \|Z - ZC\|^2, \text{ s. t. } (\text{diag}(c) = 0) \quad (36)$$

where  $\lambda_1$  and  $\lambda_2$  are two regularization parameters to account for data corruption, and  $\|\cdot\|_p$  represents an arbitrary matrix norm.

#### IV. JOINT DEEP CLUSTERING

Given a dataset  $X = \{x_1, \dots, x_n\}$  of  $n$  points, the goal of joint deep clustering techniques is simultaneously to learn a low-dimensional representation  $Z = \{z_1, \dots, z_n\}$  for the data and to cluster it into groups jointly. This can be accomplished by optimizing a joint loss function that combines two losses: the representation learning loss and the clustering loss. Then, the low-dimensional representations, network parameters (weights and biases), and clustering parameters and assignments are updated jointly. In this section, we survey these algorithms, and provides a taxonomy from the perspective of clustering algorithms. Table I summarizes existing joint deep clustering algorithms.

##### A. Deep Kullback–Leibler Divergence Clustering

Guo et al. [28] proposed improved deep embedded clustering (IDEC), an algorithm that simultaneously learns low-level representation and cluster assignment. The IDEC algorithm consists of two phases: (1) parameter initialization, and (2) parameter optimization and clustering. In the initialization phase, IDEC initiates a denoising SAE [17], which reconstructs a data point  $x$  from a corrupted (noisy) version  $\tilde{x}$  to force the encoder and decoder to capture implicitly the structure of data that generate distribution. The SAE is trained based on reconstruction loss to obtain initial values for the network's weights and biases. The clusters' centroids are initiated by applying K-means to the representations extracted from the encoder element. When the initialization is completed, IDEC removes noise from the data to apply clustering to the representation learned from the clean data. When noise has been removed, the denoising SAE degenerates into a traditional SAE, which constrains the dimension of the hidden representation  $Z$  to be less than the dimension of the input data  $X$ . Then, the optimization and clustering phase is executed by finetuning using KL divergence as clustering loss and SAE reconstruction loss. This results in the joint loss function

$$L_{IDEC} = L_r + \lambda L_{KLD} \quad (37)$$

where  $L_r$  is the reconstruction loss in equation (4),  $L_{KLD}$  is the KL-divergence clustering loss in equation (14), and  $\lambda$  is a regularization parameter to balance the two terms. Clustering is achieved by alternating between computing the soft assignment based on the student's t-distribution formula in equation (15), and auxiliary target distribution in equation (17). IDEC jointly optimizes the cluster centers  $\mu_j$  and the network parameters  $\theta$  using an SGD algorithm [30]. The gradient is calculated for the clustering loss  $L_c$  with respect to the cluster centroid  $\mu_j$  and point representation  $z_i$ , and then is utilized in backpropagation. Experimental results have demonstrated the importance of locality preservation. Guo et al. [31] developed a deep clustering method with CAEs (DCEC) for image clustering; the DCEC framework is very similar to the IDEC model, but instead of an SAE, DCEC employs a CAE to better incorporate the relationship between image pixels. The effectiveness of CAE over SAE has also been demonstrated for image datasets.

TABLE I. SUMMARY OF JOINT DEEP CLUSTERING ALGORITHMS

Algorithm	Clustering Technique	Network Architecture	Joint Loss Function	Main Contribution
IDEC	KL-divergence	SAE	$L_{IDEC} = L_r + \lambda L_{KLD}$	Joint version of DEC [35], the first well-known deep clustering algorithm.
DCEC		CAE		Improves on IDEC by using CAE instead of SAE.
ADEC		AAE	$L_{ADEC} = L_r + \alpha L_g + \beta L_{KLD}$	Preserve the relevance between representation learning and clustering and reach to better trade-off between feature drift and feature randomness issue.
DEPICT		CAE	$L_{DEPICT} = L_{r, DEPICT} + L_{KLD} + L_{BL}$	Ensures balanced clustering assignments that provide robust and superior results over image datasets.
DEN	K-means	SAE	$L_{DEN} = L_r + \alpha L_{LP} + \beta L_{GS}$	Learns clustering-oriented representations with the following properties: (1) locality preservation and (2) group sparsity.
DCN			$L_{DCN} = L_r + \lambda L_{KLM}$	First algorithm to perform K-means and representation learning simultaneously.
DKM			$L_{DKM} = L_r + \lambda L_{WKM}$	Updates DCN to use weighted K-means instead of traditional K-means.
DMC			$L_{DMC} = (1 - \alpha)L_r + \alpha L_{LP, DMC} + \beta L_{WKM}$	Utilizes deep SAE to improve the traditional multimaniifold clustering algorithm.
DSC-Nets	Spectral Clustering	CAE	$L_{DSC-Nets} = L_r + L_{SE}$	Utilizes deep CAE to improve the traditional spectral clustering algorithm.
DASC		AAE	$L_{DASC} = L_r + \alpha L_g + \beta L_{SE}$	Learns subspace clustering-friendly representations using AAE and self-expressiveness constraint.
DSC			$L_{DSC} = L_r + L_g + \text{spectral clustering}$	More robust to noise; since it enforces the reconstruction constraints for the latent representations and their noisy versions.
DCC	RCC	SAE	$L_{DCC} = \frac{1}{D} L_r + \frac{1}{d} (L_{data, DCC} + \lambda L_{pairwise, DCC})$	Utilizes deep SAE to improve on the traditional RCC algorithm.

Similar to IDEC, Zhou et al. [21] introduced Deep Embedded Clustering With Adversarial Distribution Adaptation (ADEC). Instead of SAE, ADEC utilizes AAE to learn from data space to feature space. With a backpropagation algorithm, ADEC iteratively optimizes the following objective function:

$$L_{ADEC} = L_r + \alpha L_g + \beta L_{KLD} \quad (38)$$

where  $L_r$ ,  $L_g$ ,  $L_{KLD}$  is the reconstruction loss defined in (9), the generation loss in (9), and the KL-divergence clustering loss in equation (14), respectively, and  $\alpha$  and  $\beta$  are hyperparameters to balance the importance of the generation loss and the clustering loss, respectively. In deep learning, the optimization of a neural network's loss function whose secondary component highly competes with the primary one may lead to feature drift. As a result, the global learning process will be affected, since the features learned by the primary loss can be easily drifted by updating the secondary one. Discarding one of the primary or secondary losses will lead to substitution of a significant portion of true labels for random ones, known as feature randomness. Mrabah et al. [32] enhanced the IDEC approach to reach a better trade-off between feature drift and feature randomness using AAE complemented with data augmentation.

Dizaji et al. [33] proposed the deep embedded regularized clustering (DEPICT) model to learn data representation and

perform the clustering task. DEPICT has a complicated network architecture composed of a softmax layer on top of a multilayer CAE. More specifically, DEPICT consists of four components: two encoders, one decoder, and one softmax layer. The encoder and decoder elements of the DEPICT network are referred to as paths.

Thus, there are three paths in the DEPICT architecture. The first path is called the noisy encoder, which is the encoder part of the denoising CAE that accepts noisy input data to infer noisy hidden representations. The second path is called the noisy decoder (or just decoder), and is the decoder element of the denoising CAE for reconstructing the input from the learned noisy representations. The decoder element consists of a strided CNN, which is similar to the traditional one, except that the value of the convolutional kernel stride is greater than 1. The third path is called the clean encoder, a CNN that accepts clean input data to infer clean hidden representations. The clean and the noisy encoder paths share the same network parameters, i.e., weights and biases. The softmax layer (the fourth component of the network) is stacked on top of the noisy encoder top layer and clean encoder top layer to obtain the clustering assignments. The first phase of the algorithm is initialization, where the network parameters, cluster centroids, and target distribution are initialized. Instead of initializing the network parameters randomly, DEPICT assigns the weights from a Gaussian distribution, where the input and output variances are the same for each layer. This initialization

approach is known as Xavier (or normalized) initialization [34]. Next, DEPICT is trained with reconstruction loss only (without clustering loss) to obtain initial embedded representations for the input data. Then, the K-means clustering technique is applied to obtain the initial cluster centroids and the initial target distribution  $P$ , when the initialization phase is complete, the optimization and clustering phase starts. In the softmax layer, DEPICT iteratively minimizes the following three-term joint loss function:

$$L_{\text{DEPICT}} = L_{\text{r\_DEPICT}} + L_{\text{KLD}} + L_{\text{BL}} \quad (39)$$

where  $L_{\text{KLD}}$  and  $L_{\text{BL}}$  are the KL-divergence and balanced assignment losses that were introduced in equations (14) and (32), respectively. The first term is a data-dependent regularization term, which is a reconstruction loss function introduced in DEPICT designed to enhance the representation learning process and avoid the overfitting problem. The reconstruction loss between the noisy decoder and the clean encoder representations is computed as.

$$L_{\text{r\_DEPICT}} = \frac{1}{n} \sum_{i=1}^n \sum_{l=1}^{L-1} \frac{1}{|z_i^l|} \|z_i^l - \hat{z}_i^l\|_2^2 \quad (40)$$

where  $n$  is the size of the input data,  $L$  is the number of noisy decoder and clean encoder layers,  $l$  is the layer number,  $|z_i^l|$  is the  $l^{\text{th}}$  layer output size,  $z_i^l$  is the  $l^{\text{th}}$  layer of clean representations (from the clean encoder), and  $\hat{z}_i^l$  is the  $l^{\text{th}}$  layer of noisy representations (from the noisy decoder). The second term of the DEPICT joint loss function is the KL-divergence clustering loss. A multinomial logistic regression function is employed to perform the soft clustering assignment. Note that DEPICT computes the soft assignment predictions  $Q$  based on noisy representations that are extracted from the noisy encoder, whereas the target distribution  $P$  is computed from the clean representations extracted from the clean encoder path. The third term is a regularization term that encourages balanced cluster assignments and avoids the allocation of clusters to outlier samples. The effectiveness of DEPICT has been proven empirically, especially in terms of the running time complexity.

### B. Deep K-Means Clustering

Huang et al. [36] introduced a deep embedding network, referred to as DEN, to learn clustering-oriented representations using a three-layer SAE. Similar to that of most deep clustering algorithms, the DEN learning procedure is composed of two phases: initialization (pretraining) and optimization. In the pretraining phase, a three-layer DBN [14] is trained based on the contrastive divergence loss only, to initialize the SAE parameters. Then, the learned representation from the DBN is fed into the three-layer SAE to begin the joint training optimization process. In this phase, the DEN minimizes the joint loss function.

$$L_{\text{DEN}} = L_{\text{r}} + \alpha L_{\text{LP}} + \beta L_{\text{GS}} \quad (41)$$

where  $L_{\text{r}}$  is the reconstruction loss in equation (4),  $L_{\text{LP}}$  is the locality-preserving auxiliary clustering loss defined in (34), and  $L_{\text{GS}}$  is the group sparsity auxiliary clustering loss expressed in equation (35) with  $S_{ij} = \exp\left(\frac{\|x_i - x_j\|_2^2}{t}\right)$ . Further,  $\alpha$ ,  $\beta$ , and  $t$  are tuning parameters. By considering these two auxiliary

clustering losses, the DEN imposes two constraints on the learned representations: the first is the locality-preserving constraint to preserve the local structure property of the original data, and the second is the group sparsity constraint. These are imposed to facilitate the clustering process, and ensure that the learned representation incorporates cluster information, and thus, is more suitable for clustering. After the optimization phase, the traditional K-means clustering algorithm is employed to perform clustering.

Yang et al. [37] proposed a dimensionality reduction and K-means clustering framework named the deep clustering network (DCN). A DNN, specifically an SAE, is utilized by the DCN for dimensionality reduction and representation learning. The DCN algorithm is initiated by a pretraining stage based on reconstruction loss to initialize the SAE weights and biases. To initialize the cluster centroids, K-means clustering is applied to the obtained representations from the pretraining. Then, the joint training phase is executed by iteratively optimizing the joint loss function.

$$L_{\text{DCN}} = L_{\text{r}} + \lambda L_{\text{KM}} \quad (42)$$

where  $L_{\text{r}}$  is the reconstruction loss as defined in equation (4),  $L_{\text{KM}}$  is the K-means clustering loss function described in equation (11), and  $\lambda$  is a regularization parameter, which balances the reconstruction error by finding K-means-oriented hidden representations. Instead of applying the traditional SGD for the optimization process, the DCN introduces an alternating SGD optimization algorithm to update its parameters. There are three sets of parameters to be updated in a DCN: cluster centroids, data point cluster assignments, and network parameters. The proposed alternating SGD suggests that each set of parameters should be treated as a subproblem; thus, DCN optimizes the subproblems with respect to one of the cluster centroids, data point assignments, and network parameters while keeping the other two sets fixed. For instance, to update network parameters, both the cluster centroids and data point assignment are fixed, and then the corresponding gradient is calculated by backpropagation.

Fard et al. [38] proposed a deep K-means clustering algorithm named deep K-means (DKM), which is very similar to the DCN [37]. DKM differs from the DCN in the clustering loss only, where weighted K-means is employed instead of K-means. Equation (43) shows the DKM joint loss function:

$$L_{\text{DKM}} = L_{\text{r}} + \lambda L_{\text{WKM}} \quad (43)$$

where  $L_{\text{r}}$  is the reconstruction loss as defined in equation (4),  $L_{\text{WKM}}$  is the weighted K-means clustering loss function described in equation (12), and  $\lambda$  regulates the trade-off between seeking good representation and good clustering results. The similarity weight of the K-means loss function is computed according to the softmax function.

$$S_{ij, \text{DKM}} = \frac{\exp(-\alpha \|z_i - z_{\mu_j}\|_2^2)}{\sum_{j'=1}^k \exp(-\alpha \|z_i - z_{\mu_{j'}}\|_2^2)} \quad (44)$$

where  $z_i$  is the learned representation of data point  $x_i$ ,  $k$  is the number of clusters,  $z_{\mu_j}$  is the representation of the cluster centroid  $\mu_j$ , and  $\alpha$  is a coefficient such that when its value is 0,

all of the data points in the embedding space are very close, and when its value is relatively high, the points are sparse in the space. The network architecture and learning process of DKM is similar to that of DCN, except that instead of alternating between continuous gradient updates and discrete cluster assignment steps, DKM relies on the gradient update only to learn both the representation and clustering parameters.

Chen et al. [39] proposed a deep manifold clustering algorithm called deep manifold clustering (DMC) to address multimanifold clustering (MMC) [40]. DMC's architecture is similar to that of DEN [36], where an SAE [17] is employed for representation learning and a DBN [14] is utilized to initialize the SAE parameters. In DMC, a locality-preserving auxiliary clustering loss is introduced such that the locality of a manifold can be interpreted as similar inputs, and therefore, should have similar representations. Thus, a data point can be recovered using the representation of its nearby point. Based on this observation, the DMC [39] locality-preserving loss function is defined as.

$$L_{LP\_DMC} = \frac{1}{k} \sum_{j \in N_k(i)} \|y_i - x_j\|_2^2 \quad (45)$$

where  $y_i$  is the reconstructed image of data point  $x_i$  and  $N_k(i)$  is the indices set of  $k$  nearest neighbors of  $x_i$ . After the SAE weights and cluster centroids have been initialized, the joint training procedure proceeds by iteratively optimizing the joint loss function:

$$L_{DMC} = (1 - \alpha)L_r + \alpha L_{LP\_DMC} + \beta L_{WKM} \quad (46)$$

where  $L_r$  is the reconstruction loss defined in equation (4),  $L_{LP\_DMC}$  is the locality-preserving loss function defined in equation (45),  $L_{WKM}$  is the weighted K-means clustering loss function presented in equation (12),  $\alpha$  balances the importance between the reconstruction of  $x_i$  itself and its local neighborhood, and  $\beta$  is a parameter to balance the contribution of the first two terms and  $L_{WKM}$ . DMC uses the Gaussian-dependent kernel as the similarity weight of the weighted K-means loss function.

$$S_{ij\_DMC} = \frac{\exp(-\alpha \|z_i - z_{\mu_j}\|_2^2 / 2\sigma)}{\sum_{j'=1}^k \exp(-\alpha \|z_i - z_{\mu_{j'}}\|_2^2 / 2\sigma)} \quad (47)$$

Here,  $\sigma$  is the kernel bandwidth. The keystone point of DMC is to find the manifold center, because the cluster centers are most probably surrounded by nearby points with lower local density, and because they are at a relatively large distance from any points with a higher local density. Therefore, DMC calculates the density of the new representation by computing two metrics: the local density of a point, and its distance to points with higher density. The local density  $\rho_i$  of the representation  $z_i$  is defined as.

$$\rho_i = \sum_{j=1}^n e^{-\frac{\Delta_{ij}}{\bar{\Delta}}} \quad (48)$$

where  $\Delta_{ij}$  is the distance between the representation  $z_i$  and  $z_j$  and  $\bar{\Delta}$  is a cut-off distance. Then, the points in the new embedding space are sorted based on their density in descending order, denoted by  $\{\lambda_i\}_{i=1}^n$  with  $\rho_{\lambda_1} \geq \rho_{\lambda_2} \geq \dots \geq \rho_{\lambda_n}$ . The distance metric is therefore calculated as.

$$\xi_{\lambda_i} = \begin{cases} \min_{\lambda_j} \{\Delta_{\lambda_i \lambda_j}\}, i \geq 2 \\ j < i \\ \max_{\lambda_j} \{\xi_{\lambda_j}\}, i = 1. \end{cases} \quad (49)$$

Next, a third metric is defined as

$$\gamma_i = \rho_i \xi_i \quad (50)$$

Similarly, the points in the new embedding space are sorted based on  $\gamma_i$ , as computed in equation (44) in descending order, and denoted by  $\{\pi_i\}_{i=1}^n$  with  $\gamma_{\pi_1} \geq \gamma_{\pi_2} \geq \dots \geq \gamma_{\pi_n}$ . Assuming that the number of clusters  $k$  is known in advance, the cluster centers are determined by considering the  $k$  largest  $\gamma$ . The experiments reported in [39] showed that DMC outperformed the state-of-the-art multimanifold clustering methods.

### C. Deep Spectral Clustering

Ji et al. [41] introduced deep subspace clustering networks (referred to as DSC-Nets) based on CAE [18] to learn nonlinear mapping. The network architecture of DSC-Nets includes three parts: a CNN encoder, a middle layer called the self-expressive layer, and a CNN decoder. In the self-expressive layer, the neurons are completely connected using linear weights without bias and nonlinear activation. The purpose of this FC layer is to encode the self-expressiveness property, as explained in section 3.3. Each node in this self-expressive layer is a representation  $z_i$ , and the weights correspond to the matrix  $C$  in equation (36) which are further used to construct affinities between all data points. Therefore, essentially, the self-expressive layer enables the network to learn the affinity matrix directly. First, DSC-Nets pre-train the CAE without the self-expressive layer to initialize the encoder and decoder parameters. Then, in the finetuning process, the DSC-Nets deep network is first trained, and the following joint loss function is recursively optimized:

$$L_{DSC-Nets} = L_r + L_{SE} \quad (51)$$

where  $L_r$  is the reconstruction loss defined in equation (4) and  $L_{SE}$  is the self-expressiveness loss as expressed in (36). When the training is completed, the parameters of the self-expressive layer are used to build an affinity matrix for spectral clustering, as explained in section 3.2. The experiments reported in [41] showed that DSC-Nets yielded superior results for small datasets. However, this method cannot be applied on large datasets because of the memory complexity of the algorithm [19].

Similar to DSC-Nets, in [42], Zhou et al. proposed deep adversarial subspace clustering (DASC) model which learns subspace clustering-friendly representations using AAE and self-expressiveness constraint. Given that, DASC optimizes the following objective function:

$$L_{DASC} = L_r + \alpha L_g + \beta L_{SE} \quad (52)$$

where  $L_r$ ,  $L_g$ , and  $L_{SE}$  represent the reconstruction loss defined in (4), the generation loss in (9), and the self-expressiveness loss that defined in (36), respectively, and  $\alpha$  and  $\beta$  are hyperparameters to balance the importance of the generation loss and the clustering loss, respectively. Upon the

completion of the training process, spectral clustering is applied to the resulting affinity matrix.

Yang et al. in [43] presented a deep spectral clustering (DSC) approach based on AAE. In the proposed approach, the generator is a dual AE network (one encoder and two decoders) to enforce the reconstruction constraints for the latent representations and their noisy versions. As a consequence, the resulting latent representation will be more robust to noise. Hence, the reconstruction loss is updated to be in the following format:

$$L_{r\_DSC} = \frac{1}{n} \sum_{i=1}^n \|\tilde{y}_i - y_i\|^2 + \delta L_r \quad (53)$$

where  $L_r$  is the reconstruction loss in (4),  $y_i$  is the reconstructed image of input  $x_i$ ,  $\tilde{y}_i$  is the reconstructed image of the noisy version of the input  $x_i$ , and  $\delta$  balances the strength of the two losses. Then, the mutual information estimation is employed to boost the discriminator with more information from the inputs. To achieve this, the feature map of the middle convolutional layer of the encoder is extracted and combined with the latent representation to obtain a new feature map. Therefore, the generation loss will be as follows:

$$L_{g\_DSC} = -\beta \left[ \frac{1}{n} \sum_{i=1}^n \log D(x_i, z_i) + \log(1 - D(x_i, z_i)) \right] - \frac{\beta}{hw} \left[ \sum_{i,j} \frac{1}{n} \sum_{k=1}^n \log D(C_{ij}, z_k) + \log(1 - D(C_{ij}, z_k)) \right] + \gamma L_{KL} \quad (54)$$

where  $D$  is the discriminator,  $C_{ij}$  represents the feature vector of the middle feature map at coordinates  $(i, j)$ ,  $z_i$  is the latent representation of input  $x_i$ ,  $L_{KL}$  is the KL-divergence loss in equation (14),  $h$  and  $w$  represent the height and width of the feature map, and  $\beta$  and  $\gamma$  are balancing parameters. Furthermore, the latent representations are embedded into the eigenspace to cluster them using a spectral clustering technique.

#### D. More Deep Clustering Algorithms

Shah et al. [44] presented deep continuous clustering (DCC), a framework for joint nonlinear embedding learning and clustering. The DCC framework integrates an RCC algorithm [44] with an SAE [17] as a deep representation learning technique. DCC consists of two stages: initialization and optimization. During the initialization stage, the denoising SAE is trained based on reconstruction loss only to initialize the network parameters, i.e., weights and biases. Then, the SAE is finetuned, using the reconstruction loss only, to complete the initialization. At the end of this stage, the learned representation  $Z$  is obtained from the bottleneck layer to have the initialization  $U = Z$ . Then, the optimization is conducted by minimizing the joint loss function.

$$L_{DCC} = \frac{1}{D} L_r + \frac{1}{d} (L_{data\_DCC} + \lambda L_{pairwise\_DCC}) \quad (55)$$

where  $L_r$  is the AE reconstruction loss in equation (4),  $D$  is the dimensionality of the original input dataset, and  $d$  is the dimensionality of the lower-dimensional representations  $Z$ . DCC modifies the data loss introduced in RCC [44] as.

$$L_{data\_DCC} = \sum_{i=1}^n \rho(\|u_i - z_i\|_2; \mu_1) \quad (56)$$

where  $\rho$  is the scaled Geman–McClure function defined in equation (25). The pairwise loss is also modified by DCC as.

$$L_{pairwise\_DCC} = \sum_{(i,j) \in E} w_{ij} \rho(\|u_i - u_j\|_2; \mu_2) \quad (57)$$

The parameters  $\mu_1$  and  $\mu_2$  control the radii of the convex basins of the estimators. The weights  $w_{ij}$  are computed based on.

$$w_{ij} = \frac{\frac{1}{n} \sum_{k=1}^n N_k}{\sqrt{N_i N_j}} \quad (58)$$

where  $N_i$  is the degree of  $u_i$  in the graph. To balance the different terms, DCC sets  $\lambda$  and  $A$  according to equations (29) and (30), respectively. The network parameters, the representatives  $U$ , and the lower-dimensional representations  $Z$  are updated by an SGD optimization algorithm [45] through backpropagation. Other DCC parameters, such as  $\lambda$ , are iteratively updated during the optimization as in the RCC algorithm [44].

Jiang et al. [46] proposed Variational Deep Embedding (VaDE), a probabilistic generative clustering technique within a VAE framework. In VaDE, Mixture-of-Gaussian is assumed to be the prior of the probabilistic clustering. To model the data generative procedure, VaDE utilizes GMM to pick a cluster from which a latent embedding is generated. Then, VAE decodes the latent embedding into an observable. Then, VAE is trained to maximize the evidence lower bound (ELBO) [19] according to VAE loss ( $L_{VAE}$ ) in equation (7). After maximizing the ELBO, the cluster assignment can be inferred by the learned GMM model. GMVA [47] is another probabilistic clustering algorithm based on VAE with a Gaussian mixture as a prior distribution. The main contribution of this algorithm is in introducing the minimum information constraint [48] to the VAE in order to overcome the problem of cluster degeneracy, caused by the over-regularization of the VAE. The GMVA approach is more complex than VaDE, and has shown worse results in practice [19]. However, both VaDE and GMVA suffer from high computational complexity [19].

Mukherjee et al. [49] addressed the problem of clustering in the latent space of GAN [19] by introducing the ClusterGAN framework. In order to establish non-smooth geometry of the latent space, a mixture of discrete and continuous latent variables is utilized. To accommodate that mixture of variables, a new backpropagation algorithm is introduced to obtain the latent variable given a data input. The experimental results showed that GAN is able to preserve latent space interpolation across different categories.

As shown in Table I, we compared the studied joint deep clustering algorithms based on their clustering technique, loss functions, and main contributions. From the presented review, deep clustering algorithms with autoencoders are the most common technique and this due to two reasons. We can summarize these two points as: (1) the ability to combine the autoencoders with the most clustering algorithm, (2) autoencoders reconstruction loss is capable to learn feasible representations and avoid trivial solutions. It is important to note that, the computational cost of autoencoder based deep clustering algorithms is highly affected by the clustering loss. However, for computational feasibility, such algorithms have limited network depth due to the symmetry architecture of autoencoder. On the other hand, deep clustering algorithms

with VAE, AAE, and GAN minimize the variational lower bound on the marginal likelihood of data which make them theoretically guaranteed. Unfortunately, these clustering techniques suffer from high computational complexity. Comparing VAE deep clustering algorithms with AAE and GAN clustering algorithms, AAE and GAN algorithms are more flexible and diverse than VAE algorithms. Nonetheless, AAE and GAN based clustering algorithms have slow convergence rate.

## V. CONCLUSION

Recently, clustering algorithms have benefited from the new deep learning research field. In fact, new active research studies are focused on integrating deep representation learning with clustering tasks. Beyond joint deep clustering algorithms, more recent algorithms have been proposed, some of which have been classified as separated deep clustering approaches, and others categorized as combined deep clustering techniques, but not joint. DeepCluster, clustering by unmasking, rank-constrained spectral clustering, SDEC, parameter-free clustering, and learning deep graph representation are all examples of not-joint deep clustering algorithms.

In this article, we reviewed the existing joint deep clustering algorithms by describing their network structure and analyzing their objective functions. Based on the survey of algorithms discussed here, theoretical analysis of how and why jointly optimizing reconstruction and clustering losses significantly improves the clustering performance is itself significant. Also, studying whether deep supervised learning techniques, such as data augmentation and regularization, are applicable and useful for deep unsupervised clustering is meaningful. Exploring the feasibility of applying the proposed joint deep clustering algorithms on sequential data is highly encouraged. Moreover, exploring the viability of combining deep clustering techniques with other unsupervised learning tasks such as transfer learning is strongly recommended.
