# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

### **Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

### **Alaa Sheta**

#### **Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

### **Domenico Ciuonzo**

#### **University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

### **Doroła Kaminska**

#### **Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

### **Elena Scutelnicu**

#### **"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

### **In Soo Lee**

#### **Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

### **Krassen Stefanov**

#### **Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

### **Renato De Leone**

#### **Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

### **Xiao-Zhi Gao**

#### **University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: An Effective Design of Model for Information Security Requirement Assessment

*Authors: Shailaja Salagrama*

PAGE 1 – 5

Paper 2: UAV Aided Data Collection for Wildlife Monitoring using Cache-enabled Mobile Ad-hoc Wireless Sensor Nodes

*Authors: Umair B. Chaudhry, Chris I. Phillips*

PAGE 6 – 17

Paper 3: Collaborative Recommendation based on Implication Field

*Authors: Hoang Tan Nguyen, Lan Phuong Phan, Hung Huu Huynh, Hiep Xuan Huynh*

PAGE 18 – 28

Paper 4: Taxonomy of Cybersecurity Awareness Delivery Methods: A Countermeasure for Phishing Threats

*Authors: Asma A. Alhashmi, Abdulbasit Darem, Jemal H. Abawajy*

PAGE 29 – 35

Paper 5: Visual Selective Attention System to Intervene User Attention in Sharing COVID-19 Misinformation

*Authors: Zaid Amin, Nazlena Mohamad Ali, Alan F. Smeaton*

PAGE 36 – 41

Paper 6: Head Position and Pose Model and Method for Head Pose Angle Estimation based on Convolution Neural Network

*Authors: Kohei Arai, Akifumi Yamashita, Hiroshi Okumura*

PAGE 42 – 49

Paper 7: Introduction to NFTs: The Future of Digital Collectibles

*Authors: Muddasar Ali, Sikha Bagui*

PAGE 50 – 56

Paper 8: Hybrid e-Government Framework based on Datawarehousing and MAS for Data Interoperability

*Authors: Barakat Oumkalfoum, El beqqali Omar, Ouksel Aris, Chakir Loqman*

PAGE 57 – 64

Paper 9: Analyzing User Involvement Practice: A Case Study

*Authors: Asaad Alzayed, Abdulwahed Khalfan*

PAGE 65 – 72

Paper 10: Predictive Scaling for Elastic Compute Resources on Public Cloud Utilizing Deep Learning based Long Short-term Memory

*Authors: Bharanidharan. G, S. Jayalakshmi*

PAGE 73 – 81

Paper 11: Highly Efficient Parts of Speech Tagging in Low Resource Languages with Improved Hidden Markov Model and Deep Learning

*Authors: Diganta Baishya, Rupam Baruah*

PAGE 82 – 94

Paper 12: Critical Success Factors Associated to Tourism e-Commerce: Study of Peruvian Tourism Operators

*Authors: Sussy Bayona-Oré, Romy Estrada*

PAGE 95 – 104

Paper 13: A Survey on Computer Vision Architectures for Large Scale Image Classification using Deep Learning

*Authors: D. Dakshayani Himabindu, S. Praveen Kumar*

PAGE 105 – 120

Paper 14: University Course Timetabling Model in Joint Courses Program to Minimize the Number of Unserved Requests

*Authors: Purba Daru Kusuma, Abduh Sayid Albana*

PAGE 121 – 127

Paper 15: Symbolic Representation-based Melody Extraction using Multiclass Classification for Traditional Javanese Compositions

*Authors: Arry Maulana Syarif, Azhari Azhari, Suprpto Suprpto, Khafiizh Hastuti*

PAGE 128 – 137

Paper 16: LightGBM-based Ransomware Detection using API Call Sequences

*Authors: Duc Thang Nguyen, Soojin Lee*

PAGE 138 – 146

Paper 17: Integrated Document-based Electronic Health Records Persistence Framework

*Authors: Aya Gamal, Sherif Barakat, Amira Rezk*

PAGE 147 – 155

Paper 18: Cyber Threat Intelligence in Risk Management

*Authors: Amira M. Aljuhami, Doaa M. Bamasoud*

PAGE 156 – 164

Paper 19: Expert's Usability Evaluation of the Pelvic Floor Muscle Training mHealth App for Pregnant Women

*Authors: Aida Jaffar, Sherina Mohd Sidik, Novia Admodisastro, Evi Indriasari Mansor, Lau Chia Fong*

PAGE 165 – 173

Paper 20: Aligning Software System Level with Business Process Level through Model-Driven Architecture

*Authors: Maryam Habba, Samia Benabdellah Chaouni, Mounia Fredj*

PAGE 174 – 183

Paper 21: A Review of Modern DNA-based Steganography Approaches

*Authors: Omar Haitham Alhabeeb, Fariza Fauzi, Rossilawati Sulaiman*

PAGE 184 – 196

Paper 22: Adaptive Logarithmic-Power Algorithm for Preserving the Brightness in Contrast Distorted Images

*Authors: Navleen S Rekhi, Jagroop S Sidhu*

PAGE 197 – 205

Paper 23: A Meta-analytic Review of Intelligent Intrusion Detection Techniques in Cloud Computing Environment

*Authors: Meghana G Raj, Santosh Kumar Pani*

PAGE 206 – 217

**Paper 24: Machine Learning Mini Batch K-means and Business Intelligence Utilization for Credit Card Customer Segmentation**

*Authors: Firman Pradana Rachman, Handri Santoso, Arko Djajadi*

**PAGE 218 – 227**

**Paper 25: Intrusion Detection System for Energy Efficient Cluster based Vehicular Adhoc Networks**

*Authors: M V B Murali Krishna M, C. Anbu Ananth, N. Krishna Raj*

**PAGE 228 – 235**

**Paper 26: Chest Diseases Prediction from X-ray Images using CNN Models: A Study**

*Authors: Latheesh Mangeri, Gnana Prakasi O S, Neeraj Puppala, Kanmani P*

**PAGE 236 – 243**

**Paper 27: Detection of Acute Myeloid Leukemia based on White Blood Cell Morphological Imaging using Naïve Bayesian Algorithm**

*Authors: Esti Suryani, Wiharto, Adi Prasetya Putra, Wisnu Widiarto*

**PAGE 244 – 251**

**Paper 28: Automatic Essay Scoring: A Review on the Feature Analysis Techniques**

*Authors: Ridha Hussein Chassab, Lailatul Qadri Zakaria, Sabrina Tiun*

**PAGE 252 – 264**

**Paper 29: Forensic Analysis on False Data Injection Attack on IoT Environment**

*Authors: Saiful Amin Sharul Nizam, Zul-Azri Ibrahim, Fiza Abdul Rahim, Hafizuddin Shahril Fadzil, Haris Iskandar Mohd Abdullah, Muhammad Zulhusni Mustaffa*

**PAGE 265 – 271**

**Paper 30: Design of Decentralized Application for Telemedicine Image Record System with Smart Contract on Ethereum**

*Authors: Darrell Yonathan, Diyanatul Husna, Fransiskus Astha Ekadiyanto, I Ketut Eddy Purnama, Afif Nurul Hidayati, Mauridhi Hery Purnomo, Supeno Mardi Susiki Nugroho, Reza Fuad Rachmadi, Ingrid Nurtanio, Anak Agung Putri Ratna*

**PAGE 272 – 281**

**Paper 31: Multi-lane LBP-Gabor Capsule Network with K-means Routing for Medical Image Analysis**

*Authors: Patrick Kwabena Mensah, Anokye Acheampong Amponsah, Kwame Baffour Agyemang, Gabriel Kofi Armah, Mighty Abra Ayidzoe, Faiza Umar Bawah, Adebayor Felix Adekoya, Benjamin Asubam Weyori, Mark Amo-Boateng*

**PAGE 282 – 294**

**Paper 32: Healthcare Misinformation Detection and Fact-Checking: A Novel Approach**

*Authors: Yashoda Barve, Jafinderkumar R. Saini*

**PAGE 295 – 303**

**Paper 33: Evaluating Deep and Statistical Machine Learning Models in the Classification of Breast Cancer from Digital Mammograms**

*Authors: Amel A. Alhussan, Nagwan M. Abdel Samee, Vidan F. Ghoneim, Yasser M. Kadah*

**PAGE 304 – 313**

**Paper 34: Arabic Document Classification by Deep Learning**

*Authors: Taghreed Alghamdi, Samia Snoussi, Lobna Hsairi*

**PAGE 314 – 321**

**Paper 35: Comparative Analysis of Data Mining Algorithms for Cancer Gene Expression Data**

*Authors: Preeti Thareja, Rajender Singh Chhillar*

**PAGE 322 – 328**

**Paper 36: Proactive Virtual Machine Scheduling to Optimize the Energy Consumption of Computational Cloud**

*Authors: Shailesh Saxena, Mohammad Zubair Khan, Ravendra Singh, Abdulfattah Noorwali*

**PAGE 329 – 338**

**Paper 37: Expert Review on Mobile Augmented Reality Applications for Language Learning**

*Authors: Nur Asyiah Suwadi, Nazatul Aini Abd Majid, Meng Chun Lam, Nor Hashimah Jalaluddin, Junaini Kasdan, Aznur Aisyah Abdullah, Afifuddin Husairi Hussain, Azlan Ahmad, Daing Zairi Ma'arof*

**PAGE 339 – 347**

**Paper 38: Arabic Semantic Similarity Approach for Farmers' Complaints**

*Authors: Rehab Ahmed Farouk, Mohammed H. Khafagy, Mostafa Ali, Kamran Munir, Rasha M.Badry*

**PAGE 348 – 358**

**Paper 39: An NB-ANN based Fusion Approach for Disease Genes Prediction and LFKH-ANFIS Classifier for Eye Diseases Identification**

*Authors: Samar Jyoti Saikia, S. R. Nirmala*

**PAGE 359 – 367**

**Paper 40: Load Balanced and Energy Aware Cloud Resource Scheduling Design for Executing Data-intensive Application in SDVC**

*Authors: Shalini. S, Annapurna P Patil*

**PAGE 368 – 374**

**Paper 41: Design and Implementation of Collaborative Management System for Effective Learning**

*Authors: Tochukwu A. Ikwunne, Wilfred Adigwe, Christopher C. Nnamene, Noah Oghenefego Ogwara, Henry A. Okemiri, Chinedu E. Emenike*

**PAGE 375 – 382**

**Paper 42: Selection of Learning Apps to Promote Critical Thinking in Programming Students using Fuzzy TOPSIS**

*Authors: Kesarie Singh, Nalindren Naicker, Mogiveny Rajkoomar*

**PAGE 383 – 392**

**Paper 43: Complex Plane based Realistic Sound Generation for Free Movement in Virtual Reality**

*Authors: Kwangki Kim*

**PAGE 393 – 400**

**Paper 44: Reverse Vending Machine Item Verification Module using Classification and Detection Model of CNN**

*Authors: Razali Tomari, Nur Syahirah Razali, Nurul Farhana Santosa, Aeslina Abdul Kadir, Mohd Fahrul Hassan*

**PAGE 401 – 407**

**Paper 45: How to Analyze Air Quality During the COVID-19 Pandemic? An Answer using Grey Systems**

*Authors: Alexi Delgado, Denilson Pongo, Katherine Felipa, Kiara Saavedra, Lorena Torres, Lourdes Serpa, Ch. Carbajal*

**PAGE 408 – 414**

**Paper 46: Indonesia Sign Language Recognition using Convolutional Neural Network**

*Authors: Suci Dwijayanti, Hermawati, Sahirah Inas Taqiyyah, Hera Hikmarika, Bhakti Yudho Suprpto*

**PAGE 415 – 422**

**Paper 47: Increasing Randomization of Ciphertext in DNA Cryptography**

*Authors: Maria Imdad, Sofia Najwa Ramli, Hairulnizam Mahdin*

**PAGE 423 – 429**

**Paper 48: Multistage Sentiment Classification Model using Malaysia Political Ontology**

*Authors: Nur Farhana Ismail, Nur Atiqah Sia Abdullah, Zainura Idrus*

**PAGE 430 – 436**

**Paper 49: Factors Impacting Users' Compliance with Information Security Policies: An Empirical Study**

*Authors: Latifa Alzahrani*

**PAGE 437 – 447**

**Paper 50: The Application of Image Processing in Liver Cancer Detection**

*Authors: Meenu Sharma, Rafat Parveen*

**PAGE 448 – 457**

**Paper 51: Automating Time Series Forecasting on Crime Data using RNN-LSTM**

*Authors: J Vimala Devi, K S Kavitha*

**PAGE 458 – 463**

**Paper 52: Level Transducer Circuit Implemented by Ultrasonic Sensor and Controlled with Arduino Nano for its Application in a Water Tank of a Fire System**

*Authors: Omar Chamorro-Atalaya, Dora Arce-Santillan, Guillermo Morales-Romero, Adrián Quispe-Andía, Nicéforo Trinidad-Loli, Elizabeth Auqui-Ramos, César León-Velarde, Edith Gutiérrez-Zubieta*

**PAGE 464 – 471**

**Paper 53: Improvement of Deep Learning-based Human Detection using Dynamic Thresholding for Intelligent Surveillance System**

*Authors: Wahyono, Moh. Edi Wibowo, Ahmad Ashari, Muhammad Pajar Kharisma Putra*

**PAGE 472 – 477**

**Paper 54: Forecast Breast Cancer Cells from Microscopic Biopsy Images using Big Transfer (BiT): A Deep Learning Approach**

*Authors: Md. Ashiqul Islam, Dhonita Tripura, Mithun Dutta, Md. Nymur Rahman Shuvo, Wasik Ahmmed Fahim, Puza Rani Sarkar, Tania Khatun*

**PAGE 478 – 486**

**Paper 55: Mobile Application with Augmented Reality to Improve Learning in Science and Technology**

*Authors: Miriam Gamboa-Ramos, Ricardo Gómez-Noa, Orlando Iparraguirre-Villanueva, Michael Cabanillas-Carbonell, José Luis Herrera Salazar*

**PAGE 487 – 492**

**Paper 56: Learning Pick to Place Objects using Self-supervised Learning with Minimal Training Resources**

*Authors: Marwan Qaid Mohammed, Lee Chung Kwek, Shing Chyi Chua*

**PAGE 493 – 499**

**Paper 57: Time Line Correlative Spectral Processing for Stratification of Blood Pressure using Adaptive Signal Conditioning**

*Authors: Santosh Shinde, Pothuraju RajaRajeswari*

# An Effective Design of Model for Information Security Requirement Assessment

Shailaja Salagrama

Scholar, Doctor of Philosophy, Computer Information System, University of the Cumberland's, Williamsburg, Kentucky, USA

**Abstract**—Information security is a major domain of analysis for enhancing the security of sensitive detained business organizations. These days, attackers are advancing themselves by applying highly advanced technological solutions such as artificially intelligent malicious codes, advanced phishing methods and many others to acquire sensitive and critical data from businesses. This paper presents a novel model framework to analyze the requirements of information security for a more robust information system and its assets in organizations. The framework of this model is designed in such a fashion that both new and legacy organizations can adopt it to define the requirement of security that will ensure confidentiality, integrity and availability of information systems and their components - including sensitive domain business and private data that is critical to the organization. There are two different model frameworks which are proposed here. The first one provides specifications of the security requirements and the second provides for the audit of the access logs to capture any unethical practices and violations by internal users. The proposed model for security requirements provides the roadmap to analyze and build proper security requirements to secure business sensitive data. Stepwise processes which are needed to analyze and define security requirements are the key factors of this security model, as they help in clear definitions of security frameworks and infrastructure for an organization. The Audit Model provides the framework for defining information auditing requirements, thus enabling the capture of unethical and unauthorized access to the information system components of the organization.

**Keywords**—Information security; network security; web security; confidentiality; integrity; availability; communication technology; information system; internet security; security framework introduction

## I. INTRODUCTION

Recent developments and advancements in information technology have shifted various systems onto the online platform. This new paradigm of processes and activities on the information and communication technology platform enables stakeholders to execute the required applications over the Internet so that the required services can be secured digitally without necessitating any physical movement to the service provider. Therefore, information security becomes one of the potent concerns of service providers and users. Protection of vital information such as business-related sensitive data, users' personal data, users' transaction data etc. is vital. In recent times, cybercriminals have become highly sophisticated with new-generation hacking methods and tools, making security and protection of vital information a significant challenge to business entities and users. Information security provides safeguards to systems which are typically used to process,

store, and communicate data. There are various sources of information, and these include the operating environment, management, databases, network infrastructure and the Internet. Securing all these artifacts associated with the information technology and systems is highly challenging - both directly and indirectly as they are heterogeneous in nature and in their functions. While some studies show that cryptography can provide the security to information and its related agents which are used to process, store, and transmit data, it may not be so. This is because the existing cryptographic algorithms may fail to secure the vital information once the decryption key is discovered [1]. Further, by using message analysis, the attackers can analyze the key and therefore decipher the messages that are encrypted. The numerous attacks on various cryptographic systems and their results have demonstrated that these algorithms have been breached by the attackers.

Information security has both technical and non-technical perspectives to it. Purely technical security measures are inadequate for securing information. Therefore, non-technical measures, such as social security measures should also be in place to enhance the overall security effectiveness, so that the information and information system assets can be completely secured. It is simple to design a social tool that can effectively launch a social engineering attack and secure vital information such as access identities and passwords from victims. This indicates that a purely technical security framework is not adequate for securing vital information [2][3].

Today, what we need is an adaptive security framework for securing information systems and assets. Adaptive security is considered to fall under active security measures that could secure the loopholes and vulnerabilities of the information systems and assets. The level of information security required is heavily dependent on the functional profile of the organization and the equipment and hardware used in the processing of sensitive information. Risk analysis and Vulnerability analysis are the primary processes through which security requirements are analyzed. This helps to identify, manage, and create countermeasures for securing critical information, information system assets and the components vulnerable to security threats. Adequate protection of data is very critical if the information system must generate trust among the stakeholders. A security breach may cause huge financial, trust and image losses [4]. This research article proposes the use of an Analytical Framework for Security Effectiveness that can be applied to critical business data associated with information systems.

## II. EFFECTIVE SECURITY FRAMEWORK

The analysis of various risks and vulnerabilities is performed on the information system to model the gaps in the security and privacy of sensitive and critical data. Any effective security framework should have the three basic components proposed in the Fig. 1.

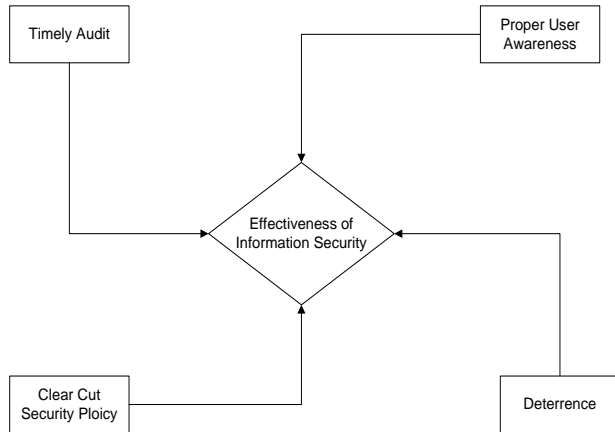

Fig. 1. Effectiveness of Information Security for any Firm, making the Information Security Effective.

To secure the vital information from misuse must be the main consideration. As shown in Fig. 1, four different aspects are mandatory for effective information security, where each one is related to the other to provide security to information [5][6].

To an individual information system firm or organization, the security policy must be very clear in concept and deployment [7]. A clear-cut security policy excludes not only the third party in practice but also direct deployment with respect to the information system assets. Deterrence always prompts the regulatory and legal aspects for the internal users not to go beyond the defined scope or violate the system to disclose sensitive information. This must be in place within the users of firm to assure robust security to the information system assets and critical information. User awareness to different categories of threats associated with social engineering attacks is mandatory and a regular process must be in place to make users aware of the latest trends and procedures of such types of attacks. Audit ensures establishing the violation parameters and depth along with the identity, so that a regular audit must be executed by using the right tools and technology to determine the violators and if necessary, to take legal actions. These four base frameworks provide effective information security to an information system.

## III. INTERNET AND SECURITY

Almost all online web application requires Internet services to be made available to the users. Internet is open to all as it is a public network in nature. Due to this fact the risks to confidentiality, integrity and availability of information are very high, with hackers constantly trying to acquire the sensitive information to gain potential benefits by disclosing and abusing the same.

## A. Security Analysis Framework

Security analysis is one of the most important processes to scope out the security requirements. Four parameters are considered to analyze the security for Internet based systems. The analysis parameters are detailed under Table I.

TABLE I. SECURITY ANALYSIS FRAMEWORK

Sl. No.	Analysis Factors & Security Breaches		
	Security Domain	Dependency Factor	Security Breaches
1	Physical Security	Medium	Theft, Loss of Data, Natural and Man-made Disasters
2	Data Security	High	Eavesdropping, Hacking, Impersonating, Malicious Activities
3	Network Security	High	Denial of Service Attack, Replay Attack, MAC Spoofing, Router Poisoning
4	Web Applications	High	Cross Site Scripting, Hijacking, Database Hacking, SQL Injection, Session High Jacking

These four security domains are mutually associated with the Internet world and analysis of security is performed with respect to the dependency factor the corresponding security breaches. The profiles of the information systems firms and organizations which deal with the business processes on Internet-based applications are detailed in Table II.

TABLE II. SECURITY DOMAIN

Sr. No	Web Applications and Security Risk Factor Level		
	Organization Type	Dependency on Web Application	Security and Risk Factor
1	Non-IT Domain	Nil	Nil
2	Mixed IT Domain	Moderate	Medium
3	Complete IT Domain	High	High
4	Third Party IT Support Domain	High	High
5	IT Cloud Support Domain	High	High

Firms are selected on the basis of the five different domains mentioned in Table I. The analysis parameters such as 'not required', 'moderate' and 'high' are defined with the security and risk factors. An equation is created to assess the risks and vulnerabilities to different domains of firms as defined below.

$R_i$ = Risk Factor Variable where $i = 1, 2, 3, 4$ $V_i$ = Vulnerability Variable where $I = 1, 2, 3, 4, \dots, n$ . $S_i$ = Severity Variable where $I = 1, 2, 3$ . $R_i \leftrightarrow V_i$ where value of $R = \text{Value } V$
---

$$\text{If } \sum_{i=1}^4 R \times \sum_{i=1}^n S \times \sum_{i=1}^3 V \geq 100 \quad (1)$$

- Analysis : All Four Domains of Security
- Include All Security Risks and Breaches
- Develop the Security Model for Each Risk and Breach
- Define Security Policy by Developed Security Model

$$\text{if } \sum_{i=1}^4 R \times \sum_{i=1}^n S \times \sum_{i=1}^3 V = 50 \text{ and } < 100 \quad (2)$$

- Analysis : Analyze only three domains of Security
- Include All Security Risks and Breaches
- Develop the Security Model for Each Risk and Breach
- Define Security Policy by Developed Security Model

If  $\sum_{i=1}^4 R \times \sum_{i=1}^n S \times \sum_{i=1}^3 = 25 \text{ and } < 50$  (3)

- Analysis : Analyze only two domains of Security
- Include All Security Risks and Breaches
- Develop the Security Model for Each Risk and Breach
- Define Security Policy by Developed Security Model

If  $\sum_{i=1}^4 R \times \sum_{i=1}^n S \times \sum_{i=1}^3 = 1 \text{ and } < 25$  (4)

- Analysis : Analyze only one domains of Security
- Include All Security Risks and Breaches
- Develop the Security Model for Each Risk and Breach
- Define Security Policy by Developed Security Model

**B. Analysis Functional Flow**

Analysis is the first critical process to advance the security to the information system and its Internet based applications to protect it from adversaries and security breaches. Functional Flow of Analysis is presented in Fig. 2.

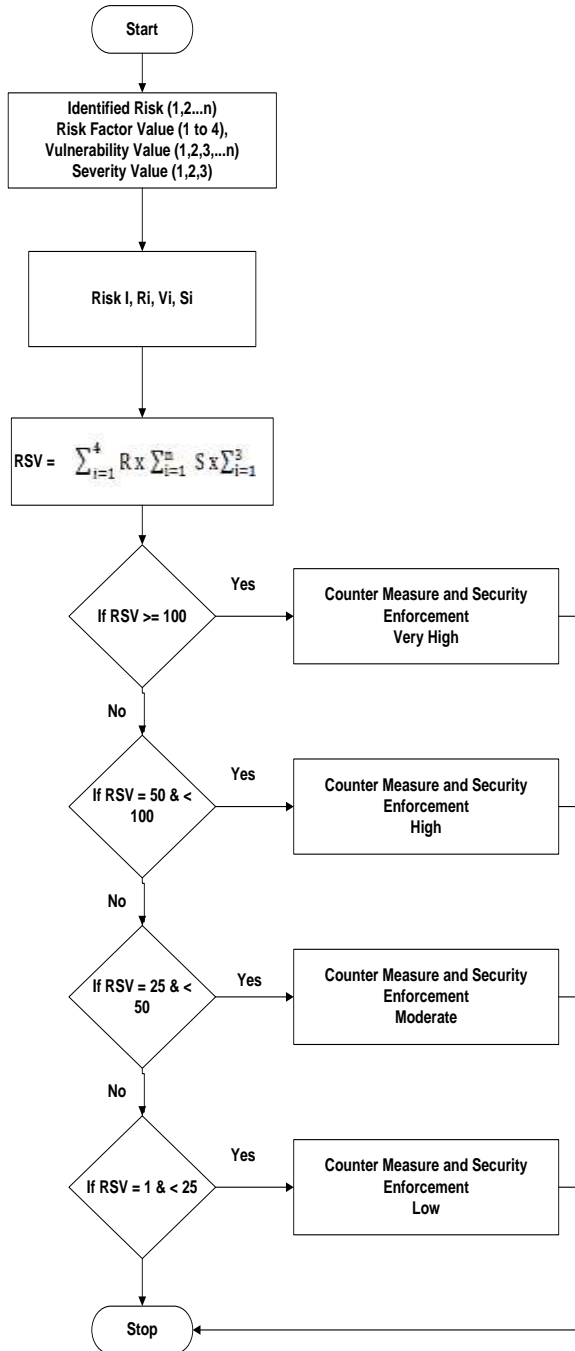

Fig. 2. Functional Flow Definition and Security Counter Measure.

#### IV. COUNTER MEASURE AND SECURITY ENFORCEMENT

Counter Measures are steps taken to secure the information system and data by preventing them from unauthorized access and disclosure, maintaining the integrity and providing the availability [8][9]. In accordance with Fig. 2 the requirement of countermeasures to secure the information system and its assets - specifically the Internet based applications and their data from security breaches - is identified by the following Table III.

In Table III, the defined equation-based countermeasure requirement specification is assessed as per the corresponding security domain. In Table IV, the security domains and counter measure tools and techniques are presented to enforce the security control.

According to Table IV, for security domain countermeasure tools and techniques that secure the information system and its assets, security from the network side can also be considered [10]. Advanced tools and technologies can also be employed to enhance the security of sensitive and vital data.

TABLE III. COUNTER MEASURE DETAILS FOR SECURITY BREACHES

Sl.No.	Security Standard and Counter Measure		
	Security Standard	Equation Map	Security Domain Counter Measure
1	Very High	1	Physical Security
			Data Security
			Network Security
			Web Application Security
2	High	2	Data Security
			Network Security
			Web Application Security
3	Moderate	3	Network Security
			Web Application Security
4	Low	4	Web Application Security

TABLE IV. SECURITY DOMAIN COUNTER MEASURE TOOLS AND TECHNIQUES

Security Domains	Tools/Technology and Techniques	
	Tools/Technologies	Techniques
Physical Security	Biometric Access, CCTV, Device Lock	Continuous Surveillance, Proper Locking Door and System Cabinets
Data Security	Storage Encryption, Storage Lock, Data Encryption	Sensitive Data backup, Backup Data Encryption, Strong Key for Encryption
Network Security	VPN, SSL, SSH, Firewall, DMZ	Proper Device Hardening, Proper Firewall Configuration
Web Application Security	Parameterized API, Input Validation, Secured Authentication, Prevent Directory Browsing, Hash and Salt Password, Role based Authentication and authorization, SSL, Proper Session Management	Validate the input of users to allow access, apply strong and robust authentication and authorization on role-based identity, use secured socket layer for all sensitive web pages, and do time out for inactive session.

#### V. SECURITY AUDIT FRAMEWORK

A parameterized security audit is important to assess all events that are being recorded with database logs and user account logs [11] [12] [13]. The parameters are defined with respect to priority. The audit parameters are derived by the given Pseudocode.

Input Security Parameter  $i = 1$  to  $n$

Priority =  $p$

Scope =  $s$

Interval =  $g$

Audit Process =  $a$

If  $p = \text{high}$  then  $\text{scope} = i \times 5$ ,  $g = 7$  and  $a = \text{Manual}$

If  $p = \text{medium}$  then  $\text{scope} = i \times 3$ ,  $g = 30$ ,  $a = \text{automated}$

If  $p = \text{low}$  then  $\text{scope} = i \times 1$ ,  $g = 90$ , and  $a = \text{Automated}$

The priority parameters with formulated Pseudocode are derived and the tentative benchmark to audit the logs related to the information system and its assets. They are presented in Table V.

TABLE V. DEFINED PARAMETRIZED SECURITY AUDIT

Role Name	Audit Parameters			
	Priority	Scope	Interval	Automated/Manual
Administrator	High	Identify all violations within the defined role	Weekly	Manual
Internal User	High	Identify all violations	Monthly	Manual
External User	Medium	Identify all accessed areas	Monthly	Automated
Others	Low	Identify as per role	Tri-Monthly	Automated

#### VI. CONCLUSION

Proposing a framework of information security is an extremely complex process. In this research, we have attempted to propose a model framework that would help analyze the security framework for a given information system and its assets; thus, enabling recommendations related to information security tools and technologies that would help in securing critical and vital data. The model framework includes two different models that provide the specifications of security such as information security requirements, tools, and technologies to apply security and security audit to capture any deviation from ethical practices by the users through access logs. The proposed models are effective in specifying the requirements and selecting the security technologies, tools and techniques that can be deployed and also for enhancing the features of security to critical system and sensitive data. The mathematical procedures ascertain the verification and assurance of the correct parameters being adopted, while analyzing the requirements of security with different security domains to secure the system and its critical assets.

#### VII. FUTURE SCOPE

The proposed Effective Design Model for Security Requirement Analysis and auditing information systems of

organizations provides an effective framework for specifying and defining the information security framework. The scope of this research can be furthered with the proposed research work to enhance the given model by adding the hazards analysis and recommendations by integrating the disaster recovery option and its various techniques. The assurance of business continuity with respect to disaster recovery requirements including all natural and other disasters related with information system can be studied along with the framework to ease the requirements-scoping and to enhance the overall security to business organizations.

# UAV Aided Data Collection for Wildlife Monitoring using Cache-enabled Mobile Ad-hoc Wireless Sensor Nodes

Umair B. Chaudhry, Chris I. Phillips

School of Electronic Engineering and Computer Science  
Queen Mary University of London (QMUL), London, United Kingdom

**Abstract**—Unmanned aerial vehicle (UAV) assisted data collection is not a new concept and has been used in various mobile ad hoc networks. In this paper, we propose a caching assisted scheme alternative to routing in MANETs for the purpose of wildlife monitoring. Rather than deploying a routing protocol, data is collected and transported to and from a base station using a UAV. Although some literature exists on such an approach, we propose the use of intermediate caching between the mobile nodes and compare it to a baseline scenario where no caching is used. The paper puts forward our communication design where we have simulated the movement of multiple mobile sensor nodes in a field that move according to the Levy walk model imitating wildlife animal foraging and a UAV that makes regular trips across the field to collect data from them. The unmanned aerial vehicle can collect data not only from the current node it is communicating with but also data of other nodes that this node came into contact with. Simulations show that exchanging cached data is highly advantages as the drone can indirectly communicate with many more mobile nodes.

**Keywords**—UAV; caching; sensors; MANETs; WSN; waypoint

## I. INTRODUCTION

The use of wireless sensor networks (WSNs) and mobile ad-hoc networks (MANETs) in various areas such as environmental monitoring, military, vehicular networks and animal tracking has been widely adopted [1]–[6]. Applications of such networks vary based on the targeted area. Humidity and seismic sensors, collision avoidance and parking sensors, pulse and temperature sensors are all examples of this. In WSNs, nodes are deployed with the intention of sensing and relaying information to a particular destination for evaluation purposes. In MANETs, nodes are mobile forming temporary networks throughout their runtime. Nodes in these networks are typically small and possess limited resources. They have restricted processing power and run on small batteries hence energy conservation is a serious concern for them. Data is routed from the source to the destination using routing protocols. The convergence and retransmission mechanisms of these protocols impose an additional overhead causing an additional energy drain. Many efforts have been put into making these protocols as efficient as possible [7]–[9]; however, there is always a trade-off. Conversely, we propose the use of an unmanned aerial vehicle (UAV) to periodically to collect data from caching assisted nodes, hence avoiding routing altogether.

In this paper, we focus on wildlife tracking and monitoring. Traditionally, this is achieved by strapping heavy tracking equipment to animals [10], [11]. Even with current technological trends, wildlife monitoring remains a challenging setting. Typical VHF transmitters are of very restricted range [12] and have a limited battery life and the ones that are longer in range are satellite oriented and hence require even more power, consequently providing a lower lifetime. Table I shows some of the existing devices available. Approaches such as [13], [14], [15], [16], [17] are either too expensive, require dedicated manpower, or the resource constraints of the devices can cause them to fail prematurely. Our aim is to make tracking and monitoring easier and less costly in terms of finance and operation.

Several tracking systems have already been proposed and some are even operational. ATLAS, in [16], employs 9 base stations and extensive computing to determine the location of flying animals. ARTS [14] uses VHF tags and hefty hardware and can only work on animals with small home ranges. [13], in addition to being composed of energy draining 3G modules, is highly dependent on manpower. [18] uses a three tier architecture and the authors claim energy conservation to be one of the biggest challenges of the model in addition to constraints such as the lack of physical intervention with the nodes after deployment and intermittent network connectivity. [15] uses dual chip collars and requires pre-processing at the nodes before transmission. Conversely, [19] requires image processing on static sensor nodes although the authors acknowledge that the accuracy of the system drops with time.

TABLE I. TRADITION DEVICES AND THEIR LIMITATIONS

Devices	<u>NANO</u>	<u>MICRO</u>	<u>SMALL</u>	<u>MEDIUM</u>
<b>Weight Range</b>	5g-20g	6g-50g	20g-100g	130g-250g
<b>Example Suitable Animals</b>	Birds, bats, and other tiny mammals	Lizards, tortoises, turtles, frogs, very small mammals	Animals that weight at least 500 grams	Foxes, Tasmanian Devils
<b>Data Recovery Method</b>	UHF Wireless	UHF Wireless	UHF Wireless	<u>Satellite</u>
<b>Drone Data Downloading</b>	Standard	Standard	Standard	N/A
<b>Base Station Battery Life</b>	2 days	5 days	2 days	N/A

This paper highlights a routing-less approach for data collection from mobile sensor nodes for wildlife monitoring using an unmanned aerial vehicle. In our application scenario, we assume the home range to be a large field or area where the animals roam. Our sensor nodes, according to our use-case scenario, will be wildlife and several of these will be dispersed across the home range. The nodes are considered to be mobile with some degree of purpose in their movement but at the same time having some randomness in their behaviour. An unmanned aerial vehicle will make periodic trips across the field. The nodes are equipped with sensing equipment, the type of which is not the focus of our research. The nodes upon encountering the UAV transfer their data to it. In this paper, we test this approach in two scenarios. One is without communication between the nodes and the other with caching enabled among the nodes allowing them to store data from the nodes they come into contact with. Our simulator uses the Levy walk movement model for the nodes.

## II. RELATED WORK

Retrieval of data from static and mobile sensor nodes deployed in a large field through an aerial vehicle is a fairly new concept. Lately, several researchers [24]–[36], have explored the use of a UAV to acquire data from sensor and ad-hoc nodes mainly due to the fact that a lot of energy draining forwarding and processing tasks are taken away from the resource sensitive nodes.

The authors in [20] describe their method of how a UAV can be used for wildlife monitoring and tracking. In their approach, the field is divided into virtual grids and each grid has a cluster of static sensors deployed. Each cluster has a cluster head which acts as a point of contact for the UAV to collect data. The network model is not a generic one and is highly dependent on data sets obtained from tracking equipment for specific animals. In their case, they used the movement data of zebras from ZEBRANET and the UAV visits the cluster heads of the most active grids for data collection. Another approach [21] has been to mount a cellular network base station on a UAV in an attempt to try to pick up cell phone data from users.

Another approach has been to mount a cellular network base station on a UAV in an attempt to try to pick up cell phone data from users [22]. While in communication with the nodes, the UAV allocates the whole bandwidth to the node with the least data in its buffer and moves towards it during the transfer. The drone moves with a moving node along the same trajectory and the base station may be in communication with more than one node at a time with different parameters. This requires it to adopt a consistent back and forth movement based on the attributes of the node(s) it is in communication with. Ignoring the back and forth movement, the synchronisation mechanism between the drone and a node may be considered suitable for cellular networks as the communication between the base station and the nodes may be extensive. However, the same cannot be said for mobile sensor nodes, especially when considering their limited resources.

Ariel assisted data collection using a UAV from limited capacity sensor nodes has also been considered in [25] using a Markov chain to model the movement of the UAV in addition

to modelling the irregularities in the movement due to several implicit and explicit factors. The authors in [26] also favour the same concept of acquiring data from sensor nodes deployed in a field using a UAV. They add to the approach by proposing a model that allows the sensor nodes to cooperate with each other to achieve simultaneous transfer of data to the UAV to reduce latency. In addition, their work highlights how they can reduce packet losses occurring in the backward direction while the UAV is receiving data and moving forward using an efficient forwarding scheme. However, one can argue that cooperation between the nodes is of limited use as multiple nodes can transmit to the UAV simultaneously using different channels.

Considering the low data transfer rates due to the brief contact duration of a UAV with a sensor node in UAV aided data collection, the authors in [27] propose a modified Media Access Control (MAC) protocol which uses beacon broadcast at the UAV together with Carrier Sense Multiple Access/Collision Avoidance (CSMA/CA) at the ground nodes. The nodes have to contend with each other to speak to the UAV in addition to remaining in the listening mode to receive the beacon which is a big drawback considering the limited battery life of the nodes.

Other researchers have focused on the most optimal traversal path of the UAV in reference to an age element associated with the data picked up from the sensor nodes [28]. They define the age of information as the time data is sensed by the node to the time it is delivered to the sink by the UAV hence the flight path and duration of the UAV plays an important role. Theoretically, they show that the optimal route for the UAV corresponds to a Hamiltonian path and hence they propose a trajectory planning scheme accordingly. Nevertheless, their approach promotes the use of static nodes and dynamic programming which is computational complex.

The feasibility of using a UAV for data collection from ground sensors has been tested in [29] against several parameters including weather, flight height, latency, throughput, jitters and communication channels an authors have recommended a configuration based on their observations. However, it can be argued that the values are highly subjective.

The authors in [30] propose an automatic tracking system that offers autonomous wildlife monitoring. In their approach, they suggest to equip the wildlife with a system that is a combination of a Global Positioning System (GPS) module and a wireless Subscriber Identity Module (SIM). The GPS coordinates are sent to a central server which is also equipped with a SIM which forwards the information to a SIM-equipped control system from where the received information is fed to a drone in addition to the drone control commands. The drone, using this information and the control commands, navigates to the coordinate location. The information is fed to the drone only at the take-off point. Thus, once the drone reaches the target location, the target might not be there resulting in waste of time, energy and the trip. In addition, the devices used to accomplish this have a limited lifespan which is greatly affected by the presence of two highly energy draining modules on the animals.

An approach that involves a combination of Q-learning and Neural Networks is considered in [31] to offer an energy-efficient method for portable base station positioning using UAV. The authors use the concept of landing spots from [32] to move the UAV. Once a suitable position is achieved by the UAV in terms of connectivity, the UAV uses the landing spots to save energy by landing and providing coverage rather than continuing to hover.

In addition to the concept of using a UAV for data collection from wireless sensor network nodes, researchers have proposed BEE-DRONES [23] to achieve energy efficiency at the UAV level and at the network level. The UAV, as with pollinating bees, visits specific targeted ground sensors for data collection. Their work in addition to dealing with minimal path planning of the UAV targets the synchronization issues between the ground sensors and the drone and proposes a wakeup mechanism for the nodes in accordance to the expected visit time of the drone. An efficient path planning approach is also considered in [24], focusing on the limited flight time and energy constraint of the UAV for data gathering in WSNs. They also show how a cluster-head can be selected from a cluster of sensor nodes based on node energy and value of information. This cluster head is the contact point of the UAV for data collection. However, choosing a cluster-head is still an additional burden for the nodes, and data communication between the nodes and the cluster-head employs a traditional routing mechanism incurring protocol overhead.

The researchers in [33] promote the concept of using a UAV for data collection and offer an approach to make it feasible in terms of energy efficiency and security. They propose a centralized framework which allows the UAV to carry the remaining energy of the nodes to the sink which then decides which nodes are suitable candidates for the cluster-head and which nodes should be marked as compromised and hence disqualified from the cluster-head election. Centralizing the cluster-head selection can add an additional delay to the communication and can result in unwanted exchanges between the nodes and a cluster-head now labelled as a disqualified candidate. Also, the approach can cause severe fluctuation of the cluster-head assignment if the nodes are mobile.

Despite the preceding research studies, intermediate caching between the nodes has, to our knowledge, never been considered. We believe that intermediate caching between the nodes can be advantageous for several reasons. Firstly, it does not impose additional strain on a particular node (i.e. a cluster-head). Secondly, there are no limitations on the positioning of the nodes and, finally, the UAV has more flexibility in terms of points of contact.

The next section outlines our proposed system. This is followed in Section 4 with a simulation-based evaluation where we employ a Levy movement model for the mobile nodes together with four different variations of caching. Finally we conclude the paper in Section 5.

### III. SYSTEM MODEL

We have implemented a discrete time event simulator in Java. Rather than feeding movement traces into the simulator

[20], our simulator has the ability to cope with different movement models, allowing for flexibility. However, for the sake of this paper, we only employ the Levy walk movement model. Historically, it was widely believed and accepted that animal movement could be explained by a simple random walk model; however, recent evidence has shown that the movement of different animal species are more relatable to the levy walk model [34], [35].

A Levy walk is based on the Levy foraging hypothesis that states that animals employ a Levy walk since it leads to optimal search efficiency. A Levy Walk according to Gautestad “describes a movement process with physical realism in the context of observing animal paths at fixed intervals” [36]. It is defined as a movement model where the subject continues to move in one particular direction and upon finding a resource patch, adopts random movement in and around it [37]. Fig. 1 from [38] highlights how a trace of a Levy walk may look.

Statistically, a Levy walk is a Markov based stochastic process. Rather than focusing on the biological nature of models, arguments over the past years have been restricted to statistical measures although the physicality and the movement pattern should matter more [39]. Humphries states “the real utility of the Levy research field is not, therefore, to accurately model animal movement paths, but as an exploratory tool to aid the behavioural analysis of animal movement datasets” [40]. Fig. 2 shows a typical Levy movement pattern of a node generated by our simulator.

In addition to the movement model, our model provides the opportunity for selectable caching depending on the scenario. In the case of Phase 1, we omit Intra-Node caching to provide baseline performance. In Phase 2 intra-node caching is enabled.

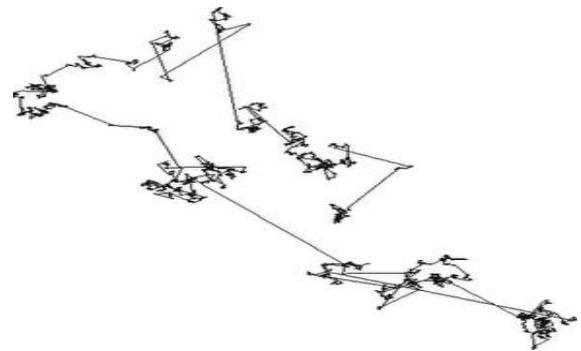

Fig. 1. Example Levy Walk [38].

Fig. 2. Single Node Movement Trace for 12hrs at 11kph.

A. Phase 1: No Intra-Node Caching

In Phase 1, mobile nodes are dispersed in a field of size  $n \times n$ . The nodes do not have any ability to cache data received from other nodes. In fact, the nodes do not even communicate with each other. Each node gathers/senses data from the host animal while the animal moves around. A UAV is to be sent out periodically from a gateway/base station and the UAV follows a fixed path based on waypoints [41], [42] which have been selected in such a way that the UAV can cover the majority of the field during its trip. In other words, the trajectory of the UAV is fixed, and the UAV moves from waypoint to waypoint as shown in Fig. 3.

Our model considers two versions of this approach. In the first (termed ‘WP’), the UAV only captures the data cached at the designated waypoints and does not pick it up directly from the mobile nodes. These waypoints are equipped with caches and can cache data from the mobile nodes they have encountered. The UAV simply collects the data from the waypoint stations. This approach of capturing data from fixed waypoints imitates the existing approach of collecting data from static cluster heads in the field. In the second variation (termed ‘UAV’), rather than collecting data from the waypoints, if during the trip, the UAV encounters any node that has data to transmit, the node transmits that data directly to the UAV. The UAV can either, store that data and bring it back to the base station at the end of the trip or can use some wireless technology to transmit that data to the base directly. In our approach, the UAV does not wirelessly transmit the data but brings it back to the sink at the end of its trip.

B. Phase 2: Intra-Node Caching

In this phase, in addition to everything described in Phase 1, the nodes have an intra-node caching ability allowing them to cache data obtained during interactions with other mobile nodes they come into contact with. The caching mechanism can be better understood from Fig. 4.

Fig. 3. Phase 1: No Intra-node Caching between Nodes.

Fig. 4. Intra-node Caching Technique.

A node not only exchanges data with the node it comes in contact with directly but also exchanges data it has accumulated in its cache. Snapshot (2) of Fig. 4 shows that A and B exchange information upon coming in range of each other. Snapshot (3) shows that when D comes in contact with A, it not only caches A’s information but in addition, caches all the information that A has in its cache (information A gathered from B in its previous encounter with B). This means that even if a node has not encountered a certain node directly, it still has the ability to carry this “second-hand” data the node if it came into contact with it indirectly. Hence we refer to this as an ‘indirect caching technique’.

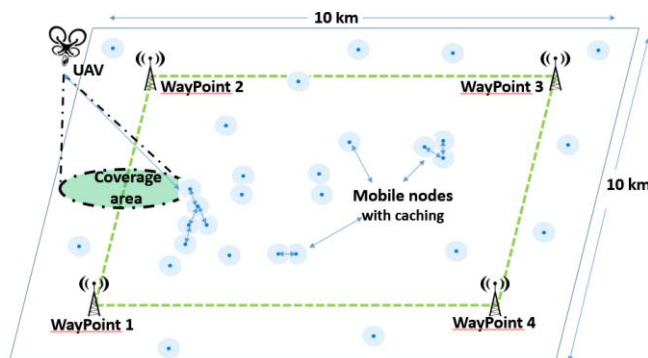

Fig. 5. Phase 2: Intra-node Caching between Nodes.

As shown in Fig. 5, the UAV follows the same path to complete its trip across the field which we term waypoint to waypoint communication. This phase also has two variants. The nodes have caching enabled in them in both versions which means if they come in contact with each other, they are allowed to exchange information and the receiving node can cache data that belongs to other nodes. In the first version (termed ‘WP+C’), the UAV only picks up data from the fixed route waypoints and not from the nodes directly. The fixed waypoints encountering a node not only take the node’s data but also accept all data that node has encountered from other nodes. In the second variant (termed ‘UAV+C’), if the UAV encounters a node that has data to send, the UAV collects that data directly. When the UAV encounters such a node, the node transfers to the UAV its own data in addition to the cached data of other nodes it has interacted with.

Data exchange between the nodes arises using a simple connectionless protocol shown as Algorithm 1. It assumes that nodes are transmitting regular beacons to announce their presence in the field in addition to scanning their coverage area to discover other nodes in their vicinity. This is the case with the UAV as well. If a node discovers another node in its vicinity (NeighborsFound = 1), it exchanges its data along with all messages of other nodes in its cache to the encountered node. For the UAV, it does not exchange its data with the encountered node; however, it does pick up the other node’s data in the same way. For intra-node communication, this is a two way process which means that both nodes in each other’s vicinity will exchange information. A node upon receiving a message (DataToReceive = 1) will first check its cache (NodeCache = null) to see if it already has that data. If this is true, the node will discard the oldest version of the data (remove old message) replacing it with the newer version (push

new message) by making use of timestamps ( $timestamp_{OldMsg}$  &  $timestamp_{NewMsg}$ ). The vicinity of the node is termed the ‘range’ of the node in this paper and is defined by ‘ $i$ ’, the radius around the node and its coverage area. The range of the node is one of the design parameters that we consider in subsequent experiments. Using this protocol, we eliminate the possibility of having duplicate data on nodes at any time.

**Algorithm 1:** Connection-Less Data Exchange Protocol

0 = False, 1 = True

**Node as a Sender**

```

while DataToSend == 1 do
    Scan for nearby nodes in coverage range;
    if NeighborsFound == 1 then
        transmit message/packet to all neighbors in range;
        DataToSend = 0;
    else
        break;
    end
end

```

**Node as a Receiver**

```

while DataToReceive == 1 do
    Receive incoming message from the sender;
    if NodeCache == null then
        push message to receiver’s NodeCache;
        DataToReceive = 0;
    else
        if message ∉ NodeCache then
            push message to receiver’s NodeCache;
        else
            if timestampNewMsg > timestampOldMsg then
                remove old message from receiver’s NodeCache;
                push new message to receiver’s NodeCache;
            else
                discard received message;
            end
        end
        DataToReceive = 0;
    end
end

```

The range of the UAV has been termed as the ‘coverage area’ of the UAV and is defined to be the projection imposed by the UAV’s antenna on the ground while flying at a constant height. The height is the altitude of the UAV whereas the coverage area is a circular area of radius ‘Radius’ as shown in Fig. 6.

The radius and coverage area of the UAV are defined by Equation 1 and 2, respectively. Throughout the evaluation, the range of the UAV is achieved by controlling the projection angle made by the UAV’s antenna with the ground.

$$\Phi = \frac{\text{Projection Angle}}{2} = \frac{\theta}{2}$$

$$\text{Radius} = \text{Altitude} \times \tan \Phi \tag{1}$$

$$\text{Coverage Area} = \pi \times (\text{Altitude} \times \tan(\Phi))^2 \tag{2}$$

Waypoints have been placed towards the edges of the field in such a way that optimum coverage is achieved by the UAV while on its flight between them. The coordinates for placing the waypoints have been set using equations 3, 4, 5 and 6.

$$WP1 = \left( \frac{\text{Radius}}{\sqrt{Nda}} \times i, \frac{\text{Radius}}{\sqrt{Nda}} \times i \right) \tag{3}$$

$$WP2 = \left( i - \frac{\text{Radius}}{\sqrt{Nda}} \times i, \frac{\text{Radius}}{\sqrt{Nda}} \times i \right) \tag{4}$$

$$WP3 = \left( i - \frac{\text{Radius}}{\sqrt{Nda}} \times i, i - \frac{\text{Radius}}{\sqrt{Nda}} \times i \right) \tag{5}$$

$$WP4 = \left( \frac{\text{Radius}}{\sqrt{Nda}} \times i, i - \frac{\text{Radius}}{\sqrt{Nda}} \times i \right) \tag{6}$$

Where ‘Radius’ is the coverage range of the UAV (m), ‘Nda’ is the node distribution area (m) and ‘ $i$ ’ is equivalent to ‘ $n$ ’ from the ‘ $n \times n$ ’ square matrix used in the code of the simulator for the node distribution area.

The flight pattern or the pattern of area coverage by the UAV can be understood from Fig. 7 which shows the series of areas covered by a UAV starting at time ‘ $n$ ’ and increasing by ‘ $x$ ’ (one second in our simulation) at each interval.

These concepts are realised in a simulation environment and then evaluated. Details of the experimental setup, the results and an assessment of their significance are provided for the different caching and non-caching variants in Section 4.

Fig. 6. Coverage Area of the UAV.

Fig. 7. Pattern of Area Coverage by the UAV.

#### IV. SIMULATION EVALUATION

To evaluate the benefit of caching, a bespoke JAVA run time event driven simulator was created. Several experiments were conducted testing comparing the various caching and non-caching variants presented in Section 3 under different conditions. The aim was to assess the efficacy of using intra-node caching on mobile wireless sensor nodes for animal monitoring.

Three different control parameters are considered, namely: node density, node coverage range and UAV coverage range. In each scenario 10 simulations have been run varying the initial node dispersion in the distribution area. The nodes are deployed with varying speeds but the speed of the UAV remains constant throughout all simulations. The speed of the UAV has been set according to some commercial copters available in the market whereas the speed of the nodes have been set assuming the animals roam under normal conditions without stress. The range of the nodes is dependent on the antenna they host and has been set according to [43] considering not just the basic motes currently available but advanced ones with a higher ranges [44]. We have tried to mimic large herbivores such as elephants which according to [45], [46] employ the Levy walk model, normally move with speeds in excess of 2mps, have a minimum home range of ten square kilometres [47], and can exist individually or in groups between 8-100 elephants in an area [48]. The mobility model is thus a stochastic Levy model where a node determines its next step according to a Markov based decision process, whereas the UAV follows a fixed linear flight path between multiple waypoints set within the distribution area. More details of the simulation parameters are provided in Tables II and III.

TABLE II. SIMULATION AND UAV CHARACTERISTICS

Simulation Parameters	
Simulations	10 per scenario
Node distribution area (Nda)	10km x 10km
Simulation duration	UAV's roundtrip ( $\approx 45$ mins)
UAV altitude	Constant (100m)
UAV speed	Constant ( $\approx 15$ m/s)
UAV coverage radius	Variable (80m - 720m)
UAV mobility	Linear (waypoint-waypoint)
Transfer time (UAV $\leftrightarrow$ node)	Instantaneous
Node Density(KM <sup>2</sup> )	1 - 7

TABLE III. NODE ATTRIBUTES

Node attributes	
Node type	Mobile
Node speed	Variable ( $\approx 2$ m/s - $\approx 5$ m/s)
Node coverage	Variable (80m - 720m)
Mobility	Levy model
Cache size	Unlimited
Energy	No Constraint

In each simulation, the UAV completes one flight starting and ending at the initial waypoint / take-off point. The field size, as pointed out previously is based on reported minimum home range of elephants however, other authors have also used such values [20] in similar scenarios. Node densities are considered using information presented in [49], [50] in addition to the values used for similar work in [51]. For the sake of simplicity, it is also assumed that the data transfer time between the nodes and the UAV is instantaneous. Specific UAV attributes can be seen in Table II which has been set considering current domestic and commercial UAV characteristics. It is assumed that the UAV is not resource-constrained compared to the sensor nodes, thus it can house an antenna potentially providing greater coverage than the sensing nodes. The node attributes can be seen in Table III. For the sake of this research, it is assumed that the nodes are not constrained by data storage or battery life; however, the coverage range has been selected based on motes available in the market and discussed in [52]. Movement speeds of nodes have been selected based on the stress free movement speed of the animals under consideration however they also match the parameters used for related work in [53].

Results are being presented using GNUPLOT version 5.2 patch 6.

Fig. 8 to Fig. 23 show the percentage of nodes encountered by the UAV and the Waypoints with and without the intermediate caching enabled between the nodes. The results are produced by varying certain perimeters to understand how it would affect the caching efficiency. All four variants of the two phases discussed in Section 3 are included.

In Fig. 8, the coverage of the UAV is set to 720m with a node density of 7 per square kilometres while varying the coverage radius of the nodes. Results show the 95% confidence intervals. Fig. 9 shows the percentage of nodes encountered by the UAV on its round trip when the coverage radius of the nodes is set to 720m, again with 7 nodes per square kilometres, while varying the coverage radius of the UAV. Fig. 10 illustrates that caching performance is consistent when the nodes are moving at lower speeds (equivalent to our animals in consideration). This means that for animals with movement speeds between  $\approx 1.9$ mps to  $\approx 5$ mps, the percentage of nodes captured by the UAV is more dependent on the parameters of the UAV and the nodes rather than the movement speeds of the sensors. Fig. 11 shows the percentage of nodes cached by the UAV on its round trip when the density of the deployed nodes in the distribution area is increased from 1 to 7 per square kilometre whilst keeping the UAV and node coverage range constant. Fig. 12, Fig. 13 and Fig. 14 is a repetition of the same scenario however; the UAV and node coverage ranges have been brought down to 560m. Fig. 15, Fig. 16 and Fig. 17 repeats this with the coverage ranges of the UAV and the nodes to be set to 400m. Fig. 18, Fig. 19 and Fig. 20 drops the coverage range further down to 240m followed by Fig. 21, Fig. 22 and Fig. 23 where the range has been set to 80m. All marking on the charts are with a 95% confidence interval.

Fig. 21. Percentage of Encountered Nodes Varying Node Coverage Range (inc. 95% CI).

Fig. 22. Percentage of Encountered Nodes Varying UAV Coverage Range (inc. 95% CI).

Observing from the figures, we see that the percentage of encountered nodes is highly dependent on the coverage range of the nodes with higher efficiencies when the nodes coverage radius increases. Also, the ability of the UAV to directly interact with the mobile nodes provides considerable benefit. The figures show that when the range of the nodes remains constant throughout, the improvement in the number of nodes seen by the UAV does increase but not dramatically. The percentage of nodes seen by the UAV greatly improves when the nodes are allowed to move at high speeds. This is mainly because nodes have a higher probability of interacting with and caching other nodes when they are moving faster compared to when they are moving slower and ultimately, more nodes will be picked up by the UAV. The figures also seem to suggest that for the animals in our consideration (elephants) and other similar animals, their real time movement state/speed will not have a big impact on the results considering their top speeds are not that significant and lie within the values we have used. The figures also show that for a very low deployed node count, unless the node and UAV perimeters are considered, the benefit of caching at node level is negligible and the system behaves the same with and without intra-node caching. The improvement in the percentage of nodes seen by the UAV tends to increase with the growing node density. We note again that the percentage of encountered nodes is highly dependent on the coverage range of the nodes with higher efficiencies when the nodes coverage radius increases. It shows that even when the UAV range is low, the advantages of using intermediate caching over no caching at all is quite significant. It shows that in a densely populated areas, the advantages of using intermediate caching outweigh the scenario where no caching is used. At low densities, intermediate caching and no caching yield the same results. At low node ranges, there is no advantage of embedding caching mechanisms into the deployed nodes however, for nodes with higher coverage range, a significant improvement can be seen over the previous case of no intermediate caching. The figures also seem to suggest that the advantages of intermediate caching over no intermediate caching rely more on a higher node coverage range compared to a higher UAV coverage range. At low range nodes, regardless of what the density of the environment is,

intermediate caching yields almost no benefit. We can see that with a higher number of nodes deployed in the distribution area, the advantage of using intra-node caching is much more beneficial.

Fig. 24 and Fig. 25 demonstrated the benefits of using intermediate caching. The trend lines clearly show that in both scenarios (when the data is being collected by the UAV directly from the nodes and when it is being collected only from waypoints by the UAV), there is an improvement over the total number of nodes captured by the UAV during its trip where, a significant advantage is shown when the UAV is allowed to capture data by directly interacting with the nodes.

Our evaluation clearly shows the benefit of using intra-node caching in a routing-less wireless mobile ad-hoc sensor network environment and a UAV is used as a relay agent to move data between the sensor nodes and the sink. Fig. 26 below shows the average number of nodes captured by the UAV at different node densities in the distribution area. The next section outlines our conclusions and future work.

Fig. 26. Average Number of Nodes Encountered by the UAV While Increasing the Deployed Node Density (inc 95% CI).

## V. CONCLUSIONS AND FUTURE WORK

It is clear from the results that the use of caching in a mobile ad-hoc sensor network where a UAV is used to relay information from the nodes to the sink and vice versa rather than a routing protocol yields significant benefits compared to the scenario where no caching is used. We can see from the results presented in Section 4 that even for a short duration (45mins), we were able to achieve around 12% improvement on the encountered node percentage when the UAV interacts with the nodes directly and around 4% improvement when the UAV only collects data from the waypoints. Another thing to notice here is that the UAV was allowed only one trip across the field in our experimentations however, we predict that we can further see a significant increase in the nodes seen percentage provided that the UAV makes more than one trips to collect data from the sensor nodes. In addition, the trip timings may also play a reasonable role in the percentage of nodes encountered by the UAV as we did notice in some cases that the number of nodes cached at the sensor nodes and the waypoints were higher than the nodes encountered by the UAV. The reason behind this was that the nodes and waypoints had encountered additional nodes after the UAV's visit to them hence the UAV was unable to get that information from them. In our experimentations, we chose the simplest locations for the waypoints, being around the edges of the field however, introducing no-go zones in the area and most visited zones can also have an impact on the results. Also, repositioning the waypoints to other locations based on the geography of the area where the model is to be deployed can also have an impact on the nodes encountered by the UAV on its trip. With the addition of different obstacles in the distribution area, the positioning of the waypoints can greatly affect the performance of the approach. Another interesting area to consider is selective caching with a finite cache size as opposed to our infinite caching model. Also, effects on the percentage of nodes seen by the UAV when the animals are moving rapidly are shown in Section 4; however, when the UAV moves at varying speed or the relationship between the speed of the nodes and the perimeters of the UAV can be further investigated and can yield different results as well.

Caching Improvement Trend At the UAV

Fig. 24. Caching Improvement Trend for Nodes Captured by UAV with Intermediate Caching (inc. 95% CI).

Caching Improvement Trend At the WAYPOINT

Fig. 25. Caching Improvement Trend for Nodes Captured by WAYPOINTS with Intermediate Caching (inc. 95% CI).

In addition to what has been discussed, there are several other parameters that we would like to check including different movement models and the use of multiple UAVs. We believe that our work opens up a very broad area of extensive research that can greatly benefit not only the field of tracking and preservation of wildlife but also, if implemented with custom parameters under different settings, can greatly assist in other areas as well including vehicular ad-hoc networks and disaster area networks as well.

**Abstract**—Recently, recommender systems has grown rapidly in both quantity and quality and has attracted many studies aimed at improving their quality. Especially, collaborative filtering techniques based on rule mining model combined with statistical implication analysis (SIA) technique also achieved some interesting results. This has shown the potential of SIA to improve the performance of recommender systems. However, it is still not rich and there are several problems to be solved for better results such as the problem of non-binary data processing, dealing with bottleneck case of data partitioning method according to the number of transactions on the very sparse transaction sets during training and testing the model, and not paying attention to exploiting the trend of variation of statistical implication. In order to contribute to solving these problems, the paper focuses on proposing a new data partitioning method, and developing the recommendation model based on equipotential planes mining generated by variation of implication intensity or implication index in the implication field on both binary and non-binary data to improve the recommendations further. Experimental results have shown the success of this new approach through its quality comparison with collaborative filtering recommendation models as well as existing SIA-based ones.

**Keywords**—Implication intensity; implication rules; implication field; equipotential surface

## I. INTRODUCTION

As a result of the available online information and the rapid increase of e-business and e-commercial services, it is difficult for users to make a proper decision without supporting of recommendation engines. And therefore, recommender systems [1], [2], [3], especially those based on collaborative filtering, are more and more popular and become an indispensable part of e-commercial services and others and one of which [2], [5], [15], [16], [17] is recommender system based on association rules mining (ARM).

Although ARM is considered as a popular and effective tool in “market-basket analysis” tasks and developing e-commerce, in recommender systems, the contribution of this technique is limited due to many reasons. Therefore, there have been many studies to improve this technique for recommender systems such as using fuzzy logic [16], [17], binarization real data [7], [8], and some others to refine and improve the rules evaluation measures, etc. While these also obtained certain results [5], [15], [16], [17], it’s so hard to keep up with collaborative filtering others. In recent years, several

recommendation models using statistical implicative analysis (SIA) [12], [13], [14] approach to improve the quality and effectiveness of recommender systems [7], [9], [10], [18], [19], [20], [21] by discover the interesting rules using measures like implication intensity, entropy implication intensity, Cohesion, and so on as similarity measures. Almost of which has not paid attention to mining the trend of variation of statistical implication, except for the works [18], [19], [20], [21] that have been published recently.

This paper focuses on three proposals (1) building a recommendation model based on implication field that can deal with both binary and non-binary dataset, (2) proposal data partition method based on rated items on each transaction instead of number of transactions on dataset, and (3) for a more comprehensive assessment of the quality of the proposed models, Item rating-based accuracy metrics are also used in addition to classification-based and prediction-based accuracy metrics to assess the quality of the recommendation listing. Experiment’s results shown that proposed model has performed better than both collaboration filtering ones and existing SIA-based ones, not only on binary data but also on non-binary one.

The paper is organized in five parts. The first one introduces the context and issues to be solved by the present systems as well as proposing our approach. The second part presents a summary of SIA theory and relevant contents about the recommender system. The next one presents proposed solution and its model to improve further the efficiency of recommender systems based on SIA. The fourth part is the experiment and evaluation of the proposed model, which focuses on comparing its performance with previous SIA models and traditional collaborative filtering-based models. Finally, the paper is finished by the conclusion.

## II. LITERATURE REVIEW

### A. Statistical Implicative Analysis

Statistical implicative analysis (SIA) theory [13], [14], proposed by Régis Gras, studies the implication relationship of data variables. It can be presented as follows.

Let  $E = \{e_1, e_2, \dots, e_n\}$  be a population of  $n$  transactions described by a finite set  $I = \{i_1, i_2, \dots, i_m\}$  of  $m$  variables (attributes, criteria, etc.). Let  $e_k \in E, i_v \in I$  where  $1 \leq k \leq n$  and  $1 \leq v \leq m$ . Denote by  $\Omega(e_k)$  the set of items taken

\*Corresponding authors.

from a transaction  $e_k$ , and  $\Omega(e_k) \subseteq I$ . Let  $a$  and  $b$  be subsets of  $I$ . Denote  $A = \{e_k \in E | \forall j \in a, j \in \Omega(e_k)\}$  and  $B = \{e_k \in E | \forall l \in b, l \in \Omega(e_k)\}$ , and  $\bar{A}, \bar{B}$  are respectively complementary set  $A, B$  in  $E$ .

Fig. 1. Illustration of an implication rule  $a \rightarrow b$  in SIA by Venn diagram.

An implication relationship (association rule/implication rule) is a pattern of the form  $a \rightarrow b$ , where  $a$  and  $b$  are disjoint itemsets ( $a \subset I, b \subset I$ , and  $a \cap b = \emptyset$ ). In fact, it is relatively common to observe a couple of transactions which contain  $a$  and not  $b$  instead of having the general trend to have  $b$  when  $a$  is present. Therefore, in addition to  $n = \text{card}(E)$  of  $E$ , it is necessary to taken into account the number  $n_A = \text{card}(A)$  of  $A$ ,  $n_B = \text{card}(B)$  of  $B$ , and  $n_{A\bar{B}} = \text{card}(A \cap \bar{B})$  of counter-examples  $A \cap \bar{B}$  to statistically accept to retain or not the rule  $a \rightarrow b$ .

The implication relationship between  $a$  and  $b$  is presented in an implication rule  $a \rightarrow b$  could be modeled in the SIA as Fig. 1.

To further illustrate about an implication rule, let's see an example movie transaction data as presented in Table I(a). We can consider it as set  $E = \{e_k, |k = 1..9\}$ , and let  $I = \{Movie_1, Movie_2, Movie_3\}$  an itemset. The set of items  $\Omega(e_1) = \{Movie_1\}$ ,  $\Omega(e_2) = \{Movie_1, Movie_2\}$ , etc. The movies data in Table I can be represented in a binary format as shown in Table II, where each row corresponds to a transaction and each column corresponds to an movie. A movie can be treated as a binary variable whose value is 1 if the movie is present in a transaction and 0 otherwise. Now, let's consider an implication rule  $a \rightarrow b$ , where  $a = \{Movie_1, Movie_2\}, b = \{Movie_3\}$  then set  $A = \{e_2, e_4, e_5, e_6, e_8, e_9\}$ , and set  $B = \{e_4, e_5, e_6, e_9\}$ . Thus,  $n = 9, n_A = 6, n_B = 4$ , and  $n_{A\bar{B}} = 2$ , so that rule  $a \rightarrow b$  can be represented by  $(n, n_A, n_B, n_{A\bar{B}})$  is  $(9, 6, 4, 2)$ .

More detail, we compare the observed number of counter-examples to a probabilistic model. Let us assume that we randomly draw two subsets  $X$  and  $Y$  in  $E$  which respectively contain  $n_A$  and  $n_B$  transactions. The complementary sets  $\bar{Y}$  of  $Y$  and  $\bar{B}$  of  $B$  in  $E$  have the same cardinality  $n_B$ . In this case,  $N_{X\bar{Y}} = \text{card}(X \cap \bar{Y})$  is a random variable and  $n_{A\bar{B}}$  an observed value. The implication rule  $a \rightarrow b$  is admissible for a given threshold  $1 - \sigma$  if  $\sigma$  is greater than the probability that the number of counter-examples in the observations is greater than the number of expected counterexamples in a random drawing

$e_9$	1	1	1

[14], i.e. if  $Pr(N_{X\bar{Y}} \leq n_{A\bar{B}}) \leq \sigma$ .

The distribution of random variable  $N_{X\bar{Y}}$  depends on the drawing pattern of  $X$  and  $Y$ . For a certain process of drawing, the random variable  $N_{X\bar{Y}}$  follows a Poissonian distribution [14]  $P(\lambda)$  with  $\lambda = \frac{n_A n_B}{n}$ . For cases where the approximation is justified (e.g.  $\lambda \geq 4$ ), the standardized random variable  $\tilde{N}_{X\bar{Y}} = \frac{\text{card}(X \cap \bar{Y}) - \lambda}{\sqrt{\lambda}}$  is approximately  $N(0, 1)$ -distributed. The observed value of  $\tilde{N}_{X\bar{Y}}$  is  $\tilde{n}_{A\bar{B}} = (\frac{n_{A\bar{B}} - \lambda}{\sqrt{\lambda}})$ .

The implication intensity expresses the unlikelihood of counter-examples  $n_{A\bar{B}}$  in  $E$ . The rule is admitted for a given threshold  $1 - \sigma$  if  $\varphi(a, b) \geq 1 - \sigma$ .

The implication intensity measure  $\varphi(a, b)$  [13], [14] of rule  $a \rightarrow b$  is defined by equation (1)

$$\varphi(a, b) = \begin{cases} 1 - Pr(\tilde{N}_{X\bar{Y}} \leq \tilde{n}_{A\bar{B}}), & \text{if } n_B < n \\ 0, & \text{otherwise,} \end{cases} \quad (1)$$

$$= \begin{cases} 1 - \sum_{s=0}^{n_{A\bar{B}}} \frac{\lambda^s}{s!} e^{-\lambda}, & \text{if } n_B < n \\ 0, & \text{otherwise,} \end{cases}$$

For cases where the approximation is justified, the standardized random variable  $\tilde{N}_{X\bar{Y}} = \frac{\text{card}(X \cap \bar{Y}) - \lambda}{\sqrt{\lambda}}$  is approximately  $N(0, 1)$ -distributed, and  $\varphi(a, b)$  is determined as equation (2)

$$\varphi(a, b) = \begin{cases} \frac{1}{\sqrt{2\pi}} \int_{q(a, \bar{b})}^{\infty} e^{-\frac{t^2}{2}} dt, & \text{if } n_B < n \\ 0, & \text{otherwise,} \end{cases} \quad (2)$$

where  $q(a, \bar{b})$  is the implication index [14], also known as the Gras implication index, and is determined as follows.

For binary variables [13], [14], the implication index  $q(a, \bar{b})$  is defined by equation (3)

$$q(a, \bar{b}) = \frac{n_{A\bar{B}} - \frac{n_A n_B}{n}}{\sqrt{\frac{n_A n_B}{n}}} \quad (3)$$

For modal variables [13]  $a, b \in [0, 1]$ , the implication index  $q_p(a, \bar{b})$  is defined by equation (4)

$$q_p(a, \bar{b}) = \frac{\sum_{t \in E} a(t)\bar{b}(t) - \frac{n_A n_{\bar{B}}}{n}}{\sqrt{\frac{(n^2 s_A^2 + n_A^2)(n^2 s_B^2 + n_B^2)}{n^3}}} \quad (4)$$

where  $a(t)$  is the values of element  $t^{th}$  of the  $a$  and  $\bar{b}(t) = 1 - b(t)$  is complement of element  $b(t)$  of  $b$  respectively; and  $s_A, s_B$  is their standard deviations.

For the frequency variables and the non-negative number variables, in order to use equation (4) they must be normalized [14] in advance by equation (5)

$$\tilde{a}(w) = a(w) / \max_{w \in E} a(w). \quad (5)$$

When  $a(t)$  and  $\bar{b}(t)$  are binary variables then  $q_p(a, \bar{b}) = q(a, \bar{b})$ .

The implication rule  $a \rightarrow b$  is admissible at the level  $\alpha$  if and only if  $\varphi(a, b) \geq 1 - \alpha$  [14].

Formula (2) definition of the implication intensity reminds its users, that it is of implication intensity interest only on condition that it is greater than 0.50, that means its  $q(a, \bar{b})$  should be negative. It is, therefore, more significant for an implication index that is strongly negative for patterns  $a \rightarrow b$ .

### B. Implication Field

Let's consider the implication index  $q(a, \bar{b})$  in the four-dimensional space, in which a point  $M$  whose coordinates are the parameters associated with  $(n, n_A, n_B, n_{A\bar{B}})$ . Then  $q(a, \bar{b})$  is a scalar field by applying the mapping from space  $R^4$  to space  $R$ . The vector  $grad q(a, \bar{b})$  containing the partial derivatives of  $q(a, \bar{b})$  by the variables  $(n, n_A, n_B, n_{A\bar{B}})$  is a special gradient field also known as implication field because it meets the Schwartz criterion for the mixed partial derivatives [12] of  $q(a, \bar{b})$  for all pairs of variables  $(n, n_A, n_B, n_{A\bar{B}})$ . That means for any pair  $(n_B, n_{A\bar{B}})$  then the partial derivatives by  $n_B$  of partial derivatives of  $q(a, \bar{b})$  by  $n_{A\bar{B}}$  equal to the partial derivatives by  $n_{A\bar{B}}$  of partial derivatives of  $q(a, \bar{b})$  by  $n_B$  as equation (6)

$$\frac{\partial}{\partial n_B} \left( \frac{\partial q(a, \bar{b})}{\partial n_{A\bar{B}}} \right) = \frac{\partial}{\partial n_{A\bar{B}}} \left( \frac{\partial q(a, \bar{b})}{\partial n_B} \right) = \frac{1}{2} \left( \frac{n_A}{n} \right)^{-\frac{1}{2}} \left( \frac{n_B}{n} \right)^{-\frac{3}{2}} \quad (6)$$

and similarly for remaining pairs.

In terms of structure, the implication field is the four-dimensional space, consisting of ordered ordinate surfaces corresponding to the successive and ordered values of  $q(a, \bar{b})$  with respect to the variation of the cardinalities  $(n, n_A, n_B, n_{A\bar{B}})$  [12], [14]. Now, the implication index is considered as a function of four parameters  $(n, n_A, n_B, n_{A\bar{B}})$ , a line or surface of equipotential in implication field is curve in  $E$ . A space along which or in which, point a variable  $M$  maintains the same value of potential of  $q(a, \bar{b})$ . The surface of equipotential is orderly. The curve equation of this surface [12], [14], [18],

[19], [20], [21] is shown in equation (7)

$$q(a, \bar{b}) - \frac{n_{A\bar{B}} - \frac{n_A n_{\bar{B}}}{n}}{\sqrt{\frac{n_A n_B}{n}}} = 0. \quad (7)$$

Consequently, on such a curve, the scalar product between gradient of  $q(a, \bar{b})$  and partial derivatives of  $M$ ,  $grad q(a, \bar{b}).dM$ , is zero [12]. This is interpreted as indicating the orthogonality of the gradient with the tangent or the hyperplane tangent to the curve, that is to say the line or the equipotential surface.

By illustrating, the potential  $S$  depends only on two variables, for example  $n_A, n_B$ . Fig. 2 below shows the orthogonal direction of the gradient for different equipotential surfaces where the potential  $S$  does not change on each surface, but it changes from the surface  $S = 7$  to  $S = 10$ . Thus,

Fig. 2. Illustration on Cartesian Coordinates for an Implication Field.

implication field can be considered a space in which a set of equipotential surfaces corresponding to successive values of  $q(a, \bar{b})$  relative to the cardinals  $(n, n_A, n_B, n_{A\bar{B}})$  which one would vary. The various gradient fields, true "lines of force", which are associated with them are orthogonal to the surfaces defined by the corresponding values of  $q(a, \bar{b})$  [12]. Behind this notion we can imagine a transport of information of variable intensity in a causal universe.

### C. Implicative Recommendation

SIA's original purpose is to analyze data for educational, psychological, and ontological applications [13], [14], etc. In recent years, however, attributable to recognize potential ability of SIA in recommender system techniques, there were several studies in recommender systems to improve their efficiency and have obtained remarkable results.

A typical proposal [7], [8], which has shown the potential of SIA to improve the performance of rule-based collaborative filtering recommender systems, however it also has a several disadvantages need to be addressed as (1) only processing on binary data, which leads to a problem to solve is the combinatorial explosion due to the binarization of non-binary data, (2) for models based on rules mining of these works, SIA is proposed in the post-processing stage of rules mining task, so they have not contributions considerably to limit the outcome rules' combinatorial explosion in large datasets. Another study using SIA to recommender systems [9], [10], which paid the attention to solve the problem on non-binary data and making some new contributions based on the recommendations

model with additional SIA metrics such as entropic version of implication intensity, cohesion, contribution, etc. This work is another proof show potential ability of SIA applying on recommender systems.

Most recently, SIA has also been proposed to recommender system models in the works [18], [19], [20], [21]. Accordingly, Nguyen *et al.* has contributed to overcome the shortcomings of previous studies following a new approach on SIA like reducing model's performance time, increasing predictions' accuracy, controlling generated rules set, compared to both traditional collaborative filtering model and former SIA model, by developing a recommender system based on implication rules mining (IRM) using implication variation measures.

In practice, research applying SIA to the development of recommender system models recently have made a positive contribution in this area, it can be seen as a potential research trend. However, in order to further improve the effectiveness of the recommendation models, there are still a few issues that need to be addressed as follows: (1) it is necessary to further mine the unique and outstanding features of the implication field such as equipotential planes, (2) the data sets for the recommendation models are mostly sparse, therefore, using cross k-folds evaluation for recommendation models by partitioning the data set by transactions is not optimal yet, because this will lead to limit number of known items (given items) in test sets, this can significantly affect to model's training quality, (3) using measures of accuracy of the predictions and classifications to evaluate the recommendation models is not enough yet, because in recommender systems, the position of items in the recommendation list is also important, therefore, it is necessary to use additional measures of items' position ranking in recommendation list.

### III. RECOMMENDATION MODEL

#### A. Model

The implication field and its particularly features, as shown in Section II-B, have opened a great potential for the implementation of recommendation models. In this paper, the implication field-based recommender system has been proposed to include the following components as shown in Fig. 3. This model has been experimentally proven on both binary and non-binary datasets to be more efficient than the traditional collaborative filtering models exploiting the association rules on both binary and quantitative data. The main components of the model include the following.

The implication field algorithms include two newly proposed algorithms. The first is responsible for generating the implication field consisting of a set of equipotential surfaces as discussed in Section II-B, This algorithm uses one of the implication variation measures. These measure are presented in Table III. They include four for implication index variation (first four rows) and four for implication intensity variation (four rows later) by  $n, n_A, n_B,$  and  $n_{A\bar{B}}$ . These SIA measures are determined as sum of the implication index (or implication intensity) and the partial derivative of the implication index (or implication intensity) by the variables  $n, n_A, n_B,$  and  $n_{A\bar{B}}$ , and SIA knowledge to generate the implication field, that is composed of a set of equipotential surfaces, from dataset. The second mines frequent implication patterns on

equipotential surfaces to provide recommendations to users. It makes personal recommendation by frequent implication pattern mining on equipotential surfaces in given threshold implication index (or implication intensity) for predicting and a recommendation the items or the top  $k$  items list to users. These algorithms will be shown in Section III-B.

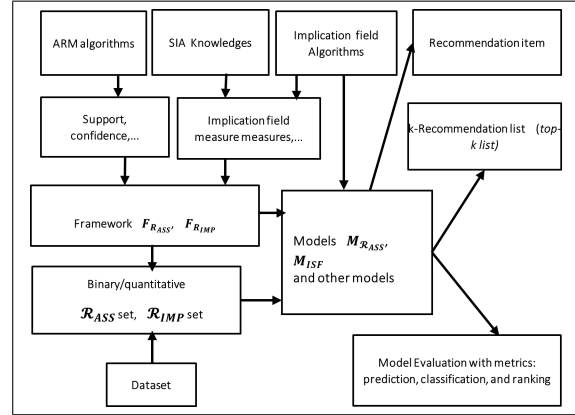

Fig. 3. The Overall Structure of Recommendation Model based on Implication Field.

In Fig. 3, The models  $M_{R_{ASS}}$ , (Model for Association), and  $M_{ISF}$ , (Model for Implication Statistical Field), are recommendation model based on ARM, and IRM respectively in implication field. These models include a set of association rules  $R_{ASS}$  or implication rules  $R_{IMP}$  and framework for association rules mining  $F_{R_{ASS}}$ , or implication rules  $F_{R_{IMP}}$  correspondingly [20], [21]. They are shown in equations (8) and (9)

$$M_{R_{ASS}} = \{X \mid R_{ASS}, F_{R_{ASS}}\}, \quad (8)$$

$$M_{ISF} = \{X \mid R_{IMP}, F_{R_{IMP}}\}, \quad (9)$$

where  $R_{ASS}$  and  $R_{IMP}$  are respective association rules set and implication rules set. Each of which is expressed by 4-tuples  $(n, n_A, n_B, n_{A\bar{B}})$  meeting the constraints as are defined as equation (10) and (11), respectively, where  $s$  (support),  $s_{min}$  (minimum support threshold),  $c$  (confidence),  $c_{min}$  (minimum confidence threshold),  $imp$  (a given SIA measures), and  $imp_{min}$  (minimum threshold of a given SIA measure) are support, confidence, and one of SIA measures (see Table III), and their respective minimum thresholds.

$$R_{ASS} = \left\{ (n, n_A, n_B, n_{A\bar{B}}) \left| \begin{array}{l} n_A \leq n, n_B \leq n, \\ \min(0, n_A + n_B - n) \\ \leq (n_A - n_{A\bar{B}}) \leq \\ \max(n_A, n_B), \\ s_{min} \leq s, c_{min} \leq c \end{array} \right. \right\}, \quad (10)$$

$$R_{IMP} = \left\{ (n, n_A, n_B, n_{A\bar{B}}) \left| \begin{array}{l} 0 \leq n_A \leq n_B \leq n, \\ 0 \leq n_{A\bar{B}} \leq n_A, \\ s_{min} \leq s, c_{min} \leq c, \\ imp_{min} \leq imp \end{array} \right. \right\}. \quad (11)$$

TABLE III. FAMILY OF VARIATION IMPLICATION MEASURES OF IMPLICATION RULES MINING FRAMEWORK

No	SIA Measures	Formulas
1	$q_n(a, b)$	$q(a, \bar{b}) + \frac{1}{2\sqrt{n}}(n_{A\bar{B}} + \frac{n_A n_B}{n})$
2	$q_{n_A}(a, \bar{b})$	$q(a, \bar{b}) - \frac{1}{2} \frac{n_{A\bar{B}}}{\sqrt{\frac{n_B}{n}}} (\frac{n_A}{n})^{\frac{3}{2}} - \frac{1}{2} \sqrt{\frac{n_B}{n_A}}$
3	$q_{n_B}(a, \bar{b})$	$q(a, \bar{b}) + \frac{1}{2} n_{A\bar{B}} (\frac{n_A}{n})^{-\frac{1}{2}} (n - n_B)^{-\frac{3}{2}} + \frac{1}{2} (\frac{n_A}{n})^{-\frac{1}{2}} (n - n_B)^{-\frac{1}{2}}$
4	$q_{n_{A\bar{B}}}(a, \bar{b})$	$q(a, \bar{b}) + \frac{1}{\sqrt{\frac{n_A(n - n_B)}{n}}}$
5	$\varphi_n(a, b)$	$\varphi(a, b) + \frac{1}{\sqrt{2\pi}} \int_{q(a, \bar{b})}^{q_n(a, \bar{b})} e^{-\frac{t^2}{2}} dt$
6	$\varphi_{n_A}(a, b)$	$\varphi(a, b) + \frac{1}{\sqrt{2\pi}} \int_{q(a, \bar{b})}^{q_{n_A}(a, \bar{b})} e^{-\frac{t^2}{2}} dt$
7	$\varphi_{n_B}(a, b)$	$\varphi(a, b) + \frac{1}{\sqrt{2\pi}} \int_{q(a, \bar{b})}^{q_{n_B}(a, \bar{b})} e^{-\frac{t^2}{2}} dt$
8	$\varphi_{n_{A\bar{B}}}(a, b)$	$\varphi(a, b) + \frac{1}{\sqrt{2\pi}} \int_{q(a, \bar{b})}^{q_{n_{A\bar{B}}}(a, \bar{b})} e^{-\frac{t^2}{2}} dt$

$F_{RASS}$  is framework of ARM [20], [21], including famous ARM algorithm, *a priori*, was proposed by [11], and measures support ( $s$ ), confidence ( $c$ ) meeting the constraints  $s \geq s_{min}$ , and  $c \geq c_{min}$  as are defined as equation (12) and  $F_{RIMP}$  is frameworks of IRM [20], [21], including IRM algorithms (see details in Section III-B following), and measures support, confidence, and ASI measures as defined in Table III meeting the constraints as are defined as equation (13)

$$F_{RASS} = \left\{ \left( \begin{array}{l} ARM\ algs, \\ supp\ s, conf\ c \end{array} \right) \left| \begin{array}{l} n_A \leq n, n_B \leq n, \\ \min(0, n_A + n_B - n) \\ \leq (n_A - n_{A\bar{B}}) \\ \leq \max(n_A, n_B), \\ s_{min} \leq s, c_{min} \leq c \end{array} \right. \right\} \quad (12)$$

$$F_{RIMP} = \left\{ \left( \begin{array}{l} IRM\ algs, \\ supp\ s, conf\ c, \\ SIA\ measure\ imp \end{array} \right) \left| \begin{array}{l} 0 \leq n_A \leq n_B \leq n, \\ 0 \leq n_{A\bar{B}} \leq n_A, \\ \min \leq s, c_{min} \leq c, \\ imp_{min} \leq imp \end{array} \right. \right\} \quad (13)$$

The evaluation models are designed for testing and evaluating recommendation models and they will be presented details in section III-C following, and then they are used in experiments of sections IV-D and IV-E.

### B. Algorithms

To generate the list of recommendations, the implication field-based recommendation system model focuses on the IRM algorithm including two phases. The first is to generate the implication field from the dataset, in this phase the IFGEN algorithm will be used to generate produce a set of equipotential planes for potential implication values, based on the variation of one of the four variables ( $n, n_A, n_B, n_{A\bar{B}}$ ). The second uses MAKEIFREC algorithm to mine implication patterns of

equipotential planes to generate a list of recommended items for the user.

### Algorithm IFGEN (Implication fields Generator)

**Input:** a dataset; the thresholds of confidence, support and an implication field measure; type of data (binary/quantitative).

**Output:** Implication rule set.

**Step 1:** Constructing implication field measure, defined as in the Table III.

**Step 2:** Generating the implication rules set from the dataset using a data mining algorithm (such as Apriori, Eclat, etc.) and the thresholds of support, confidence and implication field measure that is defined in step 1. Note that: if data is in binary form,  $q(a, \bar{b})$  is computed by equation (2); if the data is in quantitative form,  $q(a, \bar{b})$  is computed by equation (4) and (3).

**Step 3:** Presenting each implication rules by four values  $n, n_A, n_B$ , and  $n_{A\bar{B}}$  as well as its values according to the measures such as support, confidence, implication index, implication intensity, and implication field measures as shown in Table III.

With the algorithm IFGEN, the generated implication rules will be more accurate because of the high examples (from support /confidence measures) and low counterexamples (from the statistical implication measure). This will be confirmed in the Section IV.

**Algorithm MAKEIFREC** (making implication field recommendation).

**Input:** a dataset; the thresholds of confidence, support, and an implication field measure; type of data (binary/quantitative).

**Output:** predicting item or the list of top k items to be recommended to users.

**Step 1:** calling the IFGEN algorithm for generating the set of equipotential surfaces in implication rules.

**Step 2:** mining frequent implication patterns in equipotential surfaces for predicting and returning the recommendation result (1 item or k items) to users.

### C. Evaluation

Normally, to evaluate a machine learning model, evaluating procedures divide the dataset into a training set and test set based on transactions. In recommender systems, however, that can get a weaknesses for sparse datasets which have some transactions with very few users' rating, this leads to the maximal number of items to keep (*given*) on known set is limited considerable because it cannot be greater than the number of rated items on any transaction in dataset, see example in Fig. 4, because there are only two rating in transaction  $u_6$ , we cannot set  $given \geq 2$ . This could lead to limit learning ability considerably and therefore quality of recommendation model will be not good. Moreover, some of the proposed models only focus on processing the binary data and try to binarize the non-binary datasets [7], [8], [9]. This could be the main cause to the accuracy of recommendation models to be affected.

Fig. 4. An Example about Typical Partition Data Method.

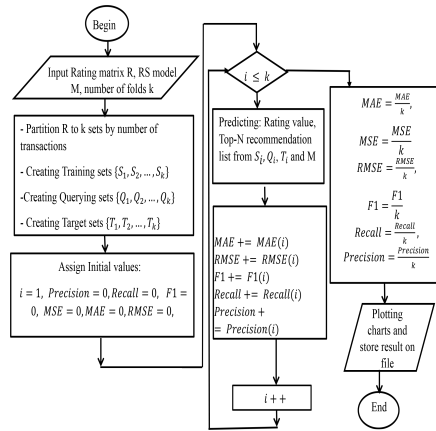

Fig. 5. Flowchart of Algorithm for Evaluation Recommendation Model.

In addition, see flowchart of evaluation model algorithm in Fig. 5, the recommended evaluation measures used in [9], [10] focus on only two main groups, the first is the accuracy of the ratings such as  $MAE$ ,  $MSE$  and  $RMSE$  [4], [6] to determine the accuracy of the prediction ratings are missing and the second group is predictive predictions such as  $precision$ ,  $recall$ , and  $F1 - score$  [4], [6], which focus on introducing items that are useful to the user and helping them make the right decision. These metrics, however, have a major downside: they are concerned with the entire dataset rather than top-N recommendation lists. Therefore, it is not easy to assess accurately the recommender systems when comparing the list of items recommended to the list of relevant items, because the metrics do not focus on the identification of rank and position of an item in the list.

In practice, good recommender systems are not only interested on how many relevant results they give, they also want to give users with a good order. They need to be able to put relevant items remarkably high up the list of recommendations. Most probably, the users will not scroll through hundreds of items to find favorite item they like. Take now famous

searching engines like Google \*, Bings † as an example, it is evident that they prioritize relevant query results in some sort of descending order. Therefore, it is necessary to need metrics of ranking awareness properly to select recommender systems that can solve major aims: (1) Where position of item that recommender system suggests is in list of recommendation result, (2) how good recommender system could solve in modeling users' relative preference.

To overcome this shortcoming of the recommender system model, two suggestions are given for improving the evaluation quality of the recommender system.

The first, in terms of dataset partitioning method for evaluating, the dataset that has  $n$  transactions and  $m$  items can be partitioned into two sets of training and testing based on number of items ranked per transaction instead based on numbers of transaction on dataset.

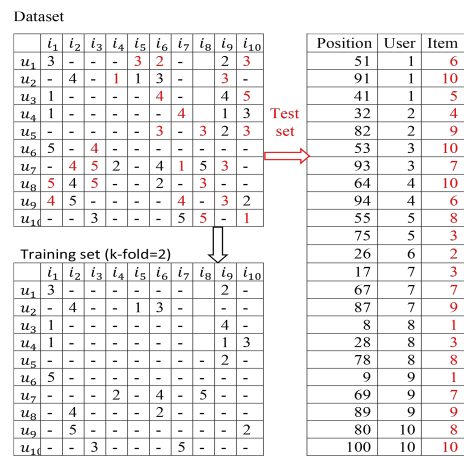

Fig. 6. An Example of Proposed Data Partition Method.

Accordingly, for each transaction, items will be randomly partitioned into  $k$  folds:  $n \times (k - 1)/k$  items for training set and  $n/k$  items for testing set. In Fig. 6, dataset's items are partitioned in 2 folds randomly (for simplicity in illustration), in which items for test set are presented in red, (remained items in black for training set). In this way the training and testing sets are formed from all transactions, which means that all transactions are involved in both the training and testing set, and the number of items per sets are  $(k - 1) \times n/k$  and  $n/k$  percent of items' dataset correspondingly. A problem in test set's presentation is that it will be very sparse compared to the dataset. In order to save memory and time for manipulation, a good suggestion that using one-dimension array namely positions for storing position of all items in test set where  $0 < position[k] < n \times m$ . Accordingly, the row  $i$  and column  $j$  of an item are defined respectively as follows the quotient +1 and the remainder in  $\frac{position}{n}$ , if  $quotient = m$  then  $(i, j) = (n, m)$ . For instance, in Fig. 6 position[1]= 51 means that transaction of user  $u_1$  rated item  $i_6$  (since the remainder of  $51/10$  is 1, and the quotient of  $51/10$  plus 1 is 6). It is apparent that items in the training and testing set are

\* <https://www.google.com/>

† <https://www.bing.com/>

extracted from all transactions of the dataset, which makes better model testing and training. Moreover, this approach also fixes the shortcoming of k-fold partitioning based on transaction because the number of items retained to build a training model that is no longer limited to the minimum number of items per transaction in dataset.

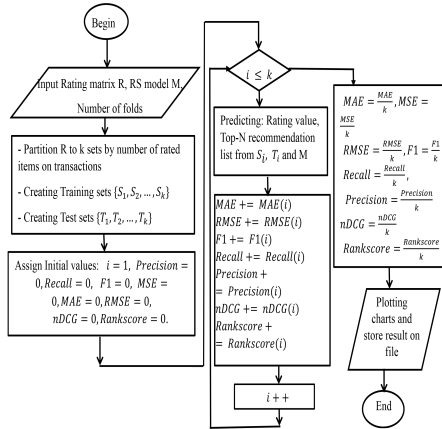

Fig. 7. Proposed Algorithm Flowchart to Improve Recommendation Model.

In addition, due to the way of partitioning the dataset by items on each transaction, it is not necessary to create the unknown and know set from the test set as in transaction-based dataset partitioning way.

The second, in relation to using of evaluating measures, besides predicting-based and classifying-based precision evaluating metrics, the ranking-based ones are also suggested to evaluate more comprehensively the recommendation list's quality. Although there are many metrics of this type like *MRR*, *MAP*, *nDCG* and *Rankscore* [4], [6], only *nDCG* and *Rankscore* are suggested because they can be used to deal with both binary and none-binary dataset.

Finally, these proposals are presented in the algorithm as shown in Fig. 7. This is a revision of algorithm in Fig. 5 based on two major changes, that is using a new method for dataset partition based on number of ranked items per transaction and adding measures *nDCG* and *Rankscore* measures. These are the major changes for improving the efficiency and quality of the recommended system as discussed in the following experiments.

#### IV. EXPERIMENT

##### A. Datasets

Using collaborative filtering based-on implication field recommendation model described above, we conduct experiments on both the binary dataset (MSWeb)<sup>‡</sup> and the quantitative dataset (MovieLens)<sup>§</sup>. The MSWeb dataset is created by sampling and processing the www.microsoft.com logs of 38.000 anonymous, randomly selected users in one-week timeframe. For each user, the dataset lists all the areas of the web site

(Vroots) that user visited in a one-week timeframe in February 1998. This dataset contains 32710 valid users and 285 Vroots. The MovieLens dataset collected by GroupLens consists of 100.000 ratings made by 943 users for 1.682 films. The ratings range from 1 to 5 corresponding to from the lowest to the highest.

To serve the experiment to be more accurate, the datasets are preprocessed by:

Normalization of data: Users who rank high (or low) for all their films/Vroots depending on the individual can lead to bias. Eliminate this effect by normalizing the data so that the average rating of each user is the same scale.

Selecting relevant data: Ignoring data can lead to bias and to speed up computation, by not interested in the films/Vroots has had only a few times, because the ratings of these films/Vroots may be subject to bias due to lack of data, and users rated only a few films because their ratings may be biased.

Using k-fold cross validation method (with k=5 for this paper): to avoid overfitting problems as well as to get better accuracy as for each model evaluation. The dataset (MovieLens or MSWeb) is split into equal sized k-fold to build training set (using k-1 fold) and test set (using remaind fold) by the number of ratings on transaction instead of by number of transactions on dataset to overcome the limitations as analyzed in Section III-B.

##### B. Tool

The experiments were performed on implication field RS tools developed in the R language<sup>¶</sup>. This tool is developed for making, performing, and evaluating models of recommender system based on implication field as described in Section III-A. In addition, it can build and run other collaborative filtering-based recommender systems for mutual comparison and evaluation. The SIA measure is used for  $F_{RIMP}$  is  $\varphi_{n_{AB}}(a, b)$ .

##### C. Analyze Equipotential Surfaces in Implication Field

1) *Experiment Description*: To analyze the implication field as a set of equipotential planes, In this experiment, the Implication field-based recommender system model was performed on the MovieLens non-binary dataset that was described in Section IV-A, on the  $F_{imp}$  (minsup = 0.1, minconf = 0.3,  $\min\varphi_{n_{AB}}(a, b) = 0.5$ ).

2) *Results and Discussions*: Results are presented in Fig. 8 and 9, they are presented in the form of 3D scatter and 3D graph, representing equipotential surfaces with a warm color (red) that is common in the implied intensity range of 0.8 to 1.0, and the remaining scattered is the equipotential surfaces have the implication intensity decreasing by the gradual cold color (blue).

In Fig. 10, contour form, accordingly, the implication field with equipotential surfaces has a variable value spectrum of implication intensity concentrated in the range 0.8 to 1 represented by the gray spectrum and the remainder is

represented by the gradual transition color spectrum green. Fig. 11, the implication intensity variation on the equipotential surfaces presented in 3-dimensional form, it is easy to see that the implication samples with high implication intensity are concentrated on warm colored equipotential surfaces and rapidly decrease. in the low intensity region is represented by blue. The common recommendations will be filtered on high intensity equipotential surfaces, whereas those for specific, rare items will be provided in low implication equipotential surfaces.

Fig. 10. Implication Field and Its Equipotential in Contour.

#### D. Scenario 1. Comparing with Traditional Recommendation Models

1) *Experiment Description:* In this experimental scenario, the recommender system model based on the implication statistical field (ISFRS), is compared with the traditional collaborative filtering recommendation models based on user for both Cosine (UBCF\_cRS) and Pearson measures (UBCF\_psRS), and collaborative filtering recommendation models based on item for both Cosine (IBCF\_cRS) and Adjusted Cosine measures (IBCF\_acRS), The data set used in this experiment is the Movielens non-binary data set described in Section IV-A. For the collaborative filtering models to have good results, a problem needs to face is how to choose the number of neighbors best, we try to experiment on many neighbor k parameters for these models including k=2, 5, 10, and 15, and finding that k = 15 is better than other values. Moreover, dataset partitioning for training and testing is conducted based on number of items in transactions instead of numbers of transaction. Recommendation models were experimented on two groups' measure: classification and ranking.

2) *Results and Discussions:* The first, models were experimented on classification measures, on ROC curve, precision/recall, F1, The results are shown in Fig. 12 to 14. As a result, the ISFRS model is the best, next is the collaborative filtering model based on user using both Pearson and cosine measures, and finally weakest model is item-based collaborative filtering model (in case of both Pearson and adjusted cosine measures).

The second, models were experimented on ranking measures, on  $nDCG$  and  $Rankscore$ . The results, have presented in Fig. 15 and 16, also show the preeminence of the ISFRS model over the collaborative filtering model, which is the same as the case of the group of classification measures that is discussed above.

These result in this experiment shows the contribution of both the proposed ISF RS model and the proposed data partitioning method to evaluation in improving the model's classification and ranking capability and training quality compared to the recommended models based on traditional collaborative filtering.

Fig. 14. F1 of ISF Model and CF others, k=15.

Fig. 15. Rankscore of ISF Model and CF others, k=15.

### E. Scenario 2. Comparing with Implicative Recommendation Models

1) *Experiment Description:* In this experimental scenario, the MSWeb binary data set is used to compare the implication statistical field recommender system (ISFRS) model with two other SIA models that was reviewed in Section II-B including works in [7], [8] (Implication index and intensity - IIRS) and [9], [10] (Phi-Cohesion- Gamma- PCGRS) on two types of measure. Reason that MSWeb is chosen to use in this experiment instead of Movielens as in previous one is attributable to models in [7], [8] was designed and performed on binary dataset only as mentioned in Section II-C. In addition, to get more precision results, dataset partitioning for training and testing sets is conducted based on number of rated items in transactions instead of numbers of transaction.

2) *Results and Discussions:* The first is classification measures including precision/ recall, ROC, F1, experimental results show the preeminence of IFS RS recommendation model compared to PCG RSmodel and IIRS model, in which the weakest is the model IIRS on all 3 evaluation measures, as shown in Fig. 17 (for Recall/Precision), Fig. 18 (for ROC curve), Fig. 19 (for F1).

The second is ranking measures, the experimental results, were shown in Fig. 20 (for Rankscore) and Fig. 21 (for nDCG), are quite similar to the results on the group of classification measures. This means that the ISFRS model has the best

results ranking items according to the nDCG and Rankscore indicators, followed by the PCGRS model and the worst is the IIRS model.

This indicates that recommender system based on the implication statistical field has ability better on both classification and ranking compared to previous recommendation model based on SIA applying. The experiment proofed that proposed ISFRS resolved three problems of recommender systems based on applying SIA previously as mentioned in Section II-B. Therefore, it is apparent that it is a new and promising trend in applying statistical implication analysis theory to the recommender systems domain.

### V. CONCLUSION

In order to ensure relevance and novelty for recommender systems, its proposal has to be personalized enough to meet the user's personal preferences and deep enough to make a pleasant surprise for the user. In this regard, the paper has proposed a novel recommendation model based on the implication field to significantly improve the quality of the recommender system compared to the traditional collaborative filtering-based recommender systems. The second contribution of the paper is to propose a new data set partitioning method to build training and test sets to build and train the recommendation model,

Fig. 16. nDCG of ISF Model and CF others, k=15.

Fig. 17. Precision/Recall of ISF Models and others in SIA.

based on the rating ratio per transaction instead of based on the number of transactions, which overcomes the limitation of sparse datasets in recommender systems, making them more likely to recommend accurately. Another contribution to this paper is to propose metrics that provide a more in-depth assessment of the quality of recommendations. In addition to the metrics for precision of classification like precision, recall, and F1, metrics for rank score were also added that evaluate the relevance of recommendations like nDCG and Rankscore and using them to compare among different models. This helps evaluate outputs' quality of recommendation models more comprehensively as shown in the experimental results. Finally, this paper also aggregates and compare the effectiveness of the works existing SIA-based recommendation systems, experiment's results showing that the application of the implication variation tendency in the implication field is the most satisfactory result in all these recommender systems.

From these results, it is clear that the exploitation of the relationships between variables (objects/ individuals/ attributes/ items) in the form implication rules in the implication field has achieved positive results for recommender systems. Therefore,

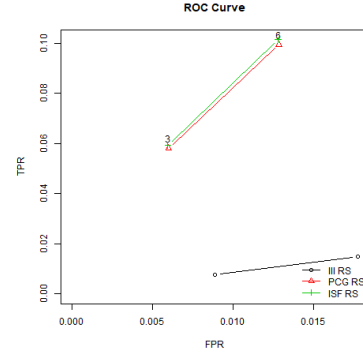

Fig. 18. ROC Curve of ISF Models and others in SIA.

Fig. 19. F1 of ISF Models and others in SIA.

the study to extend further these relationships in the form between rules or/and between rules and variables in the implication field and exploitation them to further improve the effectiveness of the recommendation system is a promising one in the future.

# Taxonomy of Cybersecurity Awareness Delivery Methods: A Countermeasure for Phishing Threats

Asma A. Alhashmi<sup>1</sup>, Abdulbasit Darem<sup>2</sup>, Jemal H. Abawajy<sup>3</sup>

Department of Computer Science, Northern Border University, Arar 91431, Saudi Arabia<sup>1,2</sup>  
Cybersecurity Research and Innovation Centre, Deakin University, Burwood, VIC 3217, Australia<sup>3</sup>

**Abstract**—Phishing is a serious threat to the Internet users and has become a vehicle for cybercriminals to perpetrate large-scale crimes worldwide. A wide range of technical and educational measures have been developed and used to address phishing threats. However, the technical anti-phishing measures have been widely studied in the current literature whereas comprehensive analysis of the non-technical anti-phishing techniques has generally been ignored. To close this gap, we develop a new taxonomy of the most common cybersecurity training delivery methods and compare them along various factors. The work reported in this paper is useful for various stakeholders. For organizations conducting or considering phishing training, it helps them understand the various awareness training and phishing campaigns capabilities and design an appropriate program with a meaningful return. For researchers, it offers a clearer understanding of the main challenges, the existing solution space, and the potential scope of future research to be addressed.

**Keywords**—Phishing attack; human factors in cybersecurity; cybersecurity threats; cybersecurity awareness; anti-phishing awareness delivery methods

## I. INTRODUCTION

Internet technology coupled with advances in mobile devices such as smartphones have enabled regular every-day people to learn, work, purchase, entertain, connect, and network from anywhere and at any time. With the increasing reliance on the Internet, so is the threat of being falling a victim to cybersecurity attacks. Cybercrime is the fastest growing crime worldwide and continue to increase in sophistication and costs to the global economy with an estimated \$6 trillion by 2021 [4]. Phishing is the most prominent attack vector used by cyber criminals today and phishing prevalence is at all-time high [5]. Phishing impacts online users and organisations of all size and sectors including banks and public services. The financial costs to victims due to phishing attacks worldwide are staggering and currently estimated to surpass a trillion dollars [38]. In the U.S. alone, the financial costs to businesses between 2013 and 2019 are estimated to be more than \$10 billion [17]. With phishing attacks accounting close to 90% of the estimated cybercrime costs [10], there is a substantial economic benefit for putting in place appropriate anti-phishing measures to fight phishing threats. As a result, a serious effort to combat phishing threats has been pursued both in academia and industry.

Various technical measures have been proposed in the literature to address phishing threats. These automated anti-phishing measures include email filtering [1,7], machine

learning based techniques to identify phishing emails and websites [20], and browser security indicators that warn end-users potential dangers from malicious email messages and fake websites [23]. Although automated anti-phishing solutions are powerful defence, phishing attacks remain a significant threat to individuals and businesses currently accounting for more than 80% of reported security incidents [24]. Moreover, it takes 32 days on average for technical countermeasures to detect and mitigate phishing attacks [42]. In addition, cybercriminals continue to become more creative and changing tactics to get around the anti-phishing measures in place and sending much more plausible-looking phishing messages [39]. Therefore, despite considerable advances in anti-phishing technical solutions, the automated anti-phishing measures are still inadequate to combat phishing threats [33].

Cybercriminals are increasingly shifting from exploiting software and hardware vulnerabilities to depending on human weaknesses to perpetrate an attack on individuals and businesses. For phishing threats to be realised, the cyber attackers must first institute a trust with the potential victims. This means automated solutions alone do not provide complete safeguard against phishing attacks. Since phishing attacks primarily exploit human vulnerability, human intelligence based anti-phishing approach is the best defence to narrow the gap left by technical measures. Therefore, intervention programs that improve human awareness and security behaviour have been developed to augment the technical solutions. These intervention programs implement different delivery methods to build vital security awareness skills and changes both awareness and behaviour of the end users.

This paper provides a new taxonomy of the most common cybersecurity training delivery methods developed to train the workforce to protect themselves from phishing threats. Second, we will survey and critically analyse a variety of phishing awareness delivery methods based on the taxonomy we developed with emphases on those that focus on what delivery methods are effective in increasing the ability of the people to detect and mitigate phishing threats. This provides useful information that will enable organisations to explore various alternatives when conducting workforce security awareness training. Third, existing literature does not provide bases for future researchers to build on in the cybersecurity awareness training sphere [14]. There are state-of-the-art reviews on various aspects of the technical solutions for phishing attack [1,3,6,8,12,19,27-28,36,43]. However, there is no work to the best of our knowledge that has conducted a review of the

Grant no. SAT-2018-3-9-F-7926 from the Deanship of Scientific Research at Northern Border University, Arar, K.S.A.).

literature about cybersecurity awareness training methods. Therefore, this study is useful for future researchers interested in developing human intelligence based anti-phishing countermeasures to combat phishing threats.

This paper is structured as follows: Section 2 presents phishing awareness techniques and the taxonomy of the delivery methods. Comparison of the delivery methods along various factors is also presented. Section 4 presents some open problems for future research. Section 5 discusses the conclusions.

## II. ANTI-PHISHING CYBERSECURITY INTERVENTION PROGRAMS

Cybercriminals are increasingly targeting employees across all sectors to infiltrate corporate networks to steal confidential client data and corporate secrets. Phishing attempts that normally evaded detection by the technical measures put in place are often recognized and reported by employees [11]. Therefore, fortifying end users to defend themselves against phishing threats through cybersecurity intervention program such as phishing awareness training is necessary to thwart phishing attacks.

### A. Cybersecurity Awareness Training

For organisations to ensure that their employees contribute to the enterprise cybersecurity program, employees should be provided with regular cybersecurity training so that they are able to make appropriate choices to prevent or mitigate the risks posed by phishing attacks. The primary aim of the anti-phishing intervention program is to improve cybersecurity awareness and behaviour at workplace by reducing end-user susceptibility to phishing threats.

Therefore, we define cybersecurity awareness training as

‘a proactive measure deployed to combat cybersecurity threats using various delivery methods to raise end-user’s awareness and foster secure behaviour with overall aims of empowering users to recognise and report malicious activities in a timely manner and use best cybersecurity practices in daily routine.’

Anti-phishing cybersecurity intervention program empowers end users and employees to recognize and neutralize phishing cyberattacks. In order for the enterprise cybersecurity intervention program to yield positive awareness and behaviour, employees should be given cybersecurity training intervention on the threats posed by phishing attacks, how to identify phishing attempts such as malicious websites, and how to take the appropriate decisions to prevent or mitigate phishing attacks [16]. Such anti-phishing intervention program will pay dividends to the organisation by protecting businesses from adverse disastrous consequences, which includes data breaches, business continuity issues (e.g., due to ransomware attacks), reputational damages, financial losses and much more. This is confirmed by a recent large-scale study that included various parts of the world (i.e., the UK, France, Germany, Spain, the US, Australia, and Japan) found that about 78% of firms involved in the study indicated that their cybersecurity awareness training resulted in measurable declines in phishing attack vulnerability [35].

There is a general consensus within the existing literature that cybersecurity intervention program can minimize human factors related cybersecurity issues including phishing threats [2,3,8,9,13,15,26,41]. For example, the study by Sheng et al. [41] showed that cybersecurity intervention programs are effective and decreased by 40% the people who enter confidential and sensitive information on fake webpages. Therefore, cybersecurity awareness and training of employees become extremely crucial in keeping enterprises and organizations better protected from phishing attacks. There are a wide range of cybersecurity awareness training intervention programs that train, educate, and persuade end users against phishing attacks. The intervention programs to instil vital security awareness skills and subsequently bring changes in employee cyber behaviours are implemented using different delivery methods. Therefore, for the cybersecurity intervention program to be effective and successful in reducing human factor related security issues, appropriate delivery methods for cybersecurity awareness training intervention programs should be used. In the next section, we propose a new taxonomy of the delivery methods.

### B. Taxonomy of Delivery Methods

Cybersecurity awareness program to raise awareness and educate users on phishing attacks is conducted using one or more delivery methods. There are various types of cybersecurity training and awareness delivery methods. In this section, we discuss the most prominent delivery methods.

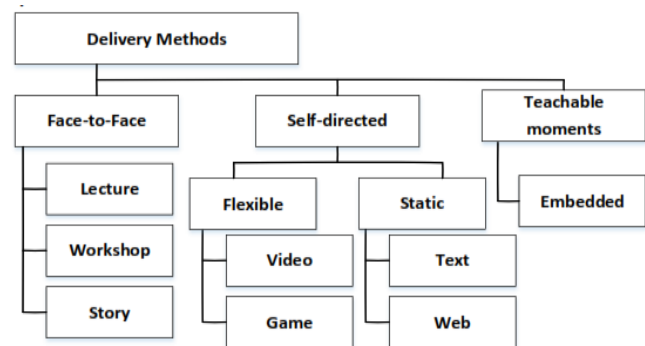

Fig. 1. Taxonomy of Cybersecurity Training Delivery Methods.

Fig. 1 shows the proposed taxonomy of cybersecurity awareness training delivery methods. Basically, we classify the delivery methods into three main classes namely, face-to-face class, self-directed class, and embedded class. The self-directed class of the delivery method is further sub-divided as flexible and static categories. In the following subsections, we describe each in detail.

1) *Face-to-face delivery methods:* The face-to-face cybersecurity intervention program delivery method involves physical learning environment with or without direct involvement of cybersecurity expert as a facilitator. Examples of such delivery methods are a lecture-based, a workshop-based and a story-based delivery method.

a) *Lecture-based delivery method:* Lecture-based cybersecurity intervention program delivery method is one of the most prevalent delivery methods [22,26,42]. The training

primarily consists of formal presentations (i.e., lectures) by an instructor in a classroom setting for a group of participants. The instructor may use power point slides as well as other resources such as audio-visual aids. The lecture is delivered by a security expert (instructor) and requires physical attendance of both the learners and the instructor in the classroom.

Although the knowledge transfer is one way (i.e., from the expert to the learners), it encourages direct interaction between learners and the instructor. Through incorporating group learning activities, it can also enable interaction as well as collaboration among the trainees allowing the learners to learn from each other. It also has the flexibility of providing tailored session to the specific industry or a particular department within a workplace. The learners can ask for further clarifications on concepts that are not clear in the class, and any question and doubt can be addressed immediately during the session.

Lecture-based delivery method is relatively costly as it includes expenses related to hiring the instructor, preparation of the content and the employee time away from their regular jobs. A major challenge of the lecture-based method is ensuring the engagement of the participants and avoiding boredom. This challenge can be easily addressed by initiating short breaks when attendees become distracted or bored and include activities that require the participants apply the concepts covered to their role or quizzes throughout the session.

*b) Workshop-based delivery method:* Workshop-based cybersecurity intervention program emphasises dialogue and plenary reflection with the ideal size of about 15 participants over several plenary discussions [13]. The participants are divided into small groups of individuals. Each group is allotted a timeframe to discuss on a given cybersecurity-related scenario among themselves to create a reflection. This is followed by a plenary discussion where each group presents its possible answer to their scenario and then the other groups were asked to provide their comments on the response provided by the group. Each plenary session is closed by a brief concluding remark of the instructor on the scenario followed by questions or remarks from the workshop participants.

Workshop-based training is similar to the lecture-based training in that it involves an expert and attendees gathered in a workshop venue such as classroom. Unlike the lecture-based program where the expert drives the training, the role and involvement of the expert is restricted mainly to define the workshop topics, develop learning materials needed for the session, manage time, occasionally answering specific questions directed to the expert during the workshop, and ensuring that the workshop discussion remain within the scope of the defined topic. The workshop participants drive the training through dialogue, participation, and collective reflection in small groups [13]. The workshop attendees steer most of the discussions among themselves by actively exchanging their thoughts with each other and the instructor in plenary reflections.

*c) Story-based delivery method:* Story-based cybersecurity awareness uses narrative stories about real-life

cybersecurity events to train employees about security as a relatable experience [30,39]. A personal story narrative may contain information about the approach used by the phisher to deceive the storyteller, the consequences of being phished and what steps to take not to make similar mistakes. Basically, the story-based training explores the intuition that people tend to learn about cyber security by hearing positive and/or negative real stories as well as security warnings from experts/peers.

For example, people who have personally experienced security attacks such as identity theft learn a hard way about security threats and how to better protect themselves against attacks. Wash and Cooper [39] used social stories about prior experience of phishing attacks to train employees in an organisation and tested to see if the employees can recognise and avoid falling victim to phishing attacks. They found that stories are more effective when the learners think that the stories originate from people with similar characteristics.

*2) Self-directed delivery methods:* The cybersecurity awareness training delivery methods within the self-directed category includes the delivery methods that cater to virtual learning environment and learners' self-regulation. It can be divided into two subcategories; one is Flexible category and the other is static category. Examples of self-directed delivery methods include web-based training, text-based, video-based, and game-based approaches.

*a) Video-based delivery:* In the video-based awareness delivery method, a 2-to-5-minute micro-learning style videos used are used for self-directed learning about phishing and how to defend against it. It is a self-paced learning where the learner can pause the video at any time and re-watch it later. The content normally contains real scenarios and examples in the form of clips, animation, and cartoons related to phishing attacks. For example, the phishing awareness video developed by Volkamer et al. [32] includes authentic-looking messages laced with tricks to seduce potential victims to click on a malicious link embedded in the message. The content also includes misconceptions about phishing normally found in the literature and warning messages such as the likely impacts of clicking on a malicious link.

The video used in Tschakert and Ngamsuriyaroj [26] is approximately 2 to 3 minutes and offers a basic overview of phishing, a brief description of the tactics used by phishers to deceive potential victims, the potential impacts, and the possible clues that can be used to recognise dishonest emails and URLs. The videos offer visual learning, which may shorten the time employees require to commit to the training. However, it could be expensive to develop and may be difficult to make the learners engaged in the content [32].

*b) Game-based delivery:* Educational game-based cybersecurity training provides a learning environment coupled with entrainment where employees (as players) learn phishing methods and how to detect them through playing the game. Learning takes place in a virtual environment involving teaching agent (virtual) and the learner (physical). Normally, story-based method in which the story is shown to the learners in a comic format is used. Game flows are structured on

progressive levels normally from basic to advanced levels such that players are required to successfully complete the content at a specific level before they are allowed to proceed further to a higher level. Each level is normally designed with several sequential activities/questions and the players may be forced to complete/answer each activity/question in the sequences program in the game before moving to the next activities/questions. Also, some games have built-in timer to restrict the player to complete a given activity/question within certain period. The side effect of a restriction on game play time is that it can make self-paced learning impossible.

The design's philosophy of exiting game-based cybersecurity delivery methods is summarized in [25]. Game-based training have emerged as a powerful security awareness and training delivery methods resulting in several systems such as Phishy [29], What Hack [44], and NoPhish [18]. Generally, this game-based training software that teaches end-users how to detect phishing URLs using cues, distinguish between fake and genuine sites using cues, and how to decide if a given site is legitimate or not using search engines. Asanka et al. [33] describe a mobile game-based delivery method that teaches people how to identify URL-related phishing threats such that the people who are trained with the game will be able to differentiate malicious websites from genuine ones. Game-based model are highly interactive and engaging medium. Also, it offers visual learning and has inherent option of self-paced, pausing the game and resuming it at any suitable time. A well-designed game-based training delivery method can potentially offer quick learning and proficiency of cybersecurity fundamentals [16].

*c) Text-based delivery:* Text-based training consists of an educational reading material that takes about 15–20 minutes. The reading material is prepared by an expert and distributed to the potential learners to master the content. Generally, the content covers topics such as "look for https", "type in URLs don't click on them", "phishing is your problem; don't rely on others to protect you", and "misspellings can signal fake emails". The content may also include examples and the description of the best security practices. In the basic form of text-based training, the learner is normally provided with a hardcopy of the material used in lecture-based training or text derived from corporate guidelines/warnings usually available on the organisation's website. However, a softcopy text in a form such as PDF require an electronic device with appropriate software (PDF reader). A tool called NoPhish [18] provides text-based delivery capability and commonly used in training [26,42].

Similar to web-based training method, text-based model has inherent option of self-paced, pausing and resuming at any suitable time and studying the material in any order. Although the reading material is expected to take 15–20 minutes of reading time, the trainees can spend as much time as they needed to go through it. Unfortunately, the text-based training is static and not interactive. Also, it does not have the option to provide feedback to the learners. Tschakert et al. [26] and Stockhardt et al. [42] used text-based delivery method for training learners on how to detect phishing emails and fake websites. The lessons cover topics on introduction to phishing,

examples of phishing emails and websites as well as the possible impacts of a successful phishing attack, markers of dishonest emails and URL addresses.

*d) Web-based training:* Web-based delivery methods can be based on anti-phishing contents on websites (basic form) or advanced for, which we refer to as a computer-based training (CBT). In its basic form, web-based training method are freely available online resources that contain facts and advice about phishing threat, various ways to identify it, and what to do to avoid falling prey to phishing scams. Examples of the basic anti-phishing web-based training material include the Anti-Phishing Working Group website (APWG) [5] and Cornell's PhishLine [6] web pages on phishing. CBT version is normally commercially available and is advanced web-based training methods. It is generally interactive, developed on the principles of instructional design and have six basic elements that enable the learner to control his/her learning namely, capability to 'skip, supplement, sequence, pace, practice (for users to assess their understanding of phishing) and guidance identified' [37]. For example, Abraham et al. [40] discusses a web-based training method with topics covering counterfeit webpages and malicious links organized as hyperlinks.

The web-based delivery method enables the learner to schedule the most convenient time to access the content of the awareness training modules, stop at any time and come back to it at a later point of time. The content can be organised in such a way that the trainees could select the topics to learn in any sequence. Normally, web-based method includes quizzes and tests that measure the performance of the trainees and provides direct feedback on the performance of the end users. Similarly, web-based training method allows for interactivity that optimizes the learning experience.

The consistency of the content and the simplicity of use are the virtues of web-based training method. Also, web-based training method is often deemed a cost-effective way of raising employee cybersecurity awareness. Web-based training method does not provide facility for further explanation, may encourage finishing the learning modules with nominal time or diligence, and it may be monotonous and unchallenging [21]. Some of these shortcomings can be addressed by incorporating resources such as visuals and animations into the content. Each learner completes the training modules online individually using desktop computers or hand-held devices (e.g., tablets, iPad, and smartphones).

*3) Teachable moment delivery methods:* This class of awareness delivery methods follows the test-train concept such that only people who fail the test will be trained using other delivery methods such as story-based or text-based methods. An example of this class is the embedded method discussed below.

*a) Embedded delivery method:* The idea of embedded phishing training is to send simulated phishing emails to users, usually without letting them know about it, to test their ability to identify phishing attempt. A user who falls for the simulated phishing attack receives a remedial training about phishing and how to recognize phishing emails immediately (known as

“teachable moments”) following the click on the link. For example, an email with embedded link to an external website is sent to the employees and urged them to click on the link where they would input their login credentials. If an employee acts upon the request and clicks the link in the email, then a remedial training is provided to the employee typically a webpage where training materials are hosted. Following the remedial training, another simulated phishing emails can be used to check if the ability to detect phishing threats have improved or not.

Essentially, embedded training provides continual real time training experience to the employees by embedding the

training into the day-to-day tasks the employees perform [39]. There are many tools such as PhishGuru [34] that provides an embedded training to end-users based on simulated phishing email. It is believed that embedded training can help the learners to retain the learnt knowledge for an extended period as compared to the other methods [34]. However, it can also increase the frequency of the click rate on phishing link by the end users [31].

In Table I, we show a comparative analysis of the delivery methods presented in the previous sections.

TABLE I. COMPARATIVE ANALYSIS OF THE DELIVERY METHODS

	Classroom		Pace		Feedback			Learning			Instructor		Communication			Tracking			Time
	Physical	Virtual	Lecturer	Self	None	Real	Direct	Active	collaborate	Personal	Active	Passive	One-one	One-many	Many-many	Participate	completed	reporting	Minutes
Lecture		×		×	×			×		×		×	×		×			×	30 to 45
Workshop		×		×	×			×		×		×	×					×	30 to 45
Story	×		×	×	×		×		×		×	×		×	×	×	×	×	15 to 20
Text	×		×			×	×		×		×			×	×			×	15 to 20
Web	×		×		×		×		×		×			×	×				15 to 20
Video	×		×			×	×		×		×			×	×				2 to 5
Game	×		×		×		×		×		×			×	×				30
Embedded	×		×	×	×		×		×		×			×	×	×	×	×	15 to 20

### III. OPEN PROBLEMS

There has been ample research in countering phishing threats with emphases on human factor dimension with encouraging results. However, phishing threat prevalence continues and expected to remain significant problem in cybersecurity. In this section, we highlight some of the gaps that need to be closed in the current state-of-the-art phishing studies.

There are still many open problems that need to be researched. First, existing research shows that the approaches proposed so far can reduce significantly click rates down to rates closer to 20% [34,39]. However, this still exposes a substantial number of users susceptible to phishing threats. Therefore, there is still room to improve existing approaches or develop novel approaches to counter phishing attacks. Also, there is very little work in terms of retaining the acquired knowledge. This requires longitudinal study of various delivery methods.

Another area that needs to be explored is the performance of various delivery methods in a multinational environment. This requires investigating how cultural traits manifest themselves in making users susceptible to phishing attacks. There is a gap in clearly identifying what factors are responsible for exactly triggers and when a person is at most vulnerable to phishing attacks. Today, users tend to have multiple emails (e.g., work emails and outside emails such as

Gmail). Some employees forward all their emails to an outside account. How this practice exacerbates the phishing attack needs to be addressed.

The attackers use a variety of persuasive techniques and channels (e.g., email, USB, social networks) to bait users into clicking on malicious links embedded in the emails or obtaining personal information. This raises several research questions. First, how effective the different persuasive techniques are in terms of enticing end users to fall prey for the phishing attacks. This research is necessary for developing an effective anti-phishing solution informed by an in-depth knowledge on the subject of persuasion techniques used by the cybercriminals. Second, how does persuasive techniques and different channels interact with user demographics to facilitate of demographically different people susceptible to phishing attack. Third, one can also consider the effect of the phishing emails content over channels and different persuasive techniques.

Several large-scale users studied in the field is really needed to validate the efficacy of the various delivery methods. Furthermore, game-based cybersecurity training for enterprise-wide users received relatively less attention in the research community. Similarly, studies with respect to the various evasive techniques employed by the cybercriminals and their degree of difficult for the end users to detect phishing threats is another research gap that need to be addressed. The challenges in how to measure the retention rate and motivate behaviour

change needs to be researched. The verdict on whether or not cybersecurity awareness training changes the behaviour of the end users has not resolved yet; finally, how to evidence the need for investment in cybersecurity awareness training.

#### IV. CONCLUSION

Phishing attacks are becoming prevalent and affecting individuals and businesses in all sectors regardless of their sizes causing losses of sensitive data and financial costs. Since phishing are only effective if they are acted upon by the end users, in addition to ensuring that technical countermeasures such as email filters are configured to prevent phishing messages from getting into employee's inbox, equipping employees with the skills necessary to protect themselves and their organization against phishing threats is a key part of a robust cybersecurity program. This paper provides a review of cybersecurity training program delivery methods used by organizations aimed at improving personnel information security awareness and behaviour in the context of phishing training. The paper also presents a description and taxonomy of the most common cybersecurity training delivery methods. Although the exiting research shows that well-crafted end-user cybersecurity awareness and training program can be very effective in minimizing susceptibility to phishing attacks, there are still room for improvement. Moreover, phishing threat remains prevalent and will continue to be a significant problem, thus more research is needed to minimize its impact.

INSIGHT: Centre for Data Analytics, Dublin City University, Dublin 9, Ireland<sup>3</sup>

**Abstract**—Information sharing on social media must be accompanied by attentive behavior so that in a distorted digital environment, users are not rushed and distracted in deciding to share information. The spread of misinformation, especially those related to the COVID-19, can divide and create negative effects of falsehood in society. Individuals can also cause feelings of fear, health anxiety, and confusion in the treatment COVID-19. Although much research has focused on understanding human judgment from a psychological underline, few have addressed the essential issue in the screening phase of what technology can interfere amidst users' attention in sharing information. This research aims to intervene in the user's attention with a visual selective attention approach. This study uses a quantitative method through studies 1 and 2 with pre-and post-intervention experiments. In study 1, we intervened in user decisions and attention by stimulating ten information and misinformation using the Visual Selective Attention System (VSAS) tool. In Study 2, we identified associations of user tendencies in evaluating information using the Implicit Association Test (IAT). The significant results showed that the user's attention and decision behavior improved after using the VSAS. The IAT results show a change in the association of user exposure, where after the intervention using VSAS, users tend not to share misinformation about COVID-19. The results are expected to be the basis for developing social media applications to combat the negative impact of the infodemic COVID-19 misinformation.

**Keywords**—Visual selective attention; COVID-19 misinformation; user attention; information sharing; implicit association test

## I. INTRODUCTION

The disruption of major changes in the digital environment makes social media applications an "omnipresence" in human life. This change also affects the overload of information on the internet. According to Statista [1], there are currently 4.2 billion active users of social media applications, and this number will remain to grow. As a result of this diverse digital environment, users relatively get distracted, primarily when they receive and share information on social media [2]. The behavioral factor of human attention has long been a key factor in science and research that focuses on Human-Computer Interaction (HCI). The study conducted by [3] states that the attention factor's role is essential when users share information on social media. In line with that, recent studies conducted by Gabielkov et al. [4] stated that about 59% of users in Twitter share information without even reading the content first (in

other words, in a hurry and without attentive behavior to share the information they have just received).

Several technological innovations have been developed, one developed by Facebook, which relies on an algorithm to detect false information. However, the approach that relies on robot-based applications needs to be re-examined by carrying out additional "hybrid" integration, specifically considering the psychological factors of human decisions. This is in line with research by [5], where they found that the spread of false information was carried out by humans more than bot-based applications. This shows that the spread of false information on social media requires a lot of collaborative studies and research that can understand human decision factors.

The spread of misinformation, especially regarding COVID-19, can have a multidimensional negative impact on society. These negative impacts include false information about treatment, belief in certain drugs and medical treatments, economic incentive motives for pharmaceutical companies, and polarization of mental exposure [6] and [7]. Furthermore, the destructive impact of spreading COVID-19 misinformation can affect the mitigation process's pace in handling democracy and economic recovery in a country, for example, in expediting the implementation of COVID-19 vaccination to the public.

Several studies from [8] - [10] state that this "visual selective attention" technique can influence user decisions when facing a task. Therefore, in this study, we build a tool with a visual selective attention technique to intervene the user's attention when deciding to share information on social media. In the context of this study, users deal with ten information they receive using the Visual Selective Attention System (VSAS). In each pre-and post-intervention task, the VSAS will stimulate the user with an interface using "spotlight" and "zoom-lens" design techniques [11], where these techniques are a sub-theory of visual selective attention, which has been known to play an important role in decision-making.

In this study, we aim to 1) intervene in user attention using VSAS when they will share misinformation about COVID-19, 2) measure the effectiveness of VSAS in intervening users, 3) measure user association and evaluation when they will share misinformation about COVID-19 using Implicit Association Test (IAT). This paper is divided into six sections. Section 1 contains the introduction. Section 2 contains relevant and related studies. Section 3 contains the methods used in study 1

\*Corresponding Author.

and study 2. Section 4 contains the results of analysis and experiments. Section 5 contains discussions and research limitations, and section 6 contains conclusions.

## II. BACKGROUND WORK

### A. User Attention Factor

The study in [2] shows that one of the key factors underlying why users share misinformation on social media is that users' attention is distracted, and when users do not think critically about the information they receive, they are likely to share the information.

The attention factor is one of the fundamental psychological factors in humans when interacting with their environment. The attention factor is a set of cognitive processes that make a person able to process a set of information in limited conditions either because the capacities of environment or the cognitive state s/he has [12]. From another perspective, the attention factor is related to a person's level of awareness and focus when receiving and confirming information [13].

A study by [14] found that the role of the attention factor is vital in explaining the phenomenon of how users behave in online media. This attention behavior relates to when a user reads tweets, surfs any websites, and accesses e-mails. The study by [15] states that social media designers need to maximize users' level of attention and awareness when accessing the information on social media. For example, design properties that can stimulate user visibility when using social media applications can be shape or pattern components with contrasting color strengths.

### B. The influence of Selective Attention on user Decisions

An example of a concrete concept of selective attention technique is when we get a pop-up message from sending an email. The design of the pop-up message with a "quick display" design can distract us and influence our decision to open the incoming email. This visual selective attention technique was also described by [9] when designing different interfaces in the form of multi-display patterns and locations. This technique can increase the user's attention when searching for information. As for the health and medical aspects, Lopes and Ramos [16] found that selective attention, integrated into the health application interface, showed significant results, particularly increasing user attention in understanding health literacy.

### C. The influence of Social Influences and Epistemic Belief in Sharing Information

According to Chen et al. [17], when sharing information on social media, users are very easily influenced by the social influence factor. For example, if users receive information from related or emotionally close people, they are more likely to trust and re-share the information. This is in line with the study conducted by [18], who found that the effect of self-actualization only appeared when the user focused on close friends (focused on bonding social relationships). Based on this, we then included the narrative stimuli of social influence in pre- and post-intervention sessions using VSAS.

Another psychological factor that can trigger the possibility of sharing information without attention is the epistemic belief factor. A study conducted by Chua and Banerjee [19] stated that epistemic belief factors could influence user decisions to share health rumors online. Users with confidence and experience with certain drugs or medical treatments tend to be easily influenced when processing false health information and are more likely to share it again.

The theoretical basis and the role of the epistemic belief factor align with the Implicit Association Test (IAT) measurement method, where the IAT measures the level of the user's association tendency or exposure to a concept in a person. In this paper context, the user is expected to evaluate the ten-information provided in pre-and post-intervention using VSAS.

## III. METHODS

### A. VSAS Tool

In the VSAS experiment, we conducted pre-and post-intervention sessions for two weeks. Thirty-eight participants joined in this experimental session. Participants (n=38) consisted of 11 females and 27 males with an average age of 20 (SD = 1.11), and all were students. Participants were compensated \$5 for their time. Each experiment section took 1.5 to 2 hours. In the first week, we used VSAS without any design intervention. In the second week, the intervention was carried out using visual selective attention by adding a label design to the ten-information provided to participants. This label design was generated based on credible fact-checking sources. The same ten items of information in weeks 1 and 2 were given to participants, while the content of the information relates to the political, sensational, and sensitive context [20].

We built and designed this VSAS using JAVA programming through the Android Studio 4.1.1 application. The storage media for each response from our participants uses the services of the Firebase Real-Time Database. This VSAS instrument concept is built and designed for mobile-based applications. The layout of the VSAS instrument wireframe design can be seen in Figures 1 and 2.

Fig. 1. Wireframe Design using Spotlight Technique.

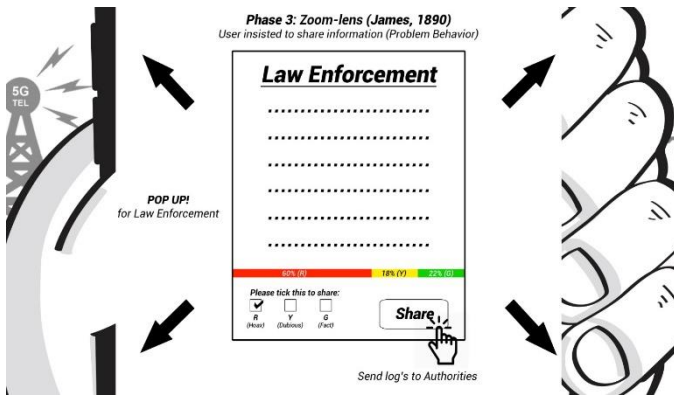

Fig. 2. Wireframe Design using Zoom-Lens Technique.

### B. Procedures

In the first week's session (pre-intervention), each participant registered in advance to communicate with the administrator. After 38 participants were registered and had an account in VSAS, they sent their respective profile and demographic data. Then, administrators sent participants through individual chats of ten information contexts, of which five items were misinformation, and the other five were fact information. Each participant was asked to respond to the chat from the administrator by replying using a Likert-based scale between 1 - 5. Participants will be asked and narrated at each delivery of context information, representing the social influence factor like "if you got this information from your family, would you share it again." To answer these questions, participants replied with the Likert scale between 1 - 5, where "1" indicates strongly disagrees with sharing information, "2" disagrees with sharing information, "3" is neutral, "4" agrees to share information, and "5" for strongly agrees to share information.

After participants responded to ten information contexts in the pre-intervention session, we stored the respondent's data in the Firebase Real-Time Database for tabulation and analysis. After the experiment using VSAS is carried out, the participants will start the Implicit Association Test (IAT) session through the Pavlovla website. The IAT content is related to how participants evaluate "Misinformation vs. Fact Information or Positive vs. Negative Words." In this IAT session (see Figure 3), participants will quickly determine the information according to their respective perceptions. The process of associating factual information and misinformation is combined with the participant's ability to determine "Positive vs. Negative Words."

In the second week session (post-intervention), participants will be sent the same ten contexts of information as in session 1. The difference is that the concept of visual selective attention through spotlight and zoom-lens design techniques has been applied. The attention of participants will be intervening by focusing on the design of the spotlight color bar properties, where red color stimuli indicate the label "hoax," yellow is "dubious," and green is "fact" (see Figure 4).

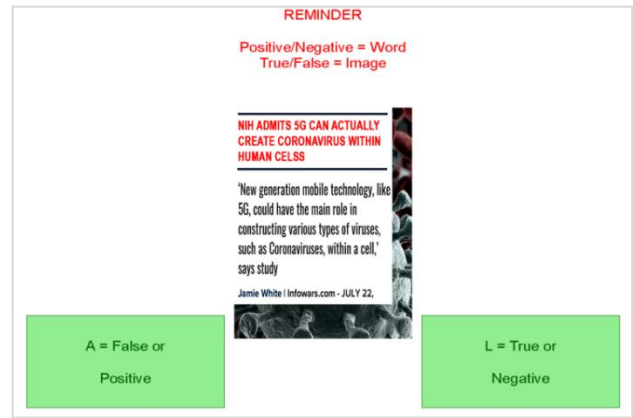

Fig. 3. Example of IAT Test Selection.

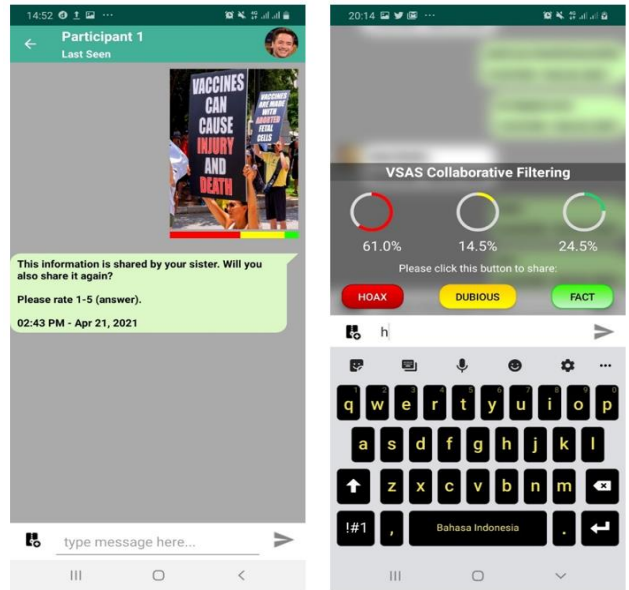

Fig. 4. Intervention Process on VSAS.

The labeling method for each of the ten information contexts is carried out based on fact-checking sources. In this intervention session, participants will also be asked to be involved in providing collaborative corrections. Next, at the last intervention stage, participants will be intervened with pop-up warning notifications in the form of law enforcement. This pop-up law enforcement increases each participant's attention with the "zoom-lens" animation technique. After the post-intervention was completed, participants would start the IAT with the same as the first-week session.

### IV. RESULTS

We summarized using descriptive statistical analysis to briefly examine the pre-and post-intervention results (see Figure 5). After conducting the second-week session (post-intervention), only 23 participants completed the entire VSAS and IAT experimental process, and 15 participants experienced errors. Therefore, we could not analyze the data responses.

Fig. 5. User Response during Post-Intervention.

The significant results in 23 participants in post-intervention showed a behavior change, whereas 15 participants increased their attention and chose to confidently respond with an answer of "1" for each context of the misinformation sent. The results in Figure 6 describe the successions of the VSAS experiments, which is 65.2% of participants strongly disagreed with sharing the misinformation provided.

This result asserts that VSAS has succeeded in intervening in users' attention when they decide to share information. A total of 7 participants, or 30.4%, chose answer "2" where they did not agree to reshare the misinformation they received. A total of 22 participants significantly chose answers in the Likert range of 1-2, especially about the context of misinformation on implementing COVID-19 vaccination. In the descriptive analysis of the post-intervention results using VSAS, we can conclude that most of the participants' decision tendencies are  $Mdn=1$ ,  $IQR=1$ . The results of  $IQR=1$  indicate that the distribution of the participants' median responses at post-intervention also shows a linear result, which has less variability about its median.

Finally, to ensure the success of changing responses and evaluating participants on the IAT, we analyzed the IAT calculations using a D-score. This D-score (see Table 1) is similar to the Cohen's d effect measurement, ranging from -2.00 to 2.00. In detail, the frequency distribution of the D-score category shows as 17 participants in the "Neutral/No Preference" D-Score category, 4 participants in the "Slight negative" D-Score category, and 1 participant in the "Slight positive" D-Score category. Based on these results (see Figure 7), we can state that the use of VSAS can validly improve participant evaluation in the context of measuring the concept of "Misinformation vs. Fact Information or Positive vs. Negative Words."

In the last IAT analysis step, we calculated the correlation between the IAT Score and the MdnScore (Median Score). We then also calculated the percentage weights for each question's score, calculated the variance and the ranking (see Figure 7). The correlation between IAT Score and MdnScore (Median) in sharing misinformation showed a significant moderate positive correlation of  $p = +0.3344$ .

Fig. 6. User Evaluation during Post-Intervention.

TABLE I. DISTRIBUTION OF IMPLICIT SCORES AFTER VSAS

D-score	Category	n	Percent
-2 to -0.65	Strong negative	0	0.0
-0.65 to -0.36	Moderate negative	1	2.6
-0.35 to -0.15	Slight negative	4	10.5
-0.15 to 0.15	Neutral/ No Preference	17	44.7
0.15 to 0.36	Slight positive	1	2.6
0.36 to 0.65	Moderate positive	0	0.0
0.65 to 2	Strong positive	0	0.0
	Missing	15	39.5
<b>Total</b>		<b>38</b>	<b>100.0</b>

Fig. 7. The Correlation between IAT Score and Median in Sharing Misinformation.

## V. DISCUSSION AND LIMITATIONS

The previous two studies have determined relevant attention-based design, including Implicit Association Test principles, later implemented on the Visual Selective Attention System (VSAS) while evaluating information about COVID-19. These findings are useful to inform researchers/designers on design requirements that should consider in developing an attention-based design that significantly influences user

decision on sharing COVID-19 misinformation. This study has also stated that visual techniques have a more optimal role in influencing user behavior and decisions on a task. For this reason, we recommend that this visual technique could be the preference when building a technology related to user behavior in sharing information on social media. Several techniques or designs in building attention-based interfaces need further exploration and adaptation. The stimulant technique using sound or video media and the multiscreen technique might be preferred in future research. This study only carried out VSAS interactions in the distribution of 10 (ten) information contexts and social influence narratives within the scope of "individual chats." In future research, we suggest that the process of sending ten contexts of information and social influence narratives can be carried out within the scope of a "group chat." The point is to determine how different user responses are between in/out-group with the same interests or beliefs. In designing and building VSAS applications, we have limitations in obtaining secondary data in the form of datasets from social media platforms. In future studies, this dataset can be used as a reference and comparison to understand the diffusion process and information dissemination patterns in social media. Knowing this real-world situation will enhance an entire perspective in developing VSAS applications.

## VI. CONCLUSION AND FUTURE WORK

Based on the results of this study, we conclude that VSAS can increase attentive behavior when deciding to share misinformation about COVID-19. The future development of VSAS requires a more extensive study of understanding other psychological factors that influence user attention when deciding to share information. The results of this study can be the basis for developing social media applications that can be used in a wider domain, not only in the context of the COVID-19 issue, but also in the context of other domains such as security issues, handling disaster mitigation, and others, especially in communication management in handling crisis.

In future research, it is necessary to have categories of participants with different and diverse demographic backgrounds. This aims to enrich the experimental results and develop the features in VSAS, especially in selecting intervention techniques to be carried out. Research collaboration is needed to understand the essence of other key psychological concepts related to attentional behavioral factors in sharing information on social media. Meanwhile, to measure in detail, future research needs to consider how to measure the "attention span" aspect and its relationship with a person's critical thinking ability. This is important so that further research can know the intervention's effectiveness precisely and then will be able to answer the challenge of how quickly the intervention process can be carried out in the context of user interaction when sharing information. The research results reported in this study ultimately clearly show that the VSAS system has succeeded in changing user behavior in deciding whether to share information, in line with the IAT results, which show significant changes in user tendencies while evaluating information about COVID-19.

## ACKNOWLEDGMENT

This work was supported by the Universiti Kebangsaan Malaysia research grant under Grant GPK-4IR-2020-019.

AUTHOR'S PROFILE

ZAID AMIN is currently pursuing the Ph.D. degree with the Institute of IR4.0, Universiti Kebangsaan Malaysia. He is currently a Lecturer with the Faculty of Computer Science, Universitas Bina Darma, Indonesia. He is very enthusiastic about human-computer interaction. His research interests include interaction design, UI/UX, persuasive technology, and social computing

NAZLENA MOHAMAD ALI received the Ph.D. degree in human-computer interaction from Dublin City University, Ireland, in 2009. She is currently an Associate Professor and a Senior Research Fellow with the Institute of IR4.0, Universiti Kebangsaan Malaysia. Her research interests include interaction design, UI/UX, persuasive technology, digital games, and user engagement.

ALAN F. SMEATON (Fellow, IEEE) is currently a Professor of computing and the Former Director of the Insight-Centre for Data Analytics, Dublin City University. His research interests include human memory, why we forget some things and not others, and how we can use technology like search systems, to compensate for when we do forget. He was the winner of the Royal Irish Academy Gold Medal for Engineering Sciences, in 2015. He is the Chair of ACM SIGMM and an IEEE Fellow.

# Head Position and Pose Model and Method for Head Pose Angle Estimation based on Convolution Neural Network

Kohei Arai, Akifumi Yamashita, Hiroshi Okumura

Faculty of Science and Engineering, Saga University, Saga City, Japan

**Abstract**—Head position and pose model is created. Also, a method for head poses angle estimation based on Convolution Neural Network (CNN) is proposed. 3D head position model is created from these locations and obtain 3D coordinate of head position. The method proposed here uses CNN. As for the head pose detection, OpenCV and Dlib of the open-source software tools are used with Python program. The images used were RGB images, RGB images + thermography, grayscale images, and RGB images assuming images obtained by near infrared rays, with only the red channel elements extracted. As a result, the RGB image model was the most accurate, but considering the criteria set, the RGB image model was used for morning and daytime detection, and the near-infrared image was used for nighttime and rainy weather scenes. It turned out that it is better to use the model obtained by the training in. The experimental results show almost perfect head pose detection performance when the head pose angle ranges from 0 to 180 degrees with 45 degrees steps.

**Keywords**—CNN; head pose; OpenCV; Dlib; open-source software; python

## I. INTRODUCTION

Head movement detection has received significant attention in recent research. One of the specific purposes for head movement detection and tracking is to allow the user to interact with a computer or new devices like mobile phone. The increased popularity of the wide range of applications of which head movement detection is a part, such as assistive technology, virtual reality, and augmented reality, have increased the size of research aiming to provide robust and effective techniques of real-time head movement detection and tracking [1].

Most of the head pose estimation method is based on computer vision approach, like [2], [3]. Liu et al. [2] introduced a video-based technique for estimating the head pose and used it in an image processing application for a real-world problem; and attention recognition for drivers. Murphy-Chutorian and Trivedi presented a static head pose estimation algorithm and a visual 3-D tracking algorithm based on image processing and pattern recognition<sup>1</sup>. Kupetz et al. [3] implemented a head movement tracking system using an IR camera and IR LEDs.

Another approach for head movement detection is by using sensors such as gyroscopes and accelerometers. King et al. [4] implemented a hands-free head movement classification system which uses pattern recognition techniques with

mathematical solutions for enhancement. A dual axis accelerometer mounted inside a hat was used to collect head movement data. A similar method was presented by Nguyen et al. [5]. The method detects the movement of a user's head by analyzing data collected from a dual-axis accelerometer and pattern recognition techniques. But still no application based on the proposed method was suggested. Other sensor-based approaches are like [6], [7]. However, it needs more theoretical proofs and more experiments and accuracy analysis.

A combination of different techniques can be used in head tracking systems. Satoh et al. [8] proposed a head tracking method that uses a gyroscope mounted on a head mounted device (HMD) and a fixed bird's-eye view camera responsible for observing the HMD from a third person viewpoint.

In our previous research work, we propose head movement detection and tracking as a controller for 3D object scene view [9] and the combination of user's head and body movement as a controller for virtual reality labyrinth game [10]. One of the problems of the previous method for head pose angle estimation is week accuracy.

In this paper, 3D head position model is created from these locations and obtain 3D coordinate of head position. Then, the method proposed here uses Convolutional Neural Network (CNN) in order to improve head pose angle estimation accuracy. As for the head pose detection, OpenCV and Dlib<sup>2</sup> of the open-source software tools are used with Python program. The experimental results show almost perfect head pose detection performance when the head pose angle ranges from 0 to 180 degrees with 45 degrees steps.

The following section describes related research works followed by the proposed method. Then experiments are described followed by conclusion with some discussions and remarks.

## II. RELATED RESEARCH WORK

Computer input just by sight, human eyes only require head pose detection and head pose angle estimation.

Communication aid and computer input system with human eyes only is proposed [11]. Meanwhile, computer input by human eyes only and its applications are presented [12]. On the other hand, electric wheelchair control with gaze detection and

<sup>1</sup> <http://dx.doi.org/10.1109/TITS.2010.2044241>

<sup>2</sup> <http://dlib.net/>

eye blinking is proposed [13] together with electric wheelchair control with gaze detection and eye blinking [14].

Computer input with human eyes only using two Purkinje images which works in a real time basis without calibration is proposed [15]. Meanwhile, a prototype of electric wheelchair control by eye only for paralyzed use is created [16].

Robot arm utilized having meal support system based on computer input by human eyes only is also proposed and developed [17]. Also, a prototype of electric wheelchair controlled by eyes only for paralyzed users is created [18].

Autonomous control of eye based electric wheelchair with obstacle avoidance and shortest path finding based on Dijkstra algorithm, is attempted [19]. Meantime, eye-based human-computer interaction allowing phoning, reading e-book/e-comic/e-learning is created [20] together with eye based electric wheelchair control system-I(eye) can control EWC (Electric Wheelchair) [21].

Evaluation of users' impact for using the proposed eye based HCI: Human-Computer Interaction with moving and fixed keyboard by using EEG signals is conducted [22] together with electric wheelchair controlled by human eyes only with obstacle avoidance [23]. Also, evaluation of users' impact for using the proposed eye based HCI with moving and fixed keyboard by using EEG (Electroencephalography) signals is proposed with experimental validations [24].

Electric wheelchair controlled by human eyes only with obstacle avoidance is proposed and created [25] together with eye based HCI, a new keyboard for improving accuracy and minimizing fatigue effect [26].

Moving keyboard for eye based HCI is proposed [27]. Also, eye-based domestic robot allowing patient to be self-services and communications remotely is proposed and created [28].

Method for psychological status estimation by gaze location monitoring using eye based HCI is created and proposed [29]. Meanwhile, method for psychological status monitoring with line-of-sight vector changes (Human eyes movements) detected with wearing glass is proposed [30].

Wearable computing system with input output devices based on eye based HCI allowing location-based web services is proposed and realized [31]. Meanwhile, speed and vibration performance as well as obstacle avoidance performance of electric wheelchair controlled by human eyes only is evaluated [32] together with speed and vibration performance as well as obstacle avoidance performance of electric wheelchair controlled by human eyes only [33].

Service robot with communication aid together with routing controlled by human eyes is created [34]. On the other hand, information collection service system by human eyes for disabled persons is proposed [35]. Meanwhile, relations between psychological status and eye movements are investigated [36].

Method for 3D image representation with reducing the number of frames based on characteristics of human eyes is proposed [37]. Also, error analysis of line-of-sight estimation

using Purkinje images for Eye-Based Human Computer Interaction: EBHCI is proposed [38].

Mobile phone operations using human eyes only and its applications are created [39]. Meanwhile, method for thermal pain level prediction with eye motion using Support Vector Machine: SVM is proposed [40]. On the other hand, pedestrian safety with eye contact between autonomous car and pedestrian is proposed [41].

### III. 3D HEAD POSITION AND POSE MODEL

#### A. 3D Head Pose Model

In 3D head pose model is used to convert 2D face features into 3D head pose. The face features such as eyes, eyebrows, nose, and mouth are used. Head are modeled into 3 planar: XY, XZ, and YZ planar. Head pose is shown as rotation degree value ( $\theta$ ) of each planar. By using this model, 3D head pose is expected can be able to calculate only using 2D image. Head pose result is shown as  $\theta(x, y, z)$ .

Fig. 1 show head pose model on each planar. On Fig. 1(a), it shows head pose model on XY planar which look at face on front side. Central axis is assumed on bellow of mouth. When head is rotate, face features position will move follow their rotation against central axis. The new position of face features determines as  $R_i < \theta_i$ , where R is face feature radial and  $\theta$  is rotation angle. On Fig. 1(b), it shows head pose model on XY planar which look at lateral view.

Assume one of face feature has location  $P(x, y)$ , radial R, initial angle  $\theta_0$ , and central axis O (0, 0). If  $P(x, y)$  rotate against central axis, new point  $P_1(x_1, y_1)$  will be obtained. Both values can obtain rotation angle value. Rotation angle is calculated using equation (1).

$$\theta_{xy} = \tan^{-1} \left[ \frac{x'}{y'} \right] - \tan^{-1} \left[ \frac{x}{y} \right] \quad (1)$$

The same way, we also can calculate it for YZ and XZ planar using rotation radial of head. By assume rotation radial value, rotation angle for each planar will be known.

$$\theta_{yz} = \sin^{-1} \left[ \frac{y'}{R} \right] - \sin^{-1} \left[ \frac{y}{R} \right] \quad (2)$$

$$\theta_{xz} = \sin^{-1} \left[ \frac{x'}{R} \right] - \sin^{-1} \left[ \frac{x}{R} \right] \quad (3)$$

In a real condition, all information is shown on pixel coordinate. Therefore central axis will has  $O(x, y)$  coordinate and face feature will have  $P_i(x, y)$ . We can directly convert from pixel coordinate into rotation angle based on equation (2).

$$\theta_{xy} = \tan^{-1} \left[ \frac{O_x - P_x'}{O_y - P_y'} \right] - \tan^{-1} \left[ \frac{O_x - P_x}{O_y - P_y} \right] \quad (4)$$

$$\theta_{yz} = \sin^{-1} \left[ \frac{O_y - P_y'}{R} \right] - \sin^{-1} \left[ \frac{O_y - P_y}{R} \right] \quad (5)$$

$$\theta_{xz} = \sin^{-1} \left[ \frac{P_x' - O_x'}{R} \right] - \sin^{-1} \left[ \frac{P_x - O_x}{R} \right] \quad (6)$$

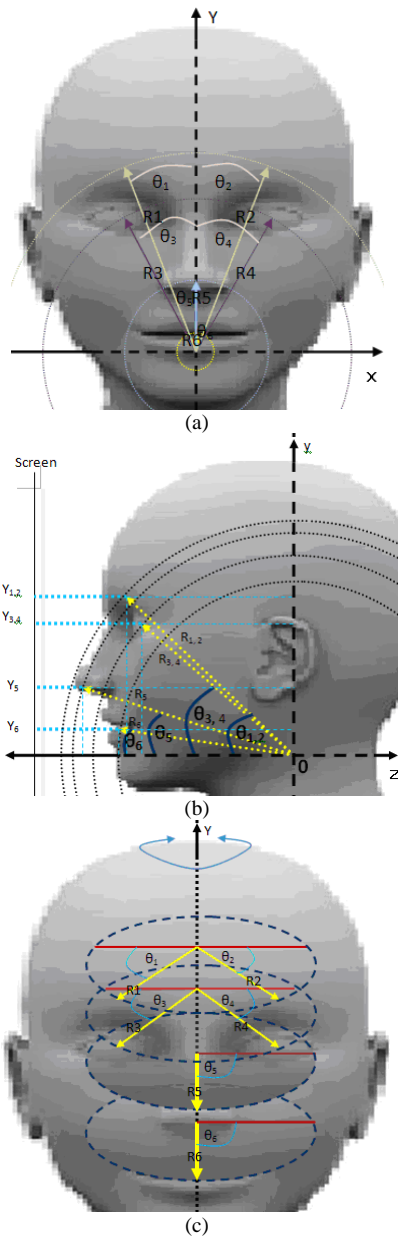

Fig. 1. 3D Head Model, (a) is Model on XY Planar, (b) is Model on YZ Planar, and (c) is Model on XZ Planar.

#### IV. PROPOSED METHOD

##### A. Head Pose Detection Overview

This section proposes a method for estimating the head posture of a pedestrian. Normally, on a road without a pedestrian crossing, when a pedestrian and a car driven by a person are close to each other, they exchange their intentions through nonverbal communication to ensure safe and secure traffic. However, in the case of an autonomous vehicle in which a person does not intervene in the operation, communication cannot be performed, and the following behavior cannot be assumed. As a result, it is easy to imagine that many people will be worried about autonomous vehicles running on the road and will feel uneasy when crossing the road.

OpenCV is an open-source computer vision and machine learning software library. It has C / C++, Python, Java, and MATLAB interfaces, and supports Windows, Linux, Android, and Mac OS. The library has over 2500 computer vision and machine learning algorithms. These are face detection and recognition, object identification, classification of human behavior in video, camera movement tracking, moving object tracking, 3D model extraction of objects, 3D point group generation from stereo cameras, image composition, scenes. It can be used to generate an entire high-resolution image, search for similar images from an image database, remove red eyes from images using a flash, and track eye movements. OpenCV is widely used by businesses, research groups and government agencies.

Dlib is an open-source software library written in C++. It is used in a wide range of fields such as robotics, embedded devices, mobile phones, and large-scale high-performance computing environments. In recent years, components for processing in a wide range of fields such as GUI (Graphical User Interface), machine learning, image processing, data mining, mathematical optimization, and Bayesian networks have been developed.

##### B. Representation of 3D Objects

A three-dimensional object with respect to a camera can be represented by the following two actions,

- 1) Translation: Moving the camera from one 3D position (X, Y, Z) to a new 3D position (X', Y', Z'). There are 3 degrees of freedom in movement, and it can move in the "X, Y, Z" directions.
- 2) Rotation: The camera can be rotated around the "X, Y, Z" axes. Rotation can be expressed by Euler angles (roll, pitch, yaw). In other words, it is possible to estimate the posture in three dimensions by finding three translations and rotations.

Fig. 2 shows an example of 3D representation of the face. Also, Fig. 3 shows the coordinate system conversion among the camera, the image (camera) and the world coordinate systems.

The coordinates of facial features shown in three dimensions are expressed in world coordinates. Three coordinate systems are used to estimate the attitude. If the attitude can be obtained, it will be possible to convert the 3D point in world coordinates to the 3D point in camera coordinates. The 3D points of the camera coordinates can be projected onto the image plane using camera-specific parameters such as focal length and lens distortion.

Fig. 2. 3D Mapping of the Face.

Fig. 3. Coordinate System Conversion.

Let the coordinate system fixed to the camera be  $(X, Y, Z)$ , the coordinate system fixed to the human head be  $(U, V, W)$ ,  $R$  be the rotation matrix, and  $t$  be the translation vector. The point  $P$  seen from the coordinate system fixed to the camera is expressed as follows.

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = R \begin{bmatrix} U \\ V \\ W \end{bmatrix} + t \quad (7)$$

Expressing this as an in-order transformation matrix, Eq. (8) is obtained.

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = [R|t] \begin{bmatrix} U \\ V \\ W \\ 1 \end{bmatrix} \quad (8)$$

If the camera-specific parameters are known and the scale factor is  $s$ , then Eq. (9) is obtained.

$$\begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = s \begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} \quad (9)$$

The relationship between  $(x, y)$  and  $(X, Y, Z)$  can be expressed. Using this relationship, if  $R$  and  $t$  can be derived so that the error between the point  $p'$  that will be projected on the two-dimensional plane and the point  $p$  that is actually projected can be minimized, the attitude estimation will be performed.

### C. Head Pose Detection based on CNN

In the head posture estimation based on deep learning in image recognition, the angle of the face is divided into 45 degrees in the left-right direction as shown in Fig. 4, and the face faces at 90 degrees, 45 degrees, 0 degrees, -45 degrees, and -90 degrees. Also, Fig. 5 shows the definition of the head pose angle (the geometric relation between the car and the pedestrian).

Preliminary experiments have shown that it is difficult to discriminate even the finest angles of the face. For example, even if two images with only one degree difference in face angle are given, it is difficult to distinguish them because there is no difference in features between the two images. Moreover, in this study, it is only necessary to be able to grasp a rough angle, so we could not find the need to discriminate even a fine angle. Therefore, classification is performed in 5 classes of 90 degrees, 45 degrees, 0 degrees, -45 degrees, and -90 degrees.

Fig. 4. Examples of Head Pose with the different Pose Angles.

Fig. 5. Definition of the Head Pose Angle (the Geometric Relation between the Car and the Pedestrian).

The angle is based on the line of sight between the car and the pedestrian. The model used is a convolutional neural network (CNN). CNN is a forward propagation network that includes a convolution layer and a pooling layer. A learning method often used for image recognition and natural language processing.

### D. Face Detection with Dlib

A trained model distributed by Dlib is used to detect facial feature points. As shown in Fig. 6, 68 feature points could be detected, and 6 of them (nose tip, chin, left end of left eye, right end of right eye, left corner of mouth, right corner of mouth) were used for head posture estimation.

Fig. 6. Face Detection with Dlib.

## V. EXPERIMENTS

### A. Head Pose Detection

The camera used in the experiment was an HD (High Definition) webcam (manufactured by Sony Corporation) equipped with an "Exmor R for PC" CMOS (Complementary Metal Oxide Semiconductor) sensor, and the frame rate was 15 [fps]. The PC specifications for running this program are OS: Windows10 (64bit), CPU: Intel Core i5-5275U, and memory: 8.00GB.

The state of estimation is as shown in the figure below. Fig. 7 shows the coordinate system fixed to the head, which uses the rotation of the three axes to represent the angle. In addition, the estimation result expresses a three-dimensional view of the face with a green cube so that it is easy to understand visually, and as the estimation result, the angle of the face can be calculated accurately to a fine value. It was a good result.

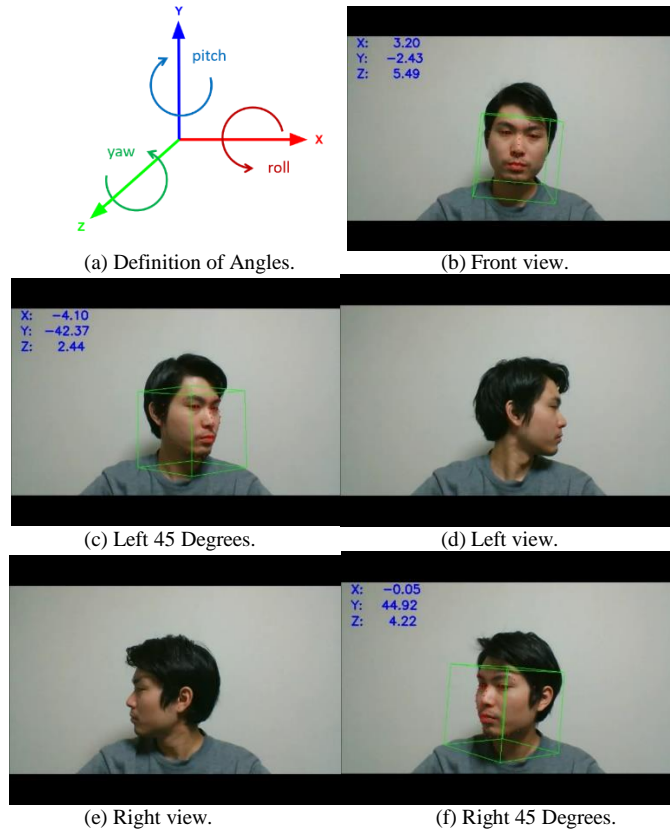

Fig. 7. Results from Head Pose Angle Detection.

### B. Head Pose Angle Detection

The verification experiment of head posture estimation and its result are described. The image used was Head Pose Image Database [23]. In the experiment, the data used was divided

Fig. 9. CNN used.

into four patterns (RGB, RGB + thermography, grayscale image, RGB image assuming an image obtained by near infrared rays, and only the red channel element was extracted), and the accuracy was compared. Classify into five classes of 90 degrees, 45 degrees, 0 degrees, -45 degrees, and -90 degrees, respectively. The evaluation criteria for the classification results are set as shown in Fig. 8.

In the Fig. 8, marks are shown as follows:

⊙: Angle estimation was successful. The only thing left is how to respond (deceleration, warning).

○: Angle estimation failed, but within the permissible range. Correspondence is the same as ⊙ and there is no problem.

△: Angle estimation failed. There is a car approaching the pedestrian's field of view, but it may not be recognized, so safety first (not visible) is taken into consideration. Therefore, there is no problem in the end.

□: Angle estimation failed. However, as with △, safety first is taken as a result, so there is no problem in the end.

×: Angle estimation failed. Even though there are no approaching cars in the field of view of pedestrians, there is a possibility of taking dangerous measures.

Designated Angle	90°	⊙	○	△	□	□
	45°	○	⊙	△	□	□
	0°	△	△	⊙	□	□
	-45°	×	×	□	⊙	○
	-90°	×	×	□	○	⊙
	Estimated Angle	90°	45°	0°	-45°	-90°

Fig. 8. Evaluation Criteria.

In this study, we do not consider the actual response method that the automobile side will take after the estimation. The structure of the convolutional neural network was generated using an open-source Python implementation known as ConvNet Drawer<sup>3</sup>. Fig. 9 shows the CNN structure used.

C. Head Pose Detection Performance

There are three cameras, visible, NIR (Near Infrared) and thermal cameras for acquisition of face images. The purpose of this study is to detect head pose in all weather condition and in day and night-time condition. Therefore, the aforementioned three cameras are considered. As for the number of images of training data for learning process of CNN and the number of images for performance evaluation, Table I shows the numbers for each designated head pose angle for visible, NIR and thermal cameras while, Table II shows these numbers for visible and thermal cameras. In the later case, both of visible and thermal camera data are used together for training and performance evaluation.

The results using RGB images are shown in Fig. 10(a). The number of data used was 480, and the ratio of training data to verification data was 4:1. The facial images used for each class are data for 15 people. Most of the classified results were successful angle estimation for RGB images. Although there are parts where estimation fails in three places, we were able to create a model with high accuracy and no problems because it corresponds to the evaluation standard ○.

The number of data used was 480 RGB images and 160 thermography. The ratio of RGB images of each class to thermography is 3:1.

TABLE I. THE NUMBER OF IMAGES OF TRAINING DATA FOR LEARNING PROCESS OF CNN AND THE NUMBER OF IMAGES FOR PERFORMANCE EVALUATION FOR VISIBLE, NIR AND THERMAL CAMERAS

Head pose angle	No. of training data	No. of test data	Total
90°	72	18	90
45°	72	18	90
0°	90	30	120
-45°	72	18	90
-90°	72	18	90
Total	378	102	480

TABLE II. THE NUMBER OF IMAGES OF TRAINING DATA FOR LEARNING PROCESS OF CNN AND THE NUMBER OF IMAGES FOR PERFORMANCE EVALUATION FOR BOTH VISIBLE AND THERMAL CAMERAS

Head pose angle	No. of training data	No. of test data	Total
90°	96	24	120
45°	96	24	120
0°	120	30	160
-45°	96	24	120
-90°	96	24	120
Total	512	128	640

In the classification results, erroneous estimation was found in the parts corresponding to △ and □. Although there is no erroneous estimation at the point x, it can be said that the accuracy is lower than the result of only RGB images, which are all within the permissible range. In addition, although it was within the permissible range, there were many false estimates at 90 degrees and 45 degrees as shown in Fig. 10(b).

The data used is a grayscale version of all 480 images used in the experiment using only RGB images.

The results were predicted to some extent, but they were the worst compared to the experimental results of the other three patterns as shown in Fig. 10(c).

This is thought to be due to the fact that grayscale images have less information than RGB images.

As the amount of information is reduced, it becomes difficult to capture the features. The results of using only the image obtained by extracting only the red channel elements from the RGB image assuming the image obtained by near infrared rays are described.

The data used is only the red channel elements extracted from all 480 images used in the experiment using only RGB images. Originally, the image actually taken by the near-infrared camera should be used, but since there is no equipment, the simulation was performed in this way. By extracting only, the elements of the red channel from the RGB image, information on short wavelengths can be dropped, so we decided to regard the image used this time as an image obtained by shooting with a near-infrared camera.

Most of the classification results were successful angle estimation. Although there was an erroneous estimation outside the permissible range at only one location, the accuracy was second only to the result using only RGB images as shown in Fig. 10(d).

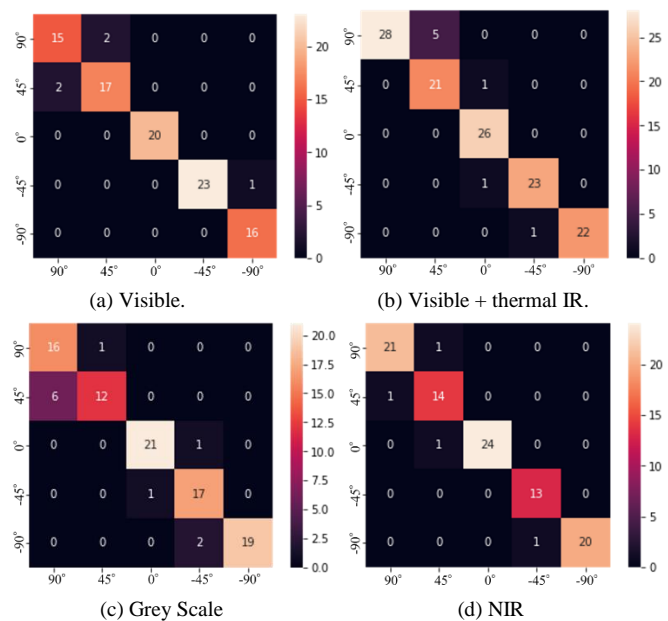

Fig. 10. Results from the Head Pose Detection Performance.

<sup>3</sup> <https://github.com/yu4u/convnet-drawer>,

In the head posture estimation using the feature points, even if the machine used has low specifications, the program can be processed with almost no delay, and the angle can be calculated with high accuracy. However, it did not work when the feature points were turned in a hidden direction, resulting in a disappointing result. If the angle can be calculated using the feature points on only one side of the face, it may be possible to handle it even when facing sideways.

In head posture estimation using deep learning, we conducted experiments with four patterns and classified angles. The order of accuracy was 1) RGB image, 2) Near infrared ray (red channel), 3) RGB image and thermography, and 4) Gray scale. From this result, it is considered better to use a normal camera for estimation in bright hours such as morning and noon. At night or in poor visibility, it is better to irradiate the front of the vehicle with near-infrared rays to make estimation, although the accuracy will be slightly lower. In addition, since automobiles usually illuminate headlights at night, we think that it may be possible to clearly capture pedestrians in combination with near infrared rays.

## VI. CONCLUSION

In this study, we proposed a method for estimating the head posture of a pedestrian and conducted a verification experiment in order for the autonomous vehicle to make contact with the pedestrian. Although the facial feature points could be detected in detail by the method using facial feature points, the necessary feature points could not be extracted when facing sideways, so angle classification was performed using a convolutional neural network.

The images used were RGB images, RGB images + thermography, grayscale images, and RGB images assuming images obtained by near infrared rays, with only the red channel elements extracted.

As a result, the RGB image model was the most accurate, but considering the criteria set, the RGB image model was used for morning and daytime detection, and the near-infrared image was used for nighttime and rainy weather scenes. It turned out that it is better to use the model obtained by the training in.

## VII. FUTURE RESEARCH WORKS

As a future task, we would like to create a mechanism to feed back the cognitive status to pedestrians. In addition, we would like to verify whether this system can behave in the same way as a human-driven vehicle and a pedestrian when this system is installed in an actual autonomous driving vehicle.

## ACKNOWLEDGMENT

The author would like to thank Professor Dr. Osamu Fukuda for their valuable discussions.

**Kohei Arai**, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 620 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>.

# Introduction to NFTs: The Future of Digital Collectibles

Muddasar Ali, Sikha Bagui  
Department of Computer Science  
University of West Florida, Pensacola, FL 32514

**Abstract**—This paper commences by introducing the essentials of blockchain technology and then goes into how Ethereum blockchain revolutionized blockchain. Smart contracts are presented in the context of showing how they play an important role in implementing rules regarding the Ethereum blockchain, allowing the user to regulate digital assets. The standards used in the Ethereum blockchain to build Non-Fungible Tokens (NFTs) are discussed. The paper concludes by presenting the benefits of NFTs as well as the use of Ethereum blockchain for future applications.

**Keywords**—Blockchain technologies; smart contracts; cryptocurrencies; ethereum; non-fungible tokens (NFTs)

## I. INTRODUCTION: WHAT IS BLOCKCHAIN TECHNOLOGY?

Blockchain technology, considered to be one of the most secure technologies to keep data safe, is constructed on blocks of data. Blockchain technology is fast, public, cheap, easy to use, transparent and programmable technology that allows for the transfer of information and/or financial assets instantaneously from one part of the world to another. It is a protocol that governs the rules and regulations for value exchange. Blockchain technology can contain any type of information and the link between each block and the next is called a chain because the blocks are connected in a way that cannot be altered [1]. Blockchain also enables users to safely transfer values globally. The safety comes from the fact that once the information is recorded in the blockchain, it becomes infeasible to alter it. This feature is called immutability [2]. This is especially important for storing bank records or transactions. The safety of this technology is based on the characteristics of the chains between the blocks. A new block is added to the chain by calculating the hash of the previous block and using that as part of the data for the next block [3].

To understand how the blockchain technology works, one needs to first understand what is stored in a single block. Each block contains three types of information, the data, its hash, and a pointer to the hash of the previous block. And each application of blockchain technology can have its own type of data that is completely different from all other applications. For example, bitcoin stores information about the transactions of bitcoins, such as the sender, the receiver, and the amount of bitcoin that is transferred. The hash of the block is a unique identifier for the block. Each block's hash will be different based on the data that is stored in it, so if the data gets changed the hash also changes. The addition of the previous block's hash is the main reason behind the success of blockchain technology and this is also why the alteration of data stored in

the blockchain becomes infeasible. And this is what makes it reliable to store any kind of information that needs to be kept safe. If one wants to alter the blockchain by changing the information stored in a block, this will also lead to a change in the hash of the block, which will consequently not match with the hash that is in its next block, causing a chain reaction. So, any alteration in a single block will invalidate the whole blockchain [3].

Even though blockchain technology is not totally new, its implementations are still in their early stages, and it is for this reason that many people struggle to understand the real use of blockchain technology. For some time, its implementation seemed limited to cryptocurrencies but there is much more to where this technology can be applied and in today's world. We constantly see new applications based on blockchain technology and we will get more familiar with them as they become part of our daily lives.

Blockchain technology has the potential to upgrade any system that requires a third-party regulatory authority that serves to define the authenticity of any changes that will take place in the system. More specifically, the technology can replace the authority decentralizing the authenticity process to every member that is present in the organization. One of the most widely known applications of blockchain technology is proposed by the Bitcoin whitepaper published in 2008 [4]. This work introduced the concept of cryptocurrencies or electronic cash that would be transferred without going through a financial institution. A digital ledger was introduced that would be distributed to every node present in the blockchain to keep track of all the transactions that were taking place in an organization. The development of bitcoin has radically changed the concept of money and currency [4]. Bitcoin is the first-ever form of a digital asset or money that not only has no backing or intrinsic value but also no centralized issuer or controller. It is decentralized. While its introduction is proof of the potential of blockchain technology, the fact that it is used as a distributed tool has attracted even more attention and has inspired more applications of blockchain technology. Colored coins [5] also use blockchain digital assets to represent custom currencies and financial instruments; Smart Property represents the ownership of an underlying physical device, NameCoin [6]. NameCoin also represents non-fungible assets such as domain names. Complex applications rely on digital currency or assets as being directly controlled by pre-programmed code with functionalities, enabling the implementation of Smart Contracts [7]. Hence a turning point in blockchain technology took place with the introduction of Ethereum in 2014 [8]. This is where

the nodes were not only keeping track of the transactions, but they could also program and execute software, hence taking the name of smart contracts. Being able to write specific instructions atop Ethereum's digital protocol makes it more resourceful for many more applications.

With this introduction to blockchain technologies, next this paper goes into how Ethereum blockchain revolutionized blockchain. Smart contracts are presented in the context of showing how they play an important role in implementing rules regarding the Ethereum blockchain, allowing the user to regulate digital assets. The standards used in the Ethereum blockchain to build Non-Fungible Tokens (NFTs) are discussed. The paper concludes by presenting the benefits of NFTs as well as the use of Ethereum blockchain for future applications.

## II. ETHEREUM BLOCKCHAIN

Transactions in bitcoin are based on who is moving money to whom and how much. But it is also important to know how much money is present in the network. For this, there must be a database storing how much money can be spent and how much money can be moved. There must also be a centralized environment with centralized authority that has access to this database where the amounts are registered. But what if we want a decentralized environment, which is the basic spirit behind blockchain technologies and more specifically, is the most important factor that made bitcoin blockchain famous [bitcoin-cash]. Nakamoto's solution [4] is the most basic and practical solution in this open permission-less context. To extend the concept of decentralization and make it accessible to any type of application, the Ethereum blockchain provides simple features. Ethereum, by its founder and inventor Vitalik Buterin [8], is described to be based on a concept of crypto-economics. Ethereum is a combination of major concepts of cryptography and economics. Concepts like hashing and digital signatures used in cryptographic algorithms, and the economic incentives that keep systems like bitcoins going, are used to create decentralized networks with memory [8]. This means that not only the network but also the database will be decentralized. This was considered a breakthrough in blockchain technology as it helped to break new ground in the areas of application of the technology [9]. This was a broader view of how blockchain could be applied, greatly improving the concept of peer-to-peer digital currency transactions. Many different applications were introduced. The first one was NameCoin [6] which was based on bitcoin technology and provided a peer-to-peer decentralized DNS service.

Using this new concept, many different applications can be decentralized. Many other digital assets can be created. But a problem arises when we want to apply this concept for each digital asset and create a different system for every type of service to be developed on the blockchain. This will end up in there being too many services running separately and keeping track of all of them would become tedious; hence the idea behind creating Ethereum. Ethereum is a single general purpose blockchain that can have different types of applications running on it [8]. This blockchain will not have specific rules for transactions for each type of application but will have general rules and access to a general-purpose

programming language. Hence Ethereum gives the freedom to build and run applications on the blockchain. Though Ethereum offers this flexibility where a broad range of applications can be built, the main categories of applications still remain related to currencies, mainly due to the fact that the main aspects of a blockchain are decentralization and shared memory, making it suitable for cryptocurrencies.

An Ethereum blockchain state is composed of accounts, which actually are objects. These accounts have a 20-byte address. The blockchain state transitions when there are direct transfers of value and information between accounts or objects. An Ethereum account has four parts:

- The nonce. A nonce is a counter set to make sure each transaction can only be processed once.
- The current balance of the ether account.
- The contract code of the account.
- The storage of the account, which is empty by default.

Ether is used to pay, and is the key crypto-fuel or cryptocurrency of Ethereum. It is used to pay transactional or operational fees. In general, there are two account types: externally owned accounts and contract accounts. Externally owned accounts, which have no code, are controlled by private keys, and contract accounts play by the rules of their contract code. Messages (or instructions) can be sent from externally owned accounts by creating transactions and signing them. Contract accounts, however, are used to send messages or instructions and/or create contracts every time the contract account receives a message. Also, when messages or instructions are received in contract accounts, internal storage can be read from and written to.

## III. SMART CONTRACTS

The concept of Smart Contracts was introduced [7] in the 1990s. This is another category of applications that will suit blockchain technology. To understand the concept behind smart contracts we can make an analogy to a vending machine. A vending machine is a device implemented in hardware that implements conditions of an agreement. In this case, a simple condition for this agreement would be that a user puts an amount of money in the vending machine and a related item comes out. If the user does not insert adequate money, the item will not come out. The vending machine is encoded with a set of rules that also keeps the items secured. The security is proportional to the value of the items that the vending machine holds. The vending machine is a very simple example of a contract with a bearer. In this case, anybody with coins in the right currency can participate in an exchange with the vendor, the vending machine. And, the lockbox and other security mechanisms (including programmed security mechanisms) protect the stored coins and contents from attackers.

This concept is applied to digital assets, but with broader rules and more complicated types of contracts. Smart contracts provide stronger and more secure verification for access to the property. Another example is digital security systems for automobiles. The protocol defines the conditions to give authority of the property based on who is the rightful owner at

a certain time. Considering cryptographic keys as means to access a car, we can determine conditions that will make the owner change, and therefore change the conditions in which the car can be used. A smart lien protocol can be created, described as follows: if the owner fails to make the scheduled payments, the smart contract invokes the lien protocol. This would give back authority of the car keys to the bank. A further step would probably remove the lien in the event the loan gets paid off [7]. A graphical representation of this example can be seen in Fig. 1.

To keep digital assets secure, a computer program that has direct control of them is put into service. This means that there is not a person that will control the asset but a computer that follows a digital contract that provides specific rules to handle it, and it cannot be controlled by any user. The decisions will be made directly by the computer program. Once again, the smart contract should include conditions that are strong enough to keep the asset secure, in proportion to the importance of the digital asset. This specific environment can be implemented on the Ethereum blockchain. Once an amount of ether is sent to a

computer program as a digital asset, and this follows a smart contract, it can then handle the money as specified in the contract. So, if the contract specifies that a certain amount of money will go to an address, the money will move as per the conditions of the contract and no human interaction will take place. The concept of smart contracts can be extended to any other application which is based on a self-executing financial contract such as insurance. Here a set of rules would be specified and when the condition is met an asset would be unlocked for the user.

Smart contracts have been used in the area of crowdfunding where the contract defines certain conditions before letting the money go to a certain project that people are supporting. For example, if a developer requires a certain amount of money to kickstart his/her project, the money will be managed by a computer program that will follow the rules given by the smart contract. In this case, no user can intervene in the process to move any asset, and everything is managed by the program. This transparency gives all the members that are participating in crowdfunding more trust in the process.

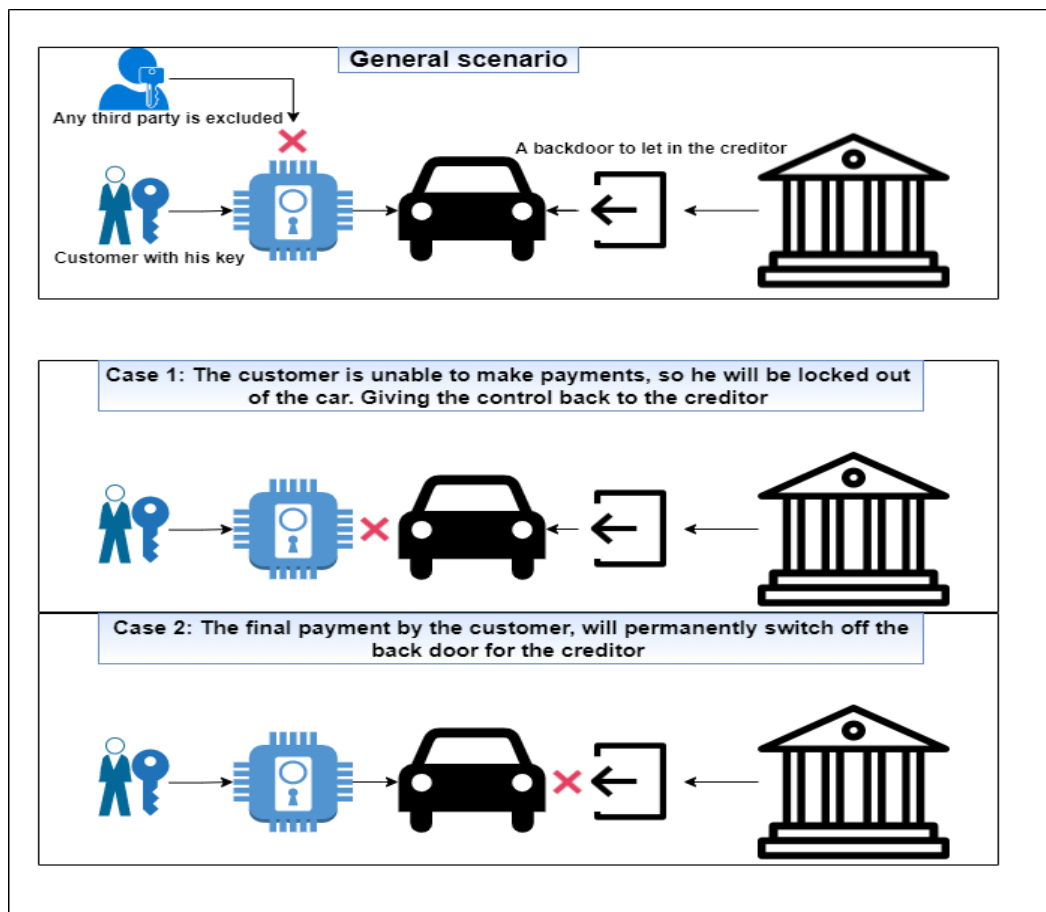

Fig. 1. Hypothetical Digital Security System for Automobiles that Relies on a Smart Contract.

#### IV. ETHEREUM STANDARDS

As presented above, smart contracts are basically pre-programmed or intelligent programs that get executed when certain conditions are met or certain events happen. Since the process is automated, they have no downtime. They also allow for the creation of decentralized applications [9].

The Ethereum Virtual Machine (EVM), which runs on an Ethereum network, simplifies the process of building blockchain applications. EVM allows developers of each application to build new blockchains from scratch. And, developers do not have to use any specific programming language. This allows Ethereum to technically build the first decentralized world computer on a public blockchain [9].

The native currency for Ethereum is Ether (ETH). The platform is mainly maintained through transactional or operational fees. One of the most useful advantages of Ethereum is its ability to create unique tokens, with various functionalities, and operate on the Ethereum blockchain. These tokens have multiple utility-like purposes.

Ethereum Request for Comments (ERC) are application level standards for Ethereum. ERCs include token standards, name registries, library/package formats, and other features. An ERC can be created by anyone, but it falls on the creator to clearly explain the standard. This will also help the creator gain support from within the community. There are common ERC standards for functions of each token type, allowing applications and smart contracts to interact with them in pre-determined or pre-planned ways. ERC-20, which allows for the simple creation, use, and exchange of Ethereum-based tokens, is the most common ERC standard used to date.

##### A. Explanation of Terms

Ethereum accounts, identified by 20-byte addresses, have externally owned user accounts and contract accounts. Users can create accounts, call or access accounts, or issue transactions (which are signed data packages) that transfer value to users of other accounts and contracts. All transactions are recorded on the Ethereum blockchain. A contract gets activated by a user transaction or by a message or instruction from another contract. Messages only exist in the execution environment of the Ethereum Virtual Machine (EVM), hence are not recorded on the Ethereum blockchain. This is because messages are consequences of an initial transaction. Their existence is limited to the execution environment of the Ethereum Virtual Machine (EVM) and this can be seen in the execution trace logs and potential state changes.

Abstract Binary Interface (ABI) [10]: Most Ethereum contracts follow the ABI standard. The ABI standard identifies functions by signatures. These signatures are made of the first four bytes of the Keccak-256 hash of the function name plus parameter types. The presence or absence of a function in a contract is checked by locating the corresponding 4-bytes hash in the deployed bytecode. This also allows the compliance of a contract with interface standards to be determined by its bytecode.

##### B. Functionalities Available for Token Contracts

There are presently several functionalities available for token contracts: (i) keeping track of token holdings; (ii) transferring ownership of token contracts. The transfer of ownership is shown in the logs. A safe transfer is where the information is known. Hence, after approval, tokens are taken or withdrawn from the known address, as opposed to being sent or transferred to an unknown address where they may be lost. So, in a safe transfer, both the sender and receiver would be known to the sender and receiver respectively; (iii) the creation of tokens and destruction of tokens. This is also called minting or burning of tokens; (iv) the distribution of tokens. This includes trading (e.g., via ICOs and airdrops) of tokens; (v) token contracts are also programmed to check for authentication and have various roles built into the system. Roles include roles that control the system, like pause or lock, and information provisions like view functions; and (vi) other functionalities including utilities.

##### C. Token Standards

There are several accepted token standards which are determined by the community that establishes standard interfaces for tokens. The programming language used is Solidity. This programming language is prevalent on Ethereum. The standards that have been accepted so far are:

- ERC-20 Token Standard [11]: This is the most widely used and most general token standard. This standard is programmed to provide very basic functionality like ability to transfer tokens. This standard also allows tokens to be approved and disapproved. This means that they can be spent by another on-chain third party. ERC-20 has six mandatory and three optional functionalities as well as two events to be implemented by a conforming API.
- ERC-721 Non-Fungible Token Standard [12]: In ERC-721, each token is distinct and non-fungible, hence this allows for the tracking of unique assets. Each asset has individual ownership and is atomically tracked. ERC-721 requires each token to have ten functions that are considered mandatory and three events.
- The ERC-777 Token Standard [13]: ERC-777 provides advanced functionalities for interaction with tokens while keeping compatibility with ERC-20. It's advanced functions include operations to send tokens on behalf of other addresses and ways or hooks for sending and receiving. This allows token holders more control over their tokens. ERC-777 requires each token to have 13 functions that can be considered mandatory and five events.
- ERC-1155 Multi Token Standard [14]: ERC-1155 is considered a multi-token standard since any combination of fungible and non-fungible tokens can be managed in a single contract with this token standard. Multiple token types can also be transferred at once. ERC-1155 requires each token to have six functions that can be considered mandatory functions and four events.

#### D. Proposed Security Token Standards

In addition to the accepted standards discussed in the last section, others token standards are being discussed. ERC-1462 is more general, while ERC-1450 and ERC-1644 are project oriented.

- ERC-1462 [15] Base Security Token. Though ERC-1462 this is similar to ERC-20, it is an extension to ERC-20. ERC-1462 provides compliance with securities regulations and legal enforceability. Though it is mainly used for general use cases, added functionality and limitations as pertaining to particular projects or markets can be enforced effectively. ERC-1426 also includes KYC (Know Your Customer) and AML (Anti Money Laundering) regulations and the ability to lock tokens for an account and restrict them from transfer due to a legal dispute. An added benefit is that this standard also allows for the attachment of documents to tokens. ERC-1426 requires it's compliant tokens to implement four mandatory checking functions while still implementing ERC-20 standards functions. It also gives the opportunity of two optional documentation functions.
- ERC-1450 LDGR Token [16]. ERC-1450, which also extends ERC20, is a security token for issuing and trading SEC-compliant securities. The ERC-1450 standard allows for the recording of ownership and transfer of securities sold in compliance with the Securities Act Regulations CF, D and A. ERC-1450 has mandatory functions of its own, and it requires some optional parts of ERC-20 to be mandatory. It also requires certain modifier and constructor arguments to be set up and implemented.
- ERC-1644 Controller Token Operation Standard [ERC-1644]. Sometimes the issuer (or an entity delegated to by the issuer) or owner, may have to have the ability to force transfer tokens. ERC-1644 allows a token to clearly declare whether or not a controller can unilaterally transfer tokens between addresses. The ERC-1644 standard requires compliant tokens to have three mandatory functions and two events.

#### E. ERC-20 Standard

The ERC-20 standard was the first to lay down the concept of dealing with tokens and their implementations. A token can virtually represent anything in Ethereum, from lottery tickets to an ounce of gold or financial assets like a share in a company. This concept has been used to re-invent the concept of crowdfunding, introducing the Initial Coin Offerings (ICOs) [17] that are equivalent to Initial Public Offerings (IPOs) but for companies looking to raise money to create a new coin, app, or service. ICOs are tokens that are bought by people that agree to invest in a company, whereas IPO investors buy stocks of a company. Having a powerful feature that can represent this variety of valuable elements comes along with the necessity of having a robust standard that is also capable of handling all the assets in a proper way. The ERC-20 standard allows for the implementation of a standard API for tokens within smart contracts. This standard provides basic functionality to transfer

tokens, as well as allows tokens to be approved so they can be spent by another on-chain third party. The implementation of this standard also provides a standard interface to allow any tokens on Ethereum to be re-used by other applications.

ERC-20 also introduces a standard for Fungible Tokens, which means that they have a property that makes each token exactly the same in type and value as another token [11]. The ERC-20 standard is one of the most important standards that led to the concept of NFTs.

If a Smart Contract implements the methods and events provided by the ERC-20 standard, it can be called an ERC20 Token Contract and once deployed it will be responsible to keep track of the created tokens on Ethereum.

#### F. ERC-721: The Standard for Non-fungible Tokens

The ERC-721 (Ethereum Request for Comments 721), proposed by [12], is a Non-Fungible Token Standard. ERC-721 has an API for tokens within Smart Contracts. This is a free open standard that allows for the building of non-Fungible or unique tokens on the Ethereum blockchain [12]. ERC-721 introduces an extension to the common interface for tokens by additional functions, which led to having unique tokens, thus non-fungible. These unique tokens took the name of NFTs [18]. The fundamental characteristic of NFTs is the uniqueness, which means they cannot be exchanged with like-for-like items, making it the most suitable way to identify something or someone that is not substitutable. This type of token can be used on platforms that offer collectibles, access keys, lottery tickets, numbered seats for concerts or sports matches, etc. Once one comes in possession of any of these unique items, he/she can use these NFTs to represent ownership. Uniqueness is guaranteed by NFTs because there is only one token that has some specific characteristic, and they are completely different from any other NFT that is present in the market. Furthermore, there is only one official owner at a time and the ownership is secured by the Ethereum blockchain, which guarantees that no one can modify the record of ownership or copy/paste a new NFT into existence.

Every NFT is essentially a decentralized application, and its properties can be summarized as follows [9].

- Verifiability: This means that the NFT's token metadata as well as ownership can be publicly verified.
- Transparent Execution: This means that all activities on NFTs including minting, selling, and purchasing are publicly available.
- Availability: This means that NFTs are always available to be sold and bought. The system for NFTs never goes down.
- Tamper-resistance: This means that trading records related to NFTs are persistently stored and cannot be changed or manipulated in any way after the transactions are confirmed.
- Usability: This means that each NFT has its most recent ownership information, and this information is clear and user friendly.

- Atomicity: The process of trading NFTs is atomic.
- Tradability: Every NFT can be traded and exchanged.

In other words, each token created or minted has a unique identifier that is not interchangeable with any other token and has only one owner which is easily verifiable. If the owner decides to sell an NFT, he/she can only use the Ethereum-based NFT market. In some cases, the original creator can also earn resale royalties. In some cases, an owner can also decide to hold the NFT forever without worrying about losing the asset because it is secured in the wallet on Ethereum. Every NFT has a creator that decides an element on which he/she wants to apply the standard to make it a digital asset. The creator can:

- Easily prove that he/she is the creator of that particular NFT.
- Determine the scarcity: The creator of an NFT can determine how many replications will exist. To make an asset unique, the creator may create an NFT where only one is minted as a special rare collectible.
- Earn royalties every time it's sold. Some creators can program royalties into it so each time the item is sold from one owner to another they earn a percentage as royalties.
- Sell it on any NFT market or peer-to-peer. The creator will not be locked to any platform and will not have the necessity of anyone to intermediate.

Non-fungible tokens are powerful due to the standards. The standards provide developers with the guarantee that the assets will behave in certain ways. Standards also describe how to interact with the basic functionality of the assets. Fungible tokens are regulated by the ERC-20 standard, whereas NFTs are regulated through an ERC-721 standard. ERC-721 was the

first standard for representing non-fungible digital assets. ERC-721 is an inheritable Solidity smart contract standard, meaning that developers can easily create new ERC-721 compliant contracts. The standard relates the unique identifiers (each of which represents a single asset) to addresses. Basically, the owner is mapped to the unique identifier. It also provides a regulated way to transfer these assets using the *transferFrom* method.

In the beginning potential use of these unique tokens was unclear, mainly because they were totally different from the concept of fungible tokens and their applications. But they soon became the most suitable way for digital artists to make their art worth [18]. Digital artists create immense amounts of content, which require a lot of time and dedication. But often they are not compensated enough for their work. The problem with creating any type of digital content is that it can be easily copied and replicated without giving the creator any compensation or credit. The market of digital art and digital collectibles grew from fifty-two million to four hundred and ninety million dollars within the past year [19].

An artist who creates digital content and wants to sell his/her product online will not be able to fully secure his/her art, since anyone can make a copy of it. But, if the same digital work is combined with the Ethereum blockchain standard ERC-721 and converted into a NFT, this will make the art unique; in this case, nobody can have ownership of the digital product other than the person written on the NFT. In this situation, even though the same product can be replicated on the internet, no one else can have the ownership until the NFT is bought from the creator. This solution gave a huge boost to the market of digital art and digital collectibles, which had a growth of more than four hundred million dollars within the past year. Table I lists the ten most valuable NFTs ever sold [19].

TABLE I. THE TABLE SHOWS THE TOP 10 MOST VALUABLE NFTS EVER SOLD (RETRIEVED ON 08/04/2021) [19]

Name	Artist	Description	Price sold \$
Metarift	Pak	Group of spherical objects moving	904,4013
Forever Rose	Kevin Abosch	Digital photograph of a rose	1 Million
CryptoPunk 4156	Algorithm-generated	Pixel art	1.5 Million
"Genesis" Estate	Axie Infinity virtual game	Estate bought within the Game	1.5 Million
CryptoPunk 6965	Algorithm-generated	Pixel art	1.6 Million
Twitter's first-ever tweet	Jack Dorsey	Twitter's first ever tweet	2.9 Million
Crossroads	Beeple	Digital video	6.6 Million
CryptoPunk 7804	Algorithm-generated	Pixel art	7.57 Million
CryptoPunk 3100	Algorithm-generated	Pixel art	7.58 Million
Everydays: the first 5000 days	Beeple	Piece made up of 5,000 images	69 Million

## V. CONCLUSION

Blockchain technologies have been around for some time now and have been used for various types of applications in the last few years. One of the most recent applications, NFTs, are revolutionizing the market of digital collectibles and digital assets. Since NFTs are a complicated technology to understand, these applications are accessible only to a restricted set of people. This paper presented a balance between the technical and theoretical aspects that make up this technology, making it suitable for beginners who have an interest in learning the background and implementation of NFTs. This paper is also suitable for those who have a basic comprehension of blockchain technologies and want to extend their knowledge in the field.

**Abstract**—The exponential growth in technological innovation is driven in large part by the digitization of multiple domains and assumes environments of increasing data volumes, arriving at high velocity and variety. e-Government is one such domain that exploits current ICT innovations to improve the delivery of public services to its citizens, businesses, and other stakeholders. This imposes to continuously maintain information on daily operations, activities, and assets as well as extensive profiles on citizens, institutions, and organizations. In addition, current centralized platform-based approaches suffer from the single-point-of-failure, which may result in data breaches and leakages, leading to the need for efficient robust mechanisms to ensure secure information sharing, data interoperability, and privacy. In this paper, we propose a business intelligence approach to design a data interoperability framework for e-governance based on data warehousing technology to improve transparency and data accessibility. We also present a hybrid data filtering mechanism, which relies both on the Extraction, Transformation, and Loading (ETL) process, and multi-agent technology to integrate data quality and data interoperability, and supports data transformation into human-readable format. Finally, the framework emphasizes the availability of materialized views to enable efficient execution of analytical queries directly on the large volumes of raw data in the data warehouse.

**Keywords**—e-Government; interoperability; multi-agent system; materialized views; datawarehouse; business intelligence

## I. INTRODUCTION

E-government refers to the development of new public services and service delivery models that use digital technologies and government and citizen information systems assets.

While the development of government electronic services may have met resistance in the past due to the complexity of governmental policies and/or the lack of flexibility and capability of available technologies. This is no longer the case, in recent years, digital government architectures[1] have received special attention from researchers, embodying contemporary technologies and methodologies that will not only improve digital government performance, but also accelerate the pace of innovation by supporting the development of secure, autonomous, and transparent digital systems for the delivery of services and the management of rapidly and continuously increasing data volumes and varieties.

E-government provides a significant motivation for moving forward in the twenty-first century with higher-quality, more cost-effective government services and a stronger citizen-government interaction. In Morocco, the e-government program is part of the “Maroc Numéric plan”[2] which was launched in 2013 as the program aims to improve government efficiency by increasing the quality-of-service delivery to customers and investors from all segments of society in an easy, quick, accurate, and efficient manner, to become a new type of government employee and government performance. Such a goal requires cross-administration coordination, which could be difficult to achieve at times.

Moroccan governments are on pace with their digital transformation. Some ministries were among the first to implement the transition, while others are still getting acquainted which is the case of the supreme council of justice, the presidency of the prosecution, and the ministry of justice, which are nevertheless among the most frequented, seem to be the least connected since this judicial system is one of the most important and complex in Morocco and is a key component of the e-government initiative, it is critical to solve one of the system's primary issues: separation of data management and data interoperability.

The interoperability affects an organization's performance and is a difficult problem for Moroccan judicial entities adopting big data systems. Because of the varied nature of the data they handle, the Heterogeneity in developing E-Gov, the quantity of Data, the Interaction between these Data, and the dynamicity of these Data. Finding trustworthy answers between data acquisition and data management is more challenging than ever, and strategic decision-making in the supreme Moroccan council of justice necessitates the utilization of numerous sources of information that involve all justice departments. Therefore, these challenges of interconnecting the government information system in general and justice information system particularly to public administrations require rapid access to essential data in an interoperable manner.

Adopting a business intelligence approach to design a data interoperability framework for e-governance based on warehousing technology seems to be the most suitable solution.

This paper is the continuation of our previous work (Big Data Interoperability for E-Governance[3]), the contribution of

our work is to propose a data interoperability framework for e-governance based on warehousing technology and also to present a secure hybrid data filtering mechanism based on business intelligence approach and multi-agent system, considering widely adopted international standards for the exchange of government data. We show the benefits of such an approach in the area of usability, security, cost-reduction, and supporting e-government projects. The remainder of this paper is structured as follows. The background section presents the basic concepts that are necessary to understand our research problem. The second section presents the proposed framework and the study methods, followed by the section that describes our case study. The fourth section discusses the security and privacy aspect of the framework and the final section concludes by briefly presenting some of the study's implications for research and practice and future works.

## II. BACKGROUND

In this section, we provide a brief overview of the related works and the basic concepts relevant to our proposed framework for the data interoperability of e-government system that are required to explain deeply this study in the article.

### A. Related Work

Researchers have recommended several approaches such as citizen-centric, one-stop portal, social networking, and integrated e-government as viable ways to improve e-government service delivery. These approaches increase e-government service by offering an efficient service interface via which users may access services. Concerning the e-governance model, the majority of designs incorporate G2G and G2C. G2B is used by just nine architectures out of fourteen. As a result, the most widely used e-governance models are G2G and G2C. The Table I present a summary of existing e-government architecture from (2017-2020).

According to some research, SOA-based architecture is more appropriate for e-government since it uses component-based applications that allow the composition of services from multiple service providers.

E-governments now-a-days require collaboration and integration of different public services entities to meet the varied requirements and desires of the end user[4]. Integration, coordination, and interaction inside and between various generated data in public sector organizations are among the requirements[5]. SOA approaches enable the reuse of services and thus the SOA layered model includes enterprise service bus (ESB) and service component architecture (ScA), which can increase interoperability in a diverse context[6].

Based on our early study[7] and the related work presented above, there is still limited work that provides a comprehensive architectural framework towards a real data interoperability for e-governance. Hence, this work proposes a hybrid and distributed e-government based on business intelligence and by using an easy and a simple architecture such as ETL mechanism and multi agent system to ensure interoperability among government services and private services. The proposed

framework helps to reduce redundancy data provided by many agencies. Inter-department service sharing and reuse can also be improved thus it enhances decision making.

### B. E-Government Interoperability

Because more administrations shift to internet operations and search for ways to improve their service provision and citizens' obligations, they are faced with bundling services, engaging with supply chains, opening up their data and developing innovative service options. Instead of only making use of their own internal data, machines are communicating to each other, and government entities now need to connect their systems to each other. Interoperability is one of the most important problems facing the government in terms of access to information from various information systems[8]. With the emergence of open data movements[9], Interoperability could become more important. When viewing interoperability as the ability of multiple systems and organizations to work together, there are different layers of abstraction. In addition to the structures and the level of organization, the following stages can be differentiated.

Organizational interoperability aims at ensuring that organizations cooperate in a harmonized manner[10]. Collaboration of networks and a single government will be accomplished in this way.

Interoperability of processes[11] refers to the ability of different business processes to collaborate, or "inter-operate. It aims at making separate managerial and policy-making systems work together. Cross-agency systems or supply chains may be generated in this manner.

Service interoperability[12] aims at developing new services or structures through the identification and composition of services and the exchange of these services. In this way, new services can be built from existing components.

Application interoperability refers to the capacity of an application to communicate with another application through the use of external services (e.g., middleware services). It seeks to combine programs with each other in such a manner that they function in collaboration, operating collectively as one.

Data interoperability[13] seeks to work together with multiple data structures in diverse query languages to exchange data from heterogeneous systems. It is concerned with the ability of systems and services that create, and consume data to have clear, shared expectations about the data's content, context, and meaning so data and information can be shared, merged and made accessible in this manner.

### C. Multi Agent System based ETL Approach

A Multi-agent System (MAS) is a group of actors that interact between each other. In addition, each agent (actor) is able to deliver specific services and has a well-defined objective[23]. Each agent is able to autonomously execute multiple tasks and dispatch the result to a receiving actor (human or software). A MAS must adhere to the programming requirements established by the Intelligent Physical Agents Foundation[24].

TABLE I. COMPARISON OF EXISTING E-GOVERNMENT ARCHITECTURE

Architecture Name	MODEL			Architectural Pattern						e-Gov performance		
	G2G	G2C	G2B	SOA	EA	Big data analytics	EDA	MAS	BI	security	privacy	scalability
Enterprise Integration of Employee Onboarding Process Using Zachman Framework[14]	×	×	×		×					×	×	
Collaboration vs. Choreography conformance in bpmn[15]	×	×										
Enterprise Architecture for e-government[16]	×	×	×		×					×	×	×
Census Web Service Architecture for e-Governance Applications[17]	×	×		×								×
A Layered Architecture for Open Data: Design, implementation and experiences [18]	×	×		×							×	×
A Model and Architecture for Building a Sustainable National Open Government Data (OGD) Portal[ 19]	×	×	×	×						×	×	×
Big Data Interoperability for E-Governance[3]	×					×				×	×	×
Toward A Business Intelligence Model for challenges of interoperability in egov system: Transparency, Scalability and Genericity[5]	×	×	×	×					×	×	×	×
Business Intelligence and EDA Based Architecture for Interoperability of E-Government Data Services[6]	×		×				×		×	×	×	×
A Feasible Community Cloud Architecture for Provisioning Infrastructure as a Service in the Government Sector [4]	×		×	×						×		×
Cloud based architecture for interoperability of Data e-government Services [7]	×	×	×			×				×	×	×
e-Government Architectural Planning Using Federal Enterprise Architecture Framework in Purwakarta Districts Government[20]	×		×	×						×		
Preserving Privacy of Integrated e-Government Information Architecture [21]	×	×		×							×	
Business Intelligence and SOA Based Architecture for E-government System Interoperability [22]	×	×	×	×					×	×	×	×

Therefore, the purpose of using and combining a MAS and ETL (Extracting, Transforming and Loading) approach is developing an interoperability and data management system that would be able to have properties such as:

- Reactivity, which is defined as the ability to respond to user requests as well as the complexities of the human organization that characterizes the system's environment.
- Proactivity in anticipating user expectations or preventing problems in relation to the organization's goals.
- Flexibility to allow the system to adapt (addition of new agents, new roles for agents, etc.) in response to information and human organization evolution (capitalization and management of new types of knowledge, addition of new people in the organization, etc.)

#### D. Overview of Data Warehousing Materialized View

A materialized view is a database entity containing the query results. For example, it may be a local copy of remotely located data, or it may be a subset of a table's rows and/or columns, or it may be a description that uses an aggregate function[25].

Basically, materialized views are used to improve the efficiency of queries when they provide query data. For a faster execution, they can be used for reporting instead of a table.

Generally, data flows on a monthly, weekly, or regular basis from one or more online transaction processing (OLTP) databases into a data warehouse. Data is usually handled in a staging file before being added to the data warehouse. Data warehouses typically vary in scale from hundreds of gigabytes to a few terabytes. Usually, in a few very large fact tables, the vast majority of the data is held.

The creation of summaries is one technique employed in data warehouses to enhance performance. Summaries are particular types of aggregate views that by pre-calculating

costly joins and aggregation operations prior to execution and storing the results in a database table, maximize query execution times. In this study we construct many summary tables, for instance, to include the number of judiciary cases by district and province or to determine for each district the cases and the rate of cases with a “judgment of innocence” by the courts under the judicial district of the Court of Appeal, in 2019

### III. BI DATA INTEROPERABILITY FRAMEWORK FOR E-GOVERNANCE

Data warehouses are gradually being accessed through so-called information portals, which provide a standardized Web interface for OLAP, query, report generation, navigation, and data mining. In addition, portals offer coordinated access to a wide range of structured and unstructured data, particularly new information channels and digital libraries, that is stored outside of data warehouses. End users are given a personalized view of all data based on their business files and access rights.

This adds new interoperability requirements for the collaboration of different government portals repositories with other government warehouse specific repositories.

The construction of the data warehouses consists of implementing a series of data marts, each of which provides a dimensional view of a single business process. These data marts can be built around a set of shared dimensions[26].

In this paper, we discuss the data interoperability in the e-government system based on data warehouses in more details. This discussion is based on a three-dimensional classification of the main types of metadata groups used by organizations as show in “Fig. 1”, these data warehouse metadata groups are divided into users, business processes, and data dimensions. The “Fig. 2” illustrates an explanation of the three dimensions mentioned in the first figure, as well as the various relationships between them.

The “users” dimension, is where we make a clear distinction between internal and external users. The internal users are primarily responsible for the system's development and maintenance (e.g., managers, analysts, and others...).

Fig. 1. Three-Dimensional Groups of Datawarehouse Metadata.

Fig. 2. Datawarehouse Metadata Classification Scheme.

The "business process" dimension is concerned with dynamic aspects and encompasses the metadata associated with the four major warehouse processes, namely model, processing, administration, and analysis. The model process is usually based on a modeling tool, which illustrates conceptual models, views, and other elements of the warehouse and data marts. It requires combining metadata obtained from different data sources. The processing process is strongly based on ETL tools [6]. The data warehouse and data marts must be provided with the data needed for analysis. It must execute data integration by transforming, cleansing, and mapping operational data into the data warehouse or data marts using rules and scripts. The administration process covers the management, maintenance, and tuning of the entire data warehouse environment except for the operational systems and finally, analysis processes are fully assisted by end-user specific data access tools for decision support, e.g., navigation, query and reporting, OLAP and data mining.

The “data” dimension organizes metadata into categories based on the information provided. We differentiate metadata associated with operational systems, data warehouses, and data marts based on warehouse architecture.

Our proposed Business Intelligence Data Interoperability Framework for e-governance (eGov-BDIF) is based on the business intelligence architecture. It addresses the challenges in terms of interoperability for data extraction, interoperability for reporting results and interoperability for data security and analysis. It develops advanced functionalities for better e-governance at different level as shown in “Fig. 3” (District, province, national). The aims of interoperability offering intuitive and straightforward public digital services to citizens and development of information sharing across different organizations and administration which represent a real complexity of cross-organizational collaboration. This is why the development of a common framework is very important for a data interoperability platform that could be scaled up and refined to elaborate robust solutions for different e-governance scenarios.

Fig. 3. Levels of Government Data Interoperability.

Fig. 4. Generic Architecture.

The eGov-BDIF is a comprehensive framework based on previous work[6]to address the government's need to maintain information about its daily operations, activities, assets and the details of its citizens, institutions and organizations secure for better e-governance in the collection, processing, storage, analysis and visualization of data stream .

Our framework illustrated in “Fig. 4” consists of an orchestration of various technological architectures that are represented as three complementary layers including presentation layer (or service access layer), Central Data warehousing & MAS layer and internal operational DW layer that consist of the diverse data mart or small DW of the different entities. The presentation layer comprises of e-government users and various devices for providing access, computing resource, and OLAP queries, reporting tools and data analysis.

The Central Data warehousing layer is meant to store different data sources such as PDFs, DOCs, contracts, and other files that are too huge to store or need to be deleted or

altered in the future. With different access-management protocols, each level (district, regional and national) of the agency builds its own data warehouse. High-priority data is not available for general access and must be secured from misuse or unwanted access.

Therefore, for access and performance reason, an important technique to speed up analytical queries is used “the materialized view” which consist of pre-computing and materializing aggregations. Since intelligent agents are used today in all aspects of life to solve difficult challenges by distributing work. In the ETL [26]Multi Agent layer, we aim to integrate different agents that operate together and each agent executes various tasks based on the assigned role in the ETL process to minimize the error’s occurrence. In fact, the addition of agents at different level of ETL process (data extraction level, data transformation and data loading level) minimizes the risk of error, improves performance and reliability and minimize execution time. Agents will invoke notifications when a problem occurs. A warning is created for missing or insignificant data. Each agent is assigned a particular function by adopting the standards for semantics and data format. In our case, the ETL-based agent method is used to help make the extraction, transformation and loading process effective, efficient and secure. In our system agents are grouped into four classes within a multi-agent system.

- Monitoring\_Environment\_Agent group1
- Extracting\_Agent group2
- Transforming\_Agent group3
- Loading group4

#### IV. CASE STUDY DESCRIPTION

##### A. E-government Data Warehousing Architecture for E-Justice

The sharing of legal and judicial information[27] is one of the areas in which the e-government interoperability project can provide a level that cannot be matched by traditional mechanisms in obtaining this type of information, whether in terms of speed in reaching the required information, accuracy in arranging and classifying it, or being able to retrieve it When necessary, and also at the level of the vast amount of legal and judicial data that can be stored, downloaded, sent, searched and exploited [28].

The key entry point for the success of the e-government interoperability is the ease of access to justice by those seeking judicial services, including professionals, litigants and the general public, which comes through taking a set of measures, on top of which is the adoption of clear, smooth and accurately targeted electronic platforms, which are easy to distinguish between what was directed at specific groups and what was related to judicial, quasi-judicial or administrative services.

The aim of our eGov-BDIF in the case of the justice system is to help establishing legal and judicial security by providing an easy-to-use database of jurisprudence and various legislative texts. In addition, it enables the digital court to provide all the information related to a specific file to help make the right decision and thus, it enables the judicial process to speed up,

especially for similar files, with the possibility of making sure to single out files that know specific peculiarities.

The scenario of our eGov-BDIF applied in the Moroccan e-justice system defines three main entities:

- MJ (Ministry of Justice)
- PMP (Presidency of the Public Prosecutor's Office)
- CSPJ (Supreme Council of the Judicial Power)

These three entities interact with each other through the Process Legal Case (PLC) "l'affaire juridique".

In fact, the process of a legal case involves a set of sub-business processes (SBP).

$$PLC = \sum_i SBP_i$$

Our approach defines for each sub-business process a set of data-marts and Data warehouses namely (DW\_MJ, DW\_PMP, DW\_CSPJ) to build the common global DW related to the legal case process which in particular facilitate access to judicial services and better management of the judicial system and guarantee data interoperability between the three entities.

The common global DW "CGDW," is at the heart of our approach, it is made up of many physical data warehouses, such as DW\_MJ, DW\_PMP, DW\_CSP, and each warehouse can be physically located on various servers and geographically in different locations, but these separate data warehouses function as a collection of materialized views by queries. We may have different data sources partitioned by regions (SDR), districts, or provinces, such as SDR-Casa, SDR-Marrakech, SDR-Rabat, SDR-Fes, etc. There will be a separate ETL process for each data source, which will be orchestrated by a multi-agent system to extract the source data to the corresponding target data warehouse.

Moreover, the most used sub-requests or other logical views are materialized in order to enable the access of the end user to information placed in various databases whenever he needs and wherever he is and to speed up the processing of requests on a vast volume of data processed in our data warehouses, so that the cost of processing requests is reduced with an optimum maintenance cost. Therefore, the "Fig. 5" present an instantiation of our proposed generic architecture detailed previously in "Fig. 4".

Withal, the main results of the application of our approach in the justice system are summarized as follows:

- Modernizing the judicial administration
- Improving the quality of services provided to users
- Facilitating access to them

- Improving the effectiveness of judicial performance on the horizon of achieving the digital court
- Simplifying and standardizing the judicial procedures, thus contributing to shortening deadlines and speeding up the procedures for resolving cases
- Contribute to speeding up the implementation of judicial decisions
- A smart environment by digitalizing judicial procedures, it contributes to the success of the zero-paper strategy and promotes environmental standards
- A smart court makes technologies at the service of judicial security
- A judicial facility that protects the rights of litigants and places the beneficiaries at the core of his mission
- Affordable justice system
- Effective, transparent and open services.

## V. DISCUSSION

### A. Security and Privacy Aspect

The security, confidentiality and privacy of the large information base envisaged are vital to the sustainability and efficiency of the data warehouse. Research on data warehouse security has allowed us to identify two classes of approaches:

- The approaches dealing with the security of operations: this work allows us to answer the questions who has the right of access and what does he have the right to?
- Approaches dealing with prevention against inference problems: they allow answering the question How to forbid a user to infer protected data from accessible data?

Obviously, the two classes of approaches complement each other in the security services they offer.

Nonetheless, many security risk concerns emerge from the implementation of ICT in Moroccan courts and imply simple security safeguards such as authentication, non-repudiation, transparency, integrity of data and intrusion into privacy. In order to be enforced, the justice system will need to consider and handle legal and non-legal security risks in the most reliable and successful way in order to excel in the data warehouse implementation. To avoid erroneous assumptions and to discourage profiling and stigmatization of some classes of people, the data warehouse should be used with caution. The Judiciary will need to determine the consistency of the data, establish quality assurance design & create standards. This may involve identifying data consistency specifications, data processing procedures and validation of records, executing ETL logic tests and business rules.

Fig. 5. E-justice Interoperability based on Datawarehousing Architecture and Multi Agent System.

## VI. CONCLUSION AND FUTURE WORK

Data warehousing is constantly being used for exploration and analysis to provide new information helping in decision-making. This work was intended to show how a hybrid approach of the ETL based on MAS and Data warehouses with Materialized views used to support the interoperability and the analysis of judicial data.

The present research is managed to simplify the data collection process by using the multi-agent ETL process to organize data loaded into the common global data warehouse. The data sources available in the Moroccan Judiciary system have been specifically outlined. The proposed Business Intelligence Data Interoperability Framework for e-governance has been developed. We also considered the query performance aspect by integrating and storing materialized views in the warehouses, which pre-aggregate the data, therefore avoiding access to the raw data and speeding up queries.

Finally, the implications of the project help the strategic choices of governments on the digital transformation within smart cities to support actors in co-creating organizational value, and societal well-being from business strategies and IT initiatives and foster the idea of environmentally sustainable e-government and create a more environmentally conscious public sector.

The perspective expounds on the study of possible improvement and validation of our eGov-BDIF framework. The main object if that will constitute our future research axe is

the development of advanced data warehousing systems by using a blockchain-based approach that constitute a crucial potential for improving the e-government business processes and data interoperability, providing transactional transparency and security in the value chain, and reducing operational cost.

## ACKNOWLEDGMENT

We would like to thank all the people who have supported this work, as well as special thanks to Pr. Aris Ouksel, Professor of Information and Decision Sciences, from the University of Illinois at Chicago, USA for the support and assistance all along the project and to Dr. Chakir Loqman professor in the department of computer science at the university Sidi Mohamed Ben Abdellah of fes, Morocco for providing us the valuable data and statistics used in this research.

# Analyzing User Involvement Practice: A Case Study

Dr Asaad Alzayed, Dr. Abdulwahed Khalfan

Computer Science Department, Public Authority for Applied Education and Training (PAAET), Kuwait

**Abstract**—Engaging users in software development is recognized as effective in furthering the likelihood of product efficacy and a successful project, together with user contentment. Furthermore, user involvement is potentially applicable to numerous organizational contexts that can incorporate a focused user-centered group. This research analyzes the findings of a case study carried out to assess the user involvement situation within a business specializing in innovative software for general consumers, service providers, and enterprises. This company has now formed a user experience group that is devoted to applying user-centered approaches for the overall development of the organizational structure. General feedback was confirmed as the most typical means of gaining user insight, with the level of user involvement in focused development falling short. Nevertheless, the study led to recognition that a firm plan for drawing users into development processes is necessary moving forward.

**Keywords**—User involvement practices; user involvement challenges; usability; user-center practice; user feedback; end users communication

## I. INTRODUCTION

Having users participate in software development is a vital hurdle to overcome but problematic to achieve. While developers are always inventing and releasing new, fancy features, they can easily overlook that their key focus needs to be on the quality of end-user experience [1]. Businesses are accustomed to incorporating new features that improve their products, but comprehending the processes their customers benefit from should in fact be their primary concern [2]. Indeed, while customers tend to be seen as the crucial factor for the cash flow their role creates, system users themselves need to also be viewed as vital, considering that the issues they face with securing smooth processes can have a profound knock-on effect on the subsequent engagement and cost-effectiveness [3]. The most difficult problem in the software development process is to understand users' needs and priorities; therefore, issues that need to be overcome and the applicability of updates are essential attributes for furthering the ultimate value a customer base will then receive. To help developers gain a better understanding of user requirements, getting those same users to be involved throughout the development process is seen as crucial for securing overall system functionality and user satisfaction [4]. User participation may also help to improve customer loyalty and sustain long connections with users [5-7]. In summary, figuring out how to answer the various user issues can result in a more profitable business, so should not be considered an inferior priority.

There are several approaches to involving users in the developmental contexts. However, going to the extent of challenging users to produce their own applications has

met with little success; indeed, it resulted in a lack of understanding between departments, although user productivity has been increased in such a manner [8]. Other approaches have also focused on having users take a planning and coordination approach to developers' workloads [9], together with occupying managerial positions in terms of adopting and implementing new IT innovations [10,11].

Getting users to closely engage with various levels of development can appear to be an inviting approach. In reality, however, it comes with many potential problems and pitfalls. Specific roles, for example, can become obscured, depending on how the user is linked with other departments [12]. Users can be both hostages and propagandists – both of which undermine the ultimate design goals. Hostage users tend to find their efforts blocked from within the design team of which they are supposed to be an important part. On the other hand, propagandists are redirected into developmental training as a result of failing to have a telling impact, but this only means their perspective is no longer relevant as users. Plus, users' involvement in developmental efforts offers no certainty that the actual system design will benefit from their presence, as developers may still overlook them [7,13]. Agile methodologies have been embraced to increase the potential of users' and customers' participation by putting them into the same area as developers, but it remains problematic to take developers' focus away from software functions, even when they are working closely with users [14].

To address these issues, the aim is to establish effective and reliable methods for incorporating users' perspectives and skills into development processes, which must be adapted to the unique company setting, as well as the departments and functions in question. So, taking marketing as an example, users will tend to be involved in research and assessment above all else, whereas product management will be more closely concerned with usability and performance [15].

This research explores the findings of an analysis of how user involvement practice is currently progressing in a business with a key focus on software solutions for various service suppliers and businesses, as well as consumers. Through assessing the means by which the varying activities of a company draw users into their everyday itineraries, together with analyzing how much information they already have on the users, we can aim for productive and in-depth observations on how effective user involvement methods have been. Ideally, we aim for the observations and insights made to serve as advice for professionals and organizations looking to make the most of user involvement moving forward.

The paper consists of five sections. Section 2 presents a literature review to analyze the concept of user involvement in greater depth, informed by available research. Section 3

covers the research methodology, interviewee backgrounds, and the organization under scrutiny. Section 4 then deals with the various case study outcomes, before Section 5 brings all this together with discussion and conclusions, backed up by research comparisons, and provides suggestions for ongoing research initiatives.

## II. LITERATURE REVIEW

### A. User Involvement

User involvement is a crucial aspect of developing any robust software. If developers continue to be unaware of the specific needs of their users, this will result in inaccurate assumptions and potentially disastrous consequences. This is backed by the literature, which shows that involving users early in the development process is effective and influential as the expense involved in making modifications grows throughout system development [16]. It has been found that user engagement and involvement have a beneficial influence on system success [5,17,18]. Bano and Zowghi [19] found that the relationship between user involvement and system success is not straightforward and is dependent on a variety of factors and conditions concerning the system development process, including the type and size of organizations and projects, the method of data collection and the phases of the system development life cycle during which data was collected, and user involvement or a participative approach to system development, such as agile, user-centered design (UCD), and participatory design (PD), are widely used. Previous research has indicated that involving users as early as possible in the development process it can be cost effective because it minimizes the expenses associated with the modification and redesigns made later in the software development process [16]. Particularly, research in Participatory Design has resulted in the development of a diverse variety of tools and approaches [20]. As defined in the standard ISO 9241-210:2010, [21], in order to fully comprehend end users' needs and requirements and to create a system that meets their job, end users should be participated across the whole development process. There are several issues, nevertheless, when you try to involve users to elicit their requirements and there are many developers also fail to exploit them to their full potential [16]. Many developers are also interested in finding out what the overall role of users should be if they have a say in software development. According to Abelein and Paech (2015) [5], the relevant context factors receive minimal attention. As a result, they requested further empirical study on numerous elements of user participation and involvement. Their research showed that the majority of user involvement and participation occurs during the validation and requirement elicitation phases, with only very few methods focusing on user participation and involvement during the software design and implementation processes, despite the fact that many important decisions are made during these processes. The function of users in design projects is not carefully decided in most companies. As a result, users are confused and believe they lack competence in engaging and running the system usually provided (Damodaran, 1996) [12].

User participation, according to Kujala (2003) [18] and Taha et al., (2013) [22], has a favorable influence on user

satisfaction and increases the likelihood of product success. Involving users in product design should benefit developers by reducing product risks, lowering product costs and market failure, and increasing business profit [23,24,25]. Several research have concluded that involving users early in the design process is beneficial. The rationale for this is because users may play an important role in product development by interacting with product developers, who then translate the input into product design specifications [24]. However, direct contact with users does not ensure the success of a new product if the product developers do not understand how to engage users in product development. Many approaches have been tried throughout the years to make the product development process more controllable and effective [22]. However, there are no precise approaches for increasing the success of a new product. Furthermore, most approaches that engage the user in the product development process have not been effectively described and clarified. Traditional approaches are more engineering-driven and mostly connected to the manufacturing phase of the design process, and they are not used correctly or employed at the incorrect point of the design process [26].

Rather than imposing techniques and tools, true user participation and involvement will always require an in-depth awareness of the organization's structure and a comprehensive grasp of local conditions to guide user representations and involvement. Users are sometimes involved as information providers to the project team. Users contribute to such projects but have little impact on important decisions, which is one reason of project and IT development failures to reflect properly for real human and organizational demands [12]. Damodaran (1996) [12], classified several forms of user involvement as 'informative' (users supply or obtain information), 'consultative' (users remark on a specified service or set of facilities), or 'participative' (users impact decisions connected to the whole system). There are several documented benefits to the implementation of user involvement in system design, such as accurate user requirements leading to higher quality systems, eliminating unwanted features, and promoting greater levels of acceptance of the system.

### B. The Level to which users are involved

According to Ives and Olson [27], the level of influence wielded over the final results is related to the extent of user involvement. The extent of user involvement, therefore, depends upon the efficacy of the system, with the following definitions applied to describe the level of contribution:

- No involvement: users are either not asked to get involved or are not keen to provide their expertise.
- Symbolic involvement: users are asked to contribute, but their perspective is not actually taken on board.
- Advisory involvement: direction is sought via various means of feedback.
- Involvement via weak participation: users do offer some expertise but have to sign off responsibility as each stage is complete.

- Involvement by action: a user is a very active part of the design team, perhaps as an on-site colleague or else as an official contact that information is fed through.
- Involvement by strong control: users take a hands-on approach as a result of funding the developments, but also in scenarios where an assessment of the user's overall performance is reliant upon robust and innovative system design.

The extent and form of user involvement can be viewed as the two levels upon which the various actions or decisions are understood. Perhaps the only kind of user participation in which it is found that the user has a real influence on results is a participatory role. With approaches that are informative and consultative, user direction is available, but there is no guarantee it will not be ignored or overlooked. A participatory form of role and the extent level of user involvement both strongly imply that the user is a member of the design team; however the form also allows the user to have a voice on developed systems, whilst the level implies that it may change.

As these comparisons show, it is entirely possible for user involvement levels to overlap, though this does not necessarily mean the outcomes will be negative. Such an overview will be applied to our findings to inform an empirical approach.

### III. METHODOLOGY

The authors conducted a qualitative research methodology consisting of a semi-structured interview with open-ended questions to collect the data for this research study. In addition, case study methods were adopted to direct our research practices. Yin [28] defined a case study as an applicable social science discipline, incorporating both organizational and managerial contexts. The use of a case study approach in this case is intended to be illustrative, since the aim is to connect the dynamics of current practice while avoiding any influence on the processes at the research analysis.

#### A. Research Analysis

Our research has been carried out by observing a software business company throughout 2020. More than 300 staff are employed by this company, whose core operations focus on software solutions sourced by general consumers, service providers, and also small and medium enterprises. Their structural approach includes having a designated user experience team, which is tasked with achieving robust user-centered practices and services for the complete company operations. However, prior to research taking place, this team had only been operational for three months. Part of the research goals, therefore, was to allow the user experience team to gain a firm overview of the situation concerning user involvement practice throughout the various departments, so they could respond by upgrading their activities to suit applicable challenges and goals.

#### B. Data Collection and Analysis

We performed 6 face-to-face semi-structured interviews with open-ended questions, each lasting approximately 30-60

minutes. All interview questions were asked in English, but the interviewees were given the right to answer the questions in English or Arabic. To reflect the diverse functional responsibilities, case study participants were selected from a variety of departments (details in Table I). The participants were then asked to reply and explain while commenting on their experiences by explaining the scenarios they faced in the context of user participation in their presently ongoing or recently completed projects. Upon completion of the interviews, a professional transcription service was applied to transcribe all interview recordings in order to extract the essential information from the recordings. Both authors were present at all interviews and made field notes as needed. The field notes and incomplete transcripts were then categorized and thematically evaluated. The data from the interviews was subjected to thematic analysis in the form of template analysis. Template analysis is ideal for comparing the views of various groups within a given setting [29]. Template analysis allows for the creation of conceptual themes that fit under bordered groupings, ultimately allowing for the identifying of master themes and their subordinate component themes.

TABLE I. ROLES AND FUNCTIONS OF CASE STUDY INFORMANTS

No.	Role	Function
1	Project Manager	Customer Involvement
2	Marketing Manager	Marketing
3	Product Manager	Product Manager
4	Technical Writer	Localization & Documentation
5	Software Architect	Research & Development
6	Software Engineering	Research & Development

### IV. RESEARCH RESULTS

The case study results are presented in this section. The user groups indicated by the participants show how the employees tasked with various organizational functions recognize the company's end users as the crucial stakeholders. The information gathered highlights the extent to which end users are understood, together with the means by which such insight has been obtained. We then move on to describe the internal communication networks in place, before indicating work practices that already draw users into system development. Lastly, we focus on the most important hurdles to overcome in order to enhance the user involvement performance.

#### A. Identified user Groups

To start with, participants were requested to provide various personal background info, together with their working priorities, and particular projects or products they had expertise in. Then questions moved on to the user groups who benefitted from their various projects and products – covered in Table II. In doing so, all participants identified home users and service providers as the two key user groups. Two interviewees identified both corporate and administrator groups, with the remaining groups all identified by one source only.

TABLE II. IDENTIFIED USER GROUPS

User Group	No.
Service provider	6
Home User	7
Administrator	3
Corporate Employee	2
Consumer	2
Corporate	2
Mobile User	2
Partner	1
Internal Customer	2
Wholesaler	3

This broad selection of different user groups is in some part due to the situation of the various departments – in some cases different employees – utilizing different terminology. For example, product management, which appeared to have closer end-user involvement than other departments, used both ‘consumer’ and ‘partner’ to indicate either home user or service provider. Other interviewees employed different definitions, using ‘partner’ to describe both service providers and corporate clients. Furthermore, studying Table II also makes it clear that, as well as using varying terminology, user groups themselves were also understood in different contexts. Some responses, for example, indicated a complete service provider as an end user, while others recognized that any company will have different levels operating within, with the customer involvement employee being one such example.

### B. User Data Types

User data is used in this study to refer to any information gathered directly from users, including their needs, challenges they must overcome, and the specific activities to which their responsibilities are applicable. The participants’ responses show how the various departments view and understand company operations, together with the reasons for why they have come to understand operations in such a way.

User response for product previously received and used, along with feedback from a trial test before to release of the product, were the most common sort of data source. The majority of employees were found to be sharing information well, although there were also signs of information being kept within specific teams. Support allows key user data feedback from products in use to be accessed, while customer involvement allows for tryout stage feedback to be readily available. See Table III for the complete lists of user data as expressed by the various departments.

Customer involvement feedback is available via tryout testing that is carried out by focused testers looking to identify specific problems with a product. While products are still in their pre-testing phase, small issues can be ironed out, while bigger problems that don’t offer a simple fix are scheduled for future product development and upgrades.

Aside from these two types of feedback, product management focuses on collecting vital insights through interaction with end users, which is regarded critical for

product concept and definition. Semi-structured interviews, which often include open-ended questions, are the most commonly utilized technique for gathering this information.

### C. User Data Distribution

Fig. 1 depicts the spread of user Data throughout the company. As the two primary data sources, support and customer participation, their combined feedback is delivered to the majority of other departments. Feedback from support is sent to all structural levels, while the tryout testing before releasing the product undertaken by customer participation is drawn upon to inform product management, research and development, localization and document. The information is particularly vital to product management, who draw feedback from all structural levels to inform their designs and also to pass on key details to other contributors. In terms of getting a product from concept to production, adhering to a common vision is the primary driver of user data.

The two key avenues of product management information are the information each employee has at their disposal and the customer, which is unlike other departments that sometimes rely on less-specific information. Plus, the overall product vision is not necessarily bought into by all the managers involved. However, if a team agrees on a product view, the information is preserved on an official site. When a product is at its conceptual stage, numerous incentives will be stimulated as research and development goals are realized. Crucially, if some of these goals are considered low-level at an early stage, then any correspondence on them will be restricted rather than risk compromising a grander vision. Typically, this vision will be summarized as part of a product vision document.

Key data are supplied by support to other departments in the shape of reports. Participants from localization and document confirmed that such reports could only be accessed via the support function, with the exception of some random examples. The majority of functions log the reports on specialized network drives, upon which they can be difficult to locate. Customer involvement shares tryout-stage feedback concerning product performance, typically as reports. The employees overseeing this task aim to gain a user’s role perspective so they can make clear judgments on what corporate partners require and how end users can benefit. Frequent meetings take place between customer involvement and research and development to assess the latest tryout test feedback.

TABLE III. USER DATA TYPES

Data	No.
Feedback from End User	8
Feature Request	2
Tryout Feedback	7
Usability Problems	2
Wholesaler Profile	1
Vision Document	2
Conceptual Requirement	1

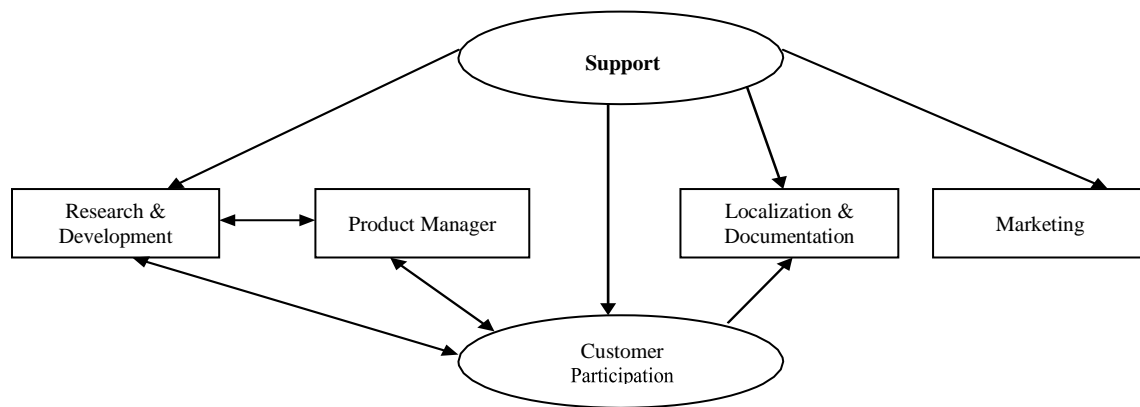

Fig. 1. User Data Communication Networks between various Company Departments.

Participants were requested to confirm their favored forms of communication. The majority preferred punchy and precise summaries or reports to set out the findings of the various tests and studies. These summaries and reports were not judged to be intriguing in themselves, but they turned out to be productive if they happened to relate clear and applicable information. The representative from product management confirmed a preference for communicating in an interactive manner, which could include events as well as more typical meetings and correspondence. As far as simple and fixed reports are concerned, the product manager expresses doubt they are always effective for communication unless some more sophisticated accompaniment is incorporated – such as being part of a presentation printout.

#### D. User Involvement Actions

According to the replies from the interviews, there are three actions that include some form of user involvement: focus groups, introspection and interviews. In doing so, all practices involved an informative or consultative form, rather than any firm participative role.

**Focus groups.** Intermittent market research had been carried out by the marketing manager via focus groups. This involved a group of consumers being asked to focus on the performance of a certain product or subject matter.

Conducting these groups offered crucial information on how the organization's key products are judged by those who actually utilize their capabilities. As a type of user involvement, this approach is clearly consultative in nature, as those involved have their attention focused on a particular product, concept, or service.

**Introspection.** Customer involvement participants confirmed that, in addition to tryout testing, employees have also looked to role play by envisioning themselves as the client, as a way of making judgments from a user's perspective. In some respects, users then become an indirect information source as part of this procedure. Consequently, this user involvement approach is clearly informative in nature.

**Interviews.** End users were sourced for interviews via product management in order to enhance a new product concept. This approach was judged to be an effective means for gaining firm and precise feedback via clear end user

insight. Because end users were acting as an information source, user involvement is clearly informative in nature.

#### E. Issues and Challenges

The interviewees identified several challenges and issues during the system implementation process:

- **Lack of User Data issues.** As the majority of participants confirmed, the largest obstacle they face in making the most of user involvement insights is making up for the lack of it. Indeed, some responses expressed real concern that usability as a concept is completely absent from procedures, with others confirming a desire to have robust user studies to draw upon. As previously stated, the user data available is largely made up of feedback, which alerts teams to existing issues but goes nowhere in terms of avoiding them during product development.

Sourcing user perspectives throughout early developmental periods or, preferably, as products are still in their conceptual stages, enables developers to focus on user value early on in the process, making it a part of the overall product life cycle. In contrast, when these concerns are only addressed in later stages of development, finding solutions can prove more problematic for going against the initial design, making fixes more expensive and possibly less effective. There are financial incentives as well, therefore, for end user involvement earlier in product development.

- **Customer value issues.** The customer involvement project manager confirmed that, at present, the organization's operations tend to be technology-led, with a commitment to addressing any issues identified rather than preventing them from occurring during design periods. This leaves us with a clear interpretation that user-centered design has yet to be fully embraced as a company priority, meaning that users' perspectives are not utilized to inform the early stages of product development.
- **User interface issues.** A big problem is how to judge end users' feedback when it is mixed. For example, if as many users complain about the user interface as those who compliment it. Drawing a conclusion on when to pay attention to criticism and when not is not

easy. At the present time, it is difficult to be confident that a feature or usability solution will increase product value for users, leaving a gray area with regard to which improvements should be given priority and whether they are necessary. Furthermore, this scenario is complicated by the range of alternatives that exist on who the most important clients are and what they are like, due to a lack of user profiles. Plus, as research and development are responsible for the majority of user interfaces, they have little to go on to assess whether an interface is offering quality performance.

- **Integration issues.** User insight, therefore, needs to be incorporated into the current process, which, according to the product manager, needs to be achieved without relying on a separate user involvement process. If approached in any other manner, there is a real danger that aligning current processes could be problematic and have knock-on negative effects. Additionally, it might be that current development processes do not integrate with a user involvement process, meaning it will create a clear risk.
- **Understanding main requirements issues.** Any major implementation process needs to be made conscious of the overall company requirements; therefore, a product management participant believed that the various employees involved in such an implementation need to have a grasp of the overall company needs, as well as low-level requirements. However, in practice, the focus should be away from low-level issues in terms of establishing the overall vision, as focusing on smaller issues too early in the restructuring risks occupying developers in an unproductive manner.
- **User Feedback issues.** As product development takes place, no outside feedback is currently available. This is another issue that needs to be addressed while pursuing new product visions. At the moment, tryout-stage consultation is in place but largely becomes available too late to make anything greater than small adjustments or upgrades. Gaining key information as products are in earlier developmental stages would pave the way for a more thorough approach to addressing usability issues that is cost-effective and less time-consuming over the long term. At the same time, however, better access to vital feedback alone will not answer all the problems if there are issues with current processes and workplace dynamics that remain unidentified. The localization and document technical writer indicated a number of departments from which no feedback is currently available; with no process underway to put avenues of communication in place either.
- **User importance issues.** The company lacks a clear means of gaining user perspectives, with the product manager raising many issues in this context. Indeed, his priority issue was that no structured approach exists at any level within the company to facilitate reaching an understanding of client needs. Even when diligent employees strive to produce their best results, they are

working without valuable insight that might enhance the efforts of even the most perceptive of developers. Plus, in the event that a developer does have extensive expertise on their user's requirements, there is no process in place for integrating this knowledge with the rest of the company's operations. Furthermore, current design practice is restricted to obtaining a list of key product features but without any greater conceptual design that would merge all user requirements and product objectives together.

- **User interaction issues.** The lack of correspondence between developers and their products' end users remains a real issue. For example, the research and development quality engineer and architect brought up a number of user involvement practice issues. In doing so, the most pressing was the absence of contact with end users in their own department, which means the communication channels are simply not open or else entirely reliant on indirect interactions. Indeed, responses can be described as passive in nature due to not being sourced with purpose or for a particular developmental context.
- **User data Access issues.** User perspectives are vague, muddled, and problematic to secure. One participant from customer involvement, for example, confirmed that the majority of feedback sourced tends to end up on a database or network drive, which might not be the most user friendly for research purposes and makes it difficult to find specific pieces of information. As a result, it is probably more accurate to describe such resources as data rather than as a live resource, as the information has by then been examined, given a category, and moved on from the attention of any employee. Furthermore, such databases and online resources are packed with various other reports and documents that employees will not immediately appreciate the context of just because they are readily available.
- **User experience issues.** Moving forward, user experience needs to be approached as integral to all company operations. Analyzing the responses of the marketing manager revealed similar issues to those raised by the technical writer, being conscious that user experience involves multiple components – not just the various software, handbooks, and packaging, but online support and Internet content too. An additional marketing issue raised was the trend of service-oriented business operations becoming more prevalent, which comes with the necessity of understanding a great deal about end users rather than relying on habit or firmly structured approaches. Another observation the marketing manager made is that client opinions and expectations are shifting as a result of software solutions becoming merged with operating systems. Consequently, the levels of market research and user feedback required are far greater than ever before, and the current marketing operations are simply not yet equipped to handle the challenge.

## V. DISCUSSION

This research has explored the results of an ongoing state analysis carried out within a software house focused on developing software solutions to suit the needs of service providers, enterprises, and general consumers. A case study approach was adopted to reach our conclusions, based largely on feedback drawn from semi-structured interviews. Furthermore, this study is conducted within the context of setting up a focused group of user experience to define user-centered working practices into which all businesses may buy into. The process has included offering clarity on which user groups utilize the organization's products, the form of user information currently available from within the company, and the methods employed for communicating that information. In addition, the research explores the practices undertaken to draw feedback from users, and at the same time looks to define the most significant obstacles the company faces, with the task of enhancing its user involvement potential.

The results show how various company functions approach this challenge differently – and view end users differently – while agreement was reached on home users and service providers being the vital players. User feedback sourced via tryout tests and support products already on the market made up the most significant portion of user data available. This means processing such information is problematic due to the large quantity involved. Overall, however, the most significant issues are the lack of applicable user data, the difficulties faced in applying what information there is to working practices, and a general absence of ongoing communication with end users. To begin answering these issues, setting up a smooth and convenient means of corresponding with end users' needs to be prioritized, with the user experience team being the obvious choice for leading the way in this breakthrough.

As mentioned in Section 2, Damodaran [12] drew upon three separate forms to define user involvement: informative, consultative, and participative. From our research, it has become clear that all the available user information is currently either informative or consultative in nature. There are no signs of any user participation at any stage of the design process. Similar results are found when analyzing the actual user involvement practices, which were also either informative or consultative. In summation, therefore, no specific form of user participation is currently undertaken within the company.

As covered in Section II, Ives and Olson [21] established six levels to indicate stages of user involvement. As far as this research is concerned, all user participation may be defined as falling between symbolic and advisory involvement. The involvement of customers and support function have to some extent been successful in drawing customer responses, however, this is ignored owing to the lack of resources to use the information. Although there have been significant marketing focus groups and interviews carried out by product management, which does show some efficacy in terms of drawing user experiences into the company's processes, it is also clear this information is not applied to the earliest design stages, so its impact is limited to response only.

Muller and Czerwinski [30] identified another distinct user-centered function that is linked with product organization methods. They explain how a central group enables a company's usability experts to correspond and continually upgrade developers' working methods and vision to suit more robust final products. This approach is crucial for making sure the most skilled developers, though they may be working in isolation, are able to benefit from in-depth insights into how their work is received by and benefits others. Our own research shows a similar scenario, with the user experience professionals responsible for the whole company's user-centered services, which needs to be achieved at the same time as adhering to their own standards. Nevertheless, to realize such an effective merging of departmental priorities, there are numerous hurdles to overcome that are holding back the usability experts from having a profound impact on earlier stages of development [31,32]. Currently, no clear information is obtainable regarding how well these efforts are progressing, as our focus has been on available user involvement channels as opposed to any that are in development.

The obstacles that need to be overcome in order for a successful user involvement upgrade mean a great deal of enhancement for the user experience team to carry out so that early development tasks and product visions can genuinely benefit from user feedback. One key example is that the team could begin by establishing a means of conveniently and effectively examining the available user and tryout-test feedback so that the most important issues can be highlighted and addressed. Moving forward, integrating an efficient way of obtaining and interpreting a variety of market research should be aspired to, and in a manner that makes the most of user input from the earliest design stages. At the moment, a reliance on feedback after product release shows an over-reliance on technology-oriented working standards, in which responding to issues and fixing them during later developmental stages is the only means via which upgrades are achieved. It would be much better, however, to incorporate user insight from the beginning of the developmental process, because incorporating such information later on is always restricted in terms of the overall benefits that can be achieved.

## VI. CONCLUSION

This research study makes it clear that the company is too technology-oriented within its current practices. A variety of organizational factors are at play in terms of obtaining user feedback, but there is no robust method of drawing such value into overall product development. Consequently, it is hard to argue that user feedback has any kind of profound impact on product design. Although it is doubtful that having users present at an early stage would be enough to deal with this issue, the majority of participants did call for enhanced user-centered practices and objectives.

The user experience team has a vital role to play if user insight is to be made the most of throughout all levels of product design. This research offers a depth of information in terms of how this can be achieved, the enhancements that need to be made, and the standards that need to be adhered to. The most important aspect to take on board moving forward is that

new methods need to be dedicated to gaining a greater comprehension of user requirements so this can be applied throughout the design stages, without undermining other standards in the process.

Looking ahead, further research should focus on the extent that the user experience team has been effective in terms of integrating themselves seamlessly with other processes and departments. Ideally, this paper will offer expertise to any practitioners keen to address similar user involvement issues, together with any who are at the stage of setting up a centralized user experience department. We also hope the conclusions drawn here are applicable for guiding future user involvement research in a number of contexts.

**Abstract**—The cloud resource usage has been increased exponentially because of adaptation of digitalization in government and corporate organization. This might increase the usage of cloud compute instances, resulting in massive consumption of energy from High performance Public Cloud Data Center servers. In cloud, there are some web applications which may experience diverse workloads at different timestamps that are essential for workload efficiency as well as feasibility of all extent. In cloud application, one of the major features is scalability in which most Cloud Service Providers (CSP) offer Infrastructure as a Service (IaaS) and have implemented auto-scaling on the Virtual Machine (VM) levels. Auto-scaling is a cloud computing feature which has the ability in scaling the resources based on demand and it assists in providing better results for other features like high availability, fault tolerance, energy efficiency, cost management, etc. In the existing approach, the reactive scaling with fixed or smart static threshold do not fulfill the requirement of application to run without hurdles during peak workloads, however this paper focuses on increasing the green tracing over cloud computing through proposed approach using predictive auto-scaling technique for reducing over-provisioning or under-provisioning of instances with history of traces. On the other hand, it offers right sized instances that fit the application to execute in satisfying the users through on-demand with elasticity. This can be done using Deep Learning based Time-Series LSTM Networks, wherein the virtual CPU core instances can be accurately scaled using cool visualization insights after the model has been trained. Moreover, the LSTM accuracy result of prediction is also compared with Gated Recurrent Unit (GRU) to bring business intelligence through analytics with reduced energy, cost and environmental sustainability.

**Keywords**—Predictive auto-scaling; business intelligence; virtual machines (VM's); deep learning models; analytics; elasticity; high performance public cloud data centre (HP-PCDC); right sizing

## I. INTRODUCTION

Cloud Computing (CC) is a paradigm aimed at retrieving a collection of computer assets such as servers, networks, storage that allow applications to expand resource on demand with agility through virtualization. Cloud computing is the developing model for delivering subscription oriented pay-as-you-go services to access compute resources for deploying applications. One such characteristic, namely, elasticity that enables customers to buy and release the correct quantity of

compute resources based on their demands so that more responsive web application developers are continually attracted to use cloud services. Cloud infrastructure and services have become the major aspect [1] [2]. The previously siloed or on-premise data Centre is obsolete immediately, since the client base tends to shift quickly based on business demands. The auto-scale technology from IaaS in cloud enables the dynamic adjustment of the number of VMs, to be added or removed based on the capacity of workloads or user traffic [3]. If a web shop in the cloud has more requests or with seasonal trends, extra VMs can be made available to handle load. Conversely in the case of reduction of traffic, VM instances may also be removed automatically. The application load balancer supports containerized applications powerfully. It operates like a gateway to receive TCP/HTTP applications received by end-users and disseminate it equally to many clusters with master and slave nodes managed by Kubernetes (K8's) minions to support modern containerized workloads. In this research, we utilize a framework intended for supporting classic and application load balancing, with predictive Auto-scaling approach which is used to forecast the traffic in advance and provision of resources with high-quality services and to minimize the expense of cloud utilization without violating Quality of Service (QoS) and Service Level Agreement (SLA).

Projection of cyclic workload is one of the most crucial and vital aspect in the perfect management of cloud infrastructure. Each request necessitates resources to finish its implementation and such resources are virtually made available through resource pool. The cutting edge CDC consists of different resources such as bandwidth, software, CPU, memory etc., in a virtualized form through Type-1 hypervisors from hardware layer whereas the users are assigned to finish their task performance on request. In accordance to preceding works, it is important to remember that resources are always larger than the real resources needed in order to finish the application [4]. The rationale for the supply of resources is that SLA violations are evaded and QoS satisfaction is attained. The resources are in most cases squandered during the allocation procedure. Although auto-scaling offers extremely excellent advantages, it is a difficult process to execute. Effective auto-scaling involves a new predictive strategy to predict the resources exactly using Machine Learning (ML) or Deep Learning (DL) to handle critical workloads. Auto-scaling shown in Fig. 1 comprises of three techniques, namely:

Fig. 1. Types of Scaling Techniques.

The strategy of reactive or manual auto-scaling where the resources has been wasted most of the times when workloads may get exceeded suddenly or decreased due to user specifies the threshold values and the required instances are automatically optimized as per the values hardcoded in the policy. The Proactive Scaling is Reactive with time scheduling to scale up or scale down the resources. In the case of predictive strategy, the cloud application workloads have been predicted through analyzing and visualizing those historical workload traces with minimum 24 hours of metrics history is needed to add or remove the instance capacity in before the first arrival of traffic. Thus, the predictive scaling is more efficient than reactive scaling and even familiar due to its spontaneous nature to allocate instances in advance to maintain optimum performance and the limitation in the predictive scaling is mixed instance policy in Auto-Scaling Groups cannot be supported, supports only CPU Metrics to forecast, and suits only for the applications which undergo periodic traffic spikes.

Precise predictions can be utilized to determine the right quantum of resources required to meet the needs. In order to accurately estimate the future workload, a precise and trustworthy prediction model is necessary. Normally in CDC, the job of the user comes in a pattern with irregular requirements on the resource. This is a big difficulty to anticipate the accurate workload [5]. Researchers have created many models for estimating workload and resource usage, focused mostly on forecasting the memory and CPU [6-8]. Several research projects have solely utilized statistical approaches to estimate load and for huge and diverse data, they cannot anticipate reliable outcomes. By means of machine learning models, numerous study efforts is done to forecast large and changing working loads in cloud. The results of these predictions are shown to be encouraging. Nevertheless, in regulated settings the statistical models can proactively anticipate time burdens. It is thus known that when using heterogeneous data, it will lead to greater predictability by integrating both statistical and machine teaching technologies. However, somewhat few research works were carried out in a field of resource forecasting at task stage [9]. The use of resources at task level helps to characterize activities that have a substantial influence on the capacity planning process, development of VM and assignment apportionment [10].

The CPU usage is one of the key metrics for the performance assessment of the cloud data center host and is utilized by researchers for server performance assessment [11]. CPUs are the utmost challenging resource in cloud data center servers and hence the main reason for not having a resource [12]. For cloud resource usage prediction and capacity

planning of CPU, several approaches have been employed namely, Auto-Regressive Moving Average (ARIMA), K-Nearest Neighbor (KNN), Feed-forward artificial Neural Network (FNN), Auto-Regression (AR), Recurrent artificial Neural Network (RNN), Extreme Learning Machine (ELM), Autoregressive Neural Network (AR-NN), and Multi-Layer Perceptron (MLP)[13], [14]. The use of CPU may be regarded as time function such that it could be pronounced as a time series issue. As a result, it becomes a regression problem that may be handled using neural networks or traditional time series.

The aim of the research is to avoid reactive nature of auto-scaling by introducing the predictive nature of auto-scaling solutions with AWS cloud platform which has the capacity to comply with the constantly changing load with QoS standards. The evaluated combinations of Maternal Data Centers in Dortmund and AWS Auto Scaling of Elastic Compute Nodes have been utilized for accessing the predictive auto scaling options. However, the trials are carried out using the LSTM deep learning concept with Explorative Data Analysis (EDA) to forecast the resource needed in advance by means of predictive scaling with visual analytics that has a capacity to auto-scale in and out to the Dev-Ops demand quickly. Hence, this technique is initially presented in the document has utilized to assess auto-scaling performance. Thus, the DCs are one of the biggest responsible for global warming and it our responsible to find some innovative ways for overcome this issues. The initiative of green cloud broker with LSTM based predictive auto-scaling has assisted to reduce CPU utilization, memory usage as well as energy consumption values to maintain in its directory.

The paper discusses the literature of elastic scaling of predictive method using time series forecasting method as well as auto-scaling of resource utilization using Machine Learning (ML) in Section 2. The Section 3 discusses the predictive auto-scaling of Dev-Ops user's resource allocation by EDA and LSTM technique for better and accurate prediction of unprecedented workload. Section 4 discusses experimental AWS platform and visualized real-world workloads to evaluate the predictive scaling approach. Section 5 has concludes that predictive auto-scaling by LSTM has improved the Dev-Ops users resource allocation for developing and running the applications with less compute and memory usage in a lesser time.

## II. LITERATURE REVIEW

The IaaS cloud uses predictive scaling technologies that guarantees cloud energy efficiency with reduced bill cost. Bi Jing et al. suggested a technique to forecast the amount of tasks at a successive interval in data center using ARIMA and hair wavelets, and findings showed that hybrid approaches lead to a greater predictive accuracy. The work does not address computer resources such as CPU, RAM, etc. which play a key role for the distribution of resources [15].

Janardhanan et al., in the Google cluster data utilized ARIMA and LSTM models to predict CPU workloads. The outcomes show that LSTM is 20 percent lower than the ARIMA model and has a higher consistency in its predictions [16]. The experiment on a single computer is implemented and

the use of CPU for this machine is projected. Furthermore, Cetinski et al. suggested an Advanced Model for Efficient Workload Prediction in the Cloud (AME-WPC) that utilizes both statistical and machine learning techniques to improve the job prediction precision over time. In aspects of lowering operational costs and handling resource, the proposed strategy is efficient. However, the prediction of certain cloud resources would help to automate and schedule the scale of resources [17].

In a novel method, M. U. Farooq et al. suggested RR. Initially, the most time of explosion is retrieved in RQ. The quantum time value is then derived by computing the 0.8 percent of this BT. If the number of processes in the queue is less than the quantum, they will be given the CPU, while the others will be queued. When all of the processes are completed, a quantum is given a new value equal to the highest BT, and the CPU is freed up for the remaining activities. This new technique worked wonderfully in terms of average waiting times, context switches, and turnaround times [18].

B. Dave et al. recommended a unique method to CPU scheduling the strategy's objective is to compute the best quantum time depending on the left over burst time in ready queue for the said work. Various tests have been carried out to determine the efficacy of this method. In evaluation to DQRRR, SARR, RR, MRR and IRRVQ algorithms, the findings show a reduction in the amount of context switches in queues or resources as well as outperformance [19]. A. Kaushik and D.Khokhar presented a novel approach to solve the RR algorithm's drawbacks. They developed a novel method for determining the optimum time quantum using the mean and median burst time of activities. Experience has proven the effectiveness of a new algorithm in terms of reducing waiting time and turnaround time [20].

Priyanka Singh, Palak Baaga, and Saurabh Gupta offer a detailed overview of the numerous methods that have been published earlier in their paper Assorted Load Balancing Algorithms in CC. Researchers looked at different algorithms and analyzed them based on numerous criteria to find a viable solution for load balancing in a CC environment. The algorithms' benefits and drawbacks are explored. The Minimum Connections Algorithm is one such algorithm. This approach takes the number of active connections that each server will have into consideration. Once a client tries to connect, the load balancer looks for the server with the fewest connections and allocates newer connections to that server. The Least Connections Algorithm is named from the fact that each server's connection is taken into account. It only prevents the server from becoming overburdened [21].

In their paper "Performance Evaluation of Round Robin (RR) Algorithm in Cloud Context," Neethu Myshri, R and Asha, M. L have highlight the RR algorithm's performance in a cloud-based atmosphere. For the goal of simulating and understanding the reaction of cloud computing and its deployment patterns, the use of a cloud analyst toolset has been chosen as a unique method. The proposed method is fairly similar to the Throttled algorithm. Load balancing is achieved in a way of delivering requests in a round-robin way to each server. RR is a typical load balancing scheduling technique for

distributing workload amongst servers. This method works well on clusters of servers that have the same specifications. It picks a node at random and distributes the job in a circular pattern [22]. Despite the fact that round robin is the simplest approach for distributing client requests over a set of servers, it suffers from non-uniformity in workload distribution owing to the servers' specs being similar. Furthermore, the Round Robin algorithm ignores priority, resource capabilities and job size. As a result, higher-priority and longer-duration operations have longer response times that can lead to server overloading.

Ming Yan et al. [23] presented a fusion elastic scaling strategy for Kubernetes (k8's) that combined reactive and proactive approaches. The proactive technique uses the Bi-LSTM model to learn the physical host and pod resource consumption history in order to anticipate future workload (Memory usage, CPU utilization). The Bi-LSTM prediction model is used with the online reinforcement learning with reactive model to achieve elastic scaling judgments. It has been shown in experiments that it can help the system achieve micro service SLAs in edge computing environments. The Bi-LSTM model has the least prediction error for the Root Mean Square Error (RMSE) metric when compared to ARIMA, LSTM, and RNN models. Despite this, no strategy for reducing oscillations has been offered.

Machine learning-based auto-scaling architecture is also suggested by Imdoukh et.al. The resource estimator tested the 1998 World Cup website dataset with the help of the LSTM model. They compared the results to those obtained using both the ANN and ARIMA models. The findings showed that while the proposed LSTM model has a little higher prediction error in one-step forecasting than the ARIMA model, it predicts 530 to 600 times faster [24].

Tang et al. proposed a Bi-LSTM-based container load prediction model that forecasts future load based on the container's historical CPU consumption. The recommended model has the lowest prediction error when compared to ARIMA and LSTM models. The authors, on the other hand, give no instructions on how to set up the parameters of the proposed model. Furthermore, the essay focuses only on future load projections and does not address auto-scaling concerns [25].

Mahmoud Imdoukh et al. proposed predictive auto-scaling for running container applications with docker containers for handling dynamic workload characteristics and for timely manner provisioning. The authors used the MAPE (Monitor, Analyzer, Planner and Executor) in auto-scaling architecture connected with Time-Series database. Further LSTM prediction model is used with multi step prediction and it as been compared with ARIMA where LSTM is 130 times faster to predict the real time usage of container auto-scaling. Further they discussed LSTM model performs better in terms of provisioning and elastic agility with auto-scaler metrics [26].

This session has discussed the literature instance of forecasting model of cloud computing resource allocation, provisioning and predictive scaling using Machine Learning ARMA, ARIMA, deep learning models like LSTM, Bi-LSTM that have played a major role in proactive scaling and to overcome the reactive scaling gaps. Similarly, the discussion

about load balancing schedule technique by dynamic Round Robin algorithm has utilized for better workload scheduler rather than classic load balancer. However, the support of this literature has addressed the issues of reactive auto-scaling and advantage of predictive auto-scaling by LSTM model. Therefore, this paper has motivated to fill the research gap using Predictive scaling on public cloud infrastructure by LSTM.

### III. RESEARCH METHODOLOGY

The cloud computing applications are involved with large variation in both development and operation areas that consist of an alternative existence during the solutions of suitable cloud infrastructure. The middleware solutions have involved by accomplishing Dev-Ops requirements with green cloud broker. However, this research has proposed a predictive scaling with green broker management method to maintain the elastic provisioning of VMs based on Public Cloud Service Provider (PCSP) to resolve Dev-Ops requirements without compromising QOS and SLA. Hence, deep learning technique has played a key role in predicting the required resource and allocates it to CSP with Dev-Ops knowledge that currently spread across various VMs or docker containers through virtualization or containerization in the form of elastic cluster management. The allocation of predictive VM resources using dynamic weighted Round Robin (RR) which is applied in scheduling the task based on the CPU time with weights for distribution over the Virtual Machines in a physical host. The RR technique efficiency act as the application load balancer that completely depends upon quantum or traffic. When the application traffic is high or quantum size is very large, then the RR technique may follow the first come first serve method with weights These application load balancers is called as new generation load balancer. It handles multiple applications on a unique physical host that contains VM's. The routing decisions are carried out in layer 7.

The proposed infrastructure of predictive scaling using LSTM technique is shown in Fig. 2. When the Dev-Ops users have cyclic workloads that have been sending through green cloud broker are sequenced as cloudlets by dynamic round robin technique applied in application elastic load balancer for regulating the incoming application traffics that has been distributed equally towards multiple target optimum instances for predictive scaling.

Then the predictive scaling engine utilizes the dataset along with timestamp to forecast the CPU resource utilization to provision the instances or nodes exactly from public Cloud data Centre which has virtualized resources to be provisioned with agility to the dev-Ops users as shown in Table I. The traces are gathered during a three-month period in the dispersed Materna Data Centers in Dortmund [27]. A month's worth of data is shown by each trace. The three dataset consists of the running 527 VMs in trace 1, 527 VM's in trace 2 and 547 VM's in trace 3 respectively of 69 cores and 6780 GB RAM. The workloads in the tracked VMs are mission-critical business applications from well-known organizations

throughout the world. It is studied using the LSTM deep learning concept as an Explorative Data Analysis (EDA) to forecast the resource needed by means of predictive scaling, having a minimum optimum capacity to auto-scale in and out to the Dev-Ops demand quickly in advance.

The steps involved in EDA has progressed LSTM algorithm by importing libraries and setting the seeds for generating random numbers by fixing a starting number. The collected raw data is made to data cleansing which removed and imputed the missing data. The data processing is done by min max scalar splitting the cleaned dataset to 60% of train dataset and 40% of validation (test) dataset which can be executed through EDA as shown in Fig. 3. Once the EDA process is done, the dataset is train to fit LSTM model based on the layer of optimizer ADAM (ADaptive Moment estimation), sequential and ReLu. Finally, the output layer of LSTM defined the predicted values through visualization report. The working principle of LSTM model as well as predictive auto-scaling algorithm using LSTM model is discussed.

#### IV. WORKING OF LSTM AND GRU METHOD IN DEEP LEARNING

Deep Learning methods executes well on large and multivariate time-series prediction problems. The performance of learning model is better after training in complex and more non-linear data. LSTM is more accurate for large dataset with long-term predictions and ultimately deep learning has automatic feature extraction on comparing flat machine learning [28].

The working mechanism of the LSTM is illustrated in Fig. 6, and the LSTM is a kind of modern Recurrent Neural Network (RNN) architecture that remembers information at variable intervals. The LSTM algorithm is well-known for classification and forecasting time series requires lagging of timestamps with uncertain periods. One of the major advantages of LSTM is about gap length over relative insensitivity that provides better solution compared to alternative RNNs, Hidden Markov Models (HMM) and various traditional techniques. However, the case of RNN and HMM are completely depend upon the hidden state which initiated before emission and sequence results in vanishing gradient problem. Instead of predicting 10 intervals, the application is predicting 1000 intervals of sequences, the model may forgot the initial points from other technique like RNN and HMM, because the last hidden state doesn't have any information of past to remember, but it can be resolved by LSTM.

GRU (Gated Recurrent Unit) can predict well and performs fast on small datasets. The architecture of GRU which was shown in the Fig. 5 is simpler on comparing LSTM structure. The flow of information in a sequence chain can be regulated by gate structure. The GRU has only two gates known as Reset and Update gates. GRU do not use memory unit like LSTM. GRU is easier to modify. But LSTM and GRU perform moreover equal but LSTM remembers long sequences. The Full GRU Unit has shown in Fig. 4.

#### FULL GRU Unit

$$\bar{c}_t = \tanh(W_c[G_r * c_{t-1}, x_t] + b_c)$$

$$G_u = \sigma(W_u[c_{t-1}, x_t] + b_u)$$

$$G_r = \sigma(W_r[c_{t-1}, x_t] + b_r)$$

$$c_t = G_u * \bar{c}_t + (1 - G_u) * c_{t-1}$$

$$a_t = c_t$$

Fig. 4. GRU Unit.

Fig. 5. GRU Working Process.

The cell state that consists of looping arrows that reference the recursive cell nature is believed to constitute the long-term memory in general. In equation 1, the long term memory acknowledges that data from previous intervals that has been stored in LSTM cell shown in Fig. 6.

$$c_t = f_t \circ c_{t-1} + i_t \circ \tilde{c}_t \tag{1}$$

The forget gate, which is below the cell state and adjacent to the input modulation gate has changed the cell state. The previous cell state is forgotten, which is multiplied by the forget gate and the latest information is gathered via the input gates output, according to equation (2).

$$f_t = \sigma(W_f[h_{t-1}, x_t] + b_f) \tag{2}$$

The remember vector is commonly referred to as the forget gate, since its output has shown the cell state, which comprises of information contained in forgot multiplied by 0 to the matrix position. When the forget gate output is 1, the information in the cell state is retained as it is indicated in equation (3). As a result, the input gate is represented as a sigmoid function that is applied to the weighted input for observation as well as the previously concealed state.

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \tag{3}$$

Furthermore, these gates can determine what data has to be put in the cell state, with the activation functions for each gate accounting for a considerable percentage of the total. As a result, the input gate is modeled as a sigmoid function with a range of [0,1]. If the summing of cell states among the previous cell states is supplied, the sigmoid function can only accumulate memory and not erase forgotten memories. Similarly, the float number is summation among [0, 1] which may never considered to be zero or forget. The input modulation gate in this example has been modeled after the tanh activation function indicated in equation (4) whereas the range of tanh is [-1, 1] which admit the forget memory present in the cell state shown in Fig. 6.

$$\tilde{c}_t = \tanh(W_c[h_{t-1}, x_t] + b_c) \tag{4}$$

Thus, the focus vector is generally named as the output gate. There are several potential values in the matrix are made to move forward to the subsequent hidden state is expressed in equation 5.

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \tag{5}$$

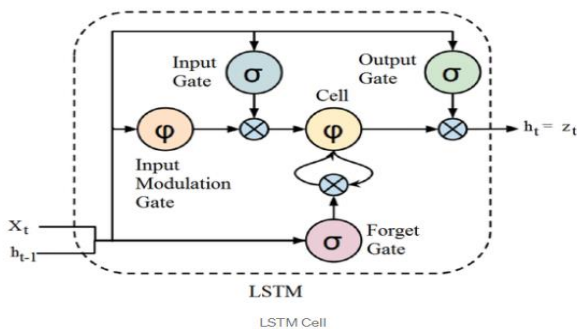

Fig. 6. LSTM Working Process.

The memory usage is generally named as hidden state whereas the data is considered for the next sequence which is illustrated in equation (6) that performs as an analog for the hidden state in RNN.

$$h_t = o_t \circ \tanh(c_t) \tag{6}$$

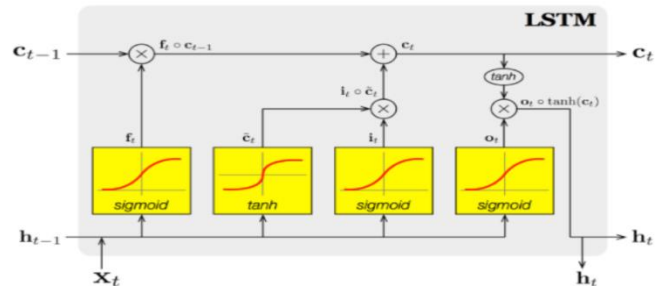

Fig. 7. LSTM Cells Activation Function.

The forget gate that aids in the forgetting of information from a previous cell state, is the sigmoid's initial activation function (Ct-1). Furthermore, the following sigmoid and initial tanh activation functions are used as input gates, and the information is either stored to the cell state or elapsed. As a result, the preceding sigmoid serves as an output gate, determining which information must be sent on to the next hidden state as shown in the Fig. 7.

**Algorithm for Predictive auto-scaling using LSTM**

**Inputs:** Resource utilization from DevOps users, VMs, Load balancer with RR technique, Data Set, CPU load capacity.

**Output:** Predicted CPU Resource utilization for auto-scaling the nodes.

- Step 1:** Request the instances by Dev-ops users for cyclic workloads.
- Step 2:** On user request the cloudlets can be sent through RR technique for further escalation to Predictive Scaling Engine to forecast the future workload demand using LSTM Model.
- Step 3:** Load the dataset for Data preprocessing which can be done through min max scalar through EDA and fit the LSTM model and GRU model for further execution to train and test.
- Step 4:** Based on the CPU workload, the data acknowledged with long term memory from earlier interval is stored in LSTM cells as per equation 1.
- Step 5:** Modification of cell state is done through forget gate as per equation 2 and the recent information gets accumulated in the output of input gate.
- Step 6:** If the forget gate is set to 1, the data is kept on its own as shown in equation 3, else the information present in the forget gate is multiplied by 0 in the matrix position.
- Step 7:** The weighted input has been applied to the optimized ADAM layer as a sigmoid function with the range [0, 1] for observation as well as prior concealed state.
- Step 8:** The forgotten memory existent in the cell state is accepted by the input modulation gate, which is a tanh activation function performed on the ReLu (Rectified Linear Unit) layer as per equation 4 with a range of [-1, 1].
- Step 9:** The hidden state representing memory usage with data is considered for the next sequence as per equation 6 that performs as sequential layer.
- Step 10:** The process of LSTM is executing the current VMs based on VM list provided through proper VM instance type by EDA.
- Step 11:** If CPU actual load\_capacity > predictive workload, trigger auto-scale in policy (VM-1) else scale-out (VM+1) with cool down time and also by enabling dynamic scaling for cost optimization.
- Step 12:** Update the provisioning instance count and repeat the steps 3 to step 11
- Step 13:** Terminate VMs and return.
- Step 14:** Visualize the Results for further auto-scaling of right instances to be deployed for running the workloads in public cloud.

Auto-Trigger Policy For Predict and Scale:

```
Cat<<EOF>> predict_sclae_policy_cpu.csv // Load History of traces
{
  Region: me-south-1
  {"Metrics": [CPU], "Instance Type":t2, "Cores":8, "Unit"=MHZ}
}
if{"Actual_Target_Value:123>Predicted_Targeted_value=109, VM-1 else
VM+1 "Predefined Metric Type: ASGCPUtilization"}}
{"Mode": Predict and Scale, "Cool down time":300 seconds} EOF
```

However, the request from the Dev-Ops user’s workload are balanced through dynamic weighted RR technique and analyzed by EDA. The process of EDA workloads are performed with predictive auto scaling as auto-scale in of VMs and auto-scale out of VMs are progressed. The progressed VMs are assigned to the respective CSP users precisely with less usage of CPU capacity as well as minimized memory usage. The proposed predictive scaling by LSTM is evaluated by comparing it with Gated Recurrent Unit (GRU) method.

V. RESULT AND DISCUSSION

This research experiment has utilized the AWS platform and simulated real-world workloads to evaluate the predictive scaling approach through Amazon Sagemaker or Google Colab compatible. The CPU core utilized is 8 with 32 GiB of memory, EBS storage, 2.20GHz Intel(R) Xeon(R) turbo boost and 6 bit platform. The host machines for this experimental instance are t2.large, t2.xlarge and t2.2xlarge of same family with burstable performance instances, all of which feature Intel scalable CPUs with speeds up to 3.0 GHz. In this paper, the implementation of the elastic resource allocation strategy is based on the Quality of Service (QoS) performance criterion. However, the recommended method has the ability to meet an appropriate demand in different kinds of varied workloads. Hence, the proposed approach has considered both reducing the CPU utilization and memory usage which progressively reduced the cost of resources utilization. The optimization outcome of QoS parameters for the proposed predictive auto-scaling by LSTM is shown in Table II reveals that the actual CPU and memory usage is high but the recommended CPU and memory usage is low and hence we can save the bill cost in usage of Compute as well as memory instances.

TABLE II. PERFORMANCE RESULTS OF PREDICTIVE AUTO-SCALING FROM LSTM METHOD

DateTime	CPU usage [MHZ]_Actual	Memory usage [KB]_Actual	CPU usage [MHZ]_Predicted	Memory usage [KB]_Predicted
2016-02-02 00:00:00	58	115763	81.240875	136286.890625
2016-02-02 00:05:00	123	332189	106.497734	405408.000000
2016-02-02 00:10:00	62	148478	67.060234	163492.187500
2016-02-02 00:15:00	49	198810	66.726730	151165.390625
2016-02-02 00:20:00	60	0	66.162521	140813.171875

VI. PERFORMANCE ON CPU UTILIZATION

Fig. 8 and Fig. 9 have illustrated the actual and predicted usage trends of CPU based on the date time through visualization insights. The range obtained in the LSTM CPU usage is from 45 to 125MHZ.

Fig. 8. CPU usage of Actual vs Predicted for LSTM Technique.

Fig. 9. CPU usage of Actual vs Predicted for GRU Technique.

The maximum CPU resource utilization of actual and predicted for LSTM at 2016-02-02 00:05:00 are 123 MHZ and 109.12 MHZ respectively but in the case of GRU, the CPU utilization at the same datetime is 123 MHZ in actual and 117.18 MHZ in prediction. When comparing the predicted CPU usage of LSTM shows that it is lesser resource utilization than GRU. Therefore, the instance provisioning of LSTM is less while compared to GRU method.

VII. PERFORMANCE ON MEMORY USAGE

Fig. 10 and Fig. 11 have illustrated the actual and predicted usage of memory based on the datetime. The range obtained in the CPU usage is from 45 to 125MHZ. The maximum memory utilization of actual and predicted for LSTM at 2016-02-02 00:05:00 are 332.19 MB and 422.45 MB respectively but in the case of GRU, the memory utilization at the same datetime is 332.19 MB in actual and 398.35 MB in prediction.

However, when comparing the predicted memory utilization of LSTM is higher in resource utilization than GRU but in the other datetime, predicted memory utilization of LSTM is very less than GRU. Therefore, the instance provisioning of LSTM is less as well as avoiding traffic while compared to GRU method.

Fig. 10. Memory usage of Actual vs Predicted for LSTM Technique.

Fig. 11. Memory usage of Actual vs Predicted for GRU Technique.

Moreover, the error rate calculation is done through RMSE value and it is a standard procedure to measure the error of the model in forecasting the quantitative data. It can be measured with the given formula shown in the Fig. 12.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{n}}$$

Fig. 12. RMSE SCORE.

The proposed predictive scaling in LSTM technique is 0.0081 whereas in the case of GRU is 0.0095 that affect the accuracy of the predictive scaling of GRU while comparing to LSTM. Thus, the accuracy of predictive scaling in LSTM is higher may assist in reducing the usage of instance provisioning by minimizing the energy consumption and reduction in bill cost.

### VIII. CONCLUSION

The essential factor required for current situation is green computing which provides the environment with beneficial computing power that believes on energy efficient computing. This paper has presented few basic concepts of predictive auto-scaling with EDA and LSTM algorithm. The working principle of tanh and sigmoid activation function as input has assisted to predict and forecast the predictive scale in and scale out process exactly and accurately. The pitfalls performance has followed the predictive nature to the web application in public cloud. Moreover, the avoidance of these pitfalls can be done through predictive auto-scaling by LSTM technique and validated in a real-time environment. Hence, the result of CPU

usage and memory utilization performances defines the performance of ReLu layer and sequential layer of LSTM technique in cloud computing application. Thus, the comparison of LSTM method is compared with GRU technique for evaluating the performance of CPU usage and memory utilization. The evaluation results determined that CPU utilization and memory usage of LSTM is lesser than GRU method and RMSE value of LSTM is 0.0081 but in GRU is 0.0095 illustrated that error rate is higher in GRU. Moreover, the utilization of predictive scaling method has illustrated an improved performance in terms of energy efficiency by determining the better and reduced utilization of CPU as well as less memory usage while compared to GRU in large data set. This presented innovative idea for Dev-Ops users for unprecedented and cyclic workloads with green cloud brokers through predictive auto-scaling by LSTM has provided the CDC to reduce power consumption without violating QOS and SLA.

# Highly Efficient Parts of Speech Tagging in Low Resource Languages with Improved Hidden Markov Model and Deep Learning

Diganta Baishya, Rupam Baruah

Department of Computer Science and Engineering  
Jorhat Engineering College  
Jorhat, India

**Abstract**—Over the years, many different algorithms are proposed to improve the accuracy of the automatic parts of speech tagging. High accuracy of parts of speech tagging is very important for any NLP application. Powerful models like The Hidden Markov Model (HMM), used for this purpose require a huge amount of training data and are also less accurate to detect unknown (untrained) words. Most of the languages in this world lack enough resources in the computable form to be used during training such models. NLP applications for such languages also encounter many unknown words during execution. This results in a low accuracy rate. Improving accuracy for such low-resource languages is an open problem. In this paper, one stochastic method and a deep learning model are proposed to improve accuracy for such languages. The proposed language-independent methods improve unknown word accuracy and overall accuracy with a low amount of training data. At first, bigrams and trigrams of characters that are already part of training samples are used to calculate the maximum likelihood for tagging unknown words using the Viterbi algorithm and HMM. With training datasets below the size of 10K, an improvement of 12% to 14% accuracy has been achieved. Next, a deep neural network model is also proposed to work with a very low amount of training data. It is based on word level, character level, character bigram level, and character trigram level representations to perform parts of speech tagging with less amount of available training data. The model improves the overall accuracy of the tagger along with improving accuracy for unknown words. Results for “English” and a low resource Indian Language “Assamese” are discussed in detail. Performance is better than many state-of-the-art techniques for low resource language. The method is generic and can be used with any language with very less amount of training data.

**Keywords**—Hidden markov models; viterbi algorithm; machine learning; deep learning; text processing; low resource language; unknown words; parts of speech tagging

## I. INTRODUCTION

Parts of speech tagging can be viewed as the problem of word classification. Each such class contains words having some common properties regarding their usage in the sentences. For example, the English language contains the following parts of speech: ‘noun’, ‘pronoun’, ‘verb’, ‘adjective’, ‘preposition’, ‘conjunction’, and ‘interjection’. The meaning of a sentence and its grammatical correctness depends on the kind of parts of speech being used in the sentence. The

accurate parts of speech tagging can only determine the correct interpretation of the text. Any Language Processing task, therefore, depends heavily on the accuracy of tagging. Information in natural languages like parts of speech can be helpful in many language-related tasks. But, most of the developments of natural language processing are observed for a few dominant languages spoken widely in the world. This is because of a lack of extensive research and the non-availability of computable resources for other languages. It is therefore very important to identify the key factors that affect the accuracy and to make proper use of them so that such languages can also benefit from the advancements of natural language processing techniques. The concern is to find the innovative idea to improve accuracy for languages with fewer amounts of data available for use. With the availability of methods to work well with low training, we can develop NLP applications for languages that are poor in terms of computable resources. Also, it is important to design systems that can be used across any language so that the benefit can be transferred to any language.

The Hidden Markov model is one of the most popular stochastic models used for natural language processing. The Viterbi algorithm uses Hidden Markov Model to find the most likely sequence of hidden states. It is used to derive an observed sequence. Thus, the algorithm can be used to predict parts of the speech tags of a sequence of words [1]. The model is trained with a large amount of already tagged training data. Such a model does not work properly when training data is less in volume. The model fails to learn the behaviour due to less training and also due to unknown words that were not used during training. The accuracy is further low in the cases of languages for which adequate training data are not available for training the model. A lot of research has been carried out to overcome this by modifying the hidden Markov model for unknown words but there is a lot of scope for improvement. Most of the research has been carried out to improve the Hidden Markov Model and Viterbi Algorithm using a large training dataset and with the imposition of some rules. Usage of huge training datasets limits the scope of the methods only to those languages that are very rich in computable resources. Also, rule-based methods limit the scope only to the specific language in context because rules are language-dependent. Hence, a language that is not studied in many details cannot get the benefit of rules-based NLP methods. This paper describes

two specific works to improve performance automatic parts of speech tagging for languages with low quantity of resources in computable form. At first, we introduce a new method to calculate the probability for unknown words. We use bigram and trigram of characters for this purpose and we have also made modifications to the Viterbi algorithm accordingly. The bigram and trigram combinations of characters are used as resources during training for the Hidden Markov model. Bigram and trigram of characters help to model unknown words and also to improve recognition for untrained words. Improving accuracy for unknown words improves the performance for languages with fewer amounts of computable resources available for training. Experiments have been conducted in English languages. We have also tested the same with a small set of Assamese, a low resource language spoken widely in North East India. We have reported results that show considerable improvement. The concept is generic and can be used with any language. This is helpful especially for languages with very less amount of computable resources. Such languages cannot be trained with a huge amount of vocabulary due to lack of data and it results in many unknown words being encountered while testing the system.

Next, a deep learning method is proposed to improve recognition for words using bigram and trigram of characters. Machine Learning and deep learning models are very much popular these days. This kind of model learns the behaviour of the system after being trained with enough labeled datasets. The model learns the association of training datasets and applies it to the real data with good accuracy. Such a model needs to be trained with a huge amount of training data to learn the behaviour well. Challenge is to make the system learn from the least amount of available data so that it works for low-resource languages. We have therefore discussed the proposed deep learning architecture that is capable of classifying the words into defined parts of speech with considerable accuracy. It is based on word level, character level, character bigrams, and character trigram level representation.

The rest of the paper is organized as follows: Section II next describes some of the earlier works and popular methods used for automatic parts of speech tagging, the Hidden Markov Model, parts of speech tagging related to low resource languages, and machine learning methods. Section III describes the research objective in brief. Section IV describes the proposed methods and the data sets used for the purpose. Section V outlines the experiments and results. Section VI discusses the outcomes and Section VII concludes with the future scope of improvements. The reference section outlines the references used in the paper.

## II. EARLIER WORK

### A. Works Related to Parts of Speech Tagging

The automatic parts of speech tagging is one of the key areas of research since people started working on processing natural languages. Rule-based methods, stochastic methods, and transformation-based learning approaches are the most widely used supervised techniques for parts of speech tagging. The stochastic or probabilistic methods use a training set and calculate the probability of a word belonging to all possible tags. Based on this calculation, it then assigns the tag with the

highest value of probability. As outlined by Martinez (2011), one of the popular methods involved in POS tagging is the Rule-Based Method which is based on a set of rules set by humans [2]. However, it requires too much manual intervention and also requires in-depth knowledge of grammatical rules that varies from language to language. Transformation Based Learning is also used recently to automatically tag POS where the rules are learned from an initially annotated corpus. This method requires a huge amount of training to make the system learn and provide accurate results. The most popular method for POS tagging is Markov Model Taggers that are based Hidden Markov Model. It works on statistical methods to find the best possible sequence of tags out of the possible tag sequences. It consists of three components: outputs, transitions, and states where states represent the tags in case of POS tagging. Maximum Entropy Methods, Support Vector Machines, Neural networks, Decision trees, etc. are some of the other methods used for this purpose. Accuracy can be obtained above 95%, but the model needs to be trained with a huge training dataset [2]. Among the early works, Janas [3] in 1977 proposed a two-step method based on knowledge of linguistic regularities for English texts. He used a large corpus to get 84% of words tagged correctly. Research into parts of speech tagging for languages other than English has also progressed a lot recently. Fernando et. al (2016) recently presented a Support Vector Machine-based Part-Of-Speech tagger for the Sinhala language [4]. Application of Hidden Markov Models based tagger for the language is far behind as stated by the authors. They reported an overall accuracy of 84.68%, and unknown word accuracy of 59.86%. Better use of techniques like the hidden Markov model will be helpful to improve accuracy for the Sinhala language. But unavailability of a huge corpus like that of English is a concern to do so. Hyun-Je Song and Seong-Bae Parkhave (2020) have recently addressed two of tagging for Korean Language problems using a two-step mechanism [5]. Udomcharoenchaikit, Boonkwan, and Vateekul (2020) have introduced an evaluation scheme of Sequential Tagging Methods based on an example-based system using known spelling errors for the Thai language [6].

### B. Related Works using Hidden Markov Model

The Hidden Markov Model is the most popular stochastic method for automatic parts of speech tagging. Cutting et al. described [1] some initial works on automatic parts of speech tagging based on the Hidden Markov Model (HMM). They reported an accuracy of 96% using Brown corpus [7], developed by Francis et al. (1979) for English. Cing et. al. (2019) presented a comparison of using HMM only, and HMM with morphological analysis for parts of speech tagging of Myanmar Language. Morphological rules are used to improve performance for unknown words. They have stated in conclusion that using only HMM for a small dataset has no scope at all. A large training dataset or rule-based method in combination with HMM is the only solution [8]. Jurgen et al. (2011) used infinite HMM for parts of speech tagging in an unsupervised manner [9]. Myint et al. [10] proposed to use lexical information with HMM for the Myanmar language as HMM is only capable of using in contexts, not lexical information. They have therefore proposed Lexicalized Hidden Markov Models (L-HMMs) for improving recognition.

Thorsten Brants [11] reported that a Markov model-based tagger performs at least as well as other approaches, including the Maximum Entropy framework. He has used some rules on top of HMM for unknown words and found an accuracy of up to 81%. Ferran PLA and Antonio Molina [12] applied Lexicalized Hidden Markov Models and reported improvement of accuracy for part-of-speech tagging. They reported 6% improvement for unknown words. Recently Tham et. al. (2020) have reported the usage of hybrid POS tagger for the Khasi language. A tagger is developed using the Hidden Markov Model (HMM). It is then integrated with conditional random fields (CRF) rules. The errors obtained from the first tagger are used to improve accuracy [13]. Rule-based features are very much dependent on language. Jassim et. al(2021) have used an N iterative HMM model for parts of speech tagging in Iraqi National Song. The iterative approach has improved accuracy as claimed by the authors [14]. Since HMM uses a huge amount of training data, it can very well map the context of the words and provide high accuracy as seen in the works conducted by the researcher discussed above. However, the model suffers in the case of words that are not trained during training. Among the early works, Ratnaparkhi (1996) proposed a maximum entropy model [15] to successfully tag unseen words with accuracy up to 96%. It uses some specialized features to take decisions and uses approximately 900 thousand of words from Wall Street Journal corpus as a training data set taken from the Treebank project (Marcus et al., 1994) [16]. Robert M. Losee [17] used tagging for improving decision-making with the help of linguistic information. Toutanova et al. [18] proposed a part-of-speech tagging using lexical features, preceding and following text context with fine-grained modeling for features of unknown words. Martin Haulrich reported [19] the implementation of a part-of-speech tagger based on the first-order Hidden Markov Model and compared different strategies to improve the result for unknown words. Other rule-based techniques take decisions based on the presence or absence of a number, upper-case letter, etc as proposed by researchers [15]. Rules may be added to improve accuracy for the unknown word. But these rules are language-dependent. Scott M.Thede [20] proposed a few statistical methods for predicting unknown words. The methods are applicable to any language. The author used Brown corpus [7] in this case too. Mikheev (1996) used the beginning and end of a word to predict the parts of speech for unknown words [21]. They used certain morphological rules: Prefix rules, suffix rules, and ending-guessing rules. Anastasyev et. al [22] described rules for detecting unknown word tagging for rich languages. Use of context, word endings are used as clues for detecting parts of speech. The following sections detail the basics principle of the Viterbi Algorithm and Hidden Markov Model.

### C. Basic Principle of Hidden Markov Model

The Hidden Markov Model (HMM) basically comprises of two kinds of events: observed events and hidden events. For the part of speech tagging problem, observed events are the words that appear in the input text and hidden events are the parts of speech that are to be predicted. Components of hidden Markov model are: a matrix of state transition probability, sequence of observation, sequence of emission probabilities and initial probability distribution [23] [24].

1) *Transition probability*: It is the first Markov assumption which implies that the current state depends only on the previous state. We will call this as transition probability. A transition probability matrix is to be calculated based on training data for all pairs of tags (states). Mathematically it is represented by:

$$P(q_i|q_1...q_{i-1}) = P(q_i|q_{i-1}) \quad (1)$$

where,  $q_i$  is the state at  $i^{\text{th}}$  instance.

### 2) *Emission probability*

$$P(o_i|q_1...q_i,...,q_T, o_1,...,o_i,...,o_T) = P(o_i|q_i) \quad (2)$$

Here,  $o_i$  is the observation at  $i^{\text{th}}$  instance.

This second Markov assumption implies that the observation at any instant depends only on the present state. We will term it as emission probability. An emission probability matrix is to be calculated based on training data for all pairs of tags (states) and words (observations).

3) *Viterbi algorithm*: It is used to predict the part of speech of a word based on maximum likelihood calculated as:

$$V(t(j)) = \max : V(t-1) * a(i,j) * b_j(O_t), \quad (3)$$

$V(t(j))$  is the Viterbi path probability of the model being at state  $j$  at any instance, after observing the first  $t$  number of observations. Here  $a$  is transition probability matrix and  $b$  is emission probability matrix [25] [26].

The problem with this basic algorithm is the fact that the emission probability  $P(o_i|q_i)$  is zero for an unknown word. It is because.

$$P(o_i|q_i) = N(o_i|q_i) / Nq_i = 0 \quad (4)$$

where,  $N(o_i|q_i)$  is the number of time observation  $o_i$  appears in training set as state  $q_i$  and  $Nq_i$  is the number of time state  $q_i$  appears in training set. Hence, over the years scientists have come up with different methods to improve accuracy for such words. One simple method is Laplace smoothing, where the following modification is made:

$$P(o_i|q_i) = (1+N o_i|q_i) / (Nq_i + V)$$

where  $V$  is the length of vocabulary trained.

Considering only the transition probability for calculation in case of unknown words is another option to overcome it by replacing the value zero by one .A brief discussion on earlier works in this area is discussed above in this section.

### D. Related Work for Low Resource Languages

The resources available for the available languages in the world are extraordinarily unbalanced [27]. There are many organizations that are working dedicatedly for technology development on low resource language. Under the LORELEI (Low Resource Languages for Emergent Incidents) Program of Linguistic Data Consortium for DARPA, researchers are working on developing NLP technologies for natural disaster management for almost three dozen low resource languages [28]. NLP research teams are working seriously on approximately 20 of the almost 7000 languages of the world

leaving a majority of the population not reachable to advanced NLP applications [29]. Low resource languages are those language that are less computerized, less privileged resource scarce languages. These are languages where statistical methods cannot be applied due to the availability of fewer data [29], [30], [31], [32]. As Simpson et. al. [33] reported that a low resource language: "All meet the basic criteria of being significant in terms of the number of native speakers but poorly represented in terms of available language resources." Christopher et. al. states that defining a language as "low resource language" depends on the Demography, Linguistics, and Resource availability of the language and the speakers [31]. Some amount of work has been done for low resource languages, but the researchers are not yet able to develop NLP applications for majority of the languages. This is because a strong language-independent method is highly essential to work with languages with fewer amounts of training data to develop NLP applications. With the low amount of training, testing always encounters more and more unknown data and it eventually makes the hidden mark model not much useful for such cases. Recently, some works [34] [35] for resource-poor language and rule-based methods have shown some improvement. But still, rule-based NLP applications are language-specific and the advantages are limited. Researchers have used unsupervised techniques for low resource languages. N-gram Models [36] can be also very useful for of processing many natural language processing tasks. Authors reported some considerable result taking help from another resourceful language as parent language and with standardized text for the two languages [37], [38]. But they also reported difficulty in choosing the parent language because typologically close languages do not always work best. Researchers have used modern days supervised techniques based on long short-term memory networks (LSTM) on multilingual embeddings to get good results. But that also requires quite a large training dataset [39], which is not available for most of the languages. Some Researchers have used bilingual lexicon available to some extent for few languages to investigate the possibility of designing language models with limited training data. The method uses the learning of cross-lingual word embeddings to train monolingual language models. The training shows improvements due to the pre-training process [40]. Some amount of work has also been done for Assamese using some stochastic methods [41], [42], [43] [44] [45]. Recently authors have discussed the key areas of NLP research in Assamese [46]. Researchers have also been working recently on parts of speech and other nlp issues on Arabic languages [47] [48].

#### E. Related Work using Machine Learning

Recently deep learning methods have gained high popularity. The same is being used for Indian and other low-resource languages. Sequential deep learning methods are very popular in this regard. Some of them are long short-term memory (LSTM), bidirectional LSTM, gated recurrent units (GRU), recurrent neural network (RNN), etc. Authors in [49], have applied deep learning for tagging the Chinese Buddhist language. Their learning model is based on RNN. The model as informed by the author is more effective than traditional methods. Bidirectional LSTM is another popular method in this regards authors in [50], experimented with

BLSTM and auxiliary loss over a set of 22 languages. They used the auxiliary loss to improve the performance for rare words. Techniques of using character level along with word-level representation are used recently for POS tagging using deep neural networks. Authors in [51] used the method for English and Portuguese. A convolutional layer was used to prepare the data with character representation. Authors in [52] discussed in detail, how to represent character-level information from raw text. They successfully did it to predict the next character from a given sequence of characters. They used a simple recurrent network for this purpose.

Authors in [53], reported using the character level outputs of convolutional neural network (CNN) as inputs to an LSTM RNN model. The authors have stated that it highly improves the performance in the case of morphologically rich languages like Russian, Spanish, French, Czech, Arabic, German. Machine learning approaches have recently been used with many low-level languages. Authors in [54] described their architecture for Korean POS tagging. They addressed the issue of rare word detection by input-feeding and copying mechanism and got considerable results. Authors in [55] used machine learning models for POS tagging of Sanskrit language. They represented each word as a point and then used clustering with LSTM autoencoder to get the tagging. Authors in [56] used deep learning methods for the Nepali language. They used Long Short-Term Memory Networks (LSTM), Recurrent Neural Network (RNN), Gated Recurrent Unit (GRU), and bidirectional variants to successfully tag Nepali words with high accuracy.

### III. RESEARCH OBJECTIVES

Parts of speech is the preliminary pre-processing step that requires to be executed for any NLP application. But the popular methods available for tagging require a huge amount of training data. They perform very poorly for languages for which a huge amount of training data is not available. The problem is to develop parts of speech tagging methods that are applicable to any language in the world with a very low amount of computable resources.

Most common methods like the Hidden Markov Model and Machine Learning are not well applicable to languages where large amounts of computable data resources are not available. Accuracy is also not very high for words that are not trained earlier because the models cannot read much information for such words. Some of the rule-based methods are mainly used to address these issues. But the scope of such a rule is limited and dependent on the language for which rules are set. The need is to develop systems that can improve accuracy, especially for unknown words, with low training and applicable to any language. This paper concentrates on language-independent approaches towards using the Hidden Markov Model and deep learning techniques with a very small amount of training data so that it can be used for any low resource language with considerable performance. Main focus is to devise language-independent methods to improve accuracy especially, the accuracy of unknown words which is the major concern for any supervised method trained with a low training dataset.

#### IV. PROPOSED METHOD

##### A. Using Modified Viterbi Algorithm

We have proposed modifications to Hidden Markov Model to improve accuracy for untrained words with a small set of training data. We have used Subset from Brown Corpus [7], which is mostly used by researchers in this area. This will give a better platform for comparing proposed modifications with exiting methods. Proposed method is based on probability of character bigrams and character trigrams. The emission probability of a character bigram  $b_i$  given tag  $t_i$  is calculated as follows:

$$P(b_i | t_i) = N(b_i | t_i) / N(t_i) \quad (5)$$

where  $N(b_i | t_i)$  is number of time bigram  $b_i$  appears in training set as tag  $t_i$  and  $N(t_i)$  is Number of time tag  $t_i$  appears in training set. Similarly

$$P(tr_i | t_i) = N(tr_i | t_i) / N(t_i) \quad (6)$$

where  $N(tr_i | t_i)$  is the number of time trigram  $tr_i$  appears in training set as tag  $t_i$  and  $N(t_i)$  is Number of time tag  $t_i$  appears in training set.

The probability of unknown words is calculated based on the fact that bigrams (and trigrams) constituting the unknown word may have already appeared in some trained words, and thus this information may be used to predict the possible tag of the unknown word being tested. We assume that the probability of a word given a tag is proportional to the product of probabilities of sequences of character bigrams (also trigrams) of the word given the tag. Thus instead of considering the emission probability of unknown word as zero or one, we make the following changes:

$$P(o_i | q_i) \propto c * P(b_1 | t_i) * P(b_2 | t_i) * \dots * P(b_n | t_i) \quad (7)$$

where  $c$  is a constant and  $b_1, b_2 \dots b_n$  are the bigrams of the characters constituting the word  $o_i$ .

Hence, equation (3) can be rewritten as

$$V(t_j) = \max: V(t-1) * P(b_1 | t_i) * P(b_2 | t_i) * \dots * P(b_n | t_i) * b_j(O_i) \quad (8)$$

If any value of  $P(b_k | t_i)$  turns out to be zero, it is considered to be a very small value to avoid zero product.

Similarly the same kind of modifications can be made for trigrams of characters:

$$V(t_j) = \max: V(t-1) * P(tr_{i1} | t_i) * P(tr_{i2} | t_i) * \dots * P(tr_{in} | t_i) * b_j(O_i) \quad (9)$$

If any value of  $P(tr_{ik} | t_i)$  turns out to be zero, it is considered to be a very small value to avoid zero product. This is an alternative to considering a zero or one value for the emission probability for the entire word as discussed in the previous section. This helps us to guess the probability of an unknown word, by using the probabilities of bigrams that may have occurred with other words that are already trained.

##### B. Using Deep Learning Architecture

The recent usage of neural network and machine learning methods has proved to be very much useful in modern technology. One of the most popular neural networks used for this purpose is a recurrent neural network (RNN). It feeds the

output of one stage as input to the next. The states in RNN can store input of variable length of sequences. This particular property makes it very much useful for inputs with variable lengths like text sentences, speech processing, etc. LSTM is a kind of RNN that uses a special unit that can store memory for the long term. This kind of model can keep information retained for a long time because of its ability to select the kind of information to retain.

We have designed an architecture for the deep learning model and have successfully implemented it to work considerably well with less amount of training data. The work is inspired by [57], [58], and [59], where authors have used character-level representation along with word-level representation to train the model. We take a sequence of tagged words and feed the words, characters, bigrams and trigrams of characters of words into the first layer of the learning model. We have experimented with different parameters of the layers to get the best-suited architecture. The first layer of the learning network transforms words into feature vectors. It captures information about words' semantic and their morphological characteristics. Every word is converted into a vector of sub vectors of word-level embedding, character-level embedding, bigram character-level wording, and trigram character-level wording.

1) *Word-level embeddings*: Word-level embeddings are encoded in an embedding matrix by column vectors where each column represents the word-level embedding of the corresponding word in the vocabulary. Every word thus is converted into its word-level embedding. A word is first encoded as a one-hot column vector. It is then fed to the input layer. A word embedding matrix is used to multiply it to finally get the word embedding. A word vector at time instant  $t$ ,  $WV_t$  is multiplied with embedding matrix  $WM_w$  to get the Word Embedding  $E_w$  as follows:

$$E_w = WV_t \times WM_w \quad (10)$$

2) *Character-level embeddings*: All characters in a word are represented by a character level embedding. Like, word-level embedding, Character-level embeddings are encoded in an embedding matrix by column vectors where each column represents the character-level embedding of the corresponding character in the character vocabulary. The word embedding is calculated by concatenating word and character embeddings.

$$E_w = (WM_w \times WV_t) \epsilon (CM_c^1 \times CV_t^1) \epsilon (CM_c^2 \times CV_t^2) \dots \epsilon (CM_c^n \times CV_t^n) \quad (11)$$

where,  $\epsilon$  is concatenation symbol. A character vector at time instant  $t$  and position  $i$ ,  $CV_t^i$  is multiplied with embedding matrix  $CM_c$  to get the Character Embedding.

3) *Bigram-character-level embeddings*: All bigram combinations of characters in a word are represented by a bigram-character level embedding. Like, word-level embedding, bigram-character level embeddings are encoded in an embedding matrix by column vectors where each column represents the bigram character-level embedding of the

corresponding bigram-character in the bigram-character vocabulary. The word embedding is then calculated by concatenating word, character embeddings, and bigram character embeddings.

$$E_w = (WM_w \times WV_t) \epsilon (CM_c^1 \times CV_t^1) \epsilon \dots \epsilon (CM_c^n \times CV_t^n),$$

$$\epsilon (BM_c^1 \times BV_t^1) \epsilon \dots \epsilon (BM_c^m \times BV_t^m) \quad (12)$$

where  $\epsilon$  is concatenation symbol. A bigram character vector at time instant  $t$  and position  $i$ ,  $BV_t^i$  is multiplied with embedding matrix  $BM_c$  to get Bigram Character Embedding.

4) *Trigram-character-level embeddings:* Similarly, trigram combination of characters in a word is represented by a trigram level embedding. It is encoded in an embedding matrix by column vectors where each column represents the trigram character-level embedding of the corresponding trigram-character in the trigram-character vocabulary.

$$E_w = (WM_w \times WV_t) \epsilon (CM_c^1 \times CV_t^1) \epsilon \dots \epsilon (CM_c^n \times CV_t^n),$$

$$\epsilon (TM_c^1 \times TV_t^1) \epsilon \dots \epsilon (TM_c^m \times TV_t^m) \quad (13)$$

where  $\epsilon$  is concatenation symbol. A trigram character vector at time instant  $t$  and position  $i$ ,  $TV_t^i$  is multiplied with embedding matrix  $TM_c$  to get Trigram Character Embedding.

The addition of bigram combinations and trigram combinations helps the model to learn the inflections and morphological patterns related to tagging very well. The results are discussed in the next section. The basic principle of concatenating the different kind of embedding is illustrated in Fig. 1.

The difference with the usual LSTM applied is in the fact that word embedding in proposed model is a concatenation of word embedding, character embedding, and bigram character embedding or trigram character embedding. The order of characters is the same as the order in which they appear in the word. Similarly, the order of bigram and trigrams of characters are also in the same order in which they appear in the word. The embedding dimensions are decided after repeated experiments to get the most suitable value.

### C. Data Sets

The English dataset is based on already tagged Brown Corpus [7]. The corpus is based on the current American English language containing about a million words. It comprises elements of statistics, psychology, linguistics, and sociology. Kučera and Francis (1967) reported their initial work on basic statistics on the corpus which eventually turned into Brown Corpus [7] [60].

Fig. 1. Concatenating the Embeddings to Feed into LSTM.

The dataset considered for Assamese is developed in-house. Assamese is the language spoken over the state of Assam and entire North-East India. However, not much information is available in computable form. A publicly available set of tagged words is not available in Assamese. Hence it is prepared in-house. It comprises an annotated text of approximately ten thousand words. The dataset is prepared from a corpus collected from TDIL (Technology Development for Indian Languages). It contains articles of different categories like storybooks, scientific articles, health articles, drama, etc. The corpus was tagged into different kinds of parts of speech as per Assamese grammar.

## V. EXPERIMENTS AND RESULTS

We have prepared three small datasets of three different sizes of words taken from already tagged Brown Corpus. The original implementation of the Viterbi algorithm performs poor due to low training data. Due to low training, it cannot approximate the transition matrix accurately. Also, it encounters many unknown words during testing because of the small training size. In the original Viterbi algorithm, due to zero utterances of unknown words in training data, the emission probability evaluates to zero, thus resulting in zero value for the observation. This is already stated in equation (4)

$$P(o_i|q_i) = N(o_i | q_i) / Nq_i = 0$$

The transition probability is only considered by many researchers for the multiplication of transition probability and emission probability. It is equivalent to consider emission probability as one for unknown words. This is obviously a biased method, thus resulting in poor performances for both unknown and known words. Again, if zero value for emission probability is considered for unknown words, then the calculated value becomes zero for all unknown words, which is an obvious fault.

For small training data, this is a big challenge because, with a small training data, the transition history cannot be learnt properly and so it can never accurately measure the transition matrix. Therefore, the performance is very poor especially for unknown words. Proposed method replaces the transition probability with the probability of multiplication of individual emission probability of bigrams. The result shows improvement as it gives the word a tag based on the probability distribution of its constituent bigrams towards the tags as per corpus. The product of individual probabilities of bigrams is multiplied with transition probability, thus considering both emission and transition rather than considering none or only transition probability.

First, experiment was conducted for 5000 words as Training Set and 1250 words as Test Set for the very basic Viterbi Algorithm. The performance is poor because the system was trained with too low data. Similarly, the same was done with 10,000 and 20,000 words of training and test them with 2,500 and 5,000 words respectively for the basic Viterbi algorithm as a baseline for comparison.

The result of the implementation of the basic Viterbi algorithm on the three small sequences only tagged words (4:1 ratio for trained and tested words) used for training is tabulated

in Table I. The result shows improvement with more training data due to better guess of transition probability because of more training.

TABLE I. RESULT OF THE BASIC VITERBI ALGORITHM TRAINED WITH SMALL SET OF TAGGED WORDS

<b>Training Size(words)</b>	5000	10000	20000
<b>Number of word tested</b>	1250	2500	5000
<b>unknown word tested</b>	318	552	1131
<b>Unknown Word accuracy</b>	35.53%	39.86%	40.58%
<b>Overall Word accuracy</b>	79.68%	82.48%	81.06%

As discussed earlier, the evaluation of the correct tag(state) is based upon the equation:

$$V(t(j)) = \max : V(t-1) * a(i,j) * bj(O_t)$$

It can be simplified as finding maximum likelihood of state over all possibility based upon the equation.

$$P(\text{State})=P(\text{Tag/PrevTag}) * P(\text{Word/Tag}) \quad (14)$$

In simple term, it can be written as:

$$P(\text{State}) = P(\text{emission}) * P(\text{transition})$$

Next, two modifications are made on the following basic formula:

$$P(\text{State}) = P(\text{emission}) * P(\text{transition})$$

#### A. Modification Method1

It is based on emission probability of character bigrams and trigrams. The probability of a state is calculated based upon the following equation:

$$P(\text{State}) = \text{Product of emission probabilities of bigrams (trigrams)} \quad (15)$$

The transition probability is discarded as work is concentrated on small set of training data.

#### B. Modification Method2

It is based on emission probability of character bigrams and trigrams and transition probability of tags. The probability of a state is calculated based upon the following equation:

$$P(\text{State})=\text{Product of emission probabilities of bigrams (trigrams)} * P(\text{transition}) \quad (16)$$

A part of the bigram probability matrix is also shown in Table II. It is calculated from first 5000 words of Brown corpus. The table shows probabilities of BIGR(Bigram) for the following parts of speech: NOU(Noun), VRB (Verb), ADJ(Adjective), DET (Determinant), ADP(Adposition), PRO (Pronoun), ADV(Adverb) and CON(Conjunction). Matrix for only five bigram combinations are shown.

The basic algorithm performs better with the larger size of the training data set. The accuracy value above 96% has been reported [1] using entire Brown Corpus [7] of approximately 540 thousand words. However, unknown word accuracy is not good. Then the proposed modifications are applied upon the same set of data. The goal is to improve the results with a small set of training data. The trigram character probability has also been used instead of using bigram probability for the same sets of data. The results with the four datasets of different sizes are described in Table III, Table IV, Table V and Table VI, respectively.

A comparison of the results for the four different sizes of training data with the same 4:1 ratio of different testing and training dataset are shown in Fig. 2. Improvement is more visible with bigram characters than that of trigrams. For subsequent experiments, bigram characters are used.

Next, Experiments were also conducted for bigrams with increased rate of testing data (50% training and 50% testing) and the results are tabulated below in Table VII. In this case three different sizes of text were taken from Brown corpus and then the systems were trained using them. Equal volume of data was used to test each of the systems. The test dataset was selected from a different part of the corpus.

TABLE II. PART OF THE BIGRAM PROBABILITY MATRIX

<b>BIGR</b>	<b>NOU</b>	<b>VRB</b>	<b>ADJ</b>	<b>DET</b>	<b>ADP</b>	<b>PRO</b>	<b>ADV</b>	<b>CON</b>

Fig. 2. Comparison of the Three Methods for unknown Words with 4:1 Ratio of different Testing and Training Dataset Bigram Characters.

Fig. 3. Comparison of the Three Methods for unknown Words with 1:1 Ratio of different Testing and Training Dataset.

With the size of test dataset being almost double than the previous experiments, the results are seen to be consistent for unknown words. A comparison is detailed in Fig. 3.

Fig. 4. Overall Accuracy for different Sizes of Train and Test Data (4:1) with Bigram of Characters.

The accuracy for unknown words is only detailed above. The overall accuracy is not any issue with Hidden Markov Model, which is high in this case too even with very low size of training data. The overall accuracy for the different sizes using bigram characters are depicted in Fig. 4.

The system is also tested with “Assamese” language with low training data. Assamese is a low resource language spoken in the state of Assam located in North East India. The findings are tabulated below in Table VIII and a brief comparison is shown in Fig. 5 and Fig. 6.

The system is also tested with “Assamese” language with 1:1 ratio of training and testing data. The findings are tabulated below in Table IX and Fig. 6.

The Assamese corpus was collected from TDIL (Technology Development for Indian Languages), which can be procured from their website after due permission. The corpus was tagged as per Assamese grammar rules to prepare train and test dataset. The result shown here is based on a train and test size of 10k words each that are non-overlapping. The

results are satisfactory even with large proportion of unknown words.

Fig. 5. Accuracy for 10K and 20 K of Training with 2.5 K and 5 K Testing Data respectively (4:1) using Bigram Characters for Assamese.

Fig. 6. Accuracy for 10K of Training and 10 K Testing data (1:1) using Bigram Characters for Assamese.

C. Result with Deep Learning Model

The proposed deep learning model is then applied to automatically tag the same set of English words used above. The result obtained is satisfactory and described in Table X and Fig. 7. The training dataset used is much smaller to check its usefulness for low resource languages. Datasets of sizes 10k and 20 k are used to train the system and it is tested with the equal size of different data.

Fig. 7. Accuracy for 10K of Training and 10 K Testing Data (1:1) using Deep Learning for English.

Next, proposed deep learning model is used for the same purpose for the Assamese Language. Initially, only the traditional machine learning method of using word-level is

applied embedding to get an accuracy of 72.51% which is comparable to the proposed traditional stochastic model. Next, the system is trained with word and character level embedding (Model1) and the accuracy jumps to 88.21%. Next, the model combining word and character sequences with tigrams (Model2) and trigrams (Model3) is implemented. As the models learn the morphological behaviours much better than before, the accuracy goes up to 93.52% for bigrams and 94.51% for trigrams. The accuracy of unknown words also raises due to better learning. Table XI and Fig. 8 compares the result of applying the proposed deep learning models for Assamese.

Fig. 8. Accuracy for 10K of Training and 10 K Testing Data (1:1) using Deep Learning for Assamese.

TABLE XI. RESULTS WITH EQUAL SIZE TRAIN AND TEST SET USING DEEP LEARNING FOR ASSAMESE

	Original Method	Traditional ML Method	Model1	Model2	Model3
<b>Train Set Size</b>	10000	10000	10000	10000	10000
<b>Test Set Size</b>	10000	10000	10000	10000	10000
<b>Unknown word</b>	5034	5034	5034	5034	5034
<b>Unknown accuracy</b>	50.26%	45.82%	76.08%	77.27%	77.89%
<b>Overall accuracy</b>	72.56%	72.41%	88.21%	93.52%	94.51%

## VI. DISCUSSION

The results of the experiments with modified HMM methods clearly state improvement of accuracy for unknown words. The training sets of 5k, 10k, 20k, and 50k are used on an experimental basis and the system can also be tested with a large dataset. However, as the goal is to improve accuracy with a small training set, so the limited sizes of data are considered for training. The methods do not use any specific rule, and hence can be implemented for any language. The initial experiments are based on a 4:1 ratio of training and testing dataset, which shows considerable improvement with Modifications even though the test size increased with an increase in training size to maintain the ratio. The results are also encouraging for the next set of experiments that are based on a 1:1 ratio of training and testing dataset. Even with equal sizes of testing and training datasets, the system performs considerably well specially for a second modification. In the experiments conducted, it is observed that the accuracy has improved with an increase in the training set from 5,000 to 50,000 particularly in the case of modification method2. This happens because, with an increase in the size of the training set, the transition probability starts contributing along with emission probability, thus increasing accuracy. The improvement observed is less in Method1 as it only considers emission probability. Table VII and Table IX clearly show that the accuracy does not degrade even after increasing test size and unknown words. The system maintains overall accuracy of above 85% in all cases, which is considered good with such a low amount of training. The overall accuracy is higher than 80% even when it is exposed to a test dataset of size equal to that of the training set.

The accuracy further improves with the proposed deep learning model. The words when trained with characters and bigram or trigrams of characters improve the accuracy further as shown in Table X and Table XI. The model learns better when bigram and trigrams of characters are fed into the input along with character sequences. The bigrams and trigrams of characters allow the model to learn better the inflections and hence accuracy improves. The improvement is more obvious for Assamese because of high inflections.

Table XII compares some of the works carried for Assamese in recent times.

TABLE XII. COMPARING THE RESULT WITH OTHER RECENT WORKS IN ASSAMESE

Reference Paper	Accuracy
[41]	89.21%
[42]	87.17%
[43]	87%
Work referred in this Paper	94.51%

## VII. CONCLUSION

It is observed that the accuracy of transition probability increases with an increase in the size of the training dataset. The transition among the different parts of speech can easily be computed in the form of transition probability with the help of a very large training set. But, for a small set of training data,

the transition probability is not predictable. Hence, for a small set of training data, emission probability plays the most important role to decide the total probability. Due to non-appearance in the training set, the emission probability for unknown words is zero and this is the root cause of the problem for detecting correct tags of unknown words. With the usage of bigram and trigram of characters in proposed modifications, unknown words may also have non-zero emission probability if such bigrams and trigrams have ever occurred during training other words. This increases the accuracy while classifying unknown words. The experiments conducted for English with low training data prove that the results are comparable with other methods used with large training data. The same technique of character sequences, bigrams sequences of characters, and trigrams sequences of characters applied to design a deep learning model also makes the system learn the behaviour so well that accuracy level increases up to a great extent. The system also performs well for low resource language like "Assamese" when used with a very small volume of training data. The methods are language independent and we hope that the methods will be useful for future implementation for any low resource language. More in-depth research on this will further improve accuracy for low resource language.

**Abstract**—The incorporation of information and communication technologies (ICT) has generated new opportunities and innovation in business models, such as electronic commerce (EC). Despite the benefits that the EC offers PYMEs, its adoption is low. Several authors have argued that many factors condition the adoption of EC in developing countries. This study proposes a model of factors associated with the adoption of EC by tourism operators based on factors categorized into organizational, individual, environmental, and technological factors. In this study, a structural equation modeling and confirmatory factor analysis tools were used to analyze the data. The data collected from 116 participants (69% males and 31% females, managers of tourism operators). The results reveal that 11 factors influence the adoption of EC. Also, the operators currently using EC consider that the most influential factor are related with organizational factors operators that have not implement EC value factors involving skills, knowledge and experience in technology. This study can be used to establish policies on ICT adoption in tourism PYMEs.

**Keywords**—Adoption; e-commerce; tourism operators; PYMEs; critical factors; TOE

## I. INTRODUCTION

The tourism sector is an emerging sector that has recently experienced diversification. Tourism is key to countries' economies, contributing to job creation [1], and is one of the premier export industries in developing countries [2]. The tourism sector plays the role of a catalyst for innovation and entrepreneurship and contributes to improving the lives of millions of people and transforming entire communities [3].

Information and communication technologies (ICTs) and the expansion of the internet have generated new opportunities and innovation in business models, changing the business structure and creating new ways of doing things. Likewise, the benefits of ICT in improving efficiency, reducing costs, and increasing productivity in organizations have been recognized. One of the sectors affected by ICT is the tourism sector, which has adopted new technologies with a growing trend in the future. This sector has remained at the forefront of the digital transformation due to the changes in how the sector operates and people travel [4]. Tourism in Peru is the third-largest industry behind fishing and mining.

A technology that has been used and is becoming more critical is electronic commerce (EC) [5], which is used in several sectors, such as the tourism sector. PYMEs in the tourism sector are not oblivious to these changes and are recognized as providers of job opportunities [6]. Despite the

benefits of ICTs, such as reduced costs per transaction, increased speed, and operational efficiency, not all PYMEs have incorporated EC. Although the global turnover of EC continued to grow steadily by about 11% in 2019, in the case of Latin America, it constitutes only 2% [7]. Moreover, EC has grown almost 15 times in revenue since 2009 [8].

In the tourism sector, EC is conducted in tourism-related activities using ICT tools by tourism organizations [9]. In developing countries, EC adoption in PYMEs is below that of large enterprises [10, 11]. One aspect that hinders adoption is that most PYMEs do not know how information technology (IT) can benefit their businesses and support them in achieving their goals; therefore, they do not invest in EC [12]. Some countries lag in adopting ICT due to poor economies, lack of infrastructure, and an unskilled workforce [9].

The process of ICT adoption has been studied by several authors [6, 13]. Some factors have been mentioned as enablers of EC in tourism PYMEs: pressure from external agents, perceived usefulness, perceived ease of use, technological readiness, ICT skills of employees, organizational readiness, management capacity, and government support, among others. Tourism is an activity that energizes the Peruvian economy, so it is essential to study how tourism PYMEs adopt EC.

The main contribution of this paper is determining the critical success factors positively associated with the EC adoption according to the perception of tour operations managers. With the recent events of the coronavirus disease 2019 (COVID-19) pandemic, an opportunity has been created for tour operators to reassess the business model. The general challenges for the tourism sector are innovating and digitizing as many activities as possible (i.e., organizations must invest in digital transformation to improve the management and planning of tourism destinations) [1].

Once the critical enabling factors of EC are known, an adoption model adapted from the technology and organizational environment (TOE) framework is proposed.

The managers of PYMEs, researchers and tourism institutions can benefit from the findings of this research.

The article is structured into five sections, including the introduction. Section II presents a comprehensive background and research hypotheses. Section III presents the material and methods. Section IV describes the results. Section V presents the discussion of the results and suggests future studies. Finally, in Section VI, the conclusions are presented.

## II. LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

This study aims to determine which factors, based on the literature review, are positively associated with the adoption of EC from the tour operator manager’s viewpoint and to increase understanding of the topic. Tourism is a sector that energizes the economy through creating jobs, for which ICT can be a strategic ally, especially for PYMEs dedicated to tourism. With the COVID-19 pandemic, new challenges have arisen for these companies, such as reassessing the business model and innovating and digitizing activities, which many PYMEs have not considered.

### A. Technology, Organizational and Environment

The Technology Acceptance Model (TAM) and Technology Organization Environment (TOE) framework can be used to measure the adoption of a technology in organizations. The TOE framework was developed by Tornatzky and Fleischer [14]. This framework describes the influence of contextual factors in adopting an innovation. Three aspects of the context of an enterprise influence the adoption of technological innovations: technological context, organizational context, and environmental context [10].

Technological context is related to technologies in the organization (internal) and those available for adoption that are not used by the organization (external). In the adoption process the technology existing in the organization is important because is related to technological change. One of the factors that affect the use of technology is usability.

Organizational context refers to the nature and resources of the organization, specifically its size, decentralization, formalization, management-structure complexity, and human resources. Environmental context refers to the aspects surrounding the organization, such as competitors and suppliers and the relationship with government entities.

This framework was adapted considering the factors identified in the literature, such as perceived utility, ease of use, and managerial skills, among others, and a new context called individual was added. Individual context refers to aspects related to people, skills, knowledge, and experience. Thus, it is possible to understand how these determinants can influence the adoption of ICT from the context of the adapted TOE framework. The following section reviews studies related to technology adoption factors.

### B. Critical Factors in the Adoption of EC

ICT play a vital role in developing the tourism sector and positive contribution to sustainable development [15]. Despite the rapid growth in the number of travelers using technology, challenges to adopting technology exist in all tourism segments. Several factors condition the adoption of EC. In a previous study [16], the systematic review method was used to determine the critical success factors for EC adoption.

The summary of the identified, prioritized, and categorized factors in this study is presented in Table I. The first column of Table I presents the categories, and the second column presents the factors that correspond to each of the identified categories. The factors in the Table I were presented with a frequency greater than two. Among the factors are the expansion of the

internet in society, positioning, distributed product types, perceived risks, subjective norms, perceived needs, socio-cultural practices of sharing information among PYMEs, and the e-readiness of government and socio-cultural practices.

TABLE I. CATEGORIES AND CRITICAL FACTORS

Category	Critical Factors
Technology (FT)	EC is perceived as useful in the business (FT1), perceived cost of e-commerce implementation (FT2), perceived ease of use (FT3), and perceived security and reliability of payment methods (FT4)
Organizational (FO)	Organizational readiness (FO1), technological readiness (FO2), and management capability (FO3)
Environmental (FA)	Customer pressure (FA1), stakeholders demand for EC (FA2), government support (FA3), access to quality information technology services and infrastructure (FA4), and expansion of the internet in society (FA5)
Individual (FI)	Employee information technology skills, knowledge, and experience (FI1), employee attitudes toward using information technology (FI2), manager information technology skills, knowledge, and experience (FI3), and manager’s attitude toward using information technology (FI4)

Factors mentioned by previous authors include whether the company staff have previously used ICT, the national policies that support EC, the size of the business, the maturity level in implementing ICT in organizations, technological resources for the EC implementation process, the external pressure or the possibility of external assistance (advice and support) to implement EC platforms [17].

According to Dahbi and Benmoussa [18], the categories that group the factors are organizational, technological, cultural, financial, and external (called environmental in other studies). Among the organizational factors, management support and the perceived need for EC are mentioned.

The mentioned technological factors are employee ICT knowledge, client confidence in technology, client confidence in transactions, and client knowledge of technology. Among the cultural factors, some authors have mentioned the attitude toward changes in conducting business, the need for human contact, and the need to feel/touch the product. Financial factors include implementation costs, logistics costs, financial resources, and price transparency. External factors include government support, customs regulations, and pressure from competitors, customers, and suppliers.

The technological factors most mentioned in the literature review were perceived utility, perceived ease of use, perceived cost of EC implementation, perceived ease of use, and perceived security and reliability of payment methods. The organizational factors were perceived organizational readiness, perceived technological readiness of the enterprise, and perceived management capability of the enterprise.

The environmental factors were customer perception for successful adoption of EC, perception of pressure from business partners, suppliers, and competitors for EC implementation, perception of government support for EC implementation, perception of access to quality ICT services and infrastructure, and perception of the expansion of the internet in society. The individual factors are the perception of

the employee and manager's ICT skills, knowledge, experience, and attitudes toward ICT use and the manager's education level.

### C. Technological Factors

Due to challenges related to ICT infrastructure and services, the percentage of ICT use is not equally distributed in large cities and the country's interior. In addition, ICT is fundamental to the expansion of EC. In this regard, Carvalho and Mamede [19] found that the infrastructure cost factor contributes positively to adopting ICT, which is in line with their findings [18]. As new technologies emerge, an essential aspect for EC is the confidence that online transactions and payments are secure.

Iddris [20] mentioned that EC security and the initial cost of EC negatively influence the adoption of EC by PYMEs. In contrast, AlGhamdi et al. [21] noted that the reliability and security of online payment options positively influence the adoption of EC. The perceived cost of implementation is considered a contributing factor to EC adoption. From the researcher's viewpoint, the security of a transaction is a barrier in the case of security problems. Taylor and Eshun [22] indicated that, although EC is perceived to have benefits, as identified by Shaharudin et al. [23], online payment processes and pricing structures influence the adoption of EC by PYMEs.

Perceived useful in the business has been mentioned in several studies as a factor related to EC adoption [24, 25]. Several authors have mentioned perceived usability as a contributing factor in EC adoption [23, 24, 25, 26].

For Ochola [27], the characteristic factors of innovation complexity and relative advantages have a significantly positive effect on adopting EC by PYMEs. Other factors, such as innovation and perceived benefits, have been mentioned in the studies. Le et al. [28] found that innovation compatibility, innovation complexity, and perceived risks influence the adoption of EC by PYMEs in Vietnam. Shaharudin et al. [23], Rahayu and Day [10], and Syah et al. [26] found a positive relationship between the perceived benefits and EC adoption by PYMEs. Al-Alawi and Al-Ali [12] indicated that the perceived benefit factor is positively related to the adoption of EC by PYMEs. Based on the identified constructs, the following hypothesis was proposed.

Hypothesis 1 (H1): Technology factors (FT) are positively associated with EC adoption.

### D. Organizational Factors

Abbasi et al. [24] found that the company's innovative character has a significantly positive effect on EC adoption. One factor is organizational readiness, which positively correlates with EC adoption [19, 25, 26, 29]. Walker, Saffu, and Mazurek [30] found that organizational readiness and decision-making were important in discerning EC adoption. Kenneth et al. [31] noted that infrastructure and competition significantly influence the adoption of EC by Kenyan tourism PYMEs.

Villa et al. [17] identified factors related to the adoption of the EC, such as ICT and the level of maturity and the resources for the EC implementation process. Rahayu and Day [10]

found that the technological readiness factor is a determinant for adopting ICT in PYMEs in Indonesia. Ochola [27] noted that the company's seniority factor has a significant positive effect on the adoption of EC by PYMEs in Kenya. Lama, Pradhan, and Shrestha [9] concluded that barriers to adopting EC include a lack of adequate infrastructure and resources. Frasquet et al. [32] argued that the organization's size is a critical factor, and Villa et al. [17] related the size of the business to the adoption of EC.

Kenneth et al. [31] found that the factors with a significant influence on the adoption of EC by PYMEs in the Kenyan tourism sector are leadership style and positioning. Iddris [20] proposed that factors with a negative influence on the adoption of EC by PYMEs in Ghana include management culture and interest. Al-Alawi and Al-Ali [12] argued that the support factor of senior management is positively related to the adoption of EC by PYMEs in Kuwait. Chee et al. [33] stated that the senior management support factor is significantly related to adopting EC by PYMEs. Lama, Pradhan, and Shrestha [34] concluded that the key drivers include awareness, value proposition, and the role of the owner or senior management.

Dahbi and Benmoussa [18] agreed with the previous authors and mentioned logistics and financial resources as critical factors for adoption, as did Kenneth et al. [31], who supported that resources [28] influence adopting EC. Taylor and Eshun [22] indicated that company resources influence the adoption of EC. Based on the identified constructs, the following hypothesis was formed.

Hypothesis 2 (H2): Organizational factors (FO) are positively associated with EC adoption.

### A. Environmental Factors

Saffu et al. [25] indicated that the external pressure factor (competitors, buyers, business partners, and suppliers) is related to the adoption of EC by PYMEs in Slovakia, whereas Shaharudin et al. [23] found that the factor influencing EC adoption by PYMEs is external pressure from customers. Chee et al. [33] noted that pressure factors from competitors influence SME adoption of EC, whereas Shaharudin et al. [23] suggested it is pressure from competitors, business partners, and suppliers.

Lama, Pradhan, and Shrestha [34] concluded that market strength is among the key motivators. For Carvalho and Mamede [19], the business partner factor contributes positively to adopting EC. Matsinhe and Kabanda [6] argued that such aspects as international market strength condition the adoption of EC. Syah et al. [26] found a positive relationship between external pressure (partners, competitors, customers and suppliers) and the adoption of EC by PYMEs. Frasquet et al. [32] supported that EC adoption by retailers in Spain, the UK, and France is influenced by such factors as the competitive environment. Le et al. [28] found that the intensity of competition, industry support, supplier behavior, buyer behavior, and government support influence EC adoption by PYMEs in Vietnam. Walker, Saffu and Mazurek [30] noted that operational support and external pressure were vital in discerning EC adoption.

Dahbi and Benmoussa [18] mentioned external factors, such as government support, customs regulations, and pressure from competitors, customers, and suppliers. Al-Alawi and Al-Ali [12] proposed the factor of government regulations. Villa et al. [17] identified factors related to the adoption of EC, including national policies that support EC, external pressure to be part of this commerce type, and the possibility of external assistance (advice and support) to implement EC platforms.

Taylor and Eshun [22] indicated that IT service providers, online banking service availability, energy service reliability, and industry competition influence the adoption of EC by Ghanaian PYMEs. Ardjouman [35] identified that infrastructure and maintenance factors, such as limited internet access and limited and unreliable power sources, negatively affect adopting EC by PYMEs in Côte d'Ivoire. For AlGhamdi et al. [21], the factors include government support and assistance in EC and developing a strong ICT infrastructure. AlGhamdi et al. [21] also found that developing a strong ICT infrastructure is an enabler for the adoption of EC. Al-Alawi and Al-Ali [12] proposed that the government regulatory factor is positively related to the adoption of EC by PYMEs in Kuwait. Based on the identified constructs, the following hypothesis was formed.

Hypothesis 3 (H3): Environmental factors (FA) are positively associated with EC adoption.

#### E. Individual Factors

Abbasi et al. [24] proposed that the subjective standards variable significantly affects EC adoption by PYMEs in Iran. Le et al. [28] found that the factors of employee knowledge of EC and the manager's attitude toward innovation influence the adoption of EC by PYMEs. Iddris [20] noted that the factors that negatively influence the adoption of EC by PYMEs are the lack of technical skills of employees and the resistance of people. Hajli et al. [29] suggested that the EC awareness factor positively correlates with EC adoption by PYMEs in Iran. Taylor and Eshun [22] indicated that such factors as skilled personnel in EC solutions and company resources influence the adoption of EC by Ghanaian PYMEs.

Carvalho and Mamede [19] noted that managers' perception of the return on investment contributes positively to EC adoption. Ardjouman [35] identified that employee technical skills are related to the adoption of EC. Ochola [27] noted that employee IT skills and education level significantly positively affect adopting EC by PYMEs in Kenya. Villa et al. [17] identified the previous use of ICTs by company staff as a factor related to adopting EC. Carvalho and Mamede [19] found that human resources contribute positively to EC adoption.

Rahayu and Day [10] argued that the innovation, IT capacity, and IT experience of the owner/manager are determinants for adopting EC in PYMEs in Indonesia. Matsinhe and Kabanda [6] determined that the characteristics of the manager, previous experience in EC, and sharing of experiences condition the adoption of EC. Based on the identified constructs, the following hypothesis was formed. Table II presents the proposed hypotheses.

Hypothesis 4 (H4): Individual factors (FI) are positively associated with EC adoption.

TABLE II. PROPOSED HYPOTHESIS

Hypothesis	Factors	Association*
H1	Technological factors are positively associated with EC adoption	(H1: FT → IMP)
H2	Organizational factors are positively associated with EC adoption	(H2: FO → IMP)
H3	Environmental factors are positively associated with EC adoption	(H3: FA → IMP)
H4	Individual factors are positively associated with EC adoption	(H4: FI → IMP)

Based on the research conducted in the literature review and the proposed hypotheses, the association between critical success factors and EC adoption for tourism operators is represented in Fig. 1.

### III. MATERIALS AND METHODS

The details regarding the research method, data collection, the instrument used, the pilot study, the study sample and demographic data are presented in this section.

#### A. Research Method

In this research, factors associated with EC adoption are analyzed using the quantitative research method to measure the variables. The research is transversal because the data were collected at a single moment. The study population comprises 2,692 managers of tourism operations located in various regions in Peru. A nonprobabilistic sample was applied. In total, 116 managers of tourism operations (31% male and 69% female) from different cities in Peru were asked to complete a questionnaire.

#### B. Data Collection

A questionnaire was designed as a data collection instrument. The questionnaire had two sections: sociodemographics and questions on each factor. Moreover, 10 and 16 items were evaluated to measure the qualifying factors for adopting the EC in tourism PYMEs. All items for this study were rated on a five-point Likert scale from 1 (strongly disagree) to 5 (strongly agree). The instrument was subjected to a validity check using a pilot test with four operator managers from outside the selected sample to check the validity and reliability of the instrument. A total of 116 questionnaires were distributed to the managers of tourism operations who completed and returned them. Table III lists the items on the questionnaire.

#### C. Data Analysis

The proposed model and hypotheses were tested using SEM (Structural Equation Modeling). The IBM SPSS Amos 22 tools were applied to analyze the data. Concerning SEM this study confirmed the prerequisites for item parceling. Cronbach's alpha was used to determine the internal consistency.

D. Structural Model

Based on the research conducted in the literature review and the proposed hypotheses, the association between critical success factors and EC adoption for tourism operators is represented in Fig. 1 as a causal diagram. Fig. 1 illustrates the causal diagram of the assessment of qualifying factors for adopting EC in tourism PYMEs. The variables are technological factors (FT), organizational factors (FO),

environmental factors (FA), and individual factors (FI). One variable adoption is EC (IMP).

The conceptual model presents 16 critical success factors organized in four categories (Table I). Cronbach’s alpha was used to assess the internal consistency of the factors. A Cronbach’s alpha value greater than 0.70 is recommended for confirmatory research [36]. Table IV lists the statistics of all elements of the model.

TABLE III. VARIABLES OF THE INSTRUMENT

Module	Items
Sociodemographics	Age, gender, and location
Technological factors	EC is useful, implementation cost and maintenance are affordable, EC is easy to use, payment method is secure and trustworthy
Organizational factors	Functions and processes are understood, information management is automated, company management capacity
Environmental factors	Customer demand the implementation of EC, stakeholders demand the implementation of EC, government support, services, and infrastructure are accessible, internet access.
Individual factors	Employees have knowledge, skills, abilities, and employees have a positive attitude,
E-commerce	EC implementation

Fig. 1. Causal Diagram.

TABLE IV. STATISTICS OF ALL ELEMENTS

Factor	Scale average if the element is deleted	Scale variation if the element is deleted	Total correlation of elements corrected	Multiple square correlation	Cronbach's Alpha if the element is deleted
FT Technological Factors					
FT1	10.90	6.67	0.57	0.34	0.78
FT2	11.68	6.74	0.61	0.39	0.76
FT3	11.44	6.44	0.69	0.48	0.72
FT4	11.55	7.15	0.61	0.38	0.76
FO Organizational Factors					
FO1	8.31	4.22	0.78	0.61	0.84
FO2	8.10	3.78	0.77	0.59	0.85
FO3	8.05	4.07	0.80	0.64	0.82
FA Environmental Factors					
FA1	13.42	5.69	0.49	0.49	0.41
FA2	13.46	6.02	0.60	0.52	0.37
FA3	14.66	8.19	0.03	0.12	0.69
FA4	13.53	7.21	0.43	0.29	0.48
FA5	12.83	7.36	0.23	0.32	0.57
FI Individual Factors					
FI1	13.01	6.36	0.81	0.77	0.90
FI2	13.01	6.43	0.82	0.78	0.89
FI3	12.94	6.14	0.78	0.72	0.91
FI4	12.84	5.96	0.85	0.78	0.88

#### IV. RESULTS

##### A. Participants Demographics

Table V provides the demographics of the sample, including education and the use of EC. Regarding the characteristics of the respondents, 31% of the respondents were male, and 69% of the respondents were female. The majority of the managers (63.7%) were over 37 years old, and 21.6% were in the age group of 33 to 37 years old. In addition, 27.6% of the respondents have considered implementing EC at some point, 25% have decided to implement EC, and 41.4% are currently using EC.

##### B. Structural Model and Hypothesis Testing

When observing the reliability analysis results, environmental factors are qualified as questionable; therefore, were analyzed the answers collected on those factors through a frequency analysis. More than one-third of the interviewees answered “neither agree nor disagree” on the frequency analysis, which affects the overall analysis. In this sense, these factors should be excluded from the analysis.

Validation steps were followed before validating the proposed theoretical model using the SEM technique of the AMOS SPSS software and analyzing the measurement estimates of the observed variables. As a first step, the confirmatory factor analysis validates the factor composition (constructs) to identify which indicators (observed variables) load to establish the number of factors and their intercorrelations. The second step was to convergent validity.

- The validation of the convergence of items and constructs refers to the fact that a variable measure what

it is supposed to measure. The erroneous assignment of latent variables to certain observed variables produces validity problems. Two conditions exist for the validity of an observed variable. First, the observed and latent variables must have a direct relationship with each other. Second, the latent factors excluded from the model must not directly affect the observed variable. The indices of convergent validity are greater than 0.70, and the average of the extracted variance (AVE) is greater than or equal to 0.50 (see Table VI).

- The validation of the hypotheses through a causality analysis determines whether the structural model is correct and approximates the actual phenomenon. The goodness-of-fit statistics, which refer to the accuracy of the assumptions of the specified model were analysed. Considerations for the evaluation of the SEM of the research include the following: (1) due to the small sample (116 surveys), the procedure for estimating the model was the maximum likelihood and (2) the multivariate distribution of the statistics used in the model is assumed to be normal. Table VI presents the results of the model estimation.

From the results in Table VI, causal Model 2 is observed, where the factor loads of the items are greater than or equal to 0.70 (factor loading or standardized regression weights  $\geq 0.70$ ), and the mean variances extracted (AVE) are greater than or equal to the recommended value of 0.50. Thus, the conformation of factors fulfills the criteria of convergent validity. The indices of adjustment of causal Model 2 are acceptable. Table VII lists the model fit indices.

TABLE V. FREQUENCY ANALYSIS

Characteristics		N	Percent
Gender	Female	80	69.0%
	Male	36	31.0%
Age	Over 37	74	63.8%
	33–37	25	21.6%
	28–32	9	7.8%
	23–27	7	6.0%
	< 23	1	0.9%
Manager education	University superior	83	71.6%
	Technical superior	30	25.9%
	High school	3	2.6%
Use EC	Don't know EC	3	2.6%
	Implementing EC has not been considered	4	3.4%
	Implementing EC has been considered at some time	32	27.6%
	Implementing EC has been decided	29	25.0%
	Currently using EC	48	41.4%

Fig. 2. Assessment of Qualifying Factors for e-commerce Adoption.

TABLE VIII. RESULTS OF HYPOTHESIS TESTING

Hypotheses	Factors	Association
H1	Technological factors are positively associated with EC adoption	33.0%
H2	Organizational factors are positively associated with EC adoption	32.7%
H3	Environmental factors are positively associated with EC adoption	11.1%
H4	Individual factors are positively associated with EC adoption	23.2%

Notes: EC: e-commerce.

According to the general modeling in structural equations regarding the qualifying factors for adopting EC in tourism operators, the most influential factors are the technological and organizational factors. Fig. 2 presents the final causal model on the evaluation of the qualifying factors for adopting EC.

Table VIII presents the results of the hypotheses.

The following observations were made when analyzing groups according to the company situation where the interviewees work concerning adopting EC:

- Group 1: Tourism operators currently using EC consider that the most influential factor is the organizational factor, mainly information management in the company.
- Group 2: Tourism operators that have not yet implemented EC equally value factors involving skills, knowledge, and experience in technology and the technological and organizational factors of the company.

## V. DISCUSSION AND FUTURE STUDIES

In a context of pandemic COVID-19 the adoption of ICT, in special EC has been recognized a key factor to give continuity with business activities due to social isolation, distancing and border closures. Also, the research on adopting ICTs has a great interest, especially business. EC is a very potent strategy to beat competitors and generate profits. Despite the benefits of the adoption of EC, the adoption of EC by SEM is low. The reasons, factors or determinants have been amply documented in the literature and several explanations such as organizational factors, environmental factors, technological factors and individual factors are mentioned. The studies corresponding to different countries and not evidences have been founded about impact of factors in the EC in Peruvian tourism operators. In this study, a total of four hypotheses were tested.

Accordingly, the results the technological factors were positively associated with EC adoption. EC is perceived useful in the business, and perceived ease of use. Are two constructs of ICT models adoption. An Information System that presents difficulties in their use discourages its use. Perceived usefulness is related to use of technology enhance the job performance and Perceived ease of use is related effort necessary to use of technology. Then individuals will be more willing to adopt EC if it is easy of use. Perceived ease of use is consistent with the studies by Ochola [27] and Syah et al. [26]. The perceived security and reliability factor, related to secure and reliable payment methods, was also consistent with the research by Ochola [27]. Today, the development of technologies and components for the EC encourages tourism operation managers to trust it and naturally adopt ICT. Specifically, if the managers of tourism operators believe that the method of payment used and the transactions are secure then they are more likely to support the adoption of EC. Technological factors were founded as influencing factors for EC.

Organizational factors are positively associated with the adoption of EC. Organizational factors include organizational readiness with clearly understood functions and processes, technological readiness due to automated information management, and management capability that enables change. Organizational readiness is related to EC adoption, which is consistent with the research by Syah et al. [26]. Only organizational readiness is associated with EC adoption. Tour operation managers may consider EC adoption the necessary next step for their businesses to grow and evolve.

Environmental factors are positively associated with EC adoption. In this case, only two out of five factors were considered: customer and stakeholders demand for EC. In the pandemic, these two environmental factors have a more significant influence, considering the immobilization in some cases and the distance and sanitary measures required by regulatory organizations. In this regard, customer pressure is a factor highlighted in the research by Syah et al. [26], Saffu et al. [25], Le et al. [28] and Sánchez-Torres et al. [37]. The fact that pressure from customers and external agents is correlated with EC adoption indicates that tour operator customers, suppliers, competitors, and business partners are increasingly

using electronic media in buying and selling transactions. This situation may increase the motivation of tour operation managers to adopt this technology to meet the need for immediacy in transactions with customers, suppliers, competitors, and business partners.

External pressure of stakeholders was related to EC adoption, which is consistent with the research by Syah et al. [26] and Saffu et al. [25]. The government support was not empirically validated which is consistent with other studies. Regulatory policies that are not clear and not significative for EC adoption could be a reason. Also, this result can be explained for the highest rates of entrepreneurship. The expansion of the internet in society is not related to the adoption of EC. This result can be explained due to internet is part of our lives and has been incorporated in the organizations.

Individual factors are positively associated with e-business adoption, such as employee ICT skills, knowledge, experience, and attitudes toward ICT use, and managers' attitudes toward ICT use. Furthermore, these factors could guarantee, to some extent, the success of the implementation of this technology and the design and execution of the processes. In PYMEs, the primary decision maker is the owner of the business [38] and top management support is statistically significant determinant of e-commerce adoption.

When comparing the manager group of tour operators that already has EC, the most influential factor is the organizational factor, mainly the information management of the company. In contrast, in groups that have not yet implemented EC, they equally value the skills, knowledge, and experience in technology and the technological and organizational factors.

This study provides an understanding of the factors considered by tour operators for adopting EC. A sample of 116 tour operators was used to conduct this study, which presents the limitation of the generalizability of the results. Although most departments were represented in the sample, further research is needed to assess factors faced during the COVID-19 pandemic. The study represents the characteristics of tour operators in Peru, so it is crucial to conduct empirical studies in other developing countries to generalize the findings. With the COVID-19 pandemic measures, such as closed airport and flight bans to prevent widespread infection, many tour operators were forced to suspend operations. Future work would include assessing the effect of COVID-19 on tour operators and adopting ICT to address new regulations.

## VI. CONCLUSION

For all kinds of organizations in different sectors, ICT has become a strategic ally. The tourism sector is considered a driving force in the economy. Despite the benefits offered by ICT, the incorporation into the tourism sector has been very slow. Several authors have argued that a set of factors influence adopting EC in tourism companies. The purpose of this research was to develop and propose a model for adopting ICT by tourism operators. The first task was to determine critical factors from the literature review and establish the identified and selected factors. The research was quantitative, with a sample of 116 tour operators surveyed using Google Forms. Confirmatory factor analysis was used to determine the

factors influencing ICT adoption. Technological, organizational, environmental, and individual factors are positively associated with the adoption of EC. Disseminating the results to tourism operators facilitates their understanding and the need to consider these factors to reinvent themselves. As future work, a plan to review the critical factors and their behavior concerning the changes due to COVID-19 through a longitudinal study to determine whether significant differences exist in the process of adopting ICT.

**Abstract**—The advancement in deep learning is increasing day-by-day from image classification to language understanding tasks. In particular, the convolution neural networks are revived and shown their performance in multiple fields such as natural language understanding, signal processing, and computer vision. The property of translational invariance for convolutions has made a huge advantage in the field of computer vision to extract feature invariances appropriately. When these convolutions trained using back-propagation tend to prove their results ability to outperform existing machine vision techniques by overcoming the various hand-engineered machine vision models. Hence, a clear understanding of current deep learning methods is crucial. These convolution neural networks have proven to show their performance by attaining state-of-the-art performance in computer vision over years when applied on humongous data. Hence in this survey, we detail a set of state-of-the-art models in image classification evolved from the birth of convolutions to present ongoing research. Each state-of-the-art model evolved in the successive year is illustrated with architecture schema, implementation details, parametric tuning and their performance. It is observed that the neural architecture construction i.e. a supervised approach for an image classification problem is evolved as data construction with cautious augmentations i.e., a self-supervised approach. A detailed evolution from neural architecture construction to augmentation construction is illustrated by provided appropriate suggestions to improve the performance. Additionally, the implementation details and the appropriate source for the execution and reproducibility of results are tabulated.

**Keywords**—Image classification; deep learning; computer vision survey; convolution neural networks; IMAGENET dataset

## I. INTRODUCTION

Previous machine vision methods mostly use hand-engineered features. They mostly rely on the morphology of the image sometimes [1]. This can eventually cause a problem in designing a model to capture essential features. To overcome this deep learning models are adapted. Deep learning is advancing in numerous domains such as image recognition, speech recognition [2-6], signal processing [7-12], language processing [13-18], and graphs [19-24]. This leverage in the use of deep learning-initiated advancements in the development of highly scalable hardware architectures which perform large computations. The availability of huge data with high computing resources eventually helped in developing deep architectures which are utilized for large scale tasks. Specifically, in computer vision, deep learning has

advanced in numerous subdomains such as image classification [25-30], object recognition [31-43], pose estimation [44-48], image segmentation [49-54], and visual question answering [55-60]. The previous research states that these advancements are held on a large scale to attain state-of-the-art results. In most of the tasks, the generic method applied is convolution neural networks (convnets). There are variant hyperparameters involved in building an effective neural architecture. There are definite properties of convolution neural networks and these properties act as advancements to the current research building large scale architectures. Hence, in this introduction a certain set of relevant concepts regarding Convnets are detailed. In the next section, a set of contributions are detailed explicitly.

## II. CONTRIBUTION

The contributions of this survey to the present existing literature are described as,

- 1) Firstly, a prerequisite introduction to convnets is provided and the successive advancements and the individual parameters involved in architecture are detailed.
- 2) The evolution of the convnets from its beginning is explained and a sequential state-of-the-art advancement in image classification utilizing the convnets are elaborated in detail.
- 3) Finally, a set of recommendations are provided to enhance the neural architectures to obtain successive state-of-the-art performance and pave a path to future advancements.

## III. ORGANIZATION OF THE SURVEY

The organization of this survey is described in three phases. Further, Fig. 1 describes the complete flow of this survey.

- 1) The first phase gives a complete description of the convolution neural networks i.e. specifically describing the components involved in convolutions and their visual illustrations are provided equivalently. This section provides a clear intuition of the working of convnets with a glimpse of the terminology used. Finally, the advantages and disadvantages are equally provided to understand where convnets can perform best and fail.

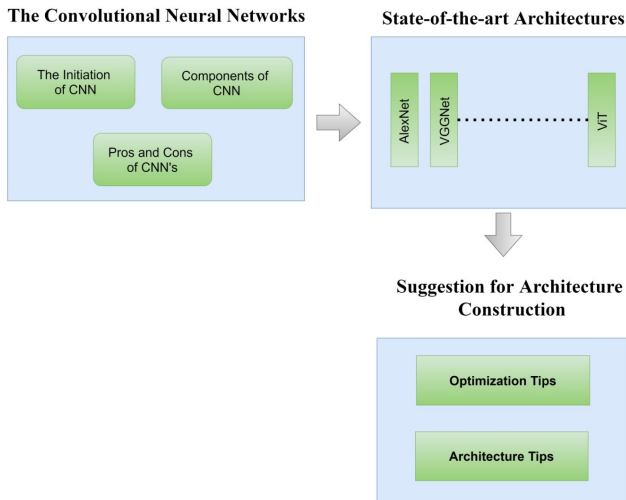

Fig. 1. The Visual Illustration of the Complete Organization of the Survey.

- 2) In the second phase, a clear understanding of the state-of-the-art networks is provided. Each architecture is described in detail by detailing the method implied and hyperparameters tuned for variant settings. This gives insights to the reader to understand the flow and the evolution of convnets and its developing aspects in the current research.
- 3) 3. The final phase provides suggestions to construct a novel architecture to provide a good transferability of features with low computational expense by considering various factors.

#### IV. THE CONVOLUTION NEURAL NETWORKS

First, it is aimed to discuss the mathematical intuition of convolution neural networks and next, the first implementation of convnets is described. Next, a set of components involved in the construction of convolution architecture are described accordingly. Subsequently, a set of properties for convnets are detailed. Finally, the advantages and the disadvantages carried by convolution neural networks are specifically mentioned [61, 62].

##### A. The Initiation of Convnets

The convnets are inspired by the convolution theorem. Convolution is a combinatory operating between two functions where their arguments are real.

$$Conv(y) \leftarrow \int f(x).g(y-x)dx$$

The equation above,  $Conv(\cdot)$  is a convolution operation. This convolution operation is mentioned typically<sup>1</sup> as,

$$Conv(y) \leftarrow (f * g)(y)$$

The first function  $f(\cdot)$ , denotes a probability density function which is referred to as input. The second argument,  $g(\cdot)$  is

<sup>1</sup>The \* mentioned denotes the convolution operation.

referred to as kernel . Hence, these mathematical implications are helped in building the first convolution neural network.

The first convolution neural network was observed in the literature by LeCun. Y et al. [63]. The main object of this research was to implement a convnets to recognize handwritten postal zip codes. To train the model, backpropagation was implied and then successively able to extract variant features. The complete architecture has 1 input layer, two convolution layers and two fully connected layers. This first work helped revolutionize the convnets to a greater extent.

Subsequently, work by LeCun. Y et al. [64] implemented multi-layered NN by training the model end-to-end using backpropagation. This helped to learn and implement gradient-based optimization. In addition to the previous work, this work implemented a graph transformer network for language understanding which utilizes convnets by training with global techniques. The convolution architecture proposed is known as LeNet-5 which had 4 convolution layers and 3 fully connected layers. The final fully connected layer i.e. final activations are Gaussian connections. This initial conceptualization of convnets produced rigorous outcomes after the evolution of large computational devices to obtain state-of-the-art performance every year in large scale visual recognition challenge ILSVRC-12.

##### B. Components in Convnets

There are a set of components involved in convnets and this help understand the terminology regarding the convnets. A visual illustration of individual components is provided accordingly.

a) *Kernel*: The kernel is described as a grid or a matrix that convolves on the input.

b) *Stride*: The stride is a step taken after each convolution i.e., the number of steps moved by the kernel on the input.

c) *Feature Map*: The feature map is considered as the output activation incurred after completion of the convolution operation.

d) *Padding*: The padding is the process of filling the borders of the input equivalently in every dimension i.e., mathematically the input is surrounded by zero eventually increasing the size of the input.

Hence, In Fig. 2 these components involved in convolution are explained in detail. The blue component which is of size 2x2 is input. The grey 3x3 size matrix refers to the kernel. Next, the dotted square grid bordered around the input is called padding. The dark green component which is projected on the top of the input is a feature map obtained. Hence, the convolution operation is carried by moving the kernel onto the input. This kernel applies dot product on the input and a set of values are obtained. Further, these values are aggregated using a sum function. Then, a feature map is obtained accordingly. This process is iterated till the complete input is convolved. In a convnet, kernel size determines the shape of the kernel to perform the convolution operation. The number of kernels determines the number of variant types of kernels with varying values inserted into them. Next, padding

Fig. 2. Visual Illustration of Convolution Operation.

is generally used to produce similar dimensional output. In the next section, a set of advantages and disadvantages involved in convolutions are detailed. Further, a detailed explanation is provided by considering varying situations and altering the above-mentioned components in the work [65].

### C. Pros and Cons of Convnets

The convnets do have certain abilities which provide higher performance on multi-domain tasks. Even having definite advantages, convolutions carry a set of disadvantages which are discussed in detail.

#### a) Advantages:

- **Transferability:** The previous deep networks such as Restricted Boltzmann Machines, deep belief networks and fully connected neural networks do not persist with transferability of weights. But, the convnets are provided with transferability of features. Hence, a certain layer in architectures can be extracted to reproduce the weights for variant tasks. It can be further implicated in architecture pruning for improving the feature extraction for variant tasks.
- **Sparse Connections:** The connections in most of the previous existing neural networks have dense connections i.e. having an extreme number of connections which in turn increases the computational budget of the model. But, whereas convnets have sparse connections reducing the redundant connectivity and reducing the computational expense.

#### b) Disadvantages:

- **Rotational Sensitivity:** The convnets cannot extract the features of the entity residing an input which is rotated until and unless the objects in the images are rotationally symmetrical. Hence, to overcome these many techniques are implied such as augmentation. Horizontal flip, vertical flip and angular rotations are provided to an individual image to extract features even having rotational changes.
- **Time-Variant signals:** The convolutions lack in understanding the signal processed during a variant time pattern to that of a non-linear system. This can lead to the problem is speech specifically problem underlying the acoustic detections. But this problem is not seen in image recognition.

## V. STATE-OF-THE-ART VISION MODELS

### A. Alex-Net

Krizhevsky et al. [66] proposed an end-to-end trainable deep convolutional network for large scale image classification

i.e., on IN12. They observed the problem of using ML methods for image classification. They developed an eight layered deep NN which has 5 conv layers and 3 fully connected layers. The kernel size and stride implied are clearly illustrated in figure.3.

Firstly, they used relu [67] as non-linearity to forward the activations from one layer to another where they observed speeding up of convergence when relu is used as non-linearity. Second, they used GPU's for training their network in which, two GPU's are used with parallelized computing and having communication mutually layer to layer. This improved the performance of the model by reducing T-1 error and T-5 error by 0.017 and 0.012 respectively. Next, for normalization a technique (which is a similar normalization technique to that of [68]), named local response normalisation, is operated for conv layers which are tuned while validation procedure. This improved the performance of the model by reducing the T-1 error and T-5 error by 0.014 and 0.012 respectively. Next, the overlapping pooling technique is utilized which pools the pixels which are not only adjacent but also which are overlapping with correspondence. It is achieved by reducing the step during convolution. This reduced error-rate of T-1 and T-5 activations by 0.004 and 0.003 respectively.

The constructed architecture has consumed 60 M parameters which are mentioned in Fig. 3. To have good generalization a sequence of tasks was done to reduce the problem of overfitting in the networks. Firstly, data augmentation is done. In this step, the samples regarding an image are increased either translating the image in horizontal (or vertical) directions or the pixels of the images are changed in terms of colour intensities. This is done by considering the principal components of images and adding weight to pixels accordingly. This procedure led to an increment of T-1 accuracy by 1%. Secondly, the fully connected layers are attached with two dropout layers [69] (for the last two layers excluding class activations) with a drop ratio of 50% i.e. 50% of the neurons are inactive during the training and the network tend to learn during validation.

The complete model was trained on 90 epochs. It is optimized using SGD with an initial learning rate of  $10^{-2}$  and  $9 \times 10^{-1}$  as momentum through 128 batches (batches considered per iteration). When no convergence invalidation was observed in the learning, the rate was decreased 10 times to that of initial learning. The model achieved a T-1 error rate of 37.5% and a T-5 error rate of 17%. Further, the model was altered in various types and different accuracy score are obtained. These details are tabulated in the Table I.

Fig. 3. Alex-Net Architecture with Varying Strides and Filters.

Fig. 4. Ze-Net Architecture with Varying Strides and Filters [5].

### B. Ze-Net

Matthew D. Zeiler et al. [70] proposed a Conv NN which is very similar to Alex-Net by visualizing the feature maps and kernels for better understanding internal computations of the convnets. They developed an eight layered deep NN which has 5 conv layers and 3 fully connected layers. The kernel size and stride implied are clearly illustrated in figure.4.

The architecture of the model is designed with a decoder and an encoder which extracts latent representations and reconstructs the image respectively. Several conv layers are used to extract the spatial features with ReLu as activation throughout the network. The decoder helps in unspooling the visual representations by a switch variable. This switch variable is used for memorizing the pooled information in the encoder structure and mapping it on the decoder structure. Further, to observe feature extraction, translation scaling and rotation mechanisms are performed in which the convnets were invariant to translation and scaling but not for the rotation. Finally, to observe the localization ability of convnets a certain part of the image consisting of important feature is occluded. It is observed that convnets significantly degraded in terms of performance due to occlusion.

The model implied is very similar to that of AlexNet with two variations, the filter size is reduced in the first layer from 11x11 to 7x7 and stride 4 of convolution is reduced to stride 2. Augmentation is performed by subtracting the input with individual pixel mean and used 10 variant sub crops techniques such as horizontal flip, vertical flip etc. The learning rate with which the SGD optimizer was initialized as 0.01. A momentum of 0.9 was implied for faster training. The bias components were initialized with zero and 50% of the densely connected layers are dropped during the training process. The model acquired T-1 and T-5 error rates of 36% and 14.7% respectively. Further, the network pre-trained on ImageNet is implied on Caltech-101 dataset with an accuracy score of 83.8 for 15 images per class whereas increasing 30 images per class it obtained an accuracy score of 86.5%.

### C. OverFeat

This work was inspired by the standard concepts that injected good improvement in the field of classification [71-74]. Sermanet et al. [75] proposed a framework implying CNN's not only for classification but also for detection and localization. The novel localization criterion in this work is obtained by capturing and aggregated to multiple object boundaries. When the localization task is performed on ImageNet the best performing OverFeat model secured the first position in the 2013 challenge.

The main objective of the OverFeat is to perform classification by simultaneously locating and detecting the objects

with the use of a single conv architecture. A novel method is implied to detect and localize the bounding boxes of the image which is predicted by the neural architecture. With a combination of various localization predictions, the process of detection acquires good features and hence the performance is increased and eventually training time can be reduced. This method not only helps to provide less computation but also with greater performance acquiring higher accuracy scores.

The complete OverFeat model has three ideologies and the methodology is implemented accordingly,

- 1) Initially, a conv net is applied at variant locations captured in the specified image. Sequentially, a sliding window approach is implied using different scales. This eventually helped to provide a better classification model but, the localization performance was degraded.
- 2) The system was not only trained to produce distribution for the set of categories but also improved localization by properly constructing the size of the bounding box to capture the region of interest for that specified category.
- 3) Lastly, a proof of concept was provided for a specific category at individual locations.

The implementation works by training a conv net by using a sliding window as the decision box by choosing the centre pixel and classifying it accordingly to a definite object. The advantages of this method are the bounding contours utilized for localization need not be rectangular. The disadvantage of the model is that it acquires numerous pixel-level labels which in turn increases computations cost. This work was the first implementation of localization, and the detection task for ImageNet by using a unified framework. The localization and detection task performed by overfeat is done by allowing the model to guess the labels for the specified object five times and if the probability of the guess turns to be 0.5 and above (matching the ground truth label) then, a definite label for the object is assigned to definite class accordingly. The five times guess the pattern is chosen to specify the correct object in the presence of multiple objects without labels.

During the construction of the OverFeat, a set of hyperparameters are tuned and are mentioned individually. The optimizer implied in this method is SGD with an initial learning rate of  $5 \times 10^{-2}$ . A momentum was used to faster the training procedure (an initial momentum of 0.6 was implied). Weight decay for the L2 regularization is initialized as  $10^{-5}$ . ReLU is used as an activation function at the utmost every layer. The initial five layers of the model implied are very similar to AlexNet with ReLU activations and successive pooling layers (max-pooling layers). But with many similarities, certain differences are to be noted and they are mentioned. No local response normalization is utilized in this work as it did not improve performance. The pooling layers implemented do not overlap as they depicted better performance. Further, implying small stride in the first two layers, better invariances was obtained i.e., large stride speedups the training process but performance in terms of accuracy can be degraded.

The OverFeat proposed 8 models of which, two are ensemble models. The fast ensemble model with four scales and fine stride acquires a T-1 error rate of 35.10% and a T-5 error

rate of 13.86%. Whereas, an accurate model acquired a T-1 error rate of 33.96% and a T-5 error rate of 13.24%.

#### D. VGGNets

Simonyan et al. [76] worked on deep neural networks with different depth of layer's in them to know the changing rate of accuracy concerning the depth of the neural network. The depth of the neural networks proposed in this paper varied from 11 to 19 layers. Six different types of networks were used by the author to know how the models perform based on different configurations in it. The kernel size or the receptive field is set to the size of 3X3 rather than 5X5 or 7X7 because a smaller receptive field help in capturing the details of the image in a more specific way and use fewer parameters. The six types of networks built in this paper have been given the following names A, A-LRN, B, C, D and E. These networks differ by the depth of layers. An A-LRN is the two networks with a depth of 11 layers, the only difference is that in A-LRN, Local Response Normalization (LRN) is used to check how the accuracy is varied when LRN is used in a network. It was observed that adding LRN to the network was not much of use to improve the accuracy score. B has a depth of 13 layers, C is just an extension of B where there are 3 extra 1X1 convolutional layers in it. D and E have 16 and 19 layers of depth in their network configurations respectively.

In the aforementioned networks, a max-pooling layer is present after a few convolutional layers or a block of these layers. Inside each block, there is a combination of 3X3 and 1X1 convolutional layers accordingly. The input image is of size 224X224 pixels, which is downsampled by the convolution and max-pooling layers next the extracted features are passed into the dense layer for the classification or detection task of the image. These architectures used Stochastic Gradient Descent (SGD) with 0.9 momentum and has a batch size of 256. Drop out was also used in two fully connected layers followed by a dense layer and a softmax layer to predict the class of the image. The learning rate was set to 10<sup>-2</sup> and this was decreased by a factor of 10 if the accuracy got saturated at a point. Training of these networks was completed after 74 epochs. During the training time, Lr was decreased by a factor of 10 for 3 times in total. First, the networks (A, A-LRN, B) were trained on a single scale of 256 and the remaining networks (C, D, E) were trained using multiple scaled images (scale jittering) with the scale ranging from 256 to 512. It was observed that the performance of these networks improved significantly with the use of scale jittering and by increasing the depth of the network, E convnet got a top-5 Val-error of 8% which is a competitive score.

To further assess the capabilities of the network, the VGG team used scale jittering even more aggressively on the train-test set this time and saw that convnets D and E got a top-5 Val-error of 7.5%. Multiple crops were also used in the next experiment and it was compared with the dense evaluation method. From this experiment, it is concluded that the multiple crop method outperforms the dense method. The testing method shown by the VGG team was very different from the previously mentioned works, where the last FC layer was converted into a convolutional layer and this receptive field was put on a whole image and then obtained a single vector

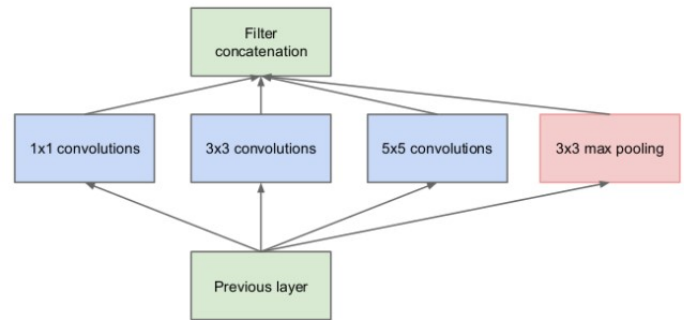

Fig. 5. Naive Inception Module.

with the individual class score. The vector was pushed into the softmax layer to get the prediction score.

An ensemble of all these convnets was made and it was seen that the seven networks ensemble model has a test error of 7.3% and the ensemble of D and E convnets had a test error of 6.8%. The 2 convnet ensemble networks secured second place in the ILSVRCV-2014 challenge. But the margin between the scores was very close when compared to Google Net (first place). The single net performance of VGG architecture outperforms all the other architectures (even Google Net) with a large margin of 0.9%.

#### E. Google-Net and InceptionV2

Szegedy et al. [77] presented a deep learning model which has an inception module in it. Google-Net mainly focuses was to develop a deep neural network architecture with a less computational expense. As the network goes deeper the arithmetic operations performed by the models also increases and this gives scope for newer error that occurs with computing gradients. Because of the previously mentioned reasons the author suggests creating a sparse network rather than a fully connected network. The goal is very simple all we have to do is find optimal weights through a sparse network that could approximate or predict an image. Translation invariances added in this work by building a network through several convolution layers.

Fig. 5 shows the naïve inception module which applies convolution to the input image with a kernel size of 1x1,3x3,

Fig. 6. Dimensionality Reduced Inception Module.

Fig. 7. Detailed Architecture of Google-Net.

and 5x5. Next, pooling is done to the input image and these activations are concatenated using correlation statistics instead of stacking up the layers can increase computational expense. With this understanding, a new inception module is created, and the dimensions are reduced by bottleneck convolutions i.e., 1x1 convolution kernel to the input image and it is observed that lower-dimensional space preserve the information of the corresponding image. These dimensionality reduced inception modules are now stacked on each other by applying max pooling layer of stride 2 in between the modules occasionally. The proposed Google-Net architecture consists of 22 layers in total. An ensemble of 7 such models was created and tested on IL-14 for classification as well as detection.

Fig. 6 shows the architecture of GoogleNet. In between this network for few inception modules, a classifier was assigned to them. This has helped to generalize images more precisely. These classifiers contain a 1x1 convolutional filter with 128 filters in it. Next, the convolutional layer is stacked with a fully connected layer with 1024 neurons in it. Followed by a dropout layer and a SoftMax layer to provide the probabilities of each class and then predict the image class. In this network, every layer uses the ReLU non-linearity function for the activation of each neuron in the network.

Seven distinct types of networks were built based on the new inception module to train them on the ImageNet dataset with different learning rates and sampling methodologies. The probabilities of all these networks were averaged to get the output. With this ensemble method, Google Net got a top-5 error rate of 6.67% on testing and validating set. An ensemble of 6 models was used in the ILSVRC 2014 detection challenge which achieved map of 43.9% and secured first place in both the classification and detection challenges. From this work, it can be deduced that the sparse network can be useful in deep neural networks to know the deep representation of the image while using less computational resources. Kindly refer Fig. 7 for detailed understanding of architecture.

A certain problem, covariant shift is observed while training a deep neural network is addressed and solved by implementing the Batch Normalization (BN) procedure. This paradigm was proposed by Sergey Ioffe and Christian Szegedy [78-80]. BN procedure was implemented on Inception ensemble with an Image resolution of 224x224 produced a T-1 accuracy score of 79.9% and T-5 accuracy score of 95.1%.

#### F. InceptionV3

Szegedy et al [81] implied the aforementioned Inception architecture and scaled the convolution layer to provide higher performance by decreasing computational expense. This is the upgraded version of GoogleNet and maintained appropriate

convolution by doing defiant regularization throughout the network. The authors illustrated the work by defining a set of principles and scale the conv layer by optimizing techniques. The principles are defined in such a way that they performed experimentation on different datasets by considering much architecture. The principles of the network are

- A cautious decrement in representation is preferable, instead of bottleneck layers at the beginning of the network.
- Higher dimensions in the network are easier to process with piling up the activations in a conv network for extracting invariant features.
- Even though pooling provides faster learning, spatial aggregation in the network holds the representational features without any loss in the lower dimensions.
- The width and depth of the network must be optimally selected with a balanced criterion.

Generally, a 5x5 or large conv layers can capture the activations of the previous layers. Reducing the feature map size would decrease the no of parameters, training time and computational cost of the network. The inception module consists of 5x5 conv layers, instead of these, the authors have replaced 5x5 conv layers with two 3x3 conv layers which are shown in Fig. 8 with 28% relative gain. But this method has a problem of loss of expressiveness or using a low filter size (below 3x3) which may produce the best outcome. So, the authors have come up with an idea of using asymmetric convolutions. The concept of asymmetric convolution is any nxn convolution can be replaced by 1xn convolution which is followed by nx1 convolution. As n increases the computation of the model decreases. The 3x3 convolutions in the network are replaced by 1x3 and 3x1 as shown in the figure.9. By using this method, it reduces the computation cost by 33%. The activation maps in the network filters are improved because to get rid of the bottleneck representation. The network consists of 42 layers and has 2.5% more computation than GoogLeNet.

The concept of asymmetric convolution is any nxn convolution can be replaced by 1xn convolution which is followed by nx1 convolution. As n increases the computation of the model decreases. The 3x3 convolutions in the network are replaced by 1x3 and 3x1 as shown in the figure.9. By using this method, it reduces the computation cost by 33%. The activation maps in the network filters are improved because to get rid of the bottleneck representation. The network consists of 42 layers and has 2.5% more computation than GoogLeNet.

The model takes SGD as an optimizer with a batch size of 32 which is trained across 100 epochs by considering a learning rate of 0.045. The model achieves the state-of-the-art results with T-1 and a T-5 error rate of 21.2% and 5.6% respectively. By ensembling 4 Inception-v3 models they got a T-1 and T-5 error rate of 17.2% and 3.58% respectively.

#### G. Inception-v4, Inception-ResNet

Szegedy et al [82]. has extended the idea of Inception-v3 by combining residual connections to it with accelerating training. This model has won the 2015 ILSVRC challenge by acquiring state of the art performance. The authors have

Fig. 8. Illustration of the Variation of Bottleneck from 5x5 to two 3x3 Convolution Blocks.

Fig. 9. Illustration of the Variation of Bottleneck from a 3x3 to 1x3 and 3x1 Convolution Blocks.

provided proof of the residual connections speed up the training of Inception networks. As the Inception networks are very deep, the filter concatenation stages in the network are replaced by residual connections. By increasing the depth and width of the Inception-v3 networks they proposed another network called Inception-v4. To provide an optimised network, the layers are tuned cautiously. To connect Residual versions with the Inception network, a cheaper Inception block is implied rather than the original Inception. Fig. 10 shows the whole architecture with residual connections inside an Inception network. There are filter expansion layers (1x1 convolutions with no activation) inside the network. Batch-normalizations are omitted on the top of the network and overall the no of inception blocks was added subsequently. While experimentation the authors have found that if the networks have more than 1000 filters, the model has died before the training has started. There is no use in increasing the batch size or lowering the learning rate. It seemed to stabilize the training process by scaling the residuals and then adding to the before layers.

Using RMSProp [83] as an optimizer and learning rate of 0.045 they achieved a T-1 and T-5 error rate of 19.9% and 4.9% respectively on ILSVRC 2012 by considering Inception-ResNet-V2 as the base model. By combining three residual and one Inception-v4 they achieved a T-5 error rate of 3.08% on the ImageNet classification challenge.

#### H. ResNext

Saining Xie et al [84] has developed a model succeeding the ResNet model which is known as “ResNext”. This model is the 1<sup>st</sup> runner-up in ILSVRC 2016 competition. This model contains extra dimensionality called cardinality which deals with the depth and width of the network. The ResNext

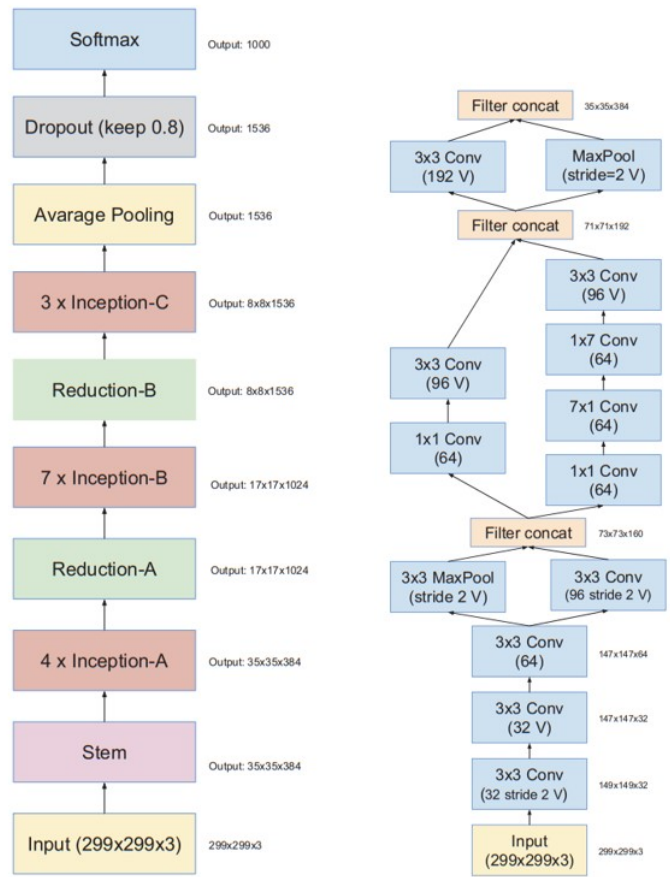

Fig. 10. The above Figure Illustrates the Complete Architectural Details of Inceptionv4.

Fig. 11. The Neural Weight Transformation with Varying Inputs and Weights.

architecture consists of aggregated transformations by splitting, transforming and aggregating a single neuron.

The model embraces the method of repeating layers in VGG and ResNet’s by making use of the split-transform-merge strategy in the Inception model. The neuron in the network splits the input and transforms the weighted sum to low dimensions by aggregating through summation fig(11).

Each neuron in the network carries out a non-linear function due to the addition of the new dimension (cardinality). The ResNext model replaces the elementary transformation with a signified function and constructed by combing a set of residual

Fig. 12. Three Variant Architecture Designs Implemented in the ResNeXt.

blocks which are subjected by two rules first, maintaining the same shape in the spatial maps i.e. ensuring width size and a filter size of each block are the same. Second, it maintains the complexity of the network where width is multiplied by 2 when the spatial maps are down sampled. This model takes fewer parameters when compared to existing ResNet's with  $4.2 \times 10^7$  FLPOs.

Each block in the ResNext network has the same number of internal dimensions. ResNext-50 (32x4d) indicates four internal dimensions with 32 paths (cardinality=32). When compared with the Inception-ResNet block ResNext model is designed with less effort in each path and implemented in different forms illustrated in the figure.12. The third form of the network is chosen because it is much faster and has grouped convolutions than the other two models. The grouped convolutions consist of 32 convolutions with input and output of 4 dimensions. The experiments were carried out with increasing the cardinality and width which results in the increase of FLOPs by a factor of 2. By increasing the cardinality, the error is reduced by 1.3% to 20.7% rather than increasing the width of the network. The ResNext-101 (64x4d) has obtained a T-1 error rate of 20.4% and a T-5 error rate of 5.3% with an image size of 224x224. They also evaluated this model on different dataset like ImageNet-5K and got an error rate of 40.1% which reduces the error by 2.3% when compared to ResNet-101.

### I. Dual Path Networks

Y. Chen et al [85] proposed an architecture Dual path network (DPN). It is the combination of a residual network (ResNet) and a Densely connected network (DenseNet). The proposed architecture takes the feature reuse from ResNet and feature exploration from DenseNet by maintaining low complexity and more number of parameters. DPN includes higher-order recurrent neural networks (HORNN) which benefit from sharing weights throughout the network and also proves that ResNets and DenseNets are the same by using HORNN. By optimizing the network they had achieved a state of the art results on ImageNet-1k.

To understand the connection between the two networks they formulated the HORNN as

$$i^j = p^j \sum_{Q=0}^{j-1} R_Q^j(i^Q)$$

Where  $i^j$  is the state which is hidden in RNN at a particular step which is denoted by Q, the current step is indicated by j.  $R_Q^j(\cdot)$  function is for extracting features.  $R_Q^j(\cdot)$  and  $p^j(\cdot)$  do not share weights but extracts the same features more times. So that it may lead to feature redundancy this is one of the drawbacks of the network. ResNet has the problem with

Fig. 13. Visual Illustration of Networks from Deep Residual Network to Dual Path Networks (DPN).

finding new features while DenseNet has the problem with high feature redundancy. The DPN architecture has a 1x1 conv layer, 3x3 conv layer and 1x1 conv layer as last layer figure. 13. The output of the network has divided into two parts first, the element-wise addition of residual combinations. Second, adjoined with DenseNets to improve the learning ability of individual micro-block. The second conv layer in the network is replaced by ResNext. ResNet is widely used so the authors choose it as the main part of the network which is combined with DenseNets to construct the architecture. A DPN can implement either by adding a "slice layer" or "concat layer" to the residual network which consumes extra memory usage and computational cost. DPN has 26% fewer parameters when compared to ResNext-101 (64x4d). The model is implemented on 40 k80 graphic cards with a batch size of 32 on individual GPU. The proposed architecture DPN-131 (40x4d) has got a T-1 error rate of 18.55% and a T-5 error rate of 4.16%. The model is also evaluated on different dataset like places 365 standard datasets where it got T-1 and T-5 accuracy scores of 56.84% and 86.69

### J. NASNets

Zoph et al. [86] contribute a new search space for constructing neural architectures by transferring the weights from a smaller dataset to that of the larger one. This research introduces a new regularization method (known as scheduled-drop-path) for the models developed through their proposed search space which improves generalization. The efficient model developed through this search space attains SOTA results in classification (IN-12 dataset). Additionally, utilizing the R-CNN framework the learned representations are captured through the best model attains SOTA on the CoCo dataset. The proposed NAS (Neural Architecture Search) [87] implements a reinforcement strategy to optimize the configurations to design a good neural architecture. This method implies 2 different cells with a similar structure and separate weights. These cells are normal and reduction which is shown in Fig. 14. The normal cell input and output are of the same dimensions whereas, the reduction cell reduces the shape of input dimensions to half the previous input (i.e. stride 2 is applied). These cells provide faster and efficient search with appropriate generalization. The NAS which is mentioned in Fig. 14, has a controller block is a recurrent neural network that predicts multiple architectures with multiple probabilities. Then a small network (child) is trained to reach convergence with a certain accuracy score. The gradients of multiple probabilities attained are scaled in such a way to attain new accuracy scores and are updated to the controller.

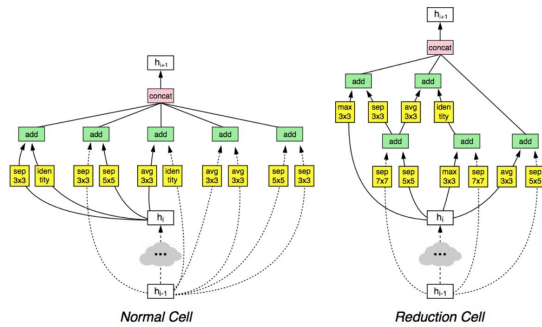

Fig. 14. Detailed Architecture of Normal and Reduction cell of NAS-Net.

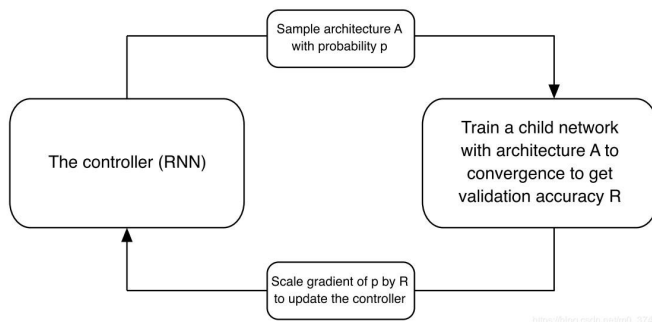

Fig. 15. A Brief Illustration of Neural Architecture Search.

Observing the Fig. 14 the cells have two hidden states. The input of the hidden states is passed from the output of the preceding cells. If there are no previous cells then each hidden state takes an image as input. The architecture is formed by predicting subsequent convolution which can be formed using those two hidden states. The complete algorithm for NAS is determined [87]. Instead of random search, NAS provides a reinforcing learning strategy to construct a deep architecture. The random search lack in providing significant result only for CIFAR-10 dataset and Fig. 15 illustrates the NAS search architecture.

The architectures which attained greater performance for the ImageNet, as well as CIFAR-10, are mentioned in Fig. 16. The controller is trained on the PPO criterion [88]. The learning rate was set as  $3510^{-5}$ . All the activations of the convolution are fed using relu as non-linearity with successive batch normalization layers. Additionally, implied bottleneck convolutions i.e.  $1 \times 1$  convolutions and implied RMS prop as the optimizer. The best performing model takes  $331 \times 331$  input image size and attains a T-1 accuracy score of 82.7% and T-5 accuracy score of 96.2% with 88.9 Million parameters. As a note, for object detection NAS-Net implied in Faster-RCNN obtained state-of-the-art mAP of 43.1%.

K. PNASets

C. Liu et al [89] proposed a network by using reinforcement learning and different algorithms. Sequential model-based optimization (SMBO) is used in the model which finds for structures in the network by increasing complexity with simultaneous learning. The model is compared with the previous method which is efficient up to 5 times within the same

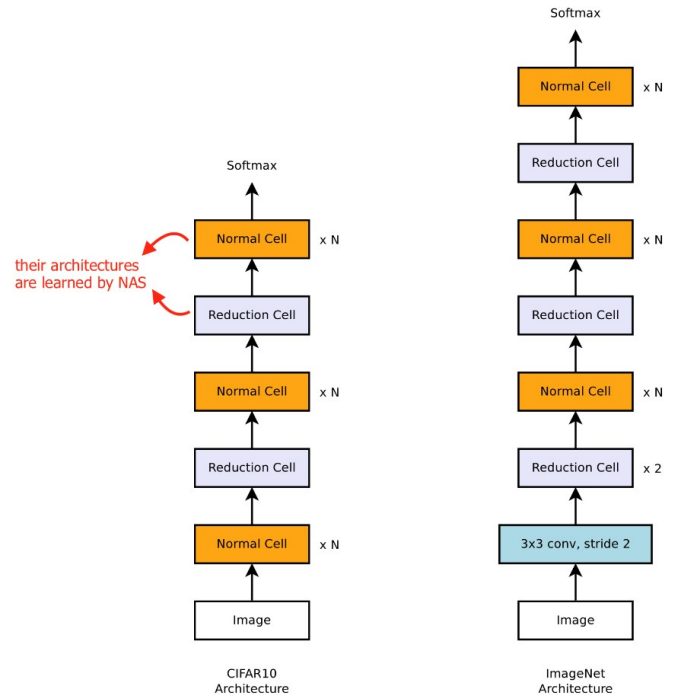

Fig. 16. Visual Illustration of Normal and Reduction Cell in NAS-Net.

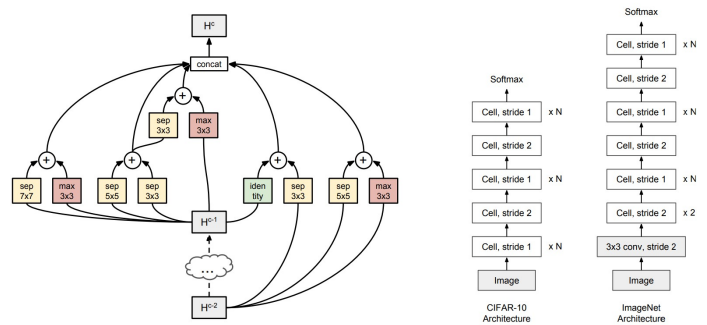

Fig. 17. The Architecture Details of the PNASNet.

search space. The architecture consists of a search algorithm where it finds the best conv “cell”. Each cell includes a certain number of blocks where it consists of two input tensors with a combination operator. These blocks are stacked and determined based on the training time this approach easy transfer datasets from one to another. The search space in the network is based on the heuristic approach which starts with a basic model and improved complexity as the search goes on. The detailed architecture of the model is shown in Fig. 17.

The architecture details of the PNASNet.

- Considering simple structures, the training of the model becomes faster and inherit the process quickly.
- A set of surrogates (proxy) are requested to obtain the predictions of the quality of the structures which tend to be higher from the input is received.
- The search space is factorized by multiplying smaller search spaces which give the advantage of finding

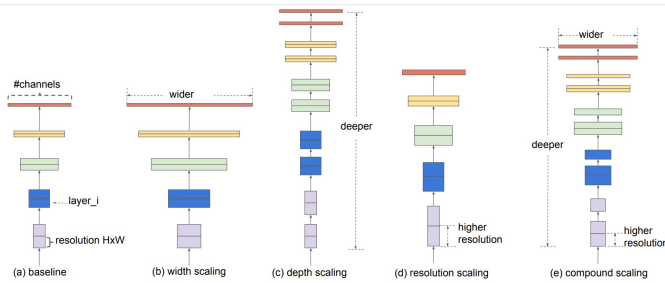

Fig. 18. The above Figure Illustrates the Scaling of Variant Components Involved in Convnets.

more block with the precise model.

The model is trained on ImageNet with RMSProp as an optimizer, an initial learning rate of 0.04 and decayed after 2.2 epochs with a batch size of 32. The architecture consists of 86.1M parameters which are smaller than NASNet. The model has achieved a state of the art results with T-1 and T-5 accuracy of 82.9% and 96.2% respectively.

#### L. EfficientNet

M. Tan and Quoc V. Le proposed a model by scaling the depth of the network, width of the network and resolution of the image [90]. The model is developed by using a combination of MobileNets and ResNets. By scaling those parameters, the model led to better performance with less computation cost. The scaling of the network is done in such a way they maintained a constant ratio throughout the network this scaling method is known as effective compound scaling. The scaling of the model is done as shown in Fig. 18. Due to various resources, they face a problem while scaling the convnet. So, they increased the depth, width and resolution of the image by a factor of  $P^k$ ,  $Q^k$  and  $R^k$  respectively where P, Q, R are small grid constant coefficients. By increasing the depth of the network, a convnet can apprehend more complicated features. Here, a problem of vanishing gradients arises and it is very complicated to train the network. By scaling the depth with a coefficient P, they maintained balance in the network. The next constraint is to balance the width of the network which is usually done in very small models. Increasing the width can capture more fine-grained features and takes less time for training. Their experimentations have shown, the wider the network, the more is the drop in accuracy. The resolution of the image is scaled by a factor R because of the higher resolution of the image takes more time for training. The proposed method enhances the accuracy and optimizes the FLOPS. By examining the depth, width and resolution values of the network to be 1.4, 1.2 and 1.3 respectively are found to be accurate with 2.3B FLOPS.

The model (EfficientNet-B7) achieved a T-1 and T-5 accuracy of 84.4% and 97.1% respectively with 66M parameters which are 8.4x smaller than the previous state-of-the-network.

#### M. FixResNeXt

Hugo et al. [91] performed augmentation trails for acquiring better generalization by choosing appropriate train and test size for a network. During experimentation, it is justified

that, lower training resolution for an image and higher testing resolution eventually improved the performance to a greater extent by reducing training computational cost. This procedure was implemented on ResNeXt-101 by outperforming the existing models and obtained state-of-the-art performance on 2019 ILSVRC. There was a good significant shift in the model when the training and the testing methods are fine-tuned separately. A joint optimization is done by scaling the train-test resolutions equivalently by maintaining individual RoC (region of classification) sampling. To overcome the distribution, shift the first two layers of the model are prioritized to fine-tune by varying the crop resolution. A detailed analysis is done to pre-process the model by increasing the crop resolution at the testing phase and during training, roc sampling is done appropriately. This eventually, acquired a good generalization by providing lower train resolutions and higher test resolutions. The computation is reduced by 3-fold by halving training resolution which in turn speed up the training procedure. Implying larger batches for training impacted a good performance with saving GPU memory. A further modification is done to the model by adjusting activation statistics of the layer which is preceding the global average pooling (GAP) layer. When these techniques are implemented on ResNet-50 by varying the test size the results obtained are mentioned (CR is equivalent to crop resolution). First, with 64 as CR, the model obtained an accuracy score of 29.4% on ImageNet. Further, with an increase in resolution by 128 the model obtained an accuracy score of 65.4%. A higher accuracy score of 78.4% was obtained for 288 as CR.

It is observed that increasing test resolution further (more than 288) the accuracy score was gradually decayed. Even after assigning appropriate test resolution a set of skewed activations were observed and they were addressed by two methods. First, a parametric adaption is chosen and the other is an adaption by tuning appropriately i.e., fine-tuning. Hence the parameters of the architecture are to be addressed in detail with experimental results. Instead of performing the train-test method for generalization 10-fold cross-validation is implied with mean and standard deviation for each execution. During the training process, extra training data was provided for most of the implementations. The best performing model (ResNeXt-101) acquired parameters of 829 M. While training ResNet-50 learning rate was initialized as 0.1 and is decayed by 10 for every 30 epochs. Initially, 512 samples were fed into the network as a batch with a horizontal flip, color jittering and random resize crop as augmentation parameters. The experimentation was performed on eight Tesla V100 GPUs. Subsequently, a set of 80 CPU clusters were inserted along with GPUs. The experimentation was carried out on standard pre-trained networks such as ResNet-50, ResNeXt-101 and PNASNet. Large network classification was done by complete fine-tuning PNASNet-5-Large with a train resolution of 331x331 which obtained the highest T-1 accuracy and T-5 accuracy of 83.7% and 98.0% on 480x480 test resolution respectively. Whereas, ResNeXt-101 was trained on 224x224 as a resolution to obtain a state-of-the-art accuracy of 86.4% with 320x320 as test image resolution. Further, this method was effective even on various transfer learning tasks and it obtained state-of-the-art performance for CUB-200-2011 and Birdsnap datasets.

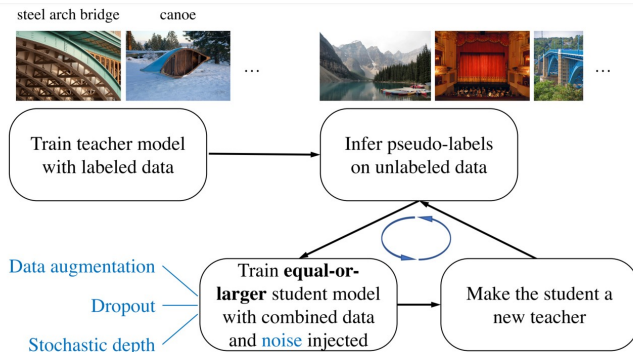

Fig. 19. The Working Principle behind the NoisyStudent Procedure.

#### N. NoiseStudent

Q. Xie et al. [92] implied self-supervised for training large scale images. This approach is based on a student-teacher learning paradigm. First, EfficientNet is trained on a set of labelled images(as a teacher model) of ImageNet and then produced pseudo labels by evaluating on a different data set which consists of 300 Images. Second, the larger EfficientNet model is considered as a student model and this is trained on the grouped labels i.e., pseudo labelled and labelled images. Next, the student model is replaced with the teacher and this process is iterated to attain significant performance. It is observed that the teacher model does not contain noisy labels as they were trained through a supervised approach. In the student model, a noise component such as dropout, stochastic depth, and random augmentations are implied. These implementations helped the student model to have greater generalization to that of the teacher model.

There are certain hyperparameters involved in tuning the model. The batch size is assigned as 2048 as default. A varying batch was implied i.e. 512, 1024, and 2048 to the EfficientNet model and all the batches turned out to have the same performance. The student model was trained for

350 epochs and smaller student models were trained for 700 epochs. The noise implied to student model with a dropout of 50%. Further, the random augmentation [18 for STNS] provided a magnitude of 27 for two operations. Finally, the probability of survival is set to 0.8 for the stochastic depth. The Noisy Student model beats the current state-of-the-art BiT Large with a 0.9% increment in accuracy i.e., the best performing NoisyStudent acquired an accuracy score of 88.4% T-1 accuracy and 98.7% T-5 accuracy respectively. This model consumed 480 Million parameters and which is approximately half the computational resource of the previous state-of-the-art by training the model with 300 unlabelled samples considered from the JFT dataset. The best performing model considered EfficientNet-L2 as the backbone to imply the NoisyStudent approach as mentioned in the Fig. 19. Further, the importance of adding a noise component in training the student model is discussed and evaluated. The training signal tends to vanish if the student samples were trained in a similar approach to that of a teacher by attaining zero cross-entropy loss. The T-1 accuracy obtained on ImageNet is 83.9%. This indeed shows large variation from the proposed method i.e., high variance from the current state-of-the-art. The co-training helps in segregating the two disjoint segments and training two models in a student-teacher self-supervised fashion helped in improving the performance to a greater extent.

#### O. BiT (Big Transfer)

Kolesnikov et al [93], performed transfer learning on large scale image recognition to improve tuning of hyperparameters and sample efficiency. The parameters are tuned cautiously by focusing on certain components for various vision tasks to improve performance with feature reproducibility. To provide greater performance transferability is provided on large scale vision tasks and performed transfer learning to produce three variant models BiT-Small, BiT-Medium and BiT-Large. The models were trained by fixing the architecture and varying the size of the data. Where small is performed on ILSVRC-2012 consisting of 1.2 million samples with 1000 classes. The medium is trained on full ImageNet with 14.2 million samples

with 21 thousand labels. Finally, the large utilized JFT dataset consisting of around 300 million samples and approximately 1.2 labels per sample. A set of tricks are considered by understanding certain components to attain higher performance for a neural network. They addressed two necessary components to build an effective neural architecture which is upstream and downstream components.

**Upstream Components:** Upstream components are implied for pre-training definite task. The components considered during up-stream pre-training are scale, Group normalization, and Weight standardization. Properly adjusting these components led to having a lower computational budget and greater efficiency. Further, group normalization and weight standardization obliged faster training over large batch structures.

**Downstream Components:** Whereas, Downstream components are applied for fine-tuning a similar visual task. In this, a heuristic rule is applied by discarding computationally expensive hyperparameters. Simple image pre-processing techniques such as resizing input to squared shape, cropping a short square randomly, and performing horizontal flip at training time. The parameters tuned while pre-training the model, at upstream and downstream are discussed independently. Most of the BiT models utilize ResNetV2 as backbone architecture to imply transferability. The upstream models utilize SGD as an optimizer and initializing the learning rate by  $3 \times 10^{-2}$ . Additionally, a momentum of 0.9 was induced for faster convergence. The input samples were isotopically resized to  $224 \times 224$  shape. Next, the small and medium models were trained with 90 epochs. But the training procedure was different as the learning rate was reduced by 10 after 30, 60 and 80 epochs. Subsequently, the large model was trained by decaying learning rate after 25%, 57.5%, 75% and 92.5% of the training progress. Similarly, for the downstream task, the SGD was implied as an optimizer with a learning initializer of 0.03 and to progress convergence, a momentum of 0.9 is added. The input shapes were reshaped appropriately to the context of the dataset. In a large scale visual classification challenge, the T1 accuracy obtained by the BiT-Large model on ImageNet-1K is 87.54% (with a standard deviation of 0.02). It remained a state-of-the-art model not only for ImageNet but also, for multiple standard data sets such as CIFAR-10, CIFAR-100, Pets, Flowers, VTAB. Further, the BiT was analysed on object detection, which implied RetinaNet as the backbone. This attained a state-of-the-art average precision of 43.8. With the BiT transferability, the object detection model attained an improvement of around 7.3%.

P. ViT (Visual Transformer)

Dosovitskiy et al. [94] utilized a transformer, the standard neural architecture for natural language processing onto computer vision task to drive self-attention for large scale visual recognition. This visual transformer was able to drive present state-of-the-art with lower computational cost to that of Convnets. The transformer is implied invariant fields depicting its performance. A Visual Transformer (ViT) is trained by appropriately setting the input embedding to the transformer to extract visual representations. The patch embeddings are obtained by resizing the image of a 2D image into sequential 2D patches. These embeddings are inserted into the transformer

Fig. 20. The above Figure Illustrates the Architecture and the Patch Embedding of the Vision Transformer.

TABLE II. IT GIVES DETAILS ABOUT THE ACCURACY SCORES OBTAINED BY SOTA MODELS.

SOTA Methods	Top-1 accuracy	Top-5 accuracy
AlexNet	62.5	83
ZeNet	64.0	85.3
Overfeat	66.0	86.7
VGGNet	76.3	93.2
InceptionV2	79.9	95.1

BiT	87.5	-
ViT	85.5	-

similar to that of BERT’s model class token. The architecture and patch embeddings are visually described in the Fig. 20.

The ViT model and the models considered for comparison were trained on certain parameters. The optimizer implied is adam with an initial learning rate set to default (0.001). Further, the  $\beta_1$  and  $\beta_2$  were set as 0.9 and 0.999 respectively. A weight decay of 0.1 was applied and it helped to construct good performance. Further, to fine-tune the model was initiated with a batch size of 512 and the optimizer as SGD. A small momentum was applied to improve the training speed. A maximum dropout of 0.1 was used for the ViT model trained on a large ImageNet dataset. Self-attention is provided by the transformer helped to combine the features extraction at the lower layer on focusing on the definite set of entities residing in the image.

VI. SUGGESTIONS FOR ARCHITECTURE CONSTRUCTION

Observing the state-of-the-art literature in the convnets there are certain factors observed in the construction of a novel architecture with greater performance and lower computational cost. These certain factors are constructed by analysing the minute parameters providing a better model. The performance

of various SOTA models is produced in Table II.

### A. Architecture Tips

The architecture tips fairly include all the factors influencing to develop a resilient architecture that extracts invariant features. Larger kernel size in the beginning layers of the convolution provides loss of information which degrades performance but, speeds the training process. Similarly, the higher the stride faster the model is trained but the accuracy degrades successively. Without adding residual connections developing a model just by increasing the depth can lead to the problem of degradation. A network architecture without bottleneck activations can explode in terms of computational cost hence, a set of bottleneck activations are to be implanted into the networks. The varying dimensionality of the receptive field can provide invariant features. An architecture trained on very small data cannot perform well on most of the unseen samples. Hence, solutions for these problems are explicitly provided for building a resilient convnet.

- A small receptive field provides a set of variant abstract features which carry detailed invariances.
- A smaller stride can eventually provide good representation by reducing the loss of the information through excessive pooling.
- To skip the problem of degradation, residual connections can be implied accordingly. Further, this improves the performance and also reduces the computational cost for deeper architectures
- A set of bottleneck connections can provide a generic feature representation and reduce computational effort while developing a convent width-wise.
- The asymmetric receptive fields with an appropriate bottleneck layer provide a greater representation of features.
- Finally, a model trained on multiple tasks with an appropriate set of samples can eventually improve in terms of performance acquiring state-of-the-art without much effort in parametric tuning.

### B. Optimization Tips

The optimization tips include developing representation in convnets by altering the hyperparameters and indicating their right implementation. The hyperparameters which are widely implied in the deep learning paradigm to observe a conventional change in the model behaviour during stochastic optimization are described in detail.

- **Dropout:** Dropout helps in generalizing the model by halting a set of neurons during training and releasing them during the validation or testing time. Hence, selecting the percentage of dropout is crucial. According to the present implementations, most of the research implies 50%. But it can be varied from 30-50% and choosing it in this interval provides good generalisation is densely connected networks.
- **Normalization:** Local response normalization implemented in AlexNet did not perform well in most of the

instances. As it has a huge number of hyperparameters it is a complicated task to imply such a normalization technique. Further, the Batch normalization technique was implied and it provided a great deal of succession in convnets by solving the problem of covariate shift. It is mostly utilized in the present research as it does not include very few parameters to tune and it works globally for variant architectures. Next, some problems were addressed in batch normalization and overridden by group normalization. It shows very minute performance variation when incurred on a smaller task but has a good variety when applied on large scale. Hence, group normalization can be used while developing a deeper model and for a small architecture batch normalization and group normalization works equivariantly.

- To skip the problem of degradation, residual connections can be implied accordingly. Further, this improves the performance and also reduces the computational cost for deeper architectures
- Lastly selecting optimizer and scheduling the learning rates is still tedious. Hence, most of the research imply SGD with varying learning rate based on the problem and varying momentum by observing the convergence. Hence, for building a small scale convnets Adam optimizer with small learning rates and high batch size is provided for good performance. Whereas, training a large-scale model the parameters might vary from the architecture and choice of dataset.

## VII. CONCLUSION

A detailed survey regarding the previous state-of-the-art is conducted. Additionally, a section explicitly gives an intuition of developing a good model with high performance and less computational power. This illustrates developing resilient architecture by tuning specific hyperparameters which as insightful in developing deep models.

Further, a set of details are not mentioned in this survey are to be described and held as our future direction. There a variant model which is developed in between these high-performance models which are not mentioned in this work. A set of small-scale models which resolve the problems in convolutions (i.e. Capsule Networks) does not describe explicitly. A detailed set of implementation framework which can reduce the effort of the implicit utility of architectures is not provided. These are taken as a challenge for the successive research and designing a framework overhauling these problems is chosen as future scope of work.

## ACKNOWLEDGMENT

We kindly thank the Department of IT for providing extensive support during the research. Further, we thank GITAM University for support and appropriate guidance.

**Abstract**—This work proposes a novel course timetable model for the national joint courses program. In this model, the participants, both students and lecturers, come from different universities. It is different from most existing university course timetabling models where the environment is physical, and the system can dictate the timeslots and classrooms for the students and lecturers. The courses are delivered online in this model, so physical classrooms are no longer required, as was the case in most previous course timetabling studies. In this model, the matching process is conducted based on the assigned timeslots and the requested courses. The courses are elective rather than mandatory. Three metaheuristic methods are used to optimize this model: artificial bee colonies, cloud theory-based simulated annealing, and genetic algorithms. Due to the simulation process, the cloud theory-based simulated annealing performs best in minimizing the number of unserved requests. This method outperforms the two other metaheuristic methods, the genetic algorithm, and the artificial bee colony algorithm. According to the simulation results, when the number of students is low, the cloud theory-based simulated annealing has 91 percent fewer unserved requests than the genetic algorithm. When the number of students is large, this figure drops to 62%.

**Keywords**—Course timetabling; joint course program; artificial bee colony; simulated annealing; genetic algorithm; online course

## I. INTRODUCTION

In January 2020, the Ministry of Education and Culture of Indonesia launched a national program called Merdeka Belajar Kampus Merdeka (MBKM). This program is conducted for undergraduate students in Indonesia. Through this program, students can take courses or earn credits outside of their study program. For example, these students can take several courses from other universities. Besides, students can also take courses which are not related to their study program. For example, a computer engineering student can take management or accounting courses from outside his university. This general program is then followed by several joint programs. In this joint program, several universities provide several courses together. Each university provides several courses so that external students can attend these courses. In some programs, students can select universities and the related courses (lecturers) explicitly. In other programs, students just select the courses without knowing the lecturers who provide the selected courses so that the students cannot choose the lecturers. As a national program, the provided courses are conducted online so

that geographic barriers do not matter, for example, in rural and remote areas [1]. It also minimizes the cost due to providing the physical classrooms [1].

Despite the fact that this program gives benefits to students, especially in the flexibility, affordability, and accessibility aspects [1], there is a problem in arranging the courses. Students who follow this national program still need to attend the physical courses conducted at their own universities. The lecturers who participate in this program also teach at their own universities. Both students and lecturers have their own schedule. Based on that, schedule matching between lecturers and students in this national program becomes a critical issue.

Unfortunately, existing course timetabling models in many studies cannot be implemented directly to solve this problem. The main reason is that, in general, the existing course timetabling models were conducted for single department [2] or university [3,4]. The system has full authority to allocate the resources (lecturers, physical rooms, and timeslots) and manage the students. The system can dictate the timeslots for both students and lecturers. Besides, most course timetabling studies were conducted in a physical environment where the courses were conducted in physical rooms, so that the limited number of rooms became a constraint [5,6]. In this national joint course program, the courses are conducted online so that the physical rooms are not needed anymore. On the other hand, the system cannot dictate timeslots for both students and lecturers.

Based on this problem, this work aims to develop a course timetabling model that suits the circumstances of this national joint course program where the participants are students and lecturers from different universities. Both students and lecturers choose their available timeslots. A lecturer handles one specific course only. A student can take or request several courses provided by the program. The objective of this model is to minimize the number of unserved requests. In the context of a timetabling study, the number of unserved requests becomes the soft constraint.

Like the existing course timetabling studies where the models were optimized by using metaheuristic techniques, for example: genetic algorithm [7,8], simulated annealing [9,10], tabu search [2], and so on, this model is also optimized by using three metaheuristic methods: artificial bee colony algorithm, cloud theory based simulated annealing, and genetic

algorithm. The artificial bee colony and simulated annealing are chosen due to their advantage in finding global optimization by avoiding local optimal traps [11]. The cloud theory-based simulated annealing is a derivative of the basic simulated annealing that gives a faster process [12].

The contributions to this work are as followed:

- This work proposes a novel course timetabling for a joint online course program where the students and the lecturers come from many universities.
- The proposed model arranges course timetables based on the available timeslots and requested courses.
- Its objective is to minimize unserved requests, which is rare in many existing course timetabling studies.

This proposed model can be used practically in many joint courses program. It can be applied not only in national scale program, as it is stated in the opening paragraph, but in smaller scale. For example, universities with same foundation or same area (district or province) can make a joint courses program. Besides, the joint courses program can be conducted for universities with same subjects, such as computer science, finance, law, and so on. The key is that the joint program is conducted in voluntary and online based approach so that this proposed model can be applied.

This paper is organized as follows. The background, research purpose, and the contribution are explained in section one. The theoretical aspects of course timetabling and several recent studies in course timetabling are reviewed in Section two. The proposed model is described in Section three. The simulation and result are presented in Section four. The findings are discussed in Section five. The conclusion of this work and the future research potential are explained in Section six.

## II. RELATED WORK

A timetable can be defined in several ways. Aziz and Aizam [13] defined a timetable as a table with all the data of events and the information about these events, such as time and place. Alghamdi, Alhakami, Alsubait, and Baz [14] defined a timetable as a table of various events or activities with their schedule. Zhu, Li, and Li [7] defined timetabling as a process of distributing activities among limited resources (place and time). The timetabling problem can be categorized as an NP-complete problem, so it is difficult to find the general optimal solution [7].

The educational timetable problem has become the most well-known among the timetable studies. An educational timetable problem is a combinatorial problem with the objective of assigning a certain number of didactic activities to a certain room within certain timeslots [3]. The entities are courses, instructors, rooms, and registered students [5]. Educational timetabling can be divided into three categories: course timetabling, school timetabling, and examination timetabling [7]. Course timetabling is assigning lecturers and courses to timeslots, rooms, and other facilities [7]. School timetabling involves assigning teachers or instructors to courses based on their specialization [7]. School timetabling

can also be called curriculum-based course timetabling [7]. Examination timetabling is assigning exams into rooms and timeslots [7]. Several factors that affect the educational timetable design are the number of courses, the average number of lectures per day, the targeted free timeslots per day, and targeted off-days in a week [14].

There are two types of constraints in the timetabling problem: hard constraints and soft constraints. Hard constraints are constraints or rules that cannot be violated [15]. Soft constraints are constraints that can improve the performance of the timetable if they are not violated [15]. Several common hard constraints are as follows:

- A lecturer can only teach a course at a certain time [3,16].
- A student cannot attend more than one lecture at one time [5].
- The attendants cannot surpass the room's capacity [3,5].
- The timeslot must be conducted within a certain time window [3].

Meanwhile, there are several soft constraints used in several educational timetabling studies. These soft constraints are as follows:

- There is a minimum number of courses in a day for the students [5].
- There is a maximum number of courses in a day for the lecturers [5,6].
- Lecturers may have preferred teaching timeslots [16].
- Lecturers may have minimum working days [17].
- Lecturers may have preferred classrooms [6].
- The last timeslots of the day should be avoided [2].

There are many studies conducted on this educational timetabling problem. Each study is developed based on its specific circumstances, objectives, and methods. Most studies use computational methods, especially metaheuristic methods, to find the optimal solution. Table I shows the recent studies on the educational timetable problem with their objectives and methods. These studies were conducted from 2016 to 2021. They are presented chronologically.

There are several notes on this presented literature. First, most studies on the course timetabling problem were conducted in face-to-face interaction between students and lecturers, so the number of limited physical rooms becomes a constraint. Second, all these studies were conducted in a department or university so that the system could dictate the timeslot allocation.

Based on these notes, this work proposes a novel course timetabling model due to specific circumstances in the national joint courses program. These circumstances are not found in the existing course timetabling studies. First, this joint program is conducted online. Second, the system cannot dictate the timeslots for both students and lecturers. The matching process is conducted based on the available timeslots that are allocated

by the students and lecturers. Third, the courses are open elective so that students can choose any course provided in the system and they can choose more than one course. Like the existing studies, this work will use several metaheuristic techniques to optimize the solution. These techniques will be compared to each other.

TABLE I. RECENT STUDIES IN EDUCATIONAL TIMETABLING PROBLEM

Authors	Objectives	Methods
[4]	improve resources utilization	genetic algorithm
[5]	minimize conflicts	genetic algorithm
[8]	minimize penalty	multi-objective genetic algorithm, hill climbing, simulated annealing
[17]	minimize total sum of penalty points	mixed integer linear programming (MILP), large neighborhood search
[10]	minimize clashes	genetic algorithm, simulated annealing
[6]	optimize resources	genetic algorithm
[19]	minimize the number of classrooms	linear programming
[2]	minimize students' maximum number of events per day, avoid the usage of the last timeslot of the day	tabu search, variable neighborhood search
[20]	improve accuracy	genetic algorithm, supervised learning (regression and classification)
[22]	maximize lecturers' presence time and education quality	three-stage heuristic algorithm
[3]	minimize idle time	genetic algorithm
[18]	reduce redundant workload, improve classroom seat utilization	genetic algorithm, fuzzy pattern algorithm
[21]	minimize soft constraints	integer linear programming (ILP), branch-and-bound algorithm

### III. PROPOSED MODEL

This model consists of several entities. A student is a person who takes a course or several courses. A lecturer is a person who delivers courses to students. A course is a unit of teaching that is delivered by a lecturer, for example: artificial intelligence, machine learning, mobile programming, and so on. A class is a group of students that take the same course and are taught by the same lecturer with the same timeslot. A Request is a course requested by a student.

The system consists of a certain number of students and lecturers. The students come from any universities, and so do the lecturers. The relationships between students and lecturers are many to many. It means a student can be taught by more than one lecturer depending on the number of courses that this student takes. The number of students is greater than the number of lecturers. Meanwhile, a lecturer can teach many students. This relation is shown in Fig. 1.

Fig. 1. Student-Lecturer Relationship.

In this system, a lecturer can only teach a course due to the expertise factor. Meanwhile, a student can take several courses. Both lecturers and students assign several available timeslots. These timeslots are week-based timeslots. It means there are a certain fixed number of timeslots in a week. The number of timeslots that are booked by a lecturer represents the number of classes that are taught by him or her. A student can take a course that is delivered by a lecturer as long as the course in this class is the same as the course that is taken by this student and the class timeslot is the same as the student's timeslot. The illustration of this relationship is shown in Fig. 2.

The explanation of Fig. 2 is as follows. There is a lecturer who teaches a course, for example, course A. He assigns two timeslots for this course so that he handles two classes, class 1 and class 2. Meanwhile, there are five students who want to take course A. Based on the matched timeslot, three students (student 1, student 2, and student 3) are assigned to class 1 and two students (student 4 and student 5) are assigned to class 2.

Fig. 2. Illustration of Classes.

This model is developed based on several hard constraints as follows:

- Students are not permitted to attend more than one class at a time [3].
- A lecturer is not permitted to teach more than one class at a time [5].
- A student cannot be assigned to a class where its timeslot is outside of his available timeslots [3].
- A student cannot be assigned to a class where the course is not his requested course.
- Students cannot request a course outside of the provided courses.
- A lecturer cannot teach a class where the timeslot is outside of his available timeslots [3].
- The number of class attendants cannot exceed the maximum capacity of the class [5].
- A class cannot be plotted outside of the available timeslots in a week.

This model is also developed by using several annotations as follows:

$c$	class
$c_{sel}$	selected class
$C$	set of classes
$C_{pos}$	set of possible classes
$s$	student
$S$	set of students
$l$	lecturer
$L$	set of lecturers
$n$	number of entities
$o$	course
$O$	set of courses
$q$	quantity (number of attendants)
$q_{max}$	maximum quantity
$r$	request
$R$	set of requests
$v$	status
$t$	timeslots
$T$	set of timeslots
$T_{pos}$	set of possible timeslots
$u$	unserved request
$U$	set of unserved requests
$v_q$	class availability status based on capacity
$v_t$	class availability status based on timeslot
$v_o$	class availability status based on course
$v_{at}$	student's availability status at certain timeslot

The objective of this model is to minimize the number of unserved requests. This objective is formalized by using (1) and (2). Equation (2) shows that the unserved request is a request where its status is 0. Meanwhile, if this request is served, its status will be 1. In this system, a request can be unserved because of several problems. First, there is a mismatch between the timeslot of the request and the timeslot of the available classes for the same course. Second, there is a

class or several classes whose course is the same as the course of the request, and the timeslot of the class is also matched, but the number of attendants has reached the maximum capacity of this class.

$$\min(n(U)) \quad (1)$$

$$u = r | v_r(r) = 0 \quad (2)$$

At the beginning, both the lecturers and the students make preparations. The lecturers assign their own timeslots or classes. Meanwhile, the students choose courses that they want to take and their available timeslots in a week. This lecturer's set up is formalized by using (3) and (7). Meanwhile, the student's set up is formalized by using (8) and (10).

$$C(l) = \{c | o(l) = o(c) \wedge c \in C\} \quad (3)$$

$$n(C(l)) = n(T(l)) \quad (4)$$

$$T(l) = \{t | t \in T\} \quad (5)$$

$$t(c_i) \neq \forall t(c) | c \in C(l) \wedge c_i \in C(l) \wedge c \neq c_i \quad (6)$$

$$n(C) = \sum_{v_l} n(C(l)) \quad (7)$$

The explanations for (3) to (7) are as follows. Equation (3) declares that all classes that are handled by a lecturer must have the same course as the lecturer. Equation (4) shows that the number of classes handled by a lecturer is equal to this lecturer's number of timeslots. Equation (5) shows that the lecturer's timeslots must be within the allocated timeslots in a week. The hard constraint where a lecturer can only visit one class in a timeslot is formalized in (6). Equation (7) shows that the number of classes is equal to the accumulation of the number of classes of all lecturers.

$$R(s) = \{r | o(r) \in O\} \quad (8)$$

$$T(s) = \{t | t \in T\} \quad (9)$$

$$n(R) = \sum_{v_s} n(R(s)) \quad (10)$$

The explanation of (8) to (10) is as follows. Equation (8) states that student can request courses within the provided courses. Equation (9) states that the students' timeslots must be within the provided timeslots in a week. Equation (10) shows that the total number of requests is the accumulation of all students' requests.

After setup, the next process is the matching process. This process is conducted iteratively from the first request to the last request. The matching order is shuffled so that the first request is not prioritized rather than the last process. Each request consists of two attributes: the student and the course. This matching process is formalized by using (11) to (17).

$$c_{sel}(r) = rand(C_{pos}(r)) \quad (11)$$

$$C_{pos}(r) = \{c | v_q(c) = 1 \wedge v_t(r, c) = 1 \wedge v_o(r, c) = 1\} \quad (12)$$

$$v_q(c) = \begin{cases} 1, & q_c(c) < q_{max} \\ 0, & else \end{cases} \quad (13)$$

$$v_t(r, c) = \begin{cases} 1, & \exists t_{pos}(s(r)) = t(c) \\ 0, & else \end{cases} \quad (14)$$

$$T_{pos}(s(r)) = \{t | t \in T(s) \wedge v_{at}(t, s) = 1\} \quad (15)$$

$$v_{at}(t, s) = \begin{cases} 1, \forall t(s), \exists t(r(s)) = t \\ 0, else \end{cases} \quad (16)$$

$$v_o(r, c) = \begin{cases} 1, o(r) = o(c) \\ 0, else \end{cases} \quad (17)$$

The explanation of (11) to (17) is as follows. Equation (11) shows that the class is selected randomly among the possible classes for the request. Equation (12) states that the possible class must meet three aspects: capacity, time, and course. Equation (13) shows that the class is available if its current number of attendants is still less than its maximum capacity. Equation (14) shows that the class meets the time aspect if there exists a possible student's timeslot that is the same as the timeslot of this class. Equation (15) shows that the set of possible timeslots of the student consists of the student's timeslots that are still available. Equation (16) shows that the student's timeslot is available if it has not been occupied by any other student's request. Equation (17) shows that the class meets the course aspect if the course of the class is the same as the course of the request.

In this work, we compare three metaheuristic algorithms: the genetic algorithm (GA) [18], cloud theory-based simulated annealing algorithm (CSA) [12], and artificial bee colony algorithm (ABC) [23]. As metaheuristic algorithms, they consist of a stochastic approach, especially during the initialization process and the improvement process. In the genetic algorithm method, the half best solution becomes the new generations during the reproduction process.

All these algorithms are population-based algorithms. A population consists of individuals or solutions. An individual consists of an array of requests. Each element consists of attributes: request, student, and class.

During the improvement process, the pairwise interchange is conducted by selecting a served request, finding a new class, assigning this request to the new class, and then allocating the abandoned seat to another unserved request. This pairwise interchange process is formalized by the use of algorithm 1.

---

**Algorithm 1: pairwise interchange**

#### IV. SIMULATION AND RESULT

This proposed model is then implemented into the course timetabling simulation. As mentioned before, there are three metaheuristic techniques that are used to optimize the model:

the genetic algorithm (GA), cloud theory-based simulated annealing algorithm (CSA), and artificial bee colony algorithm (ABC). The objective function applied in these algorithms is to minimize the number of unserved requests. The reason is that this objective function is related to the objective of this work and proposed model.

The technical parameters used in these metaheuristic algorithms are as follows. In the GA, the population size is 10 individuals and the maximum number iterations is 100 iterations. In the CSA, the population size is 5 solutions, the initial temperature is 100, the termination temperature 50, and the number of iterations is 10. In the ABC, the population size is 10 bees, the maximum number of iterations is 50 iterations, and the limit is 30.

The scenario used in this simulation is as follows. In the beginning, a certain number of students and lecturers are generated. A lecturer teaches only one course. A student can request several courses. Both students and lecturers select their available timeslots. The number of timeslots that are chosen by the lecturer represents the number of classes that he will handle. The students will be allocated based on the timeslots that they have chosen. The simulation then runs based on this initial setting. During the simulation process, students will be matched with the available classes based on their selected course timeslots. At the end of the simulation, certain requests may be unserved due to a mismatch.

There are two simulations conducted in this work. The observed parameter is the number of unserved requests. This parameter also becomes the fitness function of these three metaheuristic techniques (minimizing the number of unserved requests). There are several adjusted parameters that are set as default. There are five courses in the system. The number of lecturers is 20. The maximum capacity of each class is 40 attendants. There are 20 timeslots that can be chosen by both students and lecturers. The number of courses that are requested by a student is generated randomly and follows a normal distribution. The average number of requests is 3 courses. The number of timeslots that are chosen by both lecturers and students is also generated randomly and it follows normal distribution.

The first simulation is conducted to observe the relation between the number of students with the number of unserved requests. The number of students ranges from 400 to 600 students, with a step size of 20 students. The average number of chosen timeslots is 3 timeslots. The result is shown in Fig. 3.

In Fig. 3, it is shown that the number of unserved requests increases due to the increase in the number of students. This trend occurs in all methods. The rationale for this condition is that demand is increasing, whereas supply is still the same, so the scarcity is also increasing. Compared among methods, cloud theory-based simulated annealing performs as the best model in creating the lowest number of unserved requests. On the other hand, the genetic algorithm performs as the worst method. The artificial bee colony performs moderately. When the number of students is low (400), the simulated annealing algorithm generates 91% fewer unserved requests than the genetic algorithm. When the number of students is large (i.e., 600), the gap narrows to 62 percent.

Fig. 3. Relation between the Number of Students and the Number of unserved Requests.

The second simulation is conducted to observe the relation between the average number of timeslots and the number of unserved requests. The average number of timeslots ranges from 3 to 5 timeslots. The number of students is 500 students. The result is shown in Fig. 4.

Fig. 4. Relation between the Average Number of Timeslots and the Number of unserved Requests.

In Fig. 4, it is shown that the number of unserved requests decreases due to the increase in the average number of timeslots. This condition occurs in all metaheuristic methods. The rationale is as follows. The increasing of the lecturers' timeslots means the increasing of the supply (number of classes). On the other hand, the increasing of the students' timeslots means the matching possibility increases too. When comparing among methods, the cloud theory-based simulated annealing performs as the best model. In the beginning, simulated annealing created the lowest number of unserved customers. Starting with four timeslots, the simulated annealing performs zero unserved requests. When the average number of timeslots is 3 timeslots, the artificial bee colony performs better than the genetic algorithm. The artificial bee colony has 17% fewer unsatisfied requests than the genetic algorithm. Meanwhile, when the average number of timeslots

is 4 timeslots, their number of unserved requests is almost equal. Starting from 6 average timeslots, the genetic algorithm performs zero unserved requests. On the other hand, the artificial bee colony still creates a positive number of unserved requests, although its value is low (17 unserved requests).

## V. DISCUSSION

In general, these three metaheuristic models can be used to optimize the proposed course timetabling model. In the first simulation, the number of unsatisfied requests remains less than 50%. When the supply is fixed, the number of unserved requests is proportional to the demand (the number of students), as is shown in Fig. 3. On the other hand, when the demand is fixed, the increase in the supply (lecturers' number of timeslots) makes the number of unserved requests decrease. After the zero unserved requests are achieved, the increase in supply does not change the condition.

Compared among the metaheuristic techniques, the cloud theory-based simulated annealing outperforms the two other methods, the genetic algorithm, and the artificial bee colony. This performance comes from two aspects. First, in its basic form, simulated annealing is designed to achieve global optimization by avoiding local optimal traps [11]. This process is conducted by tolerating current worse solutions with a certain degree of probability during the iteration process, especially at the beginning of temperature declination [11]. Second, cloud theory based simulated annealing improves the basic simulated annealing by conducting multiple individuals (solutions) that act independently [12]. The final best solution can be selected among the population after the iteration process ends [12].

The artificial bee colony performs the second-best method. Like simulated annealing, the artificial bee colony can also avoid the local optimal trap. In an artificial bee colony, the local optimal trap avoidance is conducted during the scout-bee phase by finding new alternative solutions, i.e., diversifying the search process [24]. This phase is taken after the onlooker-bee phase and the employed-bee phase, whose objective is to intensify the solution around the current solution [24]. Unfortunately, the process of finding an absolute new solution is not conducted in every iteration. As previously stated, this concept differs from simulated annealing in that the local optimal trap avoidance can be performed with a high degree of probability in every iteration [11].

The genetic algorithm performs as the worst solution in creating a low number of unserved requests. This performance occurs because, in its basic form, the genetic algorithm cannot avoid the local optimal trap, despite the fact that it has been widely used to optimize the course timetabling problem in [4-6]. In genetic algorithms, new offspring are generated based on the best individuals as the improvement mechanism [11].

## VI. CONCLUSION

This work has demonstrated that the proposed course timetabling model can be used in the national joint courses program that is attended by students and lecturers from different universities. This model also meets the requirements that are stated as the hard constraints. Due to the simulation process, the cloud theory-based simulated annealing performs

best in minimizing the number of unserved requests. This method outperforms the two other metaheuristic methods, the genetic algorithm, and the artificial bee colony algorithm. Due to the simulation results, when the number of students is low, the number of unserved requests for the cloud theory-based simulated annealing is 91 percent lower than the genetic algorithm. When the number of students is large, this figure falls to 62 percent. This performance is achieved because of the characteristics of cloud theory-based simulated annealing in achieving global optimization by avoiding local optimal traps.

This model is developed based on several limitations. First, there is not any prioritization in the lecturers and courses selection. In certain conditions, a student prefers certain lecturers rather than other lecturers. It is because in the same course, some lecturers are more favorite or popular rather than other lecturers. For example, lecturers from higher-ranked universities may be more popular than lecturers from lower-ranked universities. A student may also prefer certain courses to other courses. It means a student may tolerate losing less preferred courses or lecturers. Based on this circumstance, the proposed model of this current work can be extended or improved by concerning this preference factor.

**Abstract**—Traditional Javanese compositions contain melodies and skeletal melodies. Skeletal melodies are an extraction form of melodies. The melody extraction problem is similar to the chord detection in Western music, where chords are extracted from a melody. This research aims to develop a melody extraction system for traditional Javanese compositions. Melodies which have a time series data structure were designed as a part of the supervised learning problem to be solved using the pattern recognition technique and the Feed-Forward Neural Networks method. The melody data source uses a symbolic format in the form of sheet music. The beats in melodies data are used as the input and notes in skeletal melodies are used as the target. An FFNN multi-class classifier was built with six classes as the targets, where the class represents notes of the musical scale system. The network evaluation was conducted using accuracy, precision, recall, specificity and F-1 score measurements.

**Keywords**—Melody extraction; symbolic representation-based; multiclass classification; feed-forward neural network; Gamelan

## I. INTRODUCTION

This research is part of a program to preserve traditional Javanese music using artificial intelligence methods with the expectation of preserving the authenticity of the compositions throughout the ages. Traditional Javanese compositions known as Gamelan music consist of melodies and balungan (Javanese: skeletal melodies). The Gamelan composers create compositions by first composing a melody and then extracting it into a skeletal melody, or constructing a skeletal melody first which is then filled with harmonization into a melody. The melody extraction to form skeletal melodies is chosen as the background problems in this research. Skeletal melodies can be analogous to chords in Western music, and the challenge in this research is similar to the problem of determining chords to accompany the melody.

Chord detection uses time series data, and such data structures can be designed as part of a supervised learning problem to be solved using pattern recognition techniques. Chords are detected by extracting features from audio sources, filtering and matching the patterns [1], and this method has been used in various works [2-7]. Instead of using audio sources and performing feature extraction, a symbolic representation approach is proposed using sheet music as the

dataset source. Learning directly from sheet music is to get original and complete information of the musical elements that is difficult to obtain through feature extraction from audio sources. Hence, a new method for a symbolic representation-based melody extraction was proposed by recognizing the note sequence pattern based on musical theory, which is carried out by calculating the duration of the notes. The proposed method in this research is in line with what [8] stated, the music theory approach without audio can be used as a complementary technique in the field of music information retrieval. In a different context, musical theory is disproved by using chord sequences found in the dataset so that theoretically unusual chord sequences are possible to learn [9]. The proposed method is also similar to that stated by [9] in the context of using all the sequences of notes or chords found in the dataset but the metrical structure in musical theory is still used as a reference to avoid metrical structure errors in composition. Further, a multi-class classifier using the Feed-Forward Neural Networks (FFNN) method was used to build a melody extraction system for traditional Javanese compositions. The FFNN network was trained using melodies as input and skeletal melodies as the output.

The availability of datasets is a challenge in building a melody extraction system for traditional Javanese compositions. Unlike western music, which has a well-organized composition documentation system that supports easy data access, traditional Javanese composition data in sheet music format is not well documented and difficult to access online. This causes a limited number of datasets. Data augmentation is a challenge in itself, and proper data mapping techniques are needed to increase the cardinality of the data.

This paper is structured as follows. Section II introduces traditional Javanese compositions. Section III describes the related work of chord detection which has in principle a similar task to melody extraction, as well as research on traditional Javanese compositions utilizing an AI approach. Section IV describes the methodology used in developing a melody extraction system for traditional Javanese compositions which consists of data preparation, beat detection, vector length adjustment, data mapping and feature selection, and binary representation. Section V discusses training and evaluation. Finally, Section VI discusses conclusions and future works.

## II. THE TRADITIONAL JAVANESE COMPOSITION

Traditional Javanese music called karawitan consists of a set of music instruments called Gamelan and compositions with or without vocal called gendhing. Gamelan consists of two musical scale systems, which are pelog and slendro. The pelog scale system consists of seven notes: 1, 2, 3, 4, 5, 6, 7. The slendro scale system consists of five notes: 1, 2, 3, 5 and 6. The pelog and slendro scale systems are different in their tuning. Moreover, there are dotted notes as addition that represent moments of silence. Based on their function in performing the composition, a set of Gamelan instruments is divided into three groups, which are ricikan garap, ricikan balungan and structural ricikan. The group of ricikan garap contains instruments to play the melody parts, such as gender, rebab, suling and gambang. The group of ricikan balungan contains instruments to play the skeletal melody parts, such as saron, demung, peking and slenthem. The group of structural ricikan contains instruments to play notes that form the type of compositions, such as kethuk, kempyang, kenong, kempul and gong.

There is a musical mode system called pathet on both the pelog and slendro scale systems. This system controls the dominant notes at certain positions in the sequence. The slendro mode system consists of manyura, nem and sanga, while the pelog mode system consists of barang, lima and nem. There are types of compositions, such as ladrang, lancaran and ketawang. The type of compositions is determined based on the number of beats in the skeletal melody, and it can be identified based on the play of the instruments of the group of structural ricikan. Fig. 1 shows illustration of the traditional Javanese compositions and Gamelan known as Gamelan music.

Fig. 2. A Traditional Javanese Sheet Music Example of a Composition Entitled Ladrang Wilujeng.

Time signature in Gamelan music is known as tempo, and it is divided into 1/1, 1/2, 1/4, 1/8 and so on. Tempo represents the note duration of beats of melodies and skeletal melodies. Tempo of 1/1 means that each beat in the melody and skeletal melody has note duration of 1, tempo of 1/2 means that each beat in the skeletal melody has note duration of 1 and each beat in the melody has note duration of 2. The note duration consists of 1, 0.5 or 0.25, and in the sheet music it is indicated by a single or double horizontal lines above the notes. The notes without any horizontal line have a note duration of 1, a single horizontal line represents a note duration of 0.5 and a double horizontal line represents a note duration of 0.25.

Musical element symbols, such as circular symbols and curves symbols above the notes of the skeletal melody, represent the type of the composition. Curve symbols below the notes in the melody represent the legato sign which is similar to those in Western music, horizontal line symbols above the notes in the melody represent the note duration, dotted notes above and below the notes in the melody represent the notes register (low, middle and high notes). Fig. 2 shows an example of a traditional Javanese music sheet of a composition played with a tempo of 1/2. The composition consists of four lines of the skeletal melody marked with (a) and the melody marked with (b).

## III. RELATED WORK

Pattern recognition are common for chord detection problems in which chords are detected by extracting features from audio source, giving filter and matching the pattern [1]. This approach was implemented in various works by [2-7], and the method usually uses audio signal as the input source, and a features extraction is conducted to set an input by selecting relevant features from the audio source. Features for chord detection are called pitch class profile (PCP), or known with chroma features, which consists of 12 semi-tones values attributes. Chroma features are still proven as the main features

in chord detection [10]. These 12 semi-tones were used to set 12 bin vectors for faster processing [4], while 178 bin vectors [3] and 180 bin vectors [7] were set from variations of 12 semi-tones to set a frequency range. Feature extraction for random variables data can be conducted using the  $\chi^2$  statistics method in which the target and features are discrete finite values [11].

The decomposition of each chord label into a meaningful set of musical components was used to overcome the problem of insufficient sample size for model training in chord data quality [12]. Meanwhile, target and features can be determined based on data segmentation technique then followed by supervised learning implementation [13], and this technique can also increase the number of corpuses. Sequence mapping technique is used to calculate weighted moving average based on previous data of a time ordered sequence, such as works to predict stock index that implemented sliding window technique to map sequence data [14]. So, features for chord detection or melody extraction that uses a dataset collected from symbolic data can be determined by data segmentation and followed by data mapping using sliding window technique as proposed in this research. Sequence padding and sequence truncation are common techniques to solve a vector length problem in a time series prediction. Sequence padding adds a number of zeroes in the beginning (pre-sequence padding) or in the ending (post-sequence padding) of vectors as much as the maximum number of the vector's length. While sequence truncation chops a number of elements of vector in the beginning (pre-sequence truncation) or in the ending (post-sequence truncation) of vector to obtain a defined number of vector length. Sequence padding is better to find pattern in given data than to predict based on previous data [15]. This is also proven in a pre-experiment conducted in this research in which the use of sequence truncation achieves higher prediction on accuracy than sequence padding.

Several computer and music researches have been conducted to generate a note sequence of skeletal melodies. The grammar approach was used to formalize note sequence patterns of bars of the skeletal melody [16]. Meanwhile, the

grammar based on a bar structure was analyzed to define note sequence patterns of bars of the skeletal melodies [17]. The rule-based method used for the solutions of the same problem, but the formulation includes note sequence patterns between bars, and then the note sequence rules were determined by segmenting data using the sliding window technique [18]. Further, the rules were implemented as constraints to generate note sequences of skeletal melodies using Genetic algorithm [19]. Different from existing researches, this research aims to extract note sequences of skeletal melodies from note sequences of melodies.

#### IV. METHODOLOGY

A feed-forward neural networks classifier with supervised learning approach and pattern recognition technique was proposed to build a melody extraction system for traditional Javanese compositions. The task of the classifier is to extract melodies into skeletal melodies, where the class is determined based on the notes of the musical scale system. Data of compositions are segmented into beats to reveal the patterns of the notes correlation between melodies and skeletal melodies as illustrated in Fig. 3. This technique can increase the number of corpuses, as more corpus results in better accuracy in the FFNN method. For example, a composition containing six lines contributes 12 bars and 48 beats if the beats are used as the corpus.

A collection of music sheet used as the data source was manually converted into a text-based format for computation process. Each composition data consists of melodies used as input, and skeletal melodies used as target. The difference in the number of notes in a melody beat determined by the note duration has an impact on the difference in vector length. The vector length adjustment was performed so that all vectors have the same element length as the FFNN input requirements. Further, the beats are mapped to restructure the data into time series format data and to determine features and to increase the cardinality of corpuses. Finally, the results of data mapping were converted into the binary format before being sent to train the network.

Tempo illustration for a composition played with a tempo of 1/2

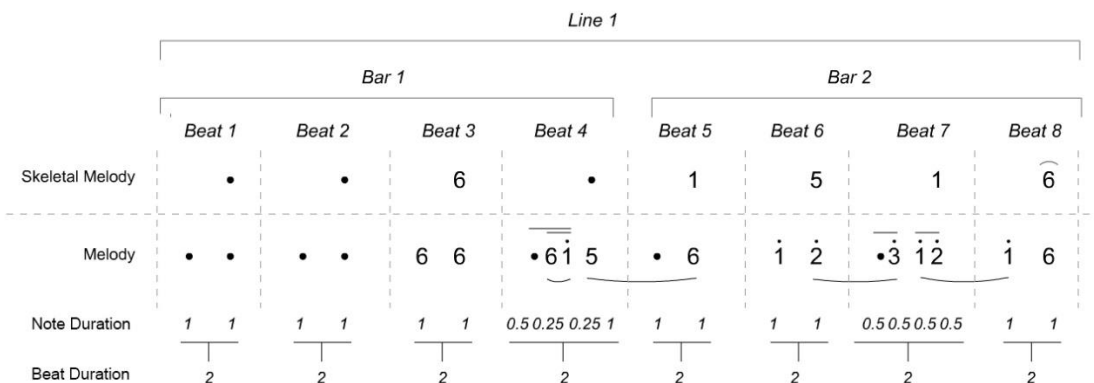

Fig. 3. Data Segmentation based on the Beats.

Fig. 4. Illustration of Text-based Format in the GSPN Model.

A. Data Preparation

The experiment was limited to the compositions of the *slendro* scale system played with a tempo of 1/2. The *slendro* scale system of *slendro* contains five notes, which are 1, 2, 3, 5 and 6, and also the dotted notes as an addition. The source of data which was 55 traditional Javanese music sheets was collected from [www.gamelanbvg.com](http://www.gamelanbvg.com). Data were converted to a text-based format using a model of a text-based note writing for traditional Javanese compositions called *Ghending Scientific Pitch Notation* (GSPN). The model was developed to represent sheet music containing data of notes, note duration, note register and legato signs in a text-based format that can be read by human and computer [20]. The text-based conversion was manually conducted using a text editor program. Data of melodies and skeletal melodies were separately typed in two text files. To store information of the melody and its skeletal melody, each line in two text files was filled with one melody and one skeletal melody from each composition. Human errors are possible during conversion but the GSPN model supports a computational process that can detect typing errors. Note duration information can be calculated to detect the duration value of each beat so that typing errors can be detected if there are beats with different duration values in a composition. Once sheet music is converted to GSPN format, the data can be explored and calculated for information.

The code to represent the musical elements in GSPN format is case sensitive. Notes in *slendro* scale system, including the dotted note, are written in the numbers 0, 1, 2, 3, 5 and 6. Note duration is coded with no code, A and B where code A represents the note duration of 0.5, code B represents the note duration of 0.25, and no code represents the note duration of 1. Note register is coded with no code, a and b where code a represents the low notes, code b represents the high notes, and no code represents the middle notes. The legato sign is coded with no code, x and y where code x represents the beginning of the legato sign, code y represents the end of the legato sign, and no code represents notes that are between the beginning and end of a legato sign or notes that are not part of any legato sign. The code is written in order of note, note duration, note value and legato sign. Fig. 4 shows an illustration of a text-based format in the GSPN model converted from a music sheet.

TABLE I. GSPN IN TABULAR DATA FORMAT

	Note Sequence of Melody

2bx1bA6Ay3Ax5A3y2003Ax5Ay301Ax2A1y6a

Table I shows illustration of GSPN in a tabular data format using melody data example above with NT stands for notes, ND stands for the notes duration, NR stands for the notes register and LS stands for the legato signs.

B. Beat Detection

In traditional Javanese sheet music, the melody part contains the musical elements of notes, note durations, note registers and legato signs, while the skeletal melody part usually contains only notes. The legato signs also do not used in the skeletal melody. The beats in the skeletal melody contains one note so every note in the skeletal melody has a duration note value of 1.

Beat detection was performed by converting letter codes in GSPN format into numbers. The note register encoded with a for low notes, and b for high notes, and no code for middle notes, was converted to 1, 0 and 2, respectively. The note duration encoded with A for the note of duration 0.5, and B for the note of duration 0.25, and no code for the note of duration 1 was converted to 0.5, 0.25 and 1, respectively. The legato sign

encoded with x for the beginning of legato, and y for the end of legato, and no code for notes that fall between the legato signs and notes that are not part of the legato signs, was converted to 1, 2 and 0, respectively.

Next, beat detection was done by calculating the notes duration value. The dataset uses compositions with a tempo of 1/2 which means each beat has a duration value of 2. The following is the pseudocode for detecting beats using data of a composition entitled Ladrang Wilujeng. The first pseudocode is to detect the number of notes duration (ND) in the sequence by adding up the note duration values, then dividing by the beat duration values based on the tempo (TP). Given NB as the number of beats then the pseudocode is:

```
TP = 2
NB = 0
ND = (1, 1, 1, 1, 1, 1, 0.5, 0.25, 0.25, 1, ..., 1)
for (i = 0; i < ND.length; i++) {
    NB += ND [i]
}
```

NB = NB/TP

Next is to group the sequence of notes (NT), notes register (NR), note duration (ND), legato signs (LS) into beats. This grouping is performed using the following pseudocode:

NT = (0, 0, 0, 0, 6, 6, 0, 6, 1, 5, ..., 6)

NR = (0, 0, 0, 0, 0, 0, 0, 0, 2, 0, ..., 1)

LS = (0, 0, 0, 0, 0, 0, 0, 1, 2, 1, ..., 0)

```
for (i = 0; i < NB; i++) {
    BT [i] = []
    BR [i] = []
    BD [i] = []
    BL [i] = []
}
```

```
k = 0
m = 0
for (i = 0; i <= ND.length; i++) {
    if (m < 2) {
        BT[k].push(NT[i])
        BR[k].push(NR[i])
        BD[k].push(ND[i])
        BL[k].push(LS[i])
    }
    m += ND [i]
    if (m > 2) {
        m = 0
```

```
k += 1
    }
}
```

Based on the pseudocode above, the sequence breakdown of NT, NR, ND, and LS into beats is stored in notes per beat (BT), notes register per beat (BR), notes duration per beat (BD) and legato signs per beat (BL) respectively. Furthermore, each beat that has been defined is correlated with each note in the skeletal melody (SM) as follows:

BT = ((0, 0), (0, 0), (6, 6), (0, 6, 1, 5), ..., (... , 6))

BR = ((0, 0), (0, 0), (0, 0), (0, 0, 2, 0), ..., (... , 1))

BD = ((1, 1), (1, 1), (1, 1), (0.5, 0.25, 0.25, 1), ..., (... , 1))

BL = ((0, 0), (0, 0), (0, 0), (0, 1, 2, 1), ..., (... , 0))

SM = (0, 0, 6, 0, ..., 6)

Table II shows illustration of the beat detection using the pseudocodes above.

TABLE II. BEAT DETECTION RESULTS

	Melody											
NT	0	0	0	0	6	6	0	6	1	5	...	6
NR	0	0	0	0	0	0	0	0	2	0	...	1
ND	1	1	1	1	1	1	0.5	0.25	0.25	1	...	1
LS	0	0	0	0	0	0	0	1	2	1	...	0
	Skeletal Melody											
SM	0	0	6	0	...	6						

### C. Vector Length Adjustment

The length of the beat element of melody data varies whereas the FFNN requires the same element length for the vector. Sequence padding and sequence truncation techniques are commonly used to solve element length problems. Truncation techniques that cut data elements can lose important information, while padding techniques that add elements in the data are computationally expensive.

Pre-experiments were conducted to compare the use of sequence padding and sequence truncation techniques based on prediction accuracy. By using the same dataset, the results show that the data managed by the sequence truncation technique achieves higher prediction accuracy results. The risk of losing important information due to truncation seems to be reduced by mapping the data using a sliding window technique after the data is truncated. So, sequence truncation technique was chosen to solve the beat element length problem.

The post-sequence truncation technique was implemented to notes per beat (BT), notes register per beat (BR), notes duration per beat (BD) and legato signs per beat (BL). Table III shows an example of the implementation of the post-sequence truncation technique to set the vector length of the notes per beat (BT) data, and the elements that are retained are two bits.

TABLE III. BEAT SEQUENCE TRUNCATION

ID	Beat Sequence	Truncation
1	(0, 0)	(0, 0)
2	(0, 0)	(0, 0)
3	(6, 6)	(6, 6)
4	(0, 6, 1, 5)	(0, 6)
...	...	...
32	(1, 6)	(1, 6)

D. Data Mapping & Feature Selection

Data mapping was performed based on the beats using the sliding window technique, a technique for data mapping by restructuring time series data to be used in a classification problem. This technique produces data segmentation based on the previous or the following sequences. The previous beat, selected beat and next beat are selected as the features. So, the sliding window implementation defines a pattern of  $(B_{n-1}, B_n, B_{n+1})$  for the data mapping, where B stands for beat and n stands for sequence index. Melody has repetitive pattern; after reaching the last pitch, melody continues to restart from the first pitch. This solves the problem in indexing a sequence. The data mapping for the first beat is set to  $(B_{last}, B_1, B_2)$ , and for the last beat is set to  $(B_{last-1}, B_{last}, B_1)$ . The sliding window technique was implemented to BT, BR, BD and BL. Table IV shows an example of the implementation of the sliding window technique to set the data mapping of the notes per beat (BT).

Features are selected based on the data mapping implemented to BT, BR, and BD. Meanwhile, BL was not used as a feature to reduce the computation cost. Beat per bar index was also used as a feature because the position of the beat order per bar affects the musical mode system so it is important to use it as a feature. Each bar consists of four beats so that the sequence of beats per bar is a repeating pattern of 1, 2, 3, 4 and back to 1. Table V shows illustration of the feature selection based on BT, BR, BD, LS and beats ID per bar.

TABLE IV. DATA MAPPING\_BT

BT (Input)			SM (Output)
ID	Beats	Data Mapping	
1	(0, 0)	(1, 6, 0, 0, 0, 0)	0
2	(0, 0)	(0, 0, 0, 0, 6, 6)	0
3	(6, 6)	(0, 0, 6, 6, 0, 6)	6
4	(0, 6)	(6, 6, 0, 6, 1, 2)	0
...	...	...	...
32	(1, 6)	(0, 1, 1, 6, 0, 0)	6

TABLE V. DATA MAPPING\_BEATS

Beats (Input)				SM (Output)
ID	BT	BR	BD	
1	(1, 6, 0, 0, 0, 0)	(0, 1, 0, 0, 0, 0)	(1, 1, 1, 1, 1, 1)	0
2	(0, 0, 0, 0, 6, 6)	(0, 0, 0, 0, 0, 0)	(1, 1, 1, 1, 1, 1)	0
3	(0, 0, 6, 6, 0, 6)	(0, 0, 0, 0, 0, 0)	(1, 1, 1, 1, 0.5, 0.25)	6
4	(6, 6, 0, 6, 1, 2)	(0, 0, 0, 0, 0, 0)	(1, 1, 0.5, 0.25, 1, 1)	0
...	...	...	...	...
4	(0, 1, 1, 6, 0, 0)	(0, 0, 0, 1, 0, 0)	(1, 0.5, 1, 1, 1, 1)	6

E. Binary Representation

Binary representation was implemented using the localist representation technique. The localist representation uses values of 0 and 1 to control an activation of variables. The *slendro* scale system consists of five notes: 1, 2, 3, 5 and 6, and the dot notation is converted into the number 0. Thus, the localist representation for each note consists of six bits, which is: 0 = 100000, 1 = 010000, 2 = 001000, 3 = 000100, 5 = 000010, and 6 = 000001. The notes register consists of three values: 1 represents the low notes, 2 represents the high notes and 0 represents the middle notes. Thus, the localist representation for each note register consists of three bits, which is: 1 = 100, 2 = 010, and 0 = 001. The notes duration consists of three values: 1 represents the value of 0.25, 2 represents value of 0.5 and 0 represents value of 1. Thus, the localist representation for each note duration consists of three bits, which is: 2 = 100, 1 = 010, and 0 = 001. The beat ID consists of four values: 1 represents the first beat in a bar, 2 represents the second beat in a bar, 3 represents the third beat in a bar, and 4 represents the fourth beat in a bar. Thus, the localist representation for each beat ID consists of four bits, which is: 1 = 1000, 2 = 0100, 3 = 0010, and 4 = 0001. Thus, the localist representation of the input data yields the length of each input:  $(6 \times 6) + (6 \times 3) + (6 \times 3) + (1 \times 4) = 36 + 18 + 18 + 4 = 76$  bits, and the length output is  $6 \times 1 = 6$  bits which is the notes elements of the *slendro* scale system.

V. TRAINING AND EVALUATION

An FFNN classifier was developed using the supervised learning approach and scaled conjugate gradient backpropagation algorithm to extract melodies into skeletal melodies. There are six classes for the melody extraction classification, where the output of each class is notes of the skeletal melodies. The length of the input vector is 76 bits and the length of the output vector is 6 bits.

The networks architecture consists of input, hidden and output layers. The best network performance was determined using an epoch with a parameter of six consecutive incorrect predictions. The number of hidden layer units was determined experimentally in multiples of 10 units and starts from 10 to 100 units. Each training was limited by 100 retrains. The training can be stopped before reaching the 100<sup>th</sup> training repetition if the results of the training meet the best prediction parameters. Later, experiments showed that the configuration of the number of hidden layer units of 40 units gives the best prediction results. Less than 40 units, the prediction error by the FFNN network is more than 40%, and more than that number the predictions are trapped in the local minima.

The best prediction parameters are determined based on the balance of the number of prediction errors between training, validation and test data in the FFNN network training with the maximum value of prediction error is 40%. The experiments used 55 music sheets, each of which contains a melody and its skeletal melody. The dataset mapped based on beats produced 2,808 beats for the corpus. Fig. 5 shows the FFNN architecture for the melody extraction.

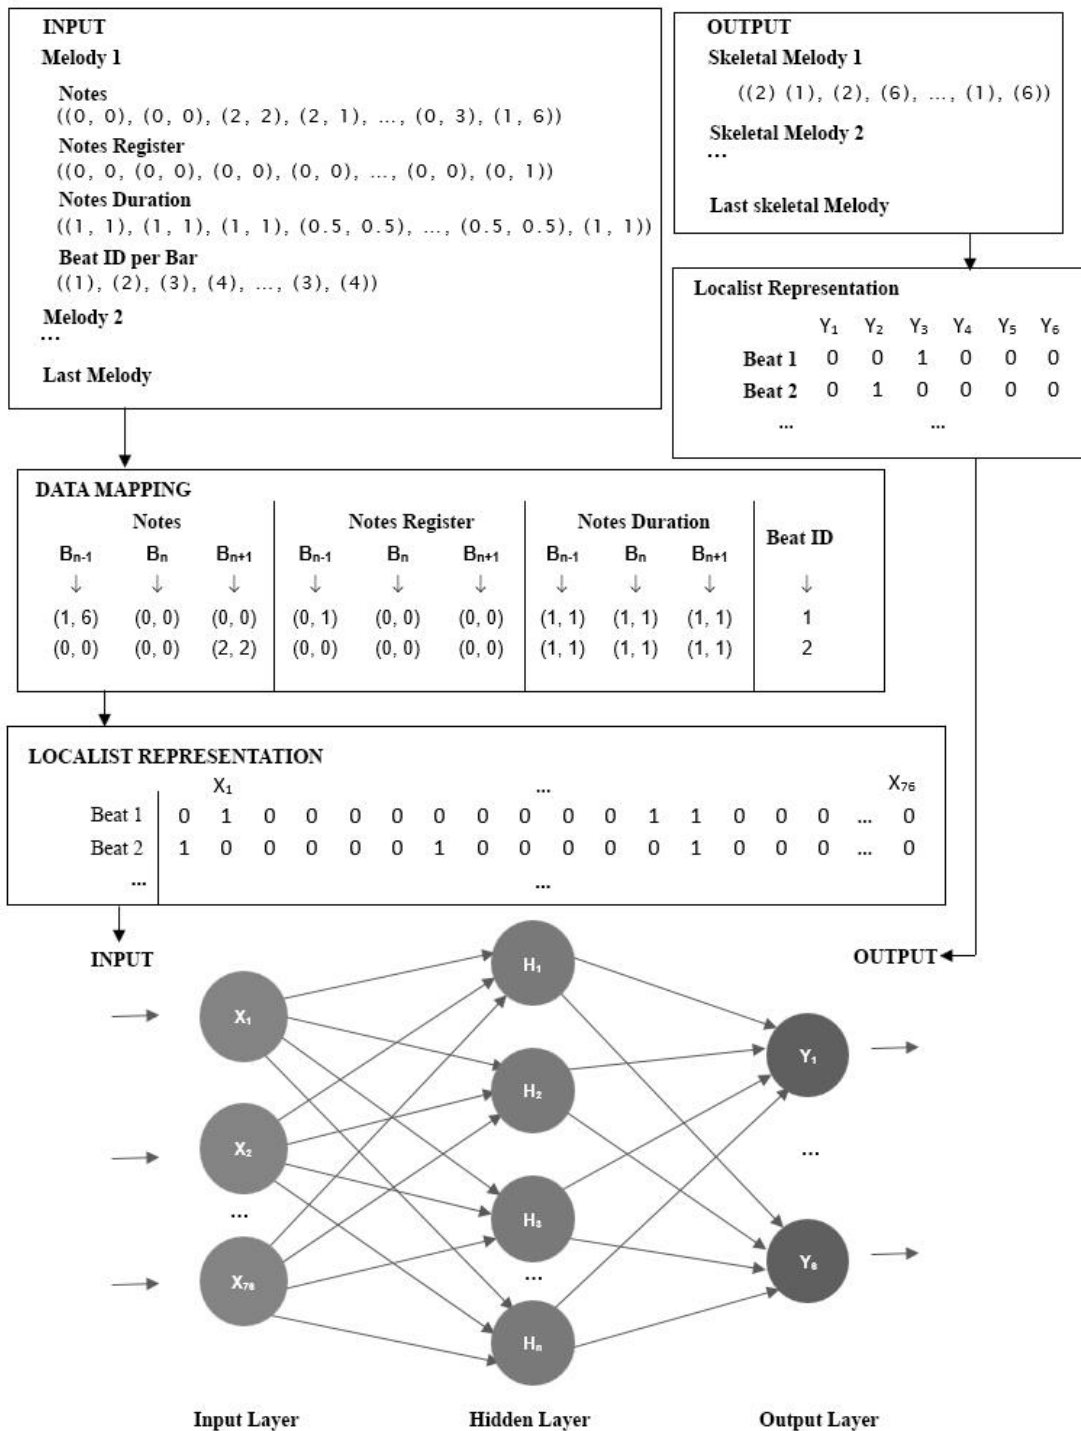

Fig. 5. The FFNN Architecture.

Of the 55 compositions used as datasets, 50 compositions were used for training data, while the remaining 5 compositions were used for test data. Of the 50 compositions used as training data, the input matrix is  $76 \times 2,568$  bits and the output matrix is  $6 \times 2,568$  bits. The distributed corpus in class 1, 2, 3, 4, 5, and 6 is 424, 387, 486, 525, 324, and 422 samples, respectively. Furthermore, the data is divided randomly into

training, validation and test data with a proportion of 80:10:10 and resulted 2,054, 257 and 257 samples, respectively. Table VI shows the dimensions of the matrix, after applying the data transpose, the results of dividing the dataset into training data, and test data consisting of five compositions for testing the composition separately.

TABLE VI. VECTOR MATRIX DIMENSIONS

Data		Input	Output
Training	Training	76 × 2054	6 × 2054
	Validation	76 × 257	6 × 257
	Test	76 × 257	6 × 257
Evaluation	Composition 1	76 × 48	6 × 48
	Composition 2	76 × 48	6 × 48
	Composition 3	76 × 48	6 × 48
	Composition 4	76 × 48	6 × 48
	Composition 5	76 × 48	6 × 48

The FFNN network with the number of hidden layer units of 40 units meets the best prediction criteria with the number of prediction errors in each training, validation and test data of 34,81012e-0%, 35,79766e-0% and 35,79766e-0%. The best validation performance was obtained with a cross-entropy value of 0.17844 at epoch 34 as shown in Fig. 6, while Fig. 7 shows the graph of the receiver operating characteristic (ROC) performance and Fig. 8 shows the results of calculating the confusion matrix.

Fig. 6. The Best Validation Performance Graph.

Fig. 8. The Confusion Matrix Results.

The ROC graph shows that the curve for class 1 initially moves along the curves of other classes before finally moving away. This condition is also shown by the results of the confusion matrix calculation, the prediction accuracy reaches 50.9%, or 216 of 424 class 1 data can be predicted correctly. In more detail, the calculation of the values of accuracy, precision, recall, specificity and F1-score of the FFNN network is shown in Table VII.

The experiment was continued by testing the networks using a hold-out test data which consisted of five compositions (abbreviated as C1, C2, C3, C4, C5). All of compositions, except C4, consist of 48 corpus, while C4 which consists of 64 corpus. The evaluation results show that, all measurements have improved performance in all compositions except C4, in which there was a decrease of 3.1% in the recall measure and 0.3% in the F1 measurement. Table VIII shows the comparison of evaluation results on training data and evaluation data which are divided into data of five compositions which are measured separately and combined, with C1 to C5 representing the first composition to the fifth composition.

TABLE VII. VECTOR MATRIX DIMENSIONS

Measurement	Training (%)	Evaluation (%)				
		C1	C2	C3	C4	C5
Accuracy	65.0	70.8	85.4	68.8	67.2	68.8
Precision	64.5	71.3	85.1	71.7	64.8	68.3
Recall	64.6	72.3	84.3	71.3	63.7	72.2
Specificity	65.0	70.8	85.5	68.8	67.1	68.7
F1 score	64.5	71.8	84.7	71.5	64.2	70.2

## VI. CONCLUSION AND FUTURE WORK

Overall, the proposed method successfully combines musical theory in notes sequence pattern recognition by extracting melodies using a multi-class classification based on notation duration and beat rules. Based on the evaluation of the measurement of accuracy, precision, recall, specificity and F1 score on the melody extraction per composition, the performance of the networks in correctly classifying the notes of skeletal melodies from the beats of melodies, including distinguishing extracted notes from targets that are not in their class, has increased compared to the results obtained in training.

Table VIII shows the results of the accuracy test per class per composition. On the melody extraction with target class 3 (note 2), the performance of the FFNN network looks good with the lowest accuracy of the five compositions being 83.3%, which are at C1 and C3, even at C2 and C5, the accuracy reaches 100%. Good performance is also shown in the class 6 (note 6) where the lowest accuracy is 70% at C4, and overall C4 does contribute to a decrease in accuracy. Similar conditions also occur in class 2 (note 1) with 100% accuracy results in C2 and C5, but there is a decrease in accuracy in C3 even though it can still be categorized as a good achievement, which is 87.5%. Meanwhile in C1 and C4, there was a decrease to 66.7% and 60%, respectively. Class 1 (note 0), 4 (note 3) and 5 (note 5) gave a poor contribution to the accuracy of the melody extraction.

TABLE VIII. ACCURACY TEST RESULTS PER NOTE CLASS

Target	Output (%)				
	C1	C2	C3	C4	C5
1 (note 0)	71.4	50	83.3	62.5	40.0
2 (note 1)	66.7	100	87.5	60.0	100
3 (note 2)	83.3	100	83.3	84.6	100
4 (note 3)	45.5	100	33.3	80.0	50.0
5 (note 5)	77.8	66.7	50.0	25.0	55.6
6 (note 6)	88.9	88.9	90	70.0	87.5

The accuracy of the melody extraction in notes 2 and 6 is directly proportional to the fact that the dominant notes or note strength in the *manyura* musical mode system in the *slendro* scale system used as a dataset is in both notes. Thus, it can be concluded that the networks can recognize the musical mode system and the musical scale system using the melody extraction approach. On the other hand, the conditions of the other four notes, which are 0, 1, 3 and 5, and some of which are still not well predicted. It still cannot be used to conclude that the networks failed in extracting melodies. The unique characteristics of *Gamelan* music allow differences in notes in the same condition not to be a mistake as long as all the different tones do not change the meaning of the composition and can still be accepted by the *Gamelan* music community (Hastuti et al., 2017).

The performance of the networks in extracting melodies into skeletal melodies can be said to be quite successful and promising. However, there are still several factors that need to be explored further to improve networks performance, such as

the need to apply artificial intelligence methods for feature selection and data mapping to increase the cardinality of the corpus to overcome the problems of limited number of datasets and confusion faced by the networks.

# LightGBM-based Ransomware Detection using API Call Sequences

Duc Thang Nguyen, Soojin Lee\*

Department of Computer Science and Engineering  
Korea National Defense University, Nonsan, Republic of Korea

**Abstract**—Along with the development of technology as well as the explosion in digital data in the era of fourth industrial revolution, cyberattacks using ransomware are emerging as a serious threat to many agencies and organizations. The harm of ransomware is not limited to the areas of information technology and finance but also affects areas related to people's lives, such as the medical field. Therefore, research to identify and detect these types of malicious code is urgent. This paper presents a novel approach of identifying and classifying ransomware based on dynamic analysis techniques combined with the use of machine learning algorithms. First, this research focused on the Application programming interface (API) call functions that are extracted during a dynamic analysis of executable samples using the Cuckoo sandbox. Second, research used LightGBM, a gradient boosting decision tree algorithm, for training and then detecting and classifying normal software and eight different types of ransomware. Experimental results showed that the proposed approach achieves an overall accuracy rate of 98.7% when performing multiclass classification. In particular, the detection rates of ransomware and normalware were both 99.9%. At the same time, the accuracy in identifying two specific types of ransomware, WannaCry and Win32:FileCoder, reached 100%.

**Keywords**—Ransomware; machine learning; API call; dynamic analysis technique; gradient boosting decision tree; GBDT; lightGBM

## I. INTRODUCTION

Ransomware is a form of malicious code which, upon infecting a victim's device, encrypts and then steals the victim's data and prevents legitimate access to it until the victim pays a ransom. In early versions of ransomware, the code mainly performed the trick of locking the victim's system, aimed at non-computer savvy users. However, today's ransomware mainly uses crypto-viral extortion techniques. These methods take advantage of the most modern encryption techniques to encrypt almost all of the victim's personal data (e.g., photos, documents, texts). Even the most knowledgeable users or experts also face considerable difficulties. It is almost impossible to recover the data until receiving the decryption key. In a properly executed crypto-viral ransomware attack, recovering data without a decryption key is a problem that is difficult to solve. The attack also requires digital currencies that are difficult to track, such as Bitcoin, for ransom, making it even more difficult to investigate and track down the culprit.

The use of ransomware is accelerated and becoming increasingly dangerous compared to levels seen in the past. Ransomware is now a national security issue for all countries

around the world, and it will only become worse. In particular, during the recent Covid-19 pandemic, attacks on many hospitals and medical facilities indicate a new risk of ransomware, considering that its influence caused the death of a patient (Fireeye's 2021 report). Ransomware at present is a real threat to humans' lives. Threat actors will increasingly target the most critical assets, such as sensitive data and architectures, held by organizations, leading to much higher ransom amounts. Ransoms have already reached the tens of millions of dollars and are expected to grow. While many organizations pay ransoms and do regain access to their data. And they often forget that the attackers still have their data and can allow anyone to buy the data right from their websites (SophosLab's Threat Report 2021). Data theft creates a secondary extortion market.

The continued success of ransomware poses a serious cyber security threat. According to the statistics of reputable security firms, ransomware can spread maliciously in many types of ways, via sophisticated techniques used to avoid detection by antivirus software. Therefore, the need to analyze these types of malware is urgent given the explosion of data in the fourth industrial revolution with millions of Internet of Things devices connected to the Internet every day.

Attackers are increasingly turning to ransomware as a service (RaaS) with more customization capabilities that rapidly increase the number of ransomware variants and types. Therefore, traditional signature-based detection techniques are not effective. Current techniques often build on complex models that combine many features extracted through static analysis or dynamic analysis, along with various transformations to distinguish between ransomware and normal software. They are based on certain features extracted from a dynamic analysis or static analysis, such as API sequences, opcode strings of files, file entropy levels, and/or change in system files. The use of the API function call sequence to detect and classify ransomware types had been applied in many practical studies, such as in [1], [2], [3], [4], showing promising results. However, the fundamental problem of detection methods based on static analysis is weak detection when attackers use code obfuscation methods or zero-day attacks. Furthermore, the malicious code classification methods based on API functions extracted from static analysis lead to one drawback. These methods are easily evaded when an attacker inserts normal API calls or declares unused API functions during a ransomware execution.

Among various features, this research focuses on the Windows API call frequency, which is extracted via a dynamic analysis technique. The proposed method uses it as the primary

\*Corresponding Author

factor in conjunction with certain transformations that improve the speed and accuracy in identifying instances of malicious code extortion. Proposal method also applies LightGBM, a gradient boosting decision tree (GBDT) algorithm, to increase the accuracy and speed of detecting and classifying ransomware.

The next sections of the paper are organized as follows: Section 2 presents ransomware detection techniques that are currently being studied. Section 3 describes the proposed approach and algorithms used, and Section 4 explains the collected dataset and the experimental method. Section 5 analyzes the experimental results and Section 6 concludes the paper.

## II. RELATED RESEARCH

There are two main approaches when analyzing and detecting ransomware: static analysis and dynamic analysis [5]. While the static analysis technique mainly focuses on analyzing and checking the file structure and executable file formats without running the file, a dynamic analysis allows malware to run to observe its behavior in the system ultimately to eliminate the infection.

This Section reviews several ransomware analysis methods which are on the basis of the above two techniques in terms of the extracted information. Then, current multiclass classification methods will be reviewed.

In terms of API sequences, to achieve malicious purposes especially when implementing ransomware, attackers must use and execute a specific API sequence. So there are big differences between malicious codes and normal software in API call sequences. There have been several studies focusing on an analysis of API call sequences to detect general malware as well as ransomware. For example, in [1] Sgandurra et al. presented a ransomware detection method based on dynamic analysis and applied a type of machine learning known as EldeRan. They collected several features extracted from their dynamical analysis, such as API calls, registry and file system change logs, dropped files, and crypto-function patterns in binary files. EldeRan studied a dataset with 1524 samples consisting of 582 ransomware and 942 benign samples. By using a regularized logistic regression method for classification, they could achieve 96.3% detection rate in binary classification.

In [3] Hwang et al. combined a Markov model with random forest model to build two-stage mixed ransomware detection model. The Markov model is used to capture the characteristics of ransomware with the Windows API call sequence pattern that obtained by a dynamic analysis. During the second stage, the random forest machine learning model's mission is to control misclassified samples in the remaining data. The accuracy of this two-stage mixed detection method is 97.3%. In binary classification, False positive (FP) and False negative (FN) rate are relatively high, 4.8% and 1.5% respectively. In [6], Bae et al. used the Intel PIN tool to extract Windows API call sequences and then generated n-gram sets from these API sequences. These n-gram sets were used to classify ransomware, malware and benign files. The authors concluded

that their method could detect ransomware with a detection accuracy up to 98.65%.

Several file-based techniques can identify the presence or existence of ransomware based on the transformation in files of system or in files of a particular format. In [7], after studying a dataset including 1359 ransomware samples from 2006 to 2014, Kharraz et al. concluded that it is not complicated to design an advanced technique to block several types of ransomware by monitoring file system anomaly activities. This method can be effective even against those using sophisticated cryptographic malware or some types of zero-day ransomware attacks. In [8], Lee et al. measured the entropy of six different file formats and then used machine learning to detect infected files to protect the original file in a backup system while synchronizing the time. By identifying files infected with ransomware, this method allows the recovery of those files from system storage when the user's system is infected. Khammas [4] proposed a method that detects ransomware based on a static analysis. The method used frequent pattern mining and the gain ratio technique to extract 1000 features directly from raw binary files. A random forest technique is applied to the classification process. The dataset consists of 1680 executable files made up of 840 ransomware and 840 normal files. The accuracy rate was 97.7%.

In network-based studies, Cabaj et al. [9] proposed a solution to identify ransomware based on HTTP traffic communication when the ransomware connects to the attacker's C&C server. The experimental results obtained detection rates of 97–98%. However, the authors only monitored and observed the network traffic communication of two types of ransomware, CryptoWall and Locky. The author in [10] presented an advanced ransomware identification method based on an analysis of network traffic activities. The study observed TCP, HTTP, DNS, and NBNS traffic and extracted 18 different features. They prototyped a multi-classifier network-based ransomware detection method that combines of two different levels: the packet level and the flow level. The highest detection accuracy rates for the two corresponding levels were 97.92% and 97.08%. However, this research only focused and analyzed on the Locky ransomware's network activities and is thus not suitable for other types of ransomware.

Other researchers also used a hybrid method that integrates dynamic and static analysis techniques to distinguish between ransomware and normalware. For instance, Shaukat et al. [11] presented a method called RansomwareWall. The set of features collected by static analysis and dynamic analysis is fed to the machine learning engine for binary classification of samples as ransomware or benign. Using a dataset of 574 samples from 12 ransomware families, the experimental result presented detection rates ranging from 85.7% (using logistic regression) to 98.25% (using a gradient tree boosting algorithm).

For multiclass classification, some researchers are not only working to distinguish between ransomware files and normal files but also looking for ways to distinguish between different types of ransomware. For example, Zhang et al. proposed an approach for multiple classifications of seven ransomware

families based on a static analysis [12]. They built N-gram sequences by extracting opcode sequences from Portable executable (PE) file samples and then calculated the term frequency - inverse document frequency (TF-IDF) to identify the feature N-gram vectors. The feature vectors were then subjected to five machine-learning methods to classify ransomware. The dataset included 1,787 ransomware samples of seven ransomware families crawled from VirusTotal that broke out from 2012 to 2017. In the experiments, the best accuracy achieved was 91.43% for the multiclass classification method when using a random forest algorithm and 99.3% for the binary classification of ransomware and 'goodware'.

In [13], Baldwin et al. presented a WEKA toolset for ransomware multiclass classification based on a static analysis. They extracted 443 opcodes from binary files and used them to calculate the percentage of each opcode occurrence relative to the overall opcode. The support vector machine (SMV) learning technique was used for binary classification between benign and ransomware, while the PUK kernel was used for multiclass classification. The best accuracy gained from the results was approximately 96.5% when differentiating a dataset consisting of 443 samples of six classes (one benign and five ransomware families). Vinayakumar et al. studied a dataset of 974 samples (219 benign files and 755 ransomware files from seven ransomware families) and focused on the API call sequence for ransomware detection [2]. Their method gathered 131 API sequences with a dynamic analysis technique and used a multi-layer perceptron (MLP) model for classification. The experimental results showed that the best accuracy rate was 98% for multiclass classification; however, the true positive rates (TPR) of crypto-locker and cryptowall ransomware were only 88.9% and 83.3%.

Current studies mainly focus on binary classification between ransomware and normalware. However, with the rapid growth of blackmail attacks as well as the variety of types of ransomware, the detection and detailed classification of each ransomware family type are necessary at present. There have been a few studies related to multiclass classification, but those studies mainly focused on classifying categories together. Moreover, the accuracy when identifying each type of ransomware is not very high, leading to the ineffective prevention of malicious code, placing user data in danger. In order to overcome the drawbacks of previous multiclass classification techniques, this paper present a novel approach based on a dynamic analysis and the LightGBM algorithm to detect multiple types of ransomware and to distinguish between ransomware and benign files.

### III. PROPOSED METHOD AND ALGORITHM

#### A. LightGBM Algorithm

Decision trees “learn” by breaking down observations based on feature values. In the decision tree learning process, finding the best split is the most time-consuming stage. Two algorithms which use different gradient boosting decision tree (GBDT) implementations to find the best splits are as follows:

- Pre-sort: Object values are pre-sorted and all split points can be evaluated.

- Histogram-based: Continuous features are divided into separate bins used to create histograms for features.

Histogram-based algorithms are more efficient in terms of memory consumption and training speeds. However, for every feature, all data instances must be scanned to find all possible split points. So that both pre-sorted and histogram-based methods become slower as the number of instances or features increases. The LightGBM algorithm aims to address the training speed and memory consumption issues associated with typical implementations of GBDT when working with large datasets.

First, LightGBM grows the tree in a leaf-wise manner using a vertical growth strategy. This is different from the horizontal growth strategy (level-wise growth) tactics of the other decision tree algorithms. When growing leaf-wise, the gradient-based method can help the errors minimize and effectively reduce the loss. The balance of the tree is maintained via a level-wise growth strategy, whereas the leaf-wise strategy helps to reduce the loss the most. With the same number of leaves, a leaf-wise-based tree will be deeper than other trees. In particular, when necessary leaf-wise growth can be used to grow a tree into a more balanced tree. Compared to horizontal growth, vertical planting can provide converge much more rapidly [14].

Secondly, LightGBM developed two techniques to reduce memory consumption and speed up the training time [15]. These are gradient-based one-side sampling (GOSS) and exclusive feature bundling (EFB). With GOSS, LightGBM reduces the number of instances by keeping all large instance gradients and random sampling instances with small gradient instances. The complexity of constructing the histogram for all features is  $O(\#data * \#features)$  and the complexity of subsequently finding the optimal split points is proportional to  $O(\#bins * \#features)$ . Generally,  $\#bins \ll \#data$ . Therefore, this approach is computationally much more efficient than earlier approaches.

---

#### Algorithm 1. Gradient-based One-Side Sampling (GOSS) Technique

---

**Input:**  $I$ : training data,  $d$ : iterations

**Input:**  $a$ : sampling ratio of large gradient data

**Input:**  $b$ : sampling ratio of small gradient data

**Input:**  $loss$ : loss function,  $L$ : weak learner

models  $\leftarrow \{\}$ , fact  $\leftarrow (1-b)/a$

topN  $\leftarrow a \times \text{len}(I)$ , randN  $\leftarrow b \times \text{len}(I)$

**for**  $i = 1$  **to**  $d$  **do**

    preds  $\leftarrow$  models.predict( $I$ )

$g \leftarrow loss(I, \text{preds})$ ,  $w \leftarrow \{1, 1, \dots\}$

    sorted  $\leftarrow$  GetSortedIndices(abs( $g$ ))

    topSet  $\leftarrow$  sorted[1:topN]

    randSet  $\leftarrow$  RandomPick(sorted[topN:len( $I$ )], randN)

    usedSet  $\leftarrow$  topSet + randSet

$w[\text{randSet}] \times = \text{fact}$  : Assign weight  $fact$  to the small gradient data.

    newModel  $\leftarrow L(I[\text{usedSet}], -g[\text{usedSet}], w[\text{usedSet}])$

    models.append(newModel)

---

Step 1: Based on the list sorted according to the data instance gradient values, GOSS selects the top  $a \times 100\%$  largest gradient instances.

Step 2: Perform random sampling  $b \times 100\%$  on the remaining instances with small gradients.

Step 3: Recalculate the information gained by amplifying the sampled data of small gradients with  $(1-a)/b$ .

In this way, LightGBM can focus more on larger gradient (under-trained) instances without altering the original data distribution much.

EFB is a technique that uses a greedy algorithm to combine (or bundle) these mutually exclusive features into a single object (bundle of exclusive objects) and thus reduce the size. The complexity of feature histogram building is now proportional to the number of bundles  $O(\#data * \#bundle)$  rather than the number of features  $O(\#data * \#feature)$ . With EFB, LightGBM can reduce the GBDT training time without having a great impact on the accuracy.

---

Algorithm 2. Exclusive Feature Bundling (EFB) Technique

---

**Input:** *numData*: number of data  
**Input:** *F*: One bundle of exclusive features  
 $binRanges \leftarrow \{0\}$ ,  $totalBin \leftarrow 0$   
**for** *f* **in** *F* **do**  
     $totalBin += f.numBin$   
     $binRanges.append(totalBin)$   
     $newBin \leftarrow new\ Bin(numData)$   
**for** *i* = 1 **to** *numData* **do**  
     $newBin[i] \leftarrow 0$   
    **for** *j* = 1 **to**  $len(F)$  **do**  
        **if**  $F[j].bin[i] \neq 0$  **then**  
             $newBin[i] \leftarrow F[j].bin[i] + binRanges[j]$

**Output:** *newBin*, *binRanges*

---

By experimenting on several public datasets, the results demonstrated that using the LightGBM algorithm increased the training speed by more than 20 times while maintaining the same level of accuracy.

In conclusion, LightGBM offers many advantages when used to address current practical issues:

- Higher efficiency as well as faster training speeds.
- Lower memory consumption.
- Better accuracy.
- Can handle large-scale data well.
- Supports GPU and parallel learning.

### B. Proposed Ransomware Detection Method

This approach fully utilizes the advantages of LightGBM algorithm described above and presented in some previous studies [16] and [17]. Because the API functions that used in the each sample (ransomware and benign) are very different, so that the dataset based on this features is spare. To fill the gap in current ransomware multiclass classification and to overcome the disadvantages of previous methods, this research present an

approach based on a dynamic analysis and apply the LightGBM algorithm to process highly sparse data. By only using the API call sequence as the primary factor, this approach is more simple than others.

To recognize a portable executable (PE) file as good software or ransomware and further to categorize ransomware into their respective categories, we utilize a machine learning architecture, as shown in Fig. 1.

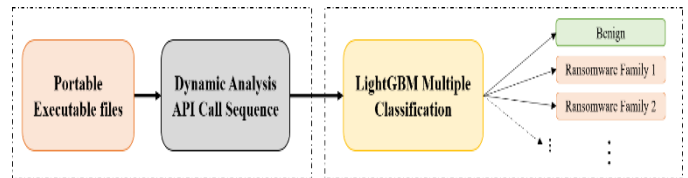

Fig. 1. Ransomware Multiple-Classification Proposed Method.

In the first step, “tagged” PE files are analyzed by means of a dynamic analysis. After which information extraction of the API call sequence functions of each individual file were performed and consider them as key features in this proposal. For the second step, samples with corresponding features and assigned labels are passed as input to the LightGBM multiclass classifier to generate learning trees that help to distinguish between good software and ransomware.

## IV. DATASET AND EXPERIMENTAL METHOD

### A. Database Gathering and Analysis

Currently, no complete dataset of ransomware on Windows platforms has been made public in cyberspace. Many authors have collected ransomware samples from multiple sources and built datasets for their own research. On the other hand, samples of ransomware often exist only sporadically in some test datasets. These dataset all malware marked ransomware, regardless of ransomware types. Previous researchers have also actively grouped ransomware types, but in experimental studies, they still mainly stop at distinguishing ransomware from normalware. Currently, there are very few researchers delving into the simultaneous identification and discernment of benign software and ransomware of various categories.

Towards the above goal, this research attempt to build a ransomware dataset for research that not only helps to distinguish between ransomware and benign software but also improves the accuracy when classifying each type of ransomware. The dataset was constructed based on a number of scientific guidelines and best practices suggested by Rossow [18]. Ransomware samples were collected from two of the most popular data-sharing sources, VirusTotal<sup>1</sup> and Virusshare<sup>2</sup>, under academic license and with the administrator's consent. Research focused on collecting both recent and earlier ransomware samples (from 2014 to early 2021) and worked to gather as much of each type of ransomware as possible. Because malicious samples were collected from two different sources, this research used a distinctive SHA hash to avoid duplications in the sample dataset. To be cautious when choosing the ransomware, we confirmed that an instance of

---

<sup>1</sup> <https://www.virustotal.com/>

<sup>2</sup> <https://virusshare.com/>

malware is ransomware if at least five antivirus engines marked it belonging to this category. Research rely on the naming policy of the Avast engine to determine the family of each sample before starting the process of analyzing and collecting data about the behavior of ransomware.

For benign samples, the executable files in the Windows system directory (...\Windows\System32) with a variety of functions and features of the files were selected. This could help to assess and classify malware in a more objective manner.

While Table I shows information about the benign files and ransomware samples that were taken from the two main sources, Table II details the types of ransomware along with the number of samples collected in each case.

After a dynamic analysis of 5,811 samples, we can realize that the number of API functions used by a sample ranges from 01 to 172 with approximately 286 different API functions. Ransomware and benign files both use the same API functions, but for separate purposes. Moreover, the number of API function calls in each executable file differs significantly. There are functions that are only called and used one to two times in one PE file but are used many times in other executables. During the dynamic analysis, it was noted that there are API functions invoked and used by a file during its execution up to hundreds of thousands of times. At the same time, the number of APIs used by the each sample also differs across ransomware and benign files. While 'goodware' files mostly use 10-20 different API functions, the number of API functions used by ransoms typically exceed 100. Therefore, the dataset is extremely sparse. This is highly suitable when applying the LightGBM algorithm given its many advantages when experimenting on this sparse dataset.

**B. Experiment**

The experimental process is depicted in Fig. 2 and is divided into five main steps, as follows:

**Step 1: Dynamic Analysis**

After being collected, the executable files were divided into categories, in this case benign files and ransomware files of different types (eight types of malicious codes).

TABLE I. THE NUMBER OF FILE COLLECTED FROM EACH SOURCE

Sample	Source	Number of sample
Benign	Windows system files	4,008
Ransomware	Virusshare.com	1,373
	Virustotal.com	430
Total		5,811

TABLE II. RANSOMWARE FAMILIES

No.	Ransomware Family	Number of sample
1	Reveton	522
2	TeslaCrypt	167
3	Win32:Ransom	204
4	Win32:Cryptor	123
5	Win32:Crypt	146
6	LockScreen	123
7	WannaCry	491
8	Win32:FileCoder	27
Total (Ransomware)		1,803

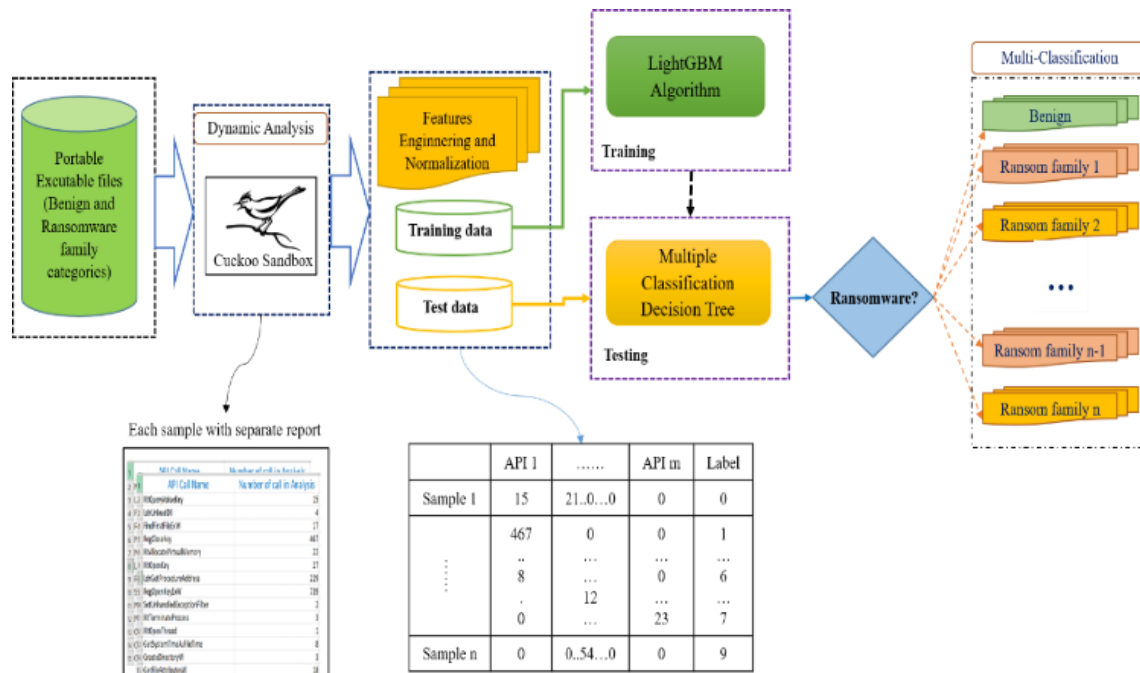

Fig. 2. Experimental Process.

The PE files are then put into the Cuckoo sandbox environment for a dynamic analysis. This is necessary and ensures safety and convenience during the dynamic analysis. The ransomware is executed in a simulated environment, during which all behaviors of every sample are collected in sandbox logs. Fig. 3 explains the Cuckoo architecture.

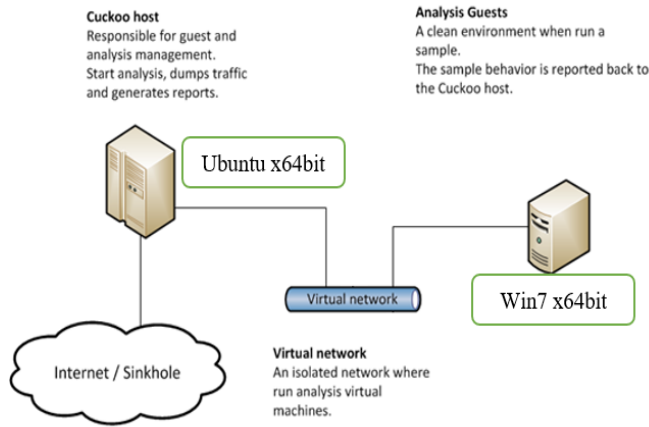

Fig. 3. The Cuckoo Sandbox’s Architecture.

Step 2: Extract API call sequence

Then information regarding the API calls that were executed during the dynamic analysis is extracted, including information about the API functions list in the order of execution and the number of times each function was executed for each individual PE file, as displayed in Fig. 4.

Step 3: Feature Engineering and Normalization

The extracted data is then compiled into a summary of information for the entire sample. The information in the resulting table includes a list of all sample PE files along with information regarding the API calls that each file used and the number of times each function was used. With regard to API functions that are not called, the corresponding value for that function for the sample file is set to 0. At the same time, each executable file pattern is labeled corresponding to the type of ransomware or benign file, as in Table III. Because LightGBM works effectively with a sparse dataset, all features will be used in the training and testing phases.

TABLE III. LIST OF CLASS LABELS

No.	Class name	Label
1.	Benign	0
2.	Reveton	1
3.	TeslaCrypt	2
4.	Win32:Ransom	3
5.	Win32:Cryptor	4
6.	Win32:Crypt	5
7.	LockScreen	6
8.	WannaCry	7
9.	Win32:FileCoder	8

Data Normalization: Research used the MinMaxScaler of scikit-learn for data normalization. Given that the scope of the raw data is very wide, for some machine learning algorithms their objective functions will not work properly and may produce bias when the data is not normalized. MinMaxScaler normalization scales the range of all features to the range of [0, 1].

The transformation is given by Alg.3:

Algorithm 3. The MinMaxScaler normalization

$$X_{std} = \frac{X - X_{\min(\text{axis}=0)}}{X_{\max(\text{axis}=0)} - X_{\min(\text{axis}=0)}}$$

$$X_{scaled} = X_{std} * (max - min) + min$$

Where: Xmin, Xmax: min, max of one feature

min, max: min, max of overall data.

The following Fig. 4 shows the data normalization process from after extracting sandbox log file to before feeding them to LightGBM algorithm.

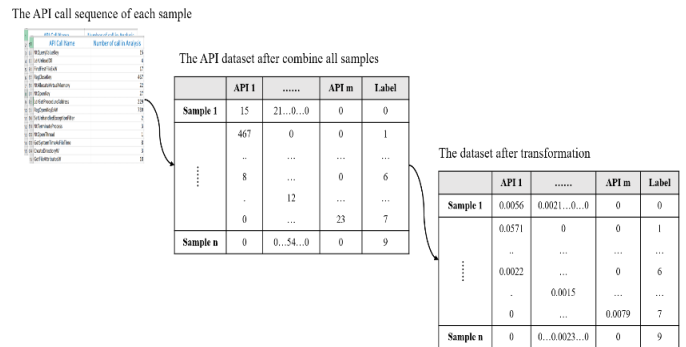

Fig. 4. The Transformation of the Data.

All data is divided as follows: training set: 80%, test set: 20%. Each dataset is then used for the subsequent training and test phases.

Step 4: Training phase

In [17], Dongzi et al. illustrated the LightGBM training process with the model consists M trees in Algorithm 4.

Algorithm 4. The training of LightGBM

Require: Input: Training set  $\{(x_i, y_i)\}_{i=1}^M$

Ensure: Output: LightGBM model  $\hat{y}_i^{(t)}$

1. Initialize the first tree as a constant:  $\hat{y}_i^{(0)} = f_0 = 0$

2. Train the next tree by minimizing the loss function:

$$f_t(x_i) = \underset{f_t}{\operatorname{argmin}} L_{(t)} = \underset{f_t}{\operatorname{argmin}} L(y_i, \hat{y}_i^{(t-1)} + f_t(x_i))$$

3. Get the next model in an additive manner:

$$\hat{y}_i^{(t)} = \hat{y}_i^{(t-1)} + f_t(x_i)$$

4. Repeat the Step 2 and Step 3 until the model reaches the stop condition.

5. Obtain and return the final model:

$$\hat{y}_i^{(t)} = \sum_{t=0}^{M-1} f_t(x_i)$$

Here:  $f_t(x_i)$  and  $\hat{y}_i^{(t)}$ : are correspondingly the learned function and predictive value of sample i at iteration t.

$L_{(t)}$ : The loss function represents the error between the prediction  $\hat{y}$  and the true value y.

The stop condition of the training process occurs when the process reaches the M-th iteration or when the loss value of the model is lower than the predefined loss value.

Step 5: Testing phase

The test dataset is classified based on GBDT trees that have been created during training phase.

V. EXPERIMENTAL RESULT

A. Evaluation Criteria

To evaluate the detection performance of the proposed method, this paper employed the following metrics: the accuracy of the entire model, precision, recall, the F1 measure of each class, and a confusion matrix.

When evaluating each class, the class being evaluated is the positive class and the remaining eight classes are the negative class. True positive (TP) refers to the number of positive class samples that are correctly classified. False positive (FP) refers to the number of negative class samples that are misclassified into the class under evaluation. True negative (TN) represents samples in the negative class are correctly classified into the negative class. False negative (FN) represents samples in the consideration class that are misclassified.

Precision is defined as the ratio of true positive scores among those classified as positive.

$$Precision = \frac{TP}{TF + FP}$$

Recall is the fraction of the relevant samples that are successfully classified.

$$Recall = \frac{TP}{TF + FN}$$

The F1 score is used to evaluate the quality of the model.

$$F1 - score = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

Accuracy is determined simply by calculating the ratio between the number of correctly classified samples and the total in the test dataset.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

For multiclass classification, the overall accuracy is the ratio of the sum of the true positives of all families divided by the total sample. It is determined according to the following formula.

$$Overall - accuracy = \frac{correctly\ classified\ instances}{total\ number\ of\ instances}$$

The confusion matrix (CM),  $M = [m_{x,y}]_{n \times n}$ , is used to evaluate the quality of the classifier's output on the dataset. The values of the diagonal elements represent the number of samples and the percentage of correct predictions, while the other elements represent the samples that have been classified incorrectly. A confusion matrix with higher diagonal values represents a higher percentage of correct predictions.

B. Experimental Results

As shown in Table IV, the classification accuracy is very high, with overall accuracy of about 98.7%. However, the correct identification rate for all ransomware is close to 96%, while the lowest rate of identification for TeslaCrypt is 89.5%.

TABLE IV. CLASSIFICATION EVALUATION RESULTS

No.	Classes	Size	Precision	Recall	F1-Score
1	Reveton	102	0.961	0.961	0.961
2	TeslaCrypt	38	0.971	0.895	0.932
3	Win32:Ransom	38	1.000	0.921	0.959
4	Win32:Cryptor	25	0.885	0.920	0.902
5	Win32:Crypt	21	0.800	0.952	0.870
6	LockScreen	22	1.000	1.000	1.000
7	WannaCry	100	0.980	1.000	0.990
8	Win32:FileCoder	3	1.000	1.000	1.000
9	Benign	814	1.000	0.999	0.999
Total		1163	Overall accuracy = 0.987		

Fig. 5 presents the CM of the eight ransomware classes, in this case Reveton, TeslaCrypt, Win32:Ransom, Win32:Cryptor, Win32:Crypt, LockScreen, WannaCry, and Win32:FileCoder, along with the benign files in the experiments. The CM shows that the proposed method provides the best classification for three ransomware families, LockScreen, WannaCry and Win32:FileCoder, in which not a single sample is misclassified. This is followed by Reveton, with accuracy of approximately 96.1%.

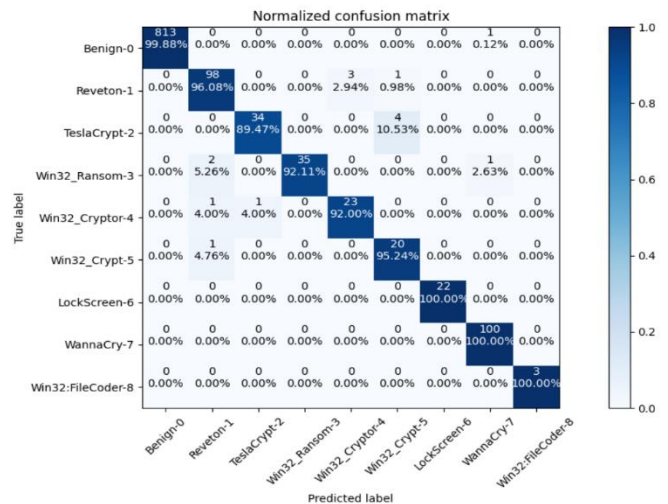

Fig. 5. Confusion Matrix.

Fig. 6 shows feature importance based on the number of times that a feature is used as split points in all learned trees. The most important API call function for detection and classification of the ransomware in this case is “NtOpenKey,” used more than 1000 times as a split point in a learned tree. This is followed by the two other API call functions of “NtAllocateVirtualMemory” and “NtTerminateProcess,” called 995 and 866 times, respectively. The three API call functions above are also among the API call functions most commonly used by samples (ranks: “NtTerminateProcess:” 1st, “NtOpenKey:” 4th, and “NtAllocateVirtualMemory:” 21st). However, while the “NtAllocateVirtualMemory” and “NtTerminateProcess” functions were used many times by all PE files (19,564,674 and 5,182,284 times) and are correspondingly ranked 3rd and 12th, the “NtOpenKey” function was only called 86,487 times and is ranked 111th of 286 (as showed in Table V). This shows that the importance of features in determining split points does not depend much on the number of times they are called or the number of file that used them.

Fig. 6. The Top 30 Important Features in the Experiment.

## VI. ANALYSIS AND DISCUSSION

The experimental results have shown that the method proposed here to identify and classify malicious codes based on API call functions obtained from dynamic analysis results combined with the GBDT LightGBM algorithm can achieve high performance.

TABLE V. THE USE OF API CALL BY PE FILES

No.	API name	Times used
1	RegSetValueExA	26,547,071
2	ShellExecuteExW	26,135,049
3	<b>NtAllocateVirtualMemory</b>	<b>19,564,674</b>
4	NtOpenFile	14,268,859
5	OpenServiceW	9,484,238
...	...	...
12	<b>NtTerminateProcess</b>	<b>5,182,284</b>
...	...	...
111	<b>NtOpenKey</b>	<b>86,487</b>
...	...	...
286	NtShutdownSystem	1

The proposed method identified ransomware samples with very high accuracy, reaching 100%. When evaluating the effectiveness of distinguishing between malicious code and normal software, the experimental results show that the system did not miss or miscategorized any ransomware sample as normal software. This promises to bring about a positive effect with regard to protecting system and user data. At the same time, the rate of misidentification of benign software was low, as less than 0.01% of benign samples were misidentified as malicious samples. Therefore, the proposed method will not affect system availability and allows the user experience to be retained.

When evaluating the effectiveness of classifying ransomware types, out of eight types of malware conducted experimentally, the proposed method has the ability to identify sensitively three types of extortion malware. In this case LockScreen, WannaCry, and Win32:FileCoder, with absolute precision of 100%. In addition, there were a few small mistakes between different types of malware, such as TeslaCrypt, Win32:Ransom, and Win32:Crypt.

The test results here also demonstrated the advantages of the dynamic analysis in support of ransomware detection. The method based on dynamic analysis greatly reduced the number of features in the sample database. According to this study of the collected dataset, the number of features (API call functions) that must be analyzed and processed during the static analysis method is very large at approximately 6,684 different features with ransomware and nearly 28,500 different features in the benign case. Meanwhile, using the dynamic method, the number of API call functions to be processed for all ransomware and benign samples was only 282. This enhances the efficiency of the data analysis, classification and processing steps while also minimizing the time required for the training and detection phases, which are very time-consuming steps given numerous features. The proposed method also minimizes interference from an attacker to bypass static-analysis-based methods, such as by adding normal API call patterns or by attempting to use an obfuscation technique.

## VII. CONCLUSION

This chapter discusses the results of the proposed method, the advantages of the dynamic analysis technique in supporting ransomware detection and classification.

In fact, proposal method achieves a 98.7% classification accuracy rate, with excellent ransomware recognition and a low error rate during benign software classification. Compared to previous studies, the experimental results not only dominate in terms of detection between ransomware samples and goodware (99.9% accuracy versus 98.65%, 97.74%, and 97.3% as in [6], [4] and [3] but is also more efficient when classifying ransom types of malware (between proposal method at 96% and corresponding rates of 88.9%, 94.2%, and 91.4% as in [2], [13], [12]. This helps to increase the efficiency of the identification process of malicious code, thereby accelerating the response and implementing countermeasures to protect the system when necessary. In particular, using LightGBM algorithm significantly shortens the time compared to other machine learning or GBDT algorithms.

The study also demonstrated the role of each API function in identifying and classifying ransomware by assessing the importance of each API function by determining the split points during the construction of the learning trees used here. This makes it possible for us to engage in more research and evaluations to reducing the number of attributes further when the number of file samples increases in the future. This helps to reduce the computational pressure while maintaining the accuracy of the method, thus enhancing the efficiency of the system.

The proposed plan has shown very positive results. Experiments also highlighted the importance of each API function in the detection and classification process. Therefore, work to reduce the number of API functions when the numbers of ransomware samples and types increase in order to reduce the computational burden while ensuring high accuracy also represents a promising research direction for future studies.

Information System Department, Faculty of Computers and  
Information, Mansoura University, Egypt

**Abstract**—Electronic health record systems work beyond just recording patients' health data. They have multiple secondary functionalities, such as data reporting and clinical decision support. As each of these systems' workloads has contradictory different needs, managing a multipurpose electronic health record is a challenge. This paper proposes a unified healthcare data framework that can simplify health information system infrastructure. It investigates the suitability of the document-based NoSQL persistence mechanism, storing electronic health records data as a design choice for managing varied complexity ad hoc queries used in operational business intelligence. The performance of the most popular two document-based NoSQL back-ends, Couchbase Server and MongoDB, is compared according to the size of the database and query execution time. Results showed that while MongoDB can execute simple single-document queries nearly in milliseconds. It does not provide satisfactory response time for unplanned complex queries spanning multiple documents. By utilizing its analytics services and multi-dimensional scaling architecture, Couchbase Server multi-node cluster outperforms the response times of MongoDB for both simple and complex healthcare data access patterns. The primary advantage of the proposed tightly coupled EHRs processing framework is its flexibility to manage workload according to changing requirements.

**Keywords**—Electronic health records; operational business intelligence; document data model; NoSQL; health information system; persistence framework; Couchbase server

## I. INTRODUCTION

Electronic health records (EHRs) system is a quintessential part of healthcare information system (HIS). It is an ecosystem for maintaining a long-term patient's health record. This system usually has multiple core functionalities. Primarily, it is used for storing and retrieving individual patient records for healthcare purposes. These EHRs data could be used in clinical decision support (CDS) to suggest the next steps for treatment or predict future conditions trends by analyzing transactional data [1]. EHRs data are not possessed by any particular healthcare provider. To interconnect these different healthcare practitioners, EHRs need to be interoperable through following certain standards to facilitate health information exchange (HIE) and sharing [2]. HIS workload usually encompasses two main practices: clinical use, which is regarded as a transactional workload, and research use which is dedicated to analytical workload.

As each of these workloads has a different access pattern, they have seemingly contradictory solutions. There is also the

operational business intelligence (BI) workload, including ad hoc queries, which are in the middle between primary and secondary uses. This data access pattern tends to be unpredictable; it typically involves reading an extensive amount of data at one time and can include various complex joins [3]. There are various architectural methodologies [4,5] to manage those conflicting workloads. Traditional HISs could use transactional systems for providing answers to analytical queries in one engine, but the system performance may degrade dependent on the number and the complexity of queries submitted to the database. Therefore, following the "one size does not fit all" rule [6], a clinical data warehouse (CDW) [7,8] a specialized storage structure, is used for data analysis to segregate tasks and maintain the performance at an acceptable level. It utilizes extract, transform, and load (ETL) to integrate patient-level data from separate silos inside or across healthcare organizations, facilitating analysis and reporting. Thus, various healthcare application frameworks [9] have been introduced to offer diversified EHRs data analytical capabilities.

Earlier healthcare data persistence systems [10] were built depending on the relational schema approach. However, these traditional relational database management systems RDBMS are built for strong consistency level and data control [11]. With the rise of the "no one size fits all" concept [12], several alternative NoSQL stores have been developed [13] to address the shortcomings of RDBMS. NoSQL databases refer to a category of flexible data storage systems that manage data using a key-value structure. They are clustered into four main classes [14,15] based on their data model: (1) key-value data stores, (2) document data stores, (3) column-family stores, and (4) graph data stores. This categorization is necessary since each data storage architecture provides different solutions depending on the application's needs.

Healthcare data is complex, dynamic, intermittent, and diverse in nature. Furthermore, HIS applications' access patterns usually need their scale, performance, and flexibility requirements to surpass their transactional needs [16,17]. Thus, NoSQL data stores are more suitable to meet the specifications of distributed EHRs systems [18]. There are several criteria, such as data model, performance, data persistence, and CAP support [19], which must be considered when choosing which NoSQL store to be used. Various data modeling approaches [3,20–27] have been introduced for medical data persistence according to use case scenarios. These works investigate not only the type of NoSQL store that has to be chosen but which NoSQL products in that type will be used [19].

\*Corresponding Author

Managing a fully functional EHRs system with the involvement of all healthcare participants is not a simple task because of the rapid development and growth of medical knowledge. To fulfill a variety of use cases, organizations nowadays commonly end up deploying different databases, leading to a “database sprawl” that causes delayed analytics. This layered architecture approach was challenged by the white paper [28] which argued that advances in memory technology enable data to be stored just once without compromising either transactions or analytical workloads. Massive parallel processing (MPP) database platform is considered as another architectural alternate to CDWs that could support medical data analytics [29]. It could be used for ad hoc population queries, which may not be quickly obtained from the CDW.

The capability to store data quickly is not a problem. But the challenge is the capability to do meaningful and quick insights with that data. Recently, Analytical application characteristics diverged from the typical characteristics of the online analytical processing (OLAP) system and become more real-time, operational, and proactive. Modern applications frameworks require blurring borders between operational and analytical workload [4]. Several terms, such as Hybrid Transactional and Analytical (HTAP) databases [30,31], are being used to describe this general trend in databases that supports hybrid workload processing requirements within a single logical database. Couchbase Server recently introduces multi-dimensional scaling (MDS) architecture [33] to support scaling workload independently according to the changing needs. It aims to offer a single, integrated platform that can be used for almost all varied complexity operational workloads as well as operational analytics. The motivation for this paper is that nevertheless, these hybrid data processing and management techniques [16,32] could provide solutions to a wide range of healthcare data problems, such as data silos. Few researchers evaluate their performance in the healthcare sector.

The main contribution of this paper is it proposes a unified multipurpose HIS framework that could improve healthcare services provision. This flexible Couchbase-based healthcare architectural framework provides different levels of services that could be efficiently adapted according to varied application workload requirements. As both database selection and its related schema architecture are aspects that affect the effective management of healthcare data, particularly in real-time usage systems [10]. This paper first discusses the suitability of the document data model as storage persistence for managing EHRs data. After that Couchbase Server and MongoDB which are the most popular document-oriented database management systems (DODBMSs) are evaluated for BI workload. These two storage back-ends storing EHRs are compared on the subject of their execution time and storage space requirements for handling varied queries complexities.

The rest of this paper is organized as follows: Section 2 reviews document-based data modeling techniques and their suitability for the healthcare domain. Section 3 describes the experimental environment, including datasets, workload specifications, and query implementation. Section 5 reports the experimental results for the two different size datasets. Section 4 briefly discusses the obtained results.

## II. DOCUMENT DATA MODELING

A document database is a set of key-value in which each key corresponds to a complex data structure value known as a document. Each document holds a unique automatically generated key which not only enables gathering related documents. But also enables an application to perform keys-based document lookup, which is extremely fast. A document's structure in the document model database is made up of the arrangement of its internal attribute-value pairs [34]. In document-oriented databases, stored values are arranged, in a self-descriptive document that can be examined easily. There are several advantages of using document-oriented modeling, unlike relational databases that force applications to fit data into predefined models, regardless of their needs [35]. First, there is no impedance mismatch between application objects models and documents data models [36]. Second, they do not impose standard document structures, even across several documents. It allows a schema to gradually evolve by adding properties and structures to the document as required without the need to update other documents in the same way. Thus, the schema is explicit but variable, since attributes may vary among instances [37]. This allows applications to change their behavior without having to overhaul all the source data or take applications offline to make a basic change. Therefore, they offer faster write performance than the conventional relational model, besides efficient indexing features. In relational databases, [38] children use foreign keys to refer to their parents. On the other hand, parents refer to their children in document databases. This is because, unlike a field in a row, a field within a document can have several values.

Embedding and referencing are two techniques that could be used to link documents. Document embedding concerns nesting documents into another. It entails merging subclass entities into superclass entities and denormalizing relationships without the need for a reference table. On the other side, document refereeing is based on two separate documents, and one is refereeing into another. It involves adding a key to the object [34,39] and it is good when the referenced objects and relationships are static. Usually, deciding how to model related data documents normalized, denormalized or a hybrid is based on the type of relationship and the access pattern.

In today's market, there are a variety of document-oriented NoSQL databases; Couchbase [40] and MongoDB [41] are the most popular. Couchbase is a scalable in-memory NoSQL database, which was designed particularly for distributed processing and has native support for JSON documents[42,43]. It was created through merging two complementary technologies: Membase Server, a distributed key-value database based on Memcached, and CouchDB, a single-node document database supporting JSON. It has N1QL, a declarative query language that can manipulate JSON documents. A Couchbase node usually comprises of cluster manager and, optionally, data, query, index, analytics, search, and eventing services. Couchbase Server introduces MDS architecture, which is independent scaling architecture, for minimizing interference between services [33]. MongoDB uses a slightly modified version of JSON called BSON (Binary JSON). It has its own DBMS, including the full set of CRUD (create, read, update and delete) operations.

### A. Document-based EHRs Data Modeling

Because of the special persistence policies of EHRs data. NoSQL systems fit better [20,21], as they allow healthcare data to be stored in a structure that is much closer to its real representation. NoSQL databases are aggregate-oriented data stores [36], as the aggregate is the unit of operation and consistency. They can be more scalable and faster where data volumes are extremely large, or when there are no internal document references that might degrade the performance or data consistency. On the other hand, healthcare applications could be an obvious example of an application type, where the presence of connections between various documents and their subcomponents has no impact on the application's basic functionality and consistency. This is because, if part of these data is updated during such medical treatment, a new extract with new information and their appropriate connections should be created, rather than overwriting any previously stored data elements [18]. This is a rigorous medical information constraint since it may be used to make medical decisions. When using a document-based store instead of a relational system, information about a particular patient is easily isolated from other patients' information.

So, healthcare tasks could be considered document-based tasks. Retrieving all patients' demographic data and linked hospital admissions. These flexible modeling approaches could efficiently adapt to the nature of healthcare data. Thus, several studies have been initiated along this path [3,20,24 ,44–47]. According to related work [20] result, MongoDB is best for handling single patient queries because of their concurrency. While Couchbase in [3,24] achieved better query response

times and throughput. Thus, it is the best for handling the analytical workload of scalable, large data size.

### III. PROPOSED DOCUMENT-BASED ELECTRONIC HEALTH RECORDS FRAMEWORK

In multi-node cluster topology, the Couchbase Server services are distributed across several nodes within the cluster, rather than a single node cluster. The main aim of this microservices architecture is deploying both query and analytics services, which are complementary services with contradicting workload needs, into two independent nodes within the cluster. Query service is used to support many users in making inexpensive operational queries. While analytics service is used to support complex and expensive analytical queries made by a much smaller number of users [43]. Data and query services provide user-facing applications with low-latency key-value and/or query-based access to their data. For analytics service, operational EHRs data is pushed into shadow buckets of the same data for immediate analysis by a dedicated massively parallel processing (MPP) analytics engine. These shadowed buckets are copies of data that are linked directly to the operational data in real-time. So, these analytical queries do not affect the performance of operational data queries. Cross data-center replication (XDCR) is used to replicate EHRs data per bucket basis between two data nodes in different clusters depending on application requirements. These replicated vBuckets can support read requests as they are kept constantly up to date by receiving a continuous stream of mutations from the active vBucket through database change protocol (DCP). Fig. 1 shows a high-level illustration of the deployed EHRs multi-node topology for varied access patterns.

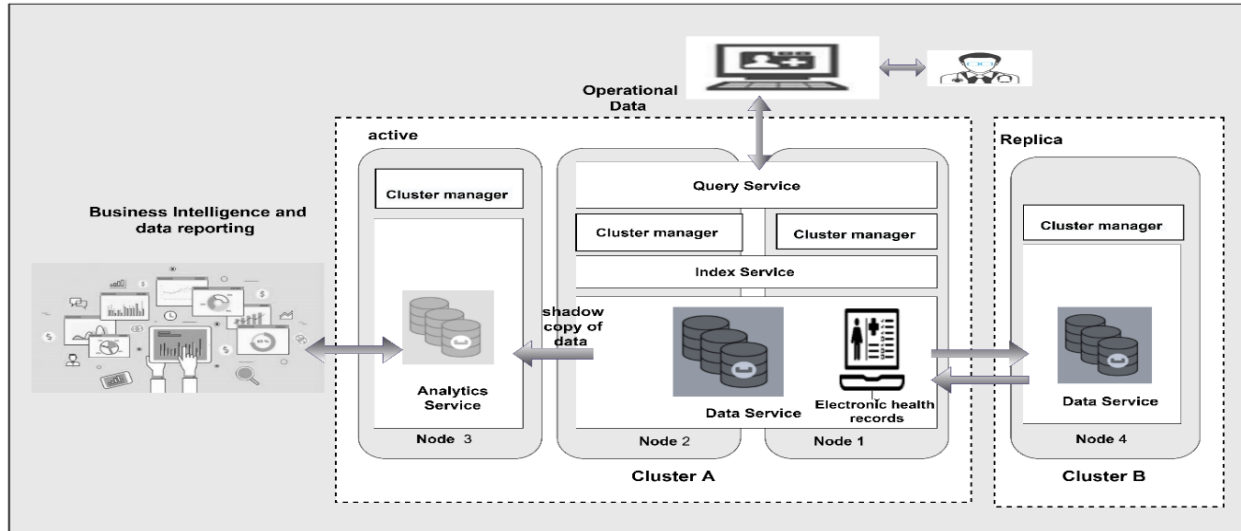

Fig. 1. Proposed Document-based Multifunctional EHRs Persistence Framework.

#### IV. EXPERIMENTAL SETUP

Two NoSQL database management systems: Couchbase 6.6.2 and MongoDB 4.4.3 are used to assess the suitability of document-based persistence to store and retrieve EHRs objects. The two NoSQL products were deployed in a single machine with the following specifications: Intel core i7 -10750h CPU @ 2.60GHz, with 16GB of memory and an SSD storage system of 256GB, running windows 10 \_64 bits.

The workloads were tested under the following conditions: data fit the memory, and replication is set to “1” signifying that just a single replica is available for each dataset. All executions are warm runs, so either caching techniques must be disabled, or each query must be performed individually to fill the cache. Queries must be prepared according to the native scripting language of the target database and run directly from the command line interpreter within the chosen system.

##### A. Dataset

Our experiment investigates the performance of the document-oriented database to store Fast Healthcare Interoperability Resources (FHIR) [48] compliant EHRs data. The used EHRs data is two different size synthetic patient datasets with COVID-19 [49,50]. These synthetic datasets have been generated by SyntheaTM [51], an open-source patient population simulation available from the MITRE Corporation.

SyntheaTM is a synthetic patient generator [52] that simulates the medical history of synthetic patients. Patient data and related health records covering several aspects of healthcare are realistic but not genuine. Every record in this EHRs dataset contains administrative, demographic, and healthcare information concerning a patient. These records are subdivided into different data sources or categories that encompass all the different aspects of healthcare. They also span practitioner, care team, device, organization, location, healthcare service, diagnostic, medications, as well as the financial tasks, such as insurance coverage. Core data elements are presented in Table I.

FHIR specification is a next-generation standard framework developed by HL7 to facilitate faster and more efficient integration, exchange, and retrieval of EHRs data. It bases on the concept of “resources”. One of the key objectives of FHIR is that it does not enforce the exchange of whole documents, but it allows the exchange of specific pieces of information. Hence, enabling interoperability across various functional applications and ultimately reducing the cost of the implementation. FHIR data model is relational in nature. It centers around the ‘patient’ object or resource. Each object has a unique identifier ‘id’ field. This id is used to reference most resources to the ‘patient’ object. As a result, the patient resource collection has been normalized into individual resource-type documents in which the objects that are associated with a patient are linked by the patient’s id in the subject field.

##### B. Workload

HIS workload usually involves clinical practice queries which are used to get single patient data and research queries that are dedicated analytical workloads.

TABLE I. DATASETS SIZE AND THEIR ATTRIBUTE NUMBER

Objects	10k patient	100k patient
Allergies	5,417	51,592
Careplans	37,715	377,726
Conditions	114,544	1,143,900
Devices	2,360	23,694
Encounters	321,528	3,188,675
Imaging_Studies	4,504	45,609
Immunizations	16,481	168,160
Medications	431,262	4,227,723
Observations	1,659,750	16,219,969
Organizations	5,499	9,175
Patients	12,352	124,150
Payer_Transitions	41,392	409,553
Payers	10	10
Procedures	100,427	979,564
Providers	31,764	60,534
Supplies	143,110	1,389,858
<b>Total Item Number</b>	2928115	28419892
<b>MongoDB Size</b>	878.732 MB	8.17 GB
<b>Couchbase Size</b>	1.37GB	14.2GB
<b>CSV Data File Size</b>	504 MB	4.78 GB

Operational BI workload is read-intensive, with writes that do not conflict with reading queries. It resembles the workload of an OLTP application, where quick response times are desired. This workload includes a type of ad hoc query that is used for real-time reporting.

The motivation behind this paper was the belief that ad hoc queries are not planned before, thus having any query indexing. It investigates two back-ends behaviors for ad hoc queries that are examples of real-time analytical queries with different levels of complexity and may have joins and aggregations. The performance of each database was evaluated under queries range in complexity, from simple ad hoc read queries to complex join queries. Simple read workload usually includes filtering constraints and sorting operations and aggregate lookups. While join workload involves join operations with grouping and aggregation functions. These queries declared in Table II and Table III were identified and written according to each database query language. Specific queries whose behavior could differ widely from the others are chosen to differentiate the performance of the databases and avoid bias.

##### C. Query Implementation

Two database architectural topologies for the two storage back-ends storing EHRs were deployed to investigate for handling different queries complexities. MongoDB experiments were deployed to single unsharded data cluster architecture. While Couchbase Server investigates two database topologies, which are single node cluster and multi-node cluster.

TABLE II. SIMPLE AD HOC READ QUERIES

Q1	Retrieve patients' names and their age
Q2	Rank the encounter count of hospitals
Q3	Find all dead patients' data.
Q4	The number of inpatients.
Q5	Arrange conditions according to their co-occurring
Q6	Arrange encounters according to the number of conducted encounter class
Q7	Count of non-survivor
Q8	The age of dead patients
Q9	The average age of non-survivor
Q10	Max-age of non-survivors
Q11	Mortality by sex
Q12	Mortality by age
Q13	Total count of supplies
Q14	Medications dispensed to patients with COVID-19 since January 20, 2020
Q15	Total cost for every medication dispensed to patients with COVID-19
Q16	Number of patients required ventilator
Q17	All the conditions starting after January 20, 2020
Q18	Cumulative case count of covid over time
Q19	Number of patients with COVID-19 conditions
Q20	The max duration length of any COVID-19 patients
Q21	Care plans for all COVID-19 patient
Q22	Allergies ordered according to co-occurrence
Q23	Maximum observed temperature
Q24	The total number of patients who take influenza immunizations
Q25	The max cost of procedures

TABLE III. COMPLEX JOIN QUERIES

Q1	Retrieve patients' names and their current unresolved conditions
Q2	All patients who were at Beverley hospital on 2011-08-18
Q3	Patients' names with their insurance claim cost
Q4	Merge patients' names with their COVID-19 conditions
Q5	Period time every covid patient connected to a ventilator
Q6	Total cost for every covid patient
Q7	The total cost of medication for every covid patient
Q8	The number and total cost of immunization for every patient
Q9	Period time for every covid patient
Q10	Number of female and male patients with covid
Q11	Number of providers in every organization
Q12	All observations for patients with covid
Q13	All observations for patients who are not diagnosed

For Single node topology in MongoDB, the aggregation pipeline framework is used to implement queries using the concepts of multi-stage data processing pipelines. It uses the \$lookup operator to apply left outer JOIN queries over an unshared collection in the same database [53].

For Couchbase Server single node cluster topology, all database services (query, index, and data) are contained in a single zone. In such architecture, the query service is used to handle all different complexity workload types. While for multi-node cluster topology, the Couchbase Server services are distributed across several nodes across several nodes rather than a single node.

## V. EXPERIMENTAL RESULTS

### A. Evaluation Criteria

The majority of the healthcare system's tasks usually entail searching the databases. An EHRs system's execution time is an essential performance parameter, and storage space efficiency could decrease future maintainability costs. Thus, reducing database query response time significantly improves the EHR system's performance and functionality [54]. This paper evaluates how DODBMSs store and retrieve EHRs in the context of storage space and response time.

### B. Database Size

Both 10k and 100k patients' datasets files [55] are initially available in the SCV format with approximately 500 megabyte and 5-gigabyte sizes. Table I shows the two data sets' sizes when stored in each backend. To upload data into the Couchbase server, a command-line utility, \$cimport, is used to import synthase COVID-19 CSV files into JSON Couchbase format. While for uploading data into MongoDB, the mongoimport tool is used. Couchbase and MongoDB demand 2.9 and 1.7 times more space correspondingly than CSV storage space for both datasets of different sizes.

## VI. RESPONSE TIME

Database performance is defined by the speed at which a database process workload. In our evaluation, the primary factors related to the performance of the database are the query complexity level and the size of the dataset. To investigate the scaling capability of the two back-ends, the same queries were applied to both 10k patients and 100 k patients' datasets, respectively. All queries' response time and the number of examined documents grouped by the database are represented in the following tables. Queries are mainly divided into two types. Simple ad hoc read queries that retrieve data from a single collection or bucket and complex join queries that span multiple collections to get data.

Table IV and Table V respectively show simple retrieval queries' execution times for the two datasets. There is a linear complexity increase in query response time as the database size grows. This is because the database execution time increases with the same queries, by scaling the dataset from 10k patients to 100k patients. However, query optimization techniques like indexing are not likely to be used for that type of ad hoc analytical query. Execution time was reported with and without documents indexing for the small dataset to declare the benefit of indexing to enhance query performance. Even Q23 scanned the observation document, which has the largest size. It achieved the smallest execution time value because the two attributes of the query are indexed to make a covering query. Covered queries usually retrieve results directly from the index without the need to access datasets documents. Without

indexing, Q23 achieved the highest execution time for both databases. The same explanation is for Q7, Q8, Q9, and Q10 execution time. These queries utilized indexing deathdate and birthdate attributes as a covering index. Q24 achieved the lowest execution time because the number of scanned attributes is quite smaller than many other queries besides that it used the covering index. Even with indexing, Q6 reported high response time values. This is because of the low selectivity of the encounter class's attribute values. MongoDB reported observable better execution time than Couchbase in the case of simple queries scanning the small 10k patient dataset.

For the larger 100k patient dataset, MongoDB still reports better execution time than Couchbase except for Q4, Q6, and Q13. This is because of the large number of the queries' scanned attributes and usually, Couchbase is reported to be better for large-scale data. By utilizing Couchbase analytical services in multi-node architecture, database performance was enhanced significantly.

TABLE IV. SIMPLE QUERIES EXECUTION TIME FOR 10K PATIENT DATASET

	Execution time (ms) with index		Execution time (ms) without index		Number of examined documents

Q21	13500	1211	607.60	377726
Q22	1700	439	146.02	51592
Q23	10m0s	31427	19510	16219969
Q24	5100	766	370.29	168160
Q25	21700	3039	781.44	979564

For complex join queries, Table VI and Table VII show execution time for the two datasets correspondingly. For the 10k dataset, Couchbase achieved better response time than MongoDB except for Q2 and Q7, which scanned few attributes. Q12 achieved the highest response time for both back-ends. As it both examined and retrieved many documents. Conversely, Q2 achieved the lowest response time for both back-ends besides Q6 for Couchbase. The number of scanned attributes results from the total number of joined documents attributes. MongoDB was considerably slower than Couchbase for join queries. It was not investigated against join queries for the 100k patient dataset, as it reported a very long response time for the small dataset. Even there is no indexing and there are many examined documents. Couchbase Analytics service enhances the execution time of ad hoc join workload dramatically. Q11 and Q12 reported the lowest and the highest execution time, respectively. This is because the Couchbase Analytics service is usually based on parallel join and those two queries examine the largest and the smallest number of scanned attributes. For two different queries with the same complexity and attribute number, the execution time is approximately the same.

TABLE VI. JOIN QUERIES RESPONSE TIME FOR 10K PATIENT DATASET

## VII. DISCUSSION

This research investigates the appropriateness of two DODBMS storing EHRs data for BI workload. For single-node topology, MongoDB performed better for simple look-up queries, but their performance decreased with JOIN queries spanning multiple collections and involving aggregation. It was considerably slower than Couchbase for join queries of larger datasets. Conversely, Couchbase single node cluster reported better performance for complex join queries, but their performance decreased for simple lookup queries.

These results motivated us to utilize Couchbase server MDS architecture to distribute services across several nodes rather than a single node. An interesting result of the Couchbase multi-node cluster performance analysis is that, by using an analytics service with no index, the Couchbase server reported better response times than MongoDB for both types of ad hoc queries. This multi-service architecture decreased the query latency dramatically.

MongoDB uses the \$lookup operator to apply JOIN operations, which traverse several collections. According to the result, this costly operation significantly increases latency and overall strain on the database. An alternative solution to handle these costly join operations in MongoDB is to denormalize the data model by embedding elements into their parent objects and performing a regular query. The major disadvantage of this denormalization approach, especially in a distributed system, is that it leads to data redundancy, which causes a significant write-performance downgrade to maintain consistency across multiple copies through multiple write operations. Furthermore, this modeling approach brings additional storage costs. It could be considered as an optimal response scenario with only one user submitting a single query at a time. Besides that, MongoDB provides a native connector for BI, which could provide support for real-time analytics by integrating with a leading BI and analytics tool.

The proposed converged Couchbase EHRs system infrastructure has significant advantages compared to the other loosely coupled alternatives. It supports using a common flexible document data model for both operational and analytical data with no transformation required for analysis. So, it could offer fast reporting and decision-making capabilities based on real-time and advanced analytics for large volumes of data without needing to move data around. Instead of managing and synchronizing many systems with several connections points [31].

The analytical workload is usually read and compute-intensive because it entails more massive costly calculations over data. So, it is typically ideal to perform analytical workload in isolation. Couchbase Server separates the competing workloads into independent services and isolates them from each other. Consequently, interference among them is minimized. Operational workload latency and throughput are isolated from analytical query workload slowdowns but without the complexity of operating a separate analytical database. It allows running analytics in extremely current data with no ETL process that delays data.

An important principle in medical systems is that when any data element is modified, it will not be overwritten. Rather, a new element with a suitable link is added. On the other hand, large-scale healthcare applications scenarios usually do not strictly enforce ACID properties. They deploy optimistic locking, as they desire isolation, but not at the rate of a significant performance penalty. For such scenarios, Couchbase Server, which is an append-only store that enforces the BASE (Basically Available, Soft State, Eventually Consistent) philosophy, seems to be a promising solution covering many EHRs systems use-cases. Their flexible MDS framework enables users to scale or shrink their cluster, involving data management resources as requirements change.

## VIII. CONCLUSION

This paper investigates the appropriateness of DODBMS for handling operational BI workload. MongoDB does not provide satisfactory response time for unplanned join queries spanning multiple documents contrarywise Couchbase which reports better performance for these complex queries. By utilizing its analytics services and multi-dimensional scaling

architecture, Couchbase Server multi-node cluster outperforms the response times of MongoDB for both simple and complex healthcare data access patterns. Couchbase is the ideal solution for our needs as long as we need to store unstructured health data in various EHR systems. This paper proposes a tightly coupled Couchbase healthcare framework that can efficiently adapt to different workload needs. Along this path, using complementary Couchbase services for architecting a monolithic framework enables new technical capabilities which serve as the foundation for a new class of intelligent applications such as machine learning, real-time operational reporting. Finally, the emergence of HTAP DBMSs does not imply the end of the massive, monolithic OLAP warehouse. But such systems will be required to serve as a universal back-end database for all an organization's front-end OLTP silos.

# Cyber Threat Intelligence in Risk Management

## A Survey of the Impact of Cyber Threat Intelligence on Saudi Higher Education Risk Management

Amira M. Aljuhami, Doaa M. Bamasoud  
Dept. of IS  
College of Computing and Information Technology  
University of Bisha, Bisha  
Saudi Arabia

**Abstract**—Cyber Threat Information (CTI) has emerged to help cybersecurity professionals keep abreast of and respond to rising cyber threats (CT) in real-time. This paper aims to study the impact of cyber threat intelligence on risk management in Saudi universities in mitigating cyber risks. In this survey, a comprehensive review of CTI concepts and challenges, as well as risk management and practices in higher education, is presented. Previous literature was reviewed from theses, reviews, and books on the factors influencing the increase of cyber threats and CTI as well as risk management in higher education. A brief discussion of previous studies and their contribution to the current paper and the impact of CTI on risk management to reduce risk. An extensive search of more than 65 research papers was conducted and 28 were cited in this survey. Cyber threats are changing in addition to the huge flow of information about them and dealing with these threats on time requires advance and deep information about the nature of these threats and how to take appropriate defensive measures, and this is what defines the concept of CTI. The use of cyber threat information in risk management enhances the ability of defenders to mitigate growing cyber threats.

**Keywords**—Cyber threat intelligence; risk management; cyberthreat; cyber security

### I. INTRODUCTION

In the twenty-first century, the world is witnessing a technological revolution and a qualitative shift in the field of cybersecurity significantly. From here emerged the awareness of the Kingdom of Saudi Arabia and its interaction with these changes and developments with what appears in this era. Therefore, the royal order was issued to establish the National Cybersecurity Authority and its relationship with the King, may God protect him, in line with Vision 2030, to be specialized in cybersecurity and its affairs, and it is considered the main reference for the Kingdom [1]. Rania in [2] assumed that despite this development in the Kingdom, the Kingdom is considered more vulnerable to cyber threats in the Middle East as organization face a new generation of cyber threats. It is distinguished by its ability to easily bypass traditional defenses, such as intrusion prevention systems or firewalls, etc. It has been considered effective for the previous generation of threats. The authors in [3] hypothesize that the old approach renders traditional defenses vulnerable to complex threats because they exploit unknown vulnerabilities. This requires the

need to prepare for these threats through cyber threat intelligence. With this technological revolution, systems have become more complex, resulting in lower levels of security. Because of the changing forms and functions of cyber threats targeting individuals, businesses, and government agencies, cyber threats are not limited to online attackers and hackers. Instead, the authors add in [3] it has grown into threats and funds that are financed and organized for financial gain or political ends.

The authors define in [4] CTI as a means of gathering knowledge to understand what the attacker wants and predict future attacks. CTI is used to achieve appropriate awareness of conditions and cyber threats can be countered by including CTI in defense systems. Threats are analyzed based on historical information about actual incidents in the past, and as one of the advantages of information about security threats, operations are improved effectiveness and efficiency in terms of preventative capabilities and investigations. The authors argue in [5] that the purpose of the CTI is to obtain evidence to aid decision-making because what determine the ability of the security team to produce accurate and actionable threat information is the maturity, skills, and resources of the CTI.

Although technology and information continue to grow in cyberspace, it becomes difficult to identify and respond to threats on time. Therefore, CTI management is needed to reduce cybersecurity risks. This paper aims to identify the role of CTI applications in risk management in the Kingdom of Saudi Arabia.

This paper is organized into six sections. Section 2 provides a deep explanation of the concept of CTI, where its types, main challenges, and characteristics are mentioned. Section 3 explains the concept of risk and its types. It also discusses the concept of risk management, its processes, and the most prominent practices of risk management in higher education. In section 4, the most prominent previous literature that discussed the reasons for the increase of cyber threats in addition to the importance of CTI and risk management in higher education was highlighted. In Section 5 discusses the relationship of previous studies to the current paper and the extent of its support and disagreement with it is. Section 6 provides concluding observations with suggestions for some future directions.

## II. CYBER THREAT INTELLIGENCE

### A. Threat Intelligence (TI)

The author in [6] defines TI as the process of understanding enterprise threats based on available data points that go beyond just collecting data points. The data must also be relevant to the organization as a whole [6]. In [7] the authors define TI as any evidence-based knowledge about threats, intending to prevent an attack or shorten the period between penetration and detection. The author explained in [6] that TI can also refer to evidence-based information, such as context, mechanisms, indicators, implications, and actionable advice for a topic regarding an existing or emerging risk or risk on an asset that can be used to make informed decisions about the response to risk or risk. TI can be information collected from a variety of technical sources (for example, local sensors) or human sources (for example, observed discussions in secret forums, communication with peers). Thus, the authors stated in [3] that threat information includes technical indicators, context, mechanisms, implications, and actionable advice about current or emerging threats.

SysAdmin Audit, Network, and Security (SANS) defines a CTI as the collection, classification, and eventual use of information about adversaries, specific information about their tactics, to discover or block them. As mentioned by one of the authors, CTI is used to determine opponent intent [8].

The study in [9] provided several definitions of CTI that are based on processes, analysis, and domain. Hence, in [9] CTIs are defined by the authors as actions taken in cyberspace to compromise and defend protected information and capabilities in the field.

The researchers proposed in [10] the definition of CTI: as “the process and product resulting from the interpretation of raw data into information that satisfies a requirement as it relates to adversaries who have the intent, opportunity, and ability to cause harm.” The research conducted in [10] claimed that Threat Intelligence (TI) involved the process of converting data into information about the adversary.

CTI can easily become an uncontrollable alert stream. The context allows the security analyst to understand the type of threat or actor they are dealing with so that they can formulate an appropriate response plan. The three main components of a CTI are relevant, timely, and actionable. A complete CTI definition needs to cover these three elements to ensure that relevant threat data is collected, analyzed, and processed on time, and the outcome can produce actionable intelligence to aid decision-making [11].

### B. Cyber Threat Intelligence Challenges

In [12] the authors discuss that cybercriminals use a variety of methods to attack their victims to:

- Steal their sensitive personal information (such as financial information).
- Accessing and controlling the victim’s device to commit other malicious acts such as ransomware which can provide malware (in case of Botnet) and lock/encrypt the victim’s device (in case of Botnet).

The authors argue in [12] that although different types of cyber-attacks use a variety of infection methods, in essence, they follow a similar life cycle: beginning with victim reconnaissance and ending with malicious activities on the victim’s device/network.

1) *Vector reconnaissance attack*: Identifying the attack point and system vulnerabilities that cybercriminals can exploit is a challenge in defending against cyberattacks. In addition to the common methods that have always been used to deceive victims (for example, phishing) into performing the actions desired by the attackers, the attackers have used more intelligent and innovative methods in recent years [12]. The authors hypothesize in [12] that methods range from delivering malicious software (malware) in an unexpected format (e.g. Word documents or PDF files) to one-day exploits of vulnerabilities, to infringing anonymous communications to contact threat actors. New families of ransomware, which have worm-like behaviors, have infected tens of hundreds of individuals, organizations, and important systems with such advanced attacks. These advances in attack techniques make it very difficult to determine the point of origin of the attack as well as to identify the attacker.

2) *Attack indicator poll*: The authors report in [12] that cybercriminals also use sophisticated methods to combat forensics and evasion in their malicious code, making standard security assessment methods, for example, CVSS (Common Vulnerability Scoring System), or persistent malware and traffic analysis, less efficient. Models, such as Software Defined Networking (SDN), Internet of Things (IoT), and cloud computing, and their widespread adoption by organizations (e.g. using cloud resources to process and store big data) require modern forensic techniques such as Well [12].

### C. Types of Cyber Threat Intelligence

In [13] the authors discussed that CTI can be classified into four types based on their features and the role of the consumer in the organization as shown in Fig. 1:

- Strategic Threat Intelligence.
- Operational Threat Intelligence.
- Tactical Threat Intelligence.
- Technical Threat Intelligence.

Fig. 1. Types of CTI.

The author hypothesizes in [13] that the purpose of strategic intelligence is to provide management personnel with high-quality information about attack trends and threats that can influence high-level business decisions. TI's operational information provides information about specialized and technically focused intelligence (mostly from campaigns, malware, forensic reports, and/or tools) of an organization's specific security incident and is consumed by security managers and the organization; Tactical TI deals with the tactics, techniques, and procedures (TTPS) used by various threat actors, IOCS (Indicators of Settlement) to advocate for signature-based settlements. The author mentioned in [13] that threat intelligence is consumed by incident response teams, and technical threat intelligence is consumed through information feeds, which are often automatically consumed by enforcement or monitoring and analysis systems such as firewalls.

#### D. Cyber Threat Intelligence Characteristics

The ability to perceive and capture the enemy's attention during the reconnaissance, armament and transmission phases of the cyberattack lifecycle provides the opportunity to take appropriate action to protect the network and prevent attacks. Effective recovery and response strategies can also be created in this way. In [14] the authors claimed that conditioning the following characteristics would result in greater efficacy in TI:

- **Timely:** For effective threat intelligence, time plays a critical role. Intelligence must be conveyed quickly with petty frivolity.
- **Relevant:** Threat information must be applied to the relevant environment.
- **Accurate:** To be able to take more reasonable and effective action against attacks, it is necessary to have more accurate intelligence. Therefore, the information provided through Threat Information must be true, complete, and frank.
- **Specific:** More detailed and more specific threat information can allow defenders to choose appropriate countermeasures.
- **Actionability:** Actions need to be defined by threat information to ensure the data necessary to respond to threats.
- The author mentioned in [14] that understanding these four aspects of the model, finding the data that corresponds to each of them, and knowing where the attacker's killing chain occurs, gives insight to the attackers and facilitates the production of threat intelligence. Both fuel the active cyber defense cycle.

### III. RISK MANAGEMENT

#### A. Classification of Risks

In [15] the authors discussed the classifications that determine the nature of the operations generated by the types of risks that have an impact on achieving goals at the level of the economic organization, as shown in Fig. 2, which are:

Fig. 2. Classification of Risks.

- Strategic risk relates directly to the development strategy of the organization and is associated with its strategic goals.
- Organizational risks are related to organizational processes, operational activities, and procedures.
- Financing risks are caused by interest rates, inflation, insurance, taxes, protectionist policy, regional policy, and the necessity to minimize losses.
- Risks of change are caused by legislative changes, professional ethics, levels of culture and training, the diversity of needs and requirements, staff fluctuations, and the issues of turnover.
- Operational risks have a direct relationship to the functional compartments within an organization and are linked to the specific objectives defined at the level of functional groups.

#### B. Types of Risks

The author stated in [15] that the identification of risks to which the organization is exposed may be divided into two categories, namely, inherent risks, and residual risks as shown in Fig. 3, and the risks inherent in any business are those that usually exist before applying internal control measures to reduce risks, or the overall The risks that lie with the entity or organization, whether internal or external, measurable or not. In this way, the inherent risk is the possibility that the administrative and financial statements contain errors or inconsistencies before the implementation of internal control measures.

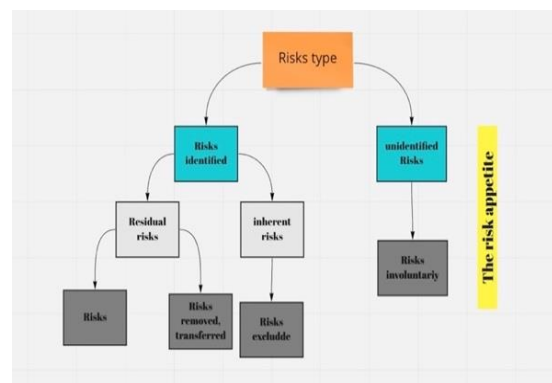

Fig. 3. The Risks Type.

- The author assumed in [15] that the residual risk is the risk that remains after taking measures to mitigate it, the risk-mitigating measure is part of the internal control, and the residual risk is a measure of the effectiveness of the internal control, which is why some countries have replaced the term residual risk with the term “residual risk.” Control, therefore, the residual risk is the residual risk after the implementation of internal control measures, the internal control measures must have the effect of reducing the inherent risks at reasonable levels for the organization, and the inherent and residual risks can be considered as illusions of the same risks. As a result, there were inherent risks before the internal controls were introduced, and residual risks emerged after they were introduced.
- Besides inherent and residual risks, there are also control risks and undetected risks that occur at the enterprise level, and there are control risks when the internal control system of the enterprise fails to prevent or detect errors, irregularities, or fraud on time, there may be individual risks associated with the account balance or a class of transactions or both, and risks can be aggregated [15]. In other words, undetectable is the risk that a particular threat cannot be identified and managed, experts in this field believe that economic organizations should focus on assessing risks and keeping them within the limits that they can accept and tolerate because risks cannot be avoided or eliminated.

### C. Risk Management

The author defined in [15] the risk management process as a plan developed by the leaders of economic organizations and implemented by all employees, and the process includes risk assessment, identification of risk tolerance, and treatment of uncontrollable risks.

Risk management at the level has become necessary due to the uncertainty like threats that may affect the achievement of organizational goals and the environment in which the organization operates, as part of risk management, and the goal is to manage risks in such a way that it can ensure the protection of resources and the protection of employees.

The author argued in [15] that risk management is continuous, and the results arise from decisions made regarding accepting, reducing, or eliminating risks that affect the achievement of objectives, and to prevent losses, avoid threats and take advantage of opportunities, exposure to risks must be optimal.

### D. The Risk Management Process

The author mentioned in [16] that it is the manager and project team members at different levels who identify and manage risks in several ways, but without a unified framework for risk assessment, this is ineffective, as there will be no full impact assessment.

Risk management is an iterative process, and every aspect of risk management must be planned and implemented at every stage [16]. The risk management process consists of four steps

as shown in Fig. 4: Identifying, analyzing, evaluating, and controlling risks.

1) *Risks management plan*: Risk management frameworks are reviewed and adapted to define project risk management plans at project initiation. The author assumes in [16] that risk management plans include the following guidelines:

- List of possible sources and categories of risk.
- Impact and probability matrix.
- Risk reduction and action plan.
- Intervention plan.
- Threshold and risk values.

2) *Identification of risks*: The author stated in [16] that risks should be identified and addressed as early in the project as possible. Risks are identified throughout the project life cycle, focusing on key stages. Risk identification is an important topic in the project landscape and the reporting sessions. Some risks emerge easily to the team (known risks), while others may take longer to identify. Risks are identified in a disciplined and systematic way, ensuring that no significant threats are overlooked:

- Risk log: list of risks from history (other projects)
  - List of potential risks
- Expert judgment, using brainstorming.
  - Project status, which includes progress reports.
  - Classification of risks by categories.

3) *Risk analyses*: Risk analysis or risk assessment involves examining how project outcomes and objectives may change because of the risk event [16]. The risks are identified and then analyzed to determine the qualitative and quantitative impact of the risks on the project so that appropriate mitigation measures can be taken. In general, the author advises in [16] a risk analysis based on these guidelines: the likelihood of occurrence, the extent to which the risk will occur, the exposure to the risk, and the period during which the risk will occur.

4) *Risk management*: The author mentioned in [16] that risk management includes planning the response to risks, identifying risk drivers, and identifying the person responsible for solving the risks.

Fig. 4. Risk Management Process.

- Planning the risk response

It may not be possible to eliminate or reduce all the risks associated with a project seamlessly. Managing some risks over longer periods may be necessary and strategically beneficial. To reduce these risks, action plans should be developed [16].

- Risk triggers

In the risk log, the trigger must be recorded for each risk.

The author mentioned in [16] that the triggers are symptoms or warning signs that indicate danger. Risk triggers also indicate when a particular risk is expected to occur, after the implementation of response plans, the degree of risk will be reduced once stakeholder consultation has taken place.

- Risk responsibility

As a basic principle, it is the responsibility of the project manager to manage all risks. The risk owner (who does not necessarily have to be the project manager) must be identified and named in the risk register [16]. The risk owner may be best suited to monitor the risk catalyst but may also be the best suited to implementing and managing the metrics identified, the author assumes in [16] that it is the responsibility of the risk owner to promptly report any change in the risk release status, as well as implement countermeasures specified.

#### 5) Risk monitoring and control

In [16] the authors note that risk monitoring and control include:

- Identifying new risks and planning for them.
- Track existing risks to verify that:
  - Reassessment of risks is necessary.
  - Any risk conditions have been triggered.
- Monitor any risks that may become more critical over time.
- Addressing other risks that require a long-term, planned, and managed approach with risk action plans.

#### E. Risk Management Principles in Higher Education Institutions

It is very important for higher education institutions that they prevent events that could lead to risk in their processes, projects, and other activities, thereby preventing harm from occurring. As well as the above principles, there are other factors to consider [17]:

- Institutions of higher education should integrate risk management into their process maps with defined process features that work in tandem with their main, ancillary, and management processes.
- They must be a key part of decision-making at all levels of management and raise awareness of their importance to the training and business processes among all stakeholders.

- Risk management is the systematic, structured, and timely activity of all institutions' leaders and processes.
- Risk management always adapts to specific situations.
- Risk management is dynamic, repeatable, and sensitive to change.
- Risk management explicitly addresses all types of uncertainty in training processes.
- Risk management is beneficial to the improvement of quality education, processes, and the whole institution.

## IV. LITERATURE REVIEW

### A. Influencing Factors of Cyber Threats

The study of [18] discussed that risk management has emerged and evolved since the emergence of human societies and has improved greatly over time, including identifying, accepting, evaluating, and controlling undesirable events, and preventing the exploitation of opportunities and threats through risk management actions. The primary function of cybersecurity research is to focus efforts on those circumstances and metrics in which the people involved gain an understanding of how to perceive and respond to specific cybersecurity challenges, bearing in mind that cybersecurity is rapidly evolving from technical specialization into a strategic concept, concluding that most security incidents Caused by inadequate management and regulation with the unpredictability of attacks and insecurity, a lack of attention to security concerns may threaten the future of the organization, so it is important to categorize and prioritize risks [18]. The study of [18] is based on the identification of necessary measures to be taken to protect the information, resources, and resources based on an assessment of threats and vulnerabilities and aim to assist governments and organizations in making decisions about security measures against threats.

The study of [19] discusses the growing popularity of information and communication technology that has led to the rapid increase in cybercrime. In addition, many countries around the world are making the necessary interventions to ensure cybersecurity. It also reported that Saudi Arabia was the worst victim of cybercrime in the Gulf region. The study [19] deals with the extent of Saudi Arabia's readiness to confront and defend cyber threats. The carried work in [19] concluded that despite the existence of an anti-cybercrime law that covers the basic areas of combating cybercrime, it is flawed in the protection against identity theft in addition to the violation of privacy and cyberbullying. Therefore, the Kingdom of Saudi Arabia needs to strengthen the cybercrime law, cybersecurity systems, and the National Cyber Security Authority, and it also needs to develop a strategy and standards for cybersecurity [19].

The study of [20] indicates that the twenty-first century has witnessed a new dimension of security known as cybersecurity. With this development, there has been an exploitation of vulnerabilities in cybersecurity, especially between countries to compete. Over time, malware has become a security threat that cannot be underestimated in cybersecurity. And the Kingdom of Saudi Arabia is a prime target for cyber-attacks due to its

economic activity and the high rate of technology use with digital transformation. The study [20] also presented a case study on attacks against Saudi Arabia and focused on two types of malwares: ransomware and Shamoon. The study of [20] suggested some best practices that can be followed to curb attacks, including restricting access, following correct password policies, developing a strong team to respond to incidents in real-time, and providing them with appropriate tools and procedures. The study of [20] showed a lack of scientific studies and investigations dealing with attacks in the Kingdom of Saudi Arabia.

The study of [21] discusses that the technological development of cyber security and the increasing dependence of individuals, societies, and states on it was the reason for the emergence of new and constantly changing threats, where the rapidly developing threats are much more than what can be assessed. The study of [21] showed that defense organizations against attacks in nation-states are considered lagging behind the rapid development of these threats, and this calls for the need to respond to threats in real-time. The study of [21] aims to provide an overview of the most prominent cyber threats and their trends. The study of [21] concluded that it is necessary to increase the capabilities of cyber-threat intelligence in addition to training because it is late and limited compared to the threats.

Cyber security is witnessing the growth and spread of data in information communication technologies, it will be difficult to obtain valid and actionable data from big data to detect and respond to an attack in real-time [22]. The study of [22] suggests a way to organize a large amount of data from different sources, they adopted a pilot approach and reviewed the methodologies for an extensive study on platforms for exchanging information about CTI, implement an online CTI platform, it works to exchange intelligence to reduce the risks of cyber security [22].

### *B. Leveraging the Cyber Threat Intelligence in Risk Management*

Real-time risk assessment is very important, given the nature of the evolving threats that arise from attackers and electronic criminal groups. The study of [23] describes the Polish national platform for cyber security for analyzing cyber risks using CTI. The approach presented came to meet the needs for numerical risk assessment at the national level, to assess risks in real-time, they aim to provide a broad and comprehensive view of cyber threats at the country level. And monitor the current situation of the various technical services, Where the proposed approach on the platform is to achieve several goals: From monitoring the cyber security space, detecting threats early, and preparing for measures against hazards in advance, This is the first approach at the national level that uses smart threats, as one of its results is that it leads to building awareness and avoiding the situation.

In [3] the authors discuss that given today's cyber threats and attacks, this requires a new approach to security defenses, since traditional defenses are incompatible with the new generation of more complex threats, any organization needs to collect and share information about cyber threats and turn it into intelligence about Threats and thus contribute to

preventing attacks or at least implementing timely disaster recovery. A study by [3] found a classification of types of CTI, providing reliable strategies for sharing information about CTI and some research and criteria to mitigate threat intelligence problems Technical (TTI) and evaluation of most-sourced tools were surveyed [3].

The rapid development of information technology has been associated with an increased risk of cyber-attacks by malicious hackers [24]. The study of [24] argues that organizations aim to develop CTI to enable effective cybersecurity decisions, and many have been interested in Major cybersecurity companies such as Anomal, FireEye, and many others are developing CTI platforms due to their many benefits, including a high ability to identify key threat actors and prioritize threats, as well as an understanding of their technologies, tools, and procedures, and identification of appropriate security controls. The study of [24] aims to provide a systematic review of the CTI platforms that exist today within the industry. This has led to potential future directions that CTI startups can explore, integrate with improved data mining capabilities, and move from CTI platforms to open-source intelligence platforms (OSINT).

The study of [25] discusses the global increase in attacks and cyber threats, and the trend of many organizations at present to CTI. The main function of CTI is to help organizations better understand and know their enemies by pre-detecting threats and responding to them on time [25]. The study of [25] clarified that prior knowledge of the nature of threats is not considered a major direction for risk management and therefore success in risk management with the massive spread of threats and their changing nature is considered low. The study of [25] proposes the work of a CTI-CM model that describes the main capabilities necessary for CTI practitioners to participate effectively in CTI activities. The study of [25] found that at present, threats spread tremendously and faster than prevention information, although this spread makes it more difficult to keep up with these threats, CTI helps to reduce these threats.

In [5] the authors claim that the success of CTI in cybersecurity requires a base that contains an error in knowledge about CTI, and in addition to a good way of representing this knowledge, classifications and sharing criteria are used to serve this purpose. The study of [5] aims to introduce the CTI model. It enables defenders to learn about their CTI capabilities and understand their behavior against changing cyber threats.

The study of [26] discussed that cyberattacks cost the global economy about \$445 billion annually. To reduce attacks, many companies have relied on Cyber Threat Information (CTI). The [26] study contributed to the creation of a new framework for CTI by utilizing a web, data, and text approach. Using this framework, many freely available malicious assets, such as encryption programs and keyloggers, have been identified.

### *C. Risk Management in Higher Education*

Higher education institutions have been exposed in recent years to an increasing number of reported security violations, which embody the importance of confidentiality, integrity, and

availability of information in universities. The study of [27] aims to systematically review the literature by examining papers that have been published in the past thirteen years in the field of information security management in higher education. The study of [27] found several theoretical contributions, including highlighting the complexity of universities in the practices they apply concerning confidentiality, safety, and access to information. The study of [27] concluded that the field of research is still emerging and that there is an urgent need to increase research efforts in the field of risk management in higher education due to the increasing interest in this field.

Information is one of the most important assets of universities and must be protected from security breaches. Whereas the study of [28] aims to analyze the security threats that develop particularly in the university network environment and recommend an information security framework for the university network environment. The study of [28], evaluation addressed issues at Vikram University, such as enforcing password policies, managing remote access, and restricting mandatory account permissions. The study of [28] when applying the proposed framework to the campus network of Vikram University concluded that the current methods of securing the network are ineffective concerning the university environment and that there is a need to apply for frameworks information protection in the university network, as the proposed framework contributed to Enhancing the level of security in the campus network.

## V. DISCUSSION

Risk management has evolved and improved significantly over time and includes identifying, accepting, evaluating, and controlling undesirable events and preventing the exploitation of opportunities and threats through risk management procedures. A study [18] concluded that one of the main reasons that led to the failure to address threats on time is the insufficient management and organization with the inability to anticipate attacks and insecurity, and thus threatens the future of the organization. This confirms the position of the current study in the importance of CTI in enhancing the role of risk management to respond to attacks on time. A study [19] also discussed that one of the reasons for the increase in threats and electronic attacks is the increasing reliance on information and communication technology. Also, many countries around the world have taken the necessary measures to ensure that cybersecurity is so important at present. A study [19] also mentioned that the Kingdom of Saudi Arabia is the worst victim of cybercrime in the Gulf. This reinforces the need to prepare in advance for these threats and to govern the vast amount of information about threats to address them. A study [20] confirmed that, despite the paradigm shift in cyber security in the twenty-first century, there is an increase in cyber threats and their degree of complexity and has even become a subject of competition between countries, and this is something that cannot be underestimated. In addition, the study [21] discussed the increasing adoption of technology by individuals, societies, and countries, which led to the emergence of new and constantly changing threats. This underlines the need to keep pace with these changes by using CTI and training risk response teams on it to reduce risks. In addition, the study [22]

discussed a way to organize a large amount of data from various sources, in addition to it focused on the importance of information exchange platforms about cyberthreat intelligence, as it works to reduce cybersecurity risks by exchanging information. A study [23] was based on the work of a Polish national platform for cybersecurity. This platform analyzes cyber risks using CTI. One of the most important and most prominent results of this platform was to achieve awareness and avoid risks, in addition to the fact that there was early detection of threats, and this is one of the most prominent benefits of the intelligence of cyber threats. Moreover, in [3] it is also found that organizations with the new generation of cyber threats need to strengthen defenses through the exchange of CTI information, which effectively contributes to preventing attacks or at least recovering from disasters on time. In [24], the study emphasized that many major companies in the field of cyber security have tended to develop CTI platforms due to their multiple benefits. This illustrates the current awareness of the importance of the CTI and its ability to identify the main actors of the threat and the priority of threats, as well as the ability through the CTI to determine the measures necessary to confront the threats. The study [25] concluded that prior knowledge of the nature of threats is not a major trend for risk management, and this makes managing risks at present with the massive spread of threats considered difficult. Therefore, to enhance risk management and keep it up to date with this development in cyber threats, the capabilities of CTI must be used. The study [5] aimed to present a CTI model characterized by this model in working on the capabilities of defenders in CTI and knowing their behavior against cyber threats. Strengthening the capabilities of defenders through CTI is one of the most important reasons that help reduce risks and make maximum use of CTI capabilities. A study [26] benefiting from the web, data, and text approach contributed to the creation of a new framework for CTI. This framework helped identify malicious assets free of charge. This indicates the multiplicity of ways to take advantage of CTI. A study [27] focuses on the increase in threats with the development in cybersecurity, including higher education, and in recent years it has had an increasing number of security violations. Maintaining the confidentiality of information in the university network is a very important matter that cannot be underestimated. Therefore, it is necessary to increase the security of the university network and to highlight the importance of protecting information and reducing the risks to which higher education institutions are exposed. In addition, the study [28] also discussed the importance of information, as it is one of the most important assets of universities that must be protected from security violations. Due to the great dependence of universities on technology, especially with the digital transformation that we are witnessing in the 21st century, and despite the importance of protecting information on the university network, there is not enough focus on this topic by another research.

Previous studies that were mentioned earlier discussed the reasons for the increase in cyber threats, in addition to the role of CTI in reducing risks, as well as the need for risk management to address threats on time and discussed the need for higher education to focus on protecting information and raising the level of security in the university network. The

REFERENCES

applications of previous studies for CTI and ways to benefit from it differed. However, previous studies did not discuss the idea of using CTI to improve the ability of risk management to address threats promptly; although she discussed the inability to manage risks to deter threats. In addition to the lack of studies that discuss the need for higher education to enhance security despite its importance. The present paper highlights the utilization of CTI's capabilities in enhancing risk management to reduce threats in higher education.

VI. CONCLUSION AND FUTURE WORK

Today, with the increasing adoption of information technology and the emergence of new opportunities and possibilities, but the rapid and continuous progress and development of information technology have increased the complexity of digital systems, which makes these systems less secure and thus leads to the complexity and change of forms and functions of cyber threats. Despite the current development in cybersecurity, there is a new generation of advanced threats that can easily bypass traditional defenses as these defenses were designed to combat a previous generation of attacks. In addition, risk management currently lacks in addressing these threats, which has resulted in them not being addressed on time. Higher education is hard without these threats. In recent years, a high rate of threats has been recorded, due to the reason that computers are an integral part of the university environment, in addition to increasing dependence on technology. Therefore, there is a need to improve these defenses using CTI, as CTI represents information about the nature of threats and a deep understanding of the attacker's objectives and thus the ability to respond to threats and take appropriate defensive measures. CTI aims to clarify the information an organization needs to know to increase awareness about threats to identify and address risks on time, as well as increase the capabilities of defenders to detect and respond. Threat information must be accurate and actionable to take full advantage of CTI. This survey focused on the impact of CTI in enhancing risk management for real-time response and discussed the main challenges and advantages of CTI as well as risk management processes and practices in higher education. CTI enables defenders to increase the ability to make decisions quickly in addition to addressing current and future attacks. The field of cyber security is an evolving field that is constantly changing, where it is possible to increase the strength and development of threats on a continuous and almost daily basis. This topic requires in-depth research on ways to take advantage of CTI, as well as a practical application that demonstrates CTI's ability to combat and reduce threats and raise the level of security in the university's network. Despite previous research efforts, studies discussing the use of CTI in risk management in higher education are almost non-existent despite the importance of the topic. One of the future directions of this survey is to propose a unified platform for Saudi universities to exchange CTI information. Training CTI specialists to raise their awareness and increase their capabilities in dealing with risks. However, gathering actionable information about threats is a significant challenge.

**Abstract**—Pelvic floor muscle training (PFMT) is the first line in managing urinary incontinence. Unfortunately, personal, and social barriers involvement hinder pregnant women to perform PFMT. Therefore, a Kegel Exercise Pregnancy Training (KEPT) app was developed to bridge the accessibility barriers among incontinent pregnant women. This study aimed to evaluate the usability properties of the KEPT app developed for pregnant women to improve their pelvic floor muscle training. A purposive sampling method of the experts was conducted from a sample of experts in informatics and a physician with a special interest in informatics. The design activities were planned in the following sequence: cognitive walkthrough for learnability of the app, heuristic evaluation for the interface of the app and usability questionnaire to evaluate the usability properties (quantitative assessment) of the app. The mHealth application usability questionnaire (MAUQ) was used as its assessment tool to assess the application usability. A total of four experts were involved in this study. Cognitive walkthrough revealed that the KEPT app has several major learnability issues especially the training interface and language consistency to ensure its learnability. Heuristic evaluation showed that the training interface must provide additional information regarding the displayed icon. KEPT app was rated by MAUQ being as ease-of-use, the interface and satisfaction with the usefulness by all the experts which scored 5.80/7.0, 5.57/7.0, and 5.83/7.0, respectively. The suggestions were shared to assist future researchers and developers in developing PFMT mHealth app.

**Keywords**—Pregnant women; pelvic floor muscle training; mHealth app; usability evaluation; cognitive walkthrough; heuristic evaluation

## I. INTRODUCTION

Urinary incontinence (UI) is an involuntary urine leakage [1]. UI commonly occurs about 40% among pregnant women and negatively affects their quality of life [2–4]. Unfortunately, despite UI affecting their daily activities, only one-tenth of pregnant women seek help due to the misperception that UI would resolve by itself [5]. Therefore, correct information on UI and its management by performing regular pelvic floor muscle training (PFMT) should be available for pregnant women.

However, there were barriers in delivering the PFMT health information to pregnant women. The issues such as healthcare providers focusing on a higher priority medical illnesses in pregnancy or antenatal services midwives have busy workloads in a service structure hindrance the health education to pregnant women [6]. Additionally, pregnant women tend to normalize and perceived that the incontinence is normal during pregnancy and will disappear after the delivery of their baby [7]. An alternative method in delivering health education is needed to educate pregnant women effectively according to their time and their availability.

Recently, smartphones gaining its popularity and has become a daily used items the most popular mobile technology. People tend to multitask using their smartphones seeking the information through smartphone applications conveniently. Additionally, they were able to search and confirm information while they use various other media or smartphone applications simultaneously [8]. The multitasking element enable the mobile health app becomes trending nowadays. Mobile health (mHealth) apps have been shown to be one of the rising in literature in sharing health information and education across several diseases. Unfortunately, mHealth apps demonstrated weak evidence in its effectiveness which may be improved in the evaluative approaches to the development and assessment of the health care improvement apps [9].

Motivation of this research is to conduct a rigor evaluation on the development of the app to ensure the usability and its effectiveness. This study aims to evaluate a newly developed mHealth application (Kegel Exercise Pregnancy Training or KEPT app) which was designed and developed to improve the delivering pelvic floor muscle strength health education to pregnant women. The specific objectives of the study are:

- 1) To understand the heuristic evaluation, cognitive walkthrough, and usability evaluation of the KEPT app from the experts' evaluation.
- 2) To suggest the improvement for the KEPT app for better usability.

## II. RELATED WORK

### A. PFMT and Pregnant Women

PFMT or Kegel exercise is an important exercise among pregnant women to strengthen their pelvic floor muscles [10], which enables them to prevent UI during their advance trimester and early postpartum period [11]. Despite having good knowledge of PFMT, the practices are still low [4]. This finding suggests that incontinent pregnant women with good PFMT knowledge are not practicing PFMT or those practicing PFMT may be less likely to perform it correctly. Pregnant women need to tailor the PFMT according to their schedules to improve its adherence.

There are a few hiccups in delivering PFMT to the pregnant women at the primary care clinics in this country. There was a dedicated physiotherapist scheduled monthly in certain clinics and for some clinics, the selected pregnant women met in a group session once or twice per year. Unfortunately, these sessions could be troublesome for some pregnant women who are busy managing their family and work at the same time. Furthermore, with the current COVID-19 pandemic, the number of daily attendances has been reduced to avoid the crowdedness in the clinic and abide with the social distancing protocol. Therefore, a carefully designed digital health intervention (mHealth app) has the potential to disseminate PFMT and improve the adherence of these women to manage their UI especially among primigravida with stress UI [12].

### B. Expert Evaluation

To ensure the quality of mHealth app, usability concept or assessment need to be assessed [13,14]. Usability evaluation or inspection is the generic name for a set of cost-effective ways of evaluating user interfaces to find usability problems [15]. Usability is defined when an app can be well understood, easily operated and has its unique attraction to the users in order to accomplish certain tasks in specific environments [16,17]. Hence, usability is also mentioned as being feasible and acceptable to be effective in changing mHealth lifestyle [18].

Nielsen explained that there are four basic ways in evaluating user interface such as via automatically (usability measures computed by running a user interface specification through some program), via empirically (usability assessed by testing the interface with real users), via formally (using exact models and formulas to calculate usability measures), and informally (based on rules of thumb and the general skill and experience of the evaluators) [15].

Additionally, the recruitment sampling of the experts is crucial whereby the experts can be either the academicians with software design (mobile application) or clinician with a special interest in mobile apps who are not from the researcher's team as the usability evaluators. Three to five experts are recommended for the usability testing for heuristic evaluation (user interface) in major issues detection [19]. In this study, we will focus on three types of usability evaluations: cognitive walkthrough, heuristic evaluation, and usability testing.

### C. Cognitive Walkthrough (CW)

Cognitive walkthrough (CW) by the experts were evaluated on the difficult task to add more depth for critical assessments [20]. CW utilizes accurate detailed procedures to simulate a user's problem-solving process at each step through the dialogue or user interface, to study whether the simulated user's goals and memory content can be assumed to direct the users to perform the next correct action [15].

To assist the experts, a persona is used for them to understand the user's characteristics and literacy in using the mobile application. Persona is defined as, "memorable representations of users that remain conspicuous in the minds of those who design and build products" [21]. Persona consists of specific facts, has a concrete representations of target users, which in this study is pregnant women. Persona is constructed in an engaging, and actionable image which provides as a design target. Persona's main role is to assist the experts to be more user focused.

The users, being complicated and varied took great effort to be understood with their health conditions, needs, and behaviors. The experts who were not from the users' socio-economic background faced difficulties to imagine and understand the users' behavior and challenges using the app. Without preliminary informative such as persona, it is more likely the experts imposed their assessment based on their own perspective and not from the users'. If the researcher and developer proceed with these findings, it will be a non-user centered app which may affect the users' involvement and jeopardize their targeted behavior changes.

### D. Heuristic Evaluation (HE)

There are challenges in creating mobile learning applications since smartphones or mobile devices built-in with small screen size, small memory, lack of input capability, and limited processing power [22]. Nielsen (1994) proposed ten heuristic evaluations to detect user interface problems cost-effectively: a) visibility system status; b) system matched with real world; c) user control; d) consistency; e) error prevention; f) recognition than recall; g) flexibility; h) aesthetic and minimalist; i) learning retention; and j) documentation.

Additionally, Kumar and Goundar (2019) added three new heuristics assessment for mobile learning applications. This is because, smartphone has limited function such as the small screen, despite its almost always accessible. The assessments included were: a) selection driven commands; b) content organization; and c) visual representation [23].

Furthermore, the mobile applications included health intervention. Hence, to further assess the heuristic element in this study, Khowaja and Al-Thani (2020) suggested a questionnaire which is called "Heuristic Evaluation of mHealth Apps (HE4EH)" to be used. HE4EH consisted of 25 checklist items, where the most relevant to this study were the self-monitoring and behavioral change items to evaluate the interface according to its objective [24].

### E. Usability Questionnaire (UQ)

There were a few validated questionnaires which can be used to evaluate the usability of an app, for example, the System Usability Scale (SUS) [25], and Post-Study System Usability Questionnaire (PSSUQ) [26]. However, a recent usability questionnaire has been developed and validated to assess usability of an mHealth app which is called the “mHealth App Usability Questionnaire (MAUQ)” [27] which has three domains focusing on the ease of use, interface and satisfaction, and usefulness of the mHealth app [27].

SUS is a ten-item questionnaire using a Likert scale, which assess a global view of usability assessments. The aim was to obtain a quantitative assessment, which was conducted based on general agreement that the evaluated system was “really easy to use”. The user must be given a chance to use the “system” in the first place. After that, the user must assess the “system” using SUS before any debriefing session. The user is required to record their immediate response to each item without any hesitancy [25].

PSSUQ indicated a 3-factor structure consistent with usability that initially described factors for System Usefulness, Information Quality, and Interface Quality. This questionnaire was used to assess the user satisfaction after participation in a scenario-based usability [28]. The 18 questions-assessment was based on a seven-point Likert scale from “Strongly agree” for 1 and “Strongly disagree” for point 7. However, these two usability questionnaires were not specifically designed for the mobile health app usability.

Hence, recently, a usability questionnaire has been developed and validated to assess 18-usability properties for the mobile Health app which is called as mHealth App Usability Questionnaire (MAUQ) [27].

### III. KEGEL EXERCISE PREGNANCY TRAINING APP

Kegel Exercise Pregnancy Training (KEPT) app was developed from a combination of Persuasive Techniques and Capability, Opportunity, Motivation-Behaviour model. It was developed using Interviewing Mapping which embedded in a user-centered design using UCD-11 framework [29]. KEPT app runs on Android platform only.

This KEPT app encouraged pregnant women to train their pelvic floor muscle according to their daily schedule and individual capability. It has five user interfaces; (1) educational video - to deliver the PFMT training sessions (Fig. 1), (2) calendar charting for user interface UI symptoms, (3) training mode stopwatch assistance, (4) progress chart to self-monitor progress, and (5) Frequently Asked Question (FAQ) for information sharing regarding correct method in PFMT.

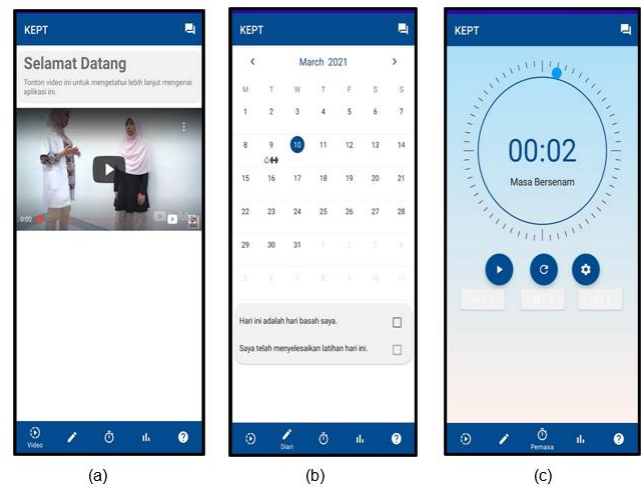

Fig. 1. Some of the KEPT App user Interfaces (a) Educational Video; (b) Calendar Charting; (c) Timer Exercise.

### IV. METHODS

The ethical approval was obtained from Ethics Committee for Research Involving Human Subjects, Universiti Putra Malaysia (JKEUPM-2019-368) and Medical Research and Ethics Committee (MREC), Ministry of Health Malaysia (NMRR-19-412-45606) before the commencement of the study.

#### A. Expert Evaluation

A total of six academics and one from the industry were invited as experts of the study. However, only four academics were agreed to become the experts in this study as listed in Table I. The study was conducted at their own time allocated and their own place.

The experts were required to evaluate the application in three sections; (a) cognitive walkthrough; (b) heuristic evaluation; and (c) usability questionnaire (Fig. 2).

TABLE I. EXPERT’S LIST

ID	Age and Gender	Ethnicity	Experts
E1	44/ Female	Malay	Senior Lecturer, Centre for Software Technology and Management, Public University
E2	41/ Male	Malay	Associate Professor, Science and Technology System, Public University
E3	42/ Female	Chinese	Associate Professor, Department of Family Medicine, Public University
E4	44/ Female	Malay	Associate Professor, School of Multimedia Technology and Communication Educational Multimedia, Public University

Fig. 2. Expert Evaluation Tasks.

### B. Cognitive Walkthrough (CW)

At the beginning of the session, a persona was introduced to the expert which was adopted from the previous study (Jaffar et al., 2020) to help the expert to understand the situation of a pregnant woman's experience of urinary incontinence as below.

- **Background.** Mrs Aida, a 38-year-old housewife, has a history of being unable to control her urination (urinary incontinence) for a month. She is currently pregnant (unplanned pregnancy but wanted), with her fifth pregnancy at 34 weeks.
- **Medical condition.** Mrs Aida has anaemia in all pregnancies, including this current pregnancy. She sometimes skipped her meals as she had no time to have lunch and suffered from gastritis.
- **Psychological.** Mrs Aida is stressed about her current pregnancy as she is having incontinence and busy managing her family. She felt tired quickly and suffered poor sleep. In the morning, Mrs Aida needs to prepare breakfast and rush to send her kids to school and manage house chores. She has to take care of her 12-year-old son, 10-year-old girl, 9-year-old son and 8-year-old-son.
- **Level of health literacy.** Mrs Aida does not know about urinary incontinence, and she thought it is “normal” during the pregnancy period and during post-natal.
- **Social.** Her husband is a technician and is seldom at home as he has another job (Grab-food delivery) to support the family.
- **Technological literacy.** Mrs Aida used her handphone to make phone calls, WhatsApp, and recently online meeting platform for her children's online schooling using her mobile data. She does not have any social media apps. She claims she has no time to use her phone and only uses her phone to make a call only or for her children's school activities.

- **Relationship with healthcare providers.** She has a good relationship with them and will try her best to follow their advice. She received a food basket from the clinic for her children as they have been diagnosed with malnourishment.
- **Information preferences.** Mrs Aida prefers watching videos, especially when it involves an expert. Unfortunately, her educational status was until secondary school, and she could not absorb too much information at one time.
- **Current issue.** Mrs Aida just downloaded the “Kegel Exercise Pregnancy Training” app (KEPT app) as she seriously wants to control her urination. She is very busy managing her daily chores and does not have time to go for a physiotherapist appointment. She hopes that using this app can help her remind her of the exercise (despite her busy daily schedule) and manage her urinary incontinence.

After understanding the persona, experts were required to interact with the application and performed the following tasks: (a) to sign-up; (b) to watch the video; (c) to do charting (self-monitoring); (d) to perform PFMT; (e) to submit feedback; and (f) to log out the app.

Then, experts were asked to evaluate the application based on the following criteria: (a) major issues - important to fix with high priority; (b) minor issues - to fix the problem with low priority; and (c) no usability issues - may fix if time is available.

### C. Heuristic Evaluation (HE)

During the heuristic evaluation session, experts were asked to rate the interfaces of the application based on 15 items. The first ten questions were based on Nielsen (1994) and adopted by Kumar et al., (2019), the next three questions emphasized on the mobile learning by Kumar and the last two questions were adopted from mobile health apps evaluation by Khowaja et al., (2020) which focus on the behavioral changes and self-monitoring [15,23,24]. The experts assessed the interface using the given rating-scale: [1] to denote a usability disaster; [2] a major problem; [3] a minor problem; [4] a superficial problem; and [5] not a problem at all [23].

#### 1) Ten-Heuristic [15]:

- **Visibility of the system status** whereby the user was given the appropriate feedback.
- **Match between the system and real world** which enable users to identify the elements of the application.
- **User control and freedom** that allowing the users to go different menus easily.
- **Consistency and standards** to ensure the consistency of the application.
- **Error prevention** whereby the users can recover from their errors.
- **Recognition rather than recalls** minimizing the user's memory load while using the apps.

- Flexibility and efficiency of use whereby the app can be adjusted by anyone.
- Aesthetic and minimalist design by removing the unnecessary information.
- Help users recognize, diagnose, and recover from errors to allow user's learning retention.

2) Mobile learning (Kumar & Goundar, 2019):

- Help and documentation whereby the app can assist the users in learning.
- Selection driven commands whereby the users engage with the apps.
- Content organization as the app can highlight the key objectives.
- Visual representation on the usage of the icons to assist the users understanding.

3) Mobile health app (Khowaja & Al-Thani, 2020):

- Behaviour changes included the app's design that gradually starts with easy tasks, until target behavior is performed.
- Self-monitoring with several specific steps to self-monitor their expected outcomes.

D. Usability Questionnaire

Finally, all experts were instructed to answer a set of questions which covered three main domains such as, the ease of use, interface and satisfaction, and the usefulness of mHealth apps using the mHealth App Usability Questionnaire [27]. The experts rated each of the items using a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree).

Zhou et al (2019) listed three main domains for usability assessment in mHealth app which are ease of use (5 questions), interface and satisfaction (7 questions), and usefulness (6 questions). The overall Cronbach alpha was 0.932, which scored 0.895, 0.829, and 0.900, for ease of use, interface and satisfaction, and usefulness, respectively.

All participants' names were replaced with an identification code. The CW reports were extracted from the word documents. The feedback from the experts was analyzed based on the severity of the issues. The suggestions were then reported, and the clarification was made directly to the experts for better understanding.

HE and UQ data were analyzed descriptively using the SPSS 26.0 to report the mean, median and standard deviation. Similarly, the suggestions from the experts have been recorded.

V. RESULTS

A. Cognitive Walkthrough (CW)

The experts listed a few major issues from the cognitive walkthrough method with the most major issue being the training interface. Training PFMT had four major issues which signified the lack of clarity and self-explanation of the training

section. However, there was heterogeneity of the assessments by the experts whereby E4 detected more major issues compared to others while E2 detected the least issues. The compilation of the reports as listed in Table II.

TABLE II. COGNITIVE WALKTHROUGH

Task	Issues and recommendation
To sign-up	<p>E1: Major Issue: Font on registration text boxes (active boxes) faded. Difficult to read. Recommendation: Change active text box font colour.</p> <p>E2: Cosmetic: Good and clear instruction</p> <p>E3: Minor issue: The (!) mark at the end of the email address said invalid email address. Recommendation: 1. The comment should read "Awaiting admin approval" instead of "invalid email address". If the app is in Malay, the comments should be in Malay as well. 2. Add a checkbox for the app to remember login details for users who have problems with remembering passwords. 3. Guided tutorial for new users on identifying the main sections of the app.</p> <p>E4: Major issues: (a) Create account, The instruction was not functioning/ clickable Recommendation: Need to fix or omit the function as it will not mainly affects the registration form (b) Patient Information Sheet Instruction was not given on how to use the KEPT apps. Recommendation: Need to give a user manual via video demo on how to use/operate the KEPT apps. The given video was about to educate the Kegel Exercise demo but not on the KEPT apps itself.</p>
The video	<p>E1, E2 and E3: Cosmetic problem only</p> <p>E4 Major issue: (a) The physiotherapist was mentioned about "imagine the muscle contraction as eating the spaghetti" in the video but the FAQ did not mention this. Recommendation: To consistently use terminology with the physiotherapist in the FAQ. (b) The name of the app was provided in the English acronym as KEPT (Kegel Exercise Pregnancy Training) but the main language used in the apps is in Bahasa Malaysia. Recommendation: It is recommended to standardize in using only one language -Bahasa Malaysia due to the main language used in this apps is in Bahasa Malaysia</p>
The charting (self-monitoring)	<p>E1, E2 and E3: Cosmetic problem only</p> <p>E4 Major Issues: (a) The language used was in English and reflects the inconsistency issue. Recommendation: Need to consistently use Bahasa Malaysia instead of using mixed languages. (b) The statement of "I have done the exercise today" was not clickable. Recommendation: Need to fix or omit the function based on the functional requirement of the apps. (c) The status of "total wet day" and "Total Day Completed exercise" were confusing as not showing any status. Recommendation: Need to omit the status based on its confusion.</p>

The Training	<p>E1 and E2: Minor issue: Difficult to understand</p> <p>E3: Minor Issue: The cogwheel icon is placed last in the row of buttons. There is no description for its function, which is to set the difficulty level. Recommendation: Place the cogwheel icon first before the play button. Label it as difficulty level.</p> <p>E3 Major Issues: (a) There is no explanation on the timer. Users may not know that they are supposed to do the exercise while the timer runs. Users cannot see how many times they have done the exercise for each set. Recommendation: Need to have instruction before start, that this page is for the exercise. 2 second timer for ready, 6 second timer for contracting muscles. Should have a counter to show completion of each set. Example: 1/6, 2/6 (b) User does not know whether the exercise was done correctly or not. Recommendation: Tips or Cues on knowing whether done correctly. Prompts to say you need to complete ... number of sets to complete today's exercise. (c) I am not sure of the function of the reset button. Recommendation: Explanation on what the reset button is for.</p> <p>E4: Major issue (a) Set 1, Set 2 and set 3 menus were not functioning, and also got typo error. Recommendation: Need to fix or omit the function based on the functional requirement of the apps.</p>
The Feedback	<p>E1- no issue E2: Cosmetic problem only Recommendation: More infographics to make interesting</p> <p>E3: Cosmetic problem: A question mark icon usually represents the help button in most apps. Here it is representing the questionnaire. Recommendation: Use the pen or notepad icon for questionnaire instead of question mark.</p> <p>E3 Minor issues: (a) Users may not know when to fill in the questionnaire. No reminder for the user of which timing to choose. (b) If the user chooses the wrong timing, not sure of how to get back to the main questionnaire screen. Recommendation: 1. Built in calendar tracking for the day of first use. Reminder to fill in a questionnaire at time points from new user registration. 2. Add instructions to the user: To go back, tap on the questionnaire icon again.</p> <p>E4 Major Issue: There was no instruction given on that page. The use of 'app' in the labelling was not suitable. Recommendation: Need assistance or cue on what to do on that page Replace the 'app' with the name of the app</p>
The Logout	<p>E1, E3 and E4 Major Issue: I cannot find the logout button. Recommendation: Logout button, account profile should be visible somewhere. Need to provide an exit/log in back widget in the app.</p>

**B. Heuristic Evaluation**

Similarly, as the CW, there was heterogeneity of the HE among the experts as illustrated in Fig. 3. The lowest score of user interface was the “visibility-provide feedback” which has been expected as this app is a standalone app without any direct communication to the healthcare providers. The highest

user interface score was the behavior change element which highlights that the KEPT app was able to encourage the users to change their behavior in a real-world situation with the user’s compliance. Therefore, the HE results may conclude that the KEPT app interfaces have been designed in an acceptable manner to assist the users’ PFMT adherence as listed in Table III.

Fig. 3. Heuristic Evaluation Expert’s overview.

TABLE III. HEURISTIC EVALUATION

Heuristic assessment	Mean (SD)	Heuristic assessment	Mean (SD)
1. Visibility of system status	3.00 (0.82)	9. Help users recognize diagnose and recover from errors	3.50 (0.58)
2. Match between system and real world	3.50 (1.29)	10. Help and documentation	3.25 (1.26)
3. User control and freedom	4.00 (1.15)	11. Selection driven commands	3.75 (1.26)
4. Consistency and standards	3.75 (1.26)	12. Content organization	3.75 (1.26)
5. Error prevention	4.00 (0.82)	13. Visual representation	4.25 (0.50)
6. Recognition rather than recall	3.75 (0.96)	14. Behaviour change	4.75 (0.50)
7. Flexibility and efficiency of use	3.75 (0.50)	15. Self-monitoring	4.00 (0.82)
8. Aesthetic and minimalist design	4.00 (0.82)		

**C. Usability Questionnaire (UQ)**

The usability questionnaire assessment was scored with “somewhat agree” to “agree” across all three components. (Tables IV, V, and VI). The average for “Ease of use”, “Interface and satisfaction”, and “Usefulness” scored 5.80/7.0, 5.57/7.0, and 5.83/7.0, respectively.

The “Ease of Use” scored highest among the three domains denotes that the app has simplicity in its design (Table IV). These results concluded that the KEPT app was easy and useful among pregnant women with several modifications needed to specific interfaces, especially the organization of the

information and acknowledgement from the app when the users completed their tasks (Table V). The experts agreed that KEPT app was a useful app in behavioral changes and healthcare services as listed in Table VI.

The least scores were: (1) The information in the app was well organized, so I could easily find the information I needed; (2) Whenever I made a mistake using the app, I could recover easily and quickly; and (3) I could use the app even when the Internet connection was poor or not available.

TABLE IV. EASE OF USE

	MAUQ: Ease of Use	Mean (SD)
1.	The app was easy to use.	5.75 (0.96)
2.	It was easy for me to learn to use the app.	5.50 (1.29)
3.	The navigation was consistent when moving between screens.	6.00 (0.82)
4.	The interface of the app allowed me to use all the functions (such as entering information, responding to reminders, viewing information) offered by the app.	6.25 (0.96)
5.	Whenever I made a mistake using the app, I could recover easily and quickly.	5.50 (1.29)

1 - strongly disagree, 2 - disagree, 3 - somewhat disagree, 4 - neither agree nor disagree, 5 - somewhat agree, 6 - agree, 7 - strongly agree

TABLE V. INTERFACE AND SATISFACTION

	MAUQ: Interface and satisfaction	Mean (SD)
1	I like the interface of the app	6.25 (0.50)
2	The information in the app was well organized, so I could easily find the information I needed	5.00 (1.41)
3	The app adequately acknowledged and provided information to let me know the progress of my action.	5.25 (1.50)
4	I feel comfortable using this app in social settings.	5.50 (1.29)
5	The amount of time involved in using this app has been fitting for me.	5.50 (0.58)
6	I would use this app again.	5.75 (0.50)
7	Overall, I am satisfied with this app.	5.75 (1.26)

1 - strongly disagree, 2 - disagree, 3 - somewhat disagree, 4 - neither agree nor disagree, 5 - somewhat agree, 6 - agree, 7 - strongly agree

TABLE VI. USEFULNESS

	MAUQ: Usefulness	Mean (SD)
1	The app would be useful for my health and well-being.	6.25 (0.96)
2	The app improved my access to healthcare services.	5.75 (0.96)
3	The app helped me manage my health effectively.	6.00 (0.82)
4	This app has all the functions and capabilities I expected it to have.	6.00 (0.82)
5	I could use the app even when the Internet connection was poor or not available.	5.00 (2.71)
6	This mHealth app provides an acceptable way to receive healthcare services, such as accessing educational materials, tracking my own activities, and performing self-assessment.	6.00 (1.41)

1 - strongly disagree, 2 - disagree, 3 - somewhat disagree, 4 - neither agree nor disagree, 5 - somewhat agree, 6 - agree, 7 - strongly agree

From these assessments, the team suggested with list of improvements such as, (1) to arrange the interface according to the user’s daily PFMT activities and monitoring steps; (2) to explain the “undo” icon; and (3) to inform to the users that the app can functioned without the internet access. They need the internet connection only when submitting the questionnaires.

## VI. DISCUSSION

This study investigated the usability of a newly user-centered PFMT app designed and developed for pregnant women with urinary incontinence. Three types of usability assessment used were the cognitive walkthrough, heuristic evaluation, and usability questionnaire. There were a few difficulties in learning of the KEPT app for example, the organization of the information, and the PFMT interface whereby the users are expected to perform three times daily. This usability evaluation was able to assist the researchers to improve the app’s design for better acceptability and usability in the KEPT app prototype for its pilot study [30].

The main objective for the KEPT app was to provide opportunities to pregnant women with UI to perform PFMT at their own convenience. It was crucial to ensure pregnant women have the confidence and understanding of the importance of PFMT especially so when they are experiencing UI. Studies reported that pregnant women face few barriers from either their own misunderstanding, lack of knowledge, lack of support from their partners and from the healthcare providers [6,7,31].

There were several key findings which could be divided into the learnability using the app, the elements of its user interface, and the usability issues of the app.

1) *Learnability of the app:* Most of the assessors were concerned about the organization of the apps and its training mode function. Poor organization of the app with lack of user manual to inform what the function of the icon and how the app works interfered with the understandability of using the app.

User manual was important to provide an overview of the app and the guidance using the app. Similarly, a mHealth app related with self-managing chronic heart failure among elderly reported that they appreciated having an instruction user manual prior to using the apps [32]. However, not all users used the instruction manual to understand the apps as some of them preferred to try a few times and be able to understand the functionality of the app [33]. Nevertheless, by having a manual it provided advantages to the users an option to read for better understanding of the app even to the professional users [34]. Hence, to improve the understanding of KEPT apps, a user’s manual will be added at the top right corner for the users’ better accessibility.

Another major concern by the experts was the lack of clarity in the training mode. The poor visibility of each icon and its function disrupt the understanding of the PFMT process. Clarity is crucial in understanding the functionality of the app especially when it involves behavioral change, for example apps for exercise or physical training. Lack of clarity will affect the user's understanding and further perceive it to be

difficult. Perceived ease of use has been highlighted by the Technology Acceptance Model (TAM) as the main domain to contribute to the actual use of the app [35,36]. Therefore, to ensure the daily use of the apps, the training mode needed to be re-designed for better clarity.

2) *User interface of the app*: Using heuristic evaluations, the experts who were providing their evaluation on the issues of the problematic user interface, were also supplementing their suggestions in their report. The insightful feedback was gathered, and further discussion will be made to improve the user interface system design for better clarity and ease of use by the users.

Another finding was the consistency using the Malay language in the KEPT app to better be understood by the users was highlighted. Consistency is one of the ten heuristic elements by Nielsen [15]. Without consistency, the flow of the app was disturbed and causing frustration to the users. Being difficult in understanding about the app leading to perceived lack of usefulness and affecting the user's attitude and behavior to use the app (TAM). Hence, the future KEPT app must have a consistency using Malay language throughout the apps.

The user interface for training was lack of clarification. There was no indicator to signal to the users on their current repetition out of ten for each set of PFMT. The expert suggests making it visible by proportion of the total set. Another major issue, they faced difficulty in understanding the training interface to be setting according to the user's PFMT ability. Therefore, their suggestions were to ensure the training mode interface is easy to understand, with the indicator showing the user's current exercise. The design needs to be simple, zero interruption, and able to record the data to the backend system without any disruption.

3) *Usability of the app*: The KEPT app was evaluated with "somewhat agree" in terms of its easy to use, good interface and satisfactory and useful as the overall overview. This signified that KEPT app development has proved its importance and could possibly improve the user's PFMT after its actual use in future. The usability questionnaire results confirmed the finding from CW and HE. Positive feedback from the result was that it scored high in its usefulness. This signals that the app might be able to improve the PFMT adherence among pregnant women through daily usage.

Therefore, the key findings when developing a mobile health (mHealth) app for pregnant women with an incontinence can be listed as the manual instruction for the users is crucial, the training interface should be designed with simplicity, and Malay language to be used throughout all the UI. Additionally, the arrangement of the icon interface should be arranged according to the users' daily activities for better systematic organization.

This usability assessment has limitation such as the session was conducted individually and not face to face with the researcher. The session was due to the restriction movement order that hinder the researcher to meet the experts. Hence, there could be issues due to technical problem such as incompatibility of the application with Android devices.

## VII. CONCLUSION

The KEPT app was developed to educate incontinent pregnant women to perform PFMT. This paper aimed to evaluate the usability properties of the app from the experts' point of view. KEPT app should be design with an efficiency, effective, and provides the users with the required information. Firstly, by conducting the cognitive walkthrough to understand and analyze the ability of the app to make the users complete their task. Next, heuristic evaluation which assessing the user interfaces available in the KEPT app conform with certain important guidelines for better usability properties.

Finally, the usability questionnaire evaluation conducted with the experts showed encouraging findings of its ease of use, interface and satisfaction, and usefulness. Nevertheless, the usability assessment indicated that a few interfaces of the KEPT app need to be improved. The organization of the interfaces, consistent Malay language usage, and system design for the training interface need to be improved according to the recommendations.

Few necessary iterations will be conducted to re-design the application prior to this usability evaluation. This study was the first usability evaluation PFMT mHealth app for pregnant women found in the literature and to the best of our knowledge such a study has not been conducted. The next step is to develop the KEPT app by improving the usability problems which were highlighted and suggested from the experts.

We hope that the findings in this study will be of assistance to other researchers in their future studies in developing the PFMT mHealth app.

## ACKNOWLEDGMENT

The authors thanked the team of experts for their contributions in evaluating the KEPT app comprehensively. This research was supported and funded by the Geran Putra Berimpak Universiti Putra Malaysia (UPM/800—3/3/1/GPB/2018/9668500).

**Abstract**—Information systems are intended to provide organisations with a new way of sustaining themselves, by helping them manage their activities using innovative technologies. Information systems require aligned levels for maximum effectiveness. In this context, business and information technology (IT) alignment is an important issue for the success of organisations. This paper presents the first step of the proposed approach to align the software system level, modelled by a Unified Modeling Language (UML) class diagram, with the business process level, modelled by the Business Process Model and Notation (BPMN) model. A model-driven architecture approach is proposed as a means to transform a set of BPMN models into a UML class diagram. A set of transformation rules is proposed, followed by guidelines that help apply those rules.

**Keywords**—Information system alignment; business process; software system; Business Process Model and Notation (BPMN); Unified Modeling Language (UML); class diagram

## I. INTRODUCTION

The effective operation of organisations requires an approach that assesses and corrects ambiguities between its different entities. In fact, an alignment approach has become crucial for the continuity of organisations' information systems, as it provides solutions to problems associated with the diverse changes that may occur in these organisations' entities. Several previous studies have examined the subject of business/IT alignment [1]–[5]. The analysis and proposed approach described in this paper are based on the relevance of alignment in various situations. Indeed, in practice, an information system with aligned levels may undergo changes in one of these levels due to the improvement of goals or other factors. As a result, the levels will become misaligned. In another context, the levels of an organisation's information system may be modelled by different teams. Each team may then have a different perspective regarding the system, which can also result misaligned levels. Another example is the case of two organizations that merge in such a way that their levels may be of different natures. As a consequence, the resulting information system will contain levels that are not aligned. For all the mentioned situations, it seems to be a strong necessity to apply an alignment approach in order to have a successful information system.

In this context, approaches of related work based on business process and software system levels are analysed through this paper. Afterwards, an alignment approach is

proposed. The first step of this approach consists of providing a series of rules to transform a set of Business Process Model and Notation (BPMN) models into a Unified Modeling Language (UML) class diagram, based on model-driven architecture (MDA).

The proposed approach contributes to the existing literature by transforming a series of source-level models that contain a significant number of BPMN elements into a UML class diagram. Moreover, the proposed approach provides a method for preserving target level information.

This paper is organised as follows: Section II presents the background of the topic; it introduces the concept of alignment and transformation through MDA. Section III provides a brief overview of related work, while the proposed approach is presented in Section 0. Section V of this paper presents a case study. Finally, a conclusion describes the future work.

## II. BACKGROUND

### A. The Concept of Alignment

Alignment is an important topic that has been of interest for decades. Various expressions have been used to describe it in the existing literature. Chan [6] uses the terms fit and synergy. Henderson and Venkatraman [7] employ the terms fit, integration, and interrelationships. Reich and Benbasat [8] use the word linkage. Ciborra [9], defines alignment as a bridge. Smaczny [10] describes it as fusion. Luftman [11] uses the term harmony, and Nickels [12] names it congruence.

According to Ullah [5], alignment between business and IT concerns “the optimized synchronization between dynamic business objectives/processes and respective technological services provided by IT”. For Luftman [11], business-IT alignment consists on the application of IT in a timely and a suitable manner, in harmony with business strategies, goals and needs. This definition of alignment considers: the way that IT is aligned with the business, and the way the business should or might be aligned with IT.

In the current work, alignment of a target level with a source level is defined as a method that ensures the continued operation of the target level, while remaining suitable to the source level.

### B. Transformation and Model-Driven Architecture

Model-driven engineering considers models to have a very important role in software development. In this context, the

Object Management Group (OMG) made their MDA initiative public [13]. Fig. 1 presents the model transformation concept [14] recommended by MDA. The model transformation takes a source model that conforms to its source metamodel and a target metamodel as input. It then uses a set of transformation rules to generate as output a target model that conforms to the target metamodel as output.

Fig. 1. Concept of Transformation in MDA [14].

### III. RELATED WORK

In the previous work [15], a pattern system was proposed as a guideline, to help organisations apply the alignment. The systematic literature review conducted by Habba et al. [16] identified various approaches of alignment of business requirement, business process and software system levels, that use different modeling languages.

We focus on UML and BPMN languages because they are standards defined by the Object Management Group (OMG). More precisely, in this paper, we focus on a business process level modelled by BPMN and a software system level modelled by a UML class diagram.

BPMN and class diagrams are subjects of interest in different approaches. Amr et al. [17] propose an MDA approach for transforming a BPMN source model into a UML class diagram, using a set of transformation rules. Brdjanin et al. [18] present an approach for the automated generation of a conceptual database model represented by a UML class diagram, from one BPMN model. Brdjanin et al. [19] take a set of business process models into account. Khelif et al. [20] describe an approach to transform a business process model into a class diagram, based on semantic and structural aspects. Rhazali et al. [21] suggest a set of transformation rules for transforming a BPMN model into a use case, state and class diagrams. Cruz et al. [22] propose an approach to obtain a data model from a business process model. Cruz et al. [23] present rules to transform a set of business process models into a data model. Kriouile et al. [24] describe an approach to transform a BPMN model into a domain class model. Bousetta et al. [25] propose an approach to building a domain class diagram, based on a BPMN model, using a set of business rules.

In organisations, models of both levels usually exist. The aim, therefore, is to align them. By analysing existing approaches, we notice that:

- Existing approaches propose transformation from the source level into the target level. However, an approach-based transformation is not always sufficient to apply alignment when business process and software system models exist. In fact, this approach causes a loss of information. Fig. 2 presents the result of applying one of the existing approaches when models exist in an organisation. M1 represents the business process level model and M2 is the software system level model. The existing approaches generate a new UML class diagram (M2') that is different from model M2. Therefore, information associated with the existing UML class diagram will be lost.

Fig. 2. Application of an Existing Approach.

- The majority of approaches take one model at the source level into consideration. Only two approaches ([19] and [23]) have achieved transformation using a set of BPMN models as a source. However, operations are not considered in the metamodel of the target model. (Table I, columns 3 and 6).
- The existing approaches do not consider all BPMN elements, such as all types of tasks and all types of data, in the source model (Table I, columns 4 and 5).

We synthesize the existing approaches in Table I, according to the criteria below:

- Preserving information: This column indicates if the proposed approach can be executed when the models of the two levels exist in the organisation.
- Considering a set of BPMN models: This column indicates if the proposed approach considers a set of BPMN models in business process level.
- Considering all types of tasks: This column indicates if the approach considers all types of tasks in the source model or not.
- Considering all types of data: This column indicates if the approach considers all types of data in the source model or not.

- Considering operations: This column indicates if the approach considers all types of data in the target model or not.

In Table I, Y shows that the criterion is considered.

TABLE I. SYNTHESIS OF APPROACH

Ref.	Preserving information	Considering a set of BPMN models	Considering all types of tasks	Considering all types of data	Considering operations
[17]	-	-	-	-	Y
[18]	-	-	-	-	-
[19]	-	Y	-	-	-
[20]	-	-	-	-	Y
[21]	-	-	-	-	Y
[22]	-	-	-	-	-
[23]	-	Y	-	-	-
[24]	-	-	-	-	Y
[25]	-	-	-	-	-

This analysis of existing approaches reveals the need for an alignment approach that preserves target level information, considers a large number of BPMN and UML elements, and uses a set of BPMN models as a source.

#### IV. PROPOSED APPROACH

##### A. Overview of the Proposed Approach

The aim of the proposed approach is to reduce the gap between the business process level and the software system level of an organisation, without losing information. The business process level is modelled using a set of BPMN models. It may be composed of a set of collaboration diagrams and expanded sub-processes, and it contains a high number of metamodel elements. The software system level is modelled by a UML class diagram. Fig. 3 illustrates a representation of the proposed approach. We assume that the organisation has two levels, composed of a set of BPMN models and one existing UML class diagram. The organisation needs to align the software system level with the business process level. The proposed alignment approach encompasses two steps:

1) *Step 1: Transformation.* This step consists of the application of rules to transform a set of BPMN models into a generated UML class diagram. It considers the important elements of the BPMN metamodel and the UML class diagram metamodel, including all types of tasks and all types of data.

2) *Step 2: Composition.* This step consists of creating a fusion between the UML class diagram generated in step 1 and the existing UML class diagram. The result is a final UML class diagram that will represent the software system level, which is aligned with the business process level.

By applying the two steps, the target level will be complete, as it contains the information related to the existing class diagram as well as the information related to the generated class diagram.

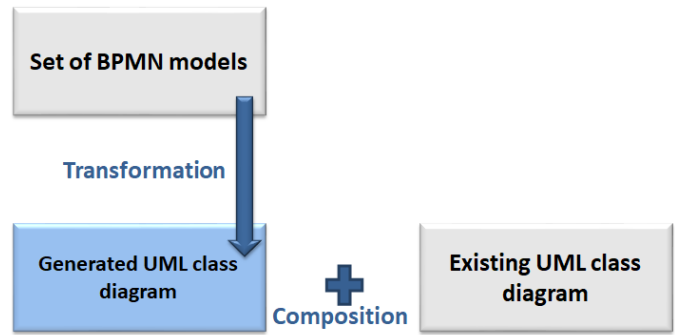

Fig. 3. Representation of the Approach.

In this paper, the first step of the approach is detailed: Transformation. This step uses a set of BPMN models as a source and applies transformation rules to derive a UML class diagram.

##### B. Example of a Set of BPMN Models

In this section, a set of BPMN models are presented. They represent the business process level of an organisation. Fig. 4 and Fig. 6 represent collaboration diagrams. Fig. 5, Fig. 7 and Fig. 8 depict expanded sub-processes, represented in collaboration diagrams as collapsed sub-processes.

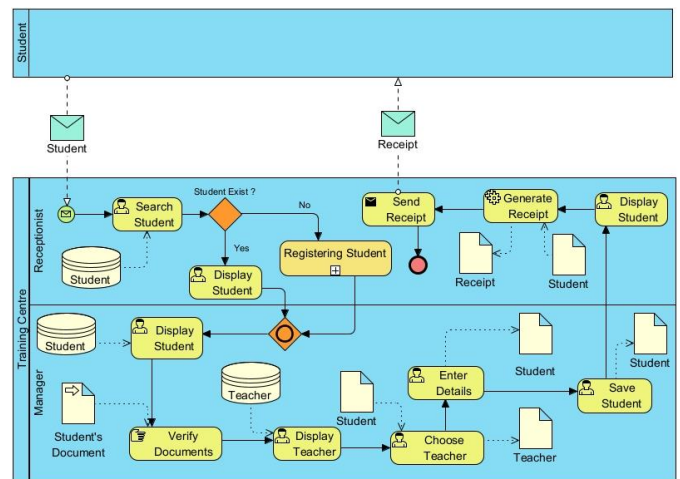

Fig. 4. Collaboration Diagram for Assigning a Professor to a Student.

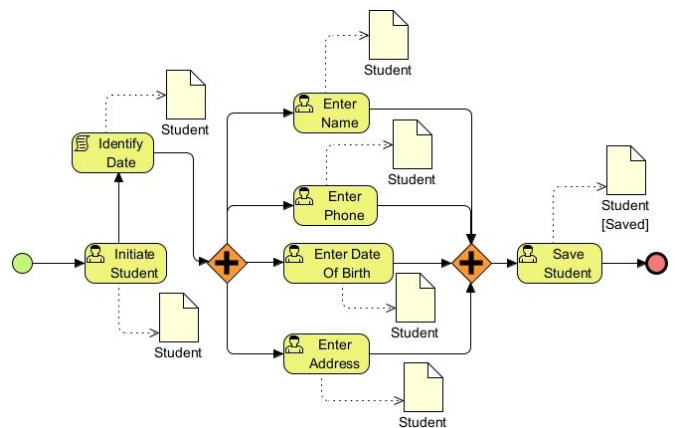

Fig. 5. Expanded Sub-process "Registering Student".

Fig. 4 illustrates the collaboration diagram for assigning a professor to a student. It is composed of two pools: "Student", as a black box and "Training Centre", which contains two lanes "Receptionist" and "Manager". The diagram begins when a student arrives at the training centre for enrolment. The first activity is performed by the receptionist. It consists of searching for a student to see if they are registered or not. Two cases are possible: if the student is registered, the student's file will be displayed. If not, the receptionist will proceed to the registration phase. Next, the manager will display the student file, verify documents, display teacher, choose teacher, enter details and then save the student file. Then, the receptionist will display the student file, generate a receipt and finally send the receipt. The second collaboration diagram (Fig. 6) contains two pools: "Supplier", represented as a black box, and "Training Centre" which contains two lanes ("Receptionist" and "Teacher"). The teacher displays a student file, and then prepares a note that will be displayed by the receptionist to prepare a quote request that will be sent to a supplier. Finally, the receptionist will receive a quote.

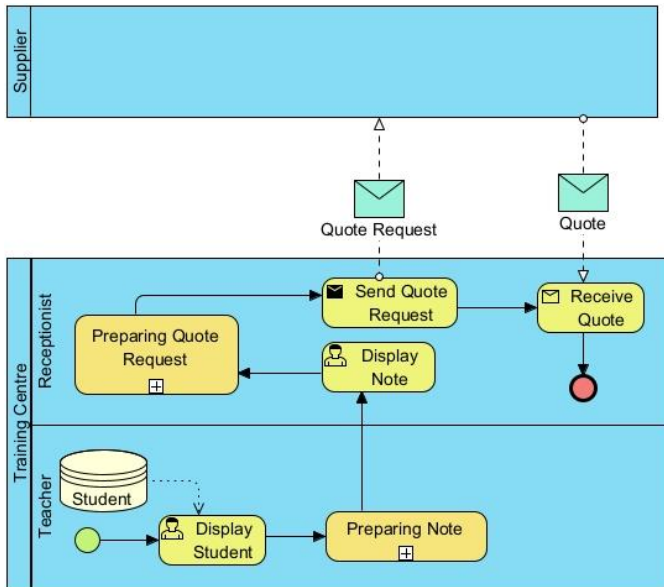

Fig. 6. Collaboration Diagram for Requesting a Quote.

Fig. 7. Expanded Sub-process "Preparing Note".

Fig. 8. Expanded Sub-process "Preparing Quote Request".

### C. Transformation Rules

In order to transform a set of BPMN models into a UML class diagram, a set of rules that take different elements of BPMN into consideration are proposed.

1) *Data* (data object, data input, data output and data store) related to send, receive, user, service, script or business rule tasks.

TR1: This rule transforms data that is related to send, receive, user, service, script or business rule tasks into a class with the same name, containing an attribute (id).

2) *Message*

TR2: This rule transforms a message into a class with the same name, containing an attribute (id).

3) *User task, service task, script task, business rule task*

a) *A task with input and output data*

TR3.1: Let TusvschrIO be a user, service, script or business rule task with data DIT (data object, data input or data store) as input, and data DOT (data object, data output or data store) as output.

TR3.1 transforms data DIT and DOT into classes, according to TR1. Then, it transforms the task TusvschrIO into an operation that will belong to the resulting class of DOT. The name of the operation is obtained by removing the spaces between words, making the first letter of the first word in the name of the task lowercase and the first letter of all other words uppercase. This name change is called "reduced form of the task name", RTusvschrIO. The DIT and DOT classes will be linked by an association (if the names of data DIT and data DOT are different). Fig. 9 presents an illustration of rule TR3.1. To identify multiplicities, the following guidelines are applied:

- If DIT is a singular data object, singular data input or data store, then the multiplicity on the side of the class corresponding to DIT is of value 1.
- If DIT is a collection data object or collection data input, then the value of the side of the class that corresponds to DIT is 1..\*.
- If DOT is a singular data object, singular data output or data store, then the multiplicity on the side of the class corresponding to DOT is of value 0..1.
- If DOT is a collection data object or collection data output, then the value of the side of the class that corresponds to DOT is 0..\*.

Fig. 10 presents an example of rule TR3.1. The user task "Initiate Note" has the data object "Student" in singular form as input, and the data object "Note" in singular form as output. Thus, in the class diagram, two classes DIT and DOT that contains an attribute (id) will be created. The class "Note" will contain the operation "initiateNote". An association will be generated between the classes with multiplicities 1 on the side of the class "Student" and 0..1 on the side of the class "Note".

Fig. 9. Illustration of Rule TR3.1.

Fig. 10. Example of Rule TR3.1.

*b) A task with output data only*

TR3.2: Let TusvscbrO be a user, service, script or business rule task with data JDOT (data object, data output or data store) as output, and no input data.

Rule TR3.2 transforms data JDOT into a class, according to TR1. Then, it transforms the task TusvscbrO into an operation that will belong to the resulting JDOT class. The name of the operation will be the reduced form of the task name, RTusvscbrO. Fig. 11 presents an illustration of rule TR3.2 while Fig. 12 presents an example.

Fig. 11. Illustration of Rule TR3.2.

Fig. 12. Example of Rule TR3.2.

*c) A task with input data only*

TR3.3: Let TusvscbrI be a user, service, script or business rule task linked to data JDIT (data object, data input or data store) as input.

Rule TR3.3 transforms data JDIT into a class, according to TR1. Then, it transforms task TusvscbrI into an operation that will belong to the resulting JDIT class. The name of the operation will be the reduced form of the task name, RTusvscbrI. Fig. 13 presents an illustration of rule TR3.3 while Fig. 14 presents an example.

Fig. 13. Illustration of Rule TR3.3.

Fig. 14. Example of Rule TR3.3.

*d) A task without input or output data*

TR3.4: Let Tusvscbr be a user, service, script or business rule task that is not linked to any data.

Rule TR3.4 transforms task Tusvscbr into a class, named by using the singular form of the direct object of the task name. It's designated by SOTusvscbr. The class will contain an attribute id and an operation. The name of the operation will be the reduced form of the task name, RTusvscbr.

Fig. 15 presents an illustration of rule TR3.4 while Fig. 16 presents an example. The task Tusvscbr, named "Display Note", is not related to any data. "Note" is a direct object of task Tusvscbr and it is in a singular form. For this reason, the task named "Display Note" will be transformed into a class named "Note", containing an attribute id and an operation named "displayNote".

Fig. 15. Illustration of Rule TR3.4.

Fig. 16. Example of Rule TR3.4.

4) Send task

a) A send task with input and output data

TR4.1: Let TsdIO be a send task with data DIsdT (data object, data input or data store) as input and data DOsdT (data object, data output or data store) as output.

Rule TR4.1 transforms data DIsdT and DOsdT into classes, according to TR1. Then, it transforms task TsdIO into an operation that will belong to the resulting DOsdT class. The name of the operation will be the reduced form of the task name, RTsdIO. The DIsdT and DOsdT classes will be linked by an association (if the names of data DIsdT and data DOsdT are different). Fig. 17 presents an illustration of rule TR4.1. To identify multiplicities, the following guidelines are applied:

- If DIsdT is a singular data object, a singular data input or data store, then the multiplicity on the side of the class corresponding to DIsdT is of value 1.
- If DIsdT is a collection data object or collection data input, then the value of the side of the class that corresponds to DIsdT is 1..\*.
- If DOsdT is a singular data object, a singular data output or data store, then the multiplicity on the side of the class corresponding to DOsdT is of value 0..1.
- If DOsdT is a collection data object or a collection data output, then the value of the side of the class that corresponds to DOsdT is 0..\*.

b) A send task with output data

TR4.2: Let TsdO be a send task with data JDOsdT (data object, data output or data store) as output.

Rule TR4.2 transforms data JDOsdT into a class, according to TR1. Then, it transforms task TsdO into an operation that will belong to the resulting JDOsdT class. The name of the operation will be the reduced form of the task name, RTsdO. Fig. 18 presents an illustration of the rule TR4.2.

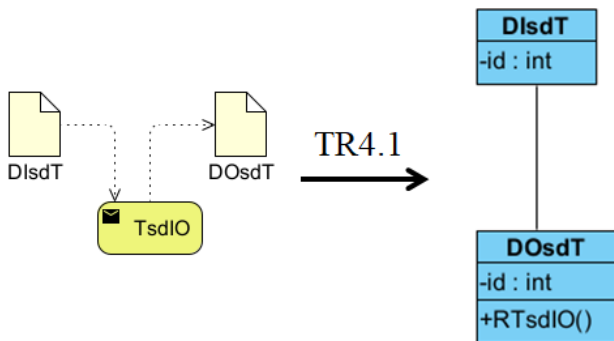

Fig. 17. Illustration of Rule TR4.1.

Fig. 18. Illustration of Rule TR4.2.

c) A send task with input data

TR4.3: Let TsdI be a send task with data JDIsdT (data object, data input or data store) as input.

Rule TR4.3 transforms data JDIsdT into a class, according to rule RT1. Then, it transforms task TsdI into a class, named using the singular form of the direct object (OTsdI) of the task name. It's designated by SOTsdI. The class will contain an attribute id and an operation. The name of the operation will be the reduced form of the task name, RTsdI. The JDIsdT and SOTsdI classes will be linked by an association (if the names of JDIsdT and SOTsdI are different). Fig. 19 presents an illustration of rule TR4.3. To identify multiplicities, the following guidelines are applied:

- If JDIsdT is a singular data object, a singular data input or a data store, then the multiplicity on the side of the class corresponding to JDIsdT is of value 1.
- If JDIsdT is a collection data object or collection data input, then the value of the side of the class that corresponds to JDIsdT is 1..\*.
- If OTsdI is in a singular form, then the multiplicity on the side of the class corresponding to SOTsdI is of value 0..1.
- If OTsdI is in plural, then the value of the side of the class that corresponds to SOTsdI is 0..\*.

d) A send task without input or output data

TR4.4: Let Tsd be a send task without data.

Rule TR4.4 transforms task Tsd into a class, named using the singular form of the direct object of the task name. It's designated by SOTsd. The class will contain an attribute id and an operation. The name of the operation will be the reduced form of the task name, RTsd. Fig. 20 presents an illustration of rule TR4.4, while Fig. 21 presents an example.

Fig. 19. Illustration of Rule TR4.3.

Fig. 20. TR4.4 Illustration.

Fig. 21. Example of Rule TR4.4

5) Receive task

a) A receive task with input and output data

TR5.1: Let TrvIO be a receive task with data DIrvt (data object, data input or data store) as input and data DOrvt (data object, data output or data store) as output.

Rule TR5.1 transforms data DIrvt and DOrvt into classes, according to TR1. Then, it transforms task TrvIO into an operation that will belong to the resulting DIrvt class. The name of the operation will be the reduced form of the task name, RTrvIO. The DIrvt and DOrvt classes will be linked by an association (if the names of data DIrvt and data DOrvt are different). Fig 22 presents an illustration of the rule TR5.1.

Fig. 22. Illustration of Rule TR5.1.

b) A receive task with input data

TR5.2: Let TrvI be a receive task with data JDIrvt (data object, data input or data store) as input. Rule TR5.2 transforms task TrvI into an operation in the class, corresponding to data TrvI. The name of the operation will be the reduced form of the task name, RTrvI. Fig. 23 presents an example of rule TR5.2.

Fig. 23. Illustration of Rule TR5.2.

c) A receive task with output data

TR5.3: Let TrvO be a receive task with data JDOrvT (data object, data output or data store) as output.

Rule TR5.3 transforms data JDOrvT into a class, according to rule RT1. Then, it transforms task TrvO into a class, named using the singular form of the direct object (OTrvO) of the task name. It's designated by SOTrvO. The class will contain an

attribute id and an operation. The name of the operation will be the reduced form of the task name, RTrvO. Fig. 24 presents an illustration of rule TR5.3. The JDOrvT and SOTrvO classes will be linked by an association (if the names of JDOrvT and SOTrvO are different). To identify multiplicities, the following guidelines are applied:

- If OTrvO is in a singular form, then the multiplicity on the side of the class corresponding to SOTrvO is of value 1.
- If OTrvO is in a plural form, then the value of the side of the class that corresponds to SOTrvO is 1..\*.
- If JDOrvT is a singular data object, singular data output or a data store, then the multiplicity on the side of the class corresponding to JDOrvT is of value 0..1.
- If JDOrvT is a collection data object or collection data output, then the value of the side of the class that corresponds to JDOrvT is 0..\*.

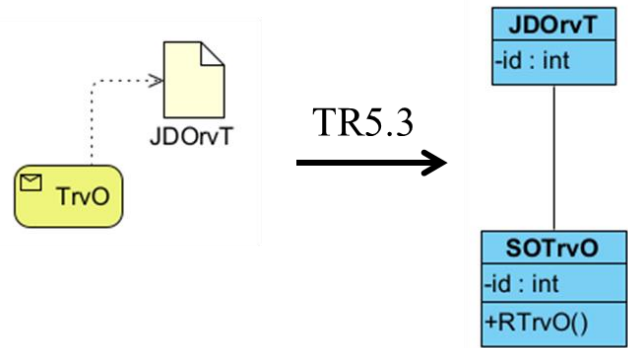

Fig. 24. Illustration of Rule TR5.3.

d) A receive task without input or output data

TR5.4: Let Trv be a receive task without data.

Rule TR5.4 transforms task Trv into a class, named using the singular form of the direct object of the task name. It's designated by SOTrv. The class will contain an attribute id and an operation. The name of the operation will be the reduced form of the task name, RTrv. Fig. 25 presents an illustration of rule TR5.4, while TR5.4 and Fig. 26 presents an example.

Fig. 25. Illustration of Rule TR5.4.

Fig. 26. Example of Rule TR5.4.

### 6) Pool

TR6: Rule TR6 transforms a pool into a class with the same name as the pool, containing five attributes (id, name, email, phone, address).

### 7) Lane within a pool

TR7: Rule TR7 transforms a lane within a pool into classes with the same names as the pool and the lane. Each class will contain five attributes (id, name, email, phone, address). Then, it adds aggregation between the class corresponding to the pool and the class corresponding to the lane (multiplicities 1 and 0..\* respectively).

### 8) Relationship between a pool/lane and a non-manual task belonging to it

TR8: Rule TR8 transforms a relationship between a pool/lane and a non-manual task belonging to it into an association between the class corresponding to the pool/lane and the class that contains the reduced form of the task's name (multiplicities 1 and 0 respectively).

### 9) Relationship between a message and an element that is the source or the target of the message flow (pool, event belonging to a pool/lane or task belonging to a pool/lane).

TR9: Rule TR9 transforms a relationship between a message and an element that is the source or the target of the message flow (pool, event belonging to a pool/lane or task belonging to a pool/lane) into an association between the class corresponding to the pool/lane and the class corresponding to the message (multiplicities 1 and 0..\* respectively).

## D. Isolated elements

In this section, the isolated elements are presented. An isolated element belongs to the BPMN metamodel and does not have an equivalent in the UML class diagram metamodel.

1) *Manual task*: A manual task is performed without the intervention of any application. Therefore, it will not be visualised by the software. For this reason, this type of task is considered an isolated element, and it has no equivalent in the class diagram.

2) *Data linked to a manual task*: Data that is linked to a manual task will not have traceability through the system.

Because the manual task has no visualisation, this data is considered an isolated element.

3) *Event*: Usually, an event is a fact that occurs during the process. Because the class diagram represents a static aspect, an event is considered an isolated element.

4) *Gateway*: The goal of a gateway is to control the convergence or divergence of flows in a process. It does not have an equivalent in the class diagram.

5) *Artifact*: An artifact (group or annotation) aims to provide more clarity to understand the process. It does not have an equivalent in the class diagram.

6) *Sequence flow*: A sequence flow can indicate the flow of activities through a process. It does not have an equivalent. In fact, the tasks linked by the sequence flows that have an equivalent in the class diagram.

7) *Association*: An association is a way to link the artifacts with different BPMN elements and does not have an equivalent in the class diagram.

## E. Steps for a Set of Models

In order to apply the rules presented in section C, a series of steps based on BPMN notation are presented in this section, to transform a set of BPMN models into a class diagram. Fig. 27 shows the process of this transformation. It constitutes five looped sub-processes.

### 1) Transformation of task: this sub-process can

- a) Identify non manual task.
- b) Identify task type.

According to the type of task, apply rule TR3.1, TR3.2, TR3.3, TR3.4, TR4.1, TR4.2, TR4.3, TR4.4, TR5.1, TR5.2, TR5.3 or TR5.4, which all call rule TR1. When applying a rule, a check is performed to determine whether an element (class, operation or association) has already been created by another rule. If it has:

- All the instructions associated with that rule are applied, except creation of the element.
- If an association already exists, such that the multiplicities are different, the existing association is kept, and the union of multiplicities is applied for each end of the association.

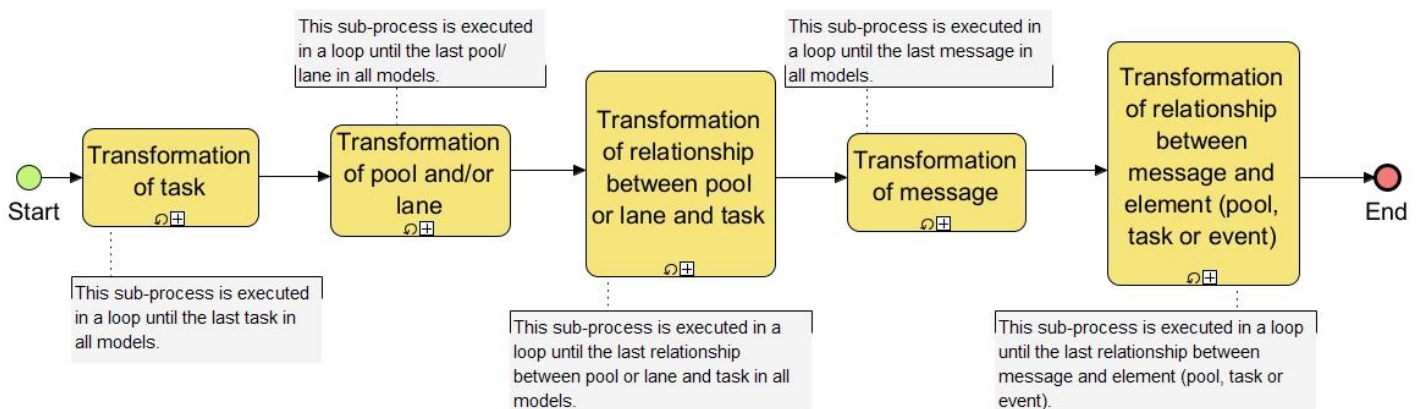

Fig. 27. The Transformation Process.

2) Transformation of pool and/or lane: for each pool that exists in the different models this sub-process can.

a) Identify the pool

b) According to the type of pool (with or without lanes), apply the rule TR6 or TR7. When applying a rule, a check is performed to determine whether an element (class, attribute or aggregation) has already been created by another rule. If this is the case, all instructions associated with that rule are applied, except creation of the element.

3) Transformation of relationship between pool or lane and task: for each relationship between a pool or a lane and a task this sub-process can.

a) Identify the relationship between the pool or lane and task.

b) According to the type of relationship, apply the rule TR8. When applying a rule, a check is performed to determine whether an association has already been created by another rule. If an association already exists such that the multiplicities are different, the existing association is kept, and the union of multiplicities is applied for each end of the association.

4) Transformation of message: for each message this sub-process can.

a) Identify a message.

b) Apply TR2.

5) Transformation of relationship between message and element (pool, task or event): for each relationship between a message and an element (pool, task or event) this sub-process can.

a) Identify the relationship between a message and an element (pool, task or event).

b) Apply TR9. When applying the rule, a check is performed to determine whether an association has already been created by another rule. If an association already exists such that the multiplicities are different, the existing association is kept, and the union of the multiplicities is applied for each end of the association.

## V. CASE STUDY

In order to illustrate the application of the proposed transformation rules, the set of BPMN models represented in section B are transformed into a UML class diagram. The example describes two collaboration diagrams and three expanded sub-processes. The first context is the training centre that receives students who want to have a teacher as a mentor. In the second context, the training centre communicates with suppliers to obtain a particular quote, related to student needs. Fig. 28 presents the class diagram obtained by the application of the transformation rules, according to the global process of transformation presented in Section EIVE.

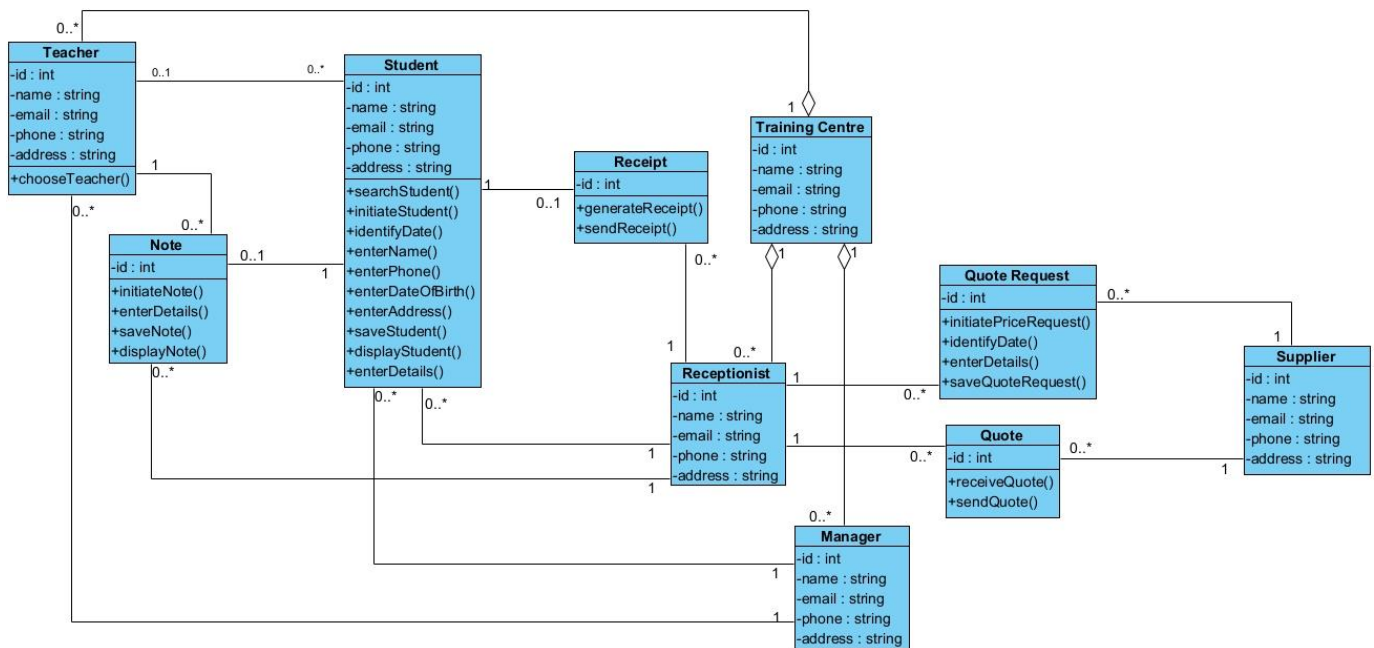

Fig. 28. Obtained Class Diagram.

## VI. CONCLUSION

In this paper, a method for aligning software system level using UML class diagram with business process level using BPMN notation is proposed. This proposal enables to contribute to the alignment process of an organization, by considering a set of models at the source level that contains a large number of BPMN metamodel elements. Furthermore, the method aims to preserve information, filling a crucial need for organisations' long-term success. The first phase was described here, detailing a series of rules for transforming a set of BPMN models into a UML class diagram. Moreover, a guideline is presented to help organisations apply rules properly. A set of isolated elements is also presented to explain the BPMN elements that are not considered by the transformation rules. The application of the proposed rules is demonstrated in a case study. In future work, we aim to use the ATLAS Transformation Language to automate the proposed transformation rules.

## ACKNOWLEDGMENT

We would like to thank the Excellence Research Scholarships Program of CNRST (National Centre for Scientific and Technical Research) of Morocco for supporting this research. This work is under research grant number 51UM52016.

**Abstract**—In the last two decades, the field of DNA-based steganography has emerged as a promising domain to provide security for sensitive information transmitted over an untrusted channel. DNA is strongly nominated by researchers in this field to exceed other data covering mediums like video, image, and text due to its structural characteristics. Features like enormous hiding capacity, high computational power, and the randomness of its building contents, all sustained to prove DNA supremacy. There are mainly three types of DNA-based algorithms. These are insertion, substitution, and complementary rule-based algorithms. In the last few years, a new generation of DNA-based steganography approaches has been proposed by researchers. These modern algorithms overpass the performance of the old ones either by exploiting a biological factor that exists in the DNA itself or by using a suitable technique available in another field of computer science like artificial intelligence, data structure, networking, etc. The main goal of this paper is to thoroughly analyze these modern DNA-based steganography approaches. This will be achieved by explaining their working mechanisms, stating their pros and cons, and proposing suggestions to improve these methods. Additionally, a biological background about DNA structure, the main security parameters, and classical concealing approaches will be illustrated to give a comprehensive picture of the field.

**Keywords**—Information security in bioinformatics; deoxyribonucleic acid-based steganography; modern hiding approaches

## I. INTRODUCTION

Nowadays, the reliance on computer systems and the Internet has dramatically increased. The huge advancement in the technology of data storage and transmission has led to an increase in the information traffic between any two parties at an exponential rate. Many of these information are considered sensitive especially those belonging to the government, the army, or the big companies. It is quite risky to send such information over an untrusted channel [1]. The field of cybersecurity has the cumbersome task of protecting information from different types of threats and attacks. The attacks on shared information may cause it to be disrupted, corrupted, or stolen. Despite the availability of many information security techniques, cryptography and steganography seem to work perfectly together to achieve the mission of securely conveying information from source to destination. While cryptography aims to alter the message in such a way it becomes unreadable to a third party, steganography provides a concealing medium to the message

[2]. In cryptography, a key is usually used to perform the task of data encryption and decryption. There are mainly two types of cryptosystems, these are symmetric key encryption and asymmetric key encryption cryptosystems. The encryption and decryption processes are applied in the symmetric key method via a secret key shared between the sender and the receiver. The length of this key is relatively short which aids in completing the decryption stage quickly. Symmetric key encryption can be categorized into stream cipher or block cipher. In a stream cipher, every character in the message will be individually encrypted. While in block cipher, many bits are assembled in a single unit. Then, this unit will be encrypted. Some of the famous and dominant encryption algorithms that use symmetric key encryption are Digital Encryption Standard (DES), AES, RC4, and IDEA [3]. In the case of asymmetric key encryption, two keys are used to handle the encryption and the decryption processes. A public key is used to encrypt the message by the sender and a private key is used to decrypt the message by the receiver. This will eliminate the risk of losing a pre-shared key as in the previous technique. Although this technique provides high-security measures, a third party must be trusted as a key manager. An instance of asymmetric key encryption is the RSA encryption algorithm [4]. In the field of steganography, mediums like text [5], image [6], audio [7], and video [8,9] are used by researchers as containers to hide a message inside them. Concurrently, technologies of data storage and transmission withstand rapid development and improvements. Also, there are a noticeable diversity of threats and attacking methods that appear every year. All the covering mediums mentioned above struggle to cope with the increasing size of information as well as meet the demanded security measures [10]. An urgent need has arisen for a concealing medium capable of holding a large amount of data without corrupting or degrading the quality of this medium. Consequently, deoxyribonucleic acid (DNA) is proposed as the ultimate concealing medium that avoids or mitigates the drawbacks of other mediums [11]. DNA's most important feature is the huge capacity it has. Around 215 petabytes of data can be stored in one gram of DNA. Another useful feature is the randomness of the building blocks forming the DNA. Besides that, low power is required when dealing with DNA computing which leads to fast execution. For all the reasons mentioned above, many DNA steganography algorithms have been suggested since the beginning of the twenty-first century. As shown in Fig. 1, three components are combined to get the fake DNA sequence. These are the covering medium (which is the DNA sequence in our case), the message, and the secret

key [12]. An additional component can be added to the formula by firstly encrypting the message before hiding it. This will decrease the penetration probability and creates a complete crypto-stego system.

Fig. 1. DNA Steganography Process.

Generally, there are three classical techniques used in DNA-based steganography to embed the hidden message in the cover medium. These are insertion, substitution, and complementary rules-based algorithms. Each one of these techniques has its way of implementation, benefits, and limitations. Even hybrid algorithms of these techniques have been proposed to improve upon them [60]. In the attempt of improving the performance of currently used DNA steganography algorithms, a new trend has evolved. This trend relies on the concept of utilizing one of the DNA biological features and/or merging a technique existing in one of the fields of computer science with a DNA-based steganography algorithm. Doing so showed promising results in terms of overcoming or at least alleviating the issues and gaps that existed in the field of DNA computing. But with the advent of new solutions, new issues have also arisen. This motivates the authors of this manuscript to address these issues and suggest different methods to solve them. Therefore, the main purpose of this paper is to highlight the strong points and drawbacks of recently proposed DNA-base steganography algorithms. It also aims to be a reference for any researcher who wants to develop his/her novel hiding technique. This is accomplished by achieving four objectives. The first objective is exploring the field of genetics, dissecting the structure of the DNA sequence, and informing the reader on the constantly used biological terms in this area without delving into unnecessary clinical concepts. Secondly is enumerating and elaborating the security parameters in this field. Then, classical techniques used to hide a secret message in a DNA sequence are briefly explained. Last but not least is conducting an in-depth analysis of modern approaches.

The rest of the paper is organized as follows: section two includes a biological background about DNA. Section three enumerates the parameters of security measures. Section four contains a concise description of classical DNA-based steganography algorithms. Most importantly section five presents a critical analysis of some modern DNA-based steganography algorithms. Finally, section six discusses the primary open issues of DNA-based steganography, suggests some solutions, and concludes the paper.

## II. BIOLOGICAL BACKGROUND

To work in the field of DNA computing, prior knowledge of biology especially in the field of genetics is required. DNA preserves the genetic information that denotes the physical shape, behavior, and functions of all living organisms. DNA is

constructed from two lengthy strands twisted on each other. These two strands are attached via units called nucleotides to give DNA the shape of a helix ladder. Nucleotides are considered the building blocks of DNA and can be one of four main types. These types are adenine (A), guanine (G), cytosine (C), and thymine (T). The two strands are linked to each other by pairs of nucleotides. This linkage is not haphazardly formed. A is always paired with T via double hydrogen bonds, while C is always paired with G via triple hydrogen bonds [13]. Fig. 2 depicts the structure of the DNA.

Every three consecutive nucleotides represent a unit called a codon. Codons represent either one of the 20 possible amino acids or a stop signal. Since each nucleotide in the three locations of the codon has one of four possible values (A, C, G, and T), there are 43 or 64 different types of codons. Amino acids are represented with 61 types, and 3 dedicated for a stop signal. Every amino acid can be either represented with a single codon up to six types of codons. For example, tryptophan represented with (TGG), glutamic acid represented with (GAA, GAG), and threonine represented with (ACT, ACC, ACA, ACG). The case when an amino acid is represented with more than one codon is called ambiguity. Essential proteins for the human body are formulated from a long chain of amino acids [14]. A complete genetic code of DNA is presented in Table I. A distinctive biological feature in DNA is mutations. These mutations refer to changes that occur in the DNA sequence which modify the contents of one or more nucleotides. One of the reasons that cause this change is due to the errors in the DNA replication or recombination processes [13]. In general, there are three types of mutations:

1) *Base substitution*: occurs when the content of one or more bases is replaced with new content. The replacement process can be either transitional or transversional. Transitional replacement appears when a purine is replaced with another purine or when pyrimidine is replaced with another pyrimidine.

Fig. 2. DNA Double Helix.

TABLE I. THE GENETIC CODE [13]

		Second position									
		T		C		A		G			
		Code	Amino	Code	Amino	Code	Amino	Code	Amino		
First Position	T	TTT	phe	TCT	ser	TAT	tyr	TGT	cys	T	Third position
		TTC		TCC		TAC		TGC		C	
		TTA	TCA	TAA		STOP	TGA	STOP	A		
		TTG	TCG	TAG		STOP	TGG	trp	G		
	C	CTT	leu	CCT	pro	CAT	his	CGT	arg	T	
		CTC		CCC		CAC		CGC		C	
		CTA		CCA		CAA	CGA	A			
		CTG		CCG		CAG	CGG	G			
	A	ATT	ile	ACT	thr	AAT	asn	AGT	ser	T	
		ATC		ACC		AAC		AGC		C	
		ATA		ACA		AAA	lys	AGA	arg	A	
		ATG	ACG	AAG		AGG		G			
	G	GTT	val	GCT	ala	GAT	asp	GGT	gly	T	
		GTC		GCC		GAC		GGC		C	
		GTA		GCA		GAA	glu	GGA		A	
		GTG		GCG		GAG		GGG		G	

On the other hand, transversional replacement appears when a purine is replaced with a pyrimidine and vice versa. Base substitution mutations lead to different kinds of situations. For instance, when replacement occurs in the third location of a codon, there is a high probability that the amino acid is still the same. This kind of mutation is called a silent mutation. Another case arises when the replacement of bases converts an amino acid to a new one. This is called missense mutation and can be either conservative or non-conservative. In conservative mutation, the new amino acid has a similar structure and working mechanism compared to the old one. Consequently, the functionality of the protein is maintained regardless of the change in one of constructing amino acids. In non-conservative mutations, the new amino acid differs greatly compared with the old one. This will lead to altering the functionality of the whole protein. The last case of base substitution mutations appears when the replacement leads to one of the three-stop signals. This is called a nonsense mutation, which will terminate the sequence of amino acids building the protein and spoil its functionality.

2) *Base deletion*: occurs when one or more bases are omitted from the DNA sequence. Deleting one or more bases will cause a frameshift to the whole DNA sequence and make it non-functional. Deleting three or more bases may or may not affect the function of the protein.

3) *Base insertion*: occurs when one or more bases are added to the DNA sequence. Similar to the deletion case, this may have a negative effect on the biological function of the DNA sequence.

Studying and understanding the different types of mutations is essential to utilize them for data hiding purposes. Silent and conservative mutations types can be used to preserve functionality and produce a blind DNA-based steganography

algorithm. Finally, researchers in the field of DNA computing need DNA sequences for testing the performance of their proposed algorithms and comparing results. Fortunately, there are over 163 million DNA sequences that can be freely downloaded from different websites. Two of the most useful websites are the National Center for Biotechnology Information (NCBI) and the European Bioinformatics Institute (EBI) [15, 16].

### III. SECURITY ANALYSIS

This section illustrates some of the most important methods and crucial factors used in the development process of the DNA-based steganography algorithms. It also includes the parameters used to evaluate the performance of these algorithms.

1) *Data encoding*: to hide a secret message of any formatting type in a DNA sequence, elements of this message need to be encoded into genetic letters. One method to achieve this task is to use a lookup table to encode every character of the message to several genetic letters [17]. This technique suffers from two main defects. Firstly, the table is fairly static and fixed. Once it is revealed by an intruder, the whole steganography algorithm is compromised. The second issue is lookup tables used by many researchers to encode only alphabetic and numerical characters [18]. Special characters are ignored due to insufficient codons number. Another data encoding method is using a binary coding rule (BCR) table as shown in Table II.

In this case, the characters of the message are converted to binary form based on their ASCII code. Then, every two bits are assigned to a genetic letter [19]. An improved N-bits BCR has been suggested to increase characters encoding probability [20].

TABLE II. 2-BITS BINARY CODING RULE

DNA nucleotide	Binary form
A	00
C	01
G	10
T	11

2) *Hiding capacity*: denotes the total amount of data DNA sequence can tolerate. It is usually measured by the number of bits per nucleotide (BPN). A higher data capacity is obtained with a higher (BPN) value [23].

3) *Security key*: a very critical element in any crypto-stego system. Different factors have a direct effect on the used key or keys. For example, the purpose of using the key whether it is for encrypting or concealing the message, the type of the key whether it is a symmetric or asymmetric key, whether the key is randomly generated or created with a specific method, the size of the key, and the possibility of encrypting the key and merging it with the hidden data [22].

4) *Data encryption*: before concealing the secret message in the covering medium, it is preferred to encrypt it to add another layer of security to the algorithm. Many ciphering techniques have been used in the field of DNA-based steganography like DES, RSA, Vigenere, AES, and Playfair. Selecting and implementing the suitable encryption method is crucial since it has a direct effect on the other security parameters like the used key, hiding capacity, and cracking probability [21].

5) *Hiding method*: denotes the way characters of the secret message are embedded in the reference DNA sequence. Authors in [19] established three possible methods adopted by the majority of researchers afterward. Chunks of the secret message can be either inserted in different locations of the DNA sequence, added before the longest complimentary rule, or substituted with characters from the original sequence. These methods are vastly elaborated in the next section.

6) *Double layer embedding*: In many literature manuscripts, researchers suggest hiding the secret message in two mediums instead of one to offer higher security. Besides DNA sequence, a secret message can be concealed in an image [29], audio [30], or microdot [31].

7) *Cracking probability*: A measurement of the success probability of a brute force attack to break the proposed security algorithm. Some of the elements that have a direct effect on the cracking probability are the total number of possibly used DNA sequences, the number and the size of segments of the DNA reference sequence and the secret message, and the way of using a binary coding rule with a lookup table [2].

8) *Payload*: is the amount of extra data added to the DNA sequence due to the implementation of the DNA steganography algorithm. The best scenario occurs when the payload equals zero [24].

9) *Modification rate*: denotes the ratio of change in the fake DNA sequence compared to the original one. A high modification rate may spoil the protein's operations in the DNA sequence [24].

10) *Random variable*: In some of the developed steganography algorithms, researchers add one or more random variables in the data encryption and hiding processes. The reason behind that is making the task of cracking the algorithm even harder for an intruder. Some examples of random variables are using a random number of segments generation for insertion method [19, 25], random locations generation [26], random key generation [27], and random sequence generator [28].

11) *Blindness*: the algorithm is considered blind when there is no need to send the original DNA sequence used by the sender to the receiver. Generally, less amount of information used in the transmission process will improve the effectiveness of the applied method [32].

12) *Preserving functionality*: Codons are arranged in the DNA sequence in a specific order to form proteins. Every protein is generated to perform a unique biological function. One of the challenging goals in the field of DNA-based steganography is preserving this function after implementing the proposed data hiding algorithm [14].

#### IV. DNA-BASED STEGANOGRAPHY TECHNIQUES

From the beginning of the new millennium, many DNA-based steganography algorithms have been proposed. Each one of them follows a specific technique for data embedding in the DNA sequence. This section illustrates these classical approaches, describes their issues, and explains how these issues affect the development of recently proposed DNA-based steganography algorithms.

##### A. Insertion-Based Techniques

The Insertion-based technique is one of the first methods to hide a message in a DNA sequence. It is performed by inserting the data of the embedded message in one or more different locations of the DNA reference sequence. In [19], both the DNA sequence and the embedded message are divided into a random number of segments. Then, each segment of the message will be inserted before a segment of the medium. It is difficult for an intruder to deduce the number of segments or packets per message and the amount of data per packet [27]. An additional layer of protection can be added by encrypting the secret message with a solid encryption algorithm. For example, data encrypted with modified Playfair [25], AES-128 [31], RSA [33], or RC4 encryption algorithms [34] before data embedding stage. In [35], two images are concealed in another image without distortion based on grayscale and Least Significant Bit (LSB) insertion of the DNA form of the secret information. An improved insertion technique is proposed by [36] with the use of two keys. The first key is XORed with every 8 bits of the secret message, while the other key is responsible for dividing the DNA sequence into segments. The binary bits of the cipher are inserted at the beginning of each segment. This technique has a strong cracking probability and high security but the payload is

not zero. A powerful algorithm with complex data encryption and embedding techniques is presented in [32]. In the encryption phase, a Playfair cipher with a randomly shuffled 8\*8 matrix is used to gain an additional layer of security via codons replacement and circular rotation of rows and columns processes. In the embedding phase, both the message and the cover DNA sequence are spliced into a random number of segments. Then, these segments are concatenated to generate the fake DNA sequence. The main drawback of the insertion-based technique is the increasing size of the DNA reference sequence. This is a clear indication that data has been added to the carrier medium and will attract the attention of attackers. Also, algorithms adopt insertion technique are usually not blind. On the positive side, insertion algorithms have a low cracking probability. Furthermore, one or multiple random variables are used in the encryption or embedding stages. This will make breaking the algorithm even harder for intruders.

### B. Substitution-Based Techniques

In substitution-based technique, nucleotides from the DNA sequence are replaced with secret message characters. The replacement method can be applied using a lookup table [17] or at specific locations like the LSBs [37]. In [38], a histogram of frequently appeared values in the selected DNA reference is created. Then, the message is hidden in locations marks with zero. A novel technique based on Chebyshev chaotic maps is developed by [39]. The plain text is encoded into a DNA sequence and encrypted to another sequence via a Chebyshev map. The result is circularly shifted for a finite number of times and embedded through character by character substitution in a word document. Excessive random substitution of bases inside the DNA sequence will ruin the function of the protein. The approach in [40] took advantage of the ambiguity feature to solve this issue. Only the Least significant bases (LSB) locations of each codon are used as hiding locations of the secret message. This technique is blind and minimized the modification rate by a third. Enhanced algorithms are offered in [20] and [41] based on a 4-bits coding rule with data encryption using Playfair and AES. Another substitution-based technique is suggested by [42]. A codon dictionary table is manually generated. Then, every 6 bits of the message will be replaced with a codon. These codons are embedded in different intervals of the DNA reference. Several elements were used in [43] to provide dual cover steganography techniques based on an image and DNA. These elements are a 2D logistic map, three secret keys, and encrypt a secret message using RC4 and hiding it in LSB locations. Although offering high-security measures with double hiding layers, this technique demands much data for the hiding and extraction processes. Another double-layered steganography technique was proposed in [30]. After encrypting the message using RC4 and hiding it in the DNA sequence, a randomized LSB replacement method is used to embed the result in an audio file. Preserving the functionality of the DNA sequence can be achieved by embedding the secret message in non-coding regions of the sequence. This was accomplished in [44] by first encrypting the message using XOR and pseudo-random bit generator (PRBG) sequence. Then, the encoded message is segmented into pieces and replaced with nucleotides in sectors from non-coding regions. Another advantage of this technique is its ability to detect and recover deleted or changed nucleotides

affected by mutations. Also, it has a decent capacity ranged from 1.2 to 2 BPN. An enhanced 4\*4 Playfair cipher is developed in [21] instead of the 5\*5 usually used grid. After encrypting the plain text with it, the hiding technique developed in [45] is used to improve hiding capacity by 25%. A double-layered hiding algorithm based on a color image as a cover is presented in [29]. The secret data is divided into three parts using the XOR operator, and each one of them is concealed in the color of the cover image. This is a highly reliable approach though it is time-consuming during the extraction phase. Two DNA strands are used in [46] to increase hiding capacity. A substitution table is used for the embedding purpose and the message is sent to the receiver via a microdot. In [18], a combination of image and DNA-based steganography is applied. A secret image is embedded in another image – both with the same pixel size – by converting their pixel values to DNA triplet based on a lookup table. Then, these triplets are converted to binary form and XORed to get the stego image. This method offers a higher security level than other techniques like LSB but with a lower hiding capacity. The prominent benefit of the substitution-based technique is implementing the embedding process without any expansion in the size of the fake DNA sequence. On the other hand, a high modification rate applied to the DNA reference sequence will ruin its biological functionality. Besides that, by restricting the replacement locations to a limited number - as in the LSBs-based methods -, will highly decrease the data hiding capacity. Trying to increase hiding capacity may lead to lowering the performance of other parameters like modification rate or cracking probability [46].

### C. Complementary Rule-based Techniques

In this method, a complementary rule is initially considered and the data is inserted before the longest complimentary substring in the reference DNA sequence. The complementary rule is set in such a way where  $x \neq c(x) \neq c(c(x)) \neq c(c(c(x)))$  and  $x$  is one of the four possible genetic letters [47]. For instance, if the following complementary rule is applied: ((AC) (CG) (GT) (TA)), the complementary string of AATGC will be CCATG [19]. In [48], each pair of encrypted secret message will be assigned to a matching index in the DNA reference sequence. Then, a list of these indices will be sent to the receiver. The hiding process can be implemented using a random generator function based on the size of the secret message [26]. Another method encoded text to DNA form and hide the result in grids of an image based on LSB and MSB [49]. A similar technique is suggested by [50] where the input message is encoded to DNA form and embedded in a randomly chosen frame of a video. A mathematical approach of data encryption and hiding is proposed in [28]. Two secret keys are generated using Elliptic Curve Cryptography (ECC) and Gaussian Kernel Function (GKF). The secret message is encrypted using these two keys, followed by DES. Characters of the encrypted message are embedded in locations from the new DNA sequence. While this technique is the simplest compared to other techniques, it is not blind and increases the message size. In some cases when a random DNA sequence is used, it is required to send the complementary rule to the receiver [51]. Security mainly depends on the selected DNA reference [52]. Also, it is not

always feasible to find the DNA sequence of all the matching elements with the secret message.

#### D. Hybrid Techniques

Many endeavors aimed to combine the advantages of the three techniques in the previous sections and nullify or at least mitigate their weaknesses by proposing hybridization between them. For example, authors in [45] used a substitution method with a complementary rule. A multi-level secured method that adopted a similar approach has been suggested in [53]. Data are firstly using Playfair and concealed in a randomly generated DNA sequence. Then, the DNA sequence is embedded in an audio file. An imperceptible double-layered algorithm based on image and DNA is proposed in [54]. Using the only component of the cover image – like blue color – to hide the DNA message is the main weakness in this algorithm. Generally, these algorithms hide the message with zero expansion and payload. Still, like their predecessors, they paid no attention to preserving the biological features of the reference DNA sequence. Also, they are un-blind algorithms. Authors in [19] employed a data hiding algorithm based on a combination of insertion and complementary rule methods. This algorithm is un-blind, expands the size of the DNA sequence, and ignores its biological functionality. In [55] the secret message is firstly encrypted with an improved Playfair cipher. After that, the encoded message is concealed via a novel substitution method in a cover DNA sequence and the result is inserted in another sequence. An improved version of this method with enhanced Generic complementary base substitution (GCBS) is recently presented in [61]. Using a DNA-based XOR cipher with a randomly generated key formulated from the cover medium is suggested. This proves to offer better results in terms of lower cracking probability and higher BPN.

#### V. ANALYSIS OF MODERN APPROACHES

Classical or traditional methods of implementing DNA steganography discussed in the previous section used the traditional protection methods in the field of data security to achieve the desired task. In the last few years, a new generation of algorithms has been evolved. The new trend aims either to exploit the biological attributes of DNA or borrow a suitable technique from another field of computer science. The reason behind that is offering better solutions and performance compared to the old generation methods. In this section, a critical analysis will be initiated to the recently suggested techniques by describing their working mechanism, stating their pros and cons, and points to the possible ways to improve upon them.

##### A. Exploiting Biological Features

One of the most interesting features of DNA is the condition called single nucleotide polymorphism (SNP). In this case, a particular nucleotide in the genome sequence differs between members of the same species. As shown in Fig. 3, the two DNA sequences have different content in a specific position.

Researchers keenly noticed that regions including SNPs have the potential to hide a secret message. Attackers cannot distinguish between changes that occur because of data hiding and changes that occur because of SNPs. In [56], the author proposed a DNA steganography algorithm based on hiding a secret message in SNPs locations. Firstly, SNPs positions in the selected DNA sequence are assigned. Then, every character in the secret message is converted to three letters based on the DNA encoding table. For example, the letter (H) is encrypted to (TAC) and stored in three consecutive SNPs positions as shown in Fig. 4.

Fig. 3. Single Nucleotide Polymorphism [56].

Fig. 4. Encrypting and Hiding a Character [56].

One of the limitations of the proposed algorithm noticed in the DNA encoding table, it has only alphabets and numbers. While SNPs offer good hiding locations in the encrypted message, they suffer from an obvious defect. The appearance probability of SNPs in a single DNA sequence is only 6%. Hence, the hiding capacity of the sequence is severely decreased. A suitable data compression technique can be used to increase the number of encrypted bits per location.

Another biological factor used in the process of data hiding is mutations. Although some types of mutations have negative effects like corrupting or terminating the protein, other types do not harm the protein. Silent and conservative mutations change nucleotides or amino acids in the protein and maintain its functionality. The approach in [23] took advantage of these types of mutations to develop a crypto-stego system with high hiding capacity and excellent security measures. This algorithm has two main stages on both sender and receiver sides. Firstly, the secret message is encrypted using an enhanced 8\*8 Playfair cipher. This new encryption technique overcomes the weakness that existed in the 5\*5 Playfair cipher where only alphabets are encrypted. Using Playfair cipher is justified since no extra information is required by the receiver in the decryption process besides lowering the cracking probability. In the second phase, LSBBase is used to hide bits of the secret message. The challenge is to hide two bits per nucleotide, where every amino acid will handle four possible substitutions. Via silent mutation, this is possible in all amino acids that can be represented with four codons or more. For instance, Alanine has four codons: GCA, GCC, GCG, and CGT. The LSBBase of these four codons can hide two bits – 00, 01, 10, and 11 – without issue. Unfortunately, not all amino acids can satisfy the rule of being represented with four codons or more. For example, Phenylalanine is an amino acid that can be represented with only two codons, TTT and TTC. These two codons can satisfy only half of the four possible values. To solve these issues, the authors suggested using the feature of conservative mutation. Here, an amino acid will replace another that shares a similar structure and functions. Amino acids that have less than four codons will be used interchangeably without disturbing the functionality of the protein. In the example mentioned above, Tyrosine will be used when Phenylalanine fails to satisfy the embedding requirements. One of the main contributions of the proposed algorithm is its ability to exploit concealing data in LSBBase locations efficiently with a high hiding capacity of 2 BPN. Another important contribution is hiding the message in a non-sequential and non-order pattern along the DNA sequence. The cracking probability is low due to the various factors required to get the secret message. The intruder must not only know which DNA reference or BCR are used, but he/she must also know how the Playfair matrix is constructed, figure out the data hiding locations, and the adopted substitution rule. The drawback of the suggested algorithm is the need to send the random number of seeds used to generate BCR to the receiver. Also, using a fixed substitution table where the same

unsatisfied amino acids always replace each other for every transition session is considered a weak point.

Maintaining the biological features of DNA after embedding the encrypted data in it is a really difficult task to achieve. Any modification or payload applied to the DNA sequence may lead to losing the functionality of this sequence. Although it seems leaving the DNA sequence intact is the only way to succeed in preserving its original signature, there are many other interesting methods to do that. In [57], the main objective is preserving the biological functionality of the DNA sequence after the embedding process. This is accomplished by exploiting a DNA feature, ambiguity, mentioned in section two. Every amino acid is composed of three nucleotides or a codon. Ambiguity arises when more than one codon represents an amino acid. As demonstrated in Table III, there are 20 different types of amino acids. Every amino acid can be represented with one to six codons. The table also includes the number of ambiguities for each amino acid and the number of required bits to represent them. Before initiating the data hiding operation, a preprocessing is deployed. Based on the content of Table III, the whole carrier DNA sequence is converted to amino acid codons. Every bit in the secret key is linked to its corresponding character of the DNA sequence in a specific way. Ones denote amino acids locations where hiding characters is possible, while zeros denote to do not care amino acid locations. In the data hiding process, the codon representing the secret character will substitute a codon in the carrier medium. This does not affect the DNA sequence functionality since both codons belong to the same amino acid. Consequently, the purpose of this work of applying the steganography process without disturbing the biological features of the medium is achieved. Also, the proposed algorithm provides low penetration probability versus different types of attacks like stego-only attack, known cover attack, and known message attack. The weaknesses of this algorithm are adding a new bit for hiding data in some cases which increases the payload. Besides that, the performance of this algorithm depends on the content of the secret message. Every amino acid used in the hiding process has its own effect on parameters like hiding capacity, BPN, and payload. This drawback can be alleviated by using only amino acids that guarantee the best performance.

### B. The Field of Networking

For the mutation/modification detection technique, the author in [56] borrowed a concept used in the field of networking to detect errors in data transmission. A block checksum method is implemented by assigning a number to each nucleotide in the encrypted sequence where ( $A = 0 / T = 1 / G = 2 / C = 3$ ). Then, the summation of nine consecutive nucleotides is divided on 4. The remainder of the division operation will be converted to the equivalent DNA value and attached to the end of the sequence as the tenth location. This operation is repeated for all components of the encrypted message. As shown in Fig. 5, three cases are presented.

TABLE III. NUMBER OF CODONS PER AMINO ACID [57]

Amino Ambiguity			A	B	C	D	E	F	G	H	I	K	L	M	N	P	Q	R	S	T	V	W	Y
			A1	0	000	GCU	UAA	UGU	GAU	GAA	UUU	GGU	CAU	AUU	AAA	UUA	AUG	AAU	CCU	CAA	CGU	UCU	ACU
A2	1	001	GCC	UAG	UGC	GAC	GAG	UUC	GGC	CAC	AUC	AAG	UUG		AAC	CCC	CAG	CGC	UCU	ACC	GUC		UAC
A3	2	010	GCA	UGA					GGA		AUA		CUU		CCA		CGA	UCA	ACA	GUA			
A4	3	011	GCG						GGG				CUU		CCG		CGG	UCG	ACG	GUG			
A5	4	100											CUA				AGA	AGU					
A6	5	101											CUG				AGG	AGC					
Number of ambiguities (X)			4	3	2	2	2	2	4	2	3	2	6	1	2	4	2	6	6	4	4	1	2
Number of bits (Y)			2	2	1	1	1	1	2	1	2	1	3	1	1	2	1	3	3	2	2	1	1

In the first case, no mutation has appeared in the encrypted sequence. This is confirmed by matching the last nucleotide with the result of the checksum method. In the second case, a mutation occurs in the first location of the sequence. This is immediately noticed since the last nucleotide in the sequence differs from the resulted sum check calculation. While the proposed mutation detection method works perfectly in the first and second cases, it sometimes flawed as presented in case three. Here, both that attached nucleotide and the result of the checksum are the same. Although the receiver thinks that the sequence has been correctly delivered, it is actually modified in different locations. The proposed mutation detection technique can work properly in the case of single location mutations. Alas, it may stumble in the case of other types of mutations cases with multiple locations frameshifting or swapped nucleotides. An enhanced modification detection technique is required to cover cases like transmission errors and deliberate change by an attacker. This can be accomplished by using two DNA sequences, one for the data hiding and the other for the modification detection. All SNPs locations of the first will be used solely for data hiding while locations in the second sequence are only used to hold data verification values. This will increase the number of locations dedicated for concealing purposes which improve hiding capacity and will make it easier to detect different kinds of changes in the carrier sequence.

C. The Field of Data Structure

Another field in computer science correlated with the field of DNA steganography to increase hiding capacity is data structure. In [58], a framework for hiding based on a balanced tree is suggested. This is accomplished by converting a randomly selected DNA sequence into a balanced tree where every node holds a single nucleotide. The height of the tree depends on the size of the message to be sent. Even levels have at most two children while odd levels have at most three. The

traversing process is done by Depth First Search (DPS) approach. The encryption process starts by converting every character in the message to four nucleotides.

Then, characters in the leaf nodes will be replaced in reverse order with letters of the encrypted message. The last stage is obtaining the fake DNA sequence by assembling the letters based on the references of the nodes in the tree. For example, encrypting letters (ABC) will start by converting them to ASCII form to become (01000001, 01000010, and 01000011). Then, it is converted to (CAAC, CAAG, and CAAT). If the selected DNA sequence to hide the message inside is (ACGGTTCCAATGCCTAAGCTA), it is converted to a balanced tree as shown in Fig. 6.

Cases	Encrypted message	(A = 0 / T = 1 / G = 2 / C = 3)
Case 1	AGT GCC TAT T	021 233 101 13 MOD 4 = 1 » T
Case 2	GGT GCC TAT T	221 233 101 15 MOD 4 = 3 » C
Case 3	GGT GCC TTG T	221 233 112 17 MOD 4 = 1 » T

Fig. 5. Examples of Mutation Detection Method.

Fig. 6. Balanced tree for Random DNA Sequence [58].

After that, the encrypted message is integrated into the leaf nodes of the tree as shown in Fig. 7. The faked DNA sequence obtained from the balanced tree is (ACGCATATACAGCAGACACAC). The proposed framework offers high hiding capacity and accepts any type of input. Also, hiding spots are scattered all over the reference sequence in non-sequential manner. Nevertheless, the algorithm is pattern-dependent. Once the pattern is revealed, the secret message is compromised. An interesting idea to improve upon this work is using a link list for holding the contents of the DNA sequence instead of the balance tree. Linked lists have higher flexibility, complexity, and more fluent transition from an element to another than a tree.

Fig. 7. Balanced Tree after Message Integration [58].

#### D. The Field of Artificial Intelligence

The field of artificial intelligence can also be used to develop a robust DNA steganography algorithm. The authors in [59] used backpropagation artificial neural network (ANN) to achieve high hiding capacity, low cracking probability, and zero payloads. In the embedding process, the inputs are the DNA reference with the secret message and the output is a set of weights from the neural network. At the beginning, every character in the secret message is converted to the equivalent ASCII binary value. Then, this value is converted to the equivalent DNA letter based on the DNA binary coding rule. Each letter in the DNA message will be assigned to a location in the DNA reference. ANN will be used to get a list of binary locations and the weights of the training phase will be stored in a set. This set and the chosen DNA reference are sent to the receiver. Fig. 8 represents a process diagram to illustrate the AI-based data encryption and data hiding processes.

At the receiver side, the extraction process is executed by implementing the steps of the embedding process in reverse order. Firstly, both the DNA sequence and the weights received from the sender are applied to the ANN. The result is a list of positions denoting the hiding locations. A set is constructed of DNA letters assembled from these locations. Based on the binary coding rule table, DNA letters are converted to binary form. The secret message is obtained by converting every 8-bits to a character using the ASCII code. Fig. 9 represents a process diagram to illustrate the data decryption and message extraction.

The proposed algorithm shows good results like 2 BPNs and zero payloads. It also preserves the biological functionality of the DNA sequence because no modification has been done to it. The weak points of this algorithm are the need to send the

original DNA sequence to the receiver. Hence, it is not a blind algorithm. Also, the main defect of using the ANN is the high consumed time, especially in the training phase. This time can be reduced by using only a segment of the DNA sequence as the input to the ANN instead of using the whole sequence. Besides that, it is really interesting to investigate using swarm intelligence techniques like particle swarm optimization (PSO), bee colony, and ant colony to create a hiding locations pattern. This may outperform ANN in terms of complexity and time consumption.

To have a comprehensive look over the classical and modern techniques discussed in this paper, Table IV states the security parameters of these approaches. It can be concluded from this table that the substitution method is more suitable with small size secret messages. It is used when preserving features like blindness, zero payloads, and sequence functionality are crucial. Besides that, the substitution method usually uses only specific locations in the cover medium like LSBase for hiding purposes. This restriction leads to using only long DNA sequences as a cover medium. This issue can be solved by reducing the size of the hidden message with a proper lossless compression method. On the other hand, the insertion method is used when large chunks of data need to be exchanged. It ignores features like blindness and preserving functionality to offer no threshold boundary for the amount of embedded data. Finally, Table V summarizes the modern algorithms in terms of their purpose, advantages and disadvantages, and possible ways to improve them.

TABLE V. SUMMARY OF THE REVIEWED MODERN APPROACHES

Author & Year	Fields	Aim of the paper	Pros	Cons	Suggestions
Hamed et al. 2018 [23]	Biology	Exploit the DNA conservative mutations to develop secured, high capacity, preserved algorithm.	Using advanced Playfair cipher. Very low cracking probability. Scattered hiding locations. High capacity. Preserve biological features.	Using fixed substitution table. BCR table is required to be send to the receiver every transmission session.	Use dynamic and randomly generated substitution table. Integrate the BCR table in the DNA sequence.
Saha et al. 2019 [58]	Data structure	Increase hiding capacity by embedding encrypted characters of the secret message in the leafs of a balanced tree.	Over 50% hiding capacity. Scattered hiding locations. Blind. Zero payload.	Pattern dependent technique. Do not Preserve biological features. High modification rate.	Use more than one nucleotide in leafs nodes will increase hiding capacity. Use a linked list instead of a tree may offer better results.
Mohammed et al. 2019 [59]	Artificial intelligence	Develop a robust DNA steganography algorithm by using ANN.	Preserve biological features. Zero payload. Low cracking probability.	Not blind. High execution time. Sequential hiding pattern.	Lower consumed time in training by reducing the range of ANN's inputs. Use swarm optimization techniques to create a hiding pattern.
Sabry et al. 2019 [57]	Biology	Maintaining DNA signature by exploiting ambiguity feature and hiding data in redundant codons of amino acids.	Preserve biological features. Very low penetration probability versus different types of attacks.	Adding new bit in some cases is required during embedding process. The performance of the algorithm depends on the contents of the secret message.	Hiding data in only locations related to amino acids guarantee best performance.
Na 2020 [56]	Biology Networking	Use SNPs in DNA as hiding locations. Developing a mutation detection method.	SNPs provide good noise cover. Single mutation detection. Zero payload. Blind algorithm. Preserve functionality.	Low hiding capacity. Deal only with alphabets and numbers. Block checksum fails in addition, deletion and swapping cases.	Compress the data before hiding process. Enhance the performance of the checksum technique by using a dedicated DNA sequence for it.

## VI. CONCLUSION AND RECOMMENDATION

DNA has proved it can be the optimal medium for data hiding and transmission. It gives promising solutions to issues that arise when other covering mediums are used. In the last twenty years, many DNA steganography algorithms have been proposed. Despite the wide range of ideas offered by steganography algorithms, there are many gaps and unresolved issues in this field. Some of them are:

- An improved data encoding method is required to convert the binary form of the secret message to genetic letters. The required number of genetic letters to hide the binary form of the secret message can be decreased using the lossless compression method. This will increase the availability of hiding locations and the value of BPN.
- One of the DNA-based cryptography techniques is using a dictionary or a lookup table to link characters of the secret message to a specific codon. Lookup tables have a limited capacity of only 64 locations if codons are used. This is sufficient to encode alphabets and numbers while special characters are ignored. Besides that, lookup tables are static, and using the same table in every data transition session is quite risky. If a third party revealed the contents of the lookup table, the whole steganography algorithm is compromised. One possible solution to this issue is using a dynamic lookup table randomly generated at each transition session. The sender will integrate the new table with the concealed secret message.
- There is a trade-off between providing high hiding capacity and preserving biological features of the DNA sequence. Using all nucleotides to hide data will ruin the functionality of the protein while exploiting biological characteristics like ambiguity or mutations will significantly decrease hiding capacity. Therefore, there is an obvious need for a technique that enables us to hide the maximum amount of data in LSB locations in codons.
- The majority of developed DNA-based steganography algorithms used adjacent or sequential locations in the DNA sequence to hide characters of the secret message. Also, the hiding process is applied to these characters with the same order of their locations in the secret message. Alternatively, scattering hiding locations all over the sequence will make deducing the secret message from the covering medium even harder for a third party. One of the applied techniques in the literature to achieve such a task is using a balanced tree to distribute the message characters all over the sequence. This approach is fairly static and adopting another data structure such as the linked list will offer a more flexible transition from one character to another.
- One of the modern trends in the field of DNA-based steganography is adopting a predefined location-based hiding structure. Both the sender and the receiver agree on a specific method like a neural network with

backpropagation and use its structure in the encryption and decryption phases. The selected method must meet several security and performance measures. For example, minimum deployment speed, variations of hiding locations at each run, and preserving the content of this secret message even if the hiding structure is predicted by an attacker. Identifying the optimal hiding structure method is still an open issue in this field.

- The transmission of the fake DNA sequence from the source to a destination over an untrusted channel may encounter different types of obstacles. Some of these obstacles are mutations, transition errors, and message modification by a third party. To authenticate the integrity of the obtained secret message, a message authentication technique is required. Previously proposed methods are limited to deal with unique cases like single mutations. A comprehensive solution to this issue is using a dedicated DNA sequence to guarantee the integrity of the fake DNA sequence. This will offer more locations for both data hiding and data checking.

All in all, the combination of exploiting biological attributes of the DNA with utilizing the different techniques borrowed from various fields of computer science proved to be fruitful. It offers promising results and solutions for the existing issues in the field of DNA-based steganography. These recently suggested novel approaches are expected to accelerate the movement towards consolidating the rank of DNA as one of the main concealing mediums. Also, they sustain using DNA-based steganography methods in real-life applications.

**Abstract**—The digital images get distorted due to non-uniform light conditions or improper acquisition settings of the digital camera. Such factors lead to distorted contrast objects. In this work, we proposed adaptive enhancement algorithm to improve the contrast while preserving the mean brightness in the image. The method developed is a combination of discrete wavelet transform and gamma correction. Firstly, the gamma scale is computed from multi-scale decomposition using 2D-discrete wavelet transform. The value of scale parameter in gamma was computed from combination of logarithmic and power function. Secondly, the gamma correction is implemented to improve the contrast in the image. Lastly, bilateral filtering is utilized for smoothness of edges in the image. The approach effectively preserved the brightness and optimized the contrast in the image. The objective quality measures used as Peak SNR, AMBE, entropy, entropy based contrast measure and median absolute deviation is computed and compared with other state-of-the-art techniques.

**Keywords**—Non-uniform images; gamma correction; multi-scale 2D- discrete wavelet transform; logarithmic-power; quality metrics

## I. INTRODUCTION

Due to imbalance of energy in the wavelength between RGB (red, green, and blue) colours, the distortion in the contrast is produced in the images. The contrast is the variation of brightness to discriminate between the features present in the image. The Fig. 1 is the exact illustration of what had been discussed by Qing Zhang et al [1]. The figure displayed an image with the distorted contrast, where most of the pixel values lies at the left extrema of the intensity scale. If the pixel values narrows at the extreme left, right, and middle values of the intensity scale, then the image is termed to be dark, bright, and low contrast images. For high contrast, the requisite amount of pixel should be uniformly distributed over the entire intensity scale [2]. Therefore, contrast is an important parameter to indicate the structural information in the image. With contrast stretching, the spread from a low to a high contrast range can be attained. Such mapping is termed to be the adjustment of dynamic range of intensity scale. Therefore, contrast stretching is a transformation technique utilized through linear or non-linear operations. The histogram equalization (HE) is one of the popular linear transformation technique, known for its simplicity and ease of use. It is an

intensity-based transformation which computes the information content based on statistical inference. Fig. 2 shows the full span of range obtained from HE technique. It generates distributed regions all over the intensity scale. But, with the stretch of contrast, contouring artifacts is occurred due to the loss of edges.

Fig. 1. Original Image.

Moreover, due to poor brightness preservation, the quality of the image is distorted. Hence, it is required to maintain the equilibrium between contrast and brightness in the image.

Fig. 2. Enhanced Image using HE Method.

## II. RELATED WORK

To overcome the limitation of HE, different techniques were proposed as mentioned in [3][4][5] to improve the quality of the image. The main idea in most of the techniques was to spread the dynamic range of the images. However, the HE does not provide sufficient information on the composition of fine details and edges. Most of the results obtained from the modified approach to HE, produced over enhancement for the darker scale and under enhancement for the lighter scale of the intensity values. The illustration in Fig. 3 was the enhanced image form the algorithm proposed by Kuldeep Singh and R. Kapoor as ‘MMSIC’ [6]. The modified HE was computed from mean-median based clipped histogram to improve picture quality. With this technique, the large number of pixel values were more towards the left extrema. This effect leads to

\*Corresponding Author

the low quality of contrast. Also, M.M. and M. Abdullah-Al-Wadud [7] had proposed the boosting algorithm for correction in over enhancement. The minor regions were boosted to suppress quantum jumps.

Fig. 3. Enhanced Image from Kuldeep Singh and R. Kapoor [6].

Another approach is the global and local HE methods. In the global HE, the overall picture is enhanced. Whereas in local HE, with the utilization of small windows, the quality of the picture is improved. Qi-Chong Tian and Laurent D. Cohen [8] proposed the combination of global and local HE to preserve the naturalness of the image. Further, fast quadratic HE was proposed by Surabhi Patel [9]. The author claimed the method was computationally faster as compared to global HE and local HE. Lastly, compared to the various modified methods of HE, BPDHE [3] produced effective results in preserving the mean brightness.

Other than HE, discrete wavelet transform is also a useful tool to improve the overall quality of the image. Hafiz Syed Muhammad Muslim et al. [10] had proposed noise reduction using 2-dimensional-discrete wavelet transform (2D-DWT) and a Gaussian low-pass filter. The DWT was used to filter the high frequency content and, for the other part, a Gaussian low pass filter was used. The algorithm was designed for improvement in the visual quality of medical images.

In recent times, the implementation of gamma is used for contrast improvement. Like sigmoid, it is also a non-linear approach to improve the contrast. In this techniques, gamma parameter is a constant value. Due to non-uniform contrast in images, the scale parameter in cannot be held constant. To meet the challenge, Huan S et al [11] developed AGCWD as adaptive gamma correction with weighted distribution mapping of the histogram to improve the contrast. The algorithm designed is limited in approach and mostly over-enhanced the low-contrast images. Gang Cao et al [12] have proposed an effective way to handle the exaggerated enhancement with gamma correction. Rather than correlating with the cumulative density function, gamma scale was used for the negative portion of the images. The modulated value of gamma alleviates the contrast of the image. For the effectiveness of gamma correction, a scale parameter is required to be computed such that, along with the contrast improvement, brightness is preserved in the image. The method of mean- variance computation of scale parameter was proposed by Meriama Mahamdioua and Mohamed Benmohammed was proposed to deal with the non-linear nature of gamma correction. But most of the experimental results were focused on facial recognition in the image. In such condition, the other details of the image could be avoided for overall enhancement. Further G. Jiang et al [13] developed

the golden search algorithm to optimize the scalability of gamma. Through the weighted sum, mean brightness was preserved. Liyun Zhuang and Yepeng Guan [14] proposed the log-exponential method to compute the scale of gamma. The HE was modified through the gamma scale to show the richness in the information details. The objective measures indicated the improvement but the subjective quality of the image was effected due to saturation effects. The hybrid combination of discrete wavelet transform and singular value decomposition was utilized by Sahnoun M. et al [15]. The experiments were restricted to MRI images for utilization of the proposed method and was dealt with grayscale content. Linwei Fan et al [16] explored the pros and cons of denoising techniques for the better visibility of the images. After formulation of denoising problem, various methods and their consequences were explored to conclude the findings of denoising techniques.

Although, HE is the simplest technique to enhance the contrast in the image. Due to serious limitation of over/under-enhancement (as clearly observed in Fig. 2 and 3), alternate approach of gamma is presented in our proposed algorithm. The key point is to preserve the mean brightness while improving the contrast. So, the estimation of brightness is computed through multiscale resolution analysis. And lastly, the scalability of contrast is increased by automated gamma scale calculated from logarithmic-power function.

The organization of the paper will be as followed. In section III, the proposed algorithm is discussed. In section IV, experimental results is demonstrated. Lastly, the conclusion of the proposed algorithm is interpreted.

### III. PROPOSED ALGORITHM

The Fig. 4 demonstrates the flow diagram of the proposed algorithm with gamma correction in contrast distorted images. The course of the work progressively followed with the conversion of raw RGB image to hue (H), saturation (S) and intensity value (I). The luminance value (I) is used for further processing stages. The computation of gamma scale function was obtained from logarithmic-power function. For the optimal value of scale parameter, multiscale resolution is implemented using 2D- discrete wavelet transform. This approach is necessary to extract the maximal luminance information in the intensity component. Lastly, the enhanced image is obtained from bilinear filtering to smooth out the edges.

#### A. Image Transformation

It is difficult to process the information for individual colors. Hence, for the given raw image, given as  $F(x,y)$ , is converted to 'I' [17] such that:

Fig. 4. The Flow Diagram of the Proposed Technique.

Fig. 5. Transformed Image Left: Grayscale and Right: Intensity Component.

$$F_{(x,y)} = T[H_{(x,y)}, S_{(x,y)}, I_{(x,y)}] \quad (1)$$

'T' denotes the transformation of RGB to HSI.

As shown in fig. 5, in comparison to grayscale, the intensity component has the maximal content of brightness in the image.

### B. Multiscale Decomposition

Most of the algorithms were designed to decompose the input image into bright and dark regions or partitioning of histogram [18] [19] [6] to obtain the luminance value in the image. Also, the 2D- DWT is utilized to compute the weighted function for selection of control parameters.

Inspired by the use of 2D-DWT in [15], multiscale resolution to the 'I' component in the HSI space is implemented to compute brightness. The primary objective is to estimate 'brightness' in the image. The information was down-sampled at a scale level of 'two'. The Fig. 6 showed the 2D-DWT decimation of information into four sub samples. The resultant image consisted of low pass filter in rows and columns direction sub-sampled at a scale level of '2'. The other followed by combination of high and low pass filter coefficients. With the profound studies [20][21], multiscale discrete wavelet transform (2D-DWT) was implemented. The 2D decomposition is obtained from one dimensional DWT decomposition. The 2D- discrete wavelet transform is implemented with mother wavelet as 'symlet5'.

$$I_{(u,v,u',v')} = \sum_{x=0, y=0}^{N_{cols}-1, N_{rows}-1} I_{x,y} \frac{1}{\sqrt{vv'}} \psi\left(\frac{x-u}{v}, \frac{y-u'}{v'}\right) \quad (2)$$

Where  $\frac{1}{\sqrt{vv'}} \psi\left(\frac{x-u}{v}, \frac{y-u'}{v'}\right)$  is the specific mother wavelet,  $I_{x,y}$  is the intensity component of the given image and  $I_{(u,v,u',v')}$  is the transformed image as shown in Fig. 5.

The choice of mother wavelet and selection of scale level was based on computation of wavelet energies [22] . The energy was calculated in a two-step formation as follows: (i) compute the wavelet energy at each scale level for different mother wavelets and (ii) the mother wavelet at preferred scale level with highest energy would be the criteria for decomposition.

Fig. 6. 2D-DWT at a Scale Level of '2'.

### C. Estimation of Scale Parameter

There could be two possible ways to determine the scale parameter, either it should be chosen a constant value obtained from testing on various images with varying light conditions. Secondly, to make it adaptable for individual intensity scale of the image. Due to unpredictable variations in color distribution, assuming a constant value is difficult to obtain desired objective. Hence, the approach based on assumption of computing the average of minimum intensity of individual colors was taken to define selection criteria. This average value was computed from the original image. Secondly, the scale parameter is computed from the modified form of scale parameter in a logarithmic function. The logarithmic function is defined by the relation as  $s=c \log(1+r)$ . The scaling constant 'c' is chosen such that input intensity is mapped to high values and is calculated as:  $= \frac{J}{\log(1+\max(I))}$ , where J is the maximum scale value (255) and  $\max(I)$  is the maximum input value. This scale constant is modified with the assumption of mean intensity of low pass coefficients and is computed from Eq. 3. From the obtained value in equation (2), the mean intensity of pixel values were calculated as  $\mu = \frac{1}{MN} \sum_{m=0, n=0}^{M-1, N-1} L_{m,n}$  Where 'μ' is the mean intensity of low pass coefficients 'LL'.

$$\gamma = \frac{J - \mu}{\ln(1 + \mu)} \quad (3)$$

Where 'γ' is the scale parameter for gamma correction.

The minimum perceptible value of gamma must be 0.5 for any change in the contrast. And if the value goes greater than 1, will produce low contrast image. Since, the value obtained from Eq. 3 is too large to produce a desirable quality. Hence, the objective function was introduced to balance the scale of gamma parameter.

$$\gamma^{new} = \gamma^{(av(\min(RGB)))} \quad (4)$$

where  $\gamma^{new}$  is the scale parameter and 'av(min(RGB))' defined the objective function and is calculated as average of minimum intensity value in RGB colors. The value of gamma ranges from zero to infinity. However, if the scale value is 1, defines the linear mapping. And if the scale tends towards zero, the mapping is at higher or in other sense, brighter output values. Otherwise, towards darker output values. The intensity range of our referred data does-not constituted darker pixel values. From Eq. 4, it is found that the value of gamma greater than 1.25, over-enhanced the final image. Hence, the primary concern was to keep the scale level less than '1'. To overcome the over or under enhancement, adaptive gamma correction is implemented. As proposed in [23] , the increment value of gamma was computed from mean and variance combination for correction in contrast. But this method is limited to facial recognition, hence the proposed approach computed the average of maximum intensity of each channel in the original image. It is clearly observed in Eq. 5, the range was selected from  $0.65 < \gamma^{new} < 1.2$  for no correction in the gamma scale. However, if the value of gamma ( $\gamma^{new}$ ) is either decreased or increased, the correction in gamma is processed from other relation as stated in Eq. 5. With this approach, the mean brightness is well preserved.

$$\gamma^c = \begin{cases} 0.5 - (\text{av}(\max(\text{RGB}))) & \gamma^{\text{new}} < 0.85 \\ 1 - (\text{av}(\max(\text{RGB}))) & 0.85 \leq \gamma^{\text{new}} < 1.2 \\ 1.25 - (\text{av}(\max(\text{RGB}))) & \gamma^{\text{new}} \geq 1.25 \end{cases} \quad (5)$$

Lastly, gamma correction is implemented on ‘HSI’ transformation. The relation is as shown below:

$$Z_{(u,v)} = (F_{(x,y)})^{1/\gamma^c} \quad (6)$$

Where  $Z_{(u,v)}$  is the final image (HSI) and  $F_{(x,y)}$  is the image obtained from Eq. 1. The Fig. 7 illustrated the comparison of entropy, peak signal to noise ratio (PSNR) and mean brightness error (AMBE) to understand the necessity of change in gamma scale. The quality metrics was compared for the images with gamma correction (M) and without correction (U). The result of ten such images were shown, where gamma scale exceeds the threshold of 1.25. The AMBE [24] is the tool to predict the preservation of mean brightness in the image. Lower the value of AMBE, better will be the preservability. Since, AMBE is not a better metrics to measure noise content in the given information. Hence, PSNR [25] is also stated to predict the noise content in the image. Higher the value of PSNR, lower will be the noise and hence, better quality of image is obtained. The effectiveness of adaptive gamma scale produced the weighted change in AMBE and PSNR. Moreover, the richness of data (entropy) could be clearly observed in comparison to unmodified gamma correction.

Further, the Fig. 8 showed the comparison of variability in gamma correction. The middle image (b) is obtained from  $\gamma^c = [1 - (\text{av}(\max(\text{RGB})))]$  which is the standard form used for every image. With this gamma correction, scale value  $\gamma^{\text{new}}$  is obtained as 1.37. Hence, the gamma scale is modified to  $[1.25 - (\text{av}(\max(\text{RGB})))]$ . The right image (c) is the enhanced image after modification. The over enhancement (color brightness) is observed in the middle image. From the modified scale, the image showed the optimal brightness with improved PSNR.

Fig. 7. Comparison of Adaptive Correction with Modified (M) and without Modification (U) based on Threshold Criteria ( $\gamma^c$ ).

Fig. 8. Illustration of Gamma Scale (Image1): (a) Original Image, (b) without Adaptive Gamma Correction, and (c) Adaptive Gamma Correction (M).

Fig. 9. Illustration of Gamma Scale <0.85, (a) Original Image, (b) without Adaptive Gamma Correction, and (c) Adaptive Gamma Correction (M).

Further, the Fig. 9 demonstrated the quality of the image, when the threshold value was less than 0.85. The middle (b) is low in contrast and when modified with the threshold  $(0.5 - (\text{av}(\max(\text{RGB}))))$ , produced the contrast enhanced image (c).

With point of human perception, ‘I’ is better for color image processing. However, conversion process of ‘rgb’ to ‘hsi’ and vice-versa produced the over-saturated colors. It is stated in [16], that convolutional neural network based denoising technique is well equipped to retain the naturalness in the image. Due to transformation and non-linear approach (gamma), the resultant image in our approach lead to disorientation in formation of colors. Hence, bilateral filtering is implemented to each channel for uniformity in color distribution. So, bilateral filtering was implemented to smooth out the edges for enhanced image. This type of filter is a noise suppression smoothing filter. Each color component is smoothed out while preserving the edges.

In summary, the algorithm proposed could be described as:-

**Algorithm:** Adaptive logarithmic-power function for contrast distorted image

**Input Image:** Original Image  $F_{(x,y)}$

**Step 1:** Convert the original image to HIS channel to obtain ‘I’ component (brightness)

**Step 2:** Decompose the ‘I’ at a scale level of ‘2’ using multiscale 2D discrete wavelet transform

**Step 3:** Using low-pass coefficients (shown in Fig. 6), compute the scale parameter using Eq. 3 and 4.

**Step 4:** Validate the scale value obtained from Eq. 4, using Eq. 5 for individual images.

**Step 5:** Finally, apply the automated gamma correction using Eq. 6 .

**Step 6:** After conversion from HIS to RGB, smooth out the edges using bilateral filtering.

**Step 7:** Obtain the Enhanced image.

#### IV. EXPERIMENTAL ANALYSIS

This section deals with the quality metrics implemented for comparison of proposed method with various state of the art techniques. The experiments were analyzed in the MATLAB 2017, platform. The machine used for evaluation was Apple MacBook, 1.8 GHz CPU and 8 GB of RAM.

A. Image Dataset

The Berkeley Image dataset BSDS500 [26] and CEED 2016 [27] is used for evaluation of the proposed work. From the referred dataset, 200 images with varying light conditions were selected.

B. Quality Metrics

The objective was to preserve the mean brightness while improving the overall contrast in the image. So, for our method, three quality metrics used as Entropy, absolute mean brightness error and Peak signal to noise ratio. The assessment of algorithm was based on full reference and no-reference measure. The full reference measure the information of the enhanced image in comparison to original image. Similarly, PSNR [25] and AMBE [28] measure the information as a full reference to predict the noise and mean brightness error in the enhanced image. Whereas, entropy, as a no-reference metrics, measures the richness in the content of the information. It is the full reference technique to assess the quality of image. Typically, high score of entropy and PSNR and low value of AMBE represents the better quality of image. In reference to the experiments conducted on 200 images of BSDS500 dataset, the 20 images with distortion in contrast is chosen for fair comparison with other relevant techniques.

Even though the AMBE is independent of the noise content, but measures the mean brightness content in reference to the original image. The Fig. 10 demonstrated the comparison of proposed technique with other algorithms published in peer reviewed journals. The brightness preserving dynamic (BPDHE) [3] and median-mean based clipped HE (MMSIC) [6] are the state-of-art techniques in modified HE.

Fig. 10. AMBE Score of Random Selected Images.

Whereas, adaptive gamma weighted distribution (AGCWD) [11] and gradient based image enhancement (IM) [29] are one of the technique referred in most of the published journals. For the proposed method, the minimum AMBE is found to be 0.099 (as shown in inset) in comparison to other methods. The average value of 20 images computed is 2.36, which was far better as compared to MMSIC (8.81), BPDHE (6.11), AGCWD (48.7), and IM (107.34).

Fig. 11. Comparison of PSNR Value.

Fig. 12. Comparison of Information Measure (Entropy).

TABLE I. AVERAGE OF QUALITY METRICS FOR RANDOM 20 IMAGES

Metric/Method	BPDHE	MMSIC	AGCWD	IM	Proposed Method
Entropy	7.54	7.31	7.33	4.82	<b>7.59</b>
PSNR	17.03	28.04	12.31	21.91	<b>28.49</b>
AMBE	6.11	8.81	48.70	107.34	<b>2.36</b>
EB	85.30	79.45	<b>133.96</b>	80.53	102.57

\*Bold letters show better results

As stated previously, AMBE is not a good measure of noise content in the information. Hence, the PSNR was computed to show, that with the low value of AMBE, the noise suppression in the enhanced image is appreciably achieved. The Fig. 11 showed the comparison of different methods with our method. From table I, the average value of AGCWD and BPDHE for PSNR computed was 12.31 and 17.03. For lower value of AMBE in BPDHE, the PSNR is found to be poor and as well in the case of AGCWD. The value of 21.97 showed a marginal improvement in PSNR with a very high value of AMBE. But, in case of MMSIC, the value of 28.04 dB was noticed for a low value of AMBE. In our proposed work, both PSNR of 28.493 and AMBE of 2.36 had effectively improved the quality of image.

The entropy is a quantitative analysis to measure the content of information in the image. With low value of entropy, lesser will be the content in the information. For the average original entropy of 7.39, the entropy (Fig. 12) of 7.59 is found in our proposed work. For the different methods: 7.3, 7.54, 7.31, and 4.82 is computed in AGCWD, BPDHE, MMSIC, and IM. Except BPDHE, all other methods showed the loss of information content in the images.

It might be concluded from Table I, even though with marginal increase in PSNR (as compared to MMSIC), considerable change in AMBE and entropy could be observed. Without the loss of information, and with preserved mean brightness, the proposed method proved to be effective in restoration of contrast distorted images. The Fig. 14 showed the enhanced images obtained from proposed method for the middle-left, narrow, spread, and middle-right of the intensity scale. Also, the median based absolute deviation had been shown in reference to the input image. It is visually evident that the enhanced image showed the wide-spread over the entire intensity scale.

The images shown in Fig. 14 is chosen to show, that even for considerable distribution of pixels (boat), the efficacy of the proposed method is proved. From the histogram, it is evident that no peaks could be noticed at the extreme right and

left of the intensity scale. Such pattern indicated no loss of information and under -exposure is found. Moreover, colors in the images did not get overlapped and hence saturation effects is negligible.

### C. Comparison with Enhancement Algorithms

In our experiments, hue and saturation is not altered and intensity is enhanced for the better quality of image. Like HE, our approach was also focused to spread the intensity values. With reference to the Fig. 13, for the narrow intensity scale (refer Fig. 1) where most of the information lies in the right half had produced widespread scale value with uniform brightness and contrast. In comparison to Fig. 2 (over enhancement) and Fig. 3 (over saturated colors), the shift of the peaks over the entire region could be observed in Fig. 13. It is attained by adjusting the gamma correction as stated in Eq. 5. The enhanced image produced improved contrast while preserving the mean brightness (in comparison to original image). From the aspect of quality metrics, table II (in reference to the Fig. 1) showed the comparison of different methods with the proposed technique. Except edge based contrast measure, the technique proved to be overall effective in better quality of the image.

The Fig. 15, showed the enhanced image for stat of the art techniques, used for comparison. For the cougar, except IM, the other methods showed the flatness (BPDHE) and over brightness (AGCWD) in the image. The median based absolute deviation is also stated at every histogram of images. It is the robust measure to estimate the distance of intensity value from the referred image. In our case, the referral image is the original and is compared with the enhanced image. With reference to parachute, narrow spread of intensity scale is noticed in comparison to the proposed technique. In case of

MMSIC, color disorientation is observed. For the uniform spread of intensity scale in the boat, over brightness was the major limitation of the AGCWD. Further, visual quality of method showed the over enhancement and color disorientation in the final image. In case of deer, all the methods showed the inconsistency in the spread of intensity values. The overbrightness in AGCWD, low contrast in BPDHE, oversaturation in IM and MMSIC, had adversely affected the detail and edges of the image. With fine details and pleasing quality of the image, the proposed technique effectively enhanced the image. For all the images, the quality metrics shown in table III, proved the efficacy of the approach used in the proposed method.

TABLE II. COMPARISON OF QUALITY METRIC FOR FIG. 1 WITH DIFFERENT METHODS

Metrics/Method	BPDHE	AGCWD	MMSIC	IM	Proposed Method
Entropy	7.23	7.63	6.755	5.28	<b>7.66</b>
AMBE	13.26	52.62	10.48	74.63	<b>1.76</b>
PSNR	14.00	12.28	23.29	24.68	<b>30.24</b>
EB	40.90	<b>102.55</b>	29.28	65.89	68.31

TABLE III. COMPARISON OF QUALITY METRICS FOR FIG. 14 & 15

Image/Method	BPDHE (AMBE/PSNR)	AGCWD (AMBE/PSNR)	MMSIC (AMBE/PSNR)	IM (AMBE/PSNR)	Proposed Method (AMBE/PSNR)
Cougar	12.11/13.38	57.87/12.13	5.33/21.75	15.24/25.89	<b>2.37/26.90</b>
Parachute	6.47/14.26	62.44/12.25	12.13/21.13	95.94/22.54	<b>0.55/28.39</b>
Boat	2.34/29.7	55.39/12.20	10.50/25.25	88.47/19.75	<b>1.77/30.37</b>
Deer	<b>3.50/14.08</b>	53.48/12.14	8.56/24.14	142.30/116.74	<b>6.59/27.38</b>

\*Bold letters show better results

Fig. 16. Enhanced Images Obtained from Proposed Method ((a) Back-Lighting, (b) Side-Lighting, (c) Front-Lighting): Up: Original Image and Down: Enhanced Image.

Lastly, the images with back, side, and front lighting is compared with the method proposed by Liyun Zhuang and Yepeng Guan [14]. The root mean square (RMS) and the entropy of the image was calculated with the same relation prescribed in Sec. 3.3.2 and 3.3.3 of the work referred in [14]. The comparative results as shown in table IV, showed the better quantitative analysis. However, in each image the entropy was more as compared to our method. But, due to over-enhancement (in reference to Fig. 9,10, and 14 of Log-Exp [14]) presented the over saturation of colors. In our

proposed method, neither the detailed information was lost (as compared to input image) and, moreover, the rms value computed is found to be better than published work.

The entropy of the input image shown in Fig. 16 is 7.28, 7.20, and 7.50. From the proposed method, the brightness is preserved for improved visual quality of the image. Also, the proposed method was compared with the method proposed by Rao B [30] using CEED 2016[27] dataset. The comparative images based on visual quality as shown in Fig. 17. The Fig. 17 (a,d and g) is the original image, (b,e, and h) is the enhanced image obtained from proposed method and (c,f and i) is the resultant image from [30].

In comparison to original image, Fig. 17 (c) showed the clipping of histogram at the extreme right of the intensity scale. It indicated the loss of detail information in the image. Whereas in Fig. 17 (b), detail had been well preserved in the proposed method. From fig. 17 (f), the pixel distribution is moved to right of the intensity scale. But in Fig. 17 (e), uniform distribution of pixel is observed.

As compared to dynamic HE [30], the enhanced images had shown spread of intensity scale with an average mean brightness error at 1.89. Similarly, the value of average PSNR is computed to be 27.39. Moreover, the optimal obtained is found to be better as compared to the final image obtained by [30]. In that case, over brightness had decreased the contrast ratio in the enhanced image. In our proposed method, mean brightness is preserved for considerable change in the contrast.

TABLE IV. COMPARISON OF LOG-EXP [14] AND PROPOSED METHOD

Image	Log-Exp (Entropy/RMS)	Proposed Method (Entropy/RMS)
Backlighting	7.79/84.45	7.30/ <b>109</b>
Side Lighting	7.75/77.86	7.26/ <b>105</b>
Front Lighting	7.79/83.59	7.64/ <b>96</b>

\* Bold letters show better results

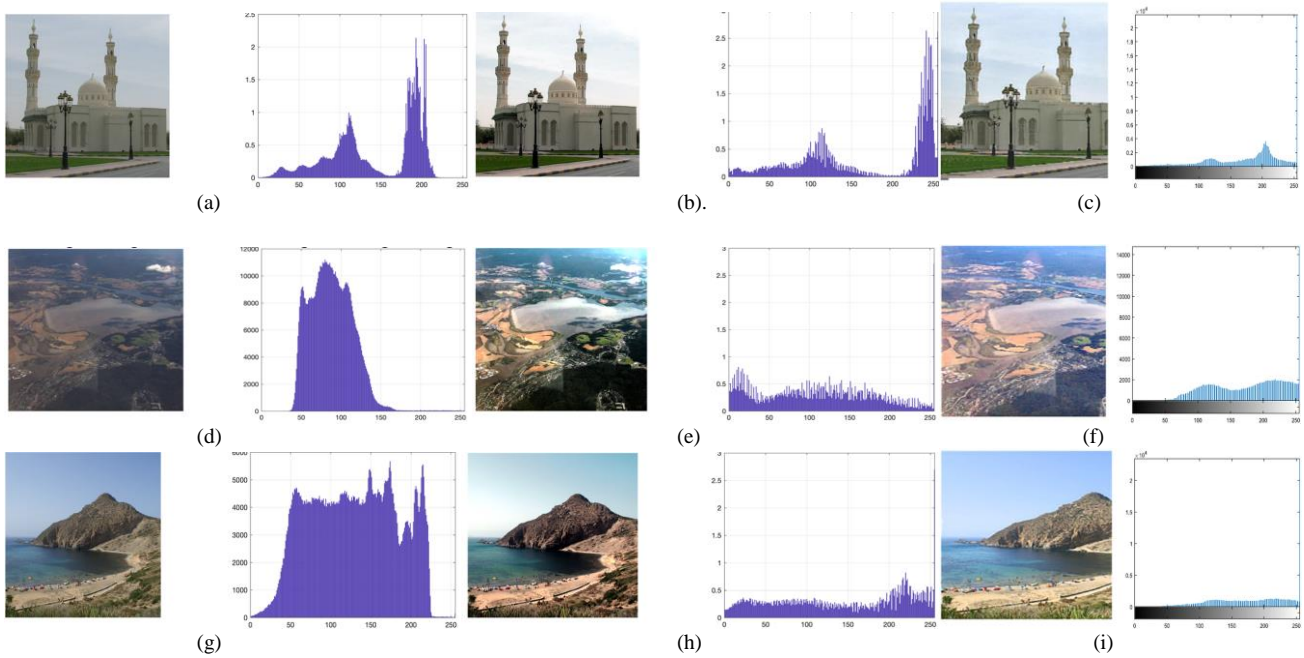

Fig. 17. Comparison of Proposed Method with Dynamic HE [30], (a), (d), and (g) Original Image; (b), (e), and (h) Enhanced Image from Proposed Method and (c), (f), and (i) Enhanced Image from Dynamic HE [30].

Lastly, it might be concluded that the objective of uniform distribution of pixel over the intensity scale, preserving mean brightness and improving the contrast had successfully achieved through the proposed algorithm. From Fig. 13, 14, and 17 (b), (e), and (h), it is clear that enhanced images showed the bell shaped and widespread of pixel values along the intensity scale. The bell shaped distribution represents, that most of the pixel existed at mid-tone values and therefore, minimum pixel distribution at extreme right/left of the histogram. Such representation of graph, is termed to have a better contrast with low under/over-exposure effects of illumination. Hence, with minimum AMBE and good PSNR, the approach in our method had appreciably improved the visual quality of the image.

## V. CONCLUSION AND FUTURE SCOPE

An adaptive procedure for preservation of mean brightness with improved contrast had been proposed. The alternate and improved use of gamma correction was presented for various low contrast images. The dataset of 200 images from Berkeley BSDS 500 was analyzed for qualitative results. Moreover, some random images from dataset of CEED 2016 was used for different conditions of lightning in the image. From the conclusive results for 200 set of images shown in table V, demonstrated that with improved PSNR and minimum error in brightness, proved the effectiveness of the technique used for contrast distorted images. The measure of information as described by Shannon theory, maximum is the value higher will be the content of information. Hence, the information content is found to be maximum in comparison to other method.

TABLE V. AVERAGE COMPARISON OF BSDS 500 DATASET WITH DIFFERENT METHODS

Metrics/Method	<i>BPDHE</i>	<i>AGCWD</i>	<i>MMSIC</i>	<i>IM</i>	<i>Proposed Method</i>
<b>Entropy</b>	7.57	7.31	7.28	6.78	<b>7.64</b>
<b>AMBE</b>	11.28	49.50	7.67	103.62	<b>3.02</b>
<b>PSNR</b>	16.63	12.32	27.14	19.19	<b>27.67</b>
<b>EB</b>	85.30	<b>121.96</b>	79.45	80.53	105.34

\* Bold letters show better results

The edge based contrast in AGCWD was maximum at the cost of over-brightness as shown in Fig. 15. It is found in our proposed method, that overall quality of the enhanced image had preserved the mean brightness and improved the contrast in the image. The over saturation of colors was also balanced with the use of bilateral filtering.

The objective of our work was to maintain the gamma scale value less than '1'. Even though the visual quality is better in Fig. 17 (b), but the considerable number of pixels could be seen in the right of the intensity scale. That causes the over-exposure of brightness. So, in the future work, thresholding based gamma correction might be implemented in such images to avoid the over exposure effect. Also, for the dark images, the value of scale parameter less than '1.5' could not produce desirable visual quality in the images. Hence, the work would be extended to deal with dark intensity scale values.

## ACKNOWLEDGMENT

We acknowledge the IKG Punjab Technical University, Kapurthala, Punjab, India and DAV Institute of Engineering & Technology, Jalandhar, and Punjab, India for providing valuable resources and necessary tools for the successful implementation of the work.

# A Meta-analytic Review of Intelligent Intrusion Detection Techniques in Cloud Computing Environment

Meghana G Raj, Dr. Santosh Kumar Pani

Department School of Computer Engineering, Kalinga Institute of Industrial Technology  
Deemed to be University, Bhubaneswar, India

**Abstract**—Security and data privacy continue to be major considerations in the selection and study of cloud computing. Organizations are migrating more critical operations to the cloud, resulting in increase in the number of cloud vulnerability incidents. In recent years, there have been several technological advancements for accurate detection of attacks in the cloud. Intrusion Detection Systems (IDS) are used to detect malicious attacks and reinstate network security in the cloud environment. This paper presents a systematic literature review and a meta-analysis to shed light on intelligent approaches for IDS in cloud. This review focuses on three intelligent IDS approaches- Machine Learning Algorithms, Computational Intelligence Algorithms and Hybrid Meta-Heuristic Algorithms. A qualitative review synthesis was carried out on a total of 28 articles published between 2016 and 2021. This study concludes that IDS based on Hybrid Meta-Heuristic Algorithms have increased Accuracy, decreased False Positivity Rate and increased Detection Rate.

**Keywords**—Intrusion detection system (IDS); machine learning; computational intelligence algorithms; hybrid meta-heuristic algorithms; cloud security; cloud computing

## I. INTRODUCTION

Cloud Computing (CC) provides on-demand network access to a group of configurable computing assets like servers, services, applications, storage, and networks that could be rapidly released with lesser management endeavors or service provider interaction. While it offers many benefits, one of the main challenges for organizations looking to adopt cloud-based solutions is security. This is because of the nature of the cloud infrastructure i.e., fully distributed and open, thus making it more vulnerable to threats and attacks. This environment creates incentives for potential intruders to initiate attacks targeting devices having access to data stored on the cloud. The threats due to attacks are to the integrity, confidentiality, and availability of cloud services and resources [56]. For example, a Distributed Denial of Service attack, is one that aims to prevent availability of data stored on the cloud, by choking the network bandwidth through packet flooding. Other potential attack types include IP Spoofing, Domain Naming System (DNS) Poisoning, Man in the Middle Attack, Port Scanning, etc. [50]. Cloud security is an interesting active field of study and various heuristics have evolved and been proposed. Basic security elements such as a firewall that protects the internal network and adoption of message encryption may be employed as initial lines of defense. However, a firewall may not be able to identify an attack initiated by an insider [33]. In order to

meet the security challenges effectively, a dedicated Intrusion Prevention System (IPS)/ Intrusion Detection System (IDS) should be integrated within the cloud environment. IDS has become an important and irreplaceable part of the network protection system. An intrusion i.e. an attempt to compromise the availability, confidentiality, and integrity of cloud-based resources can be detected utilizing cloud based IDSs [16]. Traditional network security techniques which are not integrated within the cloud environment may not be effective in meeting the requirements of cloud security. This is due to certain limitations of traditional IDS such as incorrect classification of network anomalies as attack, low rate of detection of attacks and high false positive rate among the detected attacks [27]. Techniques in IDS such as anomaly detection and misuse detection are now relying on machine learning to increase performance effectiveness. Machine learning incorporates meta-heuristic algorithms to enhance the performance, and to identify and classify normal and unusual attacks in the network. The IDS should monitor the potential means and ends for attacks, such as network traffic and audit data in a network/ computer system, and employ different methods for detecting unauthorized activities as intrusion. Fig. 1 provides a summary of IDS in cloud environments [44]. Design of an integrated IDS was described in [19] and [54]. The primary goal of IDS is to identify each intrusion in an effective way [60]. The execution of IDS enables network administrators to detect security objective violations. These security objectives include both securing cloud resources from attacks by external sources who are attempting to get unauthorized access, as well as securing them from attacks by internal sources who are attempting to abuse their access privileges. However, the efficient and effective development of IDS is a complex problem due to meeting the twin requirements of achieving low false positive rate and high true positive rate, while consuming minimal computing resources for these purposes [62]. An IDS with a high false positive rate could potentially generate unwarranted alerts and consume significant cloud resources in response to anomalous network states which were not the result of an attempted intrusion. The application of detection methods could then result in initiation of response events within the cloud environment, which eventually cause an overload in the network. Simultaneously, achieving a high true positive rate through accurate and rapid detection of intrusion is crucial in reducing the potential damage caused by an intrusion or unauthorized access to the cloud resources. Within IDS, Host-based Intrusion Detection

Systems (HIDS) functions on data collected from a computer system, and permits analysis of activities of processes and users in the attack on a specific system. It visualizes the attempted attack's outcome, access and observe data files directly and the process of the operating system [25]. It identifies the attacks which may not have been detected by Network-based Intrusion Detection System (NIDS), as it observes the events which are local to the computer system. Host-based Intrusion Detection and Prevention (HIDPS) consist of software involves in observation and analysis of events takes place in the computer and information system in identification and stopping harmful incidents in the system, becomes more important as it protects the computer system and its network activities [33].

IDSs use different methods to detect potential malicious activities during an intrusion. One such method is Signature-based method, which attempts to map the current set of system parameters with the previously recorded system parameters patterns which correspond to known attacks or intrusions which have occurred in the past [51]. A second method is Anomaly-based which attempts to detect attacks or intrusions using machine learning and statistics to create simulations, which are then compared with the current anomalies that may be seen in the cloud environment [51]. The Anomaly-based method has training and testing phases. Learning of normal traffic from data takes place during the training phase, and during the testing phase, tests are performed on previously unseen data. There are two types of IDS approaches- Hybrid and Non-hybrid. Hybrid IDS is the approach which attempts to reduce the limitations of Signature-based and Anomaly-based methods through higher accuracy and detection of known and unknown threats from a large dataset, by combining different intelligent algorithms [29]. Hybrid IDS relies on the reality that it is very difficult to manipulate cyber data without detection to carry out an attack [15]. Non-hybrid IDS is the approach which relies on a single intelligent algorithm to detect potential attacks. Numerous IDS models based on statistical models, machine learning, deep learning (DL), meta-heuristic algorithms, etc. are available in the existing literature. In recent years, hybridization of any of these approaches has been used to enhance intrusion detection performance. However, a comparative review of performance of various IDS approaches, after classifying them into different approach types- Machine Learning Algorithms, Computational Intelligence Algorithms and Hybrid Meta-Heuristic Algorithms- along selected parameters is not available in the literature. This paper provides a review of existing IDS algorithms, particularly developed for the CC environment, with the objective of comparing the performance of IDS approaches along selected parameters. The recent, state of the art IDS techniques consist of both non-hybrid IDS approaches as well as hybrid approaches. The existing IDS algorithms under each approach category have been reviewed and the merits of each algorithm have been identified. In addition, the reviewed algorithms have been compared to one another, based on selected parameters. Finally, the open issues, possible future directions, and limitations of the study have been elaborated.

Fig. 1. Overview of IDS in Cloud Environment.

## II. BACKGROUND

Riaz, A., et al., [45] conducted a brief analysis of IDS techniques presented for the cloud environment. To attain this goal, at the initial stage, the unique characteristics and limitations of all the techniques were enumerated. Next, a set of criteria were established for evaluating the IDS framework. In this work, a relative analysis of many current IDSs on different dimensions was elaborated. Lastly, the discussion of open issues and drawbacks was provided in detail. Zouhair, C. et al., in [63] presented the review of cloud infrastructure and summary of distinct intrusions in the cloud. In addition, the essential characteristics and challenges of cloud based IDS techniques were identified. Next, the researchers analyzed 24 cloud based IDS regarding their different positions, types, data sources, and detection times. Also, the strengths and limitations of various IDS, to evaluate whether they meet the security requirement of CC infrastructure or not were listed. Mthunzi, S.N. and Benkhelifa, E. in [41] identified security issues that are of catastrophic nature in the cloud environment and listed out a survey of the counter measures for cloud security with bio-inspired approaches and enumerated the advantages and limitations of the approaches. Mishra, P., et al., in [39] provided a comprehensive study of different IDSs presented for cloud infrastructure with analysis of their attack detection abilities. The researchers proposed an attack taxonomy and threat model in the cloud framework, to list out the various vulnerabilities in the cloud environment. The taxonomy of IDS techniques represented an advanced classification and provided an exhaustive literature survey of techniques using their distinct characteristics. Chattopadhyay, M., et al., in [14] examined the limitations in using machine learning techniques to detect intrusions and compared different techniques on several datasets and calculated the performance merits. The best technological solutions have been identified for various usage patterns. Sharma, S. and Kaul, A., in [53] presented a short overview about the different IDSs for a Vehicular Ad-hoc Network (VANET). Proposals were made to develop IDSs which could have potential application in VANET and VANET Cloud. This study aimed to explore open challenges, research directions in the future aspects, and leading trends in the placement of IDS in VANET. Lee, S.W., et al., in [32] focused on the Deep Learning (DL) IDS approach and

investigated how DL networks may be applied with distinct methods in various phases of the IDS, in order to achieve better results. The researchers categorized the surveyed IDS systems with respect to DL networks employed and described their major contributions. As well, in every classification, basic characteristics such as datasets, evaluated metrics, environments, and simulators were enumerated. In addition, a comparison of the results using DL IDS approach was provided, to compare the major approaches employed. Tama, B.A. and Lim, S., in [58] provided a summary of how ensemble learner may be employed in the IDS, through systematic mapping. The researchers analyzed and collected 124 high quality publications and the selected publications were later mapped to various classes like publication venues, years of publication, ensemble methods, IDS techniques, and datasets used. Furthermore, this survey analyzed and reported the experimental research of a novel classifier ensemble method for abnormality based IDSs. Shamshirband, S., et al., in [50] conducted a complete review of IDSs which used Computational Intelligence (CI) techniques in a (mobile) cloud environment. Initially, a summary of CC paradigm and service models was offered. Next, a review of the security risks in this context was provided. Earlier works related to this subject were surveyed critically, highlighting the limitations and advantages of those earlier studies. Next, a taxonomy for Intrusion Detection System was presented CI based techniques were categorized into hybrid and single approaches, for the different classifications of IDSs.

Based on the above overview of the background for this paper, research questions have been formulated, to focus on two 2 broad approaches to intelligent IDS and on hybridization of algorithms from these 2 broad approaches, to determine whether such hybridization could result in enhanced performance of Intrusion Detection Systems.

### III. RESEARCH METHODOLOGY

A Systematic Literature Review (SLR) denotes evaluation of previous works on a specific set of problems from a critical perspective, with an attempt to list out all relevant studies on the basis of first principles. This study devises a structured method in locating and assembling a body of research studies on IDS in cloud environments [47]. Previous studies state that such methods have overlooked limitations, reduced chance effect and improved data validity process [21]. The SLR structure to review past work on intelligent IDS in cloud computing are presented in this section. This requires an impartial and overall layout of literature in this SLR. First, research questions are proposed as per the objectives of the survey, search query and criteria of inclusion and exclusion bias are illustrated in sections 3.1 and 3.2 with review methodology in 3.3.

**RQ1:** What are the different Computational Intelligence Algorithms- such as Bio-inspired, Swarm Intelligence, Evolutionary Computing- used in intelligent Intrusion Detection Systems in Cloud Computing?

**RQ2:** What are the different Machine Learning Algorithms used in intelligent Intrusion Detection Systems in Cloud Computing?

**RQ3:** What are the performance advantages of hybridization of Computational Intelligence Algorithms and Machine Learning Algorithms, for cloud IDS?

These questions were considered during the process of conducting SLR for intelligent IDS in cloud environments.

#### A. Search Terms

Research articles in reference to keywords such as "Intelligent IDS in cloud computing", "Machine learning based intrusion detection systems in Cloud", "hybrid and non-hybrid approaches", "Bio-inspired IDS in Cloud", "Nature-inspired IDS in Cloud", "Swarm intelligence IDS in Cloud" and "Hybrid Meta-Heuristic IDS in Cloud" were searched from online sources including IEEE, Springer, Taylor & Francis, Scopus, Science direct, and Google Scholar. A total of 140 articles were collected based on these keywords, with preference given to the top research articles from renowned journals. Analysis was conducted in an orderly fashion, to initiate the review process, resulting in identification of 28 articles for Meta Analysis. This process has been summarized in Fig. 2.

#### B. Inclusion and Exclusion Bias

The search was commenced with journals with an overview of the research presented in: (a) articles listed in the peer-reviewed journals; (b) published in English; (c) related to cloud IDS; (d) published between from 2016 to 2021, from databases. Duplicate articles, Conference Publications, Theoretical Research articles were removed from the initial search. Irrelevant articles were excluded further after reading the Title and Abstract. After reading the remaining full text articles, 28 articles were found to be probable sources for the review.

#### C. Qualitative Review Synthesis

These twenty-eight articles were considered probable sources and their contents were streamlined in the SLR. The articles were further categorized into those that were based on machine learning models, computational intelligence (bio-inspired) algorithms and hybrid approaches for IDS. These three approaches were reviewed in terms of Accuracy, False Positive Rate and Detection Rate, as parameters [4].

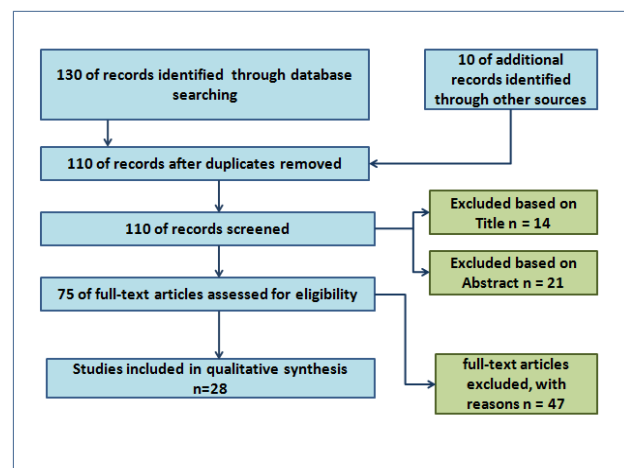

Fig. 2. Flowchart of Article Selection.

#### IV. LITERATURE REVIEW

A detailed review of IDS under each category is given in the following section.

##### A. Machine Learning based Ids Approaches in Cloud

Machine Learning (ML) is used to address the optimal solution for complex problems which have multiple non-linear constraints, high number of dimensions and time limitations in the field of science and engineering. ML techniques have many features to resolve conflicts in classification of patterns as well as regression, optimization and estimation of functions [23]. ML provides computers input or training data to facilitate the process of learning and improving, without manual programming. The main focus of ML is to develop programs that use data in the discovery process without human intervention. ML algorithms can be classified into Supervised ML algorithms— which enable predictions of output from given data; Unsupervised ML algorithms— which enable inferences to be drawn on structures which are not obvious from unknown data; and Semi-supervised ML algorithms— which enable blending of features of both Supervised and Unsupervised ML algorithms and are mostly used to quantify the training data [8]. A detailed comparison of ML based IDS approaches reviewed in this SLR is given in Table I. A brief summary of these models follows. A novel DDoS attack detection technique in CC platform was developed in [31]. The presented model was defined by the use of an ML model called Voting Extreme Learning Machine (V-ELM). A voting scheme was developed and attack class was allotted to a sample, in case of having many votes. The performance of the V-ELM technique was validated using the NSL-KDD and the ISCX intrusion detection datasets. In [59], the researchers aimed to detect the presence of DDoS attacks in SDN. This method classified the SDN traffic as normal or attack traffic with the use of ML models integrated into Neighborhood Component Analysis (NCA). In addition, a public dataset with 23 attributes was used for experimental validation and the results demonstrated the superior performance of the proposed model with limited features. Sharma, P., et al., in [52] developed a multi-layer IDS to classify different types of attacks using the ExtraTress, classification model and the Extreme Learning Machine (ELM) model was employed for the detection of individual attacks.

The outputs from the ELMs were integrated with the use of a Softmax layer. The proposed model's performance was validated using the UNSW and KDDcup99 datasets. Lopez, A.D., et al., in [35] proposed flow based traffic features for analyzing the variance in patterns among normal versus anomalous packets. They evaluated the various supervised classification approaches using parameters such as false negatives, detection accuracy, run time, and time taken to train. The researchers concluded that Decision Tree (DT) based Random Forest (RF) was the promising approach, in which a Dense Neural Network performed well on specific DDoS attack types. Sambangi, S. and Gondi, L., in [48] designed an ML method on the basis of multiple LR analyses and carried out data visualization by taking into account the respective fit charts and residual plots. The aim was to employ the Feature Selection (FS) method and define the significant features which are delivered by various predictive models. Then, the selected feature was subjected to multiple LR analyses, and the performance of the ML method was evaluated as per the set of selected significant features, on the CICIDS2017 dataset. Another study [26] proposed real-time recognition of DDoS attacks using an ML classifier which relied on a distributed processing framework. The DDoS detection rate was computed using the OpenStack based cloud testbed, through the Apache Spark architecture. In [21], a DL based IDS for DDoS attacks was proposed on the basis of 3 methods, namely Convolutional Neural Network (CNN), Deep Neural Network (DNN), and Recurrent Neural Network (RNN). The performance of each method was analyzed on the basis of 2 classification types (multiclass and binary), using 2 real traffic datasets- TON\_IoT and CIC-DDoS2019 [30]. Based on this analysis, a DL based detection method for DoS attacks was proposed, which used the CNN method to carry out multiclass classification and binary classification, and used RNN method to improve efficiency. Aborujilah, A. and Musa, S., in [2] proposed a novel application of Multi Attribute Decision Making (MADM) in CC infrastructure. The results of the experiment showed higher efficacy of MADM in identifying HTTP flooding attacks in the cloud environment, and that a higher MADM threshold value provided better efficiency than a lower MADM threshold value.

TABLE I. MACHINE LEARNING BASED IDS IN CLOUD

Paper	Algorithm Used	Objectives	Accuracy	FPR	DR
Kushwah et al. 2020[1]	V-ELM	To detect DDoS attacks in cloud	High	Low	High
Tonkal et al. 2021[59]	NCA+ML models	To detect DDoS attacks in SDN	High	Low	Medium
Sharma et al. 2019 [52]	ExtraTrees + ELM + Softmax	To classify many attacks	High	High	Low
Lopez et al. 2019 [35]	DT + RF + DNN	To detect DDoS attacks	Low	High	High
Sambangi and Gondi 2020 [48]	MLR model	To detect DDoS attacks	High	Low	Medium
Gumaste and Shinde 2020[26]	Apache Spark	To identify DDoS attacks in OpenStack-based Private Cloud	Low	High	Low
Ferrag et al. 2021 [22]	CNN + DNN + RNN	To detect intrusion in agricultural sector	High	Low	High
Kim et al. 2020[30]	CNN + RNN	To detect intrusion using DL models	Low	-	High
Aborujilah and Musa 2017[2]	Covariance matrix	To detect DDoS HTTP Attacks in cloud	Low	High	Low
Shen et al. 2020 [55]	MKELM	To detect intrusions	High	High	-
Somasundaram 2021[57]	Resource Scaling	To mitigate DDoS attack	High	High	Low

Shen, Y., et al., in [55] proposed a Mixed Kernel Extreme Learning Machine (MKELM) method integrating the ReliefF algorithm with nature inspired algorithms, for IDS. The MKELMs were developed to predict attacks, with the ReliefF algorithm providing inputs to the MKELM for selecting a suitable feature. The nature inspired algorithm determined the fitness function on the basis of kernel alignment, which was then used to build an optimum composite kernel in the MKELM. In [57] a novel approach was presented for evaluating resource consumption through 'scaling down' the resource i.e., through an improvement of the 'scale inside out' approaches. The presented approach utilized two modules- authentication model and elastic load balancing- to detect and mitigate DDoS attacks.

### B. Computational Intelligence based IDS Approaches in Cloud

Computational Intelligence approaches reviewed in this study include Bio-inspired algorithms, Evolutionary Computation algorithms and Swarm Intelligence algorithms. A detailed comparison of Computational Intelligence approaches reviewed in this SLR is given in Table II. A brief summary of these models follows. Bio-inspired algorithms aim to mimic natural biological patterns and behavior to develop novel ways to solve complex optimization problems [17]. Bio-inspired algorithms have been used to address major problems due to their features of adaptability, to attempt achievement of optimal solutions in cloud computing [12]. Bio inspired algorithms have been previously used to meet requirements of the cloud environment such as load balancing, provisioning of resources, and performance improvements, and may prove to be useful for adoption in IDS as well. Comparison of Bio-inspired algorithms for purposes such as sentiment analysis was described in [61]. Evolutionary Computation algorithms have been derived from biological evolution, and essentially aim 'to evolve' from an initial set of solutions to arrive at a best fit solution [20]. It is an approach in which different solutions adapt to different environments through processes similar to natural selection and breeding, so that only those which are truly fit and effective will survive the environment. Those which are not effective will not survive, but extreme conditions may result in mutations, similar to the biological analogy. Through iterations of this process, the best fitting solution to the problem is determined [28]. The population of potential solutions is first initialized randomly and the selection of solutions with the best fit through either survival or mutation mechanisms are devised; the rest are terminated. Evolutionary Computation has also been defined as the probable search performed for test data to be executed for a specific number of times by optimization algorithm based on Charles Darwin's theory of evolution [18]. It works on a potential solution with a permissible value for the variables coded for optimization problems, and is especially known for robustness and suited for complex domains of large numbers of variables [34]. The initialization of a population of solutions for a problem is first set at random, fitness of each individual solution in the

population is calculated, and the algorithm is run until optimization as initially defined is achieved or any of the defined stop conditions are achieved. The results are graded from very poor to good. Then, selection of pairs of individual solutions from the population results in recombination, with the resulting progeny subjected to mutation to maintain diversity. The resulting new generation solutions are evaluated for fitness, and a reinsertion process replaces the older generation solutions with fitness values which are lower than those of the new generation [62]. Swarm Intelligence algorithms emerged from observation of the behavior of social organisms, such as ants, wasps, bees and termites. Swarm Intelligence algorithms aim to mimic natural swarm behavior of organisms to forage for food or resources, to construct nests and to move in their environments. Swarm Intelligence algorithms follow five principles- proximity, quality, diverse response, stability and adaptability. Each possible solution to a problem is analogous to an organism in the swarm and has autonomy in behavior; the resulting emergence of self-organization in the swarm of solutions leads to adaptability to address the problem. The basis of self-organization includes amplification (positive feedback with the use of more resources) as well as stabilization (negative feedback to achieve counter balancing stability), random errors and multiple iterations of interaction between solutions in the swarm. Swarm Intelligence algorithms begin with in initialization phase to set the values of parameters, and continue to execute until defined stop conditions are achieved or stop is executed. Fitness function is evaluated for each solution and the Swarm Intelligence algorithm is updated mathematically based on the results. The fitness functions for each solution or search agent in the swarm leads to proposal of taxonomy and identification of the best fit solution to the problem. Swarm Intelligence algorithms have been used in optimization problems such as Agent Swarm Optimization (ASO) with the coexistence of different agents and their interaction, to ensure problem specificity, facilitation for testing and application to real-life problems [13]. One of the concepts significantly used in cloud computing is virtualization, as it enables higher resource utilization and lower operating costs. During virtualization, Computational Intelligence based optimization algorithms can play a vital role during the process of Virtual Machine Placement (VMP) scheduling. Such algorithms may be adopted for the purpose of IDS as well. Computational Intelligence algorithms are divided into two categories- Single-objective optimization algorithms and Multi-objective optimization algorithms. Examples for Single-objective algorithms include Ant Colony Optimization, Crow Search, Cuckoo Search, Fire Fly, Genetic, Grey Wolf Optimizer, Imperialist Competitive, Memetic, Particle Swarm Optimization, Simulated Annealing, and Whale Optimization Algorithm. Examples for Multi-objective algorithms include Biogeography-based Optimization, Krill Herd, Multi-Objective Evolutionary Algorithm, and Non Dominated Sorting Genetic Algorithm [37]. Taxonomy of Computational Intelligence intrusion detection techniques in mobile cloud computing environments was described in [49].

### C. Review of Hybrid Meta-Heuristic IDS Approaches in Cloud

Hybridization combines the benefits of different algorithms to form a hybrid algorithm with increased profitable synergy and minimization of disadvantages from the combination. This usually results in improved performance in terms of parameters such as computational speed, storage space and accuracy in detection of attacks. Hybrid algorithms may be classified into two types- Unified purpose hybrid algorithms, where the component algorithms are used to solve the same problem with each used at different stages; and Multiple purpose hybrid algorithms, where one primary component algorithm is used to solve the problem, while other component algorithms are used to alter the parameters of the primary algorithm. Hybrid algorithms may also be categorized as collaborative hybrid, involving a combination of two or more component algorithms run sequentially, or in parallel. These sequential or parallel runs can either comprise a single stage or have multiple stages. Another type of Hybrid algorithm is integrative hybrid, where

one algorithm is considered as a subordinate embedded into a master algorithm. It involves incorporation of operators manipulated by the subordinate algorithm into the master algorithm. The process of hybridization creates additional components but usually increases computational speed [33]. Two different algorithms could be hybridized by optimizing the parameters of both the algorithms to produce the best result. Different hybrid combinations are created and tested, in order to obtain overall best performance through experimentation. Because of the limitations of any standalone ML/DL method or Computational Intelligence algorithm, accomplishing optimum intrusion detection performance in a cloud environment requires hybridization. Since every approach has its merits and demerits, in this view, several authors have integrated the merits of two or more techniques in various aspects. For designing an effective hybrid IDS technique, the concept of mixing algorithms is essential. In this section, the hybrid IDS approaches developed for cloud environments are reviewed and a comparison is made in Table III.

TABLE III. HYBRID METAHEURISTIC INTELLIGENT IDS APPROACHES IN CLOUD

Paper	Algorithm Used	Objectives	Accuracy	FPR	DR
Moghanian et al. 2020 [40]	ANN+GOA	To detect network intrusion patterns	High	Low	High
Ali et al. 2018 [8]	ABC+BPNN	To detect DDoS attacks in cloud	Medium	Low	High
Osaniye et al. 2016 [43]	Ensemble-based multi-filter FS	To design ensemble of four filter approaches	High	-	-

Aslahi-Shahri et al. 2016 [11]	SVM+GA	To identify anomalies using hybrid method	High	Low	Low

In [27], a hybrid approach was presented which used an Artificial Neural Network (ANN) approach as a learning approach while a Swarm Intelligence algorithm- Grasshopper Optimization Algorithm- was used to reduce IDS errors. Ali et al. [28] presented a hybrid approach using a combination of Ant Colony Optimization (ACO) and Back Propagation Neural Network (BPNN). This hybrid approach was employed to detect DDoS attacks in the CC environment. Osanaiye, O., et al., in [43] proposed an ensemble based multifilter feature selection approach which integrated the output of 4 filter approaches to achieve optimal selection. The presented approach has been evaluated using standard datasets such as NSL-KDD. Ghanem, et al., [23] proposed a novel binary classification method for detecting intrusions, depending on the hybridization of Artificial Bee Colony (ABC) algorithm and Dragonfly algorithm to train an ANN and thereby increase the classification performance for non-malicious and malicious traffic in the network. The hybrid approach sets the initial parameters and appropriate weights for the ABC and Dragonfly algorithms. Ghosh, P., et al., in [24], proposed an IDS which provides security based on the concept of feature selection using Modified Firefly algorithm. The developed hybrid approach was evaluated on the NSL-KDD dataset and was found to consume lesser storage space due to the decreased number of dimensions from feature selection, and also require lower training time, thereby improving classification performance. A meta-heuristic algorithm based feature selection and recurrent neural network for DoS attack detection was proposed in [46]. Mazini, M., et al., in [38] proposed a novel hybrid approach for an Anomaly Network IDS, using ABC and AdaBoost algorithms to obtain higher detection rate and lower false positive rate. The ABC algorithm was used for feature selection and the AdaBoost algorithm was used for evaluation and classification of features. In [42], a novel multi-variable heuristic IDS was proposed, depending on distinct kinds of flags and values of entropy. The organizations distributed the data to improve the efficacy of IDS. Alharbi, A., in [6] proposed a Local Global Best Bat Algorithm with Neural Network (LGBBA-NN) for selecting hyper parameters and feature subsets for effective detection of botnet attacks. The presented hybrid approach adapted the inertia weights from the LGBB algorithm to update the parameters of the solution in the swarm. In order to address the swarm diversity for the solutions, a Gaussian distribution was employed during the initialization of the population. Bojović, P.D., et al., in [13] introduced a hybrid approach for detecting DDoS attacks, which combined volume and feature based detections. This method was dependent on an exponential moving average approach to make decisions, used on entropy values and packet number time sequences. Lv, L., Wang, et al., in [36] presented an approach for detecting several attacks on the basis of Hybrid Kernel Extreme Learning Machine (HKELM) model. This hybrid approach integrated the Gravitational Search Algorithm (GSA) and Differential Evolution (DE) algorithm to optimize the parameter of HKELM, which in turn enhanced its local and

global optimization capabilities at the time of predictive attack. A Kernel Principal Component Analysis (KPCA) method was presented for feature selection and reduction of number dimensions for the IDS. Aslahi-Shahri, B.M., in [11], presented a hybrid approach of Support Vector Machine (SVM) and Genetic Algorithm (GA) for execution of IDS. The presented hybrid approach was used to decreasing the number of features from forty-five to ten. The features were classified on the basis of priority, using the Genetic Algorithm.

## V. META ANALYSIS

Statistical analysis was performed for the above findings, using three performance metrics- Accuracy, False Positive Rate (FPR) and Detection Rate (DR), by classifying the performance of each algorithm as High, Medium or Low. Fig. 3 shows the ML based IDS approaches used in cloud environment, with the performance of the algorithms specified in terms of the three performance parameters. Algorithms employed in IDS must aim to decrease the FPR, since it represents the number of false alerts or alarms generated by the IDS, which may have a detrimental impact on cloud performance due to increase in computation time and storage space requirements of the IDS due to situations which are not really intrusions [9]. For this reason, having Low FPR is the most significant and important parameter for an effective IDS in the cloud environment. At the same time, algorithms must aim to increase Accuracy and Detection Rate, for obvious reasons.

Fig. 3 shows the comparison of ML based IDSs. First, 7 out of 11 ML based algorithms showed High Accuracy. Secondly, 4 out of the 11 ML based algorithms evaluated showed Low FPR. Thirdly, 4 out of the 11 ML based algorithms showed High Detection Rate. Incidence Rates for the desirable states of these parameters can be computed accordingly.

Fig. 4 shows the comparison of CI based IDSs. First, all 7 CI based algorithms evaluated showed High Accuracy. Secondly, 4 out of 7 CI based algorithms showed Low FPR. Thirdly, 5 out of 7 CI based algorithms showed High Detection Rate. Incidence Rates for the desirable states of these parameters can be computed accordingly.

Fig. 5 shows the comparison of Hybrid Meta-heuristic intelligent IDS approaches. First, 8 out of 10 hybrid approaches showed High Accuracy. Secondly, 8 out of 10 hybrid approaches showed Low FPR. Thirdly, 6 out of 10 hybrid approaches showed High Detection Rate. Incidence Rates for the desirable states of these parameters can be computed accordingly.

Among the three types of IDS- ML based, CI based and Hybrid Meta-heuristic- the Hybrid Meta-heuristic based IDS appear to have the highest overall incidence and scope for achieving the combination of High Accuracy, Low FPR and High Detection Rate.

Fig. 3. Performance of Machine Learning based IDSs in Cloud.

Fig. 4. Performance of Computational Intelligence based IDSs in Cloud.

Fig. 5. Performance of Hybrid Meta-Heuristic Intelligent IDS Approaches.

TABLE IV. WEIGHTED SCORE ANALYSIS FOR INCIDENCE RATES FOR DESIRABLE STATES OF PARAMETERS

Type of IDS	High Accuracy	Low FPR	High Detection rate	Weight for Accuracy	Weight for FPR	Weight for Detection Rate	Weighted Score for IDS
Machine learning IDS	63.64%	36.36%	36.36%	20.00%	60.00%	20.00%	41.82%
Computational Intelligence IDS	100.00%	57.14%	71.43%	20.00%	60.00%	20.00%	68.57%
Hybrid IDS	80.00%	80.00%	60.00%	20.00%	60.00%	20.00%	76.00%

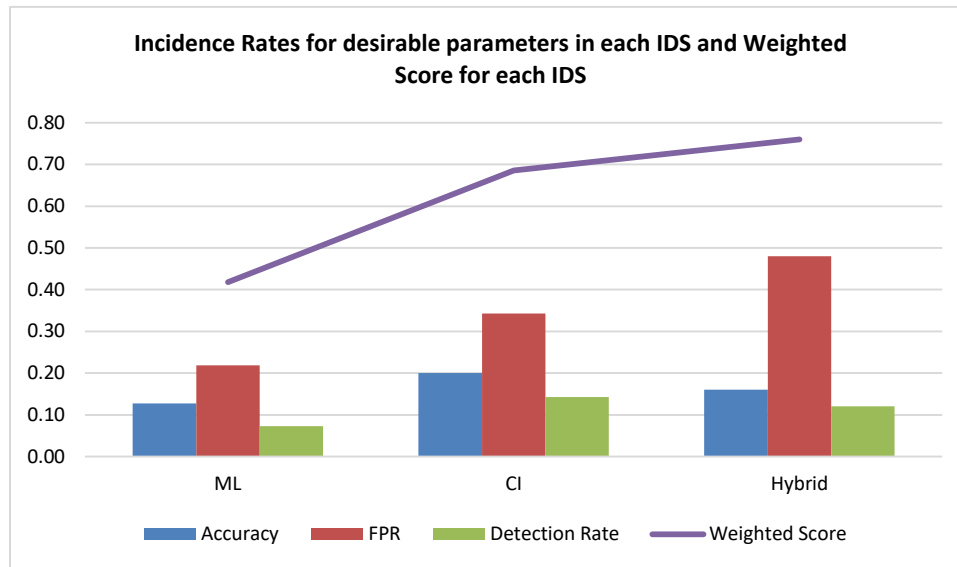

Fig. 6. Performance Comparison of IDS Approaches in Cloud.

Computation of incidence rates for desirable states of the three parameters (High Accuracy, Low FPR and High Detection Rate) across algorithms within each IDS was carried out, and using these incidence rates and associated weights assigned to parameters, a Weighted Score computed for each type of IDS. The results are presented in Table IV and plotted in Fig. 6. While the performance of Hybrid Meta-heuristic intelligent algorithms in terms of Detection Rate and Accuracy is marginally lower than that seen in Computational Intelligence algorithms, the performance is higher in terms of False Positive Rate, which is the parameter which has been assigned higher weight in determining the overall weighted performance score across the three parameters. From the results, the significance of potential adoption of Hybrid Meta-heuristic intelligent algorithms in IDS, to achieve the desirable performance states of High Accuracy, Low FPR and High Detection Rate is apparent.

## VI. OPEN CHALLENGES

This section discusses the major challenges that exist in the reviewed IDS models in the cloud environment.

- Existing IDS in the cloud environment only detect security-based events and are unable to block it. If many such events occur simultaneously, they could overwhelm the system. If the number of attacks or data breaches are very high in number, a valid threat may not be detected on time. Existing studies have not focused much on intrusion prevention.

- One of the major challenges in network-based IDS is that it cannot detect encrypted traffic without interception and decryption. In some organizations, the IDS decrypts traffic as it flows into the network. However, it will not be able to decrypt the traffic if the attacker uses a key to initiate encryption and decrypts the host.
- A high False Positive Rate is a significant and material open challenge to the execution of successful IDS. A system that generates high number of false alerts can potentially create serious business challenges for organizations, which may outweigh the benefits of even implementing the IDS itself.
- From the reviewed papers, it is evident that most of the IDS models have been developed using Machine Learning (ML) models and only a few works have concentrated on Deep Learning (DL) models. In addition, the experimental validation of the reviewed approaches should be extended to larger and real time datasets.
- In addition, the high number of dimensions of the IDS data-set should be carefully reviewed to reduce and discard irrelevant, and repetitive features. Feature selection techniques should be highly focused on minimizing the count of features in the data-set, to retain only essential features. Feature reduction and cluster techniques can be designed to boost the detection performance in large scale IDS datasets.

- Furthermore, the reviewed approaches are not designed for multi-objective formulation or multiple attacks detection, which needs to be further explored. Lastly, the offline IDS process needs to be extended to real time intrusion detection.
- The hybrid IDS technique should incorporate the combination of improved meta-heuristic optimization algorithms, to utilize their benefits.
- Most of the studies have focused on DoS and DDoS attacks. In future, IDS techniques should be designed to handle new and emerging types of attacks. The CC makes use of wireless networks for communication with the user system. Owing to few features of wireless networks such as resource limitations, mobility, and restricted bandwidth, issues related to network management and security need to be addressed. Based on the reviewer's works, hybrid methods may be employed for the detection of anomaly and signature based IDS in cloud environments.
- The choice of appraising classification model and feature selection is a major challenging issue in IDS. Therefore, it is important to design a rapid and precise IDS with minimal false positives and maximum true positives in a cloud environment.
- The choice of parameters has a significant influence in comparative analysis of various IDS approaches. Therefore, it is important to take into account any other parameter apart from the 3 parameters used in this study, which is considered significant and material for a particular IDS.
- On the other hand, the description of the implementation on setup can be a serious challenging problem for the cloud environment to accomplish security. In some cases, the models developed to improve the outcome of the IDS might be ineffective, resulting in false alarms owing to the inappropriate choice of evaluation criteria. The data integrity and security of information handled by cloud providers and probable susceptibilities which may result in data breaches need to be addressed in future. Based on the open issues and possible future directions, an effective IDS can be designed with respect to the consideration of the dimensions and features of the cloud environment.

#### VII. LIMITATIONS OF THE STUDY

The authors utilize Google scholar as a reliable electronic database that recommends highly relevant and effective studies depending upon the previous empirical works. But It could not be guaranteed that all selection is applicable studies. There is a chance that few significant works are not considered in the article selection process. Although this literature will provide an overall understanding utilization of an intelligent Intrusion Detection System in cloud environments and could be applied practically, this review article and its findings are theoretical only, which is one of the limitations of this study as it could not be reproduced in terms of practical implications. There is also a

limitation arising due to the 3 performance parameters selected, since some of the IDS approaches may theoretically perform better if other performance parameters were to be considered. Practical implementations are required to prove the benefits of the study.

#### VIII. CONCLUSION

This paper conducted SLR and Meta Analysis in order to evaluate the efficacy of Hybrid Meta-heuristic based IDSs in the cloud environment along three performance parameters, compared to two other types of IDS- ML based and CI based. The significance of various recent studies was summarized, and the performance of different algorithms/ approaches within each type of IDS was reviewed along the parameters of Accuracy, FPR and Detection Rate. The reviewed approaches were briefly explained, along with the merits and demerits. The open research issues which have to be addressed in future study have been discussed. The highlight of the study is the significance of potential adoption of Hybrid Meta-heuristic intelligent algorithms in IDS, to achieve High Accuracy, Low FPR and High Detection Rate. We strongly believe the outcome of this review study will be helpful to design new hybrid IDS approaches for cloud environments, particularly utilizing Meta-heuristic techniques.

# Machine Learning Mini Batch K-means and Business Intelligence Utilization for Credit Card Customer Segmentation

Firman Pradana Rachman, Handri Santoso, Arko Djajadi

Master of Information Technology Department, Faculty of Science and Technology  
Pradita University, Tangerang, Indonesia

**Abstract**—An effective marketing strategy is a method to identify the customers well. One of the methods is by performing a customer segmentation. This study provided an illustration of customer segmentation based on the RFM (Recency, Frequency, Monetary) analysis using a machine learning clustering that can be combined with customer segmentation based on demography, geography, and customer habit through data warehouse-based business intelligence. The purpose of classifying the customers based on the RFM and machine learning clustering analyses was to make a customer level. Meanwhile, customer segmentation based on demography, geography, and behavior was to classify the customers with the same characteristics. The combination of both provided a better analysis result in understanding customers. This study also showed a result that minibatch k-means was the machine learning model with the rapid performance in clustering 3-dimension data, namely recency, frequency, and monetary.

**Keywords**—Customer segmentation; machine learning; business intelligence; data warehouse

## I. INTRODUCTION

Knowing customer needs is a way to win the competition in the market and increase company profits. By knowing what customers want, companies can create effective marketing strategies. Every customer has different needs and expectations, but some have similar or the same characteristics. One way to group several customers who have the same characteristics is to create customer segmentation. Customer segmentation is also the key to improving customer relationships. The process of information analysis to understand the market and customer is a part of a marketing strategy known as marketing intelligence.

Previous research used machine learning for customer segmentation. The type of machine learning used is unsupervised machine learning. One of them is using k-means [1] or using Hierarchical Clustering which is combined with PCA (Principal Component Analysis) technique [2]. Several other studies combine RFM (Recency, Frequency, Monetary) Analysis with K-means to determine customer ratings [3]. Some of these studies only make segmentation based on numerical values or predictive numbers generated by machine learning such as annual income and spending scores [1] or RFM Score [3], but do not grouping them with categorical and descriptive data. When there is a question, which city does the

customer group live in with the highest annual income? So, to get the answer, we must explore the data further.

Another problem is how to make the data well integrated. Well-organized data will facilitate analysis and report generation better. The quality of the data must also be considered. Problems in data such as duplication, different formats, incomplete and dirty data are things that must be overcome for better data governance [4].

Based on that fact, a research idea emerged that utilizes machine learning and business intelligence to create customer segmentation in a data warehouse platform. The information technology advancement enables the data to be processed and analyzed better. One of the examples is machine learning and business intelligence technology utilization. The use of machine learning can display predictive data, while business intelligence displays descriptive data. The integration and the combination of both will provide knowledge for a company in making an accurate business need. Data warehouse will make the data well integrated, stored for a long time and not interfere with data in the main system or transaction operations. Data quality can be handled well through the ETL (Extract, Transform, Load) process in the data warehouse [5].

This study discussed the utilization of machine learning and business intelligence built in the data warehouse platform using SQL Server. The outcome can be analyzed by marketing through dashboard and business intelligence reports. The data used here were the credit card transaction data for three months from banking companies in Indonesia. A machine learning model that can be used is unsupervised learning known as clustering. This study also tested some machine learning models of clustering to find a model with a rapid performance.

## II. THEORETICAL FRAMEWORK

Banking is any kind of activity in banks, including organizational business activities and the process. Meanwhile, a bank is a business entity operating the business activity. The function of a bank is collecting funds and also a distributor of credit to both individuals and business entities [6]. A bank has several types of loan products, such as working capital loans, investment loans, and consumer loans. A credit card is a part of consumer credit given to an individual in the form of a card that can be used for purchasing goods and services in shops, supermarkets, restaurants, etc.

Marketing Intelligence is a process of analyzing information to understand consumers, attitudes, and market behavior for accessing changes in a business and industrial environment to support the decision-making process [7]. Marketing intelligence consists of two parts, namely marketing research and customer relationship marketing database. Marketing research focuses more on the process of marketing planning, analyzing a situation, and building a strategy, while customer relationship marketing database focuses on data processing in a database.

Customer segmentation consists of a group of customers having the same needs and wants [8]. A segmentation group can be divided into 4 parts, namely.

- 1) Geography. It divides a market based on the location of the domicile, for instance, country, province, and city.
- 2) Demography. It divides a segmentation based on age, family, income, occupation, education, religion, etc.
- 3) Psychography. It is a part of psychological and demographic science in understanding consumers better, such as lifestyle or the value of life.
- 4) Behavior. This segmentation divides customers into several groups based on their habits, knowledge, or responses to a certain product.

Customer segmentation can also be performed based on Cost to Serve, Net Price, and relationship value [9]. Net Price and Cost to Serve are types of costs that can be measured. Relationship value has qualitative characters, and the value is determined intuitively by managers. This matrix is able to provide variability in making customer segmentation.

Another method in making customer segmentation is by using the RFM (Recency, Frequency, and Monetary) analysis. The purpose is to determine the customer level based on their purchase history [10]. This method consists of 3 dimensions, namely.

- 1) Recency. The last time a customer does a transaction. The Recency value is calculated from the difference of total days by subtracting the last date of transaction from the date of the current process. The lower value will be better.
- 2) Frequency. The frequency of a customer does a transaction. The higher value will be better.
- 3) Monetary. The amount of money spent. It is equal to Frequency that the higher value will be better.

A data warehouse is separate data storage from the primary application operating an operational transaction process. In this process, the data are transformed into information that can be analyzed by consumers [11]. The data process starts from data integration that has been extracted from the primary operational application and is transformed and loaded into a format that is appropriate to the data structure in the data warehouse. This process is known as ETL (Extract Transform Load).

The ETL process contains data cleaning, filtering, aggregate, and types of transformation. After the data are collected orderly, the data can be used for data mining or business intelligence. Business intelligence (BI) is defined as

data presentation to entrepreneurs to be used for gaining knowledge or making a business decision [11]. Business intelligence is an important part of business analytics because it produces effective analysis [12].

In making a business intelligence model, two tabulated models are generally used, namely.

- 1) A fact table is a table containing a transaction table consisting of numeric data that can be changed every day. For example, sales, purchase, finance, etc.
- 2) A dimension table is a table containing data category that generally the content rarely changes, and it will be used for data classification and aggregation contained in the fact table. For example, the Customer dimension table contains customer id, customer name, date of birth, address, and the like.

A schema in business intelligence is a group of tables consisting of dimension, fact, and attribute designed in differently according to the necessity. A schema consists of several types. They are as follows.

- 1) Star Schema. This schema puts the fact table in the center and the dimension table is placed around the fact table forming a star pattern. In the star schema, the dimension table with the same hierarchical data structure is placed in one table.
- 2) Snowflake Schema. This schema is different from the star schema model, whereby the dimension table is separated for the main category. For example, in the star schema, the data in the product table for product and product group is merged, while in the snowflake schema, both data are separated. Thus, in the end, the snowflake schema model looks like a snowflake.

Machine learning is a part of Artificial Intelligence (AI) allowing a system to learn from data rather than by explicit programming. Machine learning uses several repetitive algorithms by learning from data to improve, describe data, and predict results [13].

Unsupervised learning is a process of grouping unlabeled data. One of the utilizations is for clustering. The machine learning models for clustering are as follows.

- 1) Hierarchical Clustering. It works by forming a hierarchy or based on a certain level to appear like a tree structure. Thus, the clustering process is performed according to the level or step by step. Hierarchical clustering consists of two clustering, namely Agglomerative (bottom-up) and Divisive (Top-Down).
- 2) Balanced Iterative Reducing and Clustering using Hierarchies (BIRCH). It is an algorithm that can cluster big data by making a small and brief summary at first and storing information as much as possible. The smaller and brief summary is then grouped as a substitute for the larger data cluster. The mechanism of the first BIRCH algorithm is summarizing a group of big data into a smaller one that is known as Clustering Feature (CF) tree. Each node of this tree consists of some Clustering features (CF). Then, each node,

including a leaf node, has some CF; besides, the internal node CF has a pointer to sub-node, and all leaf nodes are linked by a doubly linked list.

3) K-means. This clustering algorithm is one of the non-hierarchical clustering methods that try to make partitions for the existing objects into one or more clusters or object groups according to the characteristics. Thus, the object with the same characteristics is grouped in one cluster and the object with different characteristics is grouped in another cluster.

4) Mini Batch K-means. This algorithm forms a minibatch consisting of a collection of small randomized data with a constant size enable to be stored in a memory. The mechanism is that the sample is taken randomly from the dataset to form a minibatch, and then it is assigned to the nearby centroid. In the second step, the centroid is updated and so on.

One of the ways to find the optimal total cluster is by using an elbow method. It is done by seeing the percentage of the comparison between the total clusters that will form an elbow in a certain point. This method can be illustrated through a line plot between SSE (Sum of Squared error) compared to the total cluster and finding a point that represents ‘an elbow point’ (the point after SSE or inertia starts decreasing in a linear fashion). Elbow method is often used in previous studies for determining the optimal number of clusters [14], [15], in addition to the silhouette coefficient method [16].

### III. RELATED WORK

A study on Customer segmentation using a machine learning method was the Fuzzy C-Means Clustering utilization for Customer Relationship Management (CRM) database on an online shop, namely tokodiapers.com [17]. Subsequently, another study focused on the implementation of k-means clustering on Recency-Frequency-Monetary (RFM)-based customer segmentation [18], [19]. Customer segmentation using PCA was combined with machine learning to make clustering [20]. The combination of K-means and ANN methods used SOM [21], [22]. Some other studies compared the clustering models between k-means, fuzzy c-means, Repetitive median K-Means [10], and between k-means, k-medoids, and DBSCAN [23].

Previous studies showed that business intelligence can be used for descriptive data in marketing strategy [24], social media analysis [25], travel companies [26], and can also be implemented in small-scale companies [27]. The business intelligence implementation can be combined with the data warehouse implementation. For example, business intelligence implementation using Higher Education data in Iran [28].

Based on literature studies and previous research, this study offers a complete and different solution for customer segmentation. First, customer segmentation based on RFM analysis creates customer levels combined with Geographic, Demographic, Psychographic and Behavioral to classify customers with the same characteristics. Second, the data is presented in business intelligence reports and is based on a data warehouse. Finally, the research will test several clustering models to find the fastest model.

### IV. RESEARCH METHODOLOGY

This study was conducted through several phases as shown below.

#### A. Understanding the Business Process

In this phase, it was done by seeking information on how customer segmentation was implemented. There were two methods. They are as follows.

1) Literature study. It was performed by reading relevant books and journals.

2) Conducting a field observation and interview with users.

Based on these processes, it can be inferred that 2 methods of customer segmentation will be implemented. First, customer segmentation was ranked based on the RFM (Recency, Frequency, Monetary) analysis [10], and the second method was customer segmentation based on Geography, Demography, Psychography, Behavior [8].

#### B. Analysis Data

The study used secondary data taken from the credit card transaction history in bank XYZ in Indonesia for three months, namely October to December 2020. There are five CSV (Comma Separated File) format files that will be used, namely.

1) Cc\_transaction.csv is credit card transaction data whose information consists of customer id, category id, transaction date, amount in foreign currency, currency, card number, payee account and payee name.

2) Category.csv is shopping category data whose columns consist of category id, category name and group category.

3) Currency.csv contains a list of currencies consisting of the following columns currency id, currency code and currency name.

4) Customer.csv contains data from customer profiles consisting of customer id, customer name, gender, marital, grade, profession, address1, address2, postal code, open date, birthday, city, and province.

5) Rate.csv contains exchange rate information for all currencies consisting of currency id, date and rate.

#### C. Designing a Data Architecture and Data Flow

This phase consisted of designing tables, data architecture, and the data flow. The column structure of the created table must match the format and content of the data.

#### D. Preparation Process in the Data Warehouse

This phase consisted of an ETL (extract, transform, and load) process. The data in this phase were processed through cleaning, filtering, and normalization, thus, the data entering the database were neat and clean data. The data from the ETL process were imported into a staging table and then processed into a fact and dimension table for the needs of business intelligence and a table of RFM analysis for the machine learning process.

#### E. The Process of Machine Learning

It consisted of several stages as seen below.

1) Feature selection. The data were taken from the table of RFM analysis that was made in the preparation process in the data warehouse.

2) The production of a machine learning model. This stage consisted of several tests for machine learning clustering to find the rapid model. The models being tested here were agglomerative hierarchical clustering, Balanced Iterative Reducing and Clustering Using Hierarchies (BIRCH), K-means, and Mini Batch K-means.

3) Optimizing the total clustering. This stage was done to find the optimum total clusters using an Elbow method.

4) Implementation of clustering model. The machine learning model selected is the fastest from the previous testing process. The number of clusters is in accordance with the recommendations of the elbow method.

**F. Business Intelligence Process**

It consisted of several steps as follows.

1) The tables of load from the machine learning process and ETL at data warehouse.

2) Making a dimension model and the relationship between those tables. At this stage, it will be decided to use the star schema or snowflake model.

3) Design and dashboard visualization. This stage aims to design and present data in a business intelligence portal. The data displayed is a summary of the clustering results of machine learning and demography, geography, and customer habits. On the other hand, it displays detailed data from transaction history and customer profiles. History data is also available for each transaction and customer grouping. All data can be selected and filtered based on the results of machine learning clustering, year and month.

**V. RESULT AND DISCUSSION**

**A. The Process in the Data Warehouse**

The result from the observation and analysis was an illustration of how to design the data architecture and data

flow. The following is an illustration of the data architecture and data flow.

From the Fig. 1 we can see that the first process is data processing from the server of core banking and then it is integrated into SQL server database as data warehouse through an ETL (Extract, Transform, and Load) process using SQL commands (bulk insert method). The result of the ETL process was stored in the staging table. Subsequently, two processes were done; first, the data from the staging table were processed into a fact table and dimension table through the SQL demand. Second, the data from the staging table formed an RFM analysis table that would be used as a feature selection for a clustering process in machine learning. Processes in machine learning using Python with the Scikit-learn library. The result obtained from the machine learning process was exported into a dimension table and a fact table.

The outcome of the machine learning process and the ETL process in the data warehouse was forming a dimension table and a fact table used for a modeling process in the business intelligence. The detail of processes and data structure can be seen in Fig. 2.

Fig. 1. The Design of Data Architecture and Data Flow.

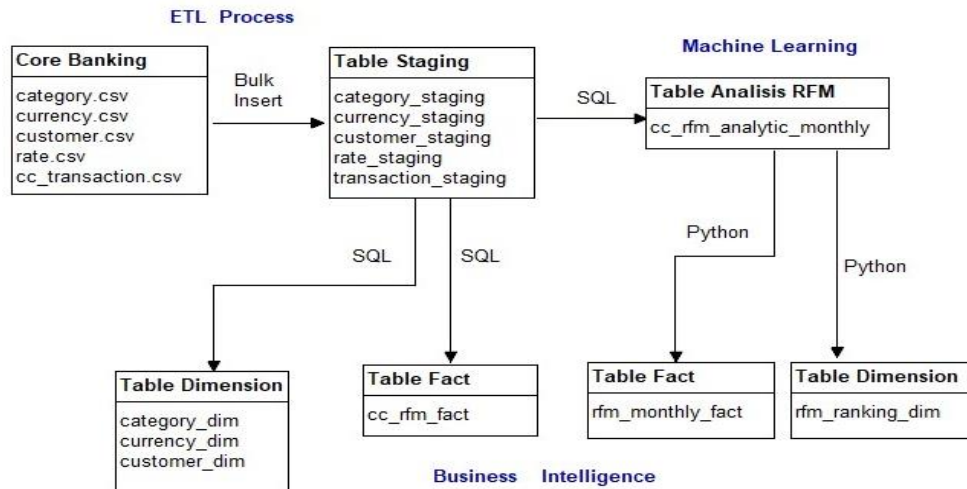

Fig. 2. Detail of Data Flow.

B. Machine Learning Process

The data used in this process was an RFM analysis table that was made in the ETL process previously. The content consisted of the summary of recency, frequency, and monetary values based on customer per month and per year as shown in Table I.

TABLE I. CC\_RFM\_ANALYTIC\_MONTHLY TABLE

Customer id	Recency	Frequency	Monetary	Month	Year
190003214887	22	1	79000	12	2020
190000291053	1	4	845800	12	2020
190001424933	1	2	831608	12	2020
190002882666	3	1	540000	11	2020
190001940395	8	3	3317177	10	2020
190003283225	7	5	1611053	12	2020
190003229073	11	1	79000	12	2020

The next process was testing the machine learning clustering model aiming at seeking a clustering model with a rapid performance. The first trial test was conducted using the data with a range of 3 months from the staging table. Overall, the total data was 46.079 rows. The test was conducted using a trial test on 2 up to 5 clusters. The computer specification used here was Intel Core i3 6006U 2 GHz, Memory 12 GB, Hard disk SSD 512 GB, and VGA Nvidia GeForce 940MX with 2GB dedicated VRAM. The Table II illustrates the detail of the test result showing the speed of the clustering process done in a second.

TABLE II. THE SPEED DIFFERENCES BETWEEN CLUSTERING MODELS

Model	2 Clusters (second)	3 Clusters (second)	4 Clusters (second)	5 Clusters (second)
Agglomerative	Error Memory	2856	2700	2239
BIRCH	31	20.36	20.03	20.01
Kmeans	1.32	1.45	1.76	2.24
Minibatch Kmeans	1.47	1.40	1.18	1.08

From the Table II, agglomerative clustering has the longest clustering process; even when trying to perform a clustering process with 2 clusters, an error message appears stating that not enough memory. BIRCH occupies the third rank for better performance than agglomerative clustering. Meanwhile, K-means reaches a far better performance than BIRCH and agglomerative clustering. Nevertheless, in general, the performance of minibatch k-means is faster with the longest duration of 1.47 seconds for 2 Clusters.

TABLE III. THE CALCULATION RESULT OF RFM TABLE IN OCTOBER 2020

Cluster	R_means	R_score	F_means	F_score	M_means	M_score	Score	Segment	Label
0	0.81	1	0.01	1	0.08	3	5	113	At Risk
1	0.46	2	0.02	2	0.08	1	5	221	Keep
2	0.16	3	0.06	3	0.37	4	11	344	Royal
3	0.13	4	0.03	4	0.08	2	9	432	Potensial

The experimental results in Table II show that when the number of clusters increases, the clustering process becomes faster. This happens for clustering using agglomerative, birch and minibatch kmeans, but for kmeans the opposite happens. The unique thing is that when using 2 clusters, the kmeans algorithm is better than the mini batch kmeans. However, when trying 3 or more clusters, the minibatch kmeans performance is superior.

The machine learning Mini Batch K-Means model is finally chosen because it is the rapid model in performing a clustering. The next phase was selecting the optimal number of clusters from the data. The method used here was the elbow method. The result shows that the total optimal cluster in each month is 4 clusters. It is shown from the intersection of lines forming a perpendicular line as a visualization of an elbow method in Fig. 3.

Fig. 3. A Graph of an Elbow Method in December 2020.

Before the data modeling, it was normalized using a Min-Max score. This process was aimed at making the data have the same range from 0 to 1. Therefore, data visualization in the form of a graphic becomes more precise. The formula used in this Min-Max method as shown in (1).

$$X_{new} = \frac{(X_{old} - X_{min})}{(X_{max} - X_{min})} \tag{1}$$

Xold is the former score. Xmin is the minimum score and Xmax is the maximum score in the data range.

The clustering prediction was done using minibatch k-means with a total of 4 clusters. After grouping the data using machine learning, the recency, frequency, and monetary scores of each datum were calculated. The scoring was done by ranking the data. The best one was scored 4 and the lower one was scored 3 and so on. The following is the calculation result of the RFM score for October 2020 in Table III.

From the Table III, it can be inferred that the highest score is cluster 3 with a score of 11 points. Even though the score is the highest, cluster 3 does not have the highest recency score since the best recency score is occupied by cluster 1. Meanwhile, the lowest score is occupied by clusters 0 and 2 with the same score of 5. However, cluster 0 is considered the lowest since it has the lowest recency and frequency scores. Subsequently, each of these clusters is labeled according to their class. The highest cluster is cluster 3 labeled with Royal; the cluster below cluster 3 is cluster 1 labeled with Potential. Then, clusters 2 and 0 are labeled with Keep and At-Risk respectively.

Clusters with the Royal label are the most important and loyal customers because the number of shopping transactions is the largest and the shopping frequency is the most frequent. Meanwhile, the group of potential clusters are customers who have the potential to become loyal credit card users, because the recency value is higher even though the amount and frequency of shopping are smaller. It is possible that the group from this cluster is a new customer. Clusters with the labels At Risk and Keep must be considered, because in this group they rarely shop in large quantities. The same grouping was also done for the data in November and December 2020. The following is the 3D visualization of customer clustering in October 2020 in Fig. 4.

Fig. 4. 3D Visualization of Clustering for the Data in October 2020.

### C. Business Intelligence Process

The table containing the result of ETL and Machine Learning processes is loaded into the business intelligence model. The modeling schema is made using a Star Schema by placing two fact tables, namely *cc\_rfm\_fact* and *rfm\_monthly\_fact*. Meanwhile, the other dimension tables are around the two fact tables as shown in Fig. 5.

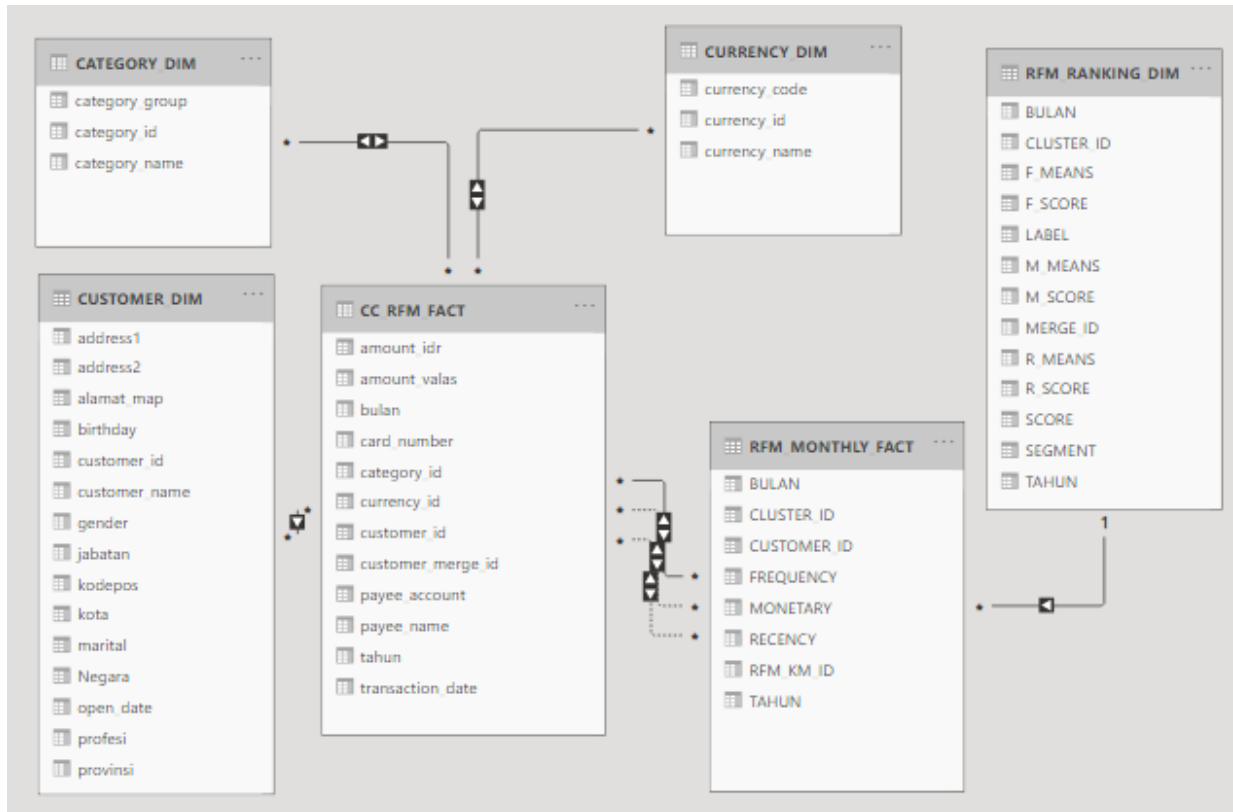

Fig. 5. Dimensional Modeling with a Star Schema.

The dashboard in the business intelligence consists of several parts as follows.

1) Main Dashboard. It displays a summary and aggregate data from all data. The top side has filtering based on year, month, and cluster choices. Besides filtering, there is a scorecard containing segmentation information of cluster, RFM score, and total customer, average recency score, average frequency score, and average monetary score. Meanwhile, the central side has a bar graph showing data on shopping habits based on the shopping category. The

demographic data, such as profession, sex, and marital status, are in the form of a pie chart or doughnut chart. On the right side, there is information about transaction amount based on the currency. The complete illustration can be seen in Fig. 6.

2) Distribution map. It shows the number of customer distribution based on the province and regency. The data are presented in the form of an Indonesian map. There is filtering on the top side according to customer segmentation, year, and month as shown in Fig. 7.

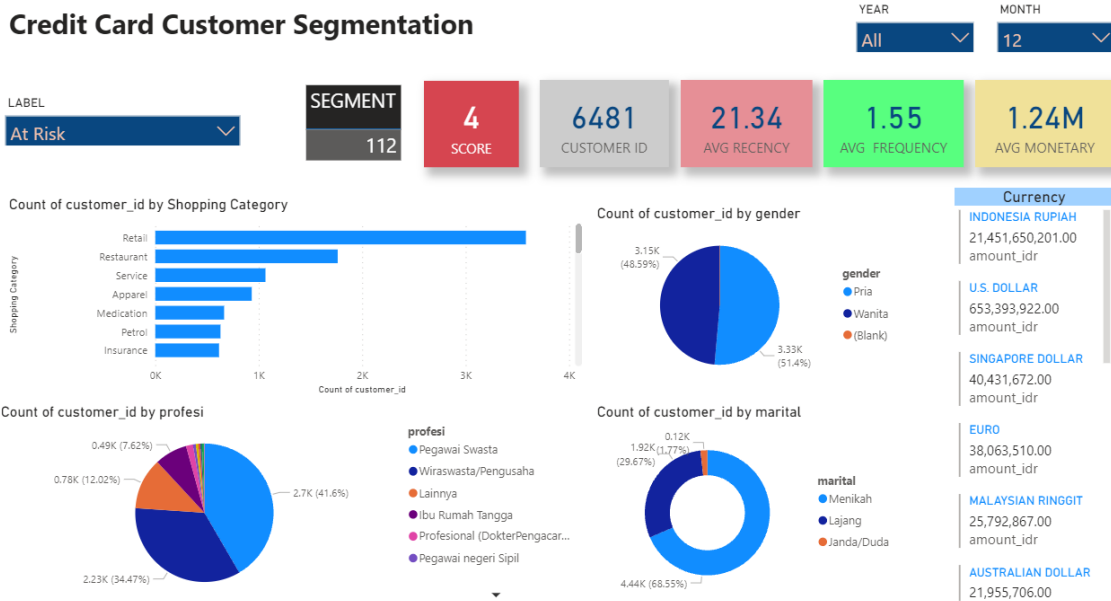

Fig. 6. The Dashboard Main Menu of Business Intelligence Portals.

Fig. 7. Customer Distribution in the Form of a Geographic Map.

3) Transaction detail. It displays detailed data of each customer transaction. The column consists of customer-id, transaction date, category id, payee account, payee name, and the amount in Indonesian rupiah (IDR). This information can be filtered based on the label, year, and month through a slicer on the top side as shown in Fig. 8.

Fig. 8. The Detail of Credit Card Transaction.

4) Customer Detail. It displays the data of customer-id, customer name, sex, position, profession, marital status, zip code, and date of birth. As in the transaction detail, on the top side, there is a slicer to filter the data based on the segmentation, year, and month.

5) Forecasting Credit Transaction. It contains credit card transaction predictions in the next few days. Forecasting uses an Exponential Smoothing method that has been available in the Power BI application. Exponential Smoothing is a forecasting method of a moving average providing an exponential or graded weight in the latest data [29]. The graph can be seen in Fig. 9.

Fig. 9. Forecasting of the Amount of Credit Card Transactions.

6) Transaction History. Show in Fig. 10, displays the transaction history based on the shopping category per month in tabular form to the side part. The far-right column contains a difference in the amount in December takes away the amount in November. If the difference is positive, it shows a green color. Meanwhile, if the difference is negative, it shows red color. The top side has filtering according to year.

Fig. 11. Monthly Credit Card Customer History.

## VI. CONCLUSION

This study makes a segmentation using a machine learning clustering model and business intelligence in the customers of data warehouse-based credit cards. The data warehouse concept utilization is used for constructing an integrated data management system that can handle a large amount of data. The machine learning clustering model is used for grouping customers according to a rank to know the most loyal customers and inactive customers. This clustering uses the RFM (Recency, Frequency, and Monetary) analysis as the measurement variable and feature selection in the clustering process. The RFM analysis is chosen because it can present customer loyalty based on their shopping behavior, such as the last time of shopping (recency), the frequency of shopping (frequency), and the amount of money spent for shopping (monetary).

The data from the machine learning clustering process are combined with other data and presented in the form of a business intelligence portal dashboard. The dimension modeling process uses a star schema because it is superior in terms of speed compared to the snowflake schema. The data and graphics displayed in the business intelligence portal present the segmentation data according to demography, geography, and behavior.

The combination of machine learning clustering segmentation for ranking customers with segmentation based on the demography, geography, and behavior provides complete and strong information as a support in a business decision for a marketing department. For example, the marketing department wants to increase the customers' credit card transactions by a limited promotional budget. First, he/she will see a group of customers having a relatively low RFM score. Then, from the group, the city with the highest number of customers is observed. Thus, the marketing department can effectively promote to a group of customers with the same characteristics.

This study also shows the minibatch k-means clustering algorithm has faster performance than that of agglomerative hierarchical clustering, BIRCH, and k-means algorithms. The result shows that out of 46.097 rows of data, the minibatch k-means method is superior to agglomerative clustering, BIRCH is superior with a thin margin to k-means. Some clusters are tested using an elbow method. The result shows that the best and optimal cluster is 4 clusters.

**Abstract**—A vehicular Adhoc Network, a subfield of Mobile Adhoc Network is defined by its high mobility and by demonstrating dissimilar mobility patterns. So, VANET clustering techniques are needed with the consideration of the mobility parameters amongst nearby nodes to construct stable clustering techniques. At the same time, security is also a major design issue in VANET which can be resolved by the Intrusion Detection Systems. In contrast to the conventional IDS, VANET based IDS are required to be designed in such a way that the functioning of the system does not affect the real-time efficiency of the performance of VANET applications. With this motivation, this paper presents an efficient Fuzzy Logic based Clustering with optimal Fuzzy Support Vector Machine, called FLC-OFSVM based Intrusion Detection System for VANET. The proposed FLC-OFSVM model involves two stages of operations namely clustering and intrusion detection. Primarily, FLC technique is employed to select an appropriate set of cluster heads and construct clusters. Besides, a lightweight anomaly IDS model named FSVM optimized with krill herd optimization algorithm is developed to detect the existence of malevolent attacks in VANET. The KH algorithm which is based on the herding behavior of krills is used to optimally tune the parameters of the FSVM model. In order to investigate the performance of the FLC-OFSVM model, an extensive set of simulations are carried out and the results are investigated in terms of several performance measures.

**Keywords**—Clustering; intrusion detection; vehicular communication; VANET; machine learning; krill herd optimization; fuzzy logic

## I. INTRODUCTION

Vehicle ad hoc networks (VANET) were developed as a part of a mobile ad hoc network (MANET) [1] application. It is deliberated a significant method for intelligent transportation systems (ITS). Recently, it is an emphasis of many scientists in the field of wireless mobile data transmission. In VANET, vehicles are utilized as network nodes. It contains three main kinds of data transmission feasible in VANET: a) Vehicle to Vehicle (V2V), b) Vehicle to Infrastructure (V2I), and c) Hybrid. However, this current data transmission kind suffers from several drawbacks like huge amount of Road Side Units (RSU) are required at standard location in V2I data transmission that aren't financially possible, security and privacy problems in V2V based data transmissions [2], hence clustering data transmission is chosen currently that has benefits on above three data transmission types [3]. This method is very congested traffic scenario that increases further load on cluster

head (CH) that finally presents delay in the data transmission and affect entire network performances. For handling this, a novel clustering framework stimulated from dolphin swarm behavior was introduced in this study where many nodes could perform as a CH in a cluster and therefore could allocate their load in heavy traffic situations which enhances the entire network efficiency. Fig. 1 depicts the architecture of cluster VANET.

Fig. 1. Architecture of Clustered VANET.

VANET provides several applications and services to the clients that are involved with the security of the navigational aid, drivers, and infotainment. It contains 2 kinds of data allocated in VANET: safety (curve warning, vehicle speed warning) and non-safety data (value added comfort application) [4]. Standard safety data provides high priority in VANET related to non-safety data, then safety data inform driver of predictable danger to permit earlier response. In spite of the advantages provided by VANET, it has several problems based on transmitted messages, security, and privacy of clients. Since vehicles exit and enter highways, they need specific safety information's like traffic road conditions and congestions, decision making on that route for taking to their destination. It is vital that this data be sent at an appropriate time; or else, it can lead to delay in attaining the destination securely [5]. In particular conditions, few malicious nodes refuse to transmit or even purposefully change the needed safety message beforehand transferring to the requested client that can lead to long delays or mortalities. Moreover, the features of VANET (such as volatility, higher mobility) are different from other wireless data transmission networks that

have made VANET vulnerable to several external and internal attacks [6]. Because of the dynamic topology and decentralized structure of VANET, the safety of the vehicles, clients, and data become significant, as the detection of faulty nodes/malicious/user becomes complex [7].

Alternatively, different from conventional Intrusion Detection Systems (IDS), VANET based IDS should be placed with care in this manner where the process shouldn't delay the real-time efficiency of VANET application. It contains several based resolutions for VANET in survey [8]. Mostly, it contains challenges such as higher false positives, lower detection rate, additional overhead on the network, higher detection time, and so are related with them. But it cannot detect modified and newer attacks. Abnormality based IDS has benefits over rule based IDS in the manner that it can detect novel attacks where the signature isn't existing in the database. However, this class of IDS requires settings of an optimum threshold and large trained set to make it proficient for differentiating among the normal and malicious nodes.

This paper presents an efficient Fuzzy Logic based Clustering with optimal fuzzy support vector machine (FSVM), called FLC-OFSVM based Intrusion Detection System for VANET. The proposed FLC-OFSVM model involves FLC technique with different input parameters to select cluster heads (CHs) and organize clusters. In addition, a lightweight anomaly IDS model named FSVM optimized with krill herd (KH) optimization algorithm is developed to detect the existence of malevolent attacks in VANET. For optimal tuning of the parameters involved in the FSVM model, the KH algorithm is employed in such a way that the intrusion detection ate can be enhanced. For examining the outcomes of the FLC-OFSVM model, a comprehensive set of experimental analyses were performed and the results are inspected interms of several aspects.

Section 2 describes the Literature Survey and Section 3 briefly explains proposed model followed by performance evaluation in section 4, finally section 5 discusses with conclusion and future directions,

## II. LITERATURE REVIEW

Several security systems have been presented by numerous scientists for addressing privacy and security problems in VANETs. This segment emphasizes few present methods which focus on related issues in VANET with same methods. An anonymous and lightweight authentication system smart card (ASC) is presented in Ying and Nayak [9] for addressing privacy preserving issues like legitimacy of the user and message transferred over the network. The verification of user and message is made by low-cost cryptographic operation. This protocol doesn't authenticate the user identity and also verify transmitted messages, however it assurances privacy of user. Wazid et al. [10] introduced a decentralized lightweight authentication and key agreement protocol (LAKAP) for VANET, that utilizes bitwise exclusive OR (XOR) operation and one way hash function.

Rajput et al. [11] presented a hybrid method for privacy preserving authentication scheme (HEPPA), that integrates the feature of pseudonym and group signature based methods,

with conditional anonymity. This technique utilizes lightweight and simple pseudonyms that provide conditional privacy. Tangade and Manvi [12] presented an efficient, scalable, and privacy preserving authentication (ESPA) protocol by a hybrid cryptography method for inter-vehicle data transmissions.

Cui et al. [13] projected a secure privacy preserving authentication scheme for VANET with cuckoo filter (SPACF) for enhancing the privacy and security of clients, and reduce data transmission overhead. Moreover, the investigators projected a novel authentication system with no bilinear pairings that could lead to heavy computation costs. The cuckoo filter is a data structure which gives an optimum search time and searches accuracy and utilizes hash function. The present methods deliberated have been chosen as the standard protocol for this work since this approach focuses on improving security and privacy preserving of user in the network. It is viewed that the present methods mainly focus on authentication and privacy preserving systems. But, another security necessity of VANET like non-repudiation, availability, and integrity, wasn't paid more interest. This provides a gap for additional development in VANET security with the deliberation of executing a novel security-based technique which is available in the present times. Hence, the resolution presented in this work tries to enhance the VANET security by employing a modern technology which can tackle the security needs and enhance road security with the help of vehicles resource and data transmission scheme.

## III. THE PROPOSED MODEL

The overall system architecture of the proposed FLC-OFSVM model is demonstrated as under. Initially, the vehicles in the VANET are placed randomly in the target area. Then, the network initialization process takes place where the single hop neighboring vehicles interact with one another. Next, the FLC technique is performed to optimally select the CHs and construct clusters proficiently. Followed by, the FSVM model is employed for the identification of intrusions in the network. Finally, the KH algorithm is used to optimally choose the parameters involved in the FSVM model.

### A. Design of FLC Technique

At this stage, the FLC technique with three input parameters is utilized to select CHs, as shown in Fig. 2. In this presented scheme, every node transmits its mobility data, average velocity to its neighbor via HELLO packet with the succeeding formats: Average Velocity, Node ID, Direction, and Location.

Fig. 2. Process Involved in FLC Technique.

1) *Node degree*: The amount of the velocity variances between adjacent vehicles is the main problem to construct relatively stable clustering topology. The neighborhood relation is made by the location data embedding from periodic message transmits by vehicles. Vehicles transmit their present state to every node with their broadcast range  $R$ :

$$N_i = \{v_j; \text{dis}_{i,j} \leq R\} \quad (1)$$

Whereas  $\text{dis}_{i,j}$  denotes average distance among vehicles  $i$  and  $j$ . According to this determination, they acquire other terms named node degree of a node ( $\psi_i$ ), that is determined by overall amount of  $R$ -neighbors. Then clusters are made with vehicles travel in a similar direction, every  $R$ -neighboring vehicle travel in the opposite direction isn't deliberated [14]. Thus, every  $R$ -neighboring nodes utilized in this analyses are restricted to this vehicle travels in a similar direction, located in other lanes and estimated by:

$$\psi_i = |N_i| \quad (2)$$

2) *Average velocity differences*: In all time intervals, every vehicle, have data regarding each vehicle with its transmission range and therefore, it would estimate its average velocity variance  $\phi_i$  from every vehicle by:

$$\phi_i = \frac{1}{\psi_{i-1}} \sum_{j=1}^{\psi_{i-1}} |v_j - v_i| \quad (3)$$

Whereas  $j$  denotes possible neighboring vehicle, and  $v_i, v_j$  indicates velocity of vehicle  $i$  and  $j$ , correspondingly in m/s. The node could attain its velocity by commercial navigation services, like Garmin Traffic.

3) *Relative velocity*: For building relative stable cluster, they assume the vehicles related to optimum neighborhood degree ( $\psi_i$ ). A low relatively velocity simply implies that the neighbor of a particular node has consumed a long time in its broadcast range. Thus, they could accomplish that the stated node comprises additional stable situations. The relative velocity of a node  $i$  is estimated by:

$$\omega_i = \frac{\phi_i}{v_i} \quad (4)$$

The lesser the value of  $\omega_i$ , the nearer the velocity of node for an average velocity of their neighbour that improves neighbourhood steadiness. In this presented system, every node calculates its neighbors based on link connectivity, average velocity difference, and relative velocity. If a node should transmit a packet, the node utilized FL for calculating fit factor value for every neighbor in terms of link connectivity duration, average absolute distance, and average velocity.

4) *Fuzzification process*: Fuzzification is the procedure of transforming mathematical values to fuzzified values by a MF. The transmitter node utilizes average absolute distance and MF for calculating the degree to which the distance factors belong to Large, Small, and Medium. The transmitter node utilizes average velocity and MF for calculating that degree the average velocity comes under Fast, Slow, Medium. The transmitter node utilizes link connectivity duration and MF for

calculating the link connectivity. When the fuzzy values of link connectivity, duration average absolute distance, and average velocity were estimated, fuzzy inference engine map the fuzzy values to the IF or THEN rules and restricted in the knowledge base for calculating the fit factor for every node. The fuzzy inference scheme is implemented according to twenty seven rules are introduced. Therefore, their equivalent calculation result should be integrated.

5) *Defuzzification process*: Defuzzification is the procedure of generating a numerical result on the basis of output MF and equivalent membership degree. Now, they utilize center of gravity (CoG) technique for defuzzifying the fuzzy results. Particularly, they cut the output MF with a straight horizontal line based on equivalent degree, and eliminate the top part. Later, they estimate the Centroid of this shape.

### B. Design of IDS Technique

Once the vehicles in the VANET are clustered, the next stage is to identify the presence of intruders in the network using the OFSVM model. In addition, the KH algorithm is employed to optimally tune the parameters of the FSVM model in such a way that the intrusion detection ate can be enhanced.

1) *FSVM model*: In conventional SVM, every data point is deliberated with equivalent significance and allocated a similar penal variable in its objective function. To resolve this problem, the system of FSVM was presented by [15]. Fuzzy membership to every instance point is presented; thus, distinct instance points could create various contributions to the creation of decision surface. Assume the trained instance is

$$S = \{(x_1, y_i, s_i), i = 1, \dots, N\} \quad (5)$$

Whereas  $x_1 \in R^n$  denotes  $n$ -dimension instance point,  $y_i \in \{-1, +1\}$  denotes class label, and  $s_i (i = 1, \dots, N)$  indicates fuzzy membership that fulfills  $\sigma \leq s_i \leq 1$  with adequately smaller constant  $\sigma > 0$ . Re quadratic optimization problem for classification is deliberated by:

$$\min_{w, s, \xi} \frac{1}{2} w^T w + C \sum_{i=1}^l s_i \xi_i \quad (6)$$

$$s. t. y_i (w^T x_i + b) \geq 1 - \xi_i, \xi_i \geq 0, i = 1, \dots, l,$$

Whereas  $w$  denotes normal vector of the splitting hyperplane,  $b$  indicates bias term, and  $C$  represents variable that should be defined before for controlling the trade-off among classification margin and cost of misclassification error [16]. Then  $s_i$  denotes attitude of equivalent point  $x_1$  to single class and the slack parameters  $\xi_i$  denotes measure of error, later the expression  $s_i \xi_i$  is deliberated a measure of error with distinct weights. It can be stated that the larger  $s_i$  is, the more prominently the equivalent point is processed; the lesser the  $s_i$  is, the lesser prominently the equivalent point is processed; therefore, distinct input points could create various contributions to learn of decision surface. Hence, FSVM could detect stronger hyperplane by increasing the margin allowing few misclassifications of lesser significant points.

To resolve the FSM optimum problem, (6) is converted to the succeeding two problems by presenting Lagrangian multipliers  $\alpha_i$ :

$$\max \sum_{i=1}^N \alpha_i - \frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N \alpha_i \alpha_j y_i y_j x_i x_j \quad (7)$$

$$s. t. \sum_{i=1}^N y_i \alpha_i = 0, 0 \leq \alpha_i \leq s_i C, i = 1, \dots, N.$$

Related to regular SVM, the aforementioned representation has a slight variance, that is the upper bound of the values of  $\alpha_i$ . By resolving these two problems in (3) for optimum  $\alpha_i, w$  and  $b$  are recovered in a similar manner as in the regular SVM.

2) *Overview of KH Algorithm:* The KH algorithm is a type of swarm intelligence technique that is inspired by the herding characteristics of krills. In the procedure of predation, the predator would alter the distribution of krill population, that would create them to move quickly, and later causes their distribution density for decreasing and the distance among the predator and the food becomes farther that is the first stage of KH. In this method, the distribution of krill population is defined as the succeeding 3 conditions: the impact of other krill individuals, arbitrary diffusion, and behavior of getting food. The KH method is defined by:

$$dX_i dt = N_i + F_i + D_i \quad (8)$$

Whereas  $N_i$  denotes impact of another krill individuals,  $F_i$  represents behavior of getting food, and  $D_i$  indicates behavior of arbitrary diffusion;  $i = 1, 2, \dots, N$ , and  $N$  represents the population size.

For the impact of another krill individuals, the movement  $N_{i,new}$  of krill  $i$  induced by another krill can be determined:

$$N_{i,new} = N_{max} \alpha_i + \omega_n N_{i,old} \quad (9)$$

Whereas  $N_{max}$  denotes maximal induced velocity,  $N_{i,old}$  indicates earlier induced motion,  $\omega_n$  denotes inertia weight and the value range zero and one and  $\alpha_i$  represents individual  $i$  is caused by the induction direction of the adjacent neighbors [17].

The succeeding behavior  $F_i$  is to get food, by:

$$F_i = V_f \beta_i + \omega_f F_{i,old} \quad (10)$$

whereas  $V_f$  represents maximal foraging speed, and its value is a constant, that is  $0.02 \text{ (ms}^{-1}\text{)}$ ;  $\omega_f$  indicates inertia weight of foraging motion, and its range is zero and one;  $F_{i,old}$  denotes earlier foraging motion, and  $\beta_i$  represents foraging direction. Fig. 3 demonstrates the flowchart of KH technique. The individual  $D_i$  in the final behavior is given by:

$$D_j = D_{max} \left(1 - \frac{I}{I_{max}}\right) \delta \quad (11)$$

Where  $D_{max}$  denotes maximal arbitrary diffusion speed;  $\delta$  indicates direction of arbitrary diffusion; and  $I$  and  $I_{max}$  denotes present amount and the maximal number of iterations,

correspondingly. From aforementioned procedure, they could attain the krill upgrade procedure of the KH method by:

$$X_i(t + \Delta t) = X_i(t) + \Delta t \frac{dX_i}{dt} \quad (12)$$

$$\Delta t = Ct \sum_{j=1}^{NV} (UB_j - LB_j) \quad (13)$$

Where  $\Delta t$  denotes time interval relevant to the certain application;  $NV$  represents dimension of the decision parameter; step factor  $Ct$  indicates constant among  $(0,2)$ ; and  $UB_j$  and  $LB_j$  denotes upper and lower bounds of equivalent parameter  $j(j = 1, 2, \dots, NV)$ , correspondingly.

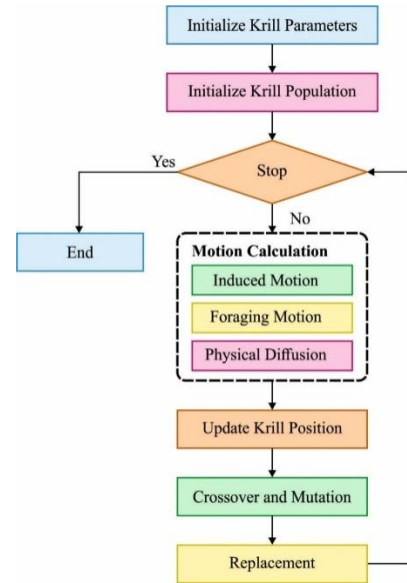

Fig. 3. Flowchart of KH.

The process of the KH algorithm (Algorithm 1) is given as follows.

Algorithm1. Pseudo code of KH algorithm
<p>Begin</p> <p>Step 1: Initiation. Initiate the generation counter <math>G</math>, the population <math>P, V_f, D_{max}</math>, and <math>N_{max}</math>.</p> <p>Step 2: Fitness evaluation. 3) *Parameter tuning of FSVM model using KH algorithm:*

In OFSVM model, the parameters (weight and bias) in the FSVM model are optimally adjusted by the use of KH algorithm. The FSVM model is trained with the parameters of the KH algorithm. Besides, 10 fold cross validation process is employed for determining the fitness function where the training data is split arbitrarily into 10 parts. Then, 9 sets of data are employed for training process and the final one is utilized for testing process. This process gets iteration ten times; therefore, every set is utilized once to test the model. The fitness function can be represented as  $1 - CA_{validation}$  of the 10-fold cross-validation (CV) technique in the training data, as given in Eqs. (14) and (15). Besides, the solution with higher CA validation holds lower fitness value.

$$Fitness = 1 - CA_{validation} \tag{14}$$

$$CA_{validation} = 1 - \frac{1}{10} \sum_{i=1}^{10} \left| \frac{y_c}{y_c + y_f} \right| \times 100 \tag{15}$$

Where  $y_c$  and  $y_f$  refers the count of true and false classifications correspondingly.

IV. PERFORMANCE VALIDATION

A brief comparative study of the FLC with other techniques in terms of NLT, EC, and throughput is made in Table 1. Fig. 4 examines the NLT analysis of the FLC technique with other methods under varying number of vehicles. The proposed FLC technique has gained maximum NLT under all distinct numbers of vehicles. For instance, with 20 vehicles, the proposed FLC technique has accomplished a higher NLT of 4600 rounds whereas the HEPPA, ASC, and LAKAP techniques have attained a lower NLT of 4400, 4000, and 3800 rounds respectively. In addition, with 60 vehicles, the presented FLC approach has accomplished a superior NLT of 4100 rounds whereas the HEPPA, ASC, and LAKAP techniques have attained a lower NLT of 3700, 3600, and 3500 rounds correspondingly. Also, with 100 vehicles, the proposed FLC technique has accomplished a higher NLT of 3600 rounds whereas the HEPPA, ASC, and LAKAP methodologies have obtained a minimum NLT of 3300, 3200, and 3100 rounds correspondingly.

An EC analysis of the proposed FLC technique with recent methods is made in Fig. 5. The figure has shown that the FLC technique has offered superior results with minimal EC over the other techniques whereas the LAKAP technique has displayed insufficient performance with the maximum EC. For instance, with 20 vehicles, the proposed FLC technique has resulted in the least EC of 32mJ whereas the HEPPA, ASC, and LAKAP techniques have demonstrated a maximum EC of 40mJ, 46mJ, and 56mJ, respectively. Additionally, with 60 vehicles, the proposed FLC method has resulted in the lesser EC of 79mJ whereas the HEPPA, ASC, and LAKAP approaches have showcased a maximal EC of 91mJ, 94mJ, and 114mJ, correspondingly. Besides, with 100 vehicles, the presented FLC algorithm has resulted in the least EC of 103mJ whereas the HEPPA, ASC, and LAKAP techniques have revealed a higher EC of 136mJ, 153mJ, and 172mJ, correspondingly.

TABLE I. RESULT ANALYSIS OF PROPOSED FLC WITH OTHER TECHNIQUES

Network Lifetime (Rounds)				
Number of Vehicles	Proposed FLC	HEPPA	ASC	LAKAP
20	4600	4400	4000	3800
40	4400	4100	3700	3600
60	4100	3700	3600	3500
80	3700	3500	3300	3200
100	3600	3300	3200	3100
Energy Consumption (mJ)				
Number of Vehicles	Proposed FLC	HEPPA	ASC	LAKAP
20	32	40	46	56
40	58	64	69	79
60	79	91	94	114
80	94	109	118	127
100	103	136	153	172
Throughput (Kbps)				
Number of Vehicles	Proposed FLC	HEPPA	ASC	LAKAP
20	67.01	65.75	57.00	53.28
40	72.42	70.35	64.45	60.65
60	77.27	74.23	69.24	64.72
80	81.61	78.75	72.21	69.19
100	83.91	80.85	78.36	73.48

Fig. 4. Network Lifetime Analysis of FLC Model.

Fig. 6 examines the throughput analysis of the FLC technique with other methods under varying number of vehicles. The proposed FLC technique has gained maximum throughput under all distinct number of vehicles. For instance, with 20 vehicles, the proposed FLC technique has accomplished a higher throughput of 67.01Mbps whereas the HEPPA, ASC, and LAKAP techniques have attained a lower throughput of 65.75Mbps, 57Mbps, and 53.28Mbps respectively. Moreover, with 60 vehicles, the presented FLC manner has accomplished a maximum throughput of 77.27Mbps whereas the HEPPA, ASC, and LAKAP techniques have achieved a lesser throughput of 74.23Mbps, 69.24Mbps, and 64.72Mbps correspondingly. Furthermore, with 100 vehicles, the projected FLC technique has accomplished a maximal throughput of 83.91Mbps whereas the HEPPA, ASC, and LAKAP approaches have attained a lower throughput of 80.85Mbps, 78.36Mbps, and 73.48Mbps rounds correspondingly.

Fig. 6. Throughput Analysis of FLC Model.

TABLE II. PDR AND ETE DELAY ANALYSIS OF PROPOSED FLC WITH OTHER TECHNIQUES

Packet Delivery Ratio (%)				
Number of Vehicles	Proposed FLC	HEPPA	ASC	LAKAP
20	0.98	0.95	0.93	0.82
40	0.87	0.84	0.80	0.71
60	0.78	0.74	0.71	0.62
80	0.72	0.67	0.60	0.55
100	0.69	0.63	0.55	0.48
End-to-End Delay (ms)				
Number of Vehicles	Proposed FLC	HEPPA	ASC	LAKAP
20	7.57	7.97	8.07	10.57
40	8.13	8.47	8.69	11.11
60	8.39	9.04	9.57	11.61
80	8.92	9.80	10.17	12.04
100	9.38	10.14	10.40	13.11

A brief comparison study of the FLC with other techniques in terms of PDR and ETE delay is made in Table 2 [18]. Fig. 7 inspects the PDR analysis of the FLC algorithm with other techniques under varying number of vehicles. The presented FLC technique has gained maximal PDR under all distinct number of vehicles. For instance, with 20 vehicles, the proposed FLC technique has accomplished a higher PDR of 0.98% whereas the HEPPA, ASC, and LAKAP techniques have attained a lesser PDR of 0.95%, 0.93%, and 0.82% correspondingly. In the meantime, with 60 vehicles, the proposed FLC method has accomplished a superior PDR of 0.78% whereas the HEPPA, ASC, and LAKAP approaches have achieved minimal PDR of 0.74%, 0.71%, and 0.62% respectively. At the same time, with 100 vehicles, the proposed FLC method has accomplished a higher PDR of 0.69% whereas the HEPPA, ASC, and LAKAP methodologies have attained a lower PDR of 0.63%, 0.55%, and 0.48% correspondingly.

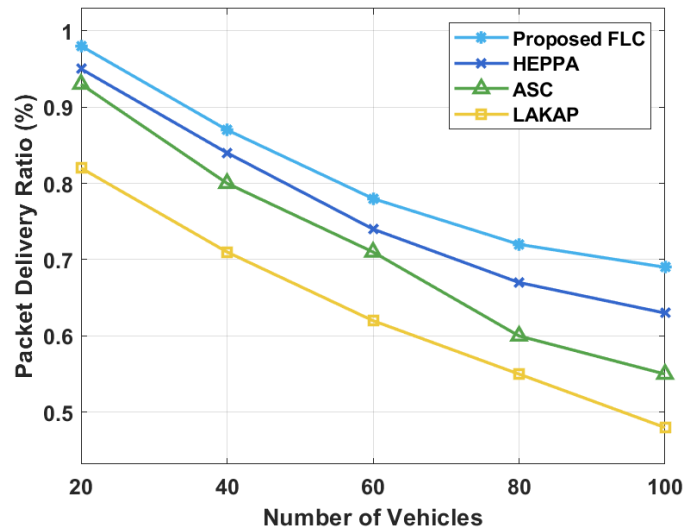

Fig. 7. PDR Analysis of FLC Model.

Fig. 8. ETE Delay Analysis of FLC Model.

An ETE delay analysis of the proposed FLC technique with recent techniques is made in Fig. 8. The figure has demonstrated that the FLC approach has offered superior results with the minimal ETE delay over the other methods whereas the LAKAP algorithm has portrayed insufficient performance with the higher ETE delay. For instance, with 20 vehicles, the proposed FLC technique has resulted in a least ETE delay of 7.57ms whereas the HEPPA, ASC, and LAKAP manners have demonstrated a maximal ETE delay of 7.97ms, 8.07ms, and 10.57ms, correspondingly. Meanwhile, with 60 vehicles, the proposed FLC technique has resulted in the least EC of 8.39ms whereas the HEPPA, ASC, and LAKAP techniques have outperformed a higher EC of 9.04ms, 9.57ms, and 11.61ms, correspondingly. Eventually, with 100 vehicles, the projected FLC technique has resulted in the least EC of 9.38ms whereas the HEPPA, ASC, and LAKAP methods have showcased a maximal EC of 10.14ms, 10.4ms, and 13.11ms, correspondingly.

For validating the IDS performance of the OFSVM method, it is tested using NSL-KDD 2015 dataset which includes a set of 125973 instances with 51 class labels and 2 classes. Table 3 and Fig. 9 demonstrate the detailed detection accuracy analysis of the OFSVM with other methods [19]. The table values showcased that the CS-PSO algorithm has gained lowest performance with the accuracy of 75.51% whereas a certainly enhanced performance is obtained by the DNN-SVM and Cuckoo optimization methods with the accuracy of 92.03% and 96.88% correspondingly. Besides, the behaviour based IDS, PSO-SVM, MLIDS, and DNN models have exhibited moderately closer accuracy of 98.89%, 99.1%, 99.93%, and 99.96% respectively. However, the proposed OFSVM model has gained maximum outcome with an accuracy of 99.98%.

TABLE III. RESULT ANALYSIS OF PROPOSED OFSVM METHOD WITH EXISTING METHODS FOR APPLIED DATASET

Methods	Accuracy
Proposed OFSVM	99.98
Deep Belief Network (2020)	99.96
MLIDS (2019)	99.93
CS-PSO (2019)	75.51
PSO-SVM (2019)	99.10
Behaviour Based IDS (2019)	98.89
Cuckoo Optimization (2018)	96.88
DNN+SVM (2018)	92.03

Fig. 9. Accuracy Analysis of OFSVM Model with Existing Techniques.

## V. CONCLUSION

This paper has presented an effective FLC-OFSVM model to achieve security and effective communication in VANET. The proposed FLC-OFSVM model begins with the deployment of vehicles in a random way and is initialized together. Then, the FLC technique is executed to determine the proper set of CHs in VANET and neighboring vehicles join the CH to develop the cluster. Moreover, the OFSVM model is applied for identifying the existence of intruders from VANET. In order to optimally tune the parameters involved in the FSVM model, the KH algorithm is employed in such a way that the intrusion detection rate can be enhanced. For examining the outcomes of the FLC-OFSVM model, a comprehensive set of experimental analyses were performed and the results are inspected in terms of several aspects. The resultant experimental values highlighted the promising performance of the FLC-OFSVM model over the state of art methods. As a part of future work, the security of the VANET is improved by the design of secure multihop routing protocols for privacy preserving data transmission with reliable vehicles in VANET.

**Abstract**—Chest Disease creates serious health issues for human beings all over the world. Identifying these diseases in earlier stages helps people to treat them early and save their life. Conventional Neural Networks play an important role in the health sector especially in predicting diseases in the earlier stages. X-rays are one of the major parameters which help to identify Chest diseases accurately. In this paper, we study the prediction of chest diseases such as Pneumonia, COVID-19, and Tuberculosis (TB) from the X-ray images. The prediction of these diseases is analyzed with the support of three CNN Models such as VGG19, Resnet50V2, and Densenet201, and results are elaborated in the terms of Accuracy and Loss. Though all three models are highly accurate and consistent, considering the factors like architectural size, training speed, etc. Resnet50V2 is the best model for all three diseases. It trained with F1 score accuracies of 0.98,0.92,0.97 for pneumonia, tuberculosis, covid respectively.

**Keywords**—Convolutional neural networks; VGG19; ResNet50V2; DenseNet201

## I. INTRODUCTION

Historically, Chest diseases are very serious health problems in the life of people. These diseases include chronic obstructive pulmonary disease, pneumonia, asthma, tuberculosis, and lung diseases. The timely infectious diseases have had civilization-altering consequences. so, diagnosis of chest diseases in the early stage is very important. To estimate the importance of diseases, different measures such as morbidity and mortality can be used. An X-ray is a quick, painless test that produces images of the structures inside your body. pneumonia, tuberculosis, or lung cancer can show up on chest X-rays. Generally, however, radiation exposure from an X-ray is low, and the benefits from these tests far outweigh the risks [1].

The study of major diseases from x-rays becomes a most challenging task. In this study, we have considered 3 diseases Pneumonia, COVID-19, and Tuberculosis (TB) these diseases can be easily identified using chest X-rays and CT scans. Chest X-rays are normally painless and non-invasive radiological tests to screen and diagnose many lung diseases also other methods such as CT and MRI can be used. Chest X-ray is fast, easy and inexpensive than CT and MRI and they are mostly used in emergency diagnosis and treatment of lungs, hearts, and chest wall diseases. Coronavirus disease 2019 (COVID-19) is an infectious disease caused by a

coronavirus strain called severe acute respiratory syndrome coronavirus [2]. Results show that chest X-rays correctly diagnosed COVID-19 in 99% of people who had COVID-19. However, it incorrectly identified COVID-19 in 1% of people who did not have COVID-19 [3]. Pneumonia is a form of acute respiratory infection that is most commonly caused by viruses or bacteria [4,5]. The X-rays scans show 92 % of accuracy. Tuberculosis (TB) is caused by a bacterium called *Mycobacterium tuberculosis*. A total of 1.4 million people died from TB in 2019 [6,7]. X -rays help in 99% of the identification of tuberculosis.

The challenges and the increase in the number of cases for these diseases motivate us to explore the methods that help to study how to accurately identify this disease to help humans. Currently, Artificial Intelligence (AI) especially Machine Learning (ML) and Deep Learning (DL) algorithms help to effectively identify these diseases. For our study, we considered pre-trained deep Convolutional Neural Networks (CNNs) as feature extractors to extract powerful and discriminative deep features from brain magnetic resonance (MR) images and Chest X-ray images for various ML classifiers and deep learning networks to identify the infected and uninfected images. Also, to investigate the benefits of combining features from different pre-trained CNN models by comparing their Accuracies.

Our experiment results demonstrate that the ensemble of deep features can help to improve performance significantly. In this paper, we considered 3 datasets of disease X-rays namely COVID19, Pneumonia, Tuberculosis, and performed comparisons on various CNN pre-trained models VGG19, Resnet50V2, Densenet201. In summary, our contributions are listed as follows:

- We designed and implemented a fully automatic disease classification, in which the pre-trained CNN VGG19, Resnet50V2, Densenet201 models extract the deep features from X-ray images.
- This is executed in three steps: (1) Training the model using CNN models (2) Comparing the pre-trained models based on their accuracies and losses (3) Selecting the top fine-tuned model to achieve state-of-the-art performance for disease classification in X-ray images.

- We conducted extensive experiments on 3 datasets namely Pneumonia, COVID, Tuberculosis, and for each 3 pre-trained models namely VGG19, Resnet50V2, and Densenet201 to analyze the classification accuracy and precision for these models.

The Related works are described in section 2. Section 3 highlights the datasets and methodology, section 4 with model architecture section 5 shows a more detailed performance analysis. The Conclusion and future work are discussed in Section 6.

## II. LITERATURE SURVEY

Many papers addressed CT scan and x-ray diagnosis of COVID, Irfan Ullah Khan et al. [8] compared the COVID-19 x-ray images by performing different deep learning techniques DenseNet121, ResNet50, VGG16, and VGG19 with accuracies of 96-99% and stated overall accuracy of 99.33% VGG16 and VGG19. Kumar [9] used ResNet50 and Support Vector Machine (SVM) classification for the diagnosis of COVID in x-ray images and got an accuracy of 95.38% for binary classes. Also, Ali [10] found the highest accuracy of 98% for ResNet50 using X-ray datasets [11]. However, most of the research is carried out for small datasets. When the size of the dataset increases it shows some in-efficiencies. Hence in our paper, we analyze the performance of the X-ray dataset in a large volume and the implications are measured.

In the research of classification of X-ray images, Rachna Jain[12] performs several pre-trained convolutional neural networks(CNN) on pneumonia x-rays to classify x-ray images into two classes i.e. pneumonia and non-pneumonia by varying different parameters and layers. She had compared 4 pre-trained models VGG16, VGG19, ResNet50, and Inception-v3 with accuracies of 87.28%, 88.46%, 77.56%, and 70.99% respectively. Similarly [13,14] examines various deep convolutional neural networks (DCNNs) for the prediction of tuberculosis and shows Densenet201 has better accuracy when compared to other algorithms. And [15] shows the analysis of various CNN algorithms in the prediction of Tuberculosis with different classification theories of tuberculosis. [16,17] proposed a deep learning-based approach using Densenet-121 with the radiology image learned by the CheXnet model to detect COVID-19 patients and performance analysis of these algorithms in the detection. [18, 19] also describes the study on pneumonia with two convolutional neural network models Xception and VGG16.

Megha Chandra et al. [20] proposed a CNN-based MobileNet architecture for detecting diseases in plants. Authors in [21,22] proposed a method performing by combining clustering and classification for the effective diagnosis of tuberculosis. This model has various algorithms such as K-means, C4.5 decision tree, K-NN, Naive Bayes, and SVM which produced an accuracy of 98.7%. They concluded that the SVM algorithm provided better accuracy in predicting tuberculosis. Lakhani P. [23] trained a deep CNN for the automated classification of pulmonary tuberculosis from chest radiographs. AlexNet and GoogLeNet, which are dual CNNs, were used for classification purposes. The dataset was pre-processed before evaluation. Their model had a high accuracy of 0.99. Their model had a specificity of 100% and a

sensitivity of 97.3%. Anthimopoulos M. et al [24] The input dataset images are of size 256X256 pixels. The accuracy of the model is 0.964 on an average specificity and sensitivity of 91% showing that deep convolutional neural networks can be developed with high classification accuracy and can help in the diagnosis procedure. [25] proposed a Reliable Learning with Partial differential equation to detect various diseases from Chest X-rays.

Along with x-rays, MRI reports also play a major role in the diagnosis of brain diseases. Studying MRI reports is much more difficult than x-rays, a researcher named Ahmed Kharrat [26], proposed a hybrid approach for classifying Brain tissues in MRI based on a Genetic Algorithm(GA) and Support Vector Machine(SVM). He performed his research with fewer datasets consisting of 83 images, due to the small size of the dataset SVM classifier is employed. These two algorithms give heady results in classifying brain tumors. 94.44% accuracy is obtained while performing the following technique SGLDM+GA+SVM and 96.29% accuracy is obtained for WT+SGLDM+GA+SVM.

From the survey, X-ray images are very helpful in detecting most chest-related diseases. As a continuation of this, we began our research in analyzing these Chest diseases once again with three CNN models and the results are discussed.

## III. METHODOLOGY

The methodology includes the analysis of the 3 datasets for three chest diseases with the three different CNN models. The execution steps include pre-processing of the x-ray images and the classification of data into normal cases and infected cases.

The dataset underwent different image processing techniques for the image analysis and to retrieve the values from those images. The given dataset is divided into three sets for the processing train data, test data, and validation data. The Pneumonia dataset is split before computation. Other datasets COVID, Tuberculosis are split with the ratios of 75:10:15 for train, test, and validation. The processed image sets are passed through the different layers present in the pre-trained model, which generates a model for disease classification by comparing it with the untrained imageset.

### A. Data Pre-Processing

The pre-processing execution starts once the images are resized and augmented. NumPy tensor is used as the function for preprocessing and it produces the output image of the same shape. In the data pre-processing image will be resized to 224x224x3 and then it is converted to an array to store the values. Each value in an array is rescaled by 255. The tensor input will insert a dimension of length at the index axis of the input's shape to refer to the values. The dimension index follows indexing rules which are given as: It's zero-based, a negative index is counted backward from the end. It helps in aligning axes for broadcasting, to add an inner vector length axis to a tensor of scalars.

**B. Classification**

Classification is a task that requires the use of machine learning algorithms that learn how to assign a class label to examples from the problem domain. The pre-trained architecture generated a model with various arguments by validating the trained set with a validation set for 50 epochs to learn from the losses of previous epochs gives good accuracy. This validation process plays a major role in the detection to classify infected and uninfected images. In the end, it tries to draw some conclusions from the input values given for training in the form of the confusion matrix and line graphs. It will predict the class labels/categories for the new data. The execution procedure is shown in Fig. 1.

In this model, we are using the algorithms of Conventional Neural Networks. VGG19, DenseNet201, and ResNet50V2 models of CNN are used for training the different datasets and the prediction accuracy is measured for these models.

**C. Datasets**

Below datasets are extracted from Kaggle namely Pneumonia, COVID, Tuberculosis dataset with the size of 1.15GB, 1.97GB, 662.49MB respectively.

The pneumonia dataset contains 5856 images of which 5216 are used for training with all three models, 624 for the test, and 16 for validation as shown in Fig. 2. This dataset consists of two categories of images – Pneumonia cases, Normal cases. The dataset was obtained from

Kaggle:<https://www.kaggle.com/paultimothymooney/chest-xray-pneumonia>.

Fig. 1. Data Flow Model of the Execution Procedure.

Fig. 2. Data Classification Pneumonia.

COVID dataset contains 4606 captured images in which 3470 are used for training the model, 562 for the test, and 674 for validation as shown in Fig. 3. This dataset consists of two categories of images – COVID, Normal. The dataset obtained from Kaggle:<https://www.kaggle.com/amanullahasraf/covid19-pneumonia-normal-chest-xray-pa-dataset?select=covid>.

Fig. 3. Data Classification COVID 19.

The tuberculosis dataset contains 4606 images in which 3470 are used for training the model, 562 for the test, and 674 for validation as shown in Fig. 4. This dataset consists of two categories of images – Tuberculosis infected chest, Normal chest. The dataset obtained from Kaggle:<https://www.kaggle.com/tawsifurrahman/tuberculosis-tb-chest-xray-dataset>.

Fig. 4. Data Classification Tuberculosis.

**IV. EVALUATION OF THE MODEL**

The untrained test set has gone through the same pre-processing steps and is used to test the generated model which predicts the image with a suitable label, where end users can test their x-rays and uses the result for their study. The saved trained model can be further converted to an API for a mobile application to create a better user interface for users.

**A. VGG19 Architecture**

VGG model consists of a variety of models like VGG11, VGG16, and many more, among them VGG19 consists of 19 layers (16 convolution layers, 3 fully connected layers, 5 MaxPool layers, and 1 SoftMax layer) and 19.6 billion FLOPs. The input to VGG based convNet is a 224x224 grayscale image. Preprocessing layer takes the grayscale image with pixel values in the range of 0 to 255. The processing model for the VGG 19 is shown in Fig. 5.

Fig. 5. VGG19 Processing Model.

B. ResNet50V2 Architecture

Resnet50V2 is a huge architecture, it is taken and modified from Resnet50 in later years for better performance than previous architectures like resnet101. It is a contemporary convolution neural network (CNN) which addresses vanishing gradient problems using residual blocks in the architecture. In a residual network, multiple residual blocks are stacked up one after another. Each residual block is formed of short-cut connections skipping one or more layers. Resnet50V2 uses the pre-activation of weight layers. ResNet50V2 achieves accurate predictions on the datasets. The processing model for Resnet50V2 is shown in Fig. 6.

Fig. 6. Resnet50V2 Processing Model.

C. DenseNet201 Architecture

DenseNet-201 is a convolutional neural network that is 201 layers deep. Recent work has shown that convolutional networks can be substantially deeper, more accurate, and efficient to train if they contain shorter connections between layers close to the input and those close to the output. DenseNet connects each layer to every other layer in a feed-forward fashion. Whereas traditional convolutional networks with L layers have L connections - one between each layer and its subsequent layer - the DenseNet network has  $L(L+1)/2$

direct connections. For each layer, the feature maps of all preceding layers are used as inputs, and their feature maps are used as inputs into all subsequent layers[21,22]. DenseNets have several compelling advantages: they alleviate the vanishing gradient problem, strengthen feature propagation, encourage feature reuse, and substantially reduce the number of parameters. The processing model for Densenet201 is shown in Fig. 7.

Fig. 7. Densenet201 Processing Model.

V. PERFORMANCE ANALYSIS

The performances of these three VGG19, Resnet50V2, and Densenet201 algorithms are analyzed for all the diseases data set COVID, Pneumonia, and Tuberculosis. The metrics used for performance analysis are defined in terms of Accuracy, Loss, Confusion matrix, and Classification report. The simulation is done in python with TensorFlow and Keras. Keras Layers are the functional building blocks of Keras Models. These layers are fed with input information, they process this information, do some computation and hence produce the output. Also, we used matplotlib for data visualization and a few standard libraries like NumPy and Pandas for calculations of image arrays.

A. Classification Report

a) Pneumonia: Pneumonia causes the lungs that fill with fluid and make breathing difficult. The analysis is made with the help of 624 values. Table 1. a and Table 1.b shows the confusion matrix and classification report of all Pneumonia datasets which is compared for all three algorithms. From the analysis, it can be identified that Resnet50V2 and VGG19 show high prediction accuracy with 92% and Densenet201 shows 91% of accuracy.

TABLE I. (A) PNEUMONIA-CONFUSION MATRIX

	Predicted Normal			Predicted Pneumonia		
	VGG 19	Resnet50V2	Densenet201	VGG 19	Resnet50V2	Densenet201
Actual Normal	376	383	384	37	41	51
Actual Pneumonia	14	7	6	197	193	183

(B) PNEUMONIA-CLASSIFICATION REPORT

	Precision			Recall			F1-Score			Support
	VGG 19	Resnet50V2	Densenet201	VGG 19	Resnet50V2	Densenet 201	VGG 19	Resnet50V2	Densenet201	
Normal	0.91	0.96	0.97	0.84	0.82	0.78	0.89	0.89	0.87	234
Pneumonia	0.93	0.90	0.88	0.96	0.98	0.88	0.94	0.94	0.93	390
Accuracy							0.92	0.92	0.91	624
Macro Avg	0.92	0.93	0.93	0.90	0.90	0.88	0.91	0.92	0.90	624
Weighted Avg	0.92	0.93	0.91	0.92	0.92	0.91	0.92	0.92	0.91	624

b) *Tuberculosis*: Tuberculosis caused by bacteria usually attacks the lungs, but TB bacteria can attack any part of the body such as the kidney, spine, and brain. TB is spread from person to person through the air. The analysis is made with the help of 422 values. VGG19 and Densenet201 show 99% of accuracy for Tuberculosis as shown in Table 2.a and Table 2.b and ResNet50V2 show 98% of prediction accuracy.

c) *COVID19*: COVID-19 is an infectious disease caused by a coronavirus strain called severe acute respiratory syndrome coronavirus. The analysis is made with the help of 422 values for testing. The result is shown in Table 3.a and Table 3.b shows VGG19 shows 98% whereas 97% for

ResNet50V2 and 96% for Densenet201. This shows that Though all the models are similar the VGG19 shows better accuracy in the prediction.

The overall analysis shows VGG19 and the Resnet50V2 show more accuracy when compared to Densenet201.

**B. Training Vs Validation Set**

This section shows the comparative analysis of the algorithms concerning Loss and Accuracy of the data during the training and the validation process of the dataset. Table 4 shows the values of performance measures in terms of loss and accuracy achieved by models VGG19, ResNet50V2 and DenseNet201.

TABLE II. (A). TUBERCULOSIS-CONFUSION MATRIX

a) *Train Loss*: The training loss for the pneumonia are 0.0308, 0.1396, 0.0889 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the training loss for each epoch is shown in Fig. 8. (a). Similarly, the training loss for tuberculosis is 0.1041, 0.0125, 0.0068 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the training loss for each epoch is shown in Fig. 8. (b). Finally, the training loss for the COVID19 are 0.0721, 0.0848, 0.1172 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the training loss for each epoch is shown in Fig. 8. (c).

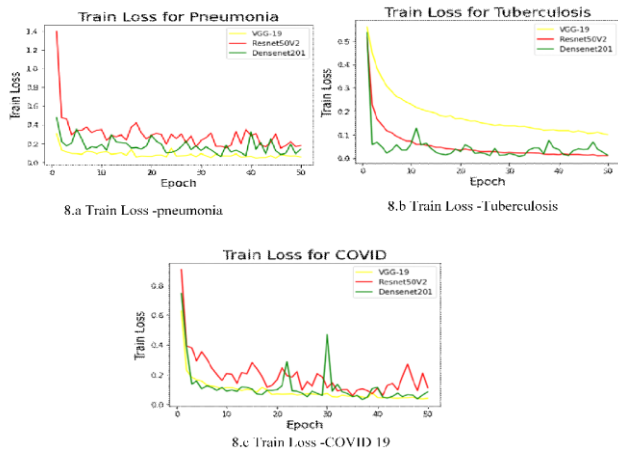

Fig. 8. Train Loss Vs Epoch.

b) *Validation Loss*: The Validation loss for the pneumonia is 0.1036, 4.8358, 0.000001 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the Validation loss for each epoch is shown in Fig. 9. (a). Similarly, the Validation loss for tuberculosis are 0.0469, 0.0212, 0.00009 for the models VGG19, ResNet50V2, and DenseNet201, and the Validation loss for each epoch is shown in Fig. 9. (b). Finally, the Validation loss for the COVID19 are 0.1201, 0.9956, 0.4328 for the models VGG19, ResNet50V2, and DenseNet201, and the validation loss for each epoch is shown in Fig. 9. (c).

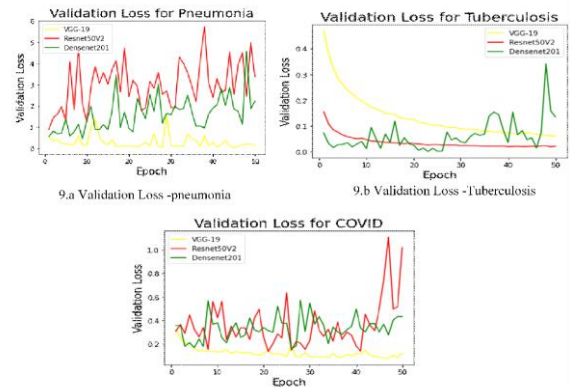

Fig. 9. Validation Loss Vs Epoch.

c) *Training Accuracy*: The training accuracy for the pneumonia is 0.9879, 0.9916, 0.9904 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the training accuracy for each epoch is shown in Fig. 10. (a). Similarly, the training accuracy for tuberculosis is 0.9699, 0.9971, 0.9996 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the training accuracy for each epoch is shown in Fig. 10. (b). Finally, the training accuracy for the COVID19 are 0.9716, 0.9930, 0.9823 for the models VGG19, ResNet50V2, and DenseNet201 shown in Table 4 and the training accuracy for each epoch is shown in Fig. 10. (c).

Fig. 10. Train Accuracy Vs Epoch.

d) *Validation Accuracy*: The validation accuracy for the pneumonia are 0.9375, 0.8750, 0.1 for the models VGG19, ResNet50V2 and DenseNet201 shown in Table 4 and the validation accuracy for each epoch is shown in Fig. 11. (a). Similarly, the Validation accuracy for tuberculosis are 0.9899, 0.9916, 0.1 for the models VGG19, ResNet50V2 and DenseNet201 shown in Table 4 and the validation accuracy for each epoch is shown in Fig. 11. (b). Finally, the validation accuracy for the COVID19 are 0.9555, 0.9570, 0.9599 for the models VGG19, ResNet50V2 and DenseNet201 shown in table 4 and the validation accuracy for each epoch is shown in Fig. 11. (c).

## VI. CONCLUSION AND FUTURE WORK

High precise diagnostic results are expected in helping the healthcare system to provide efficient services to the patient in less time. To attain this goal a CNN model was built in our research to study x-rays images of covid 19, pneumonia, tuberculosis. For this, we study VGG19, ResNet50V2, DenseNet201 architectures, and their performances have been analyzed with the X-ray images. We used Adam optimizer and trained for 50 epochs. Though all three models are highly accurate and consistent, considering the factors like architectural size, training speed, etc. Resnet50V2 is the best model for all three diseases. It trained with F1 score accuracies of 0.98,0.92,0.97 for pneumonia, tuberculosis, covid respectively.

In this study, we can't predict the diseases at the earlier stages. So, to predict the above chest diseases in earlier stages with the support of other parameters can be extended as part of future work.

# Detection of Acute Myeloid Leukemia based on White Blood Cell Morphological Imaging using Naïve Bayesian Algorithm

Esti Suryani<sup>1</sup>, Wiharto<sup>2\*</sup>, Adi Prasetya Putra<sup>3</sup>, Wisnu Widiarto<sup>4</sup>  
Department of Informatics, Universitas Sebelas Maret, Surakarta, Indonesia

**Abstract**—The process of diagnosing AML is based on the complete blood-count analysis of the patients. As such, it involves high energy consumption, long completion times, and is rather expensive compared to conventional medical practices. One of the methods for identifying tumor cells involves the utilization of image-processing techniques based on the morphology of white blood cells (WBCs). The principal objective of this study involves the identification of AML cells—especially of the AML M1 and AML M2 types—through morphological imaging of WBCs using the Naïve Bayes' Classifier. The Image-processing methods used in this study include YCbCr color space classification, image thresholding, morphological operations, chain code representation, and the use of bounding boxes. Regardless of the processing technique used, all identification procedures, performed in this study, were based on the Naïve Bayes' Classifier. The test process was performed on 30 images of each of the AML M1 and M2 cell types. The use of the cell identification method proposed in this study demonstrated an accuracy of 73.33%. While the accuracy of cell type identification is 54.92%. Based on the results obtained in this study, it is inferred that the Naïve Bayes' Classifier method can be employed in the process of identifying dominant AML cell types amongst AML M1 and AML M2 (myeloblast, promyelocyte, myelocyte, and metamyelocyte) based on the morphology of WBCs.

**Keywords**—Leukemia; acute myeloid leukemia; morphology; image processing; Naïve Bayes

## I. INTRODUCTION

Leukemia is a type of cancer, where the bone marrow tends to produce abnormal white blood cells (WBCs) [1]. Leukemia may be divided into four main types—acute myeloid leukemia (AML), chronic myeloid leukemia (CML), acute lymphoblastic leukemia (ALL), and chronic lymphocytic leukemia (CLL). AML is the most commonly diagnosed type of leukemia; of all cases of AML diagnosed to date, 80% have been found to occur in adults, and 15–20% cases have been found to occur in children [2].

National Cancer Institute, 2013 maintains a record of the occurrence of AML amongst adults belonging to different age groups. It is seen that in the age group of 30–34 years, a single case of leukemia is recorded per 100,000 people; between 65–69 years, these numbers increase by ten times to 10 cases per 100,000 people. This number increases still further for adults beyond 70 years of age and the trend continues to rise until the age group of 80–84 years[3]. In general, the process of diagnosing AML involves analysis of the complete blood count of the patient, wherein the pathologist counts the number of red

blood cells, WBCs, platelets, and checks for the presence of abnormal WBCs[4]. However, this method is time-consuming, requires energy, and is one of the most expensive routine tests performed in clinical hematological laboratories[5].

According to the French–America–British (FAB) classification, AML is classified into eight types—M0, M1, M2, M3, M4, M5, M6, M7[6]. This classification is based on the calculation of the cell-maturity level as well as the lineage from blast cells[7]. Utilization of various image-processing techniques offers an alternate approach aiding the identification of blood cells[8]-[9]. Cell identification could be performed through process analysis of digital images of a leukemia-positive blood cell preparation, captured using a digital microscope.

Previously, research has been conducted on the identification of blood cells using image processing techniques on AML images based on the white morphology of white blood cells[6],[8], as well as classification of the types of AML[8][9]. The technique used there are four stages of image acquisition, segmentation, feature extraction, and identification. The segmentation process aims to separate white blood cells and red blood cells. The techniques used in image segmentation include colour filter, Canny Edge Detection, Ellipse Detection. While the identification process uses a Fuzzy Rule-Based System with the Sugeno Order Zero method[9]. Another study used K-means data mining to separate the nucleus into white blood cells. After separating the nucleus and white blood cells, the next step is to extract the characteristics of the shape and the characteristics of densitometry, then perform the process of classification of white blood cell types using the Naïve Bayes Classifier algorithm[8].

Segmentation of the cell nucleus can be performed through the use of the C–Y color space[10]. The C–Y color space serves to transform an RGB image of WBCs into a YCbCr image. The white-blood-cell nucleus can then be segmented based on luminance (Y) [10]. WBC segmentation with other methods has also been used, namely, Active Contour Without Edge[11]. The opening morphology operation and median filter have been used to remove noise[12]. The study presented in this paper aims to identify AML cells, especially the ones belonging to the M1 and M2 types, based on the morphology of WBCs. The proposed study involves the utilization of the C–Y color space to achieve the conversion of an RGB image into a YCbCr image[12][13]. Segmentation of the nucleus and

\*Corresponding Author

WBCs is accomplished through the use of the thresholding method followed by median filtering to make the nucleus and WBC [10]. Methods to classify cell and AML types were based on naïve Bayes' classifier algorithm. The use of this method is favored because it includes an algorithm that makes use of training data to identify similarities with test data [14][15]. Additionally, the naïve Bayes classifier method has previously been used to identify cell types from digital images, which is an added advantage[8]. The Naïve Bayes Classifier is also used to classify texture images from the Describable Textures Dataset (DTD) and Brodatz albums. The classification results show very accurate results[16]. In another study, Naïve Bayes was used to classifying tomatoes into three classes, namely raw, ripe and rotten based on the histogram characteristics, the experimental results obtained an accuracy of 76%[17]. Naïve Bayes is also used to classify the type of hepatitis from the results of blood smear images using the Fuzzy C-Means Clustering and random forest methods. The segmented image is subjected to feature extraction with SITCA (Spatio-Temporal Independent Component Analysis) which extracts every required feature. The experimental results show an accuracy of 89%[18]. Other research on image classification was also carried out using the Naïve Bayes method, based on the histogram gray feature, SIFT feature, SURF feature, and dataset dimension reduction from the image data set. The Naive Bayesian method is used to obtain the accuracy, recall, and F1 values of the image for each feature. The analysis is done by comparing the features with Naïve Bayes. The evaluation results show that the image representation using the SURF feature description can achieve better classification results[19].

## II. MATERIAL AND METHOD

The data used in this study is a WBC image that identified leukemia type AML M1 and AML M2 Data in the form of a WBC image that is identified AML type AML M1 and AML M2. The process of identification is performed by and, subsequently, obtained from a clinical pathologist—RSUD Dr. Moewardi—at the Clinical Pathology Installation, Surakarta, Central Java. The data comprises 30 images of each of the M1- and M2-type AML cells. Each image was obtained through observations performed using a digital microscope at 1000 times magnification of blood-cell preparations identified as AML M1 and AML M2. Sample data images, used in this study, are shown in Fig. 1.

Acute myeloblastic leukemia with little maturation (AML M1) possesses a myeloblast cell count of more than 90% and is found in the spinal cord with fine chromatin and a prominent nuclear form at locations where azurophilic granules (blue color) may be present[20] Myeloblastic cells predominate in the AML M1 cell type.

In contrast to AML M1, AML M2 is more common in children to the extent that approximately 30–45% of all AML cases in children belong to this type. In terms of cell types, AML M2 is comprised of more than myeloblast cells (more than 20% of the total cell count), found in the blood and spinal cord, and neutrophil cells (roughly 10% of total cell count) in various stages of maturity, such as Promyelocyte, Myelocyte, and Metamyelocyte. The cytoplasm of the myeloblast cells

may or may not be comprised of azurophilic grains and Auer stems[20]. Morphological features of the dominant cells in AML M1 and M2 are listed in Table I.

Fig. 1. Identification Type of AML M1 & AML M2 by Expert; (a) AML M1, (b) AML M2.

### Information:

- 1) Myeloblast cells
- 2) Promyelocyte cells
- 3) Myelocyte cells
- 4) Metamyelocyte cells

The selection of features in the form of WBC diameter, nuclear ratio, and roundness ratio because they are the dominant features found in every granulocyte cell (Myeloblast, Promyelocyte, Myelocyte, Metamyelocyte) besides being able to see whether the cytoplasm is granular or not[21][6], as shown in Table I. However, to determine whether the cytoplasm is granular (azurophilic) or not, it is quite difficult to do because it is in the form of spots, some of which are pink, dark red, and some are purplish in the cytoplasm. It is difficult to separate the colors, so the most feasible feature was selected by measuring WBC diameter, nucleus ratio, and cell nucleus sphericity ratio in feature extraction on image data.

TABLE I. FEATURES OF DOMINANT CELLS OF AML M1 & AML M2

Cell Types	WBC Diameter (µm)	Nucleus Ratio	Nucleus Roundness
Myeloblast	15 – 20	7:1 – 5:1	Roundness
Promyelocyte	12 – 24	5:1 – 3:1	Roundness
Myelocyte	10 – 18	2:1 – 1:1	Oval
Metamyelocyte	10 – 18	1.5:1 – 1:1	Curve

Image enhancement is performed to reduce noise by converting the captured RGB image into a YCbCr image in the C–Y color space[22].

Post conversion, the YCbCr image is processed through mean and median filtering. The processes of mean and median filtering are performed to obtain a more solid image and reduce the noise that may be induced during image segmentation[23].

Image segmentation is performed to detect and segregate nuclei from WBCs by subjecting the YCbCr image to a thresholding operation based on the Y, Cr, and Cb components. The result of image segmentation is a binary image. Segmentation results are subsequently subjected to an opening operation to reduce unnecessary noise during the feature-extraction process.

The feature-extraction process relates to the quantization of image characteristics into numerical values. The methods used in this phase include those based on chain code and the bounding box algorithm. The characteristics of WBCs sought in this study are the WBC diameter, nuclear ratio, and roundness ratio [24].

1) *WBC diameter* The WBC diameter can be calculated based on the area of the detected WBC area and can be calculated using the following equation (1)[25]:

$$Diameter = 2 \sqrt{\frac{WBC\ Area}{\pi}} \quad (1)$$

2) *Nucleus ratio* This is a ratio that compares the area of the nucleus with the WBC area and can be calculated using the following equation:

$$Nucleus\ Ratio = \frac{Nucleus\ Area}{WBC\ Area} \quad (2)$$

3) *Roundness ratio* The roundness ratio of serves to quantify the curvature of a nucleus. Its value approaching unity implies that the nucleus has a high curvature. The roundness ratio can be calculated using the following equation:

$$Roundness\ Ratio = \frac{4\pi L_{Nucleus}}{Perimeter^2} \quad (3)$$

where  $L_{Nucleus}$  represents the area of the nucleus and perimeter represents the number of pixels from the edge of the nucleus.

The purpose of this step is to identify the cell and AML types. As mentioned earlier, the naïve Bayes classifier is the algorithm used in this process. Inputs for identification of the cell type include WBC diameter, nuclear ratio, and roundness ratio, while that for identification of the AML type includes number of dominant cells—myeloblast, promyelocyte, myelocyte, and metamyelocyte. The naïve Bayes' classifier method employs the Bayes' theorem, wherein laws of probability determine a possible outcome of the classification process. This method approach uses probability as a determinant of the possible outcomes of the classification process. Bayes' theorem is stated by the following formula.

$$P(H|X) = \frac{P(X|H)P(H)}{P(X)} \quad (4)$$

The Bayes classifier assumes attributes that have independent distributions. For this reason, there is the following formula:

$$P(H|X) = P(X_1|H)P(X_2|H)P(X_3|H) \dots P(X_n|H) \quad (5)$$

Where  $X$  is data with an unknown class.  $H$  is hypothesis data is a specific class.  $P(H|X)$  is the probability of hypothesis  $H$  based on condition  $X$  (posteriori probability).  $P(H)$  represents Hypothesis probability  $H$  (prior probability).  $P(X|H)$  Probability of  $X$  based on the conditions on the hypothesis  $H$ , and  $P(X)$  is Probability of  $X$ .

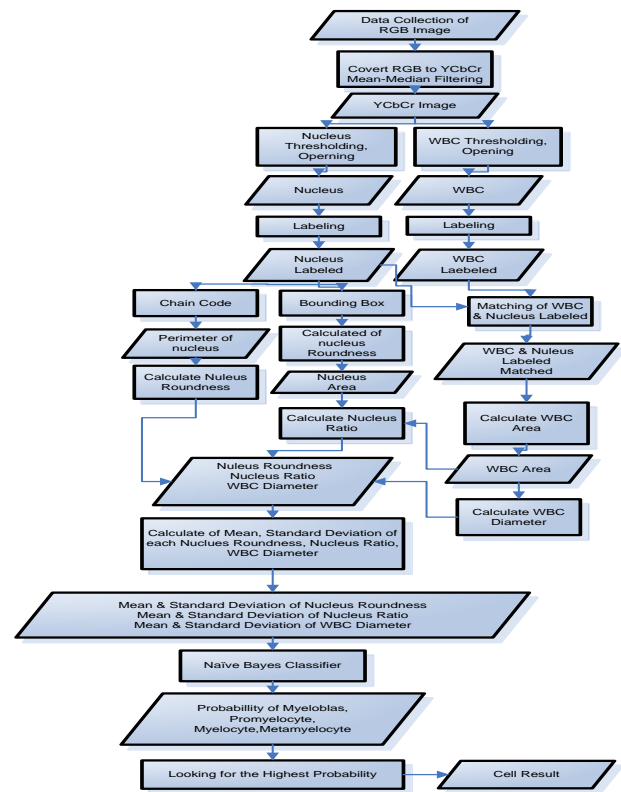

Fig. 2. The Research Methods.

The research methods of the steps can be shown in Fig. 2, from data collection, preprocessing, segmentation, characteristic extraction, and classification process with naive Bayes classifier, to find identified cell results.

### III. RESULT AND DISCUSSION

#### A. Results

As previously mentioned, a YCbCr image is obtained as a result of image enhancement and subsequent mean and median filtering. Fig. 2 depicts the result of image enhancement performed on the RGB image depicted in Fig. 1(a). Conversion of the RGB image to the YCbCr color space is performed to obtain optimum reproduction of the red-colored image components since red is a dominant color in WBC images. The red component in the YCbCr image is the Cr component, while the RGB image is the R component. Differences in the reproduction of red-colored components in the RGB and YCbCr color spaces can be recognized as shown in Fig. 4.

The result of the nucleus segmentation performed on the YCbCr image shown in Fig. 3 is depicted in Fig. 5(a) whereas WBC segmentation is shown in Fig. 5(b).

The feature-extraction process begins with the process of labeling the segmented images of the nuclei and WBCs. This is followed by the selection process performed on the segmented nucleus and WBC images using the bounding box method. Fig. 6(a) depicts results of the selection process performed on images of the nucleus, Fig. 6(b) shows selection results for WBC images, and Fig. 6(c) depicts the result of WBC selection

with the label. The characteristics of the extraction result shown in Fig. 6(c) are listed in Table II.

The attributes of feature extraction—WBC diameter, nuclear ratio, and roundness ratio—are used as test data. Based on the above feature extraction result, AML image characteristics (cell 6 in Fig. 6(c)) have WBC diameter, 18.161  $\mu\text{m}$ ; nucleus ratio, 0.647; and roundness ratio, 0.706. The percentage similarity of the cell types obtained through calculations based on the naïve Bayes' classifier algorithm is as quoted, Myeloblast = 40.1%, Promyelocyte = 39.1%, Myelocyte = 7.6%, Metamyelocyte = 13.2%.

Cell 6 in Fig. 6(c) is identified by the system as a myeloblast cell, because it has the highest percentage of 40.1%. A comparison of the results of cell type identification performed by a laboratory expert and that corresponding to Fig. 6(c) performed by the proposed system is presented in Table III.

As can be seen in Table III, there exist two cells—3 and 8—for which the result obtained using the proposed method did not match the identifications made by the expert. Cell 3 with characteristics of WBC diameter, 13.035  $\mu\text{m}$ ; nuclear ratio, 0.768; and roundness ratio of 0.815 is identified as a myeloblast cell because it has the following similarity percentages, Myeloblast = 61.2%, Myelocyte = 25.4%, Promyelocyte = 8.6%, Metamyelocyte = 4.8%. The WBC diameter of cell 3 demonstrates similarity percentages of 54.5%, 14.8%, 22.7%, and 8% with myeloblast, promyelocyte, myelocyte, and metamyelocyte cells, respectively. Thus, the proposed method identifies cell 3 as a myeloblast cell.

TABLE II. RESULTS OF CELL-FEATURE EXTRACTION

Label	Wbc Diameter ( $\mu\text{m}$ )	Nucleus Ratio	Nucleus Roundness
1	14.161	0.7428	0.866
2	17.306	0.676	0.720
3	13.035	0.768	0.815
4	13.552	0.718	0.869
5	18.212	0.640	0.855
6	18.161	0.647	0.706
7	12.987	0.833	0.771
8	16.569	0.645	0.621

TABLE III. COMPARISON OF CELLS IDENTIFICATION PERFORMED BY AN EXPERT AND THE PROPOSED SYSTEM

Label	Cell Identification by System	Cell Identification by Expert	Explanation
1	Myeloblast	Myeloblast	Matched
2	Myeloblast	Myeloblast	Matched
3	Myeloblast	Promyelocyte	Not matched
4	Myeloblast	Myeloblast	Matched
5	Myeloblast	Myeloblast	Matched
6	Myeloblast	Myeloblast	Matched
7	Myeloblast	Not Identified	Not Identified
8	Myeloblast	Promyelocyte	Not matched

The nucleus ratio of cell 3 demonstrates similarity percentages of 62.3%, 13.85%, 12.35%, and 11.5% with myeloblast, promyelocyte, myelocyte, and metamyelocyte cells, respectively. The nucleic feature of cell 3 demonstrates similarity ratios of 55.7%, 24.1%, 14.9%, and 5.3% with myeloblast, promyelocyte, myelocyte, and metamyelocyte cells, respectively. So, the nucleus ratio and roundness ratio of cell 3 has similarities to myeloblast characteristics.

Cell 8 with characteristics of WBC diameter, 16.569 μm; nuclear ratio, 0.645; and roundness ratio of 0.621 is identified as a myeloblast cell because it has the following similarity percentages, Myeloblast = 46.4%, Myelocyte = 11.3%, Promyelocyte = 23.3%, Metamyelocyte = 19%.

The WBC diameter of cell 8 demonstrates similarity percentages of 59.2%, 18%, 14.4%, and 8.4% with myeloblast, promyelocyte, myelocyte, and metamyelocyte cells, respectively. As such, the feature of WBC diameter for cell 8 has a strong resemblance to myeloblast cells. The nucleus ratio corresponding to cell 8 demonstrates similarity percentages of 44.5%, 31.3%, 14.1%, and 10.1% with myeloblast, promyelocyte, myelocyte, and metamyelocyte cells, respectively. At the same time, the nucleic feature of 8 demonstrates similarity percentages of 49.3%, 21.7%, 8.3%, and 20.7% with myeloblast, promyelocyte, myelocyte, and metamyelocyte cells, respectively. Thus, cell 8 has been assumed to possess a strong resemblance to myeloblast cells. The differences in the characteristics of WBC diameter, nuclear ratio, and roundness ratio between myeloblast cells and neutrophil cells (promyelocyte cells, myelocyte cells, and metamyelocyte cells) are almost indistinguishable in the above cases since each feature has an uncertain range of values. For example, cell 3 is identified by the expert as a promyelocyte cell, whereas cell 4, which possesses characteristic values similar to those of cell 3, is identified by the specialist as a myeloblast cell.

Results of the cell type feature extraction comprise 264 cell type data obtained from 50 AML images. Based on identifications made by the laboratory expert, these 264 cells comprised 143 myeloblasts, 62 promyelocytes, 33 myelocyte, and 26 metamyelocyte cells.

Table IV presents a comparison of these results with those obtained from cell type identification performed by the proposed system.

TABLE IV. RESULTS OF CELL TYPE IDENTIFICATION PERFORMED BY EXPERTS AND THE PROPOSED SYSTEM

Identification By Expert	Identification By System			
	Myeloblast (A)	Promyelocyte (B)	Myelocyte (C)	Metamyelocyte (D)
Myeloblast (A)	125	13	0	5
Promyelocyte (B)	41	20	0	1
Myelocyte (C)	31	2	0	0
Metamyelocyte (D)	20	6	0	0

An example of testing myeloblast cells using a confusion matrix based on Table IV. TP (True Positive): The number of myeloblast cells detected by the system and experts as myeloblast cells is 125 cells. FN (False Positive): The number of myeloblast cells identified by the expert but detected by the system as other cells (promyelocyte, myelocyte, and metamyelocyte) is 13 + 5 = 18 cells. FP (False Positive): The number of other cells (promyelocyte, myelocyte, and metamyelocyte) identified by the expert but detected by the system as myeloblast cells is 41 + 31 + 20 = 92 cells. TN (True Negative): The number of other cells (promyelocyte, myelocyte, and metamyelocyte) identified by the expert and the system as other cells (promyelocyte, myelocyte, and metamyelocyte) is 20 + 0 + 1 + 2 + 0 + 0 + 6 + 0 + 0 = 29 cells.

$$Precision = \frac{TP}{TP+FP} = \frac{125}{125+92} = 0.576$$

$$Sensitivity = \frac{TP}{TP+FN} = \frac{125}{125+18} = 0.8741$$

$$Spesificity = \frac{TN}{TN+FP} = \frac{29}{29+92} = 0.2396$$

The analysis of each cell is done by using a confusion matrix with precision, sensitivity, and specificity of each type of cell test. The results of confusion matrix testing can be seen in Table V. As seen in Table V, the precision of the myeloblast cells is 57.6% implying that the number of myeloblast cells was correctly identified as 57.6% of the total cell count. Sensitivity is the level of success achieved by the system in rediscovering information. As seen, the sensitivity of myeloblast cells is 87.41%, which means that 87.41% of the actual number of myeloblast cells was correctly identified by the system.

TABLE V. CONFUSION MATRIX TEST RESULT

Cell Type	Precision	Sensitivity	Specificity
Myeloblast	57.6 %	87.41 %	23.96 %
Promyelocyte	48.78 %	32.25 %	90.00 %
Myelocyte	0	0	100.00 %
Metamyelocyte	0	0	97.47 %
Overall Cells	54.92 %	54.92 %	85.14 %

Each cell type in the proposed study was subjected to a different mean test to examine the differences in the characteristics of WBC diameter, nucleus ratio, and roundness ratio between each cell type. The testing was performed using the T-test to know the significant value (p-value) of each cell.

An error rate of 5% was set meaning that if the p-value exceeds 0.05, it implies that the character of the compared cell is significantly different. The mean difference of the test results corresponding to each cell is listed in Table VI.

The WBC diameter of myeloblast cells, in theory, measures between 15–20 μm, and that of promyelocyte cells measures between 12–24 μm. Myeloblast and promyelocyte cells have similar typical WBC diameters between 15–20 μm. However, this similarity is not identified by the mean difference test result, which states that WBC diameters of myeloblast and promyelocyte cells are significantly different. Similarly, the nuclear ratio of the myeloblast cell, in theory, ranges from 7:1–5:1, while that of promyelocyte cells lies in the range of 5:1–3:1. This is in line with the mean difference test result that the nuclear ratios of the two cell types differ significantly.

The mean test result for the roundness ratio demonstrates that there exists no significant difference between the two cell types, which corresponds to the theoretical basis that myeloblast and promyelocyte cells have a still-filled nucleus.

K-fold cross-validation of the cell type data was performed to determine the accuracy of naive Bayes' classifier algorithm applied to new data. The test was performed using the Leave One Out Cross Validation (LOO-CV) method on the naive Bayes' classifier algorithm using the experimental values k = 2 to k = 10. The test results demonstrate that the algorithm possessed the highest accuracy at k = 4 with an accuracy of 54.92%. The complete cross-validation test results are presented in Table VII.

Out of the 60 AML images that were processed using the proposed technique, 44 were identified correctly. A summary of the results of AML identification can be seen in Table VIII.

The obtained accuracy results of the AML type identification are as follows:

$$\begin{aligned}
 \text{Accurate of System} = \text{Acc} &= \frac{\text{The amount of data is correct}}{\text{Total data tested}} \\
 &= \frac{44}{60} \times 100\% = 73.33\%
 \end{aligned}$$

**B. Discussion**

Many studies on the diagnosis of leukemia based on image processing have been carried out, including research on ALL (Acute Myeloid Leukemia) classification using the Naïve Bayes Classifier method on WBC segmentation results with k-NN (k-Nearest Neighbor), with a calcification accuracy of 75% [8]. Another study was conducted to classify AML M0 and AML M1 on the results of WBC segments with RGB to YCbCr conversion using the k-NN classification method, obtaining an accuracy of 59.87% [12]. Then the classification of AML M2 and AML M3 diseases with the Momentum backpropagation method from the results of WBC segmentation with the Watershed Distance Transform method obtained an accuracy of 94.285% [26]. While the classification on AML M1, M2 and M3 using the Backpropagation Momentum Method from the results of WBC segmentation with the ACWE method obtained an average precision of 84.754%, Sensitivity 75.88%, specificity 95.090%, and accuracy 94.285% [11]. In the same year, cell classification was carried out in AML M4, AML M5, and AML M7 with the

Support Vector Machine method on the results of WBC segmentation with K-NN and Watershed Distance Transform. The cell types were myeloblast, promyelocyte, granulocyte, monoblast, promonocyte, monocyte, megakaryoblast. and supporting cells with accuracy of 98.67%, 98.01%, 84.05% 99.67%, 95.35%, 89.70%, 99.34% and 98.01%, respectively [27]. The classification of AML M0 and AML M1 diseases has also been carried out using the Naïve Bayes Classification method from the results of WBC segmentation with Multi-Otsu Thresholding compared to Static Thresholding, respectively, the accuracy is 83.81% and 75.35% [28]. Then a comparison of the accuracy of the segmentation results on WBC in AML MI obtained an accuracy of 90.67% with the ACWE segmentation method, the results are higher than the accuracy obtained with the Sheet Region Growing and Otsu Thresholding segmentation [29].

Another study was also conducted regarding the classification of leukocyte cells in AML with the random forest method from the WBC segmentation process with Multi-Otsu Thresholding, which obtained 93.45% classification accuracy and 65% precision [30]. Then the classification is carried out on the case for ALL classification using the Naïve Bayes Classification method from the results of WBC segmentation with thresholding, 80% accuracy is obtained [31]. From the results of several studies that have been carried out for the classification of AML from the segmentation results of WBC cells in Acute Myeloid Leukemia, it is true that for this study the precision, sensitivity, specificity, and accuracy are relatively small compared to other similar studies that have been carried out.

TABLE VI. MEAN DIFFERENCE TEST OF EACH CELL TYPES

The Type of Cells That Are Compared	P-Value		
	WBC Diameter	Nucleus Ratio	Roundness Ratio
Myeloblast – Promyelocyte	0.000	0.000	0.105
Myeloblast – Myelocyte	0.008	0.169	0.922
Myeloblast – Metamyelocyte	0.092	0.515	0.001
Promyelocyte – Myelocyte	0.000	0.052	0.188
Promyelocyte – Metamyelocyte	0.468	0.014	0.010
Myelocyte – Metamyelocyte	0.002	0.542	0.002

TABLE VII. IDENTIFICATION RESULT OF CELL TYPES WITH K-FOLD CROSS VALIDATION TEST

K	2	3	4	5	6	7	8	9	10
Correct	144	142	145	144	141	140	144	143	143
Acc	54.5 5%	53.7 9%	54.9 2%	54.5 5%	53.4 1%	53.0 3%	54.5 5%	54.1 7%	54.1 7%

TABLE VIII. IDENTIFICATION RESULT OF AML

Type of Aml	Identification By System	
	AML M1	AML M2
AML M1	29	1
AML M2	15	15

#### IV. CONCLUSION

From the above analysis and supporting discussion, it can be inferred that the naïve Bayes' classifier algorithm could be used in the identification of dominant cell AML types—myeloblast, promyelocyte, myelocyte, and metamyelocyte—based on WBC morphological imaging. The AML type identification performed in this study using the naïve Bayes classifier algorithm demonstrated a system accuracy of 73.33% in a sample space comprising 60 AML images. Additionally, cell type identification accuracy of 54.92% was achieved in a sample space comprising 264 cell type data. The above accuracy was achieved with a precision of 54.92%, sensitivity of 54.92%, and specificity of 85.14%. As part of a future endeavor, the authors suggest normalization of the contrast in the image before the segmentation process to reduce noise generated in the segmentation process.

#### ACKNOWLEDGMENT

We would like to thank the National Research and Innovation Agency of the Republic of Indonesia for providing research funding under the Basic Research Grant scheme with Contract Number: 221.1/UN27.22/HK.07.00/2021. We would like to thank all those who have assisted in the completion of this research.

# Automatic Essay Scoring: A Review on the Feature Analysis Techniques

Ridha Hussein Chassab, Lailatul Qadri Zakaria, Sabrina Tiun

The Asean Natural Language Processing (ASLAN), Faculty of Information Science and Technology  
Universiti Kebangsaan Malaysia, Bangi, Selangor Darul Ehsan, Malaysia

**Abstract**—Automatic Essay Scoring (AES) is the automatic process of identifying scores for a particular essay answer. Such a task has been extensively addressed by the literature where two main learning paradigms have been utilized: Supervised and Unsupervised. Within these paradigms, there is a wide range of feature analyses has been utilized, Morphology, Frequencies, Structure, and semantics. This paper aims at addressing these feature analysis types with their subcomponent and corresponding approaches by introducing a new taxonomy. Consequentially, a review of recent AES studies is being conducted to highlight the utilized techniques and feature analysis. The finding of such a critical analysis showed that the traditional morphological analysis of the essay answer would lack semantic analysis. Whereas, utilizing a semantic knowledge source such as ontology would be restricted to the domain of the essay answer. Similarly, utilizing semantic corpus-based techniques would be impacted by the domain of the essay answer as well. On the other hand, using essay structural features and frequencies alone would be insufficient, but rather as an auxiliary to another semantic analysis technique would bring promising results. The state-of-the-art in AES research concentrated on neural-network-based-embedding techniques. Yet, the major limitations of these techniques are represented as (i) finding an adequate sentence-level embedding when using models such as Word2Vec and Glove, (ii) ‘out-of-vocabulary when using models such as Doc2Vec and GSE, and lastly, (iii) ‘catastrophic forgetting’ when using BERT model.

**Keywords**—Automatic essay scoring; automatic essay grading; semantic analysis; structure analysis; string-based; corpus-based; word embedding

## I. INTRODUCTION

The last decade has witnessed a dramatic evolution in employing Artificial Intelligence (AI) in the educational domain. This has been represented in classifying questions [32], question answering [10], or question generation [23]. Another challenging area in the educational domain is Automatic Essay Scoring (AES) or Automatic Essay Grading (AEG). AES refers to the task of automatically determining an exact or nearly score for an essay answer [26]. This would require an extensive analysis of the answer’s textual characteristics to identify an accurate score. The common method depicted in the literature for doing such an analysis is to acquire a reference answer (sometimes referred to as a model or template answer) and compare it with the student’s answer. The comparison would have taken a wide range of forms depending on the technique used for scoring.

Generally speaking, AES’s scoring techniques belong to two major categories; Supervised and Unsupervised. According to the machine learning paradigms, such categories refer to the learning mechanism [47]. For instance, in the supervised learning paradigm, a previous or example dataset is being prepared to train the classification algorithm. In this regard, previous students’ answers along with reference answers are being arranged along with their actual score given by the teacher and the aim is to train the machine learning algorithm to predict the score of upcoming, testing, or unseen answers. This process of learning is known as regression where the goal is to predict a numeric value rather than a predefined class label (i.e., machine learning classification).

After acquiring the example or training data of answers, a set of numeric features will be generated to predict the score. Such features could be derived from the answer’s textual characteristics such as morphology, semantic, structure, or frequency of terms. Regarding the regressor itself, there are a wide range of algorithms have been depicted in the AES literature where it can be categorized into two main classes; traditional regressors and deep learning regressors. Traditional regressors refer to the Linear Regression which is a statistical algorithm that intends to identify the most accurate coefficients that would turn the numeric features of the answers (i.e., X variables) into its actual score (i.e., Y output) [33]. On the other hand, deep learning regressors refer to the latest and sophisticated neural network architectures such as Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN). Such architectures are intended to process the numeric features of the answers through a neural network to predict the output score. Such a prediction is performed through a learning mechanism by randomly generated weights that are linked between the input and output layers within a hidden layer that aims at determining deep relationships [36].

On the other hand, the unsupervised learning paradigm refers to the task of categorizing data without the use of a predefined example or training set, but rather through a distance/similarity function or curated set of rules. The simple and most straightforward mechanism of unsupervised AES is where each answer is compared with reference answer or other student answers for identifying a similarity score which will be used afterward as the final score of the answer. This kind of pairwise similarity can be used separately or through a clustering technique that aims at grouping the similar answers into multiple groups [4].

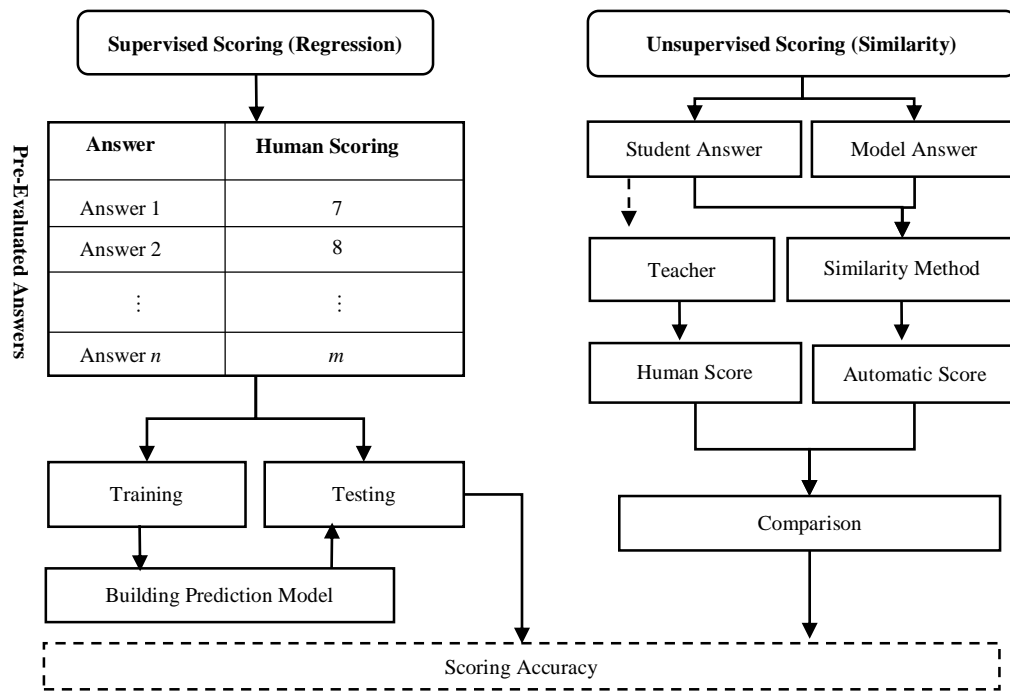

Fig. 1. General Workflow of AES Task.

Another unsupervised technique that has been depicted in the AES literature is the rule-based or ranking approach, the characteristics of the textual answer information in this method are ranked or encoded into a numeric value. Using a predefined set of rules, the numeric values associated with a particular answer would have undergone a summation or averaging procedure to get the overall score. Fig. 1 depicts the general workflow of the AES task.

Based on the general workflow of the AES task in Fig. 1, an extensive literature review is accommodated in this paper where Section 2 will depict such a review. Section 3 will depict the proposed taxonomy where the techniques used by the literature for the AES task are being categorized. Lastly, Section 4 provides a discussion on the techniques where the pros, cons, and ongoing challenges will be determined.

## II. RELATED WORK

In this section, an extensive literature review will be conducted on the recent AES research studies. The related works will be divided into two major parts; supervised AES and unsupervised AES. The following subsections will tackle these parts.

### A. Supervised AES

In a study of lexical sophistication for evaluating second language writing proficiency (L2), [25] examined two main approaches of lexical techniques. First, the authors have utilized the word frequency where the statistics of the terms within the answers are being exploited. Second, the authors have utilized the n-gram sequences (i.e., bigram) to capture multi-word sequences. Besides, the authors have adopted some ranks for the academic writing and word range. Lastly, a simple regression has been used to predict the score of the

answers. Using a corpus for the English placement test (i.e., TOFEL), the proposed method showed 92.6% of accuracy.

The author in [15] has treated the AES task as a regression problem where a Support Vector Regressor (SVR) has been used to predict the score of Portuguese student answers. For this purpose, a dataset obtained from Brazilian Schools has been used. In addition, the input of the SVR was represented as a set of numeric features that have been obtained by the structure of the answer, lexical diversity, theme, and coherence. The authors have defined scores for each feature and then use them as input to the SVR. The authors reported 74.7% as a value of correlation between regression result and teacher score. However, this study has used an imbalance dataset where five scores are used as 0, 50, 100, 150, and 200. The classes of the students' answers were imbalanced therefore, latterly the authors have proposed an improvement in their work of [14]. Using some statistical algorithms, the authors have managed to improve the accuracy of assessment by obtaining 75% of correlation.

The author in [11] has treated the AES task as regression problem where SVR algorithm has been utilized. In order to input the answer text to the regressor, the authors have used a method called Bag-of-Super-Word-Embeddings (BOSWE). This method works on existing embedding vector of words to accommodate clustering where the centroid terms will be represented as super words. Hence, the semantic meaning of terms would be converted into group of clusters. Consequentially, the authors have utilized a string similarity called Histogram Intersection String Kernel (HISK) which is a measure that has been widely used to calculate similarity between images' histograms. In this regard, the histogram of word embedding clusters would be targeted. To obtain the word embedding vectors, the authors have used a pre-trained

model based on Word2Vec introduced by [31]. An English benchmark dataset of Automated Student Assessment Prize (ASAP) has been used where the accuracy result was 78.8%.

The author in [19] established a comparison between pre-trained word embedding models and paragraph embedding models. For the pre-trained word embedding, the authors used Google Word2Vec, Glove, FastText and Elmo models. Whereas, for the paragraph embedding, the authors used Doc2Vec, InferSent and SkipThought models. Lastly, cosine similarity used to determine the similarity between student's answer vector and teacher's answer vector. Such similarity will be fed into a Ridge regression classifier. Using a benchmark dataset of English questions and answers brought from University of North Texas, the authors have concluded that the paragraph embedding using Doc2Vec has achieved the highest correlation of 56.9%.

The author in [27] proposed a self-attention method that captures long-dancer relationship for AES task. The authors first utilize the self-attention network to process two inputs including word vector embedding and word position. The word embedding has been brought from a pre-trained model of Glove where the average of each word's vector within a sentence is gained through padding approach. Another input will be depicted for the word position where each word would have a position embedding. The output of the self-attention will be processed via a Long Short-Term Memory (LSTM) architecture to accommodate the scoring. Using the benchmark of ASAP, the proposed method showed an accuracy of 77.6%.

The author in [45] proposed a deep learning architecture for the AES task. The proposed architecture begins with Word2Vec embedding for the words within the student's answer. Consequentially, the resulted embedding will be processed via a bidirectional LSTM in order to extract semantic features. Lastly, an attention layer will process the extracted features in order to give the score. The benchmark dataset of ASAP has been used in the experiments where the acquired accuracy was 83%.

The author in [41] has proposed a hybrid method of Support Vector Machine (SVM) and LSA to provide automated assessment of answers in Indonesian languages. The authors used a dataset contains students answers along with lecturer answers. Then, they treated the problem as topic modeling where SVM has been used to classify the answers into multiple generated number of topics. If a particular student answer has been classified into an irrelevant topic in respect to the lecturer answer, it would be assessed as zero.

The author in [17] examined the lexical sophistication for evaluating second language writing proficiency (L2) where Korean students are being tested on English placement test. The authors have treated the problem as regression in which the n-gram features of multi-word sequences are being addressed. For this purpose, the authors prepared answers from native speakers and compare it with the tested answers. Within such a comparison the authors addressed the occurrence of bigram and trigram sequences. A corpus of English placement test has been used to accommodate the comparison. The comparison aims at computing the associate measure between n-gram sequences. Lastly, the statistical measures' values will

be fed to a step-wise regression in order to predict the automatic score. Results of correlation between automatic and human score were 84.64%.

The author in [9] has treated the task of AES differently where the problem has been handled as a regression task. Instead of accommodating feature engineering on the answer text, the authors have used the answer as an input to a Convolutional Neural Network (CNN) architecture that has been incorporated with a regression layer. Such regression layer will predict the score of the answer based on a non-linearized function. To do so, the authors have input the embedding of words inside the answer to the architecture. Such embedding has been obtained via a pre-trained Glove model proposed by [48]. An English benchmark dataset of Automated Student Assessment Prize (ASAP) has been used. Results of accuracy obtained were 82.6%.

The author in [28] proposed a multi-way attention architecture for AES task. The proposed architecture contains a transformer layer at first which process pre-trained Glove word embedding of student's answer and model's answer. Then, the following layer represents the multi-way attention where three self-attention vectors are represented for the student's answer, model's answer and their cross vector respectively. This will be followed with an aggregation layer where word's position vectors will be added. The final layer contains the regressor where the score of the essay is being predicted. For this purpose, the authors have used a real-word educational dataset of questions and answers. Result of accuracy was 88.9%.

The author in [46] proposed a deep learning architecture for AES task. The proposed architecture begins with pre-trained word embedding vectors brought from Glove and processed via CNN layer. Then, the resulted features will be processed via LSTM in order to generate sentence embedding for each answer. The key distinguishes of this study lies in adding a co-attention layer that consider the similar sentences between student's answer and model's answer. Lastly, the final layer will give the score for each answer. Using ASAP benchmark dataset, the proposed architecture produces an accuracy of 81.5%.

The author in [34] has examined the possibility of incorporating embedding features with structural features or so-called feature-engineered. The authors have utilized an LSTM where sentence-level embedding incorporated with a set of feature-engineered. Using ASAP dataset, the proposed method showed an accuracy of 77.5%.

The author in [24] examined the lexical sophistication for evaluating second language writing proficiency (L2). The authors have used a corpus for English placement test (i.e., TOFEL). Using some lexical features such as word and n-gram overlapping along with a semantic approach of LSA, the authors have applied a simple regression in order to predict the score of the tested answers.

The author in [26] has proposed a deep learning method for AES task where two architectures of CNN and LSTM are being employed. First, the authors have processed the words' vectors of each answer through the CNN architecture in order to get the sentence embedding. For this purpose, a pre-trained

model of Glove word embedding has been used. In addition, the resulted sentence embedding from CNN has been furtherly processed via the LSTM architecture in order to get the score. Using the benchmark dataset of ASAP, the authors have shown an accuracy of 72.65%.

The author in [44] has proposed a deep learning architecture for AES task. The proposed architecture begins with word embedding vectors generated by Word2Vec and process via CNN layer in order to extract n-gram features. Lastly, a recurrent layer called Bidirectional Gated Recurrent Unit (BGRU) is being used to predict the score of the answer. Using the benchmark dataset of ASAP, the proposed architecture showed an accuracy of 86.5%.

The advancement of deep learning architecture led to the emergence of Transformers which yield a novel mechanism in learning. Such mechanism lies in the synchronized bidirectional learning. Such an architecture led to the emergence of Bidirectional Encoder Representations from Transformers (BERT) embedding. BERT has a fixed and indexed pretrained model of embedding where a vocabulary of 30,000 English terms is being stored. BERT has shown remarkable superior performance in text generation applications.

However, recently, [43] have utilized the BERT architecture for the AES task. Using ASAP dataset, BERT showed an accuracy of 74.75%. The authors have compared the BERT against the LSTM and the comparison showed that LSTM is still a competitor where it achieved an accuracy of 74.63%. The authors have justified such a miscarriage of BERT regarding a problem known as 'catastrophic forgotten' where the BERT architecture would forget quickly what it had learnt previously.

Similarly, [30] has proposed a BERT architecture for the AES task. The authors have utilized the pretrained BERT embedding and then apply the fine-tune. Using ASAP dataset, results of accuracy showed an average of 64.6% achieved by the proposed BERT.

The author in [42] has examined a Multi-Task Learning (MTL) of AES where the essay is being assessed as traits rather than holistic (i.e., Single-Task Learning). The authors have utilized structural features as traits such as the organization of the essay, the discourse of topic, and the vocabulary size of the essay; in addition, a word embedding CNN architecture using through Glove along with a sentence embedding through LSTM. The traits have been encoded through a pooling attention layer. Using ASAP dataset, the proposed MTL showed an accuracy of 76.4%.

The author in [35] has utilized much more efficient architectures derived from BERT such as Albert and Reformer for the AES task. In fact, BERT suffers from the tremendous extent of parameters (around 60 million). Therefore, the authors have concentrated on architectures that derived from BERT with considerably lower number of parameters. Using the ASAP dataset, the authors have demonstrated that the proposed architectures maintained fair accuracy of 78.2% with significant drop in the computational requirements.

## B. Unsupervised AES

The author in [18] has introduced the first benchmark of Arabic dataset for automatic scoring essays which contains 610 students' answers written in Arabic language. The domain of question was geography. The authors have applied several similarity measures including string-based, n-gram and corpus-based specifically Distributional Semantic Co-occurrence (DISCO) similarity measures independently and with combination. Then they have applied k-means clustering approach in order to scale the obtained similarity values. Results of correlation between manual and automatic score were 83%.

The author in [37] has established a comparative study on two main similarity approaches through an unsupervised paradigm for AES task. The authors have firstly used the Cosine measure to compute the similarity between student's answer and model's answer. Then, the authors have used a corpus-based method of LSA to compute the similarity between the two answers. Using a real-word dataset of questions and answers, LSA showed better performance by obtaining a correlation of 59.7%.

The author in [22] has proposed a ranking algorithm for Automatic Essay Scoring (AES) based on structural and semantic features. The structural features included number of words, number of verbs, number of sentences, and number of paragraphs in an essay, whereas semantic features brought from a corpus-based approach known as Kullback - Leibler divergence. An English benchmark dataset of Automated Student Assessment Prize (ASAP) has been used.

The author in [1] proposed an automatic essay grading system that has been utilizing ontology-based approach. The proposed approach aimed at focusing on the subject of the answer given by the students. For this purpose, the WordNet ontology has been exploited which can provide domain-specific semantic correspondences. The authors have prepared a teacher guide answer in order to be used as a benchmark when evaluating student's answer. Comparing both the guide answer and the student's answer through querying the included terms over WordNet, the authors have computed the similarity using semantic relatedness measure known as Least Common Sub-sumer (LCS). Results of the comparison were set as the automatic score where the Pearson metric has been used to compute the correlation between the automatic score and the teacher score. Experimental results showed an average correlation of 80% has been achieved.

The author in [2] has proposed a system for Arabic AES for a Saudi Intermediate school children. The criteria used for assessing the students' answers were based on spelling, grammar, structure of the answer, relation of the answer to the desired topic, and following the Modern Standard Arabic (MSA) words. For evaluating a particular answer, the authors have adopted a hybrid method of LSA RST. LSA was intended to measure the semantic similarity of the tested answer while, RST was intended to measure the cohesion and the writing style of the answer. The authors have collected a set of pre-evaluated answers of 300 essays where such answers have been written by the intermediate level students from different topics with a score out of 10. Consequentially, the authors have re-

typed the answers to the computer in order to use them for training and testing purposes. Using Pearson Correlation, the authors have compared the automatic score to the teacher score. Experimental result showed an average of 78.3% of Pearson Correlation.

The author in [39] has proposed a fingerprinting method for automatic essay scoring in Japanese language. The authors have utilized a hashing method for each essay answer by computing the ASCII values of the characters within the answer's words. This would provide a distinctive fingerprint for every answer. Then, using a model answer, answers that have been assessed with full mark, the fingerprints of the students' answers will be compared to the fingerprint of the model answer. Since the fingerprint values are numeric thus, Cosine similarity has been used to compute the distance. Based on a set of pre-assessed answers by human (i.e., teachers), the automatic score has been compared to the human's score in order to calculate the accuracy. Lastly, the authors have manipulated some parameters of fingerprint calculation such as number of N-gram characters to get the best accuracy. The proposed method managed to obtain 86.86%.

In another study, [12] described a system called TAALES which has been proposed for the AES task. The proposed system utilizes traditional features to evaluate student answer such as word frequency, academic language, N-gram frequency and other structural features. The proposed system works on user generated text.

The author in [19] has focused on the preprocessing tasks utilized for the AES task in the Indonesian language. The authors have used a corpus of questions, students' answers and teacher answers written in Indonesian. Five preprocessing tasks have been applied including lower-case, tokenization, punctuation removal, stopword removal and stemming. Lastly, Cosine similarity has been used to compute the distance between teacher's answer and student's answer. Results of correlation between manual and automatic scoring were 47%.

The author in [38] has extended the fingerprinting algorithm presented in (A. Agung Putri Ratna et al., 2018) by adding a semantic similarity of LSA. Using a real-word of Japanese questions and answers, the proposed method obtained 87.78% of accuracy. At the same year, the authors have also presented another study (A. A. P. Ratna, Noviandriani, Santiar, Ibrahim, & Purnamasari, 2019) where the authors have addressed the use of k-means clustering with LSA for AES in Japanese language. Using the same dataset, the proposed method showed an 89% of accuracy.

The author in [38] has proposed an LSA method to provide automated assessment of answers in Indonesian languages. The authors used a dataset contains students answers along with lecturer answers. Then, LSA has been used to calculate the similarity between the two answers. Using a comparison between the automatic score and human score, the proposed method showed an accuracy of 72.01%.

The author in [3] has proposed a rule-based system for Arabic AES that is evaluating the answers based on style issues such as spelling, structure, and coherence. The proposed

system utilizes a predefined set of rules that check each essay answer in terms of the aforementioned style aspect. The authors have used online dialogues and discussions among university students in order to train their system. Results of correlation between the automatic and human grading were 73% (Unsupervised).

The author in [5] has proposed an AES system that utilizes LSA along with RST. The authors have built a dataset from the scratch where a set of religious questions has been initiated along with their model answers. Then, such questions have been given to school students in order to answer them. Lastly, a set of teachers has been assigned to give a human / manual scoring that will be used later for training both the LSA and RST. Experimental result showed a 75.6% of correlation between the proposed method's scoring and the teacher's scoring.

The author in [21] has established a comparison among different embedding approaches for the AES task. The authors have utilized the benchmark dataset of ASAP. In addition, traditional vector representations such as TFIDF and Jaccard have been utilized. Furthermore, different embedding approaches such as Glove, Elmo, Google Sentence Encoder (GSE) have been also used. Lastly, using cosine similarity, the authors have identified the similarity between vectors of student answers and vectors of teacher answers. Results showed that the highest correlation achieved by GSE where it obtained 74.3%.

### III. TAXONOMY OF AES FEATURE ANALYSIS

Within the textual analysis of answers by either the supervised or unsupervised techniques, there is a wide range of features that could be used. Based on the review of literature in the previous section, this section attempts to provide a taxonomy of the AES feature analysis. As shown in Fig. 2, the taxonomy of AES's techniques is divided through the two topologies of supervised and unsupervised paradigms. However, the key characteristics of utilizing the two paradigms lies on the type of feature analysis. In fact, there are four main categories of feature analysis: Structure, Frequency and Term Occurrence, Morphology, and Semantic. Following subsections will tackle each category independently.

#### A. Structure

In this type of feature analysis, the essay answer is analyzed in terms of its structure where the coherence, writing style and spelling mistakes are being considered. The common approach for this type of feature analysis is the Rhetorical Structure Theory (RST) (Al-Jouie & Azmi, 2017). RST is a linguistic method that aims at analyzing parts of text in order to identify relations among them; it has been widely used for text summarization.

Usually, this type of feature analysis is exploited by the unsupervised technique through a ranking procedure that gives score for each criterion [22], or it could be exploited within a set of rules ([2]; [5]; [12]). On the other hand, this feature analysis can be utilized by a supervised technique through the ranking procedure where the numeric ranks would be fed to a regressor ([14]; [15]).

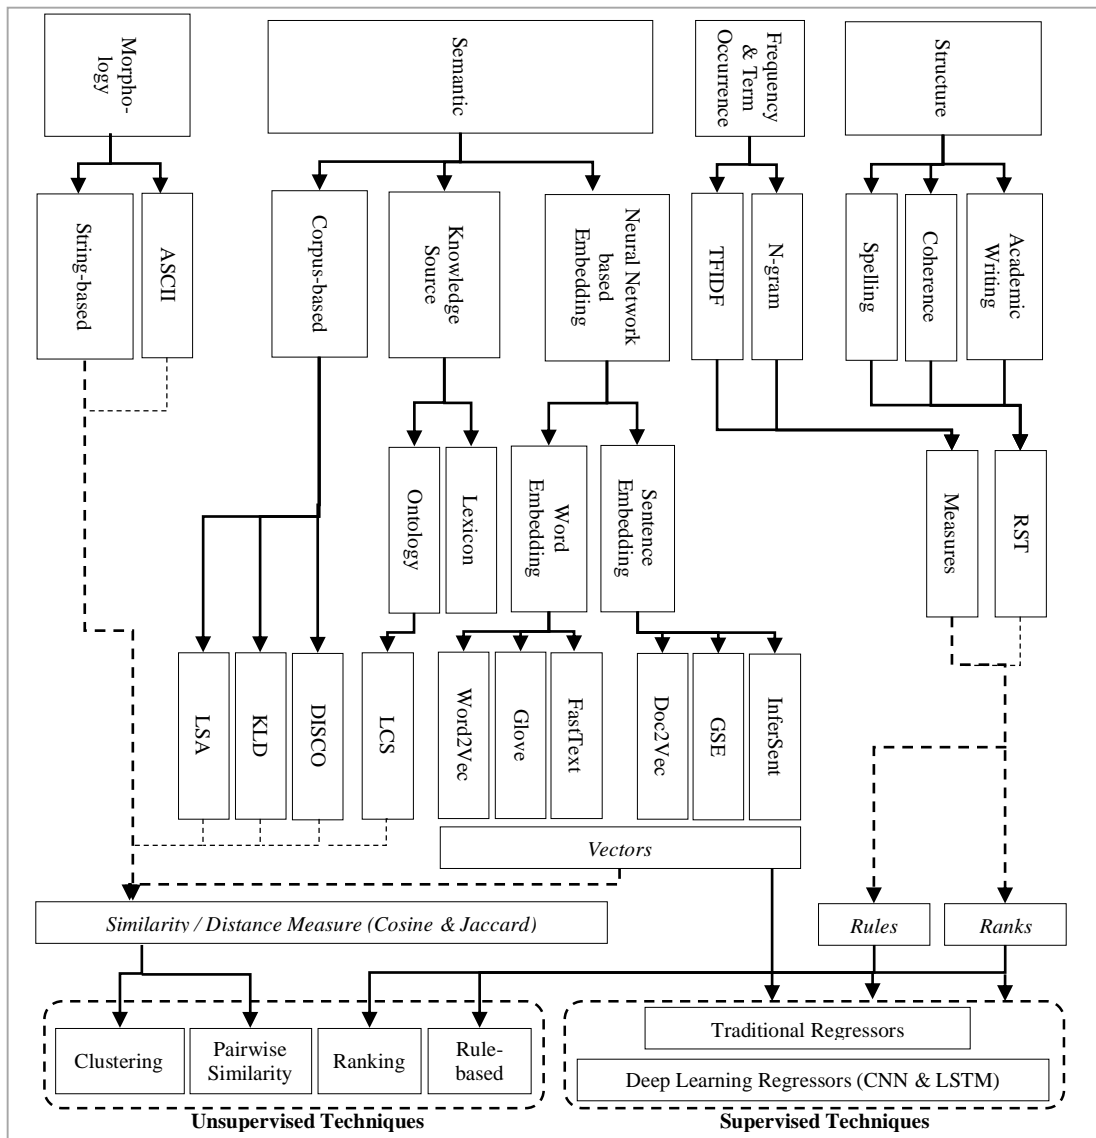

Fig. 2. Taxonomy of AES Feature Analysis.

### B. Frequency and Term Occurrence

This type of feature analysis aims at analyzing the frequencies of specific terms or the number of words, sentences and paragraphs. The common approach for counting word frequencies is the Term Frequency Inverse Document Frequency (TFIDF). On the other hand, this feature analysis focuses on the occurrence of specific term and its surrounding words to assess the student’s answer. The common approach for this occurrence analysis is the N-gram where the occurrence of unigram (i.e., single term), bigram (i.e., two terms), and trigram (i.e., three terms) can be considered.

The way of utilizing such feature analysis by an unsupervised technique is represented by a set of rules that determine the consequences of capturing specific frequencies or occurrences [12]. Otherwise, the statistics of frequency and occurrence could be exploited directly by a supervised regression technique [25].

### C. Morphology

This type of feature analysis concentrates on the lexical morphology of terms within the essay answer. The most straightforward example of this analysis is the string-based similarity between words which can be identified through similarity measures such as Cosine and Jaccard. In addition, sometimes the morphology of words could be extended to consider the ASCII code representation of characters within the essay answer ([38]; [39]; [40]). The way of adopting this feature analysis into an unsupervised technique is simply represented through the use of clustering where similarity values between answers (produced by Cosine or Jaccard) are being used to aggregate similar answers in a single cluster [18]. Otherwise, it could be adopted through a supervised regression technique by processing the similarity values and predicting the score [19].

#### D. Semantic

This type of feature is considered to be much more sophisticated where the semantic meaning of the answer's words is being analyzed. Apparently, the common way to utilize the semantic aspect is to utilize an external knowledge source such as a dictionary. However, there are other two techniques that can analyze the semantic without using knowledge source depicted in the literature; corpus-based and neural-network-based embedding. The three aforementioned techniques will be illustrated in the following.

1) *Knowledge source*: In this technique a lexicon, dictionary or ontology is being used to clarify semantic correspondences. Using a knowledge source would offer different semantic relationship between the words such as hypernymy and synonymy which might enhance the comparison between the student answer and the reference answer. WordNet is the most popular ontology that has been used for this purpose. Usually, this feature is utilized by an unsupervised technique through semantic relatedness measures such as Least Common Subsumer (LCS) [1].

2) *Corpus-based*: In this technique the semantic is being analyzed statistically and without utilizing any knowledge source. In fact, this technique aims at exploiting a corpus of text in order to identify similar contexts which usually yield semantically matching terms. To do that, a matrix of the terms along with their corresponding documents is being initiated. Consequentially, some dimensionality reduction such as Singular Value Decomposition (SVD) is applied to determine semantic correspondences. The most popular corpus-based approaches are the Latent Semantic Analysis (LSA), Latent Dirichlet Allocation (LDA), Distributional Semantic Co-occurrence (DISCO), and Kullback - Leibler Divergence (KLD). The utilization of these approaches for supervised AES is simply represented by feeding a regression technique with answer document vectors [38]. Otherwise, a distance measure such as Cosine can be used to determine similarity between answers documents through an unsupervised technique ([2]; [6]; [18]; [40]).

3) *Neural-Network-based-embedding*: Similar to the corpus-based approaches, this technique aims at analyzing the semantic aspect of the text without the use of knowledge source. The key distinguishes here is the utilization of neural

network architectures to produce special embedding. The earliest effort of this technique was represented by generating distinctive embedding vector for words which referred to as Word Embedding. The most common architectures of word embedding are Word2Vec [45], Glove [9], and FastText [19]. Afterwards, other textual levels have been examined in terms of neural network embedding such as Document Embedding, Sentence Embedding, and Paragraph Embedding. The common architectures for these levels are Doc2Vec, Google Sentence Encoder (GSE), and InferSent [19]. The way of utilizing word and sentence embedding by an unsupervised technique is simply through vector similarity computed by either Cosine or Jaccard. Otherwise, the embedding vectors would be fed to a supervised regression technique in order to predict the score.

Recent years reveal a new embedding architecture of BERT which is based on transformer learning. Such an architecture has the ability to overcome the 'out-of-vocabulary' problem. In addition, it has the capability to handle word-level and sentence-level embedding. The common way of utilizing BERT architecture for the AES task is through a supervised learning ([30]; [43]).

#### E. AES Datasets

The literature depicts a diversity in using various types of datasets for the AES task. First, there were several languages depicted by the literature such as English, Arabic, Indonesian, Japanese, Portuguese, and others. On the other hand, some efforts utilized synthesis data where students are tested to collect their results. Other efforts utilized real-world data where students' answers from previous exams have been collected. Lastly, the rest of the studies concentrated on benchmark datasets. There are two main benchmark datasets for AES, namely, Automated Student Assessment Prize (ASAP) [29] which has been presented in Kaggle.com as a challenge, and the second dataset is the ETS Corpus of Non-Native Written English from the Linguistic Data Consortium (LDC) [8].

#### F. Summary of Related Work

To conclude all the researches in AES, Table I shows the summary that briefly describes each related work, whereas, Table II depicts the summary of techniques used by the literature.

TABLE I. SUMMARY OF RELATED WORK

Author	Learning Paradigm	Method	Features	Dataset & Language	Accuracy	Limitations
Gomaa & Fahmy (2014)	Unsupervised	K-means clustering	string-based and corpus-based (DISCO)	Benchmark Arabic dataset of questions and answers	83%	String-based similarity suffers from ignoring semantic aspect. Whereas, corpus-based similarity of DISCO suffers from domain dependent
Kyle and Crossley (2016)	Supervised	Simple regression	Word frequency, n-gram, and academic writing	Real-world student answers (English Placement Test)	92.6%	More semantic features are needed
Pramukantoro and Fauzi (2016)	Unsupervised	LSA + Cosine	String-similarity + semantic similarity	Real-world student answers (English)	59.7%	corpus-based similarity of LSA suffers from domain dependent

Kopparapu and De (2016)	Unsupervised	Ranking algorithm	Structural features (# words, sentences and paragraphs) + Semantic corpus-based (Kullback - Leibler divergence)	English Benchmark Automated Student Assessment Prize (ASAP)	-	corpus-based similarity of Kullback - Leibler divergence suffers from domain dependent
Ajetunmobi and Daramola (2017)	Unsupervised	Ontology-based approach (WordNet)	Semantic relatedness (LCS)	Synthesis (English)	80%	ontology offers domain-specific semantic correspondences where open domain answers would not be assessed effectively
Al-Jouie and Azmi (2017)	Unsupervised	LSA + RST	Semantic similarity + Spelling + structure + grammar	Real-world student answers (Arabic)	78.3%	corpus-based similarity of LSA suffers from domain dependent
Crossley and Kyle (2018)	Unsupervised	Rule-based	Word frequency, n-gram frequency and academic writing	Synthesis (based on user-generated data)	-	more semantic analysis is needed
Hasanah et al. (2018)	Unsupervised	Cosine Similarity	Lowercasing, tokenization, punctuation removal, stopword removal and stemming	Real-world student answers (Indonesian)	47%	more semantic analysis is needed
Ratna et al. (2018)	Unsupervised	Fingerprinting algorithm	Characters ASCII values of the answer's words	Real-world student answers (Japanese)	86.86%	Focusing on ASCII values of characters would only determine morphological similarity and ignore the semantic similarity
Filho et al. (2018)	Supervised	SVR	Predefined numeric scores of features (Structure+ lexical diversity + theme + coherence)	Real-world student answers (Portuguese)	74.7%	More semantic analysis is needed. In addition, much more sophisticated regressor is needed (SVR is considered shallow neural network and not deep learning)
Cozma et al. (2018)	Supervised	Bag-of-Super-Word-Embeddings (BOSWE) + SVR	Histogram Intersection String Kernel (HISK)	English Benchmark Automated Student Assessment Prize (ASAP)	78.8%	This method could suffer from 'out-of-vocabulary' problem. In addition, much more sophisticated regressor is needed (SVR is considered shallow neural network and deep learning)
Hassan et al. (2018)	Supervised	Ridge regression based on vector cosine similarity	Word embedding models (Word2Vec, FastText, Glove, Elmo) + Paragraph embedding models (Doc2Vec, InferSent, Skipthought)	English Benchmark dataset (University of North Texas)	56.9%	Much more sophisticated regression is needed. In addition, regression can benefit from embedding vector features rather than feeding only on similarity values produced by cosine
Li et al. (2018)	Supervised	LSTM regression	Self-attention with Glove embedding and word position	ASAP	77.6%	Glove embedding suffers from 'out-of-vocabulary' problem.
Wang et al. (2018)	Supervised	Bidirectional LSTM with attention layer	Word2Vec word embedding	ASAP	83%	Word2Vec embedding suffers from 'out-of-vocabulary' problem.
Ratna et al. (2019)	Unsupervised	Fingerprinting algorithm + LSA	Characters ASCII values of the answer's words + semantic similarity	Real-world student answers (Japanese)	87.78%	corpus-based similarity of LSA suffers from domain dependent
Ratna et al. (2019)	Unsupervised	K-means clustering + LSA	Semantic similarity	Real-world student answers (Japanese)	89%	corpus-based similarity of LSA suffers from domain dependent
Garner et al. (2019)	Supervised	Stepwise regression	Association measures of bigram and trigram	Real-world student answers (English Placement Test)	84.64%	More semantic analysis is needed. In addition, much more sophisticated regressor is needed

Filho et al. (2019)	Supervised	SVR to solve imbalance classes	Predefined numeric scores of features (Structure+ lexical diversity + theme + coherence)	Real-world student answers (Portuguese)	75%	More semantic analysis is needed. In addition, much more sophisticated regressor is needed (SVR is considered shallow neural network and not deep learning)
Ratna et al. (2019)	Combination: Supervised (topic-modeling) Unsupervised (answer similarity)	SVM + LSA	Topic modeling (SVM) + semantic similarity (LSA)	Real-world student answers (Indonesian)	72.01%	corpus-based similarity of LSA suffers from domain dependent
Nadeem et al. (2019)	Supervised	LSTM	Doc2Vec + Structural Features	ASAP	77.5%	Doc2Vec embedding suffers from 'out-of-vocabulary' problem.
Alqahtani and Alsaif (2019)	Unsupervised	Rule-based	Spelling + structure + coherence	Real-world student answers (Arabic)	73%	More semantic analysis is needed. In addition, the dataset used was relatively small and not adequately adjusted
Azmi et al. (2019)	Unsupervised	LSA + RST	Semantic similarity + Spelling + structure + grammar	Real-world student answers (Arabic)	75.6%	corpus-based similarity of LSA suffers from domain dependent
Chen and Zhou (2019)	Supervised	CNN + Ordinal Regression	Pre-trained word embedding based on Glove	ASAP	82.6%	Glove embedding suffers from 'out-of-vocabulary' problem.
Liu et al. (2019)	Supervised	Multi-way attention architecture	Pre-trained Glove word embedding	Real-world student answers (English)	88.9%	Glove embedding suffers from 'out-of-vocabulary' problem.
Zhang & Litman (2019)	Supervised	LSTM with co-attention layer	Glove pre-trained embedding	ASAP	81.5%	Glove embedding suffers from 'out-of-vocabulary' problem.
Rodriguez et al. (2019)	Supervised	BERT architecture	BERT pretraining embedding	ASAP	74.75%	BERT architecture suffers from 'catastrophic forgetting' problem
Hendre et al. (2020)	Unsupervised	vector embedding cosine similarity	TFIDF, Jaccard, Glove, Elmo, GSE-lite, GSE-large	ASAP	74.3%	Relying on cosine to compute similarity between vectors would seem insufficient, utilizing the embedding features of GSE for a regression task can be seen promising
Kyle (2020)	Supervised	Simple regression	Word frequency, n-gram and LSA	Real-world student answers (English Placement Test)	-	corpus-based similarity of LSA suffers from domain dependent
Li et al. (2020)	Supervised	LSTM regression	Sentence embedding using CNN based on Glove word embedding	ASAP	72.65%	Glove embedding suffers from 'out-of-vocabulary' problem.
Tashu (2020)	Supervised	BGRU	Word embedding Word2Vec processed via CNN	ASAP	86.5%	Word2Vec embedding suffers from 'out-of-vocabulary' problem.
Mayfield and Black (2020)	Supervised	BERT architecture	Pretraining BERT embedding	ASAP	64.6%	BERT architecture suffers from 'catastrophic forgetting' problem
Ridley et al. (2021)	Supervised	Bidirectional LSTM with attention layer	Glove word embedding and LSTM sentence embedding with traits attention layer	ASAP	76.4%	Glove embedding suffers from 'out-of-vocabulary' problem.
Ormerod et al. (2021)	Supervised	Efficient BERT architecture	Efficient architectures derived from BERT such as Albert and Reformer	ASAP	78.2%	Still suffers of 'catastrophic forgetting' problem

#### IV. DISCUSSION

AES task has been depicted in the literature through various techniques. The traditional ones were concentrating on the essay structure, spelling and grammatical errors ([2]; [3]; [6]; [12]; [22]). Obviously, these techniques are focusing on general features of the essay and cannot provide an accurate scoring based on such general features. However, the structural features showed feasibility when combined with other semantic features.

Another type of features depicted in the literature is the ones focused on morphological aspect of the words within the essay. This has been represented by utilizing the string-based similarity ([18]; [39]; [40]). On the other hand, the statistics of words within the essay have been also utilized ([12]; [21]). The main limitation behind the aforementioned techniques lies in the absence of semantic analysis in which focusing only on the morphology of the words would discard the semantic factor.

For this purpose, some studies have utilized a semantic knowledge source in order to enhance semantic analysis. For instance, [1] have utilized the ontology of WordNet for AES task. Yet, the problem of such external knowledge source is that it can provide general synonyms of the words where the aim sometime is to focus on specific domain. On other hand, some studies attempted to include the semantic analysis without the use of any external knowledge source, but rather through corpus-based approaches ([2]; [6]; [18]; [40]). These approaches are being fed with specific corpus to analyze the similar contexts which reflects on finding semantic correspondences. The common example of these approaches is the Latent Semantic Analysis (LSA). However, the main limitation behind the corpus-based approaches, in contrary to the use of knowledge source, is that they become domain-dependent after being fed by specific corpus. This makes them too sensitive toward the domain of the answers.

Further research attempts showed different techniques for semantic analysis; in particular, the Neural-Network-based techniques. Such techniques aim at processing a set of token words as input to a neural network architecture for the purposed of outputting distinctive embedding for each term. Such an embedding would capture the semantic, lexical and other important features of the word and represent them in a vector. This vector then would be utilized for other tasks such as the AES. The common example of these techniques is the Word2Vec architecture [45]. The problem of this architecture is represented by the need to train the model on large text, meanwhile, fine tune the parameters of the network; otherwise, it would generate inaccurate embedding.

To solve the aforementioned problem, further researches have presented a pre-trained model in which the model is being trained on large text and its parameters are fine tuned. The literature showed the utilization of a pre-trained Word2Vec models [11] along with another pre-trained model known as Glove ([9]; [26]; [27]; [28]; [45]; [46]). The main limitation behind these architectures is that they only work with word-level which obstructs them from working on document/sentence-level. Since the AES task is mainly depending on sentence/document answers, the traditional word embedding architectures seem insufficient.

Other studies have utilized much more sophisticated architecture to handle document/sentence embedding such as Doc2Vec [20] or Google Sentence Encoder (GSE) [21]. However, these architectures suffer from a common limitation known as 'out-of-vocabulary'. This problem occurs when an embedding architecture is being tested with a word that has no embedding vector within its training model.

In fact, the embedding techniques are considered as the state-of-the-art techniques that have shown remarkable performance in the AES task. Therefore, it is a significant effort to overcome the 'out-of-vocabulary' problem in order to enhance the semantic analysis which indeed would reflect on improving the essay answer scoring.

A remarkable overcome for the aforementioned problems has been depicted by the emergence of Bidirectional Encoder Representation from Transformer (BERT) architecture [13]. Such an architecture has the ability to overcome the averaging embedding for larger text units (e.g., document and paragraph) by utilizing a pretrained embedding that works by treating the sentence as a combination of words with fixed an indexed embedding. In addition, it has the ability to overcome 'out-of-vocabulary' problem by dividing unseen words into an indexed and recognized words from its vocabulary repository. BERT has two models; language modeling and fine-tuning. The first model aims at understand the language of a text and its latent contextual information. Whereas, the second model aims at accommodating the desired task such as question answer, document classification or ranking.

However, multiple recent researches showed that BERT architecture has non-outstanding performance on AES task compared to techniques ([16]; [30]; [43]). Although BERT showed magnificent performance in problems like question answering, its architecture failed to give an accurate scoring for an answer. The reason behind such failure lies on a problem called 'catastrophic forgetting' where its language model forgets significant contextual information that impact the scoring. In addition, BERT suffers from the tremendous extent of parameters where around 60 million parameters represent a highly computational requirement [35].

According to [7], the application of most sophisticated embedding techniques including BERT on AES task is still lacking of latent rubrics. This is because the scoring task is still challenging for humans themselves. Hence, the language modeling architectures show an outstanding ability of capturing semantic of text. Yet, it is still lacking the writing style or structural features.

#### V. CONCLUSION

This paper has provided a review on the feature analysis used for either supervised or unsupervised AES. Within such a review, a taxonomy has been represented for the feature analysis which included four main types; Morphology, Frequencies, Structure, and Semantic. Inside each type, various subcomponents and approaches have been illustrated. After that, a critical review has been provided on the recent AES studies by linking each feature analysis type to these studies. The finding of such a critical analysis showed that the traditional morphological analysis of the essay answer would

lack the semantic analysis. Whereas, utilizing a semantic knowledge source such as ontology would be restricted to the domain of the essay answer. Similarly, utilizing semantic corpus-based techniques would be impacted by the domain of the essay answer as well. On the other hand, using essay structural features and frequencies alone would be insufficient, but rather as an auxiliary to another semantic analysis technique would bring promising results. The state-of-the-art in AES researches concentrated on neural-network-based-embedding techniques. Yet, the major limitations of these techniques are represented as (i) finding an adequate sentence-level embedding when using models such as Word2Vec and Glove, (ii) 'out-of-vocabulary' when using models such as Doc2Vec and GSE, and lastly, (iii) 'catastrophic forgetting' when using BERT model.

**Abstract**—False Data Injection Attack (FDIA) is an attack that could compromise Advanced Metering Infrastructure (AMI) devices where an attacker may mislead real power consumption by falsifying meter usage from end-users smart meters. Due to the rapid development of the Internet, cyber attackers are keen on exploiting domains such as finance, metering system, defense, healthcare, governance, etc. Securing IoT networks such as the electric power grid or water supply systems has emerged as a national and global priority because of many vulnerabilities found in this area and the impact of the attack through the internet of things (IoT) components. In this modern era, it is a compulsion for better awareness and improved methods to counter such attacks in these domains. This paper aims to study the impact of FDIA in AMI by performing data analysis from network traffic logs to identify digital forensic traces. An AMI testbed was designed and developed to produce the FDIA logs. Experimental results show that forensic traces can be found from the evidence logs collected through forensic analysis are sufficient to confirm the attack. Moreover, this study has produced a table of attributes for evidence collection when performing forensic investigation on FDIA in the AMI environment.

**Keywords**—Advanced Metering Infrastructure (AMI); False Data Injection Attack (FDIA); man in the middle (MITM); internet of things (IoT); forensic analysis

## I. INTRODUCTION

Internet of Things (IoT) offers many benefits and advantages to people in the current modern era [1]. Besides, even in our daily life, IoT has proven to be beneficial. IoT is a system of interrelated intelligent devices that are provided with unique identifiers and given the ability to connect with other devices by exchanging information over a communication network. The IoT is seen as one of the foremost important zones in future development and is expanding tremendous consideration from a wide scope of businesses [2]. IoT will play a major role in improving many sectors such as manufacturing, public security, health care, accommodation, entertainment, environment protection, agriculture, industrial monitoring, intelligent transportation, and traditional metering system.

However, little consideration has been paid to IoT adoption that may affect the IoT device's security measure, such as lack of authentication and insecure communication are among the main problems in most IoT devices [3]. These vulnerabilities will lead to many forms of attacks taking place, such as

malware injection, SQL injection [4], false data injection (FDI), man-in-the-middle (MITM) [5], zero-day exploit, distributed denial-of-service (DDoS), DNS tunnelling [6], and many more cyber-attacks. Since the case of the Mirai botnet in 2016, over 600,000 IoT devices were targeted to launch cyberattacks that reached 620 Gigabits at the peak. The number of malware in the cyber world has been growing, giving threats to cybersecurity to face other types of aggravated attacks.

There is also concern about one of the IoT environments, the Advanced Metering Infrastructure (AMI). AMI is a system consisting of modern electronic-digital hardware and software, which enables data measurement intermittently and remote communication continuously. The system gives a few important capacities that were not already possible or had to be performed manually. For instance, the ability to remotely and automatically measure power usage, connect and disconnect service, and voltage monitoring. FDIA is one of the popular attacks that can impact AMI as countries around the globe are implementing an AMI in their infrastructure. Like the MITM attack, FDIA is more toward creating falsified data, which the attacker injected from compromised smart meters to change the actual value sent by another smart meter in AMI. This threat can negatively affect both utilities and customers as it is difficult to investigate from the available log in the AMI [7]. This paper aims to simulate the impact of FDIA on the IoT environment and perform forensic analysis on digital traces from data obtained.

In the next section of this paper, related literature on cyber attacks in the smart grid was reviewed. Subsequently, Section III presents the development of a testbed that is used to simulate the cyber attack in components of the smart grid. Section IV presents the result from the simulation and how forensic investigations are done to investigate FDI attacks in the smart grid environment. Section V provides a conclusion to the paper.

## II. LITERATURE REVIEW

### A. False Data Injection Attack (FDIA)

The operation of the smart grid faces extreme consequences when the smart meters have been compromised and reporting false power consumption. Most current cases include the crime of electricity stealing. However, a few other sorts of data falsification attacks are conceivable such as FDIA. AMI would

be affected by this kind of attack badly as data falsification is difficult to detect.

Based on [8], they work on detecting falsification of data injection attacks focusing on smart grid systems. They made a successful and real-time scheme to distinguish FDIA in smart grids where they evaluate the reliabilities of state estimations by misusing spatial-temporal correlations and trust-based voting. The study's objective is to minimize the harm from the threat of FDIA in smart grids by using these solutions to conduct detection of an attack. This case study was done by simulation of the smart grid and the proposed solutions to detect malicious FDIA. It is suggested that powerful countermeasures are necessary as these kinds of attacks can become highly potential threats as those FDIA are evolving by implementing anti-forensic techniques to prevent detection of the attack.

In [9], the study proposed a system to detect cyber-attacks that aim to sabotage the Instrumentation and Control (I&C) environment. The study intends to provide a last line of defense to sabotage attacks. A system called Goosewolf was produced which has the capability to detect when an adversary has manipulated the process control of the Programmable Logic Controller (PLC). The result obtained in that study shows that the proposed system is effective in checking the capabilities of the PLC and the ability to detect FDIA.

Another study by [10] has focused their work on statistical anomaly detection techniques to solve the difficulties in detecting data falsification in AMI. To identify compromised smart meters for deductive and additive attacks, they have proposed a trust model based on Kullback-Leibler divergence. Moreover, techniques such as the generalized linear and Weibull function-based kernels were proposed for camouflage and conflict attacks. After investigation on comparison under various attacks, which is additive, deductive, camouflage, and conflict, they found out that their models have good high true positive detection and the average false positive is just 8 per cent for most attacks conducted.

### B. IoT Testbeds

For the purpose of better understanding on vulnerabilities of IoT devices, researchers utilized a security testbed designed to simulate the attack in a particular environment. The author in [11] illustrated a testbed for securing IoT devices by producing a testbed that can be used as a penetration testing platform to evaluate risks and vulnerabilities of IoT devices. The penetration testing included were port scanning, vulnerability scanning, downgrading attack, search exploits, brute force directories, passwords, port services, and SSL configuration. The software used to perform the testing were Snitch, ZAP, Wascan, Skipfish, Nmap, TLS proper, SSLScan, Nikto, Wireshark, Ettercap, Dirb, SQLmap, WAFwoof, Metasploit, Dex2jar, Binwalk, and UART. The network protocols used was WIFI and BLE. Penetration testing for this analysis was conducted on a smart bulb and IP camera. Vulnerabilities found were very common problems in IoT-based products such as no firewall, authentication in plain text, open ports, lack of certificate, etc.

Moreover, paper [12] displayed a testbed designed to analyze security issues in IoT devices. This testbed indicated design and architecture prerequisites to support the development of penetration testing for the purpose of cybersecurity forensic investigation. They conducted the tests based on the security vulnerabilities in the IoT products such as Amazon Echo, Nest Cam, Phillips hue, SENSE Mother, Samsung SmartThings, Witching HOME, WeMo Smart Crock-Pot, and Netatmo Security Camera. The study was conducted using WIFI and Bluetooth. For control and administration, they handle the process and events using NI TestStand software. A closed source software runs only on Windows OS, which is intensely prohibitive and proprietary. Following a huge downside from limitation in network penetration testing capabilities, the software used to avoid testing from handling passive capture of packets, wireless cards, and other network or low-level functionalities.

In [13], researchers used SecuWear to recognize the weaknesses of commercial hardware. The testbed collects the data needed for distinguishing different attacks, thereby assessing the security of wearables devices. Besides, it gives a method for mitigating information and performing attacks in a network that used WIFI and BLE. The software used to perform the vulnerability assessments, and penetration testing was Wireshark. In that study, the eavesdropping and the Denial of Service (DOS) attack were executed. The results of the study found that SecuWear vulnerabilities may be similar to certain open sources such as false positives when recognizing security issues.

### III. TESTBED DEVELOPMENT

Fig. 1 shows the topology of our testbed that is used to perform FDIA. The testbed consists of 4 main hardware components, two units Raspberry Pi 4 Model B, a computer and a switch. The smart meter (192.168.1.13) generates random data to mimic a real smart meter then sends the generated data to the data collector containing one virtual machine running Ubuntu Version 21.04 operating system to act as a data collector using the MYSQL version 10.14.9-MariaDB database which receives incoming data from the smart meter. Attacker smart meter (192.168.1.11) will act as an attacker to perform FDIA that will attempt to tamper the smart meter data to the data collector.

Fig. 1. Testbed Topology.

A comparative analysis between normal traffic logs and logs during the attack was made to verify the FDIA investigations in the IoT environment. Forensic evidence was analyzed based on the packet captured using Wireshark in the form of PCAP files.

#### IV. DISCUSSION OF FINDINGS

The experiments conducted on the testbed were carried out in two phases. The first phase of the experiment was the 'Normal operation', and the second phase was the 'Under Attack'. The details of the experiments will be explained later on in this chapter. Fig. 2 shows the flow of the experiment during normal traffic and under attack.

##### A. Normal Operations

During the normal traffic phase, the smart meter as shown in Fig. 1 with an IP address of 192.168.1.13 with MAC address of Raspberry bc : 06: f9 will send data to the data collector where the IP address of the database is 192.168.1.20 with MAC address of VMware\_98:1f:74. The smart meter will send power consumption data with an interval of 10 seconds between each data to imitate data for 1 week with an interval of 30 minutes between each data interval. In this experiment, 137 data will be collected using the Wireshark version 3.4.5 packet capturing tool. The consumption transmission script will run in 25 minutes to collect data in a total range of 135 to 140 data. Fig. 3 shows the data sent by the smart meter to the data collector, the value of power consumption with the timestamp.

Fig. 4 shows the sample data sent by the smart meter to the data collector in the MySQL database. The first column shows the numbers of data in the database. The second column shows the ID of the smart meter, the third and fourth rows display the timestamp of when the data was accepted, and the last row shows the data value of the power consumption.

Fig. 4. Accepted Data in a Database.

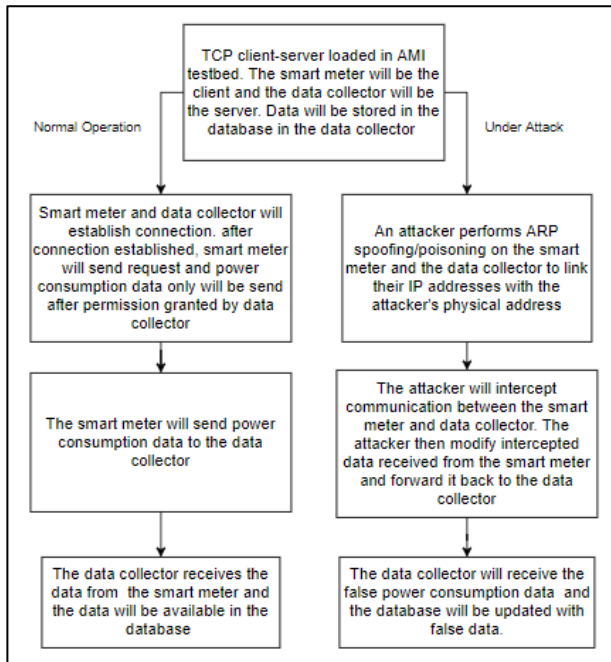

Fig. 2. Flow of Experiments.

Fig. 5 shows only the ARP packet for this communication. The results show that the smart meter with MAC address Raspberry\_bc:06:f9 with IP address 192.168.1.13 made a broadcast asking for the MAC address of the default gateway with the IP address 192.168.1.1. Moreover, it shows that the data collector is asking for the MAC address of the destination with the IP address of 192.168.1.13. As highlighted in Fig. 5, it is shown that the destination or the data smart meter answer the ARP request of the smart meter by giving its MAC address Raspberry\_bc:06:f9. The smart meter also give ARP, a reply to its MAC address as shown in Fig. 5. Sample of ARP tables for smart meter and data collector are shown in Fig. 6 and Fig. 7.

Fig. 6 shows the ARP cache of the smart meter during normal traffic, while Fig. 7 also shows the ARP cache of the data collector when there is no attack on the network.

Fig. 7. ARP Cache on the Data Collector.

Based on the data gathered during the normal operations experiment, no anomalies were detected in Wireshark, ARP cache on the smart meter and ARP cache on the data collector. The data sent from the smart meter has the same value as the data stored in the database.

### B. Under Attack

The smart meter with an IP address of 192.168.1.13 will send data as usual for the attack simulation. However, another Raspberry Pi will be included that will imitate the attacker for this phase. The attacker with IP address 192.168.1.11 and the corresponding MAC address of Raspberry\_bc:06:27 will perform ARP spoofing on the respective smart meter and data collector in the topology. Once the attacker managed to intercept and change the power consumption value, the tampered packet will be forward back to the data collector using IPV4.

By performing ARP spoofing on a legitimate smart meter and data collector, the attacker machine will be the gateway for both of these devices. The attacker can now sniff and perform further attacks as the attacker already has access to data transferred. All communication between the smart meter and data collector now needs to go through the attacker's machine first before reaching the destination.

Packet manipulation script is used to change the value of power consumption. In this experiment, the power consumption is increased by 12 on every reading. The difference is shown in Fig. 8, where the data generated and sent to the data collector is not tally with Fig. 9 which displays that the data accepted by the data collector was not the legitimate data sent by the smart meter. The data in the database has been modified because the data has been intercepted and sent to the data collector by the attacker.

Fig. 10 shows the view of the attacker machine. The data from the smart meter will be intercepted, modified, and then forwarded to the destination. Fig. 10 shows that every data intercepted will be applied increment by 12. For the MITM part, this study successfully perform packet manipulation by using pattern searching tools and some modifications on the iptables to filter only the packet that needs to be modified to come through.

Fig. 10. View on Attacker's Machine during FDIA.

The evidence captured using Wireshark is explained based on Fig. 11. Note on the highlighted line, the attacker sending a broadcast reply telling the data collector that the smart meter's MAC address is now at his MAC address which is Raspberry\_bc:06:27. Also, there are presents of duplicate use in the collected evidence.

Fig. 11. ARP Traffic Captured by Wireshark during under Attack.

Fig. 12 and Fig. 13 show the difference in ARP cache when there is no attack and under attack. During the attack, it is shown that there are two IP addresses with the MAC addresses. Supposedly, the MAC address for 192.168.1.13 was Raspberry\_bc:06:f9 but after ARP spoofing, the attacker managed to link the victim's IP address to his MAC address.

```
pi@raspberrypi:~$ arp -a
? (192.168.1.1) at <incomplete> on eth0
? (192.168.1.11) at dc:a6:32:bc:06:27 [ether] on eth0

? (192.168.1.12) at dc:a6:32:a8:be:24 [ether] on ens33
? (192.168.1.13) at dc:a6:32:bc:06:27 [ether] on ens33
```

Fig. 13. ARP Cache on the Data Collector.

Based on the data gathered during the under attack experiment, anomalies were detected in Wireshark, ARP cache on the smart meter, and ARP cache on the data collector. The data sent from the smart meter has a different value from the data stored in the database as it was changed by the attacker.

### C. Forensic Analysis

In this section, the PCAP file that stored all the digital evidence was extracted and analyzed. The analysis and comparison of the collected evidence in this study are used for in-depth analysis. Fig. 14 shows the steps taken during the forensic analysis.

The analysis process begins by collecting packets captured using Wireshark from the client during normal traffic and during under attack. The packets are also collected from the data collector during normal traffic and during the network under attack. The records from the normal traffic phase will be used as a benchmark for comparative analysis to investigate the FDIA in AMI.

Fig. 15 shows that Wireshark captured another MAC address (bc:06:27). In addition, Fig. 16 shows the use of duplicate IP addresses was reported. This strengthens the evidence collected, as shown in Fig. 12 and Fig. 13. It could be observed that the IP address 192.168.137.13, which was earlier known to be the IP address of the smart meter, now has

two MAC bindings: Raspberr\_bc:06:f9 (initial MAC address), and Raspberry\_bc:06:27 (owned by the attacker machine in the network), which was the outcome of ARP poisoning/spoofing.

Fig. 16 shows that the time to live (TTL) of the packet from the client was 64 (left), and it was still 64 when it reached the data collector (right). This is normal as there is no router involved in this topology. However, Fig. 17 shows that TTL is different when the data was sent from the smart meter (left) and when it was accepted at the data collector (right) during the network was under attack.

As shown in Fig. 17, when the data was sent out from the smart meter (left), the TTL was 64 but when it reached the database, the TTL of the packet was 63, indicate that the packet had travel somewhere else before reached the data collector. The normal topology is assumed that the smart meter should directly deliver data to the data collector with a switch and not include a router, so it should not modify the TTL of the packet. This happens because the attacker intercepted the packet and modified the packet's data before forwarding it to the real destination.

Fig. 14. Forensic Analysis Flow Chart

Fig. 15. Use of Duplicate IP Address in MAC-IP Address Binding.

Fig. 16. TTL of the Packet during Normal Traffic from the Smart Meter (Left) and the Data Collector (Right).

Fig. 19. The Average Data Collector Response Time.

Fig. 17. TTL of the Packet during under Attack from the Smart Meter (Left) and the Data Collector (Right).

TABLE I shows a list of attributes that forensic investigators can use as references on what attributes of data to be collected to perform forensic analysis in tracing FDIA. The list can be used as a reference for forensic investigators to perform evidence collection during FDIA investigations.

TABLE I. TABLE OF ATTRIBUTES

Attributes	Description
SrcIp	Source IP address
SrcPort	Source port address
DstIp	Destination IP address
DstPort	Destination port address
SrcMac	Source MAC address
DstMac	Destination MAC address
TTL	Time to live of the packets
ARPreq	ARP request traffic
ARPRep	ARP reply traffic
TimeDelay	Time delay for the client to receive a reply from the server

As displayed in Fig. 18, the time taken for the data collector to respond to the smart meter when the smart meter wants to send data is much lower than when under attack. Fig. 19 shows the average time taken by the data collector to respond when the smart meter wants to send data. This shows a huge gap of time taken for the data collector to reply during normal traffic, and the network was under attack. It can be concluded that the delay that occurred during the network was under attack is caused by the path and process that happened on the data to reach the destination. The data went through a longer path and was processed by the attacker first before the data was forwarded back to the destination.

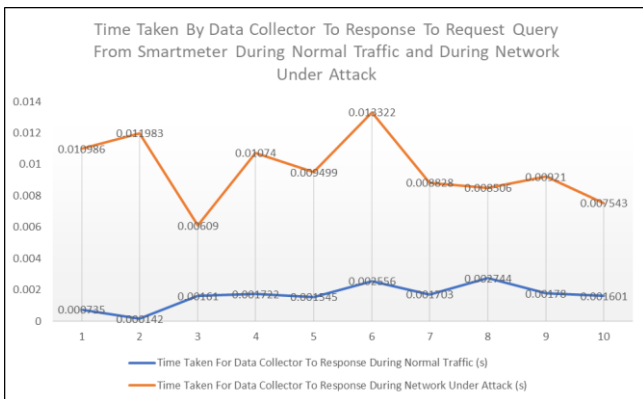

Fig. 18. Comparison of the Time Taken for the Data Collector to Respond to the Request Query from the Smart Meter during Normal Traffic and under Attack.

## V. CONCLUSION

This study's primary motivation was to study FDIA impact in the IoT environment and perform forensics analysis on digital traces from data obtained. Based on the data obtained from the experiments, the proposed list of attributes for forensic analysis could be useful to trace FDIA. In future works, there is a need to explore different types of attacks, such as buffer overflow payloads that may result in a system crash, creating a path for the hackers to initiate their malicious actions. Future studies may also focus on the integration of forensic-by-design principles in the design of any critical system because it will be quite difficult to know what has happened if there is no log or no proof. If the system is able to produce a series of events, it would be very helpful for the

forensic investigator to reconstruct the events in order to identify available sources and different types of potential evidence in such cases. Therefore, another potential study could explore how to integrate forensic-by-design principles in the design of such systems.

#### ACKNOWLEDGMENT

This study was funded by Tenaga Nasional Berhad Seed Fund (U-TD-RD-19-24) in collaboration with TNB Asset Management Department. This research team would like to thank UNITEN R&D Sdn. Bhd. for fund management.

**Abstract**—This paper discusses the implementation of smart contracts on the Ethereum blockchain system for telemedicine data storage. Telemedicine is one of the currently developing digital technologies in the health and medical sectors. Telemedicine can be more efficient when seeking treatment because patients do not need to see a doctor face to face. When using blockchain technology, the stored data becomes more transparent for each node in the blockchain network but has verification on every transaction which takes time and gas costs. However, telemedicine has several risks and problems, one of which is long data storage process time because there must be a verification process first to ensure data security. Another problem faced is the issue of the gas fee of the blockchain telemedicine system which is billed in every data storage transaction. In this study, a blockchain system was introduced for managing and securing databases on telemedicine. The implementation of this blockchain system was carried out on a website page that can add data to and retrieve data from the blockchain system. The results of this study showed that blockchain was successfully implemented to store telemedicine data with Ethereum. The analysis in this paper refers to the set and gets functions. The set function is used to send data to the blockchain, and the get function is used to retrieve data from the blockchain. From testing, the Get function has a much faster execution time than the Set function because the Get function does not require verification to retrieve its data. In the iterations carried out—namely 1, 10, and 100—the longest time on average was at 100 iterations when compared to the other iterations. In the tests carried out, the more characters that were stored, the more gas costs must be paid. In the tests, the percentage increase in costs was 0.34% per character.

**Keywords**—Blockchain; Ethereum; smart contract; telemedicine

## I. INTRODUCTION

Health is one of the most important components in life. By being healthy, one's productivity will be good and one can work optimally. The health of a person can be more easily

analyzed using data. However, a person's health information is confidential. One example of confidential medical information is an image of a medical record from a hospital. For that, we need a system mechanism to protect confidential data or information because this confidential information should not be known to just anyone. Blockchain technology can protect confidential information [1].

The blockchain system will make data storage decentralized. In general, information data are stored in a server such that the data are in one place only. This makes information or data on the server easy to hack because the data are centralized. Therefore, blockchain technology is reliable because this system decentralizes information data [1]. Thus, the use of blockchain is not managed centrally but is instead managed by each user in the network.

Blockchain has several frameworks that can be implemented, such as Hyperledger Fabric and Ethereum. These two types of blockchain have different functionalities. The difference seen is in the type of consensus. This consensus is built to build user trust in the blockchain network. A certain algorithm will be created for approval on all nodes in the network. All approved algorithms are code-based. Consensus has several types, such as Proof of Work (PoW), Proof of Authority (PoA), and Proof of Stake (PoS) [2]. Ethereum is a decentralized blockchain system. Ethereum is open source so that anyone can use it. On the Ethereum platform, the cryptocurrency unit used is Ether (ETH).

Smart contracts on Ethereum can manage transactions from every node on the blockchain network [1]. This managed transaction will become a record that will be propagated to all nodes. In telemedicine, patient data collected by the telemedicine center are a node because of the party who has the disease data or complaints at the time of treatment. The data from these patients will be decentralized with the blockchain network so that the data are much more secure and are in hashed form.

An image data management system for telemedicine transactions was developed by implementing blockchain technology to create transparency in the transaction. This transparency can improve the data integrity of telemedicine transactions through a decentralized system so that transaction activities in telemedicine can gain the trust of consumers. In the system created, image data on patients can be uploaded to the blockchain network, and medical parties can see these data in the network [1]. This makes the data much more secure because in the blockchain network there is a separate authentication and verification process. Image data can be accessed on nodes that have been confirmed and registered as valid. Therefore, the researcher designed a medical image recording application with blockchain using Ethereum.

There are various frameworks on the blockchain that can be used to develop a system, such as Hyperledger and Ethereum. The Hyperledger framework is described in the paper "Hyperledger Fabric: A Distributed Operating System for Permissioned Blockchains" [3]. From paper "Design and Implementation of Storage System for Real-time Blockchain Network Monitoring System" This paper describes how to monitor the blockchain network using an apache engine that analyzes the block size of each block on the blockchain [4]. For data management, the paper "Analysis of Data Management in Blockchain-based Systems" describes how data management can be implemented on a blockchain network and the quality of the data [5]. The implementation of Blockchain technology using Ethereum in healthcare has been described in the paper "Decentralized Telemedicine Framework for a Smart Healthcare Ecosystem" but in this paper there is no data other than String data that can be stored (images that are converted to other forms also do not exist) [1]. The healthcare flow mechanism that uses Blockchain is discussed in the paper "A Blockchain-Based Smart Contract System for Healthcare Management", the analysis of the costs required for the analysis of each parameter is mentioned in the paper [6]. To develop a user interface for interaction with users the paper "The Implementation of Blockchain in Banking System using Ethereum" discusses using react.js with development using Ethereum [7].

The purpose of this research was to design and develop a blockchain system for use in telemedicine image data storage. A smart contract function on Ethereum was designed to send and retrieve telemedicine image data to and from the blockchain network. The flow of data on the implemented blockchain system in telemedicine was examined, and the performance of this blockchain system was analyzed. In this study, the implementation is limited to analyzing the system from the blockchain only. For the telemedicine process, this research only implements uploading and downloading images through a simple website page. So the analysis used is to analyze the upload time, download images, and analyze the cost of each transaction.

## II. BASIC CONCEPT OF TELEMEDICINE SYSTEM USING SMART CONTRACT ETHEREUM

### A. Blockchain

Blockchain is a digital data storage system that contains data and records that are connected to a cryptographic system

[8]. Currently, the best-known blockchain technology is cryptocurrency transactions, one of which is Bitcoin. Blockchain technology takes the form of recording digital transactions that exist on many servers.

Blockchain has many sets of blocks that contain information. Each of these blocks will have a hash component. This hash is the character set that composes the information in the block. The character hash is entered sequentially for each piece of new information. Thus, the information from each block from blockchain will continue to add the new hash value to be recorded so that all data are not lost.

Each block on the blockchain will form a blockchain network. Any data will be replicated to all networks. Every computer that exists and is connected to this network will execute the program at the same time. Therefore, blockchain is arguably a computer on a large scale formed from communication between several computers. If it is implemented in a database, then blockchain makes the database a decentralized system.

Blockchain has characteristics that can benefit some systems, including a chain-like structure that stores and updates a chain of transaction data. Each block will store transaction data through one consensus rule to validate. Other characteristics of the blockchain system include:

- **Decentralization:** The main advantage of blockchain systems is the decentralization of data. As data centralization has many vulnerabilities, blockchain can be a solution. The consensus mechanism will validate the transaction. The decentralization of data on the blockchain will make the data in the network well verified so that security is much better than that in centralized data.
- **Transparency:** The blockchain network is data decentralized such that every node on the network can see the transactions. The principle of the blockchain network will also record every transaction and distribute it to all nodes on the blockchain network. Private and public keys in blockchain can also help data security such that even though they are transparent, blockchain still maintains data security.

Blockchain technology can be implemented in several ways in the expected conditions. There are three types of blockchain:

- **Public Blockchain:** A public blockchain is a blockchain that anyone can access and use. Public blockchains are not controlled by any individual or organization. The ledger on the blockchain is open and transparent. However, there are drawbacks to public blockchains, namely high operating and maintenance costs, and slow transaction speeds. Examples of its use are in Bitcoin, Ethereum, and Hyperledger.
- **Private Blockchain or Permissioned Blockchain:** Private blockchains are formed to facilitate the private exchange of data among a group of individuals or organizations. Unknown users cannot access this blockchain network without a special invitation. An example of its use is on the R3 Corda.

- **Blockchain Consortium:** The blockchain consortium is a combination of public and private blockchains where there is no single organization that is responsible for controlling the network; instead, the network is controlled by several predetermined nodes. These nodes can decide who can be part of the network and who can be miners. For block validation, a multi-signature scheme is used in which a block is considered valid only if it is signed by some of these nodes. An example of its use is on Fabric.

A consensus algorithm is an algorithm used to validate the data. The algorithm have hash value for each block that has been formed in the blockchain. This hash value can be formed by converting inputs, reference hashes, and random numbers using the SHA-256 hash algorithm, which produces a hash value with a certain pattern [9]. However, on Ethereum, the hash used in general is Keccak-256. This hash is used on Ethereum addresses derived from public keys or contracts. Ethereum addresses are hexadecimal numbers, with the identifier derived from the last 20 bytes of the Keccak-256 hash of the public key. Unlike Bitcoin addresses, which are coded in the client's user interface or displayed to include a built-in checksum to protect against typos, Ethereum addresses are written as raw hexadecimal without any checksums.

The PoW mining process is carried out with dependence on computing power; while in PoS, the validation capacity depends on the stakes on the network. Prizes in the form of cryptographic money are given to miners when they can solve cryptographic puzzles on PoW and transaction fees on PoS. Attacks that may occur in each consensus are also different. In PoW, it takes a large computation about 51% larger than the existing blockchain network. On the other hand, PoS can be attack if 51% of cryptocurrencies are already in the hands of hackers, but this is impossible.

Another consensus that can be used is the Proof-of-Authority (PoA) consensus. The PoA usually used in the Ethereum private network. This consensus has good performance as well [10]. The PoA consensus have different system because everyone can be a node in blockchain network. As such, it is different from the type of blockchain that uses permissions on each node. The PoA consensus is used in test networks, one of which is Rinkeby, which can be used to develop a system.

In PoA, to generate a new block is granted to a node that has proven its authority operate. Such nodes are referred to as "Validators," and they run software that allows them to place transactions in blocks. The process is automated and does not require validators to continuously monitor their computers but require good computer maintenance. PoA is suitable for both private and public networks.

There are several advantages to using PoA. It has a fairly large risk tolerance, the block creation time is predictable, and it can be used more sustainably because it does not require large computations such as PoW. But, on the other hand, PoA has a drawback, namely that the validator can be seen so that there can be manipulation from third parties.

## B. Telemedicine

Telemedicine is an information technology-based health service that allows patients to consult with doctors or other health experts without having to meet [11]. This innovation in health services with the internet can help patients use their time more efficiently because they do not have to come to a hospital or health facility for a consultation. During the remote consultation, the doctor helps the patient to get information regarding the suspected diagnosis, treatment, or first treatment for illness or injury, as well as tips to improve body health.

However, telemedicine also has a limitation in that doctors cannot detect where the patient is sick. This makes the diagnosis less accurate [12]. But if it is developed further, then telemedicine can be a breakthrough. Doctors and patients alike will be able to rest more and maintain health. Some implementations of telemedicine are being developed, one of which is the detection of skin diseases through images and disease consultations through doctors. This innovation in health services with the internet can help patients use their time more efficiently because they do not have to come to a hospital or health facility for a consultation. During the remote consultation, the doctor helps the patient to get information regarding the suspected diagnosis, treatment, or first treatment for illness or injury, as well as tips to improve body health.

Telemedicine has various types, three of which are as follows [13]:

- **Real-time Interactive Medicine:** This type allows communication between patients and doctors in realtime when there is a complaint from the patient.
- **Store and Forward:** This type allows owners of patient data to share their data with other practitioners.
- **Remote Patient Monitoring:** This type allows a medical professional to monitor patients remotely using a mobile medical device to collect data, such as blood pressure and blood sugar levels.

The use of blockchain in telemedicine has many benefits. It was mentioned in another paper that there are 6 properties of blockchain that can be useful in implementing telemedicine[14]. The first is its decentralized nature which allows data records to be accessible and managed in multiple locations. Then there is the immutability nature of the blockchain which makes patient data records cannot be changed once the data has been entered into the blockchain system, then there is asymmetric key cryptography that supports immutability. Next is data transparency which makes data exchange always traceable. Furthermore, there is also an important feature, which is open source so that patients can see the doctor's profile first. The nature of auditability and anonymity is also important to trace and hide the identity of user data.

The implementation of a simple application for telemedicine interaction using blockchain can also be applied to remote monitoring. For the selected storage, using several tools such as Filecoin, Storj.io, Napster, and IPFS [14]. The storage is usually intended to store documents that have a large enough size such as images or videos. In this section,

blockchain will play an important role in every data storage process that will be connected to the main system, users, and doctors.

### C. Ethereum

Ethereum is an open-source blockchain platform [15]. Ethereum uses PoS as its consensus algorithm, but several test networks use PoA as well. To run transactions, Ethereum uses smart contracts with the Solidity programming language. The type of cryptocurrency used in Ethereum is ether (ETH).

Solidity is a high-level programming language that is better known as being contract-based. The syntax of this programming language is similar to the Javascript programming language. This programming language is used to improve the performance of virtual machines on Ethereum. Solidity is a scripting language that is statically created for verification and compile-time constraints. In addition to the time of compilation, this programming language will also help check at runtime. The Solidity programming language also supports object-oriented programming, such as object inheritance.

Solidity is a programming language created specifically for smart contracts on Ethereum [16]. Solidity is written in the .sol storage format. Solidity is not an executable language on a blockchain virtual machine but rather a language that aims to make it easier for developers to create smart contracts. When compiling or deploying smart contracts, a Solidity Compiler is needed. Through the Solidity Compiler, the smart contract is compiled into bytecode, which is then executed by the virtual machine.

In the Solidity programming language, several data types can be used, namely strings, integers, and Booleans, and others. Strings are generally a variable from a set of characters. Integers are used for data types in the form of positive or negative numbers. Boolean is a data type with a Boolean variable (true or false). Solidity includes new resources or new languages so that the code documentation of this programming language is not too excessive.

A smart contract is a script that is stored in a blockchain system. This smart contract has a unique address and consists of executable functions and state variables [17]. The user launches the smart contract by addressing the transaction to the contract. Once launched, the code of the smart contract cannot be changed.

The workings of this smart contract correspond to the basic function of Ethereum. Because Ethereum will work based on the exchange of information on an account owned by its users, when a smart contract is created, there must be an identification for each actor entity involved in the network. Then, in the existing smart contract, certain functions are added according to the design. This function will manage the exchange of information on the existing blockchain network.

To execute this smart contract, a function is triggered. This function depends on the code used along with the programming logic that has been made previously. There are two types of accounts in Ethereum; the first is Externally Owned Accounts (EOA) and the second is contract accounts [17]. EOA is

controlled by the private key assigned to the user and the public address used to send and receive ETH from other accounts and send transactions to smart contracts. The contract account, on the other hand, does not have a private key and can only be activated by EOA. The contract account is where the smart contract resides in Ethereum.

Smart contracts are written in the Solidity programming language, which is a high-level programming language [18]. Users use EOA to make transactions on a contract account. This account is encrypted with a private key to be able to send transactions to other nodes. After that, other users verify the integrity of the transaction. This happens until a consensus is reached that has been agreed upon previously. The transaction will then be added to the block and will be recorded. The status of the network will also be updated as the smart contract has been successfully executed. The presence of this smart contract allows developers to send transactions with specific data and can check transactions between servers and inputs entered [19]. The checks performed are almost the same as the checks performed on the database. However, the specific difference is that there is an address for each data stored in the blockchain network.

In implementing the blockchain system for telemedicine, the Ethereum framework is used. Ethereum is a cryptocurrency-based blockchain like Bitcoin and is based on a public network, but it can also be used to implement a permissioned blockchain. Like Bitcoin, Ethereum also implements the PoW protocol [20]. In this implementation, a blockchain network is used which is a test network and coins from fees for each transaction that are executed can be obtained from a faucet on a website. So for every transaction that will be executed, a fee will be obtained from a faucet. Because it uses a test network, the consensus of the blockchain will change to Proof of Authority (PoA). The most important feature of Ethereum is that it supports the execution of a smart contract, which allows decentralized applications to build on top of it [20]. This is one of the considerations for choosing a framework. With the smart contract, the data that will be stored in the blockchain can be structured. So the implementation is generally not too different from the database implementation. When compared to other frameworks such as bitcoin, Ethereum has advantages such as private transactions and has higher transactions per second. When compared to Hyperledger Fabric, Ethereum has limitations, one of which is that it has a smaller throughput compared to other papers [20]. From the implementation using Ethereum, it can be investigated whether Ethereum can still be implemented to store image data with low transaction throughput.

### D. Node.js

Node.js is an open-source, cross-platform platform for developing server- and network-side applications [21]. Node.js applications are written in JavaScript and can be run in the Node.js runtime on OS X, Microsoft Windows, and Linux.

Node.js is a platform built on top of the Chrome JavaScript runtime to easily build fast and scalable network applications. Node.js uses an event-driven and non-blocking I/O model that makes it lightweight and efficient. The use of this platform is

suitable for data-intensive real-time applications running across distributed devices.

The features of Node.js are as follows:

- It is asynchronous; all API libraries in Node.js are asynchronous, which means that Node.js-based servers never wait for the API to return data.
- The speed is good; the execution speed is quite fast because it uses the Google Chrome V8 JavaScript Engine.
- It is a single thread but still scalable; Node.js uses a single-threaded program, and the same program can provide services to a much larger number of requests than traditional servers like the Apache HTTP Server.

In Node.js there is Web3, which is a collection of JavaScript Libraries (GNU Lesser General Public License version 3) that possess functionality for interacting with the Ethereum ecosystem. Web3 is built by the Ethereum Foundation and includes functionality to communicate with Ethereum nodes via Object Notation - Remote Procedure Call (JSON-RPC). Web3 allows users to interact with other Ethereum nodes using the HTTP, IPC, or WebSocket protocols [21]. Communication involves reading and writing data from the blockchain via smart contracts. Web3 providers can be set up on the frontend and backend to send transactions and listen for events happening on the blockchain network. With this, Node.js can be used because it has a library.

### III. TELEMEDICINE SYSTEM DESIGN USING BLOCKCHAIN

In this study, the design of a blockchain model for a telemedicine system used hardware and software with the following specifications. The hardware specifications used in this study are as follows:

- Manufacturer
- Asus ROG GL553VD
- Processor
- Intel® Core™ i7-7700HQ
- Graphics adapter
- NVIDIA GeForce GTX 1050 (Laptop) - 4096 MB; Core: 1354 MHz; Memory: 7000 MHz, NVIDIA GeForce GTX 1050 21.21.13.7654, Optimus
- Memory
- 16384 MB, DDR4-2400
- Storage
- Travelstar 7K1000 HGST HTS721010A9E630, 1000 GB, 7200 rpm, 1 TB HDD, 7200 RPM, 930 GB free
- Operating System
- Windows 10 (64-bit)

The following software specifications were used in this study:

- Node.js : version 14.15.4
- Solidity : version 0.4.25 - 0.7.0
- Metamask : version 9.5.4
- Truffle : version 5.3.1
- Git : version 2.24.1.windows.2
- NPM : version 6.14.10
- Solidity compiler : version 0.6.12

#### A. System Design

Smart contracts on Ethereum can be leveraged to ensure the integrity of transactions from patient care to the doctors involved. This can reduce the risk of scattered data and increase the scalability and transparency of a transaction. More specifically, this smart contract permits participating entities, especially doctors, to monitor and track all transactions on the network. In this way, both doctors and patients can feel more secure because their personal health data details are stored securely.

The blockchain technology design implemented in this telemedicine system has the advantage of being immutable. This makes the data that has been stored on the blockchain immutable as well, i.e., the data can no longer be changed. This feature can support data security from telemedicine data in the form of images represented as hash values. Access to stored data is also secured by smart contracts so that only interested parties can access the data.

The system applied in this study used a simple web page to upload the required medical images. There are two entities, namely doctors and specialists. Doctors upload images that are analyzed by specialists. The implementation is done using Node.js to run Web3, a metamask for the wallet system on transaction fees, and Infura.io to run smart contracts.

To ensure secure telemedicine and blockchain-based healthcare data transactions, in this scenario, the researcher designed a framework for patients to provide data to doctors for analysis. This agreement was carried out at the telemedicine center by approving health care data with the health organization as shown in Fig. 1. After that, the patient made an appointment with a doctor for consultation, after which the doctor gave a consultation and medication, and then updated the patient's data. The hash value was stored as a transaction when the patient was consulted. The physician could then provide access to the patient's health care data to medical research organizations to conduct trials and clinical trials. After providing a diagnosis according to the patient's illness, the data were sent back to the puskesmas through the same process, after which the puskesmas sent the data to the telemedicine center.

The problem faced today in a telemedicine system is the use of a database system that uses one server. The idea of this paper is to improve data security using a storage system on a blockchain network. But, the difference in the network used for data storage can make a difference in the speed of data storage. In this paper, we discuss how the speed of data storage to the blockchain network is discussed. A variation of the

implemented implementation is the amount of data sent to the blockchain (String). This paper involves image data that has been converted into a hash because it has a more efficient value compared to uploading the full image to the blockchain system, and the blockchain system also has a limitation on the size of the uploaded file to produce data in the form of a String which is sent to save gas usage on Ethereum.

In the sequence diagram in Fig. 2, we can see the sequence of the blockchain system for telemedicine. First, the doctor uploads pictures to send information. If the patient agrees, then the treatment process is complete. After that, the central telemedicine system in the form of a website sends image data to the blockchain system in the form of a hash value of the IPFS value. Next, the specialist who analyzes the image data continues to the center so that the hash can be known, and the image can be retrieved for analysis.

Fig. 3. Use Case Diagram for Blockchain Implementation.

In the use case diagram in Fig. 3, the telemedicine center analyzes the existing images and also provides a diagnosis of the disease from which the patient may be suffering. Meanwhile, the doctor only uploads pictures of the patient, which are then analyzed by specialist doctors at the telemedicine center.

**B. System Design**

The implementation scenario on this system was programmed in the Solidity programming language with web browser-based Remix. Entities participating in the framework were identified using their Ethereum addresses within the blockchain network. Communication between entities was possible by calling functions in smart contracts. Doctors uploaded notes in the form of images in an entity that recorded all patient care documents stored in smart contracts. Consequently, there was a flow-on of each doctor entity until the data were stored in the blockchain network using smart contracts. These stored data were in the form of a hash value generated by the IPFS system.

In Fig. 4, the implementation of scenarios that can be combined into steps can be seen.

- The doctor opens a website to upload patient data.
- Image data are telemedicine data that have been encrypted using Frenzel's thesis.
- The smart contract contains input data in the form of ID, name, description, and IPFS hash, which is generated when the image is uploaded to the IPFS system.
- The state contract is idle until there is a transaction.
- The state contract is ready to be submitted after a transaction occurs at the telemedicine center in the form of parameters set by the smart contract in the form of strings and image uploads that are converted into hash values.
- After being successfully verified, the ID appears automatically through an alert.
- Image (IPFS hash) and data are entered into the blockchain database using IPFS and smart contracts.
- To retrieve the data, the ID is needed. This Get process returns the value of the parameter that was sent previously on the blockchain network.

Fig. 1. Activity Diagram for Blockchain Implementation.

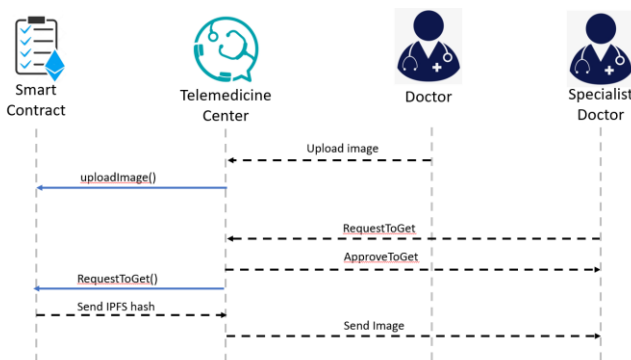

Fig. 2. Sequence Diagram for Blockchain Implementation.

Fig. 4. Get and Set Function Scenario.

### C. Collecting Data Scenario

In Fig. 5, data retrieval is done by taking the execution time of the Get and Set functions on the blockchain system. This data retrieval uses a testing function from Truffle with the Chai library. The program that runs this test is Upload.test.js, which contains tests for the Get and Set methods on the blockchain network. The test is carried out with the same data declared at the beginning of the code, which is iterated for 1, 10, and 100 transactions, respectively. The following parameters are measured in this scenario:

- The time of each Get transaction and Set transaction in milliseconds is taken on average for each iteration.
- The difference in the amount of gas fee used by the transaction is based on the number of strings entered in the description.

The system test scenario, especially the Get and Set functions, is executed with a Javascript file called Upload-test.js. This file is in the test folder in the project documents using the React framework. This document will integrate with the scripts installed in the module package from Node.js that are run using Truffle.

Fig. 6 is a flowchart of the Upload-test.js. This document contains instructions that one wants to perform in the test. There are two important functions in this document, namely

the describe() function and the assert() function. The describe() function is tested using the Mocha library. Another library that can be used is from Truffle using the contract() function; but in this test, the Mocha function was used. The assert() function is used to create a condition that must be met—for example, there is a condition for sending data. However, in this test, the testing scenario was directed to focus more on the describe() function to get the test results in the form of time.

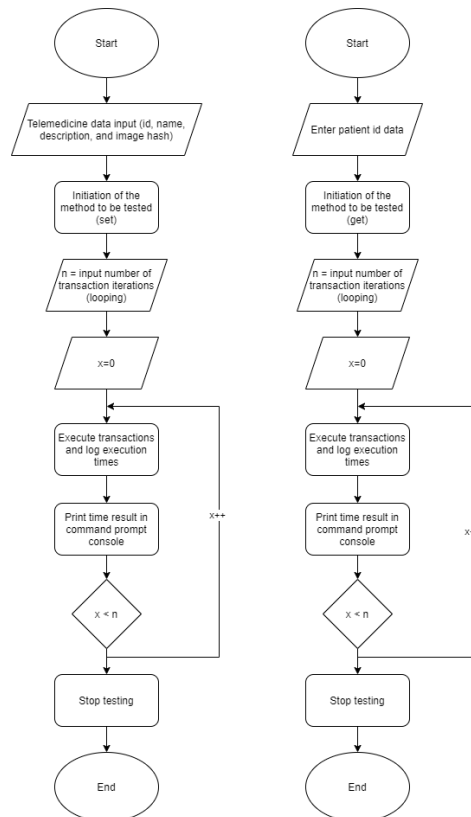

Fig. 5. Collecting Data Diagram Scenario.

Fig. 6. Process Testing Set and Get Function Diagram.

#### IV. TEST RESULTS AND ANALYSIS

The test was carried out to determine system performance based on the duration needed to send and retrieve data on the blockchain system. This time was measured using a Javascript document that was run using Truffle. The measurement time was based on the execution time of the Set and Get functions on the telemedicine data. This time measurement was performed because the blockchain network system was run on Infura.io, which uses the Rinkeby test network such that the performance of the blockchain can be known to add new blocks to the network. This performance test was performed using a Javascript document that was executed using Truffle.

The test was distinguished by iterations and the number of strings that filled the description variable. Iterations or repetitions were varied into three, namely 1, 10, and 100 iterations. This iteration was performed as a burst value that was used to load which is referred to this test performed on the blockchain test network. Iteration variations were carried out to determine the rate of three repetition variations with the previously mentioned number. As for the number of strings, these were divided into three as well, namely:

- string1 (contains 39 characters, 6 words, and 5 spaces)
- string2 (contains 96 characters, 16 words, and 15 spaces)
- string3 (contains 161 characters, 28 words, and 27 spaces)

Test implementation is using only string not image from telemedicine data to reduce gas cost from a transaction. It is possible to store image data directly to blockchain but small image. Ethereum network has an 8M gas block limit. Every new 32 bytes of storage uses 20k gas, because the cost of data storage is 640K gas per kilobyte of data and the current gas price is approximately 15 GWEI [22]. So the system can't store data that sum to more than 12.8 kb. The solution is to use IPFS to convert images as IPFS hash so only string data will store at blockchain network and will also reduce gas costs as a whole. Due to the limitations of sending data on each transaction on the blockchain network, the variation in the number of strings is not too large. This is done because the test does not test limitations and only examines the effect of variations on the time and gas costs charged for each transaction.

From each of these tests, the average time was taken to be able to represent the calculation of the time of each iteration and each string difference. This time corresponded to the time needed to make transactions, apart from the time needed for miners to mine because the time for mining blocks was 15 seconds, which, in all transactions, was the same value because it used the Rinkeby test network.

##### A. Comparison and Analysis of Time in the Set Function and Get Function

In Table I, a comparison between the average times based on the number of iterations performed on each string can be seen. Comparisons were made by comparing the average time obtained in each iteration. For this reason, in this comparison, the 1x iteration as compared to the average time of the Set and

Get functions that applied to all iterations. Thus, the results of the comparison of the amount of time taken to perform the two functions are as follows.

- 1x iteration =  $12663.3 / 576.3 = 21.97$  times faster
- 10x iteration =  $15180.2 / 589.5 = 25.75$  times faster
- 100x iteration =  $15321.3 / 594.2 = 25.78$  times faster

From the average amount of time taken to obtain each iteration, it can be seen that in the 1x iteration the execution speed was 21.97 times faster in the Get function than in the Set function. For speed, the biggest difference between the Set and Get functions was in 100x iterations, which was 25.78 times faster than the Set function than in the Get function. The significant difference was in the 1x iteration, where the average iteration obtained tended to be small. This happened because the initial initiation and lack of repetition made the blockchain network not load transactions at almost the same time. The absence of this transaction burden made the time required for verification of the Set function faster, in contrast to string data that have repetitions or iterations greater than one time.

Time parameter in this implementation is important. The time parameter in this implementation will compare the time it takes to send and retrieve data because there are verification differences. At the time of sending data, a new transaction will be made that requires gas fees and will take time to verify. While in the data collection process there is no verification process at all. Verification on this test network sometimes takes a long time, resulting in data that is much longer than the average time.

##### B. Comparison and Analysis of Gas Fee Results with String Variations

This test was intended to determine how much it costs to store data on a blockchain network. Keep in mind that the blockchain network used was the Rinkeby testing network. However, this test can be used as a reference for the number of fees that must be paid when storing data in the blockchain network. The test was varied using the number of letters, words, and spaces in the "description" variable in the form of a string. In detail, the cost of each string was as follows:

- string1 : 0.000205 ETH
- string2 : 0.00025 ETH
- string3 : 0.000296 ETH

TABLE I. AVERAGE TIME COMPARISON BETWEEN SET AND GET FUNCTIONS

String / Iteration	Function					
	Set			Get		
	1x	10x	100x	1x	10x	100x
String1	12027	14857.9	14881.3	571	546.7	593.3
String2	12962	15687.4	15465.7	552	558.6	592.1
String3	13001	14995.3	15616.8	606	663.3	597.3
Average	12663.3	15180.2	15321.3	576.3	589.5	594.2

When string1 was compared to string2, an additional cost of 0.000045 ETH, or 21.95%, occurred for storing string2 when compared to the cost required to store string1. This means that there were additional costs when data were added. It can be concluded that the addition of special characters from string1 to string2 involved 57 characters. The addition of these 57 characters required an additional fee of 0.00045 ETH. In this test, spaces were ignored because they did not affect the amount of data stored. From the comparison test of string1 and string2, it can be concluded that the average additional gas cost is 0.38% per character.

In the next test, we compared the transaction gas costs using string2 and string3. The difference in gas costs between the two was 0.000046 ETH. Then, concerning the number of characters, string2 had 96 characters and string3 had 161 characters. If these two variables are separated, it produces 65 characters. For the cost of gas required from string2 to string3, there was an increase of 18.4%. If the average value per character is taken, an increase of 0.28% is obtained for each character.

Fig. 7. Average Time Comparison between Set and Get Functions.

Fig. 7 depicts a graph of the percentage increase in the number of gas costs. The rising line has a linear tendency. Therefore, it can be concluded that the amount of string data is directly proportional to the number of gas costs that must be paid. However, in the tests carried out, the percentage increase in gas costs was slightly inappropriate. This discrepancy can be seen in Fig. 9, where the percentage increase from string1 to string3 is not the same as the sum of the percentage increase from string1 to string2 plus string2 to string3. This could be because the number of spaces was not taken into account or was ignored in this test. Thus, the percentage increase in costs had an error of 4.05% in this test.

## V. CONCLUSION

In the tests carried out in this work, several conclusions from the implementation can be made. First, we can conclude that the implementation of smart contracts on Ethereum as a blockchain system for application to telemedicine data repositories was successfully achieved. Thus, telemedicine treatment can improve the effectiveness of a person's time and can secure data. In addition, the performance of the blockchain was determined by the cost of the gas used. Using PoA, the validator block was limited in number to make the network

more scalable and faster in the transaction process. From the tests carried out, the performance for retrieving data from the blockchain was 24.4 times faster than adding data to the blockchain system. This is because the addition of data first requires a transaction verification such that the number of required time increases. Additionally, the more data one wants to store (in this study, in the form of string data), the more average time is required to make a transaction. The additional fee is as previously mentioned, the cost of each verified transaction will be following the amount of data that will be stored in the blockchain network. At the time of the experiment, the success rate of data transmission and retrieval was 100%, but there were some time spikes from time testing, especially in the Get function at 100 iterations. This was due to pending transactions at the time of verification. The gas fee that must be paid to add data to the blockchain system or for transaction validation fees to the validator was directly proportional to the amount of data stored in the blockchain. Therefore, from the experiment, it was shown that the larger the amount of data stored in the system, the higher the gas costs incurred. In this test, an additional cost of 0.34% per character string was added. The error obtained from the gas cost comparison experiment was 4.05%.

## ACKNOWLEDGMENT

This research is supported and funded by the Directorate of Research and Community Service, Deputy for Strengthening Research and Development, Ministry of Research, Technology / National Research and Innovation Agency of the Republic of Indonesia under the grant of Penelitian Konsorsium Riset Unggulan Perguruan Tinggi, contract number: 1056/PKS/ITS/2021 between researchers and Direktorat Riset dan Pengabdian kepada Masyarakat, Institut Teknologi Sepuluh Nopember.

**Abstract**—Medical images naturally occur in smaller quantities and are not balanced. Some medical domains such as radiomics involve the analysis of images to diagnose a patient's condition. Often, images of sick inaccessible parts of the body are taken for analysis by experts. However, medical experts are scarce, and the manual analysis of the images is time-consuming, costly, and prone to errors. Machine learning has been adopted to automate this task, but it is tedious, time-consuming, and requires experienced annotators to extract features. Deep learning alleviates this problem, but the threat of overfitting on smaller datasets and the existence of the “black box” still lingers. This paper proposes a capsule network that uses Local Binary Pattern (LBP), Gabor layers, and K-Means routing in an attempt to alleviate these drawbacks. Experimental results show that the model produces state-of-the-art accuracy for the three datasets (KVASIR, COVID-19, and ROCT), does not overfit on smaller and imbalanced datasets, and has reduced complexity due to fewer parameters. Layer activation maps, a cluster of features, predictions, and reconstruction of the input images, show that our model is interpretable and has the credibility and trust required to gain the confidence of practitioners for deployment in critical areas such as health.

**Keywords**—Convolutional neural networks; deep learning; Gabor filters; k-means routing; local binary pattern; power squash introduction

## I. INTRODUCTION

Health is among the top critical areas that affect human life. For instance, 50,000 people die each year from pneumonia in the United States whereas colorectal polyps are projected to increase by 60% in 2030 which is likely to increase the number of causalities [1]. Images, videos, and text are the commonly generated and analyzed data used for the evaluation of most medical conditions. The analysis of these data requires the expertise of professionals which is rare and expensive in some regions and additionally susceptible to human errors [2], less effective [3], and falls below recommended levels in clinical procedures [4]. This calls for computer vision-assisted diagnosis. Machine learning-based methods such as support vector machines have been employed to assist in the effective diagnosis of medical diseases [5]. However, the performance of these methods was below the standard practices and the feature extraction procedure is time-consuming. To address

these issues, deep learning models such as convolutional neural networks (CNNs) were adopted to improve feature extraction. Interestingly, CNNs achieved performance rivaling human experts. For example, a CNN model made up of 121 layers (termed CheXNet), was trained on 100,000 frontal view chest X-rays and performed far better than 4 radiologists [6].

Regardless of CNN's good performance, the research identified certain limitations such as being translationally invariant [7], requiring large datasets, being computationally expensive [8], and following certain criteria for effective feature selection [9]. In health, the availability of a large dataset is a major challenge coupled with the lack of unavailability of qualified annotators [8]. Therefore, to prevent CNNs from overfitting on these small datasets, data augmentation techniques are employed. These data augmentation techniques are time-consuming and laborious.

To address these challenges, Capsule Network (CapsNet) [7] was introduced, and unlike CNNs, they do not require large datasets making them suitable for health applications. Notwithstanding, CapsNets also have their limitations. They perform poorly on complex images and images with varied backgrounds, have complex routing processes, poor learning of lower-level description [10], and polarization.

The contributions of this paper, therefore, are a) architectural innovation: we propose a Local binary pattern (LBP) – Gabor Capsule Network to address the weak feature extraction problem and the inability of CapsNets to learn lower-level descriptions of a complex image, b) algorithmic innovation: we adopt K-means routing, power squash, and sigmoid functions to complement the feature extraction abilities of the LBP-Gabor layers, c) explainable artificial intelligence (XAI): we provide extensive visualizations of the outputs of our network in an attempt to “open” the “black box” in deep learning models for enhanced credibility and understandability.

The rest of the paper is organized as follows: Section 2 presents the related work leading to Section 3 where the proposed methods are outlined. The experiments and experimental results are presented in Section 4 and the work concluded in Section 5.

## II. RELATED WORK

The limitations of human-centered diagnosis led to the adoption of algorithms for predicting medical conditions found in domains such as “radiomics”. Radiomics involves the use of data-characterization algorithms to extract features from radiographic images. Studies in the literature, such as Saif et al. [5] proposed a Capsule Network algorithm for the recognition of musculoskeletal conditions from radiographic images. The proposed model outperformed a 169-layer DenseNet in recognizing abnormality in musculoskeletal radiography. To address the inability of CNNs in encoding part-whole relationships, Mobiny et al. [11] proposed an efficient bi-directional long short-term recurrent capsule network for the recognition of apoptosis (cell death). The proposed model achieved competitive performance and outperformed CNNs especially when the number of training samples is small.

One of the deadliest medical conditions is brain tumors. Detection of the correct type of brain tumor at an early stage is vital to enable early treatment and reduce mortality in both children and adults. Consequently, there has been a surge of interest in developing efficient brain tumor detection algorithms. Afshar et al. [12] proposed a capsule network algorithm for the detection of a brain tumor on segmented images generated from the training images. The segmentation was done to avoid the negative effect of miscellaneous background objects on the model’s performance. Afshar et al. [13] proposed a focus-oriented capsule network algorithm that takes coarse boundaries of brain tumor images as extra inputs to diagnose brain tumors. The proposed model achieved overall recognition accuracy of 90.89%.

Given the challenges encountered during human-centered diagnosis of other lung infections and COVID computed tomography (CT) scan and X-ray images, Afshar et al. [14] proposed a capsule network termed COVID-Caps. The proposed model achieved an accuracy of 95.7%, sensitivity of 90%, and specificity of 90% on small datasets of COVID-19. This study is more related to the works in [15, 16] and [17] where transfer learning and custom-built CNNs are designed to diagnose diseases such as COVID-19 and retinal diseases from Chest X-ray and retinal optical coherence tomography (ROCT) images respectively. However, we leverage on CapsNet’s ability to avoid overfitting and identify the pose and deformation of objects and object parts to diagnose medical conditions from challenging medical images. Furthermore, the aforementioned works did extensive data preprocessing, augmentation, segmentation, and balancing of datasets (especially [15]) before fitting their models. We, however, used the raw datasets without augmentation and preprocessing to understand the model’s performance on the natural data since it may not be feasible to perform augmentation or segmentation during a medical emergency. Although the work in [15] provided images of the regions recognized by the model, we provide elaborate visualizations of image regions that attract the attention of parts of our model, clusters of features at the class capsule layer to measure the performance of the routing algorithm, performance on imbalanced datasets in the form of Precision-Recall (PR) curves, and reconstruction of input images as a way to enhance model transparency and understandability.

## III. PROPOSED METHODS

In this section, we present the model modifications and the methodology adopted to achieve our objective of designing a capsule network with superior feature extraction capabilities compared to the original CapsNet. We avoid shallowness and at the same time strive to reduce the number of parameters by using layers that generate no or less trainable parameters.

### A. K-Means Routing

We adopt the K-means routing in [18] with Sigmoid normalization, Power squash  $v_j = \|v_j\|^n \frac{v_j}{\|v_j\|}$ , and a modified logit updates procedure, instead of dynamic routing [7] in an attempt to minimize the problem of polarization [19] leading to improved performance on difficult medical images. Instead of using dot product and initializing  $b_{ij}$  with zero and adding the old logits to perform updates, our method respectfully uses the  $\ell_2$  distance measure, initializes  $b_{ij}$  as  $b_j^{(0)} \leftarrow \sum_{i=1}^n \|W_{ij}u_i - v_j^{(0)}\|^2$  and does not add old logits to new logits during updates. Algorithm 1 shows the K-means routing procedure.

**Algorithm 1** K-Means Routing for image classification [18]

1. **procedure** ROUTING ( $u_i, r$ )
2.     **Initialize**  $v_j^{(0)} \leftarrow \frac{1}{k} \sum_{i=1}^k W_{ij}u_i$
3.      $b_j^{(0)} \leftarrow \sum_{i=1}^n \|W_{ij}u_i - v_j^{(0)}\|^2$
4.     **for**  $r$  iterations **do**
5.          $b_{ij} \leftarrow \sum_{i=1}^n \|W_{ij}u_i - v_j\|^2$
6.          $c_{ij} \leftarrow \text{Sigmoid}(b_{ij})$
7.          $v_j \leftarrow \sum_{i=1}^n c_{ij}W_{ij}u_i$
8.     **return**  $power_n(v_j)$

### B. Feature Extraction with LBP and Gabor

Both LBP [20] and Gabor filters [21] have each been shown to be superior edge and texture feature extractors [22, 23] than convolutional layers [18, 24, 25].

Gabor filters belong to a special class of bandpass filters with frequency and orientation representation mimicking those of the mammalian cortex. They are made up of real and imaginary parts. It is the real part shown in equation 1 that is used to extract image features.

$$g(x,y;\lambda,\theta,\psi,\sigma,\gamma)=\exp\left(-\frac{x^2+y^2}{2\sigma^2}\right)\cos\left(2\pi\frac{x}{\lambda}+\psi\right) \quad (1)$$

where  $x' = x\cos\theta + y\sin\theta$ ,  $y = -x\sin\theta + y\cos\theta$  with  $(x, y)$  being the pixel position in the spatial domain.  $\lambda$  controls the width of the Gabor function strips,  $\theta$  represents the orientation to the normal,  $\psi$  is the phase offset,  $\gamma$  is the spatial aspect ratio, and  $\sigma$  is the standard deviation of the Gaussian envelope. To extract features with Gabor filters, five frequencies  $f$  and eight orientations  $\theta$  are adopted. These parameters are defined in equations 3 and 4.

$$= \frac{\pi}{2} \sqrt{2}^{(n-1)} \quad (2)$$

$$\theta = \frac{\pi}{2} (m-1) \quad (3)$$

Fig. 1. The Gabor-LBP Capsule Network Architecture.

where  $n = 1, 2, \dots, 5$ ,  $m = 1, 2, \dots, 8$ , and  $\sigma = \frac{\pi}{f}$ .

The Local Binary Pattern (LBP) [20] is a powerful feature extractor that adds no trainable parameters to a model when used to extract contrast and spatial patterns of an image. It accomplishes this by thresholding  $n$  neighbouring pixels and computing its equivalent binary number based on equation 4.

$$LBP(n,r) = \sum_{n=0}^{n-1} f(i_n - i_c) 2^n \quad (4)$$

where  $i_n$  = neighboring pixels' intensity,  $i_c$  = current pixels' intensity,  $n$  = number of selected neighboring pixels at radius  $r$ , and a sign function defined as  $f = \begin{cases} 1, & \text{if } x \geq 0 \\ 0, & \text{otherwise} \end{cases}$ .

### C. LBP-Gabor CapsNet Architecture

The proposed model is a combination of Conv-LBP-Gabor layers placed in a multi-lane fashion (see Fig. 1). The input images are resized to 28x28x3 and fed to both lanes simultaneously. The first lane (upper lane) has a conv1 layer made up of 256, 7x7 kernels with ReLU non-linear activation at a stride of 1 to produce 256, 22x22 feature maps. These feature maps serve as input to the Gabor\_1 layer made up of 256, 22x22 feature maps for subsequent layers. The feature maps are processed in this manner as they pass through each layer in lane one until they reach the Primary Caps 1 layer which is a convolutional capsule layer made up of 7x7 kernels with a stride of 2. It is a 16-component capsule each with 4x4 capsules in an 8-dimensional vector.

LBP\_2 extracts the features directly from the input image to feed lane two (bottom lane). It is made up of 256, 7x7 kernels with stride 1 to produce 256, 22x22 feature maps. The features are refined as they pass through the rest of the layers to Primary Capsule 2 which has 3x3 kernels at a stride of 2. This too is a 16-component convolutional capsule each with a 1x1 capsule in an 8-dimensional vector.

The outputs of the two PCs are concatenated via axis 1 to produce a 272x8 dimensional tensor. It is the features of this tensor that are used for routing with the Disease recognition cap layer. The latter is 16-dimensional while the number of capsules is varied according to the number of classes in the

dataset. We have used (?) to indicate that the number of capsules will vary from 8, 4, 4 for KVASIR, COVID-19, and ROCT datasets respectively. Reconstruction of the input image is carried out by the decoder. The quality of the reconstructed images (see Fig. A1 in Appendix A) depends on the performance of the classification.

## IV. EXPERIMENTS

In this section, we present the experiments conducted on each dataset as well as their respective results. Three publicly available datasets were used to evaluate the performance of the model's ability to generalize on unseen data.

### A. Dataset Description

The Kvasir [24] is a dataset consisting of images from inside of the gastrointestinal (GI) tract. It consists of eight different classes made up of images from 720x576 to 1920x1072 pixels. The dataset can be used for multiclass classification [24] as the images can be categorized under three important anatomical landmarks. For a detailed description of this dataset, readers are encouraged to look at the work in [24]. This dataset is not balanced.

The COVID-19 dataset [16, 17] was collected by a team of doctors from 4 countries, and it is made up of chest X-ray images of COVID-19 positive cases plus some Normal and Viral Pneumonia images. Categories such as COVID, Lung Opacity, Normal, and Viral Pneumonia form the class in this dataset. This dataset is also imbalanced and details can be found in [16, 17].

The Retinal Optical coherence tomography (ROCT) dataset [15] contains high-resolution cross-sectional images of the retina. The dataset was collected from adult patients at the Shiley Eye Institute of the University of California San Diego, the California Retinal Research Foundation, Medical Center Ophthalmology Associates, the Shanghai First People's Hospital, and Beijing Tongren Eye Center [25]. It has four classes and is originally organized such that each test set has 250 images while the training set has 20,135 (i.e. approximately 95% to 5% train-test split). We, however, split all the three datasets into 80% training and 20% test. Additionally, we did not perform data augmentation to any of

our datasets as a means to measure the ability of the proposed model to decode the spatial orientation of the images. A summary of the datasets used in this study is provided in Table A1 in Appendix A.

### B. Experimental Setup

We performed all the experiments using the following tools and software; Keras with TensorFlow backend, one 64-bit Windows machine with NVIDIA GeForce GTX 1060 Graphic Processing Unit (GPU), 8GB GPU memory, 16GB system memory, and CUDA 10.1 toolkit. Hyperparameters such as the number of epochs, batch size range, learning rate, learning rate decay, and early stopping were respectively set to 100, 50-100, 0.001, 0.9, and 15. We varied the number of routing iterations from 2 to 7 (see Section 4.5) to test the ability of the model to scale up. To calculate the loss, we adopted the margin loss from [7]. This loss is given by:

$$L_k = T_k \max(0, m^+ - \|v_k\|)^2 + \lambda(1 - T_k) \max(0, \|v_k\| - m^-)^2$$

where  $T_k = \begin{cases} 1 & \text{if class } k \text{ is active} \\ 0 & \text{otherwise} \end{cases}$ ,  $\lambda = 0.5$ ,  $m^+ = 0.9$ , and  $m^- = 0.1$

We adopted, customized, and modified the code from <https://github.com/XifengGuo/CapsNet-Keras> for this study.

### C. Experimental Results

We present the experimental results in this Section and show that the model performed well when evaluated on the three datasets. To enhance confidence and reliability in the model's results, several evaluation methods were adopted and carefully conducted. Metrics such as the number of parameters, classification loss, and accuracy, the Area Under the Curve (AUC) for both the Receiver Operating Characteristic Curve (ROC) and Precision-Recall (PR) curves were used for the performance evaluation. Additionally, the model's robustness, ability to scale-up, fail-safe, extract only relevant features and the performance of the routing process were also evaluated. The traditional capsule network was also trained with the datasets and the results compared to our model based on the aforementioned performance metrics.

### D. Accuracy

We used the multi-class confusion matrix to summarize the performance of the model on the datasets. This method includes powerful per-class metrics such as true positive (TP), true negative (TN), false positive (FP), and false-negative (FN). The values in the principal diagonals of the confusion matrices are the TP values representing the level of correct identification of the true classes from the respective datasets. Few FNs as seen from Fig. A2 in Appendix A. indicates a good performance considering the field of application (i.e. health). In other words, the high TP values indicate good performance for a disease recognition model since it is not fatal for a healthy medical image (and by extension a healthy person) to be categorized as sick compared to when a sick person is classified as healthy.

From the confusion matrices, the accuracy of the model can be computed based on equation 5.

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (5)$$

It is worth noting that accuracy, even though very popular [26] at evaluating classification algorithms, is not appropriate for medical images since they tend to be small and highly imbalanced [27]. Despite its drawback, it can provide a snapshot of the entire system performance, especially when the datasets are balanced..

The performance of the model in terms of accuracy during training and validation can be monitored via the training and validation curves. These curves for the three datasets are depicted in Fig. 2, with (c) and (d) depicting that the model had some difficulty in extracting the relevant features from the COVID-19 dataset. This is indicated by the zig-zag nature of the curves. Consistently, the proposed GLC model outperformed the traditional capsule network on the respective datasets in terms of training and validation accuracy/loss. A comparison of the accuracies of the proposed model, the traditional CapsNet, and other models in the literature on the same datasets are shown in Table A2 in Appendix A. The 93.40% accuracy of [15] on the ROCT dataset was obtained on the original 95%-5% train-test split. However, we split the data into 80%-20% for training and testing respectively. Unavailable values in Table A2 in Appendix A are indicated by (?).

To further probe the superiority of the proposed model, we performed additional experiments to determine the accuracy of the model as it is subjected to architectural damages in what is known as ablation studies (see Section 4.6). Additionally, we performed more experiments to explore the effect of increasing the capacity of the model on accuracy by increasing the number of routing iterations from 2 to 7 (see Section 4.5).

### E. Model's Ability to Scale

Dynamic routing has an inner loop [28] [18] which contributes to hindering the algorithm to scale on complex data and increases the threat of overfitting when the network capacity is increased through an increase in the number of routing iterations. To test the models on this score, we varied the number of routing iterations and the results of these experiments are depicted in Fig. A3 in Appendix A. It is observed that the proposed GLC maintains a marginal loss in accuracy for both KVASIR (Fig. A3 (a)) and COVID-19 (Fig. A3 (b)) as the number of routing iterations increases from 2 to 7. On the contrary, the traditional model begins to overfit after the third routing iteration (Fig. A3 (a)), probable because the number of classes is comparatively higher than the other datasets while at the same time the number of images in the dataset is relatively smaller. As the traditional model scales up, it becomes "hungrier" for data and tends to depend on the number of classes, consequently increasing the number of interrelationships to a level likely to cause overfitting.

We also observe from Fig. A3 (Appendix) that at 3 iterations, the traditional CapsNet achieved optimal performance as established in [7], however, this varies for the proposed model. For instance, GLC's accuracy for KVASIR and ROCT are highest at 2 and 4 routing iterations respectively.

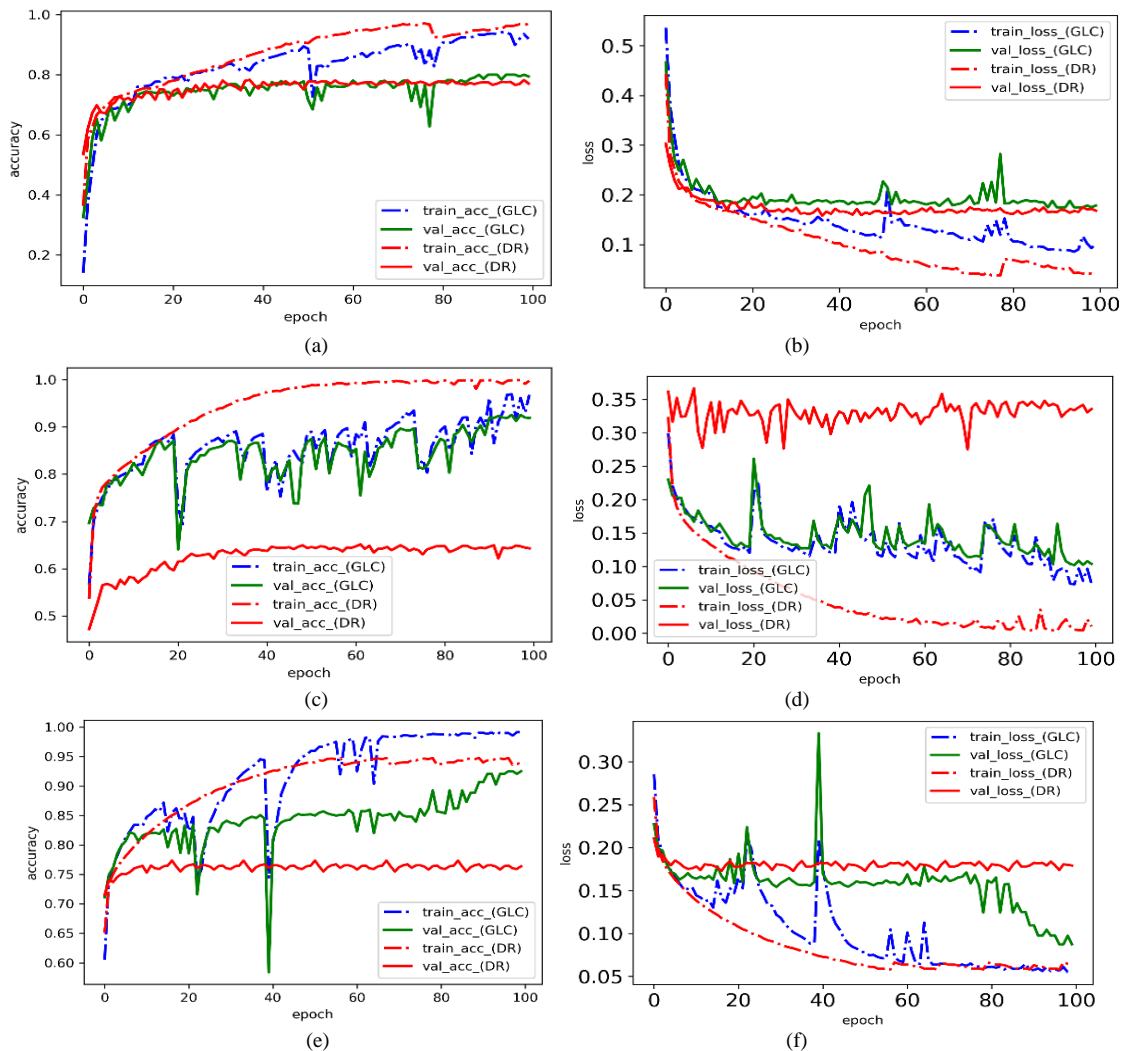

Fig. 2. Training and Validation Curves (a) Accuracy for KVASIR, (b) Loss for KVASIR (c) Accuracy for COVID-19, (d) Loss for COVID-19, (e) Accuracy for ROCT, and (f) Loss for ROCT Dataset.

#### F. Model's Robustness and Ability to Fail-Safe

Setting the number of routing iterations to 3, we performed additional experiments to determine parts and configurations of the model that made significant contributions to its high performance. We removed layers at a time and trained the network to measure the effect of their presence/absence in the network. Also, hyperparameters such as the squash and normalizer were varied and several pieces of training were carried out. This technique is called ablation study [29], and it can determine the ability of a network to fail-safe or undergo graceful degradation. Graceful degradation is a required property for critical applications. It is also a means to enhance confidence in the model since network components with the ability to stand in for failed parts can be identified and to also test for the robustness of the model to architectural changes.

From Table 1, Conv1 (row 1) and LBP2 (row 7) are very crucial in the network due to their positions as lower-layer (primary) feature extractors. Their removal causes a drop in accuracy across all the datasets. However, the removal of any of the rest of the conv layers causes a slight drop in accuracy, an indication that we could comfortably remove any one of them in situations where our objective is to reduce model parameters/size. Again, removing all the conv layers (row13) seems to have little effect on the performance compared to removing all LBP (row 11) and all LBP plus Gabor (row 12) layers. Rows 16 and 17 indicate the use of all layers in the network. We observe that the combination of the original squash and SoftMax underperformed relative to that of the Power squash and Sigmoid normalization consistent with what was reported in [18].

TABLE I. RESULTS OF ABLATION STUDY ON THE GLC MODEL

No	Layer(s) removed	Squash	Normalizer	Validation Accuracy (%)		
				KVASIR	COVID-19	ROCT
1	Conv1	Power	Sigmoid	79.11	90.02	90.13
2	Conv2	Power	Sigmoid	79.43	90.76	91.01
3	Conv3	Power	Sigmoid	79.51	90.62	90.35
4	Conv4	Power	Sigmoid	79.60	90.71	90.32
5	Gabor	Power	Sigmoid	77.07	80.23	81.56
6	LBP1	Power	Sigmoid	72.97	81.66	82.97
7	LBP2	Power	Sigmoid	70.94	79.52	80.50
8	LBP3	Power	Sigmoid	73.43	81.05	82.03
9	Gabor+LBP1	Power	Sigmoid	76.02	79.81	81.43
10	Conv1+Conv2	Power	Sigmoid	79.55	89.05	90.17
11	LBP1+LBP2+LBP3	Power	Sigmoid	66.91	70.12	75.57
12	Gabor+LBP1+...+LBP3	Power	Sigmoid	65.43	70.63	77.09
13	Conv1+...+Conv4	Power	Sigmoid	79.11	88.95	89.98
14	Lane 1 (top lane)	Power	Sigmoid	75.29	79.85	81.00
15	Lane 2 (bottom lane)	Power	Sigmoid	76.71	80.32	84.21
16	None	Original	SoftMax	78.54	88.70	89.01
17	None	Power	Sigmoid	80.91	91.96	91.30

### G. Performance on Smaller and Imbalanced Datasets

Medical images are usually smaller and highly imbalanced [33]. Class imbalance, on the other hand, contributes to a problem called the “accuracy paradox” [31] which causes the larger classes to overshadow the smaller classes during accuracy computations. In other words, accuracy under these conditions is influenced or biased towards the class with the highest number of samples. Besides, the asymmetric misclassification costs and probability estimates of the classification are not taken into consideration during accuracy computations under class imbalance. The AUCs for the ROC and PR curves become handy when fitting a model with balanced and imbalanced classes respectively [36, 37]. The AUC is invariant to the a priori likelihoods of the classes as well as being independent of the decision threshold [34]. Large AUCs are preferred over their smaller counterparts.

Fig. 3. shows the ROC and PR curves for the GLC model. We observe that the ROC curves have relatively larger areas separating them from the diagonal. The impression is that the model performed very well in all the classes, however, the PR curves depict that the model did not perform equally well in all the classes. This is so because ROC tends to be overly optimistic with insufficient data [35] as well as when there is a large skew in the dataset class distribution [32]. A medical practitioner ultimately needs to see the PR curves of a model (not only accuracy) before taking critical decisions on a patient’s condition. Compared to the ROC and PR curves of the DR model (shown in Fig. 3), the GLC model outperformed the traditional CapsNet model under class imbalanced

conditions. The respective AUC values are; ROC -KVASIR (0.96), PR-KVASIR (0.71), ROC-COVID-19 (0.97), PR-COVID-19 (0.95), ROC-ROCT (0.93), and PR-ROCT (0.87).

On smaller datasets, CapsNets are known to outperform convolutional neural networks due to the ability of CapsNets to encode pose and orientation. This reason, plus our superior feature extractors explain why our model performed well on the KVASIR dataset (see Fig. 2(a)) without any data augmentation.

### H. Prediction and Reconstruction

During prediction, the capsule outputs the class with the longest vector as the correct class. It is compared with the ground truth (GT) image to measure how well the trained model can classify an unseen image. This aspect of the model is very crucial for health applications since it quantifies the confidence the model has in its prediction. To introduce variability in the testing set, 1% of each dataset was reserved for prediction, and as such was not used as part of the training set. Sample prediction results on the unseen images are shown in Fig. A1 in Appendix A. The KVASIR dataset (Fig. A1 (a)) has eight classes, each of which is assigned a likelihood of being the correct class. The class with the highest probability is the predicted class. For both KVASIR and COVID-19 predictions, the model misclassified 0.5% of the unseen images (e.g. Fig. A1 (a) row 5 and Fig. A1 (b) row 4). We observe that the model imposed huge confidence (83%) in predicting class 2 of the KVASIR dataset as the correct class (Fig. A1 (a) row 3) while at the same time predicting class 1 with the confidence of 82% for the COVID dataset (Fig. A1 (b) row 5).

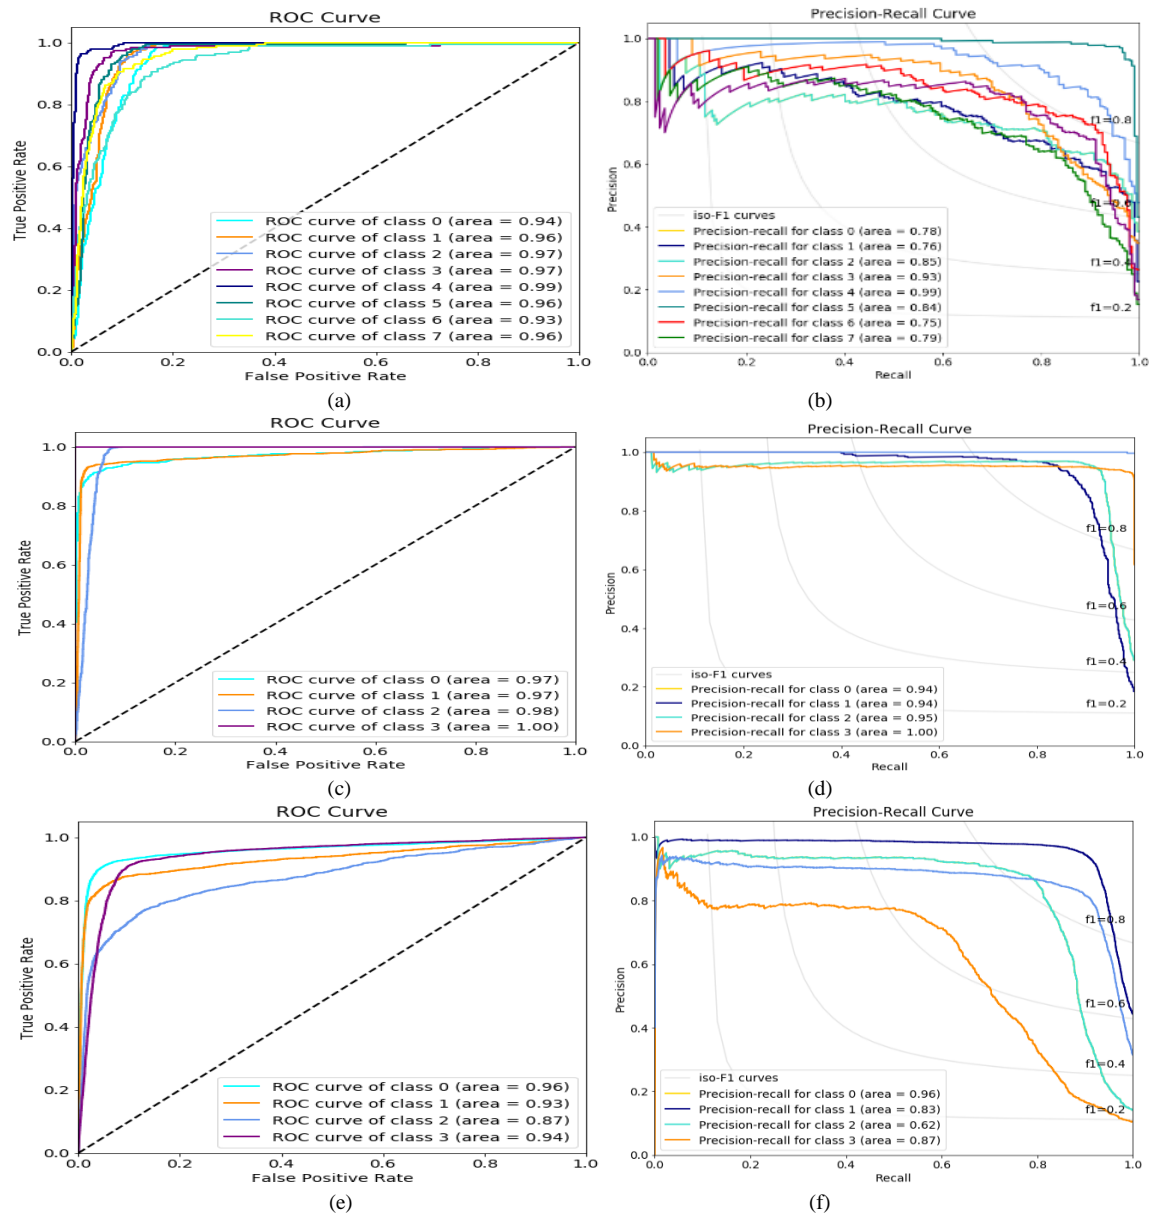

Fig. 3. ROC and PR Curves for the GLC Model. (a) ROC -KVASIR, (b) PR-KVASIR, (c) ROC-COVID-19, (d) PR- COVID-19, (e) ROC-ROCT, and (f) PR-ROCT.

Reconstruction allows visual verification of the model’s output/performance and also works as a regularizer. The reconstructed images in Fig. A1 in Appendix A. are clearly showing that the network layers effectively used the instantiating parameters to reconstruct the input mages (GT). We also carried out predictions and reconstruction on the ROCT dataset as well as using the DR model to predict and reconstruct unseen images from the three datasets. The DR model misclassified 1% of the unseen images across the 3 datasets. These results, however, are omitted for brevity.

### I. Model Complexity

Smaller deep learning models are required for efficient implementation on embedded devices such as FPGAs and

mobile phones with limited memory [36]. Such models are also important for reducing overhead to make distributed online training and inference possible. The smaller the number of a model’s trainable parameters, the less computationally complex the model is. This reduces the number of resources required by the model and also helps to prevent overfitting by ensuring that an 1-layer capsule model has  $\ln+k$  parameters required to exactly fit a d-dimensional dataset with n samples [37]. Our proposed model (see Fig. 1.) is deeper than the traditional CapsNet, but with a comparatively fewer number of parameters as shown in Table A3 in Appendix A. The values in Table A3 (Appendix) confirm that relatively smaller CapsNet models can represent complex real-life functions to outperform models with huge parameters [43, 18].

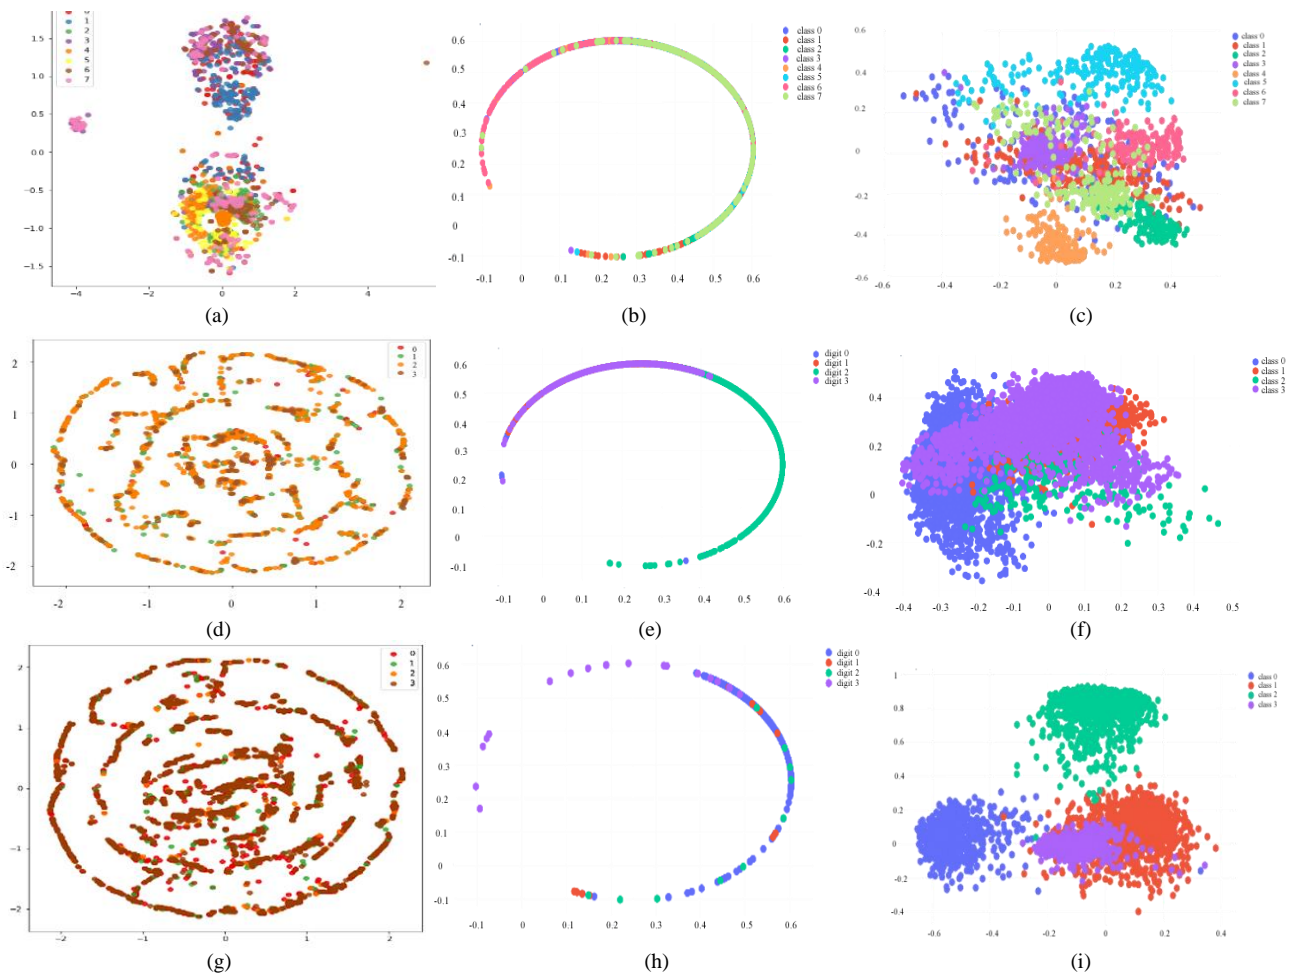

Fig. 4. *Tsne* Visualization of the Network’s Raw and Learned Features at the Class Capsule Layer, (a) KVASIR Raw Test Set, (b) GLC clusters of KVASIR, (c) DR Clusters of KVASIR, (d) COVID-19 Raw Test Set, (e) GLC Clusters of COVID-19, (f) DR Clusters of COVID-19, (g) ROCT Raw Test Set, (h) GLC clusters of ROCT, and (i) DR Clusters of ROCT.

### J. Performance of the Routing Process

We use the t-distributed stochastic neighbor embedding (TSNE) to visualize the network learned features at the class capsule layer. This method helps us to visually determine the level to which the network can differentiate between the different classes. Since primary capsules are coupled with secondary capsules with which there is a high agreement  $a_{ij}$  during routing, the features involved can be modeled as clusters. The compactness and separability of these clusters in the feature space indicate the performance of the routing algorithm at effectively making a distinction between the various classes. From Fig. 4., we observe that the clusters formed by the GLC model (second column); even though overlapping, are separable and some compact compared to those formed by the DR model (third column). These properties are linearly related to the performance of the routing algorithm and may be essential for further decision-making in case-by-case-based health applications.

We note that the reason for the GLC model forming circular clusters is that the routing algorithm is driven by K-means whose clusters are naturally circular from its use of the  $l_2$  norm [39].

### K. Feature Extraction

To uncover the network layers with good texture, edge, and shape feature extraction capabilities, we performed experiments to visualize the activation maps of the layers. This method is useful as it provides the opportunity to identify regions in the input image responsible for the activation of parts of the network. It also contributes to investigating whether a model is robust and can avoid failure through the inspection of the presence of layers with redundant features. Aside from the threat of overfitting resulting from model complexity, redundant layers are major contributors to a model’s robustness and fault tolerance capabilities. On the other hand, through this method, redundant layers can be eliminated to improve the model’s feature extraction to consequently reduce excessive oscillations and prolonged convergence during training [18]. This is a vital step for medical applications since it contributes significantly to the explainability and understandability of the “black box” [40] required to enhance confidence in model outputs for critical applications.

Fig. 5. Comparison of the Activation Maps of the Proposed GLC and the DR Models. (a) the First and Second Rows Show the Activation Maps for GLC and DR respectively on KVASIR, (b) Row One Shows the Activation Maps of GLC while Row Two Shows the Activation Maps of the DR Model for COVID-19, and (c) First and Second Rows are respectively the Activation Maps of GLC and DR Models for ROCT Dataset.

The feature maps in Fig. 5. show that the Gabor and LBP layers in the GLC have superior feature extraction capabilities than the convolutional layers. The Conv1 layer of the GLC network extracts some quality features since it is a higher-level layer with the ability to sample features from the lower-level layers (Gabor and LBP1) to represent advanced parts of the GT image. On the contrary, the Conv1 layer of the DR model is a lower-level layer, and with the difficulty of CNNs to extract quality features [18], it is not able to extract relevant features as required.

#### V. CONCLUSION AND FUTURE WORK

In this paper, we propose a capsule network architecture with superior feature extraction capabilities for the recognition of medical conditions in medical images. The adoption of

Local Binary Pattern (LBP), Gabor layers, and K-Means routing in an innovative architecture has dramatically improved the model's feature extraction capabilities leading to an appreciable performance while scaling up, preventing overfitting under class imbalance, and obtaining competitive validation and test accuracies. We further subjected the model through extensive visualization of layer activation maps, cluster of features, and ablation studies to enhance model interpretability and confidence for practical adoption. The results indicate that, it is possible to develop deep models to have smaller number of parameters (hence lower complexity) with huge potential for implementation on embedded devices with lower memories.

In the future, we will perform extensive experiments on these medical datasets for purposes of explainable artificial

intelligence (XAI). The aim will be to eliminate every ambiguity on model outputs to pave the way for its practical adoption in health.

Symbiosis Institute of Computer Studies and Research, Symbiosis International (Deemed University), Pune, India<sup>2</sup>

**Abstract**—Information gets spread rapidly in the world of the internet. The internet has become the first choice of people for medication tips related to their health problems. However, this ever-growing usage of the internet has also led to the spread of misinformation. The misinformation in healthcare has severe effects on the life of people, thus efforts are required to detect the misinformation as well as fact-check the information before using it. In this paper, the authors proposed a model to detect and fact-check the misinformation in the healthcare domain. The model extracts the healthcare-related URLs from the web, pre-processes it, computes Term-Frequency, extracts sentimental and grammatical features to detect misinformation, and computes distance measures viz. Euclidean, Jaccard, and Cosine similarity to fact-check the URLs as True or False based on the manually generated dataset with expert's opinions. The model was evaluated using five state-of-the-art machine learning classifiers Logistic Regression, Support Vector Machine, Naïve Bayes, Decision Tree, and Random forest. The experimental results showed that the sentimental features are crucial while detecting misinformation as more negative words are found in URLs containing misinformation compared to the URLs having true information. It was observed that Naïve Bayes outperformed all other models in terms of accuracy showing 98.7% accuracy whereas the decision tree classifier showed less accuracy compared to all other models showing an accuracy of 92.88%. Also, the Jaccard Distance measure was found to be the best distance measure algorithm in terms of accuracy compared to Euclidean distance and Cosine similarity measures.

**Keywords**—Misinformation detection; sentiment analysis; document similarity; fact-check; healthcare

## I. INTRODUCTION

Online social media and the web as a whole have become the spring of information to users all around the world. Due to its convenience, feasibility, unrestricted access, and reasonable cost the internet have become popular amongst the community [1], [2]. The people read, share, write, and view the articles, blogs, news, videos, audios, etc., all over the internet. The rate of sharing articles, blogs, news, etc., has been accelerated dramatically. However, the users not only share immaculate information but also try to spread wrong or incorrect information either knowingly or unknowingly in a moment. This widespread misinformation has relentless consequences on individuals, commercial, health, government, and all other facets of society. The ramification of the misinformation is catastrophic and may lead to extermination. For example, the political disinformation spread during the 2016 USA presidential elections led to public shootings. These enduring

consequences of misinformation contribute towards ferocious conflicts that are preventable otherwise [3], [4].

The internet has become the most popular and the first choice of the public to investigate health problems. However, people get misinformed with wrongly populated content. A famous and perfect example is the misconception among the public about the measles, mumps, and rubella (MMS) vaccine causing autism. Health misinformation is defined as "A health-related claim of fact that is currently false due to a lack of scientific evidence" [5]. The promulgated experiences of people over the internet or articles were written about certain diseases without knowing or verifying the fact or having a lack of evidence can cause health ruination of readers and thus can lead to complete desolation [6], [7]. The misinformation related to health can have hazardous effects on people's life directly, thus detecting misinformation in healthcare is a need of time [8]–[10].

Misinformation detection has become the topic of interest amongst researchers in the literature. The researchers have studied different types of false information. The first category is termed misinformation, which is the inaccurate or incorrect information that is confirmed with existing evidence [11]. The other categories include the fake news [12], [13], rumor [6], satire news [14], hoaxes [15], misinformation [16], [17], disinformation [18] and opinion spam [19]. To detect each of these categories of false information the authors have used several features like sentiment analysis, user-specific features, syntactical features, grammatical features, image or message specific features, etc. Also, there are readily available datasets for false information detection in various domains viz. politics, news, business, and healthcare. Few examples of these datasets are LIAR, FakeNewsNet, BSDetector, etc. With the help of features and datasets, machine learning and deep learning techniques are applied to detect false information [11]. However, detecting misinformation is an exhaustive task. This is due to two main reasons: first, is the availability of dataset in a certain domain and second is fact-checking of the data [11], [20], [21]. It is difficult to get the benchmark and gold-standard datasets in a specific domain. Also, manual fact-checking of data is time-consuming, requires expert guidance, and involves laborious tasks. Thus, automatic fact-checking of data is a need of time to endure with the speed of the newly arriving and changing data.

Document Similarity is a measure of the distance between the two documents (DS). There are several distance measures available in the literature to compute the similarity between the

\*Corresponding Author.

documents like Euclidian Distance, Cosine Similarity, Jaccard Distance, etc. The concept of document similarity can be used to fact-check the information with the existing verified documents and thus can help to detect misinformation. Document Similarity is a measure of the distance between the two documents (DS). There are several distance measures available in the literature to compute the similarity between the documents like Euclidian Distance, Cosine Similarity, Jaccard Distance, etc. The concept of document similarity can be used to fact-check the information with the existing verified documents and thus can help to detect misinformation.

Sentiment Analysis (SA) techniques to detect the polarity of data into positive, negative, and neutral have been widely used in the literature to detect misinformation, fake news, rumors, etc. The process of knowing the opinion of the people about the products, services, movie reviews, etc. can be easily captured using sentiment analysis [20], [22]–[26]. The literature related to misinformation detection or finding the credibility of information using sentiment analysis has marked that the articles or blogs containing more positive words are tend to be spreading true information while the articles having negative information contain more negative information [27], [28].

Thus, to detect misinformation and perform fact-checking automatically the authors have proposed a hybrid approach of sentiment analysis and document similarity. In this research paper, the authors have created a sentiment-based Bag-of-Words (BoW) as a dataset related to the healthcare domain. Further, features like sentiment analysis, grammatical and lexical features are used to detect misinformation and document similarity measures viz. Euclidian distance, Cosine similarity, and Jaccard distance are used to perform fact-checking.

The remaining sections of the paper are structured as follows: Section II provides the literature survey describing the techniques of using sentiment-based features to detect misinformation in the healthcare domain and also the document similarity-based approaches used to fact-check the documents which could help to detect misinformation in the healthcare domain. Section III describes the proposed model architecture, dataset collection and cleaning process, and methodology used in the proposed model. Section IV discusses the results generated based on the proposed model of a hybrid approach of sentiment analysis and document similarity and section V describes the conclusion and future enhancements.

## II. RELATED WORK

### A. Sentiment Analysis in Healthcare

In terms of web articles, the sentiment analysis is an expression that measures the attitude of the author in terms of positive, negative or neutral towards the article topic. Especially, when talked about healthcare-related articles, people like to express and share their opinions about their

experiences about the disease which they have suffered from. Therefore the readers get biased towards the opinion of the author and believe the article without verifying the facts or evidence. Due to the rich contents of health information available online, the web has become the first choice of patients or users to know about the cure of disease and related remedies. Thus, understanding the sentiment of the article contents is much needed when it comes to misinformation detection. In the state-of-the-art techniques, the authors have analyzed the moods of cancer patients from tweets. Long Short Term Memory (LSTM) techniques were used to find the sentiments from the tweets [29]. In another research, authors collected 1,000 text comments of medical experts through various medical animation videos of the Youtube repository, and applied sentiment analysis to these comments to enhance the reputation of telemedicine education across the globe [30]. To study the effectiveness or popularity of a medicine, authors have performed sentiment analysis on public reviews using weighted word representation techniques and added linguistic constraints to model the contextually similar words [31]. Also, sentiment analysis techniques were used to detect misinformation in herbal treatments of diabetes in Arabic comments of YouTube videos [32]. The sentiment analysis is widely used in the healthcare sector to understand the sentiment polarity of the text and thus it can act as a major feature for misinformation detection. Table I displays the recent techniques of sentiment analysis in the healthcare domain in comparison with the proposed model techniques.

### B. Document Similarity in Healthcare

Document similarity measures the distance between two documents in a numeric value. The document similarity measures are used to find the similarity between healthcare documents. For example, to detect medical codes of the documents the authors have used an attention mechanism which targets the most informative parts of the documents [33]. In another research, Jaccard distance measure was used to compute the similarity between medical documents using a Non-negative matrix factorization algorithm [34]. In another research, the Term Frequency-Inverse Document Frequency (TF-IDF) of a document is computed and document similarity is measure using cosine similarity, further k-means is used to cluster the documents of similar types. The authors have also used the Unified Medical Language System (UMLS) to extract domain-specific features and select the required features using Principal Component Analysis (PCA). Further, the authors have used expected maximization techniques to cluster the similar documents together [35]. The document similarity is extensively applied in the healthcare domain to group similar documents together. This technique along with sentimental features will be useful for detecting misinformation in the healthcare domain. Table II displays the recent techniques of document similarity in the healthcare domain concerning the proposed model.

4	<b>Proposed Model</b>	<b>Classifiers used like LR, SVM, NB, DT, RF</b>	<b>1000 Healthcare Web URLs</b>	<b>Jaccard Distance, Euclidean Distance, Cosine Similarity</b>	<b>Fact-Check Healthcare Web URLs</b>

### C. Sentiment Analysis and Document Similarity Approaches

The document classification can be best achieved using document similarity measures. The amalgamation of sentiment analysis and document similarity is effective in terms of document classification as found in the literature. The deep learning techniques along with cosine similarity measures are used to successfully classify documents related to stock news based on the sentiments in literature, resulting in the merging of most relevant documents together [36]. In another approach, One-Class Support Vector Machine (OCSVM) and Latent Semantic Indexing (LSI) were used to classify text documents into positive and negative [37]. In another approach, NET-LDA model was proposed to find the semantic similarity between documents using sentiment polarity and cosine similarity approaches [38]. There are three different types of measures followed in the literature for document similarity measurement viz. Jaccard Distance, Cosine Similarity, and Euclidean Distance. However, the authors didn't find any articles with document similarity measures used along with sentiment analysis to classify documents based on their similarity. Thus, the hybrid combination of document similarity and sentiment analysis is a novel approach and can be used to detect and fact-check healthcare related misinformation. Table III displays the recent techniques of document similarity and sentiment analysis and the proposed model techniques

### D. Document Similarity and Fact-Checking

The major challenge faced in detecting misinformation is performing the fact-checking of data as there fewer benchmark datasets available specific to a certain domain like healthcare. With the enormous amount of information generated online, it is a highly challenging task to perform manual fact-checking of individual articles or blogs available online. Therefore the recent tools and techniques are automated using features from the text like sentimental features, user-specific features, grammatical features, etc. In the literature, authors have used techniques like Term Frequency Inverse Document Frequency (TF-IDF), and cosine similarity measures with k-means, Support Vector Machine, and Multilayer Perceptron to detect credibility of Indonesian news. Also, in another research, Latent Dirichlet Allocation (LDA) and Jaccard distance measures are used to detect fake news on the Buzzfeed dataset. In research to collect evidence for fake news detection word embeddings were used followed by Word Mover's distance measure to measure the similarity between the documents. However, it was observed that Word Mover's distance is very expensive for a large amount of data [39]-[42]. Table IV displays the recent techniques of detecting misinformation using document similarity and sentiment analysis. Though there are few studies handling fact-checking using document similarity measures, not major work is carried out in this field. Thus, in this paper, the authors propose a model with a hybrid combination of sentiment analysis and document similarity approach to detect and fact-check the misinformation.

TABLE III. RECENT TECHNIQUES OF DOCUMENT SIMILARITY AND SENTIMENT ANALYSIS AND THE PROPOSED MODEL TECHNIQUES

### III. PROPOSED MODEL

#### A. Model Architecture

The proposed model architecture for misinformation detection in the healthcare domain and performing fact-checking automatically is shown in Fig. 1. Sections B, C, and D describe in detail the architecture building. Section B talks about the data collection method, section C describes the features extracted and used for model building in detail, and section D explains the process of working model.

#### B. Dataset Creation

The authors have crawled 60 URLs from the web on the healthcare domain and classified them as True and False with the help of expert opinion. This dataset is used to verify and classify other URLs from the healthcare domain. Further, authors have crawled 898 web URLs related to the healthcare domain. Out of which, 280 URLs are used for training the model and 618 URLs are used for testing purposes. These 1000 URLs are the combination of true and false URLs in the healthcare domain and are classified with the help of document similarity measures, sentimental features, and grammatical features along with machine learning techniques.

#### C. Feature Extraction

There are mainly three different types of features extracted from the URLs datasets. First, the authors focus on sentimental features which include a number of positive word count, number of negative word count, percentage of positive and negative word counts, and the total number of words. In a research to find sentiments of people in a covid-19 pandemic, authors have created a large benchmark dataset based on tweets generated on the twitter [43]. Thus sentimental features are crucial in healthcare domain. In grammatical features, authors have extracted noun, pronoun, verb, and adjectives from the URL text. The third type of feature is document similarity measure. There are three measures used in this paper to fact-check the URLs with manually classified web URLs related to

healthcare. The first is Euclidean Distance, which measures the straight line distance between two points in Euclidean space. Equation1 depicts the Pythagorean formula to compute the Euclidean distance between two points x and y [44].

$$d(x, y) = d(y, x) = \sqrt{(X_1 - Y_1)^2 + (X_2 - Y_2)^2 + \dots + (X_n - Y_n)^2} = \sqrt{\sum_{i=1}^n (X_i - Y_i)^2} \quad (1)$$

In this paper, the authors have used Euclidean Distance (ED) measure as a feature computed separately for true and false URLs. The other distance measure used is Jaccard Distance (JD) measures the similarity between two documents by finding the ratio of the size of the intersection and size of the union. Equation2 shows the formula to compute Jaccard Distance between two documents to find the similarity between the documents [44].

$$J(A, B) = \frac{|A \cap B|}{|A \cup B|} = \frac{|A \cap B|}{|A| + |B| - |A \cap B|} \quad (2)$$

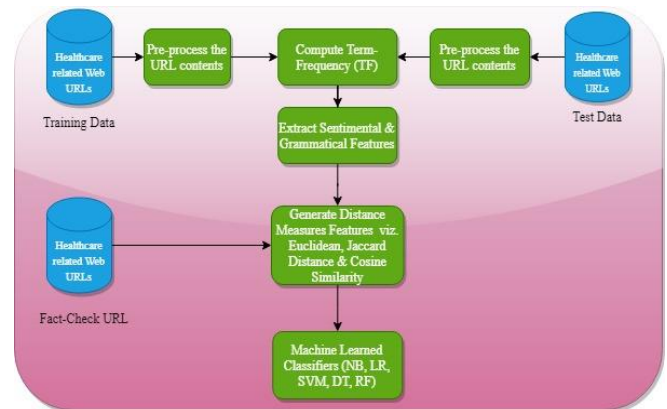

Fig. 1. Proposed Model Architecture for Misinformation Detection and Fact-Checking.

Another document similarity measure is the cosine similarity measure. Cosine similarity computes the cosine angle between the vectors. It is represented by the dot product and a magnitude between the vectors. Equation 3 shows the formula to compute the cosine similarity between two documents A and B [44].

$$\cos(\theta) = \frac{A \cdot B}{\|A\| \|B\|} \quad (3)$$

In this paper, authors have used Euclidean, Jaccard, and Cosine similarity measures as features to perform fact-checking of the URLs and thus detect misinformation in the healthcare domain. Table V lists the final set of features used in the proposed model.

TABLE V. LIST OF ALL THE FEATURES USED IN THE MODEL

Sr. No	Feature Name	Description
1	Pos_count	Positive count
2	Neg_count	Negative count
3	Per_pos_count	Percentage of a positive count
4	Per_neg_count	Percentage of a negative count
5	Total_count	Total number of words
6	Noun	Noun
7	Pro-noun	Pro-noun
8	Verb	Verb
9	Adjective	Adjective
10	ED_T	Euclidean Distance for True URLs
11	ED_F	Euclidean Distance for False URLs
12	JD_T	Jaccard Distance for True URLs
13	JD_F	Jaccard Distance for False URLs
14	C_T	Cosine Similarity for True URLs
15	C_F	Cosine Similarity for False URLs

#### D. Working Model of Misinformation Detection and Fact-Checking

In the proposed model, the training dataset is first pre-processed to remove punctuations, stop-words, numeric data, duplicate data, etc. This is required to get the cleaned data for the execution of the model. After pre-processing the URL contents, Term-Frequency (TF) is computed to find the count of terms from the URL textual contents. This term-frequency is stored in the CSV file for future use. The next step is to generate features. The first type of features is sentimental feature that focus mainly on the polarity in terms of positive and negative words of the textual contents from the URL. This is computed to the TF generated in the previous step. Along with sentimental features, grammatical features are also retrieved like noun, pronoun, verb, and adjectives. In misinformation detection, sentimental features play a significant role. It was detected that a text containing misinformation generates more negative words compared to positive words and vice-versa. Thus, more negative sentiments can lead to misinformation [17]. Thus, sentimental features and grammatical features together help to detect misinformation in this proposed model. The next aim is to perform automatic fact-checking of newly arriving URLs from the test dataset. For this reason, a fact-check URL dataset is generated. Fact-

Check URL dataset contains manually fact-checked URLs from healthcare-domain classified into True and False. To perform fact-checking of URLs from the test dataset, the authors have used standard distance measures like Euclidean Distance, Cosine Similarity, and Jaccard Distance as features. Therefore, every URL from the test dataset is first pre-processed to clean the data, term-frequency, and sentimental features are generated and finally, distance measure features are created using the standard formulas explained in section C. To compute the distance measures URL from test dataset is matched with URL from the fact-checked dataset of URLs which gives two numeric values viz. numeric value for distance between true URL from the fact-checked dataset and second numeric value with False URL from the fact-check dataset. These two values are compared and the minimum value is considered as a final feature value. This process is repeated with every URL from the test dataset and for every distance measure. When all the features are generated, machine learning classifiers are applied to test the accuracy of the model. Authors have used five machine learning state-of-the-art classifiers from the literature viz. Logistic Regression (LR), Support Vector Machine (SVM), Naïve Bayes (NB), Decision Tree (DT), and Random Forest (RF).

#### IV. RESULTS AND DISCUSSION

This section explains the experimental results carried out to evaluate the performance of the model. The proposed methodology is evaluated on five different state-of-the-art classifiers namely LR, SVM, NB, DT, and RF. Section A displays the performance matrix of the model in terms of Accuracy, Precision, Recall, and F1-Score based on the three different parameters viz. Jaccard distance, Euclidean distance, and Cosine similarity distance measures and contains the confusion matrix for the NB classifier. Section B explains the word clouds generated to show the words related to true information and false information from the URLs and Section C explains the analysis of misinformation detection.

##### A. Performance Matrix

The performance matrix is measured in terms of accuracy, precision, recall, and F1-score. Fig. 2 shows the accuracy of the proposed model based on 5 different classifiers. It was observed that NB outperformed all other models in terms of accuracy showing 98.7% accuracy whereas the decision tree classifier showed less accuracy compared to all other models showing an accuracy of 92.88%.

Fig. 3, Fig. 4 and Fig. 5 display the precision matrix, recall, and F1-score of the proposed model on various classifiers using three parameters viz. Jaccard Distance, Euclidean Distance, and Cosine Similarity measures. Table VI, Table VII and Table VIII display the performance of the distance measure technique used in terms of accuracy, precision, recall, and F1-Score per machine learning classifier. It is observed that the Jaccard Distance Measure showed maximum accuracy compared to other distance measures with maximum accuracy of 98.71% for the Naïve Bayes classifier whereas the Cosine similarity measure showed minimum accuracy of 88.19% with the Decision Tree classifier model. Euclidean Distance measure showed average accuracy in comparison with other distance measures.

Fig. 2. Performance Matrix in Terms of Accuracy (in Percentage).

Fig. 5. Performance Matrix in Terms of F1-score (in Percentage) of the Proposed Model.

Fig. 3. Performance Matrix in Terms of Precision (in Percentage) of the Proposed Model.

Fig. 4. Performance Matrix in Terms of Recall (in Percentage) of the Proposed Model.

TABLE VI. PERFORMANCE MATRIX OF JACCARD DISTANCE MEASURE (IN PERCENTAGE) OF THE PROPOSED MODEL

Jaccard Distance				
	Accuracy	Precision	Recall	F1-Score
LR	98.06%	99.78%	97.62%	98.69%
SVM	94.17%	99.31%	92.87%	95.98%
NB	98.71%	99.56%	98.70%	99.13%
DT	93.53%	99.76%	91.58%	95.50%
RF	98.22%	99.56%	98.06%	98.80%

TABLE VII. PERFORMANCE MATRIX OF EUCLIDEAN DISTANCE MEASURE (IN PERCENTAGE) OF THE PROPOSED MODEL

Euclidean Distance				
	Accuracy	Precision	Recall	F1-Score
LR	98.06%	99.78%	97.62%	98.69%
SVM	94.17%	99.31%	92.87%	95.98%
NB	98.71%	99.56%	98.70%	99.13%
DT	92.88%	99.76%	90.71%	95.02%
RF	97.90%	99.78%	97.41%	98.58%

TABLE VIII. PERFORMANCE MATRIX OF COSINE SIMILARITY MEASURE (IN PERCENTAGE) OF THE PROPOSED MODEL

Cosine Similarity				
	Accuracy	Precision	Recall	F1-Score
LR	98.06%	99.78%	97.62%	98.69%
SVM	94.17%	99.31%	92.87%	95.98%
NB	98.71%	99.56%	98.70%	99.13%
DT	88.19%	92.39%	91.79%	92.09%
RF	98.22%	99.78%	97.84%	98.80%

Fig. 6. Confusion Matrix for Naïve Bayes Classifier using Parameters as Euclidean Distance, Jaccard Distance & Cosine Similarity Measure.

Fig. 6 shows the confusion matrix for Naive Bayes classifier. It can be seen from the confusion matrix that 457 samples are correctly classified as true positive, whereas 153 samples are classified as true negative. False-positive and false-negative sample values are 2 and 6, respectively.

**B. Word Clouds**

Fig. 7 and Fig. 8 displays word clouds of URLs having misinformation and legitimate information respectively. It can be seen that the URLs having misinformation contain more negative words like death, false, etc. whereas URLs with true information contain more positive words like well, symptom, increase, etc. This shows that sentiment analysis can play a vital role in detecting misinformation.

Fig. 7. Word cloud for URLs having Misinformation.

Fig. 8. Word Cloud for URLs having True Information.

**C. Analysis of Misinformation Detected**

Fig. 9 displays the average percentage of misinformation and true information in the web URLs. It can be seen from Fig. 9 that for around 200 URLs the percentage of misinformation is high compared to true information and it is at a peak for URLs ranging from 200 to 300. Fig. 10 displays the average count of positive and negative words in the URLs classified as True. It is been observed that the average positive count of words is 71% in True URLs and the negative count is 29%. Fig. 11 displays the average count of positive and negative words in the URLs classified as False. It is been observed that the average negative count of words is 62% in False URLs and the positive count of words is 38%. Thus, the authors found that for URLs with misinformation the average count of negative words is more and positive words are less. Therefore, sentiment analysis is an important feature to detect misinformation in web URLs.

Fig. 9. A Graph showing the Average Percentage of Misinformation and true Information in URLs.

Fig. 10. A Graph showing the Average Percentage of Positive and Negative Counts in True URLs.

Fig. 11. A Graph Showing the Average Percentage of Positive and Negative Counts in False URLs.

## V. CONCLUSION AND FUTURE WORK

In this research, authors have proposed a model to detect and fact-check misinformation in the healthcare domain. The fact-checking of URLs using distance measures improves the performance of the model than standard techniques of manual fact-checking of data. It was observed that the sentimental features are crucial while detecting misinformation as more negative words is found in URLs containing misinformation compared to the URLs having true information. It was observed that NB outperformed all other models in terms of accuracy showing 98.7% accuracy whereas the decision tree classifier showed less accuracy compared to all other models showing an accuracy of 92.88%. Also, the Jaccard Distance measure was found to be the best in terms of accuracy compared to Euclidean distance and Cosine similarity measures. In the future, authors want to collect more URLs and observe the difference in the accuracy of the model. Also, the authors want to identify the spreaders of misinformation by keeping track of the percentage of misinformation containing in the text published by these authors.

**Abstract**—The application of artificial intelligence techniques in computer aided detection and diagnosis problems has been among the most promising areas with interest from the scientific community and healthcare industry. Recently, deep learning has become the prime tool for such application with many studies focusing on developing variants that optimize diagnostic performance. Despite the widely accepted success of this class of techniques in this application by the scientific community, it is not prudent to consider it as the only tool available for such purpose. In particular, statistical machine learning offers a variety of techniques that can also be applied at a much lower computational cost. Unfortunately, the results from both strategies cannot be directly compared due to the differences in experimental setups and datasets used in available research studies. Therefore, we focus in this study on this direct comparison using the same dataset and similar data preprocessing as the input to both. We compare statistical machine learning to deep learning in the context of computer-aided detection of breast cancer from mammographic images. The results are compared using diagnostic performance metrics and suggest that simpler statistical machine learning techniques may provide better performance with simpler architectures that allow explanation of results.

**Keywords**—Computer-aided detection; computer-aided diagnosis; statistical machine learning; deep learning

## I. INTRODUCTION

Breast cancer is the most frequently diagnosed cancer and accounts for a significant portion of the total cancer related deaths among women[1]. The early detection of cancer in general, and particularly in breast cancer, is crucial to patient survival. Therefore, periodic screening was recommended for women above a certain age or before that for those women with a family history of the disease. The primary imaging modality for such screening is x-ray mammography where two images in cranio-caudal and mediolateral oblique directions are taken and examined carefully by a radiologist for early signs of abnormalities including microcalcifications [2]. The resultant images in their digital form have very high resolution and quantization level (for example, 5k resolution is common at

12-16 bits of grayscale). As a result, the process for reading such images is tiring, lengthy, costly, and prone to errors. Moreover, the shortage of radiologists compounded by increase in volume of image data due to better awareness and introduction of 3D techniques such as tomosynthesis poses a challenge for healthcare services in this area. Therefore, computer-aided diagnosis is now pursued as a possible solution to this problem. Even though many such systems were proposed early on as applications of the growing artificial intelligent systems, the digital transition of radiology departments made the utilization of such assisting tools more readily available in many applications including mammography.

Computer-aided diagnosis (CAD) is generally defined as a diagnosis made by a radiologist who uses the output of a computer analysis of the images when making his/her interpretation. CAD systems can play different roles in the diagnostic process. For example, it can be used for as pre-screening where the CAD system is utilized as the first reader then the radiologist verifies such reading and makes the final diagnosis. Alternatively, concurrent reading of images between the radiologist and the CAD system, which in this case serves as a second independent reader. Also, another approach is to make the diagnosis interactively using the CAD system where the radiologist marks suspicious areas on image and uses analysis from the CAD system to confirm the likely diagnosis. Therefore, this approach improves diagnostic performance, reduces performance intra- and inter-observer variability of radiologists, improves radiologist productivity and hence serves as a mitigation of global shortage of radiologists.

The early CAD systems relied on statistical machine learning techniques (e.g., [3]), while most recent scientific studies targeting this field were overwhelmingly using deep learning techniques (e.g., [4] [5] [6]). This is a natural consequence of the usual technology hype cycle (sometimes called Gartner hype curve) of deep learning technologies where this area is within the peak of inflated expectations. In order to speed up the process of reaching the plateau of productivity of

\*Corresponding Author

such curve with its associated wide adoption of the technology, it is important to consider comparisons with earlier technologies in order to better assess potential and realize limitations.

In this study, we address the direct comparison of statistical machine learning and deep learning techniques in the context of computer-aided detection of breast cancer from mammographic images. The same dataset and similar data preprocessing are used as the input to several techniques that represent both categories. The details of all steps of implementation are provided to allow reproducibility of results and the performance is compared using statistical diagnostic performance metrics to allow objective comparison.

Performance evaluation rests at the heart of any machine learning model[7]. It is necessary in selecting the input features and it decides which model is appropriate for each data set. This is a fact that should be considered when we select an algorithm for cancer detection, classical or deep learning-based method, for a CAD system. Currently, there are a huge number of researches[5] [8] [9] that have utilized the deep learning approaches and recommending them as they have yielded higher accuracies, above 97%. However, a comparable accuracy, 96%, has been attained using the conventional machine learning paradigms as surveyed in [10]. Therefore, a comparison of deep learning techniques with the earlier artificial intelligence techniques based on statistical machine learning would provide a valuable insight in this regard. Unfortunately, there are no studies that targeted such direct comparison with common datasets and classification tasks and hence, addressing this comparison would be a useful addition to guide researchers in this field.

This paper is organized as follows. Section II includes the literature review. Section III gives detailed description about the data set employed in this work. The methodologies used in statistical machine learning models and deep learning techniques are presented in Section IV. Sections V and VI presents the results and discussion of both statistical and deep learning methods and the comparison between them. Finally, the conclusions in Section VII summarize this work and its significant results.

## II. RELATED WORK

Pretrained CNN models such as Alex net [11], VGG[12], and Googlenet[13] are the most popular pre-trained models for image classification. A survey of 83 research studies is presented by Abdelhafiz *et al.* [14] which demonstrate the significant results gained by CNN models in breast cancer detection and classification. They discuss the datasets used and all limitations and challenges that affect the results. They show the significant results in the latest research of breast cancer classification and emphasize on the significant effects of image preprocessing techniques. They also highlighted the effects of some important customized parameters such as validation techniques, activation function, and learning rates. They found that many studies depend on pretrained models, data augmentation, batch normalization, and dropout techniques to improve their results. Shen *et al.* [15] designed CAD system based on VGG and ResNet pretrained CNN networks. The datasets used to train their machine were DDSM and INbreast

datasets. They designed batch classifier and whole image classifier to detect and classify breast cancer. The networks have been adapted by adjusting the number of layers, learning rate and number of epochs. Different techniques such as batch normalization, and data augmentation have been employed to improve the model. The achieved results surpassed the results of previous studies. Also, the CAD system that proposed by Al-antari *et al.*[16] based on Deep belief network (DBN) to automatically detect and classify breast cancer. They used two techniques for mass diagnosis, the whole mass ROIs, and Randomly extracted ROI with size 32x32, then they classify the detected masses using their proposed DBN system. The results of their proposed system outperformed other conventional classifiers. Al-masni *et al.* [17] CAD system based on CNN model that is called You Only Look Once (YOLO) technique [18] for automatic detection and classification of breast cancer. In their system, DDSM dataset is used to train and test their system, in addition to the augmented data produced by different techniques such as rotation, translation, and scaling to avoid overfitting. They also utilized number of preprocessing techniques to eliminate irrelevant characteristics of the mammograms. Their CAD system achieved 99.7% for mass detection and 97% for classification. Several studies show that the pretrained CNN models such as Resnet [19], Alexnet [20], [21] and GoogleNet [30] demonstrate higher results using unaugmented patches and more enhanced results with augmented ones. Different CNN models [22][23] show different detection and classification accuracies and performance depending on the application, techniques and datasets used. On other hand, the state-of-the-art methods in building CAD system have been compared to the deep learning-based methods in few studies such as the work done in [24] that have evaluated some of the classical methods against the CNN based system. However, the complexity of the incredible performance of the pretrained CNN networks has not been yet fairly assessed and compared to the simple conventional machine learning methods.

## III. DATA PREPARATION

In The data used in this work were obtained from the popular Mammography Image Analysis Society (MIAS) database [25]. This database was prepared from x-ray films carefully selected from the United Kingdom National Breast Screening Program and digitized with to a resolution of 50 microns using a device with a linear optical density mapping range from 0 to 3.2 and quantization of 8-bits per pixel. Then, the images were reduced to 200-micron resolution and clipped/padded to maintain size of all images at 1024x1024 pixels in the mini-MIAS version of this database, which was used in this study [26]. The database contains left and right breast images for 161 patients with a total of 322 images. The images represent samples from normal, benign and malignant cases with 208, 63 and 51 images respectively. The database provided the ground truth diagnoses for all images and exact locations of abnormalities that may be present within each image given as the center and radius of the surrounding circle for each lesion. A square region of interest (ROI) of size 32x32 was selected inside the lesion. The size of the ROI was selected this way to ensure adequate statistical representation of the lesion while keeping the size as small as possible to

subsequently allow better lesion localization ability for the developed system [3]. A database of 144 ROIs was built with equal number of normal and abnormal regions (72 each). The abnormal regions were selected from the available lesions with 41 benign and 31 malignant samples such that each of them was obtained from a different case to avoid bias in testing. Also, the samples represented the various abnormality subclasses having lesion or cluster sizes that are large enough to contain the selected ROI size. The database of labelled ROIs was then used as the input to both statistical machine learning and deep learning techniques.

#### IV. METHODS

##### A. Statistical Machine Learning Methods

In this study, several statistical machine learning techniques representing the spectrum of methods in this area are implemented and their parameters are optimized to allow proper performance comparison to be conducted. The general block diagram for all statistical machine learning systems is shown in Fig. 1.

Fig. 1. Block Diagram of the Statistical Machine Learning System.

The learning system in this class of techniques is based on multiple-fold cross-validation to obtain reliable results and minimize the problem of overfitting. In particular, the data for normal and abnormal cases are randomly divided into training

and validation sets where the validation set is equal to the number of cases divided by the number of folds and the rest are assigned to the training set. In our system, the number of folds was selected to be 5 such that in each fold, 14 images from each of the normal and abnormal data are used for validation while 58 images from each are used to train the classifier. This is repeated 5 times (same as number of folds) and the results from all folds are averaged together to provide the overall system performance.

A critical part of all statistical machine learning systems is feature extraction. This is the main difference between statistical machine learning and deep learning techniques where features are implicitly learned from the data in the training process. Here, a set of 175 statistical textural features were calculated including 25 first-order features (e.g., mean, standard deviation, percentiles) [27] and 150 higher-order statistical textural features utilizing different textural analysis methods with different attributes including features from the gray-level co-occurrence matrix (GLCM) (also known as spatial gray level dependence method or SGLDM) [28], neighborhood gray tone difference matrix (NGTDM) [29] [30], spatial frequency-based method (SFM) [31], texture energy transform [32][33], fractal analysis [34], and Fourier power spectrum [35].

In order to select the best features that show statistically significant changes between normal and abnormal cases, two-sample t-test was performed between the normal and abnormal training samples in the first fold of the cross-validation process. This avoids any bias from including the validation samples in this process directly in the first fold or indirectly through their inclusion in other folds. The significance level was set at a p-value of 0.05 whereby features showing p-values lower than that are indicated as good features, while the others are deemed indiscriminate and discarded in subsequent steps. This resulted in a total of 43 selected features with 17 first-order and 26 higher-order features.

The next step in the processing pipeline is responsible for dimensionality reduction to minimize the feature space by combining features into major directions that are orthogonal to each other and spanning the directions of most variance in the data. This is done using principal component analysis (PCA) where the features are reduced to only 7 combined features or principal components that explain 95% of the variance of the data. This helps remove redundancies from multiple correlated features. Since the subsequent classification step may include techniques that rely on distance measurements, the dimensionality reduction may not always be needed. In fact, the small amount of variance that was not explained by the output of PCA may contribute to the accuracy of the classification. Therefore, the optimization of different classifiers was allowed to enable or disable such dimensionality reduction in its search for the best performance for each classifier.

The statistical machine learning system of this study included the implementation of six different families of traditional classifiers that included parametric and nonparametric classification methods. Such methods are decision trees, discriminant analysis, ensemble, k-nearest

neighbor (KNN), naïve Bayes, and support vector machines (SVM) [36]. The different parameters and variants for each classifier were optimized to reach the best performance using 5-fold cross-validation to obtain reliable estimation of the performance. The performance was measured using the accuracy (Acc), sensitivity (Sens), specificity (Spec), positive predictive value (PPV), and negative predictive value (NPV) [36]. While the accuracy is an important performance metric since it gives the percentage of correct outcomes to the total number of cases, it does not differentiate between false-positive and false-negative errors. This is problematic in the context of a computer-aided detection system where a false-negative diagnosis could have much more severe consequences than a false-positive one. The sensitivity metric addresses that where it gives the percentage of abnormal cases that were correctly diagnosed. On the other hand, the specificity gives the percentage of normal cases that were correctly diagnosed. Together they give the complete picture that allows an observer to compare different systems. For example, if two systems have the same accuracy, a system with a better sensitivity is preferred in a computer-aided detection system. The two other metrics of PPV and NPV address the post examination questions of the reliability of the results. For example, given a particular positive diagnosis outcome from a classifier, a question can be posed as how reliable such result is. Such metrics depend on disease prevalence in the patient population, unlike the sensitivity and specificity metrics.

Given the higher risk of false-negative outcomes of classification, a custom cost function that makes the cost of such errors twice that of false-positives was included in the optimization process. That is, for each classifier, the optimization process that searches through different parameter values and classifier variants is also allowed to add such custom cost function to compare the outcomes of different selections and choose the technique that minimizes this new cost function rather than the one with uniform cost for all types of error.

The results from different classifiers are reported as the cross-validation performance metrics for the best variant of optimal parameters for each classifier family. Also, to investigate the effects of dimensionality reduction and custom cost function, the best results are reported for three cases including using no dimensionality reduction or custom cost function, using custom cost function, and using both dimensionality reduction and custom cost function.

### B. Deep Learning Methods

Three deep learning networks were considered in this study. These networks are AlexNet [11][37], GoogLeNet [38], and VGG-16 [12] networks that represent different architectures with different levels of complexity as represented by the number of parameters (weights and biases). In particular, the numbers of parameters for these networks are approximately 61 million for AlexNet, 7 million for GoogLeNet, and 138 million for VGG-16. Even with the least complex of them, the huge number of parameters suggests that it is not possible to properly train such networks with the limited data set available in this study. In fact, it is difficult to collect sufficiently large data sets for such purpose for most

medical diagnosis problems given the difficulty of such collection in a standardized manner, privacy issues that prevent access without consent, as well as the severe data imbalance usually encountered in medical data with much less abnormal cases than normal cases. Therefore, two strategies are commonly utilized to mitigate this problem. The first is to use data augmentation whereby each image in the original dataset is used to generate multiple images that include the same diagnostic characteristics as the original [39]. The idea behind this approach is that changing the orientation of the abnormality in the image does not affect the diagnosis by a doctor. Therefore, using rotated or flipped versions of the image would present the network with different images that still represent the diagnostic classification of the original one. In this work, 8-fold data augmentation is used whereby each ROI in the dataset is augmented using flipping (left-right and up-down), rotation (90 and 270 degrees), image matrix transposition, in addition to their combinations of flipping left-right of 90 degrees rotated images and flipping left-right of up-down flipped images. This augmentation results in increasing the size of the dataset to 1152 samples representing 576 normal and 576 abnormal ROIs. An illustration of such augmentation is shown in Fig. 2.

Although the size of the dataset is significantly larger after augmentation, this size is still much smaller than the number of network parameters, which means that it cannot be used as is for training the network without compromising the performance due to the certain overfitting problem. Therefore, the second strategy relies on transfer learning to start from pre-trained networks and fine tune such networks to address the classification task at hand. The idea behind this strategy is that the early stages of deep learning networks are trained to extract low-level image features, which is common and similar between different image classification problems, while the rest of the network are intended to learn the specific classes for each application. Therefore, keeping such early stages intact and replacing only the application-specific final stages would make the training requirements much less demanding without sacrificing the overall performance. This is the essence of network-based transfer learning [40]. In this study, this strategy is applied using the selected networks pre-trained using ImageNet database with more than 14 million images [41]. A block diagram of the transfer learning process is shown in Fig. 3.

Fig. 2. Illustration of Augmentation Applied to a Sample Abnormal ROI. The Original Image is shown at the Top Left Corner with its Seven Orthogonal Transformations.

Fig. 3. Illustration of Network-based Transfer Learning.

Given that the input layer must not be altered as a part of the transfer learning strategy, the s ROIs in the dataset were resized to the respective size of each network (227×227 for AlexNet and 224×224 for the others) using bilinear interpolation with an anti-aliasing filter to meet network requirements and maintain the quality of the images and keep them free of aliasing artifacts. All networks require color images rather than grayscale images. This was dealt with by using the same grayscale image for each of the three color components of the network input. Then, the available resized dataset was divided into 3 independent sets at the beginning of the process with 60% designated as training, 20% for validation and 20% for testing. The training data are used to train the parameters of the trainable part of the network to minimize the error in the diagnostic task classification outcome using a suitable optimization technique. On the other hand, the validation data can be used to optimize the hyperparameters of the network including the optimization technique selection and parameters to optimize the performance metrics. Therefore, given that they are both utilized, even in different ways, in the optimization process, it is important to keep an independent set for testing to avoid bias and to be able to assess the presence of overfitting.

Fig. 4. Block Diagram of the Deep Learning System.

The process of estimating the optimal parameters for each network to give the best performance is a challenging optimization problem because of its high dimensionality and non-convex objective function. Therefore, stochastic optimization techniques are conventionally utilized. In this study, stochastic gradient descent with momentum (SGDM) optimizer is used with a learning rate: 0.0001, momentum term factor of 0.9,  $L_2$ -Regularization: 0.0005, and gradient threshold method of  $L_2$ -norm. The selected mini-batch size was 16 images, and the maximum number of training epochs was set to 100. Such settings were selected by observing validation results through experimentation and were used for all networks in order to allow direct comparison of their results and computational costs. A diagram representing the deep learning systems used is shown in Fig. 4.

## V. RESULTS

The statistical machine learning and deep learning systems were implemented on an academic license of Matlab 2020b (Mathworks, Inc.) with Statistics and Machine Learning and Deep Learning toolboxes. The computer system uses a quad-core Intel® Core™ i7-6700HQ CPU running at 2.60GHz and 16 GB of RAM and NVIDIA GeForce GTX 950M graphics card with 4 GB of memory and CUDA-supported graphics processing units (GPUs). The operating system is Windows 10 Home Edition (version 20H2). Due to the differences in machine configurations and software development environments, the reported computational time measurements of the conducted experiments may be specific to the machine and environment used but the findings derived from their relative values can still be useful to compare different techniques.

The results for the statistical machine learning techniques are presented in Table I. As can be observed, the best accuracy of 99.3% was obtained using a support vector machine classifier with a linear kernel with no feature standardization, uniform cost function, and no PCA feature dimensionality reduction. The second-best accuracy of 98.6% was obtained from a KNN classifier with a Minkowski distance metric, an exponent of 3, a number of neighbors (K) of 5, an inverse distance weight, standardized features, custom cost function that penalizes false negatives double that of false positives, and no PCA feature dimensionality reduction. From the point of view of computer-aided detection, the most important performance metric is the sensitivity. The best sensitivity of 100% was obtained from multiple classifiers including both classifiers with best accuracy, in addition to the other variants of the support vector machine classifier with custom cost function and PCA feature dimensionality reduction. The best specificity of 98.6%, best positive predictive value of 98.6% and best negative predictive value of 100% were also obtained by the same support vector machine classifier variant that provided the best accuracy and sensitivity results. This indicates that this particular classifier has the best overall performance among statistical classification techniques.

The results for the deep learning techniques from pretrained networks using transfer learning are shown in Table II. The results from AlexNet and GoogLeNet networks showed similar results that are consistent in all performance metrics with a

value of 98.3% each. On the other hand, the best results were obtained from the VGG-16 network with an accuracy of 98.7%, sensitivity of 99.1%, specificity of 98.3%, positive predictive value of 98.3%, and a negative predictive value of 99.1%. The training hyperparameters for all networks were the same where the optimization algorithm was stochastic gradient descent with momentum with a rate of 0.0001 and L2-regularization of 0.0005, and 8x data augmentation (total of

1152 images) divided as 60% for training, 20% for validation and 20 for testing. The training was done only to the fully-connected layers of all networks whereby the convolutional layers were kept the same as a part of the transfer learning strategy used. The training was performed on GPU with 100 training epochs and a mini-batch size of 16 with a total time of 25 minutes for AlexNet, 53 minutes for GoogLeNet, and 279 minutes for VGG-16 networks.

TABLE II. PERFORMANCE METRICS OF DEEP LEARNING TECHNIQUES\*

Network	Training Time (minutes)	Accuracy	Sensitivity	Specificity	PPV	NPV
AlexNet	25	98.26%	98.26%	98.26%	98.26%	98.26%
GoogLeNet	53	98.26%	98.26%	98.26%	98.26%	98.26%
VGG-16	279	98.70%	99.13%	98.26%	98.28%	99.12%

\*Training options: Stochastic Gradient Descent with Momentum (SGDM) optimizer, Mini-Batch Size: 16, Maximum number of training epochs: 100, Learning rate: 0.0001, Data shuffling: every epoch, Validation frequency: 10 steps, Validation Patience: infinity, L2-Regularization: 0.0005, Execution environment: GPU.

In order to better visualize the results and allow direct comparison between all techniques from both statistical and deep learning approaches, the results from all methods are shown in a graphical form in Fig. 5 and Fig. 6. In Fig. 5, the accuracy for all methods is shown as a square marker that varies in color for different variants. On the other hand, to distinguish the sensitivity and specificity values on the plot, the sensitivity is marked with an upward-pointing triangle, while the specificity is marked as a downward-pointing triangle. This provides an easy visual comparison of the accuracy, sensitivity and specificity values from all techniques. This also allows

direct visualization of those techniques where specificity values are higher than those of the sensitivity. In Fig. 6, a similar strategy was used to mark the results of positive predictive values as circles, while those of negative predictive values as asterisks. It is clear that deep learning techniques provide better results than several statistical learning techniques, but they are comparable to several other techniques. Furthermore, the results indicate that deep learning techniques are outperformed by a support vector machine classifier variant in all performance metrics and by several classifiers when the sensitivity metric is emphasized.

Fig. 5. Comparison of the Results of all Techniques with respect to Accuracy, Sensitivity, and Specificity (or Pretest) Performance Metrics.

Fig. 6. Comparison of the Results of all Techniques with respect to Positive Predictive Value and Negative Predictive Value (or Post-Test) Performance Metrics.

## VI. DISCUSSION

The results suggest that the performance of statistical classification and deep learning methods are both generally acceptable with performance metrics mostly well above 90%. The best result was obtained with a statistical classification technique, which is clearly a simpler, faster alternative to the deep learning methods. While all statistical learning techniques took less than a minute to train, the computational requirements of training deep learning networks were much more demanding with training times up to 279 minutes even though transfer learning was used to keep the convolutional weights the same. Even though deep learning has been heavily emphasized in most recent research studies in the field of computer-aided diagnosis, the results of this work provide an objective comparison that suggests that simpler traditional approaches may yield comparable if not better results.

The results of all techniques showed sensitivity and specificity values that are generally close as they should be in clinical practice. Given that the data used were balanced with equal numbers of normal and abnormal cases, the accuracy values are the average of those of the sensitivity and specificity where the accuracy is exactly in the middle. It should be noted that the results for several classifiers showed higher values for specificity than sensitivity such as all variants of discriminant analysis, one variant of KNN, and two variants of Naïve Bayes classifiers. Even though some of these classifiers provide good overall accuracy, they are not suitable for computer-aided detection especially in screening studies.

The results of statistical classifier variants indicate that effect of using a custom cost function varied across different variants, but the sensitivity was improved or remained the same in all variants after applying such customization. This was particularly evident in the KNN classifier where the application of such customization provided significant improvement becoming the second-best statistical classifier and showing better accuracy than two deep learning networks with a sensitivity that is better than all of them. Therefore, it is suggested that this customization is considered in experimental evaluation of different statistical classification techniques. On the other hand, the results of using PCA for dimensionality reduction along with custom cost function showed a desirable effect of making the sensitivity values go above those of the specificity for the same classifier. This is evident in discriminant analysis and Naïve Bayes classifiers in particular. This allows the use of such classifier variants in computer-aided detection rather than discarding them as suggested above. Therefore, it is suggested that such dimensionality reduction is considered in such cases when sensitivity is lower than specificity. It should be noted that the explicability of the results of the system given that the features used and their weights are explicitly defined in the eigenvectors (principal components) of PCA outcomes.

As a part of the ongoing efforts to develop regulatory standards to govern the artificial intelligence solutions, an emphasis on explicability, or the ability to explain the outcomes, is a requirement that clinical systems must be able to

meet. This is clearly an advantage for such traditional methods where simpler equations can be used to do that. On the other hand, this is largely not possible with deep learning methods due to the complexity of the networks structure and its huge number of parameters that make it difficult to understand the decision-making process inside the network and also render such networks prone to such issues as data gaps and overfitting. This is particularly evident in medical systems because of the much less data sizes available and also the data imbalance where several abnormal classes can be significantly underrepresented in the training and testing processes.

The yielded results in this research using the AlexNet have surpassed the recent results achieved in the literature. The overall accuracy of the AlexNet, GoogLeNet on the MIAS Dataset achieved in [42], and [9] was 95.70%, 91.58% respectively. And as depicted in Table I, the conventional machine learning approached has yielded an extraordinary result that is greater than the results achieved the pretrained CNN networks. It also surpasses the current results achieved in the literature. The retrieved accuracy in the work done in [43] using SVM, and KNN on the MIAS database was 87.69%, and 88.54% respectively. The higher performance of the state-of-art classification methods retrieved here in this work has been achieved by the employed image augmentation paradigm. The data augmentation has helped in increasing the size of the training and testing data. The augmented images have been shuffled before being submitted to the classification models. In addition, the data has been split into three totally independent subsets for training, validation, and testing subset to minimize the problem of overfitting. For statistical machine learning methods, the use of K-fold cross-validation explained in the Methods section also addresses the overfitting problem. The variations across different experiments were found to be less than 1% indicating that the proposed framework does not suffer from overfitting.

## VII. CONCLUSION

In this study, direct comparison between the performances of statistical machine learning to deep learning in the context of computer-aided detection of breast cancer from mammographic images was performed. The results are compared using diagnostic performance metrics and suggest that simpler statistical machine learning techniques may provide better performance with simpler architectures that require much fewer demanding computations while allowing explanation of results. In particular, a support vector machine classifier variant provided a better performance overall, while other statistical machine learning techniques such as KNN classifier variants provided comparable results to those of three widely used deep learning networks. The obtained accuracies above 98% using both classical and deep learning models surpassed reported results in the literature. Furthermore, the present study suggests that statistical machine learning based methods might be closer to meeting regulatory approval requirements for clinical use. This also emphasizes the importance of addressing such issues as data gaps and explicability of outcomes in deep learning techniques to boost their transition to clinical use.

**Abstract**—In this paper, we show how to classify Arabic document images using a convolutional neural network, which is one of the most common supervised deep learning algorithms. The main goal of using deep learning is its ability to automatically extract useful features from images, which eliminates the need for a manual feature extraction process. Convolutional neural networks can extract features from images through a convolution process involving various filters. We collected a variety of Arabic document images from various sources and passed them into a convolutional neural network classifier. We adopt a VGG16 pre-trained network trained on ImageNet to classify the dataset of four classes as handwritten, historical, printed, and signboard. For the document image classification, we used VGG16 convolutional layers, ran the dataset through them, and then trained a classifier on top of it. We extract features by fixing the pre-trained network's convolutional layers, then adding the fully connected layers and training them on the dataset. We update the network with the addition of dropout by adding after each max-pooling layer and to the fourteen and the seventeenth layers which are the fully connected layers. The proposed approach achieved a classification accuracy of 92%.

**Keywords**—Arabic document; document classification; deep learning; convolutional neural network (CNN); pre-trained network

## I. INTRODUCTION

Documents classification is traditionally considered an important task and the first step in several document image processing pipelines, including document retrieval, information extraction, and text recognition. The initial classification of documents into various predefined classes not only makes various document processing activities easier but also saves time. It's also possible to enhance document processing systems' overall efficiency [1]. A wide range of classification problems can be solved using the deep learning technique. The ability and flexibility for changeability in the deep learning model with a wide spectrum of datasets make the deep learning algorithm the most important method for the classification task [2]. Several approaches for document image classification have been proposed. There are three approaches to consider. The first category makes use of the document images' layout/structural similarity. Extracting the basic document components and then using them for classification is time-consuming. The creation of local and/or global image descriptors is the focus of the second category of work. These descriptors are then used to categorize documents. Extracting

local and global features takes a long time. Finally, the third category of methods employs CNN to automatically learn and extract features from document images, which are then categorized. With CNN's improved success in recent years, it's become easier to distinguish images without having to extract hand-crafted elements. It's the most commonly used neural network model for image classification [6]. Deep learning is preferred in image processing applications because it produces fast and significant results. Several problems in image processing and understanding have been solved using deep learning methods, including document image classification, handwriting recognition, and blind image quality assessment. Previously, various shallow-structure learning methods and handcrafted features were used to solve these issues [7].

We use supervised deep learning algorithms to identify Arabic document images in this paper. Because Arabic is a very rich language with complicated morphology, it has a very different and challenging structure than other languages. Hundreds of millions of people utilize it, and its internet presence is continually expanding. Furthermore, Arabic has several distinct characteristics that render automated handling and understanding of the Arabic language difficult and interesting [3]. As a result, it's critical to create an Arabic text classifier to deal with this difficult language. The importance of document classification stems from the vast number of Arabic document images distributed through many sources from different classes, the majority of which contain a significant amount of important knowledge. Manually classifying Arabic document images takes a long time and is extremely difficult. However, it has become possible to classify Arabic document images into their appropriate classes without requiring human intervention. This paper aims to use deep learning to introduce a model for classifying Arabic documents. The proposed deep learning model is trained using several different Arabic document image classes. It can differentiate between different classes, so it operates as multiple classifiers. The model can then be used to classify an Arabic document image that has been supplied after training. This paper is organized as follows. The current section provides a quick overview of the paper's topic and structure. The second section discusses related document classification studies. The third section discusses image recognition using deep learning. The CNN classification system is defined briefly in the fourth section. The fifth section summarizes the evaluation and its results. The final section summarizes the paper and suggests future work.

## II. RELATED WORK

The proliferation and subsequent usefulness of deep learning techniques in a wide range of machine learning tasks have been extensively discussed in the literature over the last decade. Deep neural networks have shown outstanding results in a variety of fields, including document image classification [3].

The classification of document images for the Arabic language is a subject that has received little attention.

Abdulmunim et al. [4] proposed a header-words-based printed Arabic document image classification and retrieval system based on a decision tree classifier enhanced by the bagging technique. This document's Arabic header words are detected by the proposed system. In addition, sets of discriminative features are extracted from detected header words to correctly classify them to the appropriate class. Several structural and statistical features specific to Arabic scripts can be observed. On the official printed Arabic document dataset, the experimental tests score 97.35 % for precision. This dataset contains images of various types of official printed Arabic documents collected from a variety of official websites, including ministries, universities, government departments, and other official states. The dataset includes letters, records, books, forms, notices, administrative instructions, and other official Arabic documents.

Al-Khurabi et al. [5] applied this work to Arabic documents, proposing an Arabic document Image Classification system based on Artificial Neural Networks on a set of 120 captured document images types such as text, geometric, and photographic images. This system was divided into two parts, the first of which was image processing. The second part uses an Artificial Neural Network to classify document images based on the contents into the appropriate class. It received an overall recognition rate of 86%.

On the other hand, many works in the literature in various languages, including English, have addressed the topic of document image classification.

In the field of document classification, Afzal et al. [1] used the deep Convolutional Neural Networks model (CNN). They created a network (except for the last fully connected layer) using weights from AlexNet, which was trained on images from ImageNet, in this study. The proposed network has five convolutional layers, which give the fully connected layer a lot more features for classification. On the Tobacco-3428 Legislation dataset, with 100 samples per class used for training and validation, the proposed method achieved an accuracy of 77.6%.

Kölsch et al. [6] propose a two-stage approach that combines automated deep CNN feature learning with efficient training using Extreme Learning Machines (ELM). As compared to a previous Convolutional Neural Network (CNN) method in [1] accuracy was achieved at 83.24% on the Tobacco-3428 Legislation dataset, resulting in a relative error reduction of 25%.

It's important to highlight the following crucial differences between the proposed approach and previous approaches: Though deep CNN-based approaches have made considerable progress in recent years and are now the current state-of-the-art, training these networks takes a long time. For the classification of Arabic document images, we propose a convolutional neural network supervised deep learning algorithm. To identify the dataset of four classes as handwritten, historical, typed, and signboard, we use VGG16 pertained weights that were trained on ImageNet. We used a convolutional neural network classifier to classify different classes of Arabic document images obtained from various sources. We used VGG16 convolutional layers, ran the dataset through convolutional layers, and then trained a classifier on top of that for Arabic document image classification. We extract features from the pre-trained network's convolutional layers by freezing them, then adding the fully connected layers and training them on the dataset. We added dropout after each max-pooling layer and to the fourteenth and seventeenth layers, which are the fully connected layers, to update the network. The proposed approach had a classification rate of 92%.

TABLE I. COMPARISON BETWEEN THE PROPOSED APPROACH AND PREVIOUS APPROACHES

Authors	Approach	dataset	Language of Dataset	Classification rate
Abdulmunim et al. [4]	Decision Tree Classifier and Bagging Technique to improve the performance of classification.	Official Arabic printed document images were collected from different authorized websites.	Document images in the Arabic language.	97.35%
al-Khurabi et al. [5]	The proposed system used Artificial Neural Network(NN)	Set of 120 captured document images types.	Document images in the Arabic language.	86%
Afzal et al. [1]	The proposed CNN model used pertained weights from a network (AlexNet)	Tobacco-3428 Legislation	Document images in the English language.	77.6%
Kölsch et al. [6]	The proposed CNN model used pertained weights from a network (AlexNet) and Extreme Learning Machines (ELM)s which provide real-time training	Tobacco-3428 Legislation dataset	Document images in the English language.	83.24%
The proposed work	The proposed approach is based on a convolutional neural network supervised deep learning algorithm. the CNN model uses pertained weights from a network (VGG16) with the addition of the dropout layer applied after each VGG block.	Arabic document images were collected from different sources.	Document images in the Arabic language.	92%

It should be noted that the pre-training in the proposed method did not previously apply to the classification of Arabic document images. The [1] is the first attempt to classify document images using a pre-trained model. Table I compares the proposed approach to previous methods in terms of the method used, type and language of datasets used in the experiment, and the accuracy achieved.

### III. DEEP LEARNING FOR DOCUMENT IMAGE PROCESSING

DL has opened the door to a new era of AI applications where is a subset of machine learning. It depends on artificial neural networks and representation learning as it is capable of imitating the way the human brain operates by creating patterns and processing data [8][9].

#### A. Deep Learning for Document Classification

DL contains multilayered neural networks. Its commonly applied to document and image processing. Recurrent Neural Networks (RNN) and convolutional neural networks are two of the most common supervised deep learning architectures (CNN). A recurrent Neural Network (RNN) is suitable for modeling sequential data such as texts, audio, and time series. It has been widely used in machine translation, speech recognition. A convolutional neural network (CNN) is suitable for modeling static data such as images. It has been proved to be a very powerful tool in image processing. Indeed, in the areas of computer vision such as handwriting recognition, image classification. It has become a much better tool compared to previous tools [10], [11].

We are employing deep learning because of its ability to learn useful features from raw data, which makes it extremely useful when working with unstructured data. We realize that one of the most supervised deep learning techniques is the Convolutional Neural Network (CNN). CNN is widely employed in image processing because it performs in image classification and recognition and has significantly improved the efficiency of a number of machine learning tasks. It has since developed into a powerful and widely used deep learning model. The CNN architecture enables it to extract features from images automatically, eliminating the need for manual feature extraction. Different filters are used in the convolutional layer to convolve through images to create complex features that are then passed on to the next layer. This process continues until it reaches the last feature. This makes CNN highly accurate for image classification.

Convolutional Neural Networks (CNN) have shown their efficacy in the classification of document images. In the field of document image classification, Convolutional Neural Networks (CNN) are efficient. Different classification techniques are compared by Lecun et al. [27]. The results reveal that CNN outperformed all other methods when it came to dealing with the range of 2D shapes. As a result, we consider CNN as the model for the challenging tasks of Arabic document image classification [12], [13].

Our contribution is to use CNN to classify Arabic document images and extract information. The proposed model aims to understand CNN and apply it to Arabic document image recognition filters, a CNN extracts feature maps from 2D images.

#### B. Convolution Neural Network (CNN) Architecture

We use CNN as a model for categorizing Arabic document images. With minimal preprocessing, we built a Convolutional Neural Network to recognize Arabic scripts directly from pixel images. A CNN's central building block is the convolutional layer. The parameters of the layer are made up of a collection of learnable filters (or kernels) for recognizing features (like edges) that span the whole depth of the input image. Each filter convolves over the width and height of the input image during the forward transfer. Produce a features map by computing the dot product of the kernel and the input field. As a result, the network gains an understanding of the filters. When the filter detects a particular type of feature at a specific spatial location in the input, it activates. The function maps are then fed into a pooling layer, where identical convolutions are added one patch at a time. CNN also has a completely connected layer that categorizes performance into one of four classes. Almost all CNN architectures follow the same general design principles: sequentially adding convolutional layers to the input, regular spatial downsampling (Max pooling), and increasing the number of feature maps. Layers that are fully connected, activation, and loss functions are also provided. As a result, before introducing the proposed model, we'll quickly go through these layers. The first layer where it can remove features from images is the convolutional layer. Convolution is the process of reducing the size of an image while maintaining the relationship between pixels by filtering it with a smaller pixel filter. Filter (kernel) is simply a weighted matrix of values that has been trained to detect unique features. The basic concept behind CNNs is to spatially convolve the kernel on an input image to see if the function it's supposed to detect is present. Convolution is performed by computing the kernel's dot product with the input field and then generating a features map [14]. The convolution operation is shown in Fig. 1.

After each convolution process, the ReLU (Rectified-Linear Unit) was used. It replaces all negative pixel values in the function map with zero and is added per pixel. The rectifier function is used to increase non-linearity in the CNN and convert the linear model we train into a network with more expressive capabilities, which aids in faster and more efficient training [17], [18].

Fig. 1. Convolution Operation [13].

The pooling layer is usually inserted after each convolutional layer in a CNN, and it entails selecting a pooling operation, similar to a filter applied to feature maps, to reduce the representation's spatial size. This layer reduces the computational complexity of each map by minimizing its dimensionality while preserving important data. Overfitting can also be mitigated by pooling layers. The function map typically takes up more space than the pooling or filtering operation. As a result, we pick the maximum, average, or total values within these pixels as a pooling size to reduce the number of parameters. Fig. 2 depicts the maximum pooling

operation. In CNN, the max-pooling approach is widely used, which involves placing a 2x2 matrix on the feature map and choosing the largest value in that box. The 2x2 matrix is passed around the function map from left to right, picking the largest value in each pass. These values are then combined to form a pooled feature map, which is a new matrix. It preserves the image's main features while reducing its scale. We'll use dropout to prevent overfitting, which happens when the proposed model is unable to predict new data labels. The dropout layer reduces the random set of activations in that layer to zero as data passes through it, effectively eliminating them from the layer [9].

Fig. 2. Max Pooling Operation [14].

A fully connected layer takes the outputs of the convolution and pooling processes and converts them into labels with categories. Convolution and pooling output is flattened into a single vector of values, each representing a probability that defines a specific feature of the class. In the end, we can create a fully connected network to classify the dataset [14]. The fully connected layer is shown in Fig. 3.

Fig. 3. Fully Connected Layer [14].

Fig. 4 shows the overview look of the proposed convolutional neural network. We can divide the model into seven sequences of layers.

Fig. 4. General Architecture of the Proposed CNN Model.

### C. CNN and Feature Extraction

In image processing, we can extract features from images using a variety of convolutional filters in the convolutional layer. Canny filters, for example, can detect edges. Canny normally takes a grayscale image as input and outputs an image that shows where strength discontinuities are located (i.e. edges). Filters aren't described in CNN. During the training phase, the value of each filter is learned. CNN can extract additional meaning from images that humans and human-designed filters might not be able to find. We can get more abstract and in-depth information from a CNN by stacking layers of convolutions on top of each other. Convolution may also be capable of performing hierarchical

feature learning, which is thought to be how to brains identify objects. CNN is very effective in image recognition because of its ability to discover abstract and complex features [15], [16].

## IV. CNN CLASSIFICATION SYSTEM

The general architecture of the proposed Convolutional Neural Network (CNN) model is designed for the recognition of Arabic document images, as shown in Fig. 4. We need to do some pre-processing on the document images first, such as resizing them because CNN uses a fixed-size input image So, resize the document images that we'll be experimenting with.

The first step in the proposed approach is to prepare the data. We need to set up training and testing data and reshape it into the right size before we can create the network. The original dataset folder had four subfolders, each containing four different types of Arabic document images. Arabic handwritten documents, Arabic printed documents, Arabic historical documents, and Arabic signboard images are the four main classes. We divided the original dataset folder into training and validation dataset folders using the split-folder python package, with the same four classes in each folder. For the training dataset, we used 80% of document images and 30% for the validation dataset. The training dataset was used to train the model, and the validation dataset was used to fine-tune it.

### A. Data pre-processing and Data Augmentation

We'll use Keras, an open-source python library for developing and testing deep learning models, to preprocess the document images. It includes the ImageDataGenerator class, which defines the image data preparation and augmentation configuration and is a powerful tool for image augmentation and feeding these images into the proposed model. All data in the Arabic handwritten document folder will be automatically labeled as Arabic handwritten documents by the ImageDataGenerator. It's the same for the rest of the folders. Data is effectively ready to be transferred to the neural network in this way. The names of the classes will be created automatically from the names of the sub-directories, so we won't have to identify them explicitly. The dataset directory structure is shown in Fig. 5.

Image augmentation, on the other hand, helps to minimize overfitting and improves model generalization by generating more training data based on existing training data. It takes place in memory, and the generators make it simple to set up data for training and testing. It has a lot of resizing, rotating, zooming, and flipping options. Before providing images as input to a deep learning model for training or evaluation, the pixel values in the images must be scaled. The ImageDataGenerator class will rescale pixel values from 0-255 to the preferred range of 0-1 for neural network models [19], [20].

### B. Dataset and CNN Training

We have a dataset directory where we will store all of the document image data, as shown in Fig. 5. We'll have subdirectories for each class under each dataset directory, where the actual image files will be stored.

Fig. 5. Dataset Directory Structure.

The training dataset will be stored in the dataset/train/ directory. During training, we may also have a dataset /validate/ for a validation dataset. The document images were categorized into four classes in the train folder. For example, the handwritten document subfolder contains all document images related to the Arabic handwritten document, and so on.

Data is ready to be fed into the model after the required pre-processing. Below, we'll go over the information in greater depth.

Transfer learning is a deep learning technique that involves training a neural network model on a problem that is close to the one being solved. The initial blocks of CNN in the computer vision domain extract low-level features such as edges, shapes, corners, and so on. We transfer the information (features, weights) from a pre-trained network and use them to identify new images since we know that initial blocks use more computational resources. Since the final blocks in CNN are more focused on image data, we freeze the top layers and use the bottom layers as needed. For feature extraction, we use all of the convolution layers. The completely connected and dense layer is then replaced with the layers to identify the document images as (handwritten, historical, printed, and signboard).

We'll use the VGG16 architecture, which is based on ImageNet, a research project that aims to build a broad database of images and labels. There are over 14 million images in this dataset, divided into 1000 categories. VGG16 model architecture for image classification consists of 13 convolutional layers with 3\*3 filters, max-pooling, two fully connected layers, and one SoftMax classifier based on the ImageNet database. The feature extractor, which is made up of VGG blocks, and the classifier, which is made up of fully connected layers and the output layer [17], [22], [23], are the two main components of VGG16. We can use the model's feature extraction section and add a new classifier section that is specific to our Arabic document images. Specifically, during training, we may keep the weights of all convolutional layers set and only train new fully connected layers that will learn to understand the features extracted from the model and create a document image classification.

We'll load the dataset and classes, and then begin the training process by learning ImageNet's prior weights. The network was also updated with the addition of dropout. In this case, a 30% dropout is applied after each max-pooling layer, as well as to the fourteenth and seventeenth layers, which are

fully connected. We also changed the final layers of the network to identify the classes. Fig. 6 depicts a summary of the model's proposed architecture. One of the reasons we chose the VGG16 model as the base classifier model for the classification of Arabic documents since it has been shown in [3] to be one of the most effective models for dealing with document classification tasks.

### C. CNN Implementation

Fig. 7 shows that there are five blocks in total: the first two have two convolutional layers, followed by ReLU and max-pooling layers, while the last three have three convolutional layers, followed by ReLU and max-pooling layers. The first and second convolutional layers are made up of 64 feature kernel filters, each of which is 3\*3 in size. The dimensions of the input image (RGB image with depth 3) changed to 500x750x64 as it moved through the first and second convolutional layers. The output is then sent to the max-pooling layer.

The third and fourth convolutional layers are made up of 128 feature kernel filters that are 3\*3 in size. The output will be reduced to 250x375x128 after these two layers are accompanied by a max-pooling layer. Convolutional layers with kernel size 3\*3 make up the fifth, sixth, and seventh layers. 256 function maps are used for all three. A max-pooling layer comes after these layers.

Two sets of convolutional layers, each with a kernel size of 3\*3, are used in the eighth to thirteenth layers. 512 kernel filters are used in each series of convolutional layers. The max-pooling layer comes after these two. The fourteenth through seventeenth layers are fully connected hidden layers with 256, 64, 32, and 8 units, respectively, followed by a four-unit SoftMax output layer (eighth layer). The dropout layer is added after each max-pooling layer, as well as the fourteenth and seventeenth fully connected layers, to prevent overfitting. The actual number of classes is represented by the eighth sheet.

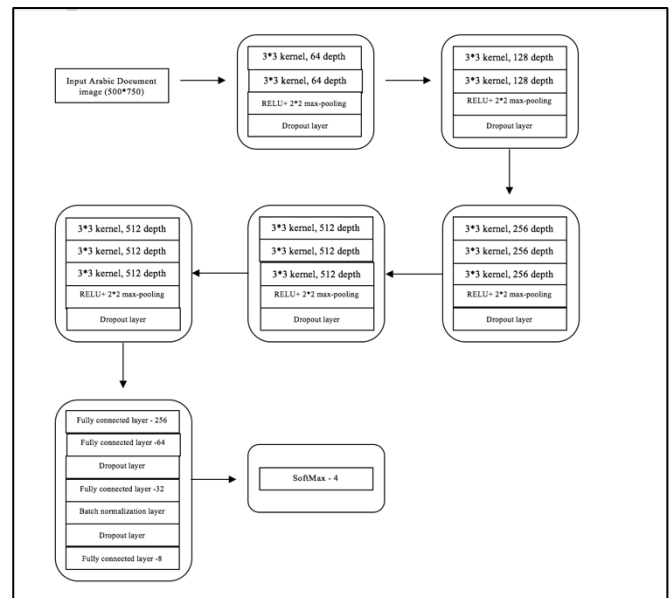

Fig. 6. The Proposed Architecture of the Model.

In this way, as in Fig. 7, CNN transforms the pixel values in the original document image to the final class, layer by layer. While some layers contain parameters, some don't. The convolution and fully connected layers, in particular, perform transformations that are dependent on both the activations in the input volume and the parameters (the weights and biases of the neurons). The Relu/pooling layers, on the other hand, will follow a fixed function. In the convolutional and fully connected layers, we train the parameters. The trained model will be prepared to recognize the document image in the test data. As a result, we can classify document images into four main categories: handwritten, historical, printed, and signboard. Training and testing the model is the third step. Finding kernels in convolution layers and weights in fully connected layers to reduce the gaps between output predictions and given actual classes on a training dataset is the method of training a network. The backpropagation algorithm is a method for training neural networks that involve the use of a loss function and a gradient descent optimization algorithm. A loss function calculates a model's performance under specific kernels and weights using forwarding propagation on a training dataset, and learnable parameters, including kernels and weights, are modified according to the loss value using optimization algorithms which include backpropagation and gradient descent [21]. The adaptive learning rate (Adam) optimization algorithm was used to construct the model and perform random gradient descent training. We used the Adam optimization algorithm to change the weight of the relation between neurons so that the loss is reduced to a minimum or stops after several epochs. Adam is defined as one of the most popular optimization algorithms for optimizing neural networks in deep learning, based on an adaptive learning rate algorithm [25], [26]. Finally, we can start CNN training by providing the training data, the built model, and the current batch of data. Only the data specified for training play a significant role in reducing CNN error. For both the forward and backward passes, we feed the training data into the network. The validation data is only used to see how the CNN reacts to new data that is close to it. The validation data isn't used to train the network. After that, we save the CNN that has been trained and prepare for the testing process. Finally, we can evaluate the model using the testing data.

Fig. 7. CNN Implementation Steps.

### V. EVALUATION AND RESULT

The proposed document collection contains 2373 documents regarding Arabic script, all of which are divided into four classes: handwritten, historical, printed, and signboard in Arabic script. These documents were collected from various sources. We must evaluate the model's performance and estimate the model prediction accuracy, which is how effective the model is at predicting the outcome of a new test dataset that has not been used to train the model, by comparing the

expected result values to the actual result values. We use a Confusion Matrix, Accuracy, Recall, Precision, and F1- Score as the most common classification evaluation metrics. In the handwritten document image class, for example, we feed the handwritten document image into the trained model before the model prediction. We compare the prediction to the correct class after the model predicts that this is a handwritten document. As compared to the class of "handwritten document," the prediction is accurate. However, if it predicts that this image is a printed document, the comparison to the correct class will be incorrect. This process is repeated for each of the document images in the test data. We'll eventually get a count of how many test records the model correctly predicted and how many it incorrectly predicted. The Confusion Matrix is a tabular architecture of prediction results that includes counts of test records correctly and incorrectly predicted by the model. It provides information about the types of errors produced by the classifier. Table II displays a confusion matrix of four classes and 20 handwritten document images that have been misclassified as printed documents. The correct classifications are represented by the yellow cells on the diagonal, while the incorrect classifications are represented by the white cells. As can be shown, this provides a much more detailed view of the proposed model's efficiency.

Table III shows the classification accuracy, recall, precision, and f1-score are all factors to consider. The following Table III will clarify everything, shows the classification accuracy, precision, recall, and f1-score for each document type in the dataset. Accuracy is a common metric used by many researchers to evaluate the efficacy of classifiers. It is defined as the percentage of correct predictions for test data. It is easy to calculate by dividing the number of correct predictions by the total number of predictions. The proposed model demonstrates that it is capable of accurately recognizing various documents. Using this dataset to run the model, we were able to achieve a 92% accuracy rate.

Precision is expressed as a percentage of (true positives) correctly predicted out of the total number of positive results predicted by the model. The recall is calculated by dividing the number of positive results correctly classified by the total number of positive examples that should have been found.

TABLE II. CONFUSION MATRIX

Truth		Arabic handwritten document	Arabic historical document	Arabic printed document	Arabic signboard image
Predicted	Arabic handwritten document	136	0	0	0
	Arabic historical document	0	134	0	0
	Arabic printed document	20	0	109	0
	Arabic signboard image	0	3	13	62

TABLE III. CLASSIFICATION REPORT

Classification report				
	Precision	Recall	F1-score	Support
Arabic handwritten document	87%	100%	93%	136
Arabic historical document	98%	100%	99%	134
Arabic printed document	89%	84%	87%	129
Arabic signboard image	100%	79%	89%	78
Accuracy			92%	477
Macro avg	94%	91%	92%	477
Weighted avg	93%	92%	92%	477

The f1-score is computed by applying the harmonic mean of precision and recall [23], [24]. All the metrics formulae are shown in the equation (1), (2), (3), and (4).

$$Accuracy (acc) = \frac{TP+TN}{TP+FP+TN+FN} \quad (1)$$

$$Recall (R) = \frac{TP}{TP+FN} \quad (2)$$

$$Precision (P) = \frac{TP}{TP+FP} \quad (3)$$

$$F - Measure = \frac{2 \times P \times R}{P+R} \quad (4)$$

The classification report, shown in Table III, provides an overview of the proposed model's performance. The handwritten class results are shown in the third row. The 'support' column indicates how many class handwritten document images were included in the test data. The model performance for the historical class is shown in the fourth row. Tables II and III show how we can describe precision and recall for each of the classes. The precision for the handwritten class, for example, is calculated as the number of correctly predicted handwritten documents (136) out of all predicted handwritten documents (136+20=156), which amounts to 136/156=87%. The recall for the handwritten document, on the other hand, is the number of correctly predicted handwritten documents (136) divided by the number of real handwritten documents (136+0+0=136), which amounts to 136/136=100%. We can measure the precision and recall for the other three classes in the same way. On the other hand, the f1-score for a handwritten document is 93% because it is harmonic between accuracy and recall (2\*0.87\*1.00)/ (.87+1.00). The three classes are all computed in the same way. The proposed model has proven its effectiveness in classifying Arabic document images by achieving higher accuracy of 92%, as shown in Table III.

## VI. CONCLUSION AND FUTURE WORK

The proposed Arabic document collection includes 2373 documents, which are divided into four categories: handwritten, historical, printed, and signboard in Arabic script. These documents were obtained from different sources, the majority of which contain a significant amount of knowledge. As a result, document classification is crucial. It takes a long

time and is extremely difficult to manually identify Arabic document images. However, it is now possible to categorize Arabic document images into their appropriate classes. In this paper, we develop a system for classifying Arabic document images into four classes: handwritten, historical, typed, and signboard. The CNN supervised deep learning algorithm was used to create the proposed approach. The pre-trained model VGG16, which was trained on ImageNet, was used in the CNN model. We used the model's feature extraction part and added a new classifier part that is specific to the Arabic document images. Specifically, we may keep the weights of all convolutional layers fixed throughout training and only train new fully connected layers that will learn to understand the features extracted from the model and classify document images. We changed the network by adding dropout after each max-pooling layer and to the fourteenth and seventeenth fully connected layers. The proposed model has proven its effectiveness in classifying Arabic document images by achieving higher accuracy of 92%. We plan to work on big data Arabic document images in the future, and the final data is to apply the same techniques to keyword searches in deep learning classified documents.

## ACKNOWLEDGMENT

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. {UJ-20-018-DR}. The authors, therefore, acknowledge with thanks the University of Jeddah technical and financial support.

# Comparative Analysis of Data Mining Algorithms for Cancer Gene Expression Data

Preeti Thareja, Rajender Singh Chhillar  
Department of Computer Science and Applications  
Maharshi Dayanand University, Rohtak, India

**Abstract**—Cancer is amongst the most challenging disorders to diagnose nowadays, and experts are still struggling to detect it on early stage. Gene selection is significant for identifying cancer-causing different parameters. The two deadliest cancers namely, colorectal cancer and breast malignant, is found in male and female, respectively. This study aims at predicting the cancer at an early stage with the help of cancer bioinformatics. According to the complexity of illness metabolic rates, signaling, and interaction, cancer bioinformatics is among strategies to focus bioinformatics technologies like data mining in cancer detection. The goal of the proposed study is to make a comparison between support vector machine, random forest, decision tree, artificial neural network, and logistic regression for the prediction of cancer malignant gene expression data. For analyzing data against algorithms, WEKA is used. The findings show that smart computational data mining techniques could be used to detect cancer recurrence in patients. Finally, the strategies that yielded the best results were identified.

**Keywords**—Colorectal cancer; breast cancer; bioinformatics; data mining; WEKA; machine learning

## I. INTRODUCTION

Non - communicable diseases (NCDs) responsible for 71 percent of all fatalities worldwide. Non-communicable diseases (NCDs) are illnesses which are never spread by pathogens. They are long-term illnesses with a sluggish course that are caused by a mix of biological, physiologic, ecological, and behavioral variables. Malignant is a non-communicable disorder in wherein some tissues grow out of control and extend to many other areas of the organism. Malignant is another name used for cancer that can begin practically at any place in the trillions of cells that make up the human body. Cancer is among the top contributors of death rate in India, accounting for 63 percent of all fatalities (9 percent). According to the National Cancer Registry Programme Report 2020, males will have a tumor incidence of 679,421 in 2020 and 763,575 in 2025, while women will have a tumor incidence of 712,758 in 2020 and 806,218 in 2025 [1]. As per research, oral, lung, and colorectal are the most frequent malignancies among men while breast and cervix uteri malignancies are most frequent amongst women. Cancer researchers require access to selected data from multiple sources in order to make advances. In medicine, data analysis has a remarkable ability to uncover hidden patterns in disease prediction [2,3].

As an emerging technique, cancer bioinformatics is one of the most important and valuable ways to facilities biochemical engineering for medical advancements, as well as improving

the outcomes of cancer victims. Bioinformatics is focused on building an infrastructure to assist researchers in storing, analyzing, integrating, accessing, and visualizing large biological datasets and supporting information [4]. Bioinformatics is a computing platform that focuses on extracting information from biology content. It entails the creation of analysis tools and techniques to obtain, store, retrieve, manipulate, model databases, visualization, and estimation. As a result, custom analytics tools have become extremely important in bioinformatics, and they help to speed up the research process [5]. Sequencing and annotating an individual's entire collection of DNAs, for instance, are two common tasks in biotechnology. Led to the creation of machine learning techniques, bioinformatics models had to be manually configured, which is extremely challenging for problems like proteomics. Massive amounts of health data are gathered and made accessible to medical researchers because of the usage of computers employing automated technologies. As a matter of fact, Knowledge Discovery in Databases, which involves machine learning techniques, has now become a successful learning tool for health investigators to locate and manipulate correlations among a huge set of samples allowing them to foresee disease outcomes using specific instances stored in databases [6].

This study discusses recent research methodologies as well as an examination of predictive approaches, with a focus on classifying co-regulated genes according to their biological function. The work, basically, aims to find the foremost learning models for predicting cancer malignant gene expression data through study of related research work. Further, this study finds out the outperforming learning model by comparing them on certain performance metrics. The work has been divided into several sections. Section 2 talks about the recent advances in the field of cancer bioinformatics and most commonly used techniques for predicting cancer data. Section 3 presents the methodology employed in this research to analyze various algorithms on cancer datasets, as well as the measures used for evaluating their performances. Section 4 discusses the findings, which is preceded by the conclusion in Section 5.

## II. RELATED RESEARCH WORK

This section will provide an overview of many cancers gene expression data-related research publications from a variety of databases, including IEEE Xplore, Google Scholar, Scopus, and Springer. Mostly, the publications are from year 2019-2021. This will aid in the discovery of techniques that have recently been used in the cancer detection. A list of

prominent algorithms and performance metrics used in publications are produced in Tables I and II, respectively. These techniques will also be used to analyze performance.

Keerthika et al. [7] used information-mining strategy for proposing the cancer prediction model. This algorithm helps to find the amount of breast malignant that will occur in the near future. The main objective of this strategy is to safeguard users while also making it cheaper for them to use. Physical injury prevention and diagnosis will be aided by a prediction model. This discovery aids in detecting a person's risk of cancer at such an initial phase of treatment.

Changhee et al. [8] developed a better prognosis model based on machine learning named Survival Quilts. This model is being developed on the 10-year data of US prostate cancer patients to predict their mortality rate. Survival Quilts was compared with 9 prognosis models that are in clinical use and it showed a better decision curve.

T. Jayasankar et al. [9] used OGHO for optimal feature selection and kernel SVM (Support Vector Machine) in conjunction with gray wolf optimization algorithm to predict the breast cancer on the Wisconsin Breast Cancer dataset from UCI.

Heydari et al. [10] took a survey of leading data mining used for cancer detection in early phases. The author compared the top techniques of data mining and listed their advantages and disadvantages.

Byra et al. [11] proposed 2 CNN (convolutional neural network) techniques for breast malignant prediction. This method combines transfer learning with pre-trained CNN to produce excellent results of prediction.

M.A.Fahami et al. [12] clustered the colon cancer patients into 2 important categories and as a result they found out top 20 genes that are effective in both the categories.

Alireza et al. [13] applied novel and traditional data mining methods viz, linear vector quantization (LVQ) neural network (NN), multi-layer perceptron (MLP), Bayesian NN, Decision Tree (DT-C5.0), kernel principal component analysis with support vector machine (KPCA-SVM), and random forest (RF). The author clearly demonstrates the impact of machine learning technology on breast cancer recur classification. In compared to other approaches, the C5.0 and the KPCA-SVM have demonstrated to perform better in terms of accuracy. C5.0, on the other hand, had the finest sensitivity result.

Mostafa et al. [14] examined the results of different classification algorithms for identifying Colorectal Cancer (CRC), namely, J-48, Bayesian NN, RF, and MLP. All methods were found to be suitable and capable of providing reasonable results. J-48, on the other hand, performed best across the board.

Yanke et al. [15] mined 7 colorectal cancer related datasets using their new technique that combined NB (Naïve Bayes), RF and DT. After analysis the final result are optimized using an appropriate optimization technique. It was found that the proposed algorithm is superior than the SVM. This helps in better discovery of the genuine possibility of colorectal cancer

target genes, and provides suggestions for its medical trials and promoting gene extraction.

Md. Rejaul et al. [16] created a technique for detecting the danger of stomach cancer beforehand. To acquire the feature score in a range of 0 to 1, the authors employed 5 distinct features extraction strategies along with ranker algorithms. The average rating was then used to provide a one exact score of each attribute. Then, apply predictive apriori algorithm to find the data's hidden pattern. The experiment had 300 patients, 150 of them were sick and the remaining 150 were not. Out of the 32 risk variables, they found 18 major risk factors for stomach cancer.

Ahmed et al. [17] proposed a Radial Basis Function NN (RBFNN) for diagnosing chronic diseases like breast cancer. The author has also compared his proposed method with other state of the art methods and found out that proposed method accuracy is the highest among all. Also, the author compared his method with learning classifier like RF, SVM, NB, ANN and many others. The result showed that his method is more accurate than other predefined classifiers.

Hooda et al. [18] employed a prediction model Bagoost to predict the breast cancer risk. The framework showed the accuracy of around 98%. The author states that it has better accuracy as compared to SVM, RF and adaboost.

Shanjida et al. [19] compared NB, k-nearest neighbor (kNN) and J48 data mining techniques on nine different types of cancer datasets. It was found that all the three algorithms were performing well but kNN outperforms the other two by a difference of around 0.4 percent in accuracy.

TABLE I. LIST OF ALGORITHMS USED IN RELATED RESEARCH WORK

Data Mining Techniques	References	Count
SVM	[9], [13], [15], [16], [18]	5
ANN	[11], [13], [14], [16]	4
NB	[13]-[16]	4

Decision Curve	[8]	1

Ray et al. [20] explored different classification methods (Gaussian NB, kNN, DT, RF) for detecting breast cancer involving both numeric and image datasets. It was found that the accuracy of RF was better in both numeric and image datasets.

Harikumar et al. [21] presented model that uses two machine learning (ML) techniques to categorize Breast Cancer (BC), viz. DT and kNN algorithms. Following feature selection with principal component analysis (PCA), these two techniques are tested on the BC dataset. The typical performance measures like accuracy, specificity, sensitivity, precision and Matthew's correlation are used to compare them. The findings show that the kNN classifier outperforms the DT classifier in the BC classification.

### III. METHODOLOGY

The mathematical aspects of the problem are presented in this section of the paper. It all begins by outlining the key features of each of the data mining algorithms applied, with an emphasis on the description of the adjustable hyper-parameters. Fig. 1 highlights the methodology of this paper.

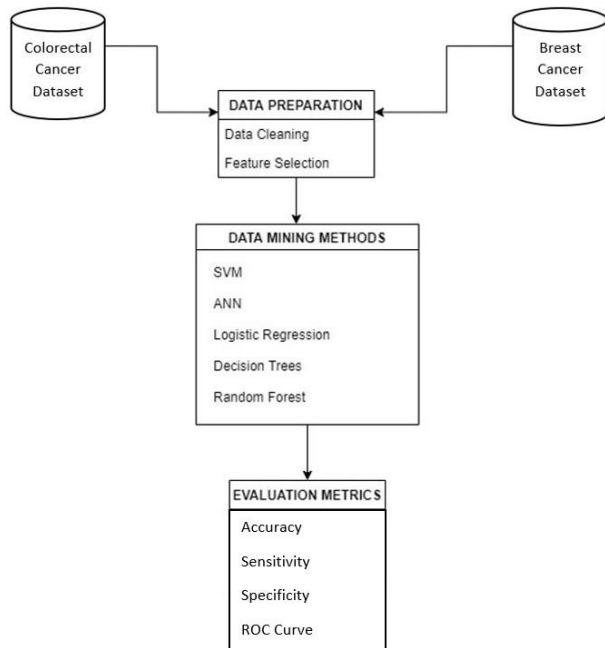

Fig. 1. Methodology for Cancer Gene Expression Data Prediction

#### A. Data Understanding and Preparation

The information was gathered from a public genomic database Gene Expression Omnibus (GEO) [22]. Two gene expressions namely, GSE45827 (Breast Cancer) and GSE41328(Colorectal Cancer). These are microarray datasets. Microarray data analysis is one of the most significant advances in statistical data and biology in the recent two decades. Microarray data may be examined using a number of methods and technologies. This section outlines a typical strategy for processing microarray data with Weka. The two most common cancers, Colorectal and Breast, will be studied here. The dataset for colorectal cancer contains 22284 attributes to be classified into four classes adenoma, carcinoma,

metastasis and normal. The dataset for breast cancer contains 54676 attributes to be classified into six classes basal, HER, cell line, normal, luminal A and luminal B. Table III lists some properties of datasets.

TABLE III. PROPERTIES OF DATASETS

Properties	Colorectal Cancer Dataset	Breast Cancer Dataset
Number of Attributes	22284	54676
Number of Instances	55	151
Missing Values	No	No
Attribute Data Type	Numeric	Numeric
Target Attribute	Class	Class

#### B. Data Mining Methods

This section discusses a brief introduction of the selected data mining techniques to be applied on the selected dataset. The motive behind selecting these techniques is that they are widely used methods for analyzing bioinformatics dataset in state-of-the-art techniques.

1) SVM: SVM stands for Support Vector Machine and is a guided technique in data mining that may be used for regression and classification. SVMs are based on the concept of determining the optimal decision boundary for dividing a sample into two groups. SVM method discovers the points from both classes that are nearest to the boundary, which are called as support vectors. The separation seen between boundary and the support vectors is termed as margin. The main objective is to increase this margin. The optimum hyperplane is the one for which the margin is the greatest. As a result, SVM seeks to create a decision boundary with as much split into two different classes as feasible. The SVM method is depicted in Fig. 2.

Fig. 2. SVM Method.

2) ANN: An Artificial Neural Network (ANN) is a system built on neurons that is motivated by biology neuron for the creation of artificial brains. It is built to evaluate and interpret data in the same way as beings do. Since more information becomes accessible, the algorithm may self-learn and provide superior outcomes. The inputs will be pushed into an aggregate of layers by an algorithm. A loss function must be used to measure the network's efficiency. The network may use the loss function to figure out which direction it wants to enforce to acquire the knowledge, as shown in Fig. 3. With the aid of an optimization, the net intends to promote its

knowledge. For predictive analytics, ANN is hardly applied. The reason behind this is that ANN tend to over-fit the correlation in most instances. In most situations, ANN is employed when something that happened in the past is replicated almost identically in the same way.

Fig. 3. ANN Method.

3) *Logistic regression*: Logistic Regression (LR) is analytical tool that is guided. This is a parametric regression models, meaning they employ numerical methods to make forecasts. The categorization issues are solved using logistic regression. The output is discrete value. The linear parameters are fitted to the sigmoid curve using logistic regression, as depicted in Fig. 4. Maximum likelihood estimation is the technique used to devise the loss function.

Fig. 4. LR Method.

4) *Decision trees*: A decision tree (DT) is a flowchart that aids in the decision-making process or displays statistical probabilities. A probable option, consequence, or response is represented by each node of the DT, as shown in Fig. 5. The tree's farthest branch reflects the outcomes of a particular choice route. DTs are a non-parametric ensemble learning approach. The aim is to understand basic rule base from extracted features to construct a system that anticipates the performance of the model. DTs are a prominent technique in neural networks and are widely used in business analytics to identify the best method for achieving a goal.

Fig. 5. DT Method.

5) *Random forest*: Random forest (RF) is a supervised learning algorithm that is commonly used to for classification and regression. It creates tree structure from several samples, using "majority vote" for classification and "average" for regression. RF collects data at random, creates a tree structure, and averages the results. It does not rely on any formulae. To create a RF, three important steps are there to follow. Firstly, randomly select slice of the whole dataset set for training particular trees separately. This is known as Bootstrapping or Sampling with Replacement. If these particular trees lack in connection, this RF Ensemble Learning performs well. Secondly, picking arbitrary features to examine at every node to accomplish connection. Lastly, Hundreds of times these steps are repeated to create a huge forest with a diverse range of trees. This variation is what distinguishes a RF from a single DT, as can be seen from Fig. 6.

Fig. 6. RF Method.

C. Performance Metrics

In terms of performance, each prediction could be one of four kinds: True Positive, True Negative, False Positive, or False Negative. These entries are a part of confusion matrix which tells how well the classifier has performed. True Positive test is expected to be positive like saying the person is predicted to get sick but the label is really positive in terms of saying the person will get the sickness in actual. True Negative test is anticipated to be negative like saying the person is not predicted to get sick and the label is also predicted to be negative in terms of saying the person will not get the sickness in actual. False Positive occurs when a test is anticipated to be positive like saying the person is predicted to get sick) but the label is really negative in terms of saying the person will not get sick in actual. The test is “falsely” forecasted as positive in this scenario. False Negative test is expected to be negative like saying the person is predicted to not get sick but the label is really positive in terms of saying the person will get sick in actual. The test is “falsely” forecasted as negative in this situation. These values will help in determining the model’s accuracy, sensitivity, specificity, and receiver operating characteristic curve.

1) *Accuracy*: The number of properly categorised points (forecasts) divided by the total range of forecasts is Accuracy. Its value varies from 0 to 1. Accuracy is basically measured as shown in equation 1.

$$Acc = \frac{True\ Positive + True\ Negative}{True\ Positive + True\ Negative + False\ Positive + False\ Negative} \quad (1)$$

2) *Sensitivity*: Among all of the algorithms, the one with the higher sensitivity should be picked. Sensitivity determines what percentage of true positives was accurately recognised as depicted in equation 2.

$$Sensitivity = \frac{True\ Positive}{True\ Negative + False\ Negative} \quad (2)$$

3) *Specificity*: The goal of specificity is to determine what percentage of real negatives were properly recognised. How many of the genuine negative cases were identified as such is the job performed by specificity. Specificity is calculated using equation 3.

$$Specificity = \frac{True\ Negative}{False\ Positive + True\ Negative} \quad (3)$$

4) *Receiver operating characteristic*: The trade-off between sensitivity and specificity is depicted by the ROC curve. Classifiers with curves that are closer to the top-left side perform better, as can be seen in Fig. 7. A random classifier is anticipated to give values that are falling diagonally mostly as baseline. The test becomes less accurate when the curve approaches the ROC space's 45° diagonally.

Fig. 7. ROC Curve.

D. *K-fold Cross Validation*

When there isn't enough data to utilize other more efficient approaches like the three - way division of training, validating and testing, then cross-validation is commonly used in deep learning to improve prediction performance. Initially dataset is scrambled such that the sequence of the inputs and outputs is totally arbitrary. This step is performed to ensure that our inputs are not skewed in any manner. The dataset then is divided into k equal portions. In this analysis, stratified 3-fold cross-validation is used. When cross-validation is used with the stratified sampling approach, the training and test sets contain the same fraction of the interested feature as the original dataset. When this is done with the class label, the cross-validation score is a close estimate of the generalization error.

E. *Software Used*

Weka – Waikato Environment for Knowledge Analysis is a machine learning package created by the University of Waikato in New Zealand [23]. The software is built in the Java programming language. It comes with a graphical interface and a variety of visualization tools and techniques for large - scale data processing. Data pre-processing, grouping, categorization, regressing, visualization, and dimensionality reduction are just a few of the common analysis methods that Weka offers. Weka v3.8.5 is used for the experiments on 11th Gen Intel® Core™

i5 @ 2.40 GHz with 8 GB RAM, windows 10 and 64-bit operating system.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

This research is intended to classify the selected datasets according to the class labels. The datasets are normalized and processed to reduce the unwanted features. Then, the data is passed through stratified 3-fold cross validation to separate it for training and testing purpose. The comparison of the two datasets, Colorectal and Breast, is done by applying algorithms, namely SVM, ANN, LR, DT and RF. The basis of comparison are the metrics, namely, Accuracy, Sensitivity, Specificity and Execution Time. Table IV shows the results of the performance metrics of Colorectal Cancer dataset and Table V shows the results of the performance metrics of Breast Cancer dataset.

The results for the algorithms with comparison on performance metrics is also depicted through graphs as shown in Fig. 8 and 9, respectively.

TABLE IV. PERFORMANCE METRICS OF ALGORITHMS AGAINST COLORECTAL CANCER DATASET

Algorithms	Performance Metrics			
	Accuracy	Sensitivity	Specificity	ROC Curve
SVM	0.709	0.793	0.709	0.977
ANN	<u>0.945</u>	<u>0.946</u>	<u>0.945</u>	<u>0.997</u>
LR	0.891	0.901	0.891	0.960
DT	0.691	0.693	0.691	0.723
RF	0.873	0.874	0.873	0.963

TABLE V. PERFORMANCE METRICS OF ALGORITHMS AGAINST BREAST CANCER DATASET

Algorithms	Performance Metrics			
	Accuracy	Sensitivity	Specificity	ROC Curve
SVM	<u>0.947</u>	0.948	<u>0.947</u>	0.984
ANN	0.583	NA	0.583	0.876
LR	<u>0.947</u>	<u>0.950</u>	<u>0.947</u>	<u>0.992</u>
DT	0.808	0.805	0.808	0.882
RF	0.934	0.934	0.934	0.990

Fig. 8. Comparison of Performance Metrics against Colorectal Cancer Dataset.

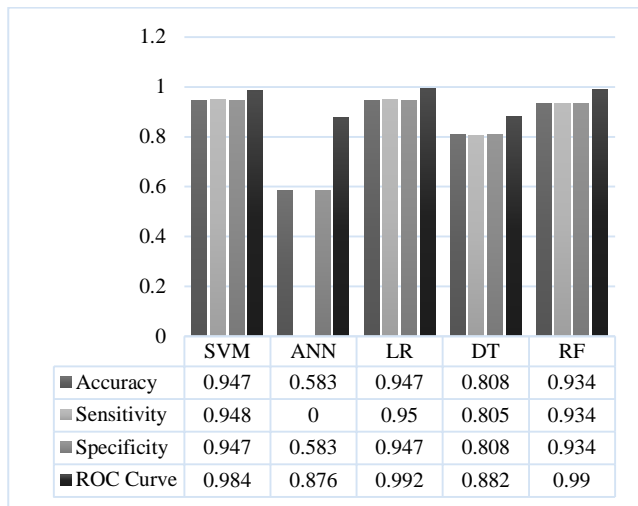

Fig. 9. Comparison of Performance Metrics against Breast Cancer Dataset.

As per the results of applying algorithms on Colorectal dataset, ANN shows the highest accuracy of around 95% with same level of sensitivity and specificity. The lowest level of accuracy, sensitivity and specificity is shown by decision trees. According to the results of applying algorithms on Breast dataset, SVM and logistic regression beats all others in accuracy of around 95%.

## V. CONCLUSION

This work is carried to provide a brief outline of the state of art techniques SVM, ANN, Logistic Regression, Decision Tree and Random Forest applied on datasets for classification. These are applied on two most common problems prevailing in India, namely, Colorectal Cancer and Breast Cancer, in men and women, respectively. The experiment is carried out in Weka and the results are compared on certain metrics like accuracy, sensitivity, specificity and ROC. The experimental test shows an accuracy of 94.5% in colorectal cancer data with ANN outperforms all other algorithms. Similarly, an accuracy of 94.7% is found in breast malignant data with SVM and logistic regression beating all other algorithms. The input dataset has a significant impact on the limitations of an algorithm analysis. Like in breast dataset the ANN model is unable to recollect the results of sensitivity; it shows a question mark for it. This work can be improved by taking more folds in cross validation and also implying hybrid models for better analysis and results. Further, it can be compared for other datasets that include cancer patients of varying types of cancer.

**Abstract**—The rapid expansion of communication and computational technology provides us the opportunity to deal with the bulk nature of dynamic data. The classical computing style is not much effective for such mission-critical data analysis and processing. Therefore, cloud computing is become popular for addressing and dealing with data. Cloud computing involves a large computational and network infrastructure that requires a significant amount of power and generates carbon footprints (CO<sub>2</sub>). In this context, we can minimize the cloud's energy consumption by controlling and switching off ideal machines. Therefore, in this paper, we propose a proactive virtual machine (VM) scheduling technique that can deal with frequent migration of VMs and minimize the energy consumption of the cloud using unsupervised learning techniques. The main objective of the proposed work is to reduce the energy consumption of cloud datacenters through effective utilization of cloud resources by predicting the future demand of resources. In this context four different clustering algorithms, namely K-Means, SOM (Self Organizing Map), FCM (Fuzzy C Means), and K-Mediod are used to develop the proposed proactive VM scheduling and find which type of clustering algorithm is best suitable for reducing the energy uses through proactive VM scheduling. This predictive load-aware VM scheduling technique is evaluated and simulated using the Cloud-Sim simulator. In order to demonstrate the effectiveness of the proposed scheduling technique, the workload trace of 29 days released by Google in 2019 is used. The experimental outcomes are summarized in different performance matrices, such as the energy consumed and the average processing time. Finally, by concluding the efforts made, we also suggest future research directions.

**Keywords**—Cloud computing; CO<sub>2</sub>; proactive scheduling; unsupervised learning; clustering; energy; prediction; cloud-sim; performance assessment

## I. INTRODUCTION

“Go Green” is the key theme of the proposed investigation. However, a significant amount of digital data is generated and consumed every day. This demand for computation leads to develop such infrastructure that can deal with such a huge load. One such technology is cloud computing which provides computational resources on demand. The proposed work is keenly focused on offering the techniques that improve the

VM workload scheduling to reduce environmental loss and preserve the energy for achieving green computing.

Green is the way of life and it teaches us how to live a sustainable and luxurious life. To support the new generation types of equipment and technologies, we depend on cloud computing to deal with bulky data. Cloud servers are an effective solution because a rich amount of data is generated using these devices and processing such big data. The cloud can scale the computational ability according to demand. On the other hand, to perform computation, we need a huge power supply and cooling system that increases the power consumption and emission of harmful gases. Thus, need to achieve green computing by reducing the power consumption of the computational cloud. In this context, in recent literature [1][2][3], we found VM (virtual machine) workload scheduling can be a good strategy to efficiently utilize the computational resources and reducing power consumption of cloud servers.

The physical machines contain several virtual machines. These VMs are used to deal with the workload that appeared for processing. If we better utilize the resources, we can process a large number of jobs in fewer VMs. Additionally, we can also turn off the ideal machines to reduce power consumption [4]. In this context, the proposed work is motivated to work with VM scheduling techniques to achieve green computing. In recent literature, we identify there are two kinds of VM scheduling approaches active and proactive. The proactive technique is more effective than the active approach due to prior knowledge of VM workload. Thus, this approach can be more beneficial for the proposed investigation.

### A. Motivation

VM scheduling provides many benefits in different scenarios of the cloud and relevant technologies. Those facts are validated by using identifying some noteworthy contributions related to the proposed domain of study. Some essential of them are discussed in this section.

Proficient VM management is extremely critical for expanding benefit, energy-saving, and forestalling SLA infringement. VM placement plans can be characterized as reactive and proactive to improve VM arrangement by

determining future workloads expectations. M. Masdari et al. [5] advances a review of the proactive VM placement and classifies them. They depict how techniques have been applied to lead viable and low overhead. Also, factors like assessment boundaries, simulators, workload, energy-saving, and predictions are analyzed. Finally, the issues and future opportunities are featured.

Fault-aware scheduling is significant for the cloud and identified with the reception of dynamic workload. R. Kaur et al. [6] proposes a pattern similarity-based scheduling for the cloud. To approve the solution, they performed two investigations with conventional technique and with the fault aware technique. The outcomes show the viability of the plan.

The server burns a tremendous measure of energy to fulfill the expanding need of computational assets. Computing and Cooling are the two frameworks that are enormous energy-devouring. Dynamic VM consolidation is a procedure to lessen energy utilization. Forceful union prompts the production of areas of interest that affects energy utilization. S. Ilager et al. [7] propose an Energy and Thermal-Aware Scheduling (ETAS) that merges VMs to limit energy utilization. The ETAS tends to compromise between time and cost-saving and can be tuned dependent on the prerequisite. They perform tests by utilizing real traces. The outcomes show that ETAS decreasing energy.

In a Virtual Symmetric Multiprocessing (VSMP) climate, the conduct of the scheduler can impact I/O responsiveness. The hinder remapping component can use different virtual CPUs. W. Zhang et al. [8] recognized an "Interfere with capacity Holder Pre-emption" (IHP) issue. The IHP presents that a virtual CPU handicapping the interferes with the capacity of the visitor's organization gadget is de-booked by a scheduler. In this manner, the creator proposes CoINT, a gasket organizer dwelling in the hypervisor, to improve the organization I/O execution. CoINT wipes out the IHP issue and lessens I/O intrudes on delay. They execute CoINT in the KVM hypervisor and assess its proficiency utilizing benchmarks. The outcomes show that CoINT can work on the netperf throughput up to 3x.

Cloud research has needed data on the qualities of the creation of VM workloads. A comprehension of these qualities can illuminate the resource management frameworks. E. Cortez et al. [9] present an interpretation of Microsoft Azure's VM workloads, including VMs' lifetime, size, and resource utilization. Then, show that specific VM is genuinely reliable. In light of this perception, present Resource Central (RC) gathers VM telemetry, learns practices, and gives predictions to administrators. They change the VM scheduler to use predictions in oversubscribing servers. Utilizing real traces show that the aware prediction schedules increment use and actual resource fatigue.

Conventional virtualization frameworks can't viably detach shared micro-architectural assets. Processors and memory-concentrated VMs fighting for assets will prompt genuine execution interference. Y. Cheng et al. [10] propose a contention-aware prediction model on the virtualized multi-core frameworks. Start with recognizing performance interference factors and plan benchmarks to get VM's

contention affectability and intensity features. Second, based on the features, fabricate a VM performance forecast model utilizing ML. The model can be utilized to streamline VM execution. The outcomes show that the model accomplishes high accuracy, and the MAE is 2.83%.

### B. Objectives

This paper investigates the energy-efficient Cloud resources scheduling for reducing the power utilization of datacenters. We focused on energy-aware VM consolidation schemes to reduce the number of running hosts to preserve energy.

We deal with this issue of selecting a power-efficient configuration that may also be suitable for mapping the client request through available VMs. The framework also considers the selection of optimal pair of the server. To scale the solution, considering client requests as time-varying, the framework enables us to virtualize the system to react to workload variations and adapt relevant configurations. The dynamic configuration improves leveraging predictions about upcoming resource demand and availability. The system takes advantage of the correlation between the historical workload and future workload demands in predictions [11].

An increasing number of datacenters are being deployed to support different applications and services. In a cloud, the applications are hosted on physical servers. These servers have great processing capabilities and can fulfill the performance demands, incurring high energy costs and increasing CO<sub>2</sub> generation and environmental losses [12].

The energy utilization for keep servers running became an important issue, which requires major investigation and immediate steps to improve energy efficiency. According to [13] the datacenters contribute to 30% of the world's CO<sub>2</sub> emissions. Thus, energy-efficient servers are a fundamental concern. To allow hosting multiple independent applications, platforms rely on virtualization to better utilize server resources. Virtualization has been adopted for resource usage efficiency; by VM consolidation and on-demand resource allocation and migration [14]. The dynamic workloads consolidation using migration of VMs, helps to increase the server utilization, reducing the use of resources and power. The ability to move workloads enables PMs to be turned off during low requirements. This offers an efficient way of running a data center in terms of energy saving. However, the data center workload often stays around 30%, and the part of under loaded servers can be as high as 70% [15].

The workloads vary with time, and prior knowledge about future demand may help to handle different critical conditions. So, we proposed a clustering scheme to predict the requests and resource requirements with network and traffic. This method improves the decisional accuracy and guaranteeing high quality of service. The aim is to provide a power aware performance management system in a virtualized environment.

Thus, we proposed a prediction approach based on ML clustering to predict the workload regarding the resource demand of requests. We also incorporate improvements that make the tunable parameters in real-time. Using this technique, we are minimizing the power utilization to meeting the

performance expectations. In order to implement, we investigate the use of dynamic configuration techniques, such as voltage scaling, the server on/off switching, and migration. We also collect evidence to verify feasibility and effects through simulations. The solution supports different types of virtualization techniques to enable resource provisioning. The framework has three major components: Data clustering, workload prediction, and power management, as shown in Fig. 1.

Fig. 1. Life Cycle of Proposed Framework.

1) *Data clustering*: The approach relies on historical workload dynamics for a time period referred to as the observation window. A VM request consists of multiple cloud resources (e.g., CPU, bandwidth etc.). This poses unique challenges to developing prediction techniques. Also, different clients may request different amount and type of the resource. Therefore, it is difficult to predict the demand for each type of resource. To address this issue of maintaining the personalized QoS requirements, we divide requests into several categories and then apply prediction for each category.

2) *Workload prediction*: We rely on the traces as training data samples to calculate the weights. One of the problems in implementation is that we will also need to train the model to adjust these weights according to the workload dynamics, which may vary over time. We refer to these predictive models as to be needed training from time to time. We will use a predictive model that increases the accuracy over time and avoids storing large traces. The model predicts a number of requests based on the learned weights. Next, the model observes requests received in each category. The algorithm uses these observations to update the weights. Therefore, we will find the optimal weights. The predictor has an overhead after observing the actual workload to update the weights. These updates increase the accuracy with time and make it dynamic to adopt the latest variations.

3) *Power management*: The predictions are passed to the Power Management module, which uses this prediction to decide when a PMs go to in ideal state and when become alive. This component is updated with the information of all PMs and maintains their utilizations and states. It uses a heuristic to predict requests and determine how many PMs are alive. The algorithm tries to map requests with live PMs. To

do that, it sorts PMs according to the best fit to the least fit. The conventional algorithm could not be used directly. Thus, a modification is made to the algorithm. This limitation has been addressed by mapping these multiple dimensions into a single metric. Furthermore, heuristic considers the energy when sorting the PMs by the following criteria:

- a) PMs that are in a working state
- b) PMs that have higher utilizations. The utilization is defined as the product of the utilization.
- c) PMs that have higher capacities. The capacity is defined as the product of the capacities of an individual resource.

The aim behind sorting conditions is to use the available PMs already being used, so live PMs are ranked first. Then use the utilization metric, since increasing the utilization of the PMs makes the cluster more efficient. Thus model allows for sleeping more PMs. Finally, based on capacities, we can fit more VMs in a PM.

## II. LITERATURE REVIEW

In this section we are exploring the recent research work carried out to improve the performance of cloud infrastructure and also contribute for VM scheduling and green computing aspects.

### A. Related Work

Cloud Computing (CC) is a multi-tenant framework used by multiple users' concurrently, each exhibiting different and varied behaviour. This heterogeneity shapes highly fluctuating load and creates new usage patterns. VMs interference plays a big part in changes at load. Server load prediction is crucial to ensure efficient resource usage.

### B. Literature Summary

The investigation of green computing is being essential for reducing the carbon footprints and for long-term sustainable computing. To understand the effect of green computing in this paper, a survey is performed on green cloud computing techniques. The key focus is paid on proactive techniques of cloud power management, which involve the predictive strategies for regulating the QoS (quality of service) requirements of applications. According to the collected literature, we found that the VM consolidation by improving the scheduling techniques can significantly preserve datacenters power demands. Additionally, proactive methodologies improve the performance on step ahead. In this context, we also summarize the recent VM scheduling approaches in Table I. These tables include the summary of recent contributions in terms of research work for achieving power efficiency. This summary includes the solutions developed for improve the virtual machine scheduling performance to reduce brown energy and those algorithms which are utilized to derive the required power optimization technique. There are two main key findings as a conclusion of this survey. First, the prediction based VM management in the cloud for consolidating the scattered future requests in multiple machines can reduce the power demand of the datacenters in effective manners. And second, the available

solutions have a lack of adjustment about the uncertainty of users' demand.

the uncertain future demands of users to maintain the effective consumption of power in cloud datacenters.

So here the proposed proactive VM scheduling focused on prediction using unsupervised learning algorithms to handle

TABLE I. REVIEW SUMMARY

Ref. No	Direction	Solution	Significance
[16]	Virtual Machines (VMs) interference	A real-time server load prediction system based on incoming task classification and VM interference.	An improved HAT, with ensemble drift detectors. Able to dealing with changes and good accuracy with less time and memory
[17]	Concerned with balancing servers load	Utilize resource and job response time, enhance scalability, and user satisfaction.	Dynamic resource allocation using EANN to predict VM load and get better performance.
[18]	Prediction of server load	Improving the resource utilization, reducing energy consumption and guaranteeing the QoS.	Integrates the cloud and Markov chain to realize CM-MC algorithm. Results show that algorithm is high accuracy and reduce energy consumption.
[19]	Host load prediction	Proposed a host load prediction method based on Bidirectional Long Short-Term Memory (BiLSTM)	BiLSTM improve the memory capability and nonlinear modeling. 1-month trace of 12K machines is used to validate accuracy.
[20]	Focusing on the issue of host load estimating in mobile cloud	LSTM, for the intricate and long-term arrangement of the cloud condition and dependent on GSO LSTM neural system.	Cloud load forecasting model using LSTM, and GSO to search optimal parameters. And compared with similar algorithms. Results show that the algorithms are offers higher accuracy.
[21]	Performance of dynamic clouds depends on efficiency of its load balancing and resource allocation	A study on the predictive approach for dynamic resource distribution. And a rule-based workload-balancing based on predictions.	Simulation of cloud using CloudSim and used an algorithm with lower computational demand and a faster balancing. The result will show a predictive workload balancing is an effective solution.
[22]	Cloud DBMS load balancing	Distribution of transactions between replicas, load balancing to improve the resources utilization.	A predictive load balancing service for replicated cloud databases.
[23]	a predictive and elastic load balancing service for replicated cloud databases	The distribution of transactions among replicas, load balancing can improve the resources utilization.	Showed that the use of prediction can help to predict possible SLA violations that represent workloads of cloud-replicated databases.
[28]	Datacenter consuming a high amount of energy and increasing carbon emissions.	VM need to be allocated to minimize resource and energy wastage.	Solution for datacenters named E-FPA. Aim is to provide energy-oriented VM allocation using Switching Probability. It enhances energy consumption, Migration, and First Fit Decreasing.
[29]	Green Computing to reduce, power and water consumption, hardware and carbon emission.	Presents an analysis report about green computing and its characteristics.	Discusses about green computing, trending concepts and future challenges. This analysis helps researchers to understand green cloud.
[30]	Economic and environmental costs of data centre and equipped for peak processing.	Idle servers and components of the network consume a significant amount of resources.	Describe the green data centre and metrics. And discuss energy-saving solutions for servers, network, and other green solutions.
[31]	Efficient VM management for energy saving, increasing profit, and preventing SLA violations.	This survey on the proactive VM placement approaches and categorizes them.	Factors such as evaluation parameters, simulation software, workload, power management, and prediction are compared to illuminate VM placement. Issues and future studies are provided.
[32]	VoIP have face a crisis: 1. Lack of resources and, overload; 2. Redundancy of resources and, energy loss.	The SDN can provide a view of the network for resource management. NFV can be used to implement a variety of devices and functions.	GreenVoIP to manage the resources of cloud VoIP centers. It not only prevents overload but also supports green computing. That framework can minimize active devices.
[33]	Communication traffic have imposed a heavy burden on data centers and resulted in high energy consumption.	Edge computing is explored to provision the latency-sensitive applications.	Geo-distribution of edge devices is leverage green computing. It is desirable to maximize utilization of green energy. Investigate cost minimization problem of VM migration, task allocation and scheduling using heuristic algorithm.
[34]	Provisioning Edge computing QoS mainly delay guarantee for delay-sensitive applications. energy consumption in edge servers may be higher	Energy-efficient and delay-guaranteed workload allocation problem in an IoT-edge-cloud computing system are investigated	Offloading workloads to servers, and computation experience, e.g., delay and energy consumption. Delay is un-negligible in a intensive environment. The workload allocations among local, neighbour, minimal energy and delay using algorithm.
[35]	Promote ecosystem services, including mitigation of storm water flooding and water quality degradation	Goals include increasing carbon sequestration, songbird habitat, reducing urban heat effects, and improving the landscape.	GI is improving water and the ecosystem by reducing storm water runoff. Provide design to enable better communication among designers and groups. Demonstrates workflows to facilitate the creation of GI, incorporated models using web applications.
[36]	VM placement	Vector Bin-Packing (VBP) problem to minimize the number of PMs used	FFD variant, Aggregated Rank in FFD is proposed. Experiments using two datasets: based on Amazon and a synthetic dataset. The efficiency of FFD-AR is better.

### III. PROPOSED PROACTIVE VM SCHEDULING

This section explains the proposed proactive virtual machine scheduling technique for optimizing the cloud datacenter performance in terms of power consumption. In this context, this section provides a discussion about the different algorithms and the data analytics steps to explain the work of the required model.

#### A. System Overview

The increasing demand for computational and storage resources motivates us to design sustainable and prolong computing technologies. In this direction, one of the most crucial development is green cloud computing. Green computing technology is providing a way to minimize the cost and consumption of infrastructural assets. Therefore, green cloud computing has become one of the most essential and trending areas of research and development. The key idea is to employ various techniques to switch off the additional computational and network devices that are unused or in an ideal state to preserve the power consumption. Additionally, when the load again appeared on datacenters, machines became alive to deal with the workload.

In this context, we are proposing an unsupervised learning technique for designing the physical machine consolidation scheme. The unsupervised learning techniques are suitable for time-critical applications and also for parameter enhancement and optimization. Therefore, to improve the capability of power management the clustering algorithms are adopted. Therefore, first implemented four popular clustering approaches (namely K-Means, SOM (Self Organizing Map), FCM (Fuzzy C-Means), and K-Medoid) that categorize the cloud datacenters workload into three categories, i.e., low, medium, and high workload groups.

Further, these trained machine learning models are being used for efficient VM allocation and making power on and off decisions based on the predicted outcomes. In this context, a modified VM scheduling algorithm has been proposed. That makes use of one step ahead predicted workload and evaluates the current wearability of data center resources. Based on this decision function, we decide the required resources which fulfill the demand. In this way, we are reducing the migration of processes and maintain less traffic overhead. In addition, by using the predictive method, we estimate the future possible resource demand. Suppose demand is higher than the available one step ahead workload. In that case, we restart the physical machines, or if the future trend shows a low demand, we turn off the machines to utilize the minimum resources.

#### B. Clustering of Workload

To utilize the proactive VM scheduling for improving the performance of cloud datacenters in terms of energy efficiency, we are intended to use the unsupervised learning techniques for predictions.

In this context, Fig. 2 demonstrates the model for learning with the historical workload patterns. Therefore, the Google workload trace dataset is being used for performing the clustering. The dataset consists of parent ID, Task ID, job type, nrmlTaskCores, nrmlTaskMem, and time. Among them,

parent ID and Task ID provide the identification of the process. Thus, we remove one of them, so here we eliminate parent ID for the dataset. The remaining attributes are utilized further for clustering of the tasks. To create clusters, we need to provide a number of clusters here; use  $k=3$  for preparing clusters of three types, to categorize and belong in low, medium and high groups.

Further, we have implemented a provision that will be used to select the clustering algorithm for training. The algorithms are discussed in the previous section. The selected algorithm is used with the trace file and clusters the data. The employed clustering algorithms result in two key outcomes, i.e., validation performance of the clustering algorithm and the centroids identified from the data. These centroids are further being used for predicting the trends of the upcoming workload.

#### C. Predictive VM Scheduling

The VM scheduling in energy efficient manner need to include the following phases:

1) *Predicting the future workload:* To demonstrate the effective VM scheduling and consolidation technique, using the proactive manner. First of all, we need to have workload trends. Therefore, to prepare future trends for each one-minute interval, we have trained machine learning algorithms. These algorithms use the cluster centroids and simple linear regression technique to compute the future trends of the host workload. In this context, let we have a set of centroids (C) such that:

$$C = [C_L, C_M, C_H] \quad (1)$$

Where,  $C_L$  = centroid for small workload,  $C_M$  = centroid for medium workload,  $C_H$  = High workload.

Each centroid  $C_L$ ,  $C_M$ , and  $C_H$  consists of memory and CPU properties of demand. Thus, when talking about the centroids, then we also considering each element of these subsets or centroids. Now, we need to predict a pattern relevant to the upcoming future workload. In this context, first, consider one hour for predicting the workload values. Thus, we extract the last one hour per minute values and keep them in a list  $L_N$  where  $N$  are minutes.

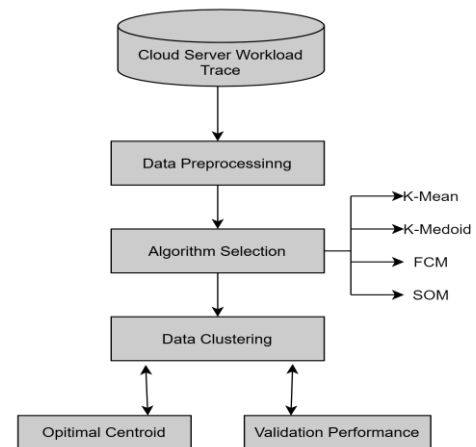

Fig. 2. Workload Clustering.

---

**Algorithm 1: Proposed load Encoding**

---

**Input:** last recent workload list  $L_N$ , list of centroids

$$C = [C_L, C_M, C_H]$$

**Output:** Encoded list  $E_n$

---

**Process:**

1. for ( $i = 1; i < n; i++$ )
    - 1)  $temp = L_i$
    - 2) for ( $j = 1; j < m; j++$ )
      - I.  $tempC = C_j$
      - II.  $d_j = temp - tempC$
    - 3) end for
    - 4)  $S = getShortest(d)$
    - 5)  $e = getlabel(S)$
    - 6)  $E.Add(e)$
  2. End for
- 

Let considering the one-hour forecast, then  $N=60$ . Now we encode the values available in the list with three symbols L, M, and H. The encoding process is demonstrated in algorithm 1. According to the given algorithm 1, we accept a list of likelihood workload list  $L_N$  and prepared centroids  $C = [C_L, C_M, C_H]$ . The algorithm processes both the inputs and prepares a list of encoded patterns of the list. The algorithm extracted each element of the list  $L_N$  and compared it with all the centroids. The most minimum distance centroid is labelled as the encoding value of  $L_N$ . After assigning a label to the load value, we get a new list E of encoded n values in terms of L, M and H.

The next step proposes to utilize the Encoded list  $E_N$  as the initial prediction of the next one-hour workload pattern. Now we need to enhance the prediction. Therefore first, we calculate or difference between the actual extracted value as well as encoded values using the following equation:

$$D_N = L_N - E_N \quad (2)$$

Where  $D_N$  is the difference between the last observed value and reference or actual value.

2) *VM consolidation*: This section explains how the prediction is used in real-time to predict and reduce power utilization by on and off the physical machines. Therefore, let at actual time  $t_a$ , we have a basic prediction taken from the list  $E_N$  for the given time  $t_a$ . That workload is denoted here as  $P_{t_a}$ . Additionally, at that time, we also get the actual workload appeared and denoted as  $W_a$ . Further, at the next time movement  $t_b$ , we need to adjust the initial prediction. Thus, the new predicted value is:

$$P_{t_b} = E_{t_b} + E_r \quad (3)$$

where,

$$E_r = W_a - P_{t_a} \quad (4)$$

Here,  $E_r$  it can be positive or negative.  $E_{t_b}$  is the basic prediction at the time  $t_b$ . Further, we make use of a difference list  $D_N$  to impure the prediction.

$$F = D_{t_a} - E_r \quad (5)$$

The measured different F is demonstrating the influence in prediction error; therefore, the system needs to adjust this for making the final prediction by restructuring the prediction equation using the following equation:

$$P_{t_b} = E_{t_b} + E_r + F \quad (6)$$

Now, the system utilizing the predicted resource demand and the available resources of the datacenter to decide to switch ON and OFF, the physical machine. In this context, we prepare an algorithm for making decisions regarding the same, steps are described as algorithm 2.

---

**Algorithm 2: Predictive VM Scheduling Technique**

---

**Input:** list of datacenters host list  $H_m$ , P predicted workload, T consolidated resource available

---

**Process:**

1. For each next time event
  2. if ( $P < T * 0.66$ )
    - a.  $S = m * 0.2$
    - b. For ( $i = 1; i < m; i++$ )
      - 1) if ( $m < S$ )
        1. *MigrateProcessofHost*( $H_i$ )
        2.  $HID = H_i$ . Sleep
      - 2) End if
    - c. end for
  3. Else
    - 1)  $HID.Start(Top,1)$
    - 2)  $H_m.Add(HID)$
  4. End if
  5. End for
- 

According to the discussed algorithm 2, we have the host lists  $H_m$  with m elements; on the other hand, we compute the total consolidated resources available as T. the algorithm starts with the analysis of each time increment. To compute the predicted demand of resources P. if the P is less than 66% of available resources in the consolidated resource T, we compute the capacity of 20% of machines available, which the existing resources will handle; thus, we turn off one physical machine at a time. These two thresholds depend on the designer and the application's quality of service requirements. Otherwise, each time we turn on one physical machine available in the sleep list of the host.

#### IV. RESULTS ANALYSIS

This section provides the experimental analysis of the proposed VM scheduling approach. Thus, first the clustering algorithms are applied on the dataset. The predictive performance of ML techniques is measured. Additionally, the performance of cloud infrastructure has also been evaluated and simulated in this section.

##### A. Experimental Scenarios

The experimental simulation of proposed proactive VM scheduling is done through Cloud-Sim simulator with a datacenter of 5 servers [Host1, Host2, Host3, Host4, Host5] having 20, 5,10 20, and 10 VMs respectively. The

computational setup of the simulated datacenter can be elaborate through Table II.

TABLE II. SIMULATION SETUP OF PROPOSED PROACTIVE VM SCHEDULING

Datcenters	Host1	Host2	Host3	Host4	Host5
CPU per VM (MIPS)	250	250	250	500	250
RAM per VM (MB)	2048	2048	2048	2048	2048
Total Storage (GB)	1M	1M	1M	1M	1M
Bandwidth (Gbits/sec)	1000	1000	1000	1000	1000
VMs	20	5	10	20	10

The VM scheduling ensures the optimal VM resource utilization and reduction in power consumption. The aim is to investigate the proactive VM scheduling techniques using ML techniques to understand the demand of resources and prepare the plan to better schedule the cloud VM for reducing the power consumption and enhancing the running cost of the cloud. Therefore, first, some unsupervised learning approaches are compared to identify the best-performing clustering approach. Further, an algorithm will be proposed to design a proactive resource scheduling technique to achieve Green Computing, reduce power consumption, and reduce carbon emission. Thus, the given experiment includes two experimental scenarios:

1) *Comparing different clustering algorithms*: Clustering is an unsupervised learning task. It automatically discovers grouping the data. Clustering only interpret the data and find natural groups. In this scenario, we compare four clustering algorithms, namely, K-Means, SOM (Self Organizing Map), FCM (Fuzzy C Means), and K-Mediod over different performance parameters and different data sizes.

2) *Comparing simulation performance of cloud for VM scheduling*: This simulation scenario implements proactive VM scheduling techniques using the above-discussed algorithms. Thus, using all the algorithms, the prepared VM Scheduling techniques are compared to investigate energy consumption.

### B. Experiments Comparing Clustering Algorithms

In this section, a comparative performance study is carried out among different unsupervised learning algorithms. The aim is to obtain an efficient and accurate algorithm for predicting the accurate future VM resource demand and can optimize the scheduling to better resource allocation. The comparative outcomes of the algorithm's performance are reported in this section.

We are investigating the efficiency of the algorithms, so it needs to compute the models' performance in terms of memory and time required to process the workload of different sizes. The memory usage of the algorithms is measured based on java function and using the following formula:

$$M_{Used} = M_{Assigned} - M_{Free} \tag{7}$$

Similarly, the time consumption of the implemented algorithms is given as the amount of time consumed for processing the data using the algorithms is given as the time consumption of the algorithm. That can be calculated using the following formula:

$$Time_{Consumed} = Time_{End} - Time_{Start} \tag{8}$$

The memory and time consumption of the implemented clustering algorithms are described using Fig. 3(A) and (B). Additionally, the observed values are given in Table III. In both the line graphs, the X-axis demonstrate the size of experimental dataset size in terms of instances, additionally, in Fig. 3(A) the Y-axis shows the memory used in terms of kilobytes (KB) and in Fig. 3(B), the Y-axis shows the time consumed in processing the data in terms of seconds (Sec). According to the obtained performance, the SOM and FCM are producing a higher amount of time and memory overhead during the computation. Therefore, these algorithms are also producing a significant delay during the cloud VM allocation. Therefore, according to all the obtained performance parameters, we can say the K-Means and K-Mediod are time and memory efficient. Thus, we recommend being using the K-Means and K-Mediod algorithms to reduce the delay in scheduling.

Fig. 3. Comparative Performance of Clustering Algorithms in (A) Memory used (B) Time Consumed.

TABLE III. PERFORMANCE OF CLUSTERING ALGORITHMS IN MEMORY USAGE AND TIME CONSUMED

Dataset Size	Memory Usage				Time Consumed			
	K-Mean	K-Medioid	FCM	SOM	K-Mean	K-Medioid	FCM	SOM
500	16712	16279	16992	21746	14	14	16	32
1000	18718	18028	19028	22817	26	28	32	68
2000	20484	19372	20582	24617	47	42	53	137
3000	21942	20478	21477	26725	61	66	78	256
5000	24837	23927	25649	29927	97	109	164	462
15000	26173	25173	27352	30002	294	318	392	736
20000	28134	27248	29428	32846	473	462	533	892

C. Proactive VM Scheduling for Green Computing

The VM scheduling by proactive techniques are demonstrated using different clustering algorithms, namely K-Mean, K-Medioid, FCM (Fuzzy C Mean), and SOM (Self Organizing Map). The aim is to find the impact on scheduling using these ML techniques over different parameters. The simulation consists of two major goals:

- a) Compare the Impact of four different clustering based proactive scheduling over average processing time ( $Pt_{AVG}$ ).
- b) Compare the impact of four different clustering based proactive scheduling over efficient power consumption (PC).

1) *Average processing time*: The process time is the amount of time for which a central processing unit (CPU) was used for processing instructions. The processing time is a combination of the total time a process resides in the processor and the time required to wait for the resource. Processing time ( $Pt$ ) is generally calculated in MS (Milliseconds).

$$Pt_{AVG} = \frac{1}{N} \sum_{i=1}^N Pt_i \tag{9}$$

Where, N number of processes to be scheduled, and  $Pt_i$  is the processing time of the  $i^{th}$  process.

Table IV have the simulation results of average processing time for proposed proactive VM scheduling based on four different clustering to evaluate which one take minimum time in VM scheduling.

The comparative evaluation of four different clustering based proactive VM scheduling using average processing time ( $Pt_{AVG}$ ) is also shown in Fig. 4. That is a bar graph that is prepared using the observations collected from the simulation. The processing time of the implemented simulation is measured here in terms of Minutes. In order to show the performance, the X-axis contains the number of VMs, and in the Y axis, the average processing time in minutes is reported. According to the system's performance, K-Medioid clustering algorithm requires less processing time than other similar algorithms.

2) *Power consumption*: The entire VM scheduling optimization techniques are works to enhance the profitability of cloud service providers. In this context, the low energy or power consumption is tried to reduce by optimal resource allocation of the cloud. Table V is used to show the simulation results of power usage during proactive VM scheduling based

on four different clustering to evaluate which one gives the efficient usage of power during VM scheduling.

TABLE IV. SIMULATION RESULT OF AVG. PROCESSING TIME

Dataset Size	K-Mean	K-Medioid	FCM	SOM
1000	10.2	9.3	11.2	9.3
2500	21.5	18.7	23.5	20.9
5000	43.3	39.1	46.3	29.5
7500	60.4	55.9	68.4	56.8
10000	80.3	73.2	90.3	76.3
15000	115.9	101.2	126.9	108.1
20000	173.3	158.8	182.3	163.2

Fig. 4. Performance of Proactive VM Scheduling's on Average Processing Time.

TABLE V. SIMULATION RESULTS OF POWER CONSUMPTION

Dataset Size	K-Mean	K-Medioid	FCM	SOM
1000	60.3	54.8	58.9	53.8
2500	98.3	108.2	94.1	86.6
5000	124.5	128.7	119.2	109.5
7500	160.3	155.5	153.1	136.9
10000	198.3	201.3	183.7	166.3
15000	225.9	241.2	216.4	201.9
20000	263.3	266.2	252.3	245.4

Fig. 5. Performance of Proactive VM Scheduling's on Power Consumption.

The Power Consumption is measured here in terms of KW/h. The recorded power consumption for all clustering based proactive VM scheduling's is shown in Fig. 5. To show the performance, the X axis shows the number of VMs, and the Y-axis shows the cloud's power consumption. According to the performance of the system, the FCM and SOM-based models report the lowest consumption.

## V. CONCLUSION

The proposed work is implementing a simulation-based experimental study for designing an effective and efficient proactive VM scheduling approach to minimize the energy consumption of the cloud infrastructure. The scheduling techniques are essential for allocating the resources to the users' request to limit the unwanted resource utilization of cloud datacenters. That also increases the energy consumption, maintenance cost, and running cost of the datacenters. Therefore, we need some effective resource allocation strategy that can deal with the dynamic nature of workload. In addition, by implementing the host switch ON and OFF technique, we can also control the power consumption and running cost of datacenters.

Therefore, the proposed work is motivated to design and develop a proactive VM scheduling model which utilizes four different unsupervised learning techniques to predict the future demand of the cloud. Additionally, based on the predicted demand trend, the proposed algorithm plans to keep switching OFF the resources when the model predicts the less resource demand trend. In this way, by replacing, we prepared four resource scheduling techniques by using the reported clustering algorithms. Based on the experimental analysis and obtained findings, we can see the model successfully preserves the energy by making inactive hosts in datacenters to minimize energy consumption. Additionally, the obtained performance of the models also justifies our argument for the proposed proactive VM scheduling model.

## VI. FUTURE SCOPE

In near future we are motivated to perform more extensive experiments on the given resource provisioning model, additionally we also compare the technique with the classical resource scheduling model to find how the proposed technique can improve the productivity of the model. Finally, in near future we also work for involving the deep learning models for making the accurate future resource demand prediction.

**Abstract**—Many mobile applications that can increase user engagement and promote self-learning have been developed to date. Nevertheless, mobile applications specific to Malay language learning for non-native speakers with relevant materials are still lacking. Moreover, expert reviews are needed to identify usability issues and check whether such applications can meet the learning goal with relevant materials features. This study developed an augmented reality (AR)-based mobile application called *RakanBM* for learning the Malay language (i.e. the language officially spoken in Malaysia), and then performed an expert review on the application contents, text presentations, learning outcomes, assessments, effectiveness, efficiency, and satisfaction. The expert review was conducted by a panel of six experts from two specific fields, namely the Malay language and Human-Computer Interaction (HCI), using methods such as cognitive walkthrough (CW), semi-structured interviews, think-aloud protocols, and survey. The results from CW, semi-structured interviews, think-aloud protocols shows that enhancement was needed on user interface and user experience in term of aesthetic and interactivity. The survey results were classified into two levels: high (mean > 4.0) and satisfied (mean > 3.5). Application factors that were recorded as satisfied were the application contents, text presentations, and satisfaction, while the factors recorded as high were the learning outcomes, assessments, effectiveness, and efficiency. The comments or suggestions for improvement were mainly around the contents of the application. Nevertheless, the application received good comments on its usefulness and the topics covered, which were suitable and best for non-native speakers. The findings of this study can guide developers and researchers in the development of future applications that can support language learning for non-native speakers in particular.

**Keywords**—AR; expert review; HCI; language learning; mobile application; self-learning

## I. INTRODUCTION

Mobile phone device is one of the most popular types of information and communication technology (ICT) as digital learning has been an evolution in the present days[1]. The use of mobile applications for language learning has shown

promising outcomes, especially for language improvement, learner interaction [2, 3], and learner motivation [4]. The use of a mobile phone in and out of the classroom can help students learn more effectively and create a conducive environment for effective teaching and learning [5]. Similarly, flexible learning would be less costly, adaptable, require little instrument, and is easy to use. These advantages allow the implementation of mobile learning in almost all learning environments. Furthermore, such technological advancements can make learning more efficient and enjoyable for students [6]. Previously, several language learning using the mobile application has been invented and conveyed positive feedback from learners, for instance, Mayo language [7], Spanish language [8], Malay language [6] and etc.

In the context of the Malay language, not only the written materials, in fact, the audio and video in electronic forms are far from adequate. It is challenging to learn Malay because it has some elements of modification from other languages such as English and Arabic [9] and was influenced by Indonesian and English pronunciation as well [10]. In another study, [6] introduced the Malay Language Mobile Learning (M-Lang) system using the near field communication (NFC) technology to utilise mobile learning in all learning environments as this technological improvement can make learning more effective and fun for students. However, the system was only in the early stages and excluded AR technologies. The study realised that it was challenging to study and teach foreign languages, which the fundamental principle is to ensure that learners are introduced to the desired foreign language accordingly. At the same time, most of the new applications are limited to elementary-level students[11], and there is also a lack of attractive functionality [12].

Previous studies have highlighted that the Malay language learning deficiency, especially in the mobile application, has become an obstacle for learners to learn the language. Therefore, a better mobile application for Malay language learning are beneficial in ensuring learners, especially foreign students, have a basic knowledge of the language, which could

help them communicate with the locals. This study aimed to validate and ensure that the low-fidelity *RakanBM* prototype was relevant and suitable to support Malay language mobile learning. An expert review was conducted to identify usability issues and check whether the prototype can meet the learning goal with relevant materials features. The remainder of this paper is organised in the following manner: Section II describes the related works and expert reviews methods; Section III presents the evaluation procedure for the developed mobile application; Section IV provides a detailed description of the results and discusses the main features of the application that bring positive results, especially for learning outcomes, assessments, effectiveness, and efficiency; and Section V concludes the findings.

## II. RELATED WORK

The related works highlighted previous studies, including mobile application, language learning, and review method to identify the potential of *RakanBM* application towards users.

### A. Mobile Applications on Languages Learning

Many approaches have been investigated on the use of mobile applications for language learning. For instance, Bojórquez, Villegas [7] aimed to identify the perceptions of undergraduates in the task of learning the Mayo language (i.e. language spoken in north-western Mexico) through a specific mobile AR (MAR) program used by a group of students. The game named *Lotería Mayo* use was based on images and audio using MAR through a card game. A survey was collected from students with items concerning the use and technology acceptance and cultural dimensions. Resultantly, although the MAR system could be easily used, there was still room for improvement, especially on the students' ability to continue their learning experience both within and outside the classroom that should be enhanced and made more effective. Similarly, [8] developed a mobile application having game-like activities with a grammar-focused mobile application to learn Spanish Languages. The study aims to determine the motivational and affective engagement of students towards mobile applications. Results revealed that students' inspiration and affective involvement were growing. The mobile apps allowed learners to work collaboratively and learn about conjugating verbs from each other. In another study, [3] found that *Busuu*, one of the most popular apps for language learning in the market, boosted the use of mobile application technology to a higher level. The app is part of the *Busuu* network for language learning and offers 12 different languages organised in levels. The majority of users evaluated were beginners and learning for personal reasons. The *Busuu* app helped users to better understand the language studied, especially in terms of vocabulary.

Other studies have investigated the learning impact of such applications. For instance, (Ng, Bakri, & Rahman, 2016) investigated the mobile courseware application's impact on children with special needs. The study found that the application was suitable for children with learning difficulties and had positively impacted their learning performance compared to the traditional teaching method. The application, which consists of basic Malay language syllables, was developed to assist educators and parents in teaching children

with special needs to improve their learning progress from time to time.

### B. Mobile Augmented Reality Applications

The ability of AR technology has been investigated by researchers because it has been proven to boost learning performance [13-16]. The AR technology enables a view of reality to be modified by the addition of digital information like three-dimensional (3D) model, two-dimensional (2D) image, video, and audio. The modification improves a person's perception of reality. This technology consists of four main components: (1) marker which is the target object in the reality; (2) a camera of a mobile phone to capture the target object, which is the marker; (3) a mobile phone to store and process information, which is the captured image or the target object (marker); and (4) digital content that will be displayed on the mobile phone screen, where the tracked image by the phone camera is the marker. Fig. 1 shows an example of an AR application where the marker is an image of fried noodles. When the camera phone has tracked the marker, digital information corresponding to the name of the food in Malay which is 'Mi goreng' will be displayed on the mobile screen.

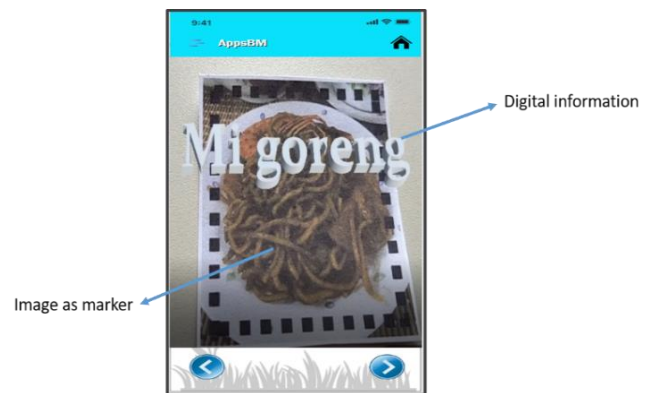

Fig. 1. Addition of Word 'Mi goreng' with Audio on Top of the Marker via AR.

AR provides simulated access to learning methods and has proved to be an effective 3D visualisation technology in educational areas [17, 18]. Ali and Azmi [12] investigated the use of AR for Malay language learning by developing a MAR Malay language application for international students to learn the language. Although the study found that students were satisfied with the developed application, the features and contents could be further extended. Moreover, the application was only in the early stages and not yet published publicly [12]. Based on the review of relevant studies, it can be concluded that studies on Malay language learning utilising AR are still limited, and further research is needed to deepen the knowledge, especially in supporting language learning. Therefore, this study introduced a Malay language mobile application known as *RakanBM* with comprehensive content embedded with AR technology to fulfill the current limitation of the domain.

### C. Expert Review Method

In this section, the expert review method is further described. An expert review is a form of testing that can be used to ensure that students are not exposed to any

inappropriate procedure that could affect their learning [19]. The selected expert evaluation method was appropriate because only a small sample of feedback was required to evaluate and support the application development. As such, the value of this expert review method has been recognised in software quality assessment [20]. This method can be classified into four categories: CW, semi-structured interviews, thinks-aloud protocols, and surveys.

1) *CW*: Walkthroughs take place where the activities as carried out in the user testing process are conducted by experts. Cognitive and pluralistic walkthroughs are the two primary walkthrough forms. CW seeks to simulate the problem-solving skill of users in each separate task, and it also relies on assessing how learnable the method is [21]. In addition, CW determines whether the end-users background knowledge and the technological cues embedded in the computer system interface are adequate to help the end-users accomplish a task. Furthermore, CW focuses on cognitive behaviour like recognising icons and behavioural or physical actions like mouse clicks necessary to complete tasks. This approach is extremely helpful when designing technologies for inexperienced users because it can recognise usability challenges that can impede task completion [22, 23]. A CW technique is a test that uses a sequence of actions or steps on a user interface to achieve a specific goal, and it is often used to test usability based on actions and ways of thinking. Besides seeking to identify problems and measure the level of complexity of each task scenario, another goal is to get an idea of the extent to which the interface supports a positive level of user experience or identify any areas that may cause difficulties [24]. CW is also a platform to detect misunderstandings between the user and the designer about a certain task involved [25]. In this study, the expert review using CW employed experts from the Malay language and HCI fields of expertise.

2) *Semi-structured interviews*: Typically, semi-structured interviews are in the form of a face-to-face interview on a relevant platform (e.g. digital) that focuses on usability-related topics such as the application's functionality, navigability, and ease of use. Such engagements are helpful to collect knowledge about a person's behaviours, values, practices, and experiences [26]. In this study, semi-structured interviews were conducted with six experts on the application prototype. The focus was on the content and interface of the materials and potential improvements based on their recommendations. The interviews determined that one of the main goals of the interactive experience should be to foster user experience while using the application [27].

3) *Think-aloud protocols*: Many studies have used the think-aloud protocol to evaluate the websites and mobile applications concerning their usability [28]. The method is a usability assessment that gathers information on functionality, navigability, and ease of use while end-users interact with the application. As part of a heuristic evaluation, users (i.e. end-users and/or experts) communicate their opinions and concerns in real-time as they perform tasks, enabling observers to see the

cognitive process involved. During the think-aloud assessment, the researcher usually uses software to record the users' responses, e.g. verbal comments and physical responses such as eye movements. This approach examines real issues faced by end-users as well as the factors causing those problems, offering insight into usability deficiencies [22, 29].

4) *Survey*: A questionnaire used in survey is a set of questions or items in form of writing. It is a method designed specifically to collect information for analytical purposes that can answer research questions. Researchers use several standardised and validated questionnaires to quantitatively evaluate the questionnaire [30]. Typically, a survey involves participants scoring items in questionnaires using a predetermined scale. This study obtained feedback from expert evaluators (respondents) on the mobile application design using a set of questions, which helped evaluate the low-fidelity application in terms of contents, text presentation, learning outcome, assessment, effectiveness, efficiency, and satisfaction. In other words, the questionnaire measured the level of user experience on the prototype. The questionnaire technique consisted of open and closed structured questions. In principle, closed-ended questionnaire questions offer a set of answer choices and are used to obtain uniform answers. On the contrary, open-ended questions provide an opportunity for respondents to give opinions or suggestions, and they complement closed-ended questions [31].

### III. METHODOLOGY

In this section, the design of the application and evaluation procedure for the developed mobile application is presented through Phase I, Phase II and Phase III. There are seven main chapters in the RakanBM application: vowel and consonant systems, greetings, numbers and currency, time, day, direction, and food. Furthermore, some elements (e.g. videos, listening exercises, quizzes, vocabulary, and practices using AR technology) diversify the approach and attract users to learn the Malay language. Interactivity is also offered by providing users with scores for each exercise (i.e. a set of tasks) completed. At the same time, the application also comes with feedback (e.g. "excellent", "very good", "keep trying", and "try again") interface, displayed according to the users' achievements after completing a task as a medium to increase user motivation and continue using the mobile learning application.

#### A. Phase I: The Development of RakanBM

The *RakanBM* prototype was developed in collaboration with experts in the Malay language and then evaluated using CW, semi-structured interviews, think-aloud protocols, and surveys (i.e. open and closed structure questions) methods. Fig. 2 illustrates the application developed using Adobe Xd software based on digital prototyping. The hardware required included a notebook and a smartphone. In addition, the related software and programming language for the application development were such as 3D Viewer - for AR model, Adobe Photoshop - for editing marker, Vuforia - for generating marker, Filmora - for video and sound editing, Unity - as the engine, and C# - for coding.

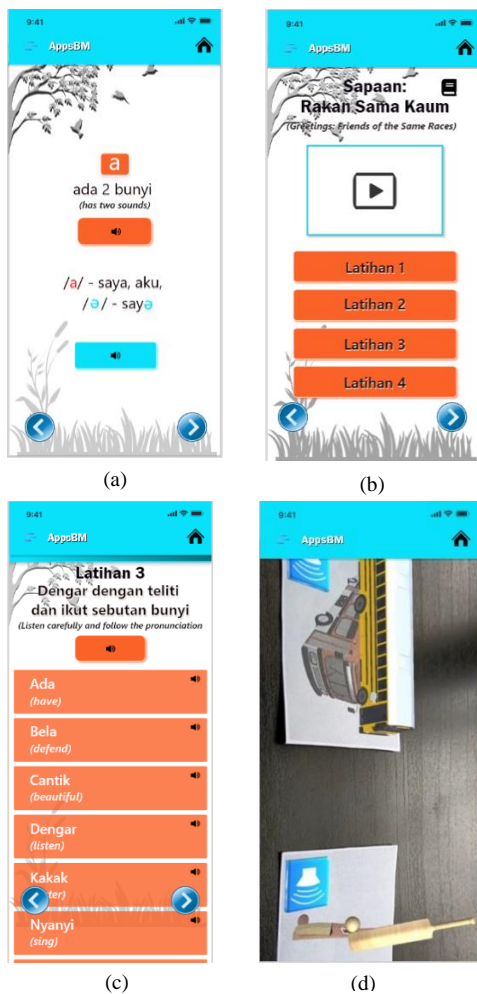

Fig. 2. Screenshots of the RakanBM Prototype. (a) Text Content. (b) Video Screen. (c) Audio Screen. (d) AR Content.

Fig. 2 shows four screenshots of the RakanBM application: Fig. 2(a) illustrates the text content used to present the language learning basics on vowels and consonants. Each vowel and consonant is supported with audio features for users to learn reading and at the same time to listen to the correct pronunciation of the particular Malay words; Fig. 2(b) illustrates the video screen concerning the daily routine conversation. From this approach, users can apply the language in their surroundings. Fig. 2(c) illustrates the audio screen for exercise. Users can learn the pronunciation of the listed words by clicking the sound button. Users also can repeat the exercise several times to ensure mastery of words, and Fig. 2(d) presents the advanced feature of the application, the AR-based content, designed to attract users' attention towards learning via the latest technology. The AR screen shows a 3D model used in several topics in the applications, such as number, currency, and time. The markers shown are images of a bus and that of a bat. Apart from a 3D model (i.e. the digital content), an audio icon appeared on the same screen when the phone camera tracked the markers. Therefore, users can relate the static images with better visualisation of the object with accurate pronunciation repeatedly.

### B. Phase II: Evaluation Procedure for CW, Semi-Structured Interviews and Think-Aloud Protocols

One of the advantages of an expert review is that it requires only a small number of experts to identify the flaw of the mobile application (Beecham et al., 2005). This study performed an expert evaluation to ensure the relevance of the RakanBM application prototype. The expert evaluation involved the perspective of contents and interface of the prototype. Table I provides the background of the six experts recruited for the review. The selected experts were from two fields, namely the HCI and the Malay language. The demographics of the experts are as follows:

- Malay language: The experts consisted of educators who specialise in the field of the Malay language and have more than five years of work experience in related fields.
- HCI: The experts consisted of individuals with more than five years of experience in the mobile application development field.

TABLE I. DEMOGRAPHIC OF EXPERTS (I.E. EVALUATORS)

Expert	Specialisation	Year of Experience	Gender
A	Malay language expert	25	Female
B	Malay language expert	11	Female
C	Malay language expert	31	Female
D	Malay language expert	28	Male
E	HCI expert	20	Female
F	HCI expert	20	Female

The Fig. 3 illustrates the evaluation procedures involved. This study started the testing by explaining the evaluation objectives to the experts. The experts were then introduced to the mobile application and explained the concept of the developed application prototype. Next, the RakanBM application workflow was described in detail to the experts for clarity on the activity workflow. Afterward, activities such as prototype testing using CW techniques, semi-structured interviews, and think-aloud protocols were also carried out.

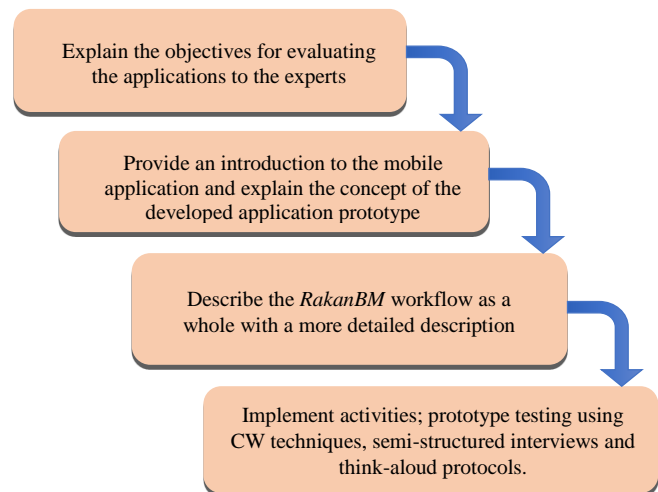

Fig. 3. Evaluation Procedure for the RakanBM Prototype using CW Techniques, Semi-Structured Interviews and Think-aloud Protocols.

For the CW, the experts evaluated the developed application for two weeks. Guidance was given to the experts on the needed steps to undergo a CW test on the prototype. During the testing process, the experts provided views and comments. Subsequently, semi-structured interviews were conducted to get feedback on the prototype from the experts. During the semi-structured interview, the experts gave their opinion on the application interface and contents as a whole. The experts' user experience was an extra knowledge that should be considered [27] to improve the application features and make it suitable for non-native speakers. The problems and requirements stated by the experts were recorded and then summarised in Table IV, which clearly shows that most of the feedback on the RakanBM prototype was related to its interface. Under the think-aloud protocol, the experts evaluated the prototype alongside researchers. During this session, the experts asked the researchers any questions or portrayed their feelings verbally about the current prototype. The session was screen recorded to allow researchers to refer again to the responses and behaviours of the experts. At the same time, the usability of the prototype was evaluated using the think-aloud protocol, whereby the experts directly gave their comments and suggestions to meet the aim of the developed application.

### C. Phase III: Evaluation Procedure for Survey

Questionnaires used for the survey in this research were adapted from Goal Question Metric (GQM) considering effectiveness, efficiency, and satisfaction as a construct [32-34]. Besides, construct named application content, text presentation, learning outcome, and assessment were built based on the studies requirement discussed by the Malay language teachers. This questionnaire was adapted into current research to describe the research objectives with the required data. It will be conducted at the end of the study. The developed questionnaire was given to the experts to identify their background and obtain their expectations on the application. Fig. 4 illustrates the evaluation procedures involved in survey techniques. In addition, the questionnaire technique was used to measure the level of user experience on the prototype.

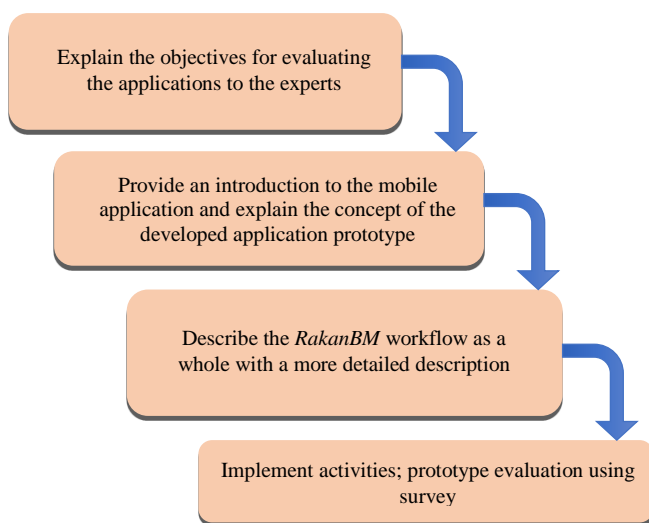

Fig. 4. Evaluation Procedure for the RakanBM Prototype using Survey.

1) *Produce questionnaire questions to users:* The questionnaire was developed in Malay language. The expert has no problem understanding the real meaning conveyed by the questionnaire. The questionnaire for this study consists of seven constructs, namely application content, text presentation, learning outcome, assessment, effectiveness, efficiency, and satisfaction. Application content was a question regarding user feedback on the content of the application. Text presentation was a question that required users to give their feedback towards the user interface available on the apps. The learning outcome was a question about the outcome that users may gain from the particular apps. The assessment was about scoring and interactive feedback provided by the apps. Last but not least, three constructs adapting GQM to gain information of effectiveness, efficiency, and satisfaction from a user by using RakanBM apps. All the constructs used a Likert five-point scale.

2) *Questionnaire reliability analysis:* The questionnaire was tested with Cronbach's alpha values to test the reliability of the questionnaire. Data should be unidimensional and consistent for purposes of internal consistency through Cronbach's alpha analysis [35]. Internal consistency can be measured in a number of ways. The most frequently used statistic was Cronbach's alpha [36]. In this study, a questionnaire was answered by six experts. The application contents constructs consisted of 10 items ( $\alpha = .89$ ), text presentations constructs consisted of 5 items ( $\alpha = .88$ ), learning outcome constructs consisted of 5 items ( $\alpha = .86$ ), assessment constructs consisted of 5 items ( $\alpha = .78$ ), effectiveness constructs consisted of 5 items ( $\alpha = .87$ ), efficiency constructs consisted of 5 items ( $\alpha = .89$ ) and satisfaction constructs consisted of 5 items ( $\alpha = .97$ ). The Cronbach's alpha values shows an excellent ( $\alpha \geq 0.9$ ), good ( $0.9 > \alpha \geq 0.8$ ) and accepted ( $0.8 > \alpha \geq 0.7$ ) internal consistency according to Tavakol and Dennick [37] benchmark.

## IV. RESULTS AND DISCUSSION

In this section, the results of the low-fidelity testing and evaluation process are further elaborated and discussed, especially concerning the field of language learning with apps. Furthermore, the gathered results provided substantial data in response to the experts' review on the RakanBM application.

### A. CW, Semi-Structured Interviews and Think-Aloud Protocol Results

The collected data were analysed and the results are as shown in Table II, specifically in terms of comments and suggestions. During this process, things that were noted were the feasibility of the experts on the given task, the accuracy of the process flow, the information developed, and the solution of the task scenario provided. Experts were required to provide feedback on whether they could perform the task or not. The experts were also free to comment on new ideas and suggestions for improvement. Open-ended questions were posed to get more complex feedbacks. Each question was analysed using a coding scheme by category adopted from Moustakas [38].

TABLE II. PROTOTYPE EVALUATION ANALYSIS RESULTS BASED ON CW, SEMI-STRUCTURED INTERVIEWS, AND THINK-ALOUD PROTOCOL

No.	Comments/Suggestions	No. of Feedback	Percentage (%)
1	Improvement on affix used	3	50
2	Improvement on the video content	2	33
3	Increase the interactivity of the application content	1	16
4	Restructure the content	4	66
5	Applying the application with others help	1	16
6	Introduce level in application	4	66
7	Improvement on aesthetic	4	66
8	Uniformity of the design	2	33

The results revealed that the task scenario completion level was 6/6, which indicates that the experts were able to complete the given task. In other words, this means that the experts completed 100% of the tasks, they were able to understand the application flow, and were aware of and knew the actions taken during the testing process. From Table IV, it can be concluded that the application's content and interface needed enhancement to increase user engagement in the self-learning applications. The results also confirmed that the function modelling and flow of the RakanBM application process were correct, but some improvisation is needed. For instance, the use of buttons, information displays, and contents needed some modification. Nonetheless, the experts agreed that the developed prototype was able to meet the needs of the user, but with some enhancements needed.

It should be noted that the open-ended questions supported the results of the questionnaire. For instance, most of the experts suggested an improvement in the content structure by adding more English translations on the earlier topics in the application. The experts also agreed on the need to introduce levels in the application. In short, the suggestions by experts to increase the aesthetic value on the current prototype supported (validated) the lowest mean value obtained by the text presentation factor of the questionnaire (see Table II).

The overall results revealed that the materials of the *RakanBM* mobile application for Malay Language learning for non-native speakers were relevant, validated by the factors that recorded a high mean: learning outcomes, assessments, effectiveness, and efficiency. The results were similar to previous studies where the mobile application was able to support language learning [6-8, 12]. In general, the *RakanBM* application is focused on Malay language learning with validated benefits. For instance, it is a novel creation for Malay language learning with complete topics suitable and best for non-native speakers. At the same time, the application is student-friendly, and users can use it easily, anytime, and anywhere. Furthermore, AR technology is also integrated into the mobile application to increase students' engagement and relate their surroundings to the learning activity.

### B. Survey Results

Descriptive statistical analysis was carried out to identify the mean, the percentage, and the standard deviation (SD) for

each item of the application factors: contents, text presentations, learning outcomes, assessments, effectiveness, efficiency, and satisfaction. Table III shows the mean for each of the items and factors, respectively. The calculated mean for each factor ranged from 3.53 to 4.50, while the average mean (for all factors) is 3.96. The results indicate that, in general, the evaluators tend to agree that the developed low-fidelity prototype was able to satisfy the factors' requirements. The results were then classified into two levels: high (mean > 4.0) and satisfied (mean > 3.5).

TABLE III. PERCENTAGE (SCALE 1 TO 3) AND (SCALE 4 TO 5) FOR THE SEVEN FACTORS OF USING THE RAKANBM APPLICATION

No.	Factor/Item	Percentage (%) (scale of 1 to 3)	Percentage (%) (scale of 4 to 5)	Mean (SD)
<b>1.0</b>	<b>Application contents</b>			<b>3.80 (1.05)</b>
1.1	The contents provided are suitable to the novice level	16.7	83.3	4.17 (1.17)
1.2	The contents provided have a clear continuity	33.4	66.6	3.83 (1.17)
1.3	The theme of the contents provided is appropriate to the novice level of learning	16.7	83.3	4.00 (1.10)
1.4	The chapters provided are adequate for the novice level	33.4	66.6	3.83 (1.17)
1.5	The language used is appropriate to the novice level of the student	50.0	50.0	3.17 (1.33)
1.6	The exercise provided is adequate	16.7	83.3	4.17 (0.75)
1.7	The exercise provided corresponds to the level of learning	16.7	83.3	4.00 (0.63)
1.8	Listening exercise through audio is adequate	16.7	83.3	4.17 (0.75)
1.9	The audio is clear and helps students listen well	16.7	83.3	3.83 (0.98)
1.10	Translation into English is limited to chapter 1 only	66.6	33.4	2.83 (1.47)
<b>2.0</b>	<b>Text presentations</b>			<b>3.53 (0.92)</b>
2.1	Presentation of contents using attractive graphics	66.6	33.4	2.83 (0.98)
2.2	The graphics used can help students understand the situation	16.7	83.3	4.33 (0.82)
2.3	The colours in the text are interesting	50.0	50.0	2.67 (0.82)
2.4	The length of the text for one chapter is sufficient	16.7	83.3	4.00 (0.63)
2.5	The presentation of the content is appropriate to the age level of the target students	50.0	50.0	3.83 (1.33)
<b>3.0</b>	<b>Learning outcomes</b>			<b>4.03 (1.00)</b>

No.	Factor/Item	Percentage (%) (scale of 1 to 3)	Percentage (%) (scale of 4 to 5)	Mean (SD)
3.1	Students will learn something new from this contents	0.0	100.0	4.67 (0.52)
3.2	Students are able to understand the Malay language is the basis of this contents	16.7	83.3	4.00 (1.55)
3.3	Students can also learn cultural information from this contents	33.4	66.6	4.00 (0.89)
3.4	Students will be excited to continue to level 2	50.0	50.0	3.83 (0.98)
3.5	These contents are sufficient for novice students	33.4	66.6	3.67 (1.03)
<b>4.0</b>	<b>Assessments</b>			<b>4.03 (0.79)</b>
4.1	The scoring for each exercise is balanced	16.7	83.3	4.00 (1.10)
4.2	Assessment is appropriate to the student's level of competence	0.0	100.0	4.17 (0.41)
4.3	The emojis used are appropriate to the student's level of competence	33.4	66.6	4.00 (1.26)
4.4	The assessment rubric is appropriate to the student's level of competence	16.7	83.3	4.17 (0.75)
4.5	Written, graphic/picture and oral tests can measure students' level of competence	33.4	66.6	3.83 (0.41)
<b>5.0</b>	<b>Effectiveness</b>			<b>3.97 (0.93)</b>
5.1	The learning contents displayed by this application are accurate and complete	33.4	66.6	3.67 (1.03)
5.2	Functions and learning contents on the application produce accurate output	33.4	66.6	3.83 (0.75)
5.3	Use of this application will increase the effectiveness in learning Malay	33.4	66.6	4.17 (0.98)
5.4	This application provides audio assistance in learning the Malay language	16.7	83.3	4.50 (0.84)
5.5	The terms contained in this application are clear and not confusing	33.4	66.6	3.67 (1.03)
<b>6.0</b>	<b>Efficiency</b>			<b>4.50 (0.91)</b>
6.1	This application helps learning the Malay language quickly	0.0	100.0	4.50 (0.55)
6.2	This application is able to increase student achievement in Malay language learning	16.7	83.3	4.33 (0.82)
6.3	Navigating this application is easy	33.4	66.6	4.00 (1.26)

No.	Factor/Item	Percentage (%) (scale of 1 to 3)	Percentage (%) (scale of 4 to 5)	Mean (SD)
6.4	This application allows for effective learning	16.7	83.3	4.17 (0.75)
6.5	The information available on this application is organised	33.4	66.6	3.83 (1.17)
<b>7.0</b>	<b>Satisfaction</b>			<b>3.90 (0.97)</b>
7.1	I am satisfied with this application	50.0	50.0	3.50 (1.05)
7.2	I would recommend my friends to use this application	50.0	50.0	4.00 (1.10)
7.3	I enjoy using this application	50.0	50.0	4.00 (1.10)
7.4	This application works just as well as I want it to	50.0	50.0	3.67 (0.82)
7.5	I want to use this application	16.7	83.3	4.33 (0.82)

Consequently, the factors that were recorded as high were the learning outcomes, assessments, effectiveness, and efficiency, while the factors that were recorded as satisfied were the application contents, text presentations, and satisfaction. The efficiency factor obtained the highest mean value of 4.50 with an SD of 0.91, which indicates that the experts (evaluators) tend to agree that the application was very efficient and necessary to help non-native speakers improve their Malay language basics, especially with the assistance of teachers. Meanwhile, the assessments (mean = 4.03, SD = 0.97) and learning outcomes factors (mean = 4.03, SD = 1.00) both obtained a mean value of 4.03, the second-highest mean value. The rest of the factors in the order of descending mean value are effectiveness (mean = 3.97, SD = 0.93), satisfaction (mean = 3.90, SD = 0.97), application content (mean = 3.80, SD = 1.05), and text presentation (mean = 3.53, SD = 0.92). The lowest mean value for the text presentation factor was likely due to feedback from some evaluators stating that the RakanBM interface was less aesthetic. Nevertheless, the positive responses were still more than the negative ones in which the percentage value for factors having a scale of more than 4 was 53% (i.e. agreed by 53% of experts).

The experts' opinions on the positive and negative aspects of the RakanBM prototype application were also collected and listed in Table IV. Following the prototype evaluation, the experts tend to agree with its interface features, elements, and functions. The experts also agreed that the application achieved a positive level of user experience. Nevertheless, analysis of the experts' opinions (i.e. related to the positive and negative aspects) and comments revealed that some improvements were needed.

Feedback on the positive aspects indicated that the application was student-friendly, a more compact learning material, and provided a more accessible and interactive Malay language learning experience. On the other hand, the negative aspects highlighted the difficulty of certain words, more interactive aspects needed, and more effective technique for

assessment required. The items that need to be improved, as indicated in Table III and Table IV will be addressed in the next prototype development to develop a more effective Malay language learning application.

TABLE IV. FEEDBACK ON POSITIVE AND NEGATIVE ASPECTS OF RAKANBM APPLICATION

Expert	Positive Aspect	Negative Aspect
A	<ul style="list-style-type: none"><li>“This application is very student-friendly, the content and learning materials are also presented in a very simple, easy, and compact way.”</li></ul>	<ul style="list-style-type: none"><li>None</li></ul>
B	<ul style="list-style-type: none"><li>“The first complete application was produced, very useful and easy for international students and can be applied on Android and iPhone”.</li><li>“Topics are very suitable and best for non-native speakers.”</li></ul>	<ul style="list-style-type: none"><li>None</li></ul>
C	<ul style="list-style-type: none"><li>“Content. Use of different languages (pronouns) according to the conversation situation as shown in Chapter 1. Various exercises such as True / False, Multiple Choice and Vocabulary that tests listening and viewing skills and the application of those skills.”</li></ul>	<ul style="list-style-type: none"><li>“As a novice student, it is quite difficult to comprehend the rich words. Words exist in conversation.”</li></ul>
D	<ul style="list-style-type: none"><li>“An effort made to develop Malay language application for foreign speakers use.”</li></ul>	<ul style="list-style-type: none"><li>“Need to add more interactive aspects.”</li></ul>
E	<ul style="list-style-type: none"><li>“Malay language learning is more accessible and interactive even on its own.”</li></ul>	<ul style="list-style-type: none"><li>None</li></ul>
F	<ul style="list-style-type: none"><li>“There is an AR element. AR can be used for collaborative teaching.”</li></ul>	<ul style="list-style-type: none"><li>“Assessment items should be based on audio not surrounding objects.”</li></ul>

Furthermore, the study finding corresponded to past research where mobile application utilization enhanced user performance and language learning [3, 7, 8]. The implementation of gamification in education has increased engagement and achieved learning more effectively[39]. For instance, the study of Sorrentino and Sorrentino and Spano [40] and Fang, Yeh [41]. Both of these studies prove how the use of mobile apps with the mobile application has really helped improve the English proficiency of non-native students. Among the focuses given were mastery of vocabulary, pronunciation practices, and the construction of simple sentences. Besides, Wang and Han [42] have used English language learning modules for native Chinese speaking students to further improve their mastery of communication strategies in English. This learning module was based on digital games using the smartphone application "Liulishou" (fluent in English). This study shows that this digital learning material has been able to help improve the level of pronunciation accuracy, fluency in communication, and the production of complex sentence structures orally among students. Another interesting mobile application was developed by Yamamoto, Rodriguez [43], who sought to innovate FinDo, which is a smartphone app capable of listing vocabulary related

to where users are located. For example, when a consumer is in a supermarket, the consumer can learn all the words related to the objects around it. Specifically, it turns out that all studies on language learning using mobile devices improved students' language proficiency well.

However, there were some challenges that lie within this expert review on mobile augmented reality applications for language learning studies. Since the whole process is majorly held by online meetings, it becomes boundaries in communication involving the experts. Nevertheless, the researchers' team has planned the method so well to lessen the impact as the situation was unavoidable due to pandemic times. Further guidelines can be taken for future research methods, especially in order to make progress more effective and efficient.

This whole chapter discusses the expert review ranging from prototype testing using CW techniques, semi-structured interviews, think-aloud protocols, and prototype evaluation using surveys upon completion of the test. It has been proven that RakanBM application was relevant and suitable to support Malay language mobile learning in line with previous studies where mobile learning has increased user's performance, especially in education [44, 45]. The analysis was conducted on seven construct and open-ended questionnaires to obtain expert feedback on the positive and negative aspects of the application as well. The analysis results show that the usefulness and the topics covered were suitable and best for foreign speakers.

## V. CONCLUSION

In this study, a review panel of six experts from the Malay language and HCI fields evaluated *RakanBM*, a newly developed mobile application prototype for Malay language learning for first speakers and foreign speakers. The evaluation methods consisted of CW, semi-structured interviews, think-aloud protocols, and surveys. The findings were analysed and summarised to determine the usability of the application and have contributed to new knowledge. In this study, it has been found that the expert review was in line with the previous literature where the mobile application was able to support learning language. The *RakanBM* application aimed to assist foreign users, especially novice user learning in classroom environments. The mobile application proved to be interesting, and the experts saw high potential in the application, especially if the needed changes could be implemented. The experts' recommendations were presented for the benefit of researchers and developers for the future development of Malay language learnings. Further research involving usability testing will be done for the target user - the non-native speakers – taking into consideration the findings of this present study.

## ACKNOWLEDGMENT

This study is supported by the Universiti Kebangsaan Malaysia under research grant scheme of GPK-PBM-2020-015.

**Abstract**—Semantic similarity is applied for many areas in Natural Language Processing, such as information retrieval, text classification, plagiarism detection, and others. Many researchers used semantic similarity for English texts, but few used for Arabic due to the ambiguity of Arabic concepts in both sense and morphology. Therefore, the first contribution in this paper is developing a semantic similarity approach between Arabic sentences. Nowadays, the world faces a global problem of coronavirus disease. In light of these circumstances and distancing's imposition, it is difficult for farmers to physically communicate with agricultural experts to provide advice and find suitable solutions for their agricultural complaints. In addition, traditional practices still are used by most farmers. Thus, our second contribution is helping the farmers solve their Arabic agricultural complaints using our proposed approach. The Latent Semantic Analysis approach is applied to retrieve the most problem-related semantic to a farmer's complaint and find the related solution for the farmer. Two methods are used in this approach as a weighting schema for data representation are Term Frequency and Term Frequency-Inverse Document Frequency. The proposed model has also classified the big agricultural dataset and the submitted farmer complaint according to the crop type using MapReduce Support Vector Machine to improve the performance of semantic similarity results. The proposed approach's performance with Term Frequency-Inverse Document Frequency-based Latent Semantic Analysis achieved better than its counterparts with an F-measure of 86.7%.

**Keywords**—Semantic similarity; latent semantic analysis; big data; MapReduce SVM; COVID-19; agriculture farmer's complaint

## I. INTRODUCTION

The semantic analysis field has an essential role in the research related to text analytics. Measuring the semantic similarity between sentences is a long-standing problem in the Natural Language Processing (NLP) field [1], [2]. With the growth of text data over time, NLP became essential to be worthy of attention for Artificial Intelligence (AI) experts [3], [4]. Semantic similarity is used for several fields in NLP like information retrieval, text summarization, plagiarism detection, question answering, document clustering, text classification, machine translation, and others [5], [6]. It is defined as determining whether two concepts are similar in meaning or not [7]. The concepts are words, sentences, or paragraphs. Each concept takes a score. When the concept has a high score refers to high similarity or semantic equivalence to another concept [8]. Concepts can have two ways to be similar that are either

lexically or semantically. Concepts are lexical similarly if words have similar character sequences and are performed using a String-based algorithm. Concepts are semantic similarly if words depend on information acquired from massive corpora, even if they have a different lexical structure. Semantic similarity can be done by a corpus-based algorithm or knowledge-based algorithm [9], [10]. Several research works of semantic similarity have been developed for English sentences. On the other side, few research works have been used for the Arabic language because Arabic is considered a complex morphological language [11]. However, the Arabic language considers the fifth most spoken language in the world. Also, it participates in the most critical foreign languages with over 300 million speakers and a wide range of functionalities that no other language can have [12]. Therefore, this paper will apply a semantic similarity approach to the Arabic dataset.

Currently, the world faces a huge disaster that threatens the world is the global Coronavirus disease (COVID-19) pandemic. COVID-19 causes destructive economic, political, and social crises in each country. All fields have been affected by the global Coronavirus, especially the agriculture field. In our life, Agriculture plays a critical role in the entire life of the economy. It can be one source of Livelihood, contributes to national revenue, the supply of food, and marketable surplus. Moreover, it provides job opportunities to a huge percentage of the population and supplies the country with an important portion from its foreign exchange through agriculture exports. Therefore, due to COVID-19 that compounds pre-existing vulnerabilities in the field of agriculture in Egypt. Initial analyzes of this epidemic have shown disrupting access to agricultural inputs, including employment, extension, advising services, and producing markets for farmers. Most significant countries became deserted that people stay indoors, either by choice or by the government, to reduce the spread of this pandemic. Because of this, the curfew and distancing imposed by COVID-19 cause many problems for farmers. So, it is difficult for farmers to communicate and interact with agricultural experts to present their complaints and find suitable solutions. Therefore, it is essential to find an appropriate way to help in solving the farmers' complaints. Agriculture Research Center (ARC) and Virtual Extension and Research Communication Network (VERCON) [13] in Egypt provide a large group of farmers' complaints and their solutions in Arabic deployed on a public cloud. The agricultural experts have resolved these complaints. Thus, under these difficult circumstances of the spread of the COVID-19, this paper aims to develop an approach for farmers to help, support, and find the

most suitable solution for their agricultural complaints. The proposed approach is based on latent semantic analysis (LSA) to measure the semantic similarity score between Arabic farmers' complaints and the Arabic agricultural dataset, further retrieving the related solution to the farmer. As an example, the farmer's complaint is "مهاجمة دودة ورق القطن لحقول البرسيم فما هي المقاومة؟" and its English equivalent is "Cotton leaf worm attack alfalfa fields, what is the resistance?". After applying the proposed model, the recommended solution is "تقاوم دودة ورق القطن في البرسيم باستخدام احد المبيدات الموصى بها مثل لانيت 90% بمعدل 300 جم/ف ثم الري بالسولار بمعدل 200 لتر للفدان" and its English equivalent is "The cotton leafworm is resisted in alfalfa by using one of the recommended pesticides such as Lannet 90% at a rate of 300 g/f, then irrigation with diesel at a rate of 200 liters per feddan."

To improve the performance of the semantic similarity approach, we used the classification. Text Classification (TC) is an active research field and an essential in information retrieval technology [14]. It aims to classify text documents into one or more predefined categories. TC is applied in many applications like sentiment analysis, sentence classification, and document classification [15], [16]. TC can use many methods such as Decision Trees, Support Vector Machine (SVM), Artificial Neural Networks (ANN), Naïve Bayes (NB), K-Nearest Neighbor (KNN), etc. [17], [18].

SVM is an extremely powerful classifier in the machine learning field and is widely used in text classification [19]. However, it is fast and easy to implement. Therefore, we applied SVM on the agricultural dataset to classify Arabic complaints into crops. But, SVM didn't achieve better accuracy results. Thus, to improve performance in classifying our Arabic agricultural dataset, we resort to a parallel programming model like MapReduce. So, this paper applied the classification by MapReduce SVM using Hadoop to classify the Arabic agricultural dataset according to its crop type.

Most of the previous works applied Arabic semantic similarity to small datasets and achieved low accuracy results. Moreover, fewer of them tested on agriculture datasets and didn't use the classification.

Thus, the main objectives in this paper are as follow:

- 1) Applying the proposed model on a big agricultural dataset with real complaints facing Egypt's farmers.
- 2) The proposed model can help farmers, especially in the circumstances of COVID-19, by providing advice and finding appropriate solutions for their complaints to enhance agriculture productivity.
- 3) Developing a semantic similarity model between Arabic complaints and obtaining better results.
- 4) Using a parallel programming model like MapReduce based on SVM to classify the agricultural dataset and improve the performance of a semantic similarity model.
- 5) Testing and validating the proposed model performance by implementation multiple experiments and applying previous models on our Arabic agricultural dataset.

The remaining parts of the paper will be structured so that Section II presents related work; Section III includes materials and methods; Section IV covers discussion; Section V shows

the experimental results. Finally, in Section VI, the conclusion is produced.

## II. RELATED WORK

This section will introduce related work about Arabic text classification and Arabic semantic similarity. Mostafa et al. [20] Proposed two models to classify the Arabic farmers' complaints based on different diseases that may affect crops. The Arabic complaint is classified into its respective crop and a specific disease in the first model. The second model could classify the complaint directly into diseases. Each preprocessed complaint is represented into a binary vector form using the vector space model by helping the crop lexicon. Experiments are conducted on the dataset by changing the training percentage with many trials using SVM and KNN classifiers. The results are shown that the proposed model is performed on par with the human expert and can be applicable for real-time operations. Moreover, Raed Al-khurayji and Ahmed Sameh [21] presented an approach that depends on a Kernel Naive Bayes classifier to solve the non-linearity problem of Arabic text classification. First, they applied preprocessing techniques on Arabic datasets like tokenization, stop word removal, and light stemmer. Then, they used the TF-IDF technique on Arabic words for feature extraction to convert them into the vector space. Experimental results are shown that the proposed approach achieved good accuracy and time compared with other classifiers. While Abutiheen et al. [22] proposed the Master-Slaves (MST) technique to classify Arabic texts. The proposed approach consisted of two phases. In the first phase, Arabic corpus text files are collected. These text files are classified manually into five categories. In the second phase, four classifiers were implemented on the Arabic collected corpus. The four classifiers were NB, KNN, Multinomial logistic regression, and maximum weight. NB classifier was applied as Master and the others as Slaves. The slave classifiers' results were used to change the NB classifier probability (Master). Each document in a corpus was represented as a vector of weights. The results of the MST have achieved a good improvement in accuracy compared with the other techniques.

Schwab et al. [23] presented a technique that depends on word embedding for measuring semantic relations among Arabic sentences. This technique relies on the characteristic of semantic words in the model of word embedding. This technique has applied three methods: no weighting method, Inverse Document Frequency (IDF) weighting method, and part-of-speech (POS) weighting method. No weighting method is used by summing the word vectors of each sentence. To improve the results, use the IDF weighting method to calculate IDF weight for each word and add the word vectors with IDF weights for each sentence. Also, use the POS tagging method that supposes weight for each POS and calculate POS for each word, then for each sentence, sum the words vectors with POS weights. This technique is evaluated the results on a small dataset. This paper demonstrated how weighing IDF and POS tagging supports highly descriptive word determination in any sentence. The performance of both IDF and POS weighting techniques achieved better results. While Amine et al. [24] proposed an Arabic search engine method depending on the MapReduce method. This method is used for finding semantic similarity among an Arabic query and the large corpus of

existing documents in the Hadoop Distributed File System (HDFS). It is also used to obtain the most relevant documents. It uses two measures in MapReduce: Wu and Palmer (WP) measure and Learrock and Chodorow (LC) measure. The results appeared that WP and LC obtained better results than the existing approaches of semantic similarity. Mahmoud et al. [25] suggested a semantic similarity technique in paraphrase identification for Arabic. This technique depends on the combination of various NLP like the TF-IDF technique and the word2vec algorithm. TF-IDF technique is used to ease the identifying of highly descriptive terms in each sentence. The word2vec algorithm is used for representations of distributed word vectors. Also, word2vec can minimize computation complexity and optimize the likelihood of word prediction in producing a model of sentence vector. This paper applied the similarity using various comparison metrics, like Cosine Similarity and Distance Euclidean. Finally, the proposed technique was tested on the Open-Source Arabic Corpus OSAC and achieved a reasonable rate. In [26] used a semantically reduced dimensional vector to represent high dimensional Arabic text. It has been accomplished by extending the standard vector space model (VSM) to enhance the representation of text that utilizes Linguistic and semantic properties from Arabic WordNet and Name Entities' gazetteers. If synonyms and similar terms obtain from the same root in clusters, the vector size reduces, and the shorter NE represents the chosen cluster members. The word similarity is also determined using distributional similarity to collect similar terms into clusters. Results demonstrated the size, form of the analysis windows, and the text's nature and category based on how much it reduced. In [27] suggested a method for finding the semantic similarity among two Arabic texts. This approach used hybrid similarity measures that are edge-counting semantic approach, cosine similarity, and N-gram similarity. The edge-counting semantic approach determined the value of a threshold. If the first approach's similarity result was lower than the threshold value, then cosine similarity is applied. Moreover, if the cosine similarity value compared with the predefined threshold was not appropriate, use N-gram similarity. This hybrid approach addresses problems of writing mistakes like repetitive, incomplete, and substituted characters. The hybrid similarity results outweigh the results of any of the three measures that have been used individually.

### III. MATERIAL AND METHODS

The proposed model aims to measure the semantic similarity's score between the current farmer's complaint and the available historical agricultural problems to provide an adequate solution to the farmer's complaint. Our proposed model was applied and tested on the agriculture problems dataset and their solutions. ARC and VERCON. It contains complaints of various causes, such as harmful weeds, fungal diseases, and other diseases that affect plants and their solutions. It also includes complaints belongs to 31 governorates and their directorates. It contains more than 10,000 complaints. The complaints are written in the Arabic language in an unstructured form and not well-formatted. These complaints related to different crops such as "rice, okra, wheat, corn, cotton, beans, etc...". It is also associated with different categories, which are "Administrative, Productivity, Marketing, and Environmental".

Due to the variety of crops in the agriculture dataset, the proposed model applied a classification method to classify the farmer complaints dataset according to the crop type.

Table I shows some examples of the dataset's complaints related to different crops and their English translation.

TABLE I. EXAMPLES FOR ARABIC FARMERS' COMPLAINTS AND THEIR ENGLISH EQUIVALENT

Complaints in the English Language	Complaints in the Arabic Language
Yellow spots on the leaves of onion plants.	وجود بقع صفراء على اوراق نباتات البصل.
The presence of whiteflies strongly in cotton.	وجود ذبابة بيضاء بشدة في القطن.
The wheat was infested with aphids.	اصابة القمح بحشرة المن.
The presence of spots on the upper surface of okra leaves with the appearance of a spider thread on its lower surface	وجود بقعة على السطح العلوي من اوراق الباميا مع ظهور خيط عنكبوتي على سطحها السفلي.
The lack of water in the Arimon canal for more than a month exposes the existing winter crops to fallow, such as clover.	عدم وجود مياه بترعة اريمون منذ اكثر من شهر مما يعرض المحاصيل الشتوية القائمة للوبار مثل البرسيم.

The proposed model consists of four phases, as shown in Fig. 1 Preprocessing, MapReduce SVM classification, and Latent Semantic Analysis. The last phase is the ranking and selection to choose the most semantically relevant solution to the farmer's complaint. The next sections explain in detail the phases of the proposed model.

#### A. Preprocessing Phase

The preprocessing phase is an essential step for Natural Language Processing (NLP) tasks. It transforms input text into a more desired form for performing better for further steps [28]. Unfortunately, the complaints' meaning is difficult to understand and interpret since farmers typically write complaints without following the Arabic grammar rules.

Data preprocessing includes four operations: tokenization, stop word removal, complaints auto-correction, normalization, and lemmatization, as shown in Fig. 1.

- Tokenization: It is a method for breaking texts into tokens. Words are separated from their neighboring words by blanks such as white space, periods, commas, semicolons, and quotations [29]. For example, The Arabic complaint is "وجود بقع صفراء لها مظهر مسحوقى فى صفوف طوليه على ورقه القمح".

After applying the tokenization, the Arabic complaint is:

And its equivalent English is: "The presence of yellow spots that have a powdery appearance in longitudinal rows on the wheat leaf."

"وجود", "بقع", "صفراء", "لها", "مظهر", "مسحوقى", "فى", "صفوف", "طوليه", "على", "ورقه", "القمح".

- Stop Word Removal: The most popular undesirable term is either a punctuation mark or a stop word. Therefore, they are eliminated from complaints since they do not have any meaning or indications about the content. We used an online Arabic stop words list for elimination [30]. Examples of these unimportant words in the Arabic language such as:

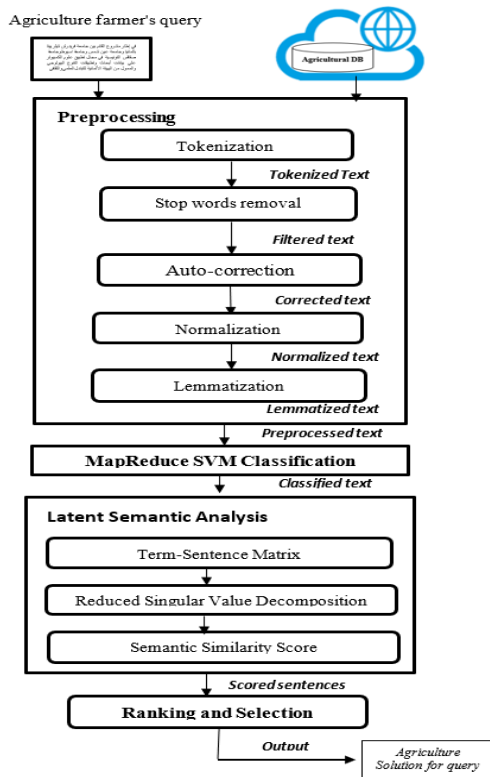

Fig. 1. The Proposed Architecture.

(كلما, اولاً, حول, اين, طالما, التي, من, الى, على, فوق, تحت, الخ.

And in the English language are (Whenever, first, about, where, as long as, which, from, to, on, above, below, etc.)

In addition, eliminating all symbols such as: (@, #, &, %, and \*).

- Auto-correction: The farmers may write their complaints with spelling errors. For example, the crop name of tomatoes "طماطم" may be incorrectly written in slag way as "اوطه", the crop name of corn "نزه" may be incorrectly written as "ززه" and the name of rice crop "ارز" may be incorrectly written as "رز" [20]. Therefore, we use auto-correction to solve these problems by substituting the incorrect word with the correct one.
- Normalization: Text normalization is transforming the input text into a canonical (standard) form. It is critical for noisy texts like comments on social media and text messages that are popular in abbreviations and misspellings. Moreover, it concentrates on removing the inconsistent language variations. For example, In English, the word "croooop" can be transformed into its canonical form "crop" and also in Arabic like "محصولوول" is normalized into "محصول" [31], [32]. So, we applied some methods for normalization such as the letters "أ، ا، إ" will convert into one form "ا." Also, the letter "ة" will replace by "ه", the letter "ي" will convert to "ى." Also, remove the diacritics from the words such as "أشجار" will convert to "اشجار". Furthermore, if there are more spaces between words, then we removed

them. We also convert numbers into words such as "15" will convert to "خمسة عشر."

- Lemmatization: It is an essential step in the preprocessing phase and a significant component for many applications of natural language processing. It is an operation to find the base form for a word. For example, in Arabic words like (ثمر) has the root "ثمر." Also, in English, "fruits" has the root "fruit." We used an online Farasa lemmatization [33].

### B. MapReduce SVM Classification Phase

Text Classification is the process of distributing each document to its labeled class [34]. MapReduce is a popular programming model developed by Google. It can process massive datasets in a parallel manner and achieves a high performance [35], [36]. The main idea of MapReduce comes from the divide and conquer algorithms which are used to divide a large problem into smaller subproblems. Therefore, we apply MapReduce SVM to classify big data preprocessed agricultural complaints according to their crop type, such as rice, wheat, okra, etc. MapReduce SVM uses the Hadoop framework to share the classification between many machines using HDFS to store the preprocessed agricultural complaints to classify and store the classification result. MapReduce model is divided into two tasks which are Map and Reduce [37]. It divides the dataset into smaller chunks and then assigns each chunk to a single map task. Map tasks' number is equal to the number of data chunks. Thus, each map task processes each data chunk in a parallel way. The model shuffles and sorts the Map outputs and transfers them to the Reduce tasks. The Reduce task is a summarization step that all associated records are processed together by a single entity. The Map and Reduce tasks are mathematically represented in (1) and (2), respectively [38].

$$\text{Map: } (K_1, V_1) \rightarrow [(K_2, V_2)] \quad (1)$$

$$\text{Reduce: } (K_2, [V_2]) \rightarrow [(K_3, V_3)] \quad (2)$$

The  $(K_1, V_1)$ ,  $(K_2, V_2)$ , and  $(K_3, V_3)$  represent the key-value pairs for map and reduce tasks.

After this phase, each complaint is classified according to its crop type. Table II shows the number of Arabic agricultural complaints in each crop after applying the MapReduce SVM model.

### C. Latent Semantic Analysis Phase

In this phase, LSA is applied to measure the semantic similarity among the agriculture dataset and the farmer complaint. It is a technique used for representing documents as a vector. It helps to find the similarity between agricultural complaints by calculating the distance between vectors.

There are three main steps for the LSA-based algorithm:

- Creating the input matrix (Term-Sentence matrix)
- Applying reduced singular value decomposition (RSVD) on the created matrix
- Calculating the semantic similarity score between the farmer's complaint and complaints document.

TABLE II. THE NUMBER OF ARABIC AGRICULTURAL COMPLAINTS IN EACH CROP

Crop Name (English)	Crop Name (Arabic)	Number of Arabic Complaints	Crop Name (English)	Crop Name (Arabic)	Number of Arabic Complaints
Wheat	قمح	890	Apples	التفاح	837
Rice	ارز	754	Orange	البرتقال	458
Cotton	قطن	735	Lettuce	الخس	579
Tomatoes	طماطم	692	Cabbage	الكرنب	699
Beans	الفاصوليا	572	Garlic	الثوم	276
Potato	البطاطس	379	Guava	الجوافة	497
Clover	البرسيم	437	Okra	الباميا	238
Peach	الخوخ	288	Banana	الموز	798
Onions	البصل	583	Peas	البسلة	436
Apricot	المشمش	400	Watermelon	البطيخ	972
Lentils	العدس	389	Mandarin	اليوسفي	697
Grapes	العنب	457	Cowpea	اللوبيا	793
Eggplant	البانجان	389			

These steps will be explained in detail in the following sections.

1) *Term-sentence matrix*: In this phase, an input matrix is created for the farmer’s complaint query and classified complaints document. Each row in the matrix represents the word or term in the farmer’s complaint or classified complaints document [39]. Each column represents the complaints. The cell value is the result of the intersection between term and complaint. There are two methods used as a weighting schema for data presentation for filling the cell values: Frequency (TF) or Term Frequency-Inverse Document Frequency (TF-IDF).

In TF-based LSA, the cells are filled with the term frequency (TF<sub>i</sub>) of terms in the complaint statement (C<sub>j</sub>) as in (3).

$$W(t_{ij}) = tf_{ij} \quad (3)$$

Where  $W(t_{ij})$  is the weight of a term (i) in each complaint statement (j) and  $tf_{ij}$  is the frequency of a term (i) in each complaint statement (j).

TF\_IDF-based LSA, the cells are filled with the weight of (TF\_IDF) of the term (i) in complaint statement (C<sub>j</sub>) as shown in (4) and (5).

$$TF\_IDF_{ij} = TF_{ij} * IDF_{ij} \quad (4)$$

Where  $TF\_IDF_{ij}$ : TF is the frequency of a term (i) in each complaint statement (j), and IDF reflects the importance of term among all sentences

$$IDF_{ij} = \log \frac{N}{ComplaintFreq(f)} \quad (5)$$

Where  $N$  represents the number of complaints in the collection, and  $ComplaintFreq(f)$  is the number of complaints containing the term.

2) *Reduced singular value decomposition*: Singular value decomposition (SVD) is an algebraic method that plays an essential role in text mining and natural language processing. SVD is used to improve the term sentence matrix, remove noise, and determine the relationships between terms and complaints statements [40]. SVD decomposes the Term Sentence Matrix into three matrices that detect all the important properties and features of the matrices.

Equation (6) shows the SVD decomposition of the  $m \times n$  matrix.

$$SVD = USV^T \quad (6)$$

Where  $U$  is the  $m$ -dimensional matrix,  $V$  is the  $n$ -dimensional matrix, and  $S$  is the diagonal matrix.

Moreover, RSVD is applied to improve and enhance the performance of SVD and reduce the matrix dimensionality.

3) *Semantic similarity score*: After applying RSVD, RSVD results are used to calculate semantic similarity between the farmer query and classified complaints document. The semantic score is calculated using the most common similarity method, which is the cosine similarity. Equation (7) represents the calculation of cosine similarity.

$$Cos\ similarity(A, B) = \frac{A \cdot B}{||A|| * ||B||} \quad (7)$$

Where  $Cos\ similarity(A, B)$  is the similarity score between the farmer query and complaints document, A is the weight of the term in the query, and B is the weight of the term in the complaint statement.

#### D. Ranking And Selection Phase

In this phase, rank the complaints according to the semantic score, then select the complaint of the highest score. Finally, retrieve the solution of the complaint with the highest score to the farmer query.

### IV. DISCUSSION

F-measure is used to evaluate the performance for the proposed classification approach and semantic similarity approach.

#### A. Classification Evaluation

The performance of the MapReduce SVM classifier using Hadoop is evaluated. Also, we compared our classification results with the previous classification works as in Mostafa et al. [20] and Mohammad et al. [41]. Authors in [20] applied two classifiers that are SVM and KNN, on the same agricultural dataset to classify agricultural complaints into crops.

Moreover, authors in [41] used two classifiers that are the Naive Bayes algorithm (NB) and the Hybrid Naive Bayes with Multilayer Perceptron network (NB-MLP), to classify the dataset into positive or negative sentiment. Therefore, we applied NB and NB-MLP algorithms to our agricultural dataset to classify complaints into crops.

TABLE III. EVALUATION OF MAPREDUCE SVM CLASSIFIERS COMPARED WITH PREVIOUS MODELS

Class	NB			NB-MLP			SVM			KNN			MapReduce SVM		
	Precision	Recall	F-Measure	Precision	Recall	F-Measure	Precision	Recall	F-Measure	Precision	Recall	F-Measure	Precision	Recall	F-Measure
Wheat	91.71	94.54	93.10	92.54	95.91	94.19	93.68	97.49	95.55	93.96	97.58	95.74	94.2	98.4	96.3
Rice	90.83	92.32	91.57	94.72	95.73	95.22	89.13	97.27	93.02	96.85	89.71	93.14	97.4	98.3	97.8
Cotton	92.52	94.84	93.67	93.03	95.45	94.22	93.06	95.32	94.18	83.87	93	88.2	94.7	97.4	96
Beans	93.77	95.61	94.68	94.18	96.48	95.32	96.82	75.43	84.8	95.24	97.62	96.42	97.5	98.8	98.1

Table III shows a comparison between our MapReduce SVM evaluation results and previous works that used NB, NB-MLP, SVM and KNN classifiers. We evaluated the results on four crops, such as wheat, rice, cotton, and beans, familiar with authors in [20].

As a conclusion, the evaluation results of MapReduce SVM achieved better results than previous classifiers of NB, NB-MLP, SVM and KNN.

### B. Semantic Similarity Evaluation

The proposed semantic similarity approach using TF-based LSA and TF\_IDF-based LSA are tested and evaluated. And finally, the results of the proposed approach are compared with the previous models. The tests applied on twenty-five crops which are Okra, Mandarin, Watermelon, Wheat, Rice, Cotton, Beans, Tomatoes, Potato, Peach, Apricot, Lentils, Onions, Clover, Apples, Eggplant, Grapes, Orange, Banana, Guava, Peas, Cowpea, Cabbage, Garlic, and Lettuce.

TABLE IV. THE NUMBER OF ARABIC QUERIES IN EACH CROP

Crop Name (English)	Crop Name (Arabic)	Number of Arabic Complaints	Number of Arabic Complaint Queries
Wheat	قمح	890	222
Rice	ارز	754	188
Cotton	قطن	735	183
Tomatoes	طماطم	692	173
Beans	الفاصوليا	572	143
Potato	البطاطس	379	94
Clover	البرسيم	437	109
Peach	الخوخ	288	72
Onions	البصل	583	145
Apricot	المشمش	400	100
Lentils	العنيس	389	97
Grapes	العنب	457	114
Eggplant	الباذنجان	389	97
Apples	التفاح	837	209
Orange	البرتقال	458	114
Lettuce	الخس	579	144
Cabbage	الكرنب	699	174
Garlic	الثوم	276	69
Guava	الجوافة	497	124
Okra	الباميا	238	59
Banana	الموز	798	199
Peas	البسلة	436	109
Watermelon	البطيخ	972	243
Mandarin	اليوسفي	697	174
Cowpea	اللوبيا	793	198

In addition, we tested 25 % of different queries on each crop. Table IV shows the number of Arabic complaint queries for each crop.

TABLE V. EXAMPLES FOR ARABIC COMPLAINTS QUERIES AND THEIR ENGLISH EQUIVALENT

Complaints queries in the English language	Complaints queries in the Arabic language
The presence of aphids inside the okra fruits.	وجود حشرة المن داخل ثمار الباميا.
The presence of brown spotting on apricot trees.	وجود بقع بني على اشجار المشمش.
The appearance of black spots on the potato leaves.	ظهور بقع سوداء على اوراق البطاطس.
The appearance of oval spots of different sizes on the onion leaves	ظهور بقع بيضاوية مختلفة الحجم على اوراق البصل.
The appearance of a minute white layer on the peach trees.	ظهور طبقة بيضاء دقيقة على اغصان اشجار الخوخ.
High rates of apple fruit fall.	ارتفاع نسب تساقط ثمار التفاح.
Yellowing of mandarin trees, complete yellowing with their fall.	اصفرار شجرة اليوسفي اصفرار كامل مع تساقط معظم اوراق اليوسفي.

TABLE VI. EXAMPLES OF EVALUATION RESULTS FOR TF-BASED LSA APPROACH

Crops Name	Evaluation Methods		
	Average Precision	Average Recall	Average F-Measure
الباميا (Okra)	83.5%	80.3%	81.9%
اليوسفي (Mandarin)	86.5%	83.3%	84.9%
البطيخ (Watermelon)	84.7%	82.0%	83.3%
القمح (Wheat)	85.6%	82.3%	83.9%
الارز (Rice)	86.2%	83.2%	84.7%
القطن (Cotton)	85.5%	83.3%	84.4%
الفاصوليا (Beans)	83.5%	81.7%	82.6%
الطماطم (Tomatoes)	86.0%	80.4%	83.1%
البطاطس (Potato)	80.7%	78.5%	79.6%
الخوخ (Peach)	86.4%	82.3%	84.3%
المشمش (Apricot)	81.5%	80.4%	80.9%
العنيس (Lentils)	85.0%	83.5%	84.2%
البصل (Onions)	79.8%	76.7%	78.2%
البرسيم (Clover)	83.5%	80.3%	81.9%
التفاح (Apples)	80.0%	78.4%	79.2%
الباذنجان (Eggplant)	82.5%	80.3%	81.4%
العنب (Grapes)	79.5%	77.7%	78.6%
البرتقال (Orange)	81.5%	80.8%	81.1%
الموز (Banana)	85.4%	81.5%	83.4%
الجوافة (Guava)	81.7%	79.5%	80.6%
البسلة (Peas)	85.7%	80.6%	83.1%
اللوبيا (Cowpea)	80.0%	78.5%	79.2%
الكرنب (Cabbage)	80.5%	76.3%	78.3%
الثوم (Garlic)	81.0%	79.5%	80.2%
الخس (Lettuce)	83.7%	79.8%	81.7%

Table V shows some examples of the Arabic queries complaints related to different crops and their English translation.

In TF-based LSA, average Precision, Recall, and F-measure values for the twenty-five crops are shown in Table VI.

In TF\_IDF-based LSA, we also apply the previous Arabic queries in Table IV on each crop of the previous twenty-five crops. Thus, average Precision, Recall, and F-measure values of the TF\_IDF-based LSA for the twenty-five crops are shown in Table VII.

As a conclusion, by comparing the evaluation results of the TF-based LSA approach with the TF\_IDF-based LSA approach, we conclude that the results of TF\_IDF-based LSA approach achieved the best results since TF-IDF measures how important a term in complaints that give high weight for important terms while TF shows the only number of times that a term appears in a complaint.

TABLE VII. EXAMPLES OF EVALUATION RESULTS FOR TF\_IDF-BASED LSA APPROACH

Crops Name	Evaluation Methods		
	Average Precision	Average Recall	Average F-Measure
الباميا (Okra)	85.4%	83.0%	84.2%
اليوسفي (Mandarin)	88.3%	85.2%	86.7%
البطيخ (Watermelon)	87.0%	84.9%	85.9%
القمح (Wheat)	86.5%	83.3%	84.9%
الأرز (Rice)	86.7%	84.0%	85.3%
القطن (Cotton)	86.8%	84.3%	85.5%
الفاصوليا (Beans)	84.3%	82.7%	83.5%
الطماطم (Tomatoes)	87.4%	83.7%	85.5%

التفاح (Apples)	78.0%	76.8%	77.4%
الباذنجان (Eggplant)	81.0%	79.9%	80.4%
العنب (Grapes)	77.9%	76.8%	77.3%
البرتقال (Orange)	80.6%	79.9%	80.2%
الموز (Banana)	82.4%	78.3%	80.3%
الجوافة (Guava)	80.5%	78.2%	79.3%
البسلة (Peas)	84.1%	79.6%	81.8%
اللوبيا (Cowpea)	78.8%	75.9%	77.3%
الكرنب (Cabbage)	78.4%	75.8%	77.1%
الثوم (Garlic)	78.6%	76.4%	77.5%
الخس (Lettuce)	80.3%	78.6%	79.4%

Finally, we compared our results with the previous models as Schwab et al. [23]. They applied three methods that are no weighting method, IDF weighting method, and POS weighting method. Schwab concluded that applying both the IDF and POS weighting methods achieved better results in performance. Therefore, we apply the previous models (IDF and POS weighting methods) to our agricultural dataset.

Table VIII shows the average Precision, Recall, and F-measure values for the previous models. We also apply IDF and POS weighting methods on the same twenty-five crops used in our proposed TF-based LSA and TF\_IDF-based LSA approach.

Finally, Fig. 2 show the F-measure evaluation results of our two proposed model TF\_IDF-based LSA and TF-based LSA compared with the previous models of IDF and POS weighting methods.

The comparison figure shows that the proposed TF\_IDF-based LSA achieves better results than the proposed TF-based LSA and previous models of IDF and POS weighting methods.

Fig. 2. Average F-Measure Values for Our Two Proposed Models and Previous Models.

V. RESULT

The LSA-based proposed model is applied to retrieve the most relevant complaint and its solution to the farmer query.

Consider the example in Table IX for an Arabic farmer query.

TABLE IX. EXAMPLE FOR ARABIC FARMERS' QUERY AND ITS ENGLISH EQUIVALENT

Arabic Farmer Query	English Farmer Query
وجود ديدانان في الباميا	Presence of worms in okra

As shown in Table IX, the Arabic farmer query is "وجود ديدانان في الباميا" and in English equivalent is "Presence of worms in okra".

The model will be followed step by step as follows:

Firstly, apply the preprocessing steps on the Arabic farmer query and all complaints in the dataset. Table X represents preprocessing steps on the Arabic farmer query.

Secondly, applying classification by MapReduce SVM approach using Hadoop to classify Arabic farmers' query into a crop that belongs to. As in Arabic farmer query "وجود ديدان باميا", this query is classified into "okra" crop.

Thirdly, applying LSA steps that the input matrix is created for Arabic farmer query and all complaints that belong to okra crop. Then, apply RSVD to the input matrix.

TABLE X. PREPROCESSING STEPS FOR ARABIC FARMERS' QUERY AND ITS ENGLISH EQUIVALENT

Preprocessing steps	Arabic farmer query after preprocessing	English farmer query after preprocessing
Tokenization	"وجود", "ديدانان", "في", "الباميا"	'Presence', 'worms', 'in', 'okra'
Stop Words Removal	"وجود", "ديدانان", "الباميا"	'Presence', 'worms', 'okra'
Auto-correction	"وجود", "ديدانان", "الباميا"	'Presence', 'worms', 'okra'
Normalization	"وجود", "ديدانان", "الباميا"	'Presence', 'worms', 'okra'
Lemmatization	"وجود", "ديدانان", "باميا"	'Presence', 'worms', 'okra'

Finally, the output of RSVD is used to measure the semantic similarity score between the farmer query and the complaints document.

According to the proposed two LSA methods, which are TF-based LSA and TF\_IDF-based LSA, Table XI shows the results semantic similarity score between the farmer query and the complaints document.

As shown in Table XI, the results of the semantic similarity score using TF\_IDF-based LSA are better than the semantic similarity score using TF-based LSA since TF-IDF shows how important a term is in complaints while TF shows the number of times that a term appears in a complaint.

Fourthly, rank the complaints according to the semantic similarity score of TF-based and TF\_IDF-based LSA, as shown in Table XII and Table XIII, respectively, then select the complaint with the highest score.

TABLE XI. SEMANTIC SIMILARITY SCORE USING TF AND TF\_IDF-BASED LSA BETWEEN THE FARMER QUERY AND THE COMPLAINTS DOCUMENT

Arabic farmer query	Complaints	Semantic similarity score using TF_IDF-based LSA	Semantic similarity score using TF-based LSA
وجود ديدانان في الباميا Presence worms in okra	تلاحظ وجود حشرة المن على نباتات الباميا. Note the presence of aphids on okra plants.	0.977	0.941
	سأل المزارع عن كيفية حفظ محصول الباميا وطريقة حفظها لاستعمالها في الوقت الغير متوفره فيها. The farmer asked how to preserve the okra crop and how to preserve it for use at a time not available in it.	0.045	0.994
	وجود ديدان صغيره داخل ثمار الباميا. The presence of small worms inside the okra fruits.	0.9998	0.865
	وجود بقع دقيقة على سطحى الورقة لنبات الباميا تتحول هذه البقع الى اللون البنى وتجف الاوراق المصابة و تموت مما يؤدى الى صغر حجم النبات. The presence of minute spots on the two leaf surfaces of the okra plant, these spots turn brown, and the affected leaves dry and die, which leads to the small size of the plant.	0.315	0.713
	وجود ثقوب فى ازهار نباتات الباميا و جفاف وسقوط الازهار مع وجود ديدان فى بعض الازهار. The presence of holes in the flowers of the okra plants, drought, and fall of the flowers, with the presence of worms in some flowers.	0.994	0.687
وجود بقع صفراء على بعض الأوراق في نباتات الباميا مع وجود أوراق صفراء ( تلاحظ وجود الحشرة الكاملة للذبابة البيضاء على الأوراق ) The presence of yellow spots on some leaves in okra plants, with yellow leaves (the presence of the adult whitefly insect is noticed on the leaves)	0.654	0.933	

TABLE XII. THE RANKED COMPLAINTS ACCORDING TO THE TF\_IDF-BASED SEMANTIC SIMILARITY SCORE

Arabic farmer query	Complaints	Ranked semantic similarity score using TF_IDF-based LSA
وجود ديدان في الباميا Presence worms in okra	وجود ديدان صغيرة داخل ثمار الباميا. The presence of small worms inside the okra fruits.	0.9998
	وجود ثغوب في ازهار نباتات الباميا و جفاف وسقوط الازهار مع وجود ديدان في بعض الازهار. The presence of holes in the flowers of the okra plants, drought, and fall of the flowers, with the presence of worms in some flowers.	0.994
	تلاحظ وجود حشرة المن على نباتات الباميا. Note the presence of aphids on okra plants.	0.977
	وجود بقع صفراء على بعض الأوراق في نباتات الباميا مع وجود أوراق صفراء ( تلاحظ وجود الحشرة الكاملة للذبابة البيضاء على الأوراق ). The presence of yellow spots on some leaves in okra plants, with yellow leaves (the presence of the adult whitefly insect is noticed on the leaves)	0.654
	وجود بقع دقيقة على سطح الورقة لنبات الباميا تتحول هذه البقع الى اللون البني و تجف الاوراق المصابة و تموت مما يؤدي الى صغر حجم النبات. The presence of minute spots on the two leaf surfaces of the okra plant, these spots turn brown, and the affected leaves dry and die, which leads to the small size of the plant.	0.315
سأل المزارع عن كيفية حفظ محصول الباميا و طريقة حفظها لاستعمالها في الوقت الغير متوفره فيها. The farmer asked how to preserve the okra crop and how to preserve it for use at a time not available in it.	0.045	

As shown in Table XII, after ranking semantic similarity score and selecting the highest score that is 0.9998 and its complaint is "وجود ديدان صغيرة داخل ثمار الباميا" which is the nearest complaint to farmer query.

As shown in Table XIII, after ranking semantic similarity score and selecting the highest score that is 0.994 and its complaint is "سأل المزارع عن كيفية حفظ محصول الباميا و طريقة حفظها" which is not the nearest complaint to farmer query.

By comparing the results of both the TF\_IDF-based LSA approach and the TF-based LSA approach, we conclude that the TF\_IDF-based LSA approach is the best method for measuring the semantic similarity score.

Finally, based on the results of TF\_IDF-based LSA approach in Table XII, the solution for the farmer query "وجود ديدان في الباميا" according to the agricultural problems/solutions dataset is "جمع القرون المصابة و اعدامها لعدم امكانية" as shown in Table XIV.

TABLE XIII. THE RANKED COMPLAINTS ACCORDING TO THE TF-BASED SEMANTIC SIMILARITY SCORE

Arabic farmer query	Complaints	Ranked semantic similarity score using TF-based LSA
وجود ديدان في الباميا Presence worms in okra	سأل المزارع عن كيفية حفظ محصول الباميا و طريقة حفظها لاستعمالها في الوقت الغير متوفره فيها. The farmer asked how to preserve the okra crop and how to preserve it for use at a time not available in it.	0.994
	تلاحظ وجود حشرة المن على نباتات الباميا. Note the presence of aphids on okra plants.	0.941
	وجود بقع صفراء على بعض الأوراق في نباتات الباميا مع وجود أوراق صفراء ( تلاحظ وجود الحشرة الكاملة للذبابة البيضاء على الأوراق ). The presence of yellow spots on some leaves in okra plants, with yellow leaves (the presence of the adult whitefly insect is noticed on the leaves)	0.933
	وجود ديدان صغيرة داخل ثمار الباميا. The presence of small worms inside the okra fruits.	0.865
	وجود بقع دقيقة على سطح الورقة لنبات الباميا تتحول هذه البقع الى اللون البني و تجف الاوراق المصابة و تموت مما يؤدي الى صغر حجم النبات. The presence of minute spots on the two leaf surfaces of the okra plant, these spots turn brown, and the affected leaves dry and die, which leads to the small size of the plant.	0.713
	وجود ثغوب في ازهار نباتات الباميا و جفاف وسقوط الازهار مع وجود ديدان في بعض الازهار. The presence of holes in the flowers of the okra plants, drought, and fall of the flowers, with the presence of worms in some flowers.	0.687

TABLE XIV. SOLUTION FOR THE FARMER QUERY

Farmer query	Complaint	Solution
وجود ديدان في الباميا Presence worms in okra	وجود ديدان صغيرة داخل ثمار الباميا. Presence of small worms inside the okra fruits.	جمع القرون المصابة واعدامها لعدم امكانية رش القرون قبل الاستهلاك (The infected pods were collected and destroyed because the pods could not be sprayed before consumption.)

## VI. CONCLUSION

Agriculture has an important role in the economy of every country. Not only supplying foods for the whole population of a country but also it helps to connect and interact with all the relative industries of the country. Due to the world's current conditions from the spread of COVID-19, the imposition of a curfew, and adequate spacing between citizens, all fields are affected, especially the agriculture field. Farmers may have problems and complaints related to the agriculture process and the productivity of the percentage of the crops. It is difficult for farmers to communicate with agricultural experts to find appropriate solutions for their complaints. A semantic similarity approach for agriculture farmers' complaints is developed to solve these issues. This approach is based on LSA to measure semantic similarity between farmer query and the complaints document. The proposed model is applied to the MapReduce SVM using Hadoop for classifying the big agricultural dataset and the farmer complaint according to the crop type to improve the performance of the proposed approach. The results are evaluated on twenty-five crops and tested 25% of different complaint queries on each crop of them. These evaluations applied to our two proposed models of TF-based LSA, TF\_IDF-based LSA, and previous work methods. The developed approach with TF\_IDF-based LSA achieved better results than the TF-based LSA and previous work methods with an F-measure of 86.7%.

**Abstract**—A key step to apprehend the mechanisms of cells related to a particular disease is the disease gene identification. Computational forecast of disease genes are inexpensive and also easier compared to biological experiments. Here, an effectual deep learning-centered fusion algorithm called Naive Bayes-Artificial Neural Networks (NB-ANN) is proposed aimed at disease gene identification. Additionally, this paper proposes an effectual classifier, namely Levy Flight Krill herd (LFKH) based Adaptive Neuro-Fuzzy Inferences System (ANFIS), for the prediction of eye disease that are brought about by the human disease genes. Utilizing this technique, completely '10' disparate sorts of eye diseases are identified. The NB-ANN includes these '4' steps: a) construction of '4' Feature Vectors (FV), b) selection of negative data, c) training of FV utilizing NB, and d) ANN aimed at prediction. The LFKH-ANFIS undergoes Feature Extraction (FE), Feature Reduction (FR), along with classification for eye disease prediction. The experimental outcomes exhibit that method's efficiency with regard to precision and recall.

**Keywords**—Disease gene identification; eye disease identification; deep learning; adaptive neuro-fuzzy inferences system (ANFIS); levy flight based krill herd (LFKH); principle component analysis (PCA)

## I. INTRODUCTION

Disease genes are the dysfunction of a collection of genes, which in turn leads to Complex diseases [1] [2]. A key step towards enlightening the fundamental molecular operations of diseases is the recognition of genes concerned with genetic as well as rare diseases [3]. Prioritizing the candidate genes using experimental approaches is very costly and tedious [4]. Matrix decomposition along with Network propagation is the '2' categories under which all these existing techniques for the prediction can well be summarized [5]. In current years, technologies, say higher-throughput [6] gene expressions profiling has permitted the characterization of molecular differences betwixt healthy and disease states, bringing about the recognition of an augmenting number of disease-linked genes [7]. A great quantity of machine learning-centered computational methods was generated for predicting disease genes [8], say restricted Boltzmann machines [9], deep belief network [10], linear regressions model [11], support vectors machine [12], multilayer perceptions (MLP) [13], et cetera. These often attain greater prediction accuracy on larger data

sets [14]. Nonetheless, on account of the lower statistical power brought about by means of smaller samples in biomedical data, the issue of smaller samples typically causes poor reproducibility of prediction outcomes among disparate patients [15]. To trounce such downsides, in this paper, an NB-ANN is proposed for identifying the disease genes as well as the LFKH-ANFIS is proposed for the identification of eye-linked diseases triggered by means of those recognized disease genes.

## II. LITERATURE REVIEW

Chen BoLin et al.[16] proffered a kernel-centric Markov random field approach. This approach was deployed for capturing the genes-diseases associations on the base of biological networks. Here, three sorts of kernels were deployed for delineating the overall relations of vertices in 5 biological networks, respectively, and weighted methodology was built with the proffered approach to merge those data. It acquired 0.771- Area under the ROC Curves (AUC) score when merging all the concerned biological data. Here, Markov Exponential Diffusions (MED) kernel rendered the low AUC performance contrasted with Laplacian Exponential Diffusions (LED) kernel on integrated '3' network situation.

Abdulaziz Yousef and Nasrollah Moghadam Charkari [17] rendered a disease gene identification technique centered on amino acids' physicochemical properties as well as classification algorithm. Amino acids physic-chemical properties were utilized to change the sequences of protein into numerical vector for the feature vector generation. Support vector data description algorithm was employed to envisage the disease genes. The rendered method performed better contrasted with the prevailing methods concerning precision, recall, along with F-measure. Data standardization was required for Principle Component Analysis (PCA) utilization. The standardization absence brought about the PCA's failure in finding optimal components which in turn affected this model's performance.

Zhen Tian et al. [18] paid attention on a framework, termed RWRB, for inferring the causal genes of disease. The Similarity Networks (SN) of 5 genes (protein) was individually constructed grounded on countless genomic data. The integrated gene SN was re-developed in respect of the SN fusion approach. The restart along with random walk algorithm

was deployed on a Phenotype-Gene (PG) bi-layer network, which integrated phenotype SN, PG association, and integrated gene SN for proffering the priority for the candidate genes (disease-associated ones). Outcomes corroborated that the RWRB was accurate when analogized to certain methods regarding the evaluation metrics. This method rendered the degraded performance with respect to Number of Successful Predictions (NSP) metric when the jumping probability is above 0.6 in disparate experiments.

Mehdi Joodaki et al. [19] put forward a gene ranking approach, named as Random Walks with Restart on a Heterogeneous Networks with Fuzzy Fusions (RWRHN-FF). Here, first, centred on disparate genomic sources, '4' gene-gene similarity networks were generated, and then, they were joined utilizing the type-II fuzzy voter scheme. The resultant gene to gene network was linked with the disease-disease similarity network. By means of integrating '4' sources via a '2'- part disease gene network, the disease-disease similarity network was created. RWRHN analyzed this network. While considering Area Under ROC Curves (AUC) as well as convergence time, the presented approach trounced the prevailing methods. On account of the bad data integration of manifold sources, the precision metric of this method was declined.

Pradipta Maji and Ekta Shah [20] recognized the disease-associated genes with the utilization of a gene selection algorithm, named SiFS. The SiFS algorithm gathered countless genes as of micro-array data as diseased genes by elevating the functional and significance similarity of the chosen gene subset. Contrarily, a similarity metric was instated for computing the functional similarity betwixt 2 genes. The experimental outcomes on disparate data sets corroborated that the algorithm recognized more disease-associated genes when analogized to prevailing disease gene selection methodologies. The similarity measure of the presented method was affected by the low coverage of human genes and reliability of protein-protein interaction (PPI).

### III. PROPOSED METHODOLOGY

Here, a novel sequence-based fusion method (NB-ANN) is proposed aimed at disease genes identification, and the LFKH-ANFIS is proposed aimed at identifying eye-related diseases that are triggered by those disease genes, say Age-associated Macular Degenerations (AMD), cataract, glaucoma, inherited optics neuropathies, Marfan syndrome polypoidal choroidals vasculopathies, retinitis pigmentosas, Stargardt disease, along with uveal melanoma.

The proposed method's architecture is exhibited in Fig. 1. Fig. 1 exhibits the proposed methodology's architecture. In the initial phase, representation methods are used to achieve the FV as of the disease and unknown disease genes. In the 2<sup>nd</sup> phase, a dataset with positive as well as reliable negative instances is created by selecting negative protein set. In the 3<sup>rd</sup> phase, disparate FV of the same instances are categorized using the NB classifier. In the 4<sup>th</sup> phase, ANN fuses together the NB classifiers to enhance the accuracy. After the identification of disease gene, FE is done. It extracts the features as of the identified disease genes for classifying the eye-related diseases caused via the disease genes. Next, PCA is employed for FR

for removing the redundant features. Lastly, the LFKH-ANFIS algorithm takes care of the eye disease classification.

#### A. Disease Gene Identification

Here, the technique for identifying along with prioritizing disease genes is elucidated. The proposed work comprises '4' steps: (i) Translate equivalent gene products (proteins) into '4' numerical FV utilizing '4' sorts of protein sequence translator, (ii) choosing negative data as of unknown genes, (iii) modeling every FV utilizing NB, (iv) ANN is utilized for making the last decision via fusing the envisaging outcomes of the base NB classifiers.

#### B. Protein Sequence Translation

Extracting FV aimed at disease and unknown genes is the utmost vital challenges while identifying disease-gene issues utilizing a machine learning algorithm. Here, for characterizing genes, equivalent gene products (Proteins) are utilized. Hereof, to extract the vital information of protein wherein fully encoded is taken, '4' sorts of representation techniques were utilized, they are i) Normalized Moreau-Broto autocorrelation (NA), ii) Geary autocorrelations (GA), iii) auto covariances (AC), and iv) Moran auto-correlations (MA). The reason for utilizing these representation techniques is to evade losing imperative information that is concealed in the protein sequences. All of these techniques are centered upon the physicochemical properties of amino acids since sequence of amino acid determines the protein. In other words, amino acids are the building block of protein. Here, '12' physic-chemical properties are employed as a descriptor to render more information concerning the amino acid sequence. These properties comprise entropy of formations (EOF), partitions coefficient (PC), polarity (POL), amino acid compositions (AAC), residue accessible surface areas in tripeptide (RAS), transfer-free energy (TFE), CC on regressions analysis (CC), hydrophilicity (HY-PHIL), polarizability (POL2), hydrophobicity (HY-PHOB), solvations free energy (SFE), along with graph shapes index (GSI), correspondingly. Min-Max normalization technique is employed for normalizing these physicochemical properties since it ensures that all physicochemical properties have exact same scale.

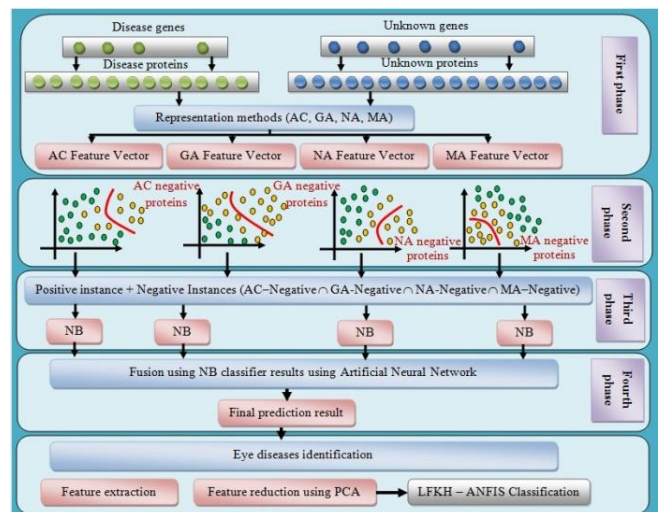

Fig. 1. Proposed Architecture.

### C. Negative Data Generation

Subsequent to generating the FV for all genes, it is essential to select a negative protein set as of the unknown proteins to construct a dataset with positive as well as reliable negative instances. With regard to it, a '6' steps algorithm is proposed.

Step1: Define four negative sets as an empty set for each of the feature vectors as

$$D_{AC} = \Phi; D_{GA} = \Phi; D_{MA} = \Phi; D_{NA} = \Phi \quad (1)$$

Step2: Second, representing each protein  $R_i$  (disease and unknown proteins) into four vector:  $S_{AC}^{R_i}, S_{GA}^{R_i}, S_{MA}^{R_i}, S_{NA}^{R_i}$  using AC, GA, MA, and NA representation methods can well be expressed as

$$S_{AC}^{R_i} = AC(R_i) \quad (2)$$

$$S_{GA}^{R_i} = GA(R_i) \quad (3)$$

$$S_{MA}^{R_i} = MA(R_i) \quad (4)$$

$$S_{NA}^{R_i} = NA(R_i) \quad (5)$$

Step3: Calculate the positive mean vector  $M_p$  of all positive proteins for every represented vectors.

$$M_p(AC) = \sum_{k=0}^n \frac{S_{AC}^{P_k}}{|D|} \quad (6)$$

$$M_p(GA) = \sum_{k=0}^n \frac{S_{GA}^{P_k}}{|D|} \quad (7)$$

$$M_p(MA) = \sum_{k=0}^n \frac{S_{MA}^{P_k}}{|D|} \quad (8)$$

$$M_p(NA) = \sum_{k=0}^n \frac{S_{NA}^{P_k}}{|D|} \quad (9)$$

Step4: Fourth, calculate the similarity,  $Sim_j$  between each unknown protein ( $R_i \in U_R$ ) and the mean vectors ( $M_p$ ) that can well be expressed as.

$$P_{U_R}^{AC}(j) = P(S_{AC} U_R, M_p(AC)) \quad (10)$$

$$P_{U_R}^{GA}(j) = P(S_{GA} U_R, M_p(GA)) \quad (11)$$

$$P_{U_R}^{MA}(j) = P(S_{MA} U_R, M_p(MA)) \quad (12)$$

$$P_{U_R}^{NA}(j) = P(S_{NA} U_R, M_p(NA)) \quad (13)$$

Step5: Fifth, for each FV, choose  $g$  negative proteins as of  $U_R$  set by selectig the  $g$  farthest proteins as of the  $M_p$ , which can well be specified as.

$$D_{AC} = \text{sort}(D_{U_R}^{AC}) \quad (14)$$

$$D_{GA} = \text{sort}(D_{U_R}^{GA}) \quad (15)$$

$$D_{MA} = \text{sort}(D_{U_R}^{MA}) \quad (16)$$

$$D_{NA} = \text{sort}(D_{U_R}^{NA}) \quad (17)$$

$$P_{AC} = \text{select}(D_{U_R}^{AC}(1:g)) \quad (18)$$

$$P_{GA} = \text{select}(D_{U_R}^{GA}(1:g)) \quad (19)$$

$$P_{MA} = \text{select}(D_{U_R}^{MA}(1:g)) \quad (20)$$

$$P_{NA} = \text{select}(D_{U_R}^{NA}(1:g)) \quad (21)$$

Manhattan distance measure is utilized as a distance measurement to gauge the distance betwixt  $R_j$  and  $M_p$ . As the number of unknown proteins is much more than disease proteins, ascertaining the appropriate number ( $g$ ) of chosen negative proteins has a direct effect on the prediction model construction.

Step6: Lastly, the proteins ascertained by means of the intersection of chosen negative protein sets will be selected as reliable negative data ( $R_{NS}$ ).

$$R_{NS} = P_{AC} \cap P_{GA} \cap P_{MA} \cap P_{NA} \quad (22)$$

### D. Naive Bayes Algorithm

Naive Bayes (NB) stands as a probabilistic classifier stimulated by the Bayes theorem under a simple assumption, i.e., the attributes are autonomous conditionally. NB is a particularly simple algorithm to execute, and good outcomes have been attained in the utmost instances. Nevertheless, utilizing the same classifier (NB) to categorize the disparate FV of the same instances produces some uncertainties and also makes some individual errors. Therefore, a practical fusion of these classifiers will more likely lessen the overall prediction inaccuracies and renders better prediction outcomes by reducing the negative effects of noise data which proportionally increases with rising negative data ratio. Here, the ANN is utilized as a fusion method in the 4<sup>th</sup> layer. The general explanation concerning the ANN is rendered in the section below

### E. Artificial Neural Network

ANN classifier comprises countless interconnected artificial neurons which have multiple interconnections connected to the adjustable weights. The inputted patterns are transmitted through the layers to solve the problem. By employing the corresponding synaptic weights, the information is mapped.

Step1: Make arbitrary weights in the interval [0, 1] and allocate it to the Hidden Layer (HL) neurons as well as the Output Layer (OL) neurons. Maintain a unity value weight for all neurons of the inputted layer for easy computation and to attain better performance together with outcomes.

Step2: Calculate the output of the hidden layer as shown in below eq.

$$H_o = B_i + \sum_{i=1}^L NB_i W_i \quad (23)$$

Where,

$B_i$  - Bias value,

$NB_i$  - Output of previous NB layer values,

$W_i$  - Weight value of the given input features.

Step3: To find the final output unit, the hidden unit is multiplied with the weight of the hidden layer output, which is given in the equation (23).

$$O_i = B_i + \sum_{i=1}^m H_o W_{ik} \quad (24)$$

Where,

$H_o$  - Hidden unit

$W_{ik}$  - Weights of the hidden layer

$O_i$  - Output unit.

The activation function for the output layer is estimated as

$$Active(o_i) = \frac{1}{1 + e^{-o_i}} \quad (25)$$

Step4: Recognize the learning error as offered beneath

$$e_r = \sum z_i - o_i \quad (26)$$

Where,

$e_r$  - Error rate,

$z_i$  - Target output value,

$o_i$  - Actual output value.

It is apparent that the NB-centered classifiers construct the model for the same dataset utilizing disparate FV. Therefore, fusing the NB-based predictors' outputs utilizing the ANN brings about concurrent utilization of optional feature descriptors along with classification procedures.

## F. Feature Extraction

After the disease gene identification, this phase is done to extract the features as of the identified disease genes for classifying the eye-related diseases caused through the disease genes. The features, namely Katz Fractal Dimension (KFD), Log Energy (LE), Hurst exponent (HE), Shannon Entropy (SE), Skewness, Mean, Kurtosis, Detrended Fluctuation Analysis (DFA), Discrete Wavelet Transforms, and also Standard Deviation are extracted.

## G. Feature Reduction

Following feature extraction, feature reduction is done with the utilization of PCA. PCA that conserves the existent information and eliminates the redundant constituents is employed to discover significant features. PCA acts as a linear combination where one set of variables in  $P_m$  space into another set in  $P_n$  space containing the maximum amount of variance in the data where  $n < m$ . This is obtained in the following steps:

Step1: Evaluate the covariance matrix " $C_m$ " as,

$$C_m = \frac{1}{N} \sum_{k=0}^N (F_k - m)(F_k - m)^T \quad (27)$$

Where,

$$m = \frac{1}{N} \sum_k F_k \text{ - Original feature vectors.}$$

Step2: Determinir the eigenvectors " $v_i$ " and Eigen values " $\mu_i$ " of the  $C_m$  by solving the subsequent decomposition

$$\mu_i v_i = L v_i \quad (28)$$

Where,

$L$  - Matrix having the properties of eigen value and eigen vector.

Step3: Sort the outcomes in decreasing order of  $\mu_i$

Step4: Choose the indispensable components (that is, features).

## H. Classification for the Identification of Eye Diseases

Here, the related eye disease prediction is performed with the utilization of the LFKH-ANFIS algorithm. Gradient-centric learning is the standard learning process in ANFIS but it is prone to trap in local minima. On this account, the ANFIS is ameliorated with the utilization of LFKH for lessening its complexity and for elevating the classification accuracy. And thereby, the ANFIS is termed as LFKH based ANFIS (LFKH-ANFIS). The ANFIS has 2 fuzzy IF-THEN rules as specified in the equations (28) and (29).

Rule i: If  $F_1$  is  $A_i$  and  $F_2$  is  $B_i$  then,  $\bar{Q}_i$

$$Rules_i = cF_i + d_iF_{i+1} + e_i \quad (29)$$

Rule ii: If  $F_1$  is  $A_{i+1}$  and  $F_2$  is  $B_{i+1}$  then,

$$Rules_{i+1} = c_{i+1}F_i + d_{i+1}F_{i+1} + e_{i+1} \quad (30)$$

Where,

$A_i, B_i, A_{i+1}$  and  $B_{i+1}$  - Fuzzy sets,

$c_i, d_i, e_i, c_{i+1}, d_{i+1}$  &  $e_{i+1}$  - Predicted design parameters during training,

$F_i$  and  $F_{i+1}$  - Disparate reduced feature values acquired as of PCA.

These provided parameters are optimized with the assist of the LFKH algorithm for attaining a better outcome. The ANFIS encompasses some layers as elucidated below,

Layer1: The first layer named a fuzzification layer gathers the input values and finds their membership functions (MF) as proffered below.

$$Z_{1,i} = \chi_i(F_i) \quad (31)$$

Where,

$F_i$  - Input to node  $i$ ,

$\chi_i$  - MF of the input  $F_i$ .

Each node here is adapted well to a functional parameter. The output acquired from each node acts as a degree of membership value that is provided by the input of an MF. The MF utilized in the proposed work is Gaussian kernel MF. The reason for choosing Gaussian kernel MF is to diminish the computational price of ANFIS since Gaussian kernel MF has least number of modifiable parameters. The MF used in the proposed work is specified in the succeeding equation.

$$\chi_i = \exp\left(-\frac{\|c_i - d_i\|^2}{2e_i^2}\right) \quad (32)$$

Where,

$c_i, d_i$  and also  $e_i$  - MF parameters that could alter the MF's shape and are concerned as the premise parameters.

Layer2: This layer named the rule layer is accountable for creating the firing strengths (FS) for the rules. The incoming signals are mathematically multiplied to acquire the output that means the FS of a rule.

$$Z_{2,i} = Q_i = \chi_i(F_i) \times \chi_i(F_{i+1}) \quad (33)$$

Layer3: It aids to normalize the evaluated FSs by dividing every value with a total FS. The  $i^{th}$  node evaluates the ratio  $(\bar{Q}_i)$  betwixt the  $i$  th rule's FS and the sum value of all rules' FSs to generate its output.

$$Z_{3,i} = \bar{Q}_i = \frac{H_i}{Q_1 + Q_2 + Q_3 + Q_4 + Q_5 + Q_6}, \quad i = 1, 2..6 \quad (34)$$

Layer4: It takes the above attained normalized values as inputs (resultant parameter sets) and it has adaptive nodes with a node function.

$$Z_{4,i} = \bar{Q}_i \cdot Rules_i \quad (35)$$

Where,

$\bar{Q}_i$  - Normalized FSs from the former layer and

$Rules_i$  - system rule. And here, the deployed parameters are named as succeeding parameters.

Layer5: The former fourth layer proffers the defuzzificated values and these values are transmitted to the fifth layer for acquiring the final output. All incoming signals are summated to acquire overall output, and here, the circle node is labeled as  $\sum$

$$Z_{5,i} = \sum_i Q_i Rules_i = \frac{\sum_i Q_i Rules_i}{\sum_i Q_i} \quad (36)$$

From the LFKH-ANFIS, the 10 classes of eye diseases for the identified disease gene, that is, Age-related Macular Degeneration (AMD), cataract, Marfan syndrome, glaucoma, inherited optic neuropathies, polypoidal choroidal vasculopathies, retinitis pigmentosa, uveal melanoma, and Stargardt disease are acquired.

#### I. Levy Flight based Krill Herd Algorithm

The Krill Herd (KH) algorithm has the potential to effectively determine the optimum solution for certain search spaces configurations. With the futile exploration of KH's search approach, it is incompetent to assure convergence. This proposed method utilizes the Levy flight (LF) in KHA with the intention of resolving the aforesaid difficulty. Hence, the parameter tuning for ANFIS utilizing this optimization is termed as LF based KH (LF-KH). With the utilization of the Lagrangian model, the krill's location is evaluated as,

$$\frac{dXi}{dt} = H_i + F_i + D_i \quad (37)$$

Where,

$H_i$  - Motion guided by other KI,

$F_i$  - Foraging motion,

$D_i$  - Physical diffusion of the  $i^{th}$  KI's.

The steps that are done in this algorithm are,

Step1: The krill individuals (KI) endeavor to hold a high density and move on account of their mutual effects. The direction of KI motion is ascertained by the density of the local - target and repulsive - swarms. The KI movement is written as:

$$H_i^{new} = H^m \alpha_i + \omega_n H_i^{old} \quad (38)$$

Where,

$H^m$  - Maximal induced speed,

$\omega_n$  - Motion' inertia weight in [0, 1],

$H_i^{old}$  - Last motion-induced.

Here,  $\alpha_i$  is evaluated as follows,

$$\alpha_i = \alpha_i^{local} + \alpha_i^{t\ arg\ et} \quad (39)$$

Where,

$\alpha_i^{local}$  - Local effects of neighbors of the  $i^{th}$  individual,

$\alpha_i^{t\ arg\ et}$  - Best solution direction as of the  $i^{th}$  individual.

The  $\alpha_i^{local}$  in a KI movement is evaluated as:

$$\alpha_i^{local} = \sum_{j=1}^{MM} \widehat{K}_{i,j} \widehat{H}_{i,j} \quad (40)$$

$$\widehat{H}_{i,j} = \frac{H_j - H_i}{\|H_j - H_i\| + \epsilon} \quad (41)$$

$$\widehat{K}_{i,j} = \frac{K_i - K_j}{K^{worst} - K^{best}} \quad (42)$$

Where,

$K^{best}$  - Best-fitness (BF) values of the KIs,

$K^{worst}$  - Worst-fitness values of the KIs

$K_i$  - Objective function or the fitness of the  $i^{th}$  KI,

$H$  - Associated positions,

$K_j$  - Fitness of  $j$ th neighbors ( $j = 1, 2, \dots, MM$ ),

$MM$  - Number of prevailing neighbors.

The least positive number termed “ $\lambda$ ” is added to the denominator for averting the singularities. Utilizing the KIs' original behavior, a sensing distance ( $S_d$ ) is evaluated as

$$S_{d,i} = \frac{1}{5M} \sum_{j=1}^N \|H_i - H_j\| \quad (43)$$

Where,

$S_{d,i}$  - Sensing distance for the  $i^{th}$  KI,

$N$  - Number of KIs,

Factor 5 - Empirically acquired value. The effect of the KI with the BF on the  $i^{th}$  KI is regarded utilizing Equation (44).

$$\alpha_i^{t\ arg\ et} = C^b \widehat{K}_{i,best} \widehat{H}_{i,best} \quad (44)$$

Where,

$C^b$  - Effective co-efficient of the KI bearing the BF to the  $i^{th}$  KI.

This coefficient is defined because  $\alpha_i^{t\ arg\ et}$  directs the solution to the global optima and it must be more effective when analogized to other KI, that is, neighbors. Herein, the  $C^b$  is evaluated as

$$C^b = 2 \left( rd + \frac{I}{I_{max}} \right) \quad (45)$$

Where,

$I$  - Actual iteration number,

$I_{max}$  - Maximal iterations.

For enhancing exploration, “ $rd$ ” which is a random value lies in the gamut of (0, 1) is utilized. The proposed approach utilizes the LF for the process of a random walk rather than a simpler one to overcome the incapability of KH search approach which led to its inability to ensure convergence. LF maximizes the efficiency of the searches in uncertain environments. Whilst generating a new solution  $X_i'$  for the  $i^{th}$  solution by performing LF, the new candidate is evaluated as,

$$X_i' = X_i \oplus \alpha \text{Levy}(\beta) \quad (46)$$

Where,

$\alpha$  - Random step size parameter

$\beta$  - LF distribution parameter

$\oplus$  - Entry wise multiplication

Here, the equation (45) is rewritten as,

$$C^b = 2 \left( X_i' + \frac{I}{I_{max}} \right) \quad (47)$$

Step2: The foraging motion is also known as searching motion is evaluated in respect of 2 vital effective parameters like i) food location along with ii) the prior experiences of the KIs' food location. They are evaluated as

$$Fa_i = F_s \gamma_i + \omega_l Fa_i^{old} \quad (48)$$

Where  $\gamma_i = \gamma_i^{best} + B_i^{best}$  (49)

Where,

$F_s$  - Foraging speed,

$w_l$  - Inertia weight for foraging,

$B_i^{best}$  - Best solution

Step3: The physical diffusion process of the KI is an arbitrary one and is the motion associated to  $Df_i$  and  $\delta$ . Its equation is,

$$Df_i = Df_m \delta \quad (50)$$

Where,

$Df_i$  - Maximal diffusion speed,

$\delta$  - Random directional vector together with its arrays of arbitrary values in (-1, 1).

The KH movement is concerned as a process on the way to the BF. So, the KI position is proffered by.

$$X_i(t + \Delta t) = X_i(t) + \Delta t \frac{dX_i}{dt} \quad (51)$$

Where,

$\Delta t$  - Scale factor of the speed vector

$\Delta t$  is an imperative parameter, and it must be adjusted in respect of the optimization issue. Its value is completely contingent on the provided search space.

#### IV. RESULT AND DISCUSSION

Here, the proposed system is analyzed and its performance is analogized to the existing algorithms regarding certain performance metrics. To ascertain the proposed method's robustness, to lessen the over fitting and to lessen the bias in the estimate of the classification model, 5 fold cross-validations have been employed utilizing a dataset with 10,000 instances (that is, 5000 positive and 5000 negative instances). Table I proffers the values acquired by the proposed NB-ANN predictor and some NB based classifiers regarding their prediction performance.

Table I evinces the f-measure, precision, together with recall values attained by the NB-based and fusion-based

predictions. The AC-NB shows 81.6% precision, which is higher when analogized to that of GA-NB (74), NA-NB (76.54), and MA-NB (72.4). But, only the proposed fusion methodology acquires the highest precision (83.52) amongst others. Likewise, for f-measure and recall, the proposed NB-ANN classifier proffers the higher most values when analogized to other NB based approach. It is found that the fusion predictor shows the topmost performance when analogized to each NB-based predictor. As the classification of disparate FVs of the same data utilizing the same classifier generates certain uncertainties, fusing the classifier outcomes would diminish the overall classification errors. Fig. 2 evinces the comparison of NB-ANN and other existing approaches regarding f-measure, precision, together with recall.

Fig. 2 contrasts the proposed NB-ANN to some existing approaches regarding f-measure, precision, together with recall. The proposed NB-ANN acquires the 86-precision, 89.2-recall, and 88-f-measure, whereas, the existing ones acquire lower values for those measures when analogized to the proposed NB-ANN. For instance, the PUDI, ProDige, and SVM-C4.5 acquired 78.3, 72.5, and 82.4 precision values, 84.2, 78.8, and 85.2-recall values, and 80, 74.6, and 83-f-measure results. Here, the existing SVM-C4.5 shows greater performance. But, when analogized to the proposed NB-ANN, the existing ones show the least performance. From this comparison, the proposed NB-ANN is confirmed to acquire a remarkable performance for disease gene identification, and it worked well than other approaches. Then, the next experiment is performed for analyzing the proposed LFKH-ANFIS and comparing the LFKH-ANFIS with the existing techniques centered on performance regarding sensitivity, precision, specificity, recall, accuracy, f-measure, PPV, NPV, MCC, and FDR. Table II proffers the outcomes of LFKH-ANFIS and some existing algorithms.

TABLE I. COMPARISON OF PROPOSED AND EXISTING TECHNIQUES

Methods	Precision (%)	Recall (%)	F-measure (%)
AC-NB	81.6	73.2	74.5
GA-NB	74	84.6	80.47
NA-NB	76.54	83.2	79.8
MA-NB	72.4	88	79.6
NB-ANN	83.52	86.47	83

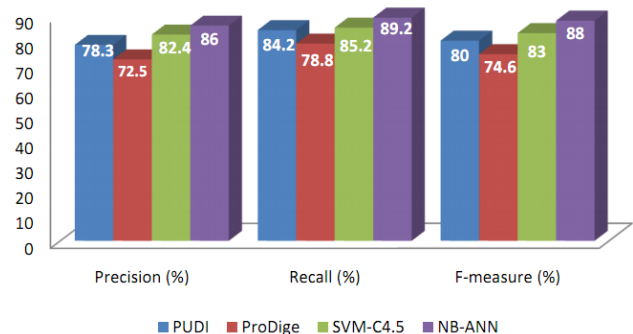

Fig. 2. Performance Graph for the NB-ANN with Existing Techniques.

TABLE II. RESULTS COMPARISON OF THE PROPOSED LFKH-ANFIS WITH EXISTING TECHNIQUES

Performance Metrics	Proposed LFKH-ANFIS	ANFIS	DNN	ANN	KNN
Sensitivity	0.9314	0.8442	0.7412	0.7845	0.7624
Specificity	0.9561	0.9315	0.8845	0.8412	0.9142
Accuracy	0.9947	0.8965	0.8874	0.8432	0.8398
Precision	0.9412	0.8417	0.8254	0.8347	0.7648
Recall	0.9412	0.8417	0.8254	0.8347	0.7648
F-measure	0.9412	0.8417	0.8254	0.8347	0.7648
NPV	0.9847	0.9321	0.9047	0.9075	0.9254
FPR	0.0072	0.0587	0.0784	0.0984	0.0871
FNR	0.0689	0.5245	0.7478	0.8471	0.8124
MCC	0.9343	0.6471	0.4728	0.5471	0.6547
FRR	0.0547	0.6417	0.874	0.8325	0.7841

Table II could be utilized for contrasting the results of the LFKH-ANFIS and the existing classifiers. The LFKH-ANFIS acquires 0.9412 for precision, f-measure, and recall, whereas, the existing ANFIS, DNN, ANN, and KNN proffered the values of 0.8417, 0.8254, 0.8347, and 0.7648 for precision, recall, f-measure. On considering the sensitivity, specificity, accuracy, NPV, and MCC, the LFKH-ANFIS evinces superior performance. Likewise, for MCC and NPV, the LFKH-ANFIS proffers the greatest outcomes analogized to existing algorithms. From these results, the proposed LFKH-ANFIS is confirmed to be better when analogized to other existing algorithms for eye disease identification. The error rate measures of the classification algorithm, namely FPR, FRR, and FNR, define the error that transpires at the time of performing classification.

For an effectual and excellent classification algorithm, the error rate measures must be low and that is achieved only by the proposed LFKH-ANFIS algorithm.

## V. CONCLUSION

When analogized to the existing PUDI, ProDige, and SVM-C4.5, the proposed NB-ANN acquires the higher most values of precision, f-measure, and recall. Likewise, the LFKH-ANFIS shows the topmost performance by acquiring the highest results of sensitivity, precision, specificity, recall, accuracy, f-measure, NPV, and MCC when analogized to ANN, KNN, DNN, and ANFIS. And, the proposed LFKH-ANFIS acquires the lowest error rates (FNR, FPR, and FRR) for eye disease identification, which evinces the proposed method's efficiency. Therefore, the disease gene identification and the possibility of eye disease incurred by those disease genes are identified more accurately using both classification algorithms. For future work, more number of physicochemical properties of amino acids will be considered for better performance in classification. For future work, more number of physicochemical properties of amino acids will be regarded for better performance in classification.

**Abstract**—Cloud computational platform provisions numerous cloud-based Vehicular Adhoc Network (VANET) applications. For providing better bandwidth and connectivity in dynamic manner, Software Defined VANET (SDVN) is developed. Using SDVN, new VANET framework are modeled; for example, Software Defined Vehicular Cloud (SDVC). In SDVC, the vehicle enables virtualization technology through SDVN and provides complex data-intensive workload execution in scalable and efficient manner. Vehicular Edge Computing (VEC) addresses various challenges of fifth generation (5G) workload applications performance and deadline requirement. VEC aid in reducing response time, delay with high reliability for workload execution. Here the workload tasks are executed to nearby edge devices connected to Road Side Unit (RSU) with limited computing capability. If the resources are not available in RSU, then the task execution is offloaded through SDN toward heterogeneous cloud server. Existing workload scheduling in cloud environment are designed considering minimizing cost and delay; however, very limited work has been done considering energy minimization for workload execution. This paper presents a Load Balanced and Energy Aware Cloud Resource Scheduling (LBEACRS) design for heterogeneous cloud framework. Experiment outcome shows the LBEACRS achieves better makespan and energy efficiency performance when compared with standard cloud resource scheduling design.

**Keywords**—Cloud computing; data-intensive applications; heterogeneous server; IEEE 802.11p; software defined network; software defined vehicular cloud; vehicular adhoc network; workload scheduling; road side unit; vehicular edge cloud

## I. INTRODUCTION

As of late, its seen that the amount of Internet associated gadgets are more when compared with the quantity of people in the world, Internet-associated gadgets are expected to exceed thirty billion by 2020, as per report suggested in [1], thus, accidentally apprehending the IoT models. As there is an enormous increase in the vehicles which are connected to the internet, the normal VANETs are merged into these Internet of Vehicles (IoV). In the Internet of Vehicles period, smart devices and sensors are connected to the vehicles which can give smart vehicle maneuvering, video streaming, prevention of accidents, traffic management, navigating capabilities, just as a large group of arising intelligent applications, a particularly augmented and virtual reality. A vast majority of these applications require complicated computation and various methods to recognize the patterns, which can compute

intensive data and thus need a processor which can provide a powerful and dedicated virtual machine for the computation. The restricted capability for the computation and the because of less resource's capacity in the vehicles, it is a challenging task for the decision-making, networking and data processing in real-time. Due to this problem, it develops an issue for computing the data and allocating the resources to the different applications in the VANETs which have limited resources.

To resolve the problems of unstable computation in the vehicles, the usage of the vehicle nodes is suggested. For the improvement of the safety and comfort for the travelers in a cloud-based vehicle network a method using the Road Side Units (RSUs) can be used. In the RSU, using the computing methods and an integrated communication technology, various offload task can be done using the cloud, hence this reduces the power consumption and the storage capacity in the Onboard Unit which is present in the vehicles. This method is called as Mobile Cloud-Computing (MCC), which provides an improved utilization of the resource, better performance for computation and also gives many benefits, yet not restricted to, 1) increasing the lifetime performance of the battery by offloading the consumption of energy to the cloud, 2) empowering complex memory exploiting gadgets to portable clients, and 3) giving more memory-storage to the clients. Nonetheless, thinking about the limit constraint and fluctuation in the delay for transmitting the data to backbone and backhaul systems [2], placing the cloud network far from the vehicular network can reduce the efficiency of the offload. All the things considered, the vehicle edge computing (VEC) has been given which places the cloud networks near the edge of the radio access organization, to be specific, near the Road Side Units, which gives the computation results within the range of communication with the help of SDN.

The concentrated idea of Vehicular Edge Computing presents critical difficulties particularly in a profoundly unique condition like VANET. Besides, in vehicles having high mobility [3], [4], particularly in roads encountering more traffic, requires an appropriate scheduling to prepare the offloaded complicated workload assignments which can oblige the tasks which are delay tolerant (for example safety related application, accident prevention) just as computationally thorough assignments (for example video observation and dynamic image/video-based applications). The intercommunication requests for quality of experience (QoE) and quality of services (QoS) to understand the related

advantages like maximized throughput, low latency, fast communication, high reliability and hence forth These prerequisites makes workload resource scheduling more testing in vehicular cloud environment [5].

In addressing above discussed research problem and challenges existing workload scheduling methods either focused on minimizing energy or makespan individually; and very limited work have been emphasized in building scheduling optimization considering both together. However, existing model failed balance load for scheduling of newly arrived task. As a result, induce scheduling delay and increases operation cost because of higher SLA violation. In addressing performance issues the future design must incorporate effective load balancing technique with energy-makespan tradeoff requirement as a major objective. This motivates the research work to develop an improved scheduling designing incorporating effective load-balancing technique namely load balanced energy aware cloud resource scheduling. The LBEACRS design present an efficient design to schedule backlog task with high resource utilization. Further, for selecting cloud resource to execute workload a tradeoffs metric of energy maximization with high resource utilization meeting task deadline is presented.

The manuscript significance is described below:

- This paper presents a load balanced and energy aware cloud resource scheduling method for executing data-intensive workload on software defined vehicular cloud (SDVC).
- The SDN is used to offload workload execution to cloud environment. It also maintains routing table for delivering the workload execution outcome to respective vehicle users.
- The LBEACRS model is designed in such a way that it can balance load among different server, maximize resource utilization and reduce energy consumption by running less number of server and also guarantee dead requirement of workload with high makespan efficiency.
- The LBEACRS reduce energy consumption and achieve better makespan performance in comparison with existing DCOH workload scheduling methodology.

The manuscript is articulated as follow. In Section II, survey of existing model and limitation is described. In Section III the present propose methodology for workload scheduling in SDN enabled VANET-Cloud environment. In Section IV, experiment analysis is presented. Finally, the research work of LBEACRS is concluded with future research direction.

## II. LITERATURE SURVEY

This section carry out critical review of various workload scheduling technique in reducing cost, makespan with deadline constraint; however, very limited work has been done to minimize energy constraint for workload execution in heterogeneous cloud environment [6]. In [6] presented energy

aware scheduling strategy for executing workload and showed heterogeneous computing platform provide multiple processing core for executing large-scale workload. However, these strategies induce high computation overhead and induce energy overhead considering different levels of computational process and storage operations [7]. In [8], analysis on a super personal computer has been performed which has 16 thousand nodes utilizes more energy. The consumption of energy is a critical problem which has a huge impact in the computation of the data and for the improvement of the system. In a heterogeneous cloud computing (HCC) condition, Directed Acyclic Graph (DAG) is used by an application which is running parallelly to allocate the jobs according to the priority. Moreover, the Directed Acyclic graph represents the edges and jobs which portrays the messages correspondingly to the different jobs [9]. In [10], it showed the critical difficulties exist for responsibility planning in a hybrid cloud environment. These are distinctive Cloud Service Providers (CSP), heterogeneous workload, which tell how to send and port the administration in the cloud environment having negligible financial spending plan. For guaranteeing prevalent asset usage they introduced a heterogeneous workload planning for the remote cloud environment. Additionally, to guarantee the execution of the workload, the execution is finished inside less time limitation a workload planning component is introduced utilizing the Backhaul Propagation Neural-Network in the hybrid cloud framework. In [11], recommended that the work process scheduling configuration considers the financial spending plan and time required for the computation in a hybrid cloud environment. The first scheduling-algorithm is planned utilizing the single-objective which works specifically for the DCOH technique. This technique is planned to decrease the monetary spending plan of workload scheduling with cut-off time essential. After this, they have introduced multi-objective on the basis of workload scheduled strategy to the specific MOH technique. This technique is intended to bring the trade-offs among the financial spending plan and execution time for workload execution. Notwithstanding, this technique is not much productive to reduce the energy for the logical work process computation in heterogenous cloud network. In Cloud network, which provides service to the market, the clients aid the cloud administrations given by CSP to perform the execution of the workload. Workload for the most part includes certain cut-off time essential for guarantying QoS. Simultaneously, the poor performance of QoS can force exacting a penalty on the CSP. Notwithstanding, the existing algorithm for workload scheduling accepts the time for the makespan of the tasks in the data concentrated workload application are fixed. In any case, this theory is for the cloud servers which have efficiently begun to help in the optimization of the energy, which is not utilized in the workload-scheduling model [11], [12].

From extensive study it can be seen existing cloud resource management technique either focused on reducing energy or makespan. Very few model presented to optimize time and cost together employing multi-objective optimization. Further, these model fails to meet dynamic load requirement of workload application; thus, limit the adoption dynamic workload application real-time requirement; in addressing an effective

load balancing mechanism is needed which is presented in next section.

### III. LOAD BALANCED AND ENERGY AWARE CLOUD RESOURCE SCHEDULING DESIGN FOR TASK EXECUTION IN SDN ENABLED VANET-CLOUD PLATFORM

This section presents load balanced energy aware cloud resource scheduling design for SDN enabled VANET-Cloud. First, we describe the system model for SDN enabled VANET-Cloud. Second, presents load balanced and energy aware cloud resource Scheduling workload execution in SDN enabled VANET-Cloud. The software architecture of the defined VANET-Cloud is shown in Fig. 1.

#### A. System Model of SDN enabled VANET-Cloud

This section present system model used for task scheduling in SDN enabled VANET-Cloud. Here the vehicle moves at varying speed in particular direction and execute different kind of data intensive and scientific applications. Here the vehicles are connected to RSU which are placed in fixed position. These RSU are connected to SDN controllers through which task execution process is outsourced to cloud computing environment. The work aimed at minimizing task execution time with minimal energy consumption aiding better resource utilization through better load balancing strategy. The cloud environment used in this work is heterogeneous in nature which has different energy consumption and processing capability for executing different task.

#### B. Load Balanced and Energy Aware Cloud Resource Scheduling Design for Workload Execution in SDN enabled VANET-Cloud

This section present load balanced energy aware cloud resource scheduling (LBEACRS) method for workload execution in SDN enabled VNET-Cloud environment. Here the workload task submitted by vehicle is submitted to near-by RSU. The RSU execute the workload if it has resource available or it is offloaded to heterogeneous cloud server connected through SDN controller. The LBEACRS method is designed in a way that can optimally distribute the task with minimal consumption of energy and meeting task deadline constraint without overloading the particular server. As this work considers dispatching task to multi-server environment here a task backlog scheduling model is presented. A backlog scheduling model for a set of  $o$  multi-server platform  $T_1, T_2, \dots, T_o$  with size  $n_1, n_2, \dots, n_o$  and its processing speed is  $t_1, t_2, \dots, t_o$  is modelled in this work. Let consider that heterogeneous multi-server platform  $T_j$  is composed of  $n_j$  similar servers with processing capability  $t_j$ .

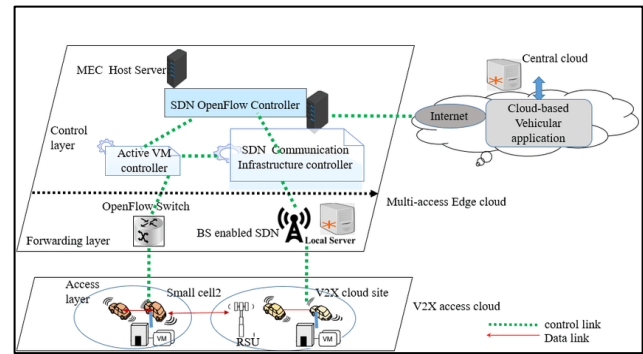

Fig. 1. Architecture of Software Defined VANET-Cloud.

Let consider a Poisson process with  $M/M/m$  backlog scheduling model considering sequence of tasks with incoming load  $\alpha$ . The incoming load is identical and independent in nature which distributed exponentially randomly ( $s$ ) with average ( $\bar{s}$ )  $1/\alpha$ . The LBEACRS method divide these task sequence into  $o$  sub-sequences, in such way that the  $j^{th}$  sub-sequences with incoming load  $\alpha_j$  is transmitted to multi-server platform  $T_j$ , where  $1 \leq j \leq o$ ,  $\alpha = \alpha_1 + \alpha_2 + \dots + \alpha_o$ . A multi-server platform  $T_j$  keeps a buffer with unbounded capability for waiting task when entire server  $n_j$  is busy. Here the tasks are executed in first come first basis considering multi-server platform with task execution are identical and independent with exponential random parameter  $s$  and average  $\bar{s}$ . The  $n_j$  servers of multi-server platform  $T_j$  possess identical execution processing capability  $t_j$ ; thus, task processing makespan on respective sever of multi-server platform is identical and independent with exponential randomness as follows.

$$\gamma_j = \frac{s}{t_j} \quad (1)$$

with average

$$\bar{\gamma}_j = \frac{\bar{s}}{t_j} \quad (2)$$

The average amount of task that can be completed by respective server within  $T_j$  (i.e., average workload execution rate) is obtained using following equation.

$$\beta_j = \frac{1}{\bar{\gamma}_j} \quad (3)$$

The server utilization (i.e., the mean percentage of time a server will be busy) is obtained using following equation.

$$\gamma_j = \frac{\alpha_j}{n_j \beta_j} = \frac{\alpha_j \bar{\gamma}_j}{n_j} = \frac{\alpha_j \bar{s}}{n_j t_j} \quad (4)$$

Let  $p_{j,l}$  represent the probability that  $l$  task will be processed or in waiting in backlogging system considering multi-server platform  $T_j$  and is obtained using following equation.

$$p_{j,l} = \begin{cases} p_{j,0} \frac{(n_j \gamma_j)^l}{l!}, & l < n_j; \\ p_{j,0} \frac{n_j^j \gamma_j^l}{l!}, & l \geq n_j; \end{cases} \quad (5)$$

where

$$p_{j,0} = \left( \sum_{l=0}^{n_j-1} \frac{(n_j \gamma_j)^l}{l!} + \frac{(n_j \gamma_j)^{n_j}}{n_j!} \cdot \frac{1}{1-\gamma_j} \right)^{-1} \quad (6)$$

The probability of freshly arrived workload task that must be waited i.e. (backlogged) in multi-server platform  $T_j$  when entire server in  $T_j$  is busy is computed using following equation.

$$P_{r,j} = \frac{q_j n_j}{1-\gamma_j} = p_{j,0} \frac{n_j}{n_j!} \cdot \frac{\gamma_j^{n_j}}{1-\gamma_j} \quad (7)$$

The mean amount of workload task that are being in execution processes or waiting within multi-server platform  $T_j$  is computed using following equation.

$$\bar{O}_j = \sum_{l=0}^{\infty} l p_{j,l} = n_j \gamma_j + \frac{\gamma_j}{1-\gamma_j} P_{r,j}. \quad (8)$$

Similarly, the mean workload task response makespan of multi-server platform  $T_j$  is computed using following equation.

$$U_j = \frac{\bar{O}_j}{\alpha_j} = \bar{y}_j + \frac{P_{r,j}}{n_j(1-\gamma_j)} \bar{y}_j = \bar{y}_j \left( 1 + \frac{P_{r,j}}{n_j(1-\gamma_j)} \right) \quad (9)$$

For simplicity the mean workload task response makespan of multi-server platform  $T_j$  is computed using following equation.

$$U_j = \frac{\bar{s}}{t_j} \left( 1 + p_{j,0} \frac{n_j^{j-1}}{n_j!} \cdot \frac{\gamma_j^{n_j}}{(1-\gamma_j)^2} \right) \quad (10)$$

The energy consumed for executing task is obtained using following equation.

$$Q = aC\mathcal{V}^2\mathcal{F} = \delta t^\mu$$

where  $a$  defines the task activity features,  $\mathcal{V}$  defines voltage,  $C$  represent load capacitance, and  $\mathcal{F}$  defines clock frequency,  $t$  defines processor execution speed. The parameter  $\delta$  is computed using following equation.

$$\delta = \frac{a\ell^2c}{c^2\rho+1} \quad (11)$$

where  $\ell$  and  $\rho$  are some constant greater than 0. The parameter  $\mu$  is computed using following equation.

$$\mu = 2\rho + 1. \quad (12)$$

This work consider heterogeneous multi-server platform; thus, the value of  $\delta$  and  $\mu$  is different for different server. Here we consider two different energy mode such as idle and active mode. In idle mode, the machine do not execute any workload task and energy consumed is obtained using following equation.

$$Q_j = n_j (\gamma_j \delta_j t_j^{\mu_j} + Q_j^*) = \alpha_j \bar{t} \delta_j t_j^{\mu_j-1} + n_j Q_j^*. \quad (13)$$

Similarly, in active mode the server is running and waiting for incoming workload task and energy consumed is obtained using following equation.

$$Q_j = n_j (\delta_j t_j^{\mu_j} + Q_j^*) \quad (14)$$

This work aimed at allocating ideal resource with minimal execution time for executing workload task under multi-server platform with varying processing speed and power consumption. Let consider a  $o$  number of multi-server cloud platform with size of  $n_1, n_2, \dots, n_o$ , with varying power consumption and processing capability for executing workload with requirement  $\bar{s}$  with task arrival rate  $\alpha$ , and establish load distribution  $\alpha_1, \alpha_2, \dots, \alpha_o$  in achieving high performance efficiency is obtained by minimizing following equation.

$$\min U(\alpha_1, \alpha_2, \dots, \alpha_o) \quad (15)$$

The above equation is subject to following constraint

$$G(\alpha_1, \alpha_2, \dots, \alpha_o) = \alpha, \quad (16)$$

where

$$G(\alpha_1, \alpha_2, \dots, \alpha_o) = \alpha_1 + \alpha_2 + \dots + \alpha_o, \quad (17)$$

and  $\gamma_j < 1, \forall 1 \leq j \leq o$ . Here the workload task are scheduled by minimizing Eq. (15) and meeting constraint defined in Eq. (16) and (17) in order to achieves high resource utilization and performance efficiency with minimal energy dissipation.

#### IV. SIMULATION ANALYSIS AND RESULTS

Here experiment is conducted for evaluating LBEACRS algorithm methodology over standard cloud resource scheduling algorithm [11], [12]. Energy efficiency and makespan are performance metrics used for validating performance. For carrying out experiment SIMITS simulator [13] is used. Further, for incorporating software defined vehicular cloud architecture CloudSimSDN [14] which is an extension of CloudSim simulator which is incorporated into SIMITS. Further for providing secure communication among communicating device such as vehicle, RSU, and SDN controller the message in SDN enabled vehicular adhoc network are encrypted using elliptical curve cryptography. Further, this assumes that each device is composed of tamper proof device obtained from trust authority for carrying out authentication and pseudo-identity-based data signing that assures anonymity of data owner and secure communication. For evaluating performance experiment is conducted by considering dynamic radio propagation model where vehicle will move from urban-to-rural-to-highway and vice versa. Experiment is conducted considering two workload such as Montage and CyberShake workload [15]. The Montage and CyberShake workflow have been used for experiment. The Montage workflow requires high I/O resource; however, the CyberShake requires CPU and memory resource. The simulation parameter considers for carrying out experiment are described Table I.

Fig. 2 shows the graphical representation of how the montage workflow is stored. Similarly in Fig. 3 the graphical representation of the CyberShake workflow has been represented.

##### A. Makespan Performance Evaluation

Here makespan performance is evaluated for both proposed LBEACRS and existing DCOH workload scheduling methodology. Two different workloads such as Montage and

CyberShake is considered for evaluation. First experiment is conducted using Montage workload where the job size is varied and makespan induced for executing workload using DCOH and LBEACRS is graphically shown in Fig. 4. The LBEACRS improves makespan performance by 66.955%, 81.48%, 86.14%, and 89.83% over DCOH when job size is 25, 50, 100, and 1000, respectively. An average makespan performance enhancement of 81.1% is achieved using LBEACRS over DCOH for executing Montage workload.

TABLE I. SIMULATION PARAMETERS CONSIDERED

Network Parameter	Value
SDN enabled vehicular Adhoc network Size	50km * 50km
Number of Vehicles	40
Number of RSU	1 per region
Modulation scheme	QAM-64
Mobility of devices	3 cycle per frame
SDN enabled vehicular Adhoc network coding rate	0.75
SDN enabled vehicular Adhoc network bandwidth	27 Mbps
SDN enabled vehicular Adhoc network data channel size	6
SDN enabled vehicular Adhoc network control channel size	1
Number of SDN switches per RSU	1
SDN enabled vehicular Adhoc network time slot size	8 $\mu$ s
Message information size	27 bytes
Radio propagation mobility model	Dynamic environment such as urban, rural, and highway
MAC used	ENCCMA, TECA & ERS
Resource scheduling used	LBEACRS & DCOH
Workload used	Montage & CyberShake

Fig. 2. A Sample Graphical Representation of Montage Workflow.

Fig. 3. A Sample Graphical Representation of CyberShake Workflow.

Fig. 4. Makespan Performance for Executing Montage Workload with different Workload Size.

Similarly, experiment is conducted using CyberShake workload where the job size is varied and makespan induced for executing using DCOH and LBEACRS is graphically shown in Fig. 5. The LBEACRS improves makespan performance by 69.95%, 82.14%, 89.23%, and 92.29% over DCOH when job size is 30, 50, 100, and 1000, respectively. An average makespan performance enhancement of 83.4% is achieved using LBEACRS over DCOH for executing CyberShake workload.

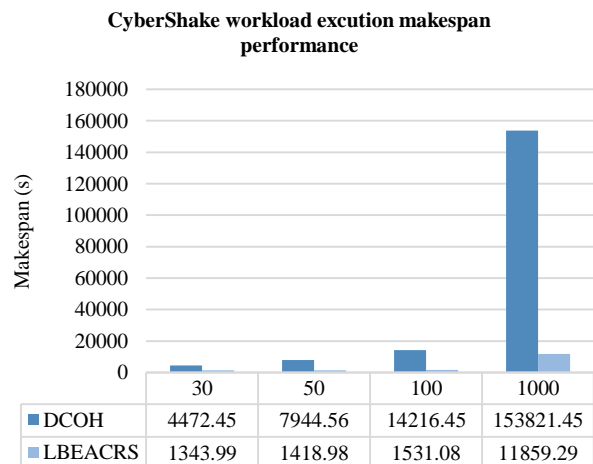

Fig. 5. Makespan Performance for Executing CyberShake Workload with different Workload Size.

**B. Energy Consumption Performance Evaluation**

Here energy performance is evaluated for both proposed LBEACRS and existing DCOH workload scheduling methodology. Two different workloads such as Montage and CyberShake is considered for evaluation. First experiment is conducted using Montage workload where the job size is varied and total energy induced for executing workload using DCOH and LBEACRS is graphically shown in Fig. 6. The LBEACRS improves energy efficiency performance by 74.63, 85.78%, 89.36%, and 92.19% over DCOH when job size is 25, 50, 100, and 1000, respectively. An average total energy consumption reduction of 85.49% is achieved using LBEACRS over DCOH for executing Montage workload. Further, the average energy incurred for executing each sub-task using DCOH and LBEACRS is graphically shown in Fig. 8. The LBEACRS improves average energy induced per task performance by 23.229% over DCOH for executing Montage workload.

Similarly, experiment is conducted using CyberShake workload where the job size is varied and total energy induced for executing workload using DCOH and LBEACRS is graphically shown in Fig. 7. The LBEACRS improves energy efficiency performance by 75.17%, 95.30%, 96.12%, and 93.63% over DCOH when job size is 30, 50, 100, and 1000, respectively. An average total energy consumption reduction of 90.057% is achieved using LBEACRS over DCOH for executing CyberShake workload. Further, the average energy incurred for executing each sub-task using DCOH and LBEACRS is graphically shown in Fig. 9. The LBEACRS improves average energy induced per task performance by 41.35% over DCOH for executing CyberShake workload.

Fig. 6. Energy Consumption for Montage Workload Execution with different Workload Size.

Fig. 7. Energy Consumption for CyberShake Workload Execution with different Workload Size.

Fig. 8. Average Energy Consumption for Montage Workload Execution with different Workload Size.

Fig. 9. Average Energy Consumption for CyberShake Workload Execution with different Workload Size.

From overall result attained it can be stated LBEACRS is scalable with respect to varying workload size and works well for both small and larger workload. And also shows they are efficient in provisioning CPU, memory and I/O intensive task.

## V. CONCLUSION

This work studies the challenges involved in workload scheduling of data-intensive application on SDN enabled VANET-Cloud environment. From study we noted most of existing workload scheduling are done by predominantly considering minimizing makespan and also minimizing cost with deadline constraint. Further, doesn't balance load among processing node. In standard the cost is generally computed based on time spent. However, reducing energy plays major role as different countries has different prices. Thus, here a load balanced energy aware cloud resource scheduling is presented. Here the tasks are scheduled to node that consumes less energy with better resource utilization. Experiments are conducted using two workloads, namely Montage and CyberShake. These workloads are CPU, I/O, and memory intensive in nature. An average makespan performance enhancement of 81.1% and 83.4% is achieved using LBEACRS over DCOH for executing Montage and CyberShake workload, respectively. An average total energy consumption reduction of 85.49% and 90.057% is achieved using LBEACRS over DCOH for executing Montage and CyberShake workload, respectively. The LBEACRS improves average energy induced per task performance by 23.229% and 41.35% over DCOH for executing Montage and CyberShake workload, respectively. From overall result we can state that the LBEACRS is scalable irrespective of workload complexity and is robust with respect to CPU, I/O and memory intensive application.

Future work would consider introducing SLA with quality of experience guarantee in proving resource to VANET users. Further, incorporate effective security mechanism that can reduce key management, storage, and computation overhead.

**Abstract**—Recently, the need for online collaborative learning in educational systems has increased greatly because of COVID-19 pandemic. The pandemic has provided an opportunity for introducing online collaboration and learning among instructors and students in Nigeria. Currently, several schools, colleges, universities in Nigeria have discontinued face to face teaching and learning. Many schools resorted to ineffective alternatives such as the use of televisions and radio programmes to carry out distance education (DE). These alternatives have challenges such as lack of monitoring and evaluation of students' learning. Collaborative Learning Management System (CLMS) is a research project that aims to assist instructors in achieving their pedagogical goals, organizing course content, collaborating, monitoring, and supporting students' online learning. It is an interactive, online based as well as android based system that has been designed, implemented, tested. The system demonstrates that it is robust, interactive, and achieves the predefined goals. As a Software Development Approach, it was created using the Rapid Application Development (RAD) Methodology. It also provides a secured and reliable platform for the schools, colleges, and universities to implement an online learning system.

**Keywords**—Collaborative learning; conventional education; effective learning; e-portfolio; interactive board

## I. INTRODUCTION

The COVID-19 pandemic has caused significant disruption to educational activities around the world, particularly in Nigeria. Many countries resorted to online based distance education (DE) for learning continuity. However, many schools in Nigeria are applying the method of use of television and radio-based programmes, to carry out distance education. This method poses a great challenge because it's difficult to monitor and evaluate students learning. A few institutions in Nigeria are now carrying out their academic activities using one form or another of Information Communication Technology (ICT). However, for some institutions in Nigeria, the desire to engage in online learning remains a dream due to inadequate ICT infrastructure. However, the rapid development of ICTs in Nigeria presents an opportunity to consider its use in the promotion of distance education [1]. According to the authors in [2], DE is regarded as a novel method for delivering computer-mediated, well-designed, student-centered, and interactive learning environments to students at any time and from any location by utilizing the internet and digital technologies in conjunction with instructional design guidelines. It benefits students by increasing access to learning

opportunities, at the right time and place, making a wide range of learning resources available, improving opportunities for personalized learning [3, 4], and ushering in more powerful cognitive tools. However, the educational sector in Nigeria continues to rely on conventional teaching methods that are incompatible with students and teachers in an age of ICT development [5].

The authors in [6] stated that the conventional education at this present time has not added educational contents to the new generation students. Conventional education has not keep-pace with modern thought and the educational sectors need, to suit with type of students in the twenty first century [6]. The Collaborative Learning Management System (CLMS) is a collaborative learning platform used to manage and integrate online learning courses between teachers and students for effective delivery of lectures through the internet. At the moment, online learning management systems (CLMS) are commonly used in educational sectors all over the world because they make it simple to create, deliver, and learn course content, as well as track and report on course and student performance [7].

The online learning system is a supplement to the conventional concept of education; the current education system is shifting from the teacher imparting knowledge to the students, to promoting the students' desire to learn. This type of transition can inspire an individual to develop a love of learning, problem solving, and comprehension, as well as a strong long-term memory. In such a learning environment, students can actively learn and acquire skills to solve a variety of problems, as well as assess and value their own works and ideas. The lecturing, listening, and note-taking processes do not entirely disappear in the CLMS, but they are supplemented by other processes based on student discussion and active work with the course material. Collaborative learning teachers see themselves as master creators of intellectual experiences for students rather than expert transmitters of information to students [8].

In view of the above discussion, this work focused on the design and implementation of CLMS to enhance, integrate an effective learning process. In general, components of the system contain interactive management features, quiz and assessment utilities and announcement medium. The assessment utilities allow instructors to systematize basic assessment tasks to the students. Assessments are delivered to

<sup>1</sup><https://blog.capterra.com/what-is-rapid-application-development/>

the students online, and upon conclusion, grades and detailed feedbacks are delivered to the students. The system provides the following solutions: collaborative learning through interactive tools, easy knowledge management, assessments, and quiz. Chats between instructors to students and students to students. Repository of course materials via e-portfolio, Personalize learning management tools, secure and customizable learning system.

The other sections of this paper presents: (1) a literature review on the need to reconsider the design of conventional educational system to include online collaborative learning in educational systems and the importance and features of online collaborative learning management system, (2) identification of problems with the conventional system of education and presented objective of this study, (3) presentation of the system overview and architecture of a new online collaborative management system and the test results and (4) conclusion and recommendations.

## II. LITERATURE REVIEW

The need to reconsider the design of conventional educational system to include online collaborative learning in educational systems has increased greatly because of COVID-19 pandemic. The pandemic has provided an opportunity for introducing online collaboration and learning among instructors most especially in Nigeria. Many schools, colleges, and higher institutions in Nigeria have discontinued face to face teaching and learning and relied on ineffective alternatives such as the use of televisions and radio programmes to carry out distance education (DE) [8]. These alternatives have challenges such as lack of monitoring and evaluation of students' learning. As a result, an online collaborative learning management System (CLMS) is required to assist teachers in achieving their pedagogical goals, organizing course content, collaborating, monitoring, and supporting students' online learning.

The process of standardizing collaborative learning technology is taking the lead in research efforts into online-based education [9]. The author in [10] emphasized the importance of researchers conducting additional research on the role of collaboration in learning in order to develop deeper theoretical frameworks that can better guide the development of technology-supported learning settings.

Some trends have necessitated the use of online-based learning. Platforms for collaborative learning management systems (CLMS) have abundant resources, sharing, and convenience. All these characteristics combine to make it one of the more potent learning tools. CLMS has good functionality for assisting students' learning and encourages positive attitudes in both students and teachers [11]. On-line collaborative learning is heavily reliant on the internet and employs collaborative learning methods. The methods make full use of internet resources, promoting learners' abilities to self-learn, communicate, and direct learners' activities with others, as well as assisting in supporting learners to solve practical problems. Based on what has been discussed thus far, one can reasonably conclude that online collaboration can be

delivered in the form of discussion among the entire group or students or within smaller groups of students, however, [12] emphasized that smaller groups make better learning outputs. The author in [13] posited that collaborative learning can help in demonstrating new knowledge.

Collaborative learning is known by a variety of names. Cooperative learning, collaborative learning, collective learning communities, peer teaching, peer learning, and team learning are some examples. All of these names have one thing in common: they all necessitate collaboration. Furthermore, research suggests that collaboration may provide more opportunities for equality in group work than conventional face-to-face group work [9], because the latter approach frequently bases group "decision-making" on students who are considered "bright" by their teachers in the class. The section that follows discusses the various types of CLMS and their features.

### A. Collaborative Learning Management System (CLMS) and their Features

There are several types of CLMS available on the market [14], including commercial or proprietary, as well as free software or free courses [15]. Among the various types of CLMS types that are implemented in higher institutions are Blackboards (proprietary environment). The best CLMS for a given institution is determined by its characteristics and objectives [15]. According to [16], several researchers investigated the necessary elements for selecting a CLMS. A team from the Federal University of Rio de Janeiro (UFRJ) Technology, Education, and Society Group [17], for example, identified seven major categories of tools in an educational platform in 2004. The categories are interface, navigation, evaluation, didactic resources, communication / interaction, coordination, and administrative support.

There are classes that enable efficient Collaborative Learning Management System (CLMS). They are 1) Interface category which creates communication between users and system. 2) Navigation category that establishes easy flow between Collaborative Learning Management System (CLMS) pages. It includes evaluation forms to determine whether a student has fully grasped the material. 3) The Communication / Interaction category that depicts flow of information between learners in a Collaborative Learning Management System. 4) The Coordination category focuses on the instructors' actions of module planning, creation, execution, and control. 5) The Administrative Support category focuses on both the administration tools and environmental management [17].

In order to analyze student interaction in online-based courses, students' interactions are divided into two main categories which include content interaction and social interaction [18]. The content interaction is focuses on the module content such as the study materials, assignment and any other important information that help the effectiveness of the student study. Social Interaction aids students to learn about their peers and resist the separation and frustration of an individual student that are common problems in Web-based course.

The presence of online CLMS to support continuing of teaching and learning will guide the implementation of education system during this challenging crisis of COVID 19 pandemic.

### III. STATEMENT OF THE PROBLEM

The following challenges are associated with the conventional education system and current alternative methods:

- 1) Learning is restricted to a specific time, this results to an inadequate attention of the student.
- 2) Inability for student in distance locations to participate in learning making it difficult for those that is far from the location to be involved in the learning.
- 3) Limited access to the learning materials to the students making it difficult for student to have access to all the study materials at a particular time.
- 4) Students are required to physically be present in the classroom in order to gain knowledge, sacrificing all other responsibilities.
- 5) Students submit assignment to the lecturer through hard copies.
- 6) The lack pre-existing collaborations for the design and broadcasting of the educational content via television and radio.

### IV. OBJECTIVES OF THE STUDY

The aim of this work is to develop and implement the Collaborative Learning Management System for online distance education with the specific objectives as follows:

- 1) To create an interactive board where student can interact and share idea with each other.
- 2) To integrate an e-portfolio in the system which would serves as the repository storage of learning material needed for the student.
- 3) To develop a web based CLMS application for student effective learning.
- 4) To create user interface is compatible and responsive to any device being used.

### V. SYSTEM OVERVIEW

The design of this collaborative learning management system platform is based on the need to provide a system that would ensure that a student is fully involve in learning activities of the institution irrespective of the geographical location. The system would provide some functionality such as interactive board/chat box which would aid student to lay comment as well allows the student-student and lecturer/teachers interactions. Also, an integration of e-portfolio in the system which would serves as the repository storage of learning material needed for the student. The system graphical user interface would be made to be easily accessible via web browsers and compatible and responsive in any device being used. Rapid Application Development (RAD)<sup>1</sup> Software methodology was adopted in the design of the proposed system. The RAD methodology has the following phases:

- Requirement planning: Also known as a project scoping meeting. Although the planning phase is shorter in this methodology than in others, it is critical to the overall success of the CLMS development. The phase specifies the reporting functions and data subject areas of the CLMS, as well as the system's scope. It is also known as the concept definition stage.
- User Design: This is also referred to as functional design. Once the project has been scoped, development can begin, fleshing out the user design through multiple prototype iterations and user feedback. We worked with users to create a functional prototype of CLMS components.
- Construction: The physical CLMS is completed during the construction phase, the conversion system is built, and a user aid and implementation work plan is developed. This stage, also known as the development stage, is broken down into several smaller steps, including program development, coding, and unit, integration, and system testing.
- Cutover: This stage, also known as the implementation phase, includes final user testing, training data conversion, and application system implementation.

The high-level model of CLMS is shown in Fig. 1. It is broken down into units and subunits so that the CLMS can be easily understood starting from the subunits. Fig. 2 shows the system architecture of the new CLMS. It defines the behaviour and structure of a system.

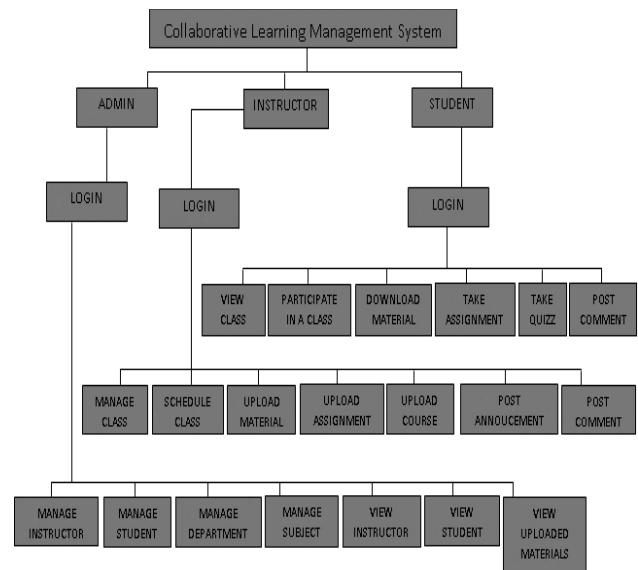

Fig. 1. High-level Model of the New CLMS.

### VI. SYSTEM ARCHITECTURE

The CLMS architecture presents a set of artifacts and their relationships, which guide the system's selection, creation, and implementation. Fig. 2 depicts the new CLMS's system architecture. These sets of artifacts depict the relationships between CLMS components and are represented in Fig. 3 by a use case diagram and Fig. 4 by an entity relationship diagram.

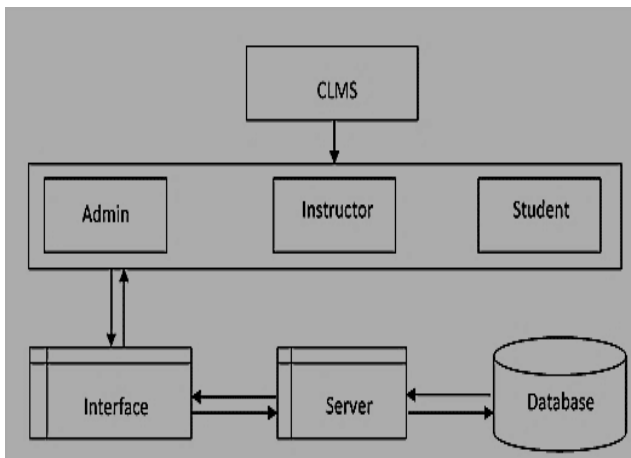

Fig. 2. System Architecture Diagram of the New CLMS.

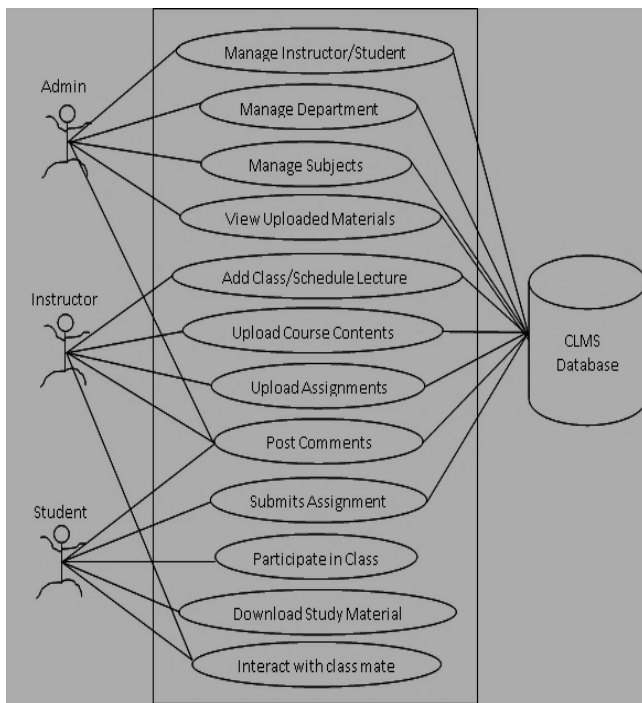

Fig. 3. The use Case Diagram of the System.

- Entity Relationship Diagram (ERD): The Entity Relationship Diagram (shown in Fig. 4) provides a clear picture of the relationships between the various entities associated with the system. It describes how one entity's flow of action is related to other system entities.

#### A. Menu Design

The main menu of this system is design in such a manner that it will enable the users of the system to easily navigate or taken to the submenu to carry out specified tasks. At the menu they are required to provide their login details after which access to other sub modules would be granted to them. There are three main group of users captured in this system. These are the Administrator of the system, the Instructor/teacher, and the Student. The main menu interface will allow either the admin or instructor and student to navigate to the various sections which will enable module to have their own menu that

serves the main functions to enable them to effectively manage the system. The diagram in Fig. 5 shows the main menu for instructors and student log in. Fig. 6 displays the main menu design for Admin.

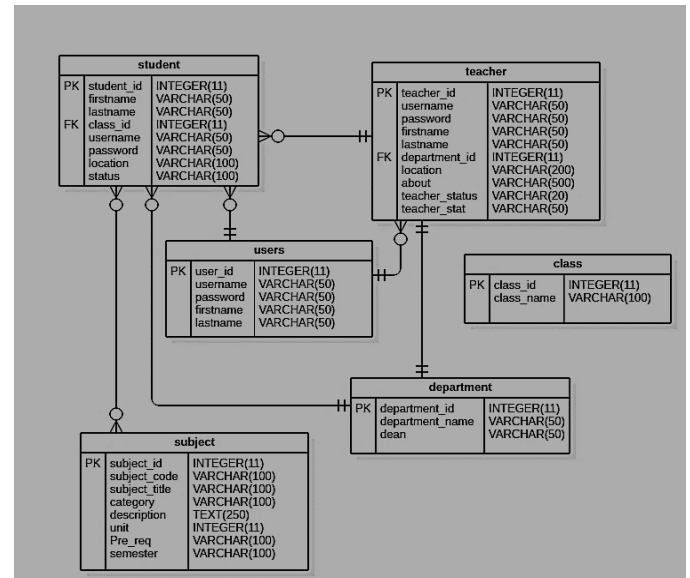

Fig. 4. Entity Relationship Diagram (ERD) of the New System.

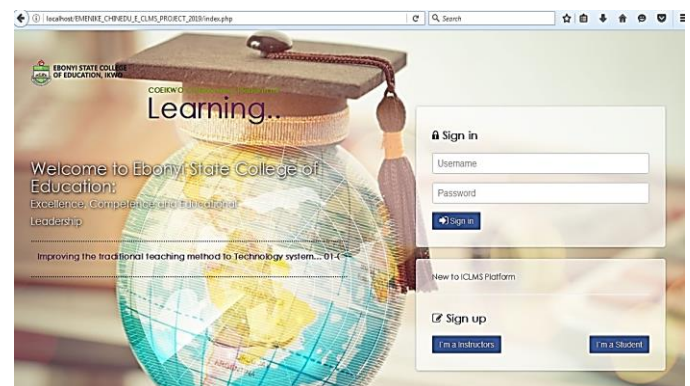

Fig. 5. The Instructor/Student Login Page.

Fig. 6. Main Menu Design for Admin.

1) *Subsystem design*: The entire system consists of subsystems whose purpose is to help to achieve the aim of the system. The subsystems include:

a) *Subsystem design*: The entire system is made up of subsystems whose purpose is to help the system achieve its goal. The subsystems are as follows: a) The Admin Sub System, depicted in Fig. 7, is designed to allow administrators to manage students and instructors.

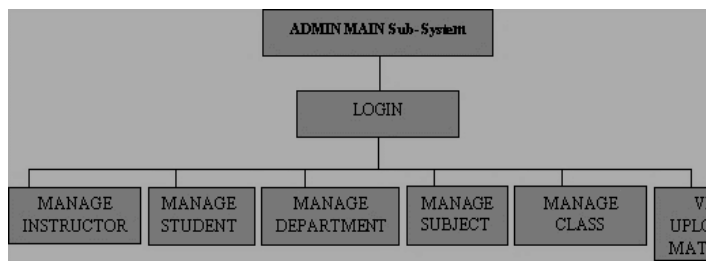

Fig. 7. The Admin Platform.

b) *The Instructors/Teachers Subsystem*, depicted in Fig. 8, is intended for instructors to perform a variety of tasks such as managing classes, scheduling classes, uploading materials, and uploading files.

c) *The Student Subsystem*, depicted in Fig. 9, is intended to allow students to interact with educational content.

2) *Design of program modules*: The new system is made up of several modules that work together to form the entire system. Here are a few examples:

- The admin subsystem consists of manage/view instructor module, manage/view student module, manage subject module, manage department module, view uploaded materials module.
- While the instructor and student subsystem consist of manage class module, schedule class module, upload material module, upload assignment module, upload course module, post comment module and view class module, submit assignment module, download material module, post comment module, respectively.

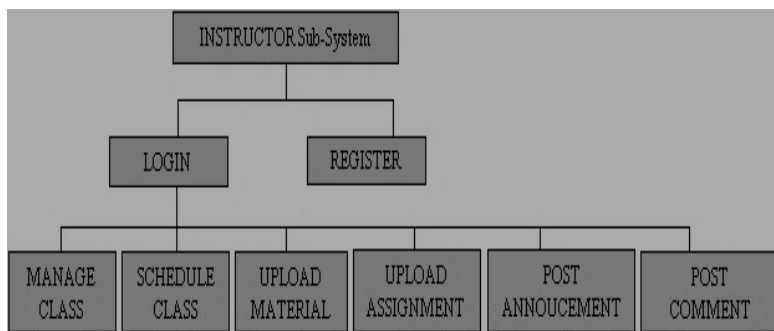

Fig. 8. The Instructor Sub System.

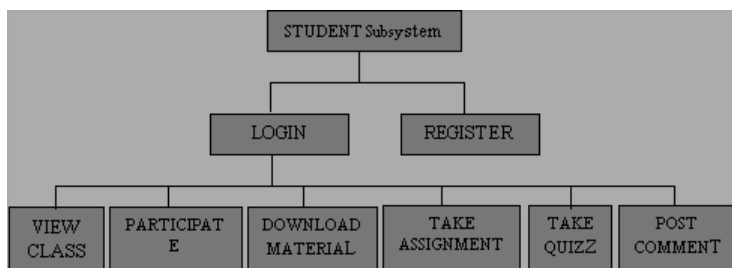

Fig. 9. The Student Platform.

3) *Database development tools and structure*: MYSQL, one of the most powerful powering tools for software that runs on the XAMPP server, was used in the development of this system. It has customizable views, query caching, cross-platform support, triggers, and built-in replication. A relational database management system (RDBMS), specifically MYSQL Server, is used to implement the database design. Tables I and II show some of the tables that were used. Table I depicts the student table, while Table II depicts the administrative table.

TABLE I. THE STUDENT TABLE

#	Name	Type	Collation	Attributes	Null	Default	Extra
1	student_id	Int(11)			NO	None	Auto_Increment
2	firstname	Varchar(50)			NO	None	
3	lastname	Varchar(50)			NO	None	
4	Class_id	Int(11)			NO	None	
5	username	Varchar(50)			NO	None	
6	password	Varchar(50)			NO	None	
7	location	Varchar(100)			NO	None	
8	status	Varchar(100)			NO	None	

TABLE II. THE ADMIN TABLE

#	Name	Type	Collation	Attributes	Null	Default	Extra
1	user_id	Int(11)			NO	None	Auto_Increment
2	username	Varchar(50)			NO	None	
3	password	Varchar(50)			NO	None	
4	firstname	Varchar(50)			NO	None	
5	lastname	Varchar(50)			NO	None	

### B. Admin Menu Implementation

This menu allows the CLMS administrator to manage instructors and students. It was designed to monitor all the activity progress of both students and instructors. Fig. 10 depicted the picture of the admin main menu showing its entire menu at the left side bar navigation. The center content is the information feature that presents activity progress of all activities of the instructor and student perform on their home pages. This Admin managed the instructors, set up the modules and could create/edit/delete users. The administrator has direct access to the database.

Fig. 10. The Admin View Implementation.

### C. Students Menu Implementation

Students complete their profile on the system on first login. Fig. 11 shows the program Flowchart for Student Registration and Verification. Upon login, checks for notification of any task. They can also receive a text message on their phone via web service notifying them of any task. The user can also see his or her group members whenever a group task is given. The user can also respond to any task as appropriate by uploading files, posting answers on the joint collaborators widget and posting links for references in other for group member to read further and communicates to the instructors if need be.

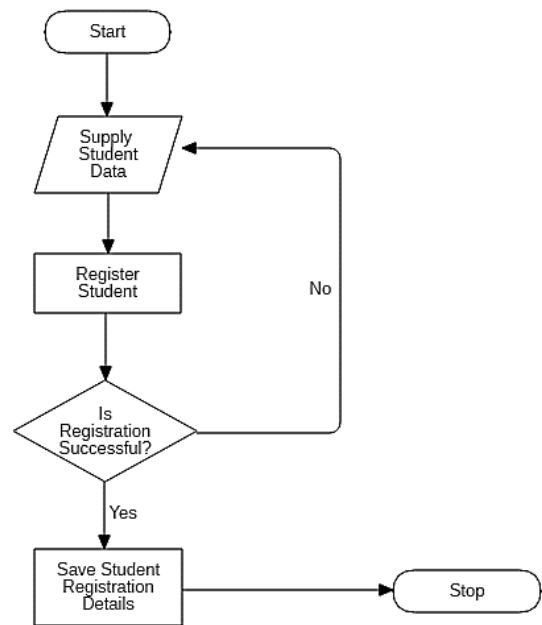

Fig. 11. Program Flowchart for Student Registration and Verification.

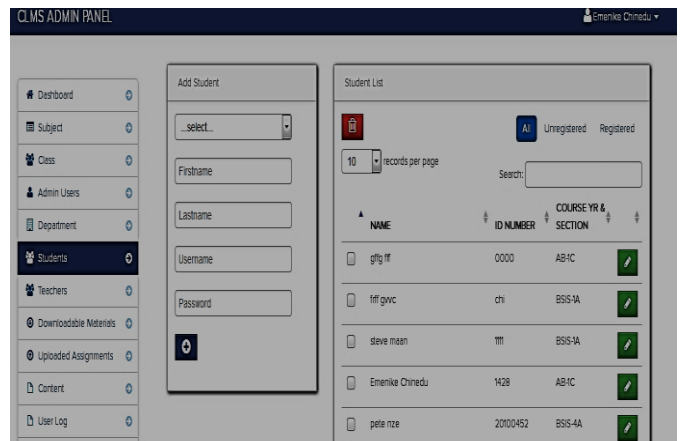

Fig. 12. Add/View of Student Sub System Module.

### D. Subsystem Implementation

1) *Manage/view instructor and students module:* The manage/view instructor and students' module are one of the modules that made up the admin subsystem. At this module, the admin must have sign in into the system to view this module. This module displays the list of all eligible students and teacher/instructor. Fig. 12 presents the add/view of student sub system module.

2) *Manage/add department module:* This module is made up of the instructor/lecturer subsystem. At this module, the instructor must be signed in before viewing the modules that were created in the department. Fig. 13 displays the add department module design.

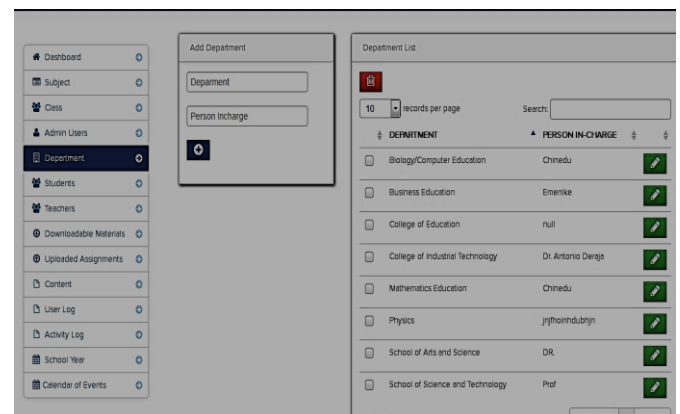

Fig. 13. Add Department Module Design.

3) Algorithm for the module of subsystem implementation:

In this section, we focused on the underground implementation of the scheduled class session in the instructors' and students' dashboards. Algorithms that implement these modules of systems in natural language are shown in Fig. 14 and Fig. 15, respectively.

- Step1: start
- Step2: display instructor dashboard after successful login
- Step3: click on my class
- Step4: click on my class name
- Step5: click on schedule class
- Step6: click on live lecture to start the class
- Step7: if class is over (complete) Go to step2

Fig. 14. The Algorithm for Schedule Class Session in the Dashboard of the Instructor.

- Step1: start
- Step2: display student dashboard after successful login
- Go to Step 3
- Step3: click on my class
- Step4: click on my class name
- Step5: click on participate in class
- Step6: click on join to start the class
- Step7: if class is over (Complete) Go to step2.

Fig. 15. The Algorithm for Class Session of the Students.

VII. TEST RESULTS

These are the outcomes of the feasibility test for the tested system. They demonstrate a fully implemented system when tested with real-time data. The following testing and debugging methods were applied namely, Unit Testing, Integration Testing, and Alpha Testing.

Unit Testing: This test was carried out on every module of the system to verify proper functionality and ascertain if they were error free. Error found were noted down and corrected immediately.

Integration Testing: This test involves testing of how the various modules interact. This was done by combining the system modules to see how they interact and ensuring that their performance does not affect or obstruct the functionality of others.

Alpha Testing: Sample data were used to test the system's functionality to see if it would perform as expected and meet requirements without errors.

Fig. 16 shows a sample output for a message module for instructors' view.

A. System Integration

The system integration depicted in Fig. 17 shows how the various subsystems were combined to form the main system. The following elements were incorporated: a) The Student Subsystem b) The Instructor/Teacher Subsystem c) The Adm Subsystem.

B. Choice of Programming Language

In the development of the CLMS, PHP (PHP: Hypertext Pre-processor) was chosen as the server-side scripting language for the back-end development of the system. MYSQL was used

for the database design. This is the database development language that served as the back end of the software for storing information because of its high maintenance and security. It was used in creating communication and connection between the application and the database. JavaScript was also used along with AJAX to make the web application interactive. It is a high-level interpreted language. JQUERY were also used for carrying out client-side manipulations. Other languages for the client side (front end development) such as HTML (Hyper Text Markup Language) used to lay out the web pages, CSS (Cascading Style Sheets) to describe hoe HTML elements are to be displayed on screen, and BOOTSRAP which consists of HTML CSS JavaScript framework used to make the design responsive on laying out the web pages.

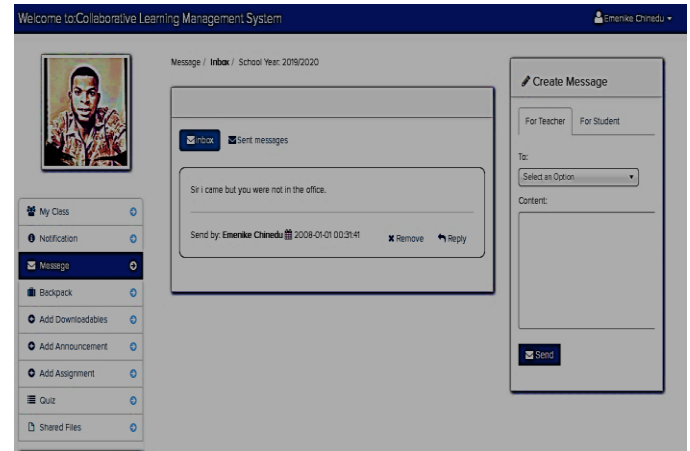

Fig. 16. Message Module Instructor View.

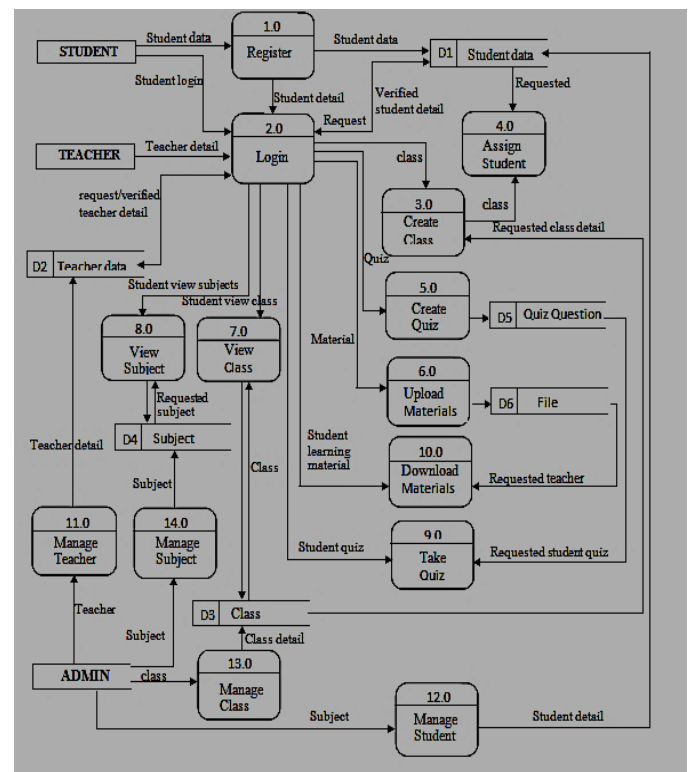

Fig. 17. An Integration of the System Subsystems.

## VIII. CONCLUSION

The challenges of conventional student teaching and learning in educational systems, as well as the abrupt disruption of our education system due to the COVID 19 pandemic, prompted this research. Despite the existence of strategies to compensate for the effects of discontinued face-to-face teaching and learning as a result of the pandemic, such as the use of televisions and radios to compensate for the effects of discontinued face-to-face teaching and learning, such alternatives have not contributed to effective student learning. This paper suggests that these issues can be addressed by implementing a new collaborative management system centered on effective learning and employing an integrated approach. As a result, the following inputs were considered during this study:

1) The system that allows a collaborative learning through interactive tools that entails receiving feedback from instructors easy knowledge management, assessments, and quiz. Providing an interactive chats box between instructors and students and students to students and providing repository of course materials via e-portfolio that students can access.

2) Instructors' module which enable instructors to various tasks to be assigned to students, set deadline for task, track and monitor the progress of each student and generate report for assessment-based students' participations on the collaborative platform of the system.

3) Students Module that allow students to complete their profile on the system on first login, checks for notification of any task. Also, the students receive a text message on their phone via web service notifying them of any task. Update's students whenever a group task is given. Students respond to any task as appropriate by uploading files, posting answers on the joint collaborator's widget, and posting links for references for other group members to read and communicates back to instructor.

The future iteration of this study will involve understanding instructors and students' perceptions about their experience of using CLMS to ascertain whether the CLMS system impacted positively to teaching and learning, and whether the use of CLMS minimize numerous learning problems with the conventional classroom learning environment in Nigeria educational system. This is importance in order to know the impact and efficacy of the CLMS with users in an educational setting.

# Selection of Learning Apps to Promote Critical Thinking in Programming Students using Fuzzy TOPSIS

Kesarie Singh<sup>1</sup>, Nalindren Naicker<sup>2</sup>, Mogiveny Rajkoomar<sup>3</sup>

Department of Information Technology, Durban University of Technology, Durban, South Africa<sup>1</sup>  
Department of Information Systems, Durban University of Technology, Durban, South Africa<sup>2,3</sup>

**Abstract**—The aim of this research was to use intelligent decision support systems to obtain student-centred preferences for learning applications to promote critical thinking in first year programming students. This study focuses on the visual programming environment and critical thinking as the gateway skill for student success in understanding programming. Twenty-five critical thinking criteria were synthesized from the literature. As a quantitative study, 217 randomly selected students from an approximate target population of 500 programming students to rate four learning Apps, namely, Scratch, Alice, Blockly and MIT App Inventor, against critical thinking criteria to establish the App that best promotes critical thinking among first year programming students. There were 175 responses received from the 217 randomly chosen programming students who willingly contributed to the study. Consequently, the distinctiveness of this paper lies in its use of the Fuzzy TOPSIS (Technique for Order Preference by Similarity to Ideal Situation) multi-criteria decision-making algorithm to rank criteria for critical thinking, calculate their weights on the basis of informed opinion and hence scientifically deduce the best rated App among the available alternatives that promote critical thinking among first year programming students. The results showed that Scratch promoted critical thinking skills the best in first year programming students whilst Blockly promoted critical thinking skills the least. As a contribution to the study, policy-makers and academic staff can be potentially supported to make informed decisions about the types of learning Apps to consider for students when confronted with multiple selection criteria.

**Keywords**—Critical thinking; visual programming environment; multi-criteria decision-making; fuzzy TOPSIS

## I. INTRODUCTION

The problem associated with teaching programming to novice learners is exacerbated by the complex and abstract nature of the field and the heavy reliance on 21st century skills such as critical and computational thinking. As a result, a kaleidoscope of research into programming self-efficacy, the complexity of the field, teaching methods and a variety of teaching tools, have emerged over the recent past. Furthermore, learning to program can be perceived as both tedious and difficult to the novice programmer for reasons such as the abstract nature of computational thinking and the burdensome syntax and semantics associated with many programming languages [1-3]. The literature has also repeatedly revealed that visual block-based programming environments have a

positively powerful impact on the performances of novices learning to program [4]. In a case study performed by Pinto-Llorente et al. in [5] on the impact of the visual programming environment (VPE) among primary school learners, it was determined to have promoted their critical thinking skills and problem solving abilities. Various other studies have revealed that visual programming environments support the constructivist approach to learning and contribute to enhancing one's skills of independent learning, creative thinking, problem-solving, reflection and collaboration [6-12]. This has resulted in an upsurge of educational programming environments and tools aimed at stimulating the learners' interest, making programming accessible to people of all interests and ages and minimizing the challenges of understanding programming [13].

The significant growth in diverse learning Apps in the last decade and the varying commercial aspirations these Apps may be designed to serve, have impacted on the need for university academics to make rigorous and well-considered decisions around their choice of learning App. Further, an online learning App becomes especially appropriate post Covid-19, where higher education institutions are strategically searching for alternate teaching methodologies to the traditional teaching approach. Interestingly, a number of learning Apps originated over the years with a variety of different characteristics, each serving a slightly different need [4]. Multi-criteria group decision-making (MCDM) entails weighing each of several alternatives against multiple, conflicting, quantitative decision criteria executed by many decision-makers to derive the optimal alternative [14-16]. The various criteria will be synthesized from an in-depth analysis of the literature in the relevant field.

According to Başaran and Haruna in [17], manually selecting these Apps can be biased, tedious, inconsistent and time-consuming, ultimately resulting in a premature selection. Therefore, to address ambiguity and uncertainty associated with human judgements, this quantitative study will use the Technique for Order Preference by Similarity to an Ideal Solution (TOPSIS), a scientific and mathematical technique in multi-criteria decision-making (MCDM) that preserves integrity and objectivity of process [16, 18]. The TOPSIS method, developed in 1981 by Yoon and Hwang, was grounded on the fundamental principle that the best option from a range of alternatives will be positioned closest to the

positive ideal solution and farthest from the negative ideal solution [19].

In a study conducted by Junior, Osiro and Carpinetti in [39], a comparison of the Fuzzy AHP and Fuzzy TOPSIS methods was undertaken to choose from a number of suppliers. The criteria central to the comparison were: “adequacy to changes of alternatives or criteria; agility in the decision process; computational complexity; adequacy to supporting group decision-making; the number of alternatives and criteria, and modelling of uncertainty”. The study revealed that Fuzzy TOPSIS provided more rigor in the decision process, lower time complexity when there was a large number of decision-makers, offered no restrictions on the number of criteria and alternatives and became the preferred choice when there were changes to alternatives or criteria as rank reversal posed a potential problem with Fuzzy AHP.

Fuzzy set theory, which was introduced by Zadeh in 1965, can be used to manage the uncertainties and subjectivity of the evaluation process [15]. More specifically, this study will implement an expansion of the TOPSIS method to accommodate fuzziness in the decision problem setting. Fuzzy TOPSIS is widely and extensively applied among researchers in diverse fields of economics, business management, engineering, ICT and education, to solve various MCDM problems associated with site selection in mining and engineering, equipment selection, risk analysis for complex infrastructure projects, portfolio selection, selection of e-Learning approaches, supplier selection and software selection [16-23]. The advantages of Fuzzy TOPSIS include its ease of implementation, capacity to compare the strongest and weakest alternatives quantitatively, that it enables linguistic expressions to be represented as fuzzy numbers, and its practicality and ability to handle incomplete or partial quantitative data [24]. A questionnaire disseminated to 217 first year programming students is used as a tool to gather the ratings of alternatives against multiple selection criteria, and the different weightings per criteria are obtained from academic experts in the field. These sets of evaluations use logical interval judgements represented by linguistic terms which can be parameterized by triangular fuzzy numbers [24].

Choosing an optimal learning application (App) is therefore a complex problem requiring an intelligent decision support system that will use multiple decision-makers to simultaneously ruminate multiple criteria such as the prior skills of the learner, the technical infrastructure of the learning environment and the 21st century skills required for success in the higher order thinking of computer programming [25]. There are no studies in the extant literature that use an intelligent decision support system that is able to find the optimal choice of learning App to suit the needs of the instructors and learners in acquiring improved student success not only to encourage their interest and excitement for programming, but also to acquire a proficiency to create their own applications. The aim of this paper is to use the fuzzy TOPSIS multi-criteria decision-making technique to rank learning Apps according to its potential to promote critical thinking among programming students. The paper comprises five sections, namely, section 1 introduces the topic, section two surveys the extant literature, section three presents the

fuzzy TOPSIS method, section four explains the results and section five culminates with the findings of the study.

## II. LITERATURE REVIEW

The definition and promotion of critical thinking for learning has become increasingly important in the 21st century information and digital age, where organizations are competing for applicants who have the ability to investigate, apply, and transform data, to collaborate and innovate, to reflect, analyze and think critically, and to arrive at optimal decisions [26]. The literature defines the higher order thinking processes associated with programming as closely aligned with the concept of computational thinking (CT), where problem-solving is implemented through the mental process of abstraction, logic, analysis, synthesis and constructive thinking [5, 27-28]. It has been justified through various studies that CT skills should not just be accessible to everyone at a much younger age, but also have the potential to be applied to various disciplines and hence to be incorporated into the basic curriculum [2, 5].

There are a variety of learning resources and learning Apps to develop CT [29, 30] and each of these include aspects of robotics [2, 4, 31-32], gaming [33-34], augmented reality simulation [35] or multimedia such as graphics, sound and animation, with the latter referred to as visual programming environments [4, 9, 28]. This study is significant in its application as it aims to extend multi-criteria decision-making using Fuzzy TOPSIS with multiple decision-makers choosing the most appropriate learning App based on well-synthesized critical thinking criteria.

Multi-criteria decision analysis (MCDA) has successfully been applied to solve a wide range of complex real-life decision problems in a variety of fields [36], despite researchers encountering many challenges associated with partial ignorance and unquantifiable, incomplete, unobtainable, uncertain, ambiguous and vague information [15]. The choice of MCDA technique rests predominantly on the nature of the decision problem and its ability to address many of the aforementioned challenges. The fuzzy approach is best suited to scenarios that are prone to ambiguity, subjectivity and uncertainty when the decision-maker is expected to make an evaluation [18, 37]. Furthermore, the TOPSIS method suggested by Hwang and Yoon in 1981, is a popular method that can rank the best alternatives quickly, address conflicting situations, is easy to use and can be integrated with other decision-making methods [18]. The fuzzy set theory combined with TOPSIS has the added advantage of addressing any uncertainty encompassing the assessment process [15].

Several refined MCDA methods have been introduced over the years. Some of the popular methods include the analytic hierarchy process (AHP) requiring many comparisons based on human preferences, with the possibility of compromising the consistency of the decisions when compared to the best-worst method developed to reduce the number of comparisons in traditional AHP; the TOPSIS method and simple additive weighting (SAW), which depend on mathematical operations, and the outranking models like ELECTRE and PROMETHEE, which are premised on the assumption that the decision is a process whereby decision-makers can alter their preferences after thorough reflection. The hierarchical model of the AHP

method requires the decision-maker to pairwise-compare multiple criteria and uses ratio and semantic scales to arrive at the decision-maker's preference. Memari et al. in [21] compared the TOPSIS method with two outranking methods namely, PROMETHEE and ELECTRE. According to the authors, TOPSIS is easy to learn and apply compared to outranking methods which proved to be more complex and less transparent to decision-makers. Sahin et al. in [38] included TOPSIS in their study due to its unique approach to the problem and it's intuitively appealing and easy to understand qualities. Palczewski and Sałabun in [36] further highlighted simplicity, computational efficiency and comprehensive mathematical concept as well as its support for group decision-making as key contributing factors to the popularity of the Fuzzy TOPSIS technique.

In the learning App selection problem, the multi-criteria decision-making approach to be applied needs to be carefully considered. The number of decision-makers, the various types of measures to promote critical thinking, the method used to weight the various criteria and the degree of uncertainty and vagueness encompassing the problem scenario are some of the qualifying factors. This study involves a sample of 217 first year programming students and questions on the performance of each alternative against multiple critical thinking criteria, some more easily measurable than others. Nursal, Omar and Nawi in [14], identify the TOPSIS method with assigning crisp or exact numerical values when rating alternatives against criteria and when rating criteria importance, which are also inadequate to simulate human judgements in real-life scenarios. Therefore, to accommodate the imprecise or vague nature of the group decision-making assessment pertaining to critical thinking criteria, this study will use a more authentic approach by enabling the use of linguistic variables to capture the decision-maker's rating more accurately and consistently [40]. Hence the Fuzzy TOPSIS approach is being more suitably applied to model the linguistic ratings as a fuzzy triplet (a, b, c) because the most promising value b will better capture the rating compared to parameter a representing the smallest possible value and parameter c representing the largest possible value in a fuzzy event [40, 41]. This becomes especially important in the group decision-making process.

The research has demonstrated various MCDM problems being solved through the application of fuzzy logic. These include facility location selection, machine tool selection problem, plant layout design problem and robot selection [42] to equipment selection [16] and supplier selection [21, 36, 40]. Although this study uses the quantitative approach, it also identifies some subjective criteria that are difficult to measure, hence the need for fuzzy sets which are capable of representing vague data [41]. According to Kahraman et al. in [42], the strength of fuzzy logic lies in its ability to imitate human reasoning capabilities during the cognitive process of decision-making, to be captured mathematically and more precisely, resulting in a better expected performance in this case scenario.

In everyday pragmatic circumstances which are frequently unpredictable, it is often inadequate to describe phenomena in crisp and precise terms. Therefore, fuzziness occurs in many areas of human judgement, reasoning, evaluations and decision-making. In this study, for example, the evaluation of

learning Apps against various subjective critical thinking criteria are more easily articulated in natural language terms such as very good, poor or satisfactory, which may affect vagueness and ambiguity. However, fuzzy set theory, introduced by Zadeh (1965), offers a rigorous mathematical framework to efficiently resolve the indistinctness associated with the subjectivity of human judgements, and in which vagueness and uncertainty can be precisely and rigorously studied [43].

Rashidi and Cullinane in [40] highlighted fuzzy sets and fuzzy logic (FL) as "powerful mathematical tools for modelling uncertain systems in industry", while de Barros et al. [44] define fuzzy logic as a "multivalued logic, that uses intermediary values between conventional evaluations such as true/false, yes/no or high/low". According to de Barros et al. [44], the language of linguistics is helpful in describing uncertain and ill-defined qualitative data, which otherwise cannot be subjected to quantitative analysis. These linguistic variables can then be represented as computational-efficient fuzzy-triples for appropriately quantifying vague information [37].

According to Samaie et al. in [37], elements in a fuzzy set have different degrees of membership, designated by membership functions, which allocates a grade of membership ranging between 0 and 1. In applications that use fuzzy techniques the decision problem can have complex mathematical membership functions such as triangular or trapezoidal. According to Rajak and Shaw in [18], modelling the decision problem using triangular fuzzy numbers yields a better result. The graphical representation of a membership function  $F(x)$  of a triangular fuzzy number  $\tilde{A}$ , is illustrated in Fig. 1 where the x axis represents the universe of discourse and the y axis represents the degrees of membership in the [0,1] interval [37, 40].

Fig. 1. A Membership Function  $F(X)$  of a Triangular Fuzzy Number  $\tilde{a}$  (Han and Trimi 2018).

A triangular fuzzy number is defined in Fig. 1 and expressed as a membership function in Fig. 2.

$$F(x) = \begin{cases} \frac{x-a}{b-a}, & a \leq x \leq b \\ \frac{c-x}{c-b}, & b \leq x \leq c \\ 0, & \text{otherwise} \end{cases}$$

Fig. 2. Membership Function of a Triangular Fuzzy Number (Han and Trimi 2018).

TABLE I. LINGUISTIC TERMS FOR CRITERIA AND ALTERNATIVES RATINGS (HAN AND TRIMI 2018)

Criteria	Alternatives	
	Linguistic term	Triangular fuzzy numbers
Very low (VL)	Very poor (VP)	(1,1,3)
Low (L)	Poor (P)	(1,3,5)
Medium (M)	Fair (F)	(3,5,7)
High (H)	Good (G)	(5,7,9)
Very high (VH)	Very good (VG)	(7,9,9)

In fuzzy set theory, linguistic terms are converted into fuzzy triples using conversion scales. Usually, a scale of 1 to 9 is applied for weighting the criteria and ranking the alternatives, as illustrated in Table I. Uniform intervals are used to represent the fuzzy triangular numbers for each of the five linguistic ratings [23].

### III. METHODOLOGY

In this research paper fuzzy set theory is introduced to model ambiguity and uncertainty in a MCDM problem and integrated with TOPSIS to appreciate the benefits of its practicality and ease of use, enabling evaluations to be expressed in a linguistic language and then converted to triangular fuzzy numbers and implementing the algorithm using a software tool.

Assume the decision problem has  $k$  decision-makers ( $D_1, D_2 \dots D_k$ ), with  $m$  possible alternatives ( $A_1, A_2 \dots A_m$ ), which is evaluated against  $n$  criteria ( $C_1, C_2 \dots C_n$ ). The rating of criteria and weight with respect to each criterion can be accurately represented in the form of matrices for each decision-maker.

$$\tilde{D} = \begin{matrix} & C_1 & C_2 & & C_n \\ \begin{matrix} A_1 \\ A_2 \\ \dots \\ A_m \end{matrix} & \begin{pmatrix} \tilde{x}_{11} & \tilde{x}_{12} & \dots & \tilde{x}_{1n} \\ \tilde{x}_{21} & \tilde{x}_{22} & \dots & \tilde{x}_{2n} \\ \dots & \dots & \tilde{x}_{ij} & \dots \\ \tilde{x}_{m1} & \tilde{x}_{m2} & \dots & \tilde{x}_{mn} \end{pmatrix} \end{matrix} \quad (1)$$

$$\tilde{W} = (\tilde{w}_1, \tilde{w}_2, \dots, \tilde{w}_n)$$

Where for all  $x_{ij}$  and  $w_{ij}$   $i = 1, 2 \dots m$  and  $j=1, 2 \dots n$ .

Hence  $x_{ij} = (a_{ij}, b_{ij}, c_{ij})$  and  $w_j = (a_j, b_j, c_j)$  are triangular fuzzy numbers representing linguistic variables.

The Fuzzy TOPSIS procedure includes the following steps [24]:

Step 1: Assign ratings to the criteria and alternatives. The criteria weights are denoted by

$$W_{NK} \quad (N = 1, 2, \dots, n; K = 1, 2, \dots, k)$$

and the performance ratings of alternatives with respect to criteria by experts are denoted as

$$X_{NKM} \quad (N = 1, 2, \dots, n; K = 1, 2, \dots, k; M = 1, 2, \dots, m).$$

Step 2: Aggregate the evaluation of the criteria and alternatives. fuzzy ratings  $W_{NK}$  and  $X_{NKM}$  is described as

triangular fuzzy numbers  $(a_K, b_K, c_K)$  where  $K = 1, 2, \dots, k$ , then the aggregated importance can be evaluated as:

$$a = \min\{a_K\} \quad b = \frac{1}{K} \sum_{K=1}^K b_K \quad c = \max\{c_K\} \quad (2)$$

Step 3: Normalize triangular fuzzy numbers. The raw data is normalized using linear scale transformation to bring the various criteria scales into a comparable scale. If  $W_{NK}$  represents benefit criteria, then:

$$\left( \frac{a_K}{c}, \frac{b_K}{c}, \frac{c_K}{c} \right) \quad (3)$$

If  $W_{NK}$  represents cost criteria, then:

$$\left( \frac{a}{c_K}, \frac{a}{b_K}, \frac{a}{a_K} \right) \quad (4)$$

Where  $(a = \min\{a_K\}, c = \max\{c_K\})$

Step 4: Compute weighted normalized fuzzy values.  $W_{NK} *$  becomes  $W_{NK}$  after normalization,  $X_{NKM} *$  is new  $X_{NKM}$  after aggregation. Let the weighted normalized value be  $V_{NKM}$ .

$$V_{NKM} = W_{NK} * X_{NKM} * \quad (5)$$

where  $N = 1, 2 \dots n; K = 1, 2 \dots k; M = 1, 2 \dots m;$

The corresponding triangular fuzzy number of  $V_{NKM}$  is

$$(a_{V_{NKM}}, b_{V_{NKM}}, c_{V_{NKM}}) \quad (6)$$

Step 5: Calculate fuzzy positive ideal solutions (FPIS) and fuzzy negative ideal solutions (FNIS);

$$FPIS = (C_V, C_V, C_V) \text{ where } C_V = \max\{C_{V_{NKM}}\} \quad (7)$$

$$FNIS = (a_V, a_V, a_V) \text{ where } a_V = \min\{a_{V_{NKM}}\} \quad (8)$$

Step 6: Calculate the distance of each alternative from  $FPIS (d^+)$  and  $FNIS (d^-)$  which is calculated, respectively, as follows:

$$d^+ = \sqrt{\frac{1}{3} [(a_{V_{NKM}} - c_V)^2 + (b_{V_{NKM}} - c_V)^2 + (c_{V_{NKM}} - c_V)^2]} \quad (9)$$

$$d^- = \sqrt{\frac{1}{3} [(a_{V_{NKM}} - a_V)^2 + (b_{V_{NKM}} - a_V)^2 + (c_{V_{NKM}} - a_V)^2]} \quad (10)$$

Step 7: Calculate the closeness coefficient ( $CC_M$ )

$$CC_M = \frac{\sum_1^n d_{NM}^-}{\sum_1^n d_{NM}^+ + \sum_1^n d_{NM}^-}, N = 1, 2 \dots n; M = 1, 2 \dots m \quad (11)$$

The  $CC_M$  value is then used to determine the ranking order of all alternatives for the purpose of selecting the best one from among a set of feasible alternatives.

### IV. RESULT

In this section, the results produced from the Fuzzy TOPSIS software application implemented on MatLab R2020a is presented with explanations in steps according to input and outputs of the application. This application utilized complex mathematical equations on the backend which corresponds with the Fuzzy TOPSIS method presented in the methodology

section. The results are based on preferences shown by decision-makers (first year programming students) on choice of visual programming learning applications based on set critical thinking criteria.

Table II shows the fuzzy rating scale where linguistic terms, namely, Not Important (N), Slightly Important (SI), Moderately Important (MI), Important (I) and Very Important (VI) are expressed as a fuzzy triple using integers in the range 1 to 9. These linguistic terms are used to rate the criteria.

Table III presents the measures for critical thinking (criteria) synthesized from the extant literature. Symbols C1 to

C25 are used to represent the critical thinking criteria for selection of programming learning applications for first year university students.

TABLE II. LINGUISTIC AND FUZZY TRIPLE FOR RATING CRITERIA

Linguistic term	Membership function
Not Important (N)	(1,1,3)
Slightly Important (SI)	(1,3,5)
Moderately Important (MI)	(3,5,7)
Important (I)	(5,7,9)
Very Important (VI)	(7,9,9)

TABLE III. MEASURES FOR CRITICAL THINKING (CRITERIA)

No.	Critical Thinking Criteria
C1	Feedback: The App helped me correct my errors while I was coding
C2	Feedback: The App alerted me to incorrect code
C3	Interactivity: The App tells me where my error lies
C4	Problem-solving: The App allows me to solve large, complex, real world, authentic problem scenarios
C5	Collaboration: The App allows me to work on a shared program with my friends
C6	Collaboration: The App allows me to re-use my code or re-use my peers' solutions
C7	Collaboration: The App allows me to communicate with my friend about my questions and queries about our projects
C8	Metacognition: The App allows me to easily and repeatedly make changes to my solution
C9	Logic: The App helped me to improve my logic skills
C10	Logic and reasoning: The App quickly alerts me when the sequencing of steps in my solution is logically incorrect
C11	Evaluation: The App helps me to make my code more efficient
C12	Evaluation: The App is able to evaluate my work
C13	Evaluation: The App allows me to compare my solution against my peers
C14	Alternate solutions: The App helps me to think about solving the problem in different ways
C15	Synthesis: The App allows me to solve problems where I have to draw my knowledge from different programming topics
C16	Application: The App allows me to apply the concepts of sequence, selection and iteration
C17	Metacognitive monitoring: The App interface is designed in a way that encourages me to improve my solution
C18	Multimedia: The interface is visually rich in multimedia and includes sound, color, graphics and animation
C19	Simulation programming: The App uses simple statements to mimic a high-level programming language in an active learning environment
C20	Creativity: The App allows me to create useful and original applications like games and movies
C21	Creativity: The App has various features that enable me to use my creative skills
C22	Creativity: The App supports the simulation of many creative ideas when solving the problem
C23	Analysis: When interpreting the problem statement, the App interface gives me clues on how to solve the problem
C24	Complexity of problem: The App allows me the flexibility to elaborate or build on my idea
C25	Disposition: The App forces me to have an enquiring mind

TABLE IV. LINGUISTIC AND FUZZY TRIPLE FOR THE CRITICAL THINKING ATTRIBUTES (CRITERIA)

Linguistic Values	CRITERIA																								
	C 1	C 2	C 3	C 4	C 5	C 6	C 7	C 8	C 9	C1 0	C1 1	C1 2	C1 3	C1 4	C1 5	C1 6	C1 7	C1 8	C1 9	C2 0	C2 1	C2 2	C2 3	C2 4	C2 5

Table IV shows the linguistic rating of the 25 criteria by 10 Academic Experts teaching programming at university level.

Their input values are represented by the symbols D1 to D10 in the table below.

The Best Non-fuzzy Performance value (BNP) for a criterion weighting  $j$ , can be calculated using the following equation [13]:

$$BNP_{wj} = [(Upper\ bound_{wj} - lower\ bound_{wj}) + (Middle\ bound_{wj} - lower\ bound_{wj})]/3 + lower\ bound_{wj} \quad (12)$$

The BNP values give an indication of the relative importance of the criteria. Table V shows the aggregated score for each criterion.

Table V also shows the calculated BNP value for each criteria using Equation 12. Linguistic Weights were assigned based on the BNP values according to descriptions given in Table II.

Table VI shows the ranking of the criteria based on the BNP values indicated in Table V.

Table VI shows that C10 (Logic and reasoning: The App quickly alerts me when the sequencing of steps in my solution is logically incorrect) was the most highly ranked criteria by the expert decision-makers. The second most highly recommended criterion is C9 (Logic: The App helped me to improve my logic skills), followed by C16 (Application: The App allows me to apply the concepts of sequence, selection and iteration) and C14 (Alternate solutions: The App helps me to think about solving the problem in different ways). The least important criterion to decision-makers is criterion C18 (Multimedia: The interface is visually rich in multimedia and includes sound, color, graphics and animation).

TABLE V. AGGREGATED SCORES AND BNP VALUES FOR CRITICAL THINKING ATTRIBUTES (CRITERIA)

Criteria	Aggregated Fuzzy Score	BNP Value	Linguistic Weight
C1	1, 7,4, 9	5,8	I
C2	1, 7,2, 9	5,733333	I
C3	1, 7, 9	5,666667	I
C4	1, 6, 9	5,333333	MI
C5	1, 5, 9	5	MI
C6	1, 4,4, 9	4,8	SI
C7	1, 5,4, 9	5,133333	MI
C8	1, 7,8, 9	5,933333	I
C9	5, 8,6, 9	7,533333	VI
C10	7, 9, 9	8,333333	VI
C11	1, 7,8, 9	5,933333	I

10.	C2	20.	C22		

Table VII shows the fuzzy rating scale for weighing critical thinking criteria. Linguistic terms such as Very Poor (VP), Poor (P), Satisfactory (S), Good (G) and Very Good (VG) are expressed as a fuzzy triple with integers in the range 1 to 9. The Not Sure (N) option expressed as (0, 0, 0) is included in the application to cater for students who are not sure what rating to assign to criteria.

Table VIII shows the numeric labels for Learning Apps (Alternatives).

Table IX presents a snapshot of the assigned ratings by 175 student decision-makers to assess Scratch using the 25 critical thinking criteria in linguistic terms as shown in Table VII.

TABLE VII. LINGUISTIC AND FUZZY TRIPLE FOR THE CRITICAL THINKING ALTERNATIVES (LEARNING APPS)

Linguistic term	Membership function
Not Sure (N)	(0,0,0)
Very Poor (VP)	(1,1,3)
Poor (P)	(1,3,5)
Satisfactory (S)	(3,5,7)
Good (G)	(5,7,9)
Very Good (VG)	(7,9,9)

Table X presents the results of the Normalised Fuzzy Decision Matrix from the MatLab R2020a application. This matrix was generated using Equation 3.

Table XI shows the results for FNIS and FPIS generated from the MatLab R2020a Application using Equations 8 and 7 respectively.

Table XII gives the results of the Closeness Coefficient values generated by the MatLab application. These values are generated by the MatLab App using Equation 11.

The C<sub>CCi</sub> value is a ratio scale rating showing the ranking of learning App by 175 decision- makers from highest to lowest,

C<sub>CCi</sub> (Scratch) > C<sub>CCi</sub> (Alice) > C<sub>CCi</sub> (MIT Inventor) > C<sub>CCi</sub> (Blockly).

The results show that Scratch is the most preferred application for learning programming as it had the highest C<sub>CCi</sub> value. This is congruent with various studies that compared visual programming environments using different methods under different contexts and found Scratch to be the most preferred learning tool [4, 11, 45]. The App with the lowest C<sub>CCi</sub> value is Blockly, which therefore is the least preferred application.

Rank Order	Programming Learning App	CCi
2	Scratch	0.9941
1	Alice	0.4345
4	MIT inventor	0.3258
3	Blockly	0.0064

V. CONCLUSION

The study used a population of 500 and a sample population of 217 decision-makers to rate four learning Apps against each of 25 critical thinking criteria. Applying the Fuzzy TOPSIS MCDM method to the decision problem would have made handling the matrices both inconvenient and cumbersome. The researcher created code using MatLab R2020a to automate the process. The implementation of the coding for the Fuzzy TOPSIS MCDM method resulted in the ranking of four learning Apps, from the App that promoted critical thinking the best to the one that promoted it least among 1st year programming learners; these Apps were

Scratch, Alice, MIT App Inventor and Blockly. The study is significant for lecturers teaching introductory programming modules to novice learners across educational institutions, especially during the global Covid-19 pandemic, when online learning has become commonplace and its teaching tools have become a requirement. Although the research suggests the positive impact of the visual programming environment on one’s critical thinking skills, further research is required to investigate its subsequent impact in a text-based programming environment.

# Complex Plane based Realistic Sound Generation for Free Movement in Virtual Reality

Kwangki Kim

Department of IT Convergence  
Korea Nazarene University, Cheon-an, South Korea

**Abstract**—A binaural rendering is a technology that generates a realistic sound for a user with a stereo headphone, so it is essential for the stereo headphone based virtual reality (VR) service. However, the binaural rendering has a problem that it cannot reflect the user's free movement in the VR. Because the VR sound does not match with the visual scene when the user moves freely in the VR space, the performance of the VR may be degraded. To reduce the mismatch problem in the VR, the complex plane based stereo realistic sound generation method was proposed to allow the user's free movement in the VR causing the change of the distance and azimuth between the user and the speaker. For the calculation of the distance and the azimuth between the user and the speaker by the user's position change, the 5.1 multichannel speaker playback system and the user are placed in the complex plane. Then, the distance and the azimuth between the user and the speaker can be simply calculated as the distance and the angle between two points in the complex plane. The 5.1 multichannel audio signals are scaled by the estimated five distances according to the inverse square law, and the scaled multichannel audio signals are mapped to the newly generated virtual 5.1 multichannel speaker layout using the measured five azimuths and the azimuth by the head movement. Finally, we can successfully obtain the stereo realistic sound to reflect the user's position change and the head movement through the binaural rendering using the scaled and mapped 5.1 multichannel audio signals and the HRTF coefficients. Experimental results show that the proposed method can generate the realistic audio sound reflecting the user's position and azimuth change in the VR only with less than about 5 % error rate.

**Keywords**—Virtual reality; realistic sound; binaural rendering; constant power panning; head related transfer function

## I. INTRODUCTION

In general, users should have their own multi-channel audio playback environment to enjoy the realistic sound by multi-channel audio signals. However, most of the users have a stereo headphone environment, so they are unable to enjoy realistic audio by the multi-channel audio signals. Therefore, a head related transfer function (HRTF) [1] based binaural rendering has been proposed to solve this limitation [2-6]. In particular, the binaural rendering is essential to deliver the more realistic audio signal to the users in a system such as a virtual reality (VR) service based on the stereo headphone environment [8-10]. In the binaural rendering, the stereo realistic sound is generated using the multi-channel audio signals and the HRTF coefficients. The stereo realistic sound

generation based on the binaural rendering can efficiently supply the realistic sound with the user in the VR service, but there is a critical limitation that the existing stereo realistic sound generation based on the binaural rendering does not reflect the user's position change. Since the stereo realistic sound generation through binaural rendering with a fixed HRTF cannot reflect the user's position change, there is a gap between the visual scene and the sound causing the performance degradation of the VR service. To solve the fixed sound scene problem in the VR, the sound scene control of the stereo realistic sound in the VR was introduced to reflect the user's head azimuth change [11]. In [11], the HRTF coefficients are replaced by the new HRTF coefficients corresponding to the user's azimuth change, and the realistic sound with the controlled sound scene is calculated with the multi-channel audio signals and the replaced HRTF coefficients. Although the realistic sound generation with the substitution of the HRTF coefficients can successfully generate the stereo realistic sound with the controlled sound scene according to the user's head movement, it needs very high data amount of the stored HRTF coefficients for all azimuth directions. The data rate of the HRTF coefficients are 23.6 Mbytes to be 32 times compared with that of the HRTF coefficients of the 5.1 multi-channel speaker layout. Therefore, the sound scene control of the realistic sound with the substitution of the HRTF coefficients is not suitable for the embedded system with low memory storage. Accordingly, the constant power panning (CPP) based sound scene control of the realistic sound was introduced [12-15]. The CPP based sound scene control scheme used only the HRTF coefficients of the 5.1 multi-channel speaker layout, so the data rate of the HRTF coefficients is exactly same as the original binaural rendering. Instead, the CPP based sound scene control method mapped the original multi-channel audio signals onto the new 5.1 multi-channel speaker layout rearranged by the user's head movement. The CPP based method can be applied to the embedded system with the low memory storage because it can generate the realistic sound reflecting the user's head movement without the increase of the HRTF coefficients.

Meanwhile, the VR service allows the user's free movement in the VR space, so the VR service should consider the user's not only head movement but also position change. Namely, the VR service should generate the realistic sound reflecting the user's free movement. However, since the sound scene control based on the HRTF coefficients and the CPP method only focuses on the modification of the stereo realistic sound scene according to the user's azimuth change, its' stereo realistic sound cannot imply the user's distance change.

---

This work was funded by the research fund of Korea Nazarene University in 2021. Also, this research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (2017R1D1A3B03034951).

Therefore, there is still a mismatch between the VR scene and the VR sound when the user freely moves in the VR space and the overall performance of the VR service may be very poor.

The realistic sound generation method based on a complex plane for tracking the user's movement is proposed to improve the performance of the VR service by reflecting the user's free movement in the VR sound. The user's free movement (position change) in the VR space causes both changes of the distance and the azimuth between the user and the speaker, while the user's head movement only effects on the azimuth change. Therefore, the proposed method separately handles the user's position change and the head movement and it calculates the distance and the azimuth between the user and the speaker by the user's free movement. Then, the proposed method can generate the realistic sound by scaling the audio signal using the measured distance and by adjusting the sound scene using the final azimuth formed by adding the measured azimuth for the position change and the azimuth change for the head movement. In conclusion, the proposed method can improve the overall performance of the VR service by generating the realistic sound that reflects the user's free movement including the head movement. This paper consists of as follows. In Section 2, the stereo realistic sound generation through the binaural rendering and the sound scene control of the realistic sound is described. In Section 3, the realistic sound generation for the user's free movement in the VR is proposed. In Sections 4 and 5, the experimental result and the conclusion will be given, respectively.

## II. STEREO REALISTIC SOUND GENERATION BASED ON BINAURAL RENDERING FOR VR

### A. Binaural Rendering for VR

The VR system needed the stereo realistic sound generation method for the immersive effect by the multi-channel audio signals since the VR system used the stereo headphone for the delivery of the VR sound. The VR system adopted the conventional binaural rendering for generating the stereo realistic sound [1-7]. The binaural rendering is a technology that generates the stereo realistic audio sound with the multi-channel audio effect for stereo headphone environment using HRTF coefficients to characterize all signal paths from speakers to human ears [1]. As shown in Fig. 1, the binaural rendering is computed with the input multi-channel signal and the HRTF coefficients. To generate the output stereo realistic sound, the input multi-channel audio signals are convolved with the HRTF coefficients as in (1) [2-4].

Fig. 1. Stereo Realistic Sound Generation through Binaural Rendering.

$$o_L = \sum_{n=1}^N (s_n \otimes h_n^L), o_R = \sum_{n=1}^N (s_n \otimes h_n^R) \quad (1)$$

where  $h_n^L$  and  $h_n^R$  are the stored HRTF coefficients in time domain from the  $n$ th channel to human left and right ear.  $o_L$  and  $o_R$  are the output left and right realistic signals in time domain and  $s_n$  is the  $n$ th channel input signal in time domain.  $N$  is the channel number of the multi-channel audio signals and  $\otimes$  is the linear convolution. Since the linear convolution in time domain between the input signals and the HRTF coefficients has very high computational complexity, the binaural rendering is calculated as the multiplication of the input signals and the HRTF coefficients in the frequency domain as in (2)[5] and Fig. 1 is updated as Fig. 2.

$$O_L = \sum_{n=1}^N (S_n \cdot H_n^L), O_R = \sum_{n=1}^N (S_n \cdot H_n^R) \quad (2)$$

where  $H_n^L$  and  $H_n^R$  are the stored HRTF coefficients in frequency domain from the  $n$ th channel to human left and right ear.  $O_L$  and  $O_R$  are the output left and right realistic signals in frequency domain and  $S_n$  is the  $n$ th channel input signal in frequency domain.

Meanwhile, (2) can be rewritten in matrix form for 5.1 multi-channel audio signals as in (3) [11].

$$\begin{bmatrix} O_L(k) \\ O_R(k) \end{bmatrix} = \begin{bmatrix} H_C^{Left}(k) & H_C^{Right}(k) \\ H_{Lf}^{Left}(k) & H_{Lf}^{Right}(k) \\ H_{Rf}^{Left}(k) & H_{Rf}^{Right}(k) \\ H_{Ls}^{Left}(k) & H_{Ls}^{Right}(k) \\ H_{Rs}^{Left}(k) & H_{Rs}^{Right}(k) \end{bmatrix}^{-T} \times \begin{bmatrix} S_c(k) \\ S_{Lf}(k) \\ S_{Rf}(k) \\ S_{Ls}(k) \\ S_{Rs}(k) \end{bmatrix}, \text{ for } 0 \leq k \leq M-1 \quad (3)$$

where  $O_L(k)$  and  $O_R(k)$  are the output left and right realistic sound.  $S_x(k)$  is the arbitrary channel  $X$  signal in frequency domain and  $k$  is the frequency index.  $C$ ,  $Lf$ ,  $Ls$ ,  $Rf$  and  $Rs$  are the center, left front, left surround, right front, and right surround of the 5.1 multi-channel audio signals.  $H_x^{Left}(k)$  and  $H_x^{Right}(k)$  are the stored HRTF coefficients in frequency domain from the arbitrary channel  $X$  to human's left and right ear.  $M$  is the number of the FFT size.

Fig. 2. Stereo Realistic Sound Generation through Binaural Rendering in Frequency Domain.

**B. Sound Scene Control of Stereo Realistic Sound Reflecting Azimuth Change in VR**

Although the conventional binaural rendering was useful for the VR system, it could not reflect the user's azimuth change. Therefore, the sound scene control of the stereo realistic sound was proposed [11, 12]. When the azimuth angle of the user changed in the 5.1 channel reproduction environment, the direction in which the 5.1 channel signal is transmitted to the user or the azimuth angle of the 5.1 channel reproduction environment also changed. So, the existing HRTF coefficients should be replaced by new HRTF coefficients corresponding to the azimuth angle of the new 5.1 channel reproduction environment. The binaural rendering with the sound scene control could generate the realistic sound with the substituted HRTF coefficients and the 5.1 channel audio signal according to the user's azimuth change as in (4).

$$\begin{bmatrix} O_{L,\theta_{hm}}(k) \\ O_{R,\theta_{hm}}(k) \end{bmatrix} = \begin{bmatrix} H_{C-\theta_{hm}}^{Left}(k) & H_{C-\theta_{hm}}^{Right}(k) \\ H_{Lf-\theta_{hm}}^{Left}(k) & H_{Lf-\theta_{hm}}^{Right}(k) \\ H_{Rf-\theta_{hm}}^{Left}(k) & H_{Rf-\theta_{hm}}^{Right}(k) \\ H_{Ls-\theta_{hm}}^{Left}(k) & H_{Ls-\theta_{hm}}^{Right}(k) \\ H_{Rs-\theta_{hm}}^{Left}(k) & H_{Rs-\theta_{hm}}^{Right}(k) \end{bmatrix}^T \times \begin{bmatrix} S_c(k) \\ S_{Lf}(k) \\ S_{Rf}(k) \\ S_{Ls}(k) \\ S_{Rs}(k) \end{bmatrix}, \text{ for } \begin{cases} 0 \leq k \leq M-1 \\ 0^\circ \leq \theta_{hm} \leq 360^\circ \end{cases} \quad (4)$$

where  $O_{L,\theta_{hm}}(k)$  and  $O_{R,\theta_{hm}}(k)$  the output left and right realistic sound with controlled sound scene according to the user's head movement.  $H_{X-\theta_{hm}}^{Left}(k)$  and  $H_{X-\theta_{hm}}^{Right}(k)$  are the substituted HRTF coefficients corresponding to the user's azimuth change from the arbitrary channel X to human's left and right ear.  $\theta_{hm}$  is the angle of the user's head movement.

Here, if the angle of any channel X minus  $\theta_{hm}$  is negative, the final azimuth of any channel is the calculated angle plus 360 degrees. Fig. 3 shows an example of the user's azimuth change in the 5.1 multi-channel speaker layout. Since the angle of the user's azimuth change is 90 degrees, the angle of existing 5.1 multi-channel speaker layout is rearranged as shown in Fig. 3 and the HRTF coefficients are substituted to reflect the rearranged multi-channel speaker layout. The binaural rendering generates the stereo realistic sound with the controlled sound scene using the 5.1 multi-channel audio signals and the substituted HRTF coefficients as in (5). Fig. 4 shows the overall procedure of the sound scene control of the realistic sound based on the substitution of the HRTF coefficients.

$$\begin{bmatrix} O_{L,90^\circ}(k) \\ O_{R,90^\circ}(k) \end{bmatrix} = \begin{bmatrix} H_{270^\circ}^{Left}(k) & H_{270^\circ}^{Right}(k) \\ H_{240^\circ}^{Left}(k) & H_{240^\circ}^{Right}(k) \\ H_{300^\circ}^{Left}(k) & H_{300^\circ}^{Right}(k) \\ H_{160^\circ}^{Left}(k) & H_{160^\circ}^{Right}(k) \\ H_{20^\circ}^{Left}(k) & H_{20^\circ}^{Right}(k) \end{bmatrix}^T \times \begin{bmatrix} S_c(k) \\ S_{Lf}(k) \\ S_{Rf}(k) \\ S_{Ls}(k) \\ S_{Rs}(k) \end{bmatrix}, \text{ for } 0 \leq k \leq M-1 \quad (5)$$

Although the above explained sound scene control scheme of the realistic sound can successfully generate the stereo realistic sound with the controlled sound scene, it needed very high data amount of the stored HRTF coefficients as 23.6 Mbytes. Therefore, the embedded system with the low memory storage could not implement the sound scene control of the realistic sound with the substitution of the HRTF coefficients.

Accordingly, the CPP based sound scene control of the realistic sound was introduced [11-15]. The CPP based sound scene control scheme fixed the HRTF coefficients of the 5.1 multi-channel speaker layout and it mapped the existing multi-channel audio signals onto the new 5.1 multi-channel speaker layout rearranged by the user's head movement. Fig. 5 shows an example of the mapping of the multi-channel audio signals to the newly formed 5.1 multi-channel speaker layout according to the user's head movement. The 5.1 multi-channel speaker layout is newly created around the user's new front, and the existing 5.1 multi-channel audio signals are mapped onto the new speaker layout using the CPP technique. The binaural rendering is performed as in (6) using the mapped 5.1 multi-channel signals and the HRTF coefficients of the 5.1 multi-channel speaker layout to generate stereo realistic sound with the controlled sound scene according to the user's head movement.

Fig. 3. Example of the user's Azimuth Change in the 5.1 Multi-channel Speaker Layout.

Fig. 4. Overall Procedure of the Sound Scene Control of the Realistic Sound based on the Substitution of the HRTF Coefficients.

Fig. 5. Example of the Signal Mapping to the Newly Formed 5.1 Multi-Channel Speaker Layout According to the user's Head Movement.

$$\begin{bmatrix} O_L(k) \\ O_R(k) \end{bmatrix} = \begin{bmatrix} H_C^{Left}(k) & H_C^{Right}(k) \\ H_{Lf}^{Left}(k) & H_{Lf}^{Right}(k) \\ H_{Rf}^{Left}(k) & H_{Rf}^{Right}(k) \\ H_{Ls}^{Left}(k) & H_{Ls}^{Right}(k) \\ H_{Rs}^{Left}(k) & H_{Rs}^{Right}(k) \end{bmatrix} \times \begin{bmatrix} S_C^m(k) \\ S_{Lf}^m(k) \\ S_{Rf}^m(k) \\ S_{Ls}^m(k) \\ S_{Rs}^m(k) \end{bmatrix}, \text{ for } 0 \leq k \leq M-1 \quad (6)$$

where  $S_X^m(k)$  is a newly generated signal of any channel X through the mapping of the 5.1 multi-channel audio signals to the newly formed 5.1 multi-channel speaker layout. For the explanation of the signal mapping using the CPP method [14, 15], let's assume that there are two channel speakers (C1 and C2) and any channel (C3) lays in between two channel speakers after the user's head movement as shown in Fig. 6. Then, a signal of channel C3 is mapped onto the channel C1 and C2 using (7) and (8).

$$\theta_{norm} = \frac{(\theta_3 - \theta_1)}{(aperture - \theta_1)} \times \frac{\pi}{2}, \text{ aperture} = |\theta_2 - \theta_1| \quad (7)$$

$$\left. \begin{aligned} S_1^m(k) &= S_1(k) + S_3(k) \times \cos(\theta_m) \\ S_2^m(k) &= S_2(k) + S_3(k) \times \sin(\theta_m) \end{aligned} \right\}, \text{ for } 0 \leq k \leq M-1 \quad (8)$$

Here,  $\theta_{norm}$  is the normalized angle of azimuth of C3 laid in between C1 and C2, and *aperture* is the reference angle between C1 and C2.  $\theta_1$ ,  $\theta_2$  and  $\theta_3$  are the azimuth of C1, C2, and C3.  $S_1(k)$ ,  $S_2(k)$  and  $S_3(k)$  are the signal gains of C1, C2, and C3.  $S_1^m(k)$  and  $S_2^m(k)$  are the new signal gains of C1 and C2 after the mapping of  $S_1(k)$  using the CPP. The signal mapping using the CPP method is applied to the entire 5.1 multi-channel signals to create the new 5.1 multi-channel audio signals with the newly formed 5.1 multi-channel speaker layout according to the user's head movement. Finally, the stereo realistic sound with the controlled sound scene can be generated through the binaural rendering with the new 5.1 multi-channel audio signals and the existing 5.1 multi-channel HRTF coefficients. Fig. 7 shows the overall procedure of the sound scene control of the realistic sound based on the CPP method.

Fig. 6. Example of the Signal Mapping using the CPP.

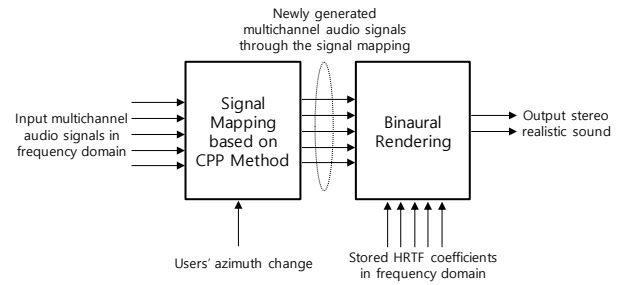

Fig. 7. Overall Procedure of the Sound Scene Control of the Realistic Sound based on the CPP Method.

### III. PROPOSED STEREO REALISTIC SOUND GENERATION FOR FREE MOVEMENT IN VR

In the VR service, the user moves freely in the VR space, so the VR sound must be adjusted according to the VR scene. Namely, the VR service allows the user's head movement and the position change in the VR space and the VR sound in the VR service should reflect the user's free movement. However, since the previously explained sound scene control based on the HRTF coefficients and the CPP method only focused on the modification of the stereo realistic sound scene according to the user's azimuth change, the previous realistic sound could not imply the user's distance change. Therefore, there is still a mismatch between the VR scene and the VR sound when the user freely moves in the VR space and the overall performance of the VR service can be severely degraded. To allow the user's free movement in the VR space and reduce the performance degradation of the VR, the realistic sound generation method based on a complex plane for the user's movement tracking is proposed. The user's position change effected on both changes of the distance and the azimuth between the user and the speaker while the user's head movement only effected on the azimuth change between the user and the speaker. Therefore, the proposed method separately handled the user's position change and the head movement. Namely, the distance and the azimuth between the user and the speaker layout by the user's position change were firstly measured, and then the final azimuth between the user and the speaker by considering two azimuths caused by the user's position change and the head movement was determined. The signal level was modified using the calculated distance between the user and the speaker while the sound scene of the realistic sound was controlled using the measured azimuth. The detail of the realistic sound generation using the calculated distance and azimuth between the user and the speaker is given in the below.

For the calculation of the distance and the azimuth between the user and the speaker by the user's position change, it is assumed that the 5.1 multi-channel speaker playback system located in the complex plane as shown in Fig. 8 and the user moved freely on the complex plane. Based on the assumption, the distance and the azimuth between the user and the speaker by the user's position change could be estimated because the user and the speaker were considered as two points in the complex plane. Meanwhile, as the azimuth measurement method could vary according to the user's location on the complex plane, the distance and azimuth between the user and the speaker were measured based on the user's location divided

into four areas around the speaker as shown in Fig. 9 and 10. Meanwhile, the four areas around the speaker in the complex plane are summarized in Table I. After setting four areas for all speakers in the 5.1 multi-channel speaker layout as shown in Fig. 9, the distance and the azimuth between the user and the speaker were calculated in each area as shown in Fig. 10. In Fig. 10,  $a + jb$  and  $c + jd$  are the position of any speaker X in the 5.1 multi-channel speaker layout and the user in the complex plane, respectively. Table II summarizes the calculation of the distance and azimuth between the user and the speaker for four areas around the speaker according to the user's position change.

Fig. 8. 5.1 Multi-channel Speaker Placed in the Complex Plane.

Fig. 9. Four Areas for All Speakers in the 5.1 Multi-channel Speaker Layout.

TABLE I. FOUR AREAS AROUND THE SPEAKER EXPRESSED IN THE COMPLEX PLANE COORDINATE

Area	Complex plane coordinate
Area 1	$Re < 0, Im \geq 0$
Area 2	$Re \geq 0, Im > 0$
Area 3	$Re > 0, Im \leq 0$
Area 4	$Re \leq 0, Im < 0$

For the realistic sound generation by reflecting the user's position change and the head movement, the 5.1 multi-channel audio signals were firstly scaled using the measured five distance values between the moved user and the 5.1 multi-channel speaker. Then, the scaled 5.1 multi-channel audio signals were mapped onto the new multi-channel speaker layout using not only the estimated five azimuths between the moved user and the 5.1 multi-channel speaker but also the azimuth according to the user's head movement. Based on the inverse square law that the sound intensity is inversely

proportional to the distance from the source [16, 17], the scaled 5.1 multi-channel audio signals were calculated using the estimated five distance values. Moreover, because all the distances between the user and the 5.1 multi-channel speaker layout are equal to one, the scaled 5.1 multi-channel audio signals were calculated as in (9).

$$S_c^s(k) = \frac{1}{r_c} S_c(k), S_{Lf}^s(k) = \frac{1}{r_{Lf}} S_{Lf}(k), S_{Rf}^s(k) = \frac{1}{r_{Rf}} S_{Rf}(k),$$

$$S_{Ls}^s(k) = \frac{1}{r_{Ls}} S_{Ls}(k), S_{Rs}^s(k) = \frac{1}{r_{Rs}} S_{Rs}(k) \text{ for } 0 \leq k \leq M-1 \quad (9)$$

where  $S_X^s(k)$  is the scaled signal of any channel X and  $r_X$  is the estimated distance between the user and any channel X. Because the virtual 5.1 channel speaker layout was set around the moved user, the scaled 5.1 multi-channel audio signals were mapped onto the virtual speaker layout using the measured five azimuths and the azimuth by the head movement. The final azimuths could be determined for the signal mapping as in (10).

$$\left. \begin{aligned} \theta_f^C &= \theta_p^C - \theta_{hm} \\ \theta_f^{Lf} &= \theta_p^{Lf} - \theta_{hm} \\ \theta_f^{Rf} &= \theta_p^{Rf} - \theta_{hm} \\ \theta_f^{Ls} &= \theta_p^{Ls} - \theta_{hm} \\ \theta_f^{Rs} &= \theta_p^{Rs} - \theta_{hm} \end{aligned} \right\} \text{for } 0 \leq \theta_{hm} \leq 2\pi \quad (10)$$

Fig. 10. Calculation of the Distance and the Azimuth in Four Areas.

TABLE II. SUMMARY OF THE CALCULATION OF THE DISTANCE AND THE AZIMUTH BETWEEN THE USER AND THE SPEAKER

Area	Azimuth ( $\theta_p$ )	Distance ( $r$ )
Area 1	$\tan^{-1}\left(\frac{ b-d }{ a-c }\right) + \frac{\pi}{2}$	$\sqrt{(a-c)^2 + (b-d)^2}$
Area 2	$\tan^{-1}\left(\frac{ a-c }{ b-d }\right) + \pi$	
Area 3	$\tan^{-1}\left(\frac{ b-d }{ a-c }\right) + \frac{3\pi}{2}$	
Area 4	$\tan^{-1}\left(\frac{ a-c }{ b-d }\right)$	

where  $\theta_f^X$  is the final azimuth of any channel X for the signal mapping and  $\theta_p^X$  is the estimated azimuth between the user and the any speaker X according to the user's position change. Here, if  $\theta_f^X$  has the minus value,  $\theta_p^X$  is  $\theta_f^X + 2\pi$ . After the signal mapping using the final azimuth as in (10), the final realistic sound could be obtained to allow the user's free movement including the head azimuth change as in (11).

$$\begin{bmatrix} O_L(k) \\ O_R(k) \end{bmatrix} = \begin{bmatrix} H_C^{Left}(k) & H_C^{Right}(k) \\ H_{Lf}^{Left}(k) & H_{Lf}^{Right}(k) \\ H_{Rf}^{Left}(k) & H_{Rf}^{Right}(k) \\ H_{Ls}^{Left}(k) & H_{Ls}^{Right}(k) \\ H_{Rs}^{Left}(k) & H_{Rs}^{Right}(k) \end{bmatrix} \times \begin{bmatrix} S_C^{s,m}(k) \\ S_{Lf}^{s,m}(k) \\ S_{Rf}^{s,m}(k) \\ S_{Ls}^{s,m}(k) \\ S_{Rs}^{s,m}(k) \end{bmatrix}, \text{ for } 0 \leq k \leq M-1 \quad (11)$$

where  $S_X^{s,m}(k)$  is the generated signal of any channel X of the virtual 5.1 multi-channel speaker layout formed by the user's position and head movement through the signal scaling as in (9) and the signal mapping using the final azimuth as in (10). Fig. 11 shows the overall procedure of the proposed the realistic sound generation for the user's free movement in the VR.

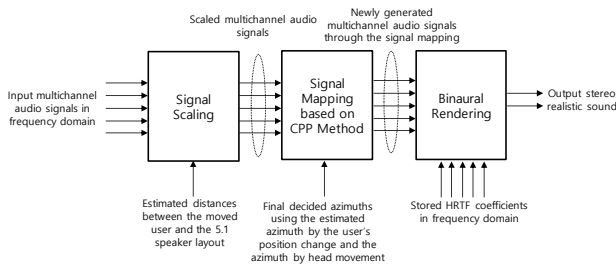

Fig. 11. Overall Procedure of the Proposed the Realistic Sound Generation.

#### IV. RESULTS AND DISCUSSION

To validate the performance of the proposed realistic sound generation method for the user's free movement in the VR, the subjective listening test was performed. Three audio contents were used for the test and listed in Table III. For simplification and clarification of the test, the realistic audio sound only using the left and the right channel signals was separately generated according to the user's position change as shown in Fig. 12. Here, it was assumed that there was no user's head movement. Five listeners participated in the test, and they evaluated the azimuth and distance of the generated realistic audio sound at the changed user's position compared to those of the realistic audio sound at the original position. Meanwhile, the azimuths and distances between the user and the speakers were theoretically calculated in each position as in Table IV.

TABLE III. TEST MATERIALS

Material	Description
Item1	Ambience
Item2	Music (back: direct)
Item3	Pathological

Fig. 12. Two Position Changes for the Test.

TABLE IV. ESTIMATED DISTANCE AND THE AZIMUTH BETWEEN THE GIVEN USER'S POSITION AND THE SPEAKER FOR THE TEST

Position	Ch.	Selected Area	Azimuth ( $\theta_p$ )	Distance ( $r$ )
1	C	Area 4	$\tan^{-1}\left(\frac{ 0-0 }{ 1-0.5 }\right) = 0$	$\sqrt{(0-0)^2 + (1-0.5)^2} = 0.5$
	Lf	Area 3	$\tan^{-1}\left(\frac{\cos(\pi/6)-0.5}{ -\sin(\pi/6) }\right) + \frac{3\pi}{2}$ = $\frac{30.62\pi}{18}$ ( $\approx 306^\circ$ )	$\sqrt{(-\sin(\pi/6))^2 + (\cos(\pi/6)-0.5)^2}$ = 0.62
	Rf	Area 4	$\tan^{-1}\left(\frac{ \sin(\pi/6) }{\cos(\pi/6)-0.5}\right)$ = $\frac{5.38\pi}{18}$ ( $\approx 53.8^\circ$ )	$\sqrt{(\sin(\pi/6))^2 + (\cos(\pi/6)-0.5)^2}$ = 0.62
	Ls	Area 2	$\tan^{-1}\left(\frac{ -\cos(\pi/9) }{ -\sin(\pi/9)-0.5 }\right) + \pi$ = $\frac{22.81\pi}{18}$ ( $\approx 228^\circ$ )	$\sqrt{(-\cos(\pi/9)-0)^2 + (-\sin(\pi/9)-0.5)^2}$ = 1.26
	Rs	Area 1	$\tan^{-1}\left(\frac{ -\sin(\pi/9)-0.5 }{\cos(\pi/9)-1}\right) + \frac{\pi}{2}$ = $\frac{13.19\pi}{18}$ ( $\approx 132^\circ$ )	$\sqrt{(\cos(\pi/9)-0)^2 + (-\sin(\pi/9)-0.5)^2}$ = 1.26
2	C	Area 3	$\tan^{-1}\left(\frac{ 1-0 }{ 0-1 }\right) + \frac{3\pi}{2} - \frac{7\pi}{4}$ ( $\approx 315^\circ$ )	$\sqrt{(0-1)^2 + (1-0)^2} = 1.41$
	Lf	Area 3	$\tan^{-1}\left(\frac{\cos(\pi/6)}{ -\sin(\pi/6)-1 }\right) + \frac{3\pi}{2}$ = $\frac{10\pi}{6}$ ( $\approx 300^\circ$ )	$\sqrt{(-\sin(\pi/6)-1)^2 + (\cos(\pi/6)-0)^2}$ = 1.73
	Rf	Area 3	$\tan^{-1}\left(\frac{\cos(\pi/6)}{ \sin(\pi/6)-1 }\right) + \frac{3\pi}{2}$ = $\frac{11\pi}{6}$ ( $\approx 330^\circ$ )	$\sqrt{(\sin(\pi/6)-1)^2 + (\cos(\pi/6)-0)^2}$ = 1
	Ls	Area 2	$\tan^{-1}\left(\frac{ -\cos(\pi/9)-1 }{ -\sin(\pi/9) }\right) + \pi$ = $\frac{26\pi}{18}$ ( $\approx 260^\circ$ )	$\sqrt{(-\cos(\pi/9)-1)^2 + (-\sin(\pi/9)-0)^2}$ = 1.97
	Rs	Area 2	$\tan^{-1}\left(\frac{\cos(\pi/9)-1}{ -\sin(\pi/9) }\right) + \pi$ = $\frac{19\pi}{18}$ ( $\approx 190^\circ$ )	$\sqrt{(\cos(\pi/9)-1)^2 + (-\sin(\pi/9)-0)^2}$ = 0.35

Fig. 13 and 14 are the subjective listening test results. In addition, Table V shows the error rate of the proposed method in the azimuth and the distance evaluation, respectively. The test results show that the proposed method could rather successfully generate the realistic sound according to the user's position change because the desired azimuth and distance overlap the confidence intervals of the evaluated ones in most test items. Nevertheless, the confidence intervals of the evaluated azimuth and distance are very wide, so the listening

test results also show that the performance of the proposed method may be rather poor. It is because the proposed method used only the HRTF coefficients of the 5.1 multi-channel speaker layout, namely, the proposed method did not have the sufficient resolution of the HRTF coefficients to generate the realistic audio sound according to the user's free movement in the VR. Therefore, it is necessary to improve the proposed method to generate realistic sound by utilizing HRTF coefficients of the 10.1 or more playback environment.

Fig. 13. Subjective Listening Test Result for Evaluation of Azimuth Change.

Fig. 14. Subjective Listening Test Result for Evaluation of Distance Change.

TABLE V. ERROR RATE OF THE AZIMUTH AND THE DISTANCE EVALUATION (%)

Position	Channel	Azimuth	Distance
Position1	Lf	4.8	2.3
	Rf	8.1	8.7
Position2	Lf	4.6	1
	Rf	1.2	2.4
Overall		4.7	3.6

## V. CONCLUSION

The realistic audio is essential to enjoy the realistic services such as VR, but there is a limitation that multi-channel audio playback environment is involved for the realistic audio. Although the binaural rendering could solve this limitation to provide the realistic sound in the stereo headphone playback environment, there was a problem that the binaural rendering alone could not reflect the user's free movement in the VR. Therefore, there was the mismatch between the visual scene and the audio sound in the VR, so the performance of the VR was degraded. In this paper, the complex plane based stereo realistic sound generation method was proposed to allow the user's free movement such as the position change and the head azimuth change in the VR. In the proposed method, the variations of the azimuth and distance between the user and the speaker were reflected according to the user's movement in the stereo realistic sound generated by the binaural rendering. The subjective listening test results showed that the proposed method could generate the realistic audio sound that successfully reflected the user's free movement only with less than 5 % error rate of the azimuth and the distance evaluation. In spite of the good performance of the proposed method, the performance improvement of the proposed method through the increase of the resolution of the HRTF coefficients remains as a future work because the proposed method only had the HRTF coefficients of the 5.1 multi-channel speaker layout and it caused the error of the azimuth and the distance evaluation.

**Abstract**—Reverse vending machine (RVM) is an interactive platform that can boost recycling activities by rewarding users that return the recycle items to the machine. To accomplish that, the RVM should be outfitted with material identification module to recognize different sort of recyclable materials, so the user can be rewarded accordingly. Since utilizing combination of sensors for such a task is tedious, a vision-based detection framework is proposed to identify three types of recyclable material which are aluminum can, PET bottle and tetra-pak. Initially, a self-collected of 5898 samples were fed into classification and detection framework which were divided into the ratio of 85:15 of training and validation samples. For the classification model, three pre-trained models of AlexNet, VGG16 and Resnet50 were used, while for the detection model YOLOv5 architecture is employed. As for the dataset, it was gathered by capturing the recycle material picture from various point and information expansion of flipping and pivoting the pictures. A progression of thorough hyper parameters tuning were conducted to determine an optimal structure that is able to produce high accuracy. From series of experiments it can be concluded that, the detection model shows promising outcome compare to the classification module for accomplishing the recycle item verification task of the RVM.

**Keywords**—Convolutional neural network (CNN); classification; detection; reverse vending machine (RVM); You Only Look Once (YOLO)

## I. INTRODUCTION

Malaysia is leaving behind in sustaining waste management awareness, especially in recycling [1]. Currently, the rate of solid waste increase significantly [2] and one of the methods that can be done in managing waste effectively is by boosting recycling activities using interactive Reverse Vending Machine (RVM). RVM works by analyzing every deposit recycle materials to the machine and provide reward to the user accordingly. Previously, a hybrid sensing based RVM [3-4] has been developed and tested in municipal office as shown in Fig. 1. However, it manage to recognize only PET bottle and aluminum can, and required tedious sensor calibration, maintenance and not suitable for long term usage.

To cater such an issue, a vision-based technology is incorporated into the RVM material identification module. Vision system capable to recognizing more types of recycle items with vast amount of the collected data from the sample.

One of the work is from [5] in which they introduced ThrashNet dataset and use SIFT feature with SVM and CNN model of AlexNet-like architecture. The former model manage to obtain average of 63% performance while the latter show deteriorate performance with 22% accuracy, in which the author argue more dataset will yield a better result. Andrey et al. [6] developed a reverse vending machine with several CNN classification model by analyzing effect of training by combining two different dataset cluster during training. In average the CNN model can produce more than 85% accuracy. They later on test the module in real implementation by combining weigh sensor with the CNN for fraud detection [7].

Recently, CNN becomes trends for thrash items classification either using standalone model, combine with conventional classifier or using ensemble CNN architecture. RecycleNet [8] was introduced to exhaustively analyze optimal state of the art CNN structure for the RVM classification task. They exhaustively tune the model based on empty-structure model, with pre-trained and fine tuning. In average for the performance wise, 90% accuracy can be obtained for each models, layer modification is necessary to ensure processing time and accuracy can be well balance. In [9], a combination of GoogleNet with SVM show promising outcome with 97.86% based on TrashNet dataset. Apart from that a MobileNet variants [10] shows at par performance with 96.57% and optimized DenseNet121 model obtain 99.6% accuracy [11] using the same dataset. An ensemble based model that combine GoogleNet, ResNet-50 and MobileNetv2 using unequal precision measurement data fusion been tested using ThrashNet and FourThrash dataset [12], apparently they claim that the combination provide more robust results during data aggregation of the CNN forecasting results.

Fig. 1. Example of RVM using Combination of Sensors.

There are many works that previously focus on classification models and detection models for the RVM application. However, to the best of our knowledge no comparison done to investigate the effectiveness between each of the models. In this paper a CNN classification based model is compare with detection based model to determine optimal structure for RVM implementation. The paper is organize as follow: section II will discuss about methodology use through this project, follow by result and discussion in section III and eventually project conclusion in section IV.

## II. MODELS AND METHOD

In this section, detail explanation about model and architecture used throughout this project is thoroughly explained. It comprises of three main subsections, namely, dataset preparation, classification model development and detection model development.

### A. Datasets Preparation

The arrangement of getting sample image of all classes are as in Fig. 2 in which the camera is vertically locate 21cm above the ground and the sample was placed 51cm from the camera. There are total of 5898 samples collected ranging from three categories of aluminum can, PET bottles and tetra-pak as depicted in Fig. 3. The collected images are then separated into training and validation cluster with a portion of 4961 samples for validation and 937 samples for validation. Details of sample distributions for each cluster can be seen in Table I. It can be noticed that. For the detection task, all images must undergo an annotating process in which in this project a Labellmg software is used.

Fig. 2. Setup Arrangement for Dataset Preparation.

Fig. 3. Sample of Tetra-Pak, PET Bottle and Aluminium Can.

TABLE I. NUMBER OF IMAGE DATASET IN EACH RECYCLE ITEM IMAGE CATEGORY

Images	Training	Validation
Aluminum Can	1335	248
PET Bottle	3018	569
Tetra-pak	608	120
Total	4961	937

### B. Classification Model Development

For the classification module, a Convolutional Neural Network (CNN) based model is employ. Basically, CNN comprises two main part which are feature extractor module, also known as convolutional layer, and classification module that will regard as dense layer. The former ensure local features from inputted image can be highlighted, while the latter utilize the extracted local features to identify the trained object inside the image. In this project, a pre-trained CNN model is utilize to recognize the three cluster of the recyclable items. It means that, the parameters from convolutional layer of state of the art CNN model will be reuse to be trained with our own dataset. During the training session, convolutional layer parameters will be frozen while dense layer parameters will by dynamically adjusted to reduce the cost function error.

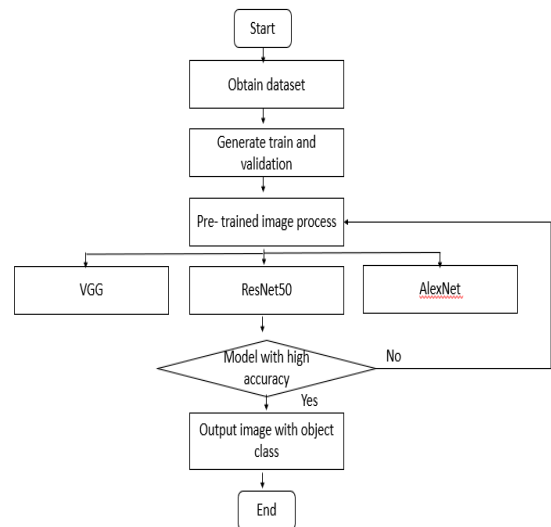

Fig. 4. Block Diagram flow of the Classification Procedure.

Fig. 4 depicted overall system flow of the classification part. From the collected sample set, the training cluster data will be tested with three pre-train models which are VGG, ResNet50 and AlexNet. All the three models will undergo rigorous hyper parameters tuning to analyses the best model that can optimally classify the three types of the recyclable items. In this paper, a free GPU from Google Colab is employed to execute the training process. This platform is a cloud based of Jupyter notebook and can be edited by the team members and easy to access without requiring any setup. It supported many types of machine learning libraries and the sample data can be simply loaded from the user Google drive.

The CNN VGG16 model [13] is the first model that will be access for the classification module. It comprises of systematic architecture of 3x3 filter throughout the 16 layers and was introduced in 2014 as an improvement of Alexnet. The model achieved 92.7% accuracy performance in ImageNe dataset and consists of 138 million parameters and make it a bit slow to train. Fig. 5 shows an architecture of VGG16 model. All the input images will be resized to 224x224 dimension prior to feed to the 13 convolutional layers. Number of channel in this layer is started with 64 channels and was incremented to the factor of two up until 512 channels. In between of the convolutional layer there are five pooling layers that

responsible to down sample an image and was done using maxpooling operation of 2x2 kernel with stride of two. The last convolutional layer outputting feature map with the size of 7x7x512. Then, this 2D features is flattened through the three fully connected layers with ReLU activation in the first two hidden layer and softmax in the output layer.

Residual Network (ResNet) [14] is the second model that will be tested for this project. ResNet is the first model that can be used to generate very deep network from hundreds to thousands layer while still providing a good performance. It able to handle such situation by introducing residual block with a skip connection, which will add a result from previous layer to the next layer of the model as shown in Fig. 6. A very deep network literally will suffer from vanishing gradient problem, in which the back propagate training error value will become smaller from layer to layer and eventually becomes zero. In the layer where the error goes to zero and in its subsequent, no more parameters update will be executed and hence the model unable to converge well with the given data. ResNet handle such situation via the skip connection which allowing the gradient to flow via the alternative path. By doing that, it will ensure the higher layer will perform as good as the lower layer.

In this project, a ResNet50 model is used in which it contains 49 convolutional layers and single dense layer as shown in Fig. 7. The former layer can be further categorize into four main blocks of conv2, conv3, conv4 and conv5 in which each block contain three convolutional layers as shown in Fig. 6. The number of channel in each block is sequentially increment by a factor of two and the model is expected an input image of 224x224 dimension. In summary, the convolutional structure can be visualize as: conv1; 3 x conv2; 4 x conv3; 6 x conv4; 3 x conv5. After series of convolutional layers, a dense layer with 1000 neurons and softmax activation function is add up to classify the dataset cluster accordingly.

	1x1	average pool, 1000-d fc, softmax

Fig. 7. ResNet-50 Structure.

The third model that will be analyze is AlexNet architecture [15]. This is one of the simplest and earliest CNN architecture that have firm grip of overfitting problem by introducing data augmentation and dropout layer. Basically AlexNet consist of eight layers that compose of five convolutional layers and three dense layer as shown in Fig. 8. The model also introduce rectify linear unit (ReLU) and max pooling layer to be use along with the convolutional layer. Regarding the input, it must be resize to 227x227 dimension prior feed to the network. In their structure, three size of filter dimensions were utilized which in dimension of 11x11, 5x5 and 3x3.

Fig. 8. AlexNet Structure.

To utilize all the mentioned state of the art CNN models in this project, a transfer learning process is implemented. Technically, the process will re-utilize all the convolutional parameters from the model, omit its original dense layer and then hook up our dense layer as shown in Fig. 9. In the figure, shade block area denotes the convolutional layer parameters and will be frozen during training session. On the other hand, the white block area is the new dense layer that consist of two hidden layers with 512 and 128 neuron and one output layer with three neurons that denote our three clusters of aluminium can, PET bottle and tetra-pak. The dense layer, will be dynamically updated during the training session based on the back propagate error value from the output layer.

Fig. 9. Visualization of Structure of Transfer Learning Process.

### C. Detection Model Development

For detection module, the main structure employ in this project is based on ‘You Only Look Once’ (YOLO) object detection. Basically, it starts with the forming of grid cells, follow by class prediction across scales, and eventually bounding box location estimation via regression process. The finer grid cell enable for smaller target detection and anchor box make it possible to detect an overlapping object with high accuracy. There are many variants of YOLO model starting from version v1 to version v5 [16-20]. In this project, the recent model which is YOLOv5 is used.

YOLOv5 is a single stage object detector and has three components which are backbone, neck (PANet) and head (output) as depicted in Fig. 10. Model backbone is mostly used to separate significant features from the input image using cross stage partial network (CSPNet) [21]. CSPNet has demonstrated huge improvement in processing time with more profound networks and solves the problems of repeated gradient information in large-scale backbones. Such structure will improve inference, speed, and accuracy and at the same time reduce the model size. In RVM verification task, detection speed, and accuracy is important, and compact model size also determines its inference efficiency on compact device controller.

Fig. 10. YOLOv5 Architecture.

Model neck is mostly used to produce feature pyramid to assist models to deduct on object scaling. It assists with recognizing similar item with various sizes and scales. Feature pyramids are extremely valuable and assist models with performing admirably on hidden data. In YOLOv5 path aggregation network (PANet) [22] is utilized as neck to get feature pyramids. PANet improve localization signals accuracy the in lower layers, and hence enhance the location accuracy of the object.

The model head is essentially used to play out the last detection part. It applied three different size of anchor boxes to cater small, medium and big objects on features, and creates final output vectors with class probabilities, object scores, and bounding boxes. The YOLOv5 model head structure is equivalent to the past YOLOv3 and YOLOv4 model.

YOLOv5 has four final architecture which are YOLOv5s (small), YOLOv5m (medium), YOLOv5l (large) and YOLOv5x (xlarge). To balance between speed and accuracy of the system, YOLOv5s which is the smallest and fastest model is utilised for the RVM implementation.

In YOLO family the cost function calculation is source from objectness score, class probability score, and bounding box regression score. YOLOv5 has utilized binary cross-

entropy (BCE) with logits loss equation from for loss calculation of class probability and object score. This loss joins a sigmoid layer and the BCE loss in one single class and more mathematically stable than utilizing a plain sigmoid followed by a BCE loss.

### III. RESULTS AND DISCUSSION

In this section performance of the selected classification and detection model is presented. Basically the section comprises of three main parts which are classification model assessment, detection model assessment and optimal model assessment in live feed video streaming. Part of the samples that will be use during the training and validation session can be seen in Fig. 11 which shown PET bottle samples, aluminum can samples and tetra-pak samples.

#### A. Classification Model Assessment

For the first classification analysis, summary of the outcomes can be seen in Fig. 12. It displays result of training session, validation session and loss in every epochs. Initially, in every training session 50 epoch will be selected, and the location where overfitting start to occurs will be selected as the new epoch for the next training session. The tuning process will be repeated until optimal outcome that well balance between training and validation data is obtained. However, if under fitting condition constantly occurs, then it can be concluded that the model cannot be used for recognizing the given dataset.

As can be seen in figure, the VGG-16 model performance keep under fitting both for training and validation with value of below 70%, and hence it can be summarize that the VGG-16 model unable to works well to classify the data. Next, for the AlexNet model it begins to under fit after 15 epochs and eventually at 50 epochs the performance for training is at 98% while for the validation is at 80%. It can be say that, the ALexNet model works well for memorizing the data but not works well for recognizing unseen data pattern. Finally, for the ResNet-50 model, it can be observed that it able to obtain high accuracy during training session with 92%, but the validation performance fluctuate significantly with the lowest value of 12% after 50 epochs.

Fig. 11. Sample of Training Images.

Fig. 12. Summary of Classification Model Analysis.

Based on the finding, for RVM classification model the best structure that can balance trade-off between training and validation is the AlexNet model with 80% performance during validation stage and the highest training performance among other two models. Sample of the classification outcome can be seen in Fig. 13.

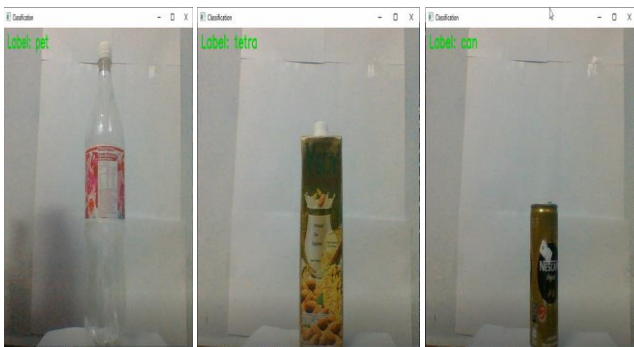

Fig. 13. Sample of Classification Module Outcome.

### B. Detection Model Assessment

This section will deliberately discuss result obtained for the YOLOv5 detection module framework. The best variable must be selected to achieve a rapid object detection model with high accuracy. There are three important parameters that are frequently used for object detection assignment: Generalized Intersection over Union (GIoU) graph, Objectness graph and mean Average Precision (mAP) graph.

GIoU graph indicates how near the ground truth with the predicted bounding box, whereas for Objectness graph means confidence score whether there is an object in the grid cell. In the event that the bounding box covers a ground truth object more than others, the relating Objectness score ought to be 1. The third graph that is important is mAP graph where the precision and recall for all the objects introduced in the images ought to be figured. It additionally needs to consider the confidence score for each object detection by the model in the picture. Consider the entirety of the predicted bounding boxes with a confidence score over a specific limit. Bounding boxes over the set threshold value are considered as positive boxes while all predicted bounding boxes underneath the set threshold value are considered as negative. Thus, the higher the threshold value is, the lower the mAP will be, however the confidence is more accurate.

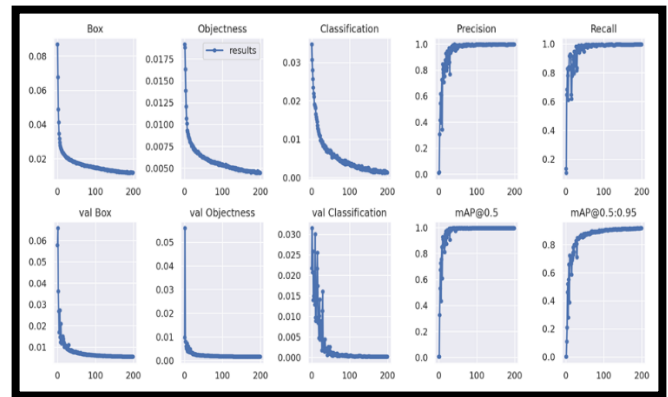

Fig. 14. Detection Training Result of Fine Tuning Process for 200 Epochs.

Fig. 14, summarize the tuning outcome after 200 epochs of training. The first three columns show loss function value for GIoU confident score, Objectness confidence score and classification confidence score, where the upper part denoted the training data while the lower part the validation data. It can be observed that all the loss value decrement constantly near to zero for the three scores. Even there is some fluctuation for the val-classification score in the beginning of training, it becomes constantly goes to zero as the epoch more than 50. Looking at another four remaining curve figures of precision, recall, mAP@0.5 and mAP@0.5: 0.95, the performance gain high confidence score after 100 epochs.

To gain more detail insight of each object class performance, precision and recall curve can be investigated and is shown in Fig. 15. Precision recall curve shows the tradeoff between the exactness and recall esteems for various limits. This curve assists with choosing the best threshold to expand both measurements. As the number of positive samples get higher (high recall), the accuracy of classification of every sample precisely get lower (low precision). From the figure, it can be observed that, the PET bottle shows highest confidence score with 0.997, follow by tetra-pak and finally the aluminium can. In average, overall performance of all class detection is at 0.995 using 0.5 confidence score of mean average precision. The performance for the detection can be conclude as much more better than the one obtain from the classification model based on the given dataset. The resultant images after running the inference/testing process were as in Fig. 16.

Fig. 15. Precision Recall Curve of the YOLOv5 Model.

Fig. 16. Sample of YOLOv5 Detection Outcome.

### C. Optimal Model Assessment with Live Feed Video

The live feed video application is done to gain insight how well the model works under real implementation scenario of the reverse vending machine. Basically the procedure will include the utilization of the webcam and the recyclable items will be slide within the camera field of view. Since based on the two model analysis the detection based architecture show a better outcome, analysis in this section was done for the detection module part only.

For the first assessment 10 samples for each class which total up to be 30 were feed in the webcam view while the detection algorithm running. The finding is PET bottle class has achieved 100% accuracy as the module correctly detects all of the input that has been fed simultaneously, whereas for aluminium can class, the module only achieved 80% accuracy and for the tetra-pak class 90% accuracy. Based from this outcome, it can be concluded that the module gained average of 90% accuracy in real implementation condition. Sample of the snapshot during experiment is shown in Fig. 17.

Fig. 17. Sample Snapshot during Live Feed Testing of the Detection Module.

Fig. 18. Result after the Detection Module has been Tested under Condition of more than Two Classes in one Frame.

For the second condition, samples of recyclable waste material will be put together in front of the webcam. The aim is to analyze module capability for detecting multiple samples in single feed of camera image. The result will be evaluated whether the module can detect the cluster precisely. Result obtained in this condition is recorded in Fig. 18 and it can be concluded that the module works well to fulfill the task by successfully detecting all the recycle materials given.

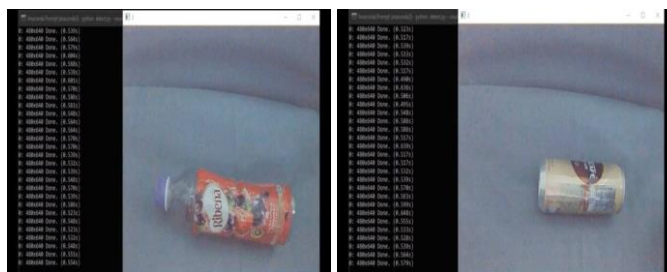

Fig. 19. Detection Result with Low Light Condition.

Finally, to imitate the real condition situation inside RVM, the detection module is tested under low light condition with only exposure from the natural light. The result can be seen in Fig. 19. This shows that, without proper lighting the module unable to works well and hence light source is crucial to guarantee system success. As for the computational cost during live feed assessment, based on the analysis of feeding the detection module with 314 images, it is found that in average the processing time is 482.1 millisecond for color image with dimension of 640x640. The processing speed is acceptable for RVM usage and can be further improve by incorporating GPU based controller such as NVIDIA Jetson Nano or by using OpenCV OAK-1 camera.

### IV. CONCLUSION

In this project, a CNN-based classification and detection module were investigated to be used as RVM verification module. Three class of sample which are PET bottle, aluminium can and tetra-pak are used during the training and validation stage with amount of 4961 and 937 respectively.

The highest performance model either from classification or detection was then undergo live feed video assessment under RVM implementation condition.

For the classification models, three CNN architecture were tested which are VGG-16, ResNet-50 and AlexNet. From series of training and fine tuning, it can be concluded that AlexNet model show high performance with 98% accuracy during training and 80% during validation stage, follow by ResNet-50 and then VGG-16. As for the detection model, YOLOv5 is used and it shows promising outcome with average of 99.5% mAP@0.5 accuracy based on the give training and validation data. Since the detection model show promising outcome compare to the classification model, it was further tested under RVM real implementation condition using a life feed webcam data. From the testing it can be concluded that, the system able to gain 90% accuracy during testing and apparently a good source of light is crucial to ensure the successfulness of the detection process.

The finding in this project is subject to several limitations that could be addressed in future research. First, the system is currently tested in a lab condition that simulating RVM functionality and hence future assessment in actual operation condition is in planning for system assessment. Second, most of the collected sample items were gathered locally and hence there is tendency that the system unable to detect recyclable items from beyond local brand. Finally, the detection model is currently tested with state of the art YOLO detector, in future, other type of detection algorithm such as single shot detector and RCNN variants can be assess to compare its outcome with the YOLO based platform.

**Abstract**—The Peruvian government declared a State of National Emergency due to the spread of COVID-19 where the closure of businesses, companies and home isolation was imposed from 03/15/2020 to 06/30/2020. In this context, the research focused on analyzing the characteristics of the air quality in Lima during said period compared to its similar in 2018 and 2019, for this purpose, data from two air quality monitoring stations in PM<sub>2.5</sub>, PM<sub>10</sub>, CO and NO<sub>2</sub> concentrations and the quality levels given by the Air Quality Index (INCA) were used for further processing with the Grey Clustering method, which is based on grey systems. The results showed that during the quarantine, air quality improved significantly, specifically the northern area of Lima, which was favored by the meteorological conditions that will be classified as good quality as well as the reduction of PM<sub>10</sub> by 46% and PM<sub>2.5</sub> in 45% to a lesser extent, NO<sub>2</sub> by 17% and CO in 11%, unlike the southern zone which, although it showed an improvement, it is still classified as moderate quality with reductions in PM<sub>10</sub> by 26%, PM<sub>2.5</sub> by 27%, CO by 19%.; however the concentration NO<sub>2</sub> registered a non-significant increase of 2%. This behaviour is explained by the lower height of the thermal inversion layer, therefore less space for the dispersion of pollutants. Finally, the study obtains essential information for regulatory agencies as it allows understanding the relationship between air quality and control measures at emission sources for the development of public policies on public health and the environment.

**Keywords**—Air quality; COVID 19; grey systems; grey clustering

## I. INTRODUCTION

On March 11, 2020, the World Health Organization (WHO) declared that the COVID 19 - disease caused by the new coronavirus SARS-CoV-2-went from being an epidemic to a pandemic [1]. In Perú, the first confirmed case was reported on March 6, 2020, in Lima, a young man had arrived from a trip to the European continent. To date March 16, there were 86 positive cases of coronavirus, being Lima the department with the highest number (70 cases) [2].

To control the increase in the number of cases confirmed by coronavirus, Peru declared a national state of emergency for a period of 15 days, during which it was decided to establish mandatory social isolation (quarantine), a measure that came into effect March 16. During the quarantine period, public access to premises and establishments (restaurants, museums, cultural, sports and leisure activities, among others) was suspended, except for commercial establishments for the

acquisition of food and basic necessities. Due to the increase in coronavirus cases, the quarantine was extended until June 30.
