Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Doroła Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Real-Time Driver's Focus of Attention Extraction and Prediction using Deep Learning

Authors: Pei-heng Hong, Yuehua Wang

PAGE 1 – 10

Paper 2: Predicting Strength Ratio of Laminated Composite Material with Evolutionary Artificial Neural Network

Authors: Huiyao Zhang, Atsushi Yokoyama

PAGE 11 – 18

Paper 3: UIP2SOP: A Unique IoT Network applying Single Sign-On and Message Queue Protocol

Authors: Lam Nguyen Tran Thanh, Nguyen Ngoc Phien, The Anh Nguyen, Hong Khanh Vo, Hoang Huong Luong, Tuan Dao Anh, Khoi Nguyen Huynh Tuan, Ha Xuan Son

PAGE 19 – 30

Paper 4: A Hybrid Encryption Solution to Improve Cloud Computing Security using Symmetric and Asymmetric Cryptography Algorithms

Authors: Hossein Abroshan

PAGE 31 – 37

Paper 5: Evil Twin Attack Mitigation Techniques in 802.11 Networks

Authors: Raja Muthalagu, Sachin Sanjay

PAGE 38 – 41

Paper 6: Solving Reactive Power Scheduling Problem using Multi-objective Crow Search Algorithm

Authors: Surrender Reddy Salkuti

PAGE 42 – 48

Paper 7: Controlling a Wheelchair using a Brain Computer Interface based on User Controlled Eye Blinks

Authors: Sebastián Poveda Zavala, Sang Guun Yoo, David Edmigio Valdivieso Tituana

PAGE 49 – 55

Paper 8: IoT based Smart Water Quality Prediction for Biofloc Aquaculture

Authors: Md. Mamunur Rashid, Al-Akhir Nayan, Sabrina Afrin Simi, Joyeta Saha, Md. Obaidur Rahman, Muhammad Golam Kibria

PAGE 56 – 62

Paper 9: A Novel High-order Linguistic Time Series Forecasting Model with the Growth of Declared Word-set

Authors: Nguyen Duy Hieu, Pham Dinh Phong

PAGE 63 – 71

Paper 10: Opinion Mining of Saudi Responses to COVID-19 Vaccines on Twitter

Authors: Fahad M. Alliheibi, Abdulfattah Omar, Nasser Al-Horais

PAGE 72 – 78

Paper 11: Indoor Localization and Navigation based on Deep Learning using a Monocular Visual System

Authors: Rodrigo Eduardo Arevalo Ancona, Leonel Germán Corona Ramírez, Oscar Octavio Gutiérrez Frías

PAGE 79 – 86

Paper 12: Firm Performance Prediction for Macroeconomic Diffusion Index using Machine Learning

Authors: Cu Nguyen Giap, Dao The Son, Dinh Thi Ha, Vu Quang Huy, Do Thi Thu Hien, Le Mai Trang

PAGE 87 – 99

Paper 13: A Review on SDR, Spectrum Sensing, and CR-based IoT in Cognitive Radio Networks

Authors: Nadia Kassri, Abdeslam Ennouaary, Slimane Bah, Hajar Baghdadi

PAGE 100 – 121

Paper 14: Artificial Intelligence based Recommendation System for Analyzing Social Business Reviews

Authors: Asma Alanazi, Marwan Alseid

PAGE 122 – 132

Paper 15: Comprehensive Analysis for Sensor-Based Hydraulic System Condition Monitoring

Authors: Ahmed Alenany, Ahmed M. Helmi, Basheer M. Nasef

PAGE 133 – 140

Paper 16: A New Communication Protocol for Drones Cooperative Network: 5G Site Survey Case Study

Authors: Youssef Shawky Othman, Mohamed Helmy Megahed, Mohamed Abo Rezka, Fathy Ahmed Elsayed Amer

PAGE 141 – 152

Paper 17: Real Time Face Expression Recognition along with Balanced FER2013 Dataset using CycleGAN

Authors: Fatma Mazen Ali Mazen, Ahmed Aly Nashat, Rania Ahmed Abdel Azeem Abul Seoud

PAGE 153 – 164

Paper 18: A Deep Learning Approach Combining CNN and Bi-LSTM with SVM Classifier for Arabic Sentiment Analysis

Authors: Omar Alharbi

PAGE 165 – 172

Paper 19: Emotional Intelligence Robotics to Motivate Interaction in E-Learning: An Algorithm

Authors: Dalia khairy, Salem Alkhalaf, M. F. Areed, Mohamed A. Amasha, Rania A. Abougalala

PAGE 173 – 183

Paper 20: Building Research Productivity Framework in Higher Education Institution

Authors: Ahmad Sanmorino, Ermatita, Samsuryadi, Dian Palupi Rini

PAGE 184 – 191

Paper 21: Method for Determination of Support Length of Daubechies Basis Function for Wavelet MRA based Moving Characteristic Estimation

Authors: Kohei Arai

PAGE 192 – 200

Paper 22: DeepfakeNet, an Efficient Deepfake Detection Method

Authors: Dafeng Gong, Yogan Jaya Kumar, Ong Sing Goh, Zi Ye, Wanle Chi

PAGE 201 – 207

Paper 23: A New Key Generation Technique based on Neural Networks for Lightweight Block Ciphers

Authors: Sohel Rana, M. Rubaiyat Hossain Mondal, A. H. M. Shahariar Parvez

PAGE 208 – 216

Paper 24: Fully Automated Ontology Increment`S user Guide Generation

Authors: Kaneeka Vidanage, Rosmayati Mohemad, Noor Maizura Mohamad Noor, Zuriana Abu Bakar

PAGE 217 – 227

Paper 25: Design of an Efficient RPL Objective Function for Internet of Things Applications

Authors: Sonia Kuwelkar, H.G. Virani

PAGE 228 – 235

Paper 26: Enhance Risks Management of Software Development Projects in Concurrent Multi-Projects Environment to Optimize Resources Allocation Decisions

Authors: Ibraheem M Alharbi, Adel A Alyoubi, Majid Altuwairiqi, Mahmoud Abd Ellatif

PAGE 236 – 246

Paper 27: Fog-based Remote in-Home Health Monitoring Framework

Authors: Fatma H. Elgendy, Amany M. Sarhan, Mahmoud A. M. Alshewimy

PAGE 247 – 254

Paper 28: What Drives Airbnb Customers' Satisfaction in Amsterdam? A Sentiment Analysis

Authors: Heyam Abdullah Bin Madhi, Muna M. Alhammah

PAGE 255 – 263

Paper 29: Motivational Factors Impacting the Use of Citizen Reporting Applications in Saudi Arabia: The Case of Balagh Application

Authors: Muna M. Alhammah, Layla Hajar, Sahar Alshathry, Mashael Alqasabi

PAGE 264 – 272

Paper 30: Securing Student Data Privacy using Modified Snake and Ladder Cryptographic Algorithm

Authors: Kamaladevi Kunkolienker, Vaishnavi Kamat

PAGE 273 – 279

Paper 31: A Method to Accommodate Backward Compatibility on the Learning Application-based Transliteration to the Balinese Script

Authors: Gede Indrawan, I Ketut Paramarta, I Gede Nurhayata, Sariyasa

PAGE 280 – 286

Paper 32: Validation: Conceptual versus Activity Diagram Approaches

Authors: Sabah Al-Fedaghi

PAGE 287 – 297

Paper 33: Identifying Small and Medium Enterprise Smart Entrepreneurship Training Framework Components using Thematic Analysis and Expert Review

Authors: Anis Nur Assila Rozmi, Puteri N.E. Nohuddin, Abdul Razak Abdul Hadi, Mohd Izhar A. Bakar

PAGE 298 – 309

Paper 34: A Framework for Protecting Teenagers from Cyber Crimes and Cyberbullying

Authors: Sultan Saud Alanazi, Adwan Alownie Alanazi

PAGE 310 – 315

Paper 35: Anonymity Feature in Android Mobile Apps for Interest Groups

Authors: Lee Sin Yi, Nurul A. Emran, Norharyati Harum

PAGE 316 – 323

Paper 36: A Method to Prevent SQL Injection Attack using an Improved Parameterized Stored Procedure

Authors: Kamsuriah Ahmad, Mayshara Karim

PAGE 324 – 332

Paper 37: From User Stories to UML Diagrams Driven by Ontological and Production Model

Authors: Samia Nasiri, Yassine Rhazali, Mohammed Lahmer, Amina Adadi

PAGE 333 – 340

Paper 38: Law Architecture for Regulatory-Compliant Public Enterprise Model: A Focus on Healthcare Reform in Egypt

Authors: Alsayed Abdelwahed Mohamed, Nashwa El-bendary, A. Abdo

PAGE 341 – 353

Paper 39: Microorganisms: Integrating Augmented Reality and Gamification in a Learning Tool

Authors: Ratna Zuarni Ramli, Nor Athirah Umairah Marobi, Noraidah Sahari Ashaari

PAGE 354 – 359

Paper 40: Emotional Evocative User Interface Design for Lifestyle Intervention in Non-communicable Diseases using Kansei

Authors: Noor Afiza Mat Razali, Normaizeerah Mohd Noor, Norulzahrah Mohd Zainudin, Nur Atiqah Malizan, Nor Asiakin Hasbullah, Khairul Khalil Ishak

PAGE 360 – 368

Paper 41: Exploring the Socio-economic Implications of Artificial Intelligence from Higher Education Student's Perspective

Authors: Sarah Areef, Lobna Amouri, Nahla El-Haggar, Aishah Moneer

PAGE 369 – 376

Paper 42: Feistel Network Assisted Dynamic Keying based SPN Lightweight Encryption for IoT Security

Authors: Krishna Priya Gurumanapalli, Nagendra Muthuluru

PAGE 377 – 392

Paper 43: Cloud-based Secure Healthcare Framework by using Enhanced Ciphertext Policy Attribute-Based Encryption Scheme

Authors: Siti Dhalila Mohd Satar, Mohamad Afendee Mohamed, Masnida Hussin, Zurina Mohd Hanapi, Siti Dhalila Mohd Satar

PAGE 393 – 399

Paper 44: Determining Optimal Number of K for e-Learning Groups Clustered using K-Medoid

Authors: S. Anthony Philomen Raj, Vidyaathulasiraman

PAGE 400 – 407

Paper 45: Abnormal Pulmonary Sounds Classification Algorithm using Convolutional Networks

Authors: Alva Mantari Alicia, Arancibia-Garcia Alexander, Chávez Frías William, Cieza-Terrones Michael, Herrera-Arana Víctor, Ramos-Cosi Sebastian

Real-Time Driver's Focus of Attention Extraction and Prediction using Deep Learning

Pei-heng Hong¹, Yuehua Wang^{2*}

Abstract—Driving is one of the most common activities in our modern lives. Every day, millions drive to and from their schools or workplaces. Even though this activity seems simple and everyone knows how to drive on roads, it actually requires drivers' complete attention to keep their eyes on the road and surrounding cars for safe driving. However, most of the research focused on either keeping improving the configurations of active safety systems with high-cost components like Lidar, night vision cameras, and radar sensor array, or finding the optimal way of fusing and interpreting sensor information without considering the impact of drivers' continuous attention and focus. We notice that effective safety technologies and systems are greatly affected by drivers' attention and focus. In this paper, we design, implement and evaluate Dfaep, a deep learning network for automatically examining, estimating, and predicting driver's focus of attention in a real-time manner with dual low-cost dash cameras for driver-centric and car-centric views. Based on the raw stream data captured by the dash cameras during driving, we first detect the driver's face and eye and generate augmented face images to extract facial features and enable real-time head movement tracking. We then parse the driver's attention behaviors and gaze focus together with the road scene data captured by one front-facing dash camera faced towards the roads. Facial features, augmented face images, and gaze focus data are then inputted to our deep learning network for modeling drivers' driving and attention behaviors. Experiments are then conducted on the large dataset, DR(eye)VE, and our own dataset under realistic driving conditions. The findings of this study indicated that the distribution of driver's attention and focus is highly skewed. Results show that Dfaep can quickly detect and predict the driver's attention and focus, and the average accuracy of prediction is 99.38%. This will provide a basis and feasible solution with a computational learnt model for capturing and understanding driver's attention and focus to help avoid fatal collisions and eliminate the probability of potential unsafe driving behavior in the future.

Keywords—Driving; attention; interesting zones; deep neural network; deep learning; models

I. INTRODUCTION

While being a basic enabler of our modern society, road vehicle transportation has become a major source of societal concerns. In 2016 alone, over 330, 655 people [1]–[3] were killed in vehicle accidents in the world, which is far greater than the number of US Soldiers killed in action in Vietnam (58,220 fatalities). Comparing to 19 high-income countries [3] including Canada, Germany, France, Spain, United Kingdom, and other 14 countries, the United States has highest vehicle accident death rate, where about 90 people die each day

in vehicle accidents. The U.S. National Security Council (USNSC) reports that vehicle accidents cause estimated 40,200 fatalities, a 6% rise from 2015 (i.e., a 14% rise from 2014), which makes 2016 the deadliest year on American roads in nearly a decade. To prevent vehicle accidents, injuries, and deaths [4], we have enforced the use of seat belts, car seats and booster seats for children through at least age 8, restricted alcohol-impaired driving [5] and speeding, and suggested to avoid distracted driving (such as texting, talking on the phone, eating or doing something else that occupies the senses you need to drive). In reality, those are far from enough for safe driving.

A wide variety of approaches [6]–[8], systems [9]–[11], and self-driving cars [12]–[15] have been developed for vehicle surrounding environment perception, including object detection, tracking, localization, navigation. In the market, most of automotive companies like Tesla, Mercedes-benz, Audi, BMW, Rolls-Royce, GM, Ford, and Honda have offered diverse advanced driver-assistance systems (ADASs) with various high-cost components including Lidar, high resolution cameras, radar sensor array, sonar, GPS, odometry, and inertial measurement unit. ADASs are electronic systems that assist the human driver while driving or during parking and have significantly improved comfort and safety in nowadays driving. Waymo [13], [14] originated by Google's self-driving car, Navya automated bus driving system [16], Uber driverless car [17], and Apple car [15] are promising autonomous driving vehicle projects to promote fully personal self-driving vehicle and related technology development. Since there are still many technological difficulties and regulatory issues that are need to be addressed, it would be close to a decade before self-driving cars are ready to use safely in a large number [18].

The emergence of artificial intelligence and rapid development of computer vision technology provide more opportunities to improve driving safety without strongly relying on the high-cost components or external information surrounding vehicles. We observe that driver's attention and focus have significant impact on driving safety and can lead to vehicle accidents or even terrible disasters. It, therefore, is extremely important to investigate and understand driver's attention and focus taking into consideration the complexity and dynamics of driver's behaviors under realistic driving conditions. Unfortunately, this topic is under-investigated and the lack of realistic experimental system does not help.

Motivated by the fact that driver's attention and focus are always changing over time in an uncertain, dynamic, and

continuous environment, we propose to capture and examine driver attention and focus using two low-cost dash cameras in real-time. Instead of using expensive, commercial eye tracker/tracking devices, dual dash cameras are placed on the windshield inside the vehicle. One camera is facing front for car-centric view and the other is facing towards the driver for driver-centric view. Based on the raw streaming data from the dash cameras, we provide an approach to extract facial features with face and eye detection, augment face images, track and predicate gaze focus zones during driving. Our first contribution is to build our drive attention database by driving from/to our campus to/from Dallas, Texas. The underlying ideas is to travel different types of roads including campus road, rural road, suburban road, highways, and metropolitan roadways to collect enough driver-centric and car-centric data under various driving circumstances.

The second contribution is to extract the driver's facial features and generate augmented face images using open source toolkit, Openface [19], [20]. The main visual cues that we are analyzing are head and eye directions that are selected based on the insights that drivers who are paying attention on driving will have a tendency to look forward and keep eyes on roads. To enable to locate the driver's focus, the driver's view is grided into 11 grids within 5 gaze zones. The a feature vector can be formed with the facial features and gaze zone to label the data. The third contribution is the introduction of a data-driven deep learning network called Dfaep. This network uses the detected features and augmented face images as the input and output accurate the focus of driver's attention. If the focus is not within the main zones, a warning alert will be issued to bring it to the driver attention. We evaluate Dfaep on two datasets, DR(eye)VE [6] and our own dataset. On DR(eye)VE, we substantially improve the predictions of the driver's focus with accurate gaze data on the real road scene. On our dataset, we test the trained model and compare our Dfaep with other deep learning networks with the same set of images and extracted features in terms of accuracy, loss, and network complexity to identify the network that is best for real-time systems and applications. We outperform all other networks and show the results that Dfaep can achieve highest prediction accuracy, 99.38% with lowest validation loss, 0.018.

The paper is organized as follows: Section II provides a brief literature review about computer vision systems and artificial intelligence relate to driver attention behaviors; Section III details the design and structure of the proposed deep learning network Dfaep for modeling the driver attention behaviors and tracking focus; Section IV presents the datasets used in experiments. The numerical performance evaluation results and our finding are then reported; and Section V concludes the paper and describes our future research plan.

II. LITERATURE

In this section, we review the existing technologies and studies used to capture and detect driver's attention and focus, which can be classified based on eye/gaze tracking to capture humans attention and detection and prediction methods driven by sensing data.

A. Eye Tracking

Eye tracking data is widely held to be a good window into attention or non-attentive states for learners or people working on tasks [21], [22]. Eye tracking refers to the careful measurement of the movements of the eyes and/or body when the participants are either positively or negatively interacting with the learning environments in a time-varying manner. The measurement devices, hardware platforms, and systems are commonly known as eye trackers. Based on the hardware setup, we classify the existing eye tracking systems into four main types: tower-mounted eye-tracker [23]–[25], screen-based eye tracker [26], [27], head mounted/wearable eye tracker [28]–[30], and mobile eye tracker [31]–[33]. An detailed discussion on those four types of eye tracking devices and platforms can be found in our papers [34]–[36]. Eye trackers can be either well-established commercial devices/systems or low-cost, portable systems designed by educators or researchers. For commercial eye trackers, they are still expensive in the current market, but well developed and maintained by companies like Tobii, SMI, ISCAN, LC Technologies, EyeTech, Oculus, Ergoneers, SmartEye, and Mirametrix [36]. With the requirements of necessary purchasing, only authorized users can use the purchased hardware and software with warranties, documentations, reachable technical support. Comparing to the commercial eye trackers, open source eye tracking devices and systems [29], [30], [37]–[39] have unique abilities to support both and low-cost eye trackers, easily alter experiments to specific scenarios, quickly prototype ideas and enable eye tracking research and applications without major restrictions. Given that, in this study, we propose an active safe driving behavior detection system with two low-cost car dash cameras, ZEdge-Z3 in \$100.

B. Attention Detection and Prediction

There are existing studies have been conducted with the eye tracking or camera data to detect and predicate driver's attention. For instance, Tran et al. [40] proposed an assisted-driving testbed with a driving simulator in a laboratory to simulate the driving environment and control the simulator's behavior using a script. Ten distracted driving behaviors like drinking, operation the radio, talking, texting, reaching behind, and making-up were defined. Based on the definition, four deep learning models, CNN, VGG-16, AlexNet, and GoogleNet are trained and tested on the simulator for driving distraction detection by distinguishing the defined distracted behaviors. The results showed that the VGG-16 achieved fastest frequency (14 Hz) while the ResNet model yielded highest accuracy of 92% with highest complexity which needed to have longest time for data processing and model calculation.

In [41], a CNN(Convolution Neural Network) is proposed and trained to mimic the driver based on training data from human driver's driving, it builds a model which takes as an input raw data and map it directly to a decision, using minimum training data and minimum computation, the car learns to drive on roads with or without human-design features. The idea of end to end self-driving car were implemented by NVIDIA [42]. They trained CNN to map raw pixels from one single front camera directly to steering commands. The network architecture is shown in Fig. 2. that consists nine layers which includes five convolutional layers, one normalization

Fig. 3. Driver Facial Detection.

layer and three fully connected layers, they used NVIDIA DevBox, Torch 7 and NVIDIA DRIVETM PX self-driving car computer for training and determining the steering angle. However, in their work, they did not consider about the throttle factor into training, they only focus on steering angle control, Therefore, based on their work, adding speed throttle factor and implementing it with RC car, can pose new challenges.

In this study, we compare the internal and external environment of the vehicle and propose a method that leverages deep learning network to predict the driver's attention in the environment inside and outside the vehicle. For the driver warning part, we have added scenes outside the vehicle as warning auxiliary factors to determine whether the driver is distracted by the driving of the vehicle.

III. PROPOSED SYSTEM AND METHODOLOGY

A. Overview of Our Driver Attention Database

The overview of this research is shown in Fig. 1. We use a camera to capture the raw images of the the driver's frontal view based on the corresponding windshield inside the vehicle, each zone for 1 minute. Then, the driver's facial features in raw images are extracted through the OpenFace [19], [20]. After that, each image of driver facial feature is cropped to 112×112 pixels for input DNN for training. We divide the data into training set, validation set and testing set. Here, our driver attention system will classify the driver's attention zone based on probability score of DNN model for each zone on the windshield. In DR(eye)VE database [6], we leverage saliency maps in the DR(eye)VE database to simulate our driving scene and label each frame of images, then we perform a synchronous comparison between the estimation zone of our driver attention detection classification system and attention zone of the DR(eye)VE database for evaluating the method

that we proposed. Finally, the synchronous comparison result is obtained, the system will give a warning to driver if the final label comparison result is not matched.

B. Detecting Facial Landmarks

The experimental environment with 11 grids within five gaze zones on the windshield of internal vehicle in this research is shown in Fig. 2. The reason we divided it into five gaze zones is to obtain more realistic driving scenarios. In this research we leverage a standard web camera to accomplish this task. A camera sensor is mounted in front of the driver. Since the size of the web camera is moderate (8 cm × 5 cm × 1.5 cm), it could be mounted in the vicinity of the windshield, and can continuously capture the driver's facial. Power to the web camera was supplied by the car using a universal serial bus (USB) line, connecting to the camera. The captured images by web camera is successively transmitted to the computer with graphics processing unit (GPU) for training via memory card of the web camera. The configuration of the web camera and the gaze zone on the windshield are shown in Fig. 2. We simulate driver's driving attention to different zone of windshield and their driving habits as if driving in real world, and save the videos recorded by the web camera, for each videos save the correspondent zone area performed by the driver. The dataset consists of 9,000 frames divided in five gaze zones, each of which is 1 minutes long, as shown in Fig. 4. The frames resolution size is 1920 × 1080 pixels.

C. Driver's Data Pre-processing

In our research, in order to improve the training efficiency and reduce unnecessary interference factors, our measures are to capture the driver's facial information and reduce the size of the original input image. In here, we leverage Openface to implement this goal. Openface was proposed by Tadas Baltrušaitis et al. [19], [20]. There are a lot of tools that can implement the face feature detection in images or videos. However, most of them did not provide the source code which makes it very difficult to reproduce experiments on different datasets. In Openface, it includes facial landmarks, head pose estimation, eye gaze estimation and the most importantly it is opens source, free and a tool that provides source code.

In our experiment, the facial feature of driver was captured based on Openface [19], [20]. Openface is a tool designed for computer vision and machine learning researchers, it leveraged Multi-task Convolutional Neural Network (MTCNN) facial feature tracker [43] to capture 68 face landmarks, eyelids, the iris, eyelids and the pupil are detected by a Constrained Local Neural Field (CLNF) landmark detector [44], and the head pose is extracted through 3D representation of facial landmarks of Convolutional Experts Constrained Local Model (CE-CLM) [45]. In the end, we obtained the appearance extraction face alignment images and cropped to 112×112 pixels for input to DFaep as shown in Fig. 5.

D. Network Structure

In this research, we propose a deep learning network for driver's focus of attention extraction and prediction (DFaep)(including six layers) as shown in Table I. The model used in this research is a simple stack of of four convolutional

layers (with ReLU activation [46]), four max pooling layers (with ReLU activation) and two fully connected layers (with ReLU and Softmax [47] activation). This model is modified from the LeNet [48]. We try to develop a DNN model with high accuracy and low parameter computation. Today we have far better models than this model, but this is the lightest one in terms of computation, and it is also the most suitable one for

	Output layer	-	400 × 1	-	-	-

our research. The performance comparison of different DNN models will be discussed in Section 4. In this model of DFAep, we executed the data augmentation in our training dataset. After extracting five features of last fully connected layer, the final attention zone of driver was estimated based on softmax function [47] of our DNN model.

The structure of our DFAep that is presented in Fig. 6 and will be illustrated in Table I. Our DFAep model is constructed of four convolutional layers (with ReLU activation [46]), 4 max pooling layers (with ReLU activation) and two fully connected layers. In the first convolutional layer, there are 32 filters of size 3 × 3 are applied to the input of 112 × 112 × 3. Here, 112 × 112 × 3 stands for width, height, and channel number, separately. Thus, a feature map of 112 × 112 × 32 is acquired. It can be computed according to the following standard: (output height = (input height - filter height + 2 × number of padding)/number of stride + 1) [49]. As shown in Table I, the height of input, height of filter, number of padding, and number of stride are 112, 3, 0, and 1 separately. From that the height of output of the feature map was obtained by the convolution is computed as 110 = ((112 - 3 + 2 × 0)/1 + 1). If the value is positive, it can be valid output used in the next layer. If the value is negative, the output is 0.

E. Activation

The Rectified linear unit (ReLU) activation function [46].

$$ReLU = \max(0, x) \quad (1)$$

The ReLU function is not differentiable across the entire interval, but the non-differentiable part can be performed using Sub-gradient. Instead, ReLU is the most frequently used excitation function in recent years. Because of its following characteristics, including: solving the problem of gradient explosions, calculating quite quickly, and converging quickly, it will be analyzed in detail below.

For neural networks such as error back transfer operation (BN), gradient calculation considerations are most important when updating weights. Sigmoid function [50] is prone to vanishing gradient problems. When the input value approaches the saturation region (sigmoid function). When the excitation is performed outside [-4, +4], the first-order differential value approaches 0, and the problem of gradient disappearance occurs, which makes the backward transfer of the error calculation impossible, and the weight update cannot be performed effectively, and the neural network layer is deepened. The time is more obvious. Therefore, it is a difficulty encountered in deep neural network training, and the piecewise linear nature of ReLU can effectively overcome the problem of gradient disappearance. In our research, each convolutional layer is followed by one ReLU activation and one max pooling layer in Table I. The size of filter and stride within each max pooling layer is 2 × 2 and 1 × 1, respectively. As shown in Fig. 6, the size of each feature map is reduced by a pooling layer, ReLU-1 (110 × 110 × 32) is decreased to Pool-1 (55 × 55 × 32), ReLU-2 (55 × 55 × 32) to Pool-2 (24 × 24 × 32), ReLU-3 (24 × 24 × 32) to Pool-3 (10 × 10 × 64) and ReLU-4 (10 × 10 × 64) to Pool-4 (5 × 5 × 64).

After the four convolutional layers (with ReLU activation [46]), and 4 max pooling layers (with ReLU activation), we obtained the final feature map size of 5 × 5 × 64 pixels. And final feature map would be processed by the additional two fully connected layers. For each fully connected layers, the feature maps are separately of 400 × 1 and 5 × 1 as shown in Table I. In our driver attention classification system, the driver's attention zone is classified by . And the gaze zones of the vehicle are five as shown in Fig.6, hence after the softmax function' [47] in the last fully connected layer, we will determine which classification among these five is our final result according to the maximum probability calculated by the softmax function. In the last fully connected layer, the softmax activation is adopted as presented in Equation (1). Here, V_i is the output of the classifier's previous output unit; i is the category index; The total number of categories is C . S_i stands for the ratio of the index of the current element to the sum of the indices of all elements. (1) From the observation during the deep learning process that the accuracy of training set is very high, but the prediction accuracy is extremely low of validation set. This is due to the over-fitting issue. The over-fitting means that the learning is performed too thoroughly, and all the features of the training set have been learned, so the machine has learned too many local features, and too many fake features due to noise, which caused the model to fail.

In this research, we leverage data augmentation and dropout methods [51] for preventing the over-fitting problem. For data augmentation methods, the details of it will be discussed. In the dropout methods, we decide to dropout probability of 50 per cent after the the 1st fully connected layer. After the four convolutional layers (with ReLU activation),

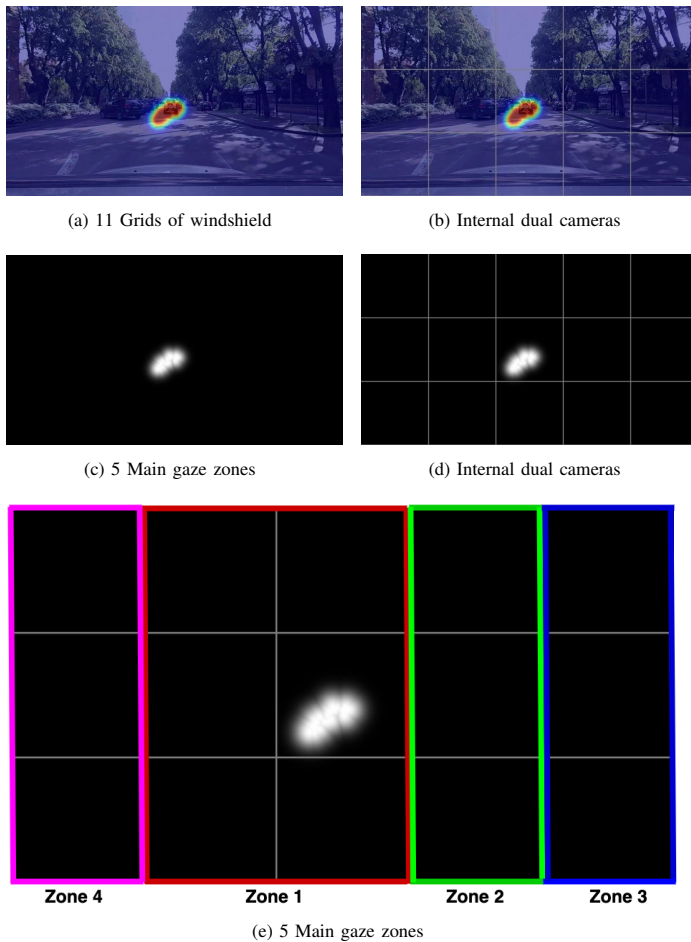

Fig. 7. Example Images of Driver's Face Landmark (left), after OpenFace Capture Driver's Attention (middle), and Driver's Facial Feature Image (right) while Looking at Distinct Zones of Fig. 2. Cases of Looking at (a) Zone 1; (b) Zone 2; (c) Zone 3; (d) Zone 4; (e) Zone 5.

and four max pooling layers (with ReLU activation), and 2nd fully connected layers (with ReLU and Softmax activation), the estimation zone of driver attention is obtained.

F. Model Improvement

We have used the DNN model to estimate the driver's gaze zone on the windshield of the vehicle. When the driver does not pay attention on the area where they should be focus, we should give a warning. We use the DR(eye)VE dataset to improve our model based on the attention zones of a real road driving scene. The DR(eye)VE dataset [6], it contains six hours of driving data, including 555,000 images, 74 video sequences of five minutes each. Videos were recorded in various environments, such as highway, downtown and countryside, sunny, rainy, cloudy, daytime and night. Because the DR(eye)VE project is currently the largest dataset of driving scenes with driving attention zones are available, we leverage its saliency maps dataset to compare to the estimation zone of driver to ensure whether or not to make the alarm during the driving.

Here we are using sequence videos in the DR (eye) VE dataset to simulate real road driving scene. In this work, we

divide at a rate of 5 frames per second to the videos into 1800 frames. In our research, the saliency maps are divided into the 15 grids. In our case, the driver's face landmark on the windshield is defined as four zones. As shown in the Fig. 7, the red block is defined as Zone 1, the reason for the larger proportion of this block is because the driver's concentration will usually focus on the front part, so our proportion in this area will be greater than other blocks. The green part is Zone 2, the blue part is Zone 3, and the purple part is Zone 4.

For performing a matching verification action with our driver's face concentration, we need to label each saliency map. For obtaining the label of our saliency maps, the filter of the size of 1×1 (stride number is 1) is used for the input of 1920×1080 pixels. We divide the 1920 by 5, then obtain a number 384 represents for each zone and then scan each pixel in each zone. The pixel of width from 1 to 384 is defined as Zone 4 (purple part of Fig. 7 (c)), 385 to 1152 is defined as Zone 1 (red part of Fig. 7 (c)), 1153 to 1536 is defined as Zone 2 (green part of Fig. 7 (c)), and 1537 to 1920 is defined as Zone 3 (blue part of Fig. 7 (c)). Since there are only pure black (0) and white (255) in the saliency map, thus the value of each pixel will be much unsophisticated. Finally, the attention zone whose final sum value is largest within 5 zones of Fig. 7 (c) is defined as the label of this saliency map.

G. Validation of Systems and Algorithms

With the road scene, we have labeled the attention area for each frame by calculating each pixel of frame. Then, we can match the prediction gaze zone of our current driver's facial image of Fig. 3 and the attention zone label of road scenarios of Fig. 7(c). After that, the driver prediction zone and road attention zone were determined whether or not identical based on label comparison. Finally, the label comparison result is obtained, the system will give a warning to driver if the final label comparison result is not matched.

IV. EXPERIMENTS AND RESULTS

A. Experiment Data

In our experiment, our dataset has been collected for the driver's attention classification system through a web camera as presented in Fig. 2. Our database was collected in an actual car instead of in a lab. There are many databases on driver concentration in previous research, such as Robust simultaneous modeling and tracking monitoring video (RS-DMV) dataset [52], The Chinese Face Database (CAS-PEAL) database [53] and Berkeley Deep Drive (BDD) [54], etc. However, these databases may not suitable for the research method we proposed this time due to the label of ground-truth attention zone is not defined. Without this key element, we cannot verify the method that purposed in this research. Therefore, we recorded our own database. In Fig. 4, 5 zones were split on the wind shield and designated to gaze at for this experiment. The size of raw image was $1920 \times 1080 \times 3$. When the experiment was starting, the driver has to perform normally, like they were actually driving in the ordinary day. After that, we cropped the size of images to 112×112 pixels of driver facial through OpenFace for DFaeP training and validation as presented in Fig. 3.

TABLE II. DESCRIPTION OF TRAINING, VALIDATION AND TESTING DATA IN OUR DATASET

Dataset	Amount
Training	7,000 (1,400 × 5) images for each gaze zone on the wind shield
Validation	2,010 (402 × 5) images for each gaze zone on the wind shield
Testing	1,802 images from the real driving scenarios

In our experiment, we performed three different DNN structures for training and validation. In here, we adopt AlexNet [55], VGG16 [56] and Dfaep model. The model structure is shown in Fig. 6. For preventing the over-fitting problem that we adopted some measures for data augmentation which are as follows. Shifting 2 pixels in vertically and horizontally and shear angle is 20 degrees in counter-clockwise direction as presented in Fig. 5. The raw images were used in validation process whereas the augmented images were used for training. In here, we used 7,000 augmented images in our dataset as training set, 2,010 images as validation set, and used completely independent 1800 images as testing set as shown in Table II. For the convolution neural network training, validation and testing, the desktop computer that we used is Intel i7-8700 CPU at 3.20 GHz and 16 GB memory. And the graphics card we used NVIDIA GeForce GTX 1070 (CUDA 10.0 and 8 GB memory). The backend was achieved by Keras (version 2.3.1) [57] with TensorFlow (version 2.1.0) [58]. And the algorithm was achieved by Visual Studio 2013, Dlib (version 19.19) and OpenCV (version 4.2.0) library.

B. Training of Dfaep Model

In this experiment, Adaptive Moment Estimation(Adam) [59] optimizer method was used in our Dfaep training. Adam is distinct to classical optimizer such as Stochastic gradient descent SGD [60], RMSprop [61] and Momentum [61], etc. Adam can be considered as a combination of RMSprop and Momentum, which uses the first and second moment estimates of the gradient to dynamically adjust the learning rate of each parameter. The main advantage of Adam is that after offset correction, the learning rate of each iteration has a certain range, making the parameters relatively stable as shown in Equations (2), (3) and (4).

$$\begin{aligned} m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_t \\ v_t &= \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \end{aligned} \quad (2)$$

$$\begin{aligned} \hat{m}_t &= \frac{m_t}{1 - \beta_1^t} \\ \hat{v}_t &= \frac{v_t}{1 - \beta_2^t} \end{aligned} \quad (3)$$

$$W \leftarrow W - \eta \frac{\hat{m}_t}{\sqrt{\hat{v}_t} + \varepsilon} \quad (4)$$

Where m_t and v_t are the weight to estimate of the first moment (the mean) and the second moment of the gradients respectively, g is the weight to gradient on current mini-batch, β_1 is used for decaying the running average of the gradient, β_2 is used for decaying the running average of the square of gradient, ε is the weight to prevent division from zero error. In our Dfaep training, the experiment was adopted for the

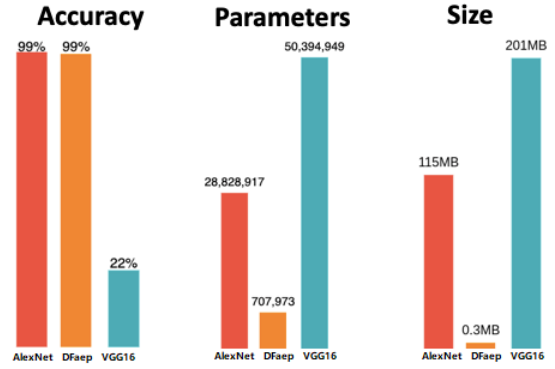

Fig. 8. The Example of Augmented Images.

TABLE III. COMPARISON OF PERFORMANCE IN THREE DIFFERENT CNNs

Network	#Parameters	#Layers	Model description	Accuracy
VGG16	50 M	16	13 conv + 3 fc layers	22 %
AlexNet	24 M	8	5 conv + 3 fc layers	99 %
Dfaep	0.7 M	6	4 conv + 2 fc layers	99 %

predefined setting. The β_1 , β_2 , and ε of Equations 2, 3 and 4 were set as 0.9, 0.999, and 10^{-8} , respectively.

In this research, we attempted AlexNet, VGG16 and Dfaep model for training and validation, respectively. As shown in Fig. 8 and Fig. 9, the visualization of the accuracy and loss during training of VGG16, AlexNet and Dfaep, respectively. The x-axis stands for epoch of training. The y-axis represents the loss and accuracy of training and validation, respectively. It can be observed from the results of training, the VGG16 model with loss 1.60952 and training accuracies 0.2046, the AlexNet model with loss 0.01979 and training accuracies 0.9934 and our Dfaep model with loss 0.01803 and training accuracies 0.9938.

It can be concluded from the observation that the accuracy of the VGG16 model is the lowest 0.2046 (20%), and the accuracy of AlexNet and our Dfaep model is very similar, their accuracy curves close to 1 (100%). However, compared to Dfaep and AlexNet, the depth of the Dfaep model structure is only 6 layers which is shallower than the 8 layers used by AlexNet. Moreover, the parameter amount of Dfaep is less than one-third of AlexNet and the storage size of Dfaep is only 0.3MB, this makes Dfaep's training efficiency and time consumption greatly lead AlexNet, and has achieved close to 100% accuracy as shown in Table III. From observation, because the rate of accuracy and amount of parameters can be changed according to the different construction of the Dfaep such as depth, dense and kernel size. Therefore, even the input data are the identical, the accuracy will not be proportional to the depth of the model.

C. Validation of Proposed Method

In the next experiment, we have made the comparison of the results of internal and external vehicle driving data as shown in Table III. We have matched the prediction results of driver's gaze zone and the salient point of DR(eye)VE

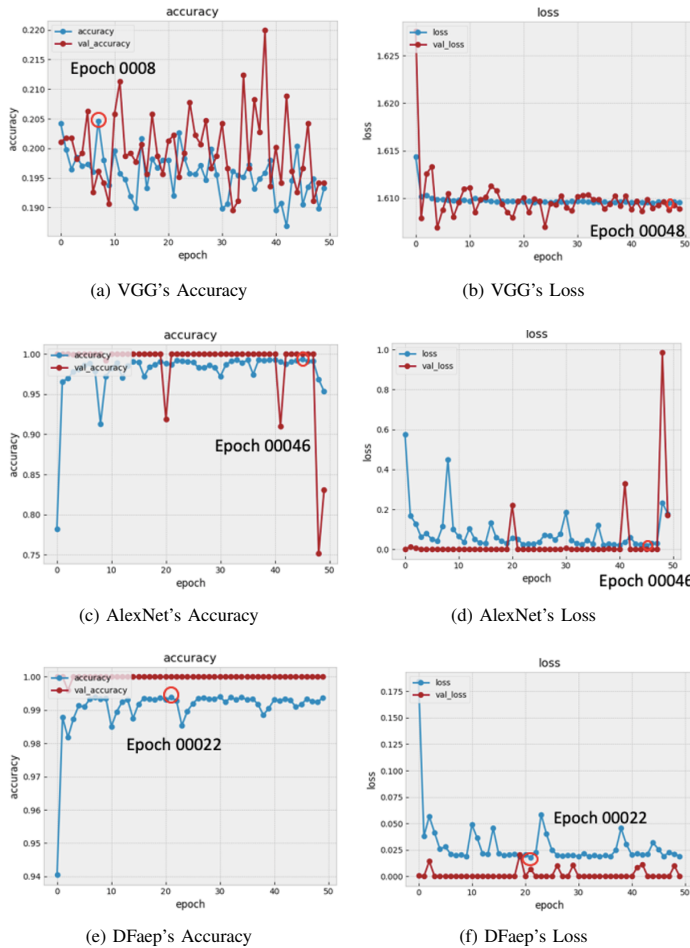

Fig. 9. The Diagram of Loss and Accuracy of Training and Validation According on the Number of Epoch with Three Models of (a-b) VGG; (b-c) AlexNet; and (e-f) DfAep.

Fig. 10. The Confusion Matrix with the DR(eye)VE Dataset.

database through the confusion matrix (as shown in Fig. 10) for evaluating whether or not the results are consistently as shown in Table III. We compared the prediction results of driver's facial feature inside the vehicle with using external vehicle driving data. Table III presents the comparison results from the data internal and external the vehicle.

“Road” and “Driver” stand for the zone which driver should be attended to and estimation zone of driver, separately. By observing the results of the confusion matrix in Fig. 10, almost

TABLE IV. ESTIMATION ZONES AND ATTENTION AREAS OF DRIVER AND ROAD SCENE

Data	Zone 1	Zone 2	Zone 3	Total
Driver	1787	3	0	1800
Road Scene	1642	153	5	1800

Fig. 11. The Synchronous Comparison of Estimation Zones and Attention Areas.

all the attention zones have concentrated on zone 1. Although the direction of gaze regions is sparse, the method proposed in this research has demonstrated is doable. Later, we obtained the different matched results by confusion matrix for giving appropriate alert to driver as shown in red block of Table IV. These matched gaze zone are mostly concentrate in zone 1. Therefore, we found that it is comply to human driving behaviors in the normal daily driving. In Fig. 11 demonstrates the synchronous comparison of estimation zones and attention areas.

V. CONCLUSION

In this paper, we have proposed a deep learning network to map the driver's attention zone interior of the vehicle environment. For driver gaze zone mapping, driver's face landmark, head position, eye gaze images are captured by the dual low-cost dash cameras. We have performed facial feature tracker with Openface for extracting the images of driver's facial landmark. We have extracted the feature of input image and located the final gaze zone from our network based on the the final score of fully connected layer. The final score of fully connected layer is obtained based on all the extracted features calculated by softmax function to derive the final result. We have compared the losses and accuracies of our idea with three different DNN architecture. Based on the performance of these three models, our DfAep network not only has shown a high scale of accuracy but also performed low level of parameters and storage size. We have demonstrated that such a focus model can detect a large proportion of a driver's focus and is even fast with high acceptable accuracy for detecting distraction and sending a warning or an alert to the driver whenever it is needed. Additionally, we show evidence that such a deep learning network and its trained model provide a feasible way for understanding the driver's attention and focus and making it possible to tame the uncertainty and dynamics of driver's attention and corresponding behaviors.

Empowered by the learnt model trained by the DFaeP network, we have conducted multiple test driving. By comparing the estimation zone of driver and the normal attention area of the road scene, warning is issued when the driver has any abnormal driving behavior or distraction during driving (see Fig. 11). From the results, we can see that the method proposed in this study is feasible and effectiveness. The propose network and trained model can be used to offer potential reduction of driving distraction and help drivers be more focus on roads during driving in such a way that road and driving safety can be significantly improved. In the future, we need to further split the zones and improve the accuracy. In our study, we notice that the distribution of driver's attention and focus are highly skewed. To estimate driver attention and focus, the zones defined in this work are needed to be further splitted or refined dynamically by road scene. Moreover, it is noteworthy to introduce road sense semantic segmentation and object detection into our network to estimate driver's interests for better prediction performance.

Predicting Strength Ratio of Laminated Composite Material with Evolutionary Artificial Neural Network

Huiyao Zhang¹, Atsushi Yokoyama²
Department of Fiber Science and Engineering
Kyoto Institute of Technology
Kyoto, JAPAN

Abstract—In this paper, an alternative methodology to obtain the strength ratio for the laminated composite material is presented. Traditionally, classical lamination theory and related failure criteria are used to calculate the numerical value of strength ratio of laminated composite material under in-plane and out-of-plane loading from a knowledge of the material properties and its layup. In this study, to calculate the strength ratio, an alternative approach is proposed by using an artificial neural network, in which the genetic algorithm is proposed to optimize the search process at four different levels: the architecture, parameters, connections of the neural network, and active functions. The results of the present method are compared to those obtained via classical lamination theory and failure criteria. The results show that an artificial neural network is a feasible method to calculate the strength ratio concerning in-plane loading instead of classical lamination and associated failure theory.

Keywords—Classical lamination theory; genetic algorithm; artificial neural network; optimization

I. INTRODUCTION

Fiber-reinforced composite materials have gained increasing attention due to their superior mechanical performance in stiffness, strength, and specific gravity of fibers over conventional materials. Laminated composite material takes advantage of fiber-reinforced composite material, and finds wide application in a variety of applications, which include electronic packaging, sports equipment, homebuilding, medical prosthetic devices, high-performance military structures, etc. The mechanical properties of composite laminated are determined by stacking sequence, ply thickness, fiber orientation, and material for each ply. Strength ratio [1], [2], [3], [4], [5], [6], [7], [8] is a critical index to predict the performance of a laminated composite material. There are two approaches for solving this problem: analytical methods, such as classical lamination theory (CLT); data-driven methods, such as artificial neural networks (ANN).

The analytical approach involves a two-step procedure to obtain strength ratio: first, develop the stress and strain relationship among in-plane loading using classical lamination theory based on a knowledge of the composite laminate properties of the individual layers and the laminate geometry; then calculate the strength ratio according to associated failure criteria, such as Tsai-Wu failure criterion, based on the above-obtained stress and strain relationship. However, the use of CLT needs intensive computation since it involves massive matrix multiplication and integration operation.

The other approach to this problem is using an artificial neural network, which is a data-driven method, instead of

an analytical method. ANN, heavily inspired by biology and psychology, is a reliable tool instead of a complicated mathematical model, which can accelerate the calculation process and reduce the computation cost. It has been widely used to solve various practical engineering problems in applications [9], [10], such as pattern recognition, nonlinear regression, data mining, clustering, prediction, etc. Evolutionary artificial neural networks are a subclass of artificial neural networks, in which evolutionary algorithms are introduced to design the topology of an ANN. For an artificial neural network, the number of layers, the connection between neurons, the activation functions used in every neuron, etc. are critical components to its performance. The design of an ANN can be treated as an optimization procedure of discrete variables, which can be solved by a genetic algorithm (GA). It is claimed that the combinations of artificial neural networks and evolutionary algorithm [11] can significantly improve the performance of intelligent systems than that rely on ANNs or evolutionary algorithms alone.

GA, inspired by Darwin's principle of survival of the fittest, is widely adopted to obtain the global optimal for discrete optimization problems. The techniques used in this algorithm, such as selection, crossover, mutation, are derived from natural selection, and individuals with better fitness get more chances to breed. Therefore, GA can be integrated into the design of ANN, in which encoding the information of an artificial neural network into a chromosome [12], [13].

The rest of this paper is organized as the following: Section II introduces the CLT and the failure criteria, which is used to check whether the composite material fails or not in the present study; Section III covers the design of an artificial neural network for a function approximation; Section IV reviews the use of the genetic algorithm in the design of neural network architecture, and the techniques of parameters optimization during the training process; Section V presents the result of the numerical experiments in different cases; in the conclusion part, we present and discuss the experiment results.

II. CLASSICAL LAMINATION THEORY AND FAILURE CRITERIA

A. Classical Lamination Theory

Classical lamination theory derives from three simplifying assumptions in laminated composite material: the laminate consist of plies bonded together through the thickness, the thickness of each ply is small, and it is consists of homogeneous, orthotropic material; the entire laminated composite

is only under in-plane loading; the Normal cross-section of the laminate is vertical to the deflected middle surface. Fig. 1 shows the coordinate system used for an angle lamina. The axis in the 1-2 coordinate system is called the local axis or the material axis, and the axis in the x-y coordinate system is called the global axis.

A few cases of laminates, such as symmetric laminates, cross-ply laminates, play an important role in the application of laminated composite material. A laminate is called an angle ply laminate if it has plies of the same material and thickness and is only oriented at $+\theta$ and $-\theta$ directions. A model of an angle ply laminate is as shown in Fig. 2.

1) *Stress and Strain in a Lamina:* For a single lamina under in-plane loading whose thickness is relatively small, suppose the upper and lower surfaces of the lamina are free from external loading. According to Hooke's law, the three-dimensional stress-strain equations can be reduced to two-dimensional stress-strain equations in the composite material. The stress-strain relation in local axis 1-2 is

$$\begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{bmatrix} = \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{bmatrix}, \quad (1)$$

where Q_{ij} is the stiffness of a lamina. And they are related to engineering elastic constants as follows:

$$\begin{aligned} Q_{11} &= \frac{E_1}{1-\nu_{12}\nu_{21}}, \\ Q_{22} &= \frac{E_2}{1-\nu_{12}\nu_{21}}, \\ Q_{66} &= G_{12}, \\ Q_{12} &= \frac{\nu_{21}E_2}{1-\nu_{12}\nu_{21}}, \end{aligned} \quad (2)$$

where $E_1, E_2, \nu_{12}, G_{12}$ are four independent engineering elastic constants, which are defined as follows: E_1 is the longitudinal Young's modulus, E_2 is the transverse Young's modulus, ν_{12} is the major Poisson's ratio, and G_{12} is the in-plane shear modulus.

Fig. 1. The Left Diagram Shows the Local and Global Axis of an Angle Lamina, which is from a Laminate as Shown in the Right Diagram.

Fig. 2. Model for Angle Ply Laminate.

Stress-strain relation in the global x-y axis is

$$\begin{bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{bmatrix} = \begin{bmatrix} \bar{Q}_{11} & \bar{Q}_{12} & \bar{Q}_{16} \\ \bar{Q}_{12} & \bar{Q}_{22} & \bar{Q}_{26} \\ \bar{Q}_{16} & \bar{Q}_{26} & \bar{Q}_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x \\ \varepsilon_y \\ \gamma_{xy} \end{bmatrix}, \quad (3)$$

where

$$\begin{aligned} \bar{Q}_{11} &= Q_{11}\cos^4\theta + Q_{22}\sin^4\theta + 2(Q_{12} + 2Q_{66})\sin^2\theta\cos^2\theta, \\ \bar{Q}_{12} &= (Q_{11} + Q_{22} - 4Q_{66})\sin^2\theta\cos^2\theta + Q_{12}(\cos^4\theta + \sin^4\theta), \\ \bar{Q}_{22} &= Q_{11}\sin^4\theta + Q_{22}\cos^4\theta + 2(Q_{12} + 2Q_{66})\sin^2\theta\cos^2\theta, \\ \bar{Q}_{16} &= (Q_{11} - Q_{12} - 2Q_{66})\cos^3\theta\sin\theta - (Q_{22} - Q_{12} - 2Q_{66})\sin^3\theta\cos\theta, \\ \bar{Q}_{26} &= (Q_{11} - Q_{12} - 2Q_{66})\cos\theta\sin^3\theta - (Q_{22} - Q_{12} - 2Q_{66})\cos^3\theta\sin\theta, \\ \bar{Q}_{66} &= (Q_{11} + Q_{22} - 2Q_{12} - 2Q_{66})\sin^2\theta\cos^2\theta + Q_{66}(\sin^4\theta + \cos^4\theta). \end{aligned} \quad (4)$$

2) *Stress and Strain in a Laminate:* For forces acting on laminates, such as in plate and shell structures, the relationship between applied forces and displacement can be given by

$$\begin{bmatrix} N_x \\ N_y \\ N_{xy} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x^0 \\ \varepsilon_y^0 \\ \gamma_{xy}^0 \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{16} \\ B_{11} & B_{12} & B_{16} \\ B_{16} & B_{26} & B_{66} \end{bmatrix} \begin{bmatrix} k_x \\ k_y \\ k_{xy} \end{bmatrix}, \quad (5)$$

where N_x, N_y refers to the normal force per unit length; N_{xy} means shear force per unit length; ε^0 and k_{xy} denotes mid plane strains and curvature of a laminate in x-y coordinates. The mid-plane strain and curvature is given by

$$\begin{aligned} A_{ij} &= \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k - h_{k-1}) i = 1, 2, 6, j = 1, 2, 6, \\ B_{ij} &= \frac{1}{2} \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k^2 - h_{k-1}^2) i = 1, 2, 6, j = 1, 2, 6, \\ D_{ij} &= \frac{1}{3} \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k^3 - h_{k-1}^3) i = 1, 2, 6, j = 1, 2, 6. \end{aligned} \quad (6)$$

The [A], [B], and [D] matrices are called the extensional, coupling, and bending stiffness matrices, respectively. The extensional stiffness matrix [A] relates the resultant in-plane forces to the in-plane strains, and the bending stiffness matrix [D] couples the resultant bending moments to the plane curvatures. The coupling stiffness matrix [B] relates the force and moment terms to the midplane strains and curvatures.

B. Failure Criteria for a Lamina

Failure criteria for composite materials are more difficult to predict due to structural and material complexity. The failure process of composite materials can be regarded from microscopic and macroscopic points of view. The most popular criteria about the failure of an angle lamina are from the macroscopic point of view, which are according to the tensile, compressive, and shear strengths. As shown in Fig. 3, there are two types of failure criteria [14], [15], [16], [17], [18], [19], [20], [21] according to failure surfaces. The first failure surface is a rectangle that includes the maximum stress failure criterion [22], and maximum strain failure criterion. The second failure surface is ellipsoidal that includes Tsai-Wu [23], [24], Chamis, Hoffman, and Hill criteria. In the present study, the two most

reliable failure criteria are adopted, Maximum stress and Tsai-wu. Both these failure criteria are based on the stress in the local axis instead of principal normal stress and maximum shear stresses, in which four normal strength parameters and one shear stress are involved. The five strength parameters are:

$(\sigma_1^T)_{ult}$ = ultimate longitudinal tensile strength(in direction 1),

$(\sigma_1^C)_{ult}$ = ultimate longitudinal compressive strength,

$(\sigma_2^T)_{ult}$ = ultimate transverse tensile strength,

$(\sigma_2^C)_{ult}$ = ultimate transverse compressive strength, and

$(\tau_{12})_{ult}$ = and ultimate in-plane shear strength.

1) *Maximum stress (MS) failure criterion:* Maximum stress failure criteria are consist of the normal stress theory and the shear stress theory. The stress applied to a lamina can be resolved into the normal stress and shear stress in the local axis. The lamina fails if either of the normal stress or shear stress in the local axis of a lamina is equal or exceeds the corresponding ultimate strengths of the unidirectional lamina. That is,

$$\begin{aligned} \sigma_1 &\geq (\sigma_1^T)_{ult} & \text{or} & & \sigma_1 &\leq -(\sigma_1^C)_{ult}, \\ \sigma_2 &\geq (\sigma_2^T)_{ult} & \text{or} & & \sigma_2 &\leq -(\sigma_2^C)_{ult}, \\ \tau_{12} &\geq (\tau_{12})_{ult} & \text{or} & & \tau_{12} &\leq -(\tau_{12})_{ult}, \end{aligned} \quad (7)$$

where σ_1 and σ_2 are the normal stresses in the local axis 1 and 2; τ_{12} is the shear stress in the symmetry plane 1-2.

2) *Tsai-Wu failure criterion:* The Tsai-Wu criterion is one of the most reliable static failure criteria derived from the von Mises yield criterion. A lamina is considered to fail if

$$\begin{aligned} H_{11}\sigma_1 + H_{22}\sigma_2 + H_6\tau_{12} + H_{11}\sigma_1^2 + H_{22}\sigma_2^2 \\ + H_{66}\tau_{12}^2 + 2H_{12}\sigma_1\sigma_2 < 1 \end{aligned} \quad (8)$$

is violated, where

Fig. 3. Schematic Failure Surfaces for Maximum Stress and Quadratic Failure Criteria.

$$\begin{aligned} H_1 &= \frac{1}{(\sigma_1^T)_{ult}} - \frac{1}{(\sigma_1^C)_{ult}}, \\ H_{11} &= \frac{1}{(\sigma_1^T)_{ult}(\sigma_1^C)_{ult}}, \\ H_2 &= \frac{1}{(\sigma_2^T)_{ult}} - \frac{1}{(\sigma_2^C)_{ult}}, \\ H_{22} &= \frac{1}{(\sigma_2^T)_{ult}(\sigma_2^C)_{ult}}, \\ H_{66} &= \frac{1}{(\tau_{12})_{ult}^2}, \\ H_{12} &= -\frac{1}{2} \sqrt{\frac{1}{(\sigma_1^T)_{ult}(\sigma_1^C)_{ult}(\sigma_2^T)_{ult}(\sigma_2^C)_{ult}}}. \end{aligned} \quad (9)$$

H_i is the strength tensor of the second-order; H_{ij} is the strength tensor of the fourth-order. σ_1 is the applied normal stress in direction 1; σ_2 is the applied normal stress in direction 2; τ_{12} is the applied in-plane shear stress.

3) *Strength ratio:* The safety factor, or yield stress, is how much extra load beyond is intended a composite laminate will take. The strength ratio(SR) is defined as

$$SR = \frac{\text{Maximum Load Which Can Be Applied}}{\text{Load Applied}}. \quad (10)$$

III. EVOLUTIONARY ARTIFICIAL NEURAL NETWORK

A. General Neural Network

In this paper, the feedforward ANN is adopted in the current study, since it is straightforward to code. For function approximation through an artificial neural network, Cybenko demonstrated that a two-layer perceptron can form an arbitrarily close approximation to any continuous nonlinear mapping [25]. Therefore, a two-layer feedforward ANN is proposed in the present study. Fig. 4 shows a general framework for a two-layer ANN, in which the number of nodes in the hidden layer and the connection with inputs, are critical in the design of an ANN. The nodes in the hidden layer are treated as feature extractors or detectors. Therefore, nodes within this layer should partially be connected with the inputs of an ANN, since the unnecessary connections would increase the model's complicity, which will reduce an ANN's performance. The number of nodes in the hidden layer should be less than the number of inputs since the nodes in the hidden layer are features. For the nodes in the last layer, every node should be fully connected with nodes in the previous layer, the relationship between the outputs and features should be direct. The rest, which affects the performance of an artificial neural network, are the activation function, and ANNs training method. In the following section, the i th node in the input layer is denoted as i_i , and the j th node in the hidden layered denoted as h_j , respectively.

B. Activation Function

The activation function is one of the critical parts of an ANN. Liu [12] et al. claims that the performance of neural

Fig. 4. Network Diagram for the Two-layer Neural Network. The Input, Hidden, and Output Variables are Represented by Nodes, and the Weight Parameters are Represented by Links between the Nodes. Arrows Denote the Direction of Information Flow Through the Network During Forward Propagation.

networks with different activation functions is different, even if they have the same architecture. A generalized activation function can be written as

$$y_i = f_i\left(\sum_{j=1}^n w_{ij}x_j - \theta\right) \quad (11)$$

where y_i is the output of the node i , x_j is the j th input to the node, and w_{ij} is the connection weight between adjacent nodes i and j . Table I display the most widely adopted activation functions in the design of an ANN, which is used in the current study.

C. Weights Learning

The weight training in an ANN is to minimize the error function, such as the most widely used mean square error function, which calculates the difference between the desired and the prediction output values averaged overall examples. Gradient descent algorithm is widely adopted to reduce the value of an error function, which has been successfully applied in many practical areas. However, this class of algorithms is plagued by the possible existence of local minima or “flat spots” and “the curse of dimensionality”. One method to overcome this problem is to adopt a genetic algorithm.

IV. METHODOLOGY

For an angle ply laminate, its strength ratio can be computed based on Tsai-Wu failure theory or maximum stress theory given the laminate’s lay-up, material properties, in-plane loading, etc. To model this function, we propose an ANN framework as shown in Fig. 6, which derives from the previous two-layer model. There are sixteen inputs of this ANN, which are in-plane loading N_x , N_y , and N_{xy} ; design parameters of a

laminate, two fiber orientation θ_1 and θ_2 , ply thickness t , total number of plies N ; five engineering constants of composite materials, E_1 , E_2 , G_{12} , and ν_{12} ; five strength parameters of a unidirectional lamina. Two outputs are strength ratio according to MS theory and strength ratio according to Tsai-Wu theory.

The work involved in the evolution process of ANN consists of three parts: search space, which includes the topology of an ANN, activation function, etc.; search strategy, which details how to explore the search space; performance estimation strategy refers to the measurement of the performance of an artificial neural network.

A. Search Space

We propose a general neural network framework as shown in Fig. 4. The search space is parameterized by four parts: (1) the number of nodes m (possibly unbounded) in the hidden layer, to further narrow down the search space, the assumption is m less than n ; (2) the type of operation every node executes, e.g., sigmoid, linear, Gaussian; (3) the connection relationship between the hidden nodes and inputs (4) the weight value in the connection if a connection exists.

Therefore, the evolution process in an evolutionary artificial neural network can be divided into four different levels: topology, learning rules, active functions, and connection weights. For the evolution of the topology, the aim is to find an optimal ANN architecture for a specific problem. The architecture

of a neural network determines the information processing capability in an application, which is the foundation of the ANN. Two critical issues are involved in the search process of an ANN architecture: the representation and the search operators. Fig. 5 summarizes these four levels of evolution in an ANN.

B. Search Strategy

It is necessary to define related operations during the GA process, which includes the representation of an artificial neural network, the fitness function that determines how good a solution is, and the search operators, such as selection, mutation, and crossover.

For the representation of an ANN, encode the h_i node as an eighteen digits binary string. The initial sixteen digits in the string correspond to the connections between i_i and h_i , with '1' implying there exists a connection between them, with '0' implying no connection exists. The last two digits in the string refer to an activation function, such as "01" which means a sigmoid function. Table II are examples of the binary representation of ANNs whose architectures are as shown in Fig. 7.

For the objective function, treat the multiplicative inverse of the mean squared error, which is the difference between the target and actual output averaged overall examples, as the fitness function.

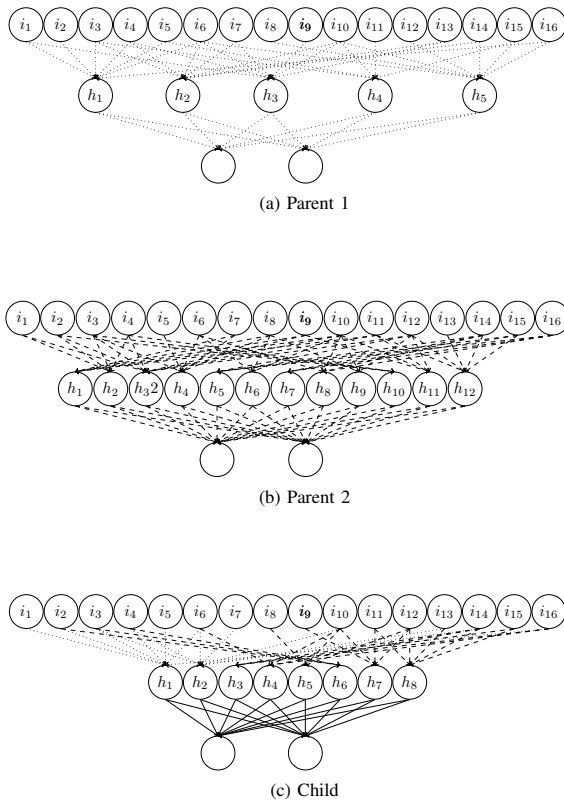

Fig. 7. Examples of three ANNs, with (a) and (b) as parent ANNs, and (c) as the child of (a) and (b). child c inherits the connection relationship part from parent 1 denoted by the darker dashed lines, and the rest from parent 2 denoted by the gray dashed line.

The crossover between individuals results in exploiting the area between the given two-parent solutions. In the present study, we search the local area by combining the genes of half number of nodes from both parents. Fig. 7 illustrates the crossover operator: Fig. 7(c) is the child of Fig. 7(a) and Fig. 7(b), the connection relationship of hidden nodes with inputs are from both parents, and the corresponding activation functions are also from both parents. In the binary representation Table II, it is shown that the first two rows of the child are the same as the first two rows of parent P_1 , and the last six rows of the child are the same as the first six rows of parent P_2 .

C. Performance Estimation Strategy

The simplest approach to this problem is to perform standard training and validation of the architecture on a dataset. However, this method is inefficient and computationally intensive. Therefore, much recent research [26] focuses on developing strategy reducing the cost of performance estimation. In this work, during the GA process, we adopt the following straightforward and efficient method to estimate the performance of an ANN: first, train a neural network one hundred times on the training dataset; second, do the validation test; measure the neural network's performance according to its fitness of objective function on the test dataset.

TABLE III. COMPARISON OF THE CARBON/EPOXY, GRAPHITE/EPOXY, AND GLASS/EPOXY PROPERTIES

Property	Symbol	Unit	Carbon/Epoxy	Graphite/Epoxy	Glass/Epoxy

V. EXPERIMENT

In the previous section, we present the details of our strategies for designing an ANN. In this section, we explain the details of the preparation of the training dataset and validation dataset.

A. Dataset Preparation

For composite material, it is impossible to obtain massive training data from the practical scenario. Therefore, we use classical lamination theory and failure theory, which follows a two-step procedure: first, evaluate the stress and strain according to classic lamination theory; second, substitute them into the corresponding equation to get the strength ratio. Repeat this procedure to yield 14000 points uniformly distributed over the domain space, and define the domain of the corresponding inputs as follows: the range of in-plane loading varies from 0 to 120; the range of fiber orientation θ is from -90 to 90; ply thickness t is 1.27mm, the number of plies ranges N is from 4 to 120. Three different composite material is used in this experiment, as shown in Table III. Table IV shows part of the training data, which are randomly selected from the generated training dataset. To speeds up the learning and accelerate convergence, the input attributes of the dataset are rescaled to between 0 and 1.0 by a linear function.

B. ANN Training and Validation

The ANN training procedure is carried out by optimizing the multinomial logistic regression objective using mini-batch gradient descent [27] with momentum. The batch size is set to 1000, momentum to 0.9. the learning rate is set to 10^{-2} . The ratio of the training dataset and validation dataset is 70/30, with 70% of the entire data for training and 30% for validation.

C. Genetic Algorithm

The genetic algorithm involves the evolution of an artificial neural network's topology, activation function, etc. in the optimizing process. The corresponding parameters are as the following. The population is 10, the percentage of parents in

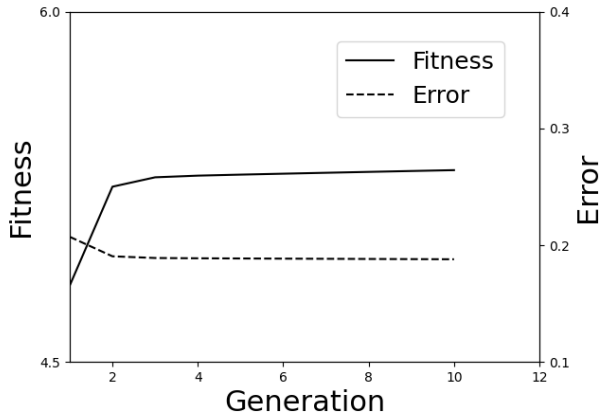

Fig. 8. Fitness and Averaged Sum-of-squares Errors of the Pre-trained Artificial Neural Network as Generations Proceed.

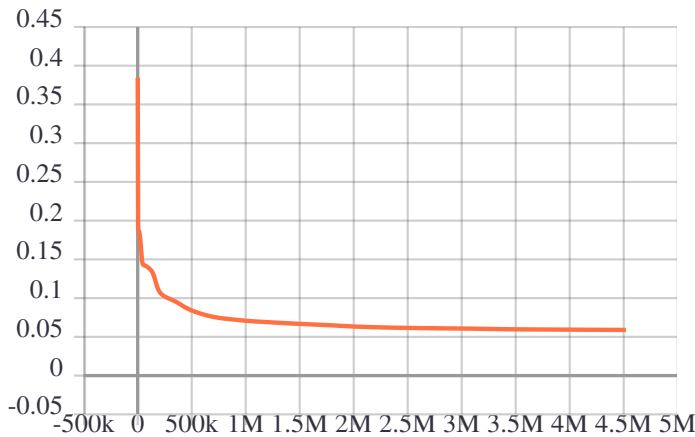

Fig. 9. The illustration of the Behaviour of Fitness on the Training Dataset During the Training Session.

the population is 40%; the strategy of selecting parents is rank-based; the mutation rate of the offspring is 0.3.

VI. RESULT AND DISCUSSION

In this work, we propose to use an artificial neural network as an alternative way to compute the strength ratio of composite material instead of a two-step procedure, based on classical lamination and failure theory. Fig. 8 shows the changes of the fitness and error during the evolution procedure. The fitness is obtained through the performance estimation technique of an artificial neural network. As shown in this figure, fitness grows during the initial stage; then, it slowly converges as generation proceeds. It implies genetic algorithm can find a better artificial neural network with the evolution of the number of neurons in the hidden layer, connection relationship, activation functions, and connection weights.

Fig. 9 shows the rest training of the artificial neural network obtained from the GA, which is a pre-trained ANN. Continue to train it with a standard gradient-based descent algorithm until the error converges. The target neural network converges rapidly at first, and further training doesn't reduce the error

TABLE V. ANN PREDICTIONS OF THE TSAI-WU AND MS STRENGTH RATIO WITH THE NUMERICAL RESULTS OBTAINED BY CLT.

Load	Input			Output			
	Laminate Structure	Material Property	Failure Property	CLT MS Tsai-Wu		ANN MS Tsai-Wu	
-10,40,20	26,-26,168,1.27	116,6,7,67,0,27,4,17	2062,0,1701,0,70,240,105	0.342	0.476	0.351	0.492
20,-70,-30	10,-10,196,1.27	181,0,10,3,0,28,7,17	1500,0,1500,0,40,246,68	0.653	0.489	0.612	0.445
60,-20,0	82,-82,128,1.27	181,0,10,3,0,28,7,17	1500,0,1500,0,40,246,68	1.663	0.112	1.673	0.189

efficiently. Then, this artificial neural network is used to predict the strength ratio of laminated composite material.

To present the evaluation result of the ANN straightforwardly, several experiment results from the validation dataset are displayed in Table V, which are randomly selected. Comparing the strength ratio outputs based on CLT and ANN from Table V, it is shown that the calculation of strength ratio can be achieved using a two-layer neural network, without the intensive computation of matrix multiplication.

VII. CONCLUSION

In this paper, an evolutionary artificial neural network model was developed to predict the strength ratio of laminated composite material under in-plane loading. We review the use of genetic algorithms and artificial neural networks as an alternative approach for calculating the strength ratio of an angle ply laminate under in-plane loading. Traditionally, it is obtained through CLT and corresponding failure criteria, such as Maximum Stress theory and Tsai-Wu failure theory.

The main contribution of this work is as follows: 1) propose a two-layer diagram model for designing a sophisticated neural network in simulating the calculation of strength ratio, and use a genetic algorithm to explore the search space; 2) suggest an efficient method to compute the strength ratio instead of adopting the two-step procedure based on classical lamination theory and related failure criteria. Compared with experimentally obtained data, it is demonstrated that ANN is an efficient and simple tool to compute the strength ratio, instead of the complex analytical mathematical model. Our findings underline the practical applicability of ANN on the analysis of composite material.

There are more improvements we can make over the search strategy and application in the area of laminated composite material. The future work is to develop a more sophisticated ANN, which not only can predict the properties for angle ply laminate, but also the other type of laminated composite material.

Abstract—Internet of Things (IoT), currently, plays an importance role in our life, also, this is one of the most rapidly developing technology trends. However, the present structure has some limitation - one of these is the communication via client-server model - the users, devices, and applications using IoT services where all the connection/requirement is managed at IoT service providers. On the one hand, the IoT service providers (e.g., individual, organization) have different method to manage their devices, services, and users. Thus, the unique standard (i.e., communication method among the service providers and between client server) is still the challenge for the developers. On the other hand, Message Queuing Telemetry Protocol (MQTT) that is one of the most popular protocols in IoT deployments, has significant security and privacy issues by itself (e.g., authentication, authorization, as well as privacy problem). Therefore, this paper proposes UIP2SOP - an unique IoT network by using Single Sign-On (SSO) and message queue to improve the MQTT protocol's security problem. Besides, this model allows the organizations to provide the IoT services to connect into a single network but does not change the architecture of organization at all. The evaluation section proves the effectiveness of our proposed model. In particular, we consider the number of concurrent users publishing messages simultaneously in the two scenarios i) internal communication and ii) external communication. In addition, we evaluate recovery ability of system when occurred broken connection. Finally, to engage further reproducibility and improvement, we share a complete code solution is publicized on the GitHub repository.

Keywords—Internet of Things (IoT); MQTT; OAuth; Single Sign-On; Kafka; message queue

I. INTRODUCTION

The Internet of Thing (IoT) services/applications grown and play a vital role in our life such services/applications have applied in most fields such as smart cities, healthcare, supply chains, industry, and agriculture. In fact, by 2025, the whole world have approximately 75.44 billion IoT-connected devices [1], [2]. However, these devices is own by the different individuals or organizations, its characteristic (e.g., capacity, communication, computation ability) is totally different. Therefore, the ability to connect IoT service providers as well as

the security issues are still an open problem and need more considerable from the developers.

The most of IoT systems, currently, are a centrally designed according to a client-server architecture [3], [4], the individual/organization requires all devices and users to authenticate exchange information through one or more of the its servers. This architecture is suitable when the number of devices is limited - one advantage can easily aware is this model can easily setup and deploy in the real environment. However, when the system is extended with a millions of users/devices join the IoT network, these may create a billion transaction among them in the short time, we should consider the latency or even the deadlock issues.

For the IoT devices, the current architecture have the limited network connectivity, power, and processing capabilities [5], [6], so there is a specific requirement for separate machine-to-machine (M2M) protocols, unlike traditional communication protocols. The five most prominent protocols used for IoT devices (i.e., communicate among them and communicate with the upper layers) are Hypertext Transfer Protocol (HTTP), Constrained Application Protocol (CoAP), Extensible Messaging and Presence Protocol (XMPP), Advanced Message Queuing Protocol (AMQP), and Message Queuing Telemetry Protocol (MQTT) [7], [8]. For the communication requirements in limited networks (constrained networks), MQTT and CoAP are more reasonable to be used [9]. Besides, we found that the MQTT protocol has faster creation time, and transmission time of the packet is twice as fast as the CoAP protocol [10]. Furthermore, for developers of low bandwidth and memory devices, MQTT is the most preferred protocol [11]. Therefore, this paper applies the MQTT protocol to develop UIP2SOP platform.

Nevertheless, the current MQTT model has some drawback especially in security and privacy issues, namely data confidentiality, availability, integrity, and privacy [12]. This model only provides identity, authentication, and authorization for the security mechanism [13] but it is very simple. Lundgren et al. [14] indicate that a simple ruby script is used to subscribe

to topic # of any random MQTT server that is public on the Internet, and the obtained result reveals the data, including the device's GPS location, without any authentication, which is a severe security risk. In the MQTT protocol, the Client ID is unique, and MQTT Broker uses this Client ID to identify the client and its status. From this feature, an attacker can take advantage of performing a denial-of-service (DoS) attack. This is considered a risk in terms of the availability of the MQTT protocol. As the studies in [12], [15] show, if the attacker subscribes to topics with the client ID, the victim encounters denial of service status, and all information sent to the victim is forwarded to the attacker.

Regarding the authentication mechanism, MQTT supports authentication by username and password pairs, but the authentication mechanism is optional and not encrypted. The MQTT client authenticates itself by sending the username and password plaintext in the CONNECT package. Attacker attacks are made quickly by blocking packets [10]. Besides, the MQTT protocol allows any user to subscribe to a broadcast topic without any authentication, and anyone who has it can easily subscribe to any MQTT server available on the Internet [13]. According to a survey of article [16] about Shodan - the world's first IoT search engine for Internet-connected devices shows that there are 67,000 MQTT servers on the public Internet, with most of them without authentication. MQTT does support an authorization mechanism to access a specific topic based on the access list (ACL). This access list must be predefined in the MQTT broker config file¹ and we must restart the MQTT broker service to apply a new access-list configuration. This is inconvenient and difficult to expand, especially for systems with billions of devices, and these devices can only have the right to act for a specified period on specific topics. The problem of access control and authorization is a significant challenge [17].

The security problems in the MQTT protocol are also in the internet connection systems aspect. In particular, due to user behavior, the MQTT's security flaws are generally vulnerable to attack by the malicious users. Users often ignore this aspect, especially privacy, until the loss of critical data [18]. Statistics from [19] show that a significant proportion of the users are not fully aware of where their pieces of information are shared. Hence, with IoT systems having a huge number of users and devices (e.g., a millions), it is quite challenging to manage all user's behavior, especially when users among IoT systems exchange information with each other.

To address the risk of security and availability of MQTT, UIP2SOP manages users, things and channels (topic). This model allows the users to own, use, and exchange messages through ensuring precisely on which channels they are sharing information. To improve the Authentication and Authorization protocol of the MQTT protocol, we propose a combination of MQTT and OAuth protocol by adding a centralized authentication management system (Single Sign-On system). Finally, we use Kafka to build a message queue system that connects discrete IoT systems. To engage further reproducibility or improvement, we share the completely code solution which is publicized on the our Github².

The rest of the paper is organized as follows. We provide the background and the related work in the next two sections. Section 4 introduces architecture of UIP2SOP and its prototype system in Section 5. In Section 6, we discuss our evaluation in the different scenarios. Finally, we conclude the key points paper and discuss further work directions.

II. BACKGROUND

A. MQTT Protocol

MQTT (Message Queue Telemetry Transport) is a messaging protocol in a publish-subscribe model, using low bandwidth and high reliability. MQTT architecture consists of two main components: Broker and Client. MQTT Broker is the central server. It is the intersection point of all the connections coming from the client. The broker's main task is to receive messages from all clients and then forward them to a specific address. Clients are divided into two groups: publisher and subscriber. The publisher is the client that publishes messages on a specific topic. Subscribers are clients that subscribe to one or more topics to receive messages going to these topics.

B. OAuth Protocol and Single Sign-On

OAuth is an authentication mechanism that enables third-party applications to be authorized by the user to access the user's resources located on another application. OAuth version 2, an upgrade of OAuth version 1, is an authentication protocol that allows applications to share a portion of resources without authenticating via username and password as the traditional way. Thereby limiting the hassle of having to enter the username, password in too many places or register too many accounts for many applications that they cannot remember.

According to the OAuth document³, there are four basic concepts, namely, Resource owners, Resource server, Clients, and Authorization server.

- **Resource owners:** are users who have the ability to grant access, the owner of the resource that the application wants to get.
- **Resource server:** a place to store resources, capable of handling access requests to protected resources.
- **Clients:** are third-party applications that want to access the resource shared by the resource owner, and before accessing, the application needs to receive the user's authorization.
- **Authorization server:** authenticates, checks the information the user sent from there, grants access to the application by generating access tokens. Sometimes the same authorization server is the resource server.

A token is a random code generated by the Authorization server when a request comes from the client. There are two types of tokens, the access token, and the refresh token. The access token is a code used to authenticate access, allowing third-party applications to access user data. This token is sent by the client as a parameter during the request when it is necessary to access the resource in the Resource server. The

¹<https://mosquitto.org/man/mosquitto-conf-5.html>

²https://github.com/thanhlam2110/uiip2sop_platform

³<https://oauth.net/2/>

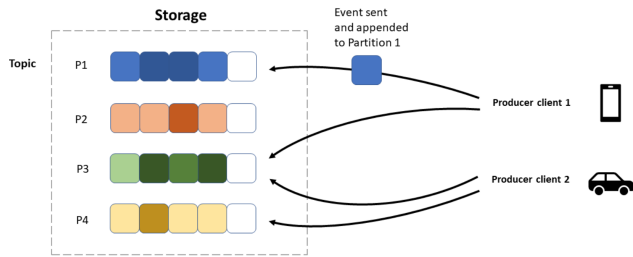

Fig. 1. The Activity Sample of Kafka [21]

access token has a reasonable time (30 minutes, 1 hour). When it expired, the client had to request the Authorization Server to get the new access token. The Authorization server also generates the refresh token simultaneously as the access token but with a different function. The refresh token is used to get the new access token when it expires, so the validity period is more extended than the access token.

Single Sign-On (SSO) is a mechanism that allows users to access multiple applications with just one authentication. SSO simplifies administration by managing user information on a single system instead of multiple separate authentication systems. It makes it easier to manage users when they join or leave an organization [20]. SSO supports many authentication methods such as OAuth, OpenID, SAML, and so on.

C. Kafka

Kafka is a distributed messaging system. Kafka is capable of transmitting a large number of messages in real-time. In case the kernel has not received the message, this message is still stored on the message queue and on the disk to ensure safety. Fig. 1 show a sample of Kafka [21].

Kafka includes the four components: producer, consumer, topic, and partition. Kafka producer is a client to publish messages to topics. Data is sent to the partition of the topic stored on the broker. Kafka consumers are clients that subscribe and receive messages from the topic. Group names identify consumers, whereas many consumers can subscribe to the same topic. Data is transmitted in Kafka by topic. Once it is necessary to transmit data for various applications, it can create many different topics. Partition is the data storage on a topic. Each topic can have one or more partitions. For each partition, the data is stored permanently and assigned an ID called offset. Besides, Kafka servers are also called a broker, and the zookeeper is a service to manage the brokers.

III. RELATED WORK

A. OAuth and MQTT

Paul Fremantle et al. [17] used OAuth to enable access control in the MQTT protocol. The paper results show that IoT clients can fully use OAuth token to authenticate with an MQTT broker. The article demonstrates how to deploy the Web Authorization Tool to create the access token and then embed it in the MQTT client. However, the article does not cover the control of communication channels, so when the properly authenticated MQTT client is able to subscribe to any topic on the MQTT broker, this creates the risk of data

disclosure. The paper presents the combined implementation of OAuth and MQTT for internal communication between MQTT broker and MQTT client in the same organization, but not the possibility of applying for inter-organization communication. Therefore, in our article, we implement a strict management mechanism for users, devices, and communication channels. We also present the mechanism of combining MQTT and OAuth protocols to authenticate users when communicating among organizations.

Benjamin Aziz et al. [22] investigated OAuth to manage the registration of users and IoT devices. These papers also introduce the concept of Personal Cloud Middleware (PCM) to perform internal communication between the device and a third-party application on behalf of the user. PCM is an MQTT broker that isolates and operates on a Docker or operating system. Each user has their PCM, and this can help limit data loss. However, Benjamin Aziz et al. also said that they do not have a mechanism for revoking PCM when users are no longer using IoT services, nor have they clearly stated the mechanism to ultimately connect PCMs to form a network for users of various organizations to communicate with each other.

B. Kafka and MQTT

A.S. Rozik et al. [21] found that the MQTT broker does not provide any buffering mechanism and cannot be extended. When large amounts of data come from a variety of sources, both of these features are essential. In the Sense Egypt IoT platform, A.S. Rozik et al. have used Kafka as an intermediary system to transport messages between the MQTT broker and the rest of the IoT system, which improves the overall performance of the system as well as provides easy scalability.

Moreover, in the previous studies [23], the authors presented Kafka Message Queue and MQTT broker's combined possibilities in Intelligent Transportation System. The deployment model demonstrates the ability to apply to bridge MQTT with Kafka for low latency and handle messages generated by millions of vehicles. They used MQTT Source Connector to move messages from MQTT topic to Kafka Topic and MQTT Sink connector to move messages from Kafka topic to MQTT topic as shown in Fig. 2.

Lam et al. [24] presented an architecture that combines MQTT broker and kafka message queue to connect different IoT service providers. This architecture allows individual service providers to communicate with each other easily without changing the existing architecture too much. In addition, Lam et al. [25] also evaluates power consumption, transfer speed, communication reliability, and security when using a combination of MQTT broker and kafka message queue. With Kafka's capabilities, we don't need to trade off transmission speed and reliability for power consumption (this is related to QoS-0 and QoS-2 levels).

In the implementation of the IoT Platform, we also adopt and extend this technique by building APIs that allow users to map their topics.

IV. UIP2SOP PLATFORM

The UIP2SOP Platform is a set of APIs combined with system architecture such as Single Sign-On system, Kafka

Fig. 2. Communication between MQTT Borker and Kafka [23].

Message Queue, and MQTT broker that provide the following capabilities:

- Authenticate information verifies the user info by granting OAuth access token and refresh token for the user.
- Management information exploits the tree model and the unlimited number of user levels created.
- Management of physical devices/ applications and communication channels participates in an IoT system.
- Sending and receiving messages locally defines a user, a thing, and a specific communication channel.
- Sending and receiving messages globally combines two various organizations through the Kafka message queue.

A. System Architecture

Fig. 3 presents an architectural proposal model of the IoT framework. Let's consider Organization A and Organization B are two separate organizations in the system. Each organization is a set of MQTT brokers that are interconnected to form a cluster MQTT broker. These MQTT brokers play two roles as follows: i) **Internal MQTT broker** is responsible for transporting messages communicating between users, IoT devices; ii) **External MQTT broker** is in charge of transporting messages communicating between two organizations. The UIP2SOP Platform system includes the Single Sign-On server and the Single Sign-On service's database cluster to perform the following tasks: i) authenticate user according to OAuth protocol; ii) manage user registration information, channels (public and local), and things. Finally, the UIP2SOP Platform

system uses the Kafka Message Queue to transport messages between two organizations' external brokers.

B. UIP2SOP Architecture

To meet the goals set out by the UIP2SOP Framework, we provide several definitions of the components involved in the system and the interaction of these components.

1) Users::

Users participate in an organization and use IoT services provided by that organization. They have two types (corresponding to the parameter field "usertype" in the database): a representation user and a normal user.

Each organization has only one representation user that created when an organization registers information of the organization with the UIP2SOP Platform. Representation users are not allow to send or receive messages through the MQTT broker or Kafka message queue. A representation user only creates an organization's public channel and the normal users use this channel to communicate with other organizations in the IoT network. Also, they manage the normal users of the organization.

The purpose in creating a representation user concept is to efficiently manage (e.g., send or receive) messages as well as the organization's (e.g., join or leave) the IoT network. All normal users have to send and receive public messages on the public channel that created and not allowed to create a public channel. Besides, the UIP2SOP Platform manager efficiently manages the entry and exit of an organization's IoT network via the organization's status (i.e., the `userstatus` parameter field in the database). When an organization leaves the IoT network or may be attacked, the UIP2SOP Platform administrator switches the `userstatus` from `ACTIVE` to `DISABLE`, which results in isolating the entire organization from the IoT network, and all normal users and devices within the organization cannot communicate with other organizations but can still communicate internally within the same organization.

Similarly, after the problem is resolved or wants to re-join the IoT network, through a representation user, the organization can request the manager of the UIP2SOP Platform to change his or her state to `ACTIVE`. By constructing a user hierarchy model tree with the child's `user_parent_id` value equal to the parent user's username, our UIP2SOP Platform allows the creation and management of multiple users' levels and is not restricted depending on the characteristics of the organization. This tree-modeled hierarchy of users makes the UIP2SOP platform more suitable for companies, especially when it comes to authorize a specific user. The user hierarchical management model is shown in Fig. 4.

A normal user registers to use the IoT services of a particular organization. They can create things, channels and assign things to channels to manage which things allowed to send and receive messages on a predefined channels. Each user has a unique `user_id` value, conforming to the `UUID4` standard created by the API and managed by the UIP2SOP Platform (user is not aware of this value). When publishing or subscribing, the user must pass his access token obtained

⁴<https://tools.ietf.org/html/rfc4122>

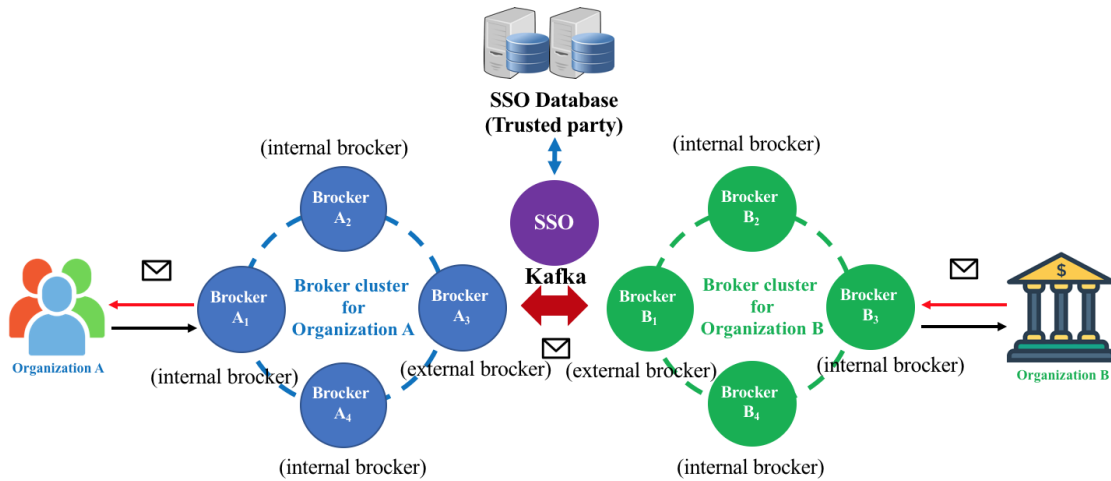

Fig. 3. UIP2SOP Platform.

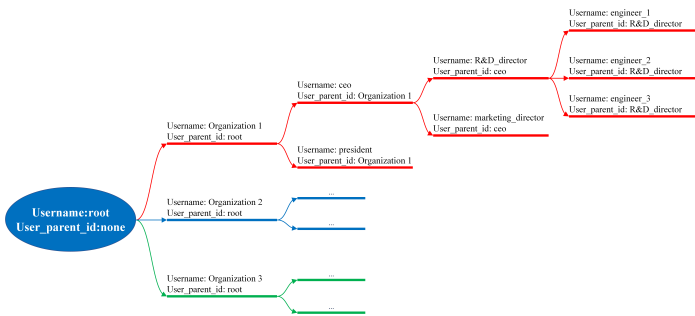

Fig. 4. Management user as a Model Tree.

from the Single Sign-On server, which contains the `user_id` information and is used as the MQTT protocol's `clientId` value. In this way, we have enhanced the authentication and authorization mechanisms for the user and minimize the risk of a denial-of-service attack when a hacker subscribes to a topic with the user's `clientId` affects the availability of the UIP2SOP Platform as we mentioned in Section I.

2) Things:

The things represent the physical devices info or the applications. To create the things, the owners need to call the API provided by the UIP2SOP Platform and pass in his/her valid OAuth token. If the user owns a valid token, the API generates the device's management information. The device's info includes two values `thing_id` and `thing_key`, corresponding to the device just created and return to the user. These two values are unique, created according to the UUID standard and used respectively with the username and password values used in the MQTT protocol. In practice, these two values are embedded in the physical device or application. Only the things that own the valid pair of `thing_id` and `thing_key`, can communicate with the MQTT broker since the other ones are not able to publish or subscribe directly to the MQTT broker. Instead, the things must go through the API layer. This layer API validates `thing_id` and `thing_key` sent by the things. Similarly, the user can create device management info to reduce the risk of denial-of-service attacks.

3) Channels and Assign Things to Channels:

In the UIP2SOP Platform, we propose, channels are the logical concept that governs topics where users and things publish and subscribe to messages. There are two types of channels: public channel and local channel.

The local channel is an MQTT topic that is created and managed by a normal user. Each normal user can create one or more local channels. Similarly, when creating a thing, the user who wants to create a channel must call the UIP2SOP Platform's API and pass in his valid OAuth token. If the user owns a valid token, the API generates the management information of the channel. This information includes value `channel_id` corresponding to the channel just created and return to the user. The `channel_id` value is unique, and according to the UUID standard, `channel_id` are returned to the user who created this channel. Each user only has his channel's informations and does not know the channel information of other users. Besides, the user has to assign things to this channels by calling the API and pass in `thing_id`, `channel_id` and his valid OAuth token. The purpose of this process is to only allow a thing with a valid `thing_id` and `thing_key` to publish and subscribe to messages on a predefined channel. From there, this help to avoid the client can subscribe to any topic. This enormously increases the authorization mechanism, which is a flexible way that the original MQTT protocol did not support. The assign things to channels mechanism also enhance security because, through our API, only things are mapped to the channel are allowed to publish and subscribe to messages on this channel.

The public channel is a Kafka topic are created by the representation user. Each organization has a unique public channel. All of the normal users of the organization have to communicate with another organization through the public channel.

4) Publish and Subscribe Message Locally: : After creating the things, the users (owners) have enough information including `channel_id`, `thing_id` and `thing_key` generated by the API layer of UIP2SOP Platform Proposal and returned to the user. Users embed three values `thing_id`, `thing_key` and their refresh token into the things (physical device or application). The process of embedding the above

information into a thing is out of this article's scope, so we are not able to elaborate on it here. The things with the necessary information embedded performs the API that provided by the UIP2SOP Platform Proposal to publish the message within the organization.

```
1 {
2   "token": "access token of publisher",
3   "thingid": "1960ff8f-ec57-4d81-b6d2-cb17e83016ad",
4   "thingkey": "3415e387-1b3b-49aa-8113-40799005f3bc",
5   "chanelid": "b7cd662c-7d15-4d6b-a8f0-d451e2f368ea",
6   "message": "Message local communication"
7 }
```

The information of token, thing_id, thing_key and channel_id are validated by the API services. If all information is correct, the message is sent to the MQTT broker; otherwise, the message is discarded. Similarly, for the Subscribe process, things also send information of token, thing_id, thing_key, channel_id to connect to the MQTT Broker through the API. If the information is not valid, the API are not allow the things to connect to the MQTT Broker.

5) *Publish and Subscribe message publicly*: : The process of publishing and subscribing to the message is described in Figure 5.

To support the communication among the users in the different organizations, our platform applies a public channel (or Kafka topic). In particular, we assign a local topic (MQTT topic) with a public channel (Kafka topic). For instance, organization A has a public channel with channel ID "95ce1a32-2136-417e-85b4-46b432f1c9ad". A user of organization A, called "user-a", wants to send a message to any user of another organization, called "user-b", he must go through this public channel and perform two steps as follows:

- Step 1: "user-a" creates a dedicated local channel to send messages to the public, assuming it is called "send-public-a". This channel is created via the API that creates a local channel, as shown in Section 4.2.3. In fact, the API uses channel_id, but for brevity, we cover the channel's name.
- Step 2: "user-a" uses the UIP2SOP Platform's API to assign the local channel just created above to the public channel. This process is equivalent create the MQTT Source Connector. After the mapping complete, "user-a" publishes the message to the "send-public-a" channel. Finally, the message is automatically routed to the public channel. The body structure to call API are as follows:

```
1 {
2   "name": "mqtt-source-for-user-a",
3   "config": {
4     "connector.class": "io.confluent.
5       connect.mqtt.MqttSourceConnector",
6     "tasks.max": "1",
7     "name": "mqtt-source-for-user-a",
```

```
  "mqtt.server.uri": "tcp://13.212.194.
    253:1883",
  "mqtt.topics": "send-public-a",
  "kafka.topic": "95ce1a32-2136-417e-85
    b4-46b432f1c9ad",
  "mqtt.clean.session.enabled": "true",
  "mqtt.connect.timeout.seconds": "30",
  "mqtt.keepalive.interval.seconds": "3
    0",
  "confluent.topic.bootstrap.servers":
    "localhost:9092",
  "confluent.topic.replication.factor":
    "1",
  "mqtt.qos": "0".
}
```

The UIP2SOP Platform builds the Kafka consumer service, which receive the message sent by "user-a", check the destination address (defined in body of public message), then forward it to the public channel of the "user-b". At that time, the message is on the public channel (Kafka topic) of "user-b". Therefore, to receive the message, the "user-b" must previously create a local channel (MQTT topic), called "receive-public-b" and map it to the public channel of "user-b". This is equivalent create an MQTT sink connector. The "user-b" uses an API provided by UIP2SOP Platform to create MQTT sink connector. The body structure creates MQTT sink connector is shown follow:

```
1 {
2   "name": "receive-public-b",
3   "config": {
4     "connector.class": "io.confluent
5       .connect.mqtt.
6       MqttSinkConnector",
7     "tasks.max": "1",
8     "mqtt.server.uri": "tcp://172.31
9       .46.150:1883",
10    "topics": "receive-public-b",
11    "mqtt.qos": "2",
12    "key.converter": "org.apache.
13      kafka.connect.storage.
14      StringConverter",
15    "value.converter": "org.apache.
16      kafka.connect.storage.
17      StringConverter",
18    "confluent.topic.bootstrap.servers":
19      "localhost:9092",
20    "confluent.topic.replication.
21      factor": "1".
22  }
23 }
```

The body structure when using API public publishing is as follows:

```
1 {
2   "token": "access token of publisher"
3   ,
4   "source": "user-a",
```

Fig. 5. Process Publish a Message to the Public.

```

4  ``destination": ``user-b",
5  ``message": ``Hello user-b"
6  }

```

V. IMPLEMENTATION

To demonstrate the practical implementation of the proposal platform, we have built a prototype of the system. We do this to answer the following research questions:

- Can UIP2SOP Platform be realizable?
- Are there any specific problems with the implementation?
- How does this performance compare to an existing system?

A. Database

As explained in Section V, the IoT Platform allows to manage the information of users, things, channels and implement assign things to channel. In practical implementation, we use MongoDB as a database management system belonging to NoSQL. To realize the model tree (select, update, delete), we have used the Aggregation technique provided by MongoDB⁵.

In the prototype system implementation we have seven data collections with the following roles:

Collection of users: store information of normal user and representation user. This collection of users are configured for the Single Sign-On system to read the information and authenticate with the parameters `username` and `password`. Our API layer (SSO proxy) also checks parameter `user_status`, if `user_status` is `ACTIVE` then API return Oauth access token and refresh token for user. We have designed the API that does not allow the users to change his or her `user_status`,

only his or her parent user can do this. Thanks to the user management design as tree model, the parent user can quickly change the status of its entire child user's status, which helps to quickly isolate all users when something goes wrong. The parameter `user_parent_id` is used to indicate the parent of the user. In our design the child user has information `user_parent_id` equal the `username` of its parent user.

Collection of things: store information of physical devices or applications managed by a normal user. The API layer (MQTT proxy) checks the parameter `thing_status`, if `thing_status` is `ACTIVE` then the things is allowed to connect to the MQTT broker. User can change the status of things which is managed by the himself. We have also designed an API that allows to change the status of the user resulting in changing the status of all of the user's things.

Collection of local channel: store local channel information (MQTT topic) managed by the normal user. API layer (MQTT proxy) checks the parameter `channel_status`, if `channel_status` is active then the thing is allowed to publish messages to the MQTT broker on this channel. User can change the status of a channel managed by the himself. We have also designed an API that allows to change the status of the user resulting in changing the status of all of the user's channels.

Collection of `things_map_channel`: stores information of thing that has been assigned to channels by a normal user to the channel. API layer (MQTT proxy) checks the parameter `map_status`, if `map_status` is active then the thing is allowed to publish the message to the MQTT broker on this channel. A user can change the status of `things_map_channel`, which is managed by himself. We have also designed an API that allows to change the status of the user resulting in changing the status of all of the user's `things_map_channel`.

Collection `MQTT_source_connector`: stores information MQTT source connector created by normal user. API layer (MQTT proxy) checks parameter `mqtt_source_status`,

⁵<https://docs.mongodb.com/manual/reference/operator/aggregation/graph-lookup/>

if `mqtt_source_status` is active then the message can be transferred from MQTT topic to Kafka topic. User can change the status of `MQTT_source_connector` managed by himself. We have also designed an API that allows to change the status of the user resulting in changing the status of all of the user's `MQTT_source_connector`.

Collection `MQTT_sink_connector`: stores the MQTT sink connector information generated by a normal user. API layer (MQTT proxy) check parameter `mqtt_sink_status`, if `mqtt_sink_status` is active then user will receive message from MQTT topic sent by Kafka topic. User can change the status of `MQTT_sink_connector` managed by himself. We have also designed an API that allows to change the status of the user resulting in changing the status of all of the user's `MQTT_sink_connector`.

B. Single Sign-On

In the prototype system, we use the open source CAS Apereo⁶ to provide the Single Sign-On service. CAS Apereo supports many protocols for implementing Single Sign-On services such as OAuth, SAML, OpenID, etc. The protocol that UIP2SOP Platform used to communicate with the Single Sign-On server is OAuth. In our implementation, the clients are not allowed interact directly with the CAS server but instead we provide the API for request OAuth token. For example, the API request token has the following body:

```
1 {  
2   ``clientid``: ``exampleOauthClient``,  
3   ``clientsecret``: ``  
4     exampleOauthClientSecret``,  
5   ``username``: ``thanhlam``,  
6   ``password``: ``12345678``.  
}
```

Fig. 6 describes an example of a the User with `DISABLE` status unable to request an `Access token`.

C. Mosquitto MQTT Broker

Mosquitto is an open source to implement MQTT broker that allows to transmit and receive data according to MQTT protocol. Mosquitto is also part of the Eclipse Foundation, the project iot.eclipse.org⁷. Mosquitto is very light and has the advantages of fast data transfer and processing speed, high stability.

D. Prototype System Deployment Model

We deploy prototype system as shown in Fig. 7.

The Prototype system we deployed on Amazon EC2 infrastructure consists of seven servers as shown in Table I.

Please add the following required packages to your document preamble:

In Table I, Organization 1 consists of two servers. The first server deploys the MQTT Broker 1a service for local communication. Second server, deploying MQTT Broker 1b

service for public communication. In addition, we deploy MQTT Proxy API service and SSO Proxy to provide APIs for users and devices to communicate with MQTT brokers and SSO through APIs in the first server. The implementation of organization 2 is similar to Organization 1.

Management Central is a single server deploying four services: Kafka, Kafka Proxy, Single Sign-On and database. Single Sign-On service creates access token and refresh token for users according to OAuth protocol. The Kafka service acts as the message queue to transport messages between Organization 1 and Organization 2. The Kafka Proxy service acts as the Kafka consumer to receive messages from Organization 1's public channel and forward it to the Organization's public channel 2. Database service to store information of users, things, channels.

VI. EVALUATION

A. Environment

After completing the deployment of the prototype system on the Amazon EC2 infrastructure, we conduct performance test scenarios of the IoT Framework. We check the number of concurrent users that can publish messages simultaneously for two cases of internal communication and external communication. We measure the time it takes to create a public channels. The test tool we use is the Apache Jmeter⁸.

Apache Jmeter is an open source, written 100% in Java, usable for performance testing on both static resources, dynamic resources and Web applications. It can be used to simulate a large number of virtual users, large requests on a server or a group of servers, a network or an object to test for load capacity or analyze the response time. Apache Jmeter provides the ability to test different applications, servers and protocols such as: Web-HTTP, HTTPS, SOAP / REST Webservice, FTP, LDAP, etc. Since our UIP2SOP Platform Protocol provides API as REST, Jmeter is a perfect fit for system load testing. Firstly, Jmeter makes requests and sends them to the server according to the predefined method, in this case it is REST. Then, it receives responses from the server, collects them and displays information in the report. Jmeter has many report parameters, but when performing system load test, we are mainly interested in two parameters: throughput and error, where the former is the number of requests processed by the server in a second and the latter is the percentage of the number of failed requests over the total number of requests. For our UIP2SOP Platform, the system crashed because the API layer is overload and can't handle request lead to crash API service.

B. Local Communication Test Cases

For the local communication test scenario, we compare the case where the user publishes the message through the MQTT Proxy API, i.e., the authentication process with Single Sign-On, checked by the MQTT Proxy and SSO Proxy, then passed to the local MQTT broker and finally received by the MQTT subscriber with case the user publishes the message directly to the MQTT broker. For two cases in the internal communication test scenario, we use Jmeter to call the API publish message locally then record the number of concurrent users and the

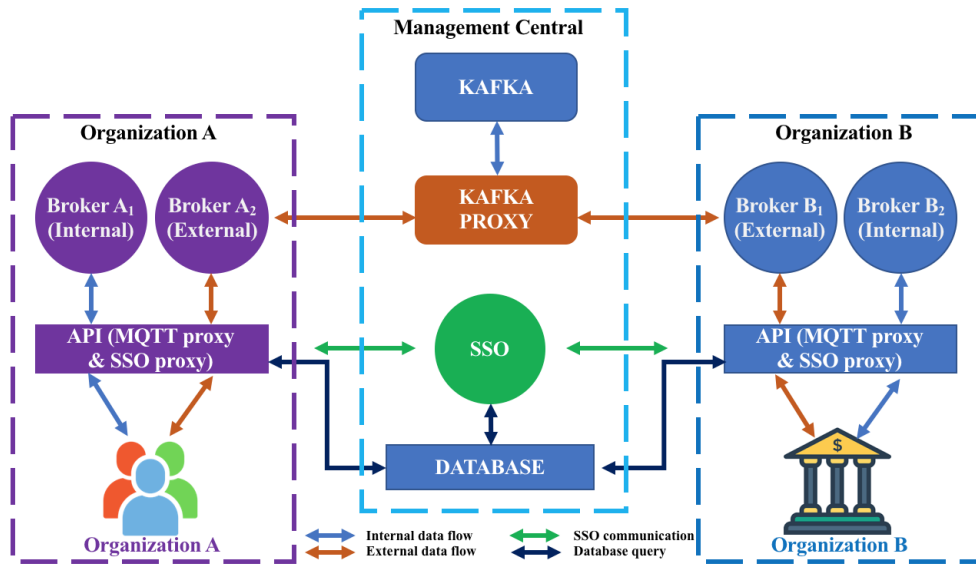

Fig. 7. Prototype System Deployment Model.

TABLE I. LIST OF INFRASTRUCTURE INFO IN THE PROTOTYPE

Zone	Server	Role	Server configuration
2*Organization A	Broker 1a	Deploy service MQTT broker for local communication Deploy service API (MQTT Proxy & SSO Proxy)	CPU 1 RAM 1 GB
	Broker 1b	Deploy service MQTT broker to serve public communication	CPU 1 RAM 1 GB
2*Organization B	Broker 2a	Deploy service MQTT broker for local communication Deploy service API (MQTT Proxy & SSO Proxy)	CPU 1 RAM 1 GB
	Broker 2b	Deploy service MQTT broker for public communication	CPU 1 RAM 1 GB
Management Central	Management Central	Deploy Single Sign-On service Deploy the Kafka service Deploy Kafka Proxy service Deploy the Database service	CPU 2 RAM 8 GB

number of requests processed per second. For MQTT Broker we use Mosquitto. The test model for internal communication is shown in the Fig. 8 and the test results are shown in Table II (via UIP2SOP Platform) and Table III (via MQTT Broker).

Through the results obtained, we found that with a server configuration of 1GB RAM and 1 CPU, the UIP2SOP Platform provides the ability to connect 450 concurrent users with a processing speed of 23.9 requests/s without error. Correspondingly, when publishing messages directly to the MQTT broker, Mosquitto can provide the ability to connect 550 concurrent users with a processing speed of 49.6 requests/s. This is reasonable and the result is completely acceptable because our UIP2SOP Platform has added the inspection and authentication mechanisms in Section IV.

C. Public Communication Test Cases

For the test scenario for public communication between organizations, we use Jmeter to call the API publish message publicly then record the number of concurrent users and the number of requests processed per second. Test model of communication between two organizations is shown in Fig. 7 and detail process is shown in Fig. 5. Test results are shown in Table IV.

According to aforementioned results, we found that with a server configuration of 1GB RAM and 1 CPU, the UIP2SOP Platform provides the ability to connect 170 concurrent users with a processing speed of 33 requests/s without error. To the best of our knowledge, we do not find any similar implementation models, so in this section we only record the measured parameters. This test result is reasonable and this result is completely acceptable because when sending messages between two organizations, the UIP2SOP Platform must perform more processing and authentication steps as we have presented in Section IV. The processing speed and the number of concurrent users can be improved by deploying the UIP2SOP Platform on a higher configuration server. In fact, APIs of the UIP2SOP Platform such as MQTT Proxy, SSO Proxy, SSO service and Kafka services should also be deployed as cluster to enhance processing capacity and high availability.

D. Broken Connection Test Cases

In addition, we also have taken test scenario with broken connection between publisher and subscriber. We compare number of receive messages in case with and without using UIP2SOP platform when occurred broken connection. The test model is shown in the Fig. 9.

The test result show that, in case without using UIP2SOP platform, subscriber only receive one message - the newest message that publisher send when occurred broken connection. This is the retain function of MQTT protocol. When we enable retain flag, MQTT broker is ability to keep only newest message that publish by publisher. This message is received by subscriber after it reconnects to MQTT broker⁹. However, when using UIP2SOP platform, subscriber can receive all message that published by publisher. This is ability of kafka message queue, therefore the system is guaranteed lost data.

E. Future Work

To develop a larger scenario and increase the number of devices/users authorized quickly, other security issues such as security, privacy, availability for objects are still the challenges. For the security aspect, further works will be deployed in different scenarios like healthcare environment [26], [27], [28], cash on delivery [29], [30]. For the privacy aspect, we will exploit attribute-based access control (ABAC) [31], [32] to manage the authorization process of the IoT Platform via the dynamic policy approach [33], [34], [35]. Finally, we will apply the blockchain benefit to improve the availability issues [36], [37], [38].

VII. CONCLUSION

The UIP2SOP Platform provides significant improvements in the security capabilities of the MQTT protocol by combining OAuth protocol (Single Sign-On), model of management user, things and channels. The procedure of assigning things to channels, strict management of local and public communication channels helps to minimize careless behavior of users when sharing data. The Kafka message queue system not only easily connects among the organizations providing IoT services to the IoT network without changing too much of the available IoT system architecture of each organization but also reduce lost data when occurred broken connection.

A Hybrid Encryption Solution to Improve Cloud Computing Security using Symmetric and Asymmetric Cryptography Algorithms

Hossein Abroshan 

Department of Business Informatics and Operations Management, Ghent University
Ghent, Belgium

Abstract—Ensuring the security of cloud computing is one of the most critical challenges facing the cloud services sector. Dealing with data in a cloud environment, which uses shared resources, and providing reliable and secure cloud services, requires a robust encryption solution with no or low negative impact on performance. Thus, this study proposes an effective cryptography solution to improve security in cloud computing with a very low impact on performance. A complex cryptography algorithm is not helpful in cloud computing as computing speed is essential in this environment. Therefore, this solution uses an improved Blowfish algorithm in combination with an elliptic-curve-based algorithm. Blowfish will encrypt the data, and the elliptic curve algorithm will encrypt its key, which will increase security and performance. Moreover, a digital signature technique is used to ensure data integrity. The solution is evaluated, and the results show improvements in throughput, execution time, and memory consumption parameters.

Keywords—Cloud computing; security; cryptography; digital signature

I. INTRODUCTION

Many organisations and individuals use cloud computing services such as PAAS (Platform as a Service), IAAS (Infrastructure as a Service), and SAAS (Software as a Service). Cloud computing is a location-independent environment that shares calculations and resources to provide high-performance services [1]. Although cloud computing makes our lives easier, it comes with security challenges and the threat of cyberattacks such as the exploitation of authentication, sniffing, spoofing, resource manipulation, etc. [2]. These security challenges become more critical in cloud computing as resources and services are shared in an open environment between and within networks. Moreover, the user is storing data in third-party locations remotely, so its security is essential [3, 4]. Therefore, the users' data should be encrypted using cryptography algorithms to protect them against unauthorised accesses and to maintain the confidentiality and integrity of the data. Several cryptographic techniques have been used to protect data in different deployment models of cloud computing: public, private, and hybrid models and different cloud services models [5]. When cloud service providers and governments provide several concurrent services for large volumes of data (i.e., Big Data), security becomes even more critical, and guaranteeing data protection, especially its integrity, becomes a difficult task [6]. Thus, it is necessary to develop new techniques to improve

security with low impact on performance and high execution time [7]. However, as cryptographic techniques are usually complex and have an overload on the processes and cloud environment (e.g., data in transit), we need better encryption solutions with the lowest possible impact on performance, hence less negative impact on the services, while providing high security and data protection. Therefore, this study proposes a hybrid cryptography solution based on an improved Blowfish algorithm.

The paper is structured as follows: the second section explains the research background and is followed by the new solution, which is explained in the third section. Finally, the proposed solution is evaluated in the fourth section, and the paper culminates with a conclusion based on the discussion thus far.

II. RESEARCH BACKGROUND

Because of the importance of security in cloud computing, many studies have been conducted on this topic. For instance, AbdElminaam [8] proposed a hybrid cryptography technique using AES (Advanced Encryption Standard) and Blowfish. They suggest that using a combination of symmetric and asymmetric techniques will provide a high cloud security. Their results show a lower encryption time and better throughput than other techniques such as using combination of AES and RSA (Rivest–Shamir–Adleman) [9]. Thabit, et al. [10] proposed a lightweight cryptography technique for cloud computing security that uses a 128-bit block cipher and key to encrypt the data. They used Feistel and substitution permutation architectural methods to make the encryption more complex. The proposed algorithm has “flexibility in the length of the secret key and the number of turns”, and the results show a low encryption time. These solutions can improve security while decreasing the encryption time, but the problem with the proposed techniques is that they need to exchange the encryption key which can make confidentiality, and as a result the whole could computing security, risky. Another study [11] utilized different cryptography techniques to improve the cloud computing security. For this purpose, an AES based encryption and asynchronous key system is consolidate in their model. They also used an Elliptic curve cryptography to secure the communications between client and cloud storage system. The proposed solution randomly generates keys based on chaotic cryptography. However, it seems that the proposed technique did not consider the time needed for split/combine of data.

There are, however, studies that use other new techniques to improve the security of cloud computing. For example, Esposito, et al. [12] suggested using blockchain for security of cloud computing. In the proposed blockchain-based ecosystem for new data a new block is instantiated and distributed to all peers in the network, and the system will insert it in the chain when majority of the peers approve the new block. This solution can provide a good level of cloud computing security as blockchain is secure by design. Although the blockchain-based solution has many benefits such as high level of data integrity as, for instance, when data stored in the chain it is not possible to alter it, there are some challenges with this solution. For example, it might breach data protection regulations (such as GDPR¹) as personal sensitive data shall be stored for the “shortest time possible” and a time limit to erase the data must be established [13, 14]. Moreover, as it needs to be approved by more than half of the peers, it will not be possible to undo the unwanted changes or fix mistakes. Another issue with the proposed solution is that blockchain is designed to store transactional data which are small, so the solution does not perfectly work for securing all cloud computing data as many of them are large data such as images. Another study evaluated the performance and effectiveness (e.g. execution time and memory consumption) of different symmetric cryptographic algorithms [15]. There results show that Blowfish and DES (Data Encryption Standard) are better in terms of required encryption/decryption time and memory. Some studies reviewed the most important and efficient cryptographic method for cloud computing security [5, 16]. The results of the previous studies show a need for new cloud computing techniques that can improve security and at the same time have no or as less as possible negative effect on performance, to make cloud computing more secure with no effect on its services.

III. PROPOSED SOLUTION

The proposed solution is an effective technique that uses different cryptographic based data protection algorithms. The solution used symmetric and asymmetric encryption combined with an improved digital signature using an MD5² hashing function to ensure data integrity. It is necessary to consider the algorithm’s encryption speed, and the balance between performance and speed. Asymmetric key generation algorithms (i.e., public key) need more generation time than symmetric algorithms such as Blowfish, so they have a lower speed. Thus, we use an improved Blowfish (symmetric key generation) algorithm for encrypting the data in this solution. Fig. 1 illustrates a high-level diagram of the solution.

First, the hash code of the original data will be generated using MD5, which will be used to verify data integrity. In the second step, an Elliptic Curve (EC) algorithm will be used for digital signature generation and securing the MD5 code and private key. We need to have a high level of security and low length of the key and hash code, and as a result, the execution time of the EC will be decreased. Finally, the original data will be encrypted using an improved Blowfish algorithm, a

symmetric algorithm with low encryption/decryption time. In the following sections, each step of the solution is described in detail.

A. Digital Signature

This study used a digital signature together with a hashing function to assure data integrity. However, as the initial digital signature model is vulnerable to cyberattacks (i.e., the cyber attacker can create a fake digital signature by manipulating the digital signature verification process), in this solution, we first hash the message and subsequently sign the hashed message. Thus, creating a fake signature does not work for the attacker as the signature does not match the hashed message’s outcome, and the attacker cannot manipulate or damage the content of the message. Therefore, using a digital signature can be considered a robust tool for securing cloud computing [17]. Fig. 2 shows the flowchart of using a digital signature and hash code in the proposed solution.

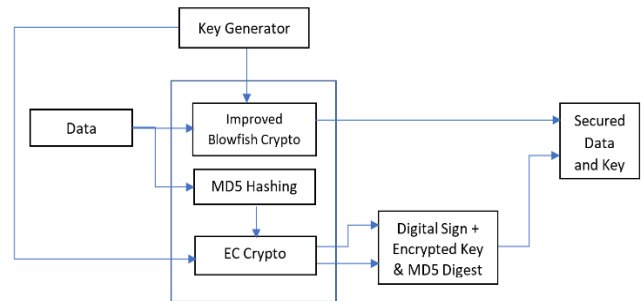

Fig. 1. High-Level Diagram of the Proposed Solution.

Fig. 2. Hash Code and Digital Signature Flowchart.

¹ General Data Protection Regulation is European personal data protection regulation.

² Message-digest algorithm

B. Data Encryption

This study aims to propose a secure cryptography technique with low execution time and high throughput, and we used an improved Blowfish algorithm in the core of the data encryption. This algorithm uses a variable key length from 32 up to 448-bits and used several subkeys [18]. The subkeys must be pre-computed before encryption/decryption of the data. This algorithm is much faster than other algorithms and requires less memory. The blowfish algorithm uses four 256 S-BOX containing a total of 1024 32-bit entries. The first byte from the first 32-bit entry will be used to find an entry in the first S-BOX, the second byte to find an entry in the second S-BOX and the same for all other entries (Modified blowfish algorithm). The same goes for the decryption procedure, starting with the cyphertext as an input, except that the subkeys will be used in a reverse way.

The F-function is the most time-consuming part of the encryption as in all rounds of the Blowfish algorithm, the F-function does the main calculation, including Adder and Rotation, in a modular format. Thus, in this study, we reduce the Blowfish's execution time by changing the F-function's module. Fig. 3 shows the overall process of the F-function module in a standard Blowfish.

To improve the algorithm, we decrease the complexity of execution time. Equation (1) calculates the value of F-function in a standard Blowfish.

$$F(X_L) = ((S_{1,a} + S_{2,b} \bmod 2^{32}) \text{ XOR } S_{3,c}) + S_{4,d} \bmod 2^{32} \quad (1)$$

We can change the F-function to equation (2), without reducing the security of the Blowfish algorithm.

$$F'(X_L) = (S_{1,a} + S_{2,b} \bmod 2^{32}) (S_{3,c} + S_{4,d} \bmod 2^{32}) \quad (2)$$

Fig. 3. F-Function Module in Blowfish.

Fig. 4. The Improved F-Function Module.

This change will allow us to do both the $(S_{1,a} + S_{2,b} \bmod 2^{32})$ and $(S_{3,c} + S_{4,d} \bmod 2^{32})$ addition operations in parallel. This parallel operation will reduce the execution time as it will reduce the needed time for two operations to one operation. As Blowfish has 16 rounds, this change should improve the execution time 16 times in each encryption and decryption. Furthermore, as the security of Blowfish is related to its keys, this change will not negatively impact the algorithm's security. Fig. 4 illustrates the mentioned change.

Pseudocode:

Pseudocode for the Blowfish algorithm based on the improved F-function

```

Element, x.
Divide x into two 32-bit halves: xL, xR
For i = 1 to 16:
    xL = xL XOR Pi
    xR = F(xL) XOR xR
    Swap xL and xR
Next i
Swap xL and xR
xR = xR XOR P17
xL = xL XOR P18
Recombine xL and xR
Function F
Divide xL into four eight-bit quarters: a, b, c and d
F(xL) = (S1,a + S2,b mod 232) XOR (S3,c + S4,d mod 232)
    
```

First, the 64-bit entry splits into two left (L) and right (R) 32-bit. The next step is a XOR operation on the first 32-bit block (L). In the third step, the calculated 32-bit data will be transferred to F-function to be XOR'd with the other 32-bit block (R). Then, the L and R will be swapped to be used in the next Blowfish rounds. The decryption operation is the same except that the P1, P2, P18 will be used in a reverse way.

C. Securing the Symmetric-Key

Symmetric-key based algorithms, such as Blowfish, need to transfer the private key, which can be risky, as attackers might steal the key (e.g., man in the middle attacks). Thus, we use an elliptic-curve-based asymmetric cryptography algorithm to secure the private key and hash code in this solution. In this method, a 164-bit key will be used to provide a higher performance than other solutions [19]. The elliptic-curve-based cryptography algorithms have a high level of security and need low memory and bandwidth [20]. One of the benefits of this encryption is cryptography over finite fields. So, the assumption is that the p is a prime number, and the finite field contains a set of numbers less than p . Following is the explanation of the two-dimensional Elliptic curve (E).

If the $p > 3$ is an odd prime, and $a, b \in F_p$ and the $4a^3 + 27b^2 \neq 0 \pmod p$, then the Elliptic curve $E(F_p)$ is equal to the equation (3).

$$y^2 = x^3 + ax + b \quad (3)$$

Using element Q , which can create a group in the $E(F_p)$ set, and considering $p=(x_1,y_1)$ and $\{p, Q\} \in E(F_p)$

For point adding $P + Q = (x_3, y_3)$ and $P \neq Q$

$$x_3 = \lambda^2 - x_1 - x_2$$

$$y_3 = \lambda(x_1 - x_3) - y_1$$

$$\lambda = (y_2 - y_1)/(x_2 - x_1)$$

For point doubling $P + P = 2P(x_3, y_3)$

$$x_3 = \lambda^2 - 2x_1$$

$$y_3 = \lambda(x_1 - x_3) - y_1$$

$$\lambda = (3x_1^2 + a)/2y_1$$

Adding two different points on the elliptic curve needs six additions, one square, two multiplications, and one inverse operation in F_p . Also, point doubling on the elliptic curve needs eight additions, two square, two multiplications, and one inverse operation. For cryptography using the elliptic curve, we first choose a random k number in a range that belongs to the field and consider it as the private key. Then, the public key Q will be calculated by $Q=kP$. In this situation, P is a point on the elliptic curve. The elliptic-curve cryptography is based on the difficulty of the discrete logarithm problem, so calculating k from the P and Q points has computational complexity, which is one of the main benefits of elliptic-curve cryptography. This method uses the following scalar multiplication.

$$Q = k.P = P + P + \dots + P \quad (4)$$

Because the operations in this method are based on the field, using Modular Multiplication can help to improve the performance of elliptic-curve cryptography. Fig. 5 shows the flowchart of this method, and the following steps describe the method in detail.

Step 1. Before the encryption, a hash code (using MD5) for the original data will be generated. This code will be used to improve the efficiency of the digital signature and data integrity verification.

Step 2. The hash code will be encrypted using the private key, and the digital signature of the data will be issued.

Step 3. The Blowfish's private key will be encrypted using elliptic-curve cryptography.

Step 4. The data will be encrypted by the symmetric cryptography algorithm (Blowfish). We use the symmetric key to encrypt the original data. Then, the encrypted data in this step and the previous steps will be transferred.

Step 5. The receiver decrypts the received data using a reverse process and the private key.

Step 6. The original data will be decrypted using Blowfish's private key, and the verification and validation process will be run using the hash function (digital signature).

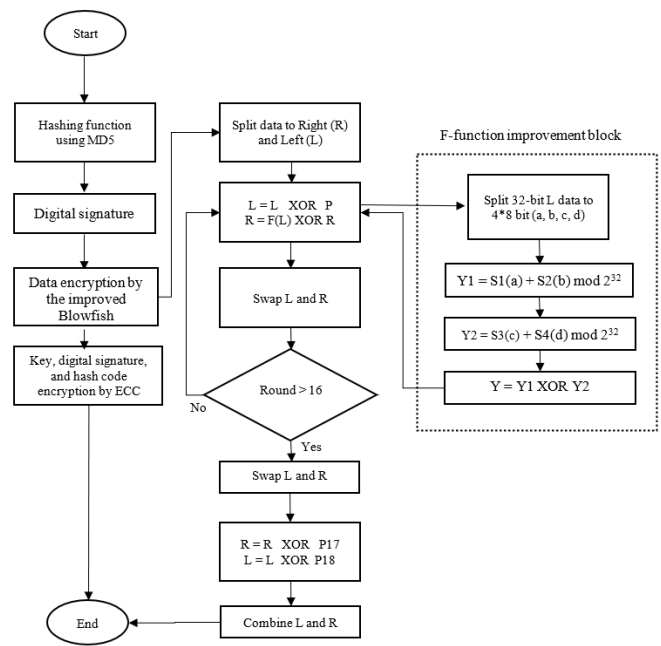

Fig. 5. The Proposed Solution's Flowchart.

IV. EVALUATION AND DISCUSSION

We implemented the proposed solution on Eclipse and by using Java development kit (JDK) version 7. The cryptography functions are available in two Java Cryptography Architecture (JCA) and Java Cryptography Extension (JCE) libraries in the JDK. The JCA provides most of the fundamental cryptography requirements, while the JCE can be used for advanced cryptography operations. The hardware used in the solution evaluation had an Intel Core2 Duo 2.5 GHz processor. All the evaluations were run in Windows 7.

Different parameters such as memory use, throughput, and execution time of the proposed solution were compared with AES, 3DES, DES, and RSA algorithms [21]. We initially evaluated the solution with a low size data (50 KB) to analyse its performance when the data is small and then evaluated the solution with larger data (i.e., 1024 KB and 2048 KB).

A. Evaluation Results – Throughput and Execution Time

The first evaluation is based on 50KB data. As fig. 6 illustrates, the execution time of the proposed technique (Hybrid) reduced 800, 550, 300 and 400 milliseconds in comparison with RSA, AES, DES, and 3DES (in order). This means that the encryption process took less time due to using the Blowfish algorithm (which is a fast algorithm) and changing the F-function. Furthermore, the asymmetric EC algorithm had no impact on the execution time as it was only used to encrypt the key and digest it.

In Fig. 7, the throughput of different techniques, with 50 KB data, are compared. As it is presented, the throughput of the proposed technique is better than the others.

Fig. 6. Execution Time with 50KB Data.

Fig. 7. Throughput with 50KB Data.

Fig. 8. Execution Time with 1024KB Data.

Fig. 9. Throughput with 1024KB Data.

Because the data size can impact the execution time, we increase the data size to 1024 KB to evaluate the solution with larger data. As shown in Fig. 8, the proposed solution has a lower execution time than the other techniques, even with a larger data size (i.e., the 1024 KB). The proposed technique (Hybrid) reduced 230, 230, 130 milliseconds in comparison with symmetric algorithms (i.e., DES, 3DES, and AES), and 731 milliseconds in comparison with the asymmetric algorithm (i.e., RSA). This shows that the proposed technique is faster than the other techniques.

Fig. 9 shows the throughputs of the selected techniques and the proposed solution with 1024 KB data. As shown, the proposed solution has better throughputs, which could be expected as the execution time of the solution is lower. The solution's throughput is, on average, 16% higher than the symmetric algorithms (AES, 3DES, and DES) and over 50% higher than the asymmetric algorithm (RSA).

Finally, we evaluate the selected algorithms with a 2049 data size. Fig. 10 and 11 show the execution time and throughput results. Increasing the data size increases the execution time, but as it was shown, the proposed solution has a lower execution time than DES, 3DES, and RSA. The execution time is 470ms lower than 3DES, 320ms lower than DES, and 670ms lower than RSA. However, the proposed solution's execution time does not work better than the AES. However, considering the other benefits such as the digital signature and hashing, we might ignore the increased execution time, as the time difference is likely to have a very low effect in the cloud computing environment. Future studies should evaluate the proposed solution in the cloud computing environment to determine how it works with larger data and if the mentioned benefits can overshadow the execution time (compared to the AES).

As Fig. 11 shows, the throughput of the proposed solution is higher than DES, 3DES, and RSA. This is because of the changes we applied to the F-function and, in fact, parallel processing in the core of Blowfish encryption. Furthermore, the data encryption and key encryption are separated in this solution, so parallel usage of Blowfish and EC did not affect the execution time and throughput as only private key hash codes are encrypted by EC, and because of their small size, this had almost no effect on the execution time. Moreover, the original data, which has a larger size, is encrypted by the improved Blowfish algorithm, which is faster and has a high performance.

Several studies proposed hybrid and multilevel encryption solutions and/or modified cryptography algorithms to improve cloud security [7, 22-26]. However, our proposed solution benefits using both symmetric and asymmetric algorithms together with a digital signature. Combining the utilised algorithms and improving the Blowfish's F-function provides high data protection and signature integrity with high-performance encryption. However, like other cloud security methods, our proposed solution should be tested and evaluated in cloud computing environments with extensive data.

Fig. 10. Execution Time with 2048KB Data.

Fig. 11. Throughput with 2048KB Data.

Fig. 12. Memory Usage.

B. Memory Consumption

Memory consumption is one of the important metrics in evaluating encryption techniques. Fig. 12 shows the used memory in the proposed solution and other selected solutions. The proposed solution used lower memory in comparison with the other techniques. The main factors that impact memory usage are the number and type of operations, size of the key and initialisation vectors [21], so we tested the memory consumption with 50KB data only. The lower memory usage of the proposed solution is because of using the Blowfish algorithm as one of the most memory-efficient cryptography

algorithms [21]. The other reason for lower memory usage is applied changes in the core of Blowfish in the proposed solution. In addition, using EC, which uses a 164-bit key that needs a low memory [27], will allow us to use the proposed solution in infrastructures with low memory resources, such as old ones.

V. CONCLUSION

This study developed an improved cryptography solution that can provide efficient and high-performance, secure cloud computing. Because the core of this solution is based on an improved Blowfish (a symmetric algorithm) which decreases the needed time for encryption, the execution time and throughput of the solution are improved. Moreover, using the EC asymmetric cryptography algorithm to encrypt the key, reduces the security challenges of symmetric key exchange algorithms, such as stealing the key in transit. In addition to the mentioned benefits, the proposed solution uses MD5-based digital signatures to provide data integrity. The solution evaluation shows an overall improvement in comparison with AES, DES, 3DES, and RSA. The throughput, memory usage, and execution time of the proposed solution were, on average, better than the other solutions. However, we found that AES was slightly faster and had higher throughput when we increased the data size. We suggest that future studies test the solution in different infrastructures, especially cloud computing environments, with a high volume of data.

Evil Twin Attack Mitigation Techniques in 802.11 Networks

Raja Muthalagu¹, Sachin Sanjay²

Department of Computer Science

Birla Institute of Technology and Science Pilani – Dubai Campus, Dubai, UAE

Abstract—Evil Twin Wi-Fi attack is an attack on the 802.11 IEEE standard. The attack poses a threat to wireless connections. Evil Twin Wi-Fi attack is one of the attacks which has been there for a long time. Once the Evil Twin Wi-Fi attack is performed this acts as a gateway to many other attacks such as DNS spoofing, SSL Strip, IP Spoofing, and many more attacks. Thus, preventing the attack is essential for privacy and data security. This paper will be going through in detail how the attack is performed and different measures to prevent the attack. The proposed algorithm sniffs for fake AP using the whitelist in all the channels, once an unauthorized AP is detected the user has an option to de-authenticate any user in the unauthorized network in case any clients do connect to it by accident also the algorithm will be checking if any de-authentication frame is being sent to any of the AP to know which of the AP is being compromised. The efficiency of proposed approach is verified by simulating and mitigating the evil-twin attack.

Keywords—Evil twin Wi-Fi attack; DNS spoofing; SSL strip; IP spoofing

I. INTRODUCTION

In today's world, wireless connections are becoming more important day by day. Almost all the appliance in use gets connected to the internet to customize, improve, and make our lives simpler, these devices are called the Internet of Things (IoT) [1]. The IoT protocol stack and some of the most used protocols and comparison of it from security aspect is discussed. Also, the paper attempts to present various challenges related to security from aspect of protocols, network, and device [2]. Various security gap in most of the current IoT technologies are reported [3-4]. The number of IoT devices will be increase in future and it is important to find specific standard and mechanism to get security in the IoT [4]. The majority of IoT devices use wireless connections to connect to the internet, this is usually IEEE 802.11 standard connection [5]. The IEEE 802.11 is specifically designed for wireless connections, the first 802.11 has been developed in 1997 and is still being improved on. This type of wireless standard is used with frequencies 2.4, 5, 60 GHz, the Evil Twin Wi-Fi attack typically targets this standard [6-9]. To detect evil-twin attack, a real-time client-side detection technique is proposed [7]. A rogue Access Point (AP) detection technique based on the round-trip time (RTT) on the mobile-user side is proposed [8]. A Convolutional Neural Network (CNN) based Evil-Twin Attack (ETA) detection technique is proposed which uses the preamble of the WiFi signal as the feature and uses it to train a CNN based classification model [9]. A novel ETS detection is proposed [10] which make use of the commonly

used network diagnostic tool traceroute. A passive ETA detection scheme is proposed [11] by using channel state information in physical layer. a scan-based self anomaly detection (SSAD), which is a client-side solution to detect and mitigate channel-based man-in-the-middle attacks using access point (AP) scans [12-13]. Even though ETA is an old attack measure taken to prevent this attack is not common and is not implemented by a majority of the population. This attack is usually performed on public Wi-Fi networks where there are multiple users connected to the public network because it is open and multiple clients are connected to it, these types of networks make it a perfect candidate to initiate and perform the attack.

The attack begins with a dummy access point being created and fooling the client's device into thinking the fake access point is a better connection, this can be done either by increasing the signal strength of the connection or by disconnecting the client from the current access point (more on this later). The attack can also be performed in another way where the attacker sniffs the previously connected Wi-Fi connections and makes a fake access point with the same configurations, the device actively searches for previously connected access point and when it finds the fake access point with the same configuration as the legitimate access point the phone connects to the fake access point (AP). Once the device has connected to the attackers AP many man-in-the-middle attacks (MITM) [14] can be performed on this device to compromise the privacy and data security of the victim. In the below sections will be going through different methods to prevent such an attack and a custom method to counter this attack which includes the algorithm and the code explained in detail.

The detection and mitigation of evil twin attacks have recently received huge attention from researchers around the world. A virtual private network (VPN) is one solution available to counter-attack the evil twin attack but it is an inappropriate solution. In general, detecting the evil twin attack can be classified into two categories: client-based solutions [15, 16] and administrator-based solutions [17-18]. Although the majority of approaches being used belong to administrator-based mechanisms, they cannot detect evil twin in real-time and have a heavy overhead. A passive user-side solution, called Wi-Fi legal access point (AP) finder (LAF) is proposed in [19], to the notorious evil twin access point problem, which provide solution to various security problems. Discrete Event System (DES) based approach for Intrusion Detection System (IDS) for evil twin attacks in a Wi-Fi network is discussed [20].

Designing a client-side approach to detect evil twins is not easy for clients because users have limited resources and without an authorization list.

This work analyzes the feature of evil twin attacks and proposes a novel algorithm for mitigating the evil twin attack in a Wi-Fi network. Our scheme can make a deterministic and accurate decision on whether the client device is connecting to an evil twin AP. The implement and evaluate the proposed scheme with real experiments is done in this paper.

The organization of the paper is as follows. The various method of performing an Evil Twin Wi-Fi attack is reported Section II. The proposed system model and algorithm discussed in depth in Section III. The outcome of the proposed methodology is illustrated in Section IV followed by conclusion in Section V.

II. HOW DOES EVIL TWIN WI-FI ATTACK WORK?

An evil twin is a fraudulent Wi-Fi access point that appears to be legitimate but is set up to eavesdrop on wireless communications [1]. To perform this attack few to no additional hardware is required as shown in Fig. 1. In the test run a laptop with a wireless card (supports monitor mode). Alternatively, one can use a raspberry pi with a wireless card and a power bank to perform the attack remotely and discretely. For simplicity, it is recommended use premade tools such as airodump-ng, airdrop-ng and aireplay-ng which can be found preinstalled in offensive operating systems such as Kali Linux, Parrot OS, and many more.

First set the card to monitor mode this can be done either through “iwconfig” or using the preinstalled tool called “airmon-ng”. Once the wireless card is in monitor mode then it can move to the next phase where it scans for the wireless connection, we want to perform the attack on. After obtain required information such as SSID, channel and other things, a malicious AP with the same configuration can be created.

Now there are two ways to do the next part one is to wait patiently for the victim’s device to connect to the attacker’s AP or we use another method, which is a flaw in the 802.11b and some other standards where the management frames are not protected or validated. This method involves sending a crafted “Death frame” to the targeted AP as depicted in Fig. 2. The AP receives the frame and forwards it to the respective clients, the clients then receive the forwarded frame and are forced to disconnect from the targeted AP. The counterfeit access point may be given the same SSID and BSSID as a nearby Wi-Fi network.

The evil twin can be configured to pass Internet traffic through to the legitimate access point while monitoring the victim’s connection [2]. What makes this attack so dangerous is that if a client does connect to this network intentionally or unintentionally, the client has no way of knowing that the device connected to the attacker’s AP and his privacy and security is compromised.

Fig. 1. Evil Twin Wi-Fi Attack Scenario.

Fig. 2. Structure of Deauthentication Frame.

III. PROPOSED SYSTEM MODEL AND ALGORITHM

The proposed system in this paper is a counterattack against the Evil Twin Wi-Fi attack. The algorithm requires a list of known BSSID for whitelisting. The algorithm sniffs for fake AP using the whitelist in all the channels, once an unauthorized AP is detected the user has an option to de-authenticate any user in the unauthorized network in case any clients do connect to it by accident also the algorithm will be checking if any de-authentication frame is being sent to any of the AP to know which of the AP is being compromised. The program checks each channel for about 2 seconds and switches to the next channel also it scans for all 14 channels available in the 2.4GHz range.

As seen in Fig. 3, there is an Evil Twin Access point that is trying to mimic the actual access point. In Fig. 4, one of the victims connects to the evil twin, the counterattack then figures out which access point gets attacked and informs the Administrator about the attack. The administrator initiates the counterattack to disconnect the user from the Evil Twin Access point. First, the wireless card must set in monitor mode. Once the mode is set, then the whitelist, network name, and wireless interface as the arguments for the program needs to be provide. The program initiates by scanning networks in all the channels and finding any BSSID which is not in the whitelist this is done by checking all the wireless beacons. In the wireless beacon, check for its BSSID if the BSSID does not exist within our whitelist then mark it.

The program also checks if there is any death frame sent this similar to the whitelist where scanning of the wireless packets is done and we specifically check if the packet contains an 802.11 death frame, if it does this packet might indicate that the transmitter of the packet is the targeted AP. For the next step, a death packet is will send to the unauthorized AP and this is done by crafting a wireless death frame and specifying the transmitter address as target AP BSSID and death reason as 7. This program can be a good counterattack against unauthorized AP. It can be used with a raspberry pi and a wireless card and placed in separate locations. This can also be used to monitor wireless networks and can trigger an attack remotely.

The Fig. 5 is the complete flow of the code done in a flowchart. Here the scanning of channel for death frames and the quit command run in parallel this is to prevent any sort of interference to the code while scanning.

Fig. 3. Evil Twin Access Point which is trying to mimic the Actual Access Point.

Fig. 4. One of the Victims Connects to the Evil Twin.

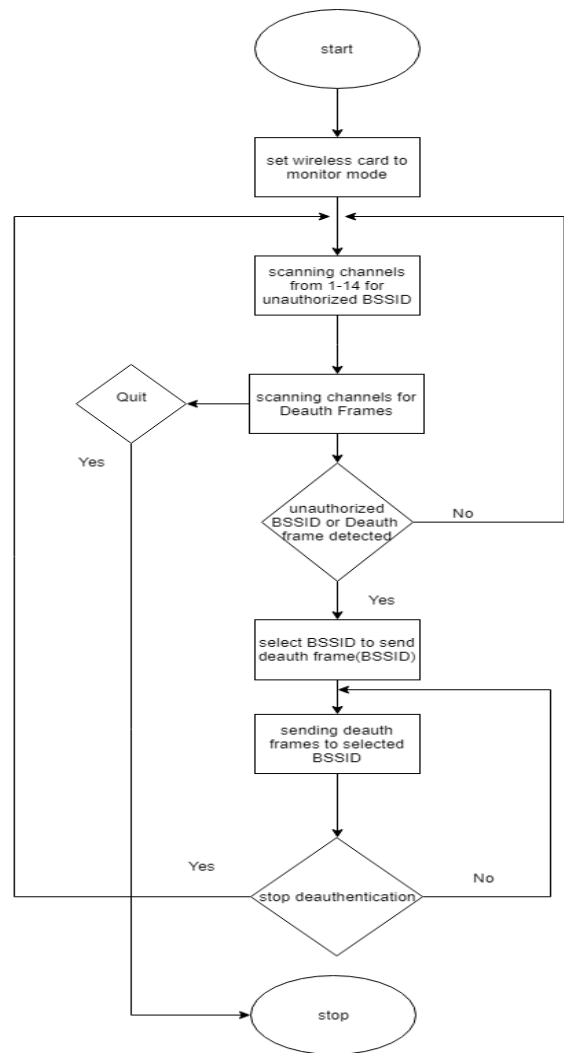

Fig. 5. Flow of the Code.

IV. RESULTS AND DISCUSSIONS

This form of counterattack provides an easier interface and simplicity as opposed to manual methods. Also, it is compulsory to spread awareness of the attack, as more people know the attack less likely they fall for the attack. There are many other methods to mitigate this attack, for example using a virtual private network whenever connecting to an open Wi-Fi connection. Another method is by the new WPA3 standards which is released couple of months ago. This standard protects the wireless management frame thereby indirectly preventing the Evil Twin Wi-Fi attack.

In the above Fig. 6, one can see that only at higher education levels that the people are more informed about the attack. A study in UK has been conducted by XIRRUS Wi-Fi Network [4], there are 8.5 million Wi-Fi hotspots available in UK. XIRRUS has surveyed over 300 respondents between 18 and 75 about how they connect to the internet, what they do when they are connected, and how they connect .79% of respondents said that they did not trust security measures on public Wi-Fi, while 62% of respondents said they still connect to public networks.

Fig. 6. Awareness Vs Education Level.

The study also showed that 58% of the survey respondents admitted using public Wi-Fi but only 7% had installed VPN service on their devices to protect their confidential data [3]. In conclusion Evil Twin Wi-Fi attack poses a serious threat to the users currently; therefore methods must be developed to prevent this attack. One of the methods which can be used to prevent such attacks is to use our proposed method where we can form an inexpensive method to counter the Evil Twin Wi-Fi attack.

V. CONCLUSION

There is always a network security threat that wireless users are vulnerable to be attacked by evil twins in WLANs so, in this paper, a novel approach to mitigating the evil twin attack to protect wireless users from the hackers is proposed. The attack is simulated, and different measures are recommended to prevent the attack. The proposed algorithm sniffs for fake AP using the whitelist in all the channels, once an unauthorized AP is detected the user has an option to de-authenticate any user in the unauthorized network in case any clients do connect to it by accident also the algorithm will be checking if any de-authentication frame is being sent to any of the AP to know which of the AP is being compromised. The efficiency of proposed approach is verified by simulating and mitigating the evil-twin attack.

Solving Reactive Power Scheduling Problem using Multi-objective Crow Search Algorithm

Surender Reddy Salkuti

Department of Railroad and Electrical Engineering, Woosong University
Daejeon, Republic of Korea

Abstract—This paper presents the solution of multi-objective based optimal reactive power dispatch (MO-ORPD) problem by optimizing the system power losses and voltage stability enhancement index (VSEI)/L-index objectives. ORPD problem is considered as an important issue from system security and operational point of view for optimal steady-state operation of power system. Here, single-objective based ORPD problem is solved using Crow Search Algorithm (CSA) and multi-objective based ORPD problem is solved using multi-objective CSA (MO-CSA). The CSA is considered as an efficient and robust algorithm which determines the global optimal solution for solving the non-linear and discontinuous objective functions. Two standard test systems, i.e., IEEE 30 and 57 bus systems are considered to show the effectiveness, suitability and robustness of CSA and MO-CSA for solving the ORPD problem.

Keywords—Optimal power flow; crow search algorithm; evolutionary algorithms; loss minimization; reactive power scheduling; multi-objective optimization

NOMENCLATURE

N_l	Number of lines
G_k	Conductance of k^{th} line
N_B	Number of buses
N_G	Number of generator/PV buses.
Q_{Gi}	Reactive power generation from the generator and VAR source at i^{th} bus
Q_{Di}	Reactive power demand at i^{th} bus
P_{Gi}	Power generation at i^{th} bus
N_c	Number of switchable capacitors/VAR sources.
$P_{inj,i}$	Active power injection at i^{th} bus
$Q_{inj,i}$	Reactive power injection at i^{th} bus
N_L	Number of load buses
N_T	Number of tap changing transformers
S_{Li}	Apparent power flowing through i^{th} transmission line

I. INTRODUCTION

Solution to the optimal reactive power dispatch (ORPD)/scheduling is required to meet the load demands at the nominal frequency as the reactive powers to maintain

nominal voltage throughout the system. The ORPD is required to obtain secured, efficient and reliable operating condition of power system. Reactive power is localized to the point where the voltage needs regulating. Generally controlling of generator voltages is done automatically at corresponding generation power plant location. Series and shunt reactive devices are on the grid also provides the required local corrections. The energy management system of power system processes the raw data to provide reliable data base for the analysis of the power network [1]. Basically it includes topology processing and state estimation. Topology processing unit uses the dynamic status of the switches, i.e. breakers and isolators, to translate the network model into a node branch representation that can be analyzed by matrix methods. State estimation calculates the complex bus voltages and branch flows using the network model parameters, and values telemetered via Supervisory Control and Data Acquisition. The state estimator output provides a reliable database for other analysis applications such as optimal power flow (OPF), ORPD, etc. From planning perspective, the OPF is used for various applications for the shunt volt ampere reactive (VAR) planning [2], transfer capability studies, series capacitor planning, loss optimization studies, and reactive interchange studies. The literature related to ORPD problem is described next.

A. Literature Review

Review of various optimization approaches developed for the solution and analysis of ORPD with the main goal of enhancing efficiency, performance and security of power system is presented in [3]. The author in [4] solves the ORPD problem with voltage stability enhancement, and power loss, voltage deviation minimizations using the evolutionary based Artificial Bee Colony (ABC) algorithm. The author in [5] solves the ORPD problem using meta-heuristic based Crow Search Algorithm (CSA) and finds the optimal control variables settings. An enhanced and efficient differential evolution (DE) with new mutation approach is described in [6, 7] to solve ORPD problem with HVDC transmission link. A methodology based on entropy evolution approach is proposed in [8] using Gravitational Search technique and fractional particle swarm optimization (PSO) for the solution of ORPD problem. The author in [9] proposes the solution to ORPD considering the system losses and voltage deviation minimization as objectives. A mathematical model of ORPD considering the energy loss minimization at the costs of adjusting control equipment and the current time interval is proposed in [10].

The author in [11] solves the ORPD problem using the marine predators' algorithm by handling uncertainties concerning to the output of solar, wind units and load demand. Differential evolution (DE) based productive stochastic search approach for solving the ORPD problem is presented in [12]. A fractional evolutionary based method that achieves the objectives of ORPD problem by including the FACTS controllers is presented in [13]. The author in [14] proposes a stochastic fractal search methodology for the solution of ORPD problem considering the voltage stability index (VSI), voltage deviation and power losses objectives. A Levy Interior Search technique is proposed in [15] for the solution of multi-objective (MO) based ORPD problem. A two-step based methodology for the solution of MO based ORPD problem is proposed in [16].

B. Motivation and Contribution

From literature review section, it can be concluded that there is a research gap for solving the single and multiple objective based ORPD problems and determining the global optimal solution using the multi-objective based CSA. The conflicting nature of the system power loss and voltage stability margins, when treated as objective functions in the ORPD problem reveal that these objective functions shouldn't be treated independently. When the power system efficiency, security, and reliability are of equal concern, the two considered important and conflicting objectives are to be minimized simultaneously using multi-objective optimization (MOO) techniques. This provided motivation to use MO based CSA for simultaneous optimization of two conflicting ORPD objectives. The major contributions of this work are:

- ORPD is formulated as a non-linear, discrete optimization problem which is solved by using evolutionary based crow search algorithm (CSA).
- ORPD problem is solved considering minimizations of power losses and L-index objectives.
- The proposed problem with these two important and conflicting objectives must be solved using the MOO techniques. In this work, multi-objective CSA is used as a MOO algorithm.
- The solution of ORPD problem has been tested on IEEE 30 and 57 bus systems.
- Obtained results depict robustness, effectiveness and superiority over the other algorithms reported in the literature.

The remainder of this work is arranged as: Mathematical modeling of ORPD is illustrated in Section II. Section III describes the simulation results on two standard systems. Section IV summarizes the contributions and conclusions of this paper.

II. PROBLEM FORMULATION

The goal of ORPD is to set optimal values to the settings of control variables such that optimal values of objective function can be met. The control variables considered for this ORPD are the voltage magnitudes of generator buses, tap settings of transformers and reactive power generation from switchable VAR/capacitor banks [17]. Fig. 1 depicts the control variables considered in the proposed ORPD problem. ORPD is solved initially as single-objective optimization (SOO) problem by selecting each objective independently, and then it is solved as MOO problem by selecting all objectives simultaneously [18]. Here, two distinct objectives are selected for solving ORPD problem and they are presented below:

A. Objective 1: Power Loss Minimization

For the ORPD problem, minimization of power loss is selected as an objective (J_1), and it is a non-linear function of system bus voltages and phase angles [19]. This objective function can be expressed as,

$$J_1 = P_{loss} = \sum_{k=1}^{N_l} G_k [V_i^2 + V_j^2 - 2V_i V_j \cos(\delta_i - \delta_j)] \quad (1)$$

The above power loss equation can be rewritten as,

$$J_1 = P_{loss} = \frac{1}{2} \sum_{i=1}^{N_B} \sum_{\substack{j=1 \\ i \neq j}}^{N_B} G_{ij} [V_i^2 + V_j^2 - 2V_i V_j \cos(\delta_i - \delta_j)] \quad (2)$$

B. Objective 2: Voltage Stability Enhancement Index (VSEI)/ L-Index Minimization

For the ORPD problem, the L-index is selected as another objective (J_2) and it utilizes the information from general load flow (LF) solution. L-index is determined at all the load buses, and it illustrates proximity of power system to the point of voltage collapse [20]. L-index is determined by,

$$L_j = \left| 1 - \sum_{i=1}^{N_G} \bar{F}_{ji} \frac{E_i}{E_j} \right| \quad j = N_G + 1, \dots, N_B \quad (3)$$

In equation (3), the \bar{F}_{ji} values are determined from the $[Y_{Bus}]$ as,

$$\begin{bmatrix} \bar{I}^G \\ \bar{I}^L \end{bmatrix} = \begin{bmatrix} Y^{GG} & Y^{GL} \\ Y^{LG} & Y^{LL} \end{bmatrix} \begin{bmatrix} E_G \\ E_L \end{bmatrix} \quad (4)$$

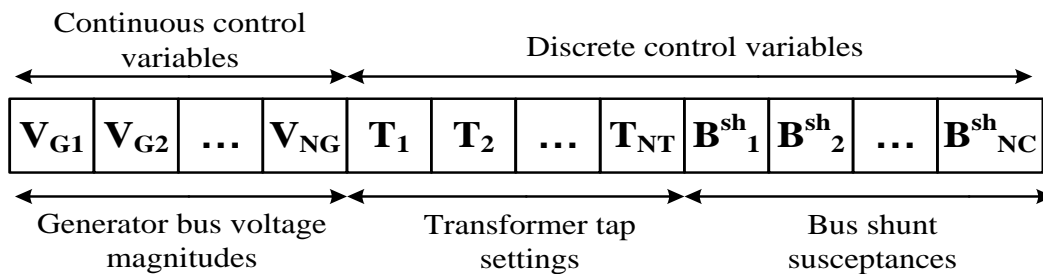

Fig. 1. Control Variables Considered in ORPD Problem.

Where E_G , E_L , \bar{I}^G , \bar{I}^L are voltage and current at generator and load nodes respectively. Rearranging the above equation [21],

$$\begin{bmatrix} E_L \\ \bar{I}^G \end{bmatrix} = \begin{bmatrix} \bar{Z}^{LL} & \bar{F}^{LG} \\ \bar{K}^{GL} & \bar{Y}^{GG} \end{bmatrix} \begin{bmatrix} \bar{I}^L \\ E_G \end{bmatrix} \quad (5)$$

This method is based on calculation of $[\bar{F}^{LG}]$, which is obtained after reordering the generator and load buses. Where $\bar{F}^{LG} = -[\bar{Y}^{LL}]^{-1}[\bar{Y}^{LG}]$. Bus with maximum L-index is the suitable location for the reactive compensation [22]. This minimization of L-index objective can be formulated as sum of squared values of L-indices, and it can be expressed as,

$$J_2 = \text{VSEI} = \sum_{j=N_G+1}^{N_B} L_j^2 \quad (6)$$

C. Equality Constraints

These are general load flow (LF) expressions, and they are represented by [23],

$$P_{Gi} - P_{Di} = P_{inj,i} = V_i \sum_{j=1}^{N_B} V_j [G_{ij} \cos \delta_{ij} + B_{ij} \sin \delta_{ij}] \quad i = 1, 2, \dots, N_B \quad (7)$$

$$Q_{Gi} - Q_{Di} = Q_{inj,i} = V_i \sum_{j=1}^{N_B} V_j [G_{ij} \sin \delta_{ij} - B_{ij} \cos \delta_{ij}] \quad i = 1, 2, \dots, N_B \quad (8)$$

Where $Y_{ij} = G_{ij} + jB_{ij}$.

D. Inequality Constraints

They represent the operational and technical limits on the power network.

1) *Generator constraints*: The amount of power output from generators must be within the specific limits [24, 25] and they can be expressed as,

$$P_{Gi}^{min} \leq P_{Gi} \leq P_{Gi}^{max} \quad i = 1, 2, 3, \dots, N_G \quad (9)$$

$$Q_{Gi}^{min} \leq Q_{Gi} \leq Q_{Gi}^{max} \quad i = 1, 2, 3, \dots, N_G \quad (10)$$

Voltage magnitudes of generators are limited by [26],

$$V_{Gi}^{min} \leq V_{Gi} \leq V_{Gi}^{max} \quad i = 1, 2, 3, \dots, N_G \quad (11)$$

Where ‘min’ and ‘max’ represent the lower and upper limits of respective variables.

2) *Reactive power source/switchable VAR source constraints*: This constraint is limited by VAR source capacity limit [27] and it can be expressed as,

$$Q_{ci}^{min} \leq Q_{ci} \leq Q_{ci}^{max} \quad i = 1, 2, \dots, N_c \quad (12)$$

3) *Transformer constraints*: The transformer tap position is limited by [28],

$$T_i^{min} \leq T_i \leq T_i^{max} \quad i = 1, 2, \dots, N_T \quad (13)$$

4) *Security constraints*: The limits on voltage magnitudes of load buses and transmission lines are considered as security constraints [29, 30], and they are expressed as,

$$V_{Li}^{min} \leq V_{Li} \leq V_{Li}^{max} \quad i = 1, 2, \dots, N_L \quad (14)$$

$$S_{Li} \leq S_{Li}^{max} \quad i = 1, 2, \dots, N_l \quad (15)$$

In this work, the SOO based ORPD problems are solved by using crow search algorithm (CSA), and MOO based ORPD problems are solved by using MO-CSA. Description of CSA and MO-CSA is presented in [31]-[33]. The detailed flow chart of MO-CSA is shown in Fig. 2.

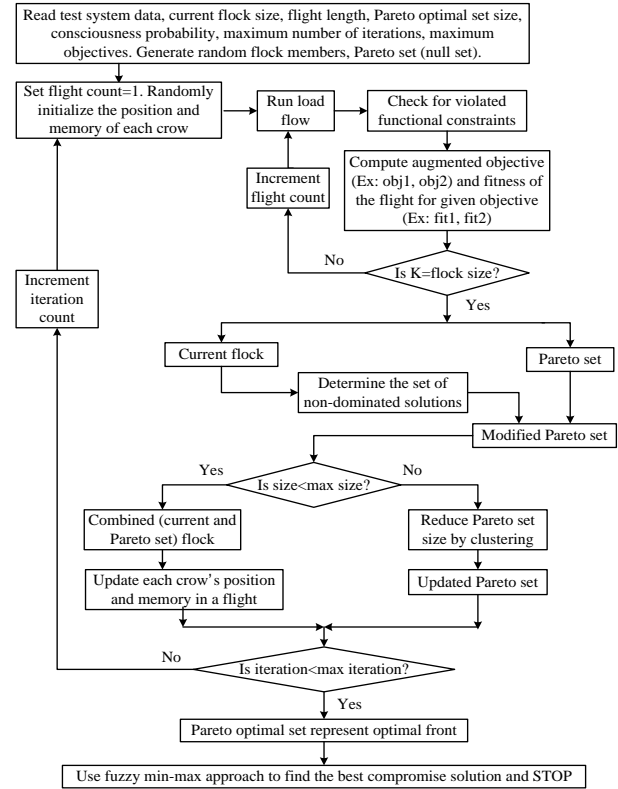

Fig. 2. Flow Chart of the MO-CSA.

III. RESULTS AND DISCUSSION

In this paper, to show the robustness and performance of proposed ORPD problem, CSA and MO-CSA algorithms are used and they are examined on IEEE 30 bus and 57 bus systems [34-37]. In this ORPD problem, voltages at generator buses, settings of transformer taps and values of shunt capacitance are considered as control variables. Here, three cases are implemented, and they are:

- Case 1: System power loss minimization
- Case 2: L-index/ VSEI minimization
- Case 3: Simultaneous optimization of active power losses and L-index

A. Simulation Results on 30 Bus System

This system has 6 generator/PV buses, 24 demands, 41 lines, 4 tap changing transformers and 9 shunt capacitance/compensation buses. In this test system, 19 control variables (6 voltage magnitudes of generator buses, 4 tap changing transformers and 9 bus shunt capacitance) are considered. Lower and upper limits of generator bus voltages, tap settings and shunt susceptance are (0.95 pu and 1.1 pu), (0.9 pu and 1.1 pu), and (0.0 pu and 0.05 pu).

TABLE I. SETTINGS OF CONTROL VARIABLES FOR 30 BUS SYSTEM

Power loss (MW)	4.2716	4.5143	4.555	4.1023	---	---	---	6.724	4.927
VSEI	---	---	---	0.1298	0.1134	0.1105	0.1126	0.1103	0.1188

Table I shows optimal settings of control variables for 30 bus system. Here, first the loss minimization objective is optimized independently (i.e., Case 1) using the genetic algorithm (GA), DE, gravitational search algorithm (GSA) and CSA, and obtained results are presented in Table I [38-39]. The power loss obtained using CSA is 4.1023 MW and the obtained corresponding VSEI value is 0.1298. Later, the VSEI/L-index objective is optimized independently (i.e., Case 2) using GA, PSO, DE and CSA, and obtained results are reported in Table I. The optimum L-index value obtained by using the CSA is 0.1188, and obtained power loss value is 4.927 MW.

From these case studies, it is clear that when the power loss is minimized then L-index has been deviated from optimum, and vice-versa. Hence, these two objectives are optimized simultaneously (i.e., Case 3) by using the MO-CSA. Pareto optimal front (POF) obtained for Case 3 has been depicted in Fig. 3. The best-compromised solution can be determined from the POF using fuzzy satisfaction method, and it has system power loss of 4.927 MW, and L-index of 0.1188.

Fig. 3. Pareto Optimal Front for Case 3 of 30 Bus Systems.

B. Simulation Results on 57 Bus System

This system has 7 PV buses, 42 loads, 80 lines, 15 tap changing transformers and 3 shunt capacitance/compensation buses. In this test system, 25 control variables (7 generator bus voltages, 15 tap changing transformers and 3 bus shunt capacitance) are considered. Lower and upper Minimum and maximum limits of generator bus voltages, tap settings and shunt susceptance are (0.95 pu and 1.1 pu), (0.9 pu and 1.1 pu), and (0.0 pu and 0.05 pu).

Table II shows optimal settings of controls for 57 bus system. Here, first the loss minimization objective is optimized independently (i.e., Case 1) using the GA, ABC, GSA and CSA, and the obtained results are reported in Table II.

The power loss obtained using CSA is 24.1022 MW and the obtained corresponding VSEI value is 0.1849. Later, the VSEI/L-index objective is optimized independently (i.e., Case 2) by using GA, PSO and CSA, and the obtained values are reported in Table II [40-41]. The values of optimum L-index obtained by using CSA is 0.1363, and obtained power loss value is 38.682 MW.

From these case studies, it is clear that when the power loss is optimized then L-index has been deviated from optimum value, and vice-versa. Hence, these two objectives are optimized simultaneously (i.e., Case 3) by using the MO-CSA. The POF obtained for Case 3 has been depicted in Fig. 4. The trade-off solution can be obtained from the POF using fuzzy satisfaction method, and it has system power loss of 29.952 MW, and L-index of 0.1513.

IV. CONCLUSIONS

This paper proposed solution to the multi-objective based nonlinear, discrete ORPD problem. System power losses and L-index/VSEI are selected as objective functions, and they are solved by using the CSA. This work also considers the discrete variables, i.e., settings of transformer taps and switchable VAR/shunt capacitors. For this ORPD problem, these two objectives are observed as the two conflicting objectives and there is a need to solve these two objectives jointly. Therefore, the MO-CSA algorithm is used to solve this multi-objective ORPD problems. The proposed MO-CSA gives the Pareto optimal set with the trade-off/best-compromised solutions, in a single run. System operator selects one trade-off solution using the higher level information or by fuzzy satisfaction method. The solution of ORPD problem gives optimum values of objective function and control variable values. The proposed CSA and MO-CSA algorithms are examined on 30 and 57 bus systems. The obtained results depict the robustness, superiority, and effectiveness over other algorithms reported in the literature.

Abstract—Data published by different organizations such as the United Nations indicates that there are a large number of people who suffer from different types of movement disabilities. In many cases, the disability is so severe that they cannot have any kind of movements. Faced with this situation, Brain Computer Interface technology has taken up the challenge of developing solutions that allow delivering a better quality of life to those people, and one of the most important areas has been the mobility solutions, which includes the brain computer interface enabled electric wheelchairs as one of the most helpful solutions. Faced with this situation, the present work has developed a Brain Computer Interface solution that allows users to control the movement of their wheelchairs using the brain waves generated when blinks their eyes. For the creation of this solution, the Incremental Prototyping methodology has been used to optimize the development process by generating independent modules. The solution is made up of several components i.e. EEG System (OpenBCI), Main Controller, Wheelchair Controller and Wheelchair that allows to have a modularity to carry out updates (improvements) of their functionalities in a simple way. The developed system has shown that it requires a low amount of training time and has a real world applicable response time. Experimental results show that the users can perform different tasks with an acceptable grade of error in a period of time that could be considered as acceptable for the system. Considering that the prototype was created for people with disabilities, the system could grant them a certain level of independence.

Keywords—BCI; EEG; brain computer interface; OpenBCI; eye blink detection

I. INTRODUCTION

Brain Computer Interface (BCI) is a technology in which the brain waves of a person are used to control an external object. It acts as a mediator between the brain and a device [1]. BCI based systems record the electrical activity of a human brain via different technologies, such as electroencephalography (EEG) [2], functional magnetic resonance imaging (fMRI) [3], and functional near infrared (fNIR) [4]. Among these alternatives, EEG is the most popular solution because of its low cost, high temporal resolution, and non-invasiveness features [5]. This technology can be applied in different fields, being one of the most important the health area [6][7][8]. BCI brings a capable and efficient way of aiding users with Motor Neuron Diseases (MND) such as Amyotrophic Lateral

Sclerosis (ALS), Progressive Bulbar Palsy (PBP), Primary lateral sclerosis (PLS), among others.

According to the United Nations, the number of individuals in the world above the age of 60 is expected to increase rapidly, and this is especially significant in developing countries where the proportion of older individuals will increase from 9% in 2015 to 16% by 2040 [9]. Additionally, according to the ALS association, most people develop ALS between the ages of 40 and 70, with an average age of 55 at the time of its diagnosis [10]. In many cases, the disability is so severe that the patients cannot have any kind of movements.

Faced with this situation, BCI technology has taken up the challenge of developing solutions that allow delivering a better quality of life to those people, and one of the most important areas has been the mobility technologies, which includes the BCI enabled electric wheelchairs as one of the most helpful solutions. In this situation, the present work has proposed and developed a system for controlling an electric wheelchair utilizing the brain signals generated by the user when blinks his/her eyes. The developed prototype will allow people with severe movement disabilities to have a higher level of independence in terms of mobility.

In summary, the objective of the present work is to design, develop and test a BCI system prototype which will allow people with movement disabilities to control an electric wheelchair using the brain signals generated when they blink their eyes.

The rest of this work is organized as follows. First, the previous works related to BCI wheelchair systems are studied. Then, the proposed solution and the used methodology are described with details. Once, explained the architecture and implementation of the proposed solution, the results of the experiments performed using the implemented prototype are analyzed. Finally, the conclusions reached in the present work are presented.

II. BACKGROUND

In the last decade, a variety of BCI technologies has been developed to help people with MND. Some of these technologies have allowed to upgrade the movement of people improving their lifestyles and bringing back their sense of

*Corresponding Author

independence which are considered as navigation assistive technologies [11]. Among the different assistive technologies, one of the solutions that could help to people with movement disabilities is the wheelchairs controlled by BCI systems. In this aspect, several alternatives for controlling wheelchairs have been proposed so far.

Turnip et al. have proposed an electric wheelchair control system utilizing Steady state visually evoked potential (SSVEP) responses. This is done by classifying 6-9Hz frequencies which are used to execute the turn left, turn right, go back, and go forward commands. These signals are processed and classified using a sixth order Bandpass Filter (BPF) and an Adaptive Neuro-Fuzzy Inference System (ANFIS) [12].

In another similar work, Li et al. developed a hybrid system for controlling a wheelchair combining P300 and SSVEP. The control is done by positioning 4 groups of flickering buttons; each group contains a large button in the center and 8 smaller surrounding it which flashes at a fixed frequency with the objective to evoke SSVEP responses. At the same time, the buttons were intensified through shape and color change in a random order to produce P300. Based on these two classifications, an output is reached. To classify both signals at the same time, they used different methods; in the P300 case, they used Support Vector Machine (SVM) and for the SSVEP, they used power ratios [13].

Additionally, Kim et al prototyped a BCI based system that allows the control of a wheelchair using motor imagery. They utilized five commands (left, left-diagonal, right, right-diagonal and forward) which are detected using a classifier that detects the imagination of left or right hand movements whilst the user simultaneously performs foot movement imagination. The signals are first spatially filtered using a common average reference and then band-pass filtered between 8 and 32 [14].

On the other hand, Y. Yu et al. proposed a hybrid BCI wheelchair system where combines motor imagery and P300 potential [15], while K. Sureshbai et al. proposed a SSVEP based BCI wheelchair where SSEVEP responses are generated by looking at four LEDs which are used to deliver forward, reverse, left, and right movements of an electrical wheelchair [16].

In another work, a novel EEG brain-controlled wheelchair with five steering behaviors is developed, which is based on two-stage control strategies combining sustained and brief motor imagery BCIs [17].

As shown in the previous works, there are a large number of BCI enabled wheelchair solutions. However, most of them uses dense techniques such as SSVEP and Motor Imagery which brings several limitations. First of all, in solutions based on SSVEP responses, the user has to look at several visual stimuli commonly implemented on blinking LEDs which could cause severe fatigue when the wheelchair has to be used by the user for a considerable period of time [18].

On the other hand, the Motor Imagery requires long time of training by users since it is based on brain signals generated by the user when simulates a physical action with his/her mind; additionally, the motor imagery commonly does not deliver high level of precision in the signal classification [19][20].

In this situation, the present work has the intention of developing a BCI enabled wheelchair which is controlled by using the brain signals generated when the user blinks his/her eyes. This method of brain signal classification has the advantage of having high level of precision and easiness of use; additionally, the solution has the benefits of not requiring a large amount of time in training processes [21, 22].

III. METHODOLOGY

In this work, Incremental Prototyping Methodology was applied for the development of the proposed solution [23]. This approach is useful when you want to create a quick prototype that is thoroughly and easily tested. In our case, we worked with two smaller increments, the first was the main controller, which manages the user interface and the processing of brain waves. The second increment (module of the prototype) was the wheelchair controller, which handles the movement of the wheelchair. The implementation of both modules creates a BCI system that can handle the movements of the wheelchair (see Fig. 1).

Fig. 1. Diagram of the Applied Methodology.

IV. PROPOSED SOLUTION

A. Architecture of the Proposed Solution

Since the purpose of the present work is to generate a BCI solution for controlling an electrical wheelchair, we have generated a general architecture of the prototype to be developed (see Fig. 2). It is also important to indicate that the proposed solution will use the brain signals generated when the user blinks his/her eyes. This method of brain signal classification has the advantage of having high level of precision, easiness of use, and low amount of time in training processes [21, 22].

Fig. 2. General Architecture of the Proposed BCI System.

In the proposed architecture, the brain signals of the user are gathered by the EEG device connected to the user, and such data is transmitted to the Main Controller which executes a BCI application that filters and classifies the raw brain signals. Once the brain signals are classified into the commands that the user wants to perform, this data is communicated to the Wheelchair Controller, which generates the movement of the wheelchair.

B. Implementation of the Proposed Solution

The architecture shown in the previous section has been implemented as follows (see Fig. 3). In the proposed system, the OpenBCI V3 Cyton biosensing board was used to acquire the brain signals. We have chosen this EEG device for its advantages over other EEG systems such as modularity, relatively low cost, open architecture, and compatibility with different research platforms such as OpenViBE, EEGLAB, BCILAB and MATLAB, and since it provides APIs for different software development languages such as Python, C# and Java [24]. Once acquired the signals, such data is sent to the Main Controller which has a Single Board Computer (SBC) called Odroid XU-4 [25] as its main component. This component has the responsibility of performing the feature extraction and feature translation processes. The SBC also has the function of communicating with the Wheelchair Controller which was implemented using an Arduino Nano. In addition, the SBC also implements the functionality of showing the user interface through an LCD Screen.

1) *EEG system:* As indicated previously, the EEG signals (brain signals) are obtained by using the Cyton biosensing board. We also have used one active reusable flap snap electrode (TDE-202) located on the surface of the scalp (FP1) following the extended 10-20 system [26][27] with a sampling frequency of 250 Hz. Once the signals are gathered by the Cyton biosensing board, they are sent to the Main Controller using the Bluetooth communication. On the other side, the signals are received by the OpenBCI dongle of the Main Controller.

2) *Main controller:* This component has the function of executing the BCI application responsible for processing the signal, delivering the commands to the wheelchair controller, and working as the user interface of the solution. The main component of the controller is the SBC called Odroid XU-4 which implements the Ubuntu 18.04 operating system. The user interface of the application is shown in a 7-inch HDMI display-C with a resolution of 1046 x 600. We have chosen this SBC because it provides higher processing capabilities compared to traditional SBCs such as Raspberry Pi while maintaining the small size [19].

The user interface has been developed with a simple design to maintain an efficient interaction with the user (see Fig. 4). The interface shows to the user when the wheelchair is in movement and which direction it is going, as well as the commands that the user is inputting. This software was developed using an open-source framework called Electron which allows the creation of lightweight cross-platform applications using JavaScript, HTML and CSS.

Fig. 3. Complete Diagram of the Proposed BCI System.

Fig. 4. Interface of the Developed Application.

As indicated in the general architecture, the SBC of the Main Controller includes a BCI application that receives the brain signals of the user to then convert the signals into wheelchair controlling commands. Once classified the commands, this data is sent to the Wheelchair Controller. The process of converting the raw brain signals into understandable wheelchair controlling commands are executed into the following steps:

a) *Feature extraction:* Once received the raw brain signals, the application applies a 0.5 Hz high pass filter, a 50 Hz notch filter, and a 5-25 Hz band pass filter, following the directions delivered from one of our previous works [21]. Fig. 5 shows the difference between the raw data and the filtered data.

b) *Feature translation:* After executing the feature extraction process, the acquired signals are classified into two types of blinks i.e. short blinks and composed long blinks [22]. According to S. Poveda Zavala et al. a short blink is detected when a user blinks normally; when a short blink is

performed by the user, the processed signal drops below $-75 \mu\text{V}$ and it rises above $85 \mu\text{V}$ in a small period of time of 1.5 seconds (see Fig. 6). On the other side, the signals are classified as a composed long blink when the user closes their eyes from 2 to 5 seconds, opens them and then blinks quickly again; when this happens, the signal drops below $-75 \mu\text{V}$, it then returns to a normal state (between -25 and $25 \mu\text{V}$), rises above $100 \mu\text{V}$ and then drops below $-75 \mu\text{V}$, all of this in a time frame of 2 to 5 seconds (see Fig. 7).

c) *Signal classification:* The classification of the signal is done by using a software developed in Python 3.7. We have chosen this programming language since it is compatible with the OpenBCI software library.

Once established the usage of short blinks and composed long blinks, the present work has generated an encoding system to classify a combination of different type of blinks into the commands that will be used to control the movements of the wheelchair. The proposed encoding system is shown in Table I, where a short blink is represented as a dot (.) and a composed long blink is represented as a dash (-). At this point, it is important to indicate that, since this encoding system must not interfere with normal blinking patterns of the user, the present work has implemented the usage of four consecutive composed long blinks as the activation/deactivation command for the whole system. This combination was selected for this purpose since this pattern is not presented in a normal blink sequence of a person.

TABLE I. ENCODING SYSTEM USED IN THE PROPOSED SOLUTION

Command	Description	Blink Combination
Activate /Deactivate	Activates or deactivates the system	----
Go forward	Moves the wheelchair forward for 1 second	---
Turn left	Turns the wheelchair left for 1 seconds	---
Turn right	Turns the wheelchair right for 1 seconds	---
Go backwards	Moves the wheelchair backwards for 1 second	---

3) *Wheelchair controller:* To control the electric wheelchair, it was necessary to rewire the control scheme of the device's joystick (see Fig. 8). The controller of the joystick includes an input device that allows to send information about the angle or direction of the movement of the wheelchair.

Fig. 8. Resistance Diagram of the Wheelchair's Joystick.

This device is powered by a 5 volts direct current. The operation is based on a variable resistor, which changes the output voltage depending on the movement of the joystick lever. In idle state, the outgoing voltage signals from the Y to X axis are 2.5 volts. The joystick sends the voltage signals depending on the position of the lever (see Fig. 9). The wheelchair controller has reproduced the aforementioned signals by using a system created in an Arduino Nano.

Fig. 5. Raw Extracted Data vs Filtered Data.

Fig. 6. Signal Generated when the user Performs a Short Blink.

Fig. 7. Signal Generated when the user Performs a Composed Long Blink.

Fig. 9. Signal Diagram.

Since the Arduino Nano does not have a Digital to Analog Converter (DAC) system and since it only can generate Pulse Width Modulation (PWM) signals, the Wheelchair Controller has implemented an RC filter to obtain a DC voltage signal with low ripple (see Fig. 10). This solution allowed the generation of 0-to-5-volt signals through the analog terminal present in the Arduino Nano. The connection between the wheelchair power pins (see Fig. 11) and the Arduino Nano cables are present in the Table II and Fig. 12.

The Arduino Nano was powered by using the VCC and GND terminals of the wheelchair control system. The Arduino Nano receives the commands from the Main Controller through a serial communication. Once received the commands, the Arduino Nano interprets them and move the wheelchair to different directions. To simulate the real signals that the variable resistors deliver, a voltage ramp was implemented, which also allows to avoid sudden movements in the wheelchair. The commands that control the movement of the wheelchair are present in the following Table III.

TABLE II. CONNECTIONS BETWEEN WHEELCHAIR POWER PIN AND MICROCONTROLLER (ARDUINO NANO) CABLES

Wheelchair control system connections	Arduino cable connections
X AXIS	Blue cable
GND	White-orange cable
VCC	Orange cable
Y AXIS	White-blue Cable

TABLE III. COMMANDS USED IN WHEELCHAIR CONTROLLER

Command	Data sent by the Main Controller
Forward	w
Backwards	x
Right	d
Left	a

The amount of time that the wheelchair realizes its movements can be customized depending on user requirements. In the present prototype, such variable was set with the period of one second since it was the most beneficial frame for the experimentation process. The speed at which the wheelchair moves can also be configured, in the present prototype; such variable was set with the slowest option in order to guarantee the safety of the user.

V. EXPERIMENTATION AND RESULTS

For the testing of the developed prototype, ten 20 to 45-year-old healthy people participated in the experiment. Before the experiment, each participant used the system for a total of 2 hours to get accustomed to its functionality.

A. Experiment

The aim of the experiment was to test the speed in which the subjects could perform two tasks (see Fig. 13). In the first task, the participants would have to complete the following steps: (1) activate the system, (2) move forward, (3) turn right, (4) move forward and (5) deactivate the system. On the other hand, the second task consisted of the following steps: (1) activate the system, (2) turn right, (3) move forward, (4) turn left, (5) move forward, (6) turn left, (7) move forward, (8) turn right, (9) move forward, and (10) deactivate the system.

We have asked the participants to complete these two tasks 10 times to validate the consistency of the results. If the participant has failed completing a command, he would start all over again and have one attempt added to his total for that task, all participants would start with 0 attempts. Table IV shows the average number of attempts the participant needed to complete the first task. We believe that 0.82 attempts at 64.73 seconds

for the first task and 0.85 attempts at 140.59 seconds for the second task are acceptable for this developed prototype. The working prototype is shown in Fig. 14.

Fig. 13. First and Second Tasks Performed during the Experimentation Process.

TABLE I. AVERAGE NUMBER OF ATTEMPTS AND TIME PER ATTEMPT FOR TASK 1 AND 2.

Particip- pant	Task 1		Task 2	
	Average Attempts	Average Elapsed Time (s)	Average Attempts	Average Elapsed Time (s)
1	0.5	61.25	0.9	134.40
2	1.2	67.26	1.0	144.64
3	0.6	62.50	0.6	129.54
4	0.7	60.50	0.8	132.57
5	1.3	70.16	1.2	161.28
6	0.8	63.56	1.0	155.64
7	0.8	64.98	0.5	125.09
8	0.2	60.04	0.6	134.54
9	1.5	72.89	0.9	138.23

VI. CONCLUSIONS

In the present work, a BCI based wheelchair control system utilizing eye blinks was developed. The solution is made up of several components i.e. EEG System, Main Controller, Wheelchair Controller and Wheelchair that allows having a modularity to carry out updates (improvements) of their functionalities in a simple way. The developed system has shown that it requires a low amount of training time and has a

real world applicable response time. Experimental results show that the users can perform different tasks with an acceptable grade of error in a period of time that could be considered as acceptable for the system. Considering that it was created for people with disabilities (e.g. people that suffer from MND), the system could grant them a certain level of independence. As future work, we will work in analyzing and classifying other brain signals for developing new solutions for people with disabilities.

Abstract—Traditional fish farming faces several challenges, including water pollution, temperature imbalance, feed, space, cost, etc. Biofloc technology in aquaculture transforms the manual into an advanced system that allows the reuse of unused feed by converting them into microbial protein. The objective of the research is to propose an IoT-based solution to aquaculture that increases efficiency and productivity. The article presented a system that collects data using sensors, analyzes them using a machine learning model, generates decisions with the help of Artificial Intelligence (AI), and sends notifications to the user. The proposed system has been implemented and tested to validate and achieve a satisfactory result.

Keywords—Smart aquaculture system; biofloc technology; machine learning; life below water

I. INTRODUCTION

In biofloc aquaculture, it is inevitable to be more intelligent to monitor the water quality in real-time and feed accurately. However, due to real-time water quality monitoring, the balance of bacteria in the aquaculture environment might be harmed; hence fish's disease-resistant ability is decreased. It is impossible to measure the water quality accurately based on experience only [1, 2]. An intelligent system could help the farmers by reading the water parameters on time to monitor and maintain the quality accordingly. Hence, identifying the water parameters suitable for the biofloc aquaculture, a water quality prediction model for the dynamic changes in water parameters, and accordingly are essential.

Biofloc technology can reduce food costs, while a smart aquaculture system can reduce labor cost. It is a good option that is cheaper and beneficial to fish's health [3, 4]. Being a low-lying country, several natural calamities like floods, cyclones, etc., have a significant effect on aquaculture at both the ponds and marine waters. Fish farmers must bear a substantial loss due to the polluted water and increasing salinity of the coastal water for those disasters. Traditional fish farming leads to several other problems, such as water

pollution caused by carbon dioxide, ammonia, and nitrogen. External filtration is needed for detoxifying, which is costly and time-consuming. Biofloc technology is an excellent alternative to the cost-effective traditional aquaculture system. Biofloc itself helps to purify the water naturally, hence the use of external tools or ingredients might be reduced. Maintaining water quality can ensure increasing production, decreasing the death of fish. Water quality parameters are the most important factors to maintain a fish farm using Bioflocs.

This article mainly focuses on water level parameters. An automated system has been implemented to collect data through sensors, analyze them using a machine learning method, analyze the water quality. The application of IoT makes it easier to monitor the water and maintain the ecology in biofloc aquaculture.

In this article, data collected from the fish farm has been used for training and testing purposes. A machine learning method has been applied to develop the model. The water quality parameters, including pH, have been analyzed, and the correlation between them is obtained. The water quality prediction model is trained based on the collected data.

II. RELATED WORKS

Deep learning (DL) technology is used in numerous fields. X. Yang et al. focused on DL applications in aquaculture. They worked on identifying live and dead fish, classified species, performed behavioral analysis, and feeding decisions. The algorithm and the results of the method were applied to the smart fish farm. The findings showed that the deep learning method could extract features automatically. They made the most valuable contribution to the field of agriculture. But the technique was failed to address complex data in aquaculture [5].

S. Liu et al. did an experiment on "Ras Carpio" using the Recirculating Aquaculture System (RAS) [6]. In 2011, RAS was an intelligent alternative to traditional aquaculture in

ponds. The water parameters were being continually monitored, and whenever the parameter's value got out of the fish's versatile range, the water was recirculated. For this purpose, there were two drainage systems. DO, pH, and the temperature was monitored by WATT TriO Matic 700IQ (SW), WATT Sensolyt 700 IQ (SW), and WATT Tri oxyTherm type sensors. Though the system had many benefits and was replaced rapidly with a regular aquaculture system, it had some disadvantages. It needs water exchange which is a lengthy and costly process.

M. I. Dzulqornain et al. implemented an innovative IoT-based system on the IFTTT model [7]. They used dissolved oxygen, water temperature, the potential of hydrogen (pH) as parameters. The water level was sensed with sensors, and for controlling the system, an aerator system was utilized integrating with microcontroller NodeMCU v3, relay, power supply, and propeller. The sensor data was uploaded to the cloud, and the client could visualize them from anywhere. The application was both web-based and android-based. The system was well enough, but its process was manual.

A. A. Nayan et al. worked on measuring river water quality for agriculture and fishing purposes [8] and identified fish diseases by detecting the changes in water quality [9]. They used a machine learning technique that evaluated the water quality and processed intelligent suggestions. They utilized pH, DO, BOD, COD, TSS, TDS, EC, PO4³⁻, NO₃-N, and NH₃-N to calculate the water quality and predicted the result using boosting technique. But the study only focused on big water sources like rivers and did not suggest any solution for small water sources like ponds.

To minimize the gap of previous studies and to provide a better understanding of the current state of the art of DL in aquaculture, we have worked on this project. The work offers good support for deploying applications for smart fish farming which is entirely new compared with other results. An automatic system with Biofloc technology has been introduced. We have tried to decrease feed costs by reducing FCR (feed conversion ratio). The nutrients used in this technology can be recycled and reused easily.

III. MATERIALS AND METHODS

A. Biofloc Technology (BFT)

Biofloc is a new technology introduced in aquaculture for low-cost fish farming. Bioflocs are used to make reusable food from organic waste nutrients. It is a thin layer made up of beneficial bacteria, microorganisms, and algae that filters the water. Bacteria is cultured for this technology because it produces flocs or algae, breaking ammonia to minimize water pollution. The biofloc method of fish farming can be helpful to grow vegetables and fish together in the yard. This method requires tanks, oxygen supply pumps, and round-the-clock electricity. It needs less amount of food and reduces the chances of the disease. Being an eco-friendly system, it reduces the impact on the environment and improves productivity. Water must be exchanged to minimal or zero in this system. It is cost-effective by reducing the usage of protein-rich feed [10, 11, 12]. Fig. 1 shows a general image captured from a biofloc farm.

Fig. 1. Biofloc Technology in Aquaculture.

B. Hardware Components

IoT innovation has brought "Sensor Development" to a new stage. IoT systems operate and use a range of sensors to provide different kinds of information and data. It helps to gather information, drive, and distribute it to a network of similar gadgets. The collected data allows it possible for the devices to work autonomously, and every day the whole world turns to be "smarter." By integrating sensors, microcontrollers, and other smart gadgets, the project was implemented. We have used the following hardware components to run the project.

- Arduino UNO [13].
- White Breadboard.
- pH sensor [14].
- Temperature Sensor [15].
- Total Dissolved Solids (TDS) Sensor [16].
- Computer.
- Wires.

C. System Architecture

Fig. 2 shows the architecture of our Smart Aquaculture Water Monitoring System. The system monitors continuously and sends notifications through a Wi-Fi [17] module to an android application. The project's primary function is to check the water parameters: pH, temperature, and TDS. We have collected samples from different farms that use Biofloc technology. Processing data from the samples, we trained the artificial neural network. The sensors connected with the system provide a continuous reading of the water parameters. The system generates output evaluating the trained data and the reading provided by the sensors. It predicts the water quality, determines the situation, and process wise decision. It sends the result and decision as a notification to the user through an android application. Fig. 3 shows the flow diagram of the project.

D. Hardware Connection

We collected the required hardware, tools and connected them according to the diagram shown in Fig. 4. The figure mentions the pin diagram of Arduino Uno with Temperature sensor and pH sensor.

Fig. 2. System Architecture.

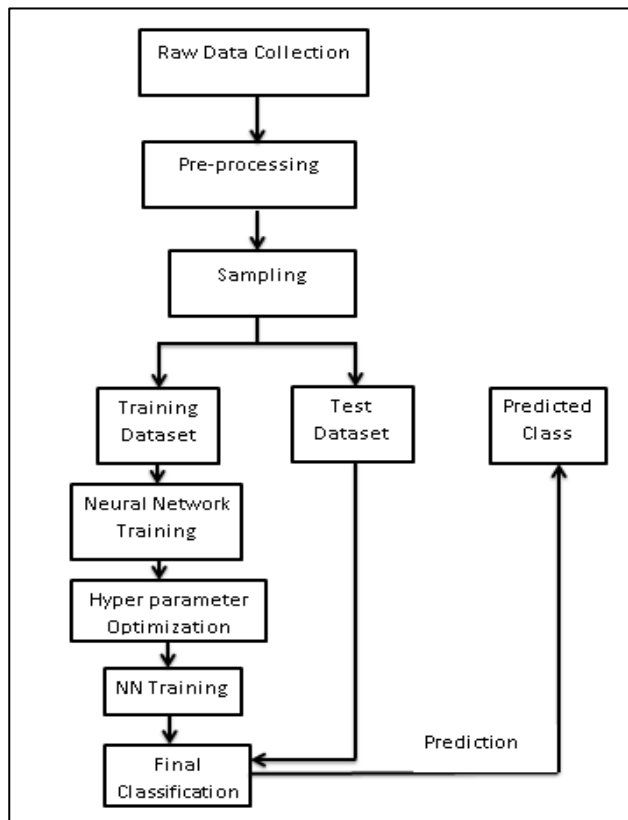

Fig. 3. Flow Diagram.

Fig. 4. Hardware Connection.

E. Study Area

Few farms have already adopted biofloc technology. We found many projects in Bangladesh and visited there. The first center named “Biotech Aquaculture” introduced the technology in Bangladesh. The center is situated at Dakshinkhan, Uttara, Dhaka where Tilapia, Golsha, Pabda, Koi, and Shing (Bengali name of the fishes) are cultivated. The project has been established on the “No Water Exchange” principle. We visited there in September 2020. Investigating their working procedure, we found that they examine the water two times every day and collect the pH, water temperature, total dissolved oxygen (TDS), ammonia (NH₃), and floc (molasses). Fig. 5 shows a complete picture of the study area.

Suppose the water parameters get out of the suitable range. In that case, they control them by taking necessary steps for example: filtering out the excess bioflocs (as it tends to increase generally), adding baking soda in a safe amount, and removing the fish from the tank before raising the pH. The tank's water is matured, so the parameters do not change frequently, and the water is adaptable for the fish species.

Another center is located at Bosila, Dhaka named “Matsabid Biofloc Aquaculture Farm”. They are using the same technology but do not follow the “No Water Exchange” method. It is a big project of 15 large tanks and two large ponds. The whole system is continuously monitored manually by a family residing there. The aerator is mandatory for the bioflocs to survive, so the aerator is turned on 24 hours a day. Only three water parameters (pH, salinity, and the number of flocs) are monitored in the farm and whenever one gets increased or decreased, they change the water. For this exchange, they have a drainage system and a water pump. So, the water is not matured here. The image of the study area is shown in Fig. 6 and 7.

F. Data Collection

We collected samples from different centers. We bought instruments and sensors for data collection purposes. We used pH, temperature, and TDS sensors to measure the values. Sample collection was more manageable, but the data processing was difficult and time-consuming. We worked for more than three months to process the necessary data from the samples. Tables I and II show the details of the collected data.

28/10/20	8.00 pm	8.2	682	45 gm

G. Data Preprocessing

We collected data from water using different instruments and stored it in a CSV file. The CSV file contains six various labels, including temperature, TDS, pH, and flocs. pH is considered as the output data by which the model was tested and the rest five are regarded as the input data by which the model was trained. A glimpse of our dataset is shown in Table III.

H. Machine Learning Algorithm for Decision Making

Artificial Neural Networks (ANN) function as the neurons of the human brain. The network contains nodes that receive the input signal and pass it to the previous nodes as the synapse of a nerve cell does [18, 19]. The covariates and input variables are weighted, and these weighted signals are then passed through activation functions. Let y be output signal and be the activation function, the mathematical expression of signal processing in ANN is:

$$y(x) = \Phi(\sum_{i=1}^n w_i \cdot x_i)$$

The network contains an input layer, an output layer, and one or more hidden layers. The hidden layers are responsible for the performance of the model. We used five hidden layers for faster execution. More layers slow down the training and testing process.

I. Dependencies

We trained the model on Ubuntu 20.04 LTS and used python 3.8. These were dependencies and libraries. We installed and imported the following libraries to run the code and train the model.

- Tensor flow
- Keras
- Pandas

- Matplot
- Numpy
- Boxplot Analysis

J. Parameters and Algorithms

The whole dataset was splatted into two different parts that are training and testing. We took 80% of the data for training, and the rest 20% was used for testing purposes. The model was trained several times using different epoch sizes. We encountered the overfeeding condition. Lastly, utilizing batch size 32 and epoch size 150, the model achieved the best accuracy. The model consists of 5 hidden layers. The layers help to increase the model’s performance. The workflow of the layers is shown in Fig. 8.

To vanish the gradient problem and allow the model to run faster and perform well, we used ReLu (Rectified Linear Unit) [20, 21] with the hidden layers. Softmax was utilized as an activation function in the output layer. The number of classes was 4 for the output [22]. 0 denotes a shallow DO level, 1 represents a low DO level, 2 denotes an average DO level, and 3 denotes a high DO level.

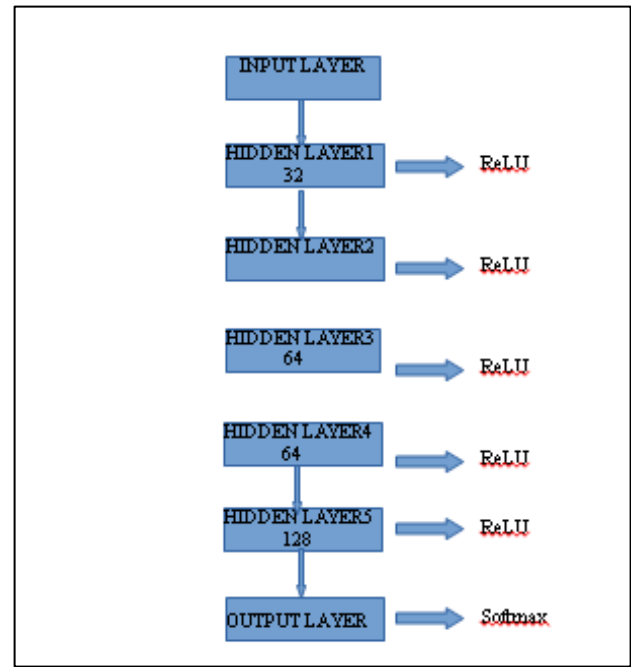

Fig. 8. Workflow of the Layers.

TABLE III. PROCESSED DATA

	A	B	C	D	E
1	Temp	D.O. (mg)	pH	TDS	Flocs (ml)

IV. SIMULATION AND RESULT

A. Training and Testing

After collecting and processing the dataset, we trained the model. The model was trained with the 80% data and later tested with the rest 20% data. We utilized a completely different type of data for training and testing purposes. The model scored 0.773 testing accuracy, which was well enough to maintain good performance. The loss was calculated with the increasing number of epochs. After 55 epochs, the loss was minimized rapidly. We calculated the loss between 0 to 1.2 range. The minimum testing loss was 0.5, and the training loss was 0.7. The training and testing accuracy and loss have been shown in Fig. 9 and 10.

Fig. 9. Training and Testing Accuracy.

Fig. 10. Training and Testing Loss.

B. System Output

Evaluating the parameter’s value, the system provides an output. Depending on the DO level (shallow, low, average, or high) in the water, the system generates a message and provides a decision analyzing the current output. To make the system more user-friendly, we have designed a smartphone application to notify the user about the result and determination that the machine generates.

A user needs the android application, an ubuntu droplet, and a droplet’s IP address for the push notification. We used GCM (Google Cloud Messaging) [23] for android, where we enabled the API for our project first and then linked the android App through it. We deployed an Ubuntu droplet and set up a python GCM simple server on Ubuntu. Lastly, a push notification was displayed on the Android app generated by the system. A snapshot of the smartphone application is shown in Fig. 11.

C. Performance Comparison

Many researchers have worked on intelligent biofloc technology. pH, DO, BOD, COD, TSS, TDS, EC, PO43-, NO3-N, and NH3-N are the standard parameters utilized by most researchers for measuring water quality and its changes. The Artificial Neural Network (ANN) [24], Group Data Handling Method (GMDH) [25], Support Vector Machine (SVM) [26], Least-Squares Support Vector Regression (LSSVR) [27] and Long Short-Term Memory (LSTM) [28] are

commonly used methods. Besides, some projects used microcontrollers and sensors only. The projects are cost-effective, but such projects do not predict the water quality, fish health condition and cannot process automatic solutions. A caretaker is needed to perform the manual functions. In this article, we have proposed and implemented a system that will help fish farmers grow fish production minimizing the feeding cost. It needs not to use big ponds or a wider area. Our project can help anyone to produce plenty of fishes in a small container or house at a small cost. We have compared our approach with other existing techniques. For comparing, we provided significant importance to the proposed method, accuracy, cost reduction rate, parameters, real-time monitoring capability, prediction capability, decision-making capability, and user satisfaction level. The comparison is shown in table 4. The information mentioned in the table is collected from different published articles. Here we did not compare among the methods. We have reached the performances of different approaches only.

Fig. 11. Notification to the Smartphone Application.

TABLE IV. PERFORMANCE COMPARISON

Method Used	Testing Accuracy (Percentage)	Real-time Monitoring	Parameters	Automatic Solution	Decision-Making Ability	User satisfaction
AAN	72 %	Monitors 24 x 7	Temperature, DO, TDS, pH, BOD, COD, TSS	Does not perform automatic solution	Can predict and process smart decision	Medium
GMDH	74%	Monitors 24 x 7	Temperature, DO, TDS, pH	Does not perform automatic solution	Better prediction and decision-making system	High
SVM	70%	Monitors 24 x 7	Temperature, DO, TDS, pH	Does not perform automatic solution	Lower quality prediction	Low
LSSVR	76%	Monitors 24 x 7	Temperature, DO, TDS, pH, EC, PO43-, NO3-N	Does not perform automatic solution	Can predict and process smart decision	Medium
LSTM	82 %	Monitors 24 x 7	pH, temperature, DO	Does not perform automatic solution	Better prediction and decision-making system	High
Our Approach	77 %	Monitors 24 x 7	Temperature, DO, TDS, pH, Floc	Performs automatic solution	Can predict and process smart decision	Android application is available for monitoring from anywhere. User satisfaction is measured as “Very High”

V. CONCLUSION

Aquaculture farmers have been surviving from economic constraints, high-paid and even unavailability of human resources, timely monitoring of water quality, and sudden increase in toxicity for decade after decade. The IoT-based water quality monitoring system monitors the water quality in real-time and reduces the cost of production, increases efficiency, reduces human dependency, and thus ensures sustainable development economically and socially. The proposed system monitors the water quality in real-time and sends a notification to the user instantly, which reduces the risk. A machine learning technique has been applied to trace the water quality. To validate the proposed model, experiments on the implemented functionalities have been performed. The experiments show 0.773 as testing accuracy which was well enough to maintain good performance. Currently, the implementation of identified functionalities has been carried out. In the future, we wish to improve the model to achieve higher accuracy and evaluate the performance in terms of the fish population.

Abstract—The existing researches have shown that the fuzzy forecasting methods based on the high-order fuzzy time series are better than the fuzzy forecasting methods based on the first-order fuzzy time series. The linguistic forecasting method based on the first-order linguistic time series which can handle directly the word-set of the linguistic variable have been examined by Hieu et al. This paper examines a novel model of high-order linguistic time series with the growth of declared word-set. A procedure for forecasting the enrollments of University of Alabama and Lahi crop production of India is developed based on the proposed model. In the proposed forecasting method, the high-order linguistic logical relationship groups will be established and utilized to calculate the forecasted values based on the quantitative semantics of the used words generated by the hedge algebras structure. The experimental results show that the forecasting accuracy of the proposed high-order forecasting method is better than their counterparts and the growth of the word-set of the linguistic variable is significant in increasing the accuracy of the forecasted results.

Keywords—Linguistic time series; high-order linguistic time series; linguistic logical relationship; hedge algebras; time series forecasting

I. INTRODUCTION

The subject of the time series forecasting model has attracted substantial attention in recent years. For almost the realistic cases, the forecasting problem is uncertainty. In other words, it seems impossible to predict the future values of things and phenomena with one hundred percent of accuracy. However, we can examine different forecasting models and find the best fit model for a certain dataset.

The living of human is a sequence of the decision-making process. In reality, they always use their linguistic experience to make decisions or in other words, they save their experiences of the real world by linguistic words and use them to make decisions in the future. In computer science, researchers have found many ways to simulate the human behaviors into the machines. The most successful one is fuzzy set theory approach. Fuzzy set theory proposed by Zadeh [1] uses fuzzy sets to represent the computational semantics of linguistic words. The utilization of fuzzy set theory to time series forecasting problem first proposed by Song and Chissom in 1993 [2]–[4]. For example, we can use linguistic words such

as “small”, “quite small”, “very small”, “large”, “rather large”, “extremely large”, etc. to describe the number of students who enroll to a university by years. By the fuzzy time series, the mentioned linguistic words can be represented by fuzzy sets. There are many publications of the fuzzy forecasting methods based on the fuzzy time series which can be found in the literature.

Chen in [5] examined the high-order fuzzy time series forecasting model where the n^{th} -order fuzzy logical relationship can be derived from the fuzzified historical data. In recent two decades, among so many improvements of the fuzzy time series forecasting methods, a number of high-order fuzzy time series forecasting methods has been proposed such as [6]–[23]. Among those studies, Singh [17] proposed a computational method of forecasting for the fuzzy time series model using high-order fuzzy logical relationships of differences of consecutive values. Most of other improvements of high-order fuzzy time are the proposals of the hybrid forecasting models with modern computational techniques using artificial neural networks [11], [12], [16], [19], machine learning [13], [14], particle swarm optimization [23], genetic algorithm [6], granular computing [8], etc.

Despite many important achievements, in the computation model of fuzzy time series, there is no formal connection between the fuzzy sets and the inherent semantics of the linguistic words represented by the fuzzy sets. In other words, the linguistic words are used in the fuzzy time series merely as the linguistic labels of fuzzy sets. Therefore, the relationships between the qualitative semantics of linguistic words and their fuzzy sets based semantics have not been thoroughly examined in the fuzzy time series forecasting models.

In the other side of natural language processing method, hedge algebras (HA) was introduced by Ho and Wechler in 1990 [24]. In hedge algebras, the linguistic variables can be modeled by an axiomatic way using inherent quantitative semantics of linguistic values. Many applications of hedge algebras can be found in the field of fuzzy control [25]–[31], data classification and regression using fuzzy rule-based systems [32], [33], image processing [34] and so on. In 2020, Hieu et al. [35], [36] proposed linguistic time series (LTS) forecasting model handling the linguistic words immediately based on the theory of hedge algebras. It is the first time that

the constructed linguistic time series can simulate the way human users describe numerical time series in terms of their linguistic words.

In this paper, inspired by the mentioned researches of fuzzy time series, we propose a novel high-order linguistic time series forecasting model. In the proposed model, the current linguistic value of the linguistic variable \mathcal{X}_L depend not only on the adjacent previous word but also the series of preceding words. In addition, the forecasting linguistic variable \mathcal{X}_L is considered as the linguistic counterpart of the numerical forecasting one \mathcal{X}_N . So, the word-set of \mathcal{X}_L is infinite and just limited words of it are selected for a specific application, so-called declared word-set. In our proposed high-order LTS forecasting models, we assume that there is not any restriction on the declared word set. The accuracy of the proposed high-order LTS forecasting models can considerably increase when the declared word-set of \mathcal{X}_L grows. The proposed high-order LTS forecasting models are applied to the problems of the enrollments of University of Alabama [4] and the Lahi crop production of India [17] to illustrate the effectiveness of the proposed forecasting models and the scalability of the word-set of \mathcal{X}_L . Besides, this study would like to present a comprehensive formalized methodology for handling linguistic words directly and simulate the way human users making a forecasting process in terms of their words. Therefore, we do not apply any optimization techniques which may improve the accuracy of forecasted results.

The rest of the paper will be organized as follows. Section II briefly introduces some fundamental knowledge of hedge algebras and the linguistic time series forecasting model. The proposed novel high-order linguistic time series forecasting model is also presented in this section. The experimental studies will be introduced and discussed in Section III. Finally, the paper will be covered with the conclusions.

II. LINGUISTIC TIME SERIES AND ITS FORECASTING MODEL

A. Some basic Knowledges of Hedge Algebras

In the human society, people utilize their historical experiences to communicate one to another by linguistic words in natural language. Linguistic words themselves reveal their inherent semantics. Because of their qualitative semantics, every word has its semantic order relation with each other in the word-domain of a linguistic variable. That motivated Ho and Wechler [24], [37] to propose hedge algebras which can deal with linguistic words directly.

Let $\mathcal{AX} = (X, G, C, H \leq)$ be a hedge algebras (HA), where X is the word-domain of a given linguistic variable \mathcal{X}_L ; G is the set of two opposite generators, the negative one denoted by c^- and the positive one denoted by c^+ ; C is the set of three constants $0, W, 1$ which are the smallest word, the neutral and the largest ones (e.g., such specific words are “absolutely small”, “medium” and “absolutely large”); H is the set of hedges such as “little”, “rather”, “very”, “extremely”, and so on; \leq is the semantic order relation in the word-domain.

Each linguistic value in HA structure has its own semantic. In order to model the quantitative semantics of all words in the

word-domain, it is necessary to construct two notions of HA which are semantically quantifying mapping (SQM) and fuzziness measure, denoted by $v : X \rightarrow [0,1]$ and $m : X \rightarrow [0,1]$, respectively. SQM and fuzziness measure of HA structure can be defined as follows.

Definition 1. [38] A function $m : X \rightarrow [0,1]$ is said to be *fuzziness measure* of terms in X provided that:

- $m(c^-) + m(c^+) = 1$;
- $\sum_{h \in H} m(hu) = m(u)$, for $\forall u \in X$;
- $m(0) = m(W) = m(1) = 0$, fuzziness measure of all constants is 0;
- For $\forall x, y \in X, \forall h \in H, \frac{m(hx)}{m(x)} = \frac{m(hy)}{m(y)}$, this proportion does not depend on any specific elements and, hence, it is called fuzziness measure of the hedge h and denoted also by $\mu(h)$ for simplicity.

The fuzziness measure m of a linguistic variable \mathcal{X}_L has the following properties:

$$m1) m(hx) = \mu(h)m(x), \text{ for } \forall x \in X;$$

$$m2) m(c^-) + m(c^+) = 1;$$

$$m3) \sum_{-q \leq i \leq p, i \neq 0} m(h_i x) = m(x), \forall x \in X;$$

$$m4) \text{ Set } \sum_{-q \leq i \leq -1} \mu(h_i) = \alpha, \sum_{1 \leq i \leq p} \mu(h_i) = \beta, \text{ where } \alpha, \beta > 0 \text{ and } \alpha + \beta = 1.$$

In the computational model of HA, each linguistic word or hedge has its sign defined as follows.

Definition 2. [38] A function $sign : X \rightarrow \{-1,1\}$ is a mapping which is defined recursively as follows. For $h, h' \in H$ and $c \in \{c^-, c^+\}$:

- 1) $sign(c^-) = -1, sign(c^+) = +1$;
- 2) $sign(hc) = -sign(c)$ ($= +sign(c)$) if h is negative (positive) with respect to c ;
- 3) $sign(h'hx) = -sign(hx)$ if $h'hx \neq hx$ and h' is negative with respect to h ;
- 4) $sign(h'hx) = +sign(hx)$ if $h'hx \neq hx$ and h' is positive with respect to h .

Definition 3. [38] For given values of the fuzziness parameters of a variable \mathcal{X}_L , its corresponding SQM $v : X \rightarrow [0, 1]$ is defined as follows:

$$v(W) = \theta = m(c^-); \tag{1}$$

$$v(c^-) = \theta - \alpha m(c^-) \text{ and } v(c^+) = \theta + \alpha m(c^+); \tag{2}$$

$$v(h_j x) = v(x) + sign(h_j x) \left\{ \sum_{i=sign(j)}^j m(h_i x) - \omega(h_j x) m(h_j x) \right\} \tag{3}$$

$$\text{where } \omega(h_j x) = \frac{1}{2} [1 + sign(h_j x) sign(h_p h_j x) (\beta - \alpha)] \in \{\alpha, \beta\}.$$

SQM and fuzziness measure are two important notions of HA. More specifically, for given α and θ parameters, all the components of the HA's computational model can be obtained.

B. Linguistic Time Series (LTS)

Humans use their own language capacity to collect the data. Their brain saves all information in the real world by linguistic experience of specific owner. Human also use their own experience to make decision. In the time series forecasting problem, simulating the behavior of human's decision making process, the model also uses preceding data to predict the future value of time series data. When all the points of historical time series data are linguistic values, we have the LTS.

Definition 4. [35] Let \mathbb{X} be a set of linguistic words in the natural language of a variable \mathcal{X} defined on the universe of discourse $U_{\mathcal{X}}$ to describe its numeric quantities. Then, any series $L(t), t = 0, 1, 2, \dots$, where $L(t)$ is a finite collection of words of \mathbb{X} , is called a linguistic time series.

Definition 5. [35] Let T be a LTS. In T , if every time $t = k - 1$, the linguistic value of LTS is x_i and x_j is the linguistic value of T at the time $t = k$, then we have linguistic logical relationship of the form $x_i \rightarrow x_j$.

Definition 6. [35] Suppose that we have more than one linguistic logical relationship with the same left-hand side denoted by $x_i \rightarrow x_{j_1}, x_i \rightarrow x_{j_2}, \dots, x_i \rightarrow x_{j_n}$, then we can group them into the linguistic logical relationship group denoted by $x_i \rightarrow x_{j_1}, x_{j_2}, \dots, x_{j_n}$.

In Def. 5, the logical relationship $x_i \rightarrow x_j$ indicates that the linguistic value x_j to be caused by the only linguistic value x_i , called the first-order linguistic logical relationship. If there is more than one element on the left-hand side of the relationship, then we have the high-order linguistic logical relationship.

Definition 7. In the linguistic time series T , if x_k , the linguistic value of \mathcal{X} at the time k , to be caused by $x_{k-1}, x_{k-2}, \dots, x_{k-\lambda}$ are the linguistic values of \mathcal{X} at the time $k - 1, k - 2, \dots, k - \lambda$, respectively, then the linguistic logical relationship is presented by $x_{k-\lambda}, \dots, x_{k-2}, x_{k-1} \rightarrow x_k$, so-called the λ -th-order linguistic logical relationship.

By Def. 7, we have first-order linguistic logical relationship when $\lambda = 1$ and we have high-order linguistic logical relationship when $\lambda > 1$.

In a similar way to Def. 6, the high-order linguistic logical relationship group is established based on the high-order linguistic logical relationships. Suppose that we have the high-order linguistic logical relationships:

$$x_{k-\lambda}, \dots, x_{k-2}, x_{k-1} \rightarrow x_{k1},$$

$$x_{k-\lambda}, \dots, x_{k-2}, x_{k-1} \rightarrow x_{k2},$$

$\dots,$

$$x_{k-\lambda}, \dots, x_{k-2}, x_{k-1} \rightarrow x_{km},$$

then we can group them into the high-order linguistic logical relationship group written in the form:

$$x_{k-\lambda}, \dots, x_{k-2}, x_{k-1} \rightarrow x_{k1}, x_{k2}, \dots, x_{km},$$

where λ is the order of the linguistic logical relationship group.

C. High-order LTS Forecasting Model

Using the high-order linguistic logical relationship groups, the high-order LTS forecasting model was established and briefly reviewed as in Fig. 1.

In the first step, the universe of discourse and the HA structure with syntactic, qualitative and quantitative semantics are determined. The second step computes the numerical semantics of the declared words of \mathcal{X}_L . In the third step, according to the historical data, the high-order linguistic logical relationship groups, used in the next step, were observed. Using the linguistic logical relationship groups, ones can calculate the forecasted values of the time series data. Some performance measures can be utilized to assert the effective of the forecasting model.

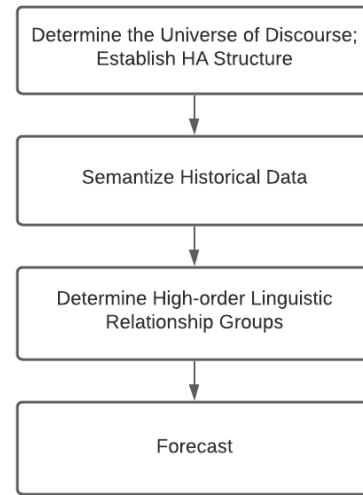

Fig. 1. The High-order Linguistic Time Series Forecasting Model.

III. SOME EXPERIMENTAL RESULTS AND DISCUSSIONS

This section presents the experimental results of the proposed high-order LTS forecasting models and shows their performance in comparison with their counterpart models. The comparative study is designed to compare the proposed high-order LTS forecasting model performance with those examined by Chen [5] and Singh [17], using the historical data of the enrollments of University of Alabama observed from 1971 to 1992, and Lahi crop production of India observed from 1981 to 2003.

The experiments are executed to show the following statements:

- The proposed high-order LTS forecasting models outperform their counterpart of fuzzy approaches with restricted linguistic words.
- In the proposed high-order LTS forecasting models, the forecasting linguistic variable \mathcal{X}_L is considered as the linguistic counterpart of the numerical forecasting one \mathcal{X}_N . So, we assume that there is not any restriction on its declared word set's cardinality. The accuracy of the proposed high-order LTS forecasting models can considerably increase when the declared word-set of \mathcal{X}_L grows.

A. Forecast the Enrollments of University of Alabama

1) Compare with the two counterparts examined by Chen and Singh: To show the efficiency of the proposed high-order LTS forecasting models, we apply them to the historical data of the enrollments of University of Alabama observed from 1971 to 1992, as shown the column “Actual Enrollment” in Table I. To be more convenient, the experiment follows the procedure as follows:

Step 1: Determine the syntactic, qualitative and quantitative semantics of the forecasting linguistic variable \mathcal{X}_L .

- The syntactic semantics are determined by declaring two primary words $c^- = small$, $c^+ = large$ (l) and the linguistic hedges. In this study, we just use two linguistic hedges $H^- = \{Little (L)\}$ and $H^+ = \{Very (V)\}$. For the model illustration and comparative study, the cardinality of the declared word-set of \mathcal{X}_L is set to 9 (2-specificity level). So, we have: $U_{\mathcal{X}_L} = X_{(2)} = \{\mathbf{0}, V_small, small, L_small, medium, L_large, large, V_large, \mathbf{1}\}$, where $\mathbf{0}$ stands for *Absolutely small* and $\mathbf{1}$ stands for *Absolutely large*.
- The qualitative semantics of \mathcal{X}_L is specified by the signs of hedges and the relative signs between them: $sign(L) = sign(L, L) = sign(L, V) = -1$ and $sign(V) = sign(V, V) = sign(V, L) = +1$.
- The quantitative semantics is defined by specifying the fuzziness parameter values of \mathcal{X}_L . In this study, they are specified by human’s experts and we have $m(c^-) = 0.437$, $\mu(L) = 0.511$.

Step 2: Compute the numerical semantics of the declared words of \mathcal{X}_L .

Transform the numerical semantics (SQM-values) of the declared words in the normalized domain $[0, 1]$ into the real numerical semantics in the universe of discourse $U_x = [13000, 20000]$ of \mathcal{X}_L by the following formula:

$$v_R(l_i) = U_{x_{min}} + (U_{x_{max}} - U_{x_{min}}) \times v(l_i), \quad (4)$$

where $l_i \in X_{(2)}$, $v(l_i)$ is the numerical semantic of the word l_i , $U_{x_{min}}$ is the lower bound and $U_{x_{max}}$ is the upper bound of U_x . Specifically, with the set $U_{\mathcal{X}_L}$, $m(c^-) = 0.437$ and $\mu(L) = 0.511$, we have the real numerical semantics of the declared words: $U_{\mathcal{X}_R} = \{13000, 13731, 14496, 15295, 16059, 17044, 18073, 19058, 20000\}$.

Step 3: Generate LTS from the given numerical time series.

Based on the real numerical semantics, the historical data of the enrollments are transformed into the linguistic words selected from the declared word-set of \mathcal{X}_L in such a way that each historical data value is assigned a linguistic word which has its real numerical semantics closest to that historical data value at that timestamp. For example, the enrollment value of 15460 is of the year of 1975 closest to the real numerical semantics of 15295 of the word *Little small* in $U_{\mathcal{X}_L}$. Therefore, that enrollment value is assigned the word *Little small*. By doing the same way for the enrollment data of other years, we obtain the LTS as shown in the column “Constructed LTS” in

Table I. Once the LTS is constructed, the high-order linguistic logical relationships (LLRs) and the high-order linguistic logical relationship groups (LLRGs) are created. Just for the illustration of the case of 2-specificity level of \mathcal{X}_L (9 declared words), the second-order and third-order LLRGs are shown in Table II and Table III, respectively.

TABLE I. THE LINGUISTIC TIME SERIES OF THE ENROLLMENTS OF THE UNIVERSITY OF ALABAMA FROM 1971 TO 1992 USING 9 WORDS

Year	Actual Enrollment	Constructed LTS
1971	13055	<i>Absolutely small</i>
1972	13563	<i>Very small</i>
1973	13867	<i>Very small</i>
1974	14696	<i>small</i>
1975	15460	<i>Little small</i>
1976	15311	<i>Little small</i>
1977	15603	<i>Little small</i>
1978	15861	<i>medium</i>
1979	16807	<i>Little large</i>
1980	16919	<i>Little large</i>
1981	16388	<i>medium</i>
1982	15433	<i>Little small</i>
1983	15497	<i>Little small</i>
1984	15145	<i>Little small</i>
1985	15163	<i>Little small</i>
1986	15984	<i>medium</i>
1987	16859	<i>Little large</i>
1988	18150	<i>large</i>
1989	18970	<i>Very large</i>
1990	19328	<i>Very large</i>
1991	19337	<i>Very large</i>
1992	18876	<i>Very large</i>

TABLE II. THE SECOND-ORDER LLRGs USING 9 WORDS

Group	2-order LLRG
1	$V_small, V_small \rightarrow V_small$
2	$V_small, V_small \rightarrow small$
3	$small, V_small \rightarrow L_small$
4	$L_small, small \rightarrow L_small$
5	$L_small, L_small \rightarrow L_small, medium$
6	$medium, L_small \rightarrow L_large$
7	$L_large, medium \rightarrow L_large, large$
8	$L_large, L_large \rightarrow medium$
9	$medium, L_large \rightarrow L_small$
10	$L_small, medium \rightarrow L_small$
11	$large, L_large \rightarrow V_large$
12	$V_large, large \rightarrow V_large$
13	$V_large, V_large \rightarrow V_large$

TABLE III. THE THIRD-ORDER LLRGs USING 9 WORDS

Group	3-order LLRG
1	$V_{small}, V_{small}, A_{small} \rightarrow small$
2	$small, V_{small}, V_{small} \rightarrow L_{small}$
3	$L_{small}, small, V_{small} \rightarrow L_{small}$
4	$L_{small}, L_{small}, small \rightarrow L_{small}$
5	$L_{small}, L_{small}, L_{small} \rightarrow medium, L_{small}$
6	$medium, L_{small}, L_{small} \rightarrow L_{large}$
7	$L_{large}, medium, L_{small} \rightarrow L_{large}, large$
8	$L_{large}, L_{large}, medium \rightarrow medium$
9	$medium, L_{large}, L_{large} \rightarrow L_{small}$
10	$L_{small}, medium, L_{large} \rightarrow L_{small}$
11	$L_{small}, L_{small}, medium \rightarrow L_{small}$
12	$large, L_{large}, medium \rightarrow V_{large}$
13	$V_{large}, large, L_{large} \rightarrow V_{large}$
14	$V_{large}, V_{large}, large \rightarrow V_{large}$
15	$V_{large}, V_{large}, V_{large} \rightarrow V_{large}$

Step 4: Calculate the crisp forecasted values. Two applied computation rules are as follows:

1) If an high-order LLRG is of the form: $l_{i1}, l_{i2}, \dots, l_{i\lambda} \rightarrow l_{j1}, l_{j2}, \dots, l_{jp}$ ($\lambda, p \geq 1$), where $l_{i1}, l_{i2}, \dots, l_{i\lambda}$ is the current state of a year, say k and $v_R(l_{j1}), v_R(l_{j2}), \dots, v_R(l_{jp})$ are the real numerical semantics of the words $l_{j1}, l_{j2}, \dots, l_{jp}$, respectively, then the numeric forecasted value of year $k + 1$ is $(v_R(l_{j1}) + v_R(l_{j2}) + \dots + v_R(l_{jp}))/p$.

2) If the current state of year k is $l_{i1}, l_{i2}, \dots, l_{i\lambda}$ and there does not exist any word in the right-hand side of any high-

order LLRG, then, the forecasted value of year $k + 1$ is $(v_R(l_{i1}) + v_R(l_{i2}) + \dots + v_R(l_{ip}))/\lambda$.

In this study, the mean square error (MSE) and average forecasting error (AFE) are used to evaluate the forecasting models, where N is the number of forecasted value, F_i and A_i are the forecasted value and the actual value, respectively; ϵ_i is forecasting error of year i :

$$MSE = \left(\frac{1}{N}\right) \sum_{i=1}^N (F_i - A_i)^2 \tag{5}$$

$$\epsilon_i \text{ (in percent)} = \frac{|F_i - A_i|}{A_i} \times 100 \tag{6}$$

$$AFE \text{ (in percent)} = \frac{\epsilon_i}{N} \tag{7}$$

The forecasted enrollments by applying the proposed high-order (from 2-order to 9-order) LTS forecasting models using 9 declared words (9 words selected from the word-set of X_L for describing the universe of discourse U_x) are shown in Table IV. The comparison of MSE values with three other high-order fuzzy time series forecasting models are shown in Table V. The MSE values of the proposed high-order LTS forecasting models are much better than all their counterparts (Chen [5], Hwang et al. [39] and Singh [17]) from the 4-order to 9-order. Evaluated based on AFE values, it is easy to see in Table VI that all proposed high-order LTS forecasting models have AFE values smaller than their counterparts (Song and Chissom [4], Hwang et al. [39] and Singh [17]).

3) The accuracy of the proposed high-order LTS forecasting models increases by allowing the current used word-set of the forecasting linguistic variable to grow.

A special feature of the LTS forecasting models is that it considers the forecasting linguistic variable X_L as the linguistic counterpart of the numerical forecasting one. So, there is not any restriction on its declared word set's cardinality. This experimental study will show that the forecasting accuracy will considerably increase when the declared word-set of X_L grows. In HA, the word-set of X_L are generated automatically by acting the linguistic hedges on two generator words [24], [37]. The maximum length of words is limited by an integer k , so-called k -specificity level. For example, in *Step 1* of the proposed high-order forecasting model described above, we use two linguistic hedges L and V acting on two generator words, so when $k = 1, 2, 3, 4$ and 5 , we have $5, 9, 17, 33, 65$ generated words, respectively. To show the scalability of the word-set of X_L , we assume that its cardinality grows from 9 to $17, 33$ and 65 words respectively corresponding to 3 -, 4 - and 5 -specificity levels. For each declared word-set cardinality, the fuzziness parameter values of X_L should be adjusted suitably by human's experts as shown in *Table VII*. For example, in case of 17 declared words, the value of $m(c^-)$ is 0.527 and the values of $\mu(L)$ is 0.412 , etc.

Intuitively seen in *Table IV* and *Table VIII*, with the same order, the greater used linguistic words, the smaller corresponding MSE and AFE values we will have. Specifically, the 9 -order LTS forecasting model using 65 words has its MSE value of 283 and its AFE value of 0.07 , better than the respective ones of the other models with same order using $33, 17$ and 9 words in turn, respectively, 1023 and $1.4, 15429$ and $0.6, 35464$ and 1.0 . We also have the same analysis results for other order (from 2 to 8) using the same words. These comparison results state that the forecasting accuracy will considerably increase when the declared word-set of X_L grows (from 9 words to 65 words) and show the effectiveness of the proposed high-order linguistic forecasting method.

B. Forecast the Lahi Crop Production of Indian

To prove that the proposed high-order LTS forecasting models are much more efficient than the ones proposed by Singh in [17], the proposed models are applied to forecast the Lahi crop production (productivity in kg per hectare) from the farm of G.B. Pant University, Pantnagar, India, observed from 1981 to 2003 [17]. With the observed production values are from 440 and 1067 , we can set the value interval of the universe of discourse of the variable X_L to be $U_X = [400, 1100]$ as in [17]. Two primary words are $c^- = low (l)$ and $c^+ = high (h)$ and two linguistic hedges are *Little (L) ∈ H⁻* and *Very (V) ∈ H⁺*. For illustration, the declared word-set of X_L in case of 2 -specificity level is $U_{X,L} = X_{(2)} = \{0, Very\ low, low, Little\ low, medium, Little\ high, high, Very\ high, 1\}$. The fuzziness parameter values are chosen by human's experts as $m(c^-) = m(low) = 0.5$ and $\mu(L) = 0.51$ for all various orders and declared words. So, the real numerical semantics of the declared words are $U_{X,R} = \{400, 484, 571.5, 662.5, 750, 837.5, 928.5, 1016, 1100\}$. Based on the given data setting, transform the observed historical data of the Lahi crop production shown the column "Actual production" in *Table IX* to the linguistic time series, establish the high-order LLRs and the high-order LLRGs, finally calculate the crisp forecasted values. The crop production forecasted results of the various high-order (from 2 to 9) LTS forecasting models are shown *Table IX*.

The comparisons of MSE and AFE values between the proposed LTS forecasting models with various orders using nine words and the corresponding ones proposed by Singh in [8] are shown in *Table X*. Indeed, the comparison results prove that the proposed high-order LTS forecasting models are much better than the ones proposed by Singh on both evaluation methods of MSE and AFE.

TABLE VII. FUZZINESS PARAMETER VALUES

17 words		33 words		65 words	
$m(c^-)$	$\mu(L)$	$m(c^-)$	$\mu(L)$	$m(c^-)$	$\mu(L)$
0.527	0.412	0.65	0.35	0.65	0.35

IV. CONCLUSIONS

The aims of the study in this paper is to establish a formalized methodology for handling words directly to solve the time series forecasting problems in such a way that it can simulate the way human users making a forecasting process in terms of their words. In fact, when observing the numerical time series data, human users can quickly transform its variations into the word variations which form a linguistic time series. They can do reasoning in their mind in some ways based on the relationships of the words in linguistic time series to estimate the forecasting values.

This paper focuses on examining the high-order linguistic time series to establish an efficient linguistic forecasting method in such a way that a formal formalism is developed to ensure that the inherent semantics of words, both qualitative and quantitative, are defined in the full linguistic variable context and the declared word-set of the linguistic variable can grow to increase the forecasted results. The growing of the declared word-set means that the human domain knowledge is grown. It is true in practice because human knowledge grows day by day. So, when human experts want to increase the forecasted results, he can make the declared word-set grow whilst keeps all semantic types of the existing words unchanged.

The proposed forecasting method is applied to the forecasting problems of the enrollments of University of Alabama and Lahi crop production of India. The experimental results have shown that the proposed forecasting method is better than the ones proposed by Song and Chissom, Chen, Hwang and Singh and the growth of the declared word-set of the linguistic variable is significant in increasing the accuracy of forecasted results of the high-order linguistic forecasting method. Therefore, that proves the effectiveness of our proposed approach.

Abstract—In recent months, many governments have announced COVID-19 vaccination programs and plans to help end the crises the world has been facing since the emergence of the coronavirus pandemic. In Saudi Arabia, the Ministry of Health called for citizens and residents to take up the vaccine as an essential step to return life to normal. However, the take-up calls were made in the face of profound disagreements on social media platforms and online networks about the value and efficacy of the vaccines. Thus, this study seeks to explore the responses of Saudi citizens to the COVID-19 vaccines and their sentiments about being vaccinated using opinion mining methods to analyze data extracted from Twitter, the most widely used social media network in Saudi Arabia. A corpus of 37,467 tweets was built. Vector space classification (VSC) methods were used to group and categorize the selected tweets based on their linguistic content, classifying the attitudes and responses of the users into three defined categories: positive, negative, and neutral. The lexical semantic properties of the posts show a prevalence of negative responses. This indicates that health departments need to ensure citizens are equipped with accurate, evidence-based information and key facts about the COVID-19 vaccines to help them make appropriate decisions when it comes to being vaccinated. Although the study is limited to the analysis of attitudes of people to the COVID-19 vaccines in Saudi Arabia, it has clear implications for the application of opinion mining using computational linguistic methods in Arabic.

Keywords—Computational linguistics; COVID-19 vaccines; lexical semantics; opinion mining; vector space classification

I. INTRODUCTION

The COVID-19 pandemic, which emerged in late 2019, has had and continues to have grave health, economic, social, and political consequences for almost all countries around the world [1-4]. So far, more than three million people have died of this coronavirus. In response, many governments have enforced lockdown laws, placing restrictions on the movement of citizens globally. This has resulted in serious economic problems for many countries, including the Arab Gulf states, which have suffered due to the lower demand for oil. As

pointed out by Kesar, et al. [5], the coronavirus pandemic has resulted in a large-scale humanitarian crisis leading to misery and suffering for all of humanity, and pushing social and economic well-being to the brink of collapse.

To alleviate the dangers of the COVID-19 pandemic, several vaccines have been developed, including the AstraZeneca, Johnson & Johnson's Janssen, Moderna, Novavax, and Pfizer-BioNTech vaccines. Given the sophisticated development and long authorization process for vaccinations, the COVID-19 vaccines were given temporary authorization for emergency use. Nevertheless, the manufacturers and researchers stressed the safety of the vaccines and their effectiveness in reducing the risks of severe illness associated with catching the virus. They confirmed that the new vaccines had undergone rigorous testing to verify their safety before they were recommended for widespread use.

In light of these developments, many governments have announced COVID-19 vaccination delivery plans to help end the crises the world has been facing since the emergence of the coronavirus pandemic. In Saudi Arabia, the Ministry of Health called for citizens and residents to take up the vaccine as an essential step in returning life to normal. However, these appeals were met by skepticism from many Saudis who had various fears about the vaccines. Furthermore, many activists fueled concerns about vaccine safety on social media platforms, especially Twitter. In response, officials and professionals stressed the safety of the vaccines, and called for citizens and residents to get the vaccines for the good and safety of everyone.

Twitter in particular was the forum for controversy and heated debates about the effectiveness and usefulness of the COVID-19 vaccines in Saudi Arabia. Millions of users voiced their opinions concerning the uptake of the vaccines on the platform. Apart from reflecting the issue of the effectiveness and safety of the vaccines, this clearly indicated the growing influence of social media platforms and networks on public opinion in Saudi Arabia, as noted by Gunter, et al. [6]. The

*Corresponding Author

increasing numbers of users of social media platforms and networks in Saudi Arabia is having a direct effect on their ever greater role and effectiveness in shaping public opinion concerning a range of social, economic, and political issues [6, 7].

Thus, it is important for policymakers and those in government to understand people's attitudes towards certain issues as represented on social media. In this regard, they could exploit the potential of opinion mining, defined as a computational linguistics science that uses text analysis and natural language processing (NLP) to understand the drivers of public sentiment through extracting people's opinions and sentiments from the Web in general, and social media networks and platforms in particular [8, 9]. Despite the importance of opinion mining applications in helping governments and organizations to make appropriate decisions concerning critical issues, especially at times of crisis, their potential has not yet been fully explored in Arab nations [10]. In response to this lack of research, our study has sought to explore Saudi responses and sentiments regarding the COVID-19 vaccination take-up calls.

The study addresses two key research questions. First, what were individuals' responses and sentiments concerning the COVID-19 vaccines in Saudi Arabia as expressed on Twitter? Second, can the opinions, attitudes, and responses of individuals regarding given issues be analyzed conceptually through computational linguistic methods in Arabic?

The remainder of the article is structured as follows. Section 2 reviews the development of opinion mining and outlines its theoretical underpinnings and its relationship with other disciplines, including sentiment analysis, NLP, and computational linguistics. Section 3 sets out the data collection methods and procedures and the corpus design. Section 4 details the computational linguistic analysis based on a vector space classification (VSC) of the selected tweets. Section 5 concludes, summarizing the main findings and highlighting the implications of the study for further research.

II. PREVIOUS WORK

Opinion mining is a rising field of study that is gaining prominence largely due to the growing influence of social media platforms and networks in today's world. Indeed, there has been an extraordinary increase in the number of social media networks, providing easy access to millions of users around the world to express their opinions freely on different issues. Given the daily growth in numbers of users around the world, social media networks have become indispensable in contemporary life, and are now integral to the economic, social, and political marketing mechanisms that are employed in many fields.

With the increasing influence of social media networks, opinion mining was developed to analyze human behavior through computational tools to help manufacturers, marketing agencies, branders, government institutions, organizations, and policymakers make appropriate decisions concerning their products, brands, services, and policies [11]. This caters to the growing need for businesses and organizations to take account

of public opinion expressed on social media networks and platforms in their decision making [12].

In the literature, opinion mining is commonly related to sentiment analysis, and the two terms are often used interchangeably [13-15]. They are both concerned with the study and analysis of human behavior as expressed on social media networks and platforms using computer modeling approaches. As Liu and Zhang [12] point out, they have in common that they entail the "study of people's opinions, appraisals, attitudes, and emotions regarding entities, individuals, issues, events, and topics and their attributes." Our study, however, considers that they differ in terms of depth, arguing that opinion mining goes to the next level in understanding the conversational drivers underpinning the sentiment.

The literature reports extensive studies that have been carried out to measure public opinion on different issues and policies through computational-based opinion mining methods. There is growing interest in opinion mining applications to analyze political issues due to the already vast and constantly increasing creation of political content on the Web and its exchange, particularly on social media networks and platforms [16-18]. The underlying principle in such studies is that the analysis of public opinions expressed on social media networks and platforms, if well done, "can be quite useful for government agencies, as it can significantly assist them to understand the needs and problems of society, and the perceptions and feelings of the citizens, and to formulate effective public policies" [16].

Despite the prolific and increasing literature on opinion mining applications, there have been very few studies based on Arabic content to date. This can be attributed to several reasons. First, as noted by Badaro et al. [19], "there are fewer freely [available] resources for Arabic opinion mining in terms of large clean sentiment lexica and annotated collections of opinions" compared to English and other western languages. In other words, most opinion mining methods have been developed for English texts. It is difficult to use these methods with Arabic, which is completely different from English [20]. Second, the morphological system of Arabic poses serious challenges for NLP applications with Arabic data [21-24]. As pointed out by Ryding [25], Arabic is a highly inflectional language. Unlike English, words in Arabic have a unique morphological system, which typically has negative effects on the reliability and effectiveness of NLP processes and applications. Finally, the diglossic nature of Arabic, and its different vernacular and colloquial dialects make it difficult for the classification systems of opinion mining applications to work properly [26-28].

It has only been over the last five years that opinion mining in Arabic has started to receive considerable interest from the research community [29]. In a recent study, Althagafi, et al. [30] studied and analyzed the attitudes and responses of people to the shift in schools and universities towards online learning in 2020 due to the COVID-19 pandemic. The authors used Arabic tweets to gain an understanding of the sentiments and opinions of Twitter users regarding online learning to help government, educational institutions, and policymakers

recognize the emotional effects of online learning on students, teachers, parents, and individuals in the Saudi community.

In another study, Omar and Hamouda [10] analyzed the responses of citizens to a new real estate law in Egypt through computational tools. They aimed to explore Egyptians' sentiments, opinions, and attitudes regarding the new Real Estate Registration Law based on Facebook posts, comments, and replies. The study concluded that the citizens' views of the new law were predominantly negative. The authors highlighted the effectiveness of applying opinion mining to examine responses to regulations and policies through citizens' responses on social media. Accordingly, they suggested that opinion mining applications should be viewed as presenting valuable opportunities for policymakers and legislators to gauge people's sentiments, attitudes, and perceptions.

Despite the importance of such studies in terms of introducing researchers to opinion mining applications in Arabic, there was no focus on the manipulation of computational linguistic tools or lexical semantic analysis in the interpretation of the data and users' opinions.

III. METHODS AND PROCEDURES

This study used Twitter posts to identify the responses of citizens and residents to the COVID-19 vaccines in Saudi Arabia since social media networks and platforms have become an integral part of the lives of the Saudis today and Saudi Arabia is one of the leading countries in terms of Internet penetration. According to a report released by the World Bank, 95% of the total population of Saudi Arabia was using the Internet in 2019. In 2021, the percentage increased to 95.7%, with mobile connections up to 112.7%. Furthermore, the number of active social media users amounted to 27.80 million, individuals constituting around 79.3 % of the total population [31], as shown in Fig. 1.

In light of these statistics, it can be claimed that social media networks can usefully be employed to identify the responses of individuals in Saudi Arabia to specific issues. Of the platforms available, Twitter is one of the most reliable and suitable sites for the application of opinion mining and sentiment analysis [32, 33], and as of January 2021, Saudi Arabia has been ranked one of the top countries in terms of Twitter users [34], as shown in Fig. 2.

Fig. 1. The use of the Internet and Social Media in Saudi Arabia.

Fig. 2. Countries with the Most Twitter users in 2021.

Furthermore, Twitter was ranked topmost for information and posts on COVID-19 in Saudi Arabia. Finally, the Twitter account of the Saudi Ministry of Health has the highest number of followers, as shown in Fig. 3.

To extract information about users' polarity and responses concerning the issue of COVID-19 vaccines, four key terms were defined, as presented in Table I.

Fig. 3. Numbers of the Ministry of Health followers on Social Media Networks.

TABLE I. LIST OF THE DEFINED KEY TERMS

Key Terms	Transliteration	English Translation
لقاح كورونا	Liqah kooruna	Corona Virus vaccine*
تطعيم كورونا	Tat'eem kooruna	Corona virus vaccine*
التحصين	Altahsin	Vaccination
الحصول علي اللقاح	Alhusul eali alliqah	Vaccine uptake

* In Arabic, unlike English, coronavirus is expressed as two words.

Keywords were chosen rather than hashtags to ensure the data sample was as inclusive and representative as possible for generalizability and reliability purposes, since hashtags are generally used by more proficient social media users.

We built a corpus of 37,467 tweets from 23,748 users drawing on posts, comments on posts, and replies to posts on the topic of COVID-19 vaccines. The selected tweets covered the period from December 15, 2020, when the Ministry of Health called for the citizens and residents of Saudi Arabia to register for the COVID-19 vaccine, until May 25, 2021. Fig. 4 shows the first two citizens in Saudi Arabia who took the vaccine on December 17, 2020.

The selected tweets were cleaned and all non-alphabetical characters were removed. A stop-word list was also generated and all function words were removed. As a next step, a vector space matrix containing only the content or lexical words was designed and comprised 9,348 lexical types. There were fewer lexical types than tweets as many of the selected posts were repeated.

One critical problem with the matrix was the high dimensionality of the data, which commonly has adverse impacts on the reliability of classification [35]. High dimensionality results from a high volume of irrelevant information, which makes the classification process problematic and leads to poor, potentially unreliable, performance. As the number of vectors or attributes increases, the texts become increasingly homogeneous. For a data matrix in which the rows are the data items and the columns the variables, the matrix defines a manifold (the shape of the data in space) in \mathcal{N} -dimensional space. Let us assume a data matrix with 1,000 3-dimensional vectors. Plotting these vectors in 3-dimensional space will result in a cloud of points, as shown in Fig. 5.

Consequently, it becomes increasingly difficult to find meaningful and distinct groups based on such a dataset. The retention of unimportant variables in analysis gives invalid results [36]. It is thus important to retain only those variables that are most distinctive within a data matrix through dimensionality reduction, improving the reliability of classification performance [37]. To do this, two tests were carried out: variance and term frequency-inverse document frequency (TF-IDF). The rationale is that the classification is based on only the most distinctive lexical variables in the corpus.

First, all 9,348 lexical types were sorted in terms of variance based on the assumption that there must be variations in the characteristics of documents, distinguishing one from another, to enable classification. It follows that measuring variance within datasets can be useful in identifying the most

distinctive features within a matrix. The variance test indicated that the first 600 lexical types were the most significant variables in terms of variance, as shown in Fig. 6.

Fig. 4. The Initiation of the Vaccination Program in Saudi Arabia.

Fig. 5. A Manifold in 3-dimensional Space.

Fig. 6. Measuring Variables in Terms of Variance.

As such, only the lexical types presenting significant variation were retained and those with low or no variation were deleted. This resulted in a reduction in lexical types within the matrix to just 600 variables. As a final step in the data dimensionality reduction process, a TF-IDF analysis was carried out. The 600 lexical types were sorted in descending order in terms of TF-IDF using the following function:

$$tfidf(t_i) = tf(t_i) \log_2 \left[\frac{M}{df_1} \right]$$

where $tf(t_i)$ is the frequency of term t_i across all documents in the data matrix M . The result is shown in Fig. 7.

Fig. 7. Term Weighting using TF-IDF.

In this process, only the 60 lexical types with the highest TF-IDF were retained. These are assumed to be the most distinctive features within the data matrix.

IV. ANALYSIS AND DISCUSSION

To classify each opinion concerning the issue as positive, negative, or neutral, a computational lexical semantic analysis was conducted based on vector space classification (VSC). VSC is one of the most reliable classification systems in data mining applications, including information retrieval (IR), annotation and summarization, sentiment analysis, and opinion mining. VSC is based on measuring the relative distances between row vectors. The size of the angle between the lines that joins vectors to the origin of the space's coordinate system and the lengths of the lines jointly determine the distance between any two vectors in a space [38]. In VSC, for each selected variable, its semantics are used to obtain an interpretation of the domain of interest, the domain thus being measured based on the semantics [39-41].

The classification is formed using opinion words and phrases, these being the dominant indicators for opinion classification. Liu and Zhang [12] define opinion words as "words that are commonly used to express positive or negative sentiments. For example, beautiful, wonderful, good, and amazing are positive opinion words, and bad, poor, and terrible are negative opinion words. Although many opinion words are adjectives and adverbs, nouns (e.g., rubbish, junk, and crap) and verbs (e.g., hate and like) can also indicate opinions. Apart from individual words, there are also opinion phrases and idioms, e.g., cost someone an arm and a leg." The 37,467

tweets were classified into three categories or classes: positive, negative, and neutral. The results are shown in Fig. 8.

It is clear that most responses to the COVID-19 vaccine take-up calls are negative. The negative responses account for approximately 54%, positive responses 34%, and neutral responses 12%.

Positive responses were reflected in words such as (فعال) effective, (آمن) safe, (طبيعية) normality, (يحمي) protect, and (وقاية) protection. These focused on the concept of reducing the risks associated with COVID-19 infection, especially for the elderly, as shown in the examples given in Fig. 9.

Fig. 8. Results of the Classification of the Selected Twitter Posts.

Fig. 9. Examples of Positive Responses to the COVID-19 Vaccines.

Negative responses, in turn, included words such as (أرفض) reject, (لا) No, (العقم) infertility, (جيش) Gates, (مؤامرة) conspiracy (الجلطات) clots, and (الحامض النووي) DNA. These responses focused on the ineffectiveness of the vaccines and that they had not been carefully evaluated in clinical trials. They also linked the COVID-19 vaccines to infertility and making changes within the DNA of individuals, as seen in the examples given in Fig. 10.

Furthermore, many posts claimed that COVID-19 vaccination was cover for a plan devised by Bill Gates to implant trackable microchips to control people. It is therefore not surprising that many hashtags rejecting vaccination were generated in response to the Saudi government's call for vaccine uptake. These included:

#لا لربط السفر بالتطعيم (No vaccine certificates for travel).

#لا للتطعيم الاجباري (No for mandatory vaccination).

#نرفض اللقاح الاجباري (We reject mandatory vaccination).

#نرفض التطعيم الاجباري (We reject mandatory vaccination).

Based on these findings, it can be claimed that computational lexical semantic and opinion mining methods can usefully be employed to define people's attitudes and responses to given issues. It was clear that the classification of the Twitter posts based on their lexical semantic properties was meaningful. In particular, it was a straightforward matter to define polarity concerning the issue of COVID-19 vaccine uptake in Saudi Arabia.

Fig. 10. Examples of Negative Responses to the COVID-19 Vaccines.

V. CONCLUSION

This study analyzed the responses of individuals to COVID-19 vaccines in Saudi Arabia through their Twitter posts. To do so, computational lexical semantic methods were used for the classification of people's responses. The results clearly indicate that most people in Saudi Arabia hold negative attitudes concerning the COVID-19 vaccination take-up programs established by the government. The findings of the study illustrate the importance of understanding people's sentiments, opinions, and attitudes regarding government decisions and policies. The results argue for the benefits of government institutions and departments making use of the potential of data mining applications to identify trends that may have adverse impacts on policies and practices, as well as to help government institutions make appropriate decisions, and adopt reliable and workable policies and procedures. In view of the significance of social media networks and platforms in modern societies, opinion mining applications should be an integral part of all government processes. Although the study is limited to analysis of the attitudes of people to the COVID-19 vaccines in Saudi Arabia, it has clear implications in terms of the value of opinion mining applications using computational linguistic methods in Arabic.

Indoor Localization and Navigation based on Deep Learning using a Monocular Visual System

Rodrigo Eduardo Arevalo Ancona¹, Leonel Germán Corona Ramírez², Oscar Octavio Gutiérrez Frías³

UPIITA-IPN SEPI Section, Instituto Politécnico Nacional
Mexico City, Mexico

Abstract—Now-a-days, computer systems are important for artificial vision systems to analyze the acquired data to realize crucial tasks, such as localization and navigation. For successful navigation, the robot must interpret the acquired data and determine its position to decide how to move through the environment. This paper proposes an indoor mobile robot visual-localization and navigation approach for autonomous navigation. A convolutional neural network and background modeling are used to locate the system in the environment. Object detection is based on copy-move detection, an image forensic technique, extracting features from the image to identify similar regions. An adaptive threshold is proposed due to the illumination changes. The detected object is classified to evade it using a control deep neural network. A U-Net model is implemented to track the path trajectory. The experiment results were obtained from real data, proving the efficiency of the proposed algorithm. The adaptive threshold solves illumination variation issues for object detection.

Keywords—Visual localization; visual navigation; autonomous navigation; feature extractor; object detection

I. INTRODUCTION

Computer systems are important for autonomous mobile robots to perform crucial tasks using sensors to extract useful information from the environment [1]. Vision-based sensors are powerful tools, providing the capability to interact with the environment [2], [3]. Cameras are used as a sensing equipment for environment perception in artificial vision systems, extracting relevant features from the image, allowing autonomous navigation, 3D mapping, visual robot localization, and object recognition [4], [5], [6].

Visual perception describes the environment extracting key-points around the system. The extracted key-points can achieve full autonomy to a mobile robot [6], [7], [8].

The robot localization problem implies the absolute current position estimation of the system, but also includes the relative position with respect to the object [2], [9], [10]. Localization is mandatory for a successful indoor navigation, and situates the system and the goal on a map.

Many visual localization methods are based on deep learning extractors. In [11] Perez, Caballero and Merino proposed an extending Monte Carlo localization method, extracting information from the images to generate a visual recognition using a map-based localization approach. Fu *et al* [12] applied a 3D mapping with an RGB-D camera, using an improved ORB algorithm as a feature extractor and measure the similarity of the descriptors with Hamming distance. Chen and Cheng proposed a cloud-based visual SLAM in [13], using

the oriented Fast and ORB features to build the dense map and estimate the position. Chiang, Hsia and Hsu [14] proposed a stereo vision self-localization system applying a trigonometric function finding coarse distances from the robot to the landmark; therefore it is applied to a neural network to increase the precision of the distance measurement. Xu, Chou and Dong [15] presented a multi sensor based indoor algorithm for a localization system, integrating a convolutional neural network (CNN) based on image retrieval, to determine the location of the robot. Another example is presented by Xie, Wang, Li and Tang [16] use a CNN robot localization to recognize the scene, reducing the error of relocating the robot.

Object detection is necessary to predict the position of the obstacles to avoid them, and move through the environment using extracted landmarks from the images to detect objects and predict the next state of the system. Many approaches for object detection use image feature extractors based on edge features, color features and textures features. Edge features methods aim on the identification of key-points from brightness changes on images. Color features detectors compare nearest regions from key-points. Texture features used regions of interest to classify pixel intensity levels in a neighborhood, such copy-move detection algorithms that search similar areas in images [17], [18], [19], [20], [21]. Ahn and Chung in [22] combined the advantages from the multi-scale Harris corner and SIFT descriptors to make an object detection using depth range features for metric information. Zheng, Barahimi, Aoun and Amar [23] present a boosted convolutional neural network for object recognition, using a boosted blocks in a succession of convolutional layers. Pertusa, Gallego and Bernabeu [24] propose an application for smartphones that allows object recognition using CNN.

Robot navigation use images to determine the system position using key-points as representations of the environment and detect obstacles [4], [5], [6], [11], [25]. Indoor navigation incorporates some knowledge of the environment, in particular a space representation, such as a map. The environment map representation is divided into three groups: Map-based navigation, the system depends on a created model or topological map. Map building-based navigation, a topological representation is contracted while the robot navigates on the environment. Mapless, the system does not have a spatial representation of the environment [26].

Visual Navigation describes the environment using landmarks on the image to build the map, locate the robot and detect obstacles. Sineglazov and Ischenko [27] used a SURF and RANSAC algorithms to locate landmarks and a neural

network to determine the object coordinates. Yilmaz and Gupta focus on combine signals from visual and inertial sensors in [28] for an indoor environment, this approach is based on visual odometry and a building information model. Shao *et al* [29] fusion the visual and inertial navigation system and applied a Kalman Filter to decline the errors of visual navigation. Sineglazov and Ischenko [30] analyze the characteristic features of different methods to develop n algorithmic maintenance for intellectual visual navigation based on neural networks.

The present approach addresses indoor map-based localization and navigation problems. A deep convolutional neural network is used to locate the system on the map and the pose estimation is based on a background modeling for feature extraction. A copy-move detection algorithm is applied to detect obstacles and a neural network for its evasion. Furthermore, a U-Net model is used for path trajectory tracking. This paper is divided in: Section II presents the proposed method for visual localization and navigation; Section III consists on the experiment results and analysis; Section IV contains the conclusions of the proposed algorithm.

II. PROPOSED METHOD

The present paper provides a solution for indoor navigation problem, including a map-based robot localization on the environment, and planning the trajectory using visual information from the mobile robot. Fig. 1 presents a general diagram from the proposed algorithm.

A. Robot Localization

Robot visual localization interprets the image information to estimate the current position of the system. Artificial neural networks are computational models capable of adapting their behavior in response to the stimulus actions from the environment [31]. The proposed visual localization stage is based on a deep neural network (Fig. 2) as a feature extractor. The convolutional deep neural network works as a feature extractor and classifies the image to locate the system in the environment; afterward it measures the robot position using the extracted interest points. The architecture of the deep neural network consists on three blocks, the first block has two CNN blocks with 64 filters, a (3,3) kernel size, a stride (1,1), a relu activation function, and an average pooling; the second block has two CNN blocks with 128 filters, a (5,5) kernel size, a stride (2,2), a relu activation function, and an average pooling; the first block has two CNN blocks with 256 filters, a (5,5) kernel size, a stride (2,2), a relu activation function, and an average pooling, therefore is used a Dense block after the Flatten stage, and classify eight classes. An Adam optimizer and a 0.0005 learning rate are used to get more accurate results.

Illumination changes influence the image scene on indoor visual localization. The neural network training process uses an image processing (gamma transformation, logarithmic transformation, blurring, rotation and translation) to reduce the error on the classification and increase the accuracy of each area of the environment, such as, rooms or corridors. The localization stage is completed by estimating the position of the robot.

Subsequently, the background model is used as a reference image. The diagram of the background subtraction is in Fig. 3, the main idea is to extract points from the image to generate a background model and analyze the image frames using an adaptive threshold to detect object when the system is static. On the other hand, a copy move detection is used to detect objects while the system is on movement [32]. One of the most frequent image forgery attacks is duplicating a fragment and place it on an image. Copy-move detection is a common technique for image forensic for detection of the tamper zones with a duplicated region from the digital image and verifies its originality [33], [34], [35], [36], [37], [38].

Key-points on the background model are used for the identification of possible objects.

$$B = \frac{\sum I_r}{N} \tag{1}$$

B is background model, I is the r^{th} frame, and N is the number of frames. A subtraction between the current frame and the reference image is applied to estimate the position of the system. This process identifies pixel intensity variations to detect possible objects.

$$S = |f_s - B_s| \tag{2}$$

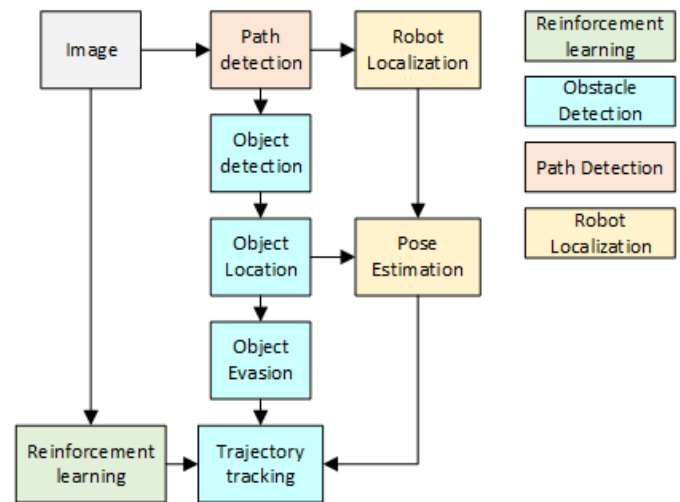

Fig. 1. Overview of the Proposed Method.

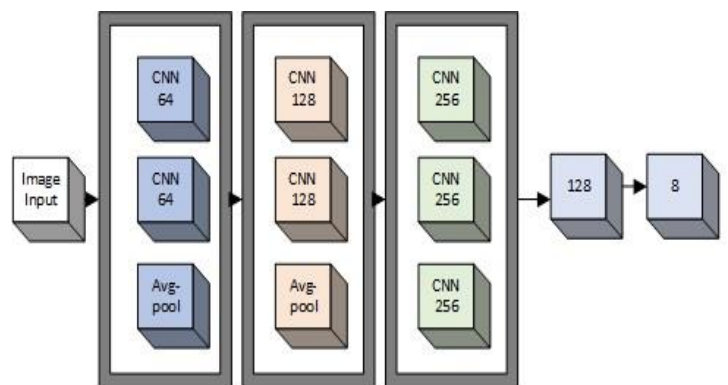

Fig. 2. Localization and Object Classification Deep Neural Network.

Fig. 3. Motion Detection Diagram.

where f_s is the current frame and B_s is the background. Therefore, it is extracted stable and invariant image features to get the position of the robot and obstacle detection, using an adaptive threshold based on copy move detection, such as in [35], [39]. The reference image S from the current image sequence and the last current image sequence are segmented the Discrete Cosine Transform is apply (DCT) [40].

$$C_{i,j}^K = \begin{pmatrix} C_{11}^k & \dots & C_{18}^k \\ \vdots & \ddots & \vdots \\ C_{81}^k & \dots & C_{88}^k \end{pmatrix} \quad (3)$$

The first stage of thresholding is obtained from C:

$$\lambda_1 = \sigma^2(\sqrt{\log(N)}) \quad (4)$$

$$\lambda_2 = \frac{\sum c_r}{r} \quad (5)$$

$$\lambda_3 = (\lambda_2 + \sigma^2) \sigma^2(\sqrt{\log(N)}) \quad (6)$$

where σ^2 is the variance, N are the number of frames, c_r are the values of each block C .

The Discrete Wavelet Transform (DWT) is applied to each block B and divides the image into signal components as level filters, approximations (low frequency), and details (high frequency) using the approximation sub-band as a noise filter and obtain characteristic features from the image.

$$D_{i,j}^K = \begin{pmatrix} d_{11}^k & \dots & d_{18}^k \\ \vdots & \ddots & \vdots \\ d_{81}^k & \dots & d_{88}^k \end{pmatrix} \quad (7)$$

The feature extraction allows the detection and recognition of the object, through the correlation between the images.

$$EV^k = (C^k \cdot D^k) \quad (8)$$

$$ev = (ev_{k2}, ev_{k3}, ev_{k4}, ev_{k5}, ev_{k6}, ev_{k7}, ev_{k8}) \quad (9)$$

The descriptors are computed using the block statics.

$$mean = \frac{\sum ev_1 - ev_2}{8} \quad (10)$$

ev_1 is the feature vector extracted from the current reference image and ev_2 is the feature vector extracted from the last reference image. The second stage from the adaptive threshold avoids the error in object detection and its localization. Each matrix D_{ij}^k of the current image are a shift to the right the column, shift down rows as in [39] and the descriptors are computed generating $\beta = \kappa = \varsigma = ME$.

$$T_1 = \frac{\beta + \kappa + \varsigma}{3} \quad (11)$$

Therefore, the thresholds are generated as in [39], then is proceed to compare the descriptors and obtain the interest points.

$$a = |mean| < \lambda_2 \text{ and } |mean| < T_1$$

$$b = \lambda_2 < T_1 \text{ and } mean < \lambda_3 \quad (12)$$

$$obj = \begin{cases} 0, a \text{ or } b \\ 1, other \end{cases} \quad (13)$$

The detection and localization of the object is owed to the pixel values changes on the image sequence. Therefore, a neural control network is applied for object classification and evasion. The neural control network allows the recognition of the detected objects, and the control tasks to evade the objects.

Once the interest points are detected, the robot position is estimated. The camera position is on the center and bottom of the image O as in Fig. 4.

The distance between the camera h and the object is given in centimeters:

$$h = mean(h_s, h_i) \quad (14)$$

where h_s is acquired by ultrasonic sensor, h_i is the calculated distance with the camera.

$$h_s = f_s - f_f \quad (15)$$

$$h_i = \sqrt{(\sin(b) * (\overline{OQ}))^2} \quad (16)$$

$$b = \frac{P * Q}{|P| * |Q|} \quad (17)$$

$$\overline{OQ} = \sqrt{(O(x) - Q(x))^2 + (O(y) - Q(y))^2} \quad (18)$$

f_s is the start time from the pulse and f_f is the final time from the pulse. The width from the detected obstacle is:

$$w = (\overline{OQ} * h) / 100 \quad (19)$$

Fig. 4. Obstacle Detection and Pose Estimation.

where:

$$\overline{PQ} = \sqrt{(Q(x) - P(x))^2 + (Q(y) - P(y))^2} \quad (20)$$

B. Robot Navigation

The neural control network classifies the detected objects and the control tasks to evade them. A path planning is implemented a control system using the neural network approach described in using predefined controls to evaded the recognized object; considering a system with multiple inputs and multiple outputs.

$$v = F(\dot{s}, s) \quad (21)$$

The system considered involve both non-moving and moving rigid objects and define the robot position (p), rotation matrix (q), velocity (v), angular velocity (w).

$$p = [p_x, p_y]^T \quad (22)$$

$$q = [q_\theta, q_x, q_y]^T \quad (23)$$

$$v = [v_x, v_y]^T \quad (24)$$

$$w = [w_x, w_y]^T \quad (25)$$

Each control v defines a force-torque pair (F, τ) acting on the mass center B , therefore the motion equations can be defined as:

$$\dot{x}(t) = \begin{bmatrix} \dot{p} & v(t) \\ \dot{q} & 1/2((w(t) - q(t))) \\ \dot{v} & F/M \\ \dot{w} & R(t)I^{-1}R(t)^T \end{bmatrix} \quad (26)$$

The system used a set of predefined controls U evaluating the current system state.

$$U = \begin{bmatrix} U_1 & 0 & 1 \\ U_2 & 1 & 1 \\ U_3 & 0 & 0 \\ \vdots & \vdots & \vdots \\ U_4 & 1 & 0 \end{bmatrix} \quad (27)$$

Evaluating the states choose the control to evade the object and track the trajectory. The trajectory is predefined using reinforcement learning, using a cost function, based on the Euclidean distance, to assign priorities for the movements.

Then the trajectory is tracked by the cloning behavioral network. The system learns the trajectory and reproduces the user's control using the knowledge of a human pilot for training a convolutional neural network (CNN) that receives as input the current camera frame and outputs the next state. The idea is to reinforce the knowledge of the trajectory using a UNET model [41], [42].

A successful path tracking depends on the path and specific object recognition. To perform path recognition in an image is required a semantic segmentation. Path detection describes the systems movements in the environment [43]. The predicted class $P(class)$ represents the coincidence between the input image $O_{detected}$ and the predicted class $O_{predicted}$.

$$P(class) = \frac{A \cap B}{A \cup B} \quad (28)$$

where:

$$A \cap B = O_{detected} * O_{predicted}$$

$$A \cup B = O_{detected} + O_{predicted}$$

The existing probability of a specific class and the object detected (in this case the trajectory) are taken in consideration. During the training, the following loss function is used the categorical cross-entropy:

$$L(y, \bar{y}) = \sum \sum (y_{ij} * \log(\bar{y}_{ij})) \quad (29)$$

y is the training image and \bar{y}_{ij} is the label. The use of the categorical cross-entropy will compare the distribution of the predictions, where the probability of the true class is 1 and 0 for other class.

III. EXPERIMENTAL RESULTS AND ANALYSIS

In this section the results are presented for the visual robot localization, object detection and trajectory tracking using a mobile robot with a Raspberry Pi 4 and a Raspberry V2 module (Fig. 5).

The proposed neural networks are trained under Windows 10 operating system using TensorFlow and Pytorch deep learning frameworks, the CPU model is 8GB Intel® Core i7-6700 @ 3.40 GHz, with a graphics card model NVIDIA GeForce GTX 960.

A. Robot Localization

The algorithm for robot localization uses extracted features from images as landmarks to determine where the robot is, by comparing this feature with the environment image.

The class coincidence in Table I has a good performance an 88% of accuracy, obtaining a high efficiency for robot localization. To increase the performance of the localization neural network more images for each class have to be added to the dataset.

The train dataset uses 1532 images from Room1, 1665 images from Room2, 1869 from Hall and 2052 from Room3, the validation dataset uses 1002 images from Room1, 1105 images from Room2, 1157 from Hall and 2500 from Room3, the test dataset uses 600 images, in addition, a pre-processing image process was applied to increase the classification accuracy (translation, rotation, and blurring). The neural network for localization presents in Fig. 6. An accuracy of 95%, reducing the classification error, then the position of the system is estimated by extracting key points from the background model and the object detection.

Fig. 5. Robot.

TABLE I. LOCALIZATION

Localization	Room 1	Room 2	Hall	Room 3
Coincidence	90 %	91 %	93 %	85 %

Fig. 6. Neural Network for Localization Accuracy.

The proposed approach tracks all the detected key points on the frame sequence, obtaining the robot position and locates the obstacle as in Fig. 7. The main advantage is the detection and points matching despite the illumination changes or the system position. In order to evaluate the proposed algorithm is used the accuracy and feature ratio sequence rs .

$$rs = \frac{np}{np_i} \quad (30)$$

where np are the detected points on the current image and np_i are the detected points on the previous image frame. In order to analyze the effectiveness of the object detection algorithm is compare in Table II with popular algorithms.

Clearly, the proposed method has a good performance tracking 97% of the detected features. In Fig. 8 is observed the behavior of the precision in a sequence, the proposed method has a 90%. The extracted features can be tracked without losing them on the frame sequence; the ratio sequence has a variation because the robot position changes.

The experiment was realizes using the robot on different conditions of illumination on the indoor environment. An advantage of the proposed algorithm is the feature detection and tracking on frame sequences, this advantage is useful for the detection and tracking of moving objects. In Fig. 8, shows that the extracted features can be tracked without losing information regardless of changes on the system position and illumination changes, being an advantage over the conventional methods. Once the obstacle is located a neural network classifies the object for its evasion. The effectiveness of the object classification is evaluated using the confusion matrix in Table III.

Fig. 7. Object Detection.

TABLE II. COMPARISON OF FEATURES EXTRACTORS

Method	Kaze [44], [45]	Harris [40], [46]	Eigen-Features [47]	Proposed Method
Accuracy	0.8322	0.6821	0.5051	0.9035
Ratio sequence	0.7418	0.544	0.3608	0.8011

(a)

(b)

Fig. 8. Object Detection, (a) Precision, (b) Ratio Sequence.

TABLE III. CONFUSION MATRIX

	False	True	Total
Negative	93	7	100
Positive	6	474	480
total	99	481	580

The accuracy and the recall from the control neural network are described using statics values from the confusion matrix. Where T_p are the true positives, F_p are the false positives and F_n the false negatives.

$$precision = \frac{T_p}{T_p+F_p} \quad (31)$$

$$recall = \frac{T_p}{T_p+F_n} \quad (32)$$

The efficiency of the object classification neural network has high accuracy. Clearly, in Table IV, the proposed algorithm has a good performance with a 93% of accuracy and a 98% recall for object classification.

The trajectory is generated using reinforcement learning, and it is tracked by the U-Net model. In order to verify the accuracy performance of the U-Net model trained for the trajectory detection, the used data was acquired using the proposed system. The dataset contains real 1500 images with the path, in addition, the pre-processing image was applied to increase the accuracy (translation, rotation, and blurring). Furthermore, a segmentation on the image detects the path to decide the control actions to track a trajectory.

The accuracy from the U-Net model in Fig. 9 is 90% for path detection. The semantic segmentation recognizes the predicted class on the image, moreover is used to track the trajectory and evade a collision. The U-Net was trained using 1500 images and labels on different conditions on the environment to get a better performance.

To verify the applicability and accuracy of the algorithm in Fig. 10 is presented the image segmentation. The red region recognizes the path.

IV. CONCLUSIONS

This paper proposes an indoor navigation method, applying a self-localization solution and novel object detection. This approach has a high precision for feature tracking, this increases object detection and evasion.

A map-based is used in the present approach to self-locate the system on the map using a neural network. The accuracy for the localization neural network is >90%. In addition, the use of a deep learning neural network reduces the error in the system localization.

Furthermore, object detection is used to estimate the position of the system. The object detection has a >90% accuracy owing to the feature extractor and an adaptive threshold solving problems with illumination changes. The proposed solution tracks the object in the image frames; therefore, the system classifies the obstacle and reinforcement learning to evade it.

The path detection and track a trajectory a U-Net model is applied, providing the detection of the path, also the image semantic segmentation reduces the possibility of a collision. Semantic segmentation is an accurate process for the identification of the path.

To get an efficient object detection the system has to be on a dynamic environment for the detection of the objects, such as, an object has to move or the system is moving through the goal. The system navigates on unknown environments, but has to be trained to get the localization of system, because is used a supervised learning, also for the path detection is necessary to train the system with on the environment.

The proposed algorithm provides a novel solution for the navigation problem. In addition, the detection of similar zones on the frames increases the accuracy and precision for the object detection stage, also the detected features are used as landmarks to estimate the position of the system. This algorithm can be used to build a map representation of the environment. Landmarks can be set on the map to train the system with a reinforcement learning to set the locations.

The proposed algorithm has many applications, such as, car detection and pedestrian detection for autonomous driving, a surveillance robot, face tracking for recognition, car tracking for speed infractions, explorer robot, a background subtraction for a surveillance system.

Abstract—Utilizing firm performance in the prediction of macroeconomic conditions is an interesting research trend with increasing momentum that supports to build nowcasting and early warning systems for macroeconomic management. Firm-level data is normally high volume, with which the traditional statistics-based prediction models are inefficient. This study, therefore, attempts to assess achievements of Machine Learning on firm performance prediction and proposes an emerging idea of applying it for macroeconomic prediction. Inspired by “micro-meso-macro” framework, this study compares different machine learning algorithms on each Vietnamese firm group categorized by the Vietnamese Industry Classification Standard. This approach figures out the most suitable classifier for each group that has specific characteristics itself. Then, selected classifiers are used to predict firms’ performance in the short term, where data was collected in wide range enterprise surveys conducted by the General Statistics Office of Vietnam. Experiments showed that Random Forest and J48 outperformed other ML algorithms. The prediction result presents the fluctuation of firms’ performance across industries, and it supports to build a diffusion index that is a potential early warning indicator for macroeconomic management.

Keywords—Firm performance prediction; machine learning algorithms; diffusion index

I. INTRODUCTION

Macroeconomic situation is always an important factor for all economic sectors, and it is trivial that macroeconomic forecasting is very important [1]. From the necessity of macroeconomic forecasting, there have been many studies on this issue, such as predicting GDP [2], forecasting inflation [3], unemployment [4], exchange rates [5]. These indicators are also predicted in different aspects, such as forecasting growth level [6], or degree of fluctuation [7].

Faced with new practical demands, due to the re-emergence of economic crises, economists are more interested in alerting abnormal situations instead of just giving out the predicted value of indicators. And along with the improvement in the availability of input data of prediction problem, new achievements in data processing methods, and computing power, a new group of studies with the concept of “nowcasting” and early warning system in macroeconomic arises. Aastveit, Gerdrup et al. used big data and machine learning techniques to forecast real-time GDP [8]. The large data was used to report and forecast macroeconomic situation [9], and Galbraith and Tkacz applied the GDP reporting

method with electronic payment data [10]. On the other side, Reinhart et al. [11] studied the development of early warning models of financial market risk assessment for emerging markets. Ciarlone and Trebeschi (2005) studied how to design an early warning system for debt crises [12], and Sevimet al. (2014) built an early warning system to forecast currency crises [13].

In most cases, the input data used for macroeconomic prediction are aggregate economic indicators, such as consumer price index (CPI) or gross domestic product (GDP). However, firm performance is an indispensable and crucial factor that needs to be considered when predicting macroeconomic conditions. In recent decades, there is a new trend of using firm-level data in predicting macroeconomic aspects [14]–[20]. The researchers have proved the importance of using firm-level information in macroeconomic prediction from both theoretical and practical points. From the theoretical point, a framework to research the effect of micro-foundations information in macro-economic aspect was proposed in [19], [20]. In practical, Joao et al have using firm performance to conduct new micro-aggregated factor that was proved to be useful in GDP prediction [14]. Productivity in firm-level data was also used to build a micro-aggregated factor that is similar to total factor productivity (TFP) and this micro-aggregated factor is facilitated in the prediction of other macro-economic indicator models.

Using firm-level data on macroeconomic prediction brings several advantages. a) micro-aggregated series presents the dynamics of the published aggregate factors reasonably. b) micro-foundation information can identify the factors underlying the differences in the efficiency of all manufacturing. c) firm-level information is measured in high frequency based on information communication technology [14]–[16], [18]. This approach also brings a great opportunity for improving qualities of prediction models thank to data’s granularity. However, it is also posing a challenge because firm-level data is normally high-volume data. With high volume data, traditional statistic-based prediction models are inefficient. In proposals of Bartelsman et al, and Brito et al, had to build a microaggregate factors before using them in prediction models. In opposite, machine learning algorithms become the highly potential methods for macroeconomic state prediction based on firm-level information directly.

However, it can be concluded that until now, there has been no study which systematically evaluates the performance

of ML algorithms on this issue. From this point of view, this article uses ML algorithms to predict firms' performance based on firm survey data and other additional information. This study differs from other studies in the way that firm performance prediction is used to support for macroeconomic perspective, rather than for microeconomic management. For this purpose, a huge data including information of a wide range of companies must be processed, and the firms' information used is public information only. Using secret firms' information for macroeconomic analysis is inappropriate. Besides, the companies of each industry group have exclusive/specific characteristics, therefore the suitable models of each group would not be the same. Inspired by "Micro-meso-macro" framework [19], therefore, this study aims to build the different predictive classifier for the firm's performance of different industry groups. This article also aims to build the warning of the macroeconomic situation based on firms' performance classification.

Firm's performance is measured by different indicators including financial indicators and market signal indicators. This article uses the two most popular indicators for the firm's performance, which are the return on asset (ROA) and the return on equity (ROE). Predicting other firm performance indicators [21] is going to be a research question for the next study.

Macroeconomic forecasting in Vietnam has been implemented by the government for a long time. However, it was not until 1984 that Vietnam had the GDP index for the first time, which is the most basic indicator of the macroeconomy. There are some forecasts of basic macroeconomic indicators such as GDP and inflation. However, there is no research applies the same approach with this study for Vietnamese macroeconomic forecasting.

In this article, the information of Vietnamese enterprises collected by the General Statistics Office of Vietnam in the 2010-2015 period has experimented. The result shows the potential application of selected machine learning algorithm to supply important information: predictive firms' performance for the overall economy, which can indicate macroeconomic condition. A proposal micro-aggregate factor, akin to diffusion index, built from firm performance classification prediction and its potential use are shown in this research.

In the remaining part of this paper, section 2 presents the related works. In section 3, the research methodology and preliminary are introduced. Section 4 presents the experiments and evaluation of the performance of algorithms on Vietnamese firm's data sets. Finally, Section 5 presents some conclusions, discussion, and research extension in the near future.

II. RELATED WORKS

Utilization of Firm Performance Prediction (FPP) for macroeconomic perspective based on Machine learning algorithms is still an ongoing research area. There are few publishes proposed the clear application of FPP for policymakers. However, machine learning algorithms have been widely applied for firms' performance prediction for other purposes [22]–[32], and these models will be also useful

for the government's approaches on macroeconomic management.

Different novel models for FPP were proposed on each application such as bankruptcy, financial rating, financial distress, business failure, and so on. These applications consider different aspects of FPP, therefore its use different FPs indicators and independent variables. In the beginning, the researchers and managers have strongly focused on FPP methods using the accounting factors, then market-based indicators have been concerned also. Recently, new technological approaches have used sentiment-based analysis to improve the firms' performance prediction [33]–[35].

In firm performance prediction, successive machine learning algorithms including decision tree, support vector machine, artificial neural network, and its modification are well-known, and the remarkable studies are briefly summarized herein.

Decision tree included boosting the algorithm, the random forest is a well-known machine learning algorithm for FPP [36]–[41]. Delen deeply researched on applying decision tree for firm performance evaluation [36]. He studied common decision tree models including CHAID, C5.0, QUEST, and C&RT for the large and rich feature dataset and proposed an application framework for FPP using a decision tree with financial factors. Bankruptcy prediction is also well studied using decision tree model. Zibanezhad and Foroghi [37] extracted 25 Financial ratios and used these ratios as independent variables for building a Classification And Regression Tree. This work adapted very well to continuous financial ratios data and showed the applicable of C&R tree for bankruptcy prediction problem. Recently, Jardin [38] proposed a novel application of decision tree for firm financial evolution prediction in mid-term, and bankruptcy. His work made an improved approach by using closed time-series data of six financial dimensions to make his model become sensitive to short-term changes. Many other works used decision tree for firm performance issues were introduced, Basti [40] and Yeo [41] were good examples.

Support vector machine (SVM) is a supervised learning algorithm developed by Vapnik [42] and is successfully applied for classification problems. In the realm of finance applications, SVM has been applied in a various problems such as selecting bankruptcy predictors [43], stock price index predicting by financial time series data [44]–[46], forecasting bankruptcy or failure abilities [31], [47]–[50]. In those aspects, SVM approaches were compared with many other methods and this algorithm showed its potential ability. Francis [46] compared SVM with back-propagation neural network (BPNN) based on criteria such as normalized mean square error (NMSE), mean absolute error (MAE), directional symmetry (DS) and weighted directional symmetry (WDS). SVM is also assessed about the predictive performance along with some traditional approaches including the Linear Discriminant Classifier (LDA), Multi-layer Perceptron (MLP), and the Learning Vector Quantization (LVQ) [43]. Min [47] evaluated the SVMs with MDA, logistics, and BPNN or Wu [48] compared a genetic algorithm based SVMs with DA, logit, probit, and ANNs. In these research, the results

indicated that SVM performed better than other approaches with higher percentage classified correctly, or higher precision and lower error rates. However, there are some studies recently proved that ANN models to be superior to SVM approaches with smaller estimated relative error costs [50].

Many proposal ANN models has been applied to finance problems especially in bankruptcy and financial distress [24], [29], [32], [51], since 1990's. Odom and Sharda were pioneers in applying ANNs to predict the failures of firms [52]. They developed an ANN model for bankruptcy prediction and compared proposal model to multivariate discriminant analysis (MDA) by empirical tests using financial data from various companies. Tam [53] applied backpropagation neural network (BPNN) for bankruptcy prediction of banks and compared with existing models include discriminant analysis (DA), factor-logistic, K- nearest neighbor (k-NN) and decision tree ID3. The results showed that ANNs offered better predictive accuracy than other models. Coats and Fant [54] proposed an ANN model as an alternative analysis method of the same ratios used by MDA. They showed the ANN approach was more effective than MDA. Bell and T.B [55] compared logistic regression and ANNs in predicting bank failures. Their results indicated that both methods having similar predictive accuracy. Besides, there were many research combining ANN with other soft computing techniques such as fuzzy sets [56], genetic algorithm [57], rough sets [58].

To build a framework that uses machine learning algorithms to predict Vietnamese FP for macroeconomic perspective, those algorithms are tested and compared with different common machine algorithms to identify the best model for each industry group.

III. RESEARCH METHODOLOGY

A. Classification Model Construction

This study aims to predict performance at firm-level data with the purpose of supporting forecasting at macroeconomic level. For this, a huge data including information of enterprises across the economy is processed. For privacy and practical issues, only publicly available information of firms' performance is used. Following the framework introduced by Dopfer [19], this study aims to build the different predictive classifier for the firm's performance of different industry groups following Vietnam Standard Industrial Classification. The results of classifiers are used to estimate a proposed index that is a trigger in an early warning system for macroeconomic management.

The study uses a research methodology which includes two critical stages, the first stage collects and preprocesses the large raw data set, and the second stage builds the typical model for each industry group. The specific steps of this research methodology are depicted in Figure 1.

Fig. 1. Steps followed in Research Methodology.

The first stage has three steps: (1) raw data collection, (2) preprocessing, and (3) sub-setting raw data to each industry group. The output of this stage is valid datasets for stage 2 that builds suitable prediction models. In the first step, the raw dataset of firms' information is collected from GSO's annual economic census. In the second step, outliers, are removed. Missing values are either removed or replaced by the average value of variables it belongs to. Data noises are processed to provide an acceptable quality dataset to later stages. In the third step, the data set is partitioned by industry group code according to Vietnam Standard Industrial Classification, a slightly modified version of the Global Industry Classification Standard, in the third step. And then, the data sets belong to industry groups are validated before being passed on to the second stage.

In the second stage, each sub-dataset is split into training and testing datasets by a specific proportion in the first step. Then, the training dataset is used to train different ML approaches including Naïve Bayes, decision tree (J48), random forest, SVM, ANN. These models are tested on the testing dataset and the models' performances are evaluated by different measurements containing precision, recall, accuracy, ROC. The testing result is analyzed to make the insight of using ML approaches for FPP in macroeconomic perspective.

1) *Naïve bayes classifier*: Naïve Bayes is a common machine learning technique that is developed based on the Bayes's theorem and it is suited when the dimensionality of the inputs is high and assume that inputs are independent is satisfied. Naïve Bayes classifier takes input instance as a feature vector $x = \{x_1, \dots, x_n\}$ and classes dependent variable y by posterior probability $\text{Prob}(y_i|x)$ where y_i is a possible outcome of y . Naïve Bayes classifier is commonly trained by a supervised method such as Maximum-likelihood on a given training set [59]. Particularly:

Posterior probability $\text{Prob}(y_i|x)$

$$\text{prob}(y_i | x) = \frac{\text{prob}(y_i)\text{prob}(x_1, \dots, x_n \vee y_i)}{\text{prob}(x_1, \dots, x_n)}$$

In practice, $\text{prob}(y_i)$ and $\text{prob}(x_1, \dots, x_n)$ are calculated from a training set directly and $\text{prob}(x_1, \dots, x_n | y_i)$ is equivalent to the joint probability model $\text{prob}(x_1, \dots, x_n, y_i)$. Applying the chain rule and Naive independent assumption of inputs, there is:

$$\begin{aligned} \text{prob}(x_1, \dots, x_n, y_i) &= \text{prob}(x_1 | x_2, \dots, x_n, y_i)\text{prob}(x_2, \dots, x_n, y_i) \\ &= \text{prob}(x_1 | x_2, \dots, x_n, y_i)\text{prob}(x_2 | x_3, \dots, x_n, y_i)\text{prob}(x_3, \dots, x_n, y_i) \\ &= \text{prob}(x_1 | x_2, \dots, x_n, y_i)\text{prob}(x_2 | x_3, \dots, x_n, y_i) \dots \\ &\quad \text{prob}(x_{n-1}, x_n, y_i)\text{prob}(x_n, y_i)\text{prob}(y_i) \\ &= \text{prob}(x_1 | y_i)\text{prob}(x_2 | y_i) \dots \text{prob}(x_{n-1} | y_i)\text{prob}(x_n | y_i)\text{prob}(y_i) \\ &= \text{prob}(y_i) \prod_{j=1}^n \text{prob}(x_j | y_i) \end{aligned}$$

Because $\text{prob}(x_j | y_i)$ is proportional to $\text{prob}(x_1, \dots, x_n, y_i)$, henceforth, the classifier model of dependent variable y to a specific class \hat{y} is:

$$\hat{y} = \arg \max_{i \in \{1, \dots, k\}} \text{prob}(y_i) \prod_{j=1}^n \text{prob}(x_j | y_i)$$

2) *Decision tree*: Decision tree (DT) is a tree-based structure model that expresses the possible consequent states with its chance events and outputs. Decision tree is a non-parametric supervised machine learning algorithm that is used popularly for classification and regression problems. Learning a decision tree is based on partitioning the set of training examples into smaller and smaller subsets where each subset is as "pure" as possible. The purity for a particular subset is measured according to the number of training samples in that subset having the same class label. In practice, a DT structure is constructed directly from a training set by an iterative process that starts with a null root node and repeatedly split a node on an attribute-based on information gain. A DT is built by C4.5, J48, C5.0 algorithms, and they all follow the same

recursive process extends from Quinlan's earlier ID3 algorithm.

The most important task in decision tree construction process is finding the normalized information gain from splitting on an attribute. This is complete by following steps [60].

Calculate information conveyed by a distribution of the set of classes P in a current dataset, also called the Entropy of P , is:

$$I(P) = -(p_1 \log(p_1) + p_2 \log(p_2) + \dots + p_n \log(p_n))$$

Calculate the incremental information by partition a set T on a non-categorical attribute X into sets T_1, T_2, \dots, T_m

$$\text{Info}(X, T) = \sum_{i=1}^m \frac{|T_i|}{|T|} * I(T_i)$$

Calculate the quantity $\text{Gain}(X, T)$ defined as is the measure of the difference in entropy from before to after the set T is split on an attribute X $\{\displaystyle A\}$:

$$\text{Gain}(X, T) = I(T) - \text{Info}(X, T)$$

3) *Random forest*: Random forest is a resampling approach for classification and regression problems. Random forest builds a classifier by assembling individual simple classifiers trained on different sub-datasets generated by bootstrapping a training set [41]. Random forest classifier improves the quality of a classifier built on a single decision tree by solving overfit and bias problems. Random forest uses Bagging (bootstrap aggregating) algorithm, which uses multiple versions of the training set, each created by bootstrapping the original training data to train the models. Each of these bootstrap data sets is used to train different component classifiers that are simple decision trees commonly, and then a final classification decision is form by a voting process of each component classifier.

4) *Support vector machine*: Recent years, support vector machine (SVM) is a new succeeded supervised learning algorithm for classification problems including the firm's performance prediction problem [47]. SVM is a non-parametric algorithm aimed to find the optimal hyperplanes that separate classes on a training dataset. An SVM is trained by solving a large quadratic programming problem. For the proposed problem, SVM is trained by a sequential minimal optimization algorithm, in which a complex quadratic programming problem is broken into a series of smallest possible quadratic programming problems and these small quadratic programming problems are solved analytically.

For a binary classification problem with a dataset $\{(x_1, y_1), \dots, (x_n, y_n)\}$, where x_i is an input vector and y_i is a relative output label. A soft-margin support vector machine is trained by solving a quadratic programming problem:

$$\max_a \sum_{i=1}^n a_i - \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n y_i y_j K(x_i, x_j) a_i a_j$$

Subject to:

$$0 \leq a_i \leq C, i = 1, 2, \dots, n$$

$$\sum_{i=1}^n y_i a_i = 0$$

Where C is a regularization of SVM model and $K(x, y)$ is a kernel function that can be linear, polynomial, or exponential kernel.

5) *Feed-Forward Artificial Neural Network (ANN)*: Feed-forward ANN is a great machine learning model that can represent a highly complex relationship between inputs and outputs. Feed-forward ANN has three layers of architecture includes input layer, hidden layers, an output layer, and the connections of nodes are represented by an acyclic directed graph. One node of ANN has multiple inputs, a weight vector w and one output with a bias, as depicted in Fig.2 [54].

Fig. 2. A Neuron of Dynamic Structural ANN.

In this study, the ANN uses sigmoid activation function is defined below:

$$\varphi(net) = \frac{1}{1 + e^{-net}}$$

In which, for the node j

$$net_j = b + \sum_{i=1}^n x_i w_{ij}$$

In the input layer, each input node is linked with only one input and this node has connections to all hidden nodes. The hidden layer is a set of consequent layers or is one full connect layer only. In any case, a hidden node connects to all nodes in the next layer, and in the last hidden layer, a hidden node has direct connections to all nodes of the output layer. The number of nodes in the output layer is the same with the number of outputs.

Feed-forward ANN is commonly trained by Back – Propagation algorithm, in which the weights of nodes are changed with subject to minimize output error.

$$\varepsilon = \sum_{i=1}^n (t_i - y_i)^2$$

where: t_i is an instance output value in training set and y_i is its relative network output.

B. A proposal on a Diffusion Index as an early Warning System of Real Business Cycle

At this stage, our prediction model is good at forecasting firms' ROA classification. Using input data from the beginning of each year, firms are predicted how well they will perform at the end of that year and classified into each of the five categories from lowest ROA to highest ROA. Each firm then can be predicted to stay in the same class, move up, or move down. We propose to use a diffusion index-based computed indicator to describe the overall situation of firms across industries in the economy by looking at the number of firms that are performing better or worse. Diffusion indexes was formally mentioned in [61] and it has been applied regularly since then, such as for macroeconomic forecasting [62].

$$DI_{fp} = \frac{1 * N_{mh} + 0.5 * N_{ss} + 0 * N_{ml}}{N_{mh} + N_{ss} + N_{ml}} * 100$$

Where

- DI_{fp} is the diffusion index based on firm performance at an time point.
- N_{mh} is the number of firm moving to higher classes: note that we compare the end-of-year predicted value to the begin-of-year actual value.
- N_{ss} is the number of firm that stay in the same class.
- N_{ml} is the number of firm moving to lower classes.

The index can vary from 0 to 100. If the index is equal to 50, it can be consider as averagely all firms are performing in the same classes. If the index is higher than 50, more firms moving up them firms moving down and that's a signal of an improving macroeconomic performance. If the index is higher lower than 50, more firms moving down than firms moving up and that's a signal of a slowing down macroeconomic performance.

This framework is similar to the use of the Purchasing Manager Index that has been widely used as a leading indicators to forecast the economy [63]. However, the index proposed in this study has a significant advange of computing from actual firms' performance across the economy rather than from getting opinions from purchasing managers of selected enterprises.

Although the data used in this expriment study was the enterprise census implemented annually, the main purpose of showing the potential use of large data on firms' information is still valid. In practice and further investigation, the government with its ability to assess firms' information at higher frequency or sometime even real time, can apply the same framework. And given that this study tries to predict firms' performance in subset of industries will also allow the government to create diffusion indexes for each industry or sector, therefore having able to detect the macroeconomic performance with more details.

IV. EXPERIMENTAL RESULT

A. Data Description and Variables Selection

This study applies and compares different well-known machine learning algorithms on the data of Vietnamese enterprises collected by the General Statistics Office of Vietnam in the 2010-2015 period. This dataset was carried out with all firms in every type of business and every industry in Vietnam. It includes more than 500,000 companies with nearly 200 variables for each observation. These variables reflect different aspects of firms such as business tax ID, type of business, asset and capital structure, employee structure, the result of business, and others.

These are annual enterprise census conducted by the General Statistic Office of Vietnam to provide the government with information about the firms' performances. These surveys have some disadvantages for the application of machine learning algorithms because the questionnaire is designed with closed-ended questions for common statistical analysis. Despite several limitations to the performance of machine learning algorithms, it is still the best existing dataset with information of firm performance for macroeconomic perspective, and therefore suitable for this research.

As mentioned in the literature review, common theory of firm performance evaluation used many indicators, but in this emerging study, two indicators including ROE and ROA are used to fulfill the study targets. Variables in the raw dataset from the General Statistics Office of Vietnam which do not support ROE, ROA prediction are removed. On the other hand, some new variables are generated from original variables to use in prediction models. The final selected variables are described in Table 1, in which ROA, ROE are output indicators whereas other variables are input indicators. All these input parameters are values at the begin of each year and they are used for predicting firm performance indicators at the end the of year.

In addition, this study aims to assess not only the different impacts of indicators on the prediction model but also the difference between industry groups, therefore the dataset is divided into subsets corresponding with industries. This division is performed according to codes of each industry in Decision on Vietnam Standard Industrial Classification of Prime Minister, No. 27/2018/QĐ-TTg. Although there are 99 industries in Vietnam in this division, the study select test on industries that have the number of firms larger than 20,000 to guarantee learning quality of prediction models. These selected industries are described in Table 2.

TABLE I. INDICATORS OF RESEARCH MODEL

Index	Indicator	Index	Indicator
1	Type of business	16	Year-opening debt ratio [total debt/total capital]
2	Business size [1=SME, 2=big]	17	Export value
3	State-ownership status	18	Gross revenue (VND million)
4	Total assets (VND million)	19	Net revenue
5	Total equity (VND million)	20	Core-business Gross revenue
6	Total debt (VND million)	21	Ratio of core business revenue to gross revenue (%)
7	Total number of employees	22	Percentage of core-business Gross revenue
8	Total number of female employees	23	Profit before tax
9	Total number of core-business employees	24	Profit after tax
10	Number of change employees	25	Business tax
11	Percentage of female employees (%)	26	Total of earning (VND million)
12	Percentage of core-business employees (%)	27	Year performing the survey
13	Second-industries status	28	Return on Asset
14	Percentage of state shares (%)	29	Return on Equity
15	Owner's equity ratio (%)		

TABLE II. THE CODES OF SELECTED INDUSTRIES

No	Code	Description
1	01	Agriculture and related service activities
2	10	Manufacture of food products
3	14	Manufacture of wearing apparel
4	42	Construction of civil engineering structures
5	43	Specialized construction activities
6	47	Retail trade, (except motor vehicles, motorcycles
7	49	Land transport and transport via railways and via pipelines
8	55	Accommodation
9	56	Food and beverage service activities
10	68	Real estate activities
11	73	Advertising and market research

B. Experiment Result

Return on asset (ROA) and return on equity are two numerous variables in raw survey data set. However, the light changes of ROA, ROE are meaningful for managers of firms but not for the policymakers. Therefore, this study transforms ROA, ROE variables into two categorical variables by the specific interval border. The ROA is discretized by intervals $\{(, 0], (0, 5], (5, 20], (20, 30], (30,)\}$ and ROE is discretized by intervals $\{(, 2.5], (2.5, 7.5], (7.5, 15], (15, 20], (20,)\}$. These segments are encoded by class labels as 0, 1, 2, 3 and 4. Table 3 and Table 4 show the number of firms belongs to different classes of every industry group.

In general, the performances of five well-known machine learning algorithms, Naïve Bayes, decision tree (j48), random forest, SVM, MLP, for Vietnamese firms' performance prediction is shown in figure 3 and 4.

According to the proportion of correctly classified instances, as shown in figures 3 and 4, in both cases, two tree-based algorithms including J48 and random-forest have outperformed other algorithms. In the case of ROA prediction, J48 algorithm has the minimum proportion of correctly classified instances is 86.31% for No.56 industry and reach maximum proportion at 95.77% for No.42 industry, and the average proportion is 91.61%. The random forest algorithm is even better, it has the minimum proportion of correctly classified instances is 87.38% for No.56 industry and reach maximum proportion at 95.77% for No.42 industry, and the average proportion is 91.81%. Two algorithm SVM and MLP have close performance and they only work well in several industry groups including No.42, No.43, and No.49 with the proportions of correctly classified instances are higher than 80%. Naïve Bayes algorithm doesn't work in this case. It has proportions of correctly classified instances from 6.92% to 44.21%.

TABLE III. NUMBER OF FIRMS IN EACH CLASS AND INDUSTRY GROUP BY ROA CLASSIFICATION

- Result of ROA prediction:

Proportion of Correctly Classified Instances

Fig. 3. The Proportion of Correctly Classified Instances of ROA.

In case of ROE prediction, J48 algorithm takes the lead with a minimum proportion of correctly classified instances is 86.31% for No.56 industry and reaches maximum proportion at 95.77% for No.42 industry, and the average proportion is 91.48%. The random forest algorithm follows with a minimum proportion of correctly classified instances is 80.05 % for No.10 industry and reaches maximum proportion at 91.48% for No.42 industry, and the average proportion is 86.37%. Three remain algorithms, Naïve Bayes, SVM, and MLP have the close performance in this case. SVM algorithm is a little better with average proportions of correctly classified instances is 55.82% while MLP reaches 54.00% and Naïve Bayes has 49.51%.

- Result of ROE prediction:

Proportion of Correctly Classified Instances

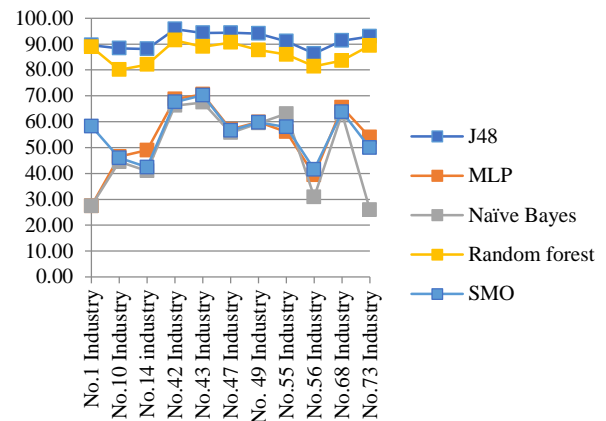

Fig. 4. The Proportion of Correctly Classified Instances of ROE.

1) Performance of ML algorithms for all industry groups:

To evaluate the performance of every selected algorithm in all industry, three measures are used including precision, recall, and ROC-area. The tables below show the performances of all algorithms, and the bold numbers show the best results of each measurement on each industry.

The tables 5-8 show that in both cases, regarding the ROC-area the random forest algorithm outperforms all other algorithms and J48 algorithm follows closely. In the case of ROA prediction, the random forest algorithm is better than J48 according to recall and precision (Table 5). However, J48 is better than random forest according to recall and precision in ROE prediction (Table 7). In this study, the random forest algorithm is the best for ROA prediction problem and J48 is chosen for ROE prediction problem.

- Result of ROA prediction:

2) Performance of best ML algorithms for each class:
Deeply analyze the efficiency of the best algorithms in both ROA and ROE prediction problems, the algorithms' performances on different classes are depicted in the following tables and figures.

- Result of ROA prediction is presented in Table 9 and Figure 5:

TABLE IX. THE PERFORMANCE OF RANDOM FOREST ALGORITHM

Class label	0	1	2	3	4
No.1 Industry	99.86	96.86	87.18	19.83	81.82
No.10 Industry	99.31	97.58	73.92	8.62	36.81
No.14 industry	96.77	96.79	84.70	27.52	53.42
No.42 Industry	99.36	99.64	70.31	16.90	50.44
No.43 Industry	100.00	98.56	65.59	7.55	33.33
No.47 Industry	99.80	97.99	86.86	42.27	75.16
No. 49 Industry	99.84	98.99	76.78	6.67	36.36
No.55 Industry	68.29	97.51	78.76	9.72	80.97
No.56 Industry	55.56	95.51	82.18	16.00	59.17
No.68 Industry	99.75	98.11	64.80	8.97	32.61
No.73 Industry	100.00	98.10	84.82	29.47	70.48
Average	92.59	97.78	77.81	17.59	55.51

Proportion of correctly classified instances per class

Fig. 5. Proportion of Correctly Classified Instances of the Best Algorithm per Class.

In the case of ROA prediction problem, the random forest algorithm is efficient for classes labeled 0,1,2 with the average proportions of correctly classified instances are 92.59%, 97.78%, and 77.81% relatively. However, it fails for a class labeled 3 with the average correction is only 17.59%, and it reached an average correct proportion at 55.51% for a class labeled 4.

- Result of ROE prediction is presented in Table 10 and Figure 6:

TABLE X. THE PERFORMANCES OF RANDOM FOREST ALGORITHM

Class label	0	1	2	3	4
No.1 Industry	96.63	87.98	76.44	48.68	87.48
No.10 Industry	94.29	79.07	11.46	45.50	82.40
No.14 industry	92.80	84.99	10.68	45.86	86.99
No.42 Industry	96.19	84.94	10.52	50.68	85.38
No.43 Industry	96.29	82.81	16.07	35.24	86.26
No.47 Industry	96.79	87.84	8.74	56.49	89.37
No. 49 Industry	95.87	85.21	12.89	47.70	82.13
No.55 Industry	95.81	84.42	13.62	28.04	79.41
No.56 Industry	93.01	82.60	13.58	43.52	82.11
No.68 Industry	97.38	79.56	14.34	41.11	86.43
No.73 Industry	95.58	88.33	10.03	57.02	89.14
Average	96.12	85.61	18.86	49.08	86.40

Proportion of correctly classified instances per class

Fig. 6. Proportion of Correctly Classified Instances of the Best Algorithm per Class.

In case of ROE prediction problem, the J48 algorithm is efficient for classes labeled 0,1,4 with the average proportions of correctly classified instances are 96,12%, 85.61%, and 86.40% relatively. However, it fails for class labeled 2 with the average correction is only 18.86%, and it reached the average correct proportion at 49.08% for class labeled 3.

In both cases, the best algorithms are not successful in all classes, however, they succeed in the classification of largest categories including classes labeled 0, 1. Predict these classes are very important to building an early warning system for macroeconomic management as proposing in session 3.

V. CONCLUSION

Forecasting firms' performance for macroeconomic perspective is still an ongoing research area however it is becoming more and more important given the development of

digital economy. This study reviewed the disjointed published studies on this research area and consolidated theoretically the application potential of firm performance prediction by ML techniques in macro-economic prediction problem. The study investigated the ability of utilizing micro-level information in macroeconomic monitoring and proposed a framework to process firm-level information to generate on demand information. This study also mentioned the major proven machine learning algorithms for firm's performance prediction used in micro perspectives chronologically, and these algorithms were fundamentals to conduct a research framework that was tested on Vietnam's economic data, keeping in mind that this data contains firm's public information only. This research gave evidence to prove the enormous potential of proposed model for macroeconomic manager.

Particularly, five great machine learning algorithms were studied on data of Vietnamese companies belong to the different industry groups to identify the most suitable model for each industry groups. The applied research methodology had two stages, with the first stage preprocessed and divided the raw data set into sub-datasets belongs to different industry groups and validated these sub-datasets to satisfy the requirements of using machine learning algorithms. The second stage performed main processes including sub-data set partitioning, training, and testing processes for each ML algorithms. The testing result was evaluated by several measurements to ensure comparing comprehensiveness. Besides, this approach opened the ability to improve quality of final models by combination new data dimensional reduction techniques and machine learning algorithms together.

Experiments showed that in both cases, ROA and ROE prediction, regarding the ROC-area the random forest algorithm outperformed all other algorithms and J48 algorithm follows closely. In case of ROA prediction, random forest algorithm was better than J48 according to recall and precision also (table 5). However, J48 was better than random forest according to recall and precision in ROE prediction (table 7). In this study, random forest algorithm was the best for ROA prediction problem and J48 was chosen for ROE prediction problem.

For both ROA and ROE, the best algorithms was not successful in all classes, however, they succeed in classification of the largest categories including classes labeled 0, 1. In fact, predicting these low performance classes is very important to build an early warning system for macroeconomic management.

The proposed approach has high opportunity to use for macroeconomic management because the fast pace of modern economy requires the monitoring decision making in shorter and shorter period time. In fact, the e-government model has been developed and digital economy supplies a large and detail data at firm-level in high frequency and this high-volume data supports to create better machine learning model for firm's performance prediction used in macroeconomic perspective. In expected case, automatic mechanism can be built, and it can generate early warnings for policy makers about economic state.

This study has some limitations on theoretical and experiment sides. The proposed approach utilizes the same selected variables for all machine learning algorithms, and this is not an ideal procedure. Theoretically, each ML algorithm might suit to different variable selection method therefore the ideal procedure should take this fact into account. On the other hand, the testing data set still contains exceptions and bizarre instances. Both limitations are going to be dealt with in the expanded stage of this study in near future.

ACKNOWLEDGMENT

This research is funded by the Ministry of Education and Training and Thuongmai University under grant number B2020-TMA-04.

Abstract—The inherent scarcity of frequency spectrum, along with the fixed spectrum allocation adopted policy, has led to a dire shortage of this indispensable resource. Furthermore, with the tremendous growth of wireless applications, this problem is intensified as the unlicensed frequency spectrum becomes overcrowded and unable to meet the requirement of emerging radio devices operating at higher data rates. Additionally, the already assigned spectrum is underutilized. That has prompted researchers to look for a way to address spectrum scarcity and enable efficient use of the available spectrum. In this context, Cognitive Radio (CR) technology has been proposed as a potential means to overcome this issue by introducing opportunistic usage to less congested portions of the licensed spectrum. In addition to outlining the fundamentals of Cognitive Radio, including Dynamic Spectrum Access (DSA) paradigms and CR functions, this paper has a three-fold objective: first, providing an overview of Software Defined Radio (SDR), in which the architecture, benefits, and ongoing challenges of SDR are presented; second, giving an extensive review of spectrum sensing, covering sensing types, narrowband and wideband sensing schemes with their pros and cons, Machine Learning-based sensing, and open issues that need to be further addressed in this field; third, exploring the use of Cognitive Radio in the Internet of Things (IoT) while highlighting the crucial contribution of CR in enabling IoT. This Review is elaborated in an informative fashion to help new researchers entering the area of Cognitive Radio Networks (CRN) to easily get involved.

Keywords—Cognitive radio; cognitive radio networks; software defined radio; spectrum sensing; machine learning; CR-based IoT

I. INTRODUCTION

The radiofrequency spectrum represents a scarce and finite resource that is used for transmitting information in the radio environment. This resource is used by several services, including radiocommunication, radio broadcasting, maritime radio, and satellite communications.

At the national level, the assignment of this spectrum to these services is managed and regulated by local authorities (governmental agencies) that are responsible for determining the appropriate frequency band, the geographical extent of the use of this band, the maximum transmission power, etc. One of the fundamental purposes of these agencies is to ensure a minimum interference level between the different radio technologies.

At the global level, the International Telecommunication Union (ITU) organizes, every three to four years, the world radiocommunication conferences (WRC)¹ so as to examine and revise the treaties governing the use of the radio frequency spectrum.

Nevertheless, the static spectrum allocation strategy adopted, where spectral frequency bands allocated to a wireless communication system can only be used by that system, has caused the shortage of frequencies. This shortage is confronted with a strong demand for spectrum resulting from the emergence and abundance of wireless technologies and the extremely rapid proliferation of radio applications developed in the scope of the Internet of Things (IoT).

In addition, while unlicensed bands like ISM (Industrial, Scientific, and Medical) bands can be freely used by all radios respecting a specific set of rules, such as a shared channel access mechanism and a maximum power per Hertz, they have become very crowded and can't accommodate more wireless applications [1].

On the other hand, the already assigned spectrum is inefficiently used in all domains, such as the time domain, the space domain, and the frequency domain, as shown in Fig. 1. This was confirmed by the Federal Communications Commission (FCC), which reported in 2002 that the radio spectrum, in most of the time, was from 15% up to 85% underutilized [2].

As a result, it has been found that while some bands are overcrowded, such as those bands used by cellular base stations, many other bands are not in use or are used only for short periods [2].

Cognitive Radio (CR) technology has been commonly regarded as an efficient solution to address the above-mentioned issues by enabling the opportunistic usage of the frequency bands that are not heavily occupied by licensed users [3,4].

Fig. 1. Spectrum Utilization [3].

A Cognitive Radio represents a Software Defined Radio (SDR) system [5] capable of exploring the radio environment, learning, and deciding to use the unoccupied portions of the spectrum, called "spectrum holes" or "white spaces", and consequently of dynamically adjusting its operating parameters, based on the decisions made. These decisions must imperatively take into account the impact on the primary users (PUs), which have a license on the chosen spectrum and have the higher priority to access it, in order not to cause them harmful interference. Unlicensed users, which use Cognitive Radio to access the spectrum, are referred to as secondary users (SUs).

Furthermore, the transition from analog to digital television has released many frequencies, known as TV white spaces, which have too high propagation and penetration qualities [6]. For this reason, the FCC authorized in 2008 the use of these frequencies by non-licensed users following a list of rules like using the geo-location capability to obtain the available TV bands, from White Space DataBase (WSDB), before operating [7–9]. That has created a lot of opportunities for Cognitive radio users.

The remarkable contribution of this promising technology to the efficient use of spectrum, the minimization of interference, the reduction of cost, etc., has pushed its use in several areas, namely the Internet of Things (IoT).

The main objective of this paper is to provide a comprehensive survey of Cognitive radio with a particular focus given to:

- Software Defined Radio, as it is the building block of Cognitive Radio system;
- Spectrum sensing, as one of the most important pillars to set up a Cognitive Radio system;
- CR-Based IoT, given that Cognitive Radio is one of the important enabler technologies of IoT.

To the best of our knowledge, in the literature, there is no such work that gives a comprehensive survey of the three aforementioned aspects, highlights the relation between them, and exhibits the future research directions to handle their

challenges in a single paper. The existing surveys dealt only with a particular aspect.

The remainder of this paper is organized as follows: Section II gives the fundamentals of Cognitive Radio technology. Section III exhibits an overview of Software Defined Radio and its different challenges. Section IV provides a detailed view of spectrum sensing and its challenges. Section V highlights the use of Cognitive Radio in IoT. Finally, this article is concluded in Section VI.

II. COGNITIVE RADIO FUNDAMENTALS

Cognitive Radio technology was first introduced by Joseph Mitola in 1999 to depict an intelligent radio system capable of reconfiguring dynamically its radio parameters according to its operational environment and to the user's QoS requirements [4]. Afterward, Cognitive Radio has been defined in many ways by different entities and researchers. The Federal Communications Commission defined CR as follows: "Cognitive radio: A radio or system that senses its operational electromagnetic environment and can dynamically and autonomously adjust its radio operating parameters to modify system operation, such as maximize throughput, mitigate interference, facilitate interoperability, access secondary markets." [10].

Moreover, Simon Haykin defined CR as "an intelligent wireless communication system, capable of being aware of its environment, learning, and adaptively changing its operating parameters (e.g., transmit-power, carrier-frequency, and modulation strategy) in real-time for providing reliable communication (anytime and anywhere) and efficient utilization of the radio spectrum" [11].

As mentioned in the above definitions, the main characteristics of Cognitive Radio are cognitive capability and reconfigurability [3,11].

Thanks to the cognitive capability feature, the CR user can sense and collect information related to its radio environment and choose the best channel to use. The collected information mainly involves transmission frequency, power, bandwidth, modulation, etc.

The reconfigurability feature allows CR users to adjust automatically its operating parameters (transmission frequency, modulation, power, etc.) based on the gathered information and without the need to change the hardware. Hence an efficient and effective Cognitive Radio system is imperatively built on Software Defined Radio platform. The latter will be briefly reviewed in the next section.

A. Dynamic Spectrum Access

By means of Dynamic Spectrum Access (DSA) techniques, Cognitive Radio enables secondary users to use the unoccupied portions of licensed spectrum which are known as spectrum holes or white spaces. When a primary user appears, the secondary user vacates the current band and moves to another spectrum hole or keeps transmitting on the same band and adjusting its transmission power level or modulation scheme in order not to cause any harmful interference to the licensed user or affect its QoS as illustrated in Fig. 2 [3].

Fig. 2. Spectrum Hole Concept [3].

There are three DSA approaches that the SUs can use to dynamically access the available spectral opportunities: underlay, interweave, and overlay [12].

1) *Spectrum underlay*: In the underlay transmission mode, the SU can coexist with the PU as long as the SU operates below the noise floor of the PU. In other words, the coexistence between the SU and the PU may occur if only the interference caused by the SU at the PU receiver remains under a predefined threshold, known as the “interference temperature” [13,14]. To meet the interference threshold requirement, SU can use some techniques such as spreading its signal over a wide bandwidth below the noise floor of the PU or using multiple antennas to direct its signals away from the PU receiver [15].

Moreover, in the case of the underlay approach, the spectrum sensing process is not required and the SUs can transmit the data over the spectrum even if it is occupied all the time by the PUs. Therefore, this paradigm is more appropriate to use in situations when the spectrum usage status of PUs changes rapidly [12].

Nevertheless, meeting the interference constraint forces the SU to limit its transmission power and consequently to operate over a small coverage.

2) *Spectrum interweave*: As regards the interweave transmission mode, it stands for the opportunistic usage of the available spectrum holes which was the major motivation behind the introduction of the Cognitive Radio technology [16]. This paradigm mandates that SUs should have only access to the unoccupied spectrum resources. Thus, spectrum sensing is needed to identify the vacant spectrum bands that are not currently occupied by the PUs.

Furthermore, in this case, harmful interferences to PUs are avoided due to the fact that SUs do not transmit concurrently with the PUs. Whereas, the constant tracking of spectrum opportunities is a challenging task, especially in rapidly changing environments in terms of spectrum occupancy. Hence, this approach is more adequate for slowly changing environments [12,17].

Concerning power resources, they are only limited by the range of the identified spectrum holes.

It is also worth noting that this class of dynamic spectrum access is also referred to as opportunistic spectrum access [18].

3) *Spectrum overlay*: In respect to the overlay transmission mode, it is like the underlay approach in that both approaches allow SUs to simultaneously transmit with PUs. However, in the overlay mode, SUs can transmit at any power without a predefined interference threshold constraint.

Moreover, in this paradigm, the performance of the PU shouldn't be negatively affected by the presence of the SU. To meet this requirement, SUs use a variety of techniques that require prior knowledge about PUs' codebooks and messages [19]. For instance, SUs can divide their power into two parts: one is assigned to transmit their packets and the other is allocated to support the PUs' transmissions. In that way, the interference caused by the SU at the PU receiver can be compensated by the enhancement of the PU's signal-to-noise power ratio (SNR), by dint of the part of SU's power that is used to relay the PU packets.

Additionally, SUs can exploit knowledge about PUs' codebooks and messages to cancel the interference caused by PUs, using techniques such as dirty paper coding [19].

Finally, hybrid schemes that combine these transmission modes can be conceived to increase the overall throughput of the wireless networks [20].

B. Cognitive Radio Functions

The various tasks performed by a Cognitive Radio, including detecting spectrum holes, selecting the best available channel, determining the transmission parameters, sharing spectrum with other users, and moving to another frequency band when a licensed user appears are referred to as the cognitive cycle (See Fig. 3) [21].

In general, the cognitive cycle can be divided into three functional steps, namely spectrum sensing and analysis, spectrum management and handoff, and spectrum allocation and sharing [21]:

- **Spectrum sensing and analysis**: in this phase, CR monitors the radio environment, detects the spectrum holes, and estimates its different characteristics.
- **Spectrum management and handoff**: at this stage, CR chooses the best spectrum white space, determines the transmission parameters, and hops among different bands based on the channel characteristics and user requirements [3,21].
- **Spectrum allocation and sharing**: through these functions, CR can share and coordinate the spectrum access with other users. The coexistence with licensed users is restricted by their allowable interference level. Thus, secondary users should adjust their transmission parameters accordingly. As for sharing spectrum access with CR users, efficient spectrum access coordination is required so as to avoid collisions and interferences [21].

Fig. 3. Cognitive Cycle [21].

With respect to the layer they are in, the aforesaid functions can be classified into three groups namely physical layer (PHY) functions, the medium access control layer (MAC) functions, and network layer functions as shown in Fig. 4 [22]:

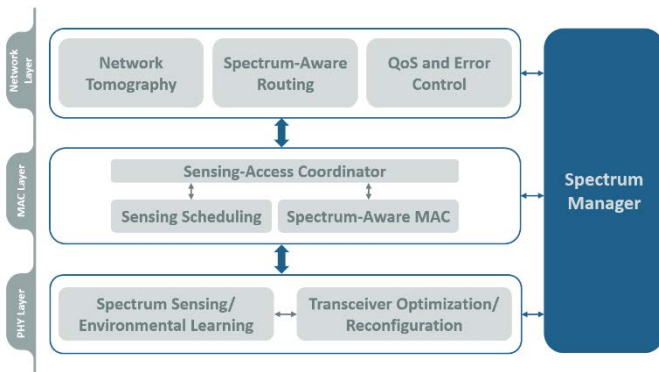

Fig. 4. Key Functions of the PHY, MAC, and Network Layers in a CR [22].

1) *Physical layer functions*: CR PHY layer is responsible for many tasks, including, but not limited to, identifying spectrum holes through spectrum sensing and acquiring advanced radio environment knowledge, such as the channel gain from the CR transmitter to the primary receiver and channel-state information (CSI), via environmental learning [22]. Based on the gathered information, cognitive spectrum access is performed by using transceiver optimization and reconfiguration.

2) *Medium access control layer functions*: CR MAC layer incorporates two key functions that allow to control and manage spectrum sensing operations as well as access to the identified spectrum opportunities. The first function is known as sensing scheduling, whereas the second is referred to as spectrum-aware access control. The operations of these functions are controlled by the sensing-access coordinator, on a time basis, by taking into consideration the compromise between the sensing requirement and the availability of the spectrum access opportunity.

In comparison with the conventional wireless communications MAC layer, the CR MAC layer is more complicated to implement because of the dynamic nature of the radio environment and the constant adaptation process that the CR should perform. More detailed information about the CR MAC layer can be found in [23,24].

3) *Network layer functions*: CR network layer provides three main functions: network tomography, quality of service (QoS) and error control, and spectrum-aware routing [22].

Network tomography refers to the operation by which the CR nodes sense the traffic patterns of the primary and the coexisting networks. The output of this operation provides important baseline data that allows a better understanding of the routing design and the network utilization at the packet level.

Quality of service (QoS) control and error control are of paramount importance to build a successful CR network. Statistical control can be used to address these tasks over CRNs that are characterized by opportunistic links.

Furthermore, In CR networks, data routing is a challenging problem due to varying link quality, frequent topology changes, and sporadic connectivity caused by the movement of PUs in the network [25]. In such a changing environment, the spectrum-aware routing function should be enabled in order to find optimal routes and paths while avoiding PUs. This function has two problems to handle [21]: the first problem relates to the fact that routing algorithms and protocols should be aware of the various network characteristics such as spectrum availability, PU activity, channel switching delay, and link qualities and take them into consideration while executing their different operations. The second problem deals with the setting up of interaction between routing algorithms and dynamic spectrum allocation routines so as to select routing paths with minimum interferences.

Moreover, the optimization of the energy consumption, the desired QoS, and the spectrum management should be considered while designing routing algorithms and protocols for CR networks. Routing protocols are further detailed in [26].

Finally, the spectrum manager serves as the means of establishing a connection between the three aforementioned layers and ensuring dynamic and efficient access to the available spectrum.

C. Cognitive Radio Networks

A Cognitive Radio Network (CRN) consists of a number of CR nodes with or without a secondary base station.

Based on the presence of infrastructure support, CRNs can be classified as either an Infrastructure-based network (centralized) or an Ad-Hoc network (distributed). Moreover, CRNs can be also deployed in another architecture known as Mesh architecture that combines Infrastructure-based and Ad-Hoc modes. A brief description of these architectures is given below.

1) *Infrastructure-based CR network*: It is a centralized architecture which contains a CR base station that is responsible for controlling and coordinating the transmission activities of the CR nodes. In this architecture, the CR base station retrieves the spectrum related information from all the SUs in the network and on the basis of the gathered information, it makes decisions on spectrum access and sharing for all CR nodes.

Compared to Ad-hoc network, infrastructure-based network provides many advantages including, the reliability of the sensing process, collision avoidance, and a high data right for SUs. However, an infrastructure is required to build such a network.

Some examples of centralized networks include:

- The IEEE 802.22 network: it is the first wireless regional area network standard that defines specifications for broadband wireless access using CR technology in TVWS bands [27];
- Spectrum Efficient Uni and Multi-cast Services Over Dynamic Radio Network in Vehicular Environments (Over DRiVE) [28];
- European Dynamic Radio for IP services in Vehicular Environment (DRiVE) [29];
- Wi-Fi (IEEE 802.11) [30].

2) *Ad-hoc mode CR network*: In Ad-hoc CRNs, there is no need for base stations or access points to coordinate the SUs. Thus, in the absence of a central controlling entity, SUs in such a distributed network, make independent decisions concerning spectrum access and transmission parameters. Additionally, SUs must use distributed DSA protocols so as to manage the spectrum access operation. Designing distributed DSA protocols for Ad-hoc CRNs is a challenging task because of the absence of central control entities and the completely distributed networking architecture [12]. These protocols should support a set of functions including, transparency for PUs, collision avoidance, accurate spectrum sensing, and efficient dynamic spectrum allocation [12].

III. SOFTWARE DEFINED RADIO: OVERVIEW

Given that SDR is considered as an enabling technology that handles the implementation of Cognitive Radio, this section will be dedicated to a brief overview of SDR.

A. Definition of SDR

Software Defined Radio [31,32] is referred to as a programmable radio transceiver where digital signal processing functions, such as modulation/demodulation, coding/decoding, error control, interleaving/deinterleaving, and scrambling/descrambling are implemented by means of software instead of hardware as it has been used in traditional radio communication systems. That enables the implementation of different waveform standards in a single platform and switching between them without any change in the hardware components. In some cases, there is just the need of a simple software upgrade to support other modes, bands, and functions.

Many hardware platforms are used to implement the software part of SDR, mainly, General Purpose Processor (GPP), Digital Signal Processor (DSP), Field Programmable Gate Arrays (FPGA), and Application Specific Integrated Circuit (ASIC) [33].

Each of the above-mentioned platforms has its own challenges, limitations, and strengths in terms of computational power, power consumption, implementation cost, flexibility and reconfigurability, and complexity of design (See Table I).

B. SDR Architecture

Joseph Mitola proposed the architecture of an ideal software radio transceiver that includes three components, namely an antenna, a Digital-to-Analog/Analog-to-Digital converter, and a processing unit as illustrated in Fig. 5. The processing unit allows performing, in software, all the digital signal processing functions, including modulation/demodulation, coding/decoding, and error control [3].

Fig. 5. Ideal Software Radio [16].

Many factors impede the real implementation of this proposed architecture such as the technology limitations, more particularly those related to ADC's performance, computing power, and power consumption of the processing unit.

Unlike the ideal software radio transceiver, the SDR transceiver is feasible. Indeed, the general architecture of SDRs contains more components that make its real implementation possible.

As shown in Fig. 6, the SDR transceiver includes mainly four parts which are an antenna, an analog RF front end, a digital RF front end, and the signal processing unit.

1) *Antenna*: One of the main tasks expected from an SDR platform is its ability to cover multiple frequency bands. Thus, SDR platforms often use Intelligent/Smart antennas so as to fulfill the aforementioned task.

A smart antenna consists of an antenna array combined with signal processing blocks that allow to smartly exploit the spatial diversity in order to select the appropriate frequency band and adapt with interference nulling, and mobile tracking [34,35].

An antenna for SDR should ideally integrate some features such as self-adaptation, self-alignment and self-healing [35]. These characteristics can be defined as follows:

- Self-adaptation: it is the capability of an antenna to adapt its parameters according to the selected band and the system requirements (gain...);
- Self-alignment: it is the capability of an antenna to control its radiation pattern;
- Self-healing: it is the capability of an antenna to avoid interferences.

2) *Analog RF front end:* The RF front end part [34] represents an analog circuitry where the following operations are performed:

In the transmission path, Digital-to-Analogue Converter (DAC) converts digital samples into an analog signal which represents the input of the RF Front End. After that, the analog signal is mixed with high frequency carriers, modulated to a preset RF frequency, and then transmitted.

In the receiving path, the RF signal captured by the antenna is fed to the RF Front end section through a matching circuitry which allows achieving an optimum signal power transfer. Then, in order to amplify very low-power signals while guaranteeing a minimum noise level, the RF signal passes through a Low Noise Amplifier (LNA) which is often mounted very close to the antenna. Afterward, the output of the LNA is mixed with a signal from the Local Oscillator (LO) so as to shift to a lower fixed frequency known as intermediate frequency (IF).

The frequency generated by the Local Oscillator is adjustable to ensure that the mixer produces a lower fixed intermediate frequency independent of the incoming RF signal.

The intermediate frequency presents several advantages: it improves the selectivity due to the fact of being fixed and it increases the performance of the processing unit and the global gain of the receiver owing to be lower than the incoming frequency.

3) *Digital front end:* The Digital Front end section [34] contains a set of blocks that are responsible for performing all of the succeeding functions:

In the transmission path, the digital baseband signal (near-zero frequency range) is shifted into the IF frequency by the Digital Up Converter (DUC) then it passes through the Digital Analog Converter (DAC) that converts it to the analog IF signal. The analog IF signal is later up-converted to RF signal.

In the receiving path, the analog IF signal is converted to digital IF samples by the Analog to Digital Converter (ADC). Next, the Digital Down Converter (DDC) changes the IF samples to a baseband signal which is then resampled and filtered before being processed by the signal processing unit.

These above-mentioned tasks can be divided into two principal functions which are Resampling and Channelization. Resampling or Sample Rate Conversion (SRC) is the process of converting samples from one sample rate to another. As for Channelization, it involves up/down conversion and channel filtering.

4) *Signal processing unit:* This block is regarded as the main part of SDR architecture which is designed to perform Digital Signal Processing functions such as modulation/demodulation and encoding/decoding.

As already mentioned in this paper many hardware platforms are used to implement this section, namely DSP, GPP, GPU, ASIC, and FPGA [36–39]. The real challenge is determining which of these platforms is best to achieve SDR goals and which design approach is appropriate to meet the requested quality of service.

Table I shows the strengths and weaknesses of some hardware platforms and highlights certain techniques used to improve their performance.

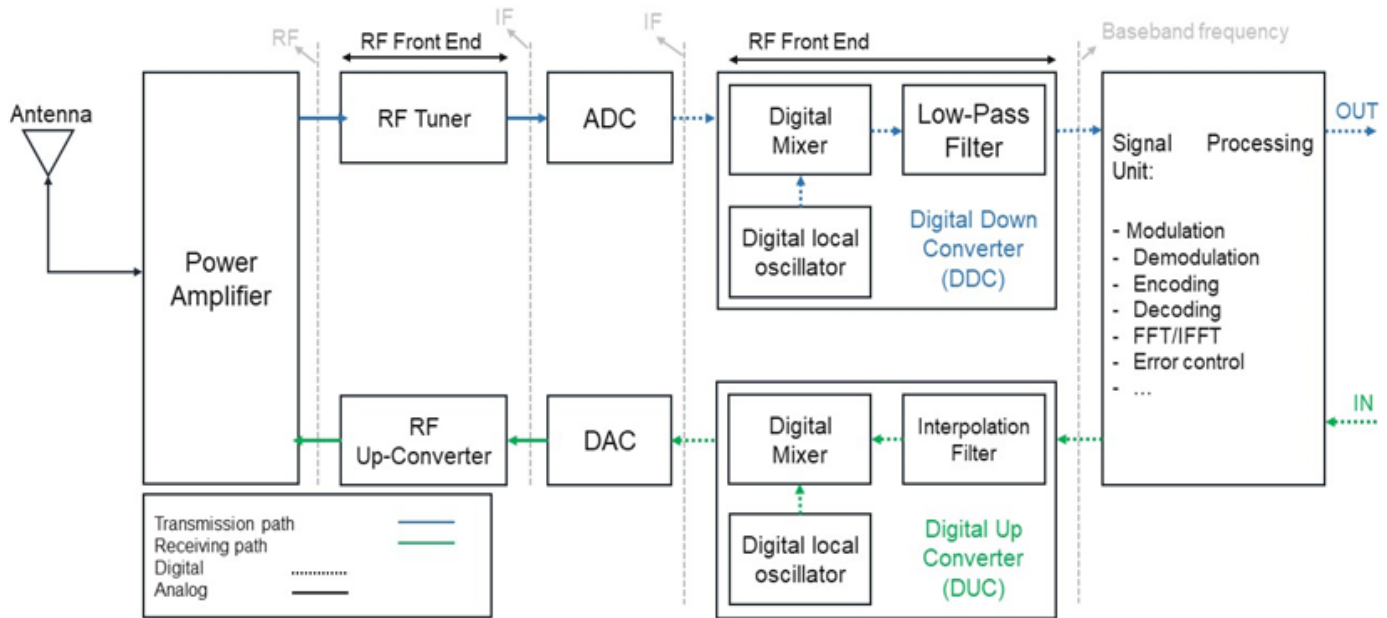

Fig. 6. SDR Transceiver.

TABLE I. COMPARISON OF SDR HARDWARE PLATFORMS

Hardware	Strengths	Weaknesses	Performance improvement
GPP [36–38]	Extremely flexible. Easily programmable. Reconfigurable. Use of high-level languages. Cost reduction. Functions portability. Extremely flexible. Easily programmable. Reconfigurable. Use of high-level languages (C++...). Cost reduction. Functions portability.	Real time applications. are not supported. Power inefficient.	Use of multi-core GPPs to enable the parallelism and perform more operations per clock cycle. Use of GPU for intensive computing task (Turbo code, Fast Fourier Transform...).
DSP [39]	Extremely flexible. Easily programmable. Power efficient. Faster than GPP. Use of high-level languages (C...).	Lack of the required processing speeds for wideband transmissions. Consuming more power than FPGA.	Running two DSPs in parallel.
ASIC [38]	Computationally powerful. Performing at higher speed than FPGA. Smaller in size. More power efficient than GPP.	Not reprogrammable. Very expensive (Each chip is designed for a specific application).	–
FPGA [38]	Computationally powerful. Capability to implement any design or function. Power efficient. Programmability. Seamless switching between. modes and functions. High speed performance. Cheaper than ASIC.	Difficulty to implement new modules. Prior Knowledge of the hardware architecture is required for an efficient module implementation. The implementation task takes a lot of time. Limited portability (HDL code). Consuming more power than ASIC. Taking more area than ASICs.	Use of High-Level Synthesis that enables the rapid implementation of new functions with no prior experience with hardware design.

Several metrics are used to compare the performance of hardware platforms, the most used are computing power, energy consumption, flexibility and reconfiguration, adaptability, cost, and complexity.

To exploit the advantages of each platform, researchers have proposed the co-design (hybrid) approach as a solution. This approach consists of regrouping design schemes that employ hardware techniques, such as FPGAs and ASICs, and those that use software solutions including GPPs, into one platform.

This approach presents some issues, the most known are the problem related to the shared access of the internal memory by different units (FPGAs, Processors ...) and the very expensive cost of the whole implementation.

One of the interesting readings that give a detailed review of the aforementioned platforms, can be found in [35].

C. SDR Advantages

Software Defined Radio technology has brought a lot of advantages to the world of wireless communications, such as reconfigurability and flexibility, interoperability, and cost reduction [34,37]:

- **Reconfigurability and Flexibility:** The main feature of SDR is its capacity to handle wireless standards newly developed by simply changing or upgrading the reconfigurable software instead of replacing the hardware platform or its analog components.

- **Interoperability:** One of the most important benefits of SDR is its ability to resolve interoperability problems between incompatible radios that work with different wireless standards.
- **Cost reduction:** Several expensive hardware components disappeared due to the fact that in SDR many digital signal processing functions are implemented by means of software.

In addition to the forenamed benefits, SDR allows to test and study several communication standards by using the same platform. Furthermore, SDR is regarded as the block building of a Cognitive Radio system and as already mentioned in this paper, SDR enables the reconfigurability of Cognitive Radio.

D. SDR Tools

There are different commercial and open-source tools that can be used for SDR development. Choosing the more appropriate development tool for a specific design methodology requires prior knowledge of the available tools' features. Examples of these tools include GNU Radio, Universal Software Radio Peripheral (USRP), MATLAB, LabVIEW, and CUDA.

GNU Radio and USRP are the most widely used tools to develop SDR systems [40]. A brief description of these two tools is given below:

GNU Radio: GNU Radio is a free & open-source software toolkit for building software radios [35]. It runs on host

computers and it provides many signal processing blocks such as filters, decoders, and demodulators which are required to implement software radios. These blocks are programmed in C++ and they are often connected using Python script that has the advantage of allowing the data flow to be at the maximum rate, without being interpreted [41]. In addition, this tool offers the possibility of easily programming and adding new blocks for supporting unavailable functions. GNU Radio can be used jointly with Universal Software Radio Peripheral systems or other alternatives to set up complete SDR platforms.

USRP: Universal Software Radio Peripheral is the most commonly used transceiver for SDR platforms, developed by Ettus² Research under GPL license. USRPs are available in several series and versions, differentiated by their hardware performances and their connection method to a host computer. Generally, USRP is a board that integrates the following components: ADC/ DAC, an FPGA board, an RF front end, and a PC host interface [42]. Based on the USRP series, a certain number of daughterboards can also be held. Daughterboards perform functions such as filtering and conversion between RF and baseband signals (up/down conversions) and may support applications operating up to 6 GHz due to being modular. Concerning the other signal processing functions, the majority of them are performed at the host machine and only some operations are processed by the FPGA board [42]. USRP platforms offer several advantages, including ease-of-use, affordability, and flexibility. However, bandwidth limitations of USRP components have an impact on system throughput. That makes USRP platforms only suitable for research experiments and rapid prototyping [35,42].

E. SDR Challenges

In this subsection, the challenges that still remain to be addressed for implementing efficient and practical SDR systems are presented.

1) *Security and attack issues:* Although SDR has brought many powerful advantages to the field of wireless communication, it has introduced new types of security threats and attack issues. Indeed, in addition to the known threats that exist in conventional wireless communication systems such as denial of service attacks, misconfiguration issues, listening and capturing data that can be used to perform malicious actions, there are several threats that are specific to SDR, including downloading and running malicious software.

In the absence of authentication and verification techniques, unauthorized software can easily be installed and activated on SDR terminals. The challenge of implementing protection techniques and security mechanisms, to prevent this issue, has been addressed by many researchers. For instance, in [43] a framework for establishing secure download for SDR is presented. This framework uses a public/private key scheme to verify the authenticity of the software. The digital signature is considered as a good solution to keep malicious and unauthorized software from being activated on SDR nodes, nevertheless, it greatly increases the complexity of the

framework due to the fact that for each combination of waveform and terminal, a digital signature should be created.

Furthermore, the data configuration of SDR components can be prone to extraction, alteration, or destruction. Those issues can be prevented by guaranteeing the integrity of the security administrative module (SAM) and implementing data integrity and protection techniques [44].

2) *Energy efficiency:* Addressing the power consumption issue is of primary importance especially when designing solutions that are intended for battery-powered devices and low power objects in an IoT network. Several reasons are behind the importance of addressing power consumption management, including limited size and battery, ensuring a longer lifetime of IoT objects, and enabling Green Computing [17,45]. In SDR, many factors contribute to the loss of energy efficiency, namely signal processing complexity and the increased hardware requirements. To alleviate this loss, the authors of [46] proposed a cooperative wireless network scheme that is based on resource sharing (Battery, processing unit, memory...).

3) *Antenna requirements for SDR:* One of the major challenges in SDR is to design wideband antennas that support different technologies and standards. Although smart and reconfigurable antennas are used to resolve this concern, several constraints still hamper the SDR implementation in portable handsets and other systems, such as bandwidth and gain limitations, which are imposed by the antenna size, and the complexity of a design that meets all the antenna requirements for SDR [47].

4) *Hybrid design:* Implementing an optimal SDR design, that meets the real-time requirements at low power and cost while maintaining flexibility and programmability, represents a great challenge. Researchers address this issue by using the hybrid approach which enables the use of hardware schemes (ASICs...) along with software schemes (GPP...) in the same platform in order to take advantage of their different benefits.

The hybrid design has also its own challenges in both physical and MAC layers, including partitioning and scheduling problems [35].

5) *ADC and DAC limitations:* The concept of an ideal software defined radio transceiver consists in placing the ADC/DAC as close as possible to the antenna. That requires a very high-speed ADC/DAC with sampling capability up to Giga Samples per second which is actually not feasible. To overcome this issue, an RF front end block is placed right after the antenna so as to shift the incoming frequency to an intermediate frequency that can be supported by the currently available ADC/DAC.

IV. SPECTRUM SENSING

Sensing is considered as the most important and critical phase in the Cognitive Radio cycle. It refers to the operation by which the CR users can be aware of the channel occupancy, the presence of the primary user, the quality of the radio channel,

² <https://www.ettus.com/>

and other parameters such as transmission power, bandwidth, modulation, etc. Based on this gathered information, the CR users can determine the vacant portion of the spectrum and choose the white spaces which meet its QoS.

This section gives a detailed view of sensing spectrum function in Cognitive Radio Networks.

A. Multi-dimensional Spectrum Sensing

Through the sensing function, Cognitive radio can identify the existing spectrum opportunities in its surrounding environment by using different sensing techniques. Spectrum opportunity is conventionally defined as “a band of frequencies that are not being used by the primary user of that band at a particular time in a particular geographic area” [48,49]. This definition takes into consideration only three dimensions, namely frequency, time, and space. However, there are other dimensions that can be exploited to create new opportunities such as code dimension and angle dimension. Developing sensing algorithms that take into account all those dimensions encounters more complex and challenging issues.

A radio environment in which all the aforementioned dimensions are exploited to share spectrum access among multiple users is known by several names including, hyperspace, electro space, and radio spectrum space. Table II shows parameters that are needed to be sensed for each dimension and highlights its main idea [49].

B. Types of Spectrum Sensing

Spectrum sensing approaches can be divided into several types on the basis of specific aspects, including the cooperation between secondary users, the bands of interest, the sensing execution time, and the number of sensed channels at a time (See Fig. 7) [50]:

Based on the bands of interest for the Cognitive Radio system, spectrum sensing falls into two groups: in-band sensing and out-of-band sensing. In-band sensing consists in sensing the channel that is already transmitting, in the aim of detecting primary user signals and avoiding harmful interferences [51,52]. As to out-of-band sensing, CR senses bands other than the band on which it is transmitting so as to discover new spectrum holes [51].

Based on the sensing execution time, two classes of spectrum sensing can be distinguished: reactive (on-demand) and proactive(periodic) sensing. The reactive sensing takes place when the secondary user intends to transmit or as a result of radio environmental changes. In proactive sensing, CR users sense the radio environment persistently so as to detect spectrum opportunities. Reactive sensing is more energy efficient but the time to identify an unoccupied channel may be longer than proactive sensing.

Among the types of spectrum sensing, we also find synchronous sensing and asynchronous sensing. In synchronous sensing, all CRs respect the same schedule to sense a frequency band. In that case, a high synchronization between CRs represents a challenging task.

TABLE II. MULTI-DIMENSIONAL SPECTRUM SENSING

Dimension	Parameters to sense	Idea and remarks
Frequency	Available frequency bands	The available frequency band is segmented into disjoint sub-bands. Identifying opportunities in the frequency domain consists in determining the unoccupied sub-bands. It is unlikely that all the bands can be used concurrently at the same time.
Time	Available time slots in a specific band	For a given frequency band, there will be times when it is unoccupied and available for opportunistic usage.
Geographic Space	PU's location (latitude, longitude, an elevation) Distance of primary users	At a specific time, certain channels may be available for opportunistic usage in some geographical zones while being entirely occupied in other zones. The path loss in space enables secondary users to identify the presence or the absence of a primary user in a given local area by just looking at the interference level. If there is no interference, then the primary user is absent otherwise it is present. However, the risk of creating harmful interferences to a hidden primary user is possible. This issue is discussed later in this article.
Angle	PU's beam directions (azimuth and elevation angle). PU's location.	By leveraging advanced antenna technologies (e.g., Beamforming technology), identifying PU's location, and determining PU's beam directions, new spectrum holes in the angle domain might be available for opportunistic usage. Indeed, the secondary user can transmit in the same frequency band along with the primary user at the same time in the same location by choosing a different direction without causing interferences to the licensed user.
Code	PU's spreading code, time hopping (TH), or frequency hopping (FH) sequences. Awareness of timing information is needed so that SU can synchronize its transmission with PU.	By being aware of code sequences that primary users are using at a given time, secondary users can transmit simultaneously along with primary users over the available spectrum by choosing different code sequences in such a way as to avoid creating interferences on primary users. It is important to note that simultaneous transmission is possible by using orthogonal codes.

In the case of asynchronous sensing, each CR has its own schedule to sense a frequency band. Distinguishing between SU signals and PU signals is a challenging problem.

In respect to the cooperation aspect, there are two classes of spectrum sensing: cooperative and non-cooperative (local) Sensing. In non-cooperative sensing, each CR settles for its own sensing data and independently decides on the channel state, i.e. the presence or the absence of the primary user. Decisions that are made through this sensing type are unreliable and error prone under bad channel conditions, multipath fading and shadowing effects, and hidden node issues [53].

The aforementioned issues can be avoided by using cooperative sensing [21,53]. Indeed, when cooperative sensing is enabled, CR users share their local observations and sensing data with others and exploit the shared sensing outcomes of other users to decide on the presence or absence of the primary user. Several works have been carried out on this topic and it has been shown that cooperative sensing contributes to the improvement of detection accuracy and reliability on the cost of increased latency and traffic overhead. It has also been proven that cooperation between secondary users can solve hidden primary user problem and decrease sensing time [53].

There are two types of cooperative sensing: centralized sensing and distributed sensing [3,54]. In centralized sensing [55], a central unit gathers local sensing information from CR users through a control channel, fuses them by means of one of the fusion decision rules [56], identifies spectrum holes by performing binary hypothesis testing algorithm such as Neyman-Pearson test or Bayesian test, and shares the result among other cognitive users or directly controls the cognitive radio traffic. In distributed sensing [54], cognitive nodes exchange their local observations among each other and make their own decisions on channel state. Distributed sensing doesn't require a backbone infrastructure or a centralized base station.

On the basis of interference detection, spectrum sensing is categorized as primary transmitter detection, primary receiver detection, and interference temperature [51]. In primary transmitter detection approaches, spectrum holes are identified by processing received signals at the PU receiver. This class includes several techniques such as energy detection and matched filter detection. In primary receiver detection, the status of primary channels is detected based on the local oscillator leakage power of the PU receiver [57]. This power is emitted by the PU receiver's RF front end while receiving the data from the PU transmitter [58]. As for interference temperature, secondary users transmit simultaneously with primary users as long as the interference caused by the SU at the PU receiver remains under a specified interference limit. In this case, the underlay DSA model is considered.

In regard to the requirement of the PU's information, spectrum sensing schemes can be categorized into two classes: blind and feature detection techniques [50]. The blind detection techniques serve to blindly determine the channel state without any prior knowledge about the primary user signals. This type

includes, among others, energy detection and Higher-Order-Statistics detection. The feature detection techniques allow performing signal classification to the detected signal. They are more advantageous than blind detection techniques in the sense that it is possible to distinguish between PU and SU signals and to characterize the different types of PU and SU signals. Matched filter and cyclostationarity detection techniques are examples of feature detection techniques.

Depending on the bandwidth (number of sensed channels at a time), spectrum sensing schemes are classified into two broad groups which are narrowband and wideband sensing techniques [59]: in the narrowband sensing, only one channel is analyzed at a time to detect available opportunities. The most widely and commonly known narrowband methods are energy detection, matched filter detection, cyclostationary feature detection, covariance-based detection, and waveform detection [59].

As for wideband sensing, multiple frequency bands are explored at a time so as to discover spectrum holes. In this case, the available spectrum is usually divided into narrower sub-bands which are sensed either concurrently or sequentially by using narrowband sensing techniques. Wideband sensing techniques contain two groups: Nyquist-based and Sub-Nyquist wideband sensing. The former type processes digital signals at the rate equal to or greater than the Nyquist rate, whereas the latter type processes the signals with a sampling rate lower than the Nyquist rate [59].

Wideband sensing allows to exploit the available spectrum more efficiently but it brings about new challenges related to its implementation.

On the basis of the latest mentioned classification of spectrum sensing schemes (Narrowband sensing/ Wideband sensing), the next subsection will review some of the most common spectrum sensing methods as well as the recent advanced spectrum sensing techniques.

Fig. 7. Types of Spectrum Sensing.

C. Spectrum Sensing Techniques

Before reviewing in detail spectrum sensing techniques, more particularly narrowband sensing techniques, the system model for spectrum sensing is given below.

1) *System Model for spectrum sensing*: The fundamental objective of spectrum sensing is to make a choice between two hypotheses:

- H_0 : Channel is temporarily available for opportunistic usage i.e. no primary user signal is present;
- H_1 : Channel is occupied i.e. a primary user signal is present.

These hypotheses can be expressed as under:

$$H_0: Y(n) = N(n) \text{ when PU's signal is absent} \quad (1)$$

$$H_1: Y(n) = h.X(n) + N(n) \text{ when PU's signal is present} \quad (2)$$

Where $Y(n)$ represents the received signal by SU, $X(n)$ represents the transmitted PU signal, $N(n)$ denotes Additive White Gaussian Noise (AWGN) with mean zero and variance σ^2 . h represents the channel gain, $n = 1, 2, 3, \dots, N$ where n is the sample index, and N is the number of samples.

Generally, a test statistic of $Y(n)$ is compared against a decision threshold value λ in order to decide between the two hypotheses. If the test statistic is greater than the threshold, H_1 is assumed to be true and thus PU's signal is declared present. In contrast, if the test statistic is less than the threshold, H_0 is assumed to be true and then PU's signal is declared absent. Fig. 8 presents the general model of spectrum detection.

Fig. 8. Spectrum Sensing Model.

Sensing accuracy is typically evaluated using the Receiver Operating Characteristic (ROC) curves. These curves are the plot of the detection probability versus the false alarm probability or plot of the probability of miss detection against the probability of false alarm [60,61]. These probabilities are defined as:

Probability of detection (Pd): It is the probability that the SU declares the presence of PU signal when it is actually present.

$$Pd = \Pr(H_1/H_1) \quad (3)$$

A high Probability of detection allows avoiding interference impact on primary receivers. Hence a high Pd is eminently desirable.

Probability of false alarm (Pfa): It is the probability that the SU declares the presence of PU signal when it doesn't truly exist.

$$Pfa = \Pr(H_1/H_0) \quad (4)$$

A high Probability of false alarm decreases the efficiency spectral due to the loss of spectrum access opportunities. In

addition, the QoS may be negatively affected as a result of this loss. Thus, Pfa should be low to avoid the under-use of potential spectrum holes.

Probability of miss detection (Pm): It is the probability of missing a PU signal when it is present.

$$Pm = \Pr(H_0/H_1) \quad (5)$$

A high Probability of miss detection causes a harmful interference on primary users because, in the case of a miss detection, SUs may transmit simultaneously with PUs in the same band. So, to avoid interference to and from license holder users, Pm should be low.

2) *Narrowband sensing techniques*: In this subsection, we discuss several narrowband sensing techniques, focusing on their functions, mathematical models, strengths, and drawbacks.

a) *Energy detection scheme*: Energy detection [1,62–64] called also Radiometry or Periodogram, is the most widely used sensing scheme due to its low computational complexity, the simplicity of its implementation, and the absence of need for PU signal information.

In this sensing technique, the received signal energy is computed and compared with a threshold value. If the measured energy is higher than the threshold, the target frequency band is considered to be occupied by a PU; otherwise, the target frequency band is considered to be vacant. The block diagram of the energy detection method is illustrated in Fig. 9 and its decision metric can be written as:

$$T = \frac{1}{N} \sum_{n=1}^N |Y(n)|^2 \quad (6)$$

Despite its aforementioned advantages, energy detection has several drawbacks, including the degradation of detection accuracy as a result of noise uncertainty (NU). The latter refers to the noise power fluctuations with time caused by the effects of various factors such as thermal noise, filtering effects, radio-frequency circuits, and interference from other signals [65]. Authors of [65] analyzed the impact of NU on energy detection performance using different OFDM system designs. The results of their analyses show that, for all OFDM system designs, the probability of detection is higher for signals, with lower NU and higher SNR, which are transmitted at higher PU transmit power and detected with a higher number of samples.

Moreover, energy detection is unreliable at low SNR values [66], ineffective in detecting spread signals [60], and unable to distinguish between PU signals from other signals.

To enhance the performance and the accuracy of energy detection, several methods based on the use of dynamics thresholds are investigated in [67–70].

Fig. 9. Block Diagram of Energy Detection [1,62–64].

b) *Matched filter detection*: The matched filter detection technique is viewed as the best method for identifying the unutilized bands when the PU transmission characteristics are known a priori, e.g., bandwidth, operating frequency, the modulation type and order, packet format, and pulse shaping [70–72]. In this technique, the received signal is correlated with the known PU signal and the result is compared with a threshold to decide on the presence of the PU. The block diagram of matched filter detection is shown in Fig. 10 and its test statistic is given by:

$$T = \sum_{n=1}^N Y(n)X^*(n) \quad (7)$$

Fig. 10. Block Diagram of Matched Filter Detection [70–73].

The main advantage of this sensing scheme is that it requires only a small number of samples and thus less sensing time to achieve good detection performance due to its resilience against noise uncertainty [73]. Nevertheless, it has several drawbacks. First, there is a need for precise and accurate prior information about the primary user signal, which may not always be available [65]. Second, the performance of the matched filter technique drops when the prior information is incorrect. Third, to detect different types of PUs, a dedicated matched filter structure for each type must be used, which increases the complexity of the system.

c) *Cyclostationary Feature Detection*: Cyclostationary Feature Detection [74–76] depends on cyclostationary characteristics of the received signals. Indeed, in wireless communications, the transmitted signals are typically characterized by the periodicity of some of their statistics such as mean and autocorrelation [76,77]. This periodicity results from the fact that signals are modulated and coupled with cyclic prefixes, hopping sequences, pulse trains, sinusoidal wave carrier, and other features before being transmitted [76,77]. Furthermore, additive noise signals are stationary with no correlation. Therefore, Cyclostationary Feature Detection schemes are very robust to noise uncertainties and can distinguish between the signal and noise by calculating and analyzing the cyclic autocorrelation of the received signals.

The periodicity of the mean and the autocorrelation, of a cyclostationary signal $y(t)$, can be expressed mathematically by:

$$m_y(t) = E[y(t)] = m_y(t + T_0) \quad (8)$$

$$R_y(t, \tau) = R_y(t + T_0, \tau) \quad (9)$$

Where T_0 represents the period of the signal $y(t)$, τ represents the time offset, E denotes the expectation operator, and R_y is the autocorrelation function of $y(t)$ and it is given by:

$$R_y(\tau) = E[y(t + \tau)y^*(t - \tau)]e^{j2\pi\alpha\tau} \quad (10)$$

The block diagram of Cyclostationary Detection scheme is illustrated in Fig. 11, in which The Analog-to-Digital Converter (ADC) digitizes the received analog signal $y(t)$ into digital samples and then it is fed into the N-point FFT block which computes its Fast Fourier Transform. Next, these FFT values are correlated with themselves and then averaged over the number of samples. Finally, in the feature detection block, the sensing decision is obtained by detecting the features of the average outcome.

This scheme has also the advantage of being able to distinguish between various types of PU signals that are characterized by different transmit features [78].

However, this detector also presents some limitations such as the need for a large number of samples and high sampling rate which results in an increase in sensing time, power consumption, and complexity [76,78].

In order to reduce computation complexity while maintaining sufficient detection sensitivity, authors of [79] proposed an improved Cyclostationary Detector with SLC Diversity over Nakagami-m Fading channels, where the test statistic of conventional Cyclostationary detector is reliably simplified. For the same purpose, in [80], an improved Cyclostationary Feature Detection Algorithm is presented, in which authors proved that the cyclic spectrum is conjugate symmetry about the relevant axis, which decreases the computational complexity.

Fig. 11. Block Diagram of Cyclostationary Feature Detection [74–76].

d) *Covariance Based Detection*: Covariance-based detection methods exploit the correlation structure inherent in the received data and the noticeable differences between the statistical covariances of signal and noise to decide on the presence of primary signals in background noise without the need for prior knowledge about signal, channel, or noise power [81].

Different statistical tests can be extracted from the covariance matrix of the received signal and used to detect the presence of the signal like the ratio of the maximum eigenvalue to minimum eigenvalue in the case of Eigenvalue-Based Detection Method [82]. The steps of the latter can be summarized as follows: First, the sample covariance matrix of the received signal is built from the received signal samples. Then, the eigenvalues of this matrix are computed using techniques such as singular value decomposition (SVD). Finally, a decision on the presence of the signal is taken by comparing the ratio between the maximum eigenvalue and the minimum eigenvalue with a threshold. The block diagram of this method is shown in Fig. 12.

Fig. 12. Block Diagram of Covariance-Based Detection [82].

The sample covariance matrix of the received signal can be expressed as [82]:

$$R_y(N_s) = \frac{1}{N_s} \sum_{n=L-1}^{L-2+N_s} \hat{y}(n) \hat{y}^H(n) \quad (11)$$

Where N_s is the number of collected samples, L is a positive integer called "smoothing factor", $\hat{y}(n)$ is the received signal vector at sampling instance n , and $\hat{y}^H(n)$ is its conjugate-transpose.

The test statistic can be written as:

$$T = \frac{\lambda_{min}}{\lambda_{max}} \quad (12)$$

Where λ_{max} and λ_{min} are respectively the maximum and minimum eigenvalues of $R_y(N_s)$;

Using a predefined threshold λ , the decision can be made as follows: if $T > \lambda$, H_1 is considered to be true, otherwise, H_0 is considered to be true.

It is noteworthy that, despite the robustness of covariance techniques against noise uncertainty, they have a high computational complexity due to two factors, namely covariance matrix computation and eigenvalue decomposition [82].

e) Waveform-based detection: Waveform-based detection method, also known as coherent detection [49], can be considered as a simplified version of the matched filter scheme. Although, unlike the latter, this method doesn't need complete information about the PU signals. It simply exploits known patterns, that are used in wireless communication systems to support many functions such as synchronization, control, and equalization so as to execute coherent detection. These patterns involve but not limited to the following:

- Preambles: a preamble is a known sequence that is sent before each burst;
- Midambles: a midamble is a known sequence that is sent in the middle of a slot or burst;
- Pilot symbols: pilot symbols are an extra overhead added to the transmitted signal.

When such patterns are available, the received signal is correlated with a known copy of itself to perform signal detection. As such, the test statistic can be expressed as:

$$T = R \left[\sum_{n=1}^N y(n)x(n)^* \right] \quad (13)$$

where $R[\cdot]$ denotes the real part, $y(n)$ is the received signal by SU, $x(n)^*$ is the complex conjugate of the signal transmitted by PU, and $n = [1, 2, \dots, N]$ is the sample index.

In the absence of the primary user's signal, the given expression can be written as follows:

$$T = R \left[\sum_{n=1}^N n(n)x(n)^* \right] \quad (14)$$

Whereas in the presence of the primary user, the test static can be simplified as under:

$$T = \sum_{n=1}^N (|x[n]|)^2 + R \left[\sum_{n=1}^N n(n)x(n)^* \right] \quad (15)$$

Where $n(n)$ denotes Additive White Gaussian Noise (AWGN) with mean zero and variance σ^2 .

The value of the test statistic T is compared to a fixed threshold λ in order to decide on the presence of a primary user signal. H_1 is considered to be true if $T > \lambda$, and H_0 is considered to be true otherwise.

It is noteworthy that the waveform-based sensing scheme can only be applied to wireless systems having known signal patterns, such as Wi-Fi (IEEE 802.11b) [83] and WIMAX [84].

In [85], it is demonstrated that compared to energy detector technique, this method is more reliable and has less sensing time. In addition, it is demonstrated that the accuracy of this sensing scheme increases with the length of the known primary signal pattern.

In [86], the authors have opted for waveform-based sensing scheme to analyze the sensing performance of the simultaneous transmission-and-sensing (TS) mode, which has proven its effectiveness under imperfect self-interference signal (SIS), unlike energy detection that cannot differentiate between a PU signal and a residual SIS.

In spite of the aforementioned advantages, there are some downsides to this scheme, mainly the need for complete and accurate information concerning waveform patterns as well as high synchronization between PU and SU, which is not always possible to attain.

Concerning the implementation complexity, coherent detection is more complex than Energy detection method and has a lower complexity compared to match filter detection technique.

Table III provides a performance comparison of the previously described narrowband sensing methods based on a set of performance criteria, namely detection accuracy, complexity, need for prior information about the primary user, robustness against noise uncertainty, and sensing time required to achieve a good performance.

3) Wideband sensing techniques: Wideband spectrum sensing enables detecting spectral opportunities that lie within frequency bands greater than the coherence bandwidth of the channel. One application of this class of sensing is to exploit the available spectrum holes in the UHF (ultra-high-frequency) TV band ranging from 300 MHz to 3 GHz.

As have been discussed earlier, narrowband sensing schemes make a single binary decision for the whole frequency band. That makes these schemes incapable to perform directly wideband sensing, since the latter intends to determine the occupancy of several sub-channels that are involved in a given wideband spectrum at a time.

The two types of wideband sensing techniques (Nyquist / Sub-Nyquist) will be briefly reviewed in this subsection.

TABLE III. PERFORMANCE COMPARISON OF NARROWBAND SENSING TECHNIQUES

Criteria	Energy detection	Matched filter detection	Cyclostationary feature detection	Covariance-based detection	Waveform-based detection
Detection accuracy	Weak performance at low SNRs	Optimal performance at all SNRs	Very good performance at all SNRs	Moderate performance at all SNRs	Very good performance at all SNRs
Complexity	Low	High	High	High	Moderate
Need for prior information about primary user	No	Yes	Yes	No	Yes
Robustness against noise uncertainty	No	Yes	Yes	Yes	Yes
Sensing time required to achieve good performance	Low	Low	High	High	Low

a) *Nyquist wideband sensing*: Nyquist wideband sensing is carried out using a standard ADC operating at Nyquist rate to digitize the wideband signal and digital signal processing methods to detect spectral opportunities. It includes, among other, wavelet-based detection, multi-band joint detection, and filter bank detection:

Wavelet-based detection [87] determines spectrum holes over a wide frequency band, which is assumed to be composed of a multitude of sub-bands whose locations and power spectral densities are unknown, by using the wavelet transform. The latter serves to identify discontinuities that are located at the boundaries (edges) of each sub-band. The discontinuous changes on the edges correspond to irregularities in power spectral density. As such, information about the locations and intensities of the sub-bands can be retrieved through the wavelet transform and then their status (occupied or unoccupied) can be deduced.

Concerning the multiband joint detection algorithm [88], it senses the primary signal over multiple frequency channels by performing the following procedures: first, sampling the wideband signal using a high sampling rate analog to digital converter. Second, dividing the sampled data into parallel data streams by a serial-to-parallel converter. Third, computing the Fast Fourier Transform (FFT) of the digital signal. Fourth, dividing the wideband spectrum into multiple sub-bands that are occupied by narrowband signals. Finally, detecting spectrum opportunities over each sub-band by using a narrowband sensing scheme such as energy detection. Furthermore, this technique allows to jointly determine the optimal threshold, that maximizes the accuracy of sensing for all the sub-channels, by formulating an optimization problem.

As for filter bank detection [89], a filter bank, consisting of a set of bandpass filters, is used to separate the wideband signal into multiple sub-bands. The bandpass filters are realized through modulation (Poly-phase decomposition) of a prototype filter. The prototype filter is a lowpass filter that is used to implement the zeroth band of the filter bank. The obtained sub-bands are then sensed separately via a narrowband sensing scheme. In this type of sensing, the sub-bands can be down-converted and consequently re-sampled at a lower sampling rate. However, a large number of RF components will be added, resulting in a high implementation complexity [90].

While Nyquist wideband sensing allows to exploit efficiently the available spectrum, it has certain limitations, including the requirement of a high sampling rate (Wavelet-based detection and multiband joint detection) and the high implementation complexity (Filter bank).

b) *Sub-Nyquist wideband sensing*: Sub-Nyquist wideband sensing offers solutions to the challenges facing Nyquist-based sensing, more particularly high sampling rate and high implementation complexity concerns. Sub-Nyquist approaches aim to identify spectral opportunities by exploiting only a few measurements derived from processing wideband signals at sampling rates less than the Nyquist rate.

Among the most important Sub-Nyquist wideband sensing types is compressive-based sensing [91–93]. The latter refers to the process of recovering a sparse signal from a few measurements by following a three-step procedure (sparse representation, measurement, and sparse recovery). In the first step, the sparsity of the signal is derived by projecting the signal on an appropriate basis. In second, only a reduced number of measurements are retrieved by multiplying the sparse signal by a measurement matrix. In third, the signal is recovered by using the few collected measurements. Finally, the sensing operation is performed to identify the spectral opportunities.

It is noteworthy that the use of comprehensive sensing, in the context of wideband sensing, is enabled due to the sparsity feature that characterizes the wideband signal in the frequency domain.

Furthermore, the reliability of sub-Nyquist wideband sensing schemes depends largely on the accuracy of sparsity level estimation. Although, the latter suffers from uncertainty because of various factors, mainly the dynamic nature of PUs transmission activities as well as wireless channel impairments.

D. Machine Learning for Spectrum Sensing

As pointed out earlier, CR is an intelligent radio system that incorporates the three main components which any intelligent system should have, namely perception, learning, and reasoning [94]. Perception refers to the ability of the system to sense its radio environment and it can be realized by means of sensing measurements of the spectrum. Learning refers to the ability of the system to convert the gathered information into knowledge and it can be achieved through classification and

generalization algorithms. Finally, knowledge is exploited by the system to attain its objectives via reasoning ability [94]. Considering this intelligent design, machine learning based spectrum sensing presents itself as a good alternative to determine the channel occupancy in Cognitive Radio Networks by addressing two main issues which are classification and decision making [94].

Machine learning algorithms can be classified into two broad groups: supervised learning and unsupervised learning.

In supervised learning, a classifier learns from a training dataset to make predictions on unforeseen data. According to the training dataset, supervised machine learning problems can be further grouped into classification and regression problems. If the input variables are mapped to discrete output values (categories, labels, classes...), then it is a classification problem. If the input variables are mapped to continuous output values, then it is a regression problem. Some examples of supervised algorithms include support vector machines (SVM), Random forest, and naive Bayesian classifier (NBC).

As for unsupervised learning, its main function consists in finding patterns in a set of untagged data. K-means is one of the simplest and most widely used unsupervised machine learning algorithms.

In the context of Cognitive Radio Networks, several papers have dealt with the use of machine learning algorithms to predict the availability of frequency channels. For instance, in [95], the authors performed a comparative analysis of different supervised and unsupervised machine learning algorithms based on computational time and classification accuracy. They also proposed a new method that combines support vector machines with the firefly algorithm. The authors of [96] proposed a deep learning approach to learn channel activities and predict its availability in future time slots. The ability to predict the channel occupancy in the next time slots may increase the efficiency of selecting the more appropriate channel at the instant t (For example, choosing the channel having the highest probability of being unoccupied in the next time slots).

Generally, in the case of spectrum sensing, researchers adopt a two-phase machine learning approach [95,97]. In the first phase, an unsupervised learning technique, such as K-means algorithm, is applied to discover the transmission patterns of primary users. In the second phase, the discovered clusters (channel busy or free) are used to train supervised learning classifiers like support vector machine (SVM) and then to assign the new input data to the suitable cluster. It is worth mentioning that in several works, the sensing clusters are assumed to be known and thus the first phase is omitted. In this case, the researchers adopt a one-phase machine learning approach in which supervised learning techniques are trained with the already known clusters [98,99].

In building machine learning models for spectrum sensing, several features are used, including energy statistic, probability vector, and occupancy over time. Obviously, the accuracy of detecting the primary users may be affected by the selected features.

Finally, to evaluate the performance of a given model, a set of metrics can be used mainly, probability of detection, probability of false alarm, total error rate, sensing time, and accuracy.

E. Sensing Challenges

This subsection is devoted to discussing the various challenges related to the spectrum sensing process in Cognitive Radio Networks as well as highlighting some possible future research directions in this field.

1) *Hidden PU problem:* As the Carrier Sense Multiple Access (CSMA), which is characterized by the presence of hidden node problem, spectrum sensing suffers also from hidden primary user problem. The latter refers to the situation in which the secondary user misses the primary user presence due to many issues, including severe multipath fading and shadowing effects experienced by primary signals, during propagation from PU transmitter to SU receiver. As such, the secondary user may induce undesirable interference to primary user receivers. In several research papers, cooperative sensing has been proposed as a successful approach to handle this issue by exploiting spatial diversity [49,100].

2) *Challenges related to cooperative sensing:* Cooperative sensing has proven to be effective in improving the reliability and accuracy of detection, especially in the case of the presence of channel impairments. Moreover, it has also been shown to be useful in decreasing individual sensing durations and local processing requirements [21,53].

Despite its different advantages, cooperation among CR users also brought many challenges and invoked significant researches. One of these challenges is mitigating the additional signaling overhead and reducing delays that are induced by the cooperation process [101].

Another challenge is to find a tradeoff between the number of users participating in cooperation and additional processing requirements. Indeed, a large number of cooperative nodes can ensure a high probability of detection, even in the presence of channel uncertainties and detectors with less sensitivity, but it introduces a considerable amount of extra overhead which leads to an increase in the sensing time and processing. Hence, there exists a compromise.

Another challenge consists in developing asynchronous cooperative spectrum sensing algorithms [102,103]. In fact, CR nodes are located at different positions and may perform spectrum sensing at different times [104]. Therefore, CR nodes cannot report their local sensing results to the fusion center at the same time and thus some of the reported information may not be up to date [103]. Furthermore, there is always a time offset between the local observation and the final decision which may incur performance degradation. In addition, reporting channel uncertainties may impact negatively the sensing accuracy.

3) *Spectrum sensing duration:* Admittedly, a long sensing duration can guarantee a higher accuracy for spectrum sensing results, but it can compromise with interference avoidance, energy efficiency, and throughput.

Regarding interference avoidance, secondary users must be aware promptly of the presence of the primary user and vacate the frequency band rapidly when the incumbent user resumes its transmission in that band. Thus, a real trade-off arises between the quickness with which the secondary user must perform the aforementioned tasks and the required sensing duration to ensure more reliable results.

Concerning energy efficiency, the gain in accuracy achieved by a long sensing duration comes at the expense of energy. Hence, sensing duration and energy efficiency should be optimized.

As for throughput, it is inversely related to sensing time. Therefore, there is a compromise between longer sensing duration for higher performance and lower sensing duration for good throughput.

These trade-offs should be addressed jointly to find an optimum solution that ensure a higher performance under certain constraints.

4) *Noise uncertainty*: Several spectrum sensing techniques rely on a threshold value to decide on the presence of primary user signals. Hence, selecting the optimum threshold is crucial and important to ensure high accuracy of sensing results. To determine the best threshold value, many parameters should be taken into consideration such as noise power. The latter is uncertain and developing techniques that are robust to noise uncertainty is still a challenging task. Some research papers have addressed this issue using different approaches. For instance, in [105] a blind spectrum sensing technique based on goodness of fit testing of t -distribution has been proposed to cope with the noise uncertainty problem.

5) *Complexity and hardware requirements*: Several issues need to be addressed to bridge the gap between the theory and the hardware implementation realities of spectrum sensing schemes from both types, narrowband and wideband sensing. These include the complexity of narrowband sensing techniques, mainly covariance-based and cyclostationary feature detection schemes, which require large processing power that is unsuitable for portable devices. Hence, Additional efforts are required to reduce the complexity of these techniques and take advantage of their various benefits in real-life application. Besides, meeting the hardware requirements of wideband sensing schemes, like high-resolution ADCs and high-speed signal processors, while maintaining acceptable complexity and moderate computation power, is a challenging task.

6) *Sparsity level uncertainty*: In wideband compressive sensing, estimating the accurate sparsity level is of paramount importance, since it is a prerequisite for determining the optimal number of measurements. However, achieving this result is very difficult, especially in rapidly changing environments, due to random changes in spectrum activities and time-varying fading channels. That may lead to calculate the number of measurements using the worst-case sparsity level assumption, resulting in high energy consumption and inefficient use of sub-Nyquist sampling technologies.

Therefore, developing blind sub-Nyquist wideband sensing schemes, in which the estimation of sparsity level isn't needed, still a challenging task [90].

In the literature, only a few papers have dealt with the issue of sparsity level uncertainty. For instance, the authors of [106] proposed an algorithm for estimating the sparsity level of the channel over a learned dictionary using Machine Learning algorithms.

7) *Security*: As with any wireless network, Cognitive Radio Networks are vulnerable to various cybersecurity attacks that can be performed by selfish or malicious users and induce disruptive effects on network operation. Selfish users exploit network facilities for their interests, namely monopolizing the use of available spectrum opportunities and thus depriving legitimate Secondary users of their fair share of spectrum. As for malicious users, they abuse network facilities by exploiting the existing vulnerabilities and thereby hindering legitimate SUs from using the spectrum.

Some of the cybersecurity attacks in Cognitive Radio Networks include most active band (MAB), primary user emulation (PUE), and spectrum sensing data falsification (SSDF) attacks.

Most active band (MAB) attack aims at detecting and making the most active band, in a multi-band CR network, unavailable by targeting it via a denial of service (DoS) attack and consequently preventing the other users (PU and SU) from using it. The authors of [107] proposed a coordinated concealment strategy to counter this attack. In this strategy, a set of SUs cooperate and transmit useless data in a free band to make it the most active and therefore the attacker's target.

Primary user emulation (PUE) attack is an attack where a selfish or malicious node adjusts its air interface to emulate primary user characteristics and thus mislead secondary users concerning the availability of the spectrum holes [108]. During the sensing process, SUs, under this attack, may detect attacker signals as primary user signals and then refrain from using the spectrum. A range of countermeasures against PUE attack has been investigated in the literature [109]. These countermeasures can be categorized into four types: countermeasures based on cryptography, countermeasures based on fingerprint, countermeasures based on game theory, and hybrid countermeasures that combine the three other types [109].

Spectrum sensing data falsification (SSDF) attack, also known as Byzantine attack, specially targets cooperative spectrum sensing and consists in compromising the fusion center with false spectrum sensing results to deceive decision-making. In [110], a reputation-based approach, in which the fusion center recognizes the malicious attackers and eliminates them from the data fusion process, was proposed to counter SSDF attack.

While significant efforts have been carried out to detect and cope with cybersecurity issues, there are still several challenges that need to be addressed, including developing advanced techniques that do not need prior knowledge about PU location

, as this is not always available in real-world scenarios, developing detection and counter-measures methods based on cryptography that take into account resource constraint (e.g., power and bandwidth), and developing spectrum sensing techniques capable of differentiating between PU signals and malicious user signals.

V. CR-BASED IOT

The wide variety of IoT technologies have led to a rapidly increasing number of networked devices that are expected to reach 51.11 billion by 2023, according to research from Cisco states (See Fig. 13). Such devices involve daily tech gadgets such as smartphones and smart home devices, as well as industrial devices like smart machines and robots. These smart connected devices are capable of gathering, sharing, and analyzing information and creating actions accordingly. By 2023, global spending on IoT will reach 1.1 trillion U.S. dollar [111]. This puts IoT at the core of current and future social and economic transformation.

Furthermore, with the massive proliferation of these connected objects, there is an increased demand for spectrum resources. Cognitive Radio proves to be a promising technology to cater to current and future IoT devices in terms of spectrum access. In this section, the integration of the Internet of Things and Cognitive Radio is explored.

Fig. 13. IoT Connected Devices Installed base Worldwide from 2015 to 2025 (in billions)³.

A. Definition of IoT

The term "Internet of Things" was coined by Kevin Ashton to depict "a system in which the Internet is connected to the physical world by ubiquitous sensors"⁴.

Internet of Things (IoT) can be defined as a network of objects connected to the Internet and can communicate with each other using different communication technologies. These objects are equipped with sensors, that allow interaction with the environment, and communication modules [112–114]. Some of those sensors include temperature sensors, pressure sensors, proximity sensors, and humidity sensors.

Today, the IoT enables the real world and the virtual/or digital world interconnection. Thanks to IoT, things will

communicate with each other and develop their own intelligence. Televisions, cars, kitchen appliances, surveillance cameras, smartphones, utility meters, cardiac monitors, thermostats, and almost anything that we can imagine will be connected every day, everywhere and every time.

The idea of the IoT dates back to 1999 [115] and became a reality due to several technologies and protocols, including Machine to Machine (M2M), Wireless Sensor Networks (WSN), Radio frequency Identification (RFID), Internet Protocol version 6 (IPv6), IPv6 Low power Wireless Personal Area Networks (6LoWPAN), Routing Protocol for Low-Power and Lossy Networks (RPL), Constrained Application Protocol (CoAP), and Cognitive Radio that comes to empower the IoT revolution. This revolution gives birth to the proliferation of small devices such as sensors and actuators, with low consumption at lower cost, and a large number of platforms allowing users to develop their own applications. Thus, the number of connected « things » is increasing exponentially in the world (See Fig. 13).

B. Motivations behind the use of Cognitive Radio in the IoT

Cognitive Radio has a great potential to address several issues and challenges related to the deployment of IoT networks, namely, resource scarcity, interferences problem, limited communication range, purchasing license, storing and analyzing the data generated by IoT objects, heterogeneity, and reconfigurability and autonomy. Dealing with these issues presents the prime motivation behind the use of Cognitive Radio in IoT.

Regarding spectrum resources, it is difficult to allocate frequency bands to all the ever-increasing number of IoT objects. CR address this issue by enabling frequency reuse.

As for the interference problem, most IoT technologies such as RFID, IEEE 802.15.4 (ZigBee) operates in UHF and ISM frequency bands which are already saturated and can't accommodate more applications. Thus, sharing these bands between a large number of objects creates inevitable interferences. CR deal with this issue by enabling dynamic spectrum access to interference-free channels.

Concerning communication range, ISM unlicensed bands allow wireless technologies to operate only over a limited range. Acquiring a frequency spectrum, that ensures communications over long distances, requires the purchase of licenses which generates superfluous expenses. CR avoids the purchase of license and allows the opportunistic usage of unoccupied bands that enables long-distance communications.

In terms of storing and analyzing the data generated by IoT objects, the objects must find communication links to transmit the generated information to numerous servers (Cloud servers). CR is a proper solution to resolve this issue.

With respect to heterogeneity problems, IoT applications represent a wide range of design options (resources, deployment, connectivity, energy, communication modality, infrastructure, network size, network topology...). Thus, new communication paradigms should be designed to support this heterogeneity by providing environmental discovery, self-organization, and self-management capabilities [116]. CR is

³ <https://www.statista.com/statistics/668996/worldwide-expenditures-for-the-internet-of-things/>

⁴ <https://www.historyofinformation.com/detail.php?id=3411>

one of these paradigms that can be used to tackle heterogeneity issues.

Another reason is related to reconfigurability and autonomy. In fact, smart objects are expected to have the capacity to reconfigure themselves without any external action. Thus, objects need to be able to recognize and analyze their environment, detect neighboring objects, and then reconfigure themselves. CR proves to be a suitable solution to fit these circumstances.

Taking into account all of the above, it can be concluded that Cognitive Radio is genuinely a promising enabler technology for IoT.

C. IoT Applications and CR

The deployment of IoT products and services will be present in all sectors and industries, from the smart home to the smart city, education, health care, manufacturing, energy, utilities, commerce, transportation, monitoring, supply chain, and logistics as illustrated in Fig. 14. In general, the opportunities offered by IoT are unlimited and its full impact and potential will be realized in the near future as more and more devices connect to the Internet. At present, there are few works in the literature dealing with potential applications of CR technology for IoT, including military applications, cognitive radio-vehicular ad hoc networks (CR-VANET), emergency networks, smart grids, smart metering, and medical applications [117–123]. Table IV describes some IoT applications while demonstrating how CR can be used to address a number of their concerns.

D. Open Research Issues in CR-Based IoT

Several open research issues need to be addressed in order to take advantage of the full potential of Cognitive Radio for IoT networks. In this subsection, some of these issues will be discussed.

1) *Optimization of network resources:* Efficient spectrum utilization, in the context of a network composed of CR IoT nodes, requires the joint optimization of a set of parameters

such as transmission power, energy efficiency, transmission delay, and transmission data rate, which is a challenging task. The authors of [125] formulated an optimization problem to converge to an optimal solution, in a constrained environment, by taking into account three variables namely; transmission power, transmission rate, and transmission delay. To solve this problem, they applied a branch-and-cut polyhedral approach. The results show that an increase in network and packet size leads to an increase in transmission delay, power, rate, and interference.

Formulating and solving multi-objective optimization problems, considering a large number of factors, still need to be addressed.

2) *Energy efficiency:* One of the main challenges that need to be addressed in CR-based IoT networks is energy efficiency. IoT objects with cognitive radio capabilities consume more energy due to performing additional functions mainly spectrum sensing, which intensifies the power consumption issue, especially for energy-constrained nodes and battery-powered devices.

Fig. 14. Applications of IoT.

TABLE IV. CR CONTRIBUTION IN IoT APPLICATIONS

IoT application	Description and CR contribution
Smart Grids [120,121]	Smart Grid is an electricity distribution network that allows the flow of information between producers and consumers in order to control and regulate the flow of electricity in real time and enable more efficient management of the electricity grid. The major challenge of this technology is the transmission of data through long distances without investing in the purchase of licenses or the installation of cable trays. Cognitive radio offers a good solution to this problem.
Smart Homes [117]	Homes will be equipped with smart objects, allowing to carry out all daily task, such as smart lamps and smart fridges. These objects will integrate sensors endowed with cognitive capabilities that help to avoid interference in the ISM band.
Healthcare and Medical Applications [122,123]	Smart sensors are deployed to monitor critical data like blood pressure, glucose levels, and temperature. With Cognitive Radio this information can be transmitted to medical staff in real time, over long distances without worrying about spectrum availability.
Smart Cities [119]	The smart city is a paradigm of urban development which integrates information and communication technology (ICT) and IoT systems. In this paradigm, continuous connectivity should be maintained. CRNs can be a good solution to support this requirement.
Internet of Vehicles (IoV) [124]	Today, the trends toward less dependence on human beings have led us to the IoV paradigm in which vehicle control is achieved through the integration of communications and embedded systems. The IoV is supposed to be an autonomous travel decision-maker. Safe navigation may be possible in the future through vehicle-to-vehicle information exchange, vehicle-mounted sensors, and user intentions. The challenge in IoVs is the availability of spectrum for mobile vehicles. CRNs may be a good solution because of their long-range and interference-free spectrum sensing.

Among the solutions that have been introduced to deal with energy efficiency concerns are energy harvesting or scavenging and Cooperative Wireless Networks. Energy harvesting is defined as the process through which energy is extracted from external sources, such as wind and solar energies, and then stored so as to be used as a source of power [126]. Energy harvesting is considered as one of the most enabling technologies for Green Computing and real-world implementation of IoT. In [127] a differential game model has been proposed to resolve the resource allocation problem in cognitive WSN using energy harvesting. Optimal resource allocation strategies for all SUs are obtained by determining the loop Nash equilibrium and the feedback Nash equilibrium solutions of the proposed model. In [128], a CR-based energy harvesting approach has been used to extend the battery's lifetime for unmanned aerial vehicles (UAVs) under reliability and secrecy constraints. To reduce energy consumption, the energy harvested is maximized and the transmission energy consumption is minimized by solving a formulated optimization problem.

Currently, Cognitive Radio networks based on energy efficiency approaches are considered an important research direction.

3) *Security*: Addressing security issues in CR-Based IoT networks is a prime concern and a challenging task as most IoT objects are inherently heterogeneous and have their proper uniform security standards. These standards are not adequate for all heterogeneous networks. Several privacy and security aspects should be taken into account in designing IoT systems, including authentication, security assurance, and intrusion soft-ware [117]. Worthy efforts have been done to tackle security issues in some IoT applications with cognitive radio capabilities. For instance, the authors of [129] proposed a distributed cooperative spectrum sensing approach to deal with the security problem in CR-VANETs. This approach uses a weighted consensus-based spectrum sensing technique with trust assistance to ensure the reliability of spectrum sensing operation in a hostile CR-VANET. The validity of the proposed approach was approved by extensive simulations. In [128], the proposed CR-Based energy management scheme for UAVs has been designed in such a way that the secrecy and reliability of the system are ensured. This is illustrated by considering the scenario for the eavesdroppers.

Security remains an open issue to be addressed as cybersecurity attacks and threats are emerging and increasing in parallel with new technologies. Therefore, developing innovative countermeasures is demanded.

VI. CONCLUSION

Nowadays, wireless network devices are emerging at an unprecedented rate, which will further exacerbate spectrum shortages. Therefore, addressing the spectrum scarcity problem becomes more urgent. Cognitive Radio is a promising technology to overcome this issue for futuristic networks (IoT and 5G) by enabling an efficient, flexible, and opportunistic usage of the scarce frequency spectrum. This paper provides a review of Cognitive Radio with emphasis is put on SDR,

spectrum sensing, and CR-Based IoT. Concerning SDR, this article highlights its architecture, tools, advantages, and some of its ongoing challenges. As for spectrum sensing, it is extensively reviewed: spectrum opportunities considering multiple dimensions are discussed, classification of spectrum sensing based on several aspects is presented, Narrowband and Wideband sensing techniques are analyzed, ML-based spectrum sensing is studied, and challenges and open research directions are reviewed. Regarding CR-Based IoT, the focus was on explaining the motivations behind the use of CR in IoT networks and reviewing some of the open issues related to CR-Based IoT.

Artificial Intelligence based Recommendation System for Analyzing Social Business Reviews

Asma Alanazi¹, Marwan Alseid²
Department of Computer Science
Fahad Bin Sultan University
Tabuk City, Kingdom of Saudi Arabia

Abstract—Recently, analysing reviews presented by clients to products that are provided by e-commerce companies, such as Amazon, to produce efficient recommendations has been receiving a lot of attention. However, ensuring and generating effective recommendations on time is a challenge. This research paper proposes an artificial intelligence-based system. The proposed system uses the Incremental Learning - based Method (ILbM) to learn a neural network classifier. The ILbM uses the bagging technique in the process of training the classifier. To ensure a high degree of performance, the ILbM is implemented on the Hadoop since it allows the execution in parallel. Compared to a similar system, the proposed system shows better results in terms of accuracy (97.5%), precision (95.7%), recall (91.5%), and time of response (36 seconds).

Keywords—ILbM; reviews; classifier; text analysing; training bagging; MapReduce; big data

I. INTRODUCTION

As technology continues to evolve in most areas of life, data is being generated daily and growing rapidly. Therefore, we are in the big data era in which data sets are too large and complex.

A. Big Data and Its Properties

To consider data as big data it must contain some characteristics including; volume, variety and velocity [1]. A summarization of these characteristics is illustrated in Fig. 1.

B. Big Data and Its Relationship with Business Intelligence and Analytics

Business intelligence and analytics (BI&A) and the field of big data analytics have become increasingly discussed and studied in both the academic and the business communities over the past two decades. Industry studies have highlighted this significant development [2]. As a strong proof of this, Amazon Company is considered as an important source for big data related to transaction details or related to the customers. In addition, Amazon Company has employed Artificial Intelligence (AI) to analyze the data for increasing gain purpose [3]. The big data generated by the systems and used in Amazon (or any other online shopping companies) forms the base of applying BI&A to improve the work of companies in terms of artificial intelligence.

C. Problem Statement

Since financial transactions are considered sensitive in companies, employing artificial intelligence to enhance the

amount of gain is critical. The reason behind this is that when using wrong (or inaccurate) BI&A on the data base, this leads to poor or wrong decisions' making, and consequently leads to financial losses. This problem is strongly highlighted when it comes to analyse and mine text. Fig. 2 illustrates the problem of having poor BI&A.

As shown in Fig. 2, the failure in the implementation step requires returning to the early steps. This in turn reflects poor accuracy, which is the main issue in this domain.

Fig. 1. IBM Characterizes of Big Data by its Volume, Velocity, and Variety [1].

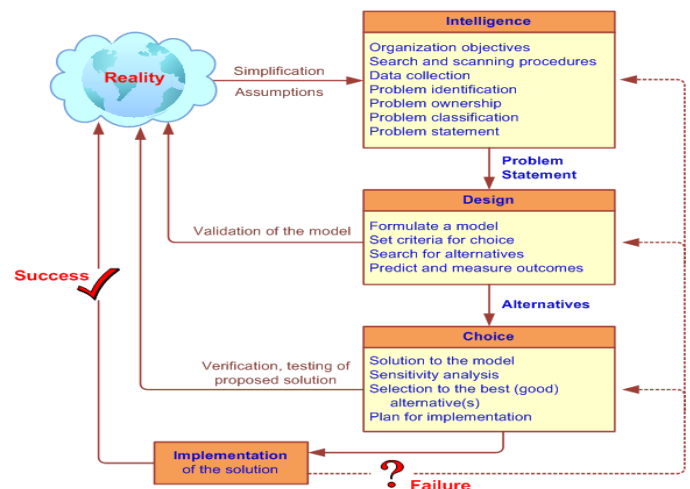

Fig. 2. General Steps in BI&A in Terms of Artificial Intelligence [4].

Besides the accuracy issue, providing decisions in the correct time is also critical. In other words, making decisions (such as providing good recommendations about a certain product for clients) taking into account the time dimension is a sensitive issue. That is because a delay in making the decision and providing it to the customer leads to change his/her mind and may direct him/her to another competitor [5]. For this reason, high performance is pressing in business domain when depending on artificial intelligence. On the other hand, dealing with big data in the business domain requires solving the performance issue [6].

D. Research Questions

Accuracy and performance issues explained above lead to setting and answering the following research questions:

- 1) How can artificial intelligence-based business systems provide satisfied decisions to customers in terms of accuracy?
- 2) How can artificial intelligence-based business systems provide satisfactory decisions on time, taking into consideration dealing with and analyzing big data effectively?

E. Contribution

In general, the contributions of this paper can be presented as follows:

- In responding to the first research question, this paper proposes a novel artificial intelligence system to provide accurate decisions. The system uses a novel algorithm called Incremental Learning based Method (ILbM). The key idea of the ILbM algorithm depends on incremental learning using the bagging method.
- For answering the second research questions, this paper employs Hadoop to perform the training phase in parallel [53]. This ensures fast time decision making in regard about providing recommendations based on using MapReduce technique.
- Extensive experiments are conducted to show the effectiveness of the proposed methods and compare them with similar approaches in term of Performance-based metric discussion and AI-based metrics discussion.

F. Paper Organization

The rest of this work is organized as follows. Section II reviews the related research works. Section III provides the proposed artificial intelligence system. In Section IV, the used metrics are presented for evaluation purposes. Section V presents the experiments and analyses and discusses the results in light of a comparison with similar approaches. Finally, the conclusion of the paper is discussed in Section VI.

II. RELATED WORK

This section provides a brief background regarding the domain we stand on, and it is followed by a review of approaches that have previously been proposed in analysing and predicting big data in social networks research field under the AI umbrella.

A. Background about Big Data

The development of information technology has led to the generation of huge data from various sources especially the social media and IoT sensors sources that is growing exponentially every day. Data created in social media networks vary from texts, images, videos, maps, and sounds. These types of data are divided into structured and unstructured data where the relationship between friends is structured data that can be placed in a specific structure, and text is considered the unstructured data [7]. Big data analysis is used primarily to handle large-scale data generated very quickly with a variety of sources and formats. It's very convenient to face challenges that relational databases cannot. Techniques and methods for analysing this type of data have been studied in many publications, such as what was studied in [8].

Analysing big data leads to what is called 'big impact' according to the research work [9]. In this context, emerging analytics research opportunities are born. They can be classified into five critical technical areas, which include data analytics, text analytics, web analytics, network analytics, and mobile analytics.

B. Social Media and Big Data

Social media big data is primarily generated from the available users' behavior data that express browsing histories, what they buy, and all the information they are accessing online. The research in [10] provides a comprehensive view of how to manage the knowledge in social media big data. There are some common problems in applying big data techniques in social media data analysis [11]. These problems are data-driven versus theory - driven approaches, measurement validity, multi-level longitudinal analysis, and data integration.

Many studies have focused on big data analysis techniques with social media data [12-14]. Due to this focus and in terms of organization, big data analytics on social media is categorized into different classes to grasp their characteristics [15].

C. Machine Learning and Social Media Big Data

In the context of big data analysis, one must choose the appropriate method. Machine learning methods today are extensively used to analyze big data. The machine learning concept can generally be defined as "the computer software learns from the experience E of a particular task T with a P performance metric, if its performance for tasks T is improved by using measure P through experiment E [16]. T represents the problem to be addressed and resolved, such as classification problem. P is the performance metric that is related to the type of Task T to solve. While experience E represents the data used to conduct the learning process.

Machine learning is a subset of artificial intelligence that can modify itself by learning without any human intervention [17].

Different machine learning methods to analyze big data are discussed in detail in [18]. It compared many machine learning methods and found that to analyze big data, neural networks have advantages over other methods. A discussion about the challenges of learning with big data and the corresponding

possible solutions in recent researches was given in [19]. It states that, for big data, there is no single machine learning method that can be generalized. This is because we need different machine learning methods for different data. In addition, an analysis of the machine learning methods for big data is given in [20]. It emphasizes on the new characteristics of machine learning used to analyze big data by proposing a machine learning framework and to analyze big data based on parallel computing and distributed storage.

D. Deep Learning

In this section, the researchers explain the main concept of deep networks. In addition to that, different deep learning network architecture will be examined. The focus will be on the architecture that suitable for the research. Neurons and layers in deep learning network are significantly greater than in traditional neural networks. This increase in neurons and layers supports solving problems that are more complex. Moreover, there are developments in how layers communicate with each other and support for automatic feature extraction. Based on this principle, deep learning is now frequently used to analyze big data.

Various studies have applied deep learning to analyze social media big data. There are many applications using deep learning such as anticipating the behavior of users via social networks, sentiment analysis of text and business analysis. The research [21] concentrated on twitter data; it investigated the behavior of shared learning via Twitter data by examining the behavior of subscribers. Traditional learning methods used to analyze social networking data in crisis were criticized in [22] and deep learning has been tried to overcome these difficulties, since it proposes a new approach to improve the social media analysis incises situations.

Analyzing sentiment by using social media data is an important process. A framework in [23] for sentiment analysis was developed to build a self-developed military sentiment dictionary using deep learning. A real-time syndromic surveillance system is introduced in [24]. This system relies on Twitter social-media data analysis in order to be aware of a syndromic surveillance. Deep learning is used in this system to analyze data and determine the prevalence of a disease. Lamos and Cristianini are used in [25] social network users as sensors to predict real-time events such as rainfall prediction.

Furthermore, the prediction of earthquakes by the same idea is developed in [26] by using deep learning. Social media post analysis is introduced in [27] to extract various meaning information to predict any events. In addition, deep learning is used to make classifications and recommendation accurately. A massive amount of posts was analyzed in [28]. It studies on hashtag, retweet, characters in each tweet, and so on to classify users by their ages. It uses Deep Convolutional Neural Network after displaying the results of some traditional machine learning techniques like SVM. The impact of the recommendation and the adaptation process has become very large today, especially data on social media are increasingly growing. For instance, Multi-view Deep Neural Networking [29] was proposed to make recommendations on computer games that one can play based on data from Sony and Microsoft.

All these previous studies have appropriately contributed to the analysis of social media data, but one can see that there is still a gap and the research presented in this paper works to bridge this gap. The business community wants to make the most of social media data, and it requests that this benefit be translated into recommendations and plans through an integrated system. Therefore, the present research concludes that the design of an integrated system which is used by the business community to improve sales and advertising campaigns and inventory management is one of the important and required actions today. This research also discusses three deep neural networks that can be used extensively because they can handle huge data. They involve Deep stacking network, long short-term memory and Deep Boltzmann machines.

E. Deep Stacking Network (DSN)

Layers in this type of deep learning architecture are arranged in a hierarchical form as illustrated in Fig. 3 [30]. This deep learning type supports parallel learning, where the training of each module is held in isolation from the other blocks. In Fig. 3, there are only four modules, but hundreds of these modules are supposed to exist according to the type of the problem to be solved. DSN is mainly used to implement huge amount of data like social network data. The DSN has been developed and extended to the Tensor Deep Stacking Network (T-DSN) [31]. They are similar to a DSN but are different by adding some new layers such as a hidden layer.

Fig. 3. A DSN Architecture using Input-output Stacking. Four Modules are Illustrated, each with a Distinct Color [30].

One advantage of DSN is that the lower module output combines with higher module inputs to be the final input for this higher unit. Applications designed based on DSN for data retrieval are described in the research [32].

F. Deep Boltzmann Machines (DBM)

Deep Boltzmann Machine (DBM) has several hidden layers [33]. Geoff Hinton defines the general Boltzmann machines as follows: "A network of symmetrically connected, neuron-like units that make stochastic decisions about whether to be on or off." DBM is an undirected model, it is used for data regression and time series. The hidden variables in DBM are used to learn the probability distribution of the input data. In another way, a network prevents any communication between nodes at the

same layer in Restricted Boltzmann Machines (RBM) [34] as illustrated in Fig. 4. In research [35], regression model was built using DBM to complete shapes. This network is successful in analysing heterogeneous data.

G. Long Short-Term Memory (LSTM)

Recurrent Neural Network is used for many purposes like speech and voice recognition, time series prediction, and natural language processing. This network is used to process sequential data such as that used to implement the autocomplete feature of words that predicts the rest of the words. Long short-term memory (LSTM) is an extension of Recurrent Neural Network [36], where it can consider much longer input sequences and overcome some obstacles. The structure of the LSTM is illustrated in Fig. 5.

Fig. 4. Deep Boltzmann Machines [34].

Fig. 5. Long Short-term memory LSTM[36].

The researchers in [37] proposed a system built on the reviews provided by Amazon Company. The system used neural network with Support Vector Machine (SVM) as a classifier and the accuracy achieved in this work is 81 %. The researchers of the current research call this system NN-SVM system for short. It is worth mentioning that this system will be compared later with the system proposed in this paper.

III. PROPOSED INTELLIGENT SYSTEM FOR SOCIAL MEDIA ANALYSIS

The proposed framework in Fig. 6 consists of a data base (data set), a number of users, and the proposed Intelligent Social Media Analysis System (ISMAS).

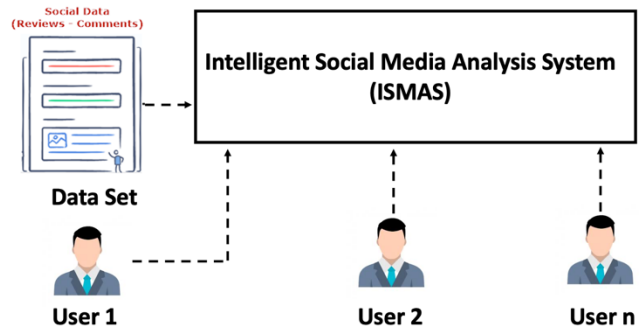

Fig. 6. Framework of the Proposed System ISMAS.

A. Data Set

The data base is used to train and test the ISMAS. The data used in this study is a set of approximately 3.5 million product reviews collected from Amazon.com by Fang et al. [38]. Thousands of Amazon product reviews were obtained for use in training and testing the deep learning model. A large group of reviews (28000) was collected in order to be classified according their ratings; each review consists of 40 words long. We adopted this length because most of these reviews fall within the scope of this length. These reviews have been labeled with ratings from 1 to 5. The resulted data are divided into two parts, the first part is used to train the model and its subset is 80% of the dataset, and the remaining part is used to test the accuracy of the model after its training. The ratings 1 and 2 are considered negative review, while the ratings 3, 4, and 5 are considered a positive review. Fig. 7 displays a review of the dataset.

Training and test data texts are extracted with their attached ratings, which are considered to their labels as illustrated in Fig. 8. The text of the reviews is divided into words and some preliminary processes are performed to prepare texts for the analysis process.

B. Proposed Intelligent Social Media Analysis (ISMAS)

The ISMAS consists of three main components. Table I summarizes the components, the task of each component, and the place where they are installed.

```
rating: 5.0 out of 5 stars
product_ID: B00DS842HS
helpfulness: 4/4
ID: A28R8UNBXGLFOR
review_by: Melliemel
title: It's working!
review_time: 20140308
review: So far so good. I bought this because I wanted to start oil pulling. It's been working great. Great taste (while swishing it around and NOT swallowing it). Put some on my arm that was very dry. It helped. Haven't cooked with it yet, but I'm sure it will be great!
```

TABLE I. COMPONENTS

Component Name	Task
Text Analyzer	Text Analyzing.
Deep Learning Model	Determining degree of acceptance.
Decision Maker	Making recommendations.

Fig. 9 illustrates the architecture of the proposed ISMAS.

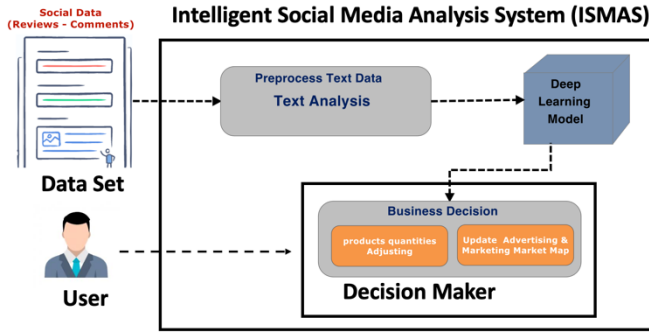

Fig. 9. The Architecture of the Proposed ISMAS.

1) *Text analyzer*: In general, texts are divided into tokens, for example, the sentence “training and test data” are divided into ‘training’ – ‘and’ – ‘test’ – ‘data’ tokens. Then, for these tokens, the researchers add Part-Of-Speech, for example adjective, noun, verb, etc. The lemmatization process is applied to reduce each token to their root form, for example “building” word can be reduced to “build”, also “words” transformed to “word”. The punctuation can be erased to adjust the accuracy. Again, words like “and”, “to” may add some noise to the texts, so the researchers need to delete those words before analyzing the product reviews. Besides, they have deleted any word that consists of two letters or less.

Upon this, the text analyzer performs a kind of text mining, where the last step of this process is extracting the knowledge (which is achieved by the deep learning model). Fig. 10 illustrates the three main steps of text mining [39].

In details, step 1 establishes the corpus, whereby all relevant unstructured data are collected. Then, the researchers digitize and standardize the collection. Finally, they place the collection in a common place (a directory consists of separate files).

In step 2, the Term-by-Document Matrix (TDM) is created. All terms are included in the TDM, such as stop words, synonyms, homonyms, and stemming.

In step 3, patterns/knowledge is extracted relying on deep learning model.

2) *Deep learning model*: Here, the intelligent model (ANN) is trained on the data that are analysed and stored in the TDM. This component performs the ILbM to determine the acceptance degree related to a certain product. The ILbM relies on the bagging technique to enable incremental learning, as shown in Fig. 11.

Fig. 10. Three-step Text mining Process [39].

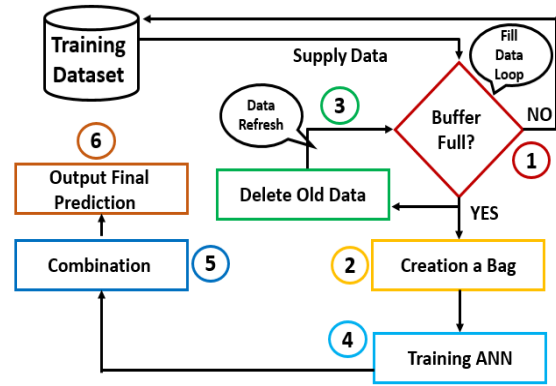

Fig. 11. Flow Chart of the Proposed Deep Learning Model.

As shown in Fig. 11, there are six steps in the proposed model, starting with filling a data loop and finishing with the final prediction step. Below is a description of each step.

a) *Filling data loop*: Here, a buffer is used as a temporal data storage and it is linked with the training data set. At the beginning the buffer is empty and gradually is filled with data. The data is supplied to the buffer from the dataset. The loop continues until the buffer is filled. The size of the buffer ($Zise_{buf}$) is calculated according to the following formula:

$$Zise_{buf} = \frac{size_{OTDB}}{10} \quad (1)$$

Where $size_{OTDB}$ denotes the size of the original training data set. When this condition is satisfied, the next step is executed.

b) *Creation a bag*: The bag represents a small training dataset that contains a part of the original dataset. The created current bag is used to train the first classifier (in the fourth step). When the buffer is filled again in the next iteration, a new bag is created.

c) *Old data deletion*: This step refers to empty the buffer. In other words, the old data used to create the current bag is deleted and a new data is supplied. This process is called data refresh. This process gives an advantage of enabling the bags in parallel as it is described later when it comes to enhancing the performance of the proposed system in terms of response time.

d) *Training artificial neural network*: In this step, the first classifier is trained on the data contained in the first bag (current one). The training process depends on two main stages, which are (1) extracting the features of the analysed text generated by the text analyser component; and (2) pooling the extracted features to draw a deep description of a product. The

extracted features are mainly inspired by strong and weak words included in the review of the products. Fig. 12 illustrates how to extract features.

In Fig. 12, the features are represented by a vector that contains highlighted words taken from the review of a product. The words included in the vector are taken from the review provided by Fig. 8. The words that have a positive trend are considered strong features that support the product, while the words that have negative trend are considered weak features. In Fig. 12, the words ‘Good and Great’ are strong features while the words ‘Very and Dry’ are weak features. Relying on the vector of features, the ANN model (classifier) is trained.

After finishing the extraction stage, the pooling stage starts. In the pooling stage, both the strong and weak features are formed to construct a sentence. The sentence is used to train the ANN to give an output (i.e., the class of the sentence to be positive or negative). The training process lasts until no reviews are found in the current bag. Consequently, the output of training ANN step is a trained classifier that can predict the class of a given review. Fig. 13 illustrates the structure of the ANN.

To generate the outputs, an activation function is used. In this work, the Softmax function is employed since it has a valuable feature called multiclass. In other words, the Softmax function has the property of handling more than two classes [40]. Therefore, the two classes (positive and negative) can be generated as a numeric data. Visually, the Softmax activation function is illustrated in Fig. 14.

The Softmax function is attached before the output layer, where positive class = 1 and negative class = -1, as shown in Fig. 15.

Fig. 12. Features Extraction.

Fig. 13. Structure of ANN.

Fig. 14. Softmax Function [39].

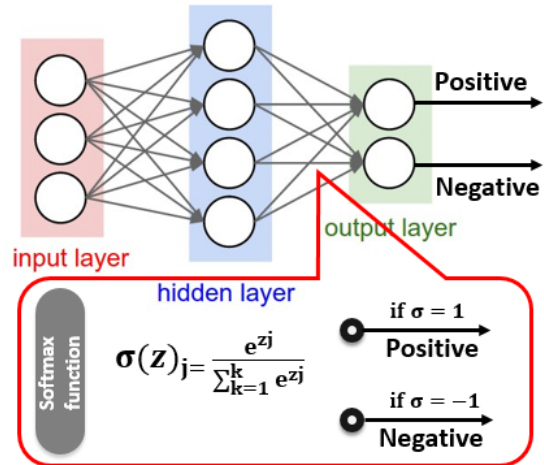

Fig. 15. Using the Softmax Function to Generate Outputs.

e) *Combination*: Based on formula 1, there will be 10 bags. Each bag is used to train an ANN classifier and consequently there will be 10 classifiers. Since each classifier generates a result, a combination process is performed to generate the result (prediction). Fig. 16 illustrates the combination of the result of each classifier.

It is worth mentioning that each classifier takes the knowledge learned by the previous one to be added as new knowledge. For example, classifier 1 learns by adding to the knowledge of classifier 2. Thus, the final classifier has the incremental knowledge learned by all the nine previous classifiers.

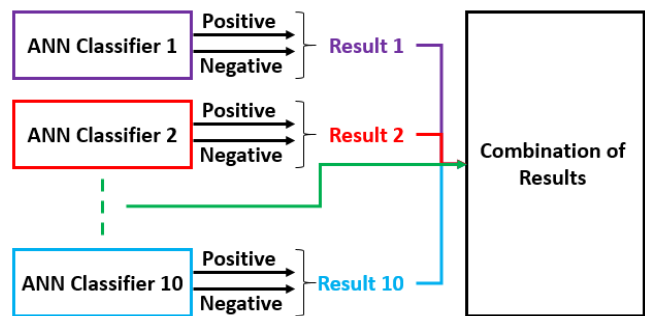

Fig. 16. Combination of results.

f) *Output final prediction:* In this step, the final prediction generated by the trained ANN model is shown as an input for the decision-maker component. This step includes marking the review by positive or negative for further manipulation by the evaluator.

3) *Decision maker:* This component is responsible for providing some recommendations. These recommendations fall in the business domain and are related to make some adaptation according to the situation that is currently dominating the market. In the context of the business domain, adaptation refers to a process that targets the most amount of gain. This can be achieved by providing some recommendations related to stop generating or supplying the market with more items of a specific product (the product that is predicted to have a positive or negative trend). Since there are many products under review each time, the decision maker groups the positive products in a cluster and does the same for the negative products. This facilitates to provide one recommendation to all positive products and all negative ones. Fig. 17 shows the clustering of products.

C. *Employing Hadoop for Better Performance*

Hadoop is an open-source distributed processing framework that manages data processing and storage for big data applications in scalable clusters of computer servers [41]. It's at the center of an ecosystem of big data technologies that are primarily used to support advanced analytics initiatives, including predictive analytics, data mining and machine learning. Hadoop systems can handle various forms of structured and unstructured data, giving users more flexibility for collecting, processing, analyzing and managing data than relational databases and data warehouses provide [42]. It is worthwhile to mention that the data supplied to the Hadoop platform should follow the security and privacy agreements. Security and privacy issues are highly highlighted according to many researches [43-52]. In this work, privacy and security of data are considered out of scope, where they will be considered in future work.

Hadoop allows parallel execution of jobs. This means that the job that is intended to be executed on Hadoop must be paralyzed. In this work, the job that is executed in parallel on Hadoop is the training phase of the model. That is because each bag is used to train one classifier, the number of bags was determined in proportion to the data in the training and consequently each classifier can be trained separately in a single thread. Fig. 18 illustrates using Hadoop to train the classifiers using threads.

Hadoop uses MapReduce technique to perform parallel execution. The major advantage of MapReduce is that it is easy to scale data processing over multiple computing nodes [53]. The MapReduce technique contains two important tasks, namely Map and Reduce. The main mission of the Map is to divide the job into parts and then distribute the parts over computational nodes (servers) for execution. The main mission of the Reduce is to collect the results of the executed parts and return them to the master node. Fig. 19 illustrates the mechanism of MapReduce technique used for training the classifier.

As shown in Fig. 19, there are 10 computation nodes. Each bag is loaded on a node (i.e., the training data set used to train a classifier). After processing (i.e., training the ANN on each node), the results are gathered by the Reduce to return them back to the master node. Here, the results are represented by the rules that the classifiers are learned. At the master node side, all the rules are combined to form the final trained classifier.

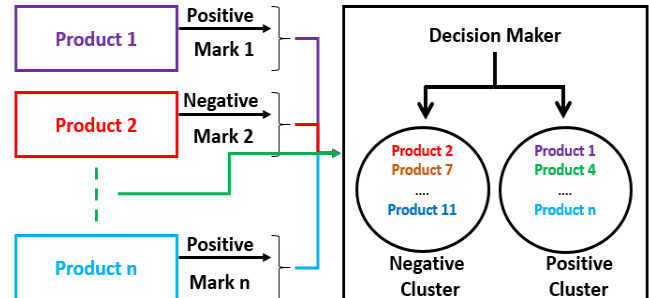

Fig. 17. Clustering of Products.

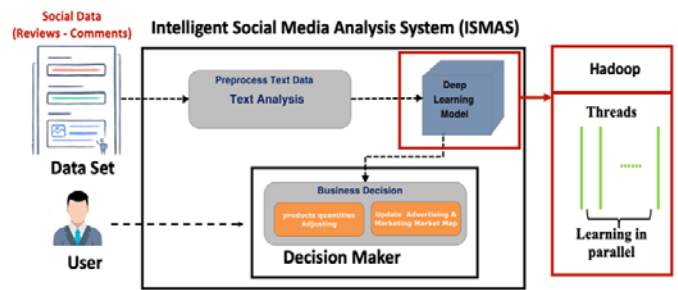

Fig. 18. Employing Hadoop for Parallel Training.

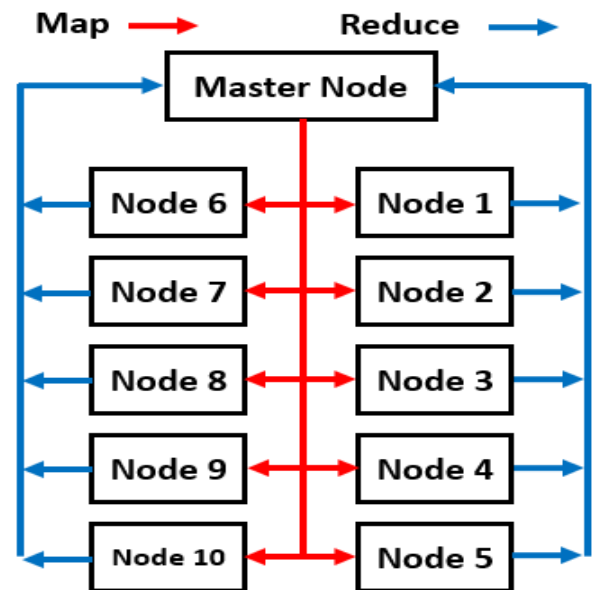

Fig. 19. Map Reduce Mechanism.

The steps of the ILbMare are shown in the following algorithm.

Algorithm 1: Incremental Learning-based Method (ILbM)

```

1: begin
2:   Read Input ( text = reviews);
3:   Pre-processing TextAnalyzing (reviews);
4:   ResultSet = ∅;
5:   for (i = 1 to 10) do
6:     begin
7:       creation (bagi) ;
8:       Training (Ci);
9:       Generate (resulti = rulesi);
10:      ResultSet = ResultSet ∪ resulti;
11:     end;
12:   Generate ResultSet;
13:   Class = Classify (new review);
14:   recommendation (class);
15: end;

```

IV. USED METRICS

Two types of metrics are presented for use in the evaluation process. They are AI-based metrics, and performance-based metrics.

A. AI-based Metrics

Basically, the confusion matrix (CoMa) is an effective benchmark for analyzing how well a classifier can recognize the images of different classes. The CoMa is formed considering the following terms [41]:

- 1) True positives (TP): positive images that are correctly labelled by the classifier.
- 2) True negatives (TN): negative images that are correctly labelled by the classifier.
- 3) False positives (FP): negative images that are incorrectly labelled as positive.
- 4) False negatives (FN): positive images that are mislabeled as negative.

Table II shows the CoMa in terms of the TP, FN, FP, and TN.

TABLE II. CONFUSION MATRIX

Actual class (Predicted class)	Confusion matrix		
	CI	¬ CI	total
C1	True Positives (TP)	False Negatives (FN)	TP + FN = P
¬C1	False Positives (FP)	True Negatives (TN)	FP + TN = N

Relying on the CoMa, the accuracy (Acc), precision (Pre), and recall (Rec) metrics are driven. For a given classifier, the accuracy can be calculated by considering the recognition rate, which is the percentage of the test set images that are correctly classified. The accuracy is defined as [41]:

$$Acc = \frac{(TP+TN)}{\text{number of all records}} \quad (2)$$

Accuracy-based evaluation. In this context, a higher accuracy corresponds to a better classifier output. The maximum value of the accuracy metric is 1 (or 100%), which is achieved when the classifier classifies the images correctly without any error during the classification process.

For precision, it refers to the exactness (what % of tuples that the classifier labelled as positive that are actually positive). It is given by [41]:

$$Pre = \frac{TP}{TP+FP} \quad (3)$$

Precision-based evaluation. In this context, a higher precision corresponds to a better classifier output. The maximum value of the precision metric is 1 (or 100%), which is achieved when FP=0.

Recall refers to the completeness (what % of positive tuples did the classifier label as positive?). It is given by [41]:

$$Rec = \frac{TP}{TP+FN} \quad (4)$$

Recall-based evaluation. In this context, a higher recall corresponds to a better classifier output. The maximum value of the recall metric is 1 (or 100%), which is achieved when FN=0.

B. Performance-based Metrics

Time of response (ToR) is used to evaluate approaches in terms of performance. The ToR is calculated based on the total time of the four main steps that are illustrated in Fig. 12 (i.e. fill data loop, bag creation, ANN training, combination, and output steps). ToR is given as:

$$ToR = T_{fdl} + T_{br} + T_{tr} + T_{cob} + T_{opt} \quad (5)$$

Where T_{fdl} , T_{br} , T_{tr} , T_{cob} , T_{opt} denote the time consumed by the fill data loop, bag creation, ANN training, combination, and output steps, respectively.

It is important to notice that the shorter the ToR is, the better the performance of this approach is.

V. EXPERIMENTAL RESULTS AND EVALUATIONS

This section is arranged so that it first presents the setup and the approach that is intended to be compared. Then, the actual results and the corresponding discussions are provided.

A. Setup

The proposed AI-based system is implemented on a laptop that has the specifications shown in Table III.

The researchers selected one system (NN-SVM system), mentioned in the related work section, to compare with the proposed ISMAS system. It is illustrated in Table IV.

TABLE III. SPECIFICATIONS OF LAPTOP

Item	Details (value)
Operating system	MacOS Cataling version 10.15.5
Processor	Dual-Core Intel Core i5
RAM	8 GB
Speed	2.9 GHz

TABLE IV. SELECTED APPROACHES

Ref	Selected System		
	Used technique	Journal	Year
[37]	NN-SVM	International Journal on Soft Computing, Artificial Intelligence and Applications	2019

B. Results and Discussion

The results are provided according to both the AI-based metrics as well as the performance metric.

1) *Results depending on the AI-based metrics:* Since there are 10 ANN classifiers due to using 10 bags, the results of the AI-based metrics are arranged in Table V.

Table V shows that the accuracy of the 10 classifiers vary within the range [90 %, 98%] and the corresponding average of all accuracies is 96.7 %. The precession achieves lower values, where they vary within the range [90 % - 97%] and the corresponding average of all precisions is 95.1%. The recall of the 10 classifiers varies within the range [88%, 94%] and the corresponding average of all recall is 91.5%.

TABLE V. 10 CLASSIFIERS EVALUATION

Iteration (Bag NO)	AI-based Metrics		
	Acc	Pre	Rec
1	98 %	97 %	93 %
2	96 %	90%	90 %
3	97 %	95 %	94 %
4	98 %	96 %	93%
5	98%	95 %	90 %
6	98 %	96.5 %	94 %
7	90 %	93 %	90 %
8	98 %	95%	88 %
9	97%	97 %	91 %
10	97 %	96 %	92 %
Average	96.7 %	95.7 %	91.5 %

TABLE VI. AI-BASED METRIC VALUES

System	AI-based Metrics		
	Acc	Pre	Rec
ISMAS	96.7 %	95.1%	91.5 %
NN-SVM	81.29 %	58.61 %	40.85 %

Table VI summarizes the comparison between the proposed ISMAS system and the NN-SVM system according to the AI-based metrics.

AI-based metrics discussion. The proposed ISMAS system achieves better scores in terms of accuracy, precision, and recall. In details, there is (96.7-81.29=15.41) extra degree for the accuracy, (95.1-58.61=36.49) extra degree for the precision, and (91.5-40.85=50.65) extra degree for the recall. The reason for these enhancement of the AI-based metrics is related to the incremental learning of the classifier. In other words, the cumulative knowledge gained by incremental learning is more efficient when compared to one learning iteration in the NN-SVM system.

2) *Results depending on the performance-based metric:* In the context of this evaluation, the ToR is calculated for each classifier, and then the average time is obtained. Fig. 20 shows the results.

Fig. 20 shows that the ToR metric has a value that varies within the range [31 - 41] seconds, where the value 31 refers to the performance of the 6th classifier, while 41 refers to the performance of the 3rd classifier. The third classifier has the worst ToR value because of some operations related to the running of the program. The average ToR values refers to the final performance of the final classifier, which is calculated as:

$$AVG = \frac{40+36+41+35+32+31+34+39+37+35}{10} = 36 \text{ second}$$

In terms of evaluating the proposed system under the comparison with the NN-SVM system, Fig. 21 shows the results.

Fig. 20. Performance of the 10 Classifiers.

Fig. 21. Performances of Systems.

REFERENCES

Performance-based metric discussion. It is obvious from Fig. 21 that the proposed ISMAS system outperformed the NN-SVM system. The speed of the performance of the proposed ISMAS can be calculated as:

$$\frac{79}{36} = 2.19$$

This means that the proposed ISMAS system has more than double speed when compared to the NN-SVM system. The reason behind the enhancement of the performance of the proposed ISMAS system is employing Hadoop to perform the training in parallel. Theoretically, the ToR of the proposed system should be 10 times lesser than the ToR of the NN-SVM system. However, the procedure of creating Mappers to distribute the job over the nodes as well as the time of creating reducers and combining the sub-results to form the final results is the reason why the ToR of the proposed system is about 2 times lesser than the NN-SVM system.

VI. CONCLUSION

Recently, analysing reviews presented by clients to products that are provided by e-commerce companies, such as Amazon, to produce efficient recommendations has received a wide attention and is considered as a vital research in the business field. In this paper, the researchers propose an artificial intelligence recommendation system for analysing reviews in the business area. The proposed system consists of three main components, which are text analyser, deep learning model, and decision-maker. The text analyser component uses the Term-by-Document Matrix (TDM) in the process of analysing the reviews. The reviews are obtained from a data base provided and available by Amazon e-commerce Company. The deep learning model (classifier) is trained based on the bagging technique. Ten bags are created with a data inspired from the data base and ten classifiers are trained. The knowledge (represented by the rules of classifying the reviews) that is gained by the first classifier is added to the next one until the 10th classifier. In regard to enhancing the response time (the performance), the ten classifiers are trained in parallel using the Hadoop platform depending on the MapReduce technique. The decision-making component clusters the final results of the classifiers to generate an efficient recommendation for better gain purpose. The proposed system is evaluated based on two kinds of metrics, which are the artificial intelligence metrics (accuracy, precision, and recall) and the performance metrics (time of response). Compared to the NN-SVM similar system, the proposed system showed better results as follows: accuracy (96.7), precision (95.1), recall (91.5), and time of response (36 seconds).

In terms of limitations, the proposed system did not consider the sentiment analysis that may be found in the reviews provided by the customers.

In future work, the researchers intend to take into account the sentiment analysis to obtain a higher accuracy percentage. In addition, they intend to apply the proposed system on a real dataset in real time taking into consideration privacy and security issues.

Abstract—Condition monitoring of equipment can be very effective in predicting faults and taking early corrective actions. As hydraulic systems constitute the core of most industrial plants, predictive maintenance of such systems is of vital importance. Due to the availability of huge data collected from industrial plants, machine learning can be used for this purpose. In this work, a hydraulic system condition monitoring (HSCM) is addressed via a public dataset with 17 sensors distributed throughout the system. Using a set of 6 features extracted from sensory data, the random forest classifier was proven, in the literature, to achieve classification rate exceeding 99% for four independent target classes, namely, Cooler, Valve, Pump and Accumulator. In this paper, sensor dependency is examined and experimental results show that a reduced set of important sensors may be sufficient for the addressed classification task. In addition, feature importance as well as implementation issues, i.e. training time and model size on disk, are analyzed. It is found that the training time can be reduced by 25.7% to 36.4% while the size on disk is reduced by 70.3% to 85.5%, using the optimized models, with only important sensors employed, in comparison with the basic model, with full set of sensors, while maintaining classification precision.

Keywords—Condition monitoring; sensory data analysis; machine learning; classification

I. INTRODUCTION

This Faults or failure of equipment in an industrial plant may have serious consequences ranging from threatening the safety of operators, causing the plant to shut down for long periods of time, and lowering production rate and revenue [1]. For these reasons, maintenance plays a crucial role in process industries.

The simplest strategy for maintenance is to wait until the fault occurs and then start reacting. In this strategy, there is cost for replacing the damaged equipment and additional cost for the loss of production during equipment downtime. More advanced strategy is scheduled maintenance which is performed periodically. This approach, despite being effective, may take corrective actions which are unnecessary and costly. The most advanced approach is predictive maintenance in which the condition of equipment is continuously monitored and faults are predicted and necessary corrective actions are taken [2].

Currently, equipment condition monitoring (CM) is possible thanks to the advances in sensor technology as well as

machine learning techniques which can process huge bulks of data from sensors distributed throughout the plant. These techniques, which extract key features from data and correlate them to possible faults [3] are successfully applied in condition monitoring of e.g. gearbox [4-6], rotating machinery [7], motor bearings [8], centrifugal pumps [9,10], hydraulic systems [11], cutting tools [12], grinding mill liners [13], and semiconductor failures [14].

Hydraulic systems are core components in most fields of industries such as water treatment plants, vehicle, aerospace [15], and other industries. The failure of hydraulic system can cause a whole plant to shut down or threaten operators' safety [16-18]. In addition, hydraulic systems are not operator-friendly environments for condition monitoring [19]. Due to these reasons, condition monitoring of hydraulic systems gain a lot interest in the past two decades. For example, Liu [16] developed a tree structure model for fault diagnosis of out-of-sync oil cylinder. El-Betar et al. [17] proposed a neural network scheme for fault diagnosis of actuator leakage and valve spool blockage. Tian et al. [18] applied support vector machines (SVM) for predicting pump faults. On the other hand, Jegadeeshwaran and Sugumaran [20] employed both SVM and decision trees for fault detection of hydraulic brake systems. Helwig et al. [21] developed a hydraulic test rig with several induced fault types. Key features are extracted from sensors' data and the most highly correlated with a given fault are determined. Linear discriminant analysis (LDA) was employed to reduce feature space. The same test rig was further examined by Chawathe [22] who applied naïve Bayes, decision trees, and random forests (RF) [23]. RF classifier achieved classification accuracy of about 99% for all classes. Furthermore, it was noted that accuracy can be retained using only small set of features. Quatrini et al. [15] have studied the same dataset and used Pearson's correlation coefficient to rank the features correlated with a given fault. Algorithms such as SVM, ANN, RF, and logistic regression are tested and again RF outperforms the other techniques for most fault types. On the other hand, König and Helmi [24] applied convolutional neural network (CNN) successfully for the same dataset [21]. In the contrary to previous studies, CNN has the ability to automatically extract key features. In addition, an analysis of misclassifications is also conducted.

The main objectives of this work are to determine the sensors and features which are more effective in detecting a

given type of fault in HSCM system, and to analyze the implementation issues of the optimized classifier models.

The paper is organized as follows: the benchmark hydraulic system and dataset are described in Section 2. Section 3 illustrates the classifier model. The experimental results are then presented in Section 4. Section 5 presents a detailed discussion and the most important findings are highlighted. Finally, conclusions and future work are given in Section 6.

II. HYDRAULIC SYSTEM DATASET

For the purpose of setting up an environment to test and diagnose common faults in hydraulic systems, Helwig, Pignanelli, and Schütze [21] developed the hydraulic test rig shown in Fig. 1. In this system, several reversible faults, with different degrees of severity, can be induced and the data of the sensors distributed throughout the system are recorded. By correlating features extracted from sensor data and known faults, an automated mechanism for fault detection can be developed.

The system consists of two hydraulic circuits: the primary working (Fig. 1, top) and the cooling-filtration circuit (Fig. 1, bottom). The two circuits are connected through an oil tank. The primary circuit contains the main pump (MP1) and a relief valve (V11) which can be used to generate different load levels in the circuit, as well as four-compartments accumulator (A1,

A2, A3, and A4) for pressure storage. The secondary circuit contains the cooler unit (C1).

The test rig is equipped with 14 sensors to measure pressure (PS1 – PS6), flow (FS1, FS2), temperature (TS1 – TS4), electrical power (EPS1), and vibration (VS1). The measurements are recorded using the standard industrial 20 mA current loop interfaces connected to a data acquisition system within Beckhoff CX5020 PLC. Additionally, three virtual sensors are designed to provide estimates for system efficiency (SE), cooling efficiency (CE), and cooling power (CP). The data is collected with sampling rates of 100 Hz for pressure and motor power, 10 Hz for flow rate, and 1 Hz for other variables.

In addition to recording 17 sensors' data, the state or condition of the following targets: Cooler, Valve, Pump and Accumulator, are also recorded. A total of 2205 cycles or training examples are collected, each is 60 second long. The training examples contains cases for each state of the four targets ranging from being fully operating to close to complete failure. A list of targets, degrees of faults, their abbreviations, and the corresponding number of training examples are given in Table I. As can be seen, the problem at hand can be considered as four separate classification problems, one for each target.

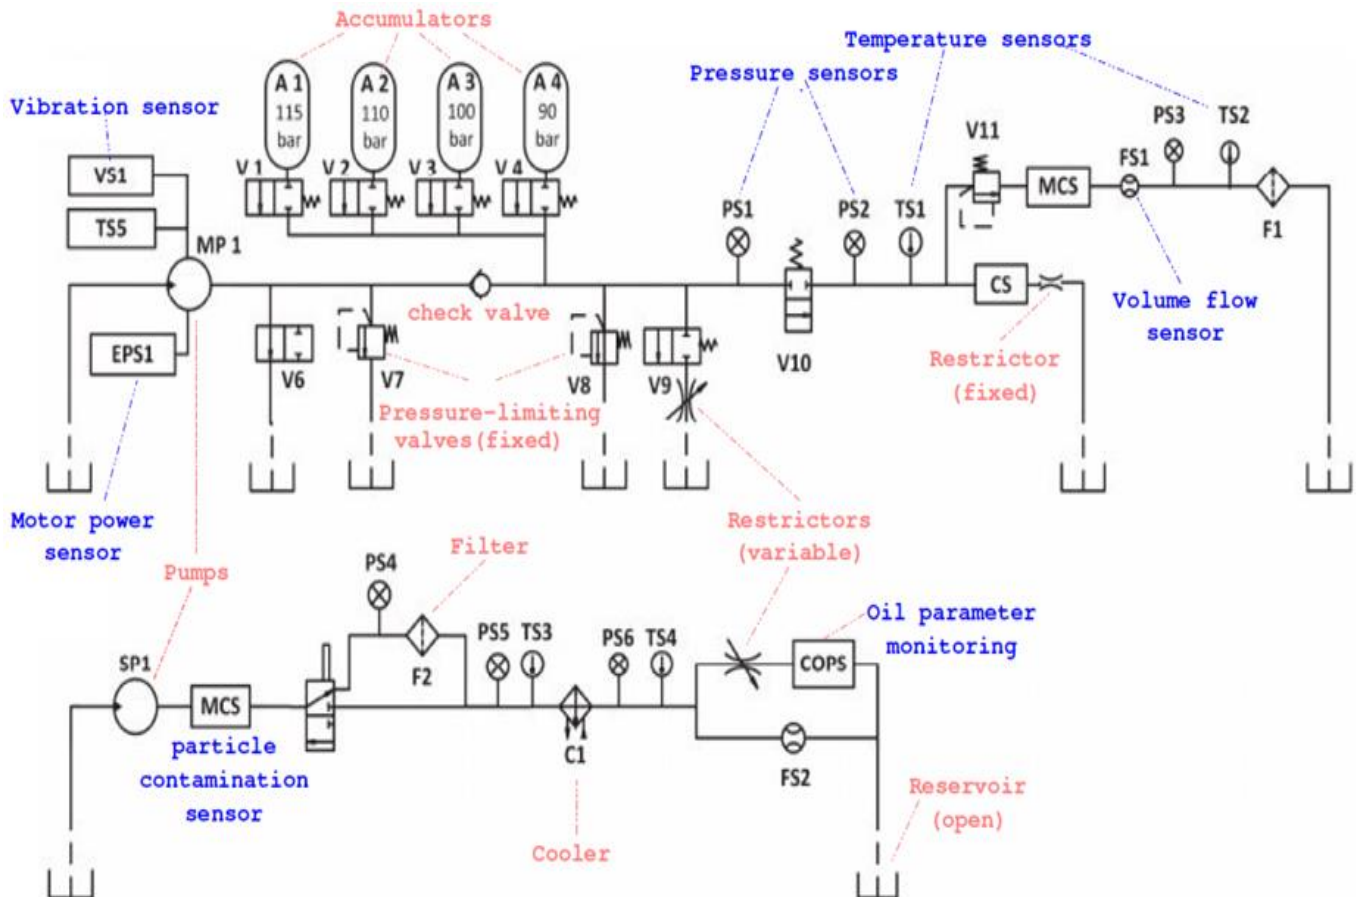

Fig. 1. Hydraulic System Under Study. Basic Monitored Units are in Light Red While Sensors are in Blue [22].

TABLE I. LIST OF TARGETS, FAULT STATES, AND THE NUMBER OF TRAINING EXAMPLES FOR EACH, IN THE BENCHMARK DATASET [21]

Condition	States	Abbr.	Examples
Cooler	Close to Complete Failure	CF	732
	Reduced Efficiency	RE	732
	Full Efficiency	FE	741
Valve	Close to Complete Failure Severe Lag	CF	360
	Small Lag	SvL	360
	Optimal Switching	SmL	360
		OS	1125
Pump	Severe leakage	SL	492
	Weak leakage	WL	492
	No leakage	NL	1221
Accum.	Close to Total Failure	CF	808
	Severely Reduced Pressure	SvP	399
	Slightly Reduced Pressure	SIP	399
	Optimal Pressure	OS	599

III. THE CLASSIFIER MODEL

The two main components of a classification task are the extraction of features and the use of a suitable type of classifier.

Features are key representative attributes of raw sensor data. They can be time domain or frequency domain. The set of features introduced by Quatrini et al. [15] are reused here to implement the experimental models. Each operation cycle is represented by 6 features, namely mean (m), standard deviation (sd), skewness (sk), kurtosis (k), slope of linear fit (slf) and position of maximum (p). The first four features characterize the distribution density of sensory signals, while slf and p features can capture the shape of the signal. These features proved very useful for fault recognition in such applications. Thus, for the 17 sensors, there are 102 features in total.

On the other hand, according to previous studies, random forest (RF) and artificial neural networks show outstanding results in the addressed dataset with a slight preference of RF [15, 24]. As the objective of the current work is not to compare different classifiers but to determine which sensors and features are important in detecting a given type of fault, random forest is employed in this paper.

Random forest classifier is an ensemble of decision trees. Each tree is fed with a set of features and provides a decision which represents a corresponding class. Within the forest, the most voted class is selected as the final classifier output [23]. To use a random forest, two parameters need to be set: the number of trees and the maximum number of splits allowed in each tree which controls the tree depth.

IV. EXPERIMENTAL RESULTS

In this section, several experiments are conducted to test the performance of RF classifier using the full set of sensors and features, and then a reduced set of them.

In all experiments, RF model is implemented with 100 decision trees and maximum number of splits equals 10. The latter parameter is selected out of values between 2 and 10. For each target, samples are randomly split into 75% for training and validation, and 25% for testing. A number of 100 independent computer runs are carried out per experiment in order to well characterize the average performance of classification models.

To evaluate the classification performance, the following set of metrics are used: *accuracy* (*Acc*), *precision* (*Pre*), *recall* (*Rec*) and *F-measure* (*F*). They are defined as follows:

$$Acc = \frac{TP+TN}{NS}, \quad (1)$$

$$Pre = \frac{TP}{TP+FP} \quad (2)$$

$$Rec = \frac{TP}{TP+FN} \quad (3)$$

$$F = \frac{2 \times Pre \times Rec}{Pre + Rec} \quad (4)$$

Where *NS* is the total number of training examples, and *TP*, *FP*, *TN*, and *FN* denote the number of true positive, false positive, true negative, and false negative examples of a given class, respectively. The environment of Matlab 2018 is used for the implementation and testing on a machine with core i5, 2.6 GHz CPU and 10 GB RAM. The implementation of RF algorithm follows [23].

A. RF for HSCM Task

In this preliminary experiment, the RF classifier is used with the full set of sensors and features. The average classification rates and implementation issues (model size, training and inference times) for the RF model are presented in Table II. The average rates of all metrics are above 0.99. High accuracy and F-measure ensure the effectiveness and robustness of employed attributes or features together with the classifier.

TABLE II. PERFORMANCE OF RF CLASSIFIER FOR FAULTS OF DIFFERENT TARGETS: COOLER (C), VALVE (V), PUMP (P), AND ACCUMULATOR (A)

	Acc	Pre	Rec	F	Size (KB)	Tr. Time (sec)	Inf. Time (sec)
C	0.998	0.998	0.998	0.998	4028	1.4	0.09
V	0.996	0.995	0.995	0.995	4510	1.76	0.091
P	0.994	0.992	0.992	0.992	4540	1.71	0.09
A	0.992	0.992	0.991	0.992	5399	2.35	0.098

Although the addressed dataset is unbalanced, the proposed model performs equally well for the recognition of different conditions of each target class. This behaviour can be confirmed by looking at the confusion matrix for the average performance of RF classifier for each target as shown in Tables III to VI. For better readability, fractions are truncated.

TABLE III. CONFUSION MATRIX FOR COOLER TARGET

	CF	RE	FE
CF	183	0	0
RE	0	183	0
FE	0	0	185

TABLE IV. CONFUSION MATRIX FOR VALVE TARGET

	CF	SvL	SmL	OS
CF	90	0	0	0
SvL	0	89	0	0
SmL	0	1	89	0
OS	0	0	0	281

As can be seen from Table V, only one observation of “Weak leakage” is misclassified as “Severely leakage” for the Pump target and vice versa. Also, from Table IV, two observations are misclassified for “Slightly reduced pressure” and one for “Severely reduced pressure” of the Accumulator target. From Table II, the size of classifier model is 4028 KB for the Cooler, with an increment of 12%, 12.7% and 32.5% for the Valve, Pump and Accumulator targets, respectively. Such variance may be explained by the different degrees of difficulty for classifying each target conditions. In addition, the training time for cooler model is the fastest with time 1.4 sec, while models of Valve and Pump require about 1.7 sec. The Accumulator model takes more training time with 2.35 seconds. Clearly, the inference time (i.e., testing the model for one observation) is almost the same for any of the four models and equals approximately 0.09 seconds.

TABLE V. CONFUSION MATRIX FOR PUMP TARGET

	NL	WL	SL
NL	305	0	0
WL	0	122	1
SL	0	1	122

TABLE VI. CONFUSION MATRIX FOR ACCUMULATOR TARGET

	CF	SvP	SIP	OP
CF	201	0	1	0
SvP	0	98	0	1
SIP	2	0	97	0
OP	0	0	0	149

Summing up, the proposed RF model alone achieves outstanding recognition rates for all targets. Unlike the work of Quatrini et al. [15], notable performance was achieved by two classifiers, ANN for the Pump with rate 0.998 for the pump target while RF was better for the Cooler, Valve and Accumulator with classification rates of 0.998, 1 and 0.991, respectively.

B. Sensor and Target Correlation

The sentiment analysis of the impact of individual sensors on recognition of severe operating conditions is extensively studied in this section. The features of each sensor are

introduced to the RF model. It might be more important to examine an employed sensor capability of recognizing every probable failure condition ignoring false alarms. Regarding this concern, precision metric is applied in this experiment. Each sensor test is repeated for 100 times in order to build up rigorous conclusions. Then, the highest-precision sensors on average are determined.

For the Cooler target, the classification task seems straightforward in agreement with previous studies [15, 24]. Precision achieved using only one of the following sensors: TS2, CE, TS1, CP, PS6, PS5, TS3 and TS4, exceeds 0.995. The use of one sensor minimizes the model size from 4028 to 651 KB and the training time from 1.4 to 1.04 sec as shown in Fig. 2(a) for the cooler. Similar behaviour is reported for the Valve target. The sensors PS3 and PS2 give Precision rates of 0.997 and 0.991, respectively. The next important sensors are PS1 and FS1 with Precision 0.957 and 0.953, respectively. Fig. 2(b) shows the model performance using the following groups of sensors: G_{V1} (PS3, PS2), G_{V2} (PS3, PS2, PS1) and G_{V3} (PS3, PS2, PS1, FS1). Model size is reduced to 892, 1137, 1432 KB for G_{V1} , G_{V2} and G_{V3} , respectively, instead of 4510 KB for the basic model with full set of sensors.

Pump and Accumulator targets are more challenging. The most effective sensors, when used individually, are FS1, SE, PS1, EPS1 and PS3 with precision 0.981, 0.979, 0.943, 0.941, and 0.929, respectively, for the Pump. The best combination of sensors are FS1, SE, PS1, giving an optimal precision 0.993. In this case, model size occupies only 657 KB and takes 1.15 seconds for training compared to 4540 KB and 1.71 seconds, respectively, when the full set of sensors are used. Fig. 2(c) summarizes the performance of different groups of sensors for Pump target: G_{P1} (FS1, SE), G_{P2} (FS1, SE, PS1), G_{P3} (FS1, SE, PS1, EPS1) and G_{P4} (FS1, SE, PS1, EPS1, PS3).

Similarly, the top 6 effective sensors when used individually, for the classification of Accumulator, are PS3, PS1, SE, FS1, TS1 and PS2 with precision 0.923, 0.88, 0.837, 0.828, 0.802 and 0.8, respectively. Fig. 2(d) illustrates the performance of combining attributes of sensors in the groups: G_{A1} (PS3, PS1), G_{A2} (PS3, PS1, FS1), G_{A3} (PS3, PS1, FS1, SE), G_{A4} (PS3, PS1, FS1, SE, PS2) and G_{A5} (PS3, PS1, FS1, SE, PS2, and TS1). The best precision of 0.986 is obtained using group G_{A5} with model size 1602 KB (compared with 5399 KB for the basic model) and training time of 1.73 sec (compared with 2.35 seconds, for basic model). This experiment reveals that the Accumulator target conditions are the hardest for classification.

In summary, this experiment justifies, to a great extent, the preliminary discrimination of target classes in this dataset into easy (Cooler and Valve) and hard (Pump and Accumulator) classifiable classes [21]. For the Cooler and Valve targets, it is sufficient to apply only one sensor for monitoring the different conditions of each one. For the pump target, however using FS1 alone can achieve precision of 0.981 but the group G_{P2} (FS1, SE, PS1) improves it to 0.993. Focusing on the most effective sensors can optimize the RF model in terms of model size and training time. Finally, several sensors are needed to give an acceptable recognition precision of Accumulator conditions. The sensors G_{A5} (PS3, PS1, FS1, SE, PS2, TS1)

can achieve a high precision of 0.986. However, this is still below the precision 0.993 of the basic model which employs all sensors.

Fig. 2. Normalized Numerical Results of Sensor Correlation Tests for Different Targets.

C. Feature Effectiveness

Based on the findings of the previous experiment, it is interesting to investigate the most effective attributes per sensor. Therefore, in section, only the most effective sensors for each target are considered. The wrapper-based approach is followed where each individual attribute is provided for the classifier. Thus, a direct judgement of the discriminating power of each attribute is obtained. For this purpose, RF model using 5 decision trees with a maximum number of split equals 2 is sufficient.

Fig. 3(a) shows that only the mean of the CE sensor (CE_m) can classify the conditions of the Cooler target with average precision of 0.998. Also, the mean of CP sensor (CB_m) can achieve precision 0.992. Moreover, the mean of each of PS5, PS6, TS1 and TS2 results in precision exceeding 0.96. Slop of linear fit of the TS1 sensor is also useful achieving a precision of 0.942.

Other effective features are determined for the Valve condition. The kurtosis and skewness of PS2 (PS2_k and PS2_sk) give precision of 0.994 and 0.972, respectively. Position of the maximum of PS3 (PS3_p) achieves 0.99 precision. Fig. 3(b) shows the effectiveness of attributes of PS2 and PS3 denoted by G_{V1} and give the highest rate for the Valve target.

Attribute effectiveness for the most useful sensors for the Pump target, namely G_{P2} (FS1, SE, PS1), is presented in Fig. 3(c). The mean of SE (SE_m) gives 0.952 and the mean of FS1 gives 0.924 precision. The rest of attributes achieve lower rates, in particular the position of the maximum of each of FS1 and SE (FS1_p and SE_p) are definitely useless for Pump target class.

For the Accumulator target, no individual attribute of the sensors group G_{A5} (PS3, PS1, FS1, SE, PS2, TS1) can exceed a precision level of 0.7 as shown in Fig. 3(d). The mean of each of TS1 and PS1 are the highest two attributes with precision 0.683 and 0.59, respectively. Such observation shows again that recognition the conditions of the Accumulator target is harder than others in this application. Also, the position of maximum of each of FS1 and SE (FS1_p and SE_p) seems useless for this target class.

Summarizing these findings, it is interesting to discover that only one attribute of one sensor can be efficient for the addressed classification task in this work for some targets. The mean of CE sensor (CE_m) and the kurtosis of PS2 (PS2_k) achieve precision of 0.998 and 0.992 for Cooler and Valve targets, respectively. Conversely, some features are useless for classification such as (FS1_p and SE_p) for both Pump and Accumulator targets.

Fig. 3. Effective Attributes for each Target Class.

V. DISCUSSION AND LIMITATIONS

Condition monitoring of hydraulic systems via sensors fixed inside the system is suspicious to some hazard situations if one or more sensors become out of service. Thus, the importance of current study stems from investigating the role of each sensor in the assigned classification task. Besides, emphasizing the most effective attributes leads to optimizing the classification model size and training time.

Table VII summarizes the outcomes of this study. The optimized RF model for the Cooler target uses only one sensor of (TS2, CE, TS1, CP, PS6, PS5, TS or TS4), keeps performance (denoted by + in Table VII) of basic model that uses all sensors. It follows that model size and training time are reduced by 83.8% and 25.7%, respectively.

TABLE VII. SUMMARY OF EFFECTIVE SENSORS AND FEATURES FOR EACH TARGET, THE IMPACT ON MODEL PRECISION (PRE. ↑), PERCENTAGE REDUCTION IN MODEL SIZE (RS) AND TRAINING TIME (RT)

	Sensors	Features	Pre.	Pre. ↑↓	Size (KB)	RS(%)	Tr. Time (sec)	RT(%)
Cooler	TS2, CE, TS1, CP, PS6, PS5, TS, TS4	Mean	0.995	+	651	83.8	1.04	25.7
Valve	PS3, PS2	Kurtosis, Skewness	0.997	+	892	80.2	1.12	36.4
Pump	FS1, SE, PS1	Mean	0.993	+	657	85.5	1.15	32.7
Accumulator	PS3, PS1, SE, FS1, TS1, PS2	Mean	0.986	-	1602	70.3	1.73	26.4

For the Valve target, the RF model, using PS3 and PS2, is as efficient as basic model with reduction in model size by 80.2% and training time by 36.4%. Using only FS1, SE and PS1 attributes can achieve slightly better performance than the basic model for the Pump target with reduction ratios of 85.5% and 32.7% for model size and training time, respectively. A different finding is reported for the Accumulator target. Using a reduced set of sensors such as PS3, PS1, SE, FS1, TS1 and PS2 might result in performance degradation (marked with “-” in Table VII). However, model size reduction ratio reaches 70.3% and training time becomes 26.4% less than using all sensors. For the attributes, it is figured out that simple time-domain features such as mean, kurtosis and skewness are very useful and efficient for such classification problem.

It is important to emphasize that, in this work, sensor role and feature importance is studied from a pure machine learning point of view. It is interesting to interpret the validity of the results obtained with the aid of an expert of such hydraulic plant. Moreover, the proposed model, and its optimized versions, should be tested in real environment where ad-hoc devices like PLC units are in charge for monitoring the system conditions. It also lacks to consider the effect of noise on recorded sensor signals, in particular low-frequency sensors.

VI. CONCLUSIONS AND FUTURE WORK

The employment of machine learning techniques for hydraulic system condition monitoring proves effective for automatic recognition of faults and severe conditions. It is common to fix various sensors in the system in order to collect enough readings for different operating conditions. The considered system in this study is provided by 17 (14 physical + 3 virtual sensors) for measuring quantities such as motor power, volume flow, pressure, temperature and vibration. These sensor signals are represented by a set of six simple time-domain attributes to classify four targets, namely, Cooler, Valve, Pump and Accumulator. The random forest classifier is very suitable for such classification task and its performance exceeds 99% for all targets. Moreover, the conducted experimental work reveals the impact of each sensor in classification of each target conditions. Using of all sensors is not essentially effective and efficient. Only one temperature sensor is sufficient for the Cooler conditions classification. The same observation holds for the Valve target where only two pressure sensors are sufficient. Interestingly, the volume flow, pressure and efficiency factor sensors can achieve better recognition rate than using all sensors for the Pump target.

On the contrary, for the Accumulator target, the use of the attributes of all sensors looks mandatory in order to achieve high performance. However, using a reduced set of pressure, volume flow, temperature, and efficiency factor sensors still gives acceptable classification rate for this target.

Using few sensors optimizes the classification model size and training time and, furthermore, minimizes the cost of purchasing and maintenance of many sensors while some of them can be sufficient. It is worth to investigate the applied methodology here for other similar applications to determine the most important sensors for a given fault.

The effect of noise commonly present in sensor measurements on the classification model is challenging and can be investigated in a future work. Moreover, noting that the classification performed in the current work employs windows of data of size 60 seconds, it is a reasonable extension to study the possibility of using shorter windows e.g. 5, 10, 20 or 30 seconds. This can have significant effect on the quick detection of severe fault conditions.

Abstract—Directing the antennas of the 5th generation mobile network optimally became a hard and tedious process due to the abundance of the antennas that the 5th generation networks relay on. Also, due to the traditional way of measuring the signal strength of the 5th generation networks. The process that could take weeks of working until it is done. So, the solution is to make an automated process to measure signal strength and to direct antennas using "Drones" rather than human power. This way will ease the process of directing antennas in a quite shorter amount of time which will be some hours instead of weeks. Plus the low cost and the high accuracy achieved. So, a cooperative network between "Drones" and a new communication protocol to support that network will be designed. "Drones" will communicate with each others and with antennas through exchanging messages by "MQTT cloud" using new designed communication protocol. "Raspberry pi" platform will be used as a server to control the direction of antennas. "Drones" will carry a "4G mobile" and a "Raspberry pi" with a "Building Identification System (BIS)" setup on it. The "(BIS)" gives every building a number and will recognize the entrance of buildings to measure signal strength at every floor. Then, performance analysis metrics (Throughput) will be measured. OMNeT++ "will be used for simulation", and "Raspberry Pi" platform will be used to implement the system and measure the performance of the new Communication Protocol.

Keywords—Drones; communication protocol; Message Queuing Telemetry Transport (MQTT); cooperative network

I. INTRODUCTION

The fifth generation of mobile communication systems aims to provide a ubiquitous mobile service with better quality. Automobiles, public transportation, medical care, energy, public safety, agriculture, entertainment, manufacturing, and other vertical industrial applications are expected to benefit from this technology. User density, traffic volume, and data rate are all expected to increase dramatically. In the coming decade, innovative solutions to the needs of both smartphone users and vertical industries are needed.

There are many challenges to realize 5G networks, i.e., high system capacity (1000× capacity per km²), high data rates (targeting 1 Gbps per user everywhere and 100× user throughput increase) and massive connectivity (100× connected users) [1]. The advent of fifth generation (5G) technology will accelerate the growth of V2V communications. A recent report from Juniper Research predicted that as 5G

technology provides lower latency and high range, automotive Original Equipment Manufacturer (OEMs) will use it as the main technology for V2V communications over other technologies [2].

The traditional way that is used now in The fifth generation (5G) of mobile communication system to measure the coverage cell phone network signal strength in cellular base stations is through the human power using smartphones, where specialists go to the antennas above the base stations to direct it. The different teams of specialists are distributed over the whole places and buildings that is under the coverage of the base station. Then they take the measure of signal strength via a mobile application like "Network cell info lite" then they communicate with the specialists on the base station and deliver the measures taken to them so that they can direct the antennas according to what they received. This process that repeated over and over again in an attempt to get the optimal direction of the antennas. But finally it doesn't get achieved for several reasons.. First is the high cost. Second is the high consumption of time "that could take days and sometimes a few weeks" and third is the lack of accuracy from the human power. Besides some changes that may happen to the coverage places in terms of the buildings and its height or the continuous variation in the number of users of the network. Which leads us to repeat the whole process many times in small period of times. Which is a big obstacle to telecommunication companies.

With advances in technology and commercially available vehicles, the interest is shifting toward collaborative drones. cooperation necessitates effective communication as well as a sound strategy for avoiding obstacles and drone collisions. Considering that drones must swap positions in order to maintain the swarm formation, cover a large area, and avoid colliding [3].

Several projects searched into the challenges of designing UAV systems for various applications. The general design principles of a multi-UAV system in civil applications are an open issue and are still being researched [4].

According to all the mentioned before, it becomes necessary to think & research to find an alternative way (using "Drones" to direct antennas) instead of the traditional way that has lots of disadvantages like the high cost, the high consumption of time and the lack of accuracy.

These disadvantages that led to the weak signal or no signal at all in mobile networks due to the poor distribution of antennas and not directing them optimally that finally make the mobile users suffer when they use the network specifically in higher floors in skyscrapers. So to avoid all these problems, the proposal is:

Replacing the human power with "Drones" by creating a cooperative network between each others. As "Drones" will be sent to the buildings and places that are under the coverage to take the measures of the signal strength. And by the connection between the "Drones" and the "Server" placed on the base station, the measures will be sent to it through MQTT Cloud (or off load when facing no connection situation). Then, by the "Servo motors" the antennas will be directed to the optimal angle.

As a result the solution presented will lead us to avoid all the disadvantages mentioned before there for there is no chance to face any high cost caused by repeating the process in the traditional way.

Contributions :

- Building Cooperative Network Between Drones.
- Building New Communication Protocol To support Cooperative Network Between Drones
- Design and implementation for mobile application on MQTT cloud
- Make a Hardware Implementation using raspberry pi for receiving the data from drones to do tilting of antenna.

Outlines of paper:

Section II presents "Related work" (Cooperative network of drones, 5G, ordinary site survey, image processing, mobile application, MQTT, hardware implementation). Section III presents "Overall Proposed model". Section IV presents "Drones Cooperative network". Section V presents "Proposed new communication protocol". Section VI presents "Mobile application". Section VII presents "Building Identification System (BIS) and Directing Antenna System (DAS)". Section VIII presents "Simulation results and Performance analysis". Section IX presents "Hardware implementation". Section X presents "Comparison with other works". Section XI presents "Conclusion and future work".

II. RELATED WORK

The rapid growth of Unmanned Aerial Vehicles (UAVs) for various applications such as package delivery, inspection, defence, and disaster relief has opened up a plethora of commercial business opportunities. For successful use of UAVs for various applications, it is critical that the vehicles be configured to operate autonomously and cooperatively.

In this section, related work will be reviewed. Also the Cooperative network of drones, 5G, ordinary site survey, image processing, mobile application, MQTT, and hardware implementation of Cooperative Network of Drones will be reviewed.

In [3] Bekhti, et al. presented The application of a swarm of drones to the intrusion detection and tracking problem. They devised an algorithm to keep the drones in a team formation in order to address the issue of coverage and collisions. Omnet simulator was used to test the algorithm in various scenarios.

In [5] Gu, et al. they proposed a cooperative network platform and system architecture of multi-UAV surveillance, they discussed the establishment of suitable algorithms based on machine learning.

In [4] presented by Yanmaz, et al. they proposed drones are being utilized in monitoring, transport, safety and disaster management, other domains. they described a high-level architecture for the design of a collaborative aerial system consisting of drones with on-board sensors and embedded processing, coordination, and networking capabilities.

In [6] Dong, et al. they studied optimizing the deployment density of Drone Small Cells (DSCs) to achieve the maximum coverage performance, they propose an algorithm to get the optimal deployment density with low complexity. they conducted both field experiments and Matlab simulations to verify the correctness of theoretical analysis.

In [1] Nirwan and Liang they investigated the problem of Placement and communications in the Drone-mounted base-stations (DBS) to provide ubiquitous connections and high spectrum efficiency.

In [7] Chakrabarty, et al. they simulated a complete urban operations in a high fidelity simulation environment. they designed a V2V communication protocol and all the vehicles "Drones" participating communicate over this system.

In [8] Manasa, et al. they discussed a new approach to the wireless communication between Ground Control Station (GCS) to Micro Air Vehicle (MAV) and vice versa.

In [9] Iranmanesh, et al. they discussed congestion problem in cellular networks through the assistance of parcel delivery drones. To this end, they proposed a novel algorithm, called CARLO.

In [10] Ma, et al. they utilized drones as air routers to establish a LAN, to collect information from pipeline networks and transmit it to pipeline inspectors. to achieve optimal drone deployment. A two-phase evolution optimal 3-D drone layout algorithm was proposed to deploy drones.

In [11] Buksz, et al. they presented an approach for autonomous radio base station inspection using cooperative drones based on Intent-driven Strategic Tactical Planning (ISTP).

In [12] Lee. He proposed a cooperative drones positioning measuring in internet-of-drones in order to obtain high accuracy positions for both egodrones and obstacles.

In [13] Bartolini, et al. They work addressed the problem of assigning location based tasks to a fleet of drones in an emergency critical scenario, to ensure early inspection of target locations.

In [14] Pu, and Logan Carpenter, they investigated the problems of service scheduling for drones and Zone Service

Providers (ZSPs) in the Internet of Drones. For performance evaluation, they conducted extensive simulation experiments using OMNeT++.

In [15] Guan, et al. they studies distributed algorithms for controlling self-organizing flying Unmanned Aerial Vehicles with massive MIMO networking capabilities, dubbed mDroneNet. The distributed solution algorithm converges in tens of iterations and can achieve around 90% of the global optimum, according to the Results.

In [16] Verri, et al. they discussed the drones' overall performance. They proposed a different approach to the problem of airspace route planning. They used a simplified simulation model.

In [17] Haas, and Zhong, they discussed the collaborative communication of multiple drones, as to create a reliable and powerful communication links, which as part of the network (they called "Network in the Sky").

In [18] Valianti, et al. they proposed Using a swarm of pursuer drones to track down and apprehend one or more rogue drones. Extensive performance assessment results show that the problem can be solved efficiently and effectively using the evolved distributed algorithm.

In [19] Khosravi, et al. they proposed designing drones trajectories that efficiently perform some transportation operation (for example, package delivery) while also providing uniform coverage over a neighbourhood area, which is required for applications such as network coverage, data collection from Internet of Things devices, wireless power transfer, and surveillance. They proposed a trajectory process that would allow for uniform coverage while maintaining transport (delivery) efficiency.

In [20] Dao, et al. they studied the Aerial radio access networks (ARANs) as a potential strategy to supplement existing terrestrial communication systems. Unmanned aerial vehicles, drones, and satellites are among the airborne components involved. The development of seamless mobile communication systems is expected to be aided by ARANs as part of a comprehensive sixth-generation (6G) global access infrastructure.

In [21] Real, et al. they presented a group of multiple Drones that would work together on autonomous construction missions. They tested and simulated the system's performance.

In [22] Huang, et al. they illustrated how to navigate a group of unmanned aerial vehicles (UAVs) to monitor traffic on a road. They tested their method using computer simulations.

A. 5g Mobile Communication System

In [23] Habibi, et al. they discussed the fifth generation of mobile communication systems aims to provide a ubiquitous mobile service with better quality (QoS). Automobiles, public transportation, medical care, energy, public safety, agriculture, entertainment, manufacturing, and other vertical industrial applications are expected to benefit from this technology. User density, traffic volume, and data rate are all expected to increase dramatically. In the coming decade, innovative

solutions to the needs of both smartphone users and vertical industries are needed, as shown in Fig. 1.

Fig. 1. Abundance of the Antennas that the 5th Generation Networks Relay on.

B. Ordinary Site Survey

The human power is the main factor in the traditional way of measuring the signal strength of the 5th generation mobile networks. Lots of specialists work using their smartphones (using mobile application like "Network Cell info Lite") [23]. They are all responsible for making that process get done. Like going to all the places and coverage areas, measuring the signal strength and even directing the antennas on the base stations by themselves. They communicate with each other to send and receive the measures and the required data to control and direct the antennas.

So according to all that lots of problems occurred through this process like the high cost, high consumption of time and the lack of accuracy. Plus the process needs to get repeated so many times in small period of time to reach the direction required. Which is not achieved at the end.

C. Image Processing

In [24] Chen, et al. they framed this drone-view building identification as building retrieval problem: given a building (multimodal query) with its images, geolocation and drone's current location, they aim to retrieve the most likely proposal (building candidate) on a drone-view image. Despite few annotated drone-view images to date, there are many images of other views from the Web, like ground-level, street-view and aerial images. Thus, they proposed a cross-view triplet neural network to learn visual similarity between drone-view and other views.

D. Mobile Application (To Measure Signal Strength)

Will be measure the signal Strength by "Network Cell Info lite app" [23]. It will measure the signal strength and display the location of your signal on a map.

E. MQTT Protocol / MQTT Cloud

In [25] Kang, et al. they discussed MQTT protocol operation. The basic concepts of it is publish/subscribe and client/broker and its basic functionality is connect, publish, and subscribe.

In [26] Mishra and Attila, they discussed MQTT protocol, For message delivery, MQTT provides three levels for quality of service (QoS 0 - QoS 1 - QoS 2). The design principles of this protocol focus on minimizing network bandwidth and device resource requirements ensuring reliable delivery.

In [27] presented by Krishna, et al. they discussed MQTT Dashboard, a mobile app that runs on a phone and can be used to track data sent from sensor nodes using the MQTT protocol. MQTT Dash is another choice. M2M, Arduino, Raspberry Pi, Microcontrollers, and other devices are supported by the application.

F. Hardware Implementation

In [28] Mathur, et al. proposed a novel approach to digital image processing by using the histogram of oriented gradients (HOG) features descriptor with the OpenCV library, which was programmed in Python and booted with the Raspberry Pi, which was equipped with a RaspyiCam to capture moving images of objects passing under the cam.

III. OVERALL PROPOSED MODEL

As shown in Fig. 2. "Proposed Model" the human power has been replaced with "Drones" by creating a cooperative network "that based on new communication protocol between drones. A Cooperative Network between Drones will be built and a "4G Mobile" will be setuped and a "Raspberry pi" will be setuped on every drone. digital map will be used with drones so drones are ready to be sent to the locations to take the measures of the signal strength . All buildings will be identified by the " (BIS) ". The signal strength will be measured by a mobile application "Network Cell Info Lite" setuped on the "4G mobile". Data will be sent from "Drones" to "Server" and vice versa using Cooperative network based on a new communication protocol and also the messages will be sent between "Drones" and" Server" and vice versa by "MQTT Cloud". So, Finally the "Server" will control the direction of the antennas using "Servo motors".

The Model Structure:

1) *Building cooperative network between drones:* "Drones" will communicate with each others and Data will be sent from "Drones" to "Server" and vice versa using Cooperative network based on our new designed communication protocol, as shown in Section 5.

2) *Building new communication protocol:* The Drones communicate with the Server or other Drones is realized in defined frame structure of new communication protocol supporting cooperative network, which consists of (payload data, header) for identification. The frame structure consists of the (header, payload) accompanied by the checksum. The protocol is a designed communication protocol to support the cooperative networks between drones to be used in 5G site survey.

3) *Mobile app SW (network cell info lite):* It will measure the signal strength and display the location of your signal on a map.

4) *Building Identification System (BIS) on drones:* As shown in [24]. The work of the "BIS based on CNN" is to give every building a specific number to recognize the entrance of the building to measure signal strength at every floor.

5) *Directing antenna system (DAS):* The (DAS) will be setuped on "Raspberry pi" and programmed using "Python language". It will receive messages "with measures "from "Drones" and according to these measures, the parameters of the angles of the antennas will be given to the three groups of "Servo motors" so that the antennas will be directed to the optimal direction.

6) *MQTT (broker/clint - publisher/subscriber):* "Drones" will communicate with each others and with the antennas through exchanging messages by "MQTT cloud".

7) *Drones:* The "4G Mobile" and "Raspberry pi" will be setuped on Drones, then the signal strength measured will be sent to the base station by the drones.

8) *Phones:* Setup the "4G Mobile" on Drones and Setup a mobile App (Network Cell Info Lite – Mobile & Wi-Fi Signal) on smart phone "4G Mobile" to measure signal Strength.

9) *Raspberry Pi:* This versatile single board machine can be used for a variety of tasks. two "Raspberry pis" will be used : First with an (DAS) and second with an (BIS).

10) *Servo motors:* The designed system requires maximum precision, in 5G, servo motors will be used to control antenna direction. The Server will give orders to the three groups of "Servo Motors" to control the direction of the antennas (every group consists of 2 servo motors to move one antenna "Pan1, Tilt1").

As shown in Fig. 3. "Proposed model flow chart" A Cooperative Network will be built between Drones and a "4G Mobile" and a "Raspberry pi" will be setuped on all drones. The digital map will be used on Drones so they are ready to be sent to their locations for taking the measures of the signal strength. The "(BIS)" will identify all buildings. Then the signal strength will be measured by a mobile application like "Network Cell Info Lite" which setuped on the "4G mobiles". Data will be sent from "Drones" to "Server" and vice versa by Cooperative network based on a new communication protocol and also the messages will be sent between "Drones" and" Server" and vice versa by "MQTT Cloud". So at the end the "Server" will control the direction of all antennas using "Servo motors". And the process will be repeated again and again till achieve our target.

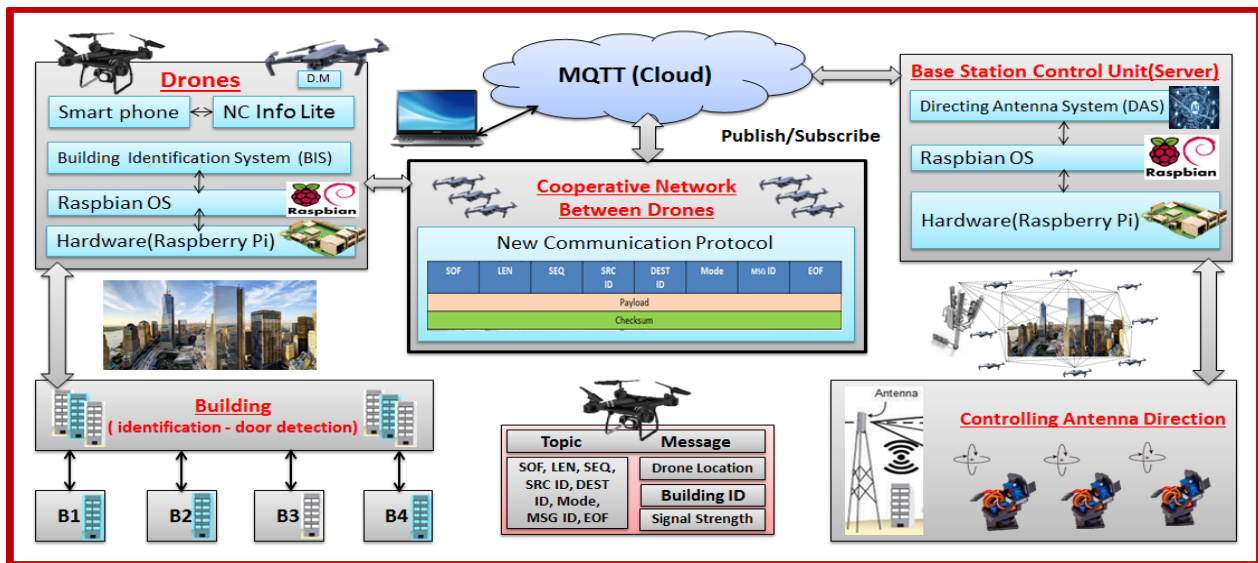

Fig. 2. Proposed Model.

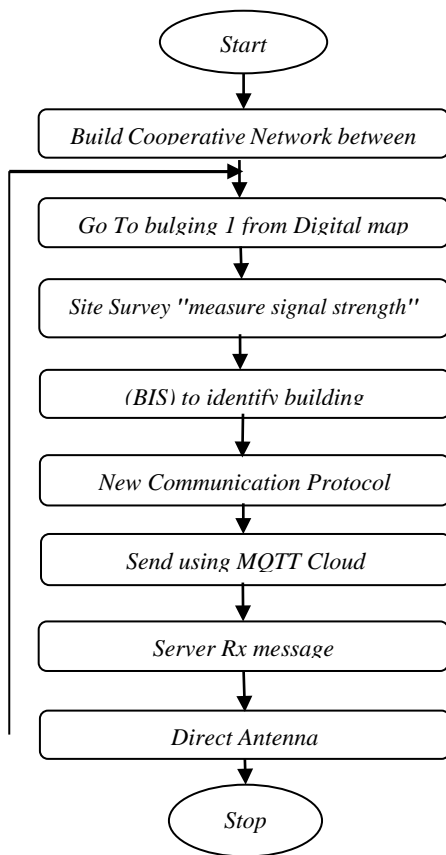

Fig. 3. Proposed Model Flow Chart.

IV. DRONES COOPERATIVE NETWORK

As shown in Fig. 4, the Cooperative Network: (Peer to Peer) in a P2P network, the "peers" are Drone which are connected to each other via the Cooperative network. Drones can be connected directly with other drones in the network without the need of a Master through MQTT Cloud through an internet connection.

Fig. 4. Peer-to-Peer Cooperative Network between Drones.

V. PROPOSED NEW COMMUNICATION PROTOCOL

- In this paper, a comprehensive solution was proposed by design a new communication protocol to support the cooperative networks between drones to be used in different fields and applications."Drones" will communicate with each others and with the antennas through exchanging messages by "MQTT cloud".
- MQTT has three components (Publisher "Drones/Server", Subscriber "Drones/Server", Broker MQTT Cloud).
- Mosquitto MQTT is used as a broker.
- The Drones communicate with the Server or other Drones is realized in defined frame structure of new communication protocol supporting cooperative network, which consists of (payload data, header) for identification. The frame structure consists of the (header, payload) accompanied by the checksum.
- The frame structure of the new communication protocol is shown in Fig. 5.

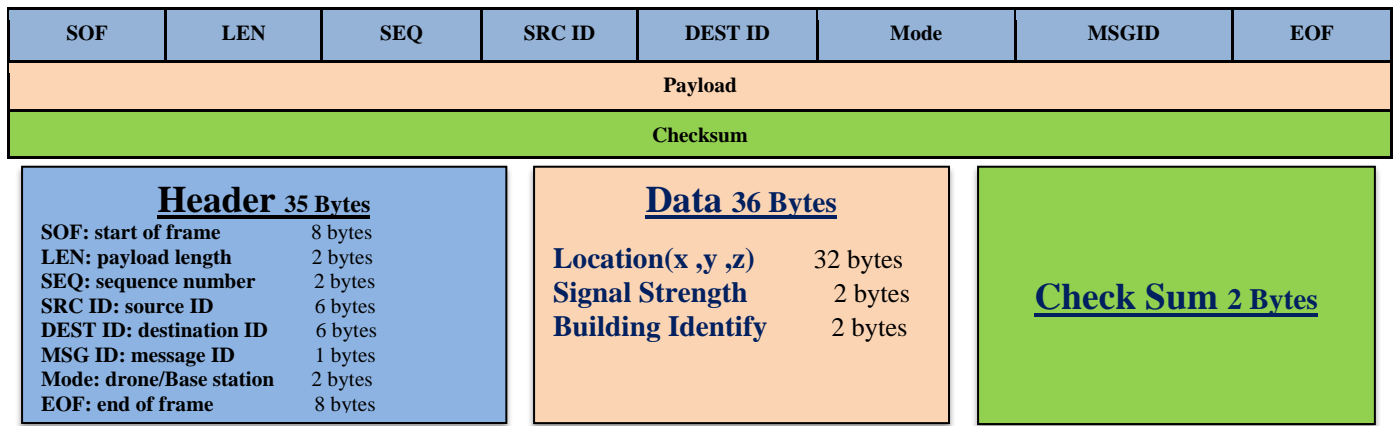

Fig. 5. Communication Frame Structure.

The frame structure fields will be explained in the following below:

a) *Header*: The protocol is including a header that contains all of the information about the payload data that must be exchanged between the Drones and the Server (Base Station antenna's) or Drones and Drones. The header is of 35 bytes, it has a set length and consists of the fields mentioned below.

- **SOF**: In continuous transmission, this Start of Frame implies the beginning of a frame. The field length is 8 Bytes. which indicates the beginning of new packet.
- **EOF**: In continuous transmission, this End of Frame indicates the end of a frame. The field is 8 bytes long. This indicates that the previous frame has come to an end.
- **LEN**: The length of the payload is indicated by this value. (Location(x,y,z)/Signal Strength/Building Identify) will be the payload, payload length max 7200 bytes which uses 2 bytes, (signal strength is 2 bytes and Building Identity is 2 bytes and GPS data is 32 bytes, taking 200 readings for each building with total of $36 * 200 = 7200$ bytes), The original data or message to be sent is referred to as the payload.
- **SEQ**: The 2 byte Sequence The long message is divided into a number of packets and numbered, allowing it to be assembled at the receiving end.
- **SRC ID**: Source identification is used to determine the system's uniqueness among the various Drones that are connected to one another. source ID has a length of 6 bytes.
- **DEST ID**: The receiving destination's address is stored in the Destination ID field, destination ID represents Drone/Server number. The length of the destination ID is 6 bytes. By including the data's destination address, it can be ensured that the data intended for a specific drone arrives there and others drone may reject them.
- **MSG ID**: 1 byte Message Identification of the parameter is used to distinguish parameters from the many that are available (control msg/cooperative

network/Drones and the Server). Each of these parameters has a unique ID prefix, which aids in faster and more reliable communication.

- **MODE**: send to drone or base station 2 bytes, indicating the number of Drones in swarm flight .

b) *Payload*: This is the original flight data, Payload of one data information is : 36 bytes.

(Navigation information of drone and camera information is not included in new communication protocol).

c) *Checksum 2byte*: This is used to verify the data's integrity. At the transmitter, the frame's checksum is calculated and appended to the frame at a specific location in the frame structure. The checksum for the received frame will be calculated and compared to the value that comes with the frame. A value mismatch between the Transmitter and the Receiver indicates that the data is incorrect and frame should be discarded, with a request for re-transmission. ITU X.25 is used to calculate the frame's checksum [8].

- There is an example of a one "Drone" sending a message from a drone to the server, message consists of three frames. Each frame measures the signal strength from a different position. (Server ID: 4, Drone 1 ID: 1, No. of frames: 3) as shown in Table I.

Header is 35 bytes

(SOF: 8 bytes, EOF: 8 bytes, LEN: 2 bytes, SEQ: 2 bytes, SRC ID: 6 bytes, DEST ID: 6 bytes, MSG ID: 1 byte, Mode: 2 bytes)

Payload of one data information is 36 bytes

(Building Identify 2 bytes, Signal Strength 2 bytes, GPS location of Drone (x, y, z) is 32 bytes)

Checksum is 2 bytes

The size of Message = total size of frames = (frame size * number of frames)

The size of one frame = Header size + Payload size + Checksum size = $35 + 36 + 2 = 73$ Bytes

The size of Message = $73 * 3 = 219$ Bytes.

TABLE I. EXAMPLE FOR TRANSLATE THE DATA

No. of frame	Header								Payload				Check Sum	
	SOF	LEN	SEQ	SRC ID	DEST ID	Mode	MSG ID	EOF	Location(x ,y ,z)			Signal Strength		Building Identify
1	50	3	1	1	4	3	90	500	398	195	104	1757	B1	2304
2	50	3	2	1	4	3	90	500	52	451	91	3843	B1	2349
3	50	3	3	1	4	3	90	500	423	97	250	7331	B1	2973

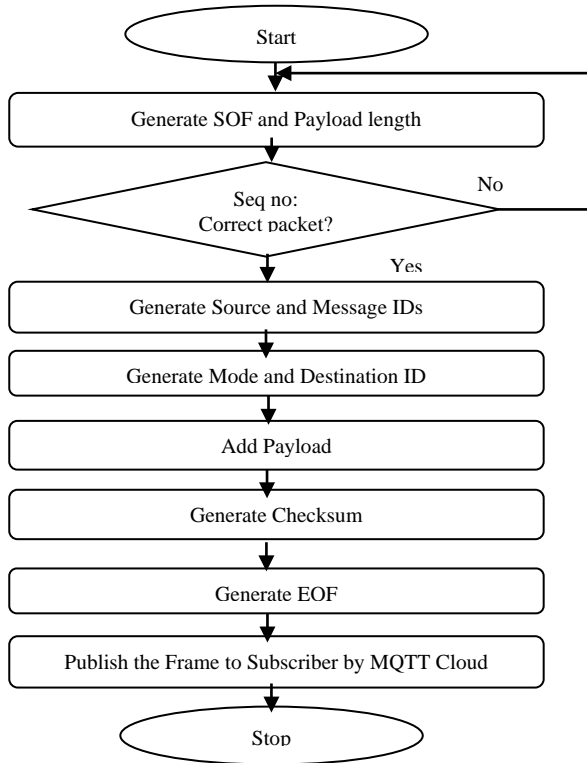

Fig. 6. Flowchart of the Publisher.

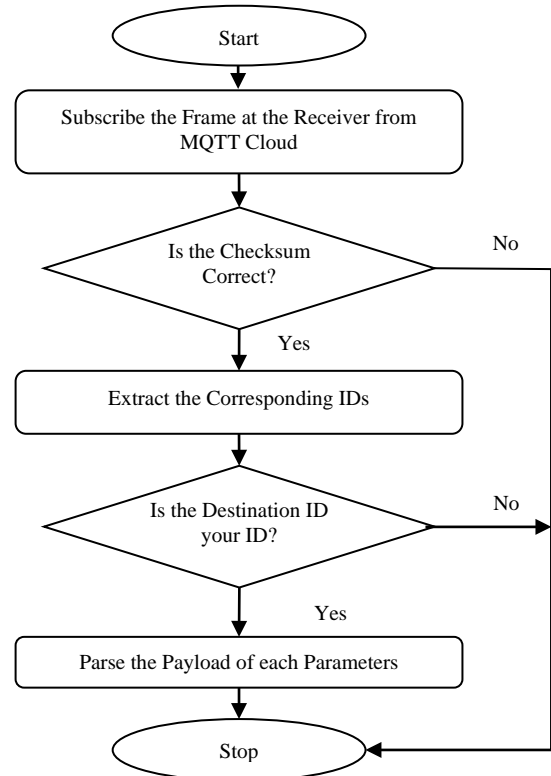

Fig. 7. Flowchart of the Subscriber.

As shown in Fig. 6. “Flowchart of the Publisher” at the transmitter "publisher" side, a fixed SOF indicates the start of new packet. Once the payload data is arrived for first time, the SEQ field is initializes and length of the payload is calculated and fed into the LEN field in the frame. The SRC ID and DEST ID is generated and appended to the frame. MODE is decided and appropriate value is appended in the frame, to this header, the payload data is added and checksum is calculated for the entire frame and a fixed EOF indicates the End of packet and appended at the last position of the frame. Now the frame is ready for transmission "publish" to the MQTT Cloud.

As shown in Fig. 7. “Flowchart of the Subscriber” At the receiver "Subscriber" side the decoding procedure is followed as given in the Fig. 9. Subscribe the Frame at the Receiver from "MQTT Cloud" Once the packet is received, it is cross checked with the transmitted checksum to check the integrity of the transmitted data. If the checksum value matches the transmitted ones, the corresponding payload parameter is parsed by extracting the corresponding IDs. The DEST ID is checked with the host ID to check the transmitted packet is intended for host or not. A mismatch in checksum indicates the packet wrong data.

VI. MOBILE APPLICATION

Network Cell Info Lite - Mobile & WiFi Signal (To measure signal Strength), with testing cell signal strength, it's easier to see how subtle differences in signal strength can affect the performance of the mobile communication system. Lots of people actually consider "Network Cell Info lite app" the best of all apps to measure signal Strength. And for good reason. It covers every cellular network.

VII. BUILDING IDENTIFICATION SYSTEM (BIS) AND (DAS)

A. Proposed Building Identification System

Fig. 8 shows the steps of Building Identification System of detecting the building entrance as shown in [24], which setuped on drone for building identification. The Raspberry Pi model “zero w” will be run by Rasbian OS, Install Building Identification System based on CNN using Python and Install OpenCV for Building Identification. First, send digital map to drones to be able to match the building image with it, then generate "SOF, LEN, SEQ", then check the SEQ no, then generate "SRC ID, MSG ID, Mode, DEST ID, Checksum, and EOF". then creating Cooperative Network between Drones

then detect the drone location then proceed to make the Building Identification by giving the OpenCV sample of Buildings photo as a training sample and matching the building image with digital map, then read the measures of the signal strength by "NC Info Lite app" which setuped on Smart phone, and finally will Publish the frames on "MQTT Cloud".

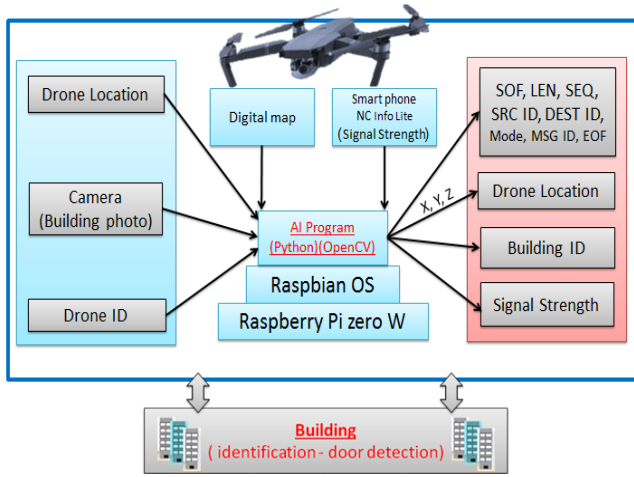

Fig. 8. Implemented Building Identification System.

Algorithm 1: The algorithm for Building Identification System to detect building entrance

Input:
 digital map sent to drone
 Declaration the parameters of header, SOF, LEN, SEQ, SRC ID, MSG ID, Mode, DEST ID, and EOF
 Declaration the parameters of payload (location x y z, building ID, Signal Strength).
 Declaration the parameters of checksum.

Output:
 SOF, LEN, SEQ, SRC ID, MSG ID, Mode, DEST ID, EOF, (location x y z, building ID, Signal Strength) and checksum
 Publish the data on MQTT Cloud

- 1: generate SOF, LEN, SEQ.
- 2: generate SRC ID
- 3: generate, MSG ID
- 4: generate Mode
- 5: generate DEST ID
- 6: generate Checksum
- 7: generate EOF
- 8: read drone location
- 9: building identification
- 10: read Signal Strength
- 11: return SOF, LEN, SEQ, SRC ID, MSG ID, Mode, DEST ID, EOF, (location x y z, building ID, Signal Strength) and checksum

B. Proposed Directing Antenna System (DAS)

Fig. 9 shows Directing Antenna System. Which setuped on "Raspberry Pi" on the base station to control the antennas, the Raspberry Pi will be run by Raspbian OS, Install (DAS) using Python to control antenna.

First, (DAS) will subscribe the Frame information, payload, and checksum value from "MQTT Cloud" that has sent from (BIS) setuped on Drones, then generate checksum value and match the checksum value received from drones with the checksum value generated. If they matched, the corresponding IDs will be extracted. And if not, the process will be repeated again (subscribe the Frame information, payload, and

checksum value from MQTT Cloud). Then generate servo motors degrees (Pan1, Tilt1, Pan2, Tilt2, Pan3, Tilt3) based on the measures of the signal strength to be sent to servo motors.

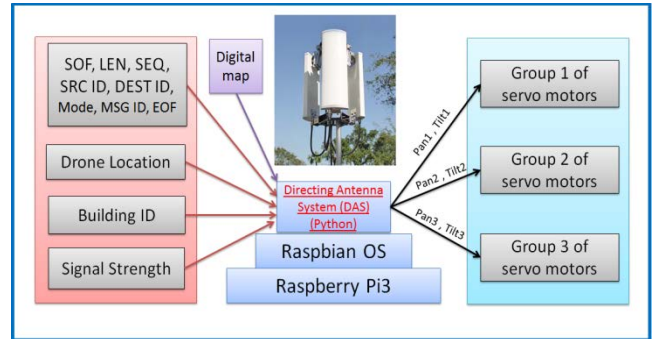

Fig. 9. (DAS) to Control Antenna.

Algorithm 2: The algorithm for (DAS) to controlling antenna

Input:

The parameter of header, SOF, LEN, SEQ, SRC ID, MSG ID, Mode, DEST ID, and EOF.
 The parameter of payload, (location x y z, building ID, Signal Strength).
 The parameter of checksum.

Output:

Write servo motors degree Pan1, Tilt1, Pan2, Tilt2, Pan3, Tilt.

Publish the data on MQTT Cloud.

- 1: subscribe the data from MQTT Cloud
- 2: generate checksum
- 3: **if** Destination checksum is correct **then**
- 4: Extract the corresponding IDs
- 5: **else**
- 6: **Goto** step 1
- 7: **end if**
- 8: **if** the Destination ID == ID **then**
- 9: **Goto** Step 13
- 10: **else**
- 11: **Goto** step 1
- 12: **end if**
- 13: generate servo motors degree Pan1, Tilt1, Pan2, Tilt2, Pan3, Tilt3
- 14: **return** Pan1, Tilt1, Pan2, Tilt2, Pan3, Tilt3.

VIII. SIMULATION RESULTS AND PERFORMANCE ANALYSIS

• Simulation tools

The simulation experiment is to verify the feasibility and performance of the communication protocol and the system. In order to validate our work, OMNeT++ (Objective Modular Network Testbed in C++) framework will be used. OMNET++ is an open source discrete event simulator with modular, component-based C++ simulation library and framework. [29]

The implementation leverages a series of shared libraries over INET, an OMNeT++ model suite for the simulation of wired, wireless and mobile networking protocols. [30].

• Simulation scenario and results

Three Drones are used and there is a cooperation network between them. And through the 2 antennas, the signals will be sent between Drones and the server. Drones measure the signal strength within all the buildings areas and send it to the server

to direct the antennas to the optimal direction. Then measuring the network throughput.

The video in this link shows our simulation scenario

https://drive.google.com/file/d/1KLneJvXlqTj2ZZzqFvQWzEzY_o u06y4Bh/view?usp=sharing

Bandwidth is measured for nine different bandwidth throttles within the speed range of [1 - 16] Mbps downlink and [1- 5] Mbps uplink, and data size 0.11138916 Mbits.

The Data Size is calculated as the following equation where The Data Size (in Mbits) equals the size of the frame (in byte) multiplied by 8 bits to convert it to bits, then multiply size of the frame (in bits) by the number of reading, And then divide by 1024/1024 to convert to Mbits, after that the result will be multiplied by the number of Buildings.

Data Size (Mbits) = (((Size of frame (Byte) * 8 bits * reading) / KB / MB) * for one Building)

$((73 * 8 * 200) / 1024 / 1024) * 1 = 0.11138916$ Mbits

Time_Downlink Throughputs = Data size (Megabits) / Downlink (Mbps) = (s)

Time_uplink Throughputs = Data size (Megabits) / uplink (Mbps) = (s)

Network throughput is one of the key network performance metrics for QoS among end-users. However, demonstrating reliability and validity of network throughput measurement deployed in vendor end-point is a critical task [31].

As shown in Fig. 10, the results of uplink and Downlink speed measurements. Each striped Brick color bar represents the measured uplink speed that is starting to rise from 1 to 5 Mbps. Similarly, each blue bar represents downlink throughput measurements. The speed is constantly increasing as the Bandwidth increases. that is starting to rise from 1 to 16 Mbps.

Fig. 10. Measured Downlink /uplink Throughputs for 9 Cases.

Fig. 11. Time_Downlink Throughputs.

Throughputs_Downlink

As shown in Fig. 11 the Downlink Time within the time range of [0.000 - 0.120] (S) for receiving the amount of data "0.11138916 Mbits" of measuring the signal strength for one building in nine different bandwidth throttles within the speed range of [1 - 16] Mbps. In order to better demonstrate accuracy of the results, will depicting overlay line diagrams for Downlink Time of 9 Cases results.

The figure also illustrates the results of Downlink time and different values for Downlink speed measurements that start to rise from 1 to 16 Mbps. Each blue dot represents the measured downlink speed for the nine cases. The speed is constantly increasing as the Bandwidth increases, On the contrary, the Downlink time decreases as the Bandwidth increases. As shown in the previous example when the data size equal 0.11138916 Mb and speed is 1 Mbps, time becomes 0.111389160 S while the speed increased to 16 Mbps, time decreased to 0.006961823 S.

Throughputs_Uplink

As shown in Fig. 12, the Uplink Time within the time range of [0.000 - 0.120] (S) for sending the amount of data "0.11138916 Mbits" of measuring the signal strength for one building in nine different bandwidth throttles within the speed range of [1.0 – 5.0] Mbps. In order to better demonstrate accuracy of the results, will depicting overlay line diagrams for Uplink Time of 9 Cases results.

Fig. 12. Time_uplink Throughputs.

The figure also illustrates the results of Uplink time and different values for Uplink speed measurements that start to rise from 1 to 16 Mbps. Each red dot represents the measured uplink speed for the nine cases. The speed is constantly increases as the Bandwidth increases, On the contrary, the Downlink time decreases as the Bandwidth increases. As shown in the previous example when the data size equal 0.11138916 Mb and the speed is 1 Mbps, time becomes 0.111389160 S but when the speed increased to 5 Mbps, time decreased to 0.022277832 S.

As shown in these figures, the results are significantly correlated with each other and can support each other which advocate validity of the performance evaluations.

IX. HARDWARE IMPLEMENTATION

In order to position the antennas, "I²C Servo Driver" will be used (using I²C protocol) connected to "Raspberry pi" (which used as a server) to control all groups of servo motors which are responsible for fully control and direct the antennas. There is three groups of "Servo motors". Every group consists of two "Servo motors" to control the antennas with PAN/TILT mechanism. "Raspberry bi" will give orders to the groups of "Servo Motors" to direct the antennas till it reaches the optimal direction.

Raspberry Pi as a Server. The I2C will be used as a communication protocol between the Server and the servo motors, and Three Groups of servo motors to controlling in three antennas, each group consist of two servo motor (Pan , Tilt).

- The prototype to control antenna

There are three groups of "Servo motors". Every group consists of 2 "Servo motors" to control the antennas with PAN/TILT mechanism. "Raspberry bi" will give orders to the groups of "Servo Motors" to direct the antennas till it reaches the optimal direction.

The video in this link shows our prototype for part of Hardware Implementation

TABLE III. PROPOSED MODEL AGAINST TRADITIONAL WORK

		The proposed work	Traditional way
1	Time	Hours	Weeks
2	Accuracy	Accurate	Not accurate
3	Human Power	No persons	Lot of persons
4	Cost	Low cost	High cost

As a result all the disadvantages that mentioned before, As shown in Table III, will be avoided and we will no longer face any high in the cost caused by repeating the process in the traditional way.

XI. CONCLUSION AND FUTURE WORK

In this paper, a comprehensive solution was proposed by designing a standard communication protocol to support the cooperative networks between drones to be used in different fields & applications. The system is for controlling the antenna direction of mobile communication using drones to resolve the problem as the 5G mobile users on higher floors of high buildings suffer from the weak signals. The proposed model included new communication protocol, cooperative network between drones, Building Identification System (BIS) to detect building entrance based on CNN, Directing Antenna System (DAS) to control antenna and hardware controlling antenna. the "Python Programming language" is used for Programming the (BIS and DAS), and " Raspberry Pi" platform to implement the system, and "Raspbian" operating system for " Raspberry Pi" and OpenCV, CNN algorithm for the Building Identification and give the OpenCV sample of Buildings photos as a training sample. MQTT Cloud used to transfer data between drones and server, "OMNeT++" for making the simulation, and the performance of the new Communication Protocol and Network throughput will be measured. At the end we will no longer face the disadvantages like the high cost, the high consumption of time and the lack of accuracy.

Build more cooperative Network to use Applications Between Drones, and Secure the New Proposed Communication Protocol of Drones Cooperative Network.

Real Time Face Expression Recognition along with Balanced FER2013 Dataset using CycleGAN

Fatma Mazen Ali Mazen^{1*}, Ahmed Aly Nashat², Rania Ahmed Abdel Azeem Abul Seoud³

Electronics and Communication Engineering Department
Faculty of Engineering, Fayoum University
Fayoum 63514, Egypt

Abstract—Human face expression recognition is an active research area that has massive applications in medical field, crime investigation, marketing, online learning, automobile safety and video games. The first part of this research defines a deep neural network model-based framework for recognizing the seven main types of facial expression, which are found in all cultures. The proposed methodology involves four stages: (a) pre-processing the FER2013 dataset through relabeling to avoid misleading results and getting rid of non-face and non-frontal faces; (b) design of an efficient stable Cycle Generative Adversarial Network (CycleGAN), which provides unsupervised expression-to-expression translation. The CycleGAN has been designed and trained with a new cycle consistency loss. (c) Generating new images to overcome the class imbalance and finally (d) building the DNN architecture for recognizing the face sign expression, using the pretrained VGG-Face model with vggface weights. The second part encompasses the design of a GPU-accelerated face expression recognition system for real time video sequences using NVIDIA's Compute Unified Device Architecture (CUDA). OpenCV library has been compiled from scratch with CUDA and NVIDIA CUDA Deep Neural Network library, cuDNN. For face detection stage Haar Cascaded and deep learning were used and tested using both CPU and GPU as backend. Results show that the designed model run time to recognize a face sign is 0.44 seconds. Besides, the average test accuracy has been increased from 64% for the original FER2013 dataset to 91.76% for the modified balanced version using the same transfer learning model.

Keywords—Facial expressions detection and recognition; multi-task cascaded convolutional networks; transfer learning; residual neural network; CycleGAN; FER2013; GPU and CUDA; HAAR

I. INTRODUCTION

Face sign expressions are one of the most active research areas in computer vision since they are a form of nonverbal communication for people in the deaf community. It is, also, used for understanding human behavior, mental disorder detection, cognition of human emotions, and lie detection. They convey non-verbal cues, which play an important role in interpersonal relations. Automatic recognition of facial expressions can be a vital component of natural human-machine interfaces; it may also be used in different areas such as artificial intelligence, computer vision, psychology, physiology, behavioral science and in clinical practice. Some robots can also benefit from the ability to recognize expressions [1]. Automated analysis of facial expressions for behavioral science or medicine is another possible application

domain. It can be used to detect the state of the learner in E-learning, help doctors to understand and analyze the behavior of children with Autism Spectrum Disorder (ASD) who are known to have difficulty in producing and perceiving emotional facial expression [2]. The system of facial expression recognition is divided into three steps: optimal preprocessing, feature extraction or selection, and classification, particularly under conditions of input data variability to attain successful recognition performance.

Dataset preprocessing is an elementary step in machine learning systems especially when the dataset contains wrongly labeled images due to source crowding and suffers from class imbalance, which leads to biased learning toward majority classes. In this paper, an innovative strategy has been adopted to overcome this shortage. CycleGAN is a promising data augmentation scheme recently adopted to solve the class imbalance problem by generating new samples of the minority class. An efficient stable CycleGAN has been designed and trained to perform style transfer from a reference domain, which is the neutral class, to a target domain, which could be any of the other face expression classes. After creating a clean balanced dataset, the transfer learning approach has been adopted for model design. Designing a model from scratch is a time-consuming process and will never outperform efficiently, since the pretrained models have been trained on datasets containing millions of images which is a huge number compared to our dataset.

Many machine learning algorithms have been proposed for successful recognition performance, but they have not reached the optimal performance due to lack of the optimal set of features required for classification. Feature extraction is the process of using domain knowledge of the data to create features that make machine learning algorithms work. Coming up with features is difficult, time-consuming, requires expert knowledge. Deep learning aims at learning feature hierarchies where features from higher levels of the hierarchy are formed by lower-level features, so it eliminates the need to feature extraction and as a result achieving better performance in less time than traditional machine learning algorithms. Convolutional Neural Networks, CNN, are currently one of the most prominent algorithms for deep learning with image data. Whereas for traditional machine learning relevant features must be extracted manually. In computer vision machines, storing the knowledge learned by solving one problem and applying it to another similar problem is challenging. The cross-domain transfer learning models have received enormous

* Corresponding Author

attention in face expression classification and generally artificial intelligence applications, where the training and test data are drawn from different feature space and different distribution. The knowledge learned from the learning dataset can help improve prediction accuracy in the testing domain, especially when the testing data are target scant. Also, knowledge from a labeled domain can help generate labels for an unlabeled domain, which may avoid a costly human labeling process.

In recent years, massive computer visions algorithms and techniques have been developed and employed for designing real time face expression recognition system due to its significance not only in human-to-human interaction but also in Human Machine Interaction (HMI). HMI is an extruded field in computer science that aims at making the computer intelligent such that it interacts with human the way human and human interact. This task can be decomposed into two stages, face detection for face localization and face expression classification. Recently, two main approaches have been adopted for face detection, the traditional machine learning approach, and the deep learning approach.

In this paper, a new framework for real time face expression recognition in video sequences has been designed and tested. It comprises two phases. For face detection phase, two versions of OpenCV library have been employed. The first version is standard OpenCV library that was used for machine learning approach. With the rapid development of GPU, deep learning became more powerful in classification tasks. The second version is compiled from scratch with CUDA and cuDNN support to achieve optimal hardware resources employment through interaction between our Graphical Processing Unit (GPU) and deep learning module of OpenCV which undoubtedly has a great effect in improving the speed of video by increasing number of frames that can be processed per second (FPS) making our system more convenient for real time applications.

The rest of the paper is organized as follows: Section 2 discusses the work related to the face expression classification problem. Section 3 illustrates the dataset and the proposed methodology for the facial expression recognition. Experimental results and discussion are presented in Section 4. Finally, Section 5 concludes the paper and outlines directions for future work.

II. RELATED WORK

In the last decade, face expression recognition has become a hot research area. Several papers have been published using classical machine learning approaches like Support Vector Machine (SVM) and Random Forest, whereas others use modern schemes like deep learning, convolutional neural networks (CNNs), transfer learning and ensemble models.

Ying Zilu and G. Zhang [3] adopted a framework for facial expression recognition based on the combination of non-negative matrix factorization (NMF) and support vector machine (SVM). They achieved a recognition rate of 66.19% with their algorithm applied to Japanese female facial expression database (JAFEE database). In [4], face expression recognition system was designed by Y. Luo, C. M. Wu and Y.

Zhang based on a hybrid scheme of principal component analysis (PCA) and local binary pattern (LBP) for feature extraction and support vector machine (SVM) for facial expression classification. They achieved a recognition rate of 93.75% using a small dataset of 350 face sign images. C. Shan, S. Gong and P. W. McOwan [5] proposed a novel scheme based on local binary pattern (LBP) for facial expression recognition. The Cohn-Kanade Database was used to demonstrate the efficiency of their proposed approach. Their model attains a recognition rate of 79.1%. In [6], Ahmed A. Nashat proposed a new approach for extracting features for facial expression classification. Firstly, the discrete wavelet packet best tree (DWPBT) decomposition is used to remove the spatial and spectral redundancies for each block of the desired face regions. Then, the radial difference LGP (RD-LGP) in radial directions of a circular grid is used as a descriptor for facial expression recognition. The average recognition rate was 83.4%.

Y. Wang, Y. Li, Y. Song and X. Rong [7] have proposed an effective hybrid approach of random forest and convolutional neural networks. Their approach achieved an accuracy of 98.9% on JAFFE dataset, 99.9% on CK+ dataset, 84.3% on FER2013 dataset and 92.3% on RAF-DB dataset. E. Barsoum, C. Zhang, C. C. Ferrer and Z. Zhang [8] worked on using a deep CNN on noisy labels acquired via crowdsourcing for ground truth images. They used 10 taggers to relabel each image in the dataset, and used various cost functions for their DCNN, achieving decent accuracy. They reached accuracy of 84.986% on FER+ dataset. C. Pramerdorfer and M. Kampel [9] formed an ensemble of recent deep convolutional neural networks. They investigated the approaches adopted by six current state-of-the-art papers and ensembles their networks to reach 75.2% test accuracy on FER2013 outperforming previous works without needing auxiliary training data.

In [10], X. Wang, J. Huang, J. Zhu, M. Yang and F. Yang have utilized transfer learning using Keras VGG-Face library and each of ResNet50, SeNet50 and VGG16 as pre-trained models. They managed to achieve test accuracy of 75.8% which surpassed all existing publications at this time. A. Chen, H. Xing, and F. Wang [11] proposed an efficient and secure facial expression recognition method based on the edge cloud framework combined with the improved CycleGAN to solve class imbalance of FER2013 dataset by generation 4000 new sample for disgust class and 800 new samples for surprised class achieving higher recognition rate not only on the data augmented classes but also on the other classes. They achieved average recognition rate of 78.61% on the enhanced dataset. Z. Zhang, P. Luo, C. C. Loy, and X. Tang [12] also achieved 75.1% test accuracy by adding auxiliary data and additional features: a vector of HoG features was computed from face patches and processed by the first FC layer of the CNN. Facial landmark registration has been also employed.

In this work, a neoteric relabeled balanced FER2013 dataset has been introduced. A balanced CycleGAN has been designed and trained using new cycle consistency loss to preserve luminance conditions of reference class to overcome class imbalance problem through generating new images for minority class (Disgust). State of the art results have been achieved through dataset cleaning and pre-processing. A new

deep neural network architecture for recognizing the face sign expression, using the pretrained VGG-Face model with vggface weights and the modified balanced version of the FER2013 dataset is designed and implemented. To enhance our work, A GPU-accelerated system for face expression recognition in real time video stream is introduced achieving 312.01% faster inference for feature-based approach and inference speed improvement by up to 169.74% for deep learning-based approach.

III. METHODOLOGY

A. The Dataset

The proposed methodology was trained and tested using the open-source FER2013 dataset [13-14], which is created for an ongoing project by Pierre-Luc Carrier and Aaron Courville from university of Montreal, then shared publicly for a Kaggle competition, shortly before ICML 2013. The dataset consists of 35.887 labelled 48x48 grayscale human facial expressions. These are afraid (11.42%), angry (11.13%), disgusted (1.21%), happy (20.1%), neutral (13.84%), sad (13.46%) and surprised (8.84%). To train and test the performance of the proposed classification model, we selected 80% of the set for training and the rest for testing. Fig. 1 shows some sample images from the FER2013 dataset.

Fig. 1. Sample Images from the FER2013 Dataset.

B. Data Set Preprocessing Phase

Crowdsourcing has become a widely used approach to gather ground truth labels to form a dataset. However, these labels can be very noisy which causes model misleading and as a result low recognition rate [8]. FER2013 suffers from severe crowdsourcing as it contains non-face images, text images, sleepy faces, profile images which are indistinguishable by humans, and large number of wrongly labelled images. According to [15], the overall accuracy of the facial expression classification using this dataset does not exceed 65%. In this research, three steps have been taken to resolve this problem. First, we deleted non-face images, text images and profile images. Second, we re-labelled wrongly labelled images based on class distribution using convolutional neural networks (CNN). Finally, the class imbalance problem has been solved by designing a CycleGAN used for generating new face expressions for the minority classes. CycleGAN phase will be discussed in detail in the next section. Fig. 2 displays some bad images, which have been deleted.

As shown in Fig. 3, a few examples of wrongly labelled misleading images due to crowd sourcing are displayed with the wrong expression in the red color and the right expression in the blue color.

Fig. 2. Samples of Bad Images that have been deleted from the Dataset.

Fig. 3. Samples of Mislabelled Images.

Besides crowd resourcing, the dataset suffers from class imbalance problem which results in model biasing. As shown in Fig. 4, class1 contains only 436 images which are too low compared to other classes which contain thousands of images. The class imbalance problem has been solved by designing a CycleGAN used for generating new samples for the minority class. CycleGAN phase will be discussed in detail in the next section.

Fig. 4. A Severe Class Imbalance with the Highest Number of Images at Class 3 and the Lowest at Class 1.

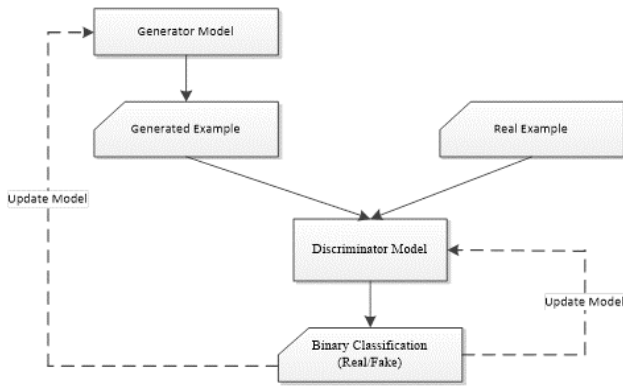

Fig. 5. Flowchart of the Generative Adversarial Network Model Architecture.

C. CycleGAN Phase

It is a challenging task to classify images with multiple class labels using only a small number of labelled examples, especially when the label (class) distribution is imbalanced. Generative Adversarial Networks (GANs) can be used to generate images from an adversarial training. The generator attempts to produce a realistic image to fool the discriminator, which tries to distinguish whether its input image is from the training set or the generated set. The flow chart of the GAN architecture is shown in Fig. 5. J. Y. Zhu, T. Park, P. Isola, and A. Efros [16] proposed the CycleGAN model, which can do image-to-image transition between two unpaired image domains. This model has been employed to build our framework.

The architecture of the discriminator, the generator and the composite model are like those used in [17] except for employing some training tricks like using dropout layers to avoid GAN failure modes, labels flipping (True label was used for generated images while false label was used for Real images) and using Batch Normalization layers to produce sharper generated images. Unlike other GAN models for image translation, the CycleGAN does not require a dataset of paired images.

The discriminator and the composite model architecture of the CycleGAN are shown in Fig. 6 and Fig. 7, respectively.

1) *CycleGAN loss functions*: Each generator model is optimized via the combination of four outputs with four loss functions and are defined by (1), (2), (3), and (4) as follows:

- Adversarial loss (L_2 or mean squared error). It is calculated as the L_2 distance between the model output and the target values of 1.0 for real and 0.0 for fake.

$$\text{Adversarial loss} = L_2 \quad (1)$$

- Identity loss (L_1 or mean absolute error). It is calculated as the L_1 distance between the input and output image for each sequence of translations.

$$\text{Identity loss} = L_1 \quad (2)$$

- Forward cycle loss

$$\text{Forward cycle loss} = \frac{1}{3}(L_1 + L_2 + \text{SSIM loss}) \quad (3)$$

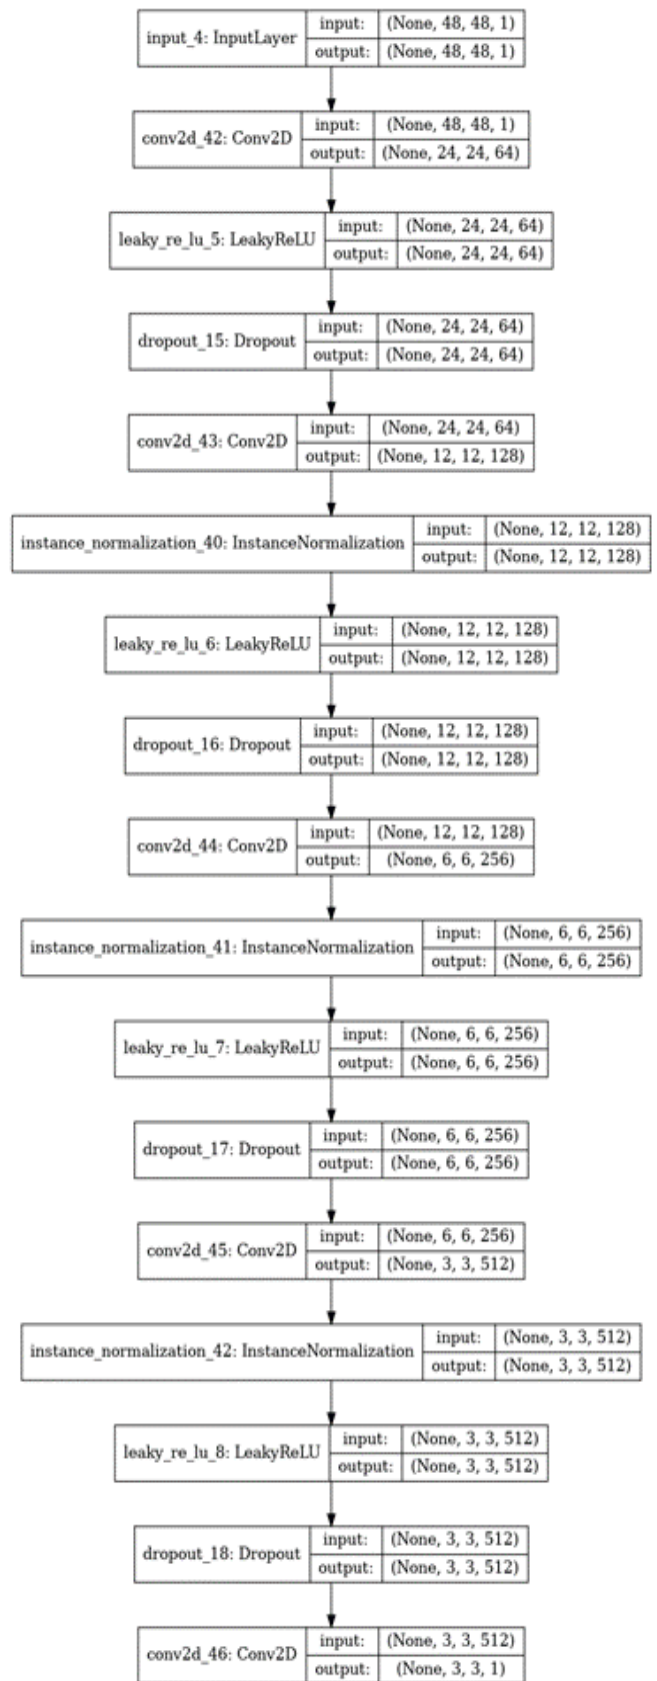

Fig. 6. The Discriminator Architecture.

Fig. 7. The Composite Model of the CycleGAN.

- Backward cycle loss

$$\text{Backward cycle loss} = \frac{1}{3}(L_1 + L_2 + \text{SSIM loss}) \quad (4)$$

In this paper, the cycle consistency loss, for a better-quality image, is defined as the average of the L_1 distance and the L_2 distance. The structural similarity index measure (SSIM) loss is defined by (5) as:

$$\text{SSIM loss} = 1 - \text{SSIM index} \quad (5)$$

Where SSIM Index is computed by considering the luminance, contrast, and structural similarity. Since the image pixels are correlated and not independent, L_2 loss is unsuitable choice to improve the quality of generated images. SSIM loss term is added to the cycle consistency loss to compensate for this disadvantage by reducing structural distortions between the input and output images. It is worthy mentioned that SSIM was designed for gray scale images.

2) *Training details:* In our design, after five trials, the forward and the backward cycle loss are given more weight than the adversarial loss whereas the identity loss weight has been set to two. In other words, λ_{cyc} is set to five and λ_{id} equals to two.

For all the experiments, the Adam optimizer has been used with a batch size of one. All networks were trained from scratch with a learning rate of 0.0002. The learning rate was kept constant for the first 100 epochs and linearly decays to zero over the next 100 epochs. Fig. 8 shows two sets of sample images of translation from class 6, (Neutral), to class 1, (Disgust).

Fig. 10 shows data distribution of the new balanced FER2013 dataset, after cleaning it from bad images and generating new images using CycleGAN for the minority class.

D. Transfer Learning Phase

In this paper, transfer learning scheme has been adopted as it has a significant role in achieving state of the art accuracy. Keras VGG-Face pre-trained model [18] has been employed with vggface weights. As this network accepts RGB images with size 224x224, the 48x48 gray scale images in FER2013 during training time have been resized and recolored using image data generator.

1) *Training details:* In our design, the top layers of the VGG-Face model, which include last fully connected layers and softmax layer have been removed and a flatten layer was added to extract the bottleneck feature vector. To reduce overfitting due to large network size, the last three fully connected (dense) layers have been replaced by only one fully connected layer with 128 neurons followed by a dropout layer with dropout rate equals to 0.3 and then a softmax layer with seven outputs has been added to match the seven output facial expressions.

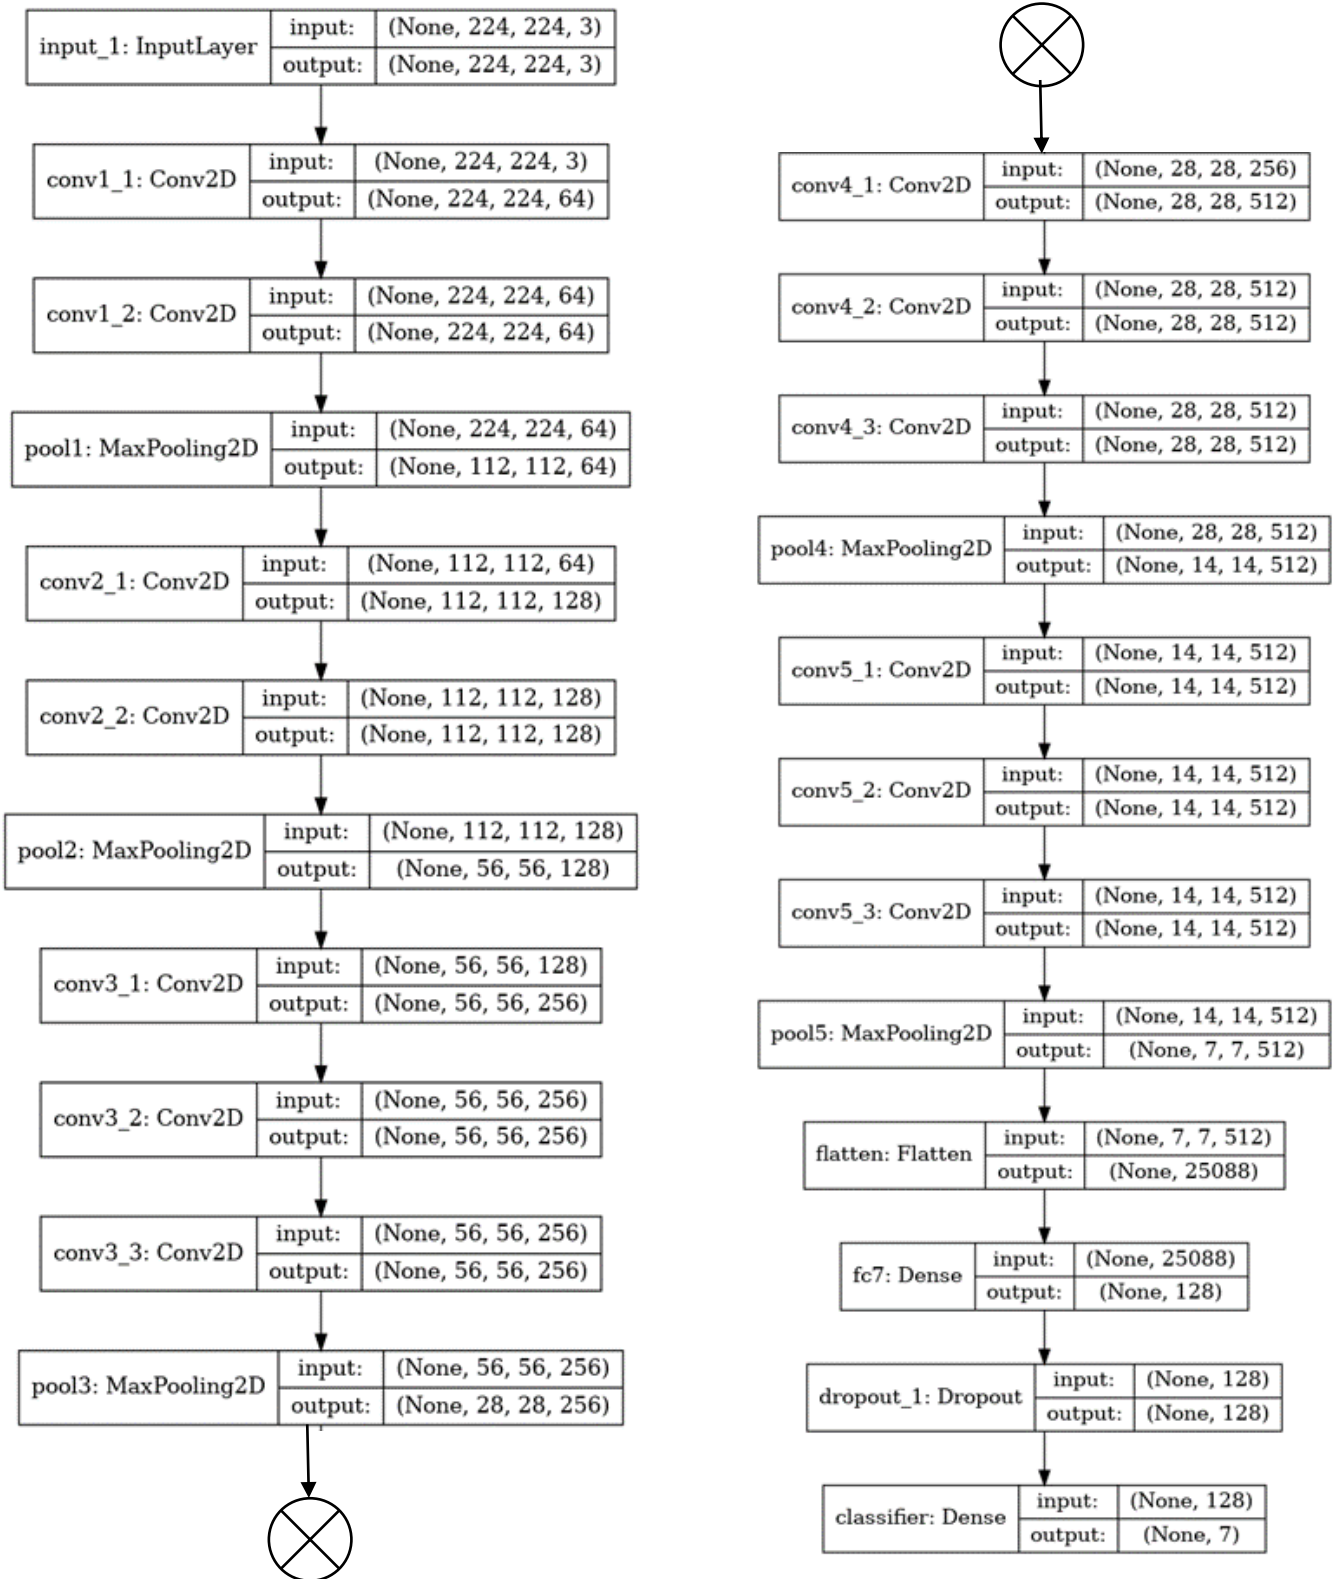

Fig. 11. The Transfer Learning Model.

During training the network, the model has been compiled using Adam optimizer with learning rate equals to 0.001 and Beta_1 equals to 0.5. The input to the network has been divided into minibatches of 128 images and the total number of epochs equals to twenty epochs. All experiments have been conducted using Keras with TensorFlow backend on Alien ware laptop with Nvidia GeForce GTX 1070 GPU. To prevent model overfitting and performance deterioration, early stopping callback function is used to halt training the model at the right time. Model Check Point callback has been used to save the model only when better results are obtained according to predefined performance measures. Reduce on Plateau callback has been used to reduce learning rate when the validation accuracy decays. The detailed description of our transfer learning model is shown in Fig. 11.

The upcoming sections discuss the procedure of designing a real time facial expression recognition system to detect face and recognize the seven standard face expressions in real time video sequences.

E. Compiling OpenCV from Source

In this stage OpenCV with CUDA and cuDNN support has been compiled from source to achieve the best optimum utilization of hardware resources (Alien ware laptop with NVidia GeForce GTX 1070 GPU). OpenCV has been compiled with eight cores which should be adjusted according to the number of processor cores you use. The block diagram of this process is shown in Fig. 12.

The CMake output for NVIDIA CUDA and cuDNN indicates that CUDA version, is 10.1 and cuDNN version is 7.6.5. Another important CMake output that should be verified before proceeding to compilation step are the proper python paths to Interpreter and Libraries.

F. Face Detection Phase

Face detection is a challenging computer vision problem which aims to identify and localize faces in images. It is a primary step for any facial expression recognition (FER) system. It can be accomplished using the classical machine learning (feature based) Haar cascaded classifier or using recent deep learning-based approaches through using the OpenCV library.

1) *Feature-based approach (Haar cascaded classifier):* OpenCV provides the cascade classifier class that can be used for face detection. The constructor can take a filename as an argument that specifies the XML file for a pre-trained model. The model can be used for face detection on an image or video by calling the detectMultiScale function whose output is a list of bounding boxes for all faces detected. ScaleFactor and minNeighbors are two parameters that should be carefully tuned for a given dataset as the ScaleFactor controls how the input image is scaled before detection.

2) *Deep learning-based approach:* After building OpenCV from source with CUDA and cuDNN support, now its Deep Neural Network (DNN) module can be used. It contains a CNN-based face detector which enhances the face detection performance compared to machine learning-based

models like Haar Cascade classifier. It utilizes the Single Shot Detector (SSD) framework with ResNet as the base network. The confidence level is extracted after looping over the detections to suppress weak detections if they do not meet the minimum confidence level. In our experiment, the minimum confidence level was set to 0.5.

G. Face Expression Recognition Phase

In this phase, the system classifies each frame of the video into one of the seven universal expressions - Anger, Disgust, Fear, Happiness, Sadness, Surprise and Neutral as labelled in the FER2013 dataset. The flowchart of the proposed deep learning framework and machine learning framework are shown in Fig. 13 and Fig. 14, respectively.

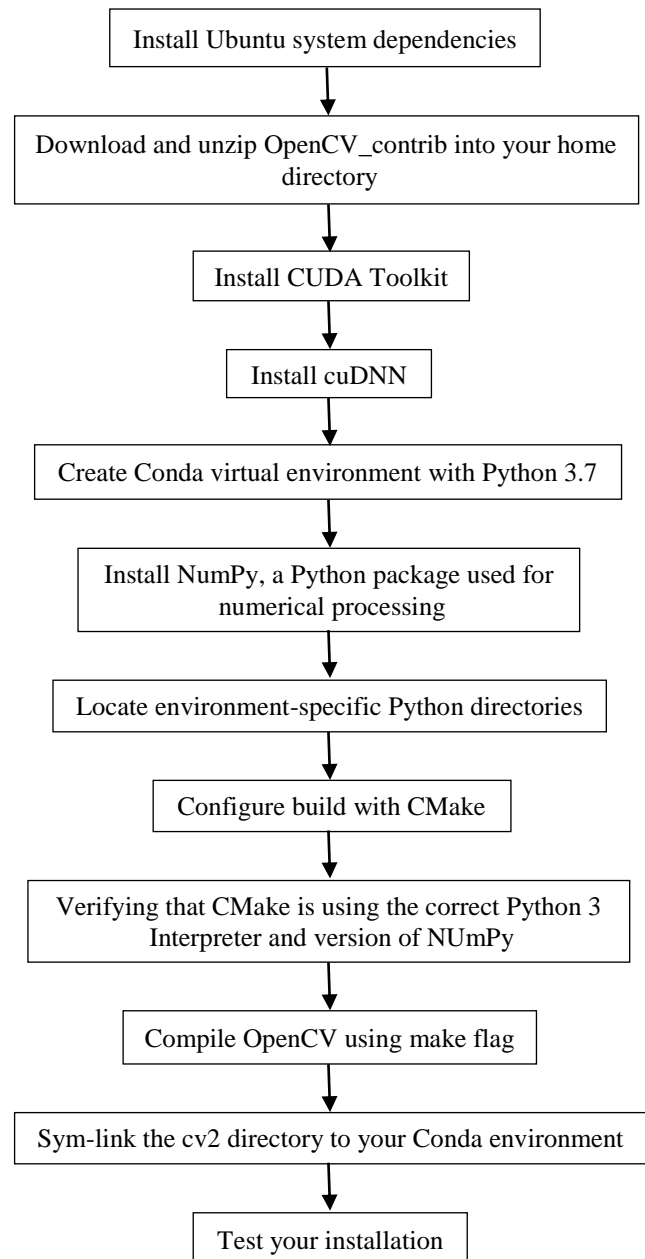

Fig. 12. The Block Diagram of OpenCV Compilation Process.

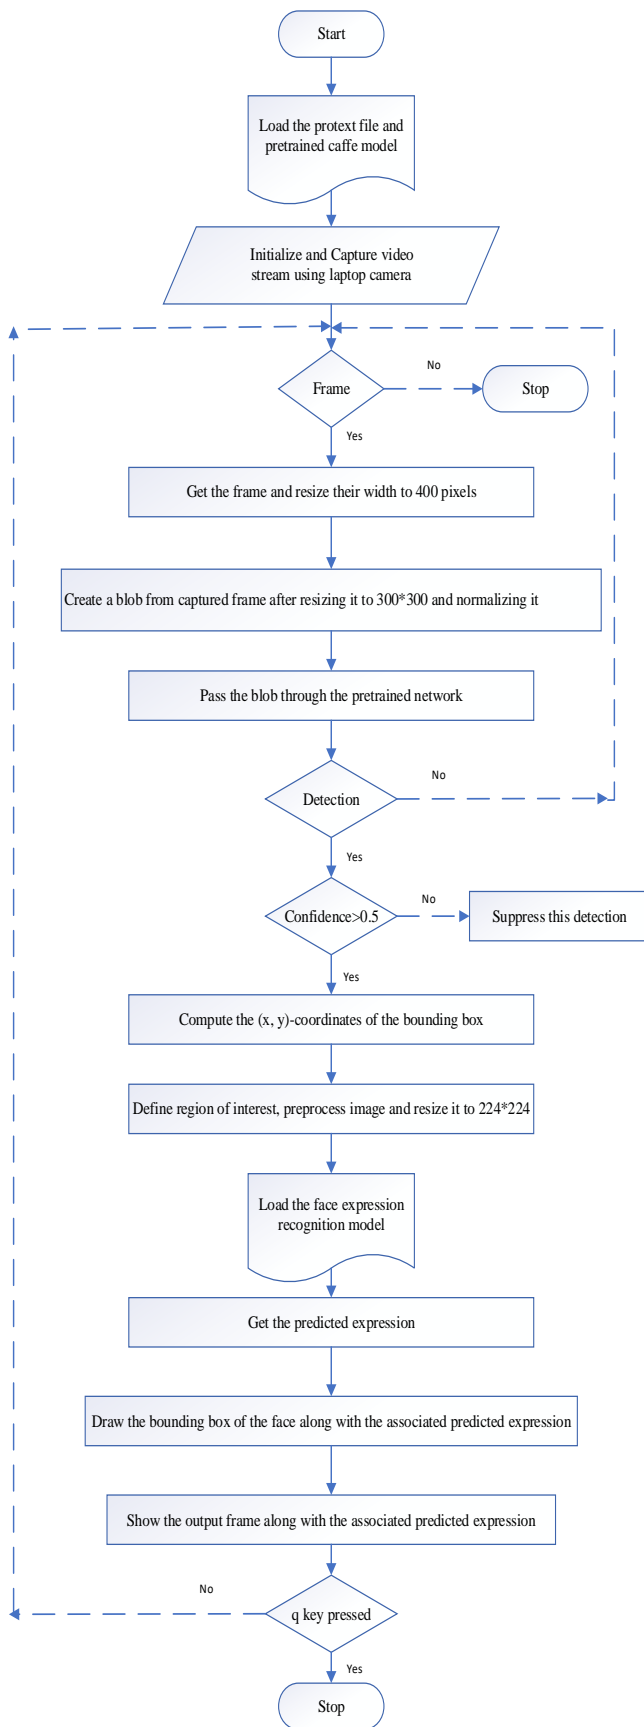

Fig. 13. Flowchart of Deep Learning-based Approach.

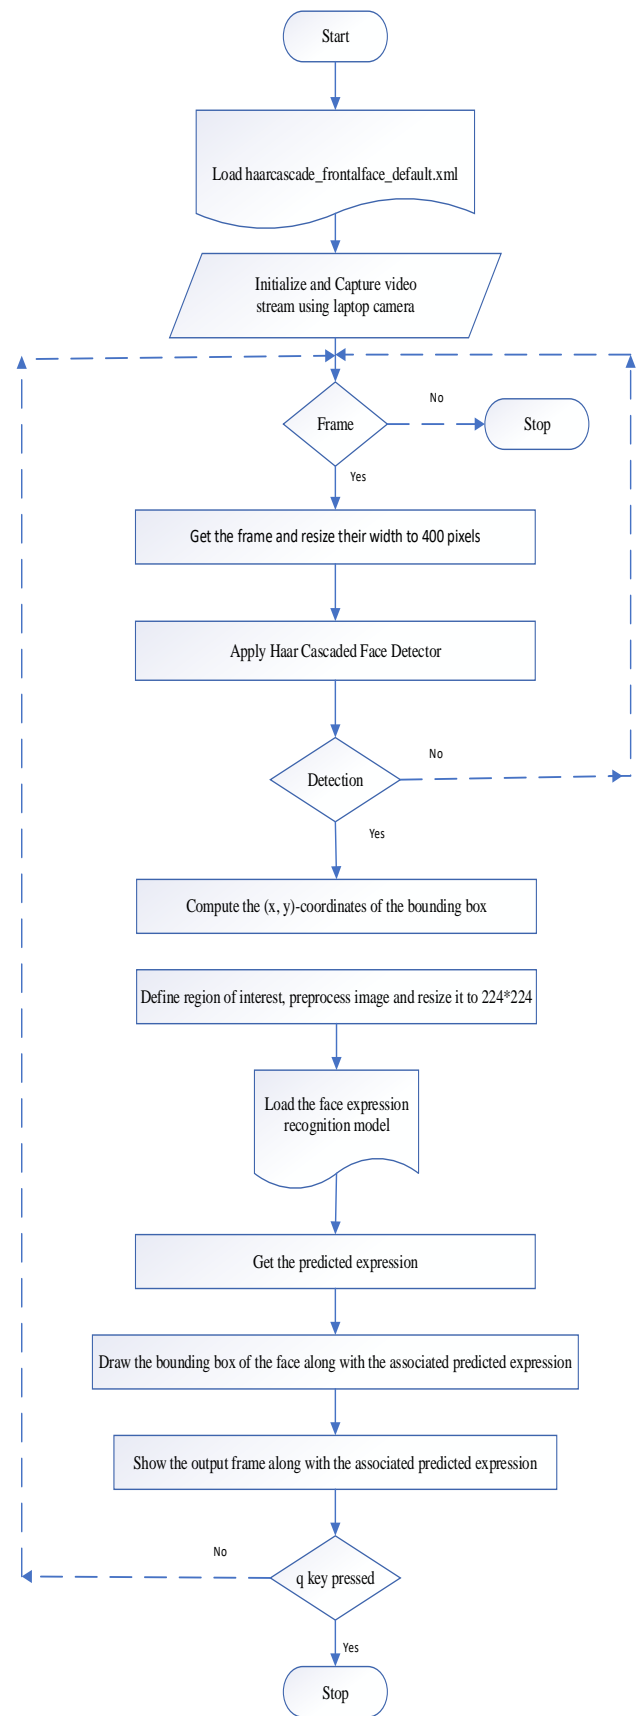

Fig. 14. Flowchart of Machine Learning (Haar Cascaded) based Approach.

IV. RESULTS AND DISCUSSION

The designed FER transfer learning model has been tested on both the original FER2013 dataset and the modified balanced version of FER2013 dataset. Fig. 15 and Fig. 16 show the robustness of the model and the effectiveness of the modified balanced dataset. It is seen that the test loss approaches zero and the overall test accuracy reaches 91.76%, which is a state-of-the-art result, for our model using the modified balanced FER2013 dataset. However, the test loss increases, and the average overall test accuracy drops to 64% for our model using the traditional FER2013 dataset despite using dropout layer and a dense layer with small number of neurons to prevent model overfitting.

Results show that our approach starting from dataset cleaning, re-labelling, and solving class imbalance problem by generating new samples of the minority class using CycleGAN is a promising scheme.

Fig. 17 shows the normalized confusion matrix for our model using the original FER2013 dataset and the modified balanced version of FER2013 dataset. It is seen that the class recognition rate has improved remarkably using the modified balanced FER2013 dataset. The recognition rate is higher by 35% for the angry class, 71% for the disgust class, 50% for the fear class, 14% for the happy class, 34% for the sad class, 21% for the surprised class, and 29% for the neutral class.

TABLE I COMPARISON OF THE STATE OF THE ART ACCURICES ON FER-2013 DATASET

Methodology	Test Accuracy
Zhang et al [12]	75.1%
Christopher Pramerdorfer et al [9]	75.2%
Amil Khanzada et al [10]	75.8%
An Chen et al [11]	78.61%
Barsoum et al [8]	84.986%
Our approach	91.76%

Table I summarizes the top test accuracies of recent approaches applied to FER-2013 dataset, where our approach achieves state of the art results.

To test our model in real time, Multi-task Cascaded Convolutional Networks (MTCNN) [19] has been used to detect the face prior to recognizing the type of the expression. Fig. 18 shows results.

In this stage, the compiled OpenCV DNN module is ready to be used. Four experiments have been conducted using Keras with TensorFlow backend on Alien ware laptop with NVidia GeForce GTX 1070 GPU. The first and third experiments used CPU as backend. On the other hand, the second and fourth experiments utilized GPU as backend.

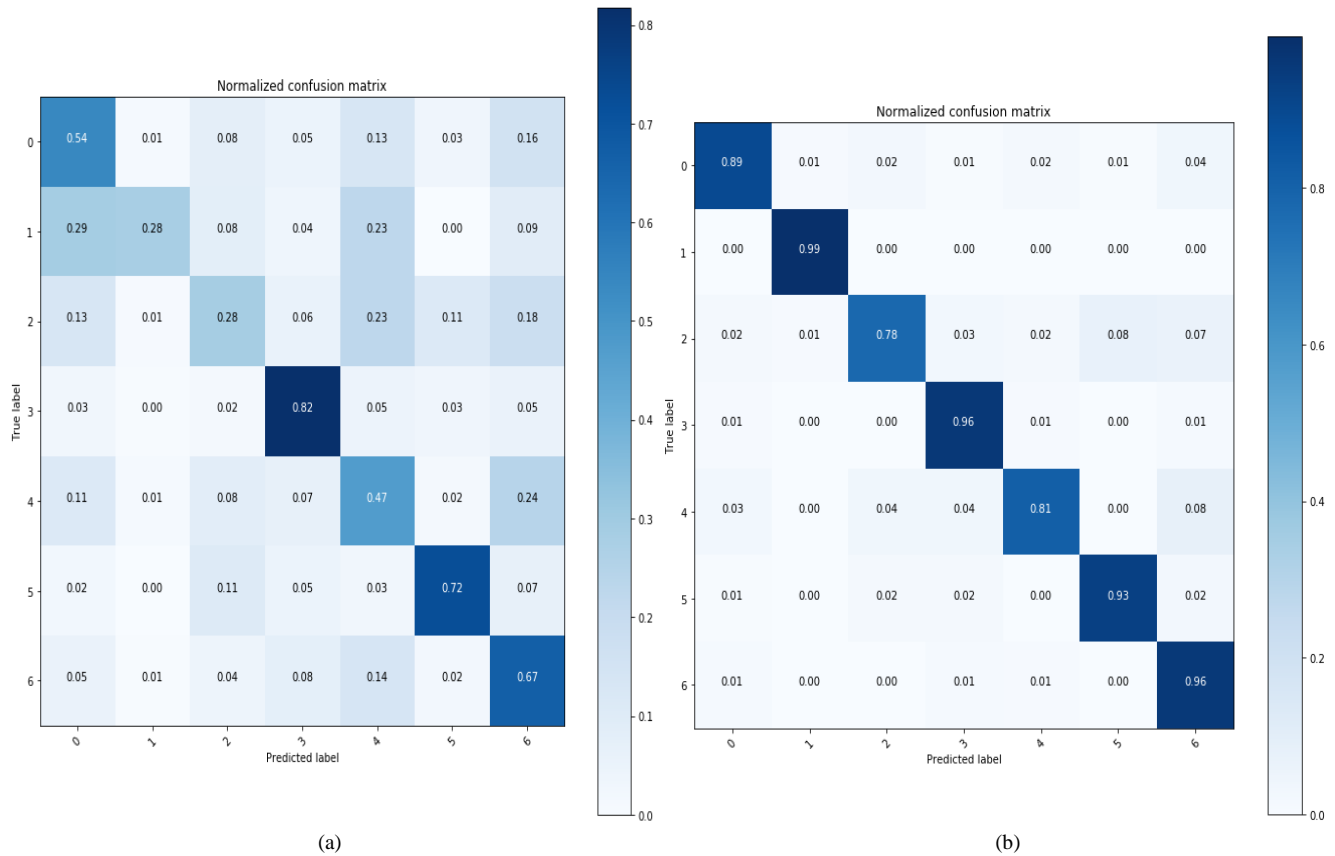

Fig. 17. The Confusion Matrix. (a) Original FER2013 Dataset and (b) Modified Balanced FER2013 Dataset.

Fig. 18. Real Time Face Expression Recognition for different Subjects Showing the Seven Principal Expressions.

TABLE II FRAME PER SECOND OF THE PROPOSED METHODOLOGIES USING CPU/GPU BACKEND

The Proposed Methodology	Face Detection	FPS
1	Haar cascade classifier	7.41
2	Haar cascade classifier	23.12
3	deep learning-based approach	30.30
4	deep learning-based approach	51.43

As shown in Table II, machine learning-based methodology which used Haar cascaded classifier in face detection phase has been tested on CPU and GPU and the frame per second (FPS) has been compared. Using NVIDIA GPU has improved inference speed by up to 312.01%.

Deep learning-based methodology which used deep learning in face detection phase has also been tested on CPU and GPU and FPS has been compared. FPS throughput rate is improved by over 169.74% with OpenCV's DNN module and an NVIDIA GPU.

Fig. 19 displays the output of FER system for real time video sequence using deep learning and Haar cascaded classifier in face detection phase, respectively.

V. CONCLUSION AND FUTURE WORK

A deep neural network model based upon VGG-Face pre-trained framework for face expression recognition has been implemented. An efficient stable Cycle Generative Adversarial Network, (CycleGAN), is designed and used to produce a balance relabeled FER2013 dataset. The designed model produced an optimal performance and a state-of-the-art overall recognition rate of 91.76% in only 0.44 second using Alien ware laptop with Nvidia GeForce GTX 1070 GPU. A GPU-based framework has been designed for face expression recognition in real time video stream. OpenCV library has been compiled from source to achieve the best exploitation of hardware resources (GPU). The framework involves two main stages, face detection and face expression recognition. The face detection phase has been realized through machine learning-based approach (Haar cascaded classifier) and deep learning-based approach. Face expression recognition has been accomplished using transfer learning approach. Both Methodologies have been tested with CPU and GPU as backend. The performance is evaluated through FPS of the whole process. Deep learning has been assessed to be faster and more accurate.

Future directions will focus on applying the model for real time face expression recognition in video sequences or online learning platform. The simplicity, the high recognition rate and the speed of the facial expression classification model make it appropriate for implementing a productive and profitable computer vision machine.

A Deep Learning Approach Combining CNN and Bi-LSTM with SVM Classifier for Arabic Sentiment Analysis

Omar Alharbi

Computer Department
Jazan University, Jazan, Saudi Arabia

Abstract—Deep learning models have recently been proven to be successful in various natural language processing tasks, including sentiment analysis. Conventionally, a deep learning model's architecture includes a feature extraction layer followed by a fully connected layer used to train the model parameters and classification task. In this paper, we employ a deep learning model with modified architecture that combines Convolutional Neural Network (CNN) and Bidirectional Long Short-Term Memory (Bi-LSTM) for feature extraction, with Support Vector Machine (SVM) for Arabic sentiment classification. In particular, we use a linear SVM classifier that utilizes the embedded vectors obtained from CNN and Bi-LSTM for polarity classification of Arabic reviews. The proposed method was tested on three publicly available datasets. The results show that the method achieved superior performance than the two baseline algorithms of CNN and SVM in all datasets.

Keywords—Sentiment analysis; Arabic sentiment analysis; deep learning approach; convolutional neural network CNN; bidirectional long short-term memory Bi-LSTM; support vector machine; SVM

I. INTRODUCTION

Sentiment analysis (SA) is one of the most active research areas in natural language processing (NLP). The SA task aims to equip a machine with the ability to categorize people opinions into positive or negative based on the sentiment expressed in the texts. SA is technically a challenging task, as human language is complex and diverse. Nevertheless, research on SA has achieved considerable progress, especially for the English language, while Arabic SA is developing slowly despite increasing Arabic language usage on the Internet [1]. That can be attributed to the Arabic language's complex morphological nature and diverse dialects [2]. Additionally, technical issues such as scarce linguistic resources and limited linguistic tools of Arabic increased the level of complexity [3]. The Arabic language is one of the most common languages that is used by more than 400 million individuals to daily communication. Arabic is formally written in a form called Modern Standard Arabic (MSA), which is understood all over the Arabic world. Despite this fact, internet users usually tend to use dialectal words alongside MSA to write reviews, tweets, or comments. Dialectal words result from behaviors such as replacing characters and changing the pronunciation or the style of writing of nouns, verbs, and

pronouns of MSA [4]. Thus, there are no standard rules that can handle the morphological or syntactic aspects of reviews written in MSA with the presence of dialects.

One of the prominent approaches employed in SA is machine learning (ML). In this context, SA is formalized as a classification problem which is addressed by using algorithms like Naive Bayes (NB), Support Vector Machine (SVM) and Maximum Entropy (MaxEnt). In fact, ML has proved its efficiency and competence; therefore, in the past two decades, it mostly dominates the SA task. However, a fundamental problem that would decay the performance of ML is the text representation through which the features are created to be fed to the learning process. For text representation, the most used model in literature is the bag-of-words (BOW) with unigram, bigram, or part of speech (POS). By using BOW, words are often weighted by their presence (binary scheme) or frequency like in term frequency (TF) or term frequency-inverse document frequency (TF-IDF). This model is relatively straightforward and important; however, it can be problematic and may degrade ML-based sentiment classification performance when it comes to a large number of features or the need for semantic information [5-8].

Over the past decade, the deep learning approach and word vector representations have attained an increasing interest from NLP researchers as they can successfully handle the limitations of traditional ML methods at NLP tasks, including SA (Kim 2014). Deep learning is an extended approach of ML and a subset of the neural network. It has a structure composed of multiple hidden layers, which enable it to automatically discover semantic representations of texts from data without feature engineering [9]. This approach has improved the state-of-the-art in many SA tasks, including sentiment classification, opinion extraction, and fine-grained sentiment analysis [10]. Along with deep learning, word vector representations, also known as word embeddings, has emerged as a powerful features representation model for the classification task. Word embeddings is a modern approach to learn real-valued low-dimensional vector space representations for a text [11]. It aims to encode continuous semantic similarities between words based on their distributional properties in a large corpus [12]. Word embeddings are typically extracted by using neural networks as the underlying predictive model [13]. One of the most used methods for word embedding is Word2Vec that was proposed by [11]. Word2Vec produces useful word representations learned by a 2-layer neural network based on

¹ <https://en.unesco.org/commemorations/worldarabiclanguageaday>

the model that has been proposed in [14]. Word2vec is one of the key methods, which has led to the state-of-the-art results achieved by the deep learning approach on SA. Word2vec can be implemented using two main learning models; they are continuous bag-of-words (CBOW) and Skip-gram.

Researchers have proposed many variants of deep learning models to address the SA of English, which have shown promising efficacy. For instance, in [15], the authors use Recursive Neural Tensor Network (RNTN) along with word embeddings to address fine-grained sentiment classification for phrase level. In another work [16], the authors apply an ensemble model that includes Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) networks on top of pre-trained word vectors for tweets sentiment classification. The authors in [17] develop an adaptive Recursive Neural Network (RNN) that uses more than one composition functions and adaptively selects them depending on the linguistic tags and the combined vectors for tweets sentiment classification. Unlike English, there have not been many studies that address the Arabic language in SA based on a deep learning approach and word embeddings, except a few such as [18-22], which will be discussed with other studies in the following section. Accordingly, there is still room for exploring different deep learning algorithms and investigating their performance in addressing Arabic SA, especially with the challenges that the Arabic language is still imposing.

In this work, we propose a new method that combines deep learning models with SVM for improving the SA of Arabic reviews. Conventionally, a deep learning model's architecture includes features extraction layers (e.g. CNN or RNN) followed by a fully connected layer used for training the model parameters and classification task. However, in this work, we decided to modify the structure and explore the impact of this structure on sentiment classification performance. The structure is altered by replacing the fully connected network with a linear SVM classifier that trains the embedded vectors generated by the combined deep learning models. This is justified by SVM's remarkable improvement in recent research in SA, including Arabic SA, such as in [20, 23, 24]. The idea of combining the neural network and SVM was initially proposed in [25] to improve multilayer perceptron classifiers. In this respect, many researchers presented various models for different classification tasks including image classification [26, 27], visual recognition [28], intrusion detection [29], object categorization [30], speech recognition [31], and sentiment analysis [32]. Although the proposed method is inspired by these studies, it is different as we use a linear SVM as a replacement for the fully connected layer instead of replacing only the top layer's activation function (i.e. Softmax or Logistic). In particular, this research presents a combination of CNN and Bidirectional-LSTM with linear SVM to improve the sentiment classification performance on Arabic reviews at the document level. To the best of our knowledge, this is the first attempt to use such a combination for Arabic SA. In this work, we used three publically available datasets for evaluation: LABR [33], OMCCA [34], and the dataset presented in [35].

The remaining sections of this paper are organized as follows: Section 2 discusses the related work in Arabic SA. In Section 3, we present the proposed method. Section 4 describes

the experimental details used to evaluate the performance of the proposed method. In Section 5, we report and discuss the obtained results. Section 6 presents the conclusion and future work.

II. RELATED WORK

Researchers have presented several methods and models to tackle Arabic SA based on three major approaches, namely, machine learning (ML) [36, 37], semantic orientation [38, 39], and hybrid approach [40]. In this research, we focus on the studies that employ the ML approach, specifically deep learning methods, which have been increasingly utilized in the past decade. These methods have presented remarkable improvements in the SA field, especially for the English language, such as in [41-45]. On the other hand, only a few studies have attempted to utilize the deep learning approach for Arabic SA. For instance, in [46], the authors use an ensemble model of CNN and LSTM proposed by [16] to predict the sentiment of Arabic tweets for the sentence level. The model is trained on top pre-trained word vectors developed in [47]. They evaluated the model on ASTD dataset [48] and achieved an F1-score of around 64% and an accuracy of around 65%. Another work applies CNN and LSTM to sentiment analysis of Arabic tweets described in [49]. They designed a system to identify the sentiment's class and intensity as a score between 0 and 1. The authors used word and document embedding vectors to represent the tweets. They translated the tweets into English to benefit from the available preprocessing tools. As they highlighted, the step of the translation led to degrading the overall performance. Although the system includes some preprocessing steps, it excludes some other important normalizing processes such as removing diacritics, punctuations and repeating characters.

In [50], the authors investigate LSTM and Bi-LSTM models' performance on Saudi dialectical tweets. After some basic normalization processes, they use the CBOW model to represent words with vectors. As reported, Bi-LSTM outperformed LSTM and SVM with an accuracy of 94%. The study of [19] explores different deep learning models, including a combination of LSTM and CNN, to predict tweets' sentiment. They also investigate the use of CBOW and Skip-gram models of available pre-trained word vectors introduced in [51]. The experiments show that the highest results were obtained by using a two-layer LSTM model. Barhoumi et al. [52] utilized Bi-LSTM and CNN to evaluate different types of Arabic-specific embeddings. They suggested using available Arabic NLP tools to address the effect of the agglutinate and morphological rich specificity of Arabic on word embedding quality. However, these NLP tools such as lemmatization, light stemming, and stemming have been mostly developed to MSA texts.

The work in [53] reports efforts to detect the sentiment of tweets of time series data in the domains of stock exchange and sport. They use a deep neural network model with eight fully connected hidden layers in which each layer has 100 neurons. They compared the model against KNN, NB, and decision tree classifiers. Their model showed superiority with an F1-score of around 91% and accuracy of around 88%. Nevertheless, the authors did not mention the kind of feature representation used

in this work. The work in [54] explores different architectures for Arabic sentiment classification using Deep Belief Networks (DBF), Deep Auto Encoders (DAE), and Recursive Auto Encoder (RAE). The experimental results show that RAE obtained the best performance due to its capability to handle the sentence's context and order of parsing. Yet, the authors focus on sentence-level sentiment classification, and they used the traditional BOW to represent texts. In [55], the authors implemented LSTM to handle Arabic sentiment classification. The model was implemented along with character/word embedding features. In their experimental results, LSTM has shown the ability to improve the sentiment classification and achieved an accuracy of around 82%. The same author in another work [56] found that SVM work better than RNN on the same dataset, but the execution time of RNN was faster. However, both studies focus on aspect-based sentiment analysis of Arabic reviews.

This current work introduces a combination of CNN with Bi-LSTM and a linear SVM classifier for Arabic sentiment classification. Unlike the studies mentioned above, the proposed model does not follow the conventional CNN and Bi-LSTM. Rather, the fully connected layers would be replaced with a linear SVM algorithm to perform the classification task.

III. PROPOSED METHOD

The proposed method for sentiment classification of Arabic reviews starts with preparing data by applying some data preprocessing techniques. Then, the word vector representation is built using pre-trained word embeddings trained on other large Arabic text corpora. After that, we combine CNN and Bi-LSTM for generating the final features representation to be passed to a linear SVM classifier.

A. Data Preprocessing

The preprocessing stage consists of removing noise from data and normalization. The process of removing noise from data includes removing repeated letters, diacritics, punctuations, numerals, English words, and elongation. After that, a normalization process was applied to particular letters, for example, the letters (ا, ا, ا) were converted to (ا), the letters (ي, ي) were converted to (ي), the letter (ة) was converted to (ة), and finally, the letter (ة) was converted to (ة). It is worth mentioning that we implemented these particular preprocessing steps to be compatible with those used in the pre-trained word embeddings model we intend to use. More details about the pre-trained word embeddings model in the next section.

B. Word Vector Representations

To generate representations for the reviews, we adopted the word vectors approach. Word vectors (also known as word embeddings) are vectors of real numbers representing the distribution of words or phrases in a given text [14]. This approach's key benefit is that high-quality word embeddings can be learned efficiently, mainly if a much larger corpus of text were used for training [57]. However, the adopted dataset's size is relatively small in our case, which might lead to low-quality word embeddings. Therefore, we decided to use a pre-trained word embeddings model that trained on other large Arabic texts. One of the most common Arabic pre-trained word embeddings is Aravec [47]. This pre-trained model was

trained on texts from multiple sources such as Twitter, Web pages, and Wikipedia with tokens of more than 3,300,000,000. This model was implemented by the well-known word2vec technique described in [11] based on CBOW and Skip-gram architectures.

C. Convolutional Neural Network Layer

We first build a CNN layer to extract the features of reviews. The inputs to the CNN are matrices of word embeddings X that reflect the word vector representations of the reviews. Each review is mapped to a matrix of size $s \times d$, where s is the number of words in the review and d is the dimension of the embedding space. All reviews must be zero-padded to have the same matrix dimension $X \in \mathbb{R}^{s' \times d}$. Then, in order to compute a new feature map, inputs are convolved with a filter matrix $w \in \mathbb{R}^{h \times d}$, where h is the size of the convolution. The convolution is computed as in Equation 1:

$$c_i = f\left(\sum_{j,k} w_{j,k}(X_{[i:i+h-1]_{j,k}}) + b\right) \quad (1)$$

Where $b \in \mathbb{R}$ is a bias term and $f(x)$ is a nonlinear activation function. The output is the result of element-wise product between an input matrix X and a filter matrix w , which then be summed as a single value in a feature map $c = [c_1, c_2, \dots, c_n]$, where $c \in \mathbb{R}^{n-h+1}$. To obtain rich features representation the model can use multiple filters of different length that can work in parallel. Then, the convolved results are passed to the pooling layer to reduce the representation dimensionality by identifying the most important features. We employed the max-pooling technique which returns the maximum k values from the feature map $\hat{c} = \max(c)$. This technique has the ability to force the network to capture the most useful local features produced by the convolutional layer [58]. A typical architecture of a CNN layer is illustrated in Fig. 1. The output of this layer is fed into the next layer that is Bi-LSTM, based on the assumption that is more informative representation will be obtained, more details in the next section.

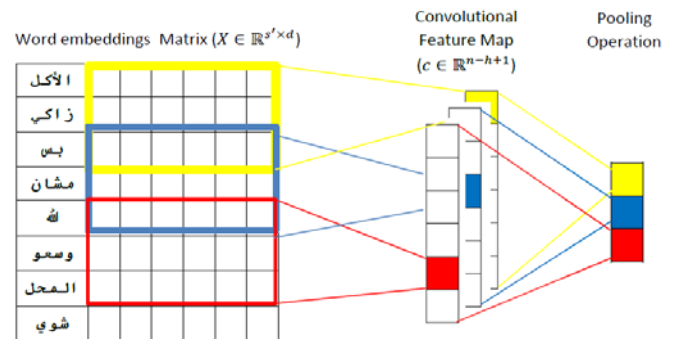

Fig. 1. A typical CNN Layer Architecture, the Colored Boxes Represent the Size of a Filter Spatially.

D. Bidirectional-Long Short-Term Memory (Bi-LSTM) Layer

As mentioned above the input into this layer is the final feature map obtained from CNN. First, let us present a little background about LSTM to understand the Bi-LSTM. LSTM is a type of recurrent neural network RNN, which was developed by [59]. The main objective of LSTM is to avoid vanishing gradient problem that encounters RNN, where the

gradient that is propagated back through the network either decays or grows exponentially over time [60]. In other words, RNN is not an effective model for understanding the context behind an input with long-term dependencies. On the other hand, LSTM with its complicated dynamics that consists of several so-called memory blocks, can effectively resolve this issue and make a prediction based on time series data. Each memory block is composed of an input gate i , a forget gate f , an output gate o , and a cell state c . These elements are used to compute the hidden state h by the following composite function in Equation 2:

$$\begin{aligned}
 i_t &= \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci}c_{t-1} + b_i) \\
 f_t &= \sigma(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf}c_{t-1} + b_f) \\
 c_t &= f_t c_{t-1} + i_t \tanh(W_{xc}x_t + W_{hc}h_{t-1} + b_c) \\
 o_t &= \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co}c_t + b_o) \\
 h_t &= o_t \tanh(c_t)
 \end{aligned} \tag{2}$$

Where x_t is the input vector to the memory cell at time t , σ is the sigmoid function, W is the weight matrices, and b is the bias.

However, one downside of LSTM inherited from RNN is that it does not consider the whole context because the sentence is only read in a forward direction [16]. In this case, the context information provided by the future words will be dismissed, resulting in low classification performance. An extension of LSTM called bidirectional LSTM (Bi-LSTM) [61] was proposed to avoid this problem. In this work, we adopted this method to obtain more informative features based on the features given by CNN. Bi-LSTM simultaneously trains two separate LSTMs of opposite directions (one for forward and one for backward) on the input sequence and then merge the outputs. More formally, as explained above, the input vectors x_t are fed one at a time t into the LSTM, making use of all the available input information up to the current time frame t_c to predict y_{t_c} . However, applying the bidirectional network's notion will enable the network to use the input information coming up later than t_c by delaying the output by a certain number M time frames up to x_{t+M} to predict y_{t_c} . The structure of Bi-LSTM is illustrated in Fig. 2 that shows the basic structure of folded Bi-LSTM which computes the forward hidden sequence \vec{h} , the backward hidden sequence \overleftarrow{h} , and the output sequence y by iterating the backward and forward layers. This layer also if followed by a max-pooling layer as outlined in the previous section.

After this layer, we have a layer that concatenates the list of outputs from the previous layers into a single vector.

Conventionally, this vector is passed to a fully connected layer that applies weights over the generated features $\alpha(w * x + b)$ to predict the class of a given input, where $w \in \mathbb{R}^{m \times m}$ is the weights matrix, and α is the activation function. However, in this work, we will replace these fully connected layers with a linear SVM to perform the prediction process, more details in the next section.

E. Support Vector Machine (SVM) Classifier

As mentioned earlier, we present a model that combines CNN and Bi-LSTM with SVM, where CNN and Bi-LSTM used for feature vectors generation and SVM for sentiment classification. SVM was employed as it has proven to be an effective algorithm in many NLP tasks, including SA. The key idea behind combining these heterogeneous methods is to use each method's advantages to improve the Arabic language's sentiment classification. In general, SVM is a machine learning algorithm for binary classification problems introduced by [63]. The SVM classifier aims to find an optimal hyperplane that classifies given data points into one of two classes by maximizing the margin. More formally, a linear SVM will receive a concatenated vector of features x_i associated with its labels y_i to be processed by a hyperplane $f(w, x) = w^T \cdot x_i + b$ to compute the coefficients of the hyperplane as feature weights, where w is the normal vector to the hyperplane and also known as the weight vector and b is the bias.

The architecture of the proposed model is illustrated in Fig. 3. Obviously, our model's architecture is essentially the same as the basic CNN and Bi-LSTM with a difference in using the SVM algorithm for classification. Further clarity, CNN or Bi-LSTM typically use a fully connected network with different activation functions (i.e. logistic) for learning and classification, as explained earlier. However, in this work, we replace the fully connected layer with a linear SVM which use a margin-based loss function for classification.

Fig. 2. Architecture of Bi-LSTM (Source: [62]).

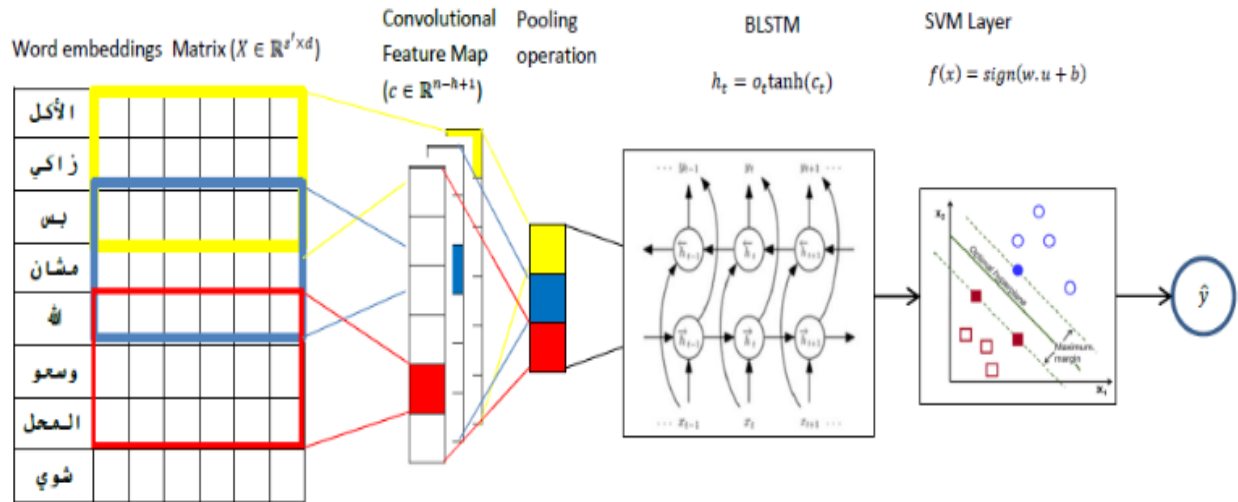

Fig. 3. Architecture of the Proposed Model.

IV. EXPERIMENTS

This section presents the datasets, models settings, and evaluation metrics. For evaluation, we developed some experiments to compare our model’s performance versus baseline models. Particularly, the author used the individual classifiers of CNN and SVM as baseline models. Additionally, we compared the proposed model results with some of the state-of-the-art deep learning models proposed by other related studies. The experiments also explore the best pre-trained word embeddings architecture for the proposed model. For this purpose, each performance experiment is carried out with CBOV and Skip-gram. To perform all the experiments in this work, we used the Keras library. More details about the experiments are provided in the following subsections.

A. Datasets

We used three publicly available datasets, namely, LABR, OMCCA, and the dataset presented in [35]. These datasets vary in size and writing form, where MSA and different Arabic dialects were detected. For example, LABR contains over 63000 reviews written mostly in MSA with the presence of dialectal phrases. On the other hand, On the other hand, OMCAA consists of over 28000 reviews written mostly in Jordanian and Saudi Arabic dialects. The last dataset presented 2400 reviews written in Jordanian dialect with the presence of MSA. All the datasets are annotated on the document level, and we considered only two polarity classes, which are positive and negative. The training/validation/testing split is set to 70%, 15%, 15%, respectively, in our experiments. Due to the limited capabilities of the device used to perform the experiments, we considered only the randomly balanced versions of these datasets. Table I presents more details about datasets.

TABLE I. CHARACTERISTICS OF DATASETS USED IN OUR EXPERIMENTS

Dataset	Balanced	Review Type
LABR	16444	Books
OMCCA	4990	Products
[35]	2400	products

B. Evaluation Metrics

The performance is quantified using the following evaluation metrics: F1-score, Precision, and Recall; see Equations 3, 4 and 5.

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

$$F1 - score = 2 \frac{Precision \times Recall}{Precision + Recall} \quad (5)$$

where TP, TN, FP FN indicate a true positive, true negative, false positive, false negative, respectively.

C. Hyper-parameters Settings

This section describes the hyper-parameters settings for each model used in the experiments. The process of selecting the optimal hyper-parameters is a challenging task, and it varies based on the characteristics of the dataset. To this end, we performed several trials to choose the hyper-parameters with which the classifiers may yield the best performance results. As a result, the hyper-parameters in Table II have been assigned to the layers of CNN and Bi-LSTM. It is worth mentioning that all the data points have been zero-padded before being passed to the deep learning models, so all the input vectors have the same length. In the case of the CNN is a baseline model, the word vectors will be fed to a fully connected layer of size 64 nodes. The dense hidden layer is trained and regularized using a Relu function and l₂-norm method, respectively. The weights are then passed to an output layer with a sigmoid function to give the final classification probability. We also applied a Dropout layer after each model and early stopping strategy to reduce the over-fitting problem. Then, we added a max-pooling layer after each layer to keep the most important features. During the networks’ training process, Adam algorithm) is employed to perform the optimization with a learning rate of 0.001, and binary cross-entropy function for loss minimizing. A linear SVM classifier with its default parameters in Keras library has been employed for the classification process. Regarding generating word

embeddings based on Aravec, after many trials, we decided to apply the skip-gram and CBOW models built on Web pages with tokens of 132,750,000 and embedding dimension of 300. For words that are not contained in the pre-trained model, the embedding is set to a vector of zeros.

TABLE II. HYPER-PARAMETERS OF CNN AND BI-LSTM

Parameter	CNN	Bi-LSTM
Filters	250	-
Kernel size	4	-
Strides	3	-
Output dimensions	-	150
Activation	Relu	Tanh
Dropout	0.5	0.5
Max Pooling	2	2
Epoch size	30	30
Batch size	30	30
Loss function	binary_crossentropy	binary_crossentropy
Optimizer	Adam	Adam
L2 regularization	0.01	0.05

V. RESULTS

Results of the proposed model against the baseline models on the datasets are summarized in Table III. As it can be seen, our model with skip-gram and CBOW outperforms the other models in all datasets. The results show a significant improvement in the F1-score of the proposed model in all datasets, where the highest is achieved in the third dataset with around 8% compared to CNN and SVM when skip-gram is used and around 7% when CBOW is applied. Although the

proposed model outperforms SVM and CNN with CBOW on OMCCA, the highest results are obtained using skip-gram with an improvement of 7% and 8% compared to CNN and SVM, respectively. It is also noticed that the proposed model show improvement on the LABR dataset when skip-gram is used with around 6% and 7% compared to CNN and SVM, respectively, and around 5% for both models in the case of skip-gram.

Additionally, the proposed model performs very well in terms of the recall and precision in all dataset with a bit of trade-off, where the recall is the highest compared to all models used with 91.6% on the third dataset. On the other hand, the highest precision value is around 91% and achieved by CNN on the OMCCA dataset. Based on the two-word embeddings models, CNN achieved classification performance close to SVM with slight superiority to the former. This might indicate that the representation captured by both models is not enough to identify the latent connections between words, and a richer representation is required for better performance.

Finally, after the proposed model has been proven to be effective in Arabic sentiment classification for all datasets used in this work, we compare our results with other studies' results that employed state-of-the-art deep learning models. We choose work that used LABR dataset as it is the most common dataset in the Arabic SA literature. To guarantee a fair comparison, we only consider those who experimented on balanced class labels and used Aravec pre-trained model. In this sense, the work in [64] reported a significant improvement in Arabic sentiment classification based on a combination of Bi-LSTM and CNN on different datasets, including LABR. However, our proposed model outperforms their model, where they achieved an F1-score of 76.9%, which is 10% less than the highest results of our model on LABR.

TABLE III. RESULTS OF A COMPARISON BETWEEN THE PROPOSED AND BASELINE MODELS ON THE USED DATASETS WITH SKIP-GRAM AND CBOW EMBEDDINGS MODELS

Dataset	Model	Representation	Recall	Precision	F1-score
LABR	CNN	Skip-gram	73.05	89.24	80.34
		CBOW	76.68	82.68	79.56
	SVM	TF-IDF	74.46	86.49	79.08
		Proposed Model	Skip-gram	85.92	86.36
	CBOW		82.0	86.31	84.10
	OMCAA	CNN	Skip-gram	74.70	91.30
CBOW			76.28	87.72	81.60
SVM		TF-IDF	83.26	79.06	81.11
		Proposed Model	Skip-gram	90.0	89.28
CBOW			88.35	84.29	86.27
[35]		CNN	Skip-gram	74.16	90.81
	CBOW		77.27	85.53	81.19
	SVM	TF-IDF	75.83	88.77	81.58
		Proposed Model	Skip-gram	91.66	86.61
	CBOW		88.33	86.88	87.60

VI. CONCLUSIONS AND FUTURE WORK

This paper presented a model that uses a linear SVM classifier on top of a combination of CNN and Bi-LSTM for Arabic sentiment classification. Unlike the conventional architecture of the deep learning model, the proposed model was tailored by replacing the fully connected layer with an SVM classifier, which receives the embedded vectors extracted by CNN and Bi-LSTM. The experimentation has shown the effectiveness of the proposed model with a significant improvement over the baseline models. Furthermore, we showed that the proposed model outperforms one of the state-of-the-art deep learning models with a considerable improvement. Yet, there is room for improvement as the proposed model does not concern with some issues that might affect the performance (e.g. negation handling). Further work is also required to explore the effectiveness of the proposed model with deeper layers and diverse architectures on different Arabic benchmark datasets. Additionally, to extend the work so that it can be applied to other Arabic SA tasks such as aspect-based sentiment analysis.

Abstract—The development of emotional intelligence robotics in the learning environment plays valuable support for social interaction among students. Emotional intelligence robots should be scalable to recognize emotions, appear empathetic in learning situations, and enrich the confidence with students for active interaction. This paper presents some related issues about integrating emotional intelligence robotics in E-learning such as its role and outcomes to motivate interaction during education and discover the main aspects of the emotional intelligence between humans and robots. This paper aims to determine the design requirements of emotional robots. Besides, this paper proposed a framework of educational Robotics with Emotional Intelligence in Learning (EREIL). EREIL consists of three main units; student emotions discovery, student emotions representation, and EREIL-Student Communication (RSC). In addition, it introduces a perception of EREIL working. In the future, this paper tries to merge more sensor devices and machine learning algorithms to integrate face analysis with speech recognition. Besides, it can add a persuasion unit in the EREIL robot to convince students with better learning choices to their abilities.

Keywords—Robotics; emotional intelligence; interaction; e-learning; motivation; robot with emotional intelligence; machine learning algorithms; face analysis; speech recognition

I. INTRODUCTION

Educational Robotics(ER) has become increasingly common to handle possible future adaptation issues in E-learning. ER presents a deeply exciting learning environment in college, encouraging collaboration among learners, and realizing the generation of innovative experience in a reflexive method instructed by the teacher[1]. Recently, Teachers have often been struggling with keeping students' motivation and social interaction to the E-learning process. Student motivation is the backbone of the E-learning process because it affects student performance. This reflects the fact that ER can help to overcome the special educational needs of students such as Autism Spectrum Disorders(ASD)[2].

Furthermore, ER is an innovative field for students to build E-learning experiences [3][4]. It is related to both the observation and simple handling of a robot as well as more demanding tasks as the students are involved in planning, problem-solving, and decision making in relation to the robot's behavior, with the aim of developing creative thinking, the highest level of thinking [5]. ER for students with special educational needs includes the use of social robots for

teaching various skills such as cognitive function, communication, and collaborative play[6][7].

Emotions have a complex structure to include specific social-cognitive dimensions to analyze things from the perspective of others and sharing other people's empathy[8][9]. Besides, emotion detection is a significant issue for special education, in two essential directions. The first regards students with special needs themselves who appear to have a deficiency in social perception and cognition[10]. The second direction regards children with insufficient mastering of social skills do not communicate and relate to others efficiently while they experience problems in playing, working, and learning with peers, which may well result in a certain degree of isolation [11].

Recently, emotional intelligence robots contribute to enhancing collaborative knowledge and individual and corporate self-efficacy[12]. In turn, they play a valuable role in promoting academic accomplishment, and cognitive-motivational features of learning in a student with intellectual disability increased significantly through the influence of robotics activities [13]. Furthermore, emotional intelligence robots enhance memory and attention for students with insufficient social experiences[14][15]. Besides, emotional intelligence robots encourage the processing of the complexity of human emotional expressions[16]. Thus, the field of Affective Computing requires to be updated and contributed with researches and experiences of emotional intelligence robots. Additionally, some practices in this field support improving creativity and sequential thinking for students[17].

The rest of the paper is organized as follows Section 2, highlights the emotional intelligence of humans and robots. In Section 3 the investigation of gender effects in students' perception is presented. Sections 4 and 5 look into age and educational robotics with educational intelligence and outcome of educational robotics with emotional intelligence in learning environment, respectively. Sections 6 and 7 display a framework of educational Robotics with Emotional Intelligence in Learning(EREIL); requirements, components, and an example of EREIL working. Section 8 concludes the paper proposing and future work to improve EREIL.

II. EMOTIONAL INTELLIGENCE FOR HUMANS AND ROBOTS

Robotics encourages integrative knowledge because of its inherent variation. Consequently, Robotics merges the learning among computational aspects, sensor devices, and

expanding rapidly to emotional intelligence. Hence, it has the potential to excite and support talent by promoting technically-minded students. Robotics has particular value in this learning domain because it depends on computational thinking and has a powerful experimental domain for sensing, measuring, designing behavior, and emotional intelligence [18][19].

Emotional intelligence enriches the quality of the learning climate and improves academic performance. Besides, Emotional intelligence provides more knowledge to solve learning obstacles, support better learning organization, enhance personal growth, and handle stress through learning environments[20][21]. Emotional intelligence enhances richness with students and provides further versatility, adjustability, and skill at working in groups in the learning environment[22].

Emotional robots have played a vital role in the future of artificial intelligence when we focus on relational agents. Furthermore, relational agents present human social experiences, such as hand signs, position changes, and facial feelings, spoken words that sent fun, empathy, culture, and kindness[23][24]. Besides, emotional intelligence is an essential part of human intelligence and cognitive performance in the learning environment. Hence, emotional intelligence promotes the human connection with students and influencing their emotional progress[25].

The communication between students and an emotional robot influences the student's understanding of an emotional robot. Also, it concerns the student's performance during the interaction. Thus, students cooperate with an emotional robot that generates more significant advances in trust and works excellently on the assignment taught by an emotional robot. Besides, emotional robot converges on how to perceives and promotes emotions in particular communicative conditions. Furthermore, an emotional robot in learning environment affects to the emergence of team dynamics methods like; communication, collaboration, team administration[26].

The researches prove that the variation of the stimuli has a great role in human-robot interactions. The stimuli like; text, audio, video, and image. Text stimulus led to even higher perceived emotional intelligence of the student than the video, audio, and image stimuli, while the variation in the stimuli-type does not affect the perceived emotional intelligence of the robot. Furthermore, the high emotional intelligence robots and humans as more trustworthy than the low emotional intelligence robots and humans. Besides, the content of the verbal interaction is essential for students' perceptions of emotional intelligence in both students and robots and not the tone of voice, posture, gesturing, or other bodily dynamics. The emotional robots in the learning environment might have to be endowed at least primary emotional intelligence capabilities. These capabilities enable them to focus on the students' emotional state, establish and maintain students' trust and build working relationships with them [27].

III. STUDENTS' PERCEPTION OF GENDER EFFECTS IN DESIGNING ROBOTICS

The emotional intelligence of students integrates gender parameters when making decisions and formed expectations in social interaction. In turn, that affects designing educational robotics[28]. Also, students have a positive attitude in their awareness, behavior, and perception towards the educational robotics have the same gender. That because the thought based on the same gender educational robotics is more believable, reliable, interactive, and engaging. Although the gender features offered in appearance more than objective parameters. For example, female students prefer educational robotics with pink lips, with a female name, and a female voice. Versus male students prefer educational robotics with gray lips, with a male name, and a male voice. As a result, this makes them feel more comfortable in social interaction, more desirable, more accepting, and more perfectly capable of performing a service task[28][29].

The female has high emotional intelligence than the male in human interactions. And the same goes for educational robotics. Consequently, students may lose their trust in male educational robotics. That indicates the essential for enhancing tools of male educational robotics to acquire them high emotional intelligence. Thus, disappearing gender-based differences in emotional intelligence [27].

Various strategies are adopted to facilitate optimal levels of perceived emotional intelligence and trust in educational robotics. For example, students will previously make decisions when discovering the gender of educational robotics regarding emotional intelligence and social interaction. As a solution, the design of educational robotics presenting emotional intelligence would be in a female voice. That is due to male educational robotics might disappoint expectations. However, for performing tasks that include sensitive social situations a male voice of educational robotics might be superior to reduce undesired results towards potential errors [30].

IV. AGE AND EDUCATIONAL ROBOTICS WITH EDUCATIONAL INTELLIGENCE

Age is relevant to expanded learning and practice experience. More youthful students manage to be limited exposure to while more experienced students seem to be extra excited with educational robotics with emotional intelligence [31]. This new trend should support various platforms, application interfaces to encourage a creative learning environment. Thus, these platforms seem to be quite promising for young students because they can reduce the age entrance for sharing in educational robotics with emotional intelligence and programming skills [32]. The integrated technologies and hybrid systems can facilitate engaging educational robotics with emotional intelligence for both young and older students. In turn, that can decrease cognitive content for students by engaging a new trend of learning through learning curriculum simultaneously [33].

V. OUTCOMES OF EDUCATIONAL ROBOTICS WITH EMOTIONAL INTELLIGENCE IN E-LEARNING ENVIRONMENT

The outcomes can be details as follows [34]:

- ER with EI assists to build an innovative learning environment and creates a valuable and attractive learning style.
- ER with EI integrates physical and mental experience for communication with the learning situations and their instruments.
- ER with EI enables students to discover by performing, managing conceptual theories, and integrating knowledge.
- ER with EI may encourage motivation for studying in courses that are commonly perceived by students as boring and not so exciting.
- ER with EI promotes knowledge spirit for both children and adult students who are further enthusiastic about robotics evolution.
- ER with EI adopted a facilitator learning environment for both students and professors. Consequently, professors prove high investment and concrete results in the use of EI in the studying environment.
- ER with EI provides more inclusive engagement in learning activities to retain students' concentration in the long-term and makes the professors' teaching further satisfying.

- ER with EI enriches the sufficient and motivation of the teaching method. Besides, it overcomes the boredom of traditional education methods.

VI. A FRAMEWORK OF EDUCATIONAL ROBOTICS WITH EMOTIONAL INTELLIGENCE IN LEARNING (EREIL)

This section describes the proposed framework called EREIL. EREIL aims to motivate interaction among students in the learning environment. EREIL improves to assist students in promoting their social connections during the daily performance in the learning environment. This section divides into two main subparts: the design requirements of EREIL and the components of EREIL.

A. The Requirements of EREIL

The requirements of EREIL can be divided into three types; needs determination & analysis, design, and technology.

1) *Needs determination and analysis requirements:* These requirements analyze the steps to integrate EREIL in e-learning environment as seen in Fig. 1.

2) *Design requirements:* These requirements regarding design principles of EREIL, the requirements explained in Fig. 2.

3) *Other requirements:* These requirements can be represented into three requirements. First, encouraging innovative teaching methods: It includes adapting teamwork and critical thinking. Second, developing programmable systems: It includes focusing on enriching observation, analysis, supporting modeling and simulation. Third, adopting project-based learning: It includes learning-based problem solving and adapting cultivating collaboration skills.

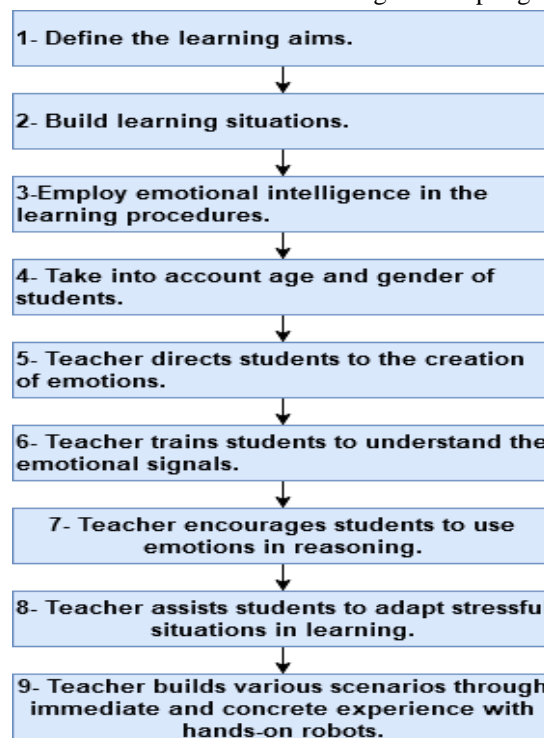

Fig. 1. Needs Determination and Analysis Requirements of Emotional Intelligence Robots.

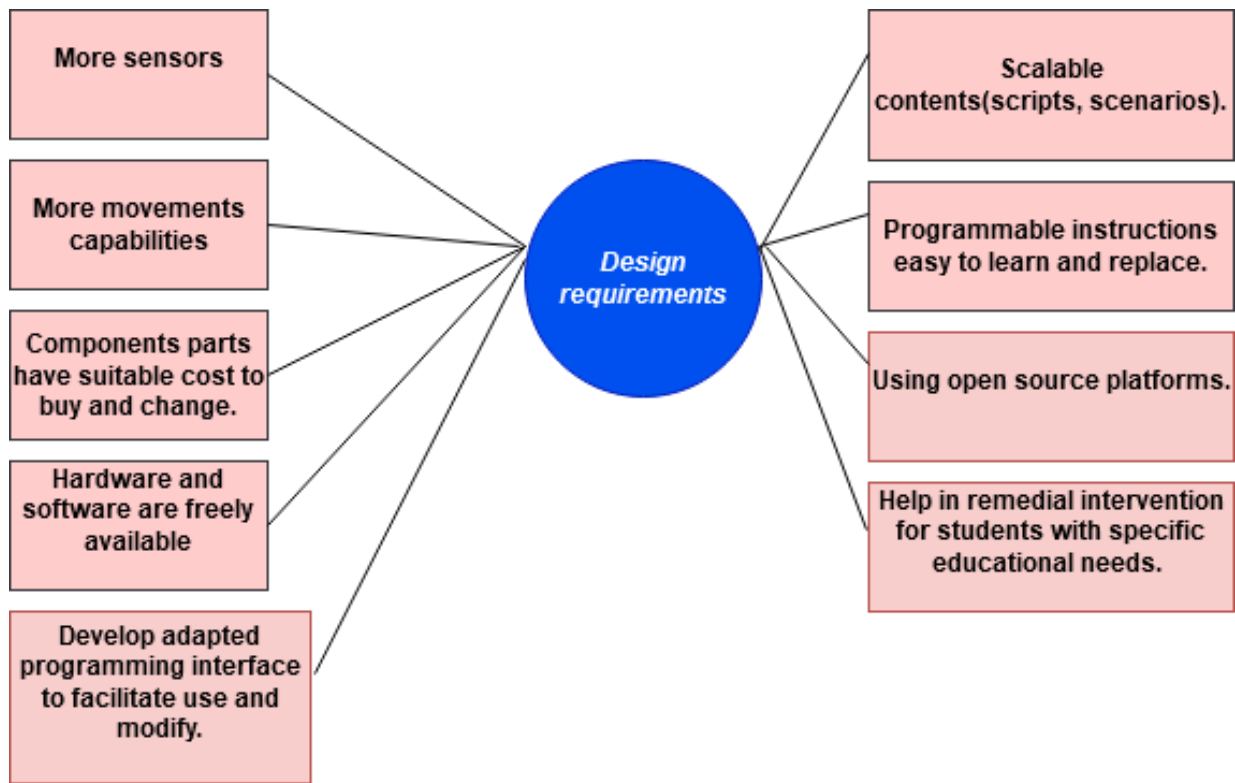

Fig. 2. Design Requirements of Emotional Intelligence Robots.

B. The Components of EREIL

EREIL consists of three main units; student emotions discovery, student emotions representation, and EREIL-Student Communication (RSC) (see Fig. 3). It is clear that the two units responsible for discovering, implementing, and processing, and representing emotions. Furthermore, the third unit enhances the student practice and supplies a running visible interface to the EREIL robot.

EREIL can implement the following essential characteristics:

- It recognizes the emotions of several students.

- It determines the common sentiment of a collection of students.
- It shows student determined sentiments according to the emotional moods of the students.
- It helps students supporting the learning schedule.
- It stores learning tasks to tell students to perform them at a determined duration.
- It convinces students by providing them reasons to confirm suggested learning activities according to their learning profile and individual abilities.

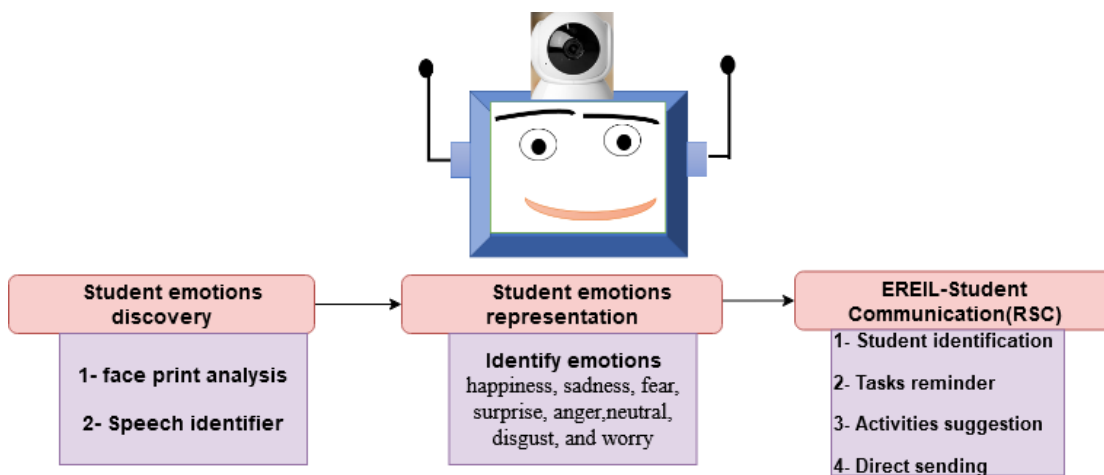

Fig. 3. Components of EREIL Robot.

1) *Student emotions discovery*: The discovery process of students' emotions plays an essential role in social interaction in the learning environment. Thus, the implementation of emotions discovery helps students to practice sharing, interaction, and collaboration. Also, it can be useful to recommend an adaptive response or recommend modifications for a better response.

EREIL is a proposed framework to support sensing devices, recognize and represent some factors of student performance. EREIL supports the student's body signals (i.e., emotions, speech level, gestures, etc.) to recognize these communications performed in the learning environment. EREIL discovers student's body signals through contacting eyes, gestures, face analyzing, and voice recognition. Through this discovery, EREIL can determine student identification. Besides, it is important to increase sensors that support EREIL to obtain students identification. Although sensor devices are not sufficient in EREIL, it is necessary to support artificial intelligence (AI) fields. AI allows to analysis and training of the collected raw data from sensor devices. With AI potentials, we can use face identification, speech recognizing, interpret natural language, and emotional discovery.

a) *EREIL for student's determination and sentiment analysis*: EREIL determines the student identification and other students who can share the learning activities with him. It aims to select suitable machine learning techniques that can contribute to students' face recognition. This process should be agile and easy to decrease the training time and not confuse the student. Furthermore, the student face recognition process depends on converting face to vectors with special determinates. Every face has specific landmarks that can be measured, such as the distance between the eyes, the length of the jaw line, the shape of the eyebrows, and more. Together, they create a unique faceprint that can later be compared with other students until a match is found, thus recognize student.

EREIL allows classifying emotions through a deep learning machine to analyze students' sentiments. EREIL classifies students' emotions to happiness, sadness, fear, surprise, anger, neutral, disgust, and worry. Besides, EREIL can use the web service to train and examine students' emotions because this procedure can be a difficult and high cost if it computes on EREIL.

b) *Emotional web assistance for EREIL*: As mentioned, to reduce the overload of computational analysis on EREIL for determining students' identifications and emotions, EREIL depends on the webserver. This web assistance supports EREIL to recognize students' faces, analyze emotions, and recognize the sharing emotions among a group of students. EREIL encourages the students to optimize the decision-making in communication with other students and enhance taking decisions regarding cooperating and sharing learning activities.

Nevertheless, if EREIL does not know the student identification. EREIL displays a collection of questions to promote communication with the student for discovering the student's name, face, and identification. Then, EREIL creates a conversation with the student to recognize more information

about him and stores the new data. Furthermore, EREIL separately recognizes students in groups. In other words, EREIL recognizes each student alone and takes assistance from a web server for analyzing face. Then, if EREIL discovers another unknown student, the same process will repeat. Also, recognizing the emotions of a students' group allows EREIL to understand what the sensitive mood of the group is. Consequently, EREIL tells the student to perform alone if this emotion is further away from his interests.

2) *Student emotions representation*: EREIL contributes to understanding emotions for students. And that is in turn influences on changing students' reactions. As a result, it is essential for EREIL to represent expressions of its own emotional situation. Thus, these representations would be directly benefited the interaction with students. So, EREIL uses sensors devices to recognize the learning environment and use this knowledge to express its emotional situation.

EREIL can express emotions by sensors of its face like contact eyes to start and manage communication. Looking at student's eyes during speech attracts attention and integrates interaction during the speech.

Face tracking technology can assist in face detection. While the student moves his eyes towards learning activities, EREIL can follow this moving to start and maintain eye contact. Thus in turn encourages the student's attention and promotes interaction. Besides, this information enriches EREIL to start of dialog at a suitable time, greet the student with a friendly smile. Furthermore, EREIL keeps eyebrows and mouth to express different emotions. Also, eye contact contributes to measure engagement between students and EREIL, better understand students' demands, and produce more appropriate information.

3) *EREIL- Student Communication (RSC)*: The student's communication is promoted with EREIL using RSC. RSC is the unit is responsible for enhancing the student practice in learning activities and supplying a running visible interface to the EREIL robot. RSC is a supporter for student to increase learning motivation through remembered daily learning assignments and proposing activities. Besides, RSC explains new activities to expand the learning experiences of students and recommends with external learning sources to encourage rounded learning by integrated the practical exercises with academic learning.

RSC consists of four subunits: 1) student identification, 2) tasks reminder, 3) activities suggestion, 4) direct sending.

- Student identification: This subunit stores the personal data and learning progress information of each student. It RSC aims to develop the students' learning aspects. Hence, storage the students' learning activities, interests, preferences, and the right time to perform them. However, RSC needs the personal information; name, address, age, parents, closer friends, learning style, and preferred subjects to create recommendations and advice related to the personal environment.

- **Activities suggestion:** This subunit decides and recommends activities to the student based on personal data and interests. It aims to keep students in active mind and continuous research to reach rounded learning, e.g., use external video, audio, documentation films, reading reference books to connect academic learning with practical needs, engage other students in learning gamification. Besides, if closer students of the student are comprised a group on RSC, in turn RSC will recommend activities and learning games suitable to shared interests and in appropriate time to all of them.
- **Tasks reminder:** This subunit displays the activities, lessons, assignments of daily tasks to students. EREIL keep these learning tasks with date and time to tell each student about its schedule.
- **Direct sending:** This subunit presents a means to send information directly to EREIL through its touchscreen. When a student wants to send information to EREIL. Besides, EREIL uses direct sender to create an interactive situation among students and respond to students' decisions. On the other hand, a student can send a message through the visual interactive screen to

use EREIL sensors devices to catch information. It is essential to teach EREIL, by keeping interaction with the students.

Fig. 4 shows Algorithm 1 for how EREIL discovers the student's face. EREIL greets the student when EREIL discovers the student's face. Besides, it explains the EREIL behavior with unknown student. EREIL does not detect the student's face. EREIL will ask the student about his name, capture a photo, and stores it.

Besides, Fig. 5 shows Algorithm 2 for how EREIL reminds the student of the scheduled tasks. For example, EREIL reminds the student of the Science Lab time at 1:00 PM by displaying on the touch screen and wait for the student's response.

Furthermore, Fig. 6 shows Algorithm 3 for the activity suggestion from EREIL to the student. For example, EREIL suggests activity "play volley ball by displaying on the touch screen and wait for the student's response". In addition, Fig. 7 presents Algorithm 4 for direct sending between EREIL and student.

Algorithm 1: How EREIL discovers the student's face

Step1: Start

Step2: EREIL senses the existence of someone.

Step3: EREIL opens the camera to discover a student.

Step4: EREIL compares the captured photo of the student with stored photos of the students.

Step5: If the captured photo matches any of the stored photos **Then**

Appear a greeting message on a touchscreen

" **Welcome** + Student's name"

Step6: Else EREIL appears a message on a touchscreen

"Who are you?"

Step7: The student writes his name on a touchscreen.

Step8: EREIL takes a photo to store it and to detect the student later.

Step9: End

Fig. 4. Algorithm1 for Discovering the Student's Face.

Algorithm 2: How EREIL reminds the student of the scheduled tasks

Step1: Start

Step2: EREIL watches time.

Step3: EREIL keeps in touch with scheduled tasks.

Step4: EREIL compares between the current time and time of scheduled tasks.

Step5: If the current time matches any of the scheduled tasks **Then** EREIL alarms a student by displaying on a touchscreen.

Step6: Appear a message " Hi + student name". It is 1:00 PM. You have to go to Science Lab.

Step7: EREIL presents two choices on a touch screen.

Step8: If the student accepts to go the task **Then** Student will click Let's go button on a touch screen.

Fig. 5. Algorithm 2 for Tasks Reminder using EREIL.

Algorithm 3: How EREIL suggests activities to the student.

Step1: Start

Step2: EREIL watches time.

Step3: EREIL keeps in touch with activities suggestion.

Step4: EREIL compares between the current time and time of activities suggestions.

Step5: If the current time matches any of the activities suggestions **Then** EREIL alarms a student by displaying on a touchscreen.

Step6: Appear a message " Hi + student name". It is 3:00 PM. Let's play volleyball.

Step7: EREIL presents two choices on a touch screen.

Step8: If the student accepts to practice activity **Then** Student will click Let's go button on a touch screen.

Step9: Else student will click Another suggestion button on a touch screen.

Step10: If the student clicks Another suggestion button **Then** go to Step 6 with changing activity.

Step11: Else go to Step 12.

Fig. 6. Algorithm 3 for Activities Suggestion using EREIL.

Algorithm 4: Direct sending between EREIL and the student.

Step1: Start

Step2: Student requests EREIL to send a message.

Step3: EREIL appears touch screen for direct sending.

Step4: Student writes the request on EREIL touch screen.

Ex.: Student writes "suggest me an external resources about the human digestive system".

Step5: EREIL appears a message "Wait a few seconds. I will display some videos".

Step6: Student watches to videos.

Fig. 7. Algorithm 4 for Direct Sending using EREIL.

VII. PERCEPTION OF EREIL WORKING: AN EXAMPLE

To explain the performance of EREIL, this section displays an example that illustrates the various processes made by EREIL as an emotional robot recommender in the learning environment.

The EREIL will communicate with students by recognizing them, identifying their emotions, and recommending actions and activities in the learning environment.

The perception of EREIL performance as seen in Fig. 8:

1) EREIL starts performance when seeing a student or group of students.

2) EREIL starts a dialogue with the student and ask him some question to detect the identification. This case when EREIL does not recognize the student.

3) Besides, EREIL captures the student's face, analyzes the coordinates of the face (x, y), and encoding the photos to recognize identification.

Note: The camera of EREIL will locate in the center of EREIL's face to easily capture the student's face. Furthermore, EREIL periodically captures students' faces and stores them with learning progress, personal profiles, interests, activities, and schedule.

4) If EREIL recognizes the student's face. Then EREIL will greet the student with his name.

5) When EREIL knows the student, it will discover his emotion. If the EREIL identifies more than one student in the same group of students in the capturing, the manner is

returned for each face, beginning the computation of engagement emotion.

6) As soon as the students' emotion is detected, EREIL will show empathy with the student. Also, it can move his eyes, mouth, and eyebrows. Besides, EREIL can suggest some learning activities and control its sensors devices to suitable for student emotion.

7) After that, EREIL reminds some tasks from the learning schedule. Then, EREIL suggests the interested students and closest to the student.

8) Furthermore, EREIL can suggest some activities and present some external learning sources as, books, video, virtual labs, and serious games.

Note: In step7 and step8, EREIL begins an active dialog with students, detects their emotions, and chooses the appropriate activities and tasks.

9) During the previous steps, EREIL can receive direct messages through the direct sender subunit and send responses to students.

10) If EREIL finds a student alone or a student refuses the suggested activity, EREIL can present joyful messages as an attempt to engage him in the learning environment again. Besides, EREIL finds a way to personalize interactions with students. EREIL can stores valuable information gathered during their previous interactions, such as their favorite learning activities, preferred external sources, closest students, and academic learning progress.

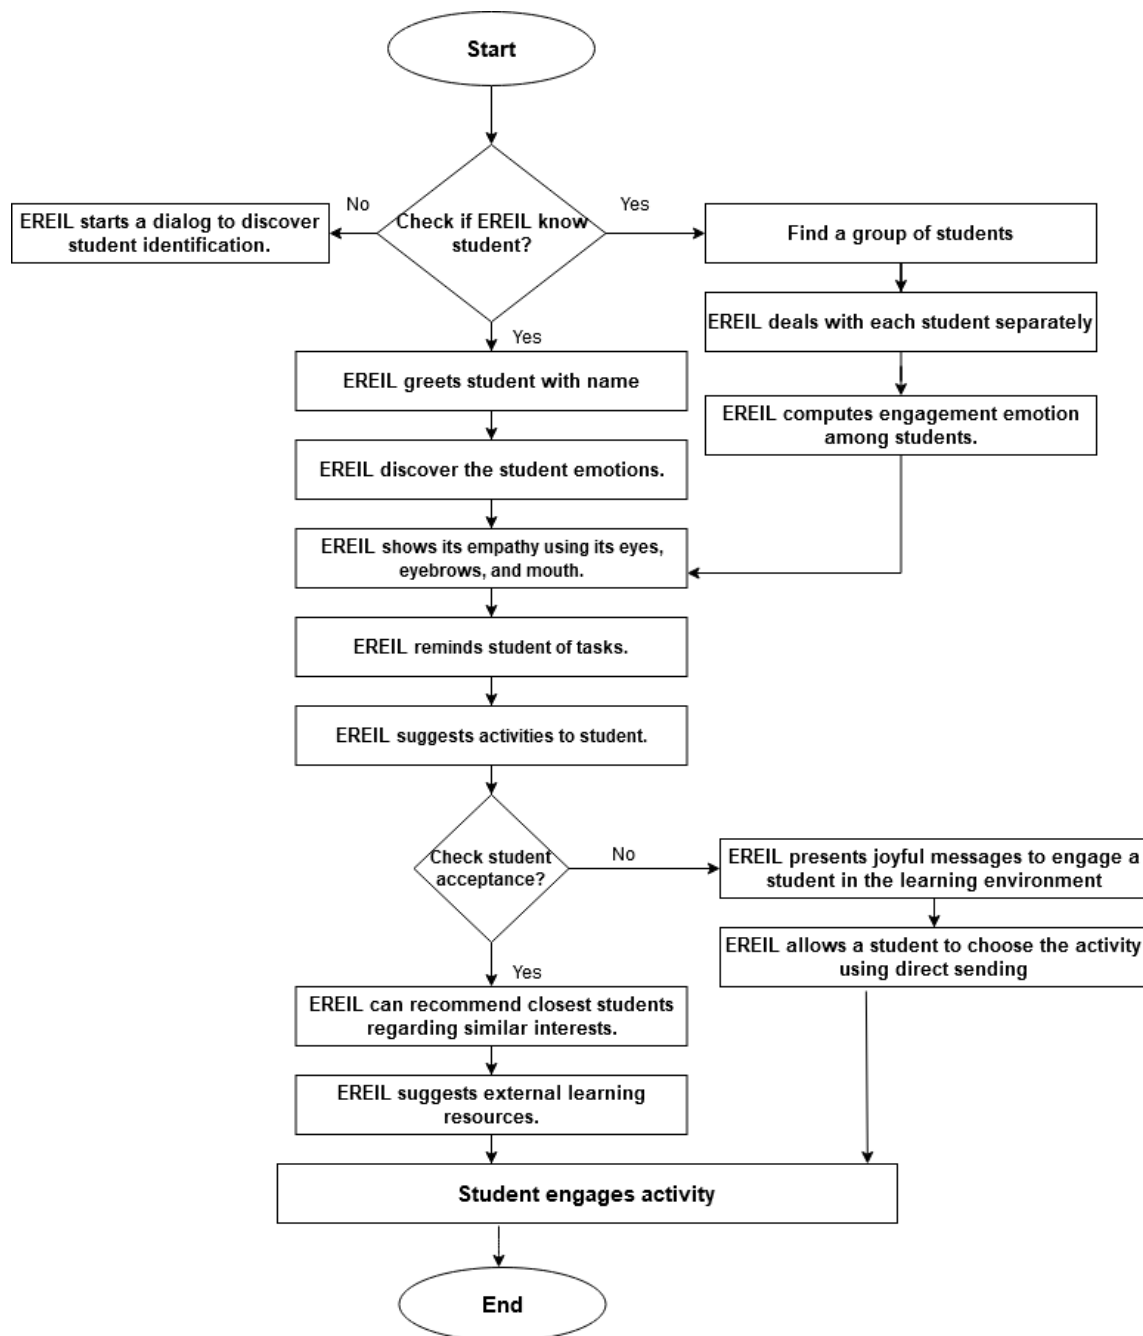

Fig. 8. Flowchart of an Example of EREIL Working.

VIII. CONCLUSION AND FUTURE WORK

This paper discussed educational robotics with emotional intelligence as an assist to motivate interaction in the learning environment. These robots can overcome the special educational needs of students such as autism spectrum disorders. Also, emotional intelligence robots can help students who have a loss in social communication and perception, mental impairment of spoken and non-spoken communication, presence of personal isolated interests, and students who reach the point of social alienation. It presented a proposed framework EREIL, as a student supporter for social interaction in the learning environment. Furthermore, it

presented the main requirements to build emotional intelligence robots as requirements of needs determination, designing, and technology. Besides, it presents proposed EREIL three main units: student emotions discovery, student emotions representation, and EREIL-Student Communication (RSC). The first two units are responsible for discovering, implementing, and processing, and representing emotions. The third unit enhances the student practice and supplies a running visible interface to the EREIL robot. Hence, the third unit is divided into four subunits: student identification, tasks reminder, activities suggestion, and direct sending. Additionally, it presented an example of EREIL working.

The existing work agrees with the following related works. The author in [35] introduced a robot that can understand and express emotions in voice, gesture, and gait using a controller trained only on voice. Besides, [5] proposed a novel algorithm for emotional intelligence robots to recognize human emotions from daily-life gestures. They used machine-learning techniques to automatically infer human emotions with high accuracy. Moreover, [8] showed that the importance of emotional intelligence has a significant effect on employee retention and performance, whereas artificial intelligence plays a significant moderating role in employee performance. Additionally, [13] presented human-robot interaction and how to recognize human emotional states. Also, it explained emotion levels from users are detected through vision and speech inputs.

As future work, we hope to execute a practical case study of the EREIL robot and enhance discovering emotions. It can be implemented by adding more sensor devices and machine learning algorithms to integrate face analysis with speech recognition. Another aspect that can be presented is to store the expert teachers' opinions of students for tracking their instructions in learning activities and their opinions in students' learning progress. Besides, it can add a persuasion unit in the EREIL robot to convince students with better learning choices to their abilities. Additionally, the persuasion unit can provide students with suggestions related to their learning.

AUTHORS' PROFILE

Mohamed A. Amasha, was born in Damietta Egypt, in 1970. He is professor in the application of computer. He worked as a vice dean the faculty of computer and information Damietta university. He is also a manager of E-portal at Damietta University. He works as a lecturer at Damietta University, Faculty of specific education, Computers Dept., With over 11 years of experience in Qassim university KSA, He has published in A.U.C in Egypt, IJACSA, IJORCS, Springer, IEEE.

Marwa F. Areed, is now a lecturer at Damietta University, Faculty of Engineering, Computers & Systems Dept., with over 13 years of experience in Mansoura University Faculty of Engineering from 2000 till 2017 and over three years in Taibah University, Computer Science Collage, Medina, KSA. She received M.Sc. (2003) and Ph.D. (2009) in Computer Engineering, both from Faculty of Engineering, Mansoura University. Her scientific interest includes Data Security in clouds, image compression, digital watermarking & steganography, Cloud Computing, Clustering Algorithms, Sentiment analysis and wireless networks. She has published in INFO2008 in Cairo, (International journal of computer Application 2012, international Journal of Engineering & technology 2014, Simulation Modeling Practice &Theory 2018 and finally in Journal of the International Measurement Confederation (IMEKO).

Dalia Khairy was born in Egypt, Damietta, in 1985. She is a lecturer in the application of computer in education. He works as lecturer, in Damietta University, Egypt.

Raian A. Abougalala, was born in Egypt, Damietta, in 1982. She is a lecture in the application of computer in education. She works as lecture, in Damietta University, Egypt. She has published in Springer.

Salem Alkhalaf , is an Associate Professor in Computer department, College of Science and Arts in Al-Rass, Qassim University. He graduated Bachelor of Education degree in Computer Since from the Department of Computer, Teachers College (Riyadh) in 2003, Also he graduated with Honors degree. And he graduated the Master of ICT from Griffith University (Brisbane, Australia) in 2008. And, he graduated the PhD in.

Building Research Productivity Framework in Higher Education Institution

Abstract—The purpose of this study is to build a framework for improving research productivity in higher education institutions. The research begins by collecting data and defining candidate variables. The next process is to determine the selected variable from the candidate variable. Variable selection is carried out in three stages, univariate selection, feature importance, and correlation matrix. After the variable selection stage, eight input variables and one target variable were obtained. The eight input variables are Article (C), Conference (CO), Grant (GT), Research Grantee (RG), Rank (R), Degree (D), IPR, and Citation (C). The target variable is Research Productivity (RP). This selected variable is used to build the framework. The next step is to test the framework that has been built. The testing process involves four data mining classifiers, Support Vector Machine, Decision Tree, K-Nearest Neighbor, and Naïve Bayes. The classification results are tested using confusion matrix-based testing, accuracy, precision, sensitivity, and f-measure. The testing results show the proposed framework is able to obtain high accuracy scores for each classification algorithm. It means the proposed framework is relevant to use.

Keywords—Framework; research productivity; variable selection; data mining classifier

I. INTRODUCTION

Lecturers are the main research actors in a higher education institution. Lecturers are required to conduct research which is one of the three main functions, besides teaching and serving the community. The research achievement target is in accordance with the research scheme chosen by the lecturer. Research results are the targets achieved by researchers from a research activity at the end of the period. Research does not only talk about the quantity of research productivity but also shows the quality of research in a higher education institution [1]. Therefore, the increase in research productivity, both quantity and quality must be measured, in order to know the extent of research progress in a higher education institution [2].

The increasing research productivity is strongly influenced by the environment and the involvement of stakeholders who have an interest in research [3]. This involvement is better known as collaboration. Research collaborations are carried out between one researcher or a group of researchers with other researchers. Each researcher comes from the same or different disciplines, or even different universities [4]. On a wide scale, research collaboration happens between countries, because distance is not a problem now [5]. In recent years, data mining-based knowledge management has been used as

the best approach to achieve the goals of an organization with a focus on knowledge creation [6]. One mechanism to increase research productivity is to use a knowledge-sharing approach that involves the role of academics in higher education [7]. The results of this study indicate that the involvement of academics in higher education in research productivity has a variance of 22.6 percent. This shows that the character of academics such as education degree, academic rank, and experience has a considerable influence on research productivity.

In higher education institutions, the data mining approach is the right solution for the analysis of very large research data. Through a data mining approach, researchers know which variables are significant in research productivity. These variables are then used as constructs to build a mechanism for increasing research productivity. The mechanism for increasing research productivity is formulated in the form of a model or framework. The framework development process starts from the preprocessing stage, by selecting the variables to be used. The role of the data mining approach in this case is as a tool for analysis or testing of the framework that has been built. Tests are carried out to determine the performance of the proposed framework. The analysis and testing process involves several data mining algorithms. Furthermore, a comparison of the test results using several data mining algorithms is carried out in order to obtain the best results. The results of this test also show the framework's performance from various points of view, because each data mining algorithm used in testing has different characteristics and approaches. Next is a discussion on research related to research productivity in higher education institutions, followed by an explanation of materials and methods, then results - discussion, and conclusion.

II. RELATED WORK

The framework is defined as mutually supporting parts to achieve a goal. The framework is analogous to a skeleton in the human body that is interconnected, mutually supportive, influencing one another. The framework has a clear direction of achievement, usually illustrated by an arrow to a point. Many researchers have developed frameworks for various needs. In the previous study, researchers built a research productivity framework by combining knowledge sharing and gamification-based variables [8][9]. Another example of developing a framework using knowledge sharing in a higher education environment has been carried out by some researchers [7]. Research productivity is used to determine the

*Corresponding Author

position of higher education institutions on a national and international scale. A mechanism is needed to optimize research productivity. Sample data were taken from tutors to professors in Malaysia with a ratio of 50:30:20 for senior lecturers: assoc. professor: professor.

Through the proposed knowledge management framework (KS), researchers have succeeded in proving that the role of academics, which 12 constructs, has a positive effect on research productivity. The 12 constructs used are commitment, social network, management support, social media, attitude, subjective norm, intention, and behavior, perceived behavior control, facilitating conditions, trust, and research productivity. The results showed that academic productivity has a variance of 22.6 percent. This suggests the academic behavior of KS has a large impact on research productivity. The academic attitude, academic commitment, trust, and social network explain the variance of 36.4 percent. Management support has a variance of 38.7 percent for subjective norms while facilitating conditions and social media have a variance of 26.5 percent for perceived behavioral control. Academics KS intention and KS behavior explain the variance of 62.1 and 47.1 percent, respectively.

The framework is composed of variables that are related to each other. The variable selection process starts with the selection of features from the dataset that has been collected. There are several studies and publications related to research productivity (Table I).

TABLE I. RELATED STUDY WITH RESEARCH PRODUCTIVITY

There are several studies related to optimization of research productivity [14]. One of them discusses the gap in the number of professors against other academics, students, or faculty members. In other words, students and faculty members need to be involved in research. The proposed model increases research productivity in higher education institutions. The idea of this model is to involve students and faculty members in intensive research through a curriculum design that focuses on research, which enables students and faculty members to participate in research projects sponsored by the industrial world.

Apart from research, the performance of a lecturer is measured based on the quality of teaching and service to the community. Research related to teacher performance has been conducted [15]. Through this research, several factors associated with teacher performance were tested. The factors that influence teacher performance are currently unclear, so

testing is needed to determine these factors. After the various factors are known, they are used to improve the quality of teacher performance in schools.

Researchers propose data mining-based classification and association models, such as decision trees, rule induction, K-NN, and Naïve Bayes to evaluate teacher performance in providing educational services in schools. Some of the attributes used in the test are teacher name, course, class, workspace, training, number of training, and several questions related to teacher performance in schools. The next step is the measurement of accuracy for the data mining method used. In addition to the use of data mining as previously stated, a data mining classifier is also used for various problem solutions such as performance prediction [16][17], performance improvement [18], or decision support system analysis which has been carried out by several researchers [19][20].

III. MATERIAL AND METHOD

The dataset in this research has been collected by the Ministry of Research and Technology Republic of Indonesia through the Science and Technology Index (SINTA) platform. SINTA was launched and has been actively used by academics since 2017. SINTA provides access to citations and scientific expertise in Indonesia. On its official website, SINTA is referred to as an information system used to measure the performance of researchers, including lecturers, and scientific journals in Indonesia. Apart from that, SINTA is a web based platform which is very easy to use. Another reason is because SINTA as an online database accommodates research data from lecturers from all over Indonesia, which is needed to carry out this research. The SINTA platform is equipped with a rating system for researchers and journals in Indonesia [21].

The framework testing process will use a data mining approach. In this study, data mining algorithms were used to measure the performance of the conceptual framework. Another goal is to find patterns and relationships between variables in the dataset. To accommodate the testing stage, this study applied the Cross-Industry Standard Process for Data Mining (CRISP-DM) methodology [22]. There are six stages in CRISP-DM [23], shown in Fig. 1.

A. Business Understanding

Business understanding is the first stage in CRISP-DM. At this stage, knowledge of business objects is required, an understanding of the scope of the problem, and how to obtain data. Activities undertaken in the business understanding stage include: (1) clearly defining goals and specifications, (2) translate goals and specifications, and (3) determine the boundaries of data mining problems. The next step is to prepare an initial strategy to achieve the goals.

B. Data Understanding

The data understanding stage begins with data collection, identifying data types, qualitative or quantitative, and measurement levels such as nominal, ordinal, binary, and interval [24]. At this stage an understanding of the dataset is needed, to determine properties such as variables or attributes used in modeling.

Fig. 1. CRISP-DM Methodology.

C. Data Preparation and Modeling

This stage begins with the identification of the variables used to build the framework. This process focuses on identifying significant variables toward the target variable and removing irrelevant or less important variables from the dataset. Irrelevant variables have a negative impact on the overall model performance. The details of the data preparation and modeling stages are shown in Fig. 2.

Variable selection is one of the core concepts which greatly affect the performance of the data mining model. Some of the advantages obtained by doing variable selection are: (a) reducing overfitting, (b) reducing training time, and most importantly, (c) increasing accuracy. There are three stages of variable selection carried out in this study: (a) univariate selection, (b) feature importance, and (c) correlation matrix.

In the univariate selection stage, the Chi-Square statistical test is used. Chi-Square is used to test the relationship between two variables. In other words, Chi-Square is used to measure how strong the relationship between variables [25][26]. In this study, the relationship tested is between the input variables and the target variables. Variables with a significant relationship value are used for the constructs of the framework. The character of Chi-Square always has a positive value. The formula for Chi-Square is:

$$X_c^2 = \sum \frac{(O_i - E_i)^2}{E_i} \quad (1)$$

Where, c = degrees of freedom, O = observed value(s), and E = expected value(s). If data from two variables are given, the observed number (O) and the expected number (E) are obtained. Chi-Square measures the deviation between the expected number E and the observed number O .

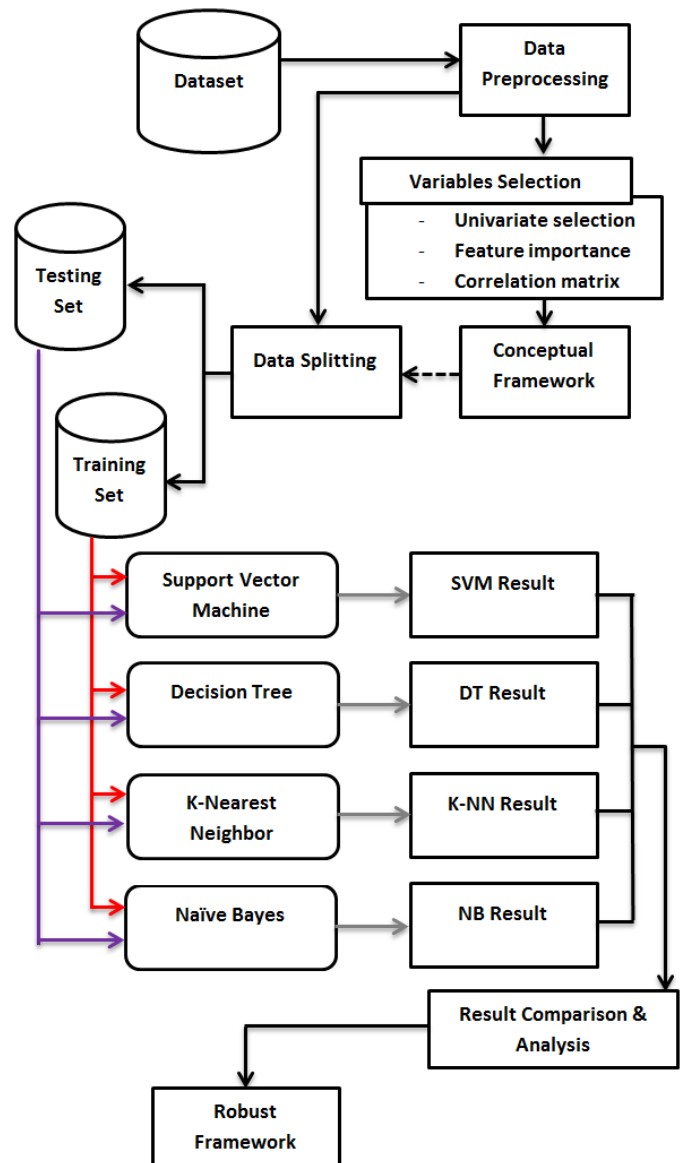

Fig. 2. Data Preprocessing and Modeling.

After the univariate selection stage, it is followed by the feature importance stage. Feature importance is similar to information gain, which extracts the information level (weight) of a feature or variable [27][28]. The results of the selection using feature importance show the score for each variable. The higher the score of a variable, the more relevant or important it is to the target variable. Feature importance uses a Tree-based classifier. In this study, the Extra Tree Classifier used to extract the important variables from the prepared dataset [29]. The correlation matrix shows the correlation between input variables with other input variables or input variables to the target variable. Correlation can be positive if an increase in the Input variable has an impact on an increase in the target variable, or conversely, an increase in the input variable decreases the target variable. Unlike univariate selection (Chi-Square), the correlation matrix can be negative. The correlation matrix test is usually visualized with a heat map. The heat map shows the variables most

related to the target variable and vice versa. After obtaining the relevant variables, the next steps are broken down into two stages: (a) building a conceptual framework, (b) dividing the sample. The sample will be divided into two parts, with a ratio of 70:30, 70 percent for training, and 30 percent for validation. Training and testing data are used as modeling input. This modeling stage is a test for the conceptual framework. In this testing phase, four data mining algorithms are used, Support Vector Machine (SVM), Decision Tree, K-Nearest Neighbor, and Naïve Bayes. This testing phase shows the framework's performance from various points of view because each data mining algorithm used in testing has different characteristics and approaches. The next step is to compare the test results to get the best results.

D. Evaluation and Deployment

The confusion matrix is used to determine the best model. By looking at the confusion matrix value, the accuracy of each model is known. Classification is included in supervised learning, which is a predictive model where the prediction results are discrete. The way to measure the performance of the classification model is to compare the actual value with the predicted value. The confusion matrix is a performance measurement for machine learning classification problems, where the output is two or more classes [30]. The Confusion Matrix is a table with four different combinations of predicted and actual values [31]. There are four terms that represent the results of the classification process in the confusion matrix, True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). Based on the Confusion Matrix, the formula for accuracy is obtained:

$$Accuracy = \frac{(TP+TN)}{(TP+FP+FN+TN)} \quad (2)$$

Accuracy shows how accurate the model is in classifying correctly.

$$Precision = \frac{(TP)}{(TP+FP)} \quad (3)$$

Precision shows the accuracy between the actual data and the prediction results displayed by the model.

$$Sensitivity = \frac{TP}{(TP+FN)} \quad (4)$$

Recall or sensitivity shows the success of the model in retrieving information.

$$F - Measure = \frac{(2*Recall*Precision)}{(Recall+Precision)} \quad (5)$$

F-Measure (f1-score) shows the weighted average comparison of precision and recall [32]. Accuracy is appropriate to use as a reference for the performance of the classification method if the dataset has a very symmetric amount of FN and FP data. However, if the numbers are not symmetric, it is suggested to use the F-Measure as a reference.

IV. RESULT AND DISCUSSION

At an early stage, candidates for the variables are defined as shown in Table II.

The next step is an analysis of the candidate variables. The analysis focuses on the relevance and ease of obtaining data

for each variable. Based on the analysis, there are several variables that cannot be used: (1) Working hours, the obstacles faced are difficulties in getting information about working hours, (2) Marital status, because this information is personal, so researcher prefers not to use it, (3) SINTA's score, is optional because the calculation of the score comes from the number of articles and the number of citations, which the variables have been determined, (4) Experience, there is no valid data yet for research experience. After defining the variables, the next step is variable selection.

TABLE II. CANDIDATE VARIABLE

Variable Name	Variable Description	Measurement Level
Degree (D)	Lecturer education degree	Nominal (Master, Doctor)
Gender (G)	Lecturer's gender	Binary(Male, Female)
Working hours (WH)	Type of working hours	Ordinal (Part time, Full Time)
Nationality (N)	Nationality	Nominal (Indonesia, Non Indonesia)
Rank (R)	Lecturer's rank	Ordinal (Lecturer, Assist Prof, Assoc Prof, Full Prof)
Marital Status (MS)	Lecturer's marital status	Nominal (Single, Married, Widowed)
Conference (CO)	The total number of attended conferences	Ordinal (Never, Ever, Often)
Article (A)	The total number of published articles on Scopus	Ordinal (None, Very Few, Few, Enough, Much)
Citation (C)	The total number of citations for the published articles on Scopus	Ordinal (None, Few, Many, Very Much)
Intellectual Property Rights (IPR)	The total number of IPR registered	Ordinal (None, Few, Many)
Experience (E)	Research experience	Ordinal (Inexperienced, Short Time, Long Enough, Very Experienced)
Research grantee (RG)	Lecturers who receive research grants	Ordinal (Yes, No)
Grant (GT)	The total number of grants obtained	Ordinal (None, Few, Many, Very Much)
SINTA's score (SS)	Lecturer's SINTA score	Ordinal (Low, Medium, High, Very High).
Research Productivity (RP)	Target variable	Binary (Fulfilled, Not Fulfilled)

A. Univariate Selection

Univariate selection is used to select the variable with the strongest relationship toward the target variable. Chi-Square statistical testing shows the results of the selection in order, as shown in Table III.

The test results show that Article (A) is in the first rank. This shows Article (A) has the strongest relationship toward the target variable, followed by Citation (C), Conference (CO), Grant (GT), and others. The results of this test also show the number of articles and the number of citations,

which play an important role in measuring the research performance of a lecturer. Then, for the two lowest ranks, it turns out that Gender (G) has the weakest relationship toward the target variable. In other words, Gender (G) does not have a significant effect on research productivity. Nationality (N) is in the lowest rank, because all lecturers are from Indonesia. This variable does not make a significant difference to the target variable. Variables with a score below 1 are not used in building the proposed framework, so only eight input variables and one target variable remain.

TABLE III. UNIVARIATE SELECTION

No	Variable Name	Chi-Square Score
1	Article (A)	76.533603
2	Citation (C)	47.256279
3	Conference (CO)	45.680553
4	Grant (GT)	22.205091
5	IPR	5.002761
6	Rank (R)	4.027538
7	Research grantee (RG)	2.538671
8	Degree (D)	1.129551
9	Gender (G)	0.118249
10	Nationality (N)	0.000000

B. Feature Importance

Through the feature importance stage, it is possible to know the importance of each variable. The higher the score of a variable, the more relevant or important it is to the target variable. The results of feature importance using the Extra Tree Classifier are shown in Fig. 3.

The selection of feature importance shows Article (A) is in the first rank, with the value 0.3447, followed by Conference (CO) and Citation (C). This measurement shows Article (A) is the variable most relevant to the target variable. Overall, the test results using feature importance are not different from the univariate selection, where the two lowest ranks are Research Grantee (RG) and Nationality (N). These two variables are the least relevant to the target variable. There is a difference in the bottom two variables between univariate selection and feature importance. As a solution, the third step was carried out, the correlation matrix.

C. Correlation Matrix

Correlation can be positive if an increase in the Input variable has an impact on an increase in the target variable, or conversely, an increase in the input variable decreases the target variable. The correlation matrix results using heat maps are shown in Fig. 4 and Fig. 5. Heat maps showing the correlation between input variables with other input variables or input variables for the target variable. Like the two previous

steps, Nationality (N) and Gender (G) have poor correlation with other variables. Even Nationality does not have a correlation (zero correlation) with other variables. Gender (G) still has a correlation. Although the correlation to the target variable is the lowest when compared to others. The correlation of Gender (G) to the target variable is 0.046. Even Gender (G) has a negative correlation with Article (A), Research Grantee (RG), and Grant (GT). For other variables, the correlation to the target variable is still > 0.2 (Table IV).

Article (A) has the highest correlation to the target variable, 0.77, followed by Citation (C) of 0.67. The average score of Article (A) on other input variables is very high, thus increasing its correlation to the target variable. The significant difference compared to the previous stage is that Degree (D) and IPR have a low correlation score. This happens because the correlation of Degree (D) and IPR for other input variables is very low so that it affects their correlation to the target variable. However, it is still fair to use as a construct for the proposed framework.

After getting the input and target variables, the next step are to build the framework. Fig. 6 shows the conceptual framework.

Framework consists of eight input variables and one target variable. The eight input variables are Article (C), Conference (CO), Grant (GT), Research Grantee (RG), Rank (R), Degree (D), IPR, and Citation (C). The target variable is Research Productivity (RP). The framework that has been built must be tested first. The data mining approach was chosen as a testing tool because it is in accordance with the characteristics of the dataset that has been prepared. In this testing phase, four data mining algorithms are used, Support Vector Machine (SVM), Decision Tree (DT), K-Nearest Neighbors (K-NN), and Naive Bayes (NB). The classification results using data mining algorithms tested using confusion matrix-based measurement. The test results using the confusion matrix-based measurement (accuracy, precision, sensitivity, f1-measure) are shown in Table V.

Fig. 3. Feature Importance.

Fig. 4. Correlation Matrix (Include Gender and Nationality).

TABLE IV. THE CORRELATION OF INPUT VARIABLES TOWARD TARGET VARIABLE

No	Variable Name	Correlation Score
1	Article (A)	0.77
2	Citation (C)	0.67
3	Conference (CO)	0.62
4	Grant (GT)	0.41
5	Research grantee (RG)	0.36
6	Rank (R)	0.27
7	Degree (D)	0.24
8	IPR	0.21

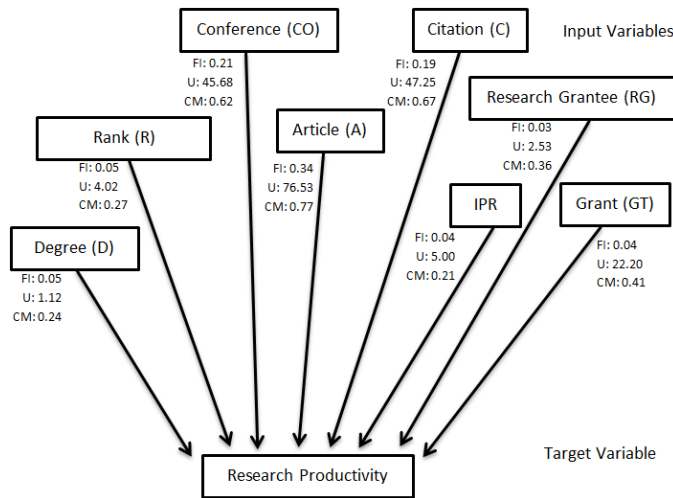

Fig. 6. Conceptual Framework.

TABLE V. ACCURACY, PRECISION, SENSITIVITY, F-MEASURE AND MISCLASSIFICATION RATE FOR 4 ALGORITHMS

Classifier	Accuracy	Precision	Sensitivity	f1-Score	Misclass. rate
SVM	78.26%	85.29%	77.27%	76.67%	21.74%
DT	86.95%	87.12%	87.12%	86.95%	13.05%
K-NN	95.65%	96.15%	95.45%	95.61%	4.35%
NB	86.95%	90.00%	86.36%	86.54%	13.05%

The testing result shows the proposed framework is able to obtain high accuracy scores for each classification algorithm. The highest accuracy score on the K-NN classification algorithm is 95.65 percent, followed by Decision Tree and Naïve Bayes, each with 86.95 percent; the last is Support Vector Machine at 78.26 per cent. Just like the accuracy score, for the measurement of precision, sensitivity, F-Measure, the K-NN algorithm is also the highest, with the lowest misclassification rate, only 4.35 percent. The results of confusion matrix-based testing prove that the proposed framework is relevant to use, with high accuracy scores and little misclassification rate. When compared with the results of other related research tests regarding research productivity, the position of the results of this test is (Table VI).

TABLE VI. THE COMPARISON OF VARIABLES, ALGORITHM, AND ACCURACY OF CLASSIFICATION TESTING RESULTS

Author Name	Variables Used	Algorithm Used	Accuracy
Henry <i>et al.</i> [10]	Age Cohort, Highest Qualification, Cluster, Lecturer Track, Achievement, Job Policy, Monthly Income, Research Leadership, Research Supervision	Logistic Regression	78.2%
Ramli <i>et al.</i> [11]	Age, Gender, Marital Status, Qualification, Experience, Position, Division, Citation, Article, Conference, and Target (Status of Research Performance)	Logistic Regression	80.31%
		Decision Tree	83.40%
		Artificial Neural Network	82.24%
		Support Vector Machine	80.47%
Nazri <i>et al.</i> [12]	Age, Designation, No. Research Grant, Gender, Performance Score, Marital Status, Working Status, Amount of Grant, Department, Administrative Post, No. PhD Student, Faculty, Invitation as Keynote Speaker, Article (Index)	Decision Tree	70.30%
		PART	75.00%
		J-48	75.30%
		C4.5	70.20%
Wichian <i>et al.</i> [13]	Age, Academic Position, Thinking, Research Mind, Volition - Control, Meeting of International, Research Skill - Techniques, Research Fund, Research Management, Communication, Networking and Teamwork, Institutional Policy, Library Expenditure, Computing Facility	Neural Network (Back Propagation)	90.72%
Sanmorino <i>et al.</i> (this study)	Article, Conference, Grant, Research Grantee, Rank, Degree, IPR, Citation, and Target (Research Productivity)	Support Vector Machine	78.26%
		Decision Tree	86.95%
		K-Nearest Neighbors	95.65%
		Naïve Bayes	86.95%

There are differences in the combination of algorithms, variables and the number of datasets used that affect the performance of the classification algorithm, but this study has proven that the framework designed based on the variable selection has a relevant good accuracy score. Researchers cannot say that the results of this test are better than other related studies. To prove the test results of a study are better than other studies, the same scenario must be used, in the sense of where to collect the data, the number of datasets, the mechanism for selecting variables, the number of variables must all be the same, because they can affect the test results.

V. CONCLUSION

The framework development process starts from collecting datasets and determining candidate variables. The next process is to determine the selected variable from the candidate

variable. Variable selection is carried out in three stages, univariate selection, feature importance, and correlation matrix. After the variable selection stage, eight input variables and one target variable were obtained. The eight input variables are Article (C), Conference (CO), Grant (GT), Research Grantee (RG), Rank (R), Degree (D), IPR, and Citation (C). The target variable is Research Productivity (RP). This selected variable is used to build the framework. The next step is to test the framework that has been built. The testing process involves four data mining classifiers. The classification results are tested using confusion matrix-based testing, accuracy, precision, sensitivity, and f1-measure. The testing results show the proposed framework is able to obtain high accuracy scores for each classification algorithm. It means the proposed framework is relevant to use. There are several things recommended for future work, such as increasing the number of datasets, using other variables relevant to research productivity, such as research collaboration, teamwork, or research facilities in a higher education institution.

Method for Determination of Support Length of Daubechies Basis Function for Wavelet MRA based Moving Characteristic Estimation

Kohei Arai

Faculty of Science and Engineering
Saga University, Saga City
Japan

Abstract—Method for determination of support length of Daubechies basis function for wavelet Multi Resolution Analysis: MRA based moving characteristic estimation is proposed. The method based on root mean square difference between original and reconstructed image from just a low frequency component from MRA. Also, one of applications of the method for detection and tracking of moving targets, typhoon and boundary between warm and cold current observed from satellite remote sensing images is shown. It is found that the proposed method allows to detect and to track for moving targets of a typhoon and a boundary in the time series of GOES images.

Keywords—Multi-dimensional wavelet transformation; multi resolution analysis: MRA; moving target detection; support length; typhoon movement; boundary detection and tracking

I. INTRODUCTION

Moving characteristics such as velocity and vibration of moving objects are being analyzed by taking advantage of the characteristics of time-frequency analysis by wavelet analysis [1]. Especially, the estimation of the moving vector of the moving object with the multi-resolution analysis based on the Daubechies basis function with the finite length support (compact support), which is widely used for the detection of the moving object because of its short support length Has been proposed [2].

A wavelet is a spatial frequency filter, and although it is desirable that its support has a finite length, in many cases the support length is infinite [3]. The Daubechies basis function is a finite length support, and its support length is short, so it is applied to moving object detection. However, there is no report that mentions how to select the optimum support length suitable for the moving speed.

From the viewpoint of making the complexity of the model that expresses the phenomenon appropriate, studies have been conducted on the optimization of base functions based on the information theory evaluation criterion Minimum Description Length: MDL [4].

It is designed to select the basis function that minimizes the code length for data representation. After that, there was a proposal for optimization based on Akaike's Information Criteria: AIC [5]. This optimization method deals with the entire basis function and is suitable for constructing filters such as noise removal. This paper proposes a method to select the

optimum support length for the moving speed of a moving object. The validity of the proposed method has been confirmed by taking typhoons and tides with different moving speeds estimated from time-series data of geostationary meteorological satellite images as examples.

Methods related to wavelet analysis, in particular, detection of moving objects [6] and estimation of movement parameters [7] based on continuous and discrete wavelet transforms and multiresolution analysis [8] have been proposed [9,10]. Also proposed are a method that considers tracking of a moving object using a Kalman filter [11] and a method that considers the selection of wavelet parameters that match the motion of the analysis target [12]. Method for support length determination of base function of wavelet for edge and line detection as well as moving object and change detections is proposed [12].

On the other hand, method for car in dangerous action detection by means of wavelet Multi-Resolution Analysis based on appropriate support length of base function is proposed [13]. Meanwhile, prediction method of El Nino Southern Oscillation event by means of wavelet-based data compression with appropriate support length of base function is proposed [14]. Bright band height assignment with precipitation radar data based on Multi-Resolution Analysis: MRA of wavelet analysis is also proposed [15].

Applying a basis function to multidimensional time series data and transforming it into the time-frequency domain is called Discrete Wavelet Transformation (DWT), and its inverse is called Inverse Discrete Wavelet Transformation (IDWT). A method for estimating the movement vector of a moving object from time-series image information using the Daubechies basis function (complete orthonormal system) that can be completely restored by these is proposed. At this time, it is considered that the method for determining the support length of the basis function has not been determined.

This depends on the frame rate of the moving image to be acquired and the moving characteristics (change rate) of the moving object. Although the optimal support length can be determined if the movement characteristics are known, it is customary that the movement characteristics to be obtained are not given in advance. Therefore, a method for determining the optimum support length by some method is required.

Here, the author proposes an experimental method for determining the optimal support length. That is, some support length candidates that are considered to be appropriate are selected (for example, 2, 4, 8, 16 etc.), DWT based on the Daubechies basis function of those support lengths is applied to only one stage, and then low frequency is applied. Reconstruction (IDWT) is performed using only the components, and the root mean square error (RMSE) of the reconstructed data and the original data is evaluated, and this is the method that maximizes the maximum support length.

Since the energy (power spectrum) of the analysis target data is invariant, when this RMSE is large, it means that the high frequency components could be extracted efficiently. Therefore, it means that the change (movement) component was effectively extracted by DWT / IDWT. The author shows the validity of this proposed method by introducing some examples.

As an application example of the proposed method, a relatively steeply moving typhoon and a relatively slowly changing tide are taken from Geostationary Operational Environmental Satellite (GOES) visible band images acquired on the hourly basis. Determine the optimal support length of Daubechies basis functions for moving analysis of.

The DWT based on this basis function is applied to the original image to separate the original image into low-frequency and high-frequency components, the low-frequency components are removed and reconstructed to extract edges, and the extracted edge time-series data is obtained.

The method of estimating the movement vector is tried based on this. As a result, it was confirmed that the desired edge could be extracted by DWT and IDWT based on the support length basis function determined based on the proposed method, and it was confirmed that it was effective for the detection and movement tracking of typhoons and tides.

Section 2 describes related research works. Section 3 details the method of constructing basis functions and the definition of their support length. Section 4 proposes the proposed method for analyzing the moving characteristics of moving objects, and Section 5 introduces the above-mentioned case to show that the optimum support length exists and how to obtain it. Finally, the conclusion is stated.

II. RELATED RESEARCH WORKS

As for wavelet analysis related research works, bright band height assignment with precipitation radar data based on Multi-Resolution Analysis: MRA of wavelet analysis is conducted [16]. Also, improvement of secret image invisibility in circulation image with Dyadic wavelet based data hiding with run-length coding is achieved [17].

Extraction of line features from multifidus muscle of CT scanned images with morphological filter together with wavelet multi resolution analysis is made [18]. On the other hand, CO₂ concentration change detection in time and space domains by means of wavelet analysis of MRA: Multi Resolution Analysis is conducted [19].

Polarimetric SAR image classification with high frequency component derived from wavelet multi resolution analysis: MRA is proposed [20]. Meanwhile, embedded object detection with radar echo data by means of wavelet analysis of MRA: Multi Resolution Analysis is conducted [21].

Maximum entropy method based blind separation by means of neural network with feature enhancements by wavelet analysis is proposed [22]. On the other hand, method for support length determination of base function of wavelet for edge and line detection as well as moving object and change detections is proposed [23].

Human gait gender classification using 2D discrete wavelet transforms energy is conducted [24]. Meanwhile, visualization of 3D object shape complexity with wavelet descriptor and its application to image retrievals is attempted together with visualization of 3D object shape complexity with wavelet descriptor and its application to image retrievals [25].

Wavelet based image retrieval method is proposed [26]. Meanwhile, DP matching based image retrieval method with wavelet Multi Resolution Analysis: MRA which is robust against magnification of image size is conducted [27]. On the other hand, wavelet based change detection for four dimensional assimilation data in space and time domains is attempted [28].

Method for image source separation by means of independent component analysis: ICA, Maximum Entropy Method: MEM, and wavelet based method is attempted [29]. On the other hand, identification of ornamental plant functioned as medicinal plant based on redundant discrete wavelet transformation is conducted [30].

Method for object motion characteristics estimation based on wavelet Multi-Resolution Analysis: MRA is proposed [31]. Also, identification of ornamental plant functioned as medicinal plant based on redundant discrete wavelet transformation is attempted [32].

Comparative study on discrimination methods for identifying dangerous red tide species based on wavelet utilized classification methods is conducted [33]. On the other hand, identification of ornamental plant functioned as medicinal plant based on redundant discrete wavelet transformation is conducted [34].

Method for car in dangerous action detection by means of wavelet Multi-Resolution Analysis based on appropriate support length of base function is proposed [35]. Meanwhile, improvement of automated detection method for clustered micro calcification base on wavelet transformation and support vector machine is conducted [36].

Prediction method of El Nino Southern Oscillation: ENSO event by means of wavelet based data compression with appropriate support length of base function is proposed [37]. Meanwhile, method for data hiding based on Legall 5/2 (Cohen-Daubechies-Feauveau: CDF 5/3) wavelet with data compression and random scanning of secret imagery data is proposed [38].

Image retrieval and classification methods based on Euclidian distance between normalized features including wavelet descriptor are proposed [39]. On the other hand, gender classification method based on gait energy motion derived from silhouettes through wavelet analysis of human gait moving pictures is proposed [40].

Multifidus muscle volume estimation based on three dimensional wavelet Multi Resolution Analysis: MRA with buttocks Computer Tomography: CT images is conducted [41]. In a meantime, method for object motion characteristics estimation based on wavelet Multi resolution Analysis: MRA is also proposed [42].

Gender classification method based on gait energy motion derived from silhouette through wavelet analysis of human gait moving pictures is proposed [43]. On the other hand, method for object motion characteristics estimation based on wavelet Multi resolution Analysis: MRA is proposed [44].

Comparative study of feature extraction components for several wavelet transformations for ornamental plants is conducted [45]. Meanwhile, human gait gender classification using 3D discrete wavelet transformation feature extraction is attempted [46].

Image retrieval method utilizing texture information derived from Discrete Wavelet Transformation: DWT together with color information is proposed [47]. Meanwhile, noble method for data hiding using steganography Discrete Wavelet Transformation: DWT and cryptography triple Data Encryption Standard: DES is proposed [48].

Phytoplankton discrimination method with wavelet descriptor based shape feature extraction from microscopic images is proposed [49]. Also, change detection method with multi-temporal satellite images based on wavelet decomposition and tiling is proposed [50]. On the other hand, circle feature extraction from remote sensing satellite images based on polar coordinate representation of wavelets is conducted [51].

III. DISCRETE WAVELET TRANSFORMATION WITH BI-ORTHOGONAL DAUBECHIES BASIS FUNCTION

A. Discrete Wavelet Transformation

The Discrete Wavelet Transformation: DWT of a given discrete scalar signal $\eta = (\eta_1, \eta_2, \dots, \eta_n)^T$ is described as $C_n \eta$ by a square matrix C_n composed of a sequence $\{p_k\}$ and a sequence $\{q_k\}$. p_i is for low-frequency components, coefficient q_i is for high-frequency components, C_n divides f into low-frequency components and high-frequency components.

The given scalar time series is divided into low frequency components and high frequency components by DWT. At this time, for example, the DWT for eight elements having a support length of 2 becomes Eq. (1), and when the support length is 4, it becomes Eq. (2).

$$C_8^{[2]} = \begin{bmatrix} \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \\ \eta_6 \\ \eta_7 \\ \eta_8 \end{bmatrix} = \begin{bmatrix} p_0 & p_1 & \dots & & & & & \\ q_0 & q_1 & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & p_0 & p_1 & & \\ & & & & q_0 & q_1 & & \\ & & & & & & & \\ & & & & & & & \end{bmatrix} \begin{bmatrix} \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \\ \eta_6 \\ \eta_7 \\ \eta_8 \end{bmatrix} = \begin{bmatrix} p_0\eta_1 + p_1\eta_2 \\ q_0\eta_1 + q_1\eta_2 \\ p_0\eta_3 + p_1\eta_4 \\ q_0\eta_3 + q_1\eta_4 \\ p_0\eta_5 + p_1\eta_6 \\ q_0\eta_5 + q_1\eta_6 \\ p_0\eta_7 + p_1\eta_8 \\ q_0\eta_7 + q_1\eta_8 \end{bmatrix} \quad (1)$$

$$C_8^{[4]} = \begin{bmatrix} \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \\ \eta_6 \\ \eta_7 \\ \eta_8 \end{bmatrix} = \begin{bmatrix} p_0 & p_1p_2 & p_3 & \dots & & & & \\ q_0 & q_1q_2 & q_3 & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & p_0 & p_1p_2 & p_3 \\ & & & & & & q_0 & q_1q_2 & q_3 \\ & & & & & & & & \\ & & & & & & & & \end{bmatrix} \begin{bmatrix} \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \\ \eta_6 \\ \eta_7 \\ \eta_8 \end{bmatrix} =$$

$$\begin{bmatrix} p_0\eta_1 + p_1\eta_2 + p_2\eta_1 + p_3\eta_2 \\ q_0\eta_1 + q_1\eta_2 + q_2\eta_1 + q_3\eta_2 \\ p_0\eta_3 + p_1\eta_4 + p_2\eta_3 + p_3\eta_4 \\ q_0\eta_3 + q_1\eta_4 + q_2\eta_3 + q_3\eta_4 \\ p_0\eta_5 + p_1\eta_6 + p_2\eta_5 + p_3\eta_6 \\ q_0\eta_5 + q_1\eta_6 + q_2\eta_5 + q_3\eta_6 \\ p_0\eta_7 + p_1\eta_8 + p_2\eta_7 + p_3\eta_8 \\ q_0\eta_7 + q_1\eta_8 + q_2\eta_7 + q_3\eta_8 \end{bmatrix} \quad (2)$$

The coefficients of base functions with different That is, the support length is different even if the order is the same. This is called a two-dimensional DWT. Similar to the two-dimensional DWT, the three-dimensional DWT is realized by performing filter processing on each dimension as shown in Fig. 1. Furthermore, multivariate multidimensional DWT is performed by filtering the dimension of each variable.

B. Support Length

Daubechies support lengths are obtained as solutions of simultaneous equations as shown in the following,

Fig. 1. 3D Discrete Wavelet Transformation (3D DWT).

When the base function is Daubechies and the support length is 2, the coefficient is obtained by solving the simultaneous equations of Eq. (3). When the support length is 4, the coefficient is obtained so as to satisfy Eq. (4). Further, in the case of an arbitrary support length (Sup), the coefficient of the basis function can be obtained by solving Eq. (5) simultaneously.

$$\begin{aligned} C_n^{[2]T} C_n^{[2]} &= I_n \\ p_0 + p_1 &= \sqrt{2}, \\ q_0 = p_1, q_1 &= -p_1, 0^0 q_0 + 1^0 q_1 = 0 \end{aligned} \quad (3)$$

$$\begin{aligned} C_n^{[4]T} C_n^{[4]} &= I_n \\ p_0 + p_1 + p_2 + p_3 &= \sqrt{2}, \\ q_0 = p_3, q_1 &= -p_2, q_2 = p_1, q_3 = -p_0, \quad 0^0 q_0 + 1^0 q_1 = 0 \\ 0^0 q_0 + 1^0 q_1 + 2^0 q_2 + 3^0 q_3 &= 0 \\ 0^1 q_0 + 1^1 q_1 + 2^1 q_2 + 3^1 q_3 &= 0 \end{aligned} \quad (4)$$

$$\begin{aligned} C_n^{[sup]T} C_n^{[sup]} &= I_n \\ \sum_{j=0}^{sup-1} p_j &= \sqrt{2}, \\ q_j &= (-1)^j p_{(sup-1)-j}, j = 0,1,2, \dots, (sup - 1) \\ \sum_{j=0}^{sup-1} j^r q_j &= 0, r = 0,1,2, \dots, (\frac{sup}{2} - 1) \end{aligned} \quad (5)$$

This is called a two-dimensional wavelet transform. The three-dimensional wavelet transform is realized by performing a filtering process on each dimension, like the two-dimensional wavelet transform. Furthermore, the multivariate multidimensional wavelet transform is performed by filtering the dimension of each variable.

C. Multi Dimensional Discrete Wavelet Transformation

By applying the DWT based on the basis function obtained by the above method to the two-dimensional image data, it is possible to obtain an arbitrary frequency component included in the image. In addition, in the case of time-series image data of moving images, it is possible to investigate any frequency component at any time by applying 3D DWT.

Detection of a moving object included in moving image data, tracking, and analysis of movement characteristics are performed by the following procedure. First, the 2D image of each frame number of the moving image is filtered in the horizontal direction of the target 2D image, and divided into two regions of low frequency component (L component) and high frequency component (H component).

Next, filter processing is performed in the vertical direction of each of these two areas. By the above processing, the two-dimensional discrete signal is divided into four (LL component, LH component, HL component, HH component). This is the two-dimensional DWT. Here, if f is the one-dimensional scalar time-series data and F is the spectrum data after DWT, DWT is expressed by Eq. (6).

$$F=Cnf \quad (6)$$

Since the discrete wavelet transform based on Daubechies basis function is considered,

$$CnCn^T=I \quad (7)$$

Therefore, the original time series data can be completely restored by reconstructing after division (reverse transformation after transformation). Also, the 3D DWT for $f_{x,y,z}$ of 3D data is as follows,

$$F=[Cn[Cm[CIf_{x,y,z}]^T]^T]^T \quad (8)$$

The change can be extracted by applying IDWT only to the high frequency components after DWT. For example, if DWT is applied to a two-dimensional image and IDWT is performed with the elements of the LL and LH or LL and HL components set to 0, the two-dimensional reconstructed image extracts vertical or horizontal change (moving) components. It has been done.

The three-dimensional reconstructed image is also obtained by applying the three-dimensional DWT of Fig. 1 to the three-dimensional moving image data for the change component in the time axis direction and performing IDWT with the LLL and LHL or LLL and HLL component elements set to 0. Means that the time change of the vertical or horizontal change (movement) component is extracted.

D. Moving Characteristic Estimation

The moving direction and moving speed are obtained through the above process. At this time, the DWT based on the Daubechies basis function can accurately extract the spatiotemporal changes of the moving object. At that time, it is necessary to appropriately select the basis function to be used and its support length. The basis function may be a perfect orthonormal system, but the support length depends on the movement characteristics to be extracted and the frame rate in moving image acquisition, so the best choice is desired.

E. Method for Optimum Support Length Determination

The Daubechies basis function is selected because it is necessary to be able to completely restore by wavelet transformation and inverse transformation for the movement tracking analysis of the object. The optimum support length differs depending on the movement characteristics of the object and the image acquisition conditions. If the low frequency component is extracted by applying DWT to the multidimensional time series data with time axis and the Root Mean Square Error: RMSE between it and the original image is small, it can be said that the edge component (high frequency component) included in the original image is small. If this difference is large, it means that the edge was extracted most efficiently.

Therefore, in order to determine the optimal support length for edge extraction, DWTs with different support lengths are applied one stage, and the RMSEs of the resulting low-frequency component image and the original image are examined, and this is the optimal support length with a large support length. Propose a method of lengthening. Attention should be paid to the effect of noise enhancement associated with edge extraction.

Wavelet analysis has the function of a filter bank, and it is possible to select the optimum part of the filter bank by adjusting the support length. It is necessary to optimize the support length to prevent the noise from being overemphasized.

This support length depends on the moving speed of the object and the observation speed, and if the observation conditions are the same, there is a support length suitable for the moving speed of the object. That is, qualitatively, it can be said that a basis function with a long support length is suitable for analyzing a phenomenon in which an object moves fast, and conversely, a short support length is suitable for an object moving slowly. Since temporal and spatial changes are generally irrelevant, the author first proposes a method for determining the optimal support length in the image space, and then determining the optimal support length on the time axis.

IV. EXPERIMENT

Here, typhoon and tide detection in GOES images and movement tracking analysis are illustrated as an example of change characteristic analysis by DWT based on Daubechies basis function for change phenomenon of time series data of 2D image.

A. GOES Data used in the Experiment

The author selected the following typical typhoons with fast moving speeds and typical tides off Sanriku with relatively slow moving speeds, and obtained the support lengths of the optimum basis functions for each moving speed.

1) Typhoon: IR1 (10.2-11.2 μm) data of the meteorological satellite GOES-9 acquired on an hourly basis from October 17, 2004, 19:00 (JST) to October 19, 02:00 (JST).

2) Tide: IR1 (10.2-11.2 μm) data of the meteorological satellite GOES-9 acquired on an hourly basis from 00:00 (JST) on October 13, 2008 to 07:00 (JST) on October 14th, 2008.

These images have an image size of 640 x 480 pixels and an image file format PGM (Portable Gray Map). From the data, the area around the typhoon and off Sanriku was extracted as an image size of 256 x 265 pixels and used for the experiment. Some GOES images of typhoons and tides are shown in Fig. 2(a) and (b), respectively.

B. Optimal Support Length Determination Method for Edge Extraction based on RMSE between Reconstructed Image and Original Image by DWT / IDWT

DWT based on Daubechies basis functions with support lengths of 2, 4, 8 and 16 was applied, IDWT was performed using only the LL component, and the RMSE with the original image was evaluated. The reconstructed image and RMSE are shown in Fig. 3 (a) and (b). In the figure, each data indicates the RMSE in each frame.

In the case of the typhoon (a), the RMSE is large up to the first 3 frames and from the last 3 frames, and it can be seen that the time change is sharp. It is also clear that the RMSE of the tide of (b) is low overall, the RMSE is large from the beginning up to about 8 frames, and there is a sharp temporal change with the movement of clouds. It can be seen that the time change is extremely low in the subsequent frames, and there is little movement of the tide.

The average and standard deviation of RMSE are shown in Table I(a) and (b). From these, it can be seen that the optimum support length is 8 for each of the typhoons and the tides off Sanriku, since the flatness of the RMSE is the largest.

C. Verification of the Proposed Method by the Number of Extracted Edge Pixels

A threshold of 240 DN (maximum pixel value); the extracted edge image obtained by binarization using 255 DN) is shown in Fig. 4(a) and (b). Table II shows the average and standard deviation of the number of edge pixels extracted by DWT / IDWT with the support length changed to 2, 4, 8 and 16.

(a) GOES IR-1 imagery data of the typhoon acquired during from 19:00 on October 17 to 2:00 on October 19 in 2004

(b) GOES IR-1 imagery data of current rip in Sanriku offshore acquired during from 0: 00 on October 13 to 7: 00 on October 14 in 2004

Fig. 2. The Time Series of Original GOES Imagery Data (32 Frames) of Japanese Vicinity.

(a)Typhoon

(b) Current rip in Sanriku offshore.

Fig. 3. RMSE between the Original and Reconstructed Images without LL Component by using Discrete Wavelet Transformation based on Daubechies Mother Wavelet Function with the different Support Length.

TABLE I. AVE.: AVERAGE AND STD.: STANDARD DEVIATION OF RMSE: ROOT MEAN SQUARE ERROR BETWEEN THE ORIGINAL IMAGE AND RECONSTRUCTED IMAGE WITHOUT LL COMPONENT FROM THE TRANSFORMED IMAGE WITH DISCRETE WAVELET TRANSFORMATION BASED ON DAUBECHIES MOTHER WAVELET FUNCTION WITH SUPPORT LENGTH OF 2, 4, 8 AND 16

(A) TYPHOON

SupportL.	2	4	8	16	
Ave.	RMSE	8.612	8.629	8.950	8.513
Std.	RMSE	2.376	2.759	2.989	2.547

(B) CURRENT RIP IN SANRIKU OFFSHORE

SupportL.	2	4	8	16	
Ave.	RMSE	3.574	3.594	3.741	3.487
Std.	RMSE	2.525	2.443	2.411	2.444

From Table II(a), the optimum support length for edge extraction and movement analysis for the tide off Sanriku is considered to be 2 (when the support length is 2, the number of flat edge pixels is 0.5% compared to when the support length is 8.

(a) Typhoon in the southern China sea of ocean area

(b) Current rip in Sanriku offshore

Fig. 4. Example of Detected Edge Images of(a) Typhoon and (b) Current Rip in Sanriku offshore Obtained from Binarized Images with the Threshold of 240 Digital Number: DN (255 in Maximum DN)of Reconstructed Images without LL Component after the Discrete Wavelet Transformation with Daubechies Mother Wavelet Function with Support Length of 8.

TABLE II. AVE.: AVERAGE AND STD.: STANDARD DEVIATION OF RMSE: ROOT MEAN SQUARE ERROR BETWEEN THE ORIGINAL IMAGE AND RECONSTRUCTED IMAGE WITHOUT LLL COMPONENT FROM THE TRANSFORMED IMAGE WITH DISCRETE WAVELET TRANSFORMATION BASED ON DAUBECHIES MOTHER WAVELET FUNCTION WITH SUPPORT LENGTH OF 2, 4, 8 AND 16

Support Length.	2	4	8	16	
Ave.	RMSE	14.292	13.229	10.860	20.474
Std.	RMSE	8.671	7.713	6.747	30.109

This is because, as can be seen from the standard deviation, the edges accompanying the movement of clouds included in the images of frame numbers 1-5 are large and the standard deviation is raised. Therefore, taking this into consideration, it was confirmed that the DWT / IDWT based on basis functions with a support length of 8 is optimal for spatiotemporal edge extraction. In addition, the effect of noise increase due to edge enhancement can be seen from Fig. 4(a), (b) and Table II. When the edge component is large like a typhoon image, the influence is large. The standard deviation in the table reflects the noise component, but when the support length is optimum, the noise component, that is, the standard deviation, is small.

D. Optimal Support Length for Moving Vector Detection along the Time Axis

As mentioned above, temporal changes and spatial changes are originally different. Therefore, it is better to determine the optimal support length in the time axis direction separately from spatial edge extraction. The method is as follows:

1) Determine the optimal support length for extracting the spatial change based on the RMSE described above by two-dimensional DWT / IDWT.

2) Next, find the optimum support length for detecting the movement vector in the time axis direction. Therefore, first, a two-dimensional DWT based on the optimal support length basis function found in (1) is applied to the original image to generate a time-series DWT transformed image data set.

3) After that, one-dimensional DWT is applied to the time-series data in which the transformed image is arranged in the time axis direction for each pixel, and IDWT is performed using only the L component.

4) After that, the RMSE between the reconstructed image and the original image is evaluated to determine the optimal support length for extracting changes in the time axis direction. At this time, the changes in the RMSE time axis direction for each support length were compared with the RMSE time average.

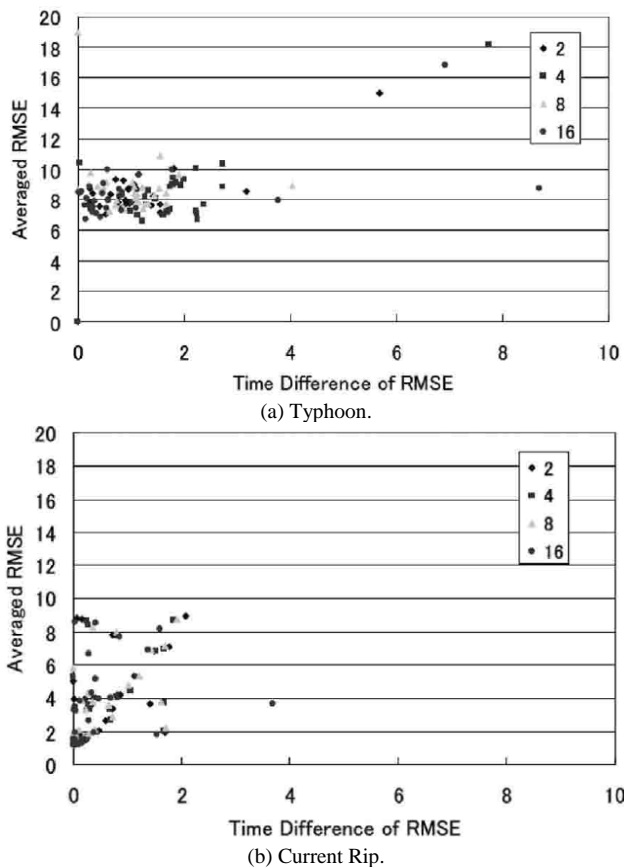

Fig. 5. Most Appropriate Support Length of Daubechies Mother Wavelet Function for Detection of Moving Targets from Time Series of GOES Imagery Data.

As shown in Fig. 5, it can be seen that, as a general tendency, the time flatness of RMSE is large when the time change is large. In addition, it can be seen that the optimum support length is different when the moving object has a steep temporal change such as a typhoon and when it moves slowly like a tide. In other words, the temporal change of RMSE in the case of the tide is concentrated within 2 and the time average of RMSE is also within 9.

A larger time change than that is the steep part of the time change associated with the movement of clouds in frame numbers 1-5. On the other hand, in the case of a typhoon, the time variation of RMSE is concentrated within about 4 and the time average of RMSE reaches 18. Furthermore, the support length of the part of the RMSE that has a large change over time is often 16 and is followed by 8, 4, and 2.

Therefore, it can be seen that the DWT / IDWT analysis based on the basis function with a long support length is suitable for detecting and tracking moving objects with large temporal changes. In summary, it can be construed that when detecting and tracking a phenomenon that changes rapidly, it is necessary to extend the support length and view the observation data over a wide time range.

V. CONCLUSION

In this paper, the author first show that spatiotemporal feature extraction based on Daubechies basis functions is effective for detecting moving objects such as typhoons, clouds, and tidal waves in Earth observation satellite image data, and analyzing movement vectors.

The author proposed a method for optimizing the support length of the basis function used in that case. In other words, the three-dimensional discrete wavelet transform based on the basis function of the support length in the assumed range (1, 2, 4, 8, 16, 32, etc.) is applied to the time-series earth observation satellite image data in one stage, and low frequency components (LLL Component (reverse discrete wavelet transform) is used to evaluate the squared deviation between the original data and the reconstructed data, and this is large (edge component due to movement of object: high-frequency component is extracted greatly). The optimum support length is determined with such support length.

The author evaluated the effectiveness of the proposed method by applying it to time-series data of geostationary meteorological satellite GOES images, and found that the Daubechies basis function, which has a long support length, can be used to analyze the motion vector of an object that moves rapidly like a typhoon. It was confirmed that the spatiotemporal feature extraction based on the spatiotemporal feature extraction based on the Daubechies basis function, which has a short support length, is effective for the motion vector analysis of the phenomenon such as the tidal movement.

VI. FUTURE RESEARCH WORKS

In the future, the author will continue to validate of the proposed method with a variety of time series of data.

ACKNOWLEDGMENT

This is a report of the research results (or part of it) by the Grant-in-Aid for Scientific Research (Special Researcher Incentive). The author would like to express my gratitude to the Grant provider. The author would like to thank Dr. Kaname Seto of former student of Saga University and Dr. Leland M. Jameson of Naval Research Laboratory for their contribution of this study. The author, also, would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

Abstract—Different CNNs models do not perform well in deepfake detection in cross datasets. This paper proposes a deepfake detection model called DeepfakeNet, which consists of 20 network layers. It refers to the stacking idea of ResNet and the split-transform-merge idea of Inception to design the network block structure, That is, the block structure of ResNeXt. The study uses some data of FaceForensics++, Kaggle and TIMIT datasets, and data enhancement technology is used to expand the datasets for training and testing models. The experimental results show that, compared with the current mainstream models including VGG19, ResNet101, ResNeXt50, XceptionNet and GoogleNet, in the same dataset and preset parameters, the proposed detection model not only has higher accuracy and lower error rate in cross dataset detection, but also has a significant improvement in performance.

Keywords—DeepfakeNet; deepfake detection; data enhancement; CNNs; cross dataset

I. INTRODUCTION

Face is one of the most representative features in human beings' biometrics, with high recognition. At the same time, with the rapid development of face synthesis technology, the security threat brought by face tampering is becoming more and more serious. Especially in the era of mobile phones highly popular and social networks increasingly mature, the deepfake video using deep network model to replace face spreads rapidly in social media and the Internet, such as deepfacelab, faceswap [1].

At the end of 2018, the Dutch Deepttrace laboratory released a Deepfake development report[2] showing: Deepfake's global search volume has stabilized to as much as 1 million by December 2018, with at least 14678 fake videos, including 96% of pornography, and risk content such as violence, political sensitivity, advertising, contraband, etc., disguised in the video. The appearance of AI face changing is undoubtedly a great impact on its objective authenticity.

The threat of fake face video to society is increasing, and it has attracted widespread attention from academia and industry. There have been some related studies, and there are also international competitions for face-changing video detection[3]. According to the features used, the existing fake face video detection technologies are roughly divided into three categories[4]: based on traditional manual features, based on biological features, and based on neural network extraction

of features. The first type of method mainly draws on the idea of image forensics and analyzes a single frame of images. Typical methods include the use of image quality measurement and principal component analysis[5] and the use of local binary pattern (LBP) features[6]. The second type of method mainly uses the unique biological information of the face. X. Yang et al. [7] proposed a model that can divide the facial landmarks into two groups according to the degree of influence during the tampering process, and use different landmarks to estimate the head posture direction and compare the differences. As a basis for discrimination, F. Matern et al. [8] found that the diffuse reflection information presented by the pupils of the two eyes in the fake face is inconsistent; The study by P. Korshunov and S. Marcel [9] uses both the video image and audio information to compare the lips in the true and false video. The difference between action and voice matching distinguishes whether there is tampering; S. Agarwal et al. [10] pointed out that every person has a unique movement pattern, and changing faces leads to a mismatch between the target object and the source object's movement patterns, which can be measured from the forehead, cheeks, nose, etc. The features are extracted from the movement changes of the region for classification decision. The third type of method mainly learns human faces by constructing a convolutional neural network, and extracts higher-dimensional semantic features for classification. Some researchers regard it as a conventional classification problem. The study by A. Khodabakhsh et al. [6] uses classic classification models such as AlexNet[11], VGG-19[12], ResNet[13], Inception and Xception[14] for image recognition to detect. D. Afchar et al. [15] Built Meso-4 and MesoInception-4, and S. Tariq et al. [16] built ShallowNet to detect single-frame images; B. Bayar and M. C. Stamm [17] pointed out that in the problem of tamper detection, tampering traces are more important than image content information. The MISLnet of the constrained convolutional layer suppresses the image content when extracting the shallow features; D. Guera et al. [18] considers the time domain information in the video and combines the convolutional neural network with the sequential neural network to find the continuous frame features in the fake face video inconsistency; S.-Y. Wang et al. [19] uses the ResNet-50[13] network model to detect different GAN composite images and Deepfake face images.

From the experimental results given in the above research, the high performance of the algorithm based on neural network extraction features often depends on the dataset used. In the

cross-dataset, due to the large domain offset, that is, the size of the dataset target is different, most of the algorithms and models performs poorly, such as VGG19, GoogleNet, XceptionNet, ResNet50. Background complexity, resolution, and the quality of the synthetic fake face are different, which makes the data distribution vary greatly, which leads to the model's inability to make correct judgments and poor detection results, resulting in a significant drop in performance during cross-dataset [6].

This paper proposes a solution to the generalization performance of face-swapping video detection. Different from the above-mentioned method based on feature detection, and starts from the image and believes that fake face tampering is a special splicing tampering problem. According to the fact that face changing mainly operates on part of the face area without modifying the content of other images, DeepfakeNet is proposed, which is a detection method based on image segmentation and deep residual network. The key contributions in this study are: (1) Extracting video data from multiple data sources, and creating a unified experimental data set through data enhancement methods; (2) Proposing an improved structure based on ResNeXt[20], as whether face change occurs judgment basis for tampering; (3) A model parameter is trained to obtain better detection results.

This paper first introduces the generation principle of deepfake and the current detection technology of deepfake; Then, the DeepfakeNet detection algorithm proposed in this paper is described, and the network structure of the model is explained; Then set up the experimental environment, expand the data set using data enhancement technology, and use relevant standards to compare the mainstream models to draw conclusions; Finally, the possible direction of further efforts in this field is put forward.

In this study, Prof. & Dr. Goh put forward the overall idea; Dr. Yogan gives guidance and improvement; Dafeng Gong designs algorithm, implementation, and analysis conclusion; Zi Ye preprocesses the dataset; Wanle Chi verifies the model.

II. RELATED TECHNOLOGY

A. The Basic Architecture of Deepfake

Deepfake is a neural network trained with an unsupervised learning method. It regenerates the original input after encoding the distorted face image, and expects this network to have the ability to restore any face. The overall process of implementing Deepfake to change the face is shown in Fig. 1, that is, the final realization of FaceA to replace FaceB in a video or image. First, obtain images with A/B faces from the video or image collection, and perform face detection and face alignment. Specifically, on the basis of face detection, the location of key facial features is performed, and the detected faces are normalized and aligned through affine transformation, which can intercept half-face or full-face facial images; then The intercepted A/B face image is sent to the neural network for training and conversion to obtain A face with B expression, action, environment and other conditions, and then the output face image is overlaid on the original image (Fig. 1), and the edges are smoothed then re-synthesize the video.

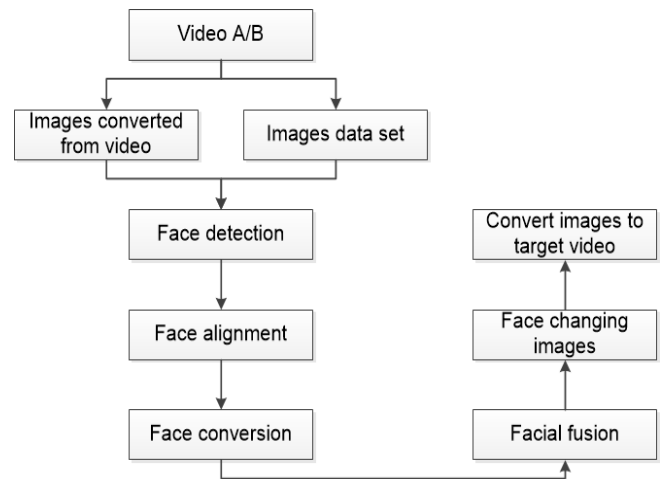

Fig. 1. Face-Swapping Process through Deepfake.

The above process is based on GAN network, and the generation process of data can be represented by the following two public announcements. Goodfellow, I. J et al. [21] proposed data is generated in the following way:

$$\lim_{\sigma \rightarrow 0} \nabla_x E_{\epsilon \sim N(0, \sigma^2)} f(x + \epsilon) = \nabla_x f(x) \quad (1)$$

The function of optimization of multilayer perceptrons is:

$$\min_G \max_D V(D, G) = E_{x \sim p_{data}(x)} [\log D(x)] + E_{z \sim p_z(z)} [\log (1 - D(G(z)))] \quad (2)$$

In the above equation, $D(x)$ represents the probability of D judging x from real data, $D(G(z))$ represents the probability of D judging $G(z)$ as real data, Z represents random noise, and $G(z)$ is the probability of generating data, that is, the probability of D judging as fake, and $1-D(G(z))$ is the probability of D judging as true; for D , the probability of other judging as true is maximized, while for G , the objective function is minimized.

B. Deepfake Detection

The development of Deepfake technology also gave birth to the corresponding detection technology. Yuezun Li et al. [22] used a deep neural network model to combine the convolutional neural network (CNN) and the recurrent neural network (RNN) to form a long and short-term memory network (LRCN). It is believed that fake videos generally do not show the characteristics of blinking, breathing, and eye movement, so that it can detect whether the face in the image or video is real or generated by AI; Matern et al. [8] proposed using image artifacts to detect facial forgery; Yuezun Li et al. [23] trained CNN to detect this facial artifact in face-changing videos; Haodong Li et al. [24] used the difference in color components between real images and forged facial images to distinguish between authenticity and fake images; Yang et al. [7] proposed an SVM support vector machine classification method based on the mismatch between the head pose and the position of the important facial features; Koopman et al. [25] predicted that the tampering of the facial region would affect the local illumination response inconsistency noise in the video frame, and proved that the noise can be used distinguish between original video and face-changing video, but a larger

data set must be studied to determine the correlation between the two; because FakeApp generates Deepfake fake video, it will cause inconsistencies within and between frames, Guera et al. [18] proposed the use of recurrent neural networks (RNN) to detect this anomaly in videos; Afchar et al. [15] proposed two low-level neural networks for detection; Korshunov et al. [5] evaluated the reliability of several detection methods and proposed: Advanced VGG and Facenet-based neural network face recognition algorithms cannot distinguish face-changing videos from original videos. Detection algorithms based on lip shape and voice inconsistency cannot distinguish Deepfake fake videos, while image quality detection based on support vector machine classification. The technology can detect high-quality (128×128) face-changing images with low error.

However, algorithms based on neural network extraction of features can often achieve higher accuracy in cross-dataset detection, and the main drawback is that the performance of cross-dataset detection drops sharply, and there is a problem of insufficient generalization performance[6].

III. DEEPAKE DETECTION ALGORITHM

This study refers to the ResNeXt network [20], using ResNet's stacking ideas [13] and Inception's split-transform-merge ideas [26]. The calculation process can be expressed as follows:

$$y = x + \sum_{i=1}^C T_i(x) \tag{3}$$

Where x is a short-cut, each feature undergoes a linear transformation, C is the cardinality of simple Inception, and T_i is any transformation, such as a series of convolution operations.

Its basic block structure is the same as ResNeXt, as shown in Fig. 2. Each box represents a layer, and the meanings of the three data representations are: input data channel, filter size, output data channel. The advantage is to improve the accuracy through a wider or deeper network under the premise of ensuring the amount of FLOPs and parameters. For each block structure, the convolution kernel is grouped by channel to reduce the dimensionality of the data to form 32 parallel branches, and then respectively perform convolution transformation and feature change on 32 low-latitude data, and then aggregate them back to the original by addition dimension. The final network structure is shown in Table I, consisting of a 20-layer network, here called DeepfakeNet. This network architecture is shown in Fig. 3.

There are five groups of convolutions in this network. The input image size of 1st group is 224x224, and the size of output data of 5th group is 7x7, which is reduced by 32 (2^5) times. Each time, the stride is set to 2 on the first layer of each group of convolutions, and each time is reduced by a factor of 2, a total of 5 times is reduced.

The overall architecture and process of the detection model is mainly composed of 3 main parts: preprocessing data module, extracting feature module and deep learning model module. In the data preprocessing module, the video data set is first processed. For frame images, then enhance the data set. Since only the face of the person in the video frame is the

detection target, the extracted video frame is intercepted, and the features of face images are extracted by CNN. At the same time, the powerful extracting feature ability of CNN can be used to more accurately judge images whether it has been modified. After sufficient training and verification, the DeepfakeNet model is continuously improved to obtain better results.

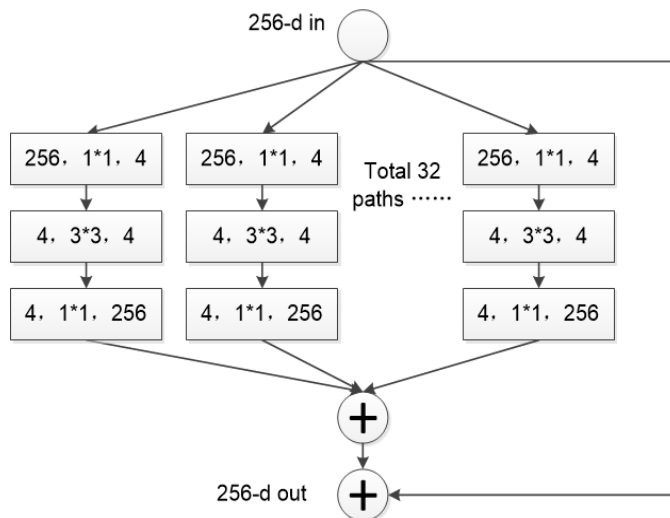

Fig. 2. A Block of ResNeXt with Cardinality = 32, with Roughly the Same Complexity.

Fig. 3. DeepfakeNet Architecture.

IV. EXPERIMENTAL SETUP

A. Lab Environment

In order to verify the performance and effectiveness of the detection model, this study selects videos from the deepfake open source datasets such as FaceForensics++[27], TIMIT[5] and Kaggle competitions[3] for experiments, as shown in Table II. Since the deep learning model in this article reads the training set according to a sequence of consecutive frames, the video must be converted into a sequence of frame images.

In order to obtain an input image of a uniform size, the videos in each dataset are divided into frames, and the face is located by the convolutional neural network detector in the Dlib library frame by frame, and k ($k > 1$) times the face is taken as the center of the face frame. The size of the image area, sampled to the size of 224×224 , as the input image. In order to effectively train and test the network, this paper expands the training samples to enhance the diversity of the data, so that the model can adapt to a wide range of application environments, and has a wide range of applications in target recognition and target detection.

Common methods of enhancing dataset include stretching, rotating, flipping, etc., as shown in Table III. Perform the following operations on each image: compress or stretch to between 0.75 and 1.25 times; each image is generated from 30 degrees left to 30 degrees right, every 2 degrees; brightness changes from the original brightness 0.75 to 1.25 times of, each 0.1 times difference generates one; at the same time, each image is flipped horizontally and vertically. These operations are performed in order to obtain a sufficiently large set of enhanced data[15][28].

This experiment was done on an ubuntu server with 2 Intel Xeon Silver 4214 CPUs, 192GB RAM, and NVIDIA Tesla V100 32GB PCIe GPU. The deep learning model is implemented using Python language and Pytorch framework.

In order for the model to fully learn the feature information of the data set, this study sets the number of iterations of the model epoch to 300, and sets the loss function of the deep learning model to the mean-square error (MSE) loss function. The calculation method is as follows:

$$L_{loss} = \frac{1}{2m} \sum_{i=1}^m (\hat{y}_i - y_i)^2 \quad (4)$$

In the formula, m is the number of samples, y_i is the label of the sample, and \hat{y}_i is the predicted value of the model. The loss function L_{loss} can well show the degree of fit between the true label and the predicted results. The smaller the value, the better the degree of fit. In deep learning, the optimization algorithm is used to optimize the model, so that the value of L_{loss} tends to the minimum, and the fitting ability of the model is increased. The dropout used in the training of this paper is set to 0.8, the learning rate is set to 1×10^{-5} , and the optimization algorithm is Adam [20]. The experimental data set is divided into a training dataset and a verification dataset. Each experiment was randomly assigned to generate them, corresponding to 80% and 20% respectively. The model is trained on the training dataset and verified on the verification dataset.

TABLE II. COMPOSITION OF DATA SOURCES

Data Source	Total Quantity	Number of Videos Selected
FaceForensics++	4000	3200
Kaggle	117812	21767
TIMIT	1199	960

TABLE III. APPROACHES OF ENHANCING DATA

Types	stretching	rotating	Brightness change	Flip horizontally/vertically
Params	[0.75, 1.25]	[-30, 30]	[0.75, 1.25]	Yes/Yes

B. Evaluation Measures

In order to evaluate the performance based on the temporal and spatial feature consistency detection model, this paper selects a variety of metrics to evaluate the model. First of all, for classification models, accuracy is often used to evaluate the global accuracy of a model. The higher the accuracy, the better the accuracy of the model. The calculation formula of the accuracy rate is as follows:

$$A_{accuracy} = \frac{T_{TP} + T_{TN}}{T_{TP} + T_{TN} + F_{FP} + F_{FN}} \quad (5)$$

In this formula, T_{TP} is true positive (TP), which refers to the number of fake images that are correctly classified; T_{TN} is true negative (TN), which refers to the number of real images that are correctly classified; F_{FP} is False positive (FP), which refers to the number of fake images that have been misclassified; F_{FN} is false negative (FN), which refers to the number of real images that have been misclassified.

In order to evaluate the model more comprehensively, in addition to selecting the accuracy rate, this article also selects the area under roc curve (AUC) as the evaluation index in addition to the receiver operating characteristic curve (ROC). The ROC curve is based on the predicted results of the model. Sort the samples by size, use the predicted probability of each sample as the threshold value one by one in this order, calculate the false positive rate (false positive rate, F_{PR}) and the true case rate, that is, the recall rate (true positive rate, T_{PR}), and Take F_{PR} as the horizontal axis and T_{PR} as the vertical axis. Among them, the calculation formulas of F_{PR} and T_{PR} are as follows:

$$F_{PR} = \frac{F_{TP}}{T_{TN} + F_{FP}} \quad (6)$$

$$T_{PR} = \frac{T_{TP}}{F_{FN} + T_{TP}} \quad (7)$$

ROC curve can well represent the generalization performance of a model. AUC is the area under the ROC curve. The larger the AUC value, the better the performance. The calculation formula of AUC is as follows:

$$A_{AUC} = \frac{1}{2} \sum_{i=1}^m (F_{PR}^{(i+1)} - F_{PR}^{(i)}) \times (T_{PR}^{(i)} - T_{PR}^{(i+1)}) \quad (8)$$

In this formula, m is the number of samples.

V. EXPERIMENTAL RESULT

A. Analysis of Algorithm Effectiveness

After a lot of experiments with the same parameters, such as Table IV (all models uses the same preset parameters), we get the data curves as shown in Fig. 4 and Fig. 5. It can be seen from Fig. 4 that as the number of training increases, the Loss function value of the model on the validation dataset and the training dataset gradually decreases, indicating that the model's fitting ability is getting stronger and stronger, which fully illustrates the effectiveness of the experimental model in this paper.

Fig. 5 shows that as the number of model iterations increases, the accuracy of the model's classification prediction on the training set and validation set also gradually increases, indicating that the model's effect is getting better and better. It can also be seen from Fig. 5 that the accuracy of the model tends to be stable around the 160th epoch. The training accuracy of the final model can reach about 97.13%, and the accuracy of the verification data set is about 96.69%, indicating that the model is good; classification and detection results. With the increase in the number of model iterations, the model's fitting ability has been slightly improved, but due to the strong fitting ability of the deep learning model, it is prone to overfitting the training dataset. In order to avoid over-fitting, this paper adopts an early stopping strategy in the experiment. The early stopping strategy is often used in deep learning model training, that is, when the loss function value of the model does not improve for a period of time, the training of the model is terminated.

As shown in Fig. 6, it is part of our experimental results. The number on the top of each small image represents the probability that the operation result is true or false, the final prediction result and the labelled value. For example, the number of the small image in the upper right corner is (0.02, 0.98 | 1 | 1), which indicates the result of operation with DeepfakeNet model. The probability of 0.02 is true, and the probability of 0.98 is false, so the prediction result is false (1), which is consistent with the actual labelled data (also false (1)).

In order to verify the effectiveness of the model, this paper uses common models to carry out comparative experiments based on the same dataset and the same preset parameters, and the comparative results are shown in Table V. It can be seen from Table V that the model proposed in this study has better accuracy than VGG, GoogleNet, XceptionNet, ResNet, ResNeXt and so on.

TABLE IV. PRESET PARAMETERS

Params	Value
batch_size	128
epochs	300
dropout	0.8
max_lr	0.00001
sample_ratio	2.0

Fig. 4. Curve of Loss Value Changing with Training Times.

Fig. 5. The Curve of Accuracy with Training Times.

Fig. 6. Samples of Experimental Results.

TABLE V. ACCURACY COMPARISON OF EXPERIMENTAL RESULTS

Models	Accuracy (%)
VGG19	80.22
GoogleNet	88.94
XceptionNet	92.03
ResNet101	93.78
ResNeXt50	94.36
Model of this paper (DeepfakeNet)	96.69

In order to compare the performance of the models in many aspects, AUC was selected as the comparison index. The comparison results are shown in Table VI. The AUC value can not only reflect the detection effect of models, but also represent the generalization ability of the model. From Table VI, it can be seen that the model in this paper has advantages over other models, indicating that the detection effect and generalization performance of the model in this paper are better than other models.

TABLE VI. AUC VALUE COMPARISON OF EXPERIMENTAL RESULTS

Models	AUC
VGG19	0.83
GoogleNet	0.92
XceptionNet	0.92
ResNet101	0.93
ResNeXt50	0.94
Model of this paper (DeepfakeNet)	0.96

B. Analysis of Algorithm Performance

This section discusses the computational complexity of each algorithm, and compares it according to the number of floating-point operations (FLOPs) and the number of parameters for each model. Generally speaking, if the same effect is achieved, the smaller the number of FLOPs and parameters, the better. Table VII shows FLOPs and the number of parameters of some current mainstream network architectures. Although Table VII shows that GoogleNet is superior in the number of FLOPs and parameters, combined with Table V and Table VI, its accuracy (88.94) and AUC (0.85) are compared with the corresponding data of DeepfakeNet (98.69 and 0.98, respectively). Compared with ResNeXt50, the FLOPs of this model (2.05) is about 48% of it (4.27), and the parameters number of this model (10.87) is about 43% of it (25.08). Overall, performance of the network structure proposed in this study is better.

TABLE VII. COMPARISON OF NUMBER OF FLOPS AND PARAMS

Models	FLOPs	Params
VGG19	19.67 * 10 ⁹	145.77 * 10 ⁶
ResNet101	7.85 * 10 ⁹	44.6 * 10 ⁶
ResNeXt50	4.27 * 10 ⁹	25.08 * 10 ⁶
XceptionNet	3.81 * 10 ⁹	22.8 * 10 ⁶
GoogleNet	1.51 * 10 ⁹	6.13 * 10 ⁶
Model of this paper (DeepfakeNet)	2.05 * 10 ⁹	10.87 * 10 ⁶

VI. CONCLUDING REMARKS

At present, most of the popular fake face video detection algorithms use deep network to extract features. The main reason for the poor cross-dataset performance is that the deep network is easy to learn too many features in the dataset, resulting in poor generalization performance. This paper treats fake face video detection as a special image mosaic tampering detection problem, and uses image segmentation and deep residual network to predict the tampered area, reduces the impact of different training datasets, and improves the generalization performance of the detection algorithm. The experimental results on multiple popular face-swapping video dataset show that compared with other similar algorithms, the method in this paper greatly reduces the average error rate of cross-dataset detection while maintaining high accuracy in the dataset detection. The algorithm has good generality. The method in this paper can obtain good fake face video detection performance in different data sources, which shows that the

idea of improving generalization performance in this paper is general. Future improvements include expanding the scope of the training set, solving the precise detection of faces with different video quality, optimizing the network model, and developing a more complex and effective face tampering video detection network to improve usage.

Abstract—In recent years, small computing devices used in wireless sensors, radio frequency identification (RFID) tags, Internet of Things (IoT) are increasing rapidly. However, the resources and capabilities of these devices are limited. Conventional encryption ciphers are computationally expensive and not suitable for lightweight devices. Hence, research in lightweight ciphers is important. In this paper, a new key scheduling technique based on neural network (NN) is introduced for lightweight block ciphers. The proposed NN approach is based on a multilayer feedforward neural network with a single hidden layer with the concept of nonlinear activation function to satisfy the Shannon confusion properties. It is shown here that NN consisting of 4 input, 4 hidden, and 4 output neurons is the best in key scheduling process. With this architecture, 5 unique keys are generated from 64 bit input data. Nonlinear bit shuffling is applied to create enough diffusion. The 4-4-4 NN approach generates the secure keys with an avalanche effect of more than 50 percent and consumes less power and memory, thus ensuring better performance than that of the existing algorithms. In our experiments, the memory usage and execution cycle of the NN key scheduling technique are evaluated on the fair evaluation of lightweight cryptographic systems (FELICS) tool that runs on the Linux operating system. The proposed NN approach is also implemented using MATLAB 2021a to test the key sensitivity by the histogram and correlation graphs of several encrypted and decrypted images. Results also show that compared to the existing algorithms, the proposed NN-cipher algorithm has lower number of execution cycles and hence less power consumption.

Keywords—Lightweight cryptography; IoT; resource limited devices; neural network; avalanche effect; FELICS; MATLAB

I. INTRODUCTION

Lightweight cryptography [1] is that the scaled-down version of traditional cryptography which target is to provide security for devices which resource capacity is restricted. While thinking in computer communication all people want to prevent his/her message from the malicious person as well as the valid one must receive/decrypt original message easily. However, there is a clear trade-off between lightweight and security of ciphers: Hence, a decent level of security is often achieved in such sort of resource-constrained devices. In recent years, the research community has been focusing on designing cryptographic primitives which are suited to those resource-constrained devices [2]. Conventional cryptographic algorithms like RSA [3] mostly perform well in powerful devices; therefore, lightweight algorithms do not seem to be

necessary for them. Resources like read-only memory (ROM), random access memory (RAM), processing speed, and battery power are limited for resource-constrained devices like Embedded systems, radio frequency identification tags (RFID), and sensor networks. Hence, the lightweight block ciphers become essential to ensure the security of these devices. Different types of cryptographic algorithms like Advanced Encryption Standard (AES) [1], Data encryption standard (DES) [1], PRESENT [4], etc. are used for resource-constrained devices. In most resource-limited devices, lightweight block ciphers use such design architectures which will ensure enough security while keeping execution cycles as less as possible. Most of the ciphers follow the Feistel Architecture like Secure Internet of Things (SIT) [5], SIMON [6], Speck [6], etc. or by Substitution-Permutation Network like PRESENT [4], AES [7], etc. or by using both Architectures like DES, SIMON [6] to supply enough Shannon's confusion and diffusion properties in cipher text. Key scheduling in the block ciphers should perform in a secure way because the security of the ciphers depends on the secret keys which are used in every round of a block cipher. To make round keys strong, different complex number theories like modular arithmetic, prime factorization, Euclidian algorithms, etc. are applied in key generation techniques that end in hamper the performance of resource-limited devices. Good key scheduling must have two properties; randomness to generate unique keys and a high avalanche effect to ensure high key sensitivity. A single bit change in the key should change at least 50% bit in the cipher-text so that an attacker cannot easily predict a plain-text or keys through a statistical attack of encrypted message. That type of effect in cipher text is regarded as an avalanche effect. To implement a strong cipher, the avalanche effect should be considered as one of the primary design objectives.

A. Motivation

To research on cryptography is a challenging and interesting topic. Cryptography is the heart of secure data transmission. It includes complex mathematics, advanced programming, advanced number theories, etc. With the increasing usage of resource-constrained devices, lightweight block ciphers will be essential to provide security for those devices in near future. HP investigate that above seventy percent of re-source-limited devices are vulnerable to attacks [8]. There is a trade-off between the safety and performance of a low-powered small computing device. Since most of the cipher proposed to date is based on [1] complex number theory

*Corresponding Author

i.e., Modular arithmetic, Prime factorization, GCD testing algorithms, etc. As conventional ciphers use complex number theory to meet (Avalanche Effect) [1] Shannon confusion and diffusion properties so these ciphers generally become computationally expensive that hinders the performance of resource-limited devices. For that reason, it becomes challenging to implement these heavy algorithms in small computing devices for ensuring security. Hence, we focus on developing a simple and less power-consuming key generation technique using feedforward neural networks [9] (NN).

B. Contribution

This paper presents a NN-based key generation technique for lightweight block ciphers to provide the lightweight devices' security and meet the challenges of limited resource utilization. This paper puts NNs into the key scheduling process to generate strong round keys. This is done to achieve a more avalanche effect: more than 50% of the output bit is changed for a single bit change in input. This property is also called Shannon confusion. In the used NN, every bit in the input neuron is connected to all the output neuron bits. So, a change of a single bit can affect all bits in the output. It has addressed nonlinearity also since the sigmoid activation function is applied in hidden layer of proposed NN architecture. The proposed technique is computationally lightweight because NN uses simple mathematical operations like addition and multiplication to generate output. It also ensures nonlinearity as NN uses nonlinear activation functions like [10] sigmoid and Step Function. Normally this nonlinear transformation is done by S-BOX [11] like in AES [7], DES [7]. We faced few challenges to put the NN in the key generation technique. These are as follows.

- The choice of a NN to be used.
- The size of the input, hidden, and output neurons.

We evaluated 6 different feedforward NN architectures: NN4-4-4, NN4-3-4, NN4-2-4, NN4-1-4, NN4-5-4, and NN4-6-4. Among these, NN4-4-4 and NN4-3-4 perform better others. The performance of NN4-5-4 is also good; however it has higher computational complexity. We used 4-4-4 architecture as its average avalanche effect is higher than NN4-3-4, although the computational power of 4-4-4 is little more expensive than NN4-3-4. We used MATLAB 2021a to test the randomness by entropy, correlation, and histogram and key sensitivity i.e., Avalanche effect by encrypting images. Thus, the proposed algorithm ensures enough security and consumes less power.

II. BACKGROUND AND LITERATURE REVIEW

Lightweight devices have security vulnerabilities. Particularly, the devices used in IoT have security threats since these devices may remain without supervision for long hours [12]. Conventional ciphers require higher computations [13]. Most of the modern cryptographic algorithms proposed are based on complex number theory like [3] RSA, [1] ElGamal, and SPN [11] network like AES and [11] Feistel architecture like [7] DES. The primary focus of using these primitives is to create keys and ciphertext more secure by ensuring more avalanche effect i.e., more confusion and diffusion in the ciphertext. The main problem with these primitives is

computation-ally expensive, which hampers the performance of resource-limited devices if implemented.

A. NN in Cryptography

The NN is a core concept of computer science that can be implanted into cipher to achieve a higher avalanche effect in cryptography. As every neuron of input is connected to each neuron of output so a change of a single bit in input can affect all bits (neurons) of output. The NN also provides nonlinear transformation like confusion by using nonlinear activation functions like sigmoid. We can fix the output of a neuron by training the NN for different weights. Backpropagation is a good choice to train the NN. After that, a trained network with fixed weights can be implanted to cipher to make enough confusion in the ciphertext. Since NN is also a one-way transformation, reverse engineering attack is not effective.

B. Other Related Works

The authors of article [9], proposed a block cipher based on NN for cryptography. They designed an encryption algorithm based on NN to provide security in resource-constrained devices. Authors applied a [17] backpropagation network as supervised learning to train the fully connected feedforward NN. They claimed that the NN performs consistently and unconditionally throughout the encryption as well as decryption process. However, their algorithm was computationally expensive due to the extra burden of the training process of NN.

In [14], the authors evaluate the performance and security of modern [18] lightweight ciphers like TEA, HIGHT, KATAN, and KLEIN which are instigated especially in resource-constrained devices. To evaluate the performance metrics like memory and power consumption, the authors used the AtTiny45 microcontroller as a resource-limited device. Besides, they assessed the level of Shannon confusion and diffusion to testing the avalanche effect.

In [2], authors proposed a cipher for lightweight devices consisting of two core concepts of genetic algorithm, namely, two-point crossover and coin flip mutation. They also tested their proposed cipher on Fair Evaluation of Lightweight Cryptographic Systems (FELICS) to compare execution cycle and memory usages.

The author in [5] presented a symmetric cipher that combined together Feistel architecture and Substitution Permutation Network (SPN) to avail the linear and non-linear transformation in cipher text. They proposed a cipher that includes: key generation and the encryption process. The key scheduling section generates 5 unique keys by taking 64 bits master key as input from the user. After initial permutation, 64-bit input is grouped into 4 blocks each of which is 16-bit data in size. Every 4 blocks are fitted as input for f-function as shown in Fig. 1. A 4x4 matrix is used to transform the output of the f-function. Here the only source of nonlinearity is the usage of the matrix. The F-function consists of two P-Boxes; used in key scheduling is just the linear transformation. We introduced NN-function in replace of F-function to provide both nonlinearity and high avalanche affect which results in high key sensitivity.

Fig. 1. 4x4 Matrix Format of Key Generation.

III. PROPOSED NN APPROACH

This section describes our proposed NN cipher approach. The proposed technique is a symmetric key block cipher based on a feedforward NN with a nonlinear activation function. The NN approach is suitable for low-powered and resource-limited devices. Using NN is to generate the keys strong enough by ensuring the avalanche effect more than 50%. We put the NN with nonlinear activation function into the key scheduling process to generate round keys used in different rounds of the encryption process. As every neuron of input is connected to each neuron of output so a change of a single bit in input can affect all bits (neurons) of output. These properties of NN meet the standard of avalanche effect that is more than 50%. We analyze the different sizes of NN to test the avalanche effect. Our experiment shows that NNs having too many or too few neurons in hidden layers than that of the input layer have less avalanche effect. We use NN consisting of 4 input neurons, 4 hidden neurons, and 4 output neurons in the key scheduling process. The size of the keys and plaintext is 64 bits.

A. Key Expansion

In a block cipher, the most fundamental component is the keys that are used to perform the encryption as well as decryption. If the key that was used to generate cipher text is compromised, the security is totally broken. Therefore, the illumination of the key should be as difficult as possible. To prevent data from different statistical attacks like chosen cipher text, chosen plain text, differential attack, etc. the sensitivity of the keys must be too high. Even if the attacker assumes the key that differs only a single bit from the original key, the result of decryption with that assumed key should be like cipher text. To ensure higher key sensitivity, the algorithm uses NN, with a nonlinear activation function for generating a key with an avalanche effect of more than 50%. Fig. 2 illustrates the process of the proposed key scheduling details.

The proposed algorithm needs 64-bit data as input to generate five unique keys for five rounds of the encryption process. These 64 bits of data are divided by 4 bits which generate 16 networks. Each network consists of 4-bit data. The proposed technique uses NN in 4 networks to create nonlinear transformation, and others are P and Q transformation to make enough diffusion in generated keys. A feedforward NN of NN 4-4-4 (4 input neurons, 4 output neurons, and 4 neurons of a hidden layer) is put on 1st, 6th, 11th, 15th networks, receipts 4 bits as input, and generates the 4-bit output with sigmoid and step activation function which is a nonlinear activation function. By using the nonlinear activation function in the hidden layer, the manufactured key is getting stronger with more confusion. Nonlinear bit shuffling is applied to create enough diffusion (linear transformation) in generated keys.

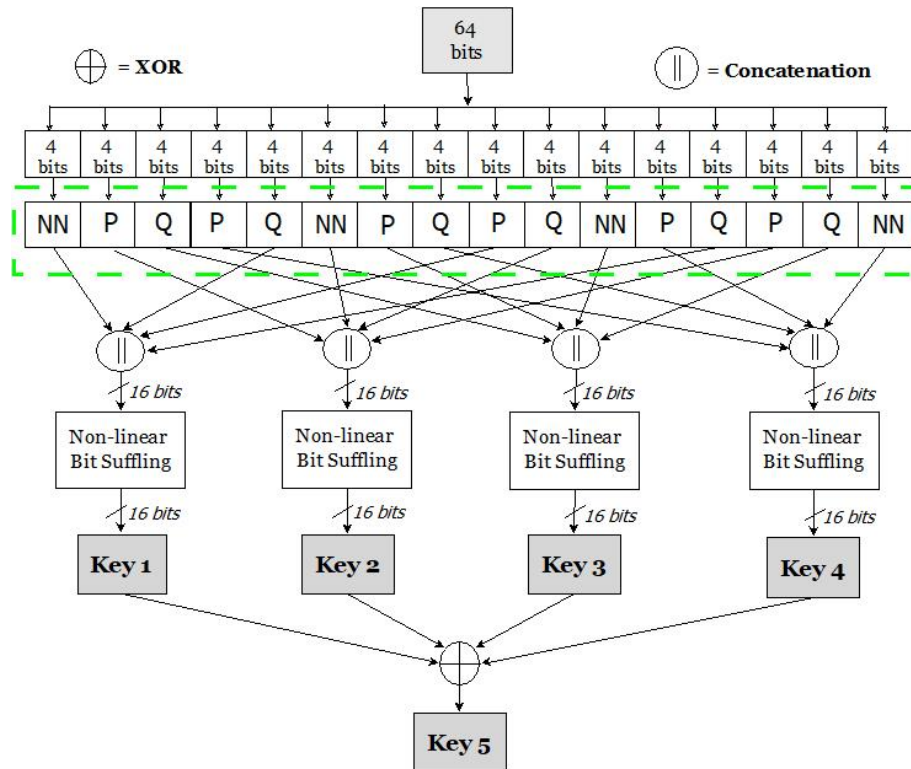

Fig. 2. NN based Key Scheduling Process.

After that the four 16-bit key (K1, K2, K3, K4) are generated, which consists of the output of four-bit networks. The next step is to apply XOR operation on every key K1, K2, K3, and K4 to generate the fifth key K5.

B. NN as a Function

In this paper, we use NN instead of the f-function [5], which is a combination of some linear transformation, i.e., permutation Box. The one-way properties of NN are more powerful to generate strong keys, and the avalanche effect of the proposed NN is more than 50 percent. This property of NN ensures the higher key sensitivity to protect different statistical cryptanalysis. Moreover, NN has less computational complexities because simple mathematical operations like addition and multiplication are used to produce output. Without NN, if anyone wants to generate the key with a higher avalanche effect, they must have to use complex number theory like prime factorization, Random numbers, and Modular arithmetic etc. For example, like RSA, large Prime numbers and modular exponential arithmetic are used to generate keys. Hence, there will be large computation power which is not acceptable for lightweight devices. In this proposed algorithm, a feedforward NN as shown in Fig. 3 is applied. The weights are trained with machine learning for a better output result. In a feedforward NN, input data travels in one direction only, passing through artificial neural nodes and exiting through output nodes. It has unidirectional forward propagation [9] but no backward propagation. Weights are static here. An activation function is fed by inputs which are multiplied by weights. The network has no cycles or loops.

Here, $X_i = [X_1, X_2, X_3, X_4]$ are four neurons of input layer that join with their corresponding weights to 4 neurons of hidden layers $H_j = [H_1, H_2, H_3, H_4]$ to generate 4 neurons of output layer $O_k = [O_1, O_2, O_3, O_4]$. The equation to calculate the each neuron of hidden layer is

$$h_j = \sum_{i=1}^n W_{ij}X_i + b_i \tag{1}$$

where h_j = hidden layer output, W_{ij} = weights, X_i = input bit and b_i =bias value.

The equation to calculate the each neuron of hidden layer is

$$O_k = \sum_{j=1}^n h_jW_{jk} + b_j \tag{2}$$

where O_k = desired output, h_j =hidden layer output, W_{ij} = weights and b_j = bias value of hidden layer.

C. Activation Function

Activation function produces nonlinearity into the output of a neuron. We used sigmoid function [10] is as activation function in the hidden layer.

$$\phi(H_j) = \frac{1}{1+e^{-H_j}} \text{ for } j = 1, 2, 3, 4 \tag{3}$$

We used step function [10] as activation function in output layer because we need either 0 or 1 as output in output layer. The output is a certain value, A_1 for the case where the input summation has a values beyond a particular threshold, and A_0 when it is less than the threshold. The perceptron values were $A_1 = 1$ and $A_0 = 0$.

$$F(O_k) = \begin{cases} 1, & O_k > 0; \\ 0, & O_k \leq 0; \end{cases} \text{ for } k = 1, 2, 3, 4 \tag{4}$$

From the truth table shown in Table I, it can be seen that the rate of bit changing is average 50% upper. This type of bit changing can make Shannon's confusion and diffusion easily. The security of the proposed key generation is standard for its image analysis because its correlation comes out in uniform patterns.

D. The Selection of Architecture NN 4-4-4

In cryptography, the keys must be generated by secure enough key scheduling algorithms. Generally, Different popular hashing algorithms like Secure Hash Algorithm (SHA), (Message Digest) MD5 etc., are used to generate rounds key to encrypt the plaintext. The most important issue in generated keys is the sensitivity of the keys. Any change in the key or the plaintext will lead to a significant change in the ciphertext so that an attacker cannot easily predict a plaintext or keys through a statistical analysis of ciphertext. This property is regarded as avalanche effect. To implement a strong cipher, avalanche effect should be considered as one of the primary design objective. The avalanche effect was identified by [1] "Shannon's property of confusion", however, the term was first mentioned by Horst Feistel. A strong encryption algorithm should always satisfy the [1] Avalanche effect > 50% criteria.

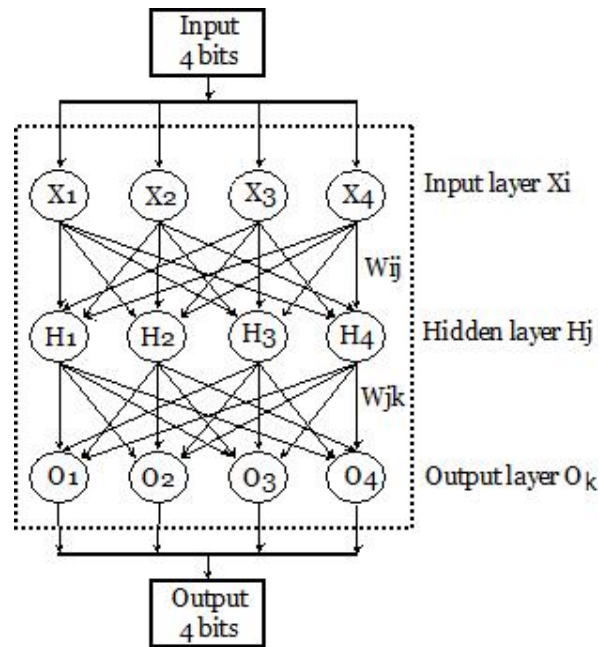

Fig. 3. Feed Forward NN (NN 4-4-4).

TABLE I. SAMPLE OUTPUT OF NN 4-4-4

Input	Output
1	1
1	0
1	0
0	1

An encryption algorithm that does not satisfies this property can favor an easy statistical attack. Considering the higher avalanche effect and lower computational power, we proposed the freed forward NN of 4 input neurons, 4 hidden neurons, and 4 output neurons for key scheduling process. As shown in Table II, we evaluate avalanche effect for different combinations of hidden neurons. We collect the outputs in python language. We do not consider all combinations of a single bit to test the avalanche effect but run the program for different combinations and put the average of collected outputs. According to the used weights, threshold values and activation functions, we got 53.125 % of avalanche effect (1-bit change) for architecture NN 4-4-4, NN 4-3-4, and NN 4-5-4 others are zeros. However, for 4-bit change, architecture NN 4-4-4 has the highest avalanche effect.

E. Computational Complexity of NN

In order to calculate the actual computational complexity of NN, it is necessary to know both the complexity for each operation and the number of operations. Assume that Computational Cost $C.C = M * 3 + A$ where M denotes the number of Multiplications and A denotes the number of addition in a NN. Here in the above equation, M is multiplied by 3 because in integer arithmetic multiplication is usually 3 times appreciably slower than addition. We do not consider the complexity of the activation function for simplicity of calculation.

TABLE II. EFFECT IN ROUND KEYS ON A SMALL CHANGE IN MASTER KEY

NN I/P - H - O/P	Affect in output for 1 bit changed in input (%)	Affect in output for 4 bit changed in input (%)	Computational cost
NN 4-4-4	53.125	59.375	32 Multiplications + 32 Additions
NN 4-3-4	53.125	56.25	24 Multiplications + 24 Additions
NN 4-2-4	00.00	00.00	16 Multiplications + 16 Additions
NN 4-1-4	00.00	00.00	8 Multiplications + 8 Additions
NN 4-5-4	53.125	56.25	40 Multiplications + 40 Additions
NN 4-6-4	00.00	00.00	48 Multiplications + 48 Additions

TABLE III. WEIGHED COMPUTATIONAL COST

NN I/P - Hidden - O/P	Computational Cost (Cycle)
NN 4-6-4	192
NN 4-5-4	160
NN 4-4-4	128
NN 4-3-4	96
NN 4-2-4	64
NN 4-1-4	32

Fig. 4. Impact on Computational Power and Avalanche effect by each Increasing Hidden Layer.

Here M= 4 input weights * 4 inputs + 4 hidden weights * 4 output neurons = 32, similar for A = 32. So, C.C = 32 * 3 + 32 = 128. Accordingly, we calculated for all the NNs shown in Table III. The impact on computational power and avalanche effect by each increasing hidden layer are illustrated in Fig. 4. Horizontal axis represents the number of hidden layers for 4 input and output neurons.

The computational power cost increases linearly as we increase the hidden layer one by one. On the other hand, a number of architecture, namely NN 4-4-4, NN 4-3-4 and NN 4-5-4 have the avalanche effect of 53.125% (> 50%) which satisfy the standard of Shannon's property of confusion. We observed that as he hidden layers exceed the input or output neuron, avalanche effect remains the same and sometimes starts to fall. The performance of architecture with 5 hidden neurons is not improved. The optimal number of hidden [8] units should be smaller than the number of inputs. So, we selected architecture NN 4-4-4 to generate keys with high sensitivity.

F. Key Sensitivity for Ciphertext

To keep data secret from different statistical analyses like chosen ciphertext, chosen plain text, differential attack, encrypted ciphertext must change drastically (at least 50%) for the change of single bit of keys or plain text. We tabulated keys with single bit change and corresponding ciphertext for all mentioned architectures. Proposed architecture showed the avalanche effect more than 50%. All most entire avalanche effect depends on the NN in key scheduling. Table IV shows 6 pairs of cipher text for six different pair of main keys while a pair of keys differs only in single bit to each other.

G. Permutation (P and Q Table)

We used the P and Q tables as reported in the literature [5]. These tables perform linear transformations resulting in diffusion. However, we used P and Q table as per our new design of the key scheduling. The transformations made by P are shown in Table V.

TABLE IV. AVALANCHE EFFECT IN CIPHER TEXT FOR SINGLE BIT CHANGED IN KEY

H. Non-Linear Bit Shuffling

We used the nonlinear bit-shuffling as reported in the literature [2]. In the nonlinear bit-shuffling, a concatenated 16-bit is transferred to each block of non-linear bit shuffling. After that, a random number is computed from the input of 16-bit data which is again logically combined with 16-bit input by performing a bitwise XOR operation. The output of the XOR operation is transferred to bit shuffling as well as to the perfect shuffling block sequentially to create enough diffusion in generated keys.

I. Encryption and Decryption Process

We used the encryption algorithm which was proposed by [2]. The encryption process consists of Feistel architecture with G-function [2] which is based on the concept of two operators of genetic algorithms: mutation and crossover. Fig. 5 illustrates the flow of operation for a single among five rounds. The encryption process takes a block of 64-bit plain messages as input at a time. The first round uses the first key K1 generated by NN based key generation technique and then K2, K3, K4, K5 for 2nd, 3rd,4th, and 5th rounds sequentially.

Fig. 5. A Single Round of Encryption Process.

$$RO_{i,j} = \begin{cases} Px_{i,j} \odot K_i ; j = 1 \text{ and } 4 \\ Px_{i,j+1} \oplus EG_{li} ; j = 2 \\ Px_{i,j-1} \oplus EG_{ri} ; j = 3 \end{cases} \quad (5)$$

The 64-bit message is equally split into four 16 bit segments. According to the Feistel structure, swapping, XOR, XNOR operations are performed among the split blocks to increase the avalanche effect in cipher text. An XNOR operation is performed between round key and left as well as rightmost blocks separately. Then the output of the XNOR operation is feed to G-function as input. The 4th block and output of the left G-function are again XORed and the 2nd block and output of the right G-function are XORed as well. After that, a swapping operation is executed among the 4 blocks except for the last round. The equation (5) represents the process of how a single rounds encrypt plaintext into cipher text. Finally, every four blocks are combined together to generate a block of 64-bit cipher text. The decryption process is the opposite of the encryption process. This time last key is used first.

J. G-Function

We replicated the G-function from the earlier research work. The G-function [2] is based on the concept of two operators of genetic algorithms: mutation and crossover. This function takes 16 bits as input and first, split equally into two eight-bit segments. Both two 8 bit data are transformed by using a substitution box that is called S-Box. After performing a two-point crossover to both outputs of S-Box, a coin flip mutation operation occurs. Finally, the 16-bit output is generated.

IV. EXPERIMENTAL SETUP

The proposed approach is initially written in a popular structure language C. We used CodeBlocks as IDE. The coded cipher is not dependent on any machine to be executed. We also used a benchmark tool ‘Fair Evaluation of Lightweight Cryptography Systems (FELICS) to measure memory usage and execution cycles that run on Linux Ubuntu. The FELICS tool is open access and free to install. We also implemented our proposed NN approach in MATLAB 2021a to evaluate the security strength of keys. The proposed NN approach is evaluated based on key sensitivity, execution cycles, bridge histogram, and correlation histograms. We also assessed the NN cipher in terms of memory usage and clock cycles to generate keys, cipher text, and regenerate plaintext.

A. Evaluation Parameters

The security strength of the proposed algorithm is tested based on key sensitivity, execution cycles, bridge histogram and correlation histograms. We also assessed the memory utilization and execution cycles for key generation, encryption and decryption of this algorithm. The FELICS [15] provides a command-line interface like GCC (GNU Compiler Collection) to test and build any lightweight cryptographic code. They provide documentation to facilitate the implementation as shown in Fig. 6. We can compile our implementation and test whether ours is runnable in FELICS or not. It provides three scenarios against which we can test our code.

We used FELICS to collect clock cycles required for the key generation, encryption, and decryption process of different reported ciphers along with the proposed cipher. We measure the program memory, RAM, and actual code size as well. Table VII shows the comparative results of different ciphers for AVR architecture. It can be seen that among the methods considered, the proposed NN method requires the lowest total execution cycles. Though other ciphers like HIGHT [16] have fewer cycles for key generation, the overall execution cycle of NN is fewer than that of others. The NN cipher needs the lowest RAM to execute and hence, it is memory efficient also.

TABLE VII. EXECUTION CYCLES OF CIPHERS ON AVR ARCHITECTURE

CIPHER	Device	Block size	Key size	CODE SIZE	RAM	Cycles (Key generation)	Cycles (encryption)	Cycles (decryption)
AES[7]	AVR	128	128	23090	720	3274	5423	5388

Fig. 7 presents bar chart comparisons among various reported ciphers with NN approach. For each ciphers, bar chart shows the status of required clock cycles to generate keys, cipher text from plaintext, plaintext from cipher text, as well as overall execution cycles. The chart shown in Fig. 7 clearly demonstrates that the NN cipher executes in less clock cycles, improving over the other reported ciphers especially than SIT [5] and G-cipher [2] which we followed most. So, the proposed NN cipher is more power efficient than that of other ciphers.

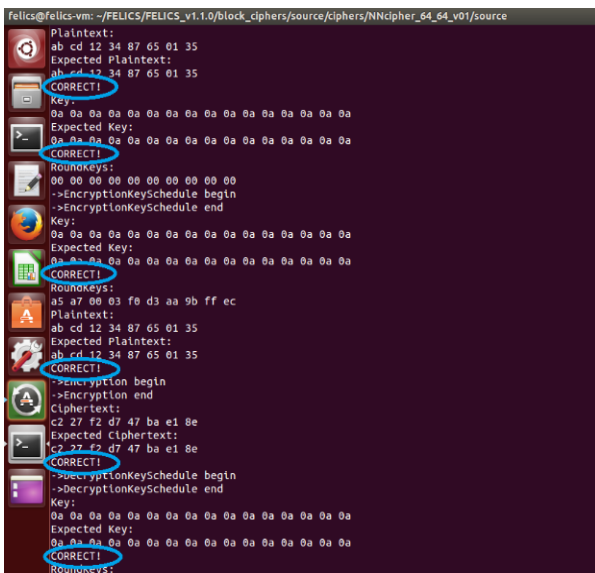

Fig. 6. Testing the Proposed Approach in FELICS.

Fig. 7. Execution Cycle of Ciphers for Hardware Implementation.

B. Analysis of Key Sensitivity

The NN approach is also demonstrated in MATLAB® which encrypts an image and then decrypts the image with the correct key for a visual observation key sensitivity. After that the images are decrypted by using a wrong key with a single bit alteration from the original key. This is also a test for the avalanche effect of the keys. This is also a test for the avalanche effect of the keys. The decryption is non-recognizable if even one bit changes in the original keys. Fig. 8 shows that for NN-cipher, the encrypted images can only be decrypted with the correct key.

Fig. 8. Analysis of Key Sensitivity.

C. Histogram and Correlation Comparisons

Fig. 9 presents the bridge histograms of original and encrypted images. The vertical line indicates the pixel available in the image, and the horizontal axis refers to image intensity. The histogram of the image shows the uniform relationship that ensures the strength of the cipher image. So any statistical attacks will not be effective to predict the plain image from the cipher image without using the correct keys.

Fig. 10 shows the correlation graph of the considered original images and the encrypted images. The correlation graph of plain image shows linear relationship that is higher positive correlated value. However, the correlation graph of cipher image shows highly randomness that is the negative values. Hence, the negative correlation values of encrypted images indicate the strong security strength of proposed cipher.

D. Power Consumption

For calculating the total power consumed by an algorithm on a particular device, first we need the execution cycle of that algorithm. By using the following equation (6), we can compute the power consumption of an algorithm on a particular device:

$$E = I * V_{cc} * N * \tau \tag{6}$$

Where, V_{cc} denotes the operating voltage and I indicates operating current used up for T seconds (unit in Ampere). τ refers to the clock period as well as N indicates the required number of execution cycle. If f be the operating frequency of

the particular device in Hertz then we can calculate the time period of the particular device that is $\tau = 1/f \text{ sec/cycle}$.

According to the absolute maximum rating (AMR) of dataset, usually maximum operating voltage of [19] Atmel Atmega128 is 5V, Maximum current is 40mA and operates at 16 MHz. Fig. 11 demonstrates the of energy consumption of different reported ciphers along with the proposed NN approach for a single block of data. The bat chart shows that NN approach consume less power than that of others.

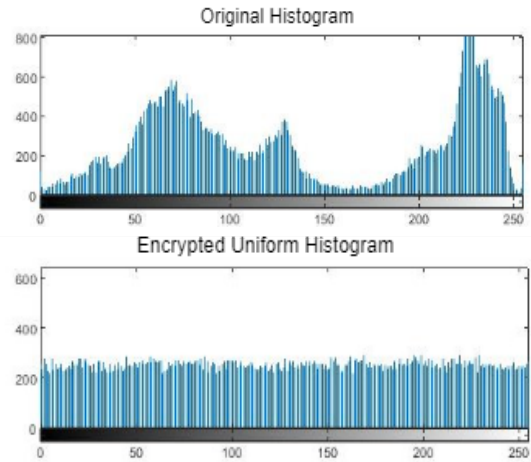

Fig. 9. Bridge Histogram.

Fig. 10. Bridge Correlations for Encrypted and Decrypted Image.

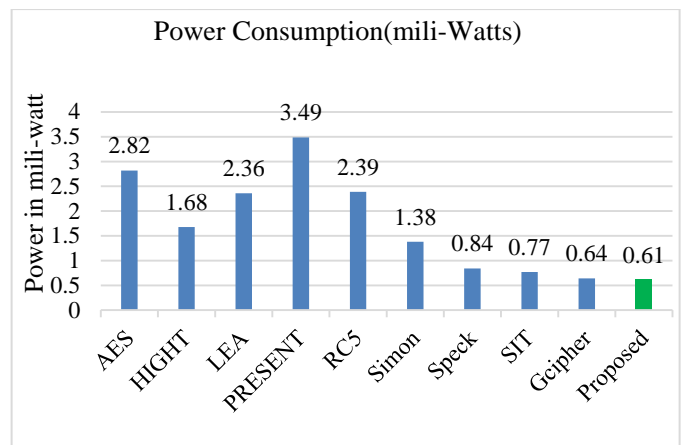

Fig. 11. Energy Consumption Comparison of Ciphers.

V. CONCLUSION AND FUTURE WORK

The security, as well as performance of resource-limited devices, is an important issue. For this purpose, a lightweight cryptographic algorithm using NN is proposed in this paper. This NN-cipher algorithm has lower key generation cycles and less power consumption than the existing ciphers. The bridge histogram and the bridge correlation plot indicate that the NN-cipher can reliably encrypt images. Moreover, the key sensitivity results indicate that for NN-ciphers, encrypted images can only be successfully decrypted using the actual key. Hence, the proposed cipher will be an excellent solution of security for those devices that are resource-limited. Besides, We intend to perform more mathematical analysis as well as hardware implementation on our proposed algorithm to investigate its security strength as future work. More evaluation metrics like the randomness of generated keys using the Chi-square test can be considered for further evaluation.

Fully Automated Ontology Increment's User Guide Generation

Google AliceBot and AIML based Algorithmic Approach

Abstract—This research focuses on a domain and schema independent user-guide generation for ontology increments. Having a user guide or a catalogue/manual is vital for quick and effective knowledge dissemination. If a user guide can be generated for an ontology as well, there could be ample advantages. Stakeholders can scan across the user guide of the ontology and verify the eligibility of it, against the intended purposes. Additionally, this could be useful in ontology's version management requisites and knowledge verification requirements as well. Even though, ontology construction being iterative and incremental operational, there will be several intermediate versions before it reaches to the fine-tuned final version. Therefore, manual user guide creation will be a tedious and impossible operation. Consequently, this research focuses on a novel algorithmic approach to domain and schema independent ontology verbalization. A special algorithm is created to alter the functionality of Google's AliceBot to work as a verbalizer, instead of a chatterbot. Artificial Intelligent Modelling Language (AIML) technology is utilized to create the templates for the ontology specific knowledge embeddings. This entire process is fully automated via the proposed novel algorithm, which is a key contribution of this research. Eventually, the generated user guide generation tool is evaluated against three different domains with the involvement of fifteen stakeholders and 82% of averaged acceptance has been yielded.

Keywords—AliceBot; artificial intelligent modelling language; ontologist; verbalizing

I. INTRODUCTION

Ontologies are recognized as domain rich conceptualizations [1] which are both machine and human-readable [2-3]. Further, as of its enriched ability on conceptualization, it's ideal to encode specialized human knowledge [4]. Subsequently, encoded knowledge will be machine-readable accomplishing endless domain-specific reasoning and knowledge representation necessities. Because of those unique features, the popularity of ontology-based applications escalated drastically. Therefore, presently, there're thousands of applied ontologies developed in numerous domains such as biology, agriculture, bioinformatics, law, management, etc. [5-6]. Applied ontologies are used to overcome issues coming from non-computing domains and by using the aforementioned benefits of the ontologies, most of those issues can be effectively resolved [30]. Construction of an accurately defined applied ontology is a complex process, which requires both ontologists and domain specialists to work hand-in-hand with mutual understanding throughout the entire

process. As a methodical workflow to fulfil the effective bridging of domain specialists and ontologists, "collaborative ontology engineering" has been emerged out as a separate niche under the umbrella of ontology engineering [7-9].

One of the crucial necessities to be fulfilled in collaborative ontology engineering is the proper glueing in-between domain specialists and ontologists [10]. Unless effective participation and collective contribution reaching towards an error-free applied ontology will not be realistic. Researchers have mentioned, ontologists need to have reasonable insight on the domain to be modelled and vice-versa domain specialists should have a sound understanding of the essential basics associated with semantic web and knowledge modelling. Once this state is achieved only, collective, and effective participation of both parties can be expected, leading towards the construction of an error-free applied ontology schemata [11-12].

Even though, there is a critical bottleneck caused due to shortage or illiteracy of comprehension, on semantic concepts, experienced by non-computing domain specialists such as lawyers, medical doctors, agricultural specialists, etc. [13-15].

Ontology construction, being a complex, iterative and incremental task, it's expected at the end of each iteration, domain specialists should cross-reference and verify, that the knowledge provided by them, are accurately and consistently modelled, and embedded to the ontology by the ontologists [16-17]. Then the errors located can be corrected then and there, without waiting until it reaches to complex conceptual flaws resulting in an erroneous schema. In accomplishing this requirement, lack of or no literacy in semantic concepts is a strong hindrance. Because to properly understand an ontological taxonomy defined, the user should have reasonable knowledge associated with basic object-oriented concepts such as inheritance and semantic concepts such as triple concept, data properties, object properties, disjoint classes, symmetric classes and, the concept of individuals, etc. Though the person understands those aspects, the next step is writing an appropriate SPARQL or SQWRL query to verify the accuracy of the knowledge embeddings. Properly understanding the schemata of the ontology and along with the use of accurate syntaxes, forming up an accurate SPARQL query is a challenging task, even for a computer scientist at once. Therefore, obviously, it's an unrealistic goal to be expected from a non-computing domain specialist like a medical doctor, business manager or lawyer. Even if the SPARQL query is

written and executed, results will be returned as a triple with URLs and pre-processing of those are required to derive the answers in plain English, where this is also could not be a feasible task based on the competency level of a non-computing domain specialist [13-15].

All these obstacles are constraining the domain specialists' involvement, in accomplishing knowledge verification necessities, which is a crucial step in collaborative ontology engineering [9,18]. On the other hand, the creation of a catalogue (i.e., user guide) for the ontology's structure is very important for its latter maintenance and knowledge diffusion requirements [21-22]. However, manually fulfilling this task could escalate the workload of the ontologists. Further, lately, if any alteration occurred in the schemata, the entire catalogue needs to be re-written or updated accordingly. This is going to be a highly effort-consuming and tedious task on the shoulders of the ontologists [21-22].

This research is focusing on a fully automated mechanism to verbalize (i.e., output the knowledge encoded in the ontology, in its natural language form) the entire ontology, despite its domain or the schemata [19-20]. This will resolve the technological challenges non-computing domain specialists need to face and it will revoke the burden of manual user guide creation efforts from the ontologists' workload as well. Therefore, both domain specialists and ontologists are benefited from this novel contribution. The key contributions of the proposed technique against the existing mechanisms are:

- The proposed technique can work with any domain → Domain independent.
- The proposed technique can work with any schema → Schema independent.
- No external / manual configuration requirements.
- Converts semantic contents in the ontology increments into layman understandable English.

II. LITERATURE REVIEW

In the process of collaborative ontology engineering, the collective opinion of both the ontologists and domain specialists are very vital. There needs to be a proper workflow to accomplish the collective opinion derivation requirements [23-24]. Otherwise, in a collaborative environment, multiple people will raise multiple viewpoints and try to stick to their perspectives. This will ultimately lead to the issue of "Tragedies of Commons" [25-26]. Hence, in Shneiderman's "Information Seeking Mantra" concept, Shneiderman has pointed a proper workflow to methodically integrate the dispersed viewpoints of the stakeholders to reach towards an overall collective insight, at the end [27]. Unfortunately, the idea of Shneiderman's "Information Seeking Mantra" requires a specialist tool support to fulfil its workflow steps. Information Seeking Mantra concept first requests the stakeholders to get an overall idea about the problem of concern. In accomplishing this request, Shneiderman suggests the use of both visualization and verbalization tool support. Next, zoom towards the required information only. Both verbalization and specially defined visualization techniques can fulfil the second step's requirements as well. The third and

fourth steps are focusing on, filtering unnecessary information and look for information on demand, respectively [27-29]. As the outcome of this research, though a special prototype is proposed to address all requirements of Shneiderman's "Information Seeking Mantra", this paper's scope is constrained to discuss its verbalization feature only, to manage the scope of this paper.

Technically, verbalization is defined as the process of translating axioms defined in ontology to natural language [19-20]. Most of the existing verbalization systems rely on the complex Natural Language Generation (NLG) pipeline to convert axioms into natural language [31]. This is a complex, technological pipeline where all the phases need to be accurately fulfilled, to get an understandable natural language output. Namely, those steps are defined as content selection step, discourse planning step, lexicalization step, aggregation step, generation of referring expressions and finally linguistic realization step [32].

Among all those steps, the discourse planning step is very vital to achieve coherent verbalization output. The discourse planning step utilizes the 'Rhetoric Structure Theory (RST)' for the coherent organization of the text [65]. RST is based on two main conceptions as nucleus and satellite. The nucleus represents the significant axioms associated with the considered domain and the satellite represents the associative properties linked with the nucleus which are required to elaborate the nucleus [65]. Therefore, if the identification of the nucleus and satellite didn't occur in a domain-specific manner, it will adversely affect the clarity of the verbalized contents [31,33]. For that reason, there is a manual phase with the domain specialist and the ontology engineer to properly assign weights to the axioms defined in the domain considered. Afterwards, with the help of the pre-defined rule sets, it will automate the RST, assuring appropriate discourse planning, leading towards accurate and coherent verbalization.

The problem that arises here is the inability of using the same verbalizer for any other domain. Complex prior configurations, which is referred to as portal configuration is a must. This makes a verbalization ready framework to become domain-dependent always [32]. This is a key limitation associated with the existing verbalizing techniques.

The next restriction is the necessity of annotations to enrich the semantic realization of the concepts in the ontology. Again, this request additional effort from the ontology engineers and in most cases eligible foundational de-facto standard meta-models are (i.e. Dublin Core, FOAF) needed to be incorporated into the ontology. Because the majority of the existing verbalization frameworks are configured to link with the pre-defined annotated endpoints of those de-facto standard meta-models only. This poses an additional overload to the ontologists, and it acts as a modelling restrictor also [34-35]. Therefore, the free will of the ontologists and domain specialists are restrained, as they need to plan everything in a manner to suit up with the de-facto standard meta-models.

As the final disadvantage, it can be pointed, that most of the existing verbalizers produce Control Natural Language (CNL) which is resembling to assembly language and it's not colloquial English that can be understood by laymen.

Therefore, another Natural Language Processing (NLP) layer must be introduced to overcome the barrier of converting technical English constructs to its colloquial format, which will be another processing overhead. One of the main causes for this is, the existing evolution of verbalizers have evolved up to the level of Attempt to Control English (ACE), which is a form of Control Natural Language (CNL). In CNL, verbalizers attempt to extract the triple formulations in the ontology and to exactly covert them into the English language, where the contextualized connectivity and colloquialism will be lost [36-38].

TABLE I. EXISTING SYSTEM ANALYSIS

Tool	Restrictions / Limitations
NaturalOWL [31, 52]	Extensive domain-specific configuration efforts.
LODE [53]	Ontology increment must be published on the web and the accessibility url must be according to the cool_URI format. XSLT script of the LODE is configured to work with only standardized metamodels like FOAF, Dublin-Core, etc. This acts as a modelling restrictor.
SWAT Tools [54]	Extensive redundancies in the HTML link sequences generated for the ontology. Split information problem with lots of dispersed information here and there. Make the role of the domain specialist very difficult.
MIKAT [55]	Verbalizer is statically attached to the breast cancer domain. It cannot work with any other domain. Fully domain-dependent.

TABLE II. EXISTING ALGORITHM ANALYSIS ACCORDING

Algorithm	Deficiencies
CNL - ER Algorithm [56]	Works only for entity relationship diagram's verbalizations. Does not work for ontologies.
Contextual Verbalization Algorithm [36]	On-demand verbalization only. Generated results cannot be saved for later use. Additionally, the verbalized outputs are primitive and restricted to the level of ACE.
Semantic Expressions Algorithm [57]	The output is not in the natural language. It's in System Verilog format. This doesn't cater to the requirement to be fulfilled.
FST Verbalizer Algorithm [58]	Incapable to verbalize an ontology
Variable Verbalization Algorithm [59]	Based on domain-specific training of a machine learning model. Doesn't address the domain independence requirement. It's not possible to organize a training dataset, without fixing the domain.
Semantic Refinement Algorithm [60]	Extensive domain-specific configuration effort.

That's the main reason for the verbalized output to look very primitive and the flow seems inconvenient to interpret by the end-users. Most of the deficiencies associated with verbalizers are schema and domain-specific [39-41]. Among those, some of the general deficiencies are reviewed above. Hence, it can be easily concluded, through the existing verbalization mechanisms, the afore-mentioned research gaps of domain-dependence, excessive human involvement associated with configurations and CNL based less colloquialism are not properly resolved. Hence, the emphasis of this research is to propose a novel approach to overcome the aforesaid shortages.

Table I contains a comparison of famous existing verbalization tools, their limitations and why they cannot resolve the issue of domain and schema independent verbalization by producing a colloquial user guide.

Further, several existing verbalization algorithms are also reviewed to recognize their deficiencies. Table II contain the details of verbalizer algorithmic analysis.

Therefore, according to the discussion conducted in the literature review section, it's apparent there is a research gap to be resolved. The following sections of the paper discuss the steps followed to fulfil the recognized research gap.

III. METHODOLOGY

After completion of an intense and extensive systematic literature assessment [42], it's concluded that the aforesaid research gaps are still not been resolved properly.

Subsequently, the blend of the think-a-loud protocol [43] and systems thinking [44] notions are used to collectively brainstorm on the problem of concern and ultimately AIML (Artificial Intelligence-based modelling/mark-up language) is selected to implement the proposed solution, as AIML is recognized as an ideal technology for creating natural language software agents with an XML dialectic [44-48].

Table III contains the analysis results of the technology review conducted.

As per the collective brainstorming results logged in Table III, it was determined AIML is the ideal technology platform to be utilized to resolve the research problem. Because it has broad external integration support and no domain-related training datasets are required to train a domain-specific model. Hence, AIML ideally matches up with the domain and schema independence requirement.

Design science research methodology is selected as of the investigative nature of this research [47]. Implemented version of the prototype is quantitatively and qualitatively assessed on its functionality Fig. 1 exposes the application workflow of design science research methodology's operation for this research.

The importance of the research problem being investigated and its timely relevance was already justified via the literature review results studied. Additionally, a comprehensive literature analysis was conducted again on existing verbalization tools and algorithms to explicitly justify the deficiencies unresolved. Consequently, it was recognized:

- a) Domain and schema independent ontology verbalization tool with.
- b) Zero configuration effort.
- c) For the fully automated user guide generation of the iterative and incremental ontology increments.

as the consolidated research, objective to be accomplished from this research.

Henceforth, via an adequate amount of collective brainstorming, the following algorithm was designed. The proposed algorithm comprises three main operational phases as depicted in Fig. 2.

TABLE III. TECHNOLOGY SELECTION

Technology	Remark
DialogFlow [61]	<ul style="list-style-type: none"> -The training requirement is a dire constraint that needs human involvement for different contexts (done via manually typing potential phrases for the training) -The basis is on Machine Learning & domain-specific training → Makes it a domain-dependent solution, as a dataset will be domain-specific -A regular expression for pattern matching support is not available -Advanced features are not freely available -Can integrate with only one webhook – interaction where external knowledge bases are restricted.
RAZA[63]	<ul style="list-style-type: none"> -Write domain-specific stories – Manual training task. → Makes it a domain-dependent solution, as a dataset will be domain-specific -Training the dialogue model – Expose the domain-specific user stories for training purposes -Complex and a challenging learning curve before the usage -Memory hungry technology – which will slow the entire system performance - External integration assistance is very minimal. -Overfitting and underfitting issues.
IBM Watson [62]	<ul style="list-style-type: none"> -Integration with third party resources is difficult -Steep learning curve -Costly
AIML / ALICE [45-48]	<ul style="list-style-type: none"> -No datasets required for training purposes -Intelligence is extracted from the knowledge scripts – can be auto-generated via axioms extraction from the ontology -Manual integrations and expansions are also supported -ALICE contains a robust collection of AIML scripts to make the bot more intelligent -Freely available -Easy to use -A lot of potential for external integrations -Stimulus-response model can be used to organize knowledge -A regular expression for pattern matching support is also available

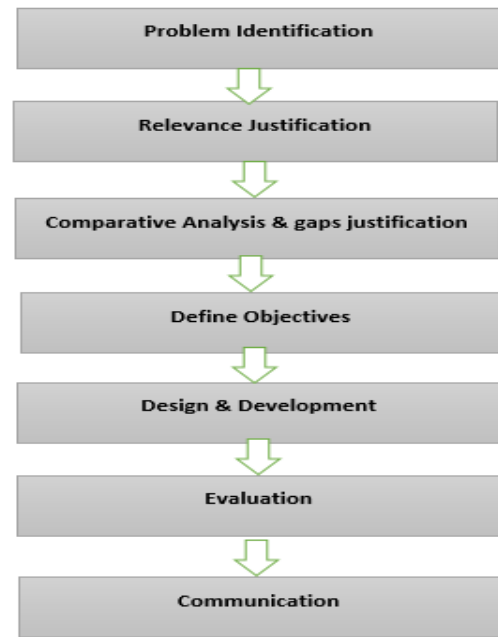

Fig. 1. Research Process.

Fig. 2. Algorithm Phases.

Phase-I - [Knowledge Extraction]

Start
Upload RDF / OWL version of the ontology increment to be verbalized.

Check for the format as RDF or OWL.
Trigger format-specific knowledge extraction logic.

While [Until EOF == TRUE]

Extract class information

Extract data properties

Extract object properties

Extract class-specific individuals (if existing)

Stow them appropriately in different relations of the

RDBMS.

End While

Ontology increment to be verbalized can be directly uploaded to phase-I of the algorithm. Phase-I of the algorithm contains code snippets for knowledge extraction from both RDF(Resource Description Framework) and OWL (Web Ontology Language) formats. Henceforth, the extracted knowledge elements will be separately stowed in the database relations as classes, data properties, object properties etc. Implementation of phase-I of the algorithm can be depicted as in Fig. 3 code snippet.

```
if (fileType.equals("rdf"))
{
String namespace=modelLoader(path);// Derive main namespace of the Knowledge Model
Document doc=XMLDocumentLoader(path);// Initialize XML dom parser
individualExtractorRDF(doc,path,namespace);// Extract Individual By Individual
}
else if (fileType.equals("owl")) // If the file extension is OWL
{
OWLOntologyManager manager = OWLManager.createOWLOntologyManager();
File file = new File(path);
OWLOntology ontology = manager.loadOntologyFromOntologyDocument(file);
individualExtractorOWL(ontology,path);
}
```

Fig. 3. Knowledge Extraction Code Snippet.

Phase-II - [Auto-generation of the ontology specific AIML template]

The main purpose of this phase is ontology increment specific AIML template generation. This can be identified as a critical contribution to this research. Reasons for the choice of AIML technology is already elaborated in Table III. The proposed pseudo-code for the phase-II operation can be listed as mentioned below:

Start

Sequentially extract stored semantic elements from the database relations.

Stow them in individually created ArrayLists

Initiate a blank baseline AIML template (Fig. 4)

```
<xml>
<aiml>
  <category>
    Extract elements from one specific ArrayList (i.e., classes).
    <pattern>
      Derive the name of the semantic element type stowed in the selected ArrayList
    <template>
      I=0
      While (I >= ArrayList. Size ())
      Extract specified semantic element contents from the selected ArrayList
      Continue the appending process until reaching the end of the ArrayList size
      I++
      End While
    </template>
  </category>
  Repeat the same process for all semantic elements residing inside all the ArrayLists.
</aiml>
</xml>
End
```

```
<?xml version="1.0" encoding="UTF-8" ?>
<aiml>
  <category>
    <pattern>GENERAL</pattern>
    <template>What is an ontology ? :-
      It's defined as a domain rich conceptualisation, which is a knowledge model, comprises of variety of domain related classes
      What is a class ? :-
      A class is a structural building block, representing an important perspective associated with the domain considered.
      There are numerous of relationship types available in linking one class with another.</template>
  </category>
  <category>
    <pattern>CLASS</pattern>
    <template>placeholder_1</template>
  </category>
  <category>
    <pattern>INHERITENCE_GENERAL</pattern>
    <template>Inheritance is much like parent-child feature resemblance.
      There exists parent classes and child classes. Child class inherits, attributes and behaviours from it's parent class.</template>
  </category>
```

Fig. 4. Snapshot of the Baseline AIML Template.

As depicted in Fig. 4, the generalistic baseline AIML template structure's placeholder contents will be filled by the information extracted from phase-II of the algorithm. Subsequently, the generalized baseline AIML template will be ontology increment specific. This will be done in a fully automated manner by phase-II of the algorithm.

Phase-III - [Verbalization Process]

The main purpose of phase -III is for the generation of the verbalized user guide. The pseudocode operation of the phase-III is as visible below.

Start

Load AliceBot Engine (Fig. 5)

Submit a class-specific semantic structure name (i.e. Data Properties of the Student Class) as a request object to the AliceBot Engine.

AliceBot Engine will traverse across the autogenerated AIML template and seek the most matching category

Locate for class-specific template contents

Derive the class specific<template> contents residing inside the matching category.

Cross-references the extracted contents against the values of the class-specific attributes via executing a parameterized database query.

Stow the extracted AIML pattern sequences and class-specific verbalized contents in an ArrayList.

Repeat the same process and stow all statements to be verbalized inside verbalizedrepositArr ArrayList.

K=0

While [K >= verbalizedrepositArr.size()]

Iterate across the ArrayList contents.

iText PDF Report Plugin (

verbalizedrepositArr.get(K).toString())

K++

End While

Generate PDF version of the verbalized user guide for the specific ontology increment

End

```

public Chat commonInitialization()
{
    String resourcesPath = getResourcesPath();
    System.out.println(resourcesPath);
    MagicBooleans.trace_mode = TRACE_MODE;
    Bot bot = new Bot("ALICEBOT", resourcesPath);
    bot.writeAIMLFiles();
    Chat chatSession = new Chat(bot);

Fig. 6. Code Snippet for the Phase-III Execution.

The initial step of phase-III is to load the AliceBot engine. Generally, AliceBot is a free chatbot engine provided by Google. However, through this algorithm, the behaviour of the AliceBot is altered from a general chatterbot to a verbalization engine. That’s a significant contribution in phase-III of this algorithm.

Loading of the AliceBot engine can be depicted as in Fig. 5.

Henceforth, contents to be verbalized will be supplied as a request to the AliceBot Engine. Afterwards, AliceBot will traverse through the customized baseline AIML template generated by phase-II of the algorithm (i.e., Fig. 4) and conduct the verbalization process as per the information placed in the AIML template and by filling the placeholder values from the contents extracted from the database. This process can be depicted as in the code snippet in Fig. 6.

IV. RESULTS AND DISCUSSIONS

A sample sketch of the portion of the verbalized report generated for a criminal law ontology increment is depicted in Fig. 7. The entire verbalized user guide is hyperlinked to facilitate easier navigation across the document. To prevent information overloading and cluttering, a segment-wise approach is followed to efficiently layout the verbalized contents, facilitating readability.

Fig. 7. Verbalized Report Sample.

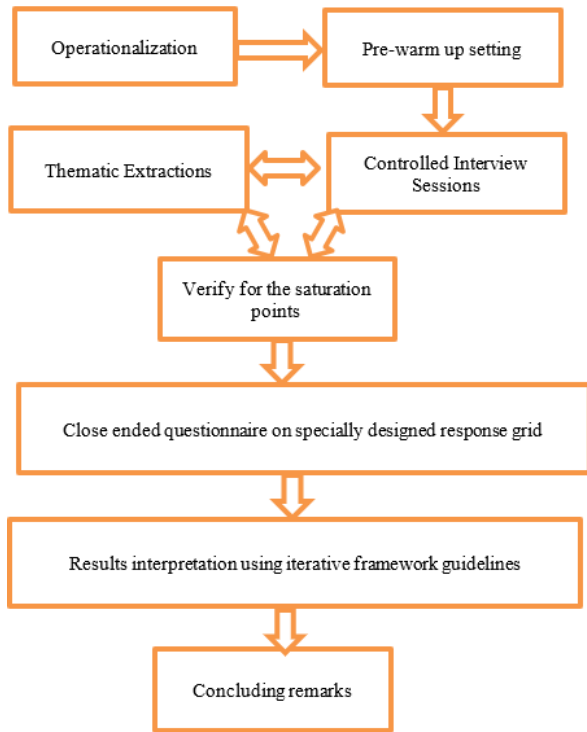

Fig. 8. Evaluation Workflow.

AliceBot is a Google chatterbot, developed on the foundations of AIML technology. With the help of the aforementioned algorithm designed, the operation of the chatterbot is altered to an automated verbalizer, which is a significant research contribution.

As a means of enhancing the validity of the experiment conducted, the same verbalized user guide generation process is conducted for three different domains. Those are on COVID-19 ontology increment, aquaculture ontology increment and the criminal law ontology increment. Snapshots of the taxonomical structures of those ontology increments are included in the appendix of this paper.

The proposed evaluation workflow is depicted in Fig. 8. The proposed evaluation framework utilized in this research can be pointed out as another contribution to this research. Both quantitative and qualitative emphasis were blended in this proposed framework.

First, the operationalization step was carried out. In there several open-ended questions were compiled against the research's objectives. This mapping of the questions in the questionnaire with the research's objective is the process of operationalization [64]. This will make sure the responses collected via the questions in the questionnaire are very much relevant and matching across with the requirements of the research. The list of open-ended questions defined for this evaluation is as mentioned below:

- 1) Have you been notified about the existing verbalization mechanisms?
- 2) In contrast to those, have you identified any positive capabilities of the proposed mechanism?
- 3) Do you think it will facilitate the role of ontology increment verification?
- 4) Can you elaborate on how it will facilitate the role of the inspectors?
- 5) What are the deficiencies you identified in the proposed verbalization mechanism?

In the pre-warm-up setup, all stakeholders were exposed to a specially created synoptic video clip about the research conducted. This phase acts as a retrospect and summarizes the significant aspects of the research conducted to all the stakeholders involved in the evaluation. This was done, before the official commencement of the evaluation process as it will resolve all unclear areas associated with this experimental setup.

In the controlled interview sessions, a face-to-face interview series were conducted with nine domain specialists belonging to the criminal law, COVID-19 and aquaculture domains and six ontologists. The above listed five questions were the main basis for the controlling of the interview sessions with the fifteen stakeholders. All controlled interview sessions were video recorded to facilitate later interpreting requirements. The recording was done, via getting prior approval and consent from all the involved participants and it was utilized only for research purposes and not for any other personnel gains.

10	20	30	40	50	60	70	80	90	100
Very Poor		Fairly OK – Major Revisions			Good & Acceptable – Minor Revisions			Exceptional	

Fig. 9. Close-Ended Response Grid.

During the thematic extraction phase, all recorded interviews were transcribed into a textual format. Henceforth, those were iteratively examined for several turns by the involved research staff. All information gathered through the repetitive analysis were segregated into a few generalistic themes. At the point of the analysis, initially at a drastic rate new themes started to emerge out, by the time of reaching the ninth transcription, a saturation of the themes were noted, where the same themes commenced repeating again and again. This characteristic was recognized as reaching the saturation state of the interview findings.

The theme extraction allowed to recognize of mostly insightful areas of the research. It was not feasible to collect all important opinions only via quantitative terms. Therefore, the qualitative phase enforced through controlled interview sessions created the opportunity to recognize significant user insights.

Henceforth, a close-ended question series was compiled to gather more insights on the located themes. This allows us to derive attention to details on the specific aspects with a numerical emphasis. A special rating grid was utilized to extract stakeholder opinions as depicted in Fig. 9.

Following five questions were provided in a close-ended format and requested to rate the opinions:

- 1) Natural English verbalization of the technical semantics of the ontology increment is accurate.
- 2) Acts as a manual / user guide for the ontology increment, enforcing offline usage as well.
- 3) Boosts comprehension when concepts are verbalized in layman terms.
- 4) Domain and schema independent, configuration free operation.
- 5) How would you rate the verbalization assistance provided by the tool support?

Following Table IV summarizes the averaged response scores derived via all 15 stakeholders involved in this experiment.

TABLE IV. RESPONSE SCORES

Verbalized User Guide [VU]	Law	85%
	COVID-19	80%
	Aquaculture	83%
	Averaged	82%

A summarized collection of the qualitative interpretations and insights gathered through the controlled interview session were depicted in Table V.

TABLE V. QUALITATIVE RESPONSE OVERVIEW

Verbalized User Guide [VU]	1.	Surface level enlightenment for the domain specialists about the conceptualizations of the ontology increments
	2.	Boosts blended comprehension when visualization and verbalizations are integrated during analysis.
	3.	Offline information reviewing facility is important, as doesn't need to stick to a computer screen all the time.
	4.	Acts as a user guide/manual for each version of the ontology increment.
	5.	Fully automated, configuration free, domain and schema independent operation.
	6.	Natural language (i.e., English) representation of the semantic concepts in a domain specialist friendly manner.

As the final phase of the evaluation process, the iterative framework was applied to reflective asses on the research objective accomplishment. Iterative framework [49-51] is an established framework to evaluate the efficacy of research objective accomplishment logically. The operation of the iterative framework is governed via three different but interconnected questions. Reflective evidence must be provided for each section in place. The discussion associated with the iterative framework steps were logged in Table VI.

TABLE VI. ITERATIVE FRAMEWORK

Steps in Iterative Framework	Reflective Evidence
01 → What are the data telling me?	<p>Quantitative Metrics:- As depicted in Table IV, multiple domain-specific qualitative opinion scores were utilized to validate the effectiveness of the constructed verbalization prototype and its operational effectiveness.</p> <p>Qualitative Assessment:- With the involvement of the stakeholders contributed for the ontology increment constructions, empirical assessment of the verbalization prototype was done, in terms of the results returned, accuracy, usability, technical aid provided & etc. Further, as visible in Table V, the stakeholders' reflective opinion themes were logged</p> <p>As a collective reconciliation, it can be concluded both the quantitative and qualitative experimental phases have yielded satisfactory results.</p>
02 → What do I want to know?	The overall operational efficacy of the verbalization algorithm/prototype developed in terms of domain/schema independence knowledge verbalization.

03 → Is there a dialectical relationship between step 01 & 02?	<p>In the quantitative phase of evaluation, the verbalization prototype is exposed to multiple ontology increments in three different domains. In all those, experiments quantitative matrices are calculated to determine the overall efficacy of the verbalization prototype and it's apparent the overall operation has yielded successful results.</p> <p>In the qualitative assessment phase, stakeholders' opinions were thematically assessed, and refined outcomes were tabulated in Table V.</p> <p>Both, quantitative and qualitative evaluation phases conducted on the criteria of the domain/schema independence verbalization, have collectively yielded successful outcomes.</p> <p>Therefore, as the overall final reflection, as per the iterative framework rationale, it can be concluded as, there is a positive and satisfactory link between step-01 and step-02, which reflects the overall efficacy of the verbalization prototype/algorithm resulted from this research.</p>
---	---

V. CONCLUSION

Effective synchronization between ontologists and domain specialists are a must to accomplish the effective operation of the collaborative ontology engineering goals. To fulfil this purpose, domain specialists should closely involve in the verification process of knowledge embeddings present in each ontology increment. Because error-free, domain-oriented applied ontology construction is an iterative and incremental operation. Hence, it's an extremely effective practice to expose the ontology increment for the cross-validations of the knowledge embeddings, at the end of each iteration.

Verbalization is recognized as a very effective procedure for fulfilling this necessity, as it's a natural language representation mechanism of the internal knowledge embeddings of the ontology of concern.

Usually, lack of technical literacy on semantic concepts, querying skill sets will act as a barrier for the non-computing domain specialists (i.e. lawyers, medical doctors, business consultants, bankers, etc. ...), to complete their role of cross-validation in collaborative ontology engineering workflow.

But as conversed in this paper, almost, all of the existing verbalizers have lots of limitations, confiding their operation to a statically attached one domain or complex configuration phases or technically complex verbalized results that are not easy to interpret. Therefore, this research focused on addressing those shortcomings of the existing verbalizers and uplifting the operational efficacy of the verbalizers to the next level, by making them operate in a domain and schema independent manner.

In this research, AIML based Alice bot's operational flow is transferred into a form of a verbalizer, by the introduction of

a fully automated newly defined algorithm, which is a significant technical contribution resulting out from this research. Henceforth, its operational accuracy is quantitatively and qualitatively evaluated, where both mechanisms have yielded an overall of 82% acceptance.

Domain and schema independent ontology verbalization with no manual configurations and fully automated user guide construction for the ontology of concern are two critical application-level contributions yielding out from this research.

But as one limitation, it can be concluded that this verbalizer will only work for ontologies with a lexicon-based schematic structure, as the backbone of this prototype is developed on top of a chatter bot's architecture.

Design of an Efficient RPL Objective Function for Internet of Things Applications

Sonia Kuwelkar¹, H.G. Virani²

Electronics and Telecommunications Department
Goa College of Engineering, Goa, India

Abstract—Over the decade, a rapid growth in use of smart devices connected and communicating over the Internet is seen in various domains. The IPv6 Routing protocol for Low power and Lossy Networks (RPL) is the routing backbone of such IOT networks. RPL is a proactive, distance vector protocol which constructs the routes based on an Objective Function. The performance of RPL protocol largely depends on the design of Objective Function. Depending on application requirements, the RPL standard offers flexibility in design of the objective function and scope for improving the routing process. In this paper, an efficient Objective Function, RPL-FZ, is proposed. Speedy communication across nodes, low energy consumption and reliable data delivery is key to achieve quality of Service. Considering this, RPL-FZ uses relevant metrics like Residual Energy of Node, Delay and ETX (Expected Transmission count) to make the routing decisions. The metrics are combined using fuzzy logic technique to obtain a single metric Quality for each neighbor node. The neighbor with highest value of Quality is chosen as best parent to forward sensed data toward the collection unit. The proposed objective function RPL-FZ is integrated in the Contiki OS and network simulations are performed using the COOJA simulator. The performance evaluation reveals that RPL-FZ achieves 7% higher Packet Delivery rate, 8% lower energy consumption and 8% lesser latency as compared to single metric based standard objective functions OF0 and MRHOF.

Keywords—Internet of things; low power Lossy Networks; IPv6 routing protocol for LLN; objective function; fuzzy logic

I. INTRODUCTION

The Internet of Things finds application in Automatic Meter Reading, Industrial Monitoring, Healthcare, Home automation, Surveillance and Weather monitoring. The sensor nodes employed in these networks have limited processing capability, constrained memory and are battery powered [1]. The links which connect the nodes support low data rates and have comparatively lower packet delivery ratios. These networks support multipoint-to-point, point-to-multipoint and point-to-point data traffic. When deployed in practical application field, these networks can scale to density of over thousand nodes. Such unique requirements classify an IOT network as a Low power and Lossy Network. The design of Routing protocol for these networks is a challenging task. The conventional routing protocols designed for Wireless Sensor Networks, ADHOC networks and MANETs are not suitable to adapt to the lossy and dynamic nature of these networks. To cater to the specific requirements of these networks, the IPv6-Routing Protocol for Low power and Lossy Network (RPL) [2] were proposed by the IETF ROLL working group.

RPL is a distance vector routing protocol which creates Destination Oriented Directed Acyclic graphs (DODAG) identical to tree topology. These DAGs have a Root node, which is generally the border router or gateway, and all other nodes in the network direct their data towards the root node. The Root node initiates the DODAG construction by broadcasting a DODAG Information Object (DIO) message to all neighboring nodes. The DIO message holds network sensitive information like DODAG ID, RPL Instance ID, Objective Function, metrics, constraints and Rank. When a particular node receives a DIO message from a neighbor, it adds the sender nodes routing related info to its parents list as a candidate parent node (CPN). A best parent will be chosen from the candidate parents list to forward the data to the DODAG root. The selection of preferred parent node is governed by the metric specified in Objective function. RPL standard lists two objective functions, OF0 [3] and MRHOF [4]. The objective function MRHOF (Minimum Rank with Hysteresis Objective Function) utilizes the link quality metric-ETX (Expected transmission count) to decide the preferred parent and best path to root. Whereas, OF0 (Objective Function Zero) uses hop count as a decision criterion. Both the Objective Functions (OF) rely on a single metric to make the best parent choice. Once the best parent is selected, the node will compute its own Rank with respect to its parent Rank. The DODAG root has the lowest Rank and every other node computes a rank which increases proportionately with its distance from the root node. Every node transmits the updated DIO message to its neighboring nodes. A Destination Advertisement Object (DAO) message is sent by nodes, except the root, to advertise their addresses and prefixes to their parents and to populate the routing tables with prefixes of their children. A node which has newly joined the network can solicit a DIO message from its neighbour using a DODAG Information Solicitation (DIS) message. The DIO message transmission is triggered by the expiration of a Trickle Timer. To reduce the control overhead the trickle timer interval is doubled after a DIO is transmitted. Fig. 1 shows a DODAG and the routing messages in the network.

The routing mechanism and data forwarding techniques in RPL is simple and flexible to suit various applications. RPL utilizes minimum memory for routing table information and minimizes routing signalling. It is included in powerline communications like G3-PLC and in Zigbee IP specifications [8].

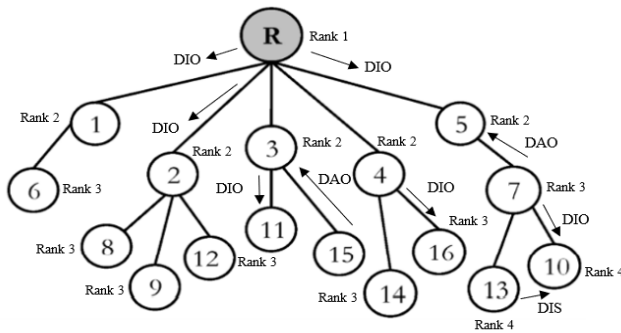

Fig. 1. DODAG.

RPL is also incorporated in IP stack of open-source operating systems like Contiki OS, Tiny OS, LiteOS, T-Kernel, EyeOS and RIOT meant for low power and constrained nodes.

To improve the performance of a RPL based network, the following contributions are presented in this paper:

1) An efficient Objective Function RPL-FZ, which makes routing decisions and best parent selection based on three metrics namely Residual Energy (RE), Delay and ETX (Expected Transmission Count) is proposed. Fuzzy logic is a very popular technique for Multi criteria decision making. These three metrics are combined using Fuzzy logic process to compute a single metric Quality. A node will compute the Quality values of every neighbor depending on Residual Energy, Delay and ETX values. The neighbor with maximum Quality is chosen as the preferred parent node for forwarding data to the root. The fuzzy Inference system is triggered at every node upon receiving a DIO message.

2) The designed Objective function RPL-FZ is extensively tested in COOJA simulator of Contiki OS by varying network density from 70 nodes to 100 nodes and increasing the data transmission rate from 2 packets/min to 10 packets/min. Improvement in Power consumption, Latency and Packet Delivery Ratio is observed in comparison to the RPL standard Objective Functions OF0 and MRHOF.

The paper is organized as follows: In section II, similar work done by other researchers is reviewed. In section III, detailed design of the proposed Objective function RPL-FZ using the fuzzy logic process is presented. In section IV, the effectiveness of the Objective function RPL-FZ is assessed through simulations. In section V, the conclusions and future work are presented.

II. RELATED WORK

RPL being the standard protocol for routing in Low power Lossy Networks, has attracted attention of researchers across the world. In this section, previous work related to optimization of RPL protocol is discussed. Some researchers have evaluated the performance of the protocol under different network conditions [5-6] and shown practical implementation [7]. Some have proposed novel methods of link estimation, neighbor table management [8], interference reduction and

load balancing [9]. Similar to our study, techniques to optimize the objective function using fuzzy logic are presented [10] – [13].

Abuein et al [5] in their study have evaluated the performance of OF0 and MRHOF objective functions of RPL under the random and grid topologies. The network density is medium and varies from 50 to 85 nodes. They concluded that the network performs best when the density is between 50-65 nodes and the RX is 60%. In an earlier study [6] the authors have analyzed the performance of OF0 and MRHOF in two network scenarios. In scenario 1, simulations were carried out by varying network densities from 30 to 70 in area of 300x300 m² and using a single sink node. In scenario 2, node density was varied from 70 to 110. Power consumption, Packet Deliver Ratios and Network convergence time was computed. It was observed that MRHOF had advantage over OF0 when node density was low, but when the network density increased beyond 90, OF0 performed better than MRHOF.

Kitagawa et al [7] have illustrated the practical implementation of the RPL protocol. Pulse sensors send the patients pulse data continuously using Zigbee technology to a remote Raspberry Pi based internet gateway. The sensors route the data using the RPL protocol. Received signal strength, Path loss and Average power consumption are plotted. It is noted that position of sensors affects the power consumption.

Ancillotti et al [8] have addressed the issue of passive link monitoring in RPL. A unique cross layer design for link estimation and novel technique for effective neighbor table management is suggested. A hybrid link estimation approach is used which improves the packet delivery ratios. S Kharche et al [9] have proposed a routing algorithm DN-RPL based on deep neural network. This algorithm attempts to resolve the issue of interference in 6LoWPANs. The deepnets based routing DN-RPL is compared with machine learning based RPL (ML-RPL).

Adeeb Saaidah et al in their work [10] have suggested an improved Objective function OFRRT-FUZZY for RPL. It combines three metrics Received Signal Strength Indicator, Throughput (TH) and Remaining Energy (RE). They have used the popular fuzzy logic process to merge these metrics and make routing decision. Simulations performed using COOJA simulator show that OFRRT-FUZZY performs better than OF0 and MRHOF. Mah Zaib Jamil et al [11] have proposed an Objective function based on a new metric ELT (Expected Lifetime metric) of node. ELT is computed by measuring ratio of residual energy to energy used. Comparison analysis of RPL implementation with ELT, HOP and ETX metrics is done. Hanane et al [12] have made an attempt to improve RPL by designing an objective function OF-EC for RPL which depends on three metrics namely ETX, hop count and Energy Consumption. They have used the Fuzzy Logic process to design this Objective Function.

In [13] the authors have proposed a cross layer Objective function ELITE. A metric SPR is proposed and used for route formation. SPR (Strobe per Packet Ratio) measures the required strobes per packet at the MAC layer. ELITE was

successful in reducing the average number of strobes needed per packet and average amount of energy consumed by sensor node.

III. DESIGN OF RPL-FZ USING FUZZY LOGIC

In this section, detailed design of proposed Objective Function RPL-FZ is explained. The RPL standard allows the designer flexibility in choice of metrics for Objective Function design [14]. In our work we have chosen three metrics namely, Residual Energy, Delay and Expected transmission count in the Objective function design. The three metrics are chosen considering the real time, reliability and low power consumption requirements of Quality of service. These three metrics have to be combined to obtain a single decision metric for routing. There are several multi criteria decision making techniques which can be used. However, the sensor nodes have limited processing and memory capability. Considering this Fuzzy logic is the ideal option [15]. Fuzzy logic is an accurate method widely used to combine several values to obtain a single precise output [16]. It is ideal in LLN as the implementation is supported by the sensor devices and can enhance network performance. In this work, the Mamdani Fuzzy Inference model [17] is used to obtain accurate output.

The selection of the best parent by a node depends on the routing metric contained in the Objective Function. Hence the routing metric plays an important role in enhancing the overall Network performance. The standard RPL utilizes either Link Quality or Hop count as the routing metric. This may lead to a node with less residual energy being continuously chosen as the Parent node, thus further draining its energy and eventually affecting the Network lifetime [18]. Hence it is necessary to consider the Node Residual Energy as well as Latency in routing process. The metrics considered in this work are as follows:

ETX (Expected transmission count): It represents the number of times transmission is required to successfully deliver a packet to its destination. A good link should be able to deliver the packet in first attempt. Ideally, a low ETX value signifies a good and reliable link.

Delay: It is the time taken for a packet to reach its destination. For real time application delay should be minimum.

Residual Energy: When a node is deployed in the network it has a level of Energy E_0 . Its energy reduces during its network operations. The difference between initial energy E_0 and energy consumed is called the Residual Energy. The intent here is to avoid selecting a node which is running low on energy as the best parent. This eventually helps in prolonging the network lifetime.

A. Combining Routing Metrics using Fuzzy Inference System

The Fuzzy Inference System is shown in Fig. 2. It contains a Fuzzifier unit, Fuzzy inference engine with the Rule base and the Defuzzifier unit.

The fuzzification process consists of following steps:

Fuzzification: In this step, the crisp inputs are specified in terms of linguistic variables. The membership functions for

the linguistic variables are defined. In our work the crisp input variables are ETX, Delay and Residual Energy.

Fuzzy inference System: The FIS combines fuzzified inputs based on set of AND-OR rules and calculates the output.

Aggregation: If the output depends on more than one rule than it is unified using aggregation method.

Defuzzification: This is process of converting the fuzzified output into a crisp value. In our work this is the metric Quality.

The first step is to specify the linguistic variables for ETX, RE and Delay. The linguistic variables for the ETX input variable are short, average and long. A link with less than 3 signifies as good link and more than 12 is considered undesirable. The Delay term is represented with linguistic variables small, average and high. A value of 3000 units signifies high delay for packet delivery. The Residual Energy is denoted using terms low, average and full. At start of deployment the nodes have full energy of value 255. The membership functions for RE, ETX and Delay are shown in Fig. 3. Rectilinear (Triangular or trapezoidal) membership functions can be chosen to quantify the linguistic variables. In this work, the fuzzy sets are specified using Trapezoidal membership functions to achieve better results.

Fig. 2. Block Diagram of Fuzzy Inference System.

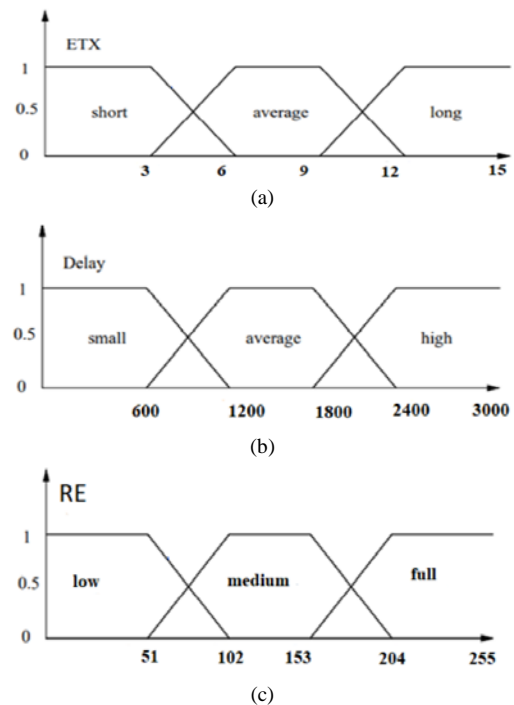

Fig. 3. Membership Functions (a) ETX (b) Delay and (c) Residual Energy.

The formula defining the membership in the short fuzzy set of ETX is given by

$$\mu(\text{short})(ETX) = \begin{cases} 0, ETX > 6 \\ \frac{6 - ETX}{6 - 3}, 3 \leq ETX \leq 6 \\ 1, ETX \leq 3 \end{cases}$$

The formula for membership in the Average fuzzy set of ETX is given by

$$\mu(\text{avg})(ETX) = \begin{cases} 0, ETX < 3 \text{ or } ETX > 12 \\ \frac{ETX - 3}{6 - 3}, 3 \leq ETX \leq 6 \\ 1, 6 \leq ETX \leq 9 \\ \frac{12 - ETX}{12 - 9}, 9 \leq ETX \leq 12 \end{cases}$$

The formula defining the membership in long fuzzy set of ETX is given by

$$\mu(\text{long})(ETX) = \begin{cases} 0, ETX < 9 \\ \frac{ETX - 9}{12 - 9}, 9 \leq ETX \leq 12 \\ 1, ETX > 12 \end{cases}$$

Similarly, the membership levels can be defined for the fuzzy sets of Residual Energy and delay inputs.

A set of IF-THEN fuzzy rules are stored in the database. These are applied to the fuzzy inputs in the fuzzy inference engine. Different fuzzy inputs are connected by AND, OR and NOT fuzzy operators. The three inputs ETX, RE and Delay have associated with them three fuzzy sets each. The rule base will therefore consist of $3^3 = 27$ rules. The Quality output has associated with it seven fuzzy sets, namely very_bad, bad, degraded, average, satisfactory, good and excellent. The membership function of Quality is shown in Fig. 4. Some of the rules used to compute Quality are shown in Table I.

The rules are stored in database as follows:

- 1) If ETX is short and Delay is small and RE is full then Quality is excellent.
- 2) (If ETX is short and Delay is small and RE is medium then Quality is good) OR (If ETX is average and DELAY is small and RE is full then Quality is good).
- 3) (If ETX is short and DELAY is high and RE is full then Quality is satisfactory) OR (If ETX is average and DELAY is average and RE is full then Quality is satisfactory).
- 4) (If ETX is average and DELAY is average and RE is medium then Quality is Average) OR (If ETX is long and DELAY is small and RE is medium then Quality is Average).
- 5) (If ETX is short and DELAY is average and RE is low then Quality is degraded) OR (If ETX is average and DELAY is small and RE is low then Quality is degraded).
- 6) (If ETX is long and DELAY is average and RE is medium then Quality is bad) OR (If DELAY is high and ETX is long and RE is medium then Quality is bad).
- 7) If ETX is long and DELAY is high and RE is low then Quality is very_bad.

Fig. 4. Quality Membership Function.

TABLE I. QUALITY VALUES

ETX	DELAY	RE	QUALITY
short	small	full	excellent
short	small	medium	good
average	small	full	good
short	high	full	satisfactory
average	average	full	satisfactory
short	high	medium	average
average	average	medium	average
short	average	low	degraded
average	small	low	degraded
long	average	medium	bad
long	high	medium	bad
long	high	low	very_bad

The Quality value varies from 0 to 100. A Quality score is assigned to each candidate parent node. For a particular candidate node when the combination of metrics yields a good Quality score it can be selected as preferred parent.

During defuzzification, the value of Quality is computed using the center of gravity (COG) defuzzification method:

$$M = \frac{\sum_{i=1}^N Vi \times \mu A (Vi)}{\sum_{i=1}^N \mu A (Vi)}$$

where M represents the defuzzified value, N corresponds to number of activated rules, V_i is the domain value of triggered rule i, and μA is the membership value.

B. Procedure of Parent Selection using RPL-FZ

In RPL the DIO messages are sent after regular intervals determined by the trickle timer. If a node does not receive a DIO, then it will transmit a DIS to solicit a DIO from a neighbor. When a node receives the first DIO message it will add the sender node as a candidate parent node (CPN) in its routing table. The metrics ETX, Delay and Residual Energy for the neighbor are obtained. If no other candidate parent node is present in the list, then this node itself is chosen as Preferred Parent. If more than one candidate is there in list then the Fuzzy Inference System is triggered and routing metrics-ETX, RE and Delay are sent as input. After defuzzification, the Quality scores of the candidate parents are compared with the Quality score of existing preferred parent node (PPN). A Candidate node which has the maximum Quality value is chosen as the new Preferred Parent Node. The

rank is calculated and DAO message is sent to the newly selected best parent node. The old PPN is removed and the new updated DIO message is multicast to neighboring nodes.

This process is indicated in flowchart of Fig. 5.

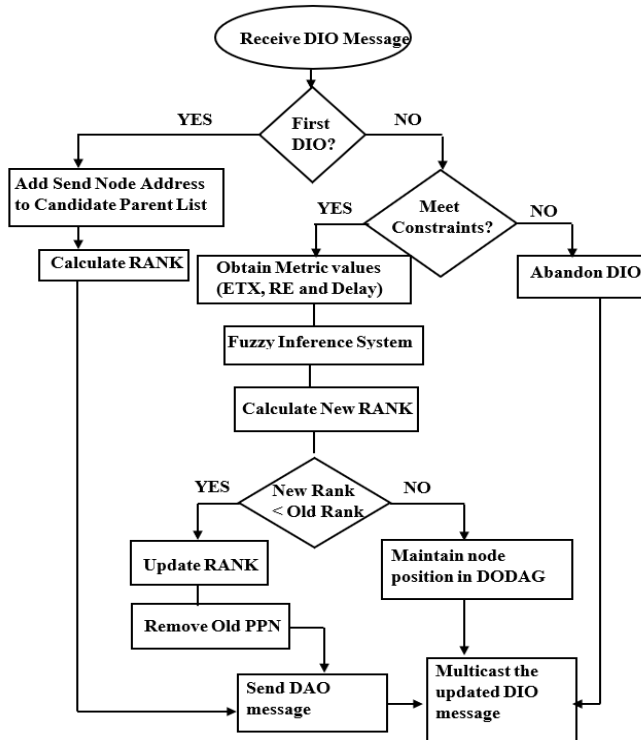

Fig. 5. Flowchart for Parent Selection.

IV. RESULTS AND DISCUSSION

The designed Objective function RPL-FZ is incorporated into the Contiki OS [19]. Simulations are performed using the COOJA network simulator available in Contiki OS [20]. It is a widely used open-source tool. The simulations are performed for evaluating the objective function under varying network density and varying data transmission rates.

The simulation parameters are shown below in Table II.

TABLE II. SIMULATION SETTINGS

Simulator Used	(Contiki OS 2.7) COOJA
Emulated Nodes	T-mote Sky
Network Density	70, 90, 100 nodes
Deployment Type	Random Topology
MAC Layer	Contiki MAC
Transmission Ratio	100%
Network Area	400m * 400m
Transmission Range	30m
Number of Sink Nodes	1
Data Transmission Rate	2 pkts/min, 5 pkts/min and 10 pkts/min
Simulation Time	3 hours

A performance comparison is made between the standard RPL Objective Functions OF0, MRHOF and the Fuzzy based RPL-FZ by varying the density of nodes from 70 to 100, and increasing data transmission rates from 2 p/min to 10 p/min. A single sink was used to collect the data form the devices.

The following performance parameters are computed from the simulation test logs using Perl scripts.

A. Simulation Results

1) *Average power consumption:* It is seen that RPL with MRHOF consumes highest power. This is because MRHOF considers only the transmission count in routing decision and does not consider energy of node. An RPL implementation with the MRHOF objective function can select paths with unreliable links since the link estimation is done by μ IPv6 using passive link monitoring techniques and RPL has no control over it [21]. Thus, it is likely that the routing decisions with MRHOF may be based on outdated link statistics. It is seen form the experiments that MRHOF performs badly as the network density and data rate increases.

At 70 nodes and data rate of 2 p/min, the power consumption with MRHOF is 5% higher than with RPL-FZ. As the node density increases, more traffic in the network causes the power consumption to rise. The sensors have to route more packets, causing them to be in ON mode for longer time duration. At 100 nodes, RPL-FZ consumption is 6% lower than OF0 and 9% lower compared to MRHOF. As the packet rate increases to 10 p/min, power consumption increases further. Higher traffic leads to congestion, collisions and packet loss due to packets being dropped. This causes retransmission of packets. Under these strained conditions of high density and high data rate, RPL-FZ consumes 8% lower power than MRHOF. Although the sensor nodes require extra computational power for the fuzzy process and calculation of rank based on the Quality score, the final power consumption of the Network with RPL-FZ is much lesser as compared to OF0 and MRHOF. RPL-FZ considers the remaining energy of a node during parent selection, thus ensuring that a node low on energy does not end up repeatedly being selected as parent and depleting its energy further. This shows that a network with RPL-FZ will have better lifetime as compared to OF0 or MRHOF. Fig. 6 shows the comparative power consumption of RPL-FZ, MRHOF and OF0.

2) *Packet delivery ratio:* The sensor nodes continuously transmit data to the Root node. Most of the packets are successfully received, but some are lost due to collisions and congestion. The ratio of total packets successfully received at the Sink to the total packets transmitted in the network is termed as Packet Delivery Ratio [22]. Fig. 7 shows the graphs of Packet Delivery Ratios for OF0, RPL-FZ and MRHOF for node density varying from 70 to 100 and packet rates from 2p/min to 10p/min. It can be seen from the graphs that PDR is better at lower packet rates and low node density. At low packet rate 100% packet delivery is obtained with RPL-FZ. RPL with OF0 does not consider the link quality, and when selecting a parent with minimum rank it may actually end up

selecting a congested parent and thus end up dropping packets. RPL-FZ considers ETX as a decision metric and thus ensures better packet delivery. As the sensor data transmission rate increases from 2 ppm to 10 ppm and node density from 70 to 100 it is seen that more packets are lost. This happens due to packet collisions and congestion in the network when packet rate increases. RPL is generally suitable for networks with low data rates. The PDR is also depended on the topology of the network. Our study shows that RPL-FZ gives 7 % better PDR as compared to OF0 and MRHOF when network has 100 nodes and at high packet rate of 10p/min.

Fig. 6. Average Power Consumption of RPL-FZ, MRHOF and OF0 for (a) 2p/min (b) 5p/min and (c) 10 p/min

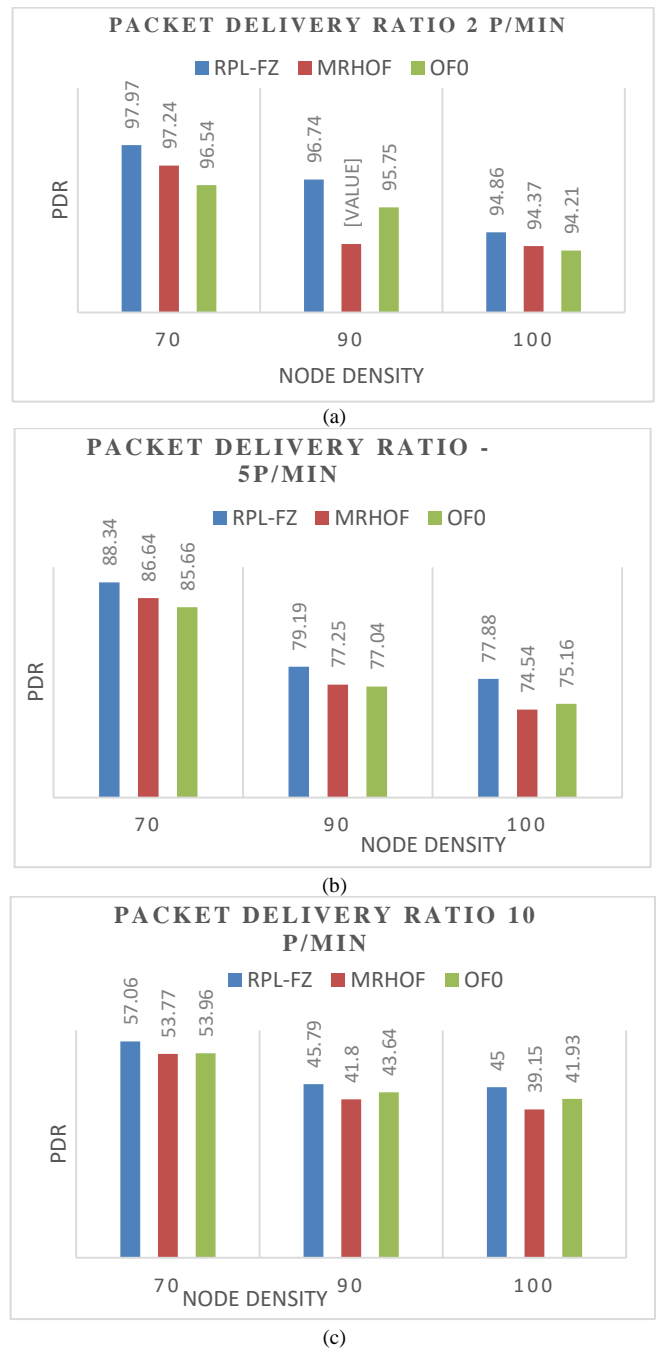

Fig. 7. Packet Delivery Ratio of RPL-FZ, MRHOF and OF0 for a) 2p/min b) 5p/min and c) 10 p/min.

3) *Latency*: The average time taken for a packet to travel from source and reach the destination is termed as latency or end-to-end Delay [23]. Fig. 8 shows the graphs of latency or end to end delay for RPL-FZ, OF0 and MRHOF for varying node densities and packet rates form 2p/min to 10p/min. The three RPL implementations keep the average delay below 2s. MRHOF has highest delay compared to other two. It is seen that the delay increases with increase in node density and packet rates. This is expected since large number of sensors transmitting packets at higher rates will cause more collisions

and packet buffering will increase the delay. RPL-FZ has a delay of 1.8 s, at data rate of 10p/min with 100 nodes, as compared to 2 s for MRHOF and OF0. RPL-FZ uses ETX, residual energy and end to end delay as decision metric for parent selection thus leading to better routing path selection than OF0 and MRHOF. RPL-FZ gives around 8% lower delay than MRHOF and OF0.

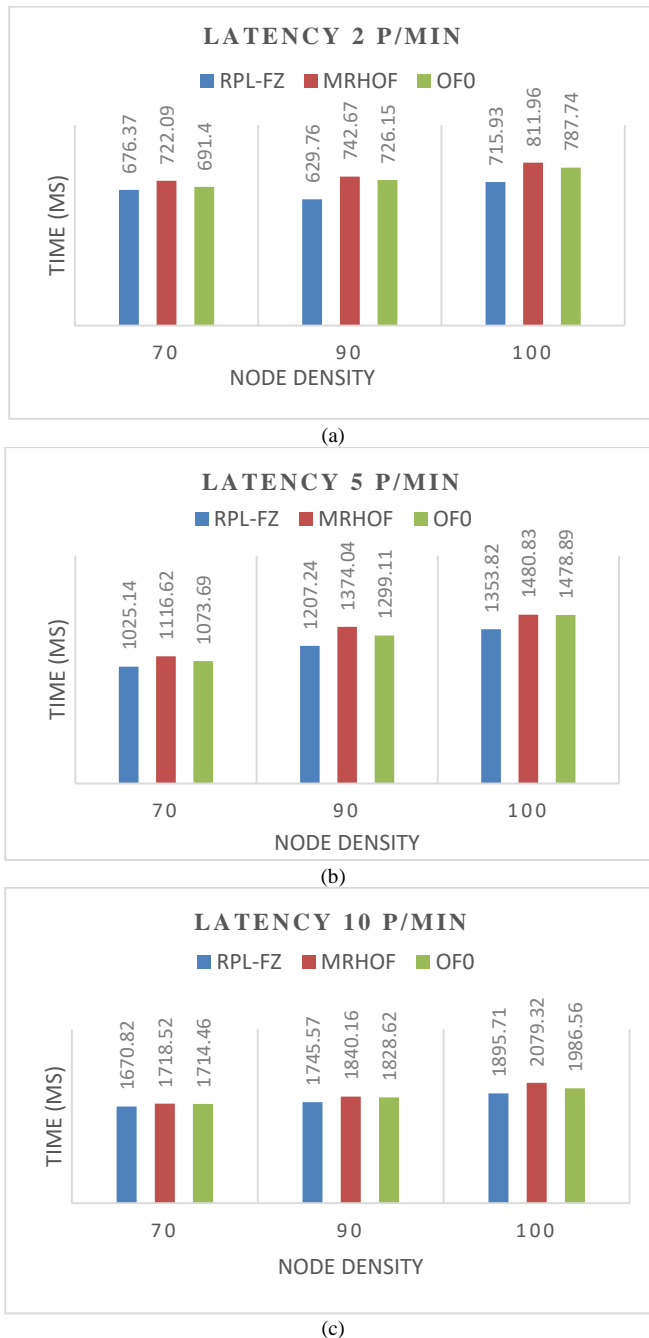

Fig. 8. Latency of RPL-FZ, MRHOF and OF0 for a) 2p/min b) 5p/min and c) 10 p/min.

V. CONCLUSION AND FUTURE SCOPE

In this paper, RPL-FZ, an efficient objective function for RPL-based Low power Lossy Networks is proposed. The existing objective functions defined in RPL standard depend only on a single metric to make the routing decisions and are not suited to meet the quality-of-service requirement of all applications. RPL-FZ combines three metrics (ETX, Delay and Residual Energy) by using the Fuzzy Logic process. The three metrics are combined using fuzzy inference system to evaluate the Quality of each neighbor node. The neighbor with highest Quality value will be selected as preferred parent node to route the data towards Root node. Thus, the sensed data will be efficiently delivered to the collection unit. RPL-FZ has been analyzed and its performance is compared with the objective functions MRHOF and OF0 specified in RPL standard. Simulations have been performed under varying network density and varying data transmission rates. The optimized objective Function RPL-FZ has 8% lower power consumption compared to MRHOF and OF0. Under strained conditions, at data rates of 10p/min, 100 nodes density and single sink node, RPL-FZ gives 7% higher PDR than MRHOF and OF0. RPL-FZ results in 8% lower Latency as compared to OF0 and MRHOF. The results show that RPL-FZ based RPL-implementation performs better in terms of Packet Delivery Ratio, Power Consumption, Network lifetime and Network Latency as compared to OF0 and MRHOF based networks.

This work provides scope for further research in which the Objective Function can take into account more metrics like Hop Count and Received Signal Strength Indicator to make the routing decisions. The performance of optimized Objective function can be tested on real-life test motes like Zolertia Z1 platform or TelosB motes.

Abstract—In software development project management, Risk management represents critical knowledge and skills at the level of a single software project and at the enterprise level, which executes multiple software projects concurrently. The best decision of Risk management contributes to optimizing resource allocation at the enterprise level for achieving its goals. Therefore, the issue needs centralized risk management at the enterprise level as a whole and not for each project. Risk management is implemented through several stages and using different methods. Various studies deal with multiple aspects of software management. This research provides an analytical view of risk assessment in multi-environment software development projects that take place simultaneously. The study uses a public dataset previously used in previous research for several simultaneous projects in one organization. It describes the multi-software project's risks through 12 variables. A comparative analysis uses classification methods (Random Forest- TreesJ48 - REP Tree - Simple Logistic) to assess risks and put them in central view. The research experiment has proven high accuracy in determining risk levels in a multi-project environment, reaching approximately 98%, using the REP tree technique.

Keywords—Risk management; multiple software projects; risk assessment; software development projects

I. INTRODUCTION

The study, analysis, and management of software project risks remain essential in research and practice, despite all the attempts to provide solutions. Still, the reports monitor high failure rates in software development projects. Risk Management (RM) is one of the critical tasks facing project managers. The importance of risk management is due to labor laws and legislation as well as industry standards and internal guidelines for enterprises. The first principle of RM according to ISO 31000 standard is that “RM creates and protects value” [14].

The Standish Group Report presented a comparative analysis on projects from 2013 until the end of 2017. In this period, the three-class of project results (success, challenge, and failure) are illustrated in Fig. 1 [33]. It displays the differences between waterfall and agile. It assures that an agile project succeeds approximately 2X more than a waterfall and

1/3 less likely to fail. According to the Standish Group, 2018 Chaos Reports, an agile project has a 60% bigger success rate than waterfall projects. The main idea learned is that all software development projects face risks regardless of the development methodology.

Therefore, IEC 31010:2019 guides the selection and application of risk assessment techniques in a wide range of situations. Many standards focus on how to manage the activities of risk management in IT organizations. These standards illustrate how to address risks in organizations and companies. Various ISO standards target management systems such as quality perspectives in ISO 9001, IT Service Management (ITSM) in ISO/IEC 20000 - 1, project management in ISO 21500, and information security in ISO/IEC 27001. These IT - related and non - IT standards are significant for many companies [6].

Risk assessment and forecasting in the early stage of software project development is essential for risk management and improved success rate of software development projects. Therefore, organizations must assess and analyze the risks of software projects to be planned by more accurately identifying potential risks and adopting scientific risk mitigation methods. Software risk factors may be diverse and complex, and historical data may be uncertain and unregulated [19].

The International Organization for Standardization (ISO) has issued a standard risk management framework [14]. The main objective of ISO 31000 is to support enterprises in managing risk. ISO 31000 displays the principles, framework, and process of Risk Management. An organization can use it regardless of its level of size, activity, or sector. The definition of risk assessment in ISO 31000 consists of three sub-processes: identifying risk, analyzing risk, and evaluating risk. The sub-process identifying risk is used to determine, recognize, and define the affected risks on the project's objectives. The main aim of analyzing risk is to know the nature, causes, and sources of the identified risks for evaluation risk level. Evaluating risk aims to determine the acceptable level of risk and what should be tolerated, based on comparing risk analysis results with risk criteria [29] [14].

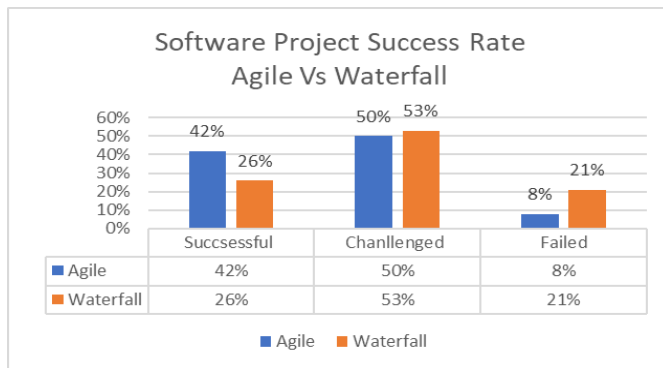

Fig. 1. Projects Success Rates (Adapted from [33]).

In NASA, enhance the safety decision process by using a Probabilistic Risk Assessment (PRA) methodology. It identifies Risks through the answer of three basic questions: the first is What can go wrong? , the second is, How likely is it? And the third is What are the consequences? These answers are prepared by systematically identifying, model, and quantify scenarios. These answers may be lead to knowing an undesired result. Qualitative and risk assessment requires quantitative semantic models. In addition, the probability theory is very descriptive and does not fit the calculation [37].

A simultaneous multi projects development environment is the common environment in software companies. Whereas rarely, software development company executes one project within the timeframe. However, various software projects are developed within the same time frame. Some of these projects consider developing government service portals, e-commerce portals, point-of-sale software, management information system software, enterprise resource planning systems, or other types of different software projects with various characteristics and features. So, the various projects are developed concurrently, and they are concurrent and sharing resources. Therefore, the management of the software development company needs to be concerned with each project restriction – scope, cost, schedule, quality, and relationships among these projects. In short, the main objective of project management, at the company level, should be expanded to improve resource allocation within the entire organization environment, not focus on each project individually.

Based on the previous paragraph, risk management in a multi-project environment has become more complex. Managers face difficult decisions on reducing the average delay per project or the time needed to complete the full range of projects using effectively allocated resources [16]. Risk management in the simultaneous software development environment will be more complex by the diversity of methodologies, policies, models, and procedures in the development process. Dealing with risk management in a single project is very different from a multi-project environment simultaneously. However, many IT organizations do not give much importance to risk management. Risk management is still subjective and often not uniform and does not take place with a systematic methodology.

Companies may need to adopt a centralized risk management methodology that helps maintain their market share through optimal resource management. They may lose if there is no proactive risk management. A supportive regulatory structure is also needed to achieve the central management of risky institutions to control risks throughout the organization.

The main objective of this paper is to clarify the relationships between the risk features and the level of risk and how risks are classified and assessed in simultaneous multiple software development projects. Therefore, this research tries to answer the following questions:

- 1) What are the relationships between risk level and risk features?
- 2) How to identify high-level risks across Simultaneous Multi-Projects?
- 3) How can the relationship between objective and subjective variables be determined and their impact on measuring the level of risk?

After the introduction section, the reminder structure of this paper consists of the following: Section 2 presents background and literature review to explain the main concepts and principles of risk Assessment in a Simultaneous Multi-Projects Development Environment. Section 3 displays the research experiment to answer the questions of the paper and explain the results. Finally, Section 4 consists of the conclusions extracted from research and future work representing expanded trends for current work.

II. BACKGROUND AND LITERATURE REVIEW

Many different studies have addressed risk management in software development projects. It has been subjected to various titles such as software development risks, software project risks, and IT projects risks. Some focus on completing a list of detailed points and risk points. Others include methods of analyzing and assessing levels of risks, including what deals with studies, statistical analysis, and methods of data mining.

Despite more than 30 years of extensive research into the analysis and management of the risks of software development projects, this has led to unified guidance on software project risk management. Adopting these risk management methods in practice still needs more attention so that software projects can be submitted in accordance with the required performance standards. Therefore, this still faces huge challenges [32].

There are six foundations for risk management. It includes risk management as modeling; rational process, factor analysis, capability, social process; and data analysis [5].

By studying more than 100 projects by [23] they found relationships between risk management practice and success in achieving projects in a timely and budgetary manner. They conclude that higher levels of risk management in project management achieve higher levels of project success [23].

In short, risk management is a critical success factor in the implementation of a successful project by identifying and eliminating project risk levels. Senior management supports risk management, the actual practice of risk management practices, and regular risk monitoring [35]. Therefore, the success of the project can occur more frequently [36].

The success of software projects is a subjective process that may vary from project to project and is linked to many risks. Project managers may differ because of these risks depending on the demographic characteristics of managers and the project's nature and features. This study attempted to identify and measure software risks' dimensions and analyze differences in perception among project managers about software risks [26].

Based on a research case study, de Packer and others concluded that risk management activities contribute to the project's success by creating a shared vision of the project with beneficial communication and direct effects [4].

The [17]study has shown a relationship between risk management, success, and self-performance of IT projects. Good risk management can lead to project success only if risks are identified and controlled before the project begins [17].

In a study conducted for measuring risk management impact on IT projects' success, researchers collected data from 200 IT project managers and used statistical analytical methods to measure this effect. The study found that there was a positive impact of risk management on IT projects' success [21].

High-tech and complex projects are more vulnerable to resource risks. Scope and resource risks are also vital risk categories for high-end, high-tech, and medium-complex projects [43].

According to [16] study, one of the complex challenges facing the multi-project environment is allocating resources between projects, especially if resources are minimal. Therefore, Project managers have to make resource allocation decisions to complete the project package in time or reduce project delays. Therefore, multi-project management is a growing area of research [16].

In a recent study, the researcher presented a viable model for monitoring software development projects in international companies. This solution is based on earned value management EVM and Monte Carlo as a simulation method. The proposed model in this study has provided proactive risk management that meets the project's objectives and adapts to changing resource needs [20].

The researchers presented a study on the analysis of risk assessment elements in a multi-project environment. Researchers used some Data Mining methods to reach the elements influencing risk assessment in the multi-project environment and suggested conducting further study and analysis on this topic [38].

A. Risk in Software Development Projects

According to the PMI definition, there are two levels for each project: individual Risks and overall risk. Individual risks can affect project objectives positively or negatively if they occur [22]. Risk refers to the factors that influence the project's success or failure. Also, agile principles include some of the principles to support risk management [18]:

- 1) Customer satisfaction has the highest priority through all phases of the project to deliver valuable software.
- 2) They welcome changing requirements until late in development, as agile's operations contribute to change in favor of customer's competitive advantage.
- 3) Developers and Businesspeople should work as a team throughout all phases of the project.

Previous principles and any best practice supporting applying those principles eliminate or mitigate the negative impact of risks (threats) or promote positive risks (opportunities) that often lead to project success, challenges, or failure [19].

Although one of the new development methodology goals, such as agile, is to reduce the harmful risks and maximize the positive opportunities for software projects' success. In contrast, three principles of agile mentioned in the previous paragraph prevent the occurrence of causes and causes that affect customer satisfaction and the quality of software products. But one of the researchers observed that the final elimination of risks is complicated. Still, there are clear differences between development software projects by a traditional methodology and projects with an agile methodology.

Fig. 2 displays a comparison of risk through the project between waterfall and agile projects. The figure illustrates that all projects have a risk regardless of the development methodology of the software project. Besides, the figure displays that agile projects have a declining risk model wherein agile projects risk declines as the project progresses, whereas in waterfall project has increased risk model. with agile project management, the days of catastrophic failure decline with the project's progress. The elimination of large-scale failure is the biggest difference between risk on a waterfall and agile projects [33].

Fig. 2. (a) Comparison of Risk and Cost between Waterfall and Agile Projects (Adapted from [33]).

B. Risk Management in Simultaneous Multi-Projects Development Environment

In most software companies, multiple software development projects are executing concurrently. The cause of existing projects is related to achieve the strategic goals of the enterprise. And there is a need to manage multiple projects together; therefore, critical success factors must be analyzed and worked in an isolated manner and an entire environment, including all parallel projects. Resource management is one of the most important aspects of a multi-project management environment because it requires a participatory vision that contributes to resource planning and coordination, allocation, and balance of projects [12].

Simultaneous projects share human and material resources, so project managers must consider the constraints imposed on each project and between projects to succeed. Risk management is addressed at all stages of the project and explicitly addresses scope, schedule, budget, and quality. In short, if resources are not managed perfectly, projects may face some challenges that could lead to project failure [39].

The author in [11] acknowledged that the comprehensive framework for risk management in multi-project environments (MPE) is still missing. This framework captures and manages the overall characteristics of MPE. The framework identifies adaptation variables that affect relationships and their risk outcomes and a core group of mediators and supervisors. [11] Risk management during the life cycle of the project has become more important and necessary. It is the best way to visualize project critical success factors entirely, support resource allocation decisions, and solve problems more efficiently. Therefore, academic researchers and industrial practitioners have still had more interest in studying risk management in recent years [39].

Multi-project management is currently a reality in software development environments. Continuous product changes or range levels characterize software development projects. The program development process is complex, particularly in human resources management, such as knowledge and technical expertise. These characteristics may be risk factors that need to be managed. Tactical management is therefore required to use information in an orderly manner, which leads us to consider using a metric-based strategy as a support tool for multiple project managers focusing on risk factors. The researchers, therefore, suggested applying the "risk points" scale and its diversity in the multi-software development project environment as a tool to support the decision and monitor risks during the project life cycle [3].

It is common for many companies to manage project risk separately and not to monitor and analyze the risk impact between projects across the organization. However, the prevailing situation is a simultaneous and shared project resource environment, so the main essence of the decision-making process is communication between partners involved in the organization's shared resources. Communication must be organized vertically and horizontally, and this is the meaning of participatory management [30].

Much of the literature ignores that the risks can be shared among different simultaneous development projects in the enterprise. At the same time, the risks in all levels of management and the relationships among risks are high. So, it would be appropriate to manage the risk from a holistic perspective. So, to better understand, consider the following toe levels of Risk Management [39]:

1) *Risk management of one project:* The enterprise has one project; the aim is to manage related risks to ensure the project's success.

2) *Risk management of multiple projects:* The enterprise has the risk management of a single project in addition to the common risks in the multiple projects' environment. So, the enterprise has a matrix of project risks. The aim is to ensure project success, system optimization, and the allocation of resources and analyze the impact of resource allocation on multiple projects.

The author in [10] illustrate those risks must be managed when managing multiple projects. With the organizational structure and the appropriate software, you can also share and monitor risks in all projects. At any time, the large organization implements different types of multiple projects at the same time. These projects have different sizes and stages of completion. In this environment, risk management can face a variety of challenges and bring significant benefits, some of which are [10]:

- 1) Cost savings by identifying overall risk mitigation.
- 2) Risk vision varied in multiple projects.
- 3) Reducing emergency budgets.
- 4) Effective distribution of resources.

C. Assessing the Impact of Risks and Prioritizing Software Development Projects

As shown in Fig. 3, assessing the impact of risks and prioritizing risks to be dealt with are outlined in the second and third steps of the risk management process. This assessment usually shows how cost or technical performance can affect the achievement of targets. However, the implications of these standards are not limited; It is also necessary to consider the political or economic consequences. The likelihood of any threat that may adversely or positively affect the project is also assessed. This assessment often involves the use of self-assessment techniques, especially if it is difficult to use objective methods to assess the possibilities directly. (i.e., engineering, analysis, modelling, and simulation) [8].

According to IEEE standard 729, a software requirement includes three types that display in Fig. 4:

Functional requirements: these are requirements that are requested by the end-user specifically standard should be provided by the system. Since non-functional requirements including scalability, security, maintainability, reliability, scalability, performance, reusability, and flexibility. Area requirements: area requirements are those of a particular category or area of the project [13]. Table I displays some software requirements standards and studies.

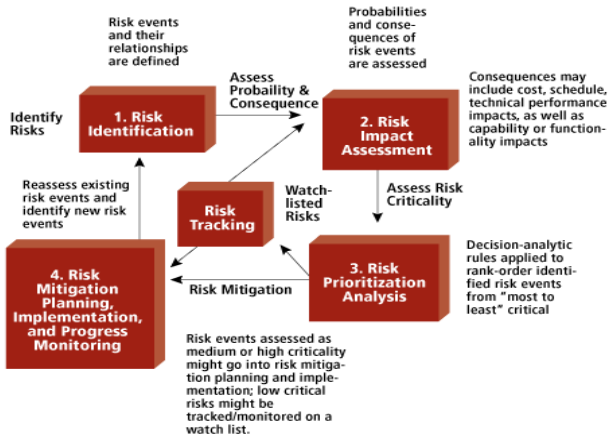

Fig. 3. The Fundamental Steps of Risk Management [8].

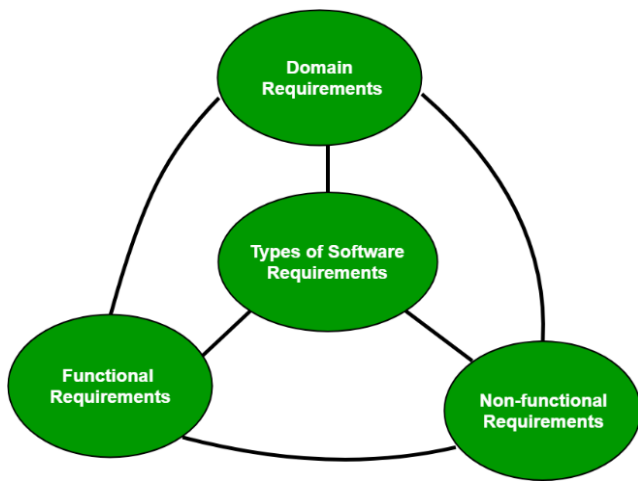

Fig. 4. Software Requirements [13].

TABLE I. SOFTWARE REQUIREMENTS

Study/standard	Software Requirements
[45] ISO/IEC 9126	"Portability" has "co-existence", "Maintainability", "Functionality", "Security", "Efficiency", "Reliability", "Usability", and "Compatibility".
[44] IEEE standard 729	Functional Requirements, Non-functional requirements (Flexibility, Scalability, Reusability Portability, Reliability Security, Performance Maintainability, and. Domain requirements)
[41]	Functional requirements (FR), Operational requirements (OR), Technical requirements (TCR), and Transitional requirements (TSR)
[27]	Security, Interfaces, Functional, Supportability, Usability, Standards, Reliability & Availability, Constraints, Performance, Safety.
[15] ISO/IEC/IEEE29148:2018	Business Requirements Specification (BRS), System Operational Concept (OpsCon), Stakeholder Requirements Specification (StRS), Software Requirements Specification (SRS) System Requirements Specification (SyRS),

According to the study conducted by [1], he found that the most frequent software risks are planning and controlling user requirements, risks associated with the project team, risks related to the organizational environment, and project complexity [1]. Another previous study by [25] showed that the risks of the software project were interrelated. the risk dimensions include technology experience, project size, and project structure used in the system requirement, planning and control, project complexity, team, and organizational environment [25]. Table II displays some software risk dimensions studies.

TABLE II. SUMMARIZES SOME OF THE STUDIES ON SOFTWARE RISK DIMENSIONS

Study	Year	No	Software Risks Dimensions

D. Research Experiment

In this part of the research, the aim is to answer research questions through the results that will be reached in this experiment. One of the data mining tools that will be used as a tool for data mining is Weka 3.8.4. Therefore, this section of the research is divided into five subsections:

- 1) Data set.
- 2) What are the relationships between Risk level and Risk Features?
- 3) How to Identify top risks across Simultaneous Multi-Projects?

- 4) Identify the association between the subjective and objective variables and their impact on measuring risk levels?
- 5) Overall comment on the search experience.

E. Data Set

In this study, the researchers used the data set in [27]. This data set includes 12 variables describing the risks of several projects for software development, some of which are project type, requirements, impact, probabilities, and priority risks where it is fully presented in Table III, The researcher based the challenge of the listed variables on several methods [27]:

- 1) Previous studies, especially studies [34].
- 2) The experts have at least five years of experience in the software industry companies that achieve the second and third levels in the maturity and ability model.
- 3) The number of cases in the dataset consists of 299 instances. the dataset is formatted in Attribute-Relation File Format (ARFF) [27].

F. Answer to Question 1: What are the Relationships between Risk Level and Risk Features?

The first question in this paper is the relationship among the risk characteristics and assess the risk levels. Determining this relationship is very important for identifying the traits with the most significant effect. Recognizing this relationship contributes to forming the risk record and risk dataset to help manage projects centrally because the appropriate volume of data is the target, neither more nor fewer. Collecting too much data represents a cost and effort lost and may distract the decision-maker and collecting too little data is insufficient.

Attribute reduction is an important area of research in machine learning, artificial intelligence, and pattern recognition to improve the performance and economics of predictions. Attribute reduction participates in identifying redundant attributes to remove this redundancy and improve decision-making [24]. So, attribute reduction represents an essential step in the preprocessor of data mining, machine learning tasks, and data pattern recognition [2].

Many factors affect the risk assessment of the software development project. These factors are divided into two types, subjective and objective. Factors that are objectively measured and objectively described are not affected by the personality of the person who counts them. In contrast, other variables describing project risk are subjective values, such as the impact, magnitude, likelihood of occurrence, and frequency of risk, and are influenced by the character of the decision-maker.

The experiments that were conducted in this research where use many methods for feature selecting. Using more than one feature selection method confirms results to solve the feature's problem. The research seeks to identify the characteristics with the most significant impact from all methods. Also, The second sub-objective in this research is what the features don't relate to assessing the risk level based on many methods. Clarifying this issue is of great importance

to decision-makers in designing the software company's risk register. The risk register is the appropriate tool for compiling project risk data, followed by analyzing these data to help the analysis results formulate proper strategies for efficiently managing software development risks. Table IV displays The results.

Six methods were used in the research experiment to determine which features are more important in risk assessment. The six methods then unanimously agreed on the importance of three features: priority, probability, risk size. Fig. 5 shows that although the relationship between the magnitude of the risk and the level of risk is substantial. In some cases, the relationship level may decrease due to other factors that may be requirements and impact, like what's shown in shape.

On the other hand, by the relationship thread, three methods confirmed no significant relationship between two features(Affecting No of Modules, Fix Cost (% of the project), and the risk level assessment.

These features (Affecting No of Modules and Fix Cost) have nothing to do with a risk assessment, which does not mean they are unimportant. However, their importance still exists as necessary information in managing the risks of the software project and not in determining the level of risk.

TABLE III. THE STRUCTURE OF DATA SET

Attributes	Value Sets
Requirements	Text to describe the requirements
Project Category (PC.)	1. Transaction Processing System (TPS) 2. Management Information System (MIS) 3. Enterprise resources planning System (ERP) 4. Safety-Critical System (SCS)
Requirement Category(RC.)	Reliability & Availability— Usability- Security- Safety - Supportability - Functional - Constraints, Interfaces - Standards- Performance
Risk Target Category (RTC)	Budget - Personal -Resource Availability-Quality-Schedule -Performance-Functional Validity-People -User- Requirement - Dimension- Time - Cost Design- Project complexity- Unrealistic Requirements Business - Overdrawn Budget-Process – Software - Planning & Control – Team- Organizational Environment-
Probability(Pro)	0 % -100 %
Magnitude of Risk(MoR)	Extreme - Very High – High - Medium - Very Low – Low- Negligible
Impact(Imp)	Catastrophic, high – moderate- Low- insignificant
Risk Dimensions (RD.)	Requirements- Estimations -Project complexity- planning and control- Project cost - Team, Planning, and Control – User - Organizational Environment- Software Requirement - Schedule - Organizational Requirements - Complexity,
Affecting No Modules(ANM)	Numbers of Modules
Fixing Duration(FD)	Period by Day
Cost of Fixing(CoF)	% project cost
Priority(Pri)	0 % -100 %
Risk Level(RL)	1- 2- 3 - 4 - 5

On the other hand, the other six characteristics: project category, risk target category, risk requirements, and risk dimensions, duration of determination (days), and impact on various centers impact risk assessment in software projects.

Fig. 5. The Relationship between the Magnitude of Risk and Risk Level.

G. The Answer of Question 2: How to Identify Top Risks Across Simultaneous Multi-Projects?

The systemic risk is the risk that often occurs throughout the organization. The treatment of risk is better to deal with when using a centralized database, although the project manager tries to search through many different project risk records in spreadsheets. Because these risks are in a multi-project environment, the project manager may be allowed to focus on his project. However, preparing the emergency budget for systemic risks is the responsibility of the program manager. Central risk management is a better methodology for reducing overall risk costs [10].

Identifying the "top 10" risks across multiple projects is a common requirement to monitor the most critical risks based on Central risk management methodology. It requires each project manager to provide information on the most significant risks to their project. However, this may lead to an error assessment of risk, as the fourth risk in one project may be more influential than the second risk in another. This situation does not mean the wrong risk assessment only but also may lead to the concealment of a great deal of potential impact, as shown in Fig. 5 [10].

The project results for the project differ from the risk data analysis for simultaneous enterprise-wide projects. Some managers may extract the results of a single project on its scale and then combine the results of project risk analysis in a single scenario [10]. This approach may face some criticism when dealing with this problem such as:

- 1) It is not commensurate with the dynamic nature and management of projects.
- 2) It may lack integrated centralized management to achieve a unified enterprise-wide vision.

Therefore, the art of research focuses on the central management of all project data together.

The graphic forms illustrate this Fig. 6 representing a static image at a particular moment in the life of the simultaneous development environment for the four projects included in the data upon which the research relied. The state

of the risks with the highest priority may differ from the view of Collective centralization from individual mono view at the level of a single project. The development of software in the environment of software companies does not take place in isolated islands; but instead, there is a sharing of resources and goals.

Fig. 7 shows the relationship between some subjective measures of risk and the level of risk. Self-assessment traits are affected by a person's assessment, such as the probability and magnitude of the risk. The figure shows that in some cases, as shown in the form, the estimated value is that the risk is high, while at the company level, this risk is at a lower level than other risks to projects that coincide with the same project.

The unique view of the project manager who focuses on a single project may differ, as shown in Fig. 7, from the holistic view, which deals with multiple simultaneous projects as explained in previous Fig. 6. Fig. 7 focuses on Transaction Processing System Projects, where it deals with it independently and then seeks to deal with the most significant threat affecting the project level and allocates resources to it that contribute to its treatment. This evaluation is a minor view because it is not the only project in the organization. After all, there may be a risk associated with another project with a more significant impact on the organization level. If it is not addressed and allocated resources, it may cause more harm to the software company's reputation.

The overall view of simultaneous projects contributes to formulating a unified picture of project risks at the enterprise level. Integrated risk management brings many benefits based on addressing threats that significantly impact the entire company for cost savings. It also delivers competitive advantages, enhances opportunities to achieve strategic and operational objectives, thereby reaping the greatest benefits and improving operational efficiency.

By conducting a comparative analysis of the classification of risk levels in a multi-project environment using the following four methods. Table V presents the results of the comparison process, showing the levels of accuracy achieved:

- 1) Random Forest
- 2) REP Tree
- 3) Trees J48
- 4) Simple Logistic.

Fig. 6. The Impact of Risk Exposure on Risk Level in Transaction Processing System Projects(Concurrent).

Fig. 7. The Impact of Risk Exposure on Risk Level in Transaction Processing System Projects.

TABLE V. SIMPLE LOGISTIC: CLASSES

Class 1:
207.79 + [RTC=Quality] * 1.28 + [MoR=Negligible] * 0.44 + [Pri] * -10.07
Class 2:
21.72 + [RTC=User] * -1.09 + [Pro] * -0.05 + [MoR=Low] * 0.64 + [MoR =High] * 1.05 + [Impact=Low] * -0.57 + [Pri] * -0.51
Class 3:
-0.49 + [RC=Performance] * -0.86 + [RTC=Budget] * 0.76 + [RTC=Performance] * 0.39 + [RTC=User] * 0.65 + [RTC=Requirement] * -0.67 + [RTC=Organizational Environment] * 3.03 + [RTC=Design] * -0.94 + [RTC=Unrealistic Requirements] * -1.31 + [MoR=Very Low] * -1.35 + [MoR =Low] * 0.36 + [MoR =Medium] * 0.77 + [MoR =Extreme] * 1.17 + [Impact=Low] * 0.41 + [DoR=Requirements] * -0.79 + [DoR =User] * -0.82 + [DoR =Software Requirement] * -0.57 + [DoR =Planning and Control] * -0.6 + [DoR =Cost] * 0.78
Class 4:
-28.32 + [RC=Constraints] * -0.72 + [RTC=Performance] * -0.64 + [RTC=Functional Validity] * 0.88 + [Pro] * 0.04 + [MoR=Medium] * 0.65 + [Impact=insignificant] * -1.14 + [FD (Days)] * 0.11 + [Pri] * 0.42
Class 5:
-154.64 + [RC=Security] * -1.69 + [RC=Constraints] * 1.34 + [RTC=Functional Validity] * -1.69 + [Impact=Low] * -3 + [Pri] * 2.04

There are many ways to classify risk levels in individual and multiple enterprise environments as shown in Table V. Initially, kappa's statistical value is between 0.9034 and 0.9713, and Kappa is used to test the reliability between the rate of the model. Classification methods have an almost degree of accuracy, with accuracy coming from 93% using a simple logistics method to approximately 98% using the REP tree. While error metrics are at very low levels, ranging from 0.0371 to 0.0126, to measure the absolute average error (MAE) and to measure the proximity of final results to projections and the value of 0.1488 to 0.0888 for the average root square error scale (RMSE). RMSE represents the standard deviation of differences between expected values and observed values.

Table V cells display a forecast model to predict risk levels according to a simple logistical method. Each of the five cells describes the characteristics of each category of risk levels from level 1 to level 5. the extract results from Wika 3.8.4.

After review, the simple logistical forecast model achieved the lowest level of accuracy among the classification methods used in the experiment. The best predictive models were the two methods of forecasting (J48 and REP Tree) in the experiment of this research by displaying the classification decision tree in these two ways. J48 algorithm deals with noise, Not much affected by lost data, and deals with continuous features. See Fig. 8, 9,10, and 11.

```

Fig. 8. J48 Pruned Tree.

Authors extract from the decision tree in the two methods; see Fig. 9,10 and 11. The main feature in the risk level classification is the priority, with rating values varying between evaluation methods. The risk priority feature represents a personal judgment of the project manager, who, according to the characteristics of each risk, determines the risk priority among the risks of simultaneous projects run by the company. In this regard, the experience and skills of project managers are critical to risk management in a multi-project environment. Therefore This requires a more in-depth and detailed study.

According to [42], J48 and REP Tree produce high classification and simple tree structure. The Reduced Error Pruning (REP) Tree in Fig. 10 and 11 show that the main factor for risk assessment is the priority of risk, which is the same result reached using the J48 tree displayed in Fig. 9, but there are some differences in digital values.

H. The Answer of Question 3: Identify the Association between the Objective and Subjective Variables and their Effect on Measuring the Level of Risk?

It is important to analyze the relationship between subjective and objective variables in assessing the risks of software development projects. Table VI shows the degree of correlation between these variables according to the data available at this research stage. It is noted from the results of the relationship analysis that there is a strong correlation between Priority, 'Risk Level', and Probability. At the same time, there is a weak correlation between 'Fixing Duration (Days), and others.

TABLE VI. PEARSON'S CORRELATIONS

Variable		Probability	'Fixing Duration (Days)'	Priority	'Risk Level'	Affecting No of Modules'
1. Probability	Pearson's r	—				
	p-value	—				
2. 'Fixing Duration (Days)'	Pearson's r	0.301	—			
	p-value	< .001	—			
3. Priority	Pearson's r	0.962	0.367	—		
	p-value	< .001	< .001	—		
4. 'Risk Level'	Pearson's r	0.923	0.356	0.958	—	
	p-value	< .001	< .001	< .001	—	
5. Affecting No of Modules'	Pearson's r	0.116	0.127	0.229	0.229	
	p-value	0.046	0.028	< .001	< .001	

I. Overall Comment on the Search Experience

It is clear from the research experience generally that the usual environment in software companies is a multi-project environment at the same time. Therefore, it requires an integrated management methodology to manage the risks of these projects together to achieve the company's general goals and then maintain its competitive capabilities and preserve its market share. This management methodology should include quantitative methods that help collect, analyze, and measure risk levels individually at the level of one project and collectively at the level of several projects that are developed simultaneously.

Project managers should also use data mining methods and statistical analysis techniques to reach knowledge levels that help allocate resources more efficiently. They must also use visual data presentation methods to determine the strengths and weaknesses that help them achieve critical success factors for software projects.

III. CONCLUSION AND FUTURE WORKS

At the end of this work, the following paragraphs summarize the findings of the results obtained and present some trends that need further study and analysis.

A. Conclusion

The central management of synchronous software projects gives a clear, integrated picture of the risk levels at the enterprise level. Data mining methods help identify the most important characteristics that must be recorded in the risk records of the enterprise database, where the study showed that the 12 characteristics included in the research data are important. This study has concluded with several important points, the most important of which are the following:

1) Priority, Probability, and Magnitude of Risk represent the main features to classify risk levels, where the six feature reduction methods in experimental ensure that.

2) The central unified risk vision of multiple simultaneous projects gives management an integrated picture to help it

allocate resources in a more efficient way that contributes to the company's overall objectives.

3) The classification methods (Simple Logistics, REP tree, trees, J48, and Random Forest) used in the research experiment contributed to high results of reliability and accuracy reached 98% and low levels of classification error measures.

4) The priority of risk is the most important factor in classification according to the best methods in the research experiment, with different percentages.

a) Relying on an integrated management methodology for risk management in a concurrent project environment helps identify the most influential risks at the company level rather than at the individual project level. Therefore, This contributes to the more efficient allocation of resources to achieve the company's overall objectives.

B. Future Work

The following points represent some of the proposed future trends for research and study in this area:

1) Conduct a more in-depth analysis of the relationship between subjective and objective variables considering the reciprocated impact on risk measurement.

2) Risk level analysis in light of multiple software development methodologies.

3) Measure the level of individual and group experiences of the project managers in measuring risk levels.

4) Analyze and study the relationship between risk characteristics in a multi-project environment and company characteristics such as size, age, organizational structure, etc.

5) Identify a model to measure the impact of knowledge Management on Risk Management in software development companies.

6) What are the impacts of Blockchain technology on concurrent project management in an overseas company? Does it reduce the risks, support fixing Mistakes, to allocate resources efficiently?

Abstract—As a result of what happened to the world during the past and current year of the spread of the Covid-19 epidemic, it was necessary to have a reliable health care system for remote observation, especially in care homes for the elderly. There are many research works have been done in this field, but still have limitations in terms of latency, security, response delay, and long execution times. To remove these limitations, this paper introduces a Smart Healthcare Framework called Remote in-Home Health Monitoring (RHHM), which provides architecture and functionalities in order to facilitate the control of patients' conditions when they are at home. The framework exploits the benefits of fog layers with high-level services such as local storage, local real-time data processing, and embedded data mining for taking responsibility for handling some burdens of the sensor network and the cloud and to become a decision maker. In addition to, it incorporates camera with body sensors in diagnosis for more reliability and efficiency with privacy preserving. The performance of the proposed framework was evaluated using the popular iFogSim toolkit. The results show the proposed system's ability to reduce latency, energy consumption, network communications, and overall response time. The efforts of this work will help support the overall goal to establish a high performance, secured and reliable smart Healthcare system.

Keywords—Fog computing; health monitoring; iFogSim; IoT; cloud computing

I. INTRODUCTION

With the increase in number of patients (like elderly people) living home alone under supervision of their doctors, it becomes necessary to add a facility for monitoring them remotely as the patient must be diagnosed for rapid intervention [1]. Moreover, some patients may have difficulties in reporting their pain condition for being impaired or disabled. Also, contagious diseases patients cannot communicate with others directly as Covid-19 patients. For such cases, smart healthcare systems represent urgent need. These systems used the technology to monitor patients at their homes or hospital and notify their doctors, caregivers or family individuals with their health status and demands [2]. These technologies involve IoT, cloud computing and fog computing.

IoT technology integrates hardware, computing devices, physical objects, software, and people via a network enabling them to interact, communicate, collect, and change data and actions are taken. Incorporating IoT technologies and healthcare improves the quality of healthcare systems.

Previous works have decomposed the architecture of IoT-healthcare system into three layers as depicted in Fig. 1 [3,4,5]: 1) body sensors that aggregate the data from the patients and the surrounding environment to be available for doctors, caregivers or authorized persons anytime and anywhere, 2) Fog gateways to receive and preprocess the sensor data, making some operations on data, and 3) cloud data center for storage, processing and analysis of data [4].

Cloud computing provides on-demand services to its users via internet in any place at any time. However, it is not adequate for meeting the requirements of rapid growth of IoT services, e.g., scalability and latency. It also has many negatives, such as: latency, network congestion, link disconnection and delayed response, in situations where the patient life may depend upon. So, fog computing can be the appropriate solution to collaborate with the cloud to fulfill the needs of real-time IoT services. Fog layer is an intermediate layer between sensors and cloud for data pre-processing, data analysis and storage rather than the cloud [6]. Fog gateway uses network switches, routers, smartphones, or embedded devices near the patient to provide cloud services with minimum latency and response time.

Fig. 1. General Architecture of SMART Healthcare Systems.

Healthcare monitoring systems in the literature comprise to two approaches: sensor-based and camera-based systems. Sensor-based approach uses the body sensor readings to diagnose patient status while camera-based depends upon capturing the patient image to analyze his emotions and body gestures. Each approach has its merits and its demerits according to the application and the objectives. This paper incorporates the two approaches in order to exploit the advantages of each in patient diagnosing whether the pain can be diagnosed by sensors only or not as the diagnosis of internal medicine, teeth pains, bones and muscles pains and

headache. The later health problems can be diagnosed efficiently using pain detection approaches rather than using sensors only.

In this paper, we introduce a smart fog-cloud based healthcare monitoring framework that uses both sensors and cameras for maintaining its various functionalities. The main contributions of our work are summarized as follows:

- Proposing a smart remote in-home healthcare monitoring system.
- Incorporating camera with body sensors in pain diagnosis for more reliability and efficiency, and for diagnosing non detected health problems such as internal medicine, teeth pains and so on.
- Taking advantages of the features of fog computing at which we add the decision maker that uses local data processing.
- Performance evaluation of the proposed fog-based system by using iFogsim toolkit.

This paper is framed in different sections. Section 2 introduces background and related work. The proposed framework is presented and explained in Section 3. Section 4 discusses the experimental results. Finally, Section 5 concludes the paper and suggests future works.

II. BACKGROUND AND RELATED WORK

The fog computing is a new paradigm in healthcare monitoring systems [6]. It can play a major role by its ability to perform data processing which preventing network congestion and reducing the amount of transmitted data. Most of the recent studies [7-17] in remote healthcare systems focus on using body sensors to monitor the patient status and provide the assistance to them. These sensors can be positioned on or embedded inside the body to measure certain signs of the patient. A specialized device is usually used to collect the data received from these sensors and is responsible for communicating them to the monitoring device. However, only few papers exploit using the camera to explain the emotional state of patients and analyzing it. According to that, healthcare related work will be discussed in the following two separated subsections where the first summarizes the usage of fog in healthcare and the second summarizes the usage of cameras in healthcare.

A. Fog Computing in Healthcare

Verma and Sood [7] introduced a fog layer for augmenting health monitoring system. They reduced the amount of data transmitted to the cloud by developing an event triggering mechanism which transfers the patient vital data in unsafe status only. Ahmad et al. [8] proposed a healthcare framework called HealthFog which concentrated on the data privacy in healthcare systems by integrating a cloud access security broker with the system in addition to cryptographic primitives. Nandyala and Kim [9] proposed an architectural view of a healthcare system known as IoT based u-healthcare monitoring system. This architecture exploits the advantages of fog computing which interacts more by serving closer to the edge at Smart Homes and Smart Hospitals.

An enhanced cloud-based Fog computing system is proposed by Gia et al. [10] where bio-signals are analyzed at the fog server side for real time applications. Negash et al. [11] concentrated on a smart e-health gateway implementation by connecting a network to such gateways, both in home and hospital use. Rahmani et al. [3] exploited the smart e-health gateways in healthcare IOT systems where the fog layer is between sensor network and cloud. A prototype of a smart e-health Gateway is presented for implementation and also an IoT-based Early warning score (EWS) health monitoring is implemented. Shree and Padmavathi [12] considered a fog-based scenario where the vital signs are collected from the patient, filtered, processed and take decisions at the fog layer.

B. Camera-based Systems in Healthcare

Mano et al. [4] developed a health smart home system based on the use of face image in patient identification and expression recognition. The authors in [13] observed the agitation in the sedated patients by installing the camera in the intensive care units. Banerjee et al. [14] proposed an approach for patient activity recognition in hospital beds using Kinect sensor. A non-invasive system for monitoring the newborns is presented by extracting and processing of motion signals, from multiple digital cameras, to estimate the periodicity of pathological movements using the Maximum Likelihood criteria [15]. Sun et al. [16] developed a video-based method for automated detection of the infants' discomfort. Chaichulee et al. [17] proposed an approach for detecting the presence of the patient and extracting cardio-respiratory signals from the patient skin with no clinical intervention using a video camera. A hybrid framework, in human behavior modeling in ambient assisted living systems, is proposed by Patel and Shah [18]. They added new events and behaviors and classified them into normal or abnormal human behavior by using camera images.

III. PROPOSED FRAMEWORK ARCHITECTURE

In this section, we describe the main architecture of the proposed framework, called Remote in-Home Health Monitoring Framework (RHHM). Fig. 2 illustrates the proposed framework architecture for remote patient monitoring, that is composed of three main layers: Sensor Network (IoT), fog and cloud layer.

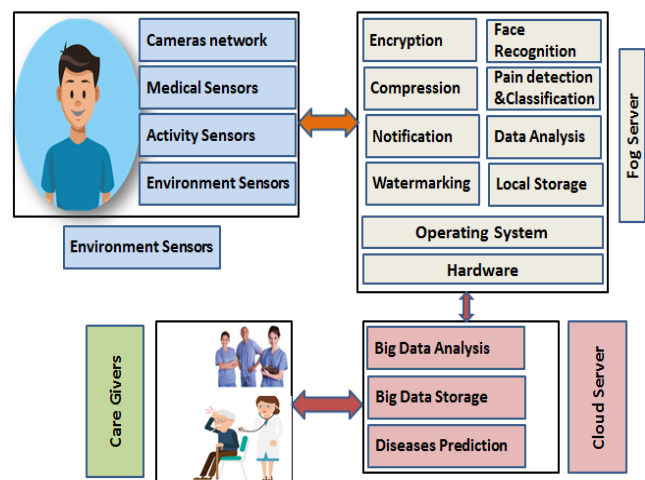

Fig. 2. RHHM Framework Architecture.

The following subsections demonstrate the details of the three main layers of the framework.

A. Sensor Network Layer

To collect the patient information that reflects his activity and medical state, several types of sensors are needed such as medical sensors, activity sensors, environment sensors and smart cameras constituting sensor network layer. Medical sensors include Electro Cardio Gram (ECG) sensor, Electro Encephalo Gram (EEG) sensor, Electro Myo Graphy (EMG) sensor, pulse oximeter sensor, temperature sensor, respiration rate sensor and glucose level sensor. Sensor's elements are responsible for detecting the presence of the patient, capturing his image, collecting readings and sending it to the fog devices via wireless or wired communication protocols. Sensors must be in all positions that the patient can move to it.

B. Fog Layer

Fog layer consists of multiple distributed smart devices or nodes, called gateways. A gateway is a device with computing, storage and network connectivity that is distributed near to the sensors which produce the data. Fog nodes handle four issues: 1) receiving patient data from sensors, 2) analyzing these data to make a decision of the health state of the patient, 3) communicating with caregivers, and finally 4) passing the data to the cloud. Local data processing is added to the fog for adding the intelligence to it in order to enhance the system by increasing its reliability, decreasing latency, overcoming the internet disconnection and speedup the decision especially at emergency situations. Fog layer has many functions and properties as followed:

1) *Data collection module:* This module can collect the physiological and environmental data from various wireless sensors embedded at different locations at home and from elderly patient and convert it to adequate form for analysis. Data filtering, preprocessing and noise removal are implemented in this module.

2) *Patient identification module:* This module is responsible for determining the identification of the patient via biometrics as face recognition, Iris recognition and finger print. However, face recognition is the easiest, fastest, cheapest and most reliable approach whereas it defines the patient identity and his emotions from videos or images, robust in different lightening conditions, able to work with faces from different angles and the camera and mobiles are available in anywhere. Face recognition consists of three steps: face detection, feature extraction and face recognition [19]. Face detection step decides if the captured image contains face or not. If it contains a face, it detects and specifies the face location in the image. Feature extraction includes extracting the features from the detected face by one of the two categories: appearance based or geometric based techniques [20]. Finally, recognition step compares the feature vector with all the stored vectors in the face database to decide the face identity by using machine learning classifiers. Fig. 3 shows the general steps of the face recognition process.

Fig. 3. Face Recognition Process.

3) *Patient pain recognition module:* this module is incorporated in the monitoring system to detect and measure the pain of the monitored patient. The pain can be detected through two methods: the first uses the vital signs as temperature, blood pressure and blood glucose which are collected from the wearable sensors that reflect the vital measures of the body. The second method uses the facial expressions to determine if the patient has pain or not and the degree of pain. Facial expression recognition is beneficial at the healthcare frameworks because it reflects the patient health status and emotions [4, 21]. It also helps the system to define the pain from diseases which do not have a device that reflects it directly such as: headache, teeth pain, and internal medicine pains. Taking a picture of a patient face periodically can give an idea of to what extent the patient is feeling pain and can enable a caregiver to decide whether help is required or not. Also, patient emotions are important factor during diseases treatment and diagnose of various diseases such as: schizophrenia, depression, autism and bipolar disorder. This module classifies the pain degree according to both facial expression and vital signs. The pain classification according to facial expression is depicted in Fig. 4.

4) *Data security module:* As the patient data can be vulnerable through being transmitted from a gateway to the cloud, the security and integrity of these data are essential requirements that must be considered in designing healthcare frameworks. Therefore, encryption and watermarking techniques as important components in secured healthcare frameworks are introduced by this module. Encryption is the process of converting data to an unrecognized form to protect it from unauthorized people. Furthermore, watermarking is the procedure of hiding information within an image without distorting the visibility or credibility of it.

Fig. 4. Pain Detection and Classification from Face Image.

The data security module in our proposed framework aims to hide the patient data when stored in the fog local server or transmitted to the cloud server by first watermarking the sensors data of the patient into the patient face image, then using a proper encryption algorithm the watermarked patient face image is converted into a cipher image that cannot be read except by the authorized parties as depicted in Fig. 5.

Fig. 5. Watermarking followed by Image Encryption.

5) *Local storage module*: The gateway should have a private local storage which stores the incoming data on a local repository to perform functions as data security and data analysis. Moreover, the data that could not be transmitted to the cloud due to network problems is stored temporally in the gateway.

6) *Notification module*: This module is responsible for sending alarms to caregivers and family persons if an urgent situation has occurred to the patient. It also tells the patient if an action is required; time of medicine, quantity of medicine, a specific food must eat, and any other desired instructions to follow. The notification may be a message, voice telephone call or voice over IP (VoIP). NG112 architecture is an example of VoIP that enables the modernization of emergency communications, allowing for far more data collection (text, video, location or additional data), which will result in a more efficient response [22]. NG112 also helps to ensure equivalent access for all citizens, including people with disabilities.

7) *Data analysis module*: This module is responsible for making decisions at fog layer in situations that need the fast intervention. The decision must be carried out by gathering information about the patient such as: age, weight, height and current diseases. Moreover, it receives the sensor data and applies machine-learning algorithms to decide if an emergency situation has occurred to send a fast alarm and send the collected data to the cloud. If the data does not contradict the patients expected behavior or health, the decision maker module does not take any action and no data will be transmitted to the cloud storage.

A generalized algorithm is proposed for decision-making and notification based on camera face image and vital signs such as body temperature, blood pressure and blood glucose percentage. The proposed algorithm is illustrated in Algorithm 1. The algorithm starts with determining the threshold of each reading such as *pain_score*, temperature threshold, blood pressure, blood glucose percentage. Sensor data is sent to the machine-learning algorithm. This data is then analyzed to determine the action to be taken as shown in the selection structure (IF statement) of Algorithm 1.

Algorithm1: Decision-making and notification algorithm

Input: Real values from Camera and sensors

Output: Notification at emergency situations

Steps: -

- Initialize the threshold of each sensor reading: pain class from face image as *pain_score*, temperature threshold as *T_threshold*, blood pressure threshold as *B_threshold*, blood glucose percentage as *G_threshold*.
- Read the sensors data and camera data.
- Determine *pain_score* using face image and machine learning model
- If (*pain_score*==strong)
 NG112 call to **CareGiver** via mobile app.
- Else If (*blood pressure*< *B_threshold* || *blood pressure*<>*B_threshold*)
 NG112 call to **CareGiver** via mobile app.
- Else If (*temperature threshold* < *T_threshold* || *temperature threshold* > *T_threshold*)
 NG112 call to **CareGiver** via mobile app.
- Else If (*blood glucose percentage* < *G_threshold* || *blood glucose percentage* > *G_threshold*)
 NG112 call to **CareGiver** via mobile app.
- Else
 NG112 call to **patient** via mobile app "Normal situation".
- End if

8) *Data compression module*: The patient data must be sent to the cloud for storage, diseases prediction, risk amount assessment and long-term analysis. Huge amount of data is sent periodically to the cloud which cause network congestion, latency and it needs a large space for storage. Image compression deals with the previous problems. There are two types of image compression algorithms; lossless and lossy methods [23]. Medical image as in our work must use the lossless methods because any loss of the information in the original image can result in improper diagnosis and risk assessment. Lossless compression is decomposed of two steps. The first step: transforms the image to another format. The second step uses an entropy encoder to remove the coding redundancy [23].

C. Cloud Layer

Cloud layer consists of distributed resources, repositories and servers that are located at far place. These devices are managed by a cloud manager that integrates them to receive process and store the patient data. The doctor/caregiver can use these data to fulfill long-term analysis evaluating the status and history of patient health. It is responsible for the following functions:

1) *Big data storage*: The data gathered from sensors, after being analyzed at the fog layer, is transmitted to the cloud storage which provides enormous amount of storage for saving large healthcare data files. The healthcare data is available to doctors, caregivers, hospitals and assurance companies for further various usages.

2) *Big data analysis*: It helps in analyzing all patient data (such as images, symptoms, therapy plans and treatment) and makes all the data available to support and improve long term clinical decision-making processes, treatment and medical research. Machine learning algorithms, predictive algorithms and data visualization algorithms can be conducted on these data to get more insights form these data.

3) *Diseases Prediction*: Based on patient information such as: age, height, weight and historical diseases in his family, this unit is responsible for the expectation of the diseases which the patient can possibly incur in the future. It uses machine-learning algorithms to compute the percentage of the expected diseases based on the correlation of the accepted vital signs as simply shown in Algorithm 2.

Algorithm. 2: Diseases prediction phase

Input: vital signs as: temperature, pressure, blood glucose.
Output: percentage of diseases prediction.
Algorithm:

- Accept each vital signs of a patient.
- Compute the correlation between vital sign and predicted diseases.
- Use machine learning algorithm to specify the percentage of each disease possibly.

IV. DATA FLOW OF THE PROPOSED FRAMEWORK

Fig. 6 depicts the components and dataflow of the proposed framework. Each component and its job are described as follows:

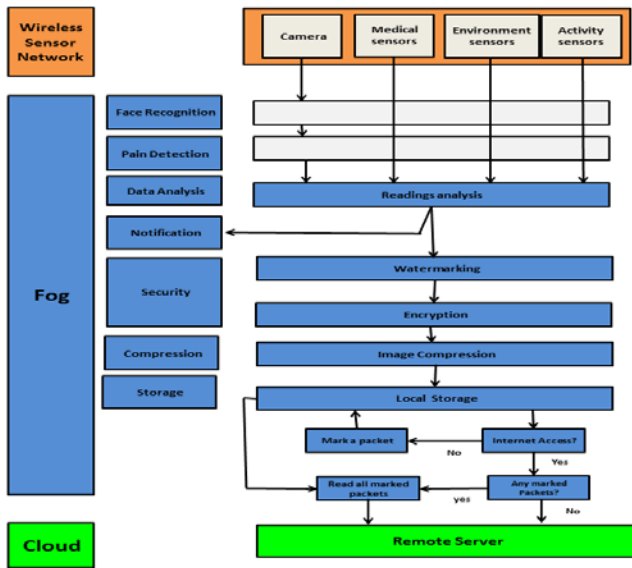

Fig. 6. RHHM Framework Dataflow.

1) The fog device receives the patient face image from the camera or mobile phone. Then, the fog device either continues its work or does nothing according to the decision of recognition phase.

2) If a pain is detected from the face expressions or unusual body activity, it alerts the data analysis unit to integrate with sensor readings.

3) Data analysis is accomplished on sensor readings. Data filtering is applied to the received sensor data to remove the noise, electromagnetic interference and improper attachments of sensors. Then, it analyzes the filtered sensors data to assist the system in diagnose the patient situation.

4) The system notifies responsible persons about the patient health status if an emergency situation is occurred.

5) The patient data is forwarded to be stored at the cloud for future needs. This data is hidden in the patient image. Then, image is encrypted and compressed.

6) The system saves a backup of patient's health data locally in case of a connection problem with the cloud.

V. DISCUSSION

Improvements in using the fog-based framework against cloud based only for remote pain monitoring will be illustrate in the experimental results. To validate the effectiveness of the proposed fog-based framework, the results are compared to the cloud-based framework for health monitoring. The comparison is accomplished in terms of energy consumption, latency, network usage and response time. The results of the simulations are performed on different scales confirmed the effectiveness of the proposed framework compared to the cloud based one. Also, we briefly compare the proposed framework to the existing healthcare frameworks as shown in Table II. To the best of our knowledge, none of the existing systems uses both the face emotions and pain detection in patient identification together.

From Table I, it is obvious that the proposed framework exceeds its predecessors in different aspects.

TABLE I. COMPARISON OF THE PROPOSED FOG FRAMEWORK WITH THE EXISTING FRAMEWORKS

Reference	Paradigm	Use of IoT sensors	Use of image processing	Patient identification	Face as identification

Proposed framework	Fog	√	√	√	√

VI. EXPERIMENTAL RESULTS

Considering suitability as tool for simulating applications, iFogSim [24] was employed to evaluate the proposed RHHM framework by using the basic functionalities such as datacenters and cloudlets. As first simulator of IoT objects, it connects to the fog devices and cloud in a hierarchical manner [25].

A. Model Building

The simulation is accomplished with four types of fog devices. Four physical topology configurations of a monitored home are conducted to obtain accurate results: config1, config2, config3 and config4 which represent homes composed of one room, 2 rooms, 3 rooms and 4 rooms to be monitored, respectively as in Fig. 7. Each room is equipped with 2 smart cameras monitoring the areas, temperature sensor and pressure sensor, in addition to ISP gateway. The whole home has a WiFi gateway which transmits data to the cloud. Smart cameras transmit live video streams to the mobile phone which recognizes the patient and in order to send to ISP Gateway. Smart phone has 1GB RAM, 1GHz CPU and needs 87.53 W of power while ISP Gateway has 4 GB RAM, 2.8 GHz CPU and needs 107.330W of power as the WiFi Gateway but the cloud has 8 GB RAM, 4 GHz CPU and needs 1648W of power.

Table II shows the latency from each fog device to another in a hierarchy manner. Through the conducted experiments, two scenarios were evaluated as depicted in Fig. 8: the first one is cloud-based RHHM where the sensors including smart cameras send their readings to the cloud for decision making while the second scenario is fog based RHHM where the data is analyzed at the fog gateways to make the decision.

Fig. 7. Physical Topology Configurations: (a) Config1, (b) Config2, (c) Config3 and (d) Config4.

TABLE II. LATENCY BETWEEN FOG DEVICES

Source	Destination	Latency (ms)
Camera	Smart Phone	1
Smart Phone	ISP Gateway	2
Temperature or Pressure sensor	ISP Gateway	5
ISP gateway	WIFI Gateway	2
WIFI Gateway	Cloud	100

These models are evaluated in terms of work delay, energy consumption, network usage and execution time and the simulation charts are given. In the experiments, each scenario is built and evaluated individually using the following steps:

1) The application modules are constructed, which are represented by 11 squares in Fig. 8(a), and 9 squares in Fig. 8(b), as: face recognition, pain detection, watermarking, and so on with the following features: RAM=100MB, MIPS(million instruction per second)=1000, Bandwidth=1000 and VM (virtual machine) is Xen.

2) The application edges connect the application modules with each other; where each application edge is described by its source, destination, tuple CPU length, tuple network length and direction.

3) The application loops, which represent the flow of data, are conducted according to each model. Two application loops were used to represent the delay; the first loop starts from capturing images to caregiver notification while the second loop starts from data analysis model to patient knowledge with the decision.

4) Fog devices are considered.

5) Adding application modules to the fog devices as described in Fig. 8.

6) Finally, the experiment is conducted.

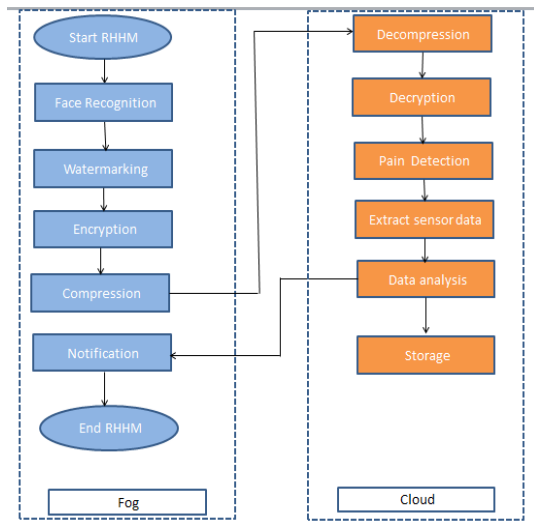

B. Energy Consumption

To prove our framework, we have measured the energy consumed by the different categories of devices (mobile phones, edge devices and cloud) as illustrated in Fig. 9. It is observed that the energy consumed at the mobile phones and edge devices are semi-equal at the two scenarios because the devices work periodically in the two situations. But the energy consumption at the cloud in cloud-based RHHM is higher by 8%-20% than it in fog-based RHHM, because the data analysis and decision making is implemented at the fog in fog based RHHM while they are shifted to the cloud in cloud-based RHHM. The total energy consumed in cloud-based RHHM is 9%-22% higher than that consumed in the fog-based RHHM which means that the proposed fog-based RHHM saves the energy of the system components and meet the performance requirements.

C. End to End Latency

The time from sending the data from camera, or sensors, until the result or the decision appears on the patient smart phone is recognized as the end-to-end latency. It computes the time needed to take the decision according to the patient status. It is noted from Fig. 10 that the processing time on fog devices in fog/cloud-based RHHM is very small compared to the processing on the cloud in cloud-based RHHM. The

latency also increases as data transmission increases resulting from the number of rooms under consideration. The average latency is reduced at fog-based RHHM by 97% than that at the cloud-based RHHM.

(a) Cloud based RHHM.

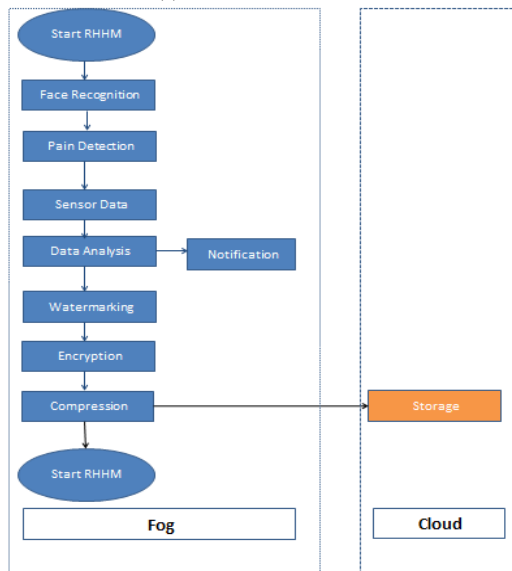

Fig. 8. (b) Fog based RHHM.

Fig. 9. Energy Consumption of Mobile Phones (Cameras), Edge Devices and Cloud.

Fig. 10. Average Latency of Control Loops.

D. Network Usage

Fig. 11 shows the network usage at the cloud and the fog. It is obvious that the network time usage and the data transmitted via the network is 15% to 16% less using the fog/cloud based RHHM.

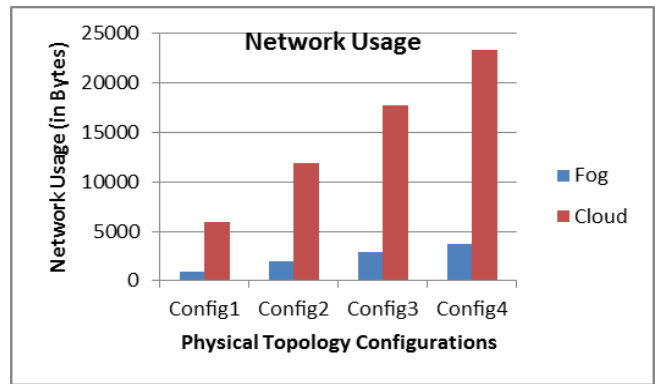

Fig. 11. Network usage.

E. Total Response Time

Fig. 12 shows that the total response time increases when the number of rooms increases and consequently data transmission increases due to the amount of collected data increases and the need for processing increases. The figure also shows the high contrast between the processing at fog layer in fog/cloud based RHHM and cloud in cloud based RHHM.

Fig. 12. Total Response Time of the Frameworks.

VII. CONCLUSION AND FUTURE WORK

In this work, we propose a fog/cloud based RHHM framework that moves the decision making to the fog gateways and incorporates a camera with wearable sensors in detecting some pains that cannot be diagnosed or detected through sensors only such as: internal medicine, teeth pain and headache. The framework archives the security of the patient data using watermarking and encryption algorithms. Our conducted experiments illustrate the RHHM system with various merits as enhanced overall system intelligence, energy efficiency, less network usage, and high response time.

So that, RHHM is a good choice to be used at homes, elderly care homes, or hospitals in the near future. The framework can be improved by using alarming systems and incorporating other image analysis techniques as fall detection to improve patient status assessment.

What Drives Airbnb Customers' Satisfaction in Amsterdam? A Sentiment Analysis

Heyam Abdullah Bin Madhi¹, Muna M. Alhammad²

Management Information System Dept
King Saud University, Riyadh
Saudi Arabia

Abstract—The sharing economy is a new socio-economic system that allows individuals to rent out their personal belongings, such as their private car or a room in their home, for a short period. This study aims to investigate the attributes that impact customers' satisfaction when using the sharing economy propriety rentals websites. Large data sets of Airbnb's online reviews and listings in Amsterdam were analyzed using sentiment analysis, word clustering, ordinal logistic regression, and visualization techniques. Findings reveal that the polarity of Airbnb guests reviews in Amsterdam is significantly impacted by property price, value, cleanliness, rate, host communication, easiness of check-in, the accuracy of property description, and whether the host is super host or not. Surprisingly, the property neighborhood was not found to impact customers' sentiment in Amsterdam. In addition, Airbnb guests in Amsterdam tend to positively express their experience satisfaction level mainly based on property exact location and host interaction followed with the facilities surrounding the property, property cleanliness, and room quality. On the other hand, negative online reviews tend to be mainly linked to problems with check-in services followed by aspects related to weak host interaction, location, and room quality. The results indicate that Airbnb hosts need to offer clear and easy check-in services with emphasizing the importance of keeping a good communication channel with their guests to enhance customers' experience and increase customers' satisfaction level. Future studies should investigate the applicability of the findings of this study in the context of other cities.

Keywords—Airbnb; customer satisfaction; customer experience; big data; sentiment analysis; ordinal logistic regression

I. INTRODUCTION

The development of media technology has contributed to the prosperity of a new business concept, which is the sharing economy [1]. A sharing economy is an advanced approach for conducting businesses, where people can share their own resources in a decentralized or peer-to-peer (P2P) platform for an exchange of money [2]. It has generated new business opportunities, especially for those who don't have the essential resources. Additionally, property owners have granted the chance to liquidate and utilize their unused assets across the globe, allowing them to serve customers from different regions and cultures [3]. The sharing economy had provided the necessary services in different qualities and prices 24/7 in order to provide suitable services to fulfill individual needs and cater to a different level of purchasing power. As a result, consumption and production sustainability have been accelerated [4]. The concept of the sharing economy has been

applied in different fields including, shared mobility, hospitality, on-demand staffing, and media streaming. Lime, JustPark, and Uber are some examples of sharing economy applications. In the context of hospitality, several companies have emerged, such as Airbnb, Couchsurfing, HomeAway, Roomorama, and HomeExchange. These organizations act as an intermediary between guests and hosts to facilitate communications between them [5].

Looking at Airbnb as an alternative option for hotels, several existing research have explored this platform from different perspectives. The author in [6] examined the substitution and complementary effects of Airbnb supply on hotel sales performance patterns while [7] studied the extent to which Airbnb is used as a substitute for hotels and [8] studied the price difference between hotel property and the nearby Airbnb listings offers. Additionally, many other researchers have studied the social contact of guests in the Airbnb accommodation. For instance, [9] explored the social contact of Airbnb guests during their stay, taking into account these types of contact: guest to host, guest to the community, and guest to guest communications whereas [10] studied the reciprocal aspect of social interactions in P2P accommodations. Several other studies have examined factors that might affect guests' booking intentions such as studying the impact of gender congruity between guests and hosts on guests' booking [11], and the impact of properties and hosts descriptions on guests' booking and posting reviews [12]. Moreover, some authors recognized the importance of studying online advertising strategies [13], price determination [14], trust-attachment building mechanisms [15], and customers' psychological behavior [16]. Despite the diversity of Airbnb research fields, few studies have examined guests' reviews toward their Airbnb stay. [17] have investigated the attributes that influence Airbnb users' experiences through the use of text mining and sentiment analysis. Similarly, [18] have investigated hidden dimensions in textual reviews through the use of Latent Aspect Rating Analysis (LARA). Analyzing big data such as customer reviews is a key success factor for sharing economy businesses [19]. It enables a business owner to understand the organization's strengths and weaknesses along with customers' habits. Therefore, it helps to predict future trends, improve decision making, detect frauds, and eventually increase business revenues.

However, to the best of the authors' knowledge, there are no previous studies investigating factors that drive customers' satisfaction through analyzing guests' online reviews

simultaneously with the listing features. Therefore, to better understand customers' needs and achieve customers' satisfaction, there is a need to identify factors that make customers satisfied. Analyzing users' comments and reviews, through the use of various data mining techniques, helps to identify factors impacting users' satisfaction [19]. Therefore, the research question to be answered in this research is:

What makes customers satisfied when using the Airbnb platform in Amsterdam?

Airbnb online reviews dataset in Amsterdam will be analyzed simultaneously with the listings details dataset by using sentiment analysis, topic clustering, regression, and visualization techniques. The paper begins with reviewing relevant literature, clarifying the applied methodology, presenting the results and discussion, and finally concludes the paper.

II. LITERATURE REVIEW

A. Sharing Economy

According to [20], sharing economy concept is the result of a massive shift, not a new phenomenon in itself. This is because sharing economy is an online community that includes economic aspects such as selling, buying, and renting which already existed before. However, the new concept is distinguished by allowing users to participate using different types of resources, in both economic and social aspects, whether it was a human, merchandise, service, or property [21]. A more comprehensive description was provided by [22], where they defined sharing economy as a P2P environment that enables a person to be a client and a provider at the same time. The sharing economy facilitates social participation and cooperative consumption which in turn supports protecting the environment, minimizing resource waste, and enhancing community awareness [4]. The sharing economy covers five main areas: product-service systems, redistribution markets, collaborative lifestyles, access-based consumption, and commercial sharing systems.

As mentioned earlier, sharing economy businesses have witnessed rapid development in the last decade. The author in [5] justifies the reason to be related to the fact that sharing economy businesses are less expensive for consumers, especially in the case of accommodation as it is cheaper for travelers to choose a place from Airbnb to stay, rather than renting a room in a hotel. Additionally, [19] have demonstrated that science and technology revolutions are playing a huge role in sharing economy growth through the development of electronic social networking (e-SN) platforms which contributed to the development of society and the economy.

Although business fields differ, online hospitality is one of the most famous fields in sharing economy. The word hospitality was defined by [22] as two associated meanings. From the guests' perspective, hospitality is a process of delivering a service of high quality while from hosts' perspectives; it is about providing services and rooms with a focus on profitability. In terms of hospitality, using the sharing economy, hospitality means allowing individuals to invest their properties to host visitors for a small financial return through

the use of online sharing economy portals such as the Airbnb website.

B. Customers' Satisfaction

The word satisfaction is defined as "a psychological statement with the fulfillment of a need or desire and the pleasure obtained by such fulfillment" [19]. Customers' satisfaction can be interpreted as customers' judgments, opinions, feelings, impressions, or emotional reactions towards their comprehensive experiences of a product or a service [23]. [22] have indicated that it is essential to understand customers' satisfaction and how it is impacted to ensure customers' commitments and obtaining their loyalties. Increasing customer satisfaction will increase customer retention and loyalty. Consequently, organizations' revenues and profits will rise as there is a direct link between customers' satisfaction and profit [24]. However, increasing customers' satisfaction comes at a cost, so organizations must be careful not to reach excessive satisfaction that costs them a lot without returns. To achieve the maximum customer satisfaction level with minimum cost, organizations must understand their customers and what makes them satisfied [24].

Obtaining customers' satisfaction could be a big challenge for many organizations. The first step to increase customers' satisfaction is identifying customers' current satisfaction levels and the reasons that led to this satisfaction level. Capturing and measuring customer experience is an excellent way to achieve that. Analyzing rating scores and comments that were produced by customers after the end of a service, can grant comprehensive knowledge about customers' satisfaction [25]. In this research, Airbnb guests' reviews will be analyzed, to better understand customers' satisfaction along with factors that affect their level of satisfaction.

C. Airbnb

Airbnb, Inc. is an online marketplace that was founded in 2008 for offering accommodates, homestays, or tourism experiences. It is one of the most leading and profitable platforms within the sharing economy [26]. The organization works as a broker that connects real estate owners with hospitality seekers. In particular, it links individuals who need to lease out their homes (hosts) with individuals who are searching for lodging (guests) in that region in exchange for a small commission from each reservation [27]. Hosts are taking part in Airbnb as an approach to obtain some pay from their property even though they are facing the risk that guests may harm their property. On the other hand, guests are taking advantage of having accommodation with relatively lower prices than other places while at the same time facing the risk that the property's quality will not be as expected. Generally, Airbnb provides services for both guests and hosts to provide a better coordinating outcome [28].

Several types of research have been applied to Airbnb, some focusing on user experience and multimedia, others on administration, tourism, and architecture [29]. Covering multiple areas including review bias, hospitality exchanges, price and neighborhood prediction, neighborhoods ranking, socio-economic characteristics, listing recommendation system, rentals' distribution, users' preferences and expectations, image mining, demand mining, grading schema,

matching schema, consumer segmentation, trust evaluation, innovation adoption, and adoption evaluation. In addition to some researches that focus on analyzing customers' satisfaction dimensions [30], analyzing customers feedback using text mining [3], and analyzing public opinions using content analysis [21]. Previous studies have almost exclusively focused on analyzing user reviews separately without linking them to listings data. A more comprehensive analysis is required for analyzing factors affecting customers' satisfaction, in a way that enables non-technical users to understand it without any effort.

III. METHODOLOGY

A. Data Collection and Preparation

Over time, extensive literature has confirmed the importance and usefulness of analyzing online review comments for researchers, business owners, as well as other customers. Since users' comments illustrate their perceptions and feelings formed while using a service or a product, it could be used to measure and analyze users' satisfaction level, along with identifying key factors that led to such a level of satisfaction [31].

On the Airbnb website, guests are posting reviews that reflect their experiences and opinions about the property they stay on. This provides data that can be analyzed, to identify factors that make customers satisfied [32]. The current study obtained online review comments of Airbnb' guests about their accommodations in Amsterdam, as well as detailed listing data from the Inside Airbnb website [33]. Given the fact of the massive availability of Airbnb data as public Datasets available on the Inside Airbnb website, both datasets were obtained easily. The listing dataset contains 107 attributes that describe host, property features, and scored reviews while the review dataset contains six attributes and more than 400 thousand review records. Datasets were then pre-processed or cleaned before the analysis phase, as performing this step usually helps to generate feasible results [34]. For the listings dataset, the cleaning process was done by eliminating attributes containing errors, no values (blank), and useless values. Thereafter, new columns were generated or derived from existing attributes, such as host experience in months derived from the host starting date, weekly and monthly discounts derived from prices. On the other hand, the review dataset was checked for missing data and non-English content to be removed. Google Online Spreadsheet was used to detect comments' language, and to clean non-English data from the set, which represents 18% of the records. Unwanted columns were eliminated including comment ID, reviewer ID, and reviewer name. Additionally, a filter was applied using the date of the comment, choosing comments within 2019 only, to minimize the number of reviews and make it manageable to analyze the data using home devices with limited capabilities. Dummy comments containing characters or numbers only were also removed leaving a total of 110,747 comments eligible for the analysis.

B. Data Analysis

1) *Sentiments analysis*: The first step in the analysis stage began with sentiment analysis. The sentiment analysis has

been conducted using MeaningCloud's Text Analytics add-in in Excel. MeaningCloud sentiment analysis produces two sheets. The first one is for the global sentiment analysis sorting includes the polarity, i.e., positive (P), negative (N), or Neutral (NEW), and a confidence score while the other one is for comments' topics sorting including topics categories and topics types (which were used later on in text mining).

2) *Regression analysis*: The second step in the analysis was identifying factors affecting users' satisfaction. To begin this step, the two datasets were merged. Ordinal logistic regression (OLR) test was chosen as suggested by [35], to answer the research question, by determining which of the independent variables (IV) have a statistically significant effect on our dependent variable (DV), which is polarity.

The reason for selecting the OLR test in this study is because the DV is an ordinal categorical variable where the value is represented with three points scale (N=0, NEW=1, and P=2) and the IVs are a mix of continuous and categorical. Multicollinearity test was conducted to ensure there are no highly correlated IVs, and only two IVs (accommodates and beds) were highly correlated with a result of >0.8; accordingly, the beds variable was removed from the test. Without performing the multicollinearity test, there would be a problem with determining the variable that contributes to the interpretation of the DV [35]. After eliminating the highly correlated variables, the final variables set contained 32 attributes as following: host experience in months, host response time, host response rate, the host is super-host, host total listings count, the host has profile pic, host identity verified, neighborhoods cleansed, is location exact, property type, room type, accommodates, bathrooms, bedrooms, bed type, square feet, price, weakly discount, monthly discount, security deposit, cleaning fee, extra people fee, instant bookable, cancellation policy, require guest phone verification, review scores rating, review scores accuracy, review scores cleanliness, review scores check-in, review scores communication, review scores location, and review scores value.

Taking the results from the OLR test, factors that affect polarity were visualized using Power BI software. Power BI was also used to conduct a text mining test to find the most frequent words within comments. Word's visualization helped to derive additional insights about repeated words in different polarity levels.

IV. FINDINGS AND DISCUSSION

A. Sentiment Analysis and Topic Clustering

The results of the sentiment analysis indicate that Airbnb users were mostly having a positive experience in Amsterdam (see Fig. 1). The topic clustering result shows that users were overwhelmingly positive about two aspects of their experience i.e. location and host (Table I). For instance, the likelihood score of 52% for a location means that reviews with the term location represent 52% of the positive sentiments. Location is an essential indicator for customers' satisfaction since they care about the proximity of different facilities to their residence such as public transportation, restaurants, park, station,

markets, and shops. As a second major topic within the positive sentiments, the term host represents 31.66% of the positive results; this indicates that many users were satisfied with the way their hosts were treating them. In contrast, the topic that consistently received a negative sentiment was check-in (Table II). The term Check-in represents the majority of the negative sentiment with a likelihood score of 95.69%. This result gives an indicator for hosts to improve their check-in services, to make this process quick, efficient, and smooth. This can be achieved by following the authoritative guide to the Airbnb check-in process. Fig. 2 shows word clouds that support the previous findings.

Although Airbnb's comments are mainly positive, taking a closer look at areas where negative sentiments have occurred, allows Airbnb hosts to address these areas by fixing any problems or setting future expectations (e.g., improving check-in services). Moreover, the strong appearance of topics related to the city's environment (such as location, facilities, transportation, restaurants, parks, stations, markets, and shops) among positive sentiments compared to their weak presence among negative ones, indicating that Amsterdam's general environment can play an essential role in shaping the Airbnb guests positive experience.

Fig. 1. Polarity Likelihood, Where N is Negative, NEU is Neutral, and P is Positive.

Fig. 2. Word Cloud for Airbnb Positive (Left) and Negative Reviews (Right).

B. Factors Influencing Comments Polarity

After applying an OLR test, the authors found that only nine out of thirty-two factors were influencing customers' satisfaction with a significant P value of < 0.05 (Table II). These affecting factors are price, room type (Entire Home/Apartment), the host is not a super-host, review scores rating, review scores accuracy, review scores cleanliness, review scores check-in, review scores communication, and review scores value. Surprisingly, the property neighborhood was not found impacting customers sentiment in Amsterdam which might be a case only limited to Amsterdam as it is one of the safest cities in the world.

1) *Price*: Price is the first-factor influences customers' satisfaction ($B= 5.957, p<0.05$). Fig. 3 illustrates the relationship between properties' daily prices and the polarity of comments sentiment. The figure shows that as the price raises, the negative reviews decline. In other words, positive comments are more commonly associated with high price properties comparing with negative ones. According to [14], properties with some features such as luxurious, penthouse, unique, chic & designed, duplex, Sauna, Jacuzzi & Spa, are relatively more expensive than other properties. It is, hence, expected that the benefits of obtaining luxurious characteristics, make customers willing to pay more.

Similarly, [36] indicates that some amenities are considered a price determinant. The availability of these amenities will give Airbnb customers the quality they are seeking. Eventually, they will be more satisfied and happier compared to customers who didn't obtain these amenities. Therefore, property price impacts customers' satisfaction indirectly since prices are determined by quality, which is critical to gain customers' satisfaction.

2) *Room type*: The second affecting factor is the room type, including the entire home/apartment, hotel room, private room, and shared room. Fig. 4 showing the percentage of negative and positive comments among the four property types (calculated as a percentage out of the same polarity). For example, entire home/apt negative comments represent 29% out of the total negative sentiments for the four types. The type of entire home/apt is more likely to get negative reviews than positive ones. After comparing the average of different attributes based on user sentiment (Positive versus Negative), the researchers found some factors that affect the entire home/apt polarity (see Fig. 5). The result indicates that decreasing the average square feet influences making negative feelings. Moreover, as host listing increased, the probability of getting a dissatisfied guest will be increased as well. Hence, it is evidence that there's a negative relationship between host total listings and customers' satisfaction. This could be due to hosts being busy handling all their properties simultaneously, therefore providing poor customer services. Eventually, hosts will fail to deliver the expected level of care to their guests.

Fig. 3. Price Distribution for Negative and Positive Polarity.

Fig. 4. Likelihood of Polarity, Grouped by Room Type.

Fig. 5. Factors Influencing users' Polarity when Renting Entire Home/Apt.

3) *Super-host*: The third affecting factor is when the host is not a super-host. Fig. 6 is showing a similar distribution of super-host within the positive comments, which illustrates that whether a host is super-host or not, it will not affect the positivity of a sentiment. In contrast, the negative sentiments are widely affected by the host being not a super-host. Fig. 6 illustrated that 88.8% of unsatisfied customers were hosted by non-super-hosts. This supports [24] findings, who confirmed that poor services have a more significant impact on satisfaction level than good services. People tend to expect a certain level of quality. Obtaining this level will not positively

affect their satisfaction degree, but failing to reach this level will significantly affect their satisfaction negatively. According to [10], what distinguishes P2P accommodation from traditional hotels is to create a sense of place by providing a closer interaction with a resident (host). In such an aspect, online and face-to-face interactions with the host can influence customers' satisfaction, due to the atmosphere host creates. This fact supports our contribution here since low host interactions will lead to customer dissatisfaction.

4) *Neighborhood*: Surprisingly, though location plays an important role as an affecting element on polarity within topic clustering results (see Fig. 2), the OLR test provided evidence that neighborhood wasn't affecting the polarity (Table II). After a careful review of the results, it seems that the neighborhood by itself has no impact, while the exact location inside each neighborhood does. The reason for this situation is that different location within the same neighborhood district in terms of facilities, quietness, transportation, etc. To confirm OLR result, the relationship between polarity and neighborhoods were represented in Fig. 7 using maps and a bar chart. The maps show a similar distribution between the Ps and Ns comments, and the bar chart supported this result by indicating that each neighborhood has almost the same distribution rate of the Ps and Ns (top 15 neighborhoods). This could be due to the characteristic that made Amsterdam a unique city that everyone would like to visit. Such as its high quality of life, the European culture lifestyle, the small village feeling, and its beautiful landscape in all neighborhoods. One of these characteristics is safety, as [37] illustrated that Amsterdam is considered the fourth safest city in the world and the safest among all of Europe. The level of safety of all Amsterdam's neighborhoods is high in terms of personal security, health security, infrastructure security, and digital security. This support our findings that Amsterdam's neighborhoods do not affect Airbnb customer's satisfaction since the visitors (guests) will be positively biased toward this city and all of its neighborhood in general.

Fig. 6. Superhost Proportion in Positive Comments (Right) and in Negative Comments (Left).

Fig. 7. Polarity Distribution based on Locations.

V. CONCLUSION AND FUTURE WORK

Airbnb represents a flourishing implementation of the sharing economy generally, and hospitality mainly. While Airbnb remains a topic of significant attention within the sector, preliminary literature on Airbnb has examined customers' reviews independently. This study is the first endeavor to analyze Airbnb's listings features as factors impacting review polarity. The authors found that prices, the host being a super-host, and room type are the main impacting factors on customers' satisfaction. Moreover, in the topic clustering test, positive comments contained "Location" as the most frequent word, while negative comments contained "Check-In". However, Amsterdam as a place has been confirmed that it's affecting Airbnb's customers' satisfaction and could be a motive to generate positive comments. This study was attempting to avoid the biased sample effect, by looking at factors as a percentage of each factor polarity out of the same polarity total in visualization. Regarding this attempt, there are some limitations to this study. The use of one sample such as Amsterdam could affect the result since there are limitations with a non-random sample.

This study highlights some possible orientations for future research. It would be beneficial to compare the results of different countries, to distinguish common factors versus cultural factors. Accordingly, this will help to confirm whether customers' satisfaction is affected by a country's general environment or not. Furthermore, it would be interesting to test text attributes such as room description and host "about" against polarity. Lastly, this study introduced a new method of determining factors affecting customers' satisfaction, by examining factors against polarity using sentiment analysis and regression test, then confirm the results using visualization. This approach can be applied to other studies in hospitality and beyond.

Motivational Factors Impacting the Use of Citizen Reporting Applications in Saudi Arabia: The Case of Balagh Application

Muna M. Alhammad¹, Layla Hajar², Sahar Alshathry³, Mashael Alqasabi⁴

Management Information System Department, King Saud University, Riyadh, Saudi Arabia

Abstract—Citizen reporting applications are considered a new approach for interaction between government authorities and citizens. Citizen reporting applications are implemented to collectively gather information from citizens on issues related to public interest such as accidents, traffic violations, and commercial frauds. Through utilizing citizen reporting applications, citizens are able to provide information about incidents efficiently and conveniently to the local authorities via mobile applications that are designed for these specific purposes. For such applications to be successful, citizens' willingness to participate continually and to become daily users of these applications is required. This paper applies the self-determination theory to investigate the factors that encourage citizens to participate in citizen reporting applications. In this study, the factors impacting behavioural intention to use the applications are divided into two categories. First, intrinsic motivation factors that include self-concern, social responsibility, and revenge. Second, extrinsic motivation factors that include output quality and rewards. The study empirically surveyed 297 Saudi citizens from different age groups. The partial least square (PLS) approach validates the research model. Findings reveal that output quality, revenge, and self-concern are significantly associated with citizens' motivations to use the applications, whereas rewards and social responsibility do not significantly influence citizens' motivations to engage with such applications. This study contributes theoretically by enriching literature on the identification of the factors behind user's engagement in citizen reporting applications. It also contributes practically by supporting the developers of citizen reporting applications to consider these factors when designing and marketing this kind of application.

Keywords—Crowdsourcing; self-determination theory; intrinsic motivation; extrinsic motivation; citizens reporting

I. INTRODUCTION

Crowdsourcing is the utilization of various potential external contributors to accomplish a certain task via an online platform [1]. There are two types of users in crowdsourcing [2]. The first type is individuals or organizations who request tasks or assistance in solving problems. The second type is crowd members who offer to contribute to the problem solution.

Due to the unprecedented advancement of the Internet and online technologies, the process of crowdsourcing has become truly a phenomenon. Crowdsourcing applications are being used in several fields around the globe, such as in scientific research, education, business, and medicine [3]. Also, several

countries employed crowdsourcing applications as part of their disaster relief efforts. During the Colorado wildfires in 2012 and 2013, crowdsourcing played a significant role in allocating resources to the affected areas [4]. Such applications are also being used to report health cases and deploy disaster relief services instantaneously, such as during the cholera outbreak in Haiti in 2010, the dengue outbreak in Thailand and Indonesia in 2010, and most recently, during the COVID-19 pandemic in 2020 [4]. Several countries have developed crowdsourcing applications as an emergency response to the spread of COVID-19. For example, to decrease the spread of the disease, data on symptoms of COVID-19 were collected and analysed using smartphones to wirelessly crowd-map positive cases [4].

COVID-19 is a highly contagious disease that has forced several governments to impose quarantine restrictions around countries [5]. Saudi Arabia was one of the affected countries. The Saudi government, like many other governments, implemented several countermeasures to reduce the outbreak of COVID-19 among its citizens. For example, travellers who came directly or indirectly from China were examined in the Saudi airports and any recent travel to China needed to be declared into immigration and passport offices [6]. Despite the significant impact of these countermeasures, studies [6] have shown that these countermeasures would not be fully effective in preventing the spread of the virus. Further countermeasures were applied and a quarantine was imposed by the Saudi government to control the pandemic effectively. Educational institutions at all levels transformed all their activities online, regular face-to-face meetings were switched to online meetings and attendance to workplaces were suspended and telework was applied instead [7]. Saudi authorities emphasized the importance of social distancing and believed that it is a key measure to minimize the outbreak of the virus. Therefore, the Saudi government decided to close restaurants, grocery stores and shopping malls and allowed only home delivery services through websites or mobile applications [7]. As a result, e-commerce in Saudi Arabia increased by 400 per cent in April and May, 2020 causing 30,000 complaints about shipping delays [8]. These complaints were filed by citizens and handled by the Ministry of Commerce through an application called "Balagh App" [9]. Balagh app is a citizen-reporting application that was launched by the Ministry of Commerce to enable citizens to file commercial violations or frauds. The awareness towards citizen-reporting applications in Saudi Arabia, such as "Balagh app", has increased during the curfew due to the increased number of issues related to the delayed or missing

shipments. “Balagh app” is not only used to file complaints about online stores, but is, also, used to handle issues related to physical stores. In order for citizen-reporting applications to work effectively, citizens have to be motivated to utilize and participate in the applications. Therefore, this research aims to answer the following research question:

What are the factors that contribute the most in motivating users to engage in citizen reporting applications to report commercial issues?

Therefore, this research will address the motivational factors behind the use of citizen reporting applications to report commercial issues. The research will apply the self-determination theory to identify the main factors that enhance citizens’ engagement and participation in citizen-reporting applications.

II. LITERATURE REVIEW

A. Citizens Sourcing and Reporting

Zhao and Zhu [10] define crowdsourcing as a “collective intelligence system” that has three components: the organization, the crowd, and the platform. The organization in the context of this research is the government; the crowd component is the citizens; and the platform is the technology [11]. In the context of open government, crowdsourcing is also known as ‘citizen-sourcing’ or ‘citizen-reporting’ [12].

There is evidence that government agencies can utilize crowdsourcing to improve public services with lower costs, produce policy innovations, and engage larger numbers of public participants [13]. Estellés-Arolas and González-Ladrón-de-Guevara [12] believe that ‘crowdsourcing’ itself is sometimes used in the same breadth as many other concepts such as ‘co-creation’, ‘open innovation’, and ‘citizen-sourcing’. Governments use citizen-sourcing to engage citizens in information production that would help the government in its activities [14]. Therefore, governments can improve public services from the information generated by citizens via citizen reporting applications or online platforms. Citizen reporting is considered one of three sub-categories of citizen sourcing [14]. Citizens reporting allows citizens to report issues to governments and be part of the development process [15]. Several governments have developed citizen reporting applications for different purposes. In Switzerland, there is a citizen reporting application called “FixMyStreet”. The aim of the “FixMyStreet” application is to allow citizens to report issues regarding the infrastructure of the city of Zurich to the local government [15]. The Portuguese government also developed an android mobile application called Citizens@City. This application allows citizens to report urban problems such as holes in the pavement, lack of public lighting, or poor access to wheelchairs to the local authority. Citizens can open the application and report the problem expressed by a subject, description, location, and optional picture of the reported spot [16].

The government of Saudi Arabia realized the value of citizen sourcing and citizen reporting applications as well. The Ministry of Interior launched a citizen reporting application called “Kulluna Amn”. The purpose of “Kulluna Amn” is to make citizens part of the country’s security systems by

reporting incidents. Citizens are able to attach photos or videos with their reports and send them immediately to the concerned local authority. In addition, “Kulluna Amn” has a GPS system to determine the location of the incident. Similar to “Kulluna Amn”, the Ministry of Commerce and Investment launched a citizen reporting application called “Balagh”. “Balagh” enables customers to report any commercial violation through their smartphones with the possibility of attaching photos and locations of the violations. Customers can add the name of the stores, and type of the violations committed as well. The application additionally allows the customers to view the latest news and product recalls launched by the Ministry of Commerce and Investment. In order for the “Balagh” application to work efficiently and effectively, there is a need to motivate customers to participate and engage in the application. This paper will address the motivational factors behind user participation in reporting commercial violations using “Balagh”.

B. Motivational Theory

One of the most important topics in psychology over many years has been the studying of human behaviours and the motivations behind such behaviours. Abraham Maslow intensively studied motivation and articulated his first theory in 1943 under the title of ‘A Theory of human Motivation’. He illustrated in detail the human needs that motivate human behaviour. Motivation is the dynamic relationship between the individual and their surrounding environment that incites them to do something [17]. The topic of motivation has been studied from multiple angles. Although motivation is present in the actions of every individual, there are variations in the level and orientation of these motivations. The psychological literature differentiates between motives and motivation. According to Leimeister, et al. [18] “In the field of motivation psychology, a motive is seen as an individual’s psychological disposition”. Motivation is a combination of a person with specific motives and a situation, which gives certain incentives that trigger certain behaviour [19, 20]. Motives are relatively stable over the lifespan of an individual and do not automatically lead to certain actions. Typically, an activator is needed to initiate behaviour.

The question that arises in this context is what motivates individuals to adopt new technologies and accept them. There are many models that already exist in the field of Information Technology Acceptance that investigates how individuals come to accept new adoptions of information system technologies. This line of models and research also looks into ways to motivate potential users of such systems. Each model explains user behaviour using a different set of various factors. Examples of such models include the Theory of Reasoned Action (TRA) [19]; Self-Determination Theory (SDT) [21], the Theory of Planned Behaviour (TPB) [20]; the Technology Acceptance Model (TAM) [22]; and the Extension of the Technology Acceptance Model (TAM2) [23]. One of the most prominent theories that discuss the concept of motivation is the Self-Determination Theory (SDT) [21]. This theory classifies motivation into two categories: intrinsic and extrinsic. From an intrinsic motivation perspective, individual behaviour is driven by the sake of enjoyment for the activity itself rather than the instrumental value of that activity. On the other side, from an

extrinsic motivation perspective, the behaviour is done to attain some separable consequence, external prods, or reward [21]. In this research, the self-determination theory (SDT) will be applied and extended.

C. Factors Behind user Participation

There is a bulk of literature that examines the motivational factors that affect engagement in citizen-sourcing applications. For example, Alshehri, et al. [24] prove that performance expectancy, effort expectancy, and facilitating conditions have positive influences on user intention (i.e. motivation) to use e-government services in general. The study also found that social influence to be insignificant in terms of predicting the behavioural intention to use e-government services.

Lin [25] examines extrinsic motivations (i.e. expected organizational rewards and reciprocal benefits) and intrinsic motivations (i.e. knowledge self-efficacy, and enjoyment in helping others) of employees' attitudes and behaviour towards knowledge sharing. The results demonstrate that employee knowledge-sharing attitudes and behaviours are significantly influenced by mainly three motivational factors: knowledge self-efficacy, reciprocal benefits, and enjoyment from helping others. The study finds that organizational rewards do not have any significant impact but reports that employee attitudes toward knowledge-sharing do significantly influence behavioural intentions.

Another study by Kumar, et al. [26] shows that the adoption of e-Government is directly influenced by both user characteristics and the website design. User characteristics include perceived risks that are related to the user's financial status, performance risk, data privacy and security. Another user characteristic that is found to be significant in the determination of e-government adoption is the perceived control over the process and the degree of the user's Internet literacy (i.e. the amount of time users are exposed to the Internet, the usage frequency, and the length of time spent in each visit). Furthermore, website design factors comprise the perceived ease of use and the perceived usefulness of the website as explained on the technology acceptance model. The study finds that the adoption rate can be enhanced significantly by the user's perception of the usefulness of the services or online information that is provided by the government. Nevertheless, the perceived usefulness is associated with the perceived ease of use [26]. Service delivery quality also has an impact on user satisfaction, which in turn influences the adoption of e-Government.

Abu-Tayeh, et al. [15] determines how local authorities can be greatly benefited from the use of citizen reporting in the context of smart city areas. The study investigates the ZWN cross-channel platform that aims to enhance civic engagement in Switzerland. It shows that factors such as self-concern and other-orientation (i.e. concern towards others' wellbeing) motivate citizens to voluntarily use the platform in order to support the government. Nonetheless, several essential issues should be taken into consideration as well, such as socio-economic characteristics. For example, gender has been shown to influence the actual participation in citizen reporting systems (e.g. the average number of reports submitted by males and females can vary significantly).

III. HYPOTHESES AND MODEL DEVELOPMENT

The self-determination theory is a suitable theory for examining the motivational factors behind a user's adoption and use of citizen reporting applications. It allows for extending the traditional theory to include factors that might trigger both intrinsic and extrinsic motivations which in turn impact the individual's behavioural intention to use such applications. Engagement in citizen reporting applications can be either driven by an extrinsic motive, such as having a good personal image, expecting rewards, or maintaining better service quality for reporting such incidents; or driven by an intrinsic motive, such as having a sense of inner social responsibility or settling an issue related to self-concern. Therefore, it is hypothesis that:

H1: Extrinsic motivation positively influences users' behavioural intention to use citizen reporting applications.

H2: Intrinsic motivation positively influences users' behavioural intention to use citizen reporting applications.

In the following subsections, we define each of the components of the extrinsic and intrinsic motivations and construct the corresponding hypotheses for the proposed model (see Fig. 1).

Fig. 1. Proposed Model.

A. Extrinsic Motivation Factors

Extrinsic motivation is closely related to the achievement and increase in value via the means of external benefits, monetary rewards, promotion, as well as other tangible rewards. It is thought of as a significant motivator in the literature relating to information systems. Davis, et al. [27], for instance, suggests that perceived usefulness is reflected by extrinsic motivation whilst intrinsic motivation relates to enjoyment.

1) *Output quality*: Output Quality refers to "an individual's perception about how well the system performs the tasks" [23]. Output quality in this context is the quality of services that are provided by governments to citizens. The government services can be enhanced effectively if citizens collaborate with their governments and participate in citizen reporting applications [15]. Output quality was found to influence the perceived usefulness as explained in TAM2 [23]. The perceived usefulness (PU) can generally be defined as "

measure of the individual's subjective assessment of the utility of an information technology in a specific task-related context" [23]. According to Venkatesh, et al. [28], perceived usefulness is a similar concept to extrinsic motivation. Therefore, we can conclude that the output quality will be one of the reasons that will influence extrinsic motivation toward using citizen reporting applications. In light of the aforementioned, we derive the following hypothesis.

H3: Output Quality positively influences a user's extrinsic motivation towards using citizen reporting.

2) *Reward*: Reward refers to the positive feedback as compensation or remuneration that can motivate citizens to perform the desired behaviours and to encourage them to share their knowledge about any system they used. Rewards can either be verbal or tangible. Verbal rewards, such as explicit positive performance feedback, are found to reinforce intrinsic motivation. Although some studies found that tangible rewards might weaken intrinsic motivation [17], several other studies found that monetary rewards encourage users and motivate them extrinsically to use the system [29, 30].

According to Assegaff, et al. [31], if employees believe they can receive organizational rewards by offering their knowledge, they will develop more positive attitudes towards knowledge sharing at VCoPs (Virtual Communities of Practices). The study, also, found that these rewards significantly affect employees' intentions to participate in VCoPs and share their knowledge. Accordingly, we imply that rewards will affect the extrinsic motivation and will have an indirect impact on behaviour intention to use citizens reporting applications. Therefore, we hypothesise that:

H4: Reward positively influences a user's extrinsic motivation towards using citizen reporting.

B. Intrinsic Motivation Factors

Intrinsic motivation is considered when tackling the success and adoption of information systems. Intrinsic motivation refers to the engagement in behaviour that is inherently satisfying or enjoyable [32]. Enjoyment influences intrinsic motivation positively to the extent that "the activity of using a specific system is perceived to be enjoyable in its own right, aside from any performance consequences resulting from system use" [33].

1) *Revenge*: Definitions of customer revenge in the literature are consistent to a greater or lesser extent. Customer revenge involves a customer exerting some harm to a firm in return for the perceived damages the firm has caused [34]. Previous studies show that a desire for revenge (i.e. a felt need to exert harm) increases the likelihood of "tangible" revenge behaviours [35]. An emphasis on a desire for revenge is important because users are not always able, depending on the context, to transform their desire into actions. This leaves room for the incorporation of moderators (such as power) that could explain when a desire for revenge produces real manifestations that are designed to harm the firm. Hence, we

assume that revenge will have a major effect on individuals' intrinsic motivation and that it will indirectly affect individual's behavioural intention to use citizens reporting applications. Therefore, we hypothesise that:

H5: Revenge positively influences a user's intrinsic motivation towards using citizen reporting.

2) *Self-concern*: Abu-Tayeh, et al. [15] found that self-concern and other-orientation are important factors that impact citizen reporting engagement. They also found that self-concern has the strongest effect among other orientations on engagement. Self-concern can be defined as the inclination to base one's behaviour on the desire to protect and enhance one's self-interest. Citizens can be motivated to engage in citizen reporting because they expect to benefit from it. For example, when the government settles an issue, they had previously reported, because it personally irritated them. This demonstrates that citizens are largely self-concerned. Nevertheless, if citizens report infrastructure issues as they desire to help others, other orientations are the main motive. In a study done by De Dreu and Nauta [36], they state that self-concern can be raised by setting higher aspirations. Research on social dilemmas has shown that people have higher self-concern when potential outcomes are outlined as losses rather than gains. Therefore, we suggest that self-concern impacts an individual's intrinsic motivation which influences individuals' behavioural intention. Hence, we hypothesise that:

H6: Self-concern positively influences intrinsic motivation towards using citizen reporting.

3) *Social responsibility*: Social responsibility is considered as the desire for an individual to help others and participate in a positive way to provide benefits to the society. One of the means of social responsibility is the participation in crowdsourcing applications. Previous studies have shown that social responsibility is positively associated with individuals' engagement in citizen reporting [15].

The study of Razmerita, et al. [37] illustrated that altruism, i.e. the enjoyment of helping others, is the most important factor that impacts the frequency of knowledge sharing. Consequently, we will propose that social responsibility will affect individual's intrinsic motivation to use citizens reporting applications. Therefore, we hypothesise that:

H7: Social responsibility positively influences intrinsic motivation towards using citizen reporting.

IV. RESEARCH METHODOLOGY

A. Sample and Data Collection

The aim of this study is to identify the factors that motivate citizens to engage in citizen reporting applications to report commercial issues. To test the proposed hypotheses, we select a sample of users from the citizen reporting mobile application "Balagh" (translation: "report app") in Saudi Arabia. The Balagh app enables citizens to report commercial violations or frauds. Users' intrinsic and extrinsic motivational factors

toward the usage of this app were collected using a close-ended structured questionnaire. SmartSurvey was used to design the questionnaire then the link was distributed through online channels like emails, WhatsApp, and social media accounts. In order to examine the accuracy, meaningfulness, and clarity of the questionnaire, the questionnaire was pilot-tested and filled by 30 respondents who were chosen randomly. Thereafter, the survey was distributed to 500 individuals, and 297 responses were received. Table I shows the demographic information of the respondents.

B. Measurements

All of the 26 items used in this research were developed using items validated in prior studies and adapted to fit the purpose of this research. Measurements items used in this research and the source of these measurements are presented in Table II. Each factor that might influence the behavioural intention and motivate the citizens to engage with the Balagh App was measured by five-point Likert-scale questions (i.e. from strongly disagree “1” to strongly agree “5”).

C. Data Analytical Procedure

The study uses the Partial Least Squares (PLS) method to analyse the collected data. The PLS path modelling is a variance-based Structural Equation Modelling (SEM) technique that is widely applied in many research fields such as: business and social research for its ability to model composites and factors. This makes it suitable for studying the adoption and engagement with new technology and an ideal method to tackle the higher-level statistical performance of the study. Therefore, this method of analysis was chosen due to its proven validity to test models and relationships as well as its usefulness in test models in the case of a limited number of participants [41].

The analysis was done using SmartPLS software version 3.3.2. for Mac to evaluate the measurements and test the structural models simultaneously. Using SmartPLS, two steps were taken to examine the model. The first step was confirming the reliability and validity. The second step was analysing the structural equation model to evaluate the hypotheses.

TABLE I. RESPONDENTS DEMOGRAPHIC INFORMATION (N = 297)

Variable	Value	Frequency	Percentage
Age	Under 18	7	2.4%
	18-24	28	9.4%
	25-34	76	25.6%
	35-54	153	51.5%
	Over 55	33	11.1%
Gender	Male	40	13.5%
	Female	257	86.5%
Educational level	High school	66	22.2%
	Bachelor degree	187	63.0%
	Master degree	24	8.1%
	PhD.	6	2.0%
	Other	14	4.7%

TABLE II. MEASUREMENT ITEMS

VBs	Items	Source
Behavioural Intention	BI1: I am considering using this app to report incidents. BI2: I would seriously contemplate using this app. BI3: It is likely that I am going to use this app. BI4: I am likely to make future reports using this app.	Adapted from Davis, et al. [27] and Venkatesh, et al. [28]
Extrinsic motivation	EM1: I find using this application useful. EM2: Using this application enables me to report commercial incidents more efficiently. EM3: I can forward my commercial concerns to local government directly.	
Intrinsic motivation	IM1: I participate in this application because I think that this participation is interesting. IM2: I participate in this application because this participation is fun IM3: I participate in this application because I feel good when doing this reporting	
output quality	OQ1: The use of this application will improve the quality of provided commercial services. OQ2: The use of this application will contribute to the development of commercial services. OQ3: Using this application will enhance the overall quality and efficiency of the provided commercial services.	Adapted from Compeau and Higgins [38]
Reward	RW1: My willingness to participate in this application would increase if there were monetary rewards RW2: I will really like to participate in this application if I would receive monetary rewards in return for my knowledge sharing.	Adapted from Wijnhoven, et al. [39]
Revenge	RV1: My feeling of anger towards violators pushes me to use the application and report them RV2: I use this app to publicize the practices of violators and punish them. RV3: I submit a complaint via the application to avenge violators	Adapted from Aquino, et al. [40]
Self-concerned	SC1: I took part in “Balag” because I could report problems that concerned me personally. SC2: I took part in “Balag” because I could report problems that prevented me from fulfilling my needs SC5: I participate in this application because I believe that this kind of reporting is important for me	Adapted from Abu-Tayeh, et al. [15]
Social responsibilities	SR1: I took part in Balag application because it gives me the opportunity to protect others from commercial fraud. SR2: I took part in this application because I could help the community by doing so. SR3: I want to contribute to the development of the commercial services provided in my city by using this application. SR4: I would feel bad about myself if I don’t share information about commercial violations with the relevant authorities. SR5: I participate in this application because I feel that this is something that I have to do it for the society.	Adapted from both Abu-Tayeh, et al. [15] and Schmidhuber, et al. [32]

V. RESULTS

A. Measurement Model

In this step, we present the assessment of the reliability and validity of the measurement model. Cronbach’s alpha and composite reliability (CR) were used to assess the reliability while convergent validity and discriminant validity were used to check the validity of our model. Table III shows 24 out of 26 indicators have factor loadings above 0.7. Only two indicators, rewards and intrinsic motivation, have a lower factor loading. Intrinsic motivation has a factor loading of 0.665 while reward has a factor loading of 0.507 which, according to Hair, et al. [42], are still above the minimum acceptable threshold value of 0.5 for factor loadings. The t-values also demonstrate a satisfactory reliability level of all indicators as all the indicators are significantly linked with their corresponding constructs ($p < 0.001$) [43]. Furthermore, Cronbach’s alpha (α) of all variables exceeds the threshold of 0.7 [44] except for two factors (i.e. intrinsic motivation and revenge). Intrinsic motivation has a Cronbach’s alpha (α) value of 0.669 while revenge has a value of 0.618. According to Hair, et al. [45], any variable with Cronbach’s alpha (α) value above 0.6 still shows acceptable level of internal consistency. Therefore, all of our constructs show a good level of internal consistency. Table III also shows that all composite reliability (CR) values are greater than the recommended value of 0.7 [43]. It also shows that the values of all the average variance extracted (AVE) of our constructs exceed the critical threshold value of 0.5 showing a good convergent validity [46]. Lastly, the correlation of the square root of AVE for all of the constructs, as shown in Table IV, are higher than their correlations with other constructs, proving the discriminant validity of our measurement model.

B. Structural Model Assessment

As the reliability and validity of our measurement model have been confirmed, we proceeded with testing of the structural model. This step is used to examine the relationship between variables and to assess the model’s predictive capabilities. The significance of path coefficients and the R2 are the key criteria for assessing the structural model. The nonparametric bootstrapping procedure in the PLS analysis with 500 samples was performed to examine the structural models and to calculate the path coefficients and their significance levels.

As shown in Table V, all of our hypotheses are supported except two hypotheses that are rejected. Extrinsic motivation has a positive significant relationship with behavioural intention ($\beta = 0.553$, $t = 9.557$, $p < 0.001$) and intrinsic motivation also has a positive significant relationship ($\beta = 0.220$, $t = 4.576$, $p < 0.000$) supporting both H1 and H2. In addition, output quality positively influences extrinsic motivation ($\beta = 0.696$, $t = 18.940$, $p < 0.001$) while reward has no significant relationship with extrinsic motivation ($\beta = -0.084$, $t = 1.215$, $p < 0.225$); supporting H3 and rejecting H4. Intrinsic motivation is also found to be positively impacted by revenge ($\beta = 0.384$, $t = 6.273$, $p < 0.001$) and self-concern ($\beta =$

0.258 , $t = 3.139$, $p < 0.001$) supporting H5 and H6. On the other hand, social responsibility does not significantly impact intrinsic motivation ($\beta = 0.258$, $t = 3.139$, $p > 0.121$); rejecting H7. To determine the predictive power of our model, the value of R² is used. R² is a statistical measure that reports the variance in the dependent variable that can be explained by the independent variables. In general, the model managed to explain the variance in a user’s behavioural intention by 45.6% ($R^2=0.456$). The identified extrinsic motivational factors, i.e. output quality and reward, were able to explain variance in users’ extrinsic motivation by 49.9% ($R^2=0.499$). On the other hand, revenge, self-concern, and social responsibility were able to explain variance in intrinsic motivation by 43% ($R^2=0.431$). All R² values are higher than 0.1 which is the minimum acceptable level as defined by [46]; indicating a good predictive power for our model. Fig. 2 and Table V summarize the analysis results.

VI. DISCUSSION AND CONCLUSION

The results indicate that both extrinsic and intrinsic motivational factors influence a citizen’s behavioural intention to report commercial incidents using citizens’ reporting applications. It is found that extrinsic motivation is much more influential than intrinsic motivation, nonetheless. Citizens’ extrinsic motivation is significantly influenced by output quality. However, rewards are found to have no significant influence on a citizen’s extrinsic motivation to report commercial incidents. Mainly, citizens are more concerned about the output quality that results from their engagement with the citizens’ reporting applications for them to be motivated to report commercial incidents. This result is aligned with previous studies, such as [23] and [27], which demonstrated that individuals will be more motivated and encouraged to use a system if they believe the system will help them achieve their desired outcomes. According to [47], it is important to keep citizens informed about the improvements and actions taken based on their reports so that they feel that their reports are taken seriously. On the other hand, though reward was expected to impact a user’s extrinsic motivation to participate in the system, it was not found significant. Previous research studying the role of rewards on impacting users’

extrinsic motivation in several other contexts is conflicted. Some studies, such as [29-31], found that rewards play a significant role in encouraging users to participate, while others such as [17], found no significant role in influencing users’ extrinsic motivation but instead it may weaken users’ intrinsic motivation to use the system. This indicates that government institutions should concentrate on emphasising the effectiveness of citizens’ participation to report commercial incidents on improving the quality of delivering commercial services within the city rather than offering rewards in return for their participation.

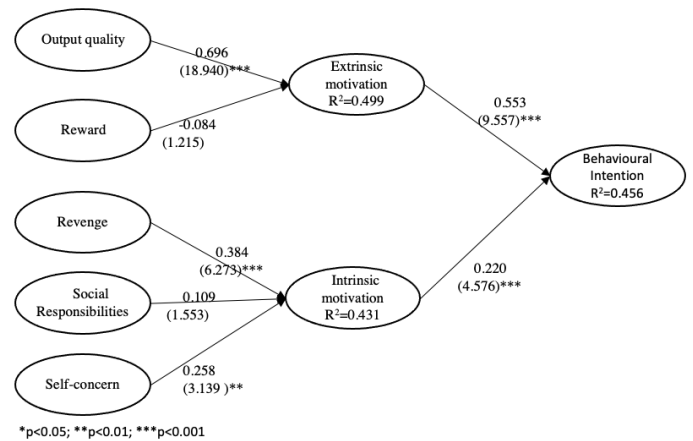

Fig. 2. The Results of the Empirical Study.

On the other hand, citizens’ intrinsic motivation is found to be influenced by self-concern. This is supported by existing literature in the field, such as the work of [15], where they found that self-concern plays a significant role in the actual number of reports filed by an individual on a specific citizen’s reporting application designed to enhance the infrastructure of the city. According to [48], individuals who are highly concerned about their self-gain are found to be more persistent contributors. As this study concentrates on reporting commercial incidents, it makes sense that citizens will report issues that impact them directly to solve their own problems and satisfy their needs. In alignment with this finding, we also found that revenge plays a significant role. When citizens personally face a problem with a certain commercial institution, such as shopping fraud or problems with their purchase, and the institution neglects their complaint, some of them feel anger and experience the urge to seek revenge. Thus, they feel that the use of citizen’s reporting applications to report commercial incidents is a way for punishing the accountable commercial institution and gaining revenge. According to [34], typically customers feel that revenge is an appropriate response, especially after a series of failed amendment requests. Therefore, as citizens’ reporting applications facilitate the process of restoring their rights and forcing the responsible commercial institution to solve the problem, it is justified that revenge plays a significant role in the context of this study. On the other hand, social responsibility is empirically found to have no influence on a user’s intrinsic motivation. This contradicts the findings of [15] where they empirically found that other-orientation is a significant predictor of citizens’ participation in citizens’

reporting applications. This contradiction can be due to the differences in the context of the studies. The authors in [15] studied the motivational factors behind citizens' participation in reporting incidents related to infrastructure, while the context of this study is related to reporting commercial incidents. When reporting commercial incidents, citizens are mostly aware of the issues that impact them directly and are hardly aware of the issues that face others. Therefore, although social responsibility is important, its role in the context of this study is proven to be limited and of no significant impact. Hence, when reporting commercial incidents, citizens participate mainly for self-gain rather than being concerned about the quality of commercial services provided to others. Government institutions running this kind of applications should market their applications by emphasising the personal benefits that users can acquire as a result of using this kind of applications.

As per the above discussion, this study is limited to the context of citizens' reporting applications that are mainly designed to report commercial incidents. Therefore, its result cannot be generalised to other contexts. Future research should concentrate on studying the impact of context in moderating the motivational factors behind citizens' behavioural intention to use citizens' reporting applications. It will also be useful to investigate factors impacting the quality and accuracy of reported incidents and how these factors can be reflected in the design of citizens' reporting applications.

India

Abstract—Transformed by the advent of the Digital Revolution, the world deals with a gold mine of data every day. Along with improvement in processing methods for the data, data security is of utmost importance. Recently, there was a noticeable surge in online learning during the pandemic. Modifying their workflow strategies, the educational institutions provided courses for students designed to suit the need of the hour. This opened up the avenue for a greater number of students to take part in the online learning. With the increase in number of students registered, there exist a substantial repository of data to deal with. Hackers have been targeting student data and using it for illegal purposes. In this research paper, an attempt has been made by modifying the classic Snake and Ladder game to perform encryption on short text student data to ensure data privacy. The Novel algorithm maintains simplicity yet produces a strong cipher text. The algorithm stands strong against the brute-force attack, cipher-only attack, etc. Decryption also uses same key as used for encryption, the key being symmetric in nature. New variable keys are generated every time the algorithm is used.

Keywords—Student data; privacy; encryption; decryption; snake and ladder; variable keys

I. INTRODUCTION

The 'Digital Revolution' is providing us abundant data which has to be dealt with caution. It was evidently noted that since there is lack of awareness of cybersecurity among the students, they tend to ignore the threat and turnout to be the most vulnerable target for the cyber-attacks. Though most of the students in the survey knew about the online risks and threats, but they lacked to understand basic knowledge about privacy [1]. In an empirical study among the students, it was explored that the students expressed concerns about their online data privacy and believed that the teachers or concerned authorities should put in efforts to safeguard it [2]. Hence, Cryptography will play a vital role in securing the data. This paper puts forth a novel algorithm for encryption and decryption for the short text. Board games as we know stimulate brain areas responsible for developing cognitive skills and memory. Here, the board games serve a different purpose altogether. The modified version of the board game will perform encryption and decryption activities for the desired short text placed on the board. The classic snake and ladder game is used with a twist to generate the cipher text.

A. Role of Technology in Education

Educational institutions with the help of technology have made great strides in improving the understanding and

interaction of the students. Students are provided with different online opportunities in terms of courses, tutorials, workshops, seminars to enhance their academic growth. With rise in these opportunities provided, there is enormous rise in the collection of student related data through registrations, personalization preferences and feedbacks.

B. Student Data

The student data usually consist of their personal details, demographic details, student preferences, evaluation reports, faculty observations etc. This data is essential for parents, faculty and policymakers to enable them to streamline their plan of action according to the student requirements.

Most of the organization store the student data and provide it to firms which help them analyze this data using technology like data mining, where several unseen underlying patterns can be highlighted in text.

II. STUDENT DATA PRIVACY

A crucial aspect that needs to be taken care of is to prevent the exploitation of these data-driven systems by the hackers. Hackers can get hold of this data through performing remote attacks on the system, by eavesdropping and can misuse the data, leading to identity theft, creation of fake accounts, modification of student details, etc. [3].

Though the student data has a very good potential and scope for bringing in improvements on various fronts, it is also a matter of concern. Digital learning captures real time information of students and along with their personal information the data captured may be used by hackers for non-educational purposes. It also discusses several legal provisions to safeguard the student data privacy [4].

In order to safeguard the sensitive student data while transferring online or stored on the administrative systems, it should be efficiently encrypted to withstand the possible attack [5].

A. Impact of Student Data Breach

Student data once hacked can open up not only their personal details to the hackers but also the details about their parents and their bank accounts which they use to pay the student fees. The exhaustive student information is sold by hackers through spam mails; a sample snapshot of the email is depicted in Fig. 1 (The snapshot was taken from authors' personal email).

Sr.No	Category / City / State	Database Quantity	Price
01	10 th old 12 th Degree Engg Working professionals		Rs30,000 Discounted Price

Fig. 1. Snapshot of Email Selling Student Data.

Students in their teens are vulnerable to the data breach activities as they are either unaware of the reality or fall prey to the attackers' malicious intents. Data like unique identification number, name, date of birth can be misused leading to identity theft. Identity theft can falsely implicate an innocent student and ruin their life in a big way. Students with weak financial background can be targeted by 'pretext calling' using this stolen data and in the need of the job or suddenly winning a lottery, the students give away more and more private and confidential information with respect to them and their family. 'Phishing' being the most common attack where the attacker posing as authorized person sends out emails to the student email address available from the hacked institution database and requests them for further information and talks about next course of action to take place from the student's side. Students, believing the sender provide the necessary information and are duped, documents are misused, photographs are inappropriately utilized for gaining profits. An instance where a student's photograph gets misused, can draw the student towards the dark world. Harassment, Stalking and human trafficking can take place at a bigger scale if the student data is not handled with utmost care [6] [7].

III. LITERATURE REVIEW

The Snake and Ladder game is directly applied to perform Steganography, which hides the data in a media like images. The algorithm uses concepts on Image Processing like Pixel Value differencing are used along with the development of the snake and ladder game on the data [8].

This research paper consists of a survey of different scenarios from different research papers, for example, storing protected data for platform like Facebook, concerns when mobile systems are used for payments and their key generation. It also surveys a concept called as Software Defined Networking – a new approach in designing, building and managing networks [9].

This paper illustrates how a game of scrabble can be utilized to generate cipher text for big length data. Several permutations and combinations of words are possible making it difficult for the attacker to guess the actual words directly hence providing good security to the plain text [10].

Security to E-Learning System is provided by Elliptic curve. cryptography algorithm and content is filtered using Decision tree algorithm. Cryptography along with Data Mining techniques proves to be a good combination. Several Data Mining Classification Techniques are compared to figure out which yields good results [11].

Another technique to ensure data privacy is the use of Digital signature. They use a different sort of balance cryptography. It is generally used for monetary exchanges, configuring dispersion, and in various circumstances where it is necessary to identify bogus or changing. Other techniques like DES and RSA Algorithm are frequently used cryptographic techniques [12].

IV. CRYPTOLOGY

Heraclitus, one of the most influential thinkers in ancient Greek Philosophy expressed hid deep philosophical insights in aphoristic and cryptic form. His writings are full of riddles which are cryptic in nature. He liked this pungent oracular style as it required a penetration of thoughts which provoked human thinking and it helped him in maintain the confidentiality of his writings [13].

Cryptology as a tool of technology is a culmination of techniques for ensuring the secrecy and/or authenticity of information. Cryptology has two main branches in the form of 'cryptography' and 'cryptanalysis' [14].

A. Components of a Cryptosystem

- Plain Text - It is the message or information that sender intends to send. Example in our case will be the student's name, date of birth, etc.
- Cipher Text – It is the result of transformation on the plain text after encryption algorithm has been applied.
- Key – It is a piece of information that will scramble the plain text as required by the algorithm.
- Encryption algorithm – It consists of sequence of steps of how and when to apply the key to the plain text to produce the cipher text.
- Decryption algorithm – It consists of sequence of steps of how and when to apply the key to the cipher text to get back the plain text [15].

Fig. 2 illustrates the various components in order of their reference.

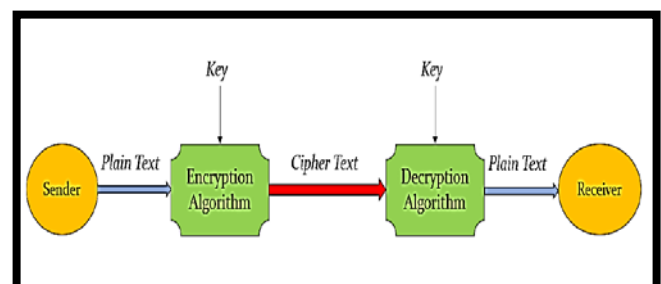

Fig. 2. Components of Cryptosystem.

B. Cryptography

The science and art of secret writing has its inscription since the beginning of human civilization. Ancient civilizations of India, Egypt, China, Japan testify the evidences of use of cryptography. The goal of cryptography is to provide secure communication over insecure channel [16].

C. Cryptanalysis

Working upon the weakness, improves the strength. This is the principal upon which cryptanalysis is based. Analyzing and understanding the cipher text, trying to decipher it without the knowledge of plain text to identify the weakness and work upon it.

D. Goals of Cryptography

- Confidentiality – A cryptosystem ensures that no one other than the sender and the receiver is able to read the input data.
- Integrity – During transmission of data, the cryptosystem should not allow any unauthorized person to modify, alter, change or delete the data.
- Authenticity – The sender and the receiver should be able to identify and validate each other [16].

V. SNAKE AND LADDER ENCRYPTION ALGORITHM

A. Concept of the Proposed Algorithm

The proposed algorithm titled ‘Snake and Ladder Encryption Algorithm (SLEA)’ gets its name from the classic game of Snake and Ladder. ‘SLEA’ is a ‘block cipher’ with variable length, symmetric keys. In the block cipher category, the input plain text is divided into fixed size of blocks and then encrypted. Block ciphers are mainly characterized by the block size and its key. Here, though a fixed size block is used for encryption, still the cells only which contain the data are encrypted, the vacant cells on the board are not considered for the encryption. This speed up the process and key variable key length shorter [17]. Symmetric keys mean same keys are used for encryption and decryption. The algorithm provides three layers of encryption. One through character set mapping and the second layer through placement of the snakes and ladders on the board and third through the snake and ladder game moves. The sender and the receiver should have the same interface setup so that pre-decided objects can be shared before the encryption and decryption process begins through the secured channel.

Sample plain text considered for the purpose of illustration is “SMILE IS JOY”. Length of the plain text including the blank space is 12 characters.

Character Set - The plain text will be first mapped to the characters set and an intermediate cipher text will be generated. There are ‘n’ number of character sets pre-decided between the sender and the receiver available to both when the algorithm interface is installed from the setup file.

Here for the illustration following character set is considered given in Table I. As for the alphabets, numbers can also be mapped to the character set.

Level 1 encryption- the given plain text ‘SMILE IS JOY’ will be mapped to intermediate cipher text as illustrated in Fig. 3.

B. Snake and Ladder Board

The game board is of the size 4x4, consisting of 16 cells. Fig. 4 shows the pattern for inserting the plain text data is always from left to right direction, whereas the traversal of data alternates in direction every time. A minimum of two snakes and two ladders adds sufficient complexity to the data. As the size of input data increases the board size also can be increased and so are the number of snakes and ladders on the board.

Fig. 3. Level 1 Intermediate Encrypted Text Output.

Fig. 4. Modified Board.

TABLE I. CHARACTER SET MAPPING

A	#	I	4	Q	{	Y	,	5	q	“	%]	n	\$	'	+	b
B	1	J	5	R	7	Z	&	6	z	”	<	{]	^	'	-	c
C	2	K	}	S	9		—	7	j	:	>	}	[~	\$	/	e
D	?	L	(T	+	0	a	8	k	'	^	@	o	`	n	*	d

H	8	P	6	X	-	4	t	;	”	[l	?	v	>	w		

C. Snake and Ladder Encryption Algorithm

Step 1: Create a 4x4 board and select any one arrangement of the snakes and ladders from the predetermined set.

Step 2: Place the level 1 encrypted text onto the 4X4 board.

Step 3: Note the last data entry cell on the board. (This step ensures that the vacant cells are not traversed, hence less time taken for encryption process.).

Step 4: Point the ‘marker’ to the first cell on the board and roll the dice till all of the entries on the board are visited at least once. Simultaneously, frame the data from the visited cells into a sequence, which is our cipher text to be transmitted or stored.

Step 4.1: Travel the cells on the boards depending on the count on the dice.

Step 4.2: At the end of the traversal for that particular move, if a ladder is encountered- climb up and record the data in the cell in to the cipher text sequence. Similarly, if a snake is encountered- drop down and again record the data in the cell in to the cipher text sequence.

Step 4.3: At any point of time if looping takes place, i.e. dice and cell on the board remain same, do not record the data and roll the dice till the number on the face of dice is different. This resolves looping.

Step 5: If the current cell visited on the board is the last cell, check if there exist any unvisited cells on the board. (Unvisited entries may be due to sudden climbing using ladder or dropping down through the snake). Repeat the process till all cells on the board have been visited at least once.

D. Encryption Algorithm Illustrated

Fig. 5 shows the mapped text on the game board with snakes and ladders already placed on the game board. Table II provides stepwise execution of the encryption algorithm.

Fig. 5. Mapped Text on the Board.

TABLE II. STEPWISE ILLUSTRATION

Dice Roll Count	Number on the Dice Face	Ladder / Snake at the end of traversal	Cipher Text Generated
1	3	YES	9=4
		Ladder	9=49
2	1	NO	9=494
3	1	YES	9=494_
		Snake	9=494__9
4	6	YES	9=494__9
		SNAKE - LOOPING	No change in the cipher text
5	5	NO	9=494__9=4(94
6	4	NO	9=494__9=4(94__@__5
7	3	NO	9=494__9=4(94__@__5,
		End of Characters on the Board	Extra places not counted
End of Characters on the Board - Check if all entries are visited.			
All entries are visited on the board			

Final Cipher Text Generated is shown in Fig. 6, which consists of 17 characters.

Fig. 6. Final Cipher Text.

Original Plain Text: “SMILE IS JOY”

Length of original plain text: 12

Generated Cipher Text: 9=494__9=4(94__@__5,

Length of Generated cipher text: 17

E. Snake and Ladder Key Generation during Encryption

For the decryption of the cipher text at the receiver side, we need a Key that will help us get back the plain text. As the cipher text is generated, simultaneously the key is also generated. The key is the numbers on the face of dice plus the pattern number for the board arrangement for snake and ladder plus the character set pattern used.

F. Snake and Ladder Decryption Algorithm

The receiver side will use the key transferred through the secured channel and decode the cipher text. Table III provides stepwise decryption.

TABLE III. DECRYPTION USING KEY

Key	Cipher Text	Board Arrangement

VI. SECURITY ASPECT

In this section, we will analyze the strength of the snake and ladder algorithm against several types of attacks. Snake and Ladder Cryptographic algorithm provides three levels of security.

Level 1: First, in the form of character mapping set. The set consist of 68 characters mapped uniquely to each other. For every encryption, the character mapping will be changed. If any intruder tries to guess the mapping it will be difficult to select from 248003554243683059960099041856917158104739920135536767237171073801822144571218329600000000000000 options, that is 68! (68 factorial). This step considerably increases the security in a simple manner.

Level 2: Second, in terms of the placement of the snakes and ladders on the board. The board is selected of 4x4 as it can hold average length of information like student name, roll number, subject name, etc. Depending upon the data length per student, the size of the board can be increased to 5x5 or 6x6 accordingly. For every encryption, the number of snakes and ladders can be decided and a different arrangement of snakes and ladders can be selected from the predefined pattern.

For the current illustration, a board of 4x4 consists of 2 snakes and 2 ladders, sufficient for adding complexity to the encryption process. When the interface will be setup between the sender and the receiver, these predefined patterns and arrangements will be known to both. So, during encryption, along with the key the unique pattern identification number is to be attached before transfer of the cipher text.

Understanding the complexity provided by the placement of snakes and ladders – consider, the 4x4 board with two snakes and two ladders. Initially, total available cells on the board for the placement were 16. Placing the 1st snake -16

options available, placing 2nd snake – 15 options available, placing 1st ladder 14 options available, placing 2nd ladder – 13 options available. It is difficult to gauge the positions by simple guessing.

Level 3: Third, the algorithm itself. The manner in which the cipher text will be generated by rolling the dice will be different every time. And occurrences of the snakes and ladders in the route will change the course of cipher text generated.

Now, we will slide through several types of attacks possible during encryption and how the algorithm provides resistance to them.

Ciphertext Only Attacks – In this kind of attack, the encrypted message is intercepted by the attacker. This attack will be successful only if the corresponding plain text is retrieved from the encrypted message.

The Snake and Ladder algorithm has a huge initial character base to transform the plain text into unmeaningful message. The cipher text characters are further jumbled by the movements in the game. So, it is impossible for the attacker to know the plain text within a finite time without the authentic keys.

Known Plaintext Attack – The attacker knows the partial plaintext for the generated ciphertext. So, the attacker's task is to study the remaining cipher text, derive the key if possible and get the plain text.

The Snake and Ladder algorithm holds an advantage with respect this attack. Since, the plain text is neither used as direct part of cipher text nor as part of key formation, and even if the attacker knows that it is the student data that the algorithm is dealing with, it cannot conclude anything directly only from the cipher text.

Man in Middle Attack – Mostly, this attack can target the public key cryptosystems. Here, key exchange has to take place before communication begins.

In the Snake and Ladder algorithm, since key is simultaneously generated with the cipher text and also transmitted with it, this attack does not affect the encryption algorithm.

Chosen Plaintext Attack – The attacker has the ability to encrypt plain text of his choice and generate corresponding cipher text in the given system. By performing this act, the attacker tries to study the relation between plain text to cipher text generation.

In the Snake and Ladder algorithm, at level one itself the attacker will have to go through and execute 68! possibilities.

Brute Force Attack – Try several combinations of keys, to decrypt the cipher text.

In the Snake and Ladder algorithm, though the dice has only 6 faces, we don't know how many times it will be rolled, because the dice rolling depends on the length of the text to be encrypted when it is placed on the board. This is the advantage of the variable nature of the key, which makes it difficult to

guess what it is. And if one tries to do so, it might require exponential time [18] [19].

Running Time Analysis – the problem statement is - with how many minimum dice rolling can the text on board be traversed at least once. There are three important factors affecting this, one is the number of filled places on the board, second variable number of snakes and ladders do affect the traversal and the number appearing on the dice face.

For illustration, a 4X4 board was considered, means total number of blocks to be traversed 16. So, running time would be close to $O(16 * C)$, where C is a constant and dice is assumed to have 6 faces. 16 because the block has to be visited at least once. C includes the time including waiting for the dice to roll again and repetitive traversal of the blocks, and climbing up and down the ladders and snakes, respectively. General running time is $O(N * D * C)$ where N is the number of blocks on the board, D is the number of faces on the dice, if dice of a greater number of faces used and C remains the constant.

VII. ADVANTAGES AND DISADVANTAGES OF THE SNAKE AND LADDER ALGORITHM

A. Advantages

- The nature of the game makes the moves during the encryption unpredictable, which strengthens the cipher text.
- Time required for execution is comparatively less as the encryption is not done on entire block but only the part of data present in it.
- Key generation is simultaneous to encryption process.
- Rolling the dice makes the key Variable in length and the Variable key makes it difficult for the attackers to predict the nature of the key.
- Though, there are large number of students, each student's data in a school / college repository is limited to certain details. Hence, encrypting this short length data with this flexible size algorithm avoids unnecessary space and time complexities.
- Considering the best or average time cases (number on the dice face from 6 to 4, every time it rolled) the algorithm can be considerably fast or average during encryption.

B. Disadvantages

- As the board size increases, the complexity for the algorithm's implementation increases.
- Considering the worst case (number on the dice face from 3 to 1, every time it rolled) the algorithm can be a bit slow during encryption.

VIII. CONCLUSION

The 'randomness' of the 'dice', 'movements' on the 'board' add the twist to the generation of the cipher text just as required. Since, student data can be categorized into distinct fields like their first name, last name, date of birth etc. this algorithm on the board of 4x4 is most suitable to encrypt the

data part by part and store it in the same manner. Though there exist several cryptographic algorithms that provide cipher text, the Snake and Ladder algorithm consumes minimum time and generates the cipher text in length close to the length of plain text and key length is maintained less than cipher text length, hence reducing overall processing time.

Future research could examine improving the key transmission from sender to the receiver. Also, improvements in hardware can considerably increase the efficiency of the algorithm.

As mentioned before, the student data breach can have devastating psychological effects on the students. The pillars of the nation have to be necessarily protected against these hidden cyber-attacks. Ensuring the confidentiality of the student data while collecting, proper cryptographic techniques to be used while storing or transmitting, and enforcing strict laws modified according to the emerging cyber-attacks are some of the basic steps that need to be enforced by the concerned authorities.

Abstract—This research proposed a method to accommodate backward compatibility on the learning application-based transliteration to the Balinese Script. The objective is to accommodate the standard transliteration rules from the Balinese Language, Script, and Literature Advisory Agency. It is considered as the main contribution since there has not been a workaround in this research area. This multi-discipline collaboration work is one of the efforts to preserve digitally the endangered Balinese local language knowledge in Indonesia. The proposed method covered two aspects, i.e. (1) Its backward compatibility allows for interoperability at a certain level with the older transliteration rules; and (2) Breaking backward compatibility at a certain level is unavoidable since, for the same aspect, there is a contradictory treatment between the standard rule and the old one. This study was conducted on the developed web-based transliteration learning application, BaliScript, where its Latin text input will be converted into the Balinese Script output using the dedicated Balinese Unicode font. Through the experiment, the proposed method gave the expected transliteration results on the accommodation of backward compatibility.

Keywords—Backward compatibility; Balinese Script; learning application; transliteration

I. INTRODUCTION

As one of the diversity of local language knowledge in Indonesia, the endangered Balinese Script transliteration knowledge [1]–[3] raises concerns for the preservation. The Bali Government has already conducted the preservation efforts through the Bali Governor Regulation [4], [5] and strengthen them with the Bali Governor Circular Letter [6]. These efforts make the Balinese Language, including its Balinese Script transliteration knowledge, running as a mandatory local subject from elementary school to senior high school in Bali Province.

Multiple approaches other than the governmental approach should strengthen the preservation effort and should have a greater impact. This research joined the effort through the technological approach by multi-discipline collaboration between Computer Science and Language discipline. It proposed a method to accommodate backward compatibility on the learning application-based transliteration to the Balinese Script. This work has never been conducted yet and applied to the previous works that were still based on the older

transliteration rules (for short, the older rules) from The Balinese Alphabet document¹. It exposes the backward compatibility method to accommodate the standard transliteration rules (for short, the standard rules) from the Balinese Language, Script, and Literature Advisory Agency [7]. This Bali Province government agency [4] carries out guidance and formulates programs for the maintenance, study, development, and preservation of the Balinese Language, Script, and Literature.

This study was conducted on the developed web-based transliteration learning application, BaliScript, for further ubiquitous Balinese Language learning since the proposed method reusable for the mobile application [8], [9]. It also advances the previous work by (1) accommodating special words [1], [10] through a certain table structure in the database rather than hard-coding them in the application code; (2) making use of the more developed and the less bug of Noto Serif Balinese (NSB) font^{2,3} [11] to represent the Balinese Script rather than the Noto Sans Balinese font⁴. The NSB font is a dedicated Balinese Unicode font which makes it recognized on the computer system including mobile devices and makes the proposed method reusable on the mobile application; and (3) improving the learning experience on the application, that uses this method, through the addition of the Indonesian and English translation for the transliterated word (see the next Fig. 3). Overall, all of those advances are considered as the contribution of this work.

This paper is organized into several sections, i.e. Section I (Introduction) states the problem background related to the transliteration to the Balinese Script; Section II (Related Works) describes the related works in the area of the transliteration to the Balinese Script and its backward compatibility aspect; Section III (Research Method) exposes the supporting algorithm, the implementation, and the testing

of the proposed method; Section IV (Result and Analysis) covers the analysis of the testing result; and finally, Section V (Conclusion) consists of important conclusion and future work points.

II. RELATED WORKS

Several related works on Latin-to-Balinese Script transliteration were conducted on the previous works [10], [12]–[20]. All of those were still based on the older rules from The Balinese Alphabet document, except [20]. Displaying Balinese Script output on those previous research was done by non-dedicated Balinese Unicode fonts (i.e. Bali Simbar⁵ and Bali Simbar Dwijendra [21]) and dedicated Balinese Unicode font² [11] (i.e. Noto Sans Balinese and Noto Serif Balinese). The Bali Simbar (BS) font was utilized in [12] and gave a relatively good accuracy result on testing cases from The Balinese Alphabet document. It was also utilized in the developed robotic system that writes the Balinese Script from the Latin text input [13], and on the exploration of the line-break handling during the transliteration [14]. The Bali Simbar Dwijendra (BSD) font, as the improvement of the BS font, was utilized in [15] with additional testing cases from the Balinese Script dictionary [7] to the same testing cases on [12]. It was also utilized in the exploration of the mathematical expression transliteration [16]. Ten transliteration lessons were also learned by using this font on the other testing data [17]. The Noto Sans Balinese font was utilized in [10] with the same testing cases in [12] and gave a relatively good accuracy result. It was also utilized in the developed robotic system that writes Balinese Script from the Latin text input [18]. Extensive accuracy analysis on the developed algorithm [10] was done in [19] for future improvement. the Noto Serif Balinese font was utilized in [20] for the unavoidable affixed words that need to be transliterated.

The other side of transliteration related to the Balinese Script-to-Latin transliteration that utilized the GNU Optical Character Recognition (OCR), i.e. Ocrad⁶ [22]. This research was limited only to the basic syllable recognition (see The Balinese Alphabet document) from the Balinese Script image that was based on the glyph shape of the Bali Simbar font. For advancing functionality and mobile adoption for ubiquitous learning, the utilization of the Tesseract⁷ OCR was conducted that needs several future improvements [23].

III. RESEARCH METHOD

The proposed method to accommodate backward compatibility on the transliteration to the Balinese Script covers two aspects related to the older transliteration rules from The Balinese Alphabet document. Those two aspects, i.e. (1) Backward compatibility allows for interoperability at a certain level with the older rules; and (2) Breaking backward compatibility at a certain level is unavoidable since, for the

same aspect, there is a contradictory treatment between the standard rule and the old one.

This section describes (1) the supporting algorithm of the proposed method; (2) the implementation on the BaliScript, which is the web-based transliteration learning application; and (3) the testing by using the updated testing cases of The Balinese Alphabet document to comply with the standard transliteration rules from the Balinese Language, Script, and Literature Advisory Agency [4], [7].

A. The Algorithm

The proposed method involves the NSB font with its dedicated Balinese Unicode Table [20]. The algorithm to accommodate backward compatibility on the transliteration to the Balinese Script covers two aspects, as described previously. The first aspect involves transliteration of the letter set MBC (Maintaining Backward Compatibility), i.e. the vowel “*ē*” (U+011B) with sound [ə] [24], “*ō*” (U+00F6) with the long sound of the vowel “*ē*”, the consonant na rambat “*ṅ*” (U+0146) with sound [ŋa], sa sapa “*ś*” (U+015B) with sound [ʃa], sa saga “*ṣ*” (U+015F) with sound [ea], ta latik “*ṭ*” (U+0163) with sound [ta], or its uppercase letter “*Ē*” (U+011A), “*Ö*” (U+00D6), the consonant “*Ṇ*” (U+0145), “*Ś*” (U+015A), “*Ṣ*” (U+015E), “*Ṭ*” (U+0162). The second aspect involves transliteration of the letter set BBC (Breaking Backward Compatibility), i.e. the vowel “*e*” (U+0065) or its uppercase letter “*E*” (U+0045) that has sound [e]. Noted that the uppercase letters were not the concern, since each of them has the same transliteration result as its counterpart lowercase letter.

Those two aspects should be handled by the proposed method. Fig. 1 shows the flowchart of the algorithm and uses regular expression [25], [26] on the implementation.

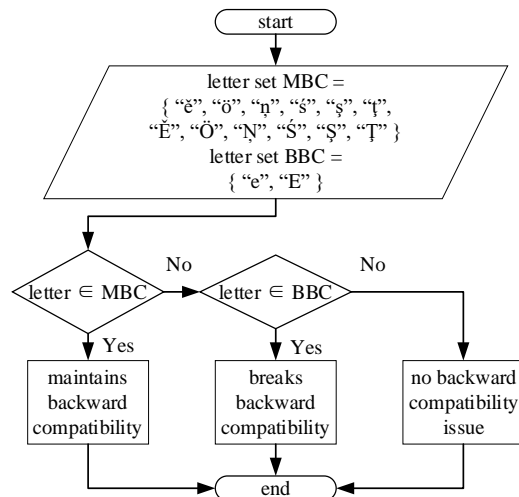

Fig. 1. The Flowchart of the Algorithm.

B. The Implementation

Fig. 2 (a) shows the Model-View-Controller (MVC) architecture [27]–[29] of the web-based transliteration learning application, BaliScript, that was used by the proposed method. The supporting database’s table (Fig. 2 b) consists of records from the Balinese Script dictionary [7]. Fig. 3 shows the Indonesian and English translation of the example transliterated word for improving the learning experience on the application. As described previously, this feature is one of several advances as the contribution of this work. The BaliScript was constructed by Apache web server, MySQL database server, and PHP code combined with JavaScript code. This application was also used for the exploration of scriptio continua management in the previous work [30].

Fig. 3 (a) shows the View of the MVC, i.e. (1) the input view that uses the Select box⁸; and (2) output view that displays the transliteration result and other results from the closest similar words in the database where the similarity calculation is based on the Levenshtein distance [31], [32]. Fig. 3 (b) shows the transliteration output from the example homonym word [33], [34] at the similarity list by using AJAX-based switching (clicking on the word “USE” related to the certain word).

C. The Testing

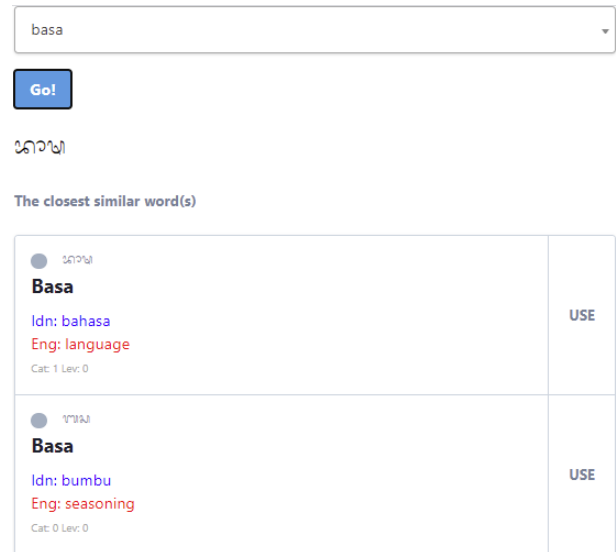

The testing of the proposed method was conducted on the BaliScript, which was run on the Intel Core i7-4600U CPU @2.09GHz platform with 8 GB RAM and Windows 8 64-bit Operating System.

IV. RESULT AND ANALYSIS

Table I shows the testing cases consist of sections of interest (the marked sections) related to the result of backward compatibility (see Fig. 4). Noted that the testing used the updated testing cases that comply with the standard transliteration rules from the Balinese Language, Script, and Literature Advisory Agency [7] rather than the original testing cases [10] that refer to The Balinese Alphabet document.

^a. The original testing cases

^b. The updated testing cases that comply with the standard transliteration rules

^c. The Balinese Alphabet document

For example in case 2 of Table I, since the vowel “e” of the Balinese word “Sēla” (Yam) has sound [e] [24] for a certain meaning (the other “e”, U+0065, with sound [ə] has a different meaning), to comply with the standard rule, the writing of that vowel should be changed to “ē”. This condition breaks backward compatibility of the transliteration since the vowel “e” is a member of the letter set BBC (see The Algorithm section).

There are several sections of interest in Table I related to the testing result, i.e.:

- The bold underlined section on the original testing case shows a section of interest related to the backward compatibility of the transliteration.
- The bold underlined section on the updated testing case shows a section of interest that has backward compatibility where its transliteration result adheres to [7] and is the same as the transliteration result of the original testing case. This backward compatibility was achieved due to the process related to the algorithm.
- The bold dotted-underlined section on the updated testing case shows a section of interest that has a transliteration result that adheres to [7] but different from the transliteration result of the original testing case using The Balinese Alphabet document.
- The bold gray section on the updated testing case shows a section of interest that has broken backward compatibility by using different writing where its transliteration result adheres to [7] and the same to the transliteration result of the original testing case.
- The underline-across-space section on the updated testing case shows a section of interest that has a transliteration result that adheres to [7] and different from the transliteration result of the original testing case. This is because continuous (phrase or sentence) transliteration was used rather than word-by-word transliteration. If both updated and original testing cases use the same kind of transliteration then the result should be the same. It needs to be mentioned as a perspective that relatively was not related to backward compatibility. For example in case 2 of Table 2, the Balinese phrase “Kādep Jēro” (Sold House) has continuous transliteration result “කොඳිභිච්චිතො” adheres to [7] and different from word-by-word transliteration result “කොඳිභිච්චිතො”. In continuous transliteration, the second word of “Jēro” (House) has its consonant “J” was transliterated in appended form as “භිච්චි” (hanging below the regular form of consonant “p” of word “Kādep”) while its vowel “ē” was transliterated as a vowel sign (upper form). In word-by-word transliteration, the second word of “Jēro” has its consonant “J” was transliterated in regular form as “ච්චි” (positioned on the side after the sound killer *adeg-adeg* “ච්චි”) that kill the inherent sound of consonant “p” of

word “Kādep”) while its vowel “ē” was transliterated as a vowel sign (upper form).

Even though Balinese Script employs scriptio continua style [35], Fig. 4 shows its transliteration result in non-scriptio continua style (including preserved line breaks) which is possible to be generated for ease of visual analysis by the BaliScript learning application. This style was supported by the white-space⁹ property of Cascading Style Sheets (CSS) that was set as *pre-line*. This kind of non-scriptio continua style has the same space and line break format as its Latin text input from the testing transliteration cases of Table I. It has a clear mapping between the input section of the Latin text (i.e. alphabet, syllable, word, or punctuation) and its related output section of the Balinese Script. That clear mapping was caused by the spaces and line breaks between those sections that were preserved by the transliteration algorithm [30].

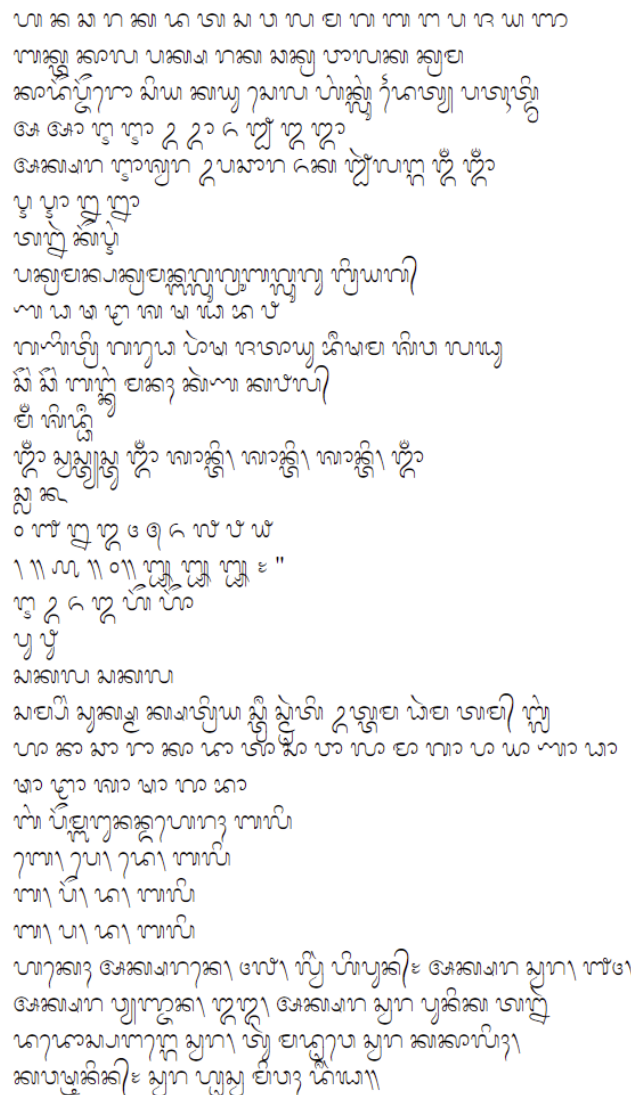

Fig. 4. The Balinese Script Transliteration Result with non-scriptio Continua Style, Including Preserved Line Breaks, from the BaliScript Learning Application.

⁹ CSS white-space, https://www.w3schools.com/cssref/pr_text_white-space.asp (Retrieved June 16, 2021)

The backward compatibility analysis of the transliteration results in Fig. 4 was based on the marked sections in Table I. The algorithm maintains backward compatibility and on the other side unavoidably breaks backward compatibility to comply with the standard transliteration rules [7].

Related to maintaining backward compatibility, the bold underlined section on the updated testing case shows a section of interest where its transliteration result adheres to [7] and is the same as the transliteration result of the original testing case. For example, in case 2 of Table I, the Balinese phrase “Kādep Jěro” (Sold House) has its continuous transliteration result “ꦏꦩꦥꦺꦫꦺꦴꦗꦺꦴꦫꦺ” that adheres to [7] and is the same as the continuous transliteration result from The Balinese Alphabet document (see the previous underline-across-space section).

The bold underlined sections, i.e. the vowel “e” (U+0065) of the word “Kādep” and “ē” (U+011B) of the word “Jěro” has the same sound [ə] [24] and should be transliterated the same by using “ꦺ” (Balinese vowel sign *pepet*, U+1B42). Their variant words from [7], i.e. “adep” (only available in its root word) and “jero” should be transliterated the same. These variances of words “Kādep”, “kadep”, “Jěro”, “jero”, and others should be registered with their related same value in column “sword” of database’s table (see Fig. 2 b) for the same transliteration result. This is the effort for maintaining transliteration backward compatibility along with other cases in Table I, i.e. word “Akšara”, “Išwara”, “Gaṇitri”, “Bhišama”, “Šiwa”, “Karna”, “Šanti”, “sekalē”, “Sukśma”, “Kšatria”, “Pembangunan”, “Daerah”, “Akeh”, “talē”, “pangangge”, “madrēwe”, “kawāštanin”, and “hrēswa”.

From those cases with bold underline marks, certain of those were also marked with bold dotted-underline since each of them has a transliteration result that adheres to [7] but different from the transliteration result of the original testing case. For example, the Balinese word “Išwara” (God’s name) and “Bhišama” (Decree), each in case 3 and case 6 of Table I, have their variant words from [7], i.e. “Išwara” and “bisama” should be transliterated the same “ꦲꦱꦮꦫ” and “ꦧꦶꦱꦩ” [7] but different from the transliteration result “ꦲꦱꦮꦫ” (without vowel sign *tedung* “ꦠ”) and “ꦧꦶꦱꦩ” (without vowel sign *ulu sari* “ꦱ”). This is a condition that should be taken care of by the effort for maintaining backward compatibility transliteration. Above that condition, these variances of word “Išwara”, “Iswara”, “Bhišama”, “bisama”, and others should be registered with their related same value in column “sword” of database’s table (see Fig. 2 (b)) for the same transliteration result that adheres to [7].

From those cases with bold underline marks, certain of those were safe to associate its vowel “e” (U+0065) to the vowel “ē” (U+0113) through the database registration because of its sound [e] [24]. This condition was possible since no counterpart word has the vowel “e” (U+0065) with sound [ə]. This condition is related to the next testing cases with the bold gray section. For example, the Balinese word “Akeh” (Many), in case 16 of Table I, has its variant words from [7], i.e. “akēh”

should be transliterated the same “ꦲꦏꦺꦲ” [7]. As the exception to the standard rule [7] where the vowel “e” (U+0065) should be transliterated by using “ꦺ” (Balinese vowel sign *pepet*, U+1B42) while the vowel “ē” (U+0113) should be transliterated by using “ꦺ” (Balinese *adeg-adeg*, U+1B44), these variances of the word “Akeh”, and “akēh” should be registered with their related same value in column “sword” of database’s table (see Fig. 2(b)) for the same transliteration result that adheres to [7]. This is a condition that should be taken care of by the effort for maintaining backward compatibility transliteration since by nature people write the word in the easiest way (write “e” rather than “ē”), including inputting text to the transliteration application.

Related to unavoidable breaking backward compatibility to comply with the standard transliteration rules [7], the bold gray section on the updated testing cases shows a section of interest that has broken backward compatibility by using different writing where its transliteration result adheres to [7] and the same to the transliteration result of the original testing case. For example, in case 2 of Table I, the Balinese word “Sēla” (Yam) with its vowel “ē” (U+0113) has its transliteration result “ꦱꦺꦭ” that adheres to [7] and is the same as the transliteration result from The Balinese Alphabet document (see the previous standard rules [7] where the vowel “e” and “ē”, each should be transliterated by using vowel sign *pepet* and sound killer *adeg-adeg*). If using the Balinese word “Sela” with its vowel “e” (U+0065) from the original testing case, its transliteration result “ꦱꦺꦭ” does not adhere to [7] even though is the same as the transliteration result from The Balinese Alphabet document.

V. CONCLUSION AND FUTURE WORK

A method to accommodate backward compatibility was proposed on the learning application-based transliteration to the Balinese Script. It covered two aspects related to considered sets of letters. The first aspect concerns the transliteration of a certain set of letters that causes backward compatibility to be maintained. The second aspect concerns the transliteration of a certain set of letters that causes backward compatibility to be broken unavoidably to comply with the standard rules from the Balinese Language, Script, and Literature Advisory Agency.

ACKNOWLEDGMENT

This work was supported by the Indonesian Ministry of Education, Culture, Research, and Technology through the multi-years Applied Research Grant.

Validation: Conceptual versus Activity Diagram Approaches

Sabah Al-Fedaghi
Computer Engineering Department
Kuwait University
Kuwait

Abstract—A conceptual model is used to support development and design within the area of systems and software modeling. The notion of validation refers to representing a domain in a model accurately and generating results using an executable model. In UML specifications, validation verifies the correctness of UML diagrams against any constraints and rules defined within the model. Currently, significant research has been conducted on generating test sets to validate that UML diagrams conform to requirements. UML activity diagrams are a specific focus of such efforts. An activity diagram is a flexible instrument for describing a system's behaviors and the internal logic of complex operations. This paper focuses on the notion of validation using activity diagrams and contrasts that process with a proposed method that involves an informal validation procedure. Accordingly, this informal validation involves comparing requirements to specifications expressed by a diagram of a modeling language called thinging machine (TM) modeling. The informal validation is a type of model checking that requires the model to be small enough for the verification to be done in a limited space or time period. In the proposed method, the model diagram is divided into subdiagrams to achieve this purpose. We claim the TM behavioral model comes with a particular dispositional structure that allows a designer to “carve” a model into smaller components for informal validation, which is shown through two case studies.

Keywords—Validation; conceptual model; activity diagram; thinging machine; informal validation

I. INTRODUCTION

A conceptual model is a mathematical/logical/verbal representation (mimic) of a domain (real or proposed), situation, policy, or phenomenon developed for a particular study [1][2][3]. A conceptual (in contrast to an intentional mental representation such as sensation [4]) model describes “how we conceive of that domain” [5]. It is used to support development and design within the area of systems and software modeling (e.g., databases or business processes).

An example of such a model is a description developed using the Unified Modeling Language (UML) to construct a representation of a domain using primitive constructs and concepts such as the “lens” through which reality is perceived to capture that domain's meaning [5]. Nonconceptual models such as mathematical models are presented in terms of variables and quantitative relationships (i.e., equations). By contrast, in conceptual models, the variables and relationships between variables are represented visually as a system of icons in a diagram [5]. Visual representations can help to shift the

focus to enhanced qualitative conceptual reasoning, serve as representations of an internal (mental) model, and provide a means for communication and analysis. In the context of conceptual modeling, to ensure a system's quality, it is critical that the model that represents the domain be semantically correct. This is confirmed by checking that the model satisfies some correctness properties and the system requirements.

A. Validation

Validation is the process of confirming that models are understood, defined well, documented, and based on established fundamentals [6][7]. It conveys a sense that “a scientific effort must be justified in some logical, objective, and algorithmic way” [6]. However, determining whether a particular model fulfills requirements by validating it over the complete domain of its intended applicability often is not possible (e.g., due to cost and time). Instead, tests and logical reasoning are conducted until adequate assurance is achieved that the model can be considered valid for its intended application.

Regarding UML, as a semi-informal notation, significant research efforts have gone into the so-called model-driven testing of UML diagrams. Such efforts mostly involve generating high-level test cases that can be used to validate both specifications and implementations [8]. Specifically, activity diagrams are highly useful for validating requirements with customer representatives [9]. Activity diagrams have become an established modeling notation for various levels of abstraction, ranging from fine-grained descriptions of algorithms to high-level workflow models in business applications [10].

B. Problem: Semantics of the UML Diagram

According to Tariq, Sang, Gulzar, and Xiang [11], the absence of formal semantics for UML activity diagrams makes it difficult to build automated tools for analyzing and validating such diagrams. Recently, UML 2.0 introduced token-driven semantics for activity diagrams inspired by Petri nets. One of the goals of the Foundational UML Subset (fUML [12]) is to provide a well-defined execution of UML activity diagrams. Accordingly, additional validation tools are needed for diagrammatic representation in the context of conceptual modeling. This paper proposes such a tool using a new type of conceptual model.

C. Approach and Limitations

This paper focuses on works that solely examine the notion of validation using activity diagrams, as an example of the current state of research in the validation field. Validation of UML activity diagrams using directed test cases is very promising [8]. The present paper complements such studies by examining validation under “equivalent” representations using a diagrammatic model based on thinging machine (TM) modeling. The aim is to propose a particular technique for model validation based on TM.

II. REVIEW

An UML activity diagram is a semi-formal semantic specification that is intuitive and flexible. It is used to describe a system’s behaviors and the internal logic of complex operations. Therefore, it is widely utilized as a front-end tool for system-level design of software and/or hardware systems.

A. Review: Graphs, Petri Nets, and Event B

The validation literature on developing test cases for activity diagrams is extensive (e.g., [8]). According to Chen and Mishra [8], “Most directed test case generation work is performed by human intervention. Hand-written test cases entail laborious and time-consuming effort of verification engineers who have deep knowledge of the design. Due to the manual development, it is difficult to generate all directed test cases to achieve a coverage goal. The problem is further aggravated due to the lack of comprehensive functional coverage metrics.” Many tools and methods have been developed to support test specifications and test case generation. For example, dSPACE developed a tool that uses activity diagrams for test descriptions and test script generation [13]. Chen, Poon, Tang, and Tse [14] presented a framework with which to construct test cases from specifications by identifying a set of input categories for the activity diagrams as test cases. Hettab, Kerkouche, and Chaoui [15] converted activity diagramming into grammar rules for graphs to capture all the relevant features for test case generation. Shirole, Kommuri, and Kumar [16] transformed activity diagrams into extended control flow graphs. Sunitha [17] incorporated Object Constraint Language (OCL) into activity diagramming for test case generation involving difficulties identifying complete behavior and static changes [18]. Chen et al. [19] matched Java program traces with behavior activity diagramming to identify changes resulting in a failure to identify static changes [18]. Sapna and Mohanty [20] converted UML activity diagrams into tree structures to prioritize scenarios by assigning weights to nodes and edges; however, this approach lacks in-depth code coverage and cannot identify static changes [18]. Some authors have developed frameworks to transform a UML activity diagram into Petri nets automatically using a model checker for analysis (e.g., [21][22]). A different approach involves transforming UML activity diagrams into Event B to specify and verify the distributed and parallel workflow solicitations [23].

B. Approach in this Paper: Informal Validation

In our approach to validation, we first produce an equivalent TM representation of the activity diagram. We consider the complexity of the representation and thus aim for

quick model checking by adopting informal reasoning. All of the reviewed validation methods discussed in the previous subsection can be applied to TM. Informal validation leads to discussing formal validation.

Formal specifications can be used to deliver a precise addition to different descriptions and can be validated, leading to specification faults being detected. Formal validation verifies the correctness of specifications, so it can be used to guarantee the quality of models (e.g., UML [8]). Despite the long interest in formal validation methods, “It seems that practitioners judge formal methods to be insufficiently beneficial to outweigh pragmatic problems” [24]. According to Amey [25], “Customers are often ‘aghast’ at the idea of formal methods being used to develop their products and might say ‘couldn’t you use UML?’” Amey [25] suggests overcoming such prejudices through “formality by stealth” and cites semantically strengthened UML as an example [24].

On the other hand, informal validation techniques rely on the opinions of modelers to draw a conclusion [26]. According to Petty [27], “Informal methods are more qualitative than quantitative and generally rely heavily on subjective human evaluation, rather than detailed mathematical analysis. Experts examine an artifact, for example, a conceptual model expressed as UML diagrams, and assess the model based on that examination and their reasoning and expertise.” Examples of informal methods include inspection, face validation, the Turing test, desk checking, and walkthroughs [27]. According to Banks [26], “In all cases though it is important to note that informal does not mean it is any less of a true testing method. These methods should be performed with the same discipline and structure that one would expect in ‘formal’ methods. When executed in such a way, solid conclusions can be made.”

The purpose of informal validation is to examine the accuracy of a domain’s representation in a conceptual model and in the results produced by the executable model [27]. In this type of validation, the concept of a system is viewed as a group of interacting components, and its desired functionality is articulated by graphical means [28].

Accordingly, in our proposed approach, the validation process involves requirements (e.g., expressed in English) versus specifications (expressed by TM diagrams). The validation here involves showing that the TM model is the correct model for the requirements. Thus, informal validation is a type of model checking that requires “the model to be small enough so that the verification can be done in a limited space or time” [29]. Accordingly, the TM diagram is divided into subdiagrams for this purpose. Our claim is that the TM behavioral model comes with a particular dispositional structure that allows a designer to “carve” a diagram into smaller components for informal validation.

C. Outline

The next section reviews the basic constructs of a TM model. Section 4 presents a case study of validating the process of buying a beverage from a vending machine. Section 5 presents a second case study of validating an online shopping system.

III. THE THINGING MACHINE

TM modeling is a way of understanding how things and processes have come to be structured (see [30] and its TM-related references by the author of the present paper). As shown in Fig. 1, a TM can be described as the following generic (basic) actions:

- Arrive: A thing moves to a machine.
- Accept: A thing enters the machine. For simplification, we assume that all arriving things are accepted; hence, we can combine the arrive and accept stages into one stage: the receive stage.
- Release: A thing is ready for transfer outside the machine.
- Process: A thing is changed, but no new thing results.
- Create: A new thing is born in the machine.
- Transfer: A thing is input into or output from a machine.

Additionally, the TM model includes the mechanism of triggering (denoted by a dashed arrow in this study's figures), which initiates a flow from one machine to another. Multiple machines can interact with each other through the movement of things or triggering. Triggering is a transformation from one series of movements to another.

IV. VALIDATING A VENDING MACHINE

Sapna and Arunkumar [20] considered an example of an activity diagram for the process of buying a beverage from a vending machine (Fig. 2).

Fig. 2. Partial Views of the Diagrams used to Model the Process of Buying a Vending Machine Beverage Found in Sapna and Arunkumar [20].

In this section, we first produce the corresponding TM models and then apply the validation strategy to this vending-machine example.

A. Static Model

Fig. 3 shows the corresponding static TM model. In Fig. 3,

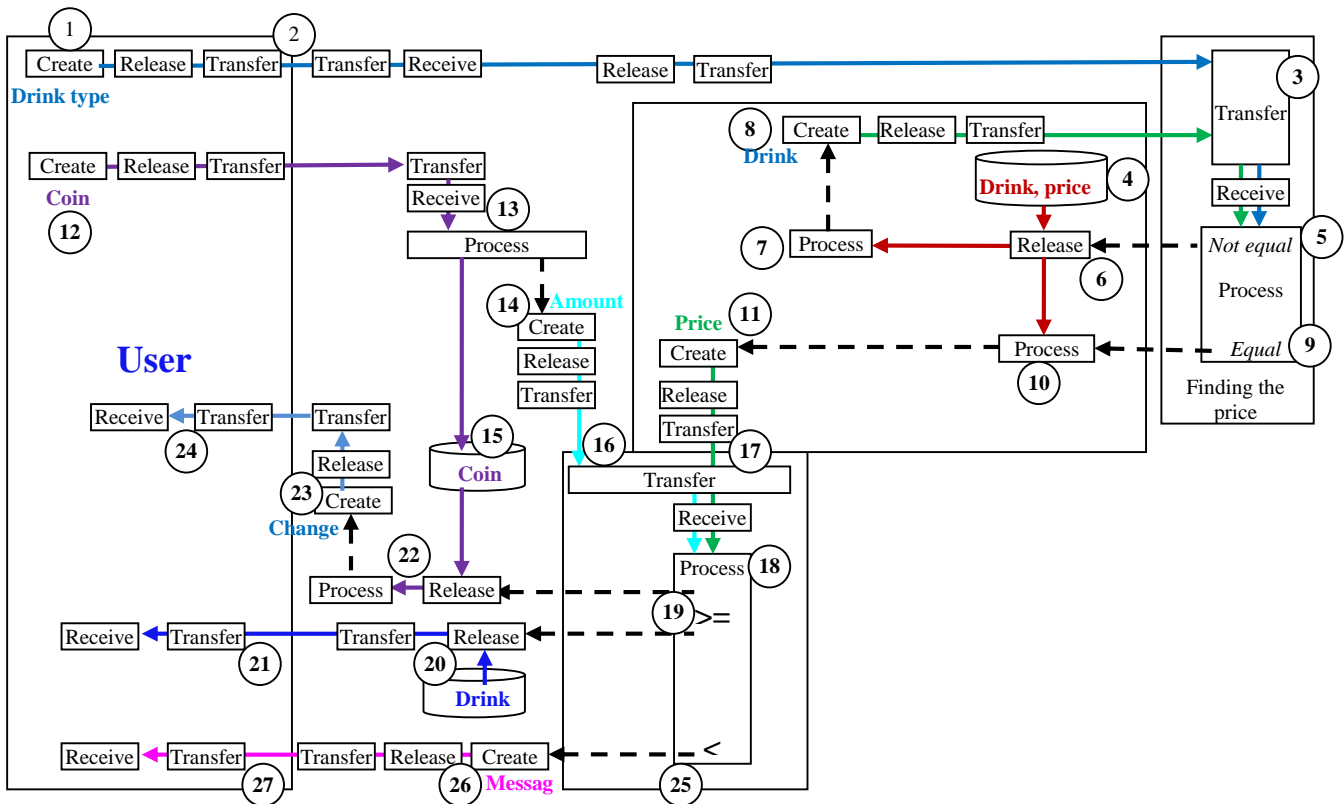

Fig. 3. The Static TM Model of a Vending Machine.

- The user creates (circle 1) a drink selection that flows to the machine (2), where it is sent to a module that finds the (drink, price) record (3). The drink data are found by extracting records (drink, price) (4) one by one and comparing the input drink with the drink data in the matching record.
 - If the drink data inside the record are not equal to the input drink (5), then the next record is released from the set of records and processed (7) to trigger the creation of drink data (8). Note that the drink item is *created* in the sense that it was not known to the machine as an independent thing before it was extracted from the record.
 - If the drink data inside the record match the input drink (9), then this triggers processing of (10) the record to extract the price (11). (Note that, in the activity diagram, the price is a thing “dropped from the sky”. There is no connection between the drink and its price.)
- Meanwhile, the user inputs coins (12), which are processed (13) inside the machine to calculate their value (14). (Note that the activity diagram does not distinguish the coins as physical objects from their amount and value.) Then, the coins are stored in coin boxes (15).
- Both the amount (16) and the price (17) flow to a module that compares them (18).

- If the amount is equal to or greater than the price (19), then the drink is released to the user (20 and 21). Additionally, the coin storage is processed (22) to create change, which flows to the user (23 and 24).
- If the amount is less than the price (25), then a message is created and flows to the user (26 and 27).

B. Behavioral Model

To produce the TM behavioral model, we must identify all events in the vending-machine model. An event in TM modeling is formed from a subset of the static model in addition to a time subthimac. For example, Fig. 4 shows the event *the machine receives a drink selection*.

Identifying a phenomenon’s behavior involves dividing it into component parts and then fitting the behaviors of these parts into a whole. Accordingly, the static model (Fig. 3) can be divided into events as shown in Fig. 5, which shows only the regions of the events for simplification. The resulting list of events is as follows.

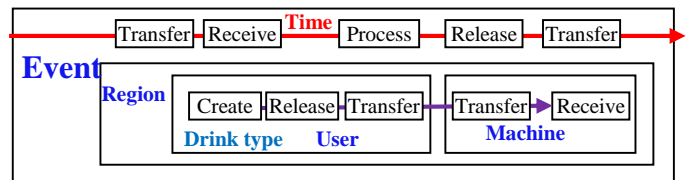

Fig. 4. The Event the Machine Receives a Drink Selection.

Fig. 5. The TM Events Model of the Vending Machine.

Event 1 (E₁): The machine receives a drink selection.

Event 2 (E₂): The selected drink flows to the price-finding module.

Event 3 (E₃): A record (drink, prices) is retrieved from the list.

Event 4 (E₄): The selected drink is extracted from the record.

Event 5 (E₅): The drink is sent for comparison with the input drink.

Event 6 (E₆): The input drink is compared with the stored drink.

Event 7 (E₇): The input drink is not the same as the stored drink.

Event 8 (E₈): The input drink is the same as the stored drink.

Event 9 (E₉): The price is extracted.

Event 10 (E₁₀): The user inputs coins.

Event 11 (E₁₁): The amount of the coins' value is calculated.

Event 12 (E₁₂): The coins are deposited into the coin boxes.

Event 13 (E₁₃): The amount flows to a comparison with the price.

Event 14 (E₁₄): The price flows to a comparison with the amount.

Event 15 (E₁₅): The amount and the price are compared.

Event 16 (E₁₆): The amount is equal to or greater than the price.

Event 17 (E₁₇): The coin boxes are processed.

Event 18 (E₁₈): The change is extracted from the coin boxes.

Event 19 (E₁₉): The change flows to the user.

Event 20 (E₂₀): The drink is released to the user.

Event 21 (E₂₁): The input amount is less than the price.

Event 22 (E₂₂): A message is sent to the user.

Fig. 6 shows the behavioral model for the vending machine.

C. Validation Strategy

Until this point, we have focused only on the modeling notations. It is time to ask whether the vending-machine blueprint fulfills the requirements. Requirements typically are written in natural language, but the behavioral diagram provides a skeletal structure of events.

Plato famously employed the "carving" metaphor as an analogy for the reality of Forms (Phaedrus 265e): As if we were animals, the world comes to us predivided. Ideally, our best theories will be those that carve nature at its joints [31]. The behavioral model comes with a particular dispositional structure rooted in the five generic types of events: create, processes, release, transfer, and receive.

Validation in TM modeling refers to event validity, which involves the model's events being compared to those of the reality to determine whether they are similar. In TM modeling, a general approach to validating the developed model can be developed using a logical process in which one takes higher-level events produced by the carving process and reduces them to the constituent events, which, in turn are based on generic events. This implies validating each generic action or sequence of these actions. However, because of space limitations and the informal nature of this study, we will not employ such a process but rather simply sketch operational descriptions of events with which to validate the model. This method assumes that the model's validity can be determined from observations.

Fig. 7 shows the decomposition of the behavioral model (Fig. 6) into three parts (super-events), for which the joints suggest division among three super-events as follows.

- Super-event 1: Selecting a drink and finding the price
 - The machine shall accept requests for n types of drinks.
 - The machine determines the price of the selected drink.

Fig. 8 shows the events involved: E₁ through E₉. The figure shows that the verification method involves feeding, internally, all drinks stored in the machine to the machine to verify that the machine performs the two requirements specified above. This verification process covers all legitimate inputs to E₁. An actual verification system can be constructed to input the tuples to E₁.

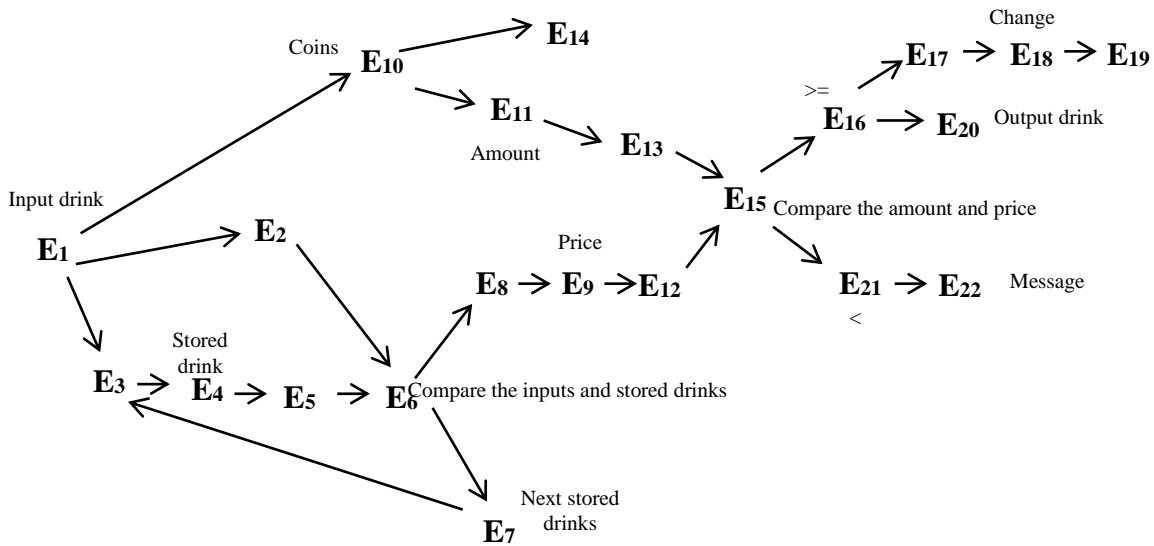

Fig. 6. The Behavioral Model.

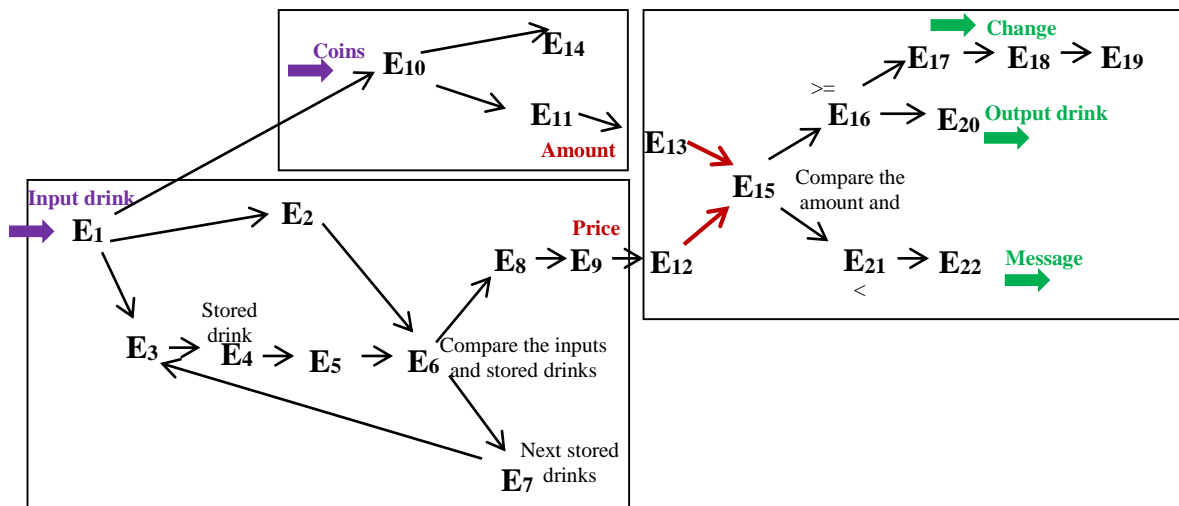

Fig. 7. Three Super-Events in the Behavioral Model.

Fig. 8. Verifying that All Drinks have Prices.

Verification of selecting a drink and finding the price

Verification version of E_1 : loop for all drinks:
Read a tuple from the (drink, price)
Extract the drink from the tuple
Perform $E_2, E_3, E_4, E_5, E_6, E_7, E_8,$ and E_9
If (ERROR), then process a report

- upper-event 2: Validating the coins
 - The machine accepts all specified coin types, assuming there are three types.
 - The machine calculates the digital values of these coins.
 - The machine stores the coins in their appropriate places.

Fig. 9. Validating All Combinations of Coins to be sorted in their Boxes and Generating the Right Amount.

Fig. 9 shows the validation of all combinations of coins to be stored in their boxes and the generation of the correct amount.

We assume that the machine initially has some coins from each of the assumed three types of coins, to return change when the input amount is greater than the price. For validation purposes, this initial amount is increased to cover all types of combinations of input amounts. Accordingly, different combinations of coins are fed to E_{10} , which are distributed to their appropriate places (E_{14}), and their amount is generated (E_{11}). It is not difficult to develop such an internal system in a vending-machine factory with which to test each machine.

- Super-event 3: Comparing the amount and price and outputting the result

The third validation process involves comparing the amount and price and observing the results of that comparison, as shown in Fig. 10.

Fig. 10. Validating All Types of Output.

- All prices and amounts produced in phases 1 and 2 are fed to E_{15} , during which the amount and price are compared. The results of this comparison are as follows.

If the amount is less than the price, then a message is produced (E_{21} and E_{22}).

If the amount is equal to or greater than the price, then the correct change is produced by processing the coins (E_{17} , E_{18} , and E_{19}).

- A drink is output.

We assume that a validation system takes the outputs of super-events 1 and 2 and produces the physical activities above in super-event 3. The level at which all possible variations of inputs are exhausted depends on the amount and price values produced in the first two super-events.

Nevertheless, in reality, the level of testing is a subjective decision based on evaluations conducted as part of the model-development procedure.

V. VALIDATING AN ONLINE SHOPPING SYSTEM

Bures, Ahmed, and Zamli [32] proposed a model-based test-case-generation algorithm that uses directed graphs and test requirements to model the system being tested. They proposed a method using a directed graph and a set of test requirements to try to satisfy a defined test-coverage level together. They modeled an online shopping system, as presented in Fig. 11, as a running example to document the presented concepts and algorithms. Fig. 12 shows the TM model constructed to reflect the given activity diagram of Fig. 11.

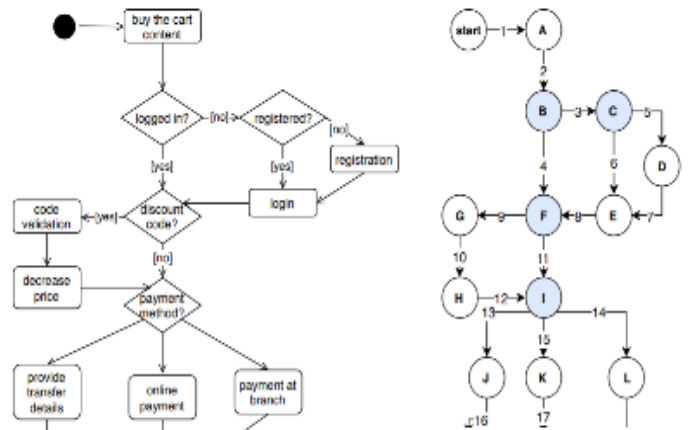

Fig. 11. Partial Views of the Diagrams used in Modeling the Online Shopping System in [31].

Fig. 12. The Static TM Model of the Online Shopping System.

First, the customer applies for registration (circle 1), which is processed by the system (2) to create a login account (3) that is added to the set of registered accounts (4 and 5). Note how the login account file is processed to add a new account.

- The customer requests to log in (6) and the request is processed (7) to extract the login account from the request (8). Additionally, the accounts file is processed (9) to retrieve an account (10), which is compared with the input account (11). If the two accounts are not the same, then the next account in the accounts file is retrieved for comparison. This process continues until the two accounts are found to be the same (13). Here, we ignore the situation in which the account is not filed in the file because the activity diagram does not mention it. Here, we can add a trigger for an error message to flow to the customer.
- Then, the system sends a request for a discount (14), which is processed by the user (15), to reply (16) with a code (*no discount* is a type of code). The code is processed (17) to be compared with the set of codes (18, 19, 20, and 21). When the code is found, the percentage of discount is calculated (22) and, together with the price (23), is processed to calculate the payment (24) and invoice (25).
- Accordingly, the system requests the method of payment (26), and the customer processes (27) that request to input such a method (28), which flows to the system, where it is processed (29). According to the payment method, the system either sends an invoice online (30) or to the branch (31).

Fig. 13. Events Model. Note that in the Activity Diagram, the Price is considered an Input to the Whole Process.

The events in the model can be specified as follows (see Fig. 13).

- Event 1 (E₁): A customer registers to log in.
- Event 2 (E₂): The system creates a new login account.
- Event 3 (E₃): The system adds the new account to the accounts file.
- Event 4 (E₄): A customer sends a login request.
- Event 5 (E₅): The system extracts the login account from the request and sends it to be checked as a legal account.
- Event 6 (E₆): The accounts file is processed to retrieve an account, which is sent for comparison with the input account.
- Event 7 (E₇): The input account is compared with the account retrieved from the file.
- Event 8 (E₈): The input account is not the same as the account from the file.
- Event 9 (E₉): The input account is found among the legitimate accounts; hence, a request for the discount code is sent to the customer.
- Event 10 (E₁₀): The customer sends a discount code (possibly a code for no discount).
- Event 11 (E₁₁): The code is sent to find its corresponding discount percentage.

- Event 12 (E₁₂): The list of codes is processed to retrieve one code at a time.
- Event 13 (E₁₃): The retrieved code is sent to be processed.
- Event 14 (E₁₄): The code is compared with the list of codes.
- Event 15 (E₁₅): The code is found; thus, a request for the payment method is sent to the customer.
- Event 16 (E₁₆): The customer sends the payment method.
- Event 17 (E₁₇): The payment method is processed.
- Event 18 (E₁₈): The payment method is in the branch.
- Event 19 (E₁₉): The online payment method is chosen.
- Event 20 (E₂₀): The code is found; thus, the discount percentage is extracted.
- Event 21 (E₂₁): The price is received.
- Event 22 (E₂₂): The discount percentage and price are used to calculate the required payment.
- Event 23 (E₂₃): The payment is used in generating the invoice.
- Event 24 (E₂₄): The invoice is sent to the branch.
- Event 25 (E₂₅): The invoice is sent to the online payment system.

Fig. 14. The Behavioral Model.

Fig. 15. Carving Small Components from the Behavioral Model.

Fig. 14 shows the behavioral model decomposed into three parts (super-events), in which the joints suggest division among five super-events. As shown in Fig. 15, these super-events are as follows.

- Registration component
- Login component
- Discount percentage component
- Payment component, and
- Method-of-payment component

Apparently, our hypothesis that TM representation would lend itself to such division of high-level events is true for this shopping-system representation. We can apply the same type of informal validation.

However, it is important to point out that the super-events may have relationships with “use cases”; thus, UML use case diagrams are a topic to be investigated in future research.

VI. CONCLUSION

This paper focused on examining the notion of validation using activity diagrams and proposed an informal validation process. This validation process involved requirements, versus specifications expressed by a diagram. Informal validation is a type of model checking that requires the model to be small enough to verify in a limited space or time. Accordingly, the model diagram is divided into subdiagrams for this purpose. We claimed that the TM behavioral model comes with a particular dispositional structure that allows designers to “carve” a diagram into smaller components for informal validation. This was shown through two case studies concerning vending machine and online shopping systems.

This result seems plausible because TM modeling is founded upon five generic actions. Thus, generic events have no subevents, and higher-level events are built from these generic events. Generic events can happen in diverse regions, and they can reoccur. It seems the building structures from the five generic actions “collapse” into smaller structural partitions according to certain aspects such as functionality. The number

(e.g., 7 ± 2) and nature (e.g., basic) of these actions seem to be crucial features that determine the system's overall level of complexity. Additionally, the TM model (Fig. 1) seems to generate nested hierarchies or levels with loosely coupled connections (through only transfers and triggers), which inhibit large structural complexity.

These explanations are still a type of speculation and require further research to be applied in different aspects of modeling systems beyond validation.

Abstract—Small and Medium Enterprises (SMEs) today are facing a competitive business environment, in a complex and rapidly changing environment. For that technology is seen as a mediator capable of transforming SMEs to greater heights in an amid and vigorous pace of a borderless world. The agenda of SMEs to generate national income as well as to create more employment opportunities has made the government much focused in providing improvements in business opportunities to SMEs to boost the country's economic growth. To ensure that the SME owners sustain their business, they should be able to adapt the use of the internet as a key component in designing new business model values, customer experiences and internal capabilities that support the key operations. However, there are still some SME owners who do not leverage on the use of Information and Communication Technology (ICT) in their business operations. This study interviewed eight SME owners who operated their businesses in Kuala Lumpur and Selangor to identify a list of most important business training courses needed for SMEs in Malaysia. The data was analyzed using Thematic Analysis method and it was found that there are five main components of courses in SMEs, namely, Business Management, Sales and Marketing, Accounting and Finance, ICT and Technology, and Production and Operations. As a result of this Thematic Analysis study, researchers have developed a smart entrepreneurship training framework related to the five components and produced a system called, the Malaysian SMEs Psychometric Test or U-PPM which has been reviewed and endorsed by the respective panels of experts. This proposed framework is important for SME owners and management and also the government and stakeholders, when making the correct decisions in selecting business training courses as well as to increase ICT and digital technologies usage in providing a positive impact to all SMEs in Malaysia.

Keywords—Small Medium Enterprise (SME); business owner; thematic analysis method; expert panel; Information and Communication Technology (ICT); course selection system; smart entrepreneurship training framework

I. INTRODUCTION

Entrepreneurship has become an important agenda in order to build a more sustainable national future [38] [77].

Entrepreneurial development approaches improved modern economy [44] and provides spaces in creating employment opportunities [10]. The importance of this field has been applied at the university level [49] with the cooperation of both government and private sectors. There are various programs, training sessions, courses, workshops, seminars, and entrepreneurship education activities that have been implemented to encourage entrepreneurs to obtain formal knowledge and education in the field of entrepreneurship, to face challenges in today's sophisticated business models.

In order to realize the government's expectations to produce more entrepreneurs in the country, various initiatives have been made. Courses and training sessions have been conducted to make SMEs more competitive, provide a simple service and customer support system. SMEs that have been operating for a long time have lots of experience in running their business, but they sometimes face difficulties in several aspects such as internal management, marketing capabilities, technological capabilities, access to knowledge networks, and finance [74].

Thus, it is important for the training providers to implement standards and models of entrepreneurship-based education as well as to develop courses and skills that can be used by the entrepreneurs. This is because the role of training and courses is to help SME entrepreneurs and staff to enhance their performance [35]. In addition, the skills and knowledge are required for them to perform their functions. Entrepreneurs, especially micro-sized businesses are encouraged to find relevant courses to improve their business and their employee's performance. They should be given these trainings and courses so that they can be multi task entrepreneurs.

Among the courses and training activities that are essential to SME owners and staff are those covering management skills [51], leadership [27], communication [63], technical skills [39] [48], according to the field of enterprise, digital marketing [24] [25], and financial management skills [15] [59]. Training is required to ensure that the employees are able to perform their tasks in order to meet the objectives of the enterprise. Hence,

this training needs to be planned carefully in order for it to have an impact on the success of the business.

To ensure that the correct selection is done properly, this study has developed a Psychometric Test model for SMEs using the Thematic Analysis (TA) method. The construction of this model has been evaluated and reviewed by a group of experts from the government and private sectors in the areas of Business Management, Digital Marketing, Accounting, Business Operations, and Language.

II. LITERATURE REVIEW

A. Impact of Courses on Organizations

Entrepreneurs' level of education contributed to the performance and development of the business organization [84]. This happens because they did not emphasize the importance of training and improving knowledge and skills. The lack of skills and access to finance, knowledge of marketing, infrastructure and information had made it difficult to achieve success [40]. Therefore, SME owners need to get training and education at an earlier stage for the training programs to have a greater impact on enterprises [50].

The impact of entrepreneurial training on businesses is through a proactive attitude, innovation, and willingness to take any risks [4]. Additionally, SME entrepreneurs who participate in entrepreneurship training and courses experience a short-term improvement in entrepreneurial self-efficacy [28]. By choosing the right course, SME owners are able to improve their business skills [58]. Employees and SME owners who attended short-term courses can see results of their self-skills training attended by business entrepreneurs and employees [72]. Such impacts had an increase in sales revenue and profits, helped broaden the mind, and inculcated in the owners and employees the ability to take strong personal initiatives and to have perseverance, which further improved business practices.

The positive impacts of such courses were continued to be discussed in the study by [16] where they concurred that the effectiveness of such training is seen to be a valuable investment. In addition, the positive impact of course involvement can also be detected through an increase in the income as well as improvement in the financial performance of the enterprises [41].

The disposition of unskilled and unknowledgeable workers in enterprises is seen as a risk in losing business opportunities [46] other than having the tendency of becoming bankrupt [73]. On the other hand, employees who have gone through self-improvement courses and training provide a positive impact on the job, showing improvements in their performance and job quality, in addition to being motivated and loyal to the enterprise [30]. Therefore, SMEs should seize the available opportunities and take the necessary initiatives to improve and enhance the employees' knowledge and skills to boost competitiveness [69]. In addition, after they have undergone the courses and trainings, it would affect the growth, profitability and job creation in the enterprise [56].

B. Courses Options for Organizations

The Part of SME operations include management, finance, sales and marketing, ICT and technology, and production and

operations, which are also listed as elements that determine the success of an SMEs. Thus, courses and training that act as a medium for knowledge enhancement are seen to improve the performance of the sales force [16]. A decade ago, course selection was made based on performance competency models that built individual competencies [23]. Additionally, the competency model by [75] has been used as an instrument in providing a skilled workforce and meeting job needs.

There are various courses that can be studied by every SME employee in order to boost their skills or knowledge to improve their job performance. These courses include orientation training, internal and external company management training. The designed courses usually depend on the needs of SMEs [22], financial estimates [26] that can be spent and other priorities focused on by the SMEs. Before creating training contents, training providers need to evaluate the training needs so that the program meets the needs of the organization [47].

Other management functions had been prioritized such as accounting, marketing, finance, and production [50]. Therefore, these designed courses need to be holistic in nature, where the knowledge gained can be applied in the daily work of the employees, and it would also help in improving their work performance. Seven key areas are important for SMEs, and among the four courses that can be fitted and have impacts onto the training system in Malaysian SMEs are organizational management, sales and marketing, finance and accounting, and business planning [36].

Business Management courses are very important for owners in training individuals that they believe can lead the organization and other employees [43]. Among the topics covered in this organizational management course are leadership skills, personal skills such as how to motivate and delegate, development of industry and market analysis, operations planning, human resource management, developing sales strategies, and developing financial foundations, analysis and systems for start-ups. The goal of the course is to boost productivity, which is one of the core values of an organization.

According to [83], Human Resource Management (HRM) covers human resource planning, training, performance management, compensation management, safety, and health and employee relations. Good HRM can improve organizational performance by contributing to employees, customers, innovation, and productivity satisfaction. However, for small businesses such as SMEs, the importance of a new management approach is seen as a success if it can manage teamwork, job flexibility, and performance appraisal. SME owners need to understand the various management practices and the importance of staff training on SME performance.

Every enterprise requires the incorporation of digital marketing strategies to enhance sales [32] in today's economy. Therefore, a digital marketing course is seen as a holistic course because it is one of the best transformation platforms for businesses today. SMEs running online businesses need to implement digital marketing strategies that help online users to see them. Digital marketing is important to small businesses because it helps to further sales at a lower cost [71].

There are many benefits of digital marketing such as growing the business, cost effectiveness, ease of getting targeted with larger volume, availability of an exceptional marketing platform, ease of updating products or services, and ease of customer access to impart information on products or services [31] [76]. Digital marketing through social media, search engines, emails, contents, videos, infographics, photos, podcasts, e-books and newsletters can serve as a platform to potential customers who seek for products and services. Information technology has changed our lives and is now transforming traditional marketing methods into digital marketing. This course provides an in-depth focus on the application of marketing principles in the process of implementing marketing functions in new enterprises, including distribution channels, pricing strategies, promotion through social media, location, direct and indirect sales methods, consultation, customer management, and customer service.

This course provides an in-depth focus on the application of principles from accounting and finance courses, including applied activities such as earning, managing, and administering cash. In terms of specific competencies, it explores the use of financial software, as well as income development, income statements, balance sheets, and cash flow statements for commencement, together with their use in evaluating and managing an organization's finances, especially at an early stage. Financial knowledge is related to the managers' level of confidence in managing an enterprise [13].

Finance is the catalyst in economic growth and development in SMEs [2]. Therefore, it is important for every SME owner to participate in financial and accounting training programs, to acquire the knowledge of finance, financial attitudes, and financial behaviour, for it will have a positive impact on every financial step and financial access of the SME. Additionally, SME owners will be able to understand their financial situation better and plan their future finances and make accurate financial decisions as well as improve their level of financial access.

It is essential for employees to acquire the technology-related courses in regard to the technical aspects while working [33]. In terms of retails, it is insightful for employees to have knowledge on computers whilst communicating with customers. From a sales point of view, to be knowledgeable in technology is crucial to get new customers other than maintaining data of the existing customers. As for office management, technology knowledge has a basic usage in managing customers' data [65].

Technology has now changed the way customers access and obtain information. SMEs were also found to lack experts in the human resource field. SME owners should invest and support more activities such as training, expanding human resource development policies, and develop appropriate training methods using the latest technology of mass media such as Facebook or Instagram based on the specific needs for SMEs [19].

Currently, SMEs have been exposed to the use of ICT in making business transactions to compete in highly competitive markets while gaining access at the global level. The

importance of using e-businesses for the economic success and survival of SMEs has forced them to adapt to remain sustainable in the future. SMEs are now more likely to use ICT to improve data accuracy, speed up processes and reduce employees' blunders. The use of technology in financial matters has proven to spur the use of ICT among SMEs [12].

ICT can help SMEs in improving the standard of living. On the contrary, there are still SMEs who do not utilize online business transactions despite having an internet connection [85]. Thus, the role of this course is to encourage SMEs to use ICT in their daily business activities. ICT can help to improve business [11]. Nonetheless, SME owners should invest in relevant courses in training staff to manage the technology.

According to [5], training and taking courses in ICT can make the industry much mature in accordance with the relevant field. SME owners who provide formal courses have been proven to increase the level of readiness among their employees in accepting new technologies as well as creating skilled workers [78]. For example, the Kenyan government should support the training programs and widen the use of ICT among SMEs and they will see positive impacts on the country's development [45].

C. Limitations Faced by SME Owners in Course Selection

SME owners need to intensify their knowledge regularly [37]. They cannot afford to be left behind as the world is moving very fast, and they would incur losses if the way they do business is traditional [57]. There are various government initiatives to encourage SMEs to participate in courses and trainings to increase knowledge and skills. A study conducted by [68] shows that the support given by the government has resulted in a tremendous improvement in ICT skills amongst the SMEs. However, there are still many SMEs who have not yet had the opportunity to follow the courses provided. There are several factors that contribute to the limitations of SMEs in participating in the courses and training provided.

Among the factors are commitments such as family, children, and others. Thus, they are unable to find a suitable time to enhance their skills and knowledge of the business [70]. Additionally, time is also the main deterrent for them, preventing them to pursue the skills and knowledge that they need for their business. Therefore, for those who want to enforce or carry out short courses, they need to understand these constraints and find ways so that the courses that were developed can overcome these problems, and also are able to facilitate the affairs for both parties. Other than that, one of the major concerns shouldered upon the SME owners are the financial constraints [7] [70]. This is because with the present commitments, they are not ready for additional hardships. This is not the case for younger generations, as they have more opportunities and financial assistance for their learning level. Most SME operators are unaware of the existence of free courses provided by the government. This is due to the inadequate disclosure about the courses offered for them. They assume that the courses offered for them cover supplementary knowledge related to ICT, and that they are incapable to participate because they think it will incur a high cost.

In order to enhance knowledge, SMEs are urged to continuously provide mental and physical support to their employees. This is because a consistent support system from family, friends and employers will poise their spirit and diligence to seek knowledge. There is a positive opportunity for employees to complete course sessions if they get support from their employers [21]. In ensuring them to stay focused and motivated while engaging in a course, it is important for them to know the purpose and outcome of them attending the course [20]. This is needed to make them feel confident with their learning process.

D. Thematic Analysis (TA)

Thematic Analysis developed by [17] which have later been applied in various fields of study. According to them, TA is a process of identifying patterns or themes in qualitative data. The goal of TA is to identify themes and patterns in important data and use these themes to articulate an issue in research. This method will not only summarize the data but will also interpret and understand the data better. The interview method has been identified as the main method in finding the theme.

TA is a qualitative method that can be learned easily because it has complete methods and procedures [17]. TA is also described as flexible theory and meaningful knowledge [18], therefore, researchers should perform a structured procedure in controlling data thus producing reliable reports. This clearly proves that this method provides unique flexibility in accordance with the research questions and data forms developed by the researchers. This analysis takes into account the experiences, perspectives, practices and behaviors of the respondents through direct interaction. Qualitative research should show that the analysis that has been conducted is reliable, accurate, consistent, and covers the whole subject through recording, systematic in nature, with complete details to prove that a method such as TA is reliable to use [53]. An article wrote by [62] implemented TA as a method to identify factors affecting SME owners in adopting ICT in business and found reliable reasons that can contribute to other research. For the number of respondents, four is the minimum number of respondents coming from various backgrounds to get a clear picture of the problems encountered [42]. There are six phases developed by [17]. Table I shows the phases and descriptions of TA method.

For the first phase, the first step in qualitative analysis by [17] is for the researchers to familiarize themselves with the data by reading, repeating and understanding the entire data and transcripts. As for the second phase which is to generate the initial code, [17] suggested that researchers should manage the data in a more systematic way by encoding each relevant data segment on research study questions and used open code when it does not have pre-code-set, and should also grow and modify the code as it does through the coding process. After that, the researcher needs to discuss and develop some introductory ideas about the code. Then the transcript code assignment is done separately. Transcript encoding is performed on each relevant text segment to address the research question. After that, the code is compared and discussed before moving on to another transcript. Researchers have the option to create manually through printed transcripts

or by using qualitative data analytics software such as ATLAS.ti and Nvivo [34] which are suitable for large data sets. In addition, Microsoft Excel can also be used as an option in identifying themes.

For the third phase of finding the theme, [17] identified that the theme is a pattern that captures something important about the data from the research questions. If the data set is small, there may be similar data between the encoding level and the initial theme identification level. In this case the researcher studies the codes that eventually become the theme. At the end of this step, the code has been organized into a broader and more specific theme of the research question. This theme is descriptive and illustrates patterns in data related to research questions. This fourth phase as the theme review phase, where researchers need to study, modify, and develop the introductory theme already known in Phase 3 [17]. At this point, all data related to each theme is collected and classified according to colors. The next step is to relate with the function of the theme in an interview. The themes should be clear, and they should be different from the others. This is the final stage of the theme which is developed by [17], where the fifth phase is the determination phase, used to identify the essence of the theme. Themes need to be discussed, to know if there are sub-themes, how they interact and relate to the main theme and how the themes relate to one another. In this analysis, feedback is a holistic theme rooted in other themes. Lastly, the results of this study from TA should be recorded in the form of a report.

E. Expert Panel Judgement

In the development of a model or the use of modified research instruments, a panel of experts can be involved as individuals who can provide feedback on the importance, appropriateness, and accuracy of the content, as well as clarity of meaning of each item in the research instrument [6]. There are three steps in the instrument validation staged by the panel of experts, namely, pilot study, reliability, validity analysis and item improvement [8]. The panel of experts is selected from a population of experienced researchers and industry players from various fields in entrepreneurship and language. Definition of panel of experts in the context of this study as people who have published journals in their respective fields or have experience working in the field for several years and hold important positions in an organization [14]. According to the study, the appropriate number of expert panels for each study depends on the research's needs. There are studies that use the services of three expert panels [29], and five expert panels [3] [9] [80].

TABLE I. PHASES OF THEMATIC ANALYSIS BY [17]

Phase	Description
1	Familiarizing yourself with the data
2	Generating initial codes
3	Searching for themes
4	Reviewing potential themes
5	Defining themes
6	Producing the report

III. METHODOLOGY

A. Objectives and Aims

The methodology used in this study is divided into two main phases, namely, the data collection phase and the conceptual development phase of the qualitative study. These two main phases have their own methods, but the output from the first phase is the input for the second phase. The first phase is the data collection phase using the Thematic Analysis method. The second phase is the development phase of the smart entrepreneurship training framework for the use of SMEs in Malaysia. The purpose of this study is to identify courses that are relevant for SMEs in Malaysia. The target groups in this study are SME owners who own businesses in Kuala Lumpur and Selangor.

B. Thematic Analysis Method

The first phase conducted in this study is the data collection process. This study was conducted through the method of interviewing a total of eight SME owners and analyzing them using the TA method developed by [17]. This is the method to identify and analyze the meaning patterns in data sets, and to describe the themes that are the most important in a conducted study. TA method is suitable to identify the objectives for this study. Furthermore, this process begins when researchers are able to identify potential issues while collecting the data [17].

C. Instruments

The method used for this study was interview. Interviews are used to gather information ranging from how to select the appropriate courses and the type of courses, to the performance changes shown after attending the course. The first part of the interview begins with the consent notice requesting that each respondent express their consent to record the interview using a Sony ICD-UX543F digital voice recorder. Next, demographic questions are provided in the second part of the interview form to get more information about the participants and businesses. The third part of the form presents objective of the study along with the questions used by the researcher, to each respondent. The questions are used as the basis of the interview and the researcher reserves the right to add to the other questions depending on the answers given by the respondents. This is to get the actual reactions and reality faced by the respondents in sharing information about the course and the impact after attending the course.

After recording the data from the respondents, the researchers transcribed the data into word form and used Microsoft Excel to store the data. Survey data were then analyzed using the Thematic Analysis method. The list of interview questions is as follows:

- 1) Do you know about the courses?
- 2) Is there a need for employees to attend courses?
- 3) List the courses that you or the staff has attended?
- 4) How often do you send employees to attend courses?
- 5) Which section needs the most courses?
- 6) How do companies / employees find suitable courses?
- 7) Is the employer or employee deciding to attend the course?

- 8) Does the company provide financial assistance for the use of the course?
- 9) What is your opinion on the duration of the course?
- 10) How to identify the appropriate time for employees to be sent for courses?
- 11) How are the changes shown by the employees after attending the course?
- 12) What changes are seen in the employees after attending the course?
- 13) Is there a connection between the course and the performance of employees?
- 14) What is your response to the course you have attended?
- 15) Can you share what you want in a course?

D. Respondents

A total of eight SME owners had agreed to be the respondents for this study. All respondents were selected randomly after identifying their business background. The respondents consisted of 2 males (33.3%) and 6 females (66.7%). The age of the respondents selected was between 32 and 57 (Average: 42.625; Standard Deviation: 7.652). The type of businesses of the respondents was based on products (33.33%) and on services (66.67%). All respondents had been in business for 4 to 21 years. 75% of the respondents had been in business from 1 to 10 years, 12.5% from 11 to 20 years, and 12.5% from 21 to 30 years. Table II shows the details of the respondents' background. The eight respondents came from various business backgrounds. Their age ranged from 32 to 57 years, and the year of establishment was from 1999 to 2016. All eight respondents had attended business courses throughout their business.

TABLE II. DETAILS OF EIGHT (8) RESPONDENTS FOR INTERVIEW SESSIONS

R	Gender	Establishment Year	Product / Service	Type of Business
R1	Female	2016	Product	Cosmetic
R2	Female	2013	Service	Tailor
R3	Male	1999	Product	Halal Meats
R4	Female	2016	Product	Bakery
R5	Female	2006	Service	Tailor
R6	Male	2010	Service	Medical Supplies
R7	Female	2014	Product	Printing and Souvenirs
R8	Female	2016	Service	Tailor

E. Procedure

As mentioned before, this study was conducted through interviews. The respondents required to complete this study are the SME owners who have been conducting business activities for more than four years by selling products or offering services. The selection of respondents is random, and business is conducted around Kuala Lumpur and Selangor, Malaysia. Researchers had contacted respondents and set a time to meet. After meeting at the promised place and time, the researcher explained about the study to be conducted and followed by an agreement form to record the interview. Respondents were

asked to sign a consent form for the interview to be recorded and asked to fill in personal and business information in the second part of the form. In the third part of the consent form, the researcher had listed three (3) study objectives and questions used for the study. During the interview, the researcher used the question and occasionally added questions depending on the answers and information shared by the respondents. As a token of appreciation, the researchers presented souvenirs from the Famous Amos shop at the end of the interview session. The same process was repeated until the eighth respondent.

Phase 1: Thematic Analysis:

After the interview session, the researchers collected all the audio data and uploaded the file to a laptop and created a set of storage files for security purposes. All twelve audio data files were then transcribed into words using Excel software. The Excel data was then printed and repeated reading was done to understand the details of the interview.

Based on the set of questions asked during the interview session, the researchers tried to get the starting code based on the answers given by the respondents. Researchers reduced the data to be more focused on important data. After creating almost nine types of code and classifying using pencil colors, the process then moved on to the next transcript.

After identifying the starting code, the researcher performed the third phase which is to find the theme by collecting the codes which then formed the same set of data sets for each transcript.

After finding the theme, the researcher reviewed, modified, and developed the initial theme and reviewed the theme to ensure it coincides with the objectives of this study. The data was then reviewed repeatedly and only data that felt like it was important was stored. The theme should be clear with the objectives of the study and should be found in all twelve of the transcripts.

The researcher then analyzed and determined the theme and found sub-themes where this data interacts and relates between the main themes in the data set. After obtaining the code, themes and sub-themes, the researcher then formed a model framework based on the findings from the study. A report is produced which includes the objectives of the study, literature review, research methods, analysis, results, and a thorough discussion of this study.

Phase 2: Expert Panel for Course Selection Concept Framework

The involvement of a panel of experts is aimed at obtaining their confirmation of the accuracy of the concept framework of suitable course selection for SMEs presented by the researchers. It refers to the basic knowledge that SME owners need to know in managing an organization. All instruments and items identified were brought to a group of experts to check their accuracy according to the purpose of the study. To this end, researchers have met with four experts in the areas of organizational management, marketing and digital marketing, accounting, operations, and Language. In the meeting, the researchers demonstrated the smart entrepreneurship training

framework developed using the TA method. The concept was then accompanied by 55 items based on the theme namely business management, sales and marketing, accounting and finance, information technology and operations and production. The combination of these four experts consisting of academics and business consultants aims to get a more comprehensive view of the SME course selection concept framework. These experts not only look at the theoretical aspects, but also look at the practical aspects that can be applied and will have an impact on SME entrepreneurs in Malaysia. Table III shows the background of the U-PPM system expert panels according to expertise [1].

TABLE III. BACKGROUND OF THE EXPERT PANEL

Panel Experts	Work Experiences
Panel Expert 1 Educational Leadership and Language Expert	1. Associate Professor Universiti Teknologi Malaysia (1989 – Current) 2. Director General Dept. of Community College (2009-2011)
Panel Expert 2 Marketing and Entrepreneur Development Expert	1. Lecturer Politeknik Sultan Abdul Halim Mu'adzam Shah (2017 – current) 2. Lecturer Politeknik Mu'adzam Shah Pahang (2016-2017) 3. Lecturer Politeknik Tuanku Syed Sirajudin Perlis (2010-2013) 4. Lecturer Politeknik Sultan Abdul Halim Mu'adzam Shah (2008-2009)
Panel Expert 3 Business Management, Logistic and Operation Expert	1. Director Technoputra Division Universiti Kuala Lumpur (2019 – Current) 2. General Manager UniKL Resources Sdn.Bhd (2014 – 2018) 3. Senior Lecturer UniKL Malaysian Institute of Industrial Technology (2009 – 2014)
Panel Expert 4 Accounting and Digital Marketing Consultant Expert	1. Founder & Director UpRiser Success Terminal 2. Director of Training Management JNJ Management Consultants

IV. RESULTS

A. Phase 1: Thematic Analysis

As indicated earlier, the TA method was used in this study to identify the list of relevant courses for the SMEs. The results of this method will be used as an input for the development of a smart entrepreneurship training framework for SMEs. This study has found a list of courses attended by entrepreneurs, and it has been divided into five basic divisions in an organization. The divisions are in the areas of business management, sales and marketing, accounting and finance, ICT and technology and production and operations. Table IV is an analysis using the TA Method to identify the theme. It is arranged with the prefix code obtained by the researcher according to the same set of answers given by the respondents.

TABLE IV. THEMES, SUB-THEMES AND CODES FOR THE LIST OF COURSES ATTENDED

Theme	Sub-Theme	Code	Respondents
Management	Management Strategy	Find ways to plan strategies for business fundamental, management and communication	R2, R4, R5, R8
	Leadership Skills	Find the internal skills you need to have as an owner	R7
	Human Resource Management	Courses on managing Human Resource	R1
Sales & Marketing	4P's (Place, Price, Promotion, Product)	Courses on digital marketing, Marketplace	R1, R2, R4, R5, R7, R8
Account & Finance	Cash Flow	Courses on accounts and finance	R1, R2, R4, R7, R8
	Tax	Courses on tax	R3
	Asset Management	Courses on managing company assets	R5
ICT & Technology	Infrastructure	Courses on technical and computer	R2, R6
	Digital Platform	Courses on apps and internet	R2, R7
Production & Operation	Standard Operating Procedure	Courses based on organization's need	R3, R5

Researchers identify that through the code of business planning strategy, business basics, and communication; it coincides with the sub-theme of management strategy and is directly within the business management theme. Four respondents have said that they have attended courses related to this topic to gain knowledge and understanding for the purpose of improving their business. Two of the narratives are as follows:

"Motivation classes, apps and knowledge about accounts been thought in the second week. Other than that, communication course and the techniques depend on each field." - R2.

"When I started my business, I took a basic business course from MARA. Then, I joined Baitulmal Entrepreneur Program, and they gave more entrepreneur courses." - R8.

For the code under internal skills, the sub-themes are leadership skills and management. The narratives from the respondents are as follows:

"Dr Azizan's course - Marketing and internal strength as an owner. He taught us how we have to handle a company, how we want to drive. What is the future holds? Mastering Marketing, Zero Marketing, Account. We went to all courses." - R7.

Still under the theme of Management with the sub-theme of Human Resource Management, the initial code achieved is to find a course on human resources and its narrative, which is as follows:

"I have attended the Hasbul Brothers course for Management. We have to take care of everything including cash flow, handle customer rejection and HR to take care of staff." - R1.

Under the theme of Sales and Marketing, the sub-themes listed include four 'Ps', namely, Place, Price, Promotion, and Product. The pre-code leads to the need of finding the courses related to marketing, digital marketing, and online platforms. Examples of narratives are as follows:

"Entrepreneurship courses, pre-business courses, Marketing courses." - R5.

"We went to Dr. Azizan's courses because it is more to Marketing." - R7.

"It is an online marketing now. Hence, we can't wait for customers at the store. So, we have to do something for example to search for suitable platform to go online." -R8.

For the accounting and finance theme, the first sub-theme is Cash Flow, and the initial code is looking for financial and account management courses. The narratives are as follows:

"Now, after attending the course, we knew that the cash flow has to be recorded and saved. Before this, the money was spent just like that. Hence, we managed to get the Management awareness which is an impact after attending the course." - R8.

"Motivation classes, apps and knowledge about accounts been thought in the second week. - R2.

"I went to Entrepreneurship course, ways to manage a business, managing financial data and our business channel and digital marketing." - R4.

Next, in the theme of accounting and finance, the sub-theme is taxation, where the code is a course on taxation. The narrative is as follows:

"It's all like Tax. You see, I'm good at talking, I can approach, but in terms of management, I am not good at that. The staff who went for the course had to handle everything (tax)." - R3.

Still under the theme of accounting and finance, the important course is to start with the initial code of managing the company's assets and lead to the sub-theme of asset management, the respondents' narrative is as follows:

"There are also financial and asset management courses for companies. That is important." - R5.

Under the theme of ICT and technology, the courses are considered important by the respondents. Under the infrastructure sub-theme, the initial codes are technical, and computer related. The narrative is as follows:

"Sometimes, we have to know the ICT and computers." - R2.

Furthermore, still under the theme of ICT and technology, the initial codes found are of applications and the internet. Both are under the sub-themes of digital platforms. The narrative is as follows:

"I went through a course at Taylor's University to learn about promoting our own products. I learnt to download the apps to beautify those pictures and the importance of WhatsApp Business." - R2.

"Irfan Khairi is more to Technical. He taught on the technical part on how to upload something through the Internet. It was in 2010 and the internet did not go very well back then." - R7.

Under the initial code of requirements of a particular organizational field, it leads to the sub-theme of Standard Operating Procedures (SOP), which is under the theme of production and operation. The respondents' narrative is as follows:

"It is a course for Halal to cut chicken and beef so this course is a must for hygiene." - R3.

"I am in the field of sewing. In 1994, I studied the course for full-time for a year." - R5.

Researchers have developed a smart entrepreneurship training conceptual framework using the results of the study using the TA method. Fig. 1 shows a complete chart on the selection of courses that are important for the needs of SME organizations doing businesses in Malaysia.

B. Phase 2: Findings from Expert Panel's Feedback

Following the development of a smart entrepreneurship training conceptual framework, a website was developed to help SME owners to make the right course selection for their organization. This is important because, there are various selections of courses available in the market; hence the SME owners have to make the right decision in choosing the courses that offer knowledge and experience which will then be beneficial for their business.

Researchers have developed the items based on the result of the analysis and the course selection concept framework development. Next, the development of the items and instruments needs to get an approval from the experts in the various fields. Hence, a group of experts in the related fields have conducted a research and validated the items and instrument used in the system known as the Malaysian SMEs Psychometric Test or U-PPM. This activity is done to examine the accuracy of items and instrument developed by researchers, to determine the courses chosen by SMEs to meet the needs of their organizations. Prior to the development of this U-PPM, a study was conducted based on in-depth interviews with eight SME owners. Researchers have analysed the results of the interviews using TA method and have produced an instrument that has five themes along with fifty-five items.

For that purpose, each expert has been asked to validate each theme and item. After reviewing all the items, the experts are required to fill out a form as an evidence of their agreement and feedback. Feedback obtained from all experts leads to the removal, addition, modification, and positioning of items. The development of this holistic and practical U-PPM system is expected to contribute to the field of theory and practice that benefits SMEs, especially to the training providers in Malaysia. Table V shows the results by the four experts. Items have been reduced to 50 from 55.

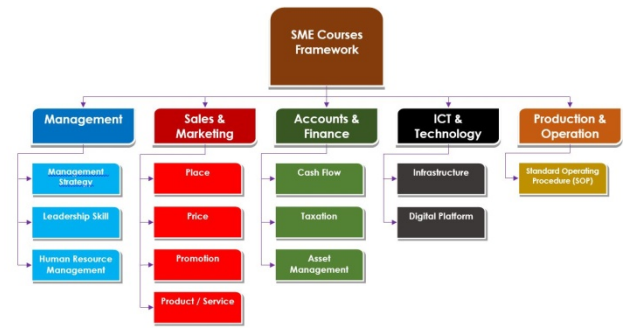

Fig. 1. SME's Smart Entrepreneurship Training Framework Components.

TABLE V. EXPERT PANEL (EP) RESULTS FOR U-PPM ITEMS

No	Details	EP 1	EP 2	EP 3	EP 4	%
1.	The format of the study instrument is appropriate and interesting	Agree	Agree	Agree	Agree	100
2.	The meaning of each item is clear	Agree	Agree	Agree	Agree	100
3.	The language used is easy to understand	Agree	Agree	Agree	Agree	100
4.	The instructions given are clear	Agree	Agree	Agree	Agree	100
5.	The instructions for the measurement scale are clear	Agree	Agree	Agree	Agree	100
6.	The objectives of the instrument stated are clear	Agree	Agree	Agree	Agree	100
7.	The number of items used is appropriate	Dis agree	Agree	Agree	Dis agree	50
8.	The whole idea presented in the instrument is interesting	Agree	Agree	Agree	Agree	100

V. DISCUSSION

Based on the result from the researcher's interview with eight SME owners, there are five main components in the selection of business training courses for SMEs in Malaysia. The main themes are business management, sales and marketing, accounting and finance, ICT and technology, and production and operations. These themes show that most SMEs chose to deepen their knowledge in the related field towards the organization they are leading. Table VI lists the themes and sub-themes derived from the TA method.

As for Business Management theme, the sub-themes resulting from the findings of this study are business management strategies, leadership skills, and human resource management. According to a study conducted by [52], SMEs can upgrade the entrepreneurial skills among them by acquiring lofty knowledge and management capabilities. This includes competency in distributing the tasks in the business, followed by assessing skills, and proficiency in human resource management. This finding is supported by [55] who says that human resource management is one branch of economics that is closely related to the success of an organization and business. For that, SME owners are encouraged to attend management and leadership skills courses

to boost their internal and peripheral capabilities in order to maintain sustainability and success in developing the enterprises [79].

As for the sales and marketing theme, an important sub-theme in marketing development is the application of mixed marketing elements, which are also known as 4P's, namely, place, price, promotion, and product. This mixed marketing framework plays an important role in strengthening the brand of SME products nationwide [66] other than influencing consumer purchasing decisions [64]. SMEs are found to be accomplished in conducting market research and defining the criteria and advantages of the products to customers and are capable in determining the rivalry strengths and weaknesses as well as to boost organisational monthly profits [52]. Apart from that, SMEs should engage in courses that apply knowledge related to ICT in order to enhance the way they do marketing and promotion of the products [84].

On the other hand, for accounting and finance codes in TA, the theme arising was involved with the knowledge of cash flow, taxation, and asset management. A study on financial management practices on MADA entrepreneurs conducted by [81] shows that those with a moderate level of financial experience were unable to manage their own finances without the need of help from others. Scores on financial knowledge, skills, attitudes, and financial planning are in the rank because they followed programs organized by their top management in acquiring the knowledge on financial management. Some of the entrepreneurs did not practice the system in documenting their transactions in the ledger, thus making the course on cash flow and taxation an important element in accounting and financial management [81].) Investigation on KADA entrepreneurs shows that their financial management is at a bearable level [67]. This is because, they have less experience. Therefore, KADA entrepreneurs are encouraged to participate in courses to improve financial knowledge and smoothen their business progress.

TABLE VI. THEMES AND SUB-THEMES FOR TA METHOD

Theme	Sub-theme
Management	Management Strategy
	Leadership Skills
	Human Resource Management
Sales & Marketing	Place
	Price
	Promotion
	Product
Accounts & Finance	Cash Flow
	Taxation
	Asset Management
ICT & Technology	Infrastructure
	Digital Platform
Production and Operation	Standard Operating Procedure

For the ICT and technology theme, the sub-themes are related to the infrastructure provided by SME owners and the importance of digital platforms. ICT has a tremendous economic impact on entrepreneurs if they have benefited to the fullest on the effective use of technology in advancing their businesses. However, their monthly income also affects the status of computer ownership among SMEs [61]. For SME participation in the digital field, a study by [54] said that digital participation is important for the advancement of their business and the source of information related to the latest products in the market. Entrepreneurs no longer need to face customers or have a one-way communication, because they have switched to streamline sales. Therefore, the application of knowledge on ICT needs to be further strengthened to bring these SMEs to a greater height. A study conducted by [60] showed that the factors of digital literacy, customer relationship building, and digital ecosystem building play an important role in influencing the use of digital platforms by SMEs. He added that these findings are a useful guide to stakeholders in designing educational programs related to the use of digital platforms for SME entrepreneurs.

For the production and operational theme, the sub-themes involved are related to the Standard Operating Procedures (SOPs) in an organization. According to [82], informal learning and previous experience have given lots of input to SMEs in managing their businesses. Therefore, SMEs need to acquire knowledge related to the management and products operation and services, because this would provide a positive impact in their business, will help in boosting their income, and hence help them remain competitive.

VI. CONCLUSION

This survey was conducted to develop a comprehensive course selection system for SMEs. The reason being, selecting an appropriate course could influence the performance of the SMEs other than to enhance profits for the organization. The development of this model uses two qualitative methods, which are, Thematic Analysis and Expert Panels. Through this study, the researcher found that there are five important business education courses needed by the organizations. The themes are business management, sales and marketing, accounting and finance, ICT and technology, and production and operations. For the management theme, there are three sub-themes, namely, management strategy, leadership skills, and human resource management. For the sales and marketing theme, sub-themes are mixed with marketing, which follows the 4Ps, namely, place, price, promotion, and product. The three sub-themes for the accounting and finance theme are cash flow, taxation, and asset management. The two sub-themes to the ICT and technology theme are infrastructure and digital platform. Finally, the sub-theme for production and operations is the Standard Operating Procedures in accordance with the needs of the respective organizational area of expertise.

These findings are useful for SME owners and the top management, who would be able to ensure that efforts and actions are taken in order to fully utilize the usage of an ICT in their business operation, and that the sustainability of their

organization would be maintained. As a result of the Thematic Analysis method, researchers have developed a smart entrepreneurship training framework of courses selection system for SMEs that has led to the development of items and instrument for a website known as the Malaysian SMEs Psychometric Test or U-PPM. Four expert panels from the areas of organizational management, marketing and digital marketing, accounting, and operations and language have agreed to carry out their responsibilities to validate the items used in the development of this U-PPM system for the next agenda of the study. It is hoped that with the existence of this U-PPM, SME owners can make the right decision in identifying the needs for acquiring business knowledge in entrepreneurship courses.

A Framework for Protecting Teenagers from Cyber Crimes and Cyberbullying

Sultan Saud Alanazi¹, Adwan Alownie Alanazi²
College of Computer Science and Engineering
University of Ha'il, Ha'il
Saudi Arabia

Abstract—Social applications consist of powerful tools that allow people to connect and interact with each other. However, its negative use cannot be ignored. Cyberbullying is a new and serious Internet problem. Cyberbullying is one of the most common risks for teenagers to go online. More than half of young people report that they do not tell their parents when this will occur, this can have significant physiological consequences. Cyberbullying involves the deliberate use of digital media on the Internet to convey false or embarrassing information about others. Therefore, this article provides a way to detect cyberbullying in social media applications for parents. The purpose of our work is to develop an architectural model for identifying and measuring the state of Cyberbullying faced by children on social media applications. For parents, this will be a good tool for monitoring their children without invading their privacy. Finally, some interesting open-ended questions were raised, suggesting promising ideas for starting new research in this new field.

Keywords—Cyberbullying; cyber bullying; internet crimes; social media security; e-crimes

I. INTRODUCTION

Due to increased use of social media and trending social applications, children are involving in different internet-based activities. The ratio of increase in the use of social media is shown in Fig. 1. On one side it is proving to be an informative and interactive medium for indolence's but on the other side it has a lot of emerging issues as well. One of the biggest concerns is towards the increasing cyberbullying cases day by day. As the technologies are increasing day by day and many of the parents are not well aware about it, more children are curious towards using internet-based facilities which led them to cyberbullying victimization [1][2]. Cyberbullying effects individual's life mentally and physically. Some cases of cyberbullying lead to death as well. So, the motivation of this article is to educate parents to monitor their children online activates, make them aware of such increasing cyberbullying crime and to provide their children an E- safe environment [1].

In recent years, the continuous development of technology has made it possible to keep in touch with friends and family around the world anytime, anywhere, making many conveniences and ease of life. With its increasing use we must focus on its uses to help us in our daily lives. As human is a social animal, we need to build a social network to survive [3][4]. In this modern era, social networking is most important. As a result, social networking sites are now widely used for a variety of purposes, including entertainment and networking. All social media platforms require the consent of

all participants forming a network to communicate [4].

Benefits of this include the ability to acquire, deploy, maintain, and enhance the software used by consumers quickly and effectively. As a result, the number of new applications for platforms such as Mac, Android and iPhone have increased, and this model has been adopted to provide consumers with a variety of modern, low-cost applications. However, this paradigm shift has created a series of new security challenges [6].

As the market for new applications grows rapidly, so do the security threats with this software provisioning model. In the Android market, there are many reports of applications infected with malware and spyware [6].

As the use of cell phones increases, so does the misuse of information. Organized criminal groups may use services such as the WhatsApp mobile messaging application to engage in illegal activity, and the encryption technology used in these applications [7] is helping to cover the traces of this behaviour and make it undetectable to trace [8]. The growth of digital technology is mainly focused on the virtual life of individuals (mainly adolescents (11-19 years)) [9]. Internet users have a great opportunity to exchange ideas, interact and engage with people by developing a virtual community [1][2][10]. Often these interactions lead to passive use rather than active use. Cyberbullying is one of the most dangerous incidents in social media applications like WhatsApp and Facebook, and individuals (especially teens) are victims of cyberbullying [11]. Cyber security is a major concern of all security companies around the globe.

Fig. 1. Number of People using Social Media Platforms, 2004 to 2018 [5].

II. CYBERBULLYING

In recent years, many studies have been proposed to make the Internet a safer place to work. Security threats are on the rise, most notably cyber bullying and online grooming. Cyberbullying is a way to bully someone online. This can be done by maliciously posting or posting bad content online. This situation is disastrous for social media users, especially teenagers [11]. There have been many reported cases of cyberbullying as a cause of adolescent suicide. Online platforms like Facebook and WhatsApp are most commonly used by teens for all types of relationships as shown in Fig. 2. This social networking portal attracts more cybercriminals and engages in more illegal activities. As you know, billions of people around the world use it for many purposes [9][11].

On the other hand, online grooming presents you as dislike and uses victims to achieve their goals, usually through sexual activity [11]. As an open access platform, cyber-groomers also have access to the same internet platforms that are used by young people. Cyber bullying can take many forms, including posting harmful or threatening content on the Internet, spreading rumours, taking, and posting disgusting photos of someone without permission, posting pornographic images and information, and much more as shown in Fig. 3. Many teens suffer from cyber bullying and many of them engage in cyber bullying. More than a third of teens fell victim to cyberbullying, and they didn't even tell their parents about cyberbullying [11][12].

Fig. 2. Use of Social Media by Teens [9].

Fig. 3. Some Form of Cyberbullying [11].

The consequences of cyberbullying include anxiety, depression, and even suicide. Cyberbullying is primarily aimed at young people [11][13]. Cyberbullying begins when the victim begins to react to the harmful messages [13][14]. Internet use has been found to be a reliable predictor of victims experiencing cyberbullying. For men, Internet use is also an indicator of online cyberbullying [13][14].

III. DEADLY CHALLENGES

Now a day's cyberbullying is of great concern especially for teenagers. Parents need to check their children for such incidents which could reportedly took lives. Increasing social media use and growing apps have led to high level of curiosity among teenagers [13]. Due to this, teenagers try different games or interactive applications which led them to cyberbully victimization. One of these applications is the famous Blue Whale game. It is also known as Blue Whale Online Challenge, is a life-threatening online game that is believed to have killed hundreds of teenagers [15][16]. This online game is a great challenge for teenagers on various internet portals. Our dependence on technology is increasing. When curiosity leads teenage boys to online games, it can explain the Cyberbullying victimization very well. The boy faces a challenge online. He called the blue whale and agreed [15]. He gets a job, and he must do it. But is this task really important or problematic? These missions forced him to leak personal information used by criminals and began to threaten. The accident had a psychological impact on the victims, and sometimes even led to suicide. The game administrator has strict control over who can play or download. After research and analysis of the victims, they decide whom to grasp and who can be a very suitable and easy victim [15][16].

Social media cyberbullying can lead to suicides [17]. Another new WhatsApp group, MOMO CHALLENGE, was discovered by the popular YouTuber ReignBot in July 2018, and it has caught the attention of the public. After a few days, someone might accept the Peach Challenge. Momo information has been sent to countries such as Mexico, India, Argentina, the United States, France and Germany. In early August, WhatsApp Momo game reportedly killed two people, Manish Sarki (18) on August 20 and Aditi Goyal (age 26) in Kursong in Darjeeling the next day [18]. Police suspect they may have taken action because they are playing this suicide game.

After messaging a man named Momo on WhatsApp, a 12-year-old girl was found dead in a backyard near Buenos Aires, Argentina. "After searching for videos and chats on WhatsApp via a phone hack, they are now looking for a teenager who allegedly exchanged these messages with," police told the news portal [19]. Police believe the teenager's intention was to "upload the video to social media as part of a challenge, crediting the Momo game" for the suicide [19]. One of the challenges in this game is that people have to communicate with unknown numbers.

IV. MONITORING THE CHILD

With the growing technology parents are falling behind to cope up and understand the security threats of using internet. This is due to a lack of time and inadequate knowledge of

computers usage, social networking and rapid growing mobile apps they are unable to inspect what their children are doing when they are using internet. Parents are unaware or do not fully understand the evolution of bullying. Thus, it is necessary for parents of modern era to monitor their child.

Parents cannot control all of their children's behaviours, but there are steps they can take to prevent cyberbullying and protect their children from harm [20]:

- Track and monitor teenagers' social media, apps, and browsing history. Cyberbullying is usually occurring when parents notice negative changes in adolescent behaviour.
- View or reset the privacy settings and phone location (GPS) of your child.
- Follow your child on social media, and try to be in his friends list, or ask a trusted adult to do the same.
- Parents should pay attention and to be aware of the latest applications, social media platforms and digital languages used by teenagers.
- Know your child's social media email address, username, and password.
- Establish rules for good behaviour, digital content and applications.
- Limit internet use accordingly.

Following (Fig. 4) is a depiction of different stages to cyberbullying victimization.

Parents can use different available parental control tools and techniques that can help to build a non-invasive approach towards their teenage children and thus prevents them from cyberbullying, malicious behaviour on the internet, and inappropriate content. Free monitoring software and apps are available that can be used to help parents restrict inappropriate and unwanted content, block specific domains, and view children's online activities (including social media activities) without having to physically check their children's devices daily. In fact, it is also less invasive and sometimes invisible to children [21][22][23].

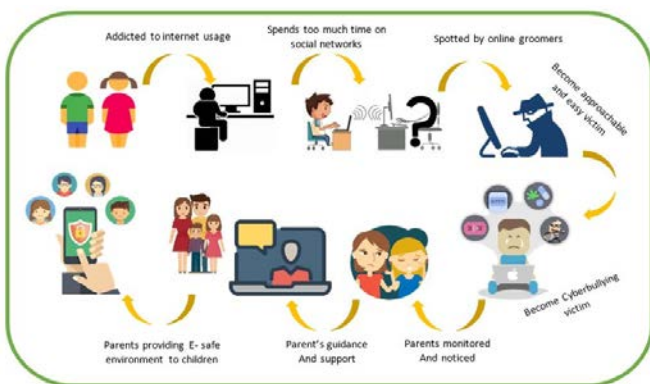

Fig. 4. Stages to Cyberbullying Victimization [13].

When choosing the right internet application for a child, parents should consider their children's ages, device usage, and digital network behaviour, which may help. Parents should build trust relationships with their children by engaging in open and honest discussions. These conversations provide an opportunity to exchange values and expectations regarding digital family-friendly behaviours, such as viewing and sharing content, and available and unavailable applications. Ask your child about their online experiences to avoid potential risks of cyberbullying and abuse. Make it clear to them that your goal is to protect them and that you want to have an open conversation with them. Discuss their concerns, opinions and also manifest your opinion [21][22][23].

V. CYBERBULLYING DETECTION FRAMEWORK

In this section, the proposed cyberbullying detection architecture is presented. The proposed architecture includes five different modules, which not only detects the bullying content on the social application but also helps in the detection of mobile security level used by the child. As the use of mobile phones is growing tremendously, various mobile phone applications are also emerging. Different Social media applications are emerging through which youth can communicate in many different ways. Popular example of these type of social applications includes, WhatsApp, Facebook, Line and many more. The proposed architecture will help parents to monitor the child and detect the bullying content before time. This helps to save child from becoming victims to such crimes online. The details of the architecture are shown in Fig. 5 and also discuss in the following sections.

A. Registration Module

This module is used to ask the user (parent) to enter the Application login information of his or her minor. This login information is used to retrieve the relevant data from the desired logged-in App. It also provides information of the application used by his or her minor.

Fig. 5. Cyberbullying Detection Framework.

B. Data Collection Module

The Data Collection Module is the component that collects all the relevant information from the logged-in application for example:

- Contacts.
- Chat history.
- Backup of chat database.
- Avatars of contact.
- Received files.
- Sent files.
- Locations.

C. Data Bank

Stores all the relevant information regarding the particular topic and area of cyberbullying that is used by the application and helps to detect the bullying rank status further. It works as a repository of persistence information, keywords, chats, history, and any other relevant information based on the user requirements that can be used for reference for detection module.

D. Cyberbullying Detection Module

The Cyberbullying Detection Module uses the retrieved data to determine if a child or teenager is being bullied online. The main result of this component is the Bullying Rank (BR) calculated according to the state of art and specific vulnerability. Since we are focusing on Android apps, the following security settings will be checked accordingly.

E. Application Platform Level Security Check

A mobile application platform is a set of software tools used in the development, creation and maintenance of mobile applications. In part, it is an enterprise mobile application platform that provides organizations with mobile application tools. It is also vulnerable to many security threats. The continued emergence of mobile malware not only provides knowledge and copyright for developers, but also leads to information leakage and even financial loss. The security requirements of mobile applications have become a serious issue in the development of the entire application market. A tabularized Platform Level Security Comparison is shown in the Table I below.

TABLE I. PLATFORM LEVEL SECURITY COMPARISON

Feature	Android	iOS
App Download	Crowdsourcing	iOS App store only
Signing Technology	Self-Signing	Code signing
Inter-process Communication	Yes	No
Open/ Close Source	Open source	Close
Memory Randomization	Yes	Yes
Storage	Internal & External	Internal only
Shared User ID	Yes	No

F. Application-Level Security Check

Application-level security refers to the security services that are invoked on the interface between the application and the queue manager connected to it. A tabularized Comparison is shown in Table II.

TABLE II. APPLICATION-LEVEL SECURITY CHECK

Feature	Found (✓)/ Not Found (x)
Shared User ID	✓
No. of permissions	✓
Application Verification	✓
Encrypted Messages	✓
Decrypted Messages	✓
Contacts	✓
Media	✓
Location	✓

G. Text Mining Check

Here, we're going to use two sets of data. It uses the Bad Words Dataset and Sensitive Word Dataset to categorize the user's message and record the bad history in the database. If a user exceeds the limit for inappropriate posts or adult photos, they will be automatically blocked. Some abusive words are given in the Table III.

TABLE III. ABUSIVE WORDS

ABUSIVE WORDS
BAD WORDS (Retarded, Dumb)
SWEAR WORDS (Bit**)
SECOND PERSON (You, Yours)

H. Merge Monitoring Software

Implementing monitoring software will help to understand the big picture. There are different types of monitoring software available (paid or free), including Spyzie and net nanny. Spyzie is a professional monitoring solutions provider that provides tracking and surveillance tools for smartphone users [24]. It is used to protect children from online threats and to ensure that they are always in a safe place. Parents will be able to track and store call logs, messages, social activities, etc.

I. Cyberbullying Rank Module

Rank the cyberbullying according to the following scale:

No.	RANK	RANGE
1	Low	0-3
2	Medium	4-6
3	High	7-10

The ranking will be based on the severity of the words which affects the mentality and behaviour of the teenagers and attract other teenagers and public opinion of the circle. Keywords will low affect will have less effect and thus will be

ranked low accordingly. For example, sexting and related keywords will be considered as high severity, posting embarrassing photos, stealing identity of a person will be considered high ranking but keywords related to beauty, body, may be considered as low rank or medium rank.

VI. ADVICE FOR PARENTS

To reduce the harms of cyberbullying and online behaviour, parents can:

- Set clear expectations about their child online reputation and behaviour.
- Make their children aware about the negative consequences of cyberbullying, make annoying and inappropriate comments and messages, share nude photos of you and other people, sexting etc. and the legal issues associated with all this.
- Be clear and strict about what can be viewed and what can be shared.
- Determine which apps are right and allowed to use for your child and which are not.
- Set rules for how your child spends time online or on the device.
- Simulate positive and respectful online behaviour to him through your devices and online and social media accounts.
- Talk to your child about the bad effects of being a bystander of cyberbullying.

Talking to your children about cyberbullying and digital behaviour is not a one-off activity, but a continuous conversation. Before your child switches to text messaging, social media, online games, and chatting, discuss these topics with them. It can help them better understand the reality and potential bad effects of cyberbullying and provide them with ongoing opportunities to practice the coping skills. In this way, you can support the transition from a bystander to ally. SAMHSA provides a free 'Learn about Bullying' app for parents, teachers and educators with dialogue options, tips and other tools to help prevent bullying [25].

If you think your child has witnessed cyberbullying, you can encourage them to do something they should and shouldn't. For example, encourage children to dislike or not like, share, or comment on someone's racial, or hurtful text or posted information, or send hurtful text to others. Without sharing and participating on the malicious or cyberbullying content, you can limit the harm the message can do to others or to yourself.

When the children feel they should react, encourage them to respond calmly, clearly, and constructively. Anger and violent reactions to a situation can make the situation worse. Encourage children (and adults!) To stay away from the device and not accuse, insult, or retaliate against others. It helps you stay calm and focused and shows that the digital behaviour of others is harmful and unacceptable.

Please reply directly to the person who sent the offending message or comment. If you feel safe, you can contact each other online, by phone, or directly with people creating or transmitting malicious messages. This way you can clearly show that they can't stand the negative behaviour. This is also an opportunity to honestly share concerns about the behaviour and its causes.

VII. CONCLUSION

This section concludes this article by identifying a complex set of open-ended research questions and compelling solutions. Cyber bullying is an emerging concern with growing technology. Main victims of cyberbullying are teenagers who are bullied online. Teenagers are emotionally weak and fall an easy prey. In this era to provide an e safe environment to children we proposed an architecture to detect cyberbully, rank it and provide information to the concerned parent.

In future, we will develop a prototype of this framework for general purpose use for both Android and iOS.

VIII. NOTES ON CONTRIBUTORS

Sultan Saud Alanazi completed his bachelor's in Information Technology from Deakin University in 2019. He is currently working for Al-Shamli General Hospital, Saudi Arabia as an IT admin. He is also doing his Master's in Cybersecurity at University of Ha'il. His area of interests includes Application security and Network security.

Dr. Adwan Alownie Alanazi received the PhD degree in Computer Science and engineering from the University of Bridgeport, USA. He is currently holding an assistant professor position with the University of Hail, Saudi Arabia. His research interests include Internet of things (IoT) and security in wireless Sensor networks.

Anonymity Feature in Android Mobile Apps for Interest Groups

Lee Sin Yi¹, Nurul A. Emran², Norharyati Harum³

Fakulti Teknologi Maklumat dan Komunikasi,
Universiti Teknikal Malaysia Melaka,
Malaysia

Abstract—Mobile apps that provide platforms for interest-oriented communities (or interest groups) allow people with common interests to gather virtually in sharing their shared passion and ideas. While the participation of such apps is voluntary, some people feel uncomfortable revealing their real identities due to privacy and safety concerns. Thus, some mobile apps provide an anonymity feature that allows people to join the group anonymously. Nevertheless, little is known on how the anonymity feature relates to the people who prefer to join interest groups. Thus in this paper, we hypothesize that mobile apps users that highly value interest groups will also highly appreciate the anonymity feature provided in the interest groups. In particular, we explored the market segment of mobile Android apps with anonymity features within selected interest groups. A pilot study was conducted where 34 Android apps users, primarily Malaysian, filled up the questionnaires designed to investigate the anonymity feature in the apps. The results of the pilot study show that most Android apps nowadays offer their users to remain anonymous. The findings show that most users who give a high score on the importance of interest-based groups also provide a high score on the importance of the anonymity feature offered by the mobile apps providers.

Keywords—Anonymity feature; mobile social apps; quantitative observation; android apps; anonymous social media; interest groups component

I. INTRODUCTION

Online communities are often connected to common interest communities voluntarily. The advantage of online communities is that there will be no face-to-face or physical access requirements. With the interest-based groups that can be accessed through mobile apps, more people can easily find new friends with similar interests. The so-called social apps are not limited to the young generation and have become more popular among the elders [1]. For example, people who are fond of hiking can find other people with similar interests in the hiking-interest community from mobile apps.

Furthermore, with the proliferation of interest-oriented mobile apps such as Meetup, Smactive, WeGoDo, the mobile apps users community can connect with people with a similar passion more than ever before [2]. Major social media apps platforms like Facebook, Whatsapp, and Telegram also provide accessible platforms for interest group creations. Martin, in 2019 reported that marketers could use interest-based groups in Facebook to boost their product sales against the targeted audience [3], which is an indication of the potential of interest-based groups from a marketing perspective.

Facebook keeps profiles of its users' interests based on users' behavior, such as the pages a user likes, the previous ads they clicked, the websites and posts they engaged. For example, we can see various interest-based categories and subcategories if we utilize Facebook's ads manager platform. An 'interest' category like Hobbies and activities has several subcategories such as Arts and music, Home and garden (Furniture, Gardening, Do it yourself (DIY)).

Within the interest groups, the members usually seek to exchange information or ideas on specific topics or get solutions for their problems. Participation in an interest group can be entertaining, compelling and people often return and stay active for an extended period. Most of the time, these people cannot be defined by a specific geographical area. Without knowing each other's real identity, everyone will have equal rights and freedom to express their minds. Self-disclosure can help in releasing stress and pressure, satisfying needs, and adapting communications behaviors [4].

As the identity of the members is usually being disclosed, there is a rising concern about the privacy and confidentiality of the members. Thus, the anonymity topic has become a focus in many application domains [3]–[8], and a new type of social media apps called anonymous social media has emerged [9]. Anonymous apps (such as Secret and Yik Yak) gain popularity because many people want to express themselves freely [10]. Such apps also become a 'tree hole' (confidant) where people can share their problems anonymously. The actual name and information of the app users will not be made compulsory during the registration process. In this way, people will share the problems that they do not want their family and close friends to know. Help or guidance from the other members can be received without the pressure of being judged by the people who do not know them personally. People with low self-esteem especially suffer the most when it comes to identity disclosure [11]. Besides, in research conducted by Ma, Hancock, and M. Naaman (2016), they found that people tend to minimize self-disclose as content intimacy increases [4].

In online platforms, people usually tend to express themselves more openly. They can share the things that they will not share in the face-to-face world as they feel more uninhibited in cyberspace. From the psychological perspective, this is being called the disinhibition effect by the researchers [12]. People tend to align their virtual identity with their self-guide when reconstructing a new identity in an anonymous application. The self-discrepancy between their self-guided and

This work is sponsored by the Universiti Teknikal Malaysia Melaka under research grant PJP/2020/FTMK/PP/S01771

virtual identity will be lesser as they will show more true selves with the latest online identity [12].

They may be more satisfied and motivated to show their true self freely without much constraint in an anonymous community online. According to Suler (2004), when people tend to show more generosity and kindness without their real identity being known by people, this is called benign disinhibition. However, there may be toxic disinhibition in the form of rude language or harsh criticisms [13], which lead to cyberbully. Denzil et al. (2015) divide anonymity based on the sensitivity level of the social media contents where anonymity is beyond the binary concepts of anonymous or non-anonymous types [9].

As there is a call for mobile apps that subscribe for anonymity feature, in this paper, we are motivated to answer the following research questions:

a) What is the proportion of the market segment for mobile apps with anonymity features in interest groups understudy?

b) How perception of the importance of interest group relates to the perception of the anonymity feature?

In the next section, related work on the anonymity feature will be presented. Section III consists of the methods used to answer the research questions; Section IV covers the findings and discussion. Finally, Section V concludes the research.

II. RELATED WORK

There is a 13.4% increase in the number of social app downloads from the Google Play Store from the year 2019 to 2020, which makes 1.18 billion downloads in 2020 [14]. On average, people spent 131 minutes every week on the Social app, which is the most extended amount of time spent within the mobile apps category. Gaming, Communication, and Music are also among the top apps category in time spent statistics. Facebook is the most popular social media platform worldwide, with 2.6 billion users, as of July 2020, followed by YouTube and Whatsapp [14].

A survey conducted from September 2016 to January 2021 revealed that 86 percent of Malaysians were actively engaged with social media. Facebook was the most popular social media platform of choice among Malaysian, followed by Instagram, Facebook Messenger, and LinkedIn [15].

The popularity of Facebook might be driven by its flexibility in creating and joining interest-based groups. In Facebook, a Facebook Group feature allows the creation of interest-based groups for its members to communicate, express their minds, and share their mutual interests or passion [16][17]. Facebook allows Facebook users to join up to 6000 groups at the same time. One requirement set by Facebook is the real-name policy, where Facebook users must use their real name to register a Facebook account and configure the user's profile. This is a compulsory requirement for all Facebook users. Through this method, the real-name policy will ensure the safety of the group members as one will know about the identity of the persons they are connecting with.

A "real name" refers to the actual name in this policy as it would be shown on the identity card, student ID, driving license, or credit card of Facebook users. This naming policy of Facebook has prohibited names that are prone to judgemental elements, such as names that contain too many words, excessive capital letters, or first names that have initials. The Facebook accounts that have such names will be detected and thus suspended by the monitor software of Facebook [18]. However, the real-name policy maintained by Facebook has raised safety concerns on the privacy and data protection of Facebook users. This situation is due to the reason that one's real name often reflects some identities and cultures. The real name of some people may also contain many potentially sensitive details that might be obtained by people with bad intentions while browsing their Facebook profiles [19]. With the rising privacy demands in the surveillance society, some Facebook users started to protest against this real-name policy which causes Facebook to relax the real names requirement to "provide the name they use in real life" [20]. Despite the real name issue, some argue that real name is crucial to establish the trustworthiness of the apps [21].

Nevertheless, as privacy and safety issues have received more weight in interest-based groups, the anonymity feature becomes more attractive than trustworthiness. Socializing within the interest-based groups that do not require their members to provide their real identities is a desired characteristic of a social app for some people. Besides, due to the disinhibition effect of being anonymous, people tend to loosen up and share personal things about themselves. They may reveal their wishes, fears, or secret emotions when they can separate what they express from their real identity and their natural world. Anonymity gives them more courage to say and speak more openly. Everyone has an equal opportunity to express their mind regardless of their race, gender, or status in the real world [22]. Privacy and secrecy issues also have been highlighted in mobile apps/systems in education and business domains [23], [24]. In 2017 a survey on awareness of privacy has been conducted among Android users, which revealed that the level of understanding is still low [25] even though there is a raising need for privacy.

Caution must be taken as the true negative self that is usually hidden in the physical world may no longer be hidden in anonymous social media platforms [12]. Should there be any user with negative minds and intentions, they can quickly spread inappropriate or unhealthy information. Thus, a feedback or reporting feature should be added to this apps to lodge a report about any inappropriate behavior of its members. As little is known on the need of reporting feature and on how perception of the importance of interest group relates to the perception of the anonymity feature these are the research gaps addressed by this paper.

III. METHODOLOGY

This section will describe how we answer the research questions as stated earlier in Section I. An explanatory approach has been adopted for market segment analysis to observe the anonymity feature in Android apps worldwide. In particular, we adopted the quantitative observation method

which is usually adopted in studying market segments for marketing purposes such as in [26], [27].

A quantitative approach has been adopted in a pilot study to determine the relationship between the interest-based and anonymity features, especially among Malaysian users. Descriptive statistical analysis is adopted to analyze the result of questionnaire responses. IBM SPSS software, version 2, was used to perform the statistical analysis and for data screening (error and missing values checking). A pilot study is a part of our full-scale project that aims to determine the potential of anonymity features in mobile apps development for Malaysian interest-based groups.

A. Research on Market Segment

To answer the first research question, we use Google Play Store to find inter-est-based group apps on the Android platform. As we set English as the apps' language, apps in other languages such as Chinese, Japanese, and Korean are excluded. The apps with invitation links and software bugs are also excluded from this study as they cannot be accessed quickly during the research phase.

After filtering all of the apps, we further analyze them by conducting a member registration process. Unlike the mobile apps reported in [28], not all app providers reveal the anonymity feature in their apps. Thus, registration of a new member account is performed. This process is crucial to check the anonymity features within the apps by experiencing an actual registration process. In this study, we perform binary classification. Apps requiring a real name or actual information (such as the mobile phone number) are classified as apps without anonymity. In contrast, apps allow the member to be anonymous as apps with anonymity.

We also observed the criteria of whether the app offers a single-interest group or multiple-interest groups. Apps that serve one main topic but with multiple groups are classified as multiple-interest groups. For example, an app focuses on drawing art as the main topic with multiple groups such as the water-color community, oil painting community, and sketch community. A market segment analysis of this quantitative observation study will be reported in Section IV.

B. Questionnaire Development

A questionnaire has been designed based on samples of best practices of online questionnaires related to mobile apps usability and UX [29]–[31]. The questionnaire is divided into three categories: demographic, mobile user experience, and preference. The demographic category consists of three items, namely gender, age, and nationality; mobile usage experience has four items where respondents will tell whether they have experience with interest group apps and the anonymity feature. The preference category consists of nine items. The first two categories consist of close-ended questions, while the third category has five closed-ended questions (Yes/No and five-scale Likert-chart questions) and four open-ended questions. The questionnaire is developed using an online Google form, as shown in Fig. 1.

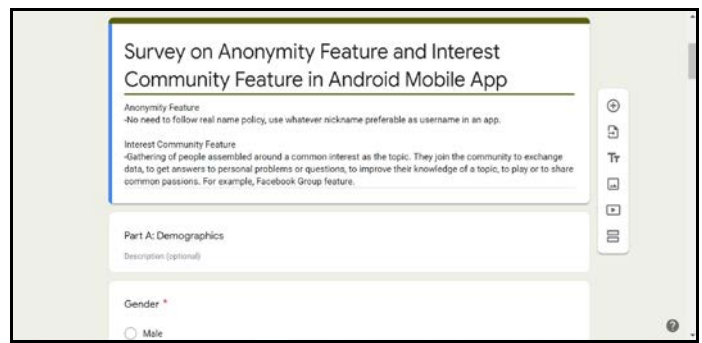

Fig. 1. The Online Questionnaire.

We utilize Facebook's interest-based group to distribute the questionnaire as it is the most popular social media platform to date. In particular, we use a public Facebook group called "Thesis / Survey Questionnaire Filling Group" with 14.0K members and a private group called "Student Survey Exchange" with 13.8K members. Both groups facilitate their member worldwide in getting the respondents for research surveys that are based on mutual collaboration and voluntary basis. The members mainly gather in this group to collect responses for their surveys. To exchange for the responses from other members, they are required to help other group members to fill up their questionnaires or do their surveys. A call for the survey is made in the group posting, as shown in Fig. 2. Even though the focus of the pilot study is Malaysian users, we also record responses from other countries that took part in the survey. We set to observe if non-Malaysians show common or different characteristics from Malaysians. In this pilot study, we allow the respondents to answer the questionnaire within seven days before collecting the results.

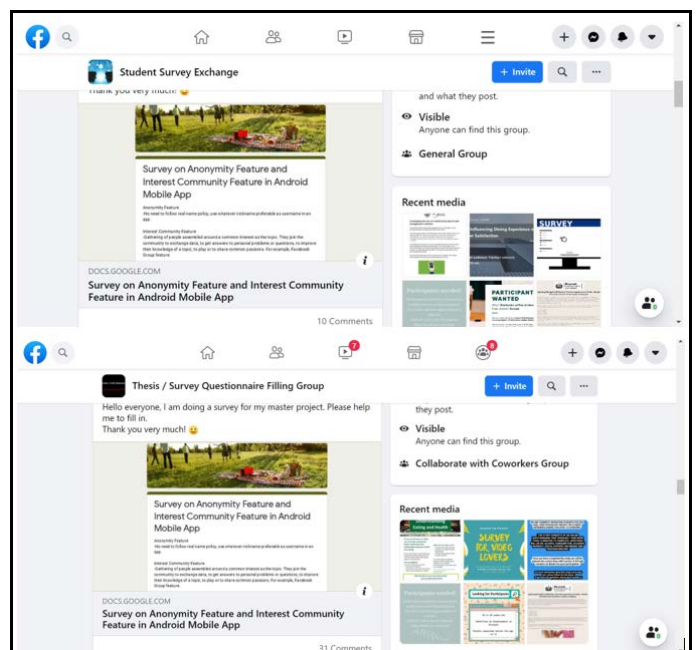

Fig. 2. Posting on the Call for the Survey.

IV. RESULTS AND DISCUSSION

A. Market Segment Analysis

In this section, the results of market segment analysis using descriptive statistics will be presented. A set of interest-based Android apps (n=65) have been selected from the Google Play Store, as shown in the Appendix. These apps belong to interest group categories such as social, gaming, communication, and art.

The top pie chart in Fig. 3(a) shows that apps that offer anonymous features dominate the Android apps market segment by 69%. In contrast, Fig. 3(b) shows that most of the apps under study offers multiple interest groups, with 68% of the market segment.

To analyze further, we seek to examine the number of apps with (and without) anonymity features by interest group types. As shown in Fig. 4, it has been found that the apps with the anonymity feature offer more multiple interest group creation than the apps without the feature, with 43%. Only 23 % of the apps without anonymity feature offer multiple interest group creation.

Based on the results presented so far, we can see that most Android apps provider are ready to give options for their users to be anonymous or not. As a result, these kinds of apps dominate the Android apps market segment. The results also indicate the popularity of multiple interest group creation within a single app regardless of whether it comes along the anonymity feature or not.

Fig. 3. (a)The Proportion of Android Apps based on Anonymity, (b) the Proportion of Android Apps based on the Type of Interest Group.

Fig. 4. The Proportion of the Interest Group Type by the Anonymity Type.

B. Close-Ended Question Responses Analysis

Data collection was facilitated via Facebook interest groups, as mentioned earlier in Section 3.0, where 34 responses (n=34) were received from Android app users. Table I shows the demographic information of the participants.

Table II consists of the results retrieved from the Experience category items that cover questions regarding the experience of users with interest groups and anonymity features. The results show that, in terms of age group, those within 18-24 years old are more familiar with interest groups app and apps with anonymity features as compared to those from 25-34 age category. We can say that respondents who use these apps are among the early adults based on their age range. It is also found that female dominates both, apps with interest groups and with anonymity features. 44% of Malaysian have experience with group interest apps, and 41.2 % of them also used apps with anonymity features before. If we accumulate the scores for non-Malaysian, we can also see most of the respondents already exposed to the group interest apps and apps with anonymity features.

TABLE I. DEMOGRAPHIC INFORMATION OF THE PARTICIPANTS

Characteristic	Value
Age (years), n (%)	
18-24	19 (55.9)
25-34	15 (44.1)
Gender, n (%)	
Female	21 (61.8)
Male	13 (38.2)
Country, n (%)	
Austria	1 (2.9)
British	2 (5.9)
Brunei	1 (2.9)
Egyptian	1 (2.9)
Indian	3 (8.8)
Kenyan	1 (2.9)
Malaysian	16 (47.1)
Maltese	1 (2.9)
Pakistani	5 (14.7)
Singaporean	2 (5.9)
Swiss	1 (2.9)

TABLE II. THE RESULTS OF CLOSED-ENDED ITEMS IN THE EXPERIENCE CATEGORY

Characteristic	Have you used apps with interest groups before? (%)		Have you used apps with anonymity features before? (%)	
	Yes	No	Yes	No
Age (years)				
18–24	44.1	11.8	47.1	8.8
25–34	41.2	2.9	41.2	2.9
Gender				
Female	50.0	11.8	52.9	8.8
Male	35.3	2.9	35.3	2.9
Country				
Austria	2.9	0.0	2.9	0.0
British	5.9	0.0	2.9	2.9
Brunei	2.9	0.0	2.9	0.0
Egyptian	2.9	0.0	2.9	0.0
Indian	5.9	2.9	8.8	0.0
Kenyan	2.9	0.0	2.9	0.0
Malaysian	44.1	2.9	41.2	5.9
Maltese	0.0	2.9	0.0	2.9
Pakistani	11.8	2.9	14.7	0.0
Singaporean	2.9	2.9	5.9	0.0
Swiss	2.9	0.0	2.9	0.0

Table III consists of the results retrieved from the closed-ended question items in the Preference category. In this category, respondents state their preference regarding apps with an interest group and anonymity feature and the type of interest group. The results show that most respondents prefer apps with interest groups and anonymity features, in which female users and those from 18-24 years old dominate the score. Respondents from the same categories also show the highest preference on multiple interest groups than the single-interest group. The findings also reveal that most Malaysian prefer apps with interest groups and anonymity features. The same behavior also can be seen among non-Malaysian. Nevertheless, in terms of groups, Malaysians equally prefer the single and multiple interest groups, while non-Malaysians show more interest in the multiple groups' apps.

To examine the relationship between one's perception of the importance of apps with interest groups and anonymity features, we extract the responses from the five-scale Likert-chart questions in the Preference category. The questions require the respondents to rate the importance of apps with interest groups and anonymity features from 1 (the least important) to 5 (the most important).

Fig. 5 illustrates the Scatterplot graph that shows the distribution of users based on the rating on the importance of interest groups and anonymity features. If we divide the chart equally into four quadrants, we can see that most users are grouped at the top right quadrant, where a high rating was given to the importance of both interest and anonymity features. However, four respondents who value the importance of interest groups do not have the same opinion on the

importance of the anonymity feature (11.76%). Only one respondent who gives a high rating on the anonymity feature gives a low rating on the importance of the interest group. As the left bottom quadrant is empty, we can say none of the respondents think less about the importance of the interest group and the anonymity features.

TABLE III. THE RESULTS OF CLOSED-ENDED ITEMS IN THE PREFERENCE CATEGORY

Characteristic	Do you prefer apps with an interest group?		Do you prefer apps with an anonymity feature?		Type of preferred interest group apps	
	Yes	No	Yes	No	Single	Multiple
Age (years)						
18–24	50.0	5.9	44.1	17.6	14.7	41.2
25–34	41.2	2.9	38.2	0.0	20.6	23.5
Gender						
Female	55.9	5.9	50.0	11.8	14.7	47.1
Male	35.3	2.9	32.4	0.0	20.6	17.6
Country						
Austria	0.0	2.9	0.0	2.9	0.0	2.9
British	5.9	0.0	2.9	2.9	2.9	2.9
Brunei	2.9	0.0	2.9	0.0	0.0	2.9
Egyptian	2.9	0.0	0.0	2.9	0.0	2.9
Indian	8.8	0.0	8.8	0.0	0.0	8.8
Kenyan	2.9	0.0	2.9	0.0	0.0	2.9
Malaysian	44.1	2.9	44.1	2.9	23.5	23.5
Maltese	0.0	2.9	2.9	0.0	2.9	0.0

Swiss	2.9	0.0	2.9	0.0	0.0	2.9

Fig. 5. The Distribution of Users on the Rating on the Importance of Interest Groups and Anonymity Features.

C. Open-Ended Question Responses Analysis

The responses to the open-ended questions from the Preference category allow the participant to express their opinion regarding the rating they give on the importance of interest group and anonymity feature and the type of interest group they prefer. According to some of the responses collected, most participants think that the interest group is important because this feature increases the possibility of meeting people with similar interests and helps introverts discover people with the same interest. Some think that it is nice to post or communicate with others with similar topics and interests and get valuable and specific topic information. Some of the respondents who prefer the multiple-interest group over the single-interest group mentioned that the multiple-interest group allows more options, more choices, and more possibilities to find groups that match their interests. They think that the group will enable people to exchange ideas and thoughts about the shared passion and receive more information. One of the respondents mentioned that the group helps make the mobile phone more organized as the number of applications installed can be minimized.

However, some respondents prefer the single-interest group over the multiple-interest type. A female respondent mentioned that "I don't like to mix up all the interest community in a single app. I tend to categorize the social apps so that I can know that these certain apps are aimed for which community". A respondent who does not favor the interest groups mentioned that "I have less willingness to come together to address issues and have no commitment to deliver ideas."

Those who favor the anonymity feature stated that they think the feature helps in privacy and security aspects and makes them feel safer. They mentioned that the anonymity feature is essential as it can improve internal communications. The feature also enables people to communicate with strangers anonymously through their smartphones when they are unwilling to disclose their real names to the public or people not so close to them. They also suggested that users be given more options to hide their identity and that there should be more options to be anonymous on different applications. A female respondent says that "The interest groups feature in mobile apps allow users to be anonymous for more honesty, openness, and diversity of opinion, meanwhile encourage expressiveness and interaction among users."

Some respondents also suggested that a real name is required for identity verification but only shows the username in the application. A male respondent who likes the anonymity feature mentioned that "Even though anonymity feature is preferable, the authority should have some form of access to a small portion of users' data like age and name to avoid any illegal behavior and the application users have to know about it."

The results yielded from the questionnaires in the pilot study imply the on-demand characteristics of the mobile apps market, especially for Android users. The market segment analysis shows the readiness of the apps providers in terms of providing interest groups (single/multi groups) with anonymity features. As for Malaysian users, the anonymity feature is highly desirable for interest group apps, but there is no

difference in their preference in the type of interest group. Nevertheless, as Malaysia is a multi-racial country, we discovered that a better understanding of the categories of the interest-based apps with anonymity features favored by Malaysians (races/ethnicity) could be gained if the questionnaires include questions regarding this topic. A similar improvement can also be made on the market segment analysis of the mobile apps.

V. CONCLUSIONS

In conclusion, we have approached anonymity features in mobile apps interest groups using an explanatory, quantitative approach in a pilot study. Within the scope of the research presented in this paper, the results support our hypothesis that mobile apps users' who highly value interest groups will also highly appreciate the anonymity feature provided in the interest groups. The study has allowed us to provide three implications for mobile apps design: including the anonymity feature and interest groups, considering the multi-interest groups in a single app, and the need to embed fair security aspects when the anonymity feature is activated. Even though they are preliminary, the results of this pilot study are adequate for us to proceed with wider audiences (i.e., more age groups, nationality). They need to be validated using representative research or similar case studies in different contexts. Also, the scope of this research is limited to the Android platform. Thus, the results of the study cannot be used to represent other platforms. However, the results could open new research ideas and the design of focused mobile apps. Research that looks at the security feature of mobile apps with anonymity will contribute to a broader understanding of the subject. Such a study could consider such questions as "How can we embed the acceptable security aspect of mobile apps that allow anonymous users?"

ACKNOWLEDGMENT

We would like to thank the *Fakulti Teknologi Maklumat Dan Komunikasi, Universiti Teknikal Malaysia Melaka (UTeM)* for supporting this research. This work is under research grant *PJP/2020/FTMK/PP/S01771*.

A Method to Prevent SQL Injection Attack using an Improved Parameterized Stored Procedure

Kamsuriah Ahmad¹, Mayshara Karim²

Center for Software Technology and Management
Faculty of Information Science and Technology
Universiti Kebangsaan Malaysia, 43600, Bangi, Selangor, Malaysia

Abstract—Structured Query Language (SQL) injection is one of the critical threats to database security. The effects of SQL injection attacks cause the data contained in the database to be at risk of being exploited by irresponsible parties, compromising data integrity, disrupting server operations and in return affecting the organization's image. Although SQL injection is an attack performed at the application level, SQL injection prevention requires security controls at all levels, namely application level, database level and network level. The absence of SQL injection prevention measures at the application level makes the database vulnerable to attack. Reviews indicate that the current approaches still not sufficient in addressing these three issues, which are i) improper use of dynamic SQL, ii) lack of input validation process and iii) inconsistent error handling. Currently, program and database code security is based solely on basic security measures that are focused at the network level such as network firewalls, database access control and web server request filtering. Unfortunately, these measures are still inadequate and not sufficient to safe guard the program code and databases from the attack. To overcome this shortcoming as addressed by these three issues, a new comprehensive method is proposed using an improved parameterized stored procedure to enhance database security. Experimental results prove that the proposed method is able to prevent SQL injection from occurring and able to shorten the processing time when compared with existing methods, hence able to improve database security.

Keywords—SQL injection prevention; database security; parameterized stored procedure; network firewall

I. INTRODUCTION

The sophistication of information technology makes life easier but at the same time poses a threat if the security aspect is not given special attention [1]. The internet that connects people around the world carries the threat of hackers. SQL injection is used as a method to steal and exploit information on the database [2]. SQL injection can affect organizational data security, and now they start to realize the importance of preventing this attack before it happens [3]. The prevention from this injection has become the focus of database administrators, network administrators, application code programmers, database system providers, software developers and the top management of the organization. The problems brought by SQL injection have been around for a long time and are still a hot topic in information security issues [4] [5]. Web application security and database security are inter-

dependent. If a web application is manipulated by hackers, databases that have been equipped with security features can still be exploited. There are a number of threats to database security: among them are i) excessive privilege which refers to users who are given permission to access or carry out various transactions in the database but abuse the permission instead, and ii) SQL injection which is the entry of unauthorized input into the database to carry out any instructions that are not valid [6]. In addition, weak audit trails or automatic recording of database transactions that are not performed properly and media used as storage for backups such as hard disks and tapes are also prone to theft [7]. Therefore to improve database security, this paper aims to propose a new method in preventing SQL injection. To discuss the existing prevention methods on SQL injection and the motivation of this work, this paper is organized as follows: section II discusses the issues of SQL injection attack. Section III describes various ways that cause web applications to be attacked by SQL injection. Section IV highlights the impact of SQL injection on database security. Section V reviews the existing SQL injection prevention method. Based on the limitations faced by the existing methods, a new method is proposed in Section VI. Section VII explains the experiment conducted to prove the efficiency of the proposed method and Section VIII concludes the study and future work suggestion.

II. SQL INJECTION ATTACK

SQL is a standard programming language used to access databases. SQL injection is the act of putting malicious code as an input to a web application and sending it to a database to execute various commands [8]. An attack occurs when a hacker exploits an SQL injection to execute an unauthorized command [9]. Examples of common exploits are: stealing confidential information that can bring profits such as credit card numbers, bank savings account numbers, passwords, business transaction records and medical records. In addition, exploitation can also involve data modification [10]. For example; students trying to change grades or exam marks. There are also cases which are not personal attacks; such as sabotage the database by deliberately deleting certain tables, shutting down database operations and disrupting network traffic [4]. The term 'injection' is used because malicious code which considered as a non-valid input is injected into a valid SQL statement. The database will execute this command because it is valid in terms of the syntax and rules [11]. Fig.1 explains the scenario of SQL injection attack.

Fig. 1. SQL Injection Attack [2].

The term attack in the context of SQL injection is defined as an unauthorized access to applications or systems which normally done by hackers [12]. This access is obtained through SQL injection mechanisms derived from SQL query modifications [9]. Web applications that have user input can be attacked by SQL injection because the application code has certain vulnerabilities that expose to the attacks.

This will lead to the occurrence of bugs, loopholes, vulnerabilities or defects. These weaknesses shall be manipulated by unauthorized users to gain unrestricted access to stored data [10]. Therefore, a proper mechanism is needed to prevent the attack, such as validate the user input both at the client and server side [13] [14]. Since lack of proper mechanism in preventing the attack at the application and database level exists in the literature, therefore it has become the motivation of this study. In order to understand in details, next section will discuss the types of SQL injection that usually attack databases.

III. SQL INJECTION MECHANISM

Web applications have many loopholes and make them vulnerable to SQL injection attacks. There are various ways that cause web applications to be attacked by SQL injection. Among them are discussed as follows.

- SQL Injection through error messages.

An error-based injection is a type of SQL injection derived from an error message to figure out the structure and the type of database [15]. The attacker intentionally enters wrong input logically in order to allow database generates an error message. This error message contains information that allows the attacker to identify the parameters vulnerable to the injection.

- Boolean-based blind SQL injection

The term blind means that the SQL injection is performed when the programmer has set a generic custom error message in case web application encounters an error [16]. Without displaying error messages, database vulnerabilities can be protected. The hacker has to deal with a database system that does not display error messages and as an alternative, hackers submit a series of "TRUE" and "FALSE" queries via SQL queries [17]. Information about the database will be revealed through the results of these queries.

- Time-based blind SQL injection

Time-based SQL injection means hackers obtain information on database based on response times. SQL

command is sent to database with code to force the database to wait for a specified amount of time during the execution of the queries. The response time indicates whether the result of the query is true or false. While waiting for the query to be processed, the attacker able to execute another query and might inject malicious code in the query [18].

- UNION-based SQL injection

The hacker connects the SQL injection to the original SQL query by using the UNION clause to retrieve data from another table. The result of this injection is that the database provides a data set that contains a combination of the results of the original query and the results of the SQL injection query [19].

To avoid SQL injection through error messages will be the focus of this study. Hackers have a variety of reasons and motivations when it comes to hacking. Hackers gain access and control to databases illegally through SQL injection. With such access hackers can perform various actions to manipulate the data stored in the database. The main impact when SQL injection occurs is the disruption of the confidentiality and integrity of the data in the database [20]. Table I describes the actions that hackers can take and the consequences of the actions taken.

TABLE I. THE ACTION AND THE EFFECTS OF SQL INJECTION ATTACKS

	Action	Effects
1	Identify parameters that can be injected	Attackers able to find input parameters that are vulnerable to SQL injection
2	Perform a fingerprint on the database	An attacker can find out the type and version of the database being used. Easier to devise a more specific attack strategy.
3	Identify database schema	Attackers able to extract the information on database schema accurately
4	Extraction of data	Attackers able to extract complete data from database table
5	Add, remove and edit data	Attackers can alter certain data for their own benefit

IV. THE IMPACT OF SQL INJECTION ATTACK ON DATABASE SECURITY

Most organizations are unaware that their web applications are vulnerable to SQL injection attack or have been attacked by SQL injection [21]. Awareness and knowledge of SQL injection is still lack in the organization, any prevention steps are mostly at the basic level such as network firewall installation, the use of Secure Socket Layer (SSL) and network access control [2]. However, these measures only provide protection at the network level, and not at the application level [11]. Reviews state that the weakness in preventing SQL injection lies in the programming code of the web application itself [15]. Although various types of techniques have been introduced, most of the researchers insist that the application program code needs to be ensured its security first [22]. Firewalls and protocol information unable to protect web applications from hackers due to their position are behind the web application infrastructure [12]. The risks of attacks are increased due to the exposure of web application, firewall-friendly HTTP protocols and lack of database security [23].

Even though, there are approaches to improve database security through SQL injection prevention both at application and database level, however they are not capable to protect database against these three attacks which are:

- 1) vulnerabilities triggered when using dynamic SQL[13][18].
- 2) malicious code entered through input data [5][6].
- 3) inappropriate error handling message [10][14].

The cause of these attacks is explained as follows:

- Dynamic SQL usage

Dynamic SQL is a query language to build SQL statements and performs functional logic such as data search, user login and others, where this query is created dynamically at run-time. Although, these language are beneficial and user-friendly; but at the same time they expose the web applications to SQL injection. Often web applications are vulnerable to the attacks when dynamic SQL statements are being used [7]. Because, this language is dynamic in nature, therefore, an unauthorized user can modify the original query by injecting a malicious code to the query at run-time [24]. The following shows the impact of using dynamic SQL on database security. An example is used to show how SQL injection attacks might occur when using dynamic SQL. During runtime, the following dynamic SQL statement is sent by the web server to the database server:

```
SELECT * FROM program WHERE ID = 9
```

The intention of this query is to list the data from all the columns in a table named program; where column ID is 9. Since the query is dynamic, an hacker with a good knowledge of programming able to manipulate the query by injecting malicious code and modify the query dynamically at runtime, for example adding the symbol (') after the number 9. SQL statement is changed to

```
SELECT * FROM program WHERE id = 9'
```

This example shows that the use of dynamic SQL gives an opportunity to the unauthorized user to perform attack on database. Therefore the used of dynamic SQL should be avoided [18]. Since most organization used stored procedure with dynamic SQL [10], therefore, a preventive step at the database level is needed to avoid SQL injection attempts.

- Input validation

Web applications allow users to log in into the system. However, the data entered by the user may contain some malicious code and can easily exploit through SQL injection [25]. The inputs need to be checked and validated beforehand. The absence of an input validation process will contribute to the vulnerability of SQL injection. When a web application ensures that the received input is within the expected range, the malicious code could be prevented from entering the database server thereby preventing SQL injection. Therefore, a proper mechanism is needed to validate the input in order to prevent malicious code from entering the database server.

- Error handling process

During data processing, system will prompt an error message if they encounter problems. However, the default error messages reveal sensitive information and weaknesses of the database. The intruder of the system will learn from these errors, and this will give an opportunity for them to breach the system [14].

The limitations of the existing prevention methods at the application and database levels in the organization have become the motivation of the study. An improved method that able to overcome these three issues discussed above is needed in enhancing organization security level.

V. AN OVERVIEW OF THE EXISTING SQL INJECTION PREVENTION METHOD

Measures to improve the security of web applications and databases can be done at the server, network, database and application levels. However, most organizations take the basic security measures at the server and network level only [26]. The server and ICT network level is the physical level which is also an asset subject to the security procedures set by the existing policies. For example, organizations in the public sector need to comply with the Security Policy which outlined rules for internet access control, use of firewalls, server configuration settings, user access control and others.

Since this study focuses on the improvement of SQL injection prevention at the application and database level, the reviews of the existing methods are based on these two levels, which are summarized in Table II. Existing methods are reviewed based on their ability to address the threats causes by the three issues discussed namely i) dynamic SQL usage, ii) data validation at both client and server side, iii) error handling process. These three issues need to properly address to prevent SQL injection.

As Table II indicates, the existing methods did not address the three issues highlighted in one single method; therefore they are not sufficient in securing the database from SQL injection attacks. The method proposed by [4][12][21][24] validates the data at the client side and ignore the validation process at the server side. Therefore malicious code might enter the database. Even though methods proposed by [6][23][27][28] used parameterized query however dynamic SQL is still used. Therefore, this method is unable to prevent unauthorized user from modifying the original query by injecting malicious code. The used of dynamic SQL should be avoided to increase database security [2]. Dynamic analysis as used in [25] increases the query processing response time. As an organization that constantly deals with users through web applications, fast response times are essential. There are previous researchers who embedded handled error messages in their approaches, but the usage is inconsistent since the data is not validated at the application and database level [2][14]. Therefore these approaches are not sufficient in dealing with SQL injection attacks.

TABLE II. EXISTING APPROACHES IN SQL INJECTION

Author	Method used	Remarks
[2]	Error handling	Users are able to access database information through error messages. However, the error handling messages are not done consistently
[4]	Input Validation	The validation is only at the application side
[6]	Parameterized query	The data given by the users is encoded. However since this approach used dynamic SQL to encode the data, therefore the method did not prevent the system from the attack.
[12]	Input Validation	Input validation is only at the application or client side and ignores the validation at the server side.
[13]	Dynamic SQL	The data is not properly validated and error messages are not handled consistently.
[14]	Error handling	Proposed signature-based detection to handle error messages. However, this approach did not embed the input validation at both client and server side.
[18]	Dynamic SQL	Validate the input at both client and server. However, SQL injection is still being used and error handling is not properly done.
[21]	Input Validation	Input validation is only at the application or client side and ignores the validation at the server side.
[23]	Parameterized query	This approach did not validate the input data; therefore invalid data might enter the database.
[24]	Input validation	Use dynamic SQL to separate between normal data and malicious data. However, this process still vulnerable to the attack.
[25]	Dynamic SQL	This method uses combined static and dynamic analysis to prevent malicious code produced by dynamic SQL. However, the process will increase the query processing time. The data is not properly validated and error messages are not handled consistently.
[26]	dynamic SQL	Used dynamic SQL in the methodology, therefore not efficient in preventing SQL injection
[27]	Parameterized query	Use Knuth-Morris-Pratt matching algorithm and parameterized query to detect and prevent SQL injection. However, the error messages are not handled properly.
[28]	Parameterized query	Use signature-based approach to prevent the attack. However, the error messages are not handled properly.

Based on the comparative analysis and to overcome the limitations of the existing methods this study proposed a comprehensive method to address the highlighted issues. The existing stored procedure methods is referred and improved by incorporating parameterized queries as a SQL injection prevention mechanism at the database level and developing input validation and error handling as a preventive mechanism at the application level. The proposed method intends to address the issues highlighted in Section IV. The details on the proposed method are discussed in the next section.

VI. AN IMPROVED STORED PROCEDURE WITH PARAMETERIZED QUERY

Currently, most organization used stored procedure as a prevention method at the application level [23][27][28].

Stored procedures are subroutines which contain a set of predefined SQL code that can be saved and reused over and over again when needed. The code is written, compiled and executed before it is being used by the web application to communicate with databases. Frequently used queries can be saved in a stored procedure and can be recalled when requested. Since the location of stored procedure is within the database server, therefore the interaction between the program code and the table containing the data can be avoided [29]. This will improve the security of application program code because it can add another layer of abstraction before interacting with database [19]. With these features, stored procedure is able to provide high security feature to the database.

A parameterized query (or a prepared query statement) is a pre-compiling SQL statement. One or more parameters (or variables) need to embed into the statement for it to be executed. Parameters are sent to the query as soon as the user presses the 'Submit' button or presses the link in the web application. Normally, the existing code for the web application contains dynamic SQL statements when performing a query in the search functions. Due to limitation in dynamic SQL, parameter queries will be used instead, in conjunction with stored procedures. Parameter queries have program code security features that can be used instead of dynamic SQL. Parameters containing embedded user input will not be interpreted as commands to execute, thus will not allow code to be injected by SQL injection. The use of these parameterized queries is intended to replace dynamic SQL queries that can cause vulnerabilities to SQL injection. Application code will be more secured because functional logic is defined first and input parameters are entered after functional logic is processed [2].

Therefore this study proposed a comprehensive method to overcome the three issues highlighted earlier as discussed in Section 4. The proposed method makes an improvement based on these three steps:

- 1) use stored procedure with parameterized query instead of SQL dynamic,
- 2) validate the input at both client and server to reduce vulnerabilities to SQL injection. This is to ensure the input parameters sent to the database server do not contain malicious code and to prevent the code from accessing and harm the stored procedure,
- 3) improve the error handling process by not displaying confidential database information. Since error messages may reveal the limitation of the system to the intruder.

Fig. 2 shows the workflow of the proposed method. The workflow consists of four components which are:

- 1) the search page where the user enters the data to search,
- 2) the data validation at the client and the server site,
- 3) the error message if problems encountered during the process, and
- 4) the output of the query.

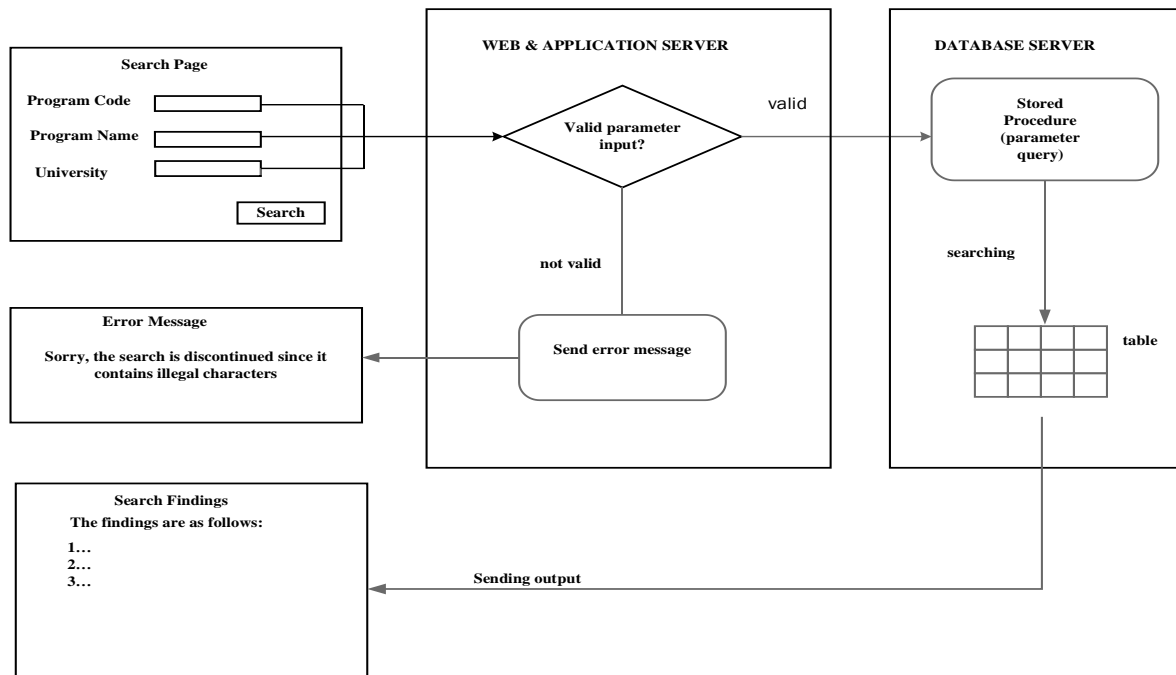

Fig. 2. The Workflow of the Parameterized Stored Procedure Improvement.

```

USE [ProgDB]
GO
/*****Object: StoredProcedure [dbo].[search_programmes] *****/
SET ANSI_NULLS ON
GO
SET QUOTED_IDENTIFIER ON
GO
ALTER PROCEDURE [dbo].[search_programme]
    @arg_programmcode NVARCHAR(10),
    @arg_programmename NVARCHAR(25),
    @arg_instname NVARCHAR(25),
AS
BEGIN
    DECLARE @sql NVARCHAR(max),
            @a NVARCHAR(100),
            @b NVARCHAR(100),
            @c NVARCHAR(100),
            SET @sql 'SELECT programme_code,
                    autoID,
                    inst_name_E,
                    inst_name_ML,
                    inst_name_EL,
                    prog_name_EN,
                    programme_name_E,
                    Category,
                    Status,
                    Valid_date, AA_yes,
                    FROM Q_search where 1=1'
    SET @a = '%' + @arg_programmcode + '%'
    SET @b = '%' + @arg_programmename + '%'
    SET @c = '%' + @arg_instname + '%'
    IF (@arg_programmcode is not NULL)
        SET @sql @sql + ' AND programme_code LIKE ' + @a
    IF (@arg_programmename is not NULL)
        SET @sql @sql + ' AND programme_name LIKE ' + @b
    IF (@arg_instname is not NULL)
        SET @sql @sql + ' AND inst_name_E LIKE ' + @c
    EXECUTE sp_executesql @sql,
        N '@a NVARCHAR(100), @b NVARCHAR(100), @c NVARCHAR(100)
    ',
    @a = @a, @
    -
    
```

Fig. 3. The Proposed Method using Parameterized Stored Procedure.

A stored procedure with parameterized query will be constructed that consists of the search function and the four components described above. SQL dynamic is not used in the query. For instance, the user will enter data regarding the program code, program name and university in the search page and the search button is clicked when finished. The input parameter will be validated at both the application and the database site. If the input data is not valid at the application site then an error message will be displayed. If the input data is valid then parameters of the search function will be sent to the stored procedure. The query will search from the table for the answers and displays the result.

The stored procedure that has the search function and the four components used in this study is shown in Fig. 3. This stored procedure consists of validating features and a proper error handling process.

VII. EXPERIMENTAL DESIGN

Since most approaches used dynamic SQL in preventing SQL injection attacks [13][18][25]; therefore this study intends to prove that the proposed method using parameterized query stored procedure is better than the existing approaches. To evaluate the effectiveness of the proposed approach, two experiments are conducted. The purposes for evaluation are to prove that:

- 1) The stored procedures that have parameterized queries are better than dynamic SQL in terms of preventing databases from SQL injection attacks.
- 2) The proposed approach has a shorter query processing time when compared the approaches that used dynamic SQL.

To achieve the aims, the experiment is conducted in two versions, which are:

- Experiment 1: the simulation attacks on web applications with dynamic SQL queries, and
- Experiment 2: the simulation attacks on web applications with stored procedures.

In this study, the web application that used as a case study will be represented by a pseudo-version web application. This application is developed to simulate and to prove the existence of web application vulnerabilities to SQL injection and subsequently became a medium for the experiment. A pseudo web application is considered a basic replica of the original web because it is developed with the same program code and functional logic as the original web application. Fig. 4 explains the used of pseudo-version web application in identifying the SQL injection attacks.

Pseudo-version web application is developed and experiment is conduct to simulate the SQL injection attacks. The experiment is run in a computer using the Microsoft Windows 7 Enterprise Edition operating system, 4GB of RAM, Intel (R) Core (TM) i5-2320 CPU @ 3.00GHz processing chip. Pseudo web applications are developed using

Microsoft SQL Server 2008 database. The web server operating system used is Windows 2008 R2 with ASP.Net, Coldfusion and Microsoft IIS 7.5 web application technologies. The stored procedures are written in the Transact-SQL language in Microsoft SQL Server.

SQLMap is used in the experiment which works in conjunction with the Python library and Netsparker Trial Edition software. SQLMap is chosen as the SQL injection vulnerability scanner instrument in this study due to its availability as open source software. This software is the most effective and popular among hackers and web application penetration testers [25]. Both experiments used the same test plan and software namely SQLMap, Netsparker and web browser. The query used for these experiments are based on the search query as in the stored procedure in Fig. 3. The setting for these experiments is explained in Fig. 5.

A. Experiment 1

The purpose of experiment 1 is to investigate the capabilities of dynamic SQL and the proposed parameterized stored procedure in preventing SQL injection attacks. To accomplish this experiment, two testing are required.

- Test 1: to evaluate SQL Injection attack on web application with the existence of dynamic SQL queries, and.
- Test 2: to evaluate SQL Injection attack on web application with parameterized stored procedures.

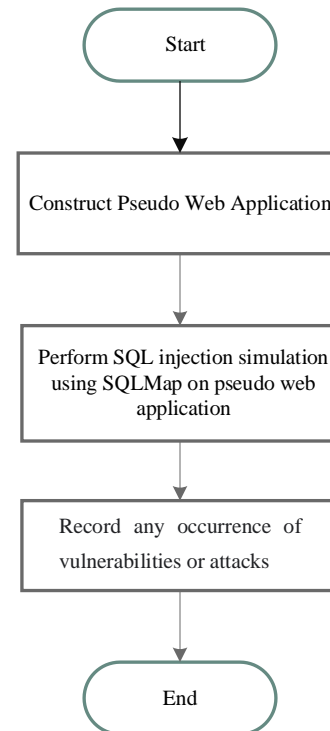

Fig. 4. Process Flow to Identify Web Application Vulnerabilities against SQL Injection.

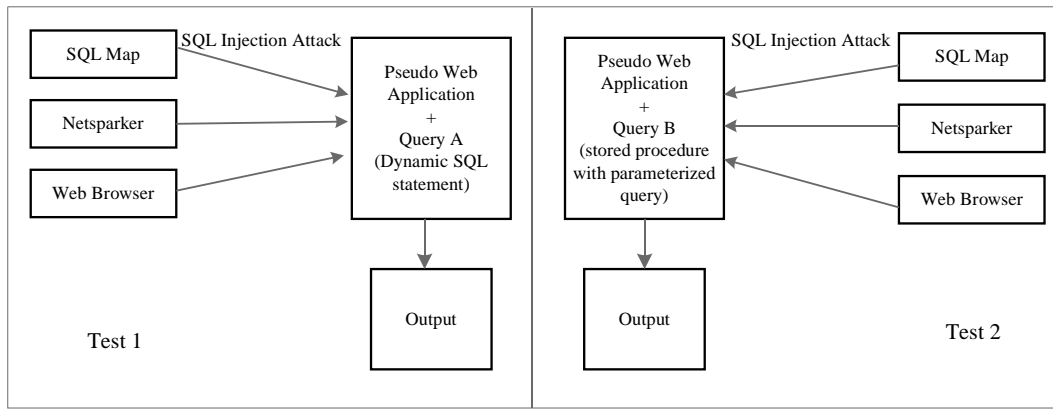

Fig. 5. The Setting for Experiment 1.

SQL which contains a malicious code is injected to SQLMap, Netsparker and web browser separately. SQL injection will penetrates web applications with queries containing dynamic SQL. Web applications that have strong defenses will be able to prevent attacks caused by SQL injection. Upon completion of the experiment, the outputs from these two tests were compared to investigate whether web application with dynamic SQL and stored procedures successful prevent SQL injection attacks. The results of this experiment are displayed in Table III.

TABLE III. THE RESULTS FOR EXPERIMENT 1

Attack	Experimental Results	
	Test 1	Test 2
SQLMap	Prevention Fail	Successful prevention
Netsparker	Prevention Fail	Successful prevention
Web Browser	Prevention Fail	Successful prevention

It is found that web applications with dynamic SQL is unable to prevent the attack cause by SQL injection when using SQLMap, Netsparker or web browser as stated in Test 1. The same instruments are used to test the web applications equipped with parameterized query, error handling and input validation. However when using the proposed approach, the web application able to prevent the attack. This proves that the proposed parameterized stored procedure is able to prevent web applications from SQL injection attacks.

B. Experiment 2

The purpose of Experiment 2 is to evaluate the performance of the proposed method and dynamic SQL in terms of time processing. This study used two evaluation instruments, namely

- Microsoft SQL Server Client Statistics and
- SQLQueryStress.

Client Statistics is a facility available in Microsoft SQL Server while SQLQueryStress is a standalone tool available as open source.

1) Evaluation using microsoft SQL server client statistics: This evaluation use MS SQL Server Client Statistics as an instrument to investigate the amount of data transmitted from server to client side. The intention is to evaluate whether SQL statement contributes to high traffic workload. The client execution time and processing time will be recorded during this evaluation.

a) Measuring client execution time: Client execution time is the cumulative amount of time used at the client side to execute query. To obtain the average execution time, ten trials were performed. In this evaluation, Test 1 represents the pseudo-web application which uses dynamic SQL during the trial, while Test 2 represents web-application which uses the proposed parameterized stored procedure. The output from this evaluation is displayed in Fig. 6.

Fig. 6 states that for each execution, Test 1 generates high execution time when compared with Test 2. This is due to a stored procedure which located at the database server. The SQL query is executed first before the web application submits the request. As such, the client is able to shorten the execution time by calling SQL queries that are already executed at the database server. In contrast, dynamic SQL are executed at runtime when the requests are submitted by the user. However, the query execution can be influenced by various factors. Such as, network traffic conditions as well as web and database server workloads. This will increase client execution time during query processing when using dynamic SQL. As the results show, the proposed parameterized stored procedure is better than dynamic SQL in terms of processing time.

Fig. 6. Query Processing Time at the Client Side.

b) *Measuring Time Statistic:* Time statistics provide information on the amount of time used during query processing at the client side versus the time used to wait for the server. Three metrics that can be used to measure time statistics namely client processing time, server response time and total execution time.

- Client processing time- to measure query processing time at the client side.
- Wait-time on server replies - is the time spent by the client waiting to receive the response from a database server after submitting the request.
- Total execution time - the time spent by the system to execute the query, including the time spent waiting for the server to respond. Using the same instrument, the results from this experiment are shown in Table 4. Comparison of time statistics between Test 1 and Test 2.

TABLE IV. THE OUTPUT FOR TEST 1 AND TEST 2

Evaluation Criteria	Test 1 (ms)	Test 2 (ms)
i. client processing time	3.5	1.9
ii. server response time	40.2	39.6
iii. total execution time (i+ii)	43.5	41.5

As can be seen in Table IV, web applications that use stored procedures are able to process queries at the client side in a shorter time. Also in the second and third evaluation criteria, the applications with stored procedure are able to improve query processing time at the server and total execution time both at the client and server when compared with the applications with dynamic SQL. This is due to the query in the stored procedure is executed first before the web application submits the request. Using this improvement method, the time taken to process the queries will be reduced.

2) *Evaluation using SQL query stress:* This evaluation uses SQLQueryStress software and used as a benchmark to investigate the performance of the query when given heavy workload. The intention is to investigate the impact of SQL queries (whether dynamic SQL queries, parametric queries or stored procedures) towards system performance. The differences in the structure of dynamic SQL queries and stored procedures make the query executed in different ways. Therefore, it is important to know the impact of both SQL queries on the system performance. Based on the result in Table V, it is found that the time taken by Test 2 is less than the time taken by Test 1.

The results state that Test 2 has a logic reading of 1547 compared to 1620 in Test 1. SQL queries that have low logic readings were more efficient than SQL queries that produced high logic readings. This is because high logic readings have negative implications to system memory. In other words, high logic readings place heavy workload to computer systems. The results show that query embedded in stored procedures produce less workload than dynamic SQL when using the same data hence improve query performance. This is due to

the query is processed earlier at the database server rather than at the runtime. Thus, it will reduce the elapsed time, the CPU time, the actual processing time and the client time as well.

TABLE V. COMPARISON OF SQL QUERY STRESS CRITERIA ON WEB APPLICATIONS USING DYNAMIC SQL QUERIES (TEST 1) AND STORED PROCEDURES (TEST 2)

Criteria (average)	Test 1	Test 2
elapsed time (ms)	1.3600	0.7350
CPU seconds (ms)	0.0996	0.0167
actual seconds (ms)	0.2834	0.0401
client seconds (ms)	0.1009	0.0475
logical reads	1620.0	1547.0

VIII. CONCLUSIONS

This study successfully proposed a new comprehensive method using an improved parameterized stored procedure to overcome the three issues highlighted in preventing web application from SQL injection attack. These three issues are i) improper use of dynamic SQL, ii) lack of input validation process and iii) inconsistent error handling. Unfortunately, the existing approaches did not properly address these issues. Hence they are not able to prevent SQL injection attacks at both the application and database side. In this study, a stored procedure is constructed that consists of a comprehensive method to address these three issues which are built in the code. To prove the effectiveness, the proposed method was evaluated through three approach of attack simulation, namely using SQLMap software, Netsparker and web browser. The experiments conclude that SQL injection does not successfully penetrate web applications and databases when the proposed method is implemented hence able to overcome the limitations faced by the existing methods. This indicates that the SQL injection prevention method developed has successfully prevents SQL injection from occurring. The proposed method is also evaluated from the perspective of time used and its impact on the overall system. Evaluations using Microsoft SQL Server Client Statistics and SQLQueryStress software have concluded that although there are slight differences in time processing, the proposed method uses a shorter query processing time when compared with dynamic SQL. It can be concluded that the SQL injection prevention method used does not generate high overhead that may lead to high response time. This study can be further improved by focusing the prevention of SQL injection in network systems. There are various factors to be considered such as the types of server used, network traffic and the attacks from various sources. More efforts are needed and further enhancements are required to improve database security.

Abstract—The User Story format has become the most popular way of expressing requirements in Agile methods. However, a requirement does not state how a solution will be physically achieved. The purpose of this paper is to present a new approach that automatically transforms user stories into UML diagrams. Our approach aims to automatically generate UML diagrams, namely class, use cases, and package diagrams. User stories are written in natural language (English), so the use of a natural language processing tool was necessary for their processing. In our case, we have used Stanford core NLP. The automation approach consists of the combination of rules formulated as a predicate and an ontological model. Prolog rules are used to extract relationships between classes and eliminate those that are at risk of error. To extract the design elements, the prolog rules used dependencies offered by Stanford core NLP. An ontology representing the components of the user stories was created to identify equivalent relationships and inclusion use cases. The tool developed was implemented in the Python programming language and has been validated by several case studies.

Keywords—Ontology; prolog rules; natural language processing; UML diagrams; user stories

I. INTRODUCTION

Requirements engineering (RE) represents an important role in all types of software development processes. They aim to define the scope of development together with customers [1]. In agile software development, requirements are presented in documents named user stories. These documents are an efficient way to express requirements from the user. User stories are written in natural language that renders them easily understandable to stakeholders, indeed they are short text that depicts a semi-structured specification. A user story often uses the following format type: As <role>, I want <feature> to <reason> [2, 3].

Recently, agile software development has become more and more widely used. However, unlike the extensive automation research on RE in traditional software development, the automation of RE in agile development has not yet been investigated sufficiently, especially in the area of requirements modeling [4]. Requirements modeling is a critical process in the software engineering life cycle. It is a multi-faceted and time-consuming process. However, it provides a solid guide for the final product. The success of software projects depends mainly on careful and timely analysis and modeling of system requirements. In [5], the authors propose an approach to generate a conceptual model using heuristic

rules and the NLP tool, but this model is not complete as it lacks the attributes of each entity. In [6], the authors also analyzed user stories in order to generate a UML use case diagram, but their approach is limited as they did not extract the relationships between the use cases. Furthermore, the authors of both approaches have not refined the relationships in the conceptual model or in the use cases in the use case diagram.

Our contribution aims to automate RE in agile development in order to generate automatically three UML diagrams which are class diagram, use case diagram, and package diagram with the refinement of results. To achieve the refinement task, at first, ontology engineering is created for defining synonyms and relationships between actions, given that action is a relationship or part of the use case, secondly, Prolog rules are used to eliminate the relationships that are at risk of error in the class diagram. Our purpose is to minimize the errors of the relationships extraction and to avoid the redundancy of the associations not taken into account by Wordnet in the class diagram. Prolog rules are applied at first to determine the relationship between engineering requirements. All statements are converted to rules and facts in the SWI-Prolog language. A user story is made up of three elements: the role which represents the actor who acts, then the action represented by a verb, and finally the object which has undergone the action. Ontology is created to describe the components of user stories as the role, the action and the object. This ontology represents the field of agile methods by focusing on the part of user stories.

After the creation of the classes in ontology editor, we proceeded to the stage of filling the ontology by enriching it with vocabulary and equivalent of class instances; we concentrated on the class "action" which represents the relation between the classes in a diagram of UML. The object properties reflect the relations that can be established between instances of the ontology classes.

The structure of this paper is as follows: This section introduces agile methods and our proposed approach. In Section 2, we present the related work of our proposal. However, we detail our proposal approach, and we present the main of the platform in Section 3. Then, we present a generated UML diagrams in Section 4. In Section 5, we present the discussion and analysis. At finally, conclusion is presented in Section 6.

II. RELATED WORK

Several research projects have been carried out to automate the requirement engineering, but few researchers have developed a tool to automate the agile requirement presented in user stories. Since the agile method is the most used in software engineering, it was necessary to think about developing a solution to automate the design phase in the software development Life cycle. A user story is a very effective means of communication between future users of the software and developers and designers.

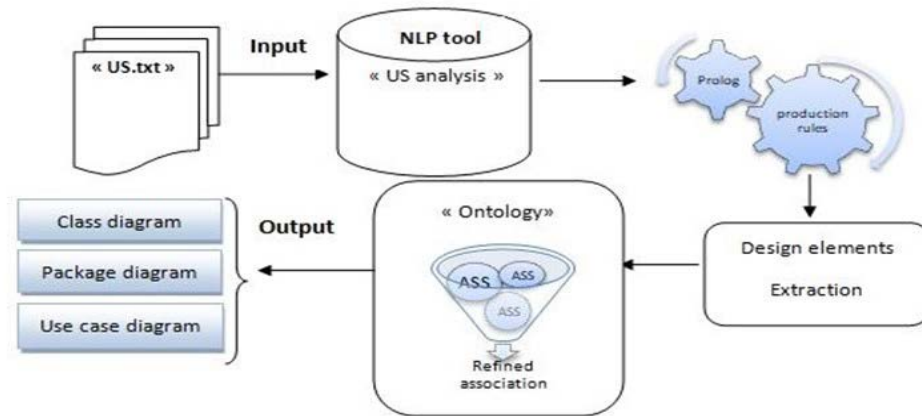

Our approach automates the design phase, i.e. from several user stories; our tool generates several diagrams as output: the class diagram, package diagram, and use cases. The tool is carried out by developing prolog language rules allowing the extraction of design elements such as actors and associations between classes, and subsequently refining the associations obtained by using ontology. The created ontology represents the user stories and based on looking for the synonyms of the associations that are found in the ontology. The use of ontology was primordial, firstly, in order to avoid the redundancy of the associations in a generated class diagram, secondly, in order to detect the inclusion between use cases in the use case diagram.

To analyze requirement engineering most of the researchers used the ontology domain to achieve their goal. Our approach combines prolog rules and the domain of ontology. The majority of the researchers have tended to analyze the requirement engineering [1] but in our approach, we start with the extraction of the design elements constituting the UML diagrams, and then we analyze the requirements using the ontology that represents the strong point of our approach. In [7], the authors propose the business process ontology design scheme. The built ontology is considered as a knowledge base by collecting the user stories to reuse them from previous projects. Classes are created in ontology according to Role-Action-Object relations. In [8], the authors used an NLP tool named "OpenNLP Parser" and Wordnet in order to analyze the requirements. Their aim is to extract concepts to constitute a class diagram. The authors developed a desktop tool named "RAPID", the limitation of this tool is that each sentence in the requirements must match a specific structure. In [9], the authors develop a formal Web Ontology Language ontology for the standard representation of engineering requirements. The proposed ontology uses explicit semantics that makes the ontology amenable to automated reasoning. The approach allows the evaluation and classification of engineering requirements. In [10], the author's Approach allows to Test Case Generation Based on Inference Rules. In [11], the authors are built an automated tool named "ABCD" for class diagram generation from user requirements. They used NLP techniques to extract class diagram concepts and generate an XMI file representing a class diagram. The limitation of their tool is that the system does not focus on the problem of concept redundancy. In [12], the authors have developed a framework

to automate the documentation by elaborating the ontology. 60 percent is a percentage of their automation. In [5], a conceptual model is generated from a set of user stories, their tool named visual narrator, this tool does not extract attributes of entities in the conceptual model, and they focus on detecting entities and relationships. In [13], the conceptual model is generated from an unrestricted format such as general requirements, user stories, or use cases; but the attribute extraction rule is based on a set of previously designed verbs. In [14], the searchers suggest an approach that generates a class diagram from use case specifications, parts of speech tags (POS tags), and typed dependencies (TD), were used to reach their objective, however, the developed tool analyses simple sentences. The rules used to extract attributes are not valid in most sentence structures, due to the failure of consecutive names processing. In [6], the authors used the NLP tool named TreeTagger analyzer and developed a JAVA plugin to generate the use case diagram from the user stories; their tool does not handle sentences containing compound nouns. Also; it does not support inclusion or exclusion relationships between use cases. In [15], the authors analyze the requirements by combining the ontological model with prolog rules. This analysis relies on tracing the requirements, eliminating duplicate requirements, and identifying conflicting requirements. The authors used agile requirements. In [16], an NLP-based tool is implemented to generate an Entity Relationship diagram from requirement specification. The machine-learning module is implemented by using a supervised learning mechanism. In [17], through a linguistic analysis of sentence structures and action verbs in user stories, the authors discover patterns of labeling refinements. The refinement goal is a transformation of User Stories into Backlog Items. In [18] the authors propose a technique to automatically transform textual user stories into visual use case scenarios.

III. AN APPROACH TO EXTRACT DESIGN ELEMENTS AND ANALYSE RELATION BETWEEN THE CLASSES AND USE CASES

In our previous approach [19], our objective was to define the extraction rules of the object-oriented design elements, such as actors, classes, attributes, operations of classes, and associations. These components were essential to generate a class diagram, presented in an XMI file and also in a PNG image. We used a natural language processing (NLP) tool named "Stanford CoreNLP" and python language to achieve our goal. After extraction of associations, we have used Wordnet to delete the redundancy associations between the two classes. The use of Wordnet was not sufficient to avoid Redundancy that's why we have thought of another approach that integrates artificial intelligence materialized firstly in the use of prolog language for the definition of production rules to generate associations. Secondly in the use of requirement ontology in which we have defined synonyms of verbs presenting associations. The ontology is created in Protégé editor.

US: user stories; Ass: Association

Fig. 1. Architecture of the Proposed Approach.

All treating was done in python language, even access to ontology to search for synonyms. Prolog language is used firstly to define the Production rules for extraction of the design elements. Secondly to define rules to detect errors in association extraction. The output of our framework is three diagrams: class diagram presented in XMI file, use case, and package diagrams presented in a PNG image. This image is carried out by using Plant UML.

The processing of a text in user stories goes through several steps: Splitting, Tokenizing, POS, Lemmatization, and typed dependencies. The user stories analysis was done using the NLP tool named Stanford core NLP. Fig. 1 shows the architecture of the proposed approach.

A. Prolong Rules for Extracting Relations

To extract the design elements which constitute the class diagram, from a set of user stories, we followed the steps described in the algorithm presented below:

Algorithm: Design elements extraction

- 1: Procedure (Stories S, Actors A, Classes C, Rels R, Attributes ATT, Operations Op)
- 2: for each s in S
- 3: p=POS(s)
- 4: Word_tokenize(s)
- 5: Dependency_parse(s)
- 6: Extract_Nouns(s)
- 7: Extract_Verbs(s)
- 8: A=Extract_Actor(s)
- 9: C=extract_class(s)
- 10: R= Extract_all_relationships(s) [prolog rules: Association(X,Y,Z); X is association name, Y and Z are classes]
- 11: Comp= filtrate_composite_rel (R)
- 12: for each c in C

13: if c in comp then ATT=extract_attribute (Comp)

14: for each r in R

15: If ATT in r

16: Op=r

Based on rules previously defined in [19], we have defined a production rules written in prolog language to extract actors, classes, and associations which connect classes (lines 8-10). The facts are provided from NLP tool that provide the nouns, the verbs and typed dependencies (lines 3-7). To extract attributes of classes we have followed the same approach of [19] i.e. from the resulting classes we do a refinement; some classes become attributes and thereafter some associations become operations of a class (lines 10-16).

The rules are presented in this form: Association(X, Y, Z); The objective of these prolog rules is to extract X which represents the association name, and Y and Z which are classes in the UML class diagram.

B. Prolog Rules for Detecting Errors in Relation Extraction

After extraction of association between classes, we proceed to the refining step by applying some prolog rules which detect errors in the list of association.

Rule1: if two or more actors have the same action to execute.

Rule2: if there is an association between A class and B class and the same association between B class and C class then there isn't an association between A class and C class. This rule avoids transitivity between associations which can clutter the class diagram with several unsuccessful relations.

C. Ontology for Analysis of Relations between the Classes in Class Diagram and use Cases in use case Diagram

Our ontology is important to represent knowledge of the application domain and to identify the relations between requirements such as composition or synonyms. USOn is an ontology that describes an agile requirement; we have created ontology classes and instances through Protégé ontology editor.

Fig. 2 shows the hierarchy of the ontology USon. Table I presents the description of some classes.

Fig. 2. Hierarchy of the Ontology USon.

TABLE I. DESCRIPTION OF SOME CLASSES

Class name	Description
Action	class whose elements are verbs which represent the associations in class diagram
Object	class whose elements are nouns which represent the classes in class diagram
Actor	Class whose elements are nouns which represent the role in user story (As role,...). The actor is who perform the action. Actors are present in the use case diagram.
Association	Symantec link between classes in the class diagram
Class	class whose elements are nouns which represent the classes in class diagram
Attribute	class whose elements are nouns which represent the attributes of classes in class diagram
Word	class whose elements are tokens which represent part of user story

We have defined a set of Synonyms to *Action* class in order to refine association name. The same process is for the *Actor* class. Fig. 3 shows an example of defined synonyms and inclusion action.

Our tool accesses the *USon* ontology in order to compare the names of the associations obtained using the prolog rules with those defined as synonym of the *Action* class. Subsequently, the associations will be refined. The refinement of actors in use case diagram is done by browsing synonyms of Actor instances.

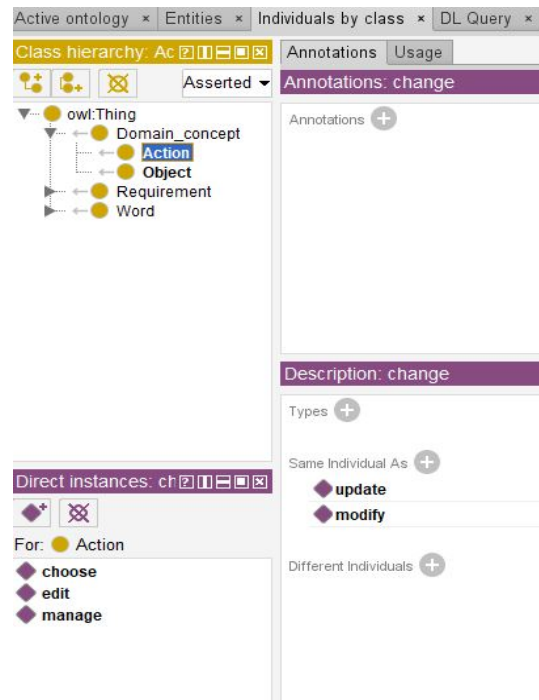

Fig. 3. Synonyms of Change Action.

Consider an example of user stories:

- US1: As a manager, I want to manage account of users.
- US2: As a manager, I can create a new account.
- US3: As a user, I can modify login account.
- US4: As a user, I can update my login.

In US1 the action is the verb “manage”, according to our approach the following association is extracted: Manage (manager, account).

In US2 the action is the verb “create”, according to our approach the following association is extracted: Create (manager, account).

Our tool, at first looks for the relationships between the same classes as in US1 and US2, and US3 and US4, after Wordnet is used in order to avoid redundancies, then browsing of *USon* ontology is mandatory to detect synonym and inclusion relations between use cases; in the example, the actions modify and update are synonyms as shown in Fig. 3 so an association will be removed from the list of associations in order to avoid duplicate associations.

In *USon* Create is part of Manage as shown in Fig. 4, then there is an inclusion between two use cases extracted from US1 and US2: “manage account” and “create account”.

Consider these user stories:

- As a user, I can change the account information.
- As a user, I am able to edit account information.

Fig. 4. Composition of Manage Action.

Our tool with the help of the Stanford NLP tool and prolog rules allows extracting two use cases: “change account information” and “edit account information”.

According to the ontology USon, the update action is part of Edit. In Fig. 3 the update action is a synonym of change action then change is part of the Edit action.

We can deduce from this combination between ontology and prolog rules that there is an inclusion between two use cases: “change account information” and “edit account information”.

IV. GENERATION OF UML DIAGRAMS

A. Generated Class Diagram

After extracting the design elements, the next task was to regroup these elements to constitute the class diagram. The developed tool generates an XMI file which is an Ecore file. Ecore file is the Eclipse Modeling Framework (EMF) meta-model, which illustrates the names of the classes, their attributes, and their types, as well as the methods and relationships with their classifications. Also, PlantUML API is used to visualize the class diagram. These treatments were done in python language. To implement our new approach, we used the same case studies^{1,2} from article [19] and compared the results. We found that in our old approach, the class "people" (case study¹ number 2) was detected, yet in our approach; there is an association of inheritance between "people" and all the

actors thanks to our ontology. This association has been added to the generated class diagram.

Regarding the first case study², there is redundancy in the operations obtained (filtrate (type) and choose (type)) which are at the origin of associations before refinement. Wordnet could not detect that these verbs are equivalent, so we used the ontology.

We noted that the associations obtained from the old approach are all obtained using the extended rules of our second approach.

B. Generated Package and use Case Diagrams

A package diagram offers many advantages to designers who want to create a graphical representation of their UML system or project. This diagram simplifies the complex class diagram into a tidy visual form. In our case, we used the package diagram to organize the class diagram.

After generating the class diagram, the next task was to generate the package and use case diagrams. To do this, we based on the design elements already extracted such as: classes, associations, and actors.

To extract a package, we first use the associations that link the actor and another class, and secondly, we add the term "manage" before each class to form a package. To detect the dependency between the packages, we take into consideration the relationship between the classes that make up the packages. The use cases are formed from the associations between classes provided that one of the classes is an actor. PlantUML API is used to visualize the package and use case diagrams. All treatments were done in python. Fig. 5 shows the generated package diagram of the case study¹ which represents inline course management: videos, quizzes, and others.

The generated package diagram is based on associations and classes of the class diagram. The red arrows between the packages represent the dependencies between them. Table II represents some use case diagrams for each package presented in Fig. 5.

Fig. 5. The Generated Package Diagram.

² https://github.com/MarcelRobeer/StoryMiner/blob/master/example_storie s.txt

TABLE II. USE CASE DIAGRAMS OF PACKAGES

Package name	Use case diagrams
Manage Course	
Manage Element	
Manage Quiz	
Manage Event	
Manage Video	

By comparing the results obtained manually with those which are automatic, we noted that our approach extracts 99% of the relationships. Generating the package and use case diagrams based on the associations of the class diagram has revealed its effectiveness.

Regarding the class diagram, the Uson ontology allows firstly detecting inheritance association between actors such as actor named People and other actors, secondly determining the synonyms of associations.

Regarding the use case diagram, the Uson ontology allows firstly determining the synonyms of use cases, secondly the inclusion relationships between two use cases.

Our approach remains very effective thanks to the strong point of the combination of the domain of ontology and prolog rules. We can say that the ontology we created complements the prolog rules in order to obtain better results.

Table III shows a comparison between my old approach [19] and my proposal. However, Table IV depicts a comparison between related work and my proposed.

Our approach is the unique method that defined extraction rules for associations of class diagram using prolog language. Subsequently, the association and use cases are analyzed and refined using our built ontology named “Uson”. The associations are the key for building the UML diagrams: use case and package diagram.

TABLE III. COMPARISON BETWEEN MY OLD APPROACH AND MY PROPOSAL

	Association		Composition relationship	Inheritance relationship	Synonyms	Output
Old approach [19]		Python heuristic rules	Python heuristic Rule s: H1, H2, H3	Python heuristic H4 and H5	Wordnet: Synonym of associations (verb which link two classes)	Class diagram: XMI file
Proposal approach	NLP tool: Stanford coreNLP	- python language - Prolog rules	- Prolog rules - Ontology USon	Ontology USon	- Wordnet - Ontology USon: 1. synonym of use cases (action in use case) 2. synonym of associations	- Class diagram: XMI file and PNG image (using plant UML) - Package diagram: PNG image(using plant UML) - Use case diagram: PNG image(using plant UML)

TABLE IV. COMPARISON BETWEEN SOME RELATED WORK AND MY PROPOSED

Related work	Input	Output	Approach and tool
[7]	User stories	Business process ontology	Reuse of user stories
[8]	Business document	Concept-classes	- Wordnet - Linguistic rules
[9]	Engineering requirements	Formal Web Ontology	Evaluation and classification of Engineering requirements
[5]	User stories	Conceptual model without attributes	Visual narrator tool
[14]	Text requirement and user stories	Conceptual model	Visual C # language and Stanford CoreNLP
[15]	User stories	- Elimination of duplicate requirements, and identification conflicting requirements - not any generation of the UML diagram or conceptual model	- Prolog and python language - Ontology
[19]	User stories	Class diagram	Python language and Stanford CoreNLP
My proposal	User stories	- Class diagram - Package diagram - Use case diagram	- Standford coreNLP - Python and prolog language - Ontology

V. CONCLUSION

This paper have proposed an approach to automate the analysis phase in an agile context, to extract the design elements which are essential to constitute the generated UML diagrams: the class diagram, the package and use case diagrams.

Our approach is based on the combination of prolog rules and an ontology which present the user stories. The prolog rules used dependencies offered by Stanford core NLP. This combination is the strong point of our approach. The main advantages of the proposed technique are:

- Improvement of the results obtained from our previous approach by Applying artificial intelligence presented in prolog rules and ontology.
- Generation of three UML diagrams which facilitate the design of analytical tasks in the team.
- Refined classes have been obtained following a transformation of some classes into attributes using composition relationships, and some relationships to operations.
- Definition of prolog rules for detecting errors in relation extraction.

Our proposed approach is very useful to ease the analytical tasks in the design team. Next, minimize time and costs. The benefits of our approach are the utilization of agile requirement to automate them, these requirement named user stories are the best way to describe the engineering requirement. In the future, our work will be completed by generating user interfaces and code of the software.

Abstract—Public business operations are governed by a set of legal sources, which regulate their implementation under administrative laws that are increasingly influencing software system design and development. Enterprise Architecture (EA) is a critical approach for driving business and Information Systems (IS) transformation in the public sector. On the other hand, EA frameworks lack representation schemas that support law models. Understanding of the law Architecture in the government domain is required for EA work and is thus the first architecture activity that must be completed. As EA approaches for Law compliance reviews are performed by legal experts, there is a gap between law experts and technical system architects. To cover these gaps, this paper proposes a novel framework for analyzing the administrative laws, extracting the legal policies and legal rules, identify their relationships with other EA domains, and identifying the law compliance requirements. Moreover, the integration of our proposed law architecture framework with existing EA frameworks to reach a law-compliant public enterprise model is identified. Finally, the applicability of the proposed framework is shown and validated through a case study. Moreover, subject matter experts of the legal domain also evaluated the extracted legal policies and rules during the implementation of our proposed framework.

Keywords—Law architecture; regulatory compliance; requirements engineering; enterprise architecture; law ontology; TOGAF

I. INTRODUCTION

Administrative laws are the law acts that regulate the operations of government agencies. The branch of law governs administrative agencies' development and operation. Administrative law, commonly known as (regulatory law), includes the rules and regulations that an administrative body promulgates and enforces. Administrative laws are compulsory for the institutional domain and are a benchmark for officials and architects in government and government digital transformation initiatives. Enterprise architecture (EA) is the method of aligning an authority's business with information technology, including the convergence of business procedures, Information Systems (IS), technology, and people[1]. EA has been in progress and deployment for the past years[2]. However, most authorities continue to have issues with EA practices; EA practice is not a simple task. Despite a large

number of current EA frameworks, public authorities have been unable to translate EA solutions to meet their needs [3].

In the study [1], the Gartner Group stated that a big percentage of EA implementations fail in the world because they start with modeling rather than defining business requirements first where the business requirements must meet the needs of IS. The business needs of the public agencies should comply with laws. Regulatory or law compliance management is a general concept that encompasses all practices and procedures used to ensure that a public authority adheres to all legal rules mandated by local or international laws. These laws are typically outlined in a natural language text that is difficult to comprehend for non-legal professionals. Existing laws pose a different set of problems. New digital transformation solutions may not be properly tested until they are put into operation and laws are developed to fix previous issues caused because of business and social shifts. To overcome the law compliance problem, several research studies have been conducted. Some researchers propose a law ontology approaches as a solution for law compliance. Some other researchers proposed regulatory compliance frameworks with the business process [4]. Moreover, other studies were conducted to regulatory compliance for requirements engineering [5] [6] [7] Enterprise architecture frameworks are used to guide the creation of enterprise models in terms of three domains namely business architecture, IS architecture, and technology architecture. Thus, extending the enterprise model to represent the policies identified by law can be obtained by defining the law architecture (our proposed framework) and integrating it with other enterprise architecture domains, as illustrated below in Fig. 1.

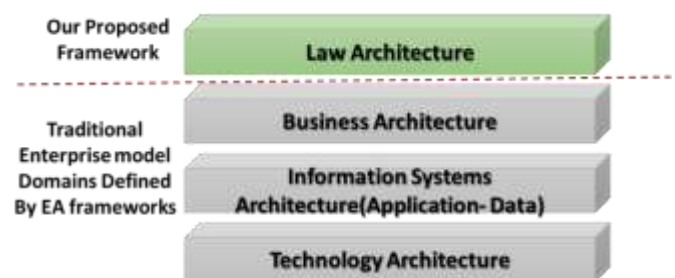

Fig. 1. Public Enterprise Model View after Integrating the Proposed Framework with EA Frameworks.

Knowledge of the law Architecture in the government domain is a prerequisite for architecture work. The law Architecture is also often necessary as a means of defining the governance layer and regulatory compliance requirements of following EA activities for all enterprise model domains.

Many emerging approaches to e-Government architecture, on the other hand, do not take legal sources into account. There is no formal structure for e-Government enterprise model enforcement with legal sources in these approaches. Compliance with regulatory issues and e-Government business models is a critical problem for governments. Thus, this study proposes a novel framework to address the following questions:

- How to manage compliance with laws across all enterprise model domains; business, IS, and Technology?
- How to design Government IS that complies with administrative laws?

- How to transfer laws policies into a machine-readable format?

In the next section, we present a state-of-the-art review of the related works. a detailed description for the proposed law architecture framework components and method including the integration with EA frameworks will be presented in Section III. Section IV presents the applicability of the proposed framework to real-life cases; the case study of the Egyptian Universal Health Insurance program is demonstrated. Finally, in Section V, a brief analysis of the obtained conclusions and future work are discussed.

II. STATE OF THE ART

Law compliance or regulatory compliance is a concept of acting in accordance with established laws, regulations, etc. In order to judge that a public authority is following the given legal rules or not, compliance auditing is conducted.

TABLE I. COMPARISON OF SURVEYED STATE-OF-THE-ART OF REGULATORY COMPLIANCE

The proposed framework		√	√	√	√	√	√

A compliance review is an important activity of compliance auditing which depends on the extraction of regulatory compliance requirement from administrative laws. There have been an increasing number of research challenges to automate regulatory requirements extraction from legal acts.

Administrative laws, which drive the development of regulatory compliance solutions, are generally available as natural language text documents (semi-structured format), and understanding them is performed by legal domain expertise. Testing a given business model for enforcement is, unsurprisingly, a manual process performed by accredited domain experts. Moreover, effective regulatory compliance requires good knowledge of the enterprise model of public authority by the legal auditors and a good knowledge of the compliance framework by the enterprise architects. This makes the close collaboration of legal auditors with enterprise architects a necessity. The challenge of automated compliance checking can be seen as extending an enterprise model to include concepts defined by the regulatory compliance framework and enabling the needed automation in checking an enterprise model against the policies defined in a regulatory compliance framework.

This is because most legal acts are written in natural language, which a conventional computer system cannot understand. A legal ontology is a theory that describes the concepts that exist in the legal acts and how they are connected. Many kinds of research have been undertaken to develop ontological representations for legal documents to achieve law compliance [8] [9] [10] [11]. On other hand, a big number of studies exist for achieving law compliance through linking laws policies with Business Process Models (BPM) [12] [13] [14] [15] [16] [17] [18] [19]. Moreover, Regulatory compliance is a well-studied area in software requirements engineering, including research on how to model, check, analyze, extract, and validate compliance of software different requirements engineering techniques for achieving software compliance as discussed in [20] [21] [22] [23] [24] the below Table I outlines the comparison between different approaches for achieving regulatory compliance. Based on the comparison Table I, we argue that this literature survey could not find any contribution that addresses the topic of how to integrate law compliance solutions with the enterprise model.

III. PROPOSED FRAMEWORK

The proposed Law Architecture Framework (LAF) provides the baseline for mapping various legal policies related to regulatory requirements to business process, stakeholders, capabilities, IS, data concepts, and technology architecture. Regulatory compliance planning and subsequent deployment projects require mapping and tracking the evolution of the following artifacts of law architecture:

- Legal policies tied to business capabilities.
- Legal rules tied to business processes.
- Legal policies and rules tied to data concepts.
- Legal policies and rules tied to Information systems.
- Legal policies and rules tied to Technology.

The law architecture framework is a goal-oriented, law-driven framework aimed to define compliance requirements through which a particular public enterprise and its related information systems can comply with a given administrative law. We define the law architecture as a holistic representation, multidimensional views of legal policies and their derived legal rules, and identifying their relationships with the business, data, information systems, and technology domains, in addition to identifying the requirements of compliance with these rules and policies. Law architecture requires a complete framework to guide its development and practice. We argue that the effort required to accomplish the law architecture activities should be performed by a team that has both bits of knowledge of technology and law domains, a team with the following key roles:

- Law Architect is an information and communications technology professional that is responsible for analyzing administrative laws and extracting from them the regulatory compliance requirements of business, IS, and technology architectures. The law architect must be reasonably knowledgeable of the administrative laws and public sector domains to be familiar with public sector services and the operational environment.
- Legal Counsel: According to the BIZBOK Guide [25]" A Legal Counsel is a person who is legally qualified and licensed to represent an organization in a legal matter, such as lawsuits, policy formations, contract negotiation, and patent activities". A legal counsel regularly works in legal departments of the public authorities and is considered the subject matter expert during the law architecture cycle. The legal council is responsible for the analysis, and validation of extracted policies and rules. The objectives of the law architecture framework can be summarized as follows:
 - To align laws and regulations with business and IT Systems.
 - To identify and model legal policies and rules and linking them with the enterprise model domains namely; business architecture, information systems, and technology architecture.
 - To identify the relationship between legal rules and other architecture domains.
 - To identify the regulatory compliance criteria with the legal rules.
 - To manage any suggested law amendments and assess their impact on the enterprise model.
 - To develop the appropriate viewpoints, models, and matrixes that enable the demonstration of how the legal policies are addressed in the business, IS, and technology architectures.

As shown in Fig. 2, the law architecture framework consists of the following components:

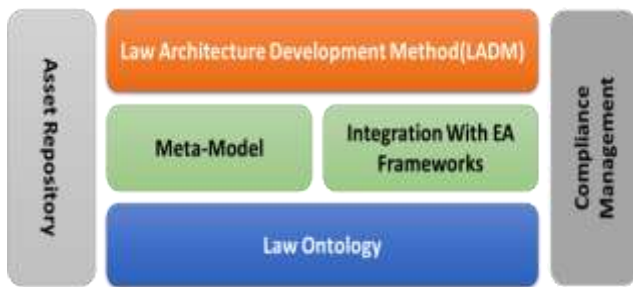

Fig. 2. Components of the Proposed Law Architecture Framework.

- Law-Architecture-Development-Method (LADM): describes a set of guidelines and activities for developing a law Architecture.
- Law Architecture Meta-model: defines a formal structure of core concepts and their relationships to ensure consistency within the law architecture.
- Asset Repository: outlines different taxonomies and guidelines to categorize and store the inputs and outputs of law-architecture effort such as laws catalogs.
- EA framework integration: describes the ability to integrate the law architecture framework with other enterprise architecture frameworks.
- Law Ontology: defines an ontological and semantic representation of the law architecture Meta-model for getting a machine-understandable model that is enabled easily for automation and model analysis.
- Regulatory Compliance Management: defines different approaches for checking a public enterprise model against the legal policies and rules defined within the LADM.

The details of some selected components of the proposed framework are detailed as follow:

A. Law-Architecture-Development-Method (LADM)

The LADM is the product of the continuous efforts of law architects and legal counsels. It describes a method for modeling and managing the compliance requirements of laws that govern the public enterprise and forms the core of the Law architecture framework. It describes the steps, guidelines, and tools to analyze, extract, and model the legal policies and rules from administrative laws. Moreover, it guides the definition of the correlation between extracted legal policies and rules with other public enterprise model domains, to align the public authority and its IT systems with the law.

Fig. 3 depicts the phases of the proposed LADM which consists of the following:

- Law Architecture Initiation.
- Phase (A): legal Policy Mapping.
- Phase (B): Legal Rule Mapping.
- Phase (C): Definition of legal Policies/ Business architecture correlation.

- Phase (D): Definition of legal Policies / IS architecture correlation.
- Phase (E): Definition of Legal Policies / Technology architecture correlation.
- Management of Suggested Law amendments.

The level of detail addressed in Law Architecture will depend on the scope and objectives of the overall law-architecture effort. The key steps in details of the LADM include the following:

1) *Law architecture initiation*: The Objectives of this phase include initiating the law Architecture Capability planned by the public authority, defining the law Architecture Principles, and Identifying the set of administrative laws that applies to the business performed by a public organization which is related to the IT systems' Scope. The LADM is a generic approach that can be used by a broad range of public bodies and, if necessary, in combination with a wide range of EA frameworks. The recommended steps within the initiation phase are as follows:

a) *Determine the Scope of the Public Agency Impacted*: Identify the public entity core units that would be most affected or gain the most benefit from the law architecture work.

b) *Define and Establish the Law Architecture Team*: The required team members that will develop the law architecture should be identified.

c) *Define Law Architecture Principles*: A principle is an agreed-upon fact that can guide one's analysis and reasoning. Core principles that apply to law architecture, in general, are:

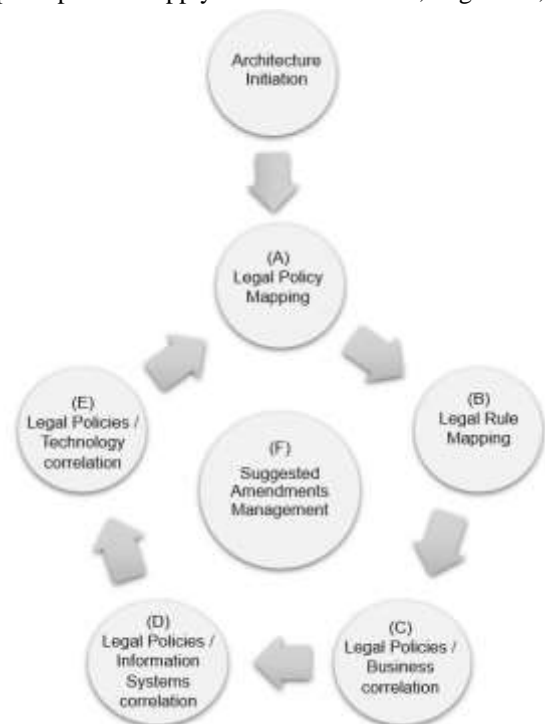

Fig. 3. Law-Architecture-Development-Method (LADM) Phases.

- Legal policies are accessible and shared.
- Common Vocabulary and legal policy Definitions.
- Law architecture's scope is defined by a set of laws applied to the public authority.
- The law architecture process is iterative.
- Law architecture artifacts are reusable especially those extracted from domain-specific laws.

d) *Develop Law Catalogs*: Catalogs form the raw legal documents for the development of models and views and represent a key artifact for driving the law architecture activities. The following catalogs should be developed:

- Project-Related Acts Catalog.
- Domain-Related Acts Catalog.
- Legal Policy catalog.
- Suggested Amendments Catalog.
- Ontology Representation.
- Suggested Amendments Catalog.
- Regulatory Compliance Requirements.
- Approved Amendments Catalog.
- Suggested Amendments Catalog.
- Compliance Requirements Catalog.

2) *Phase (A) Perform legal policy mapping*: The objectives of this phase are analyzing architecture scope impacted acts and extract the legal policies representations, Reviewing extracted policies with different legal experts and ensuring their correctness and consistency, and finally updating the legal policy catalog. Administrative laws define the legal limits for public authority by enforcing requirements that specify which actions are legal and which must be prohibited during the conduct of daily operations. A legal policy is a statement or set of statements that describe the course of events and how a specific action should be carried out. A policy is defined to achieves a business goal. A legal policy has a subject, who is the stakeholder(s) who is/are responsible for carrying out the policy's actions. A legal policy requires a business capability to be executed, a business capability is defined as a set of resources and activities that integrate to deliver a value to an internal or external stakeholder (target). Legal Policy mapping is the core of law architecture and an excellent starting point. Describe the policies and legal rules associated with the law articles, the main idea in the law architecture is that legal policies define decisions on whether a state of the business activity is allowed or not. The extraction of legal policies and rules is a hardworking and time-consuming activity and is recommended to be carried out by legal architects (or business analysts) with the help of legal counsels. To extract the legal policies the architects must look for important information by

scanning the legal articles and try to answer the following questions:

- Why was the article written? The answer to this question identifies the objectives that the policy intends to achieve.
- What rules/actions intended by the policy? And what are the required capabilities required to achieve these rules?
- Who responsible for executing these rules/actions and who will be affected by them?
- When are these rules/actions allowed to be performed?
- Where these rules/actions are applicable? By answering when and where questions the event and scope of the legal policy can be identified.

A legal Policy can be classified as follow:

a) *Business Function*: Identified by article(s) that defines a course of business activities that should be performed in a predefined manner to achieve some business outcomes.

b) *Organization Unit*: Mapped by an article(s) that define an organizational structure and responsibilities.

c) *Technical Function*: Mapped by an article(s) that directly describe an IT resource or system.

Legal Policy Mapping Approaches include the following:

a) *Top-Down Approach*: The top-down approach to policy mapping is performed by scanning and analyzing the administrative law starting from the first article until the last article. For each article try to answer the five whys' questions listed above to extract the Legal policies essential to regulate the operation and services provided by the public enterprise.

b) *Goal-Oriented Approach*: the legal councils identify the main objectives of each administrative law, and for each goal, the team scans the law and extracts the related policies.

3) *Phase (B) Perform legal rules mapping*: The objectives of this phase are analyzing legal policies and laws then extract the intended legal rule, reviewing and validating extracted legal rules with different legal experts and ensuring their correctness and consistency, and finally, update the legal rule catalog. To perform legal rule mapping properly the following concepts should be considered:

- A legal rule is derived from one or many legal policies, in other words, many legal rules can be sequentially implemented to achieve a certain legal policy. A legal rule is also has a business goal and has a scope. A legal rule requires input data to process and has an input event that triggers the execution of the legal rule.
- A legal rule contains an action that is implemented in a business process usually in a form of a business decision.
- A constraint is an assertion that, by one of its properties or a relationship to another concept, such as as a role in

an activity, restricts or reduces the potential representation for a concept. For example, the statement “a beneficiary who under-poverty-line” constrains the set of all possible beneficiaries to the possibly smaller set of only those beneficiaries who are under the poverty line.

- A stakeholder is an entity afforded rights and/or obligations by the law.
- A right refers to one or more actions that deliver a defined stakeholder a certain value or benefit. If a stakeholder is not obligated to perform an action or to receive an action value, called an anti-obligation.
- An obligation refers to one or more actions that are required to be undertaken by a certain stakeholder.
- An anti-right refers to one or more actions that are not permitted to be performed by a certain stakeholder.
- A rule’s action is either a right, obligation or anti-right per our above definitions.

4) *Phase (C) Identify the correlation between extracted policies and business architecture:* Legal policies represent the governance layer that organizes the business functions, therefore linking legal policies with their related capabilities, processes, organization units, and stakeholder will simplify the alignment of these business objects with laws and will result in a law-compliant Information system when these business artifacts mapped to IS. In other words, will help the administrative entity to deliver the right service to the right citizen at the right time. Moreover, will enhance the efficiency and transparency of the public institutions. The correlation between legal policies and business architecture can be illustrated through the analysis of the legal policies catalog and developing the following matrixes:

- Legal policy Mapping to Business Capabilities describes.
- Legal Rule Mapping to Business Process.
- Legal policy Mapping to Organization Structure.
- Legal Rule Mapping to Stakeholder.

5) *Phase (D) Identify the correlation between extracted policies and Information Systems(IS) architecture:* Information systems designed to support business processes in public authorities must conform to the relevant legal acts and regulations. The correlations between business architecture and legal policies should be transferred into technical system requirements and IS should be designed to comply with these requirements. IS architecture is consists of data architecture and application architecture. After identifying the business regulatory compliance requirements through phase (C), the following steps should be performed in this phase to design, a law-compliant IS in a later detailed IS architecture definition cycle using any EA frameworks. Typical dimensions of the

correlations between extracted legal policies and IS architecture include the following:

a) *Define Data Concepts:*

- Extract data concepts from the legal rules.
- Extract the data modalities from the constrains.
- Classify the data concepts (internal or external).

b) *Define Role/Application Function Matrix:*

- Each participant stakeholder with the legal rules should be mapped to an application role.
- Each action assigned to a legal rule should be mapped to an application function.

c) *Define Application Interaction Matrix:*

- Stakeholders and data concepts defined in the legal rule catalog should be classified into internal or external (of the scope of the public authority).
- Each external concept defines a possible integration requirement with external systems.

6) *Phase (E) Identify the correlation between extracted policies and technology architecture:* Technology Architecture consists of software and hardware assets that are used to implement and realize information system solutions, legal policies, and rules that have a direct impact on technology architecture. The correlation between legal policies and technology architecture can be identified as follow:

a) *Availability of the Systems:* Based on the scope and type of services identified by legal policies the availability of the systems can be identified for example the availability of health services should be 24/7, the technology services should grantee the operation of the systems 24 Hours in 7 days each week. The availability of some other public services mandated by law could be only within the official working hours or for a certain time like examination systems or submission of tax declaration requests.

b) *Data Archiving and Retention Plans:* Data retention refers to the storage of transaction data for a certain time. The primary objective in government data retention is traffic analysis and judicial arbitration. Each country has its data retention policies and plans that are defined in its administrative laws.

c) *Network and Communications:* Based application interaction matrix defined in phase D, the requirement of communication lines between the public authority and external entities should be identified, the detailed specifications of these lines can be identified later in the detailed technology architecture cycle of EA practice. The scope of the legal policy also can identify the locations where the required IS should be accessed, thus also implies communication lines requirements.

d) *Security Requirements:* The access rights for data assets can be defined based on the Roles/ application function matrix developed in Phase C.

7) Phase (F) Collect and communicate the suggested law amendments: The object of proposing new law amendments is to improve the effectiveness, efficiency, and fairness of the administrative processes. Architecture practice implemented in Law, business, data, IS and technology phases may propose new procedures designed to afford more time for this function. It is hoped that delays and costs will be reduced and that new prestige will be provided for those who make the decisions. Suggested Law amendments should be handled as follow:

- a) Build the Suggested amendments Catalog.
- b) Update the Catalog with any suggested law amendments during architecture phases (Law, Business, data, IS, and Technology).
- c) Prioritize Law amendments and assess their impact.
- d) Communicate the amendments to the relevant Stakeholders.

B. Law Architecture Meta-Model

In the previous section, a method to create and manage the law architecture artifacts within the government enterprise was defined. At each step, a discussion of architectural work and artifacts was presented such as the legal policy map and legal rule map. The content Meta-model provided here defines a formal structure for the core concepts of the law architecture and their relationships to ensure consistency within the law architecture and to guide the implementation of the law architecture within a public enterprise. Fig. 4 depicts the proposed law architecture Meta-model.

C. Integrating Law Architecture with EA Frameworks

In the context of digital transformation in the public sector, the integration between law architecture and EA frameworks is a natural architectural alignment of two related disciplines. Law architecture represents the mapping of legal policies and rules related to IT architecture while EA provides a guiding framework for business and IT architecture alignment. According to the Federation of Enterprise Architecture Professional Organizations, EA “represents the holistic planning, analysis, design, and implementation for the development and execution of strategy by applying principles and practices to guide organizations through the integration and interoperation of all other architecture domains”[26]. Most EA approaches do agree on the foundational domains, which include:

- Business Architecture.
- Information Systems (Application- Data) Architecture.
- Technical Architecture.

For each architectural domain, there is an associated set of Law related concerns, each set can be described by law architecture models that define the legal rules governing that domain. Integrating Law architecture with EA offers the following benefits:

- Brings a robust, Law-centric focus to the practice of EA in the public sector.
- Integrates all aspects of law compliance through all layers of the IT solution.
- Facilitates the adoption and implementation of new law amendments in public enterprises.

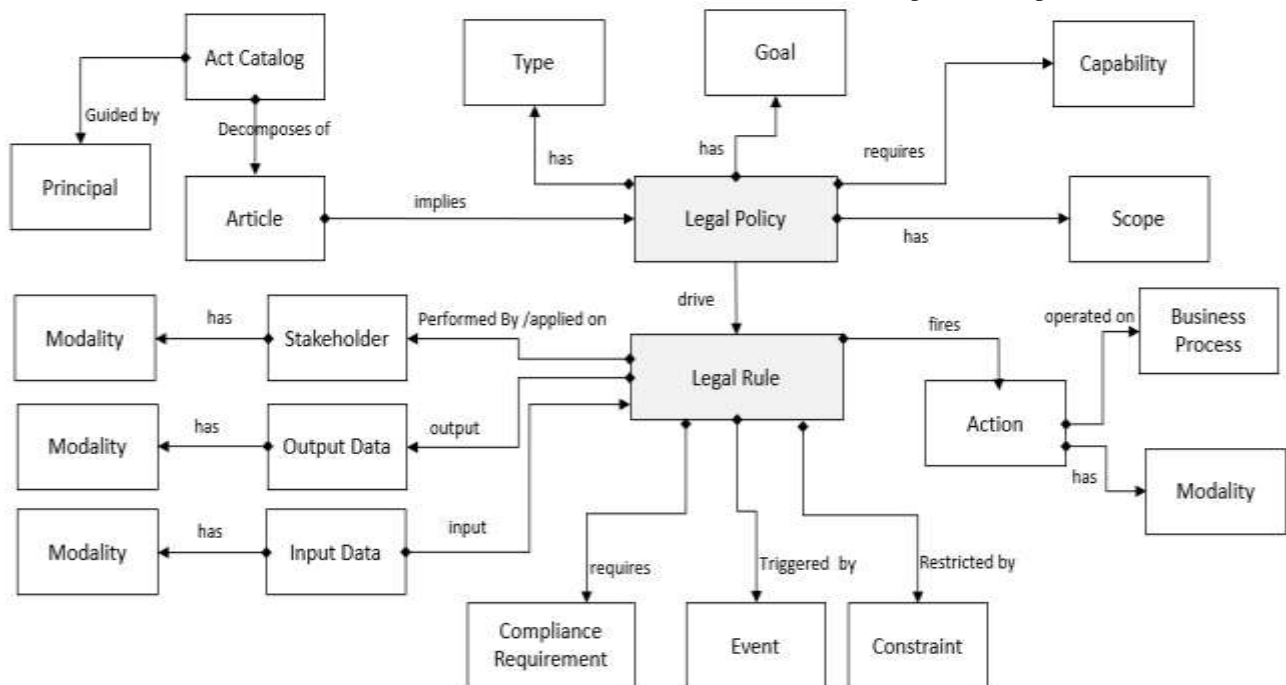

Fig. 4. Law Architecture Meta-Model.

TOGAF [27] is an architecture framework. TOGAF that is widely used by many EA practitioners within the public sector was selected here to demonstrate the capability of our proposed framework to integrate with EA frameworks. At the core of the TOGAF framework is the architecture development method (ADM) that “provides the methods and tools for assisting in the acceptance, production, use, and maintenance of enterprise architecture. It is based on an iterative process model supported by best practices and a re-usable set of existing architecture assets” [20]. The proposed Law Architecture Framework (LAF) here, has a Law-architecture-development-method (LADM) that provides the methods for assisting in the production and maintenance of law architecture. The ADM of the TOGAF can be adapted to integrate with the LADM of our proposed LAF.

Fig. 5 depicts the ADM in a larger form and Fig. 6 illustrates how TOGAF ADM can be integrated with LADM. The Suggested ADM Adaptation to be integrated with the proposed LADM can be listed as follow:

1) After the architecture vision (Phase A) of the ADM: Then the LADM should be initiated and completed according to the detailed description listed above.

2) After the end of the LADM: Then the TOGAF Business architecture phase should be performed.

3) The result from LADM Phase (A): Should be added as an input to the TOGAF Business architecture phase.

4) One of the objectives of the TOGAF business architecture phase is to develop the target business architecture, the target business architecture may have any suggested business process engineering that is based on some law amendments suggestions, these amendments should be linked with LADM Phase (F), Collect and Communicate the suggested Law amendments .

5) After the completion of the TOGAF business architecture phase, the information systems architecture phase should be initiated by adding the result from the LADM phase (D) to the inputs of that phase of the ADM.

6) One of the objectives of the TOGAF IS architecture phase is to develop the target IS architecture, the target IS architecture may have any suggested IS improvements is based on some law amendments suggestions, these amendments should be linked with LADM Phase (F).

7) After the completion of the TOGAF IS architecture phase, the technology architecture phase should be initiated by adding the result from LADM Phase (E) to the inputs of the phase.

8) Any suggested technology improvements that require some law amendments suggestions, should be linked with LADM Phase (F)

9) The TOGAF ADM phases will be completed then as defined in TOGAF Standard.

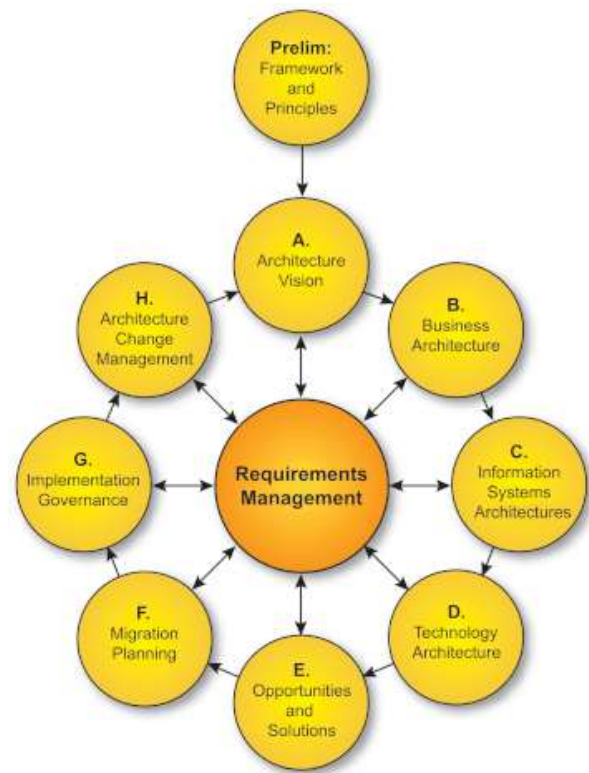

Fig. 5. ADM Process of the TOGAF Framework.

Fig. 6. Adapting the TOGAF ADM to Integrate with LADM.

IV. HEALTHCARE REFORM IN EGYPT THROUGH THE LENS OF THE LAW ARCHITECTURE: A CASE STUDY

TABLE II. UHI PROJECT-SPECIFIC ACTS CATALOG

A. Universal Health Insurance (UHI) Law at a Glance

The Egyptian Parliament endorsed a fresh law on universal health coverage that was formally promulgated on January 11, 2018, by the President. The Universal Health Insurance Law (2/2018) is regarded as an unprecedented effort to control the healthcare industry in Egypt, expanding the extensive protection of healthcare to every industry of culture. Healthcare was dealt with on a case-by-case ground before this law. The 27 governorates of Egypt will be split into six regional fields when applying the fresh law, and the law will then be implemented gradually over the next 15 years. Existing laws and regulations in the health insurance sector will stay in effect during the transformation era. Subscription to the new health insurance scheme will be compulsory for all Egyptians living in the Arab Republic of Egypt and free for Egyptians employed or remaining onboard with their relatives. Fees are laid by revenue and extra financing sources to include tariffs on the tobacco industry and other extra regions. The state has dedicated to offering the strategy to about 25 percent of the population who are unable to afford it free of cost.

B. Defining the UHI Law Architecture based on the LADM

The Ministry of Health has formed a technical committee including representatives from the Ministry of Communications and Information Technology (MCIT), the Ministry of Finance, and a consortium of experienced international and local experts. The mandate of this committee was to explore how to realize the objectives of the UHI law, study each use case defined in the law, and define the technical specification of the required systems. As the corresponding author of this manuscript was one of the enterprise architecture team assigned by MCIT to achieve the technical design and architecture of the required systems. The architecture team depended on analyzing the UHI law as the prime source of information in identifying the high-level system requirements. By following the steps and guidelines of the LADM proposed above and illustrated in Fig. 2, the team analyzed the UHI available laws and identified the law architecture of the UHI program before performing a detailed enterprise architecture activity, the extracted law architecture models resulted from this exercise can be illustrated as follow:

1) *Law architecture initiation*: During this phase, the law architecture work will follow the principles identified in section (III), and Table II represents the Project-Specific Acts Catalog that stores the core administrative laws related to the UHI project.

2) *Phase (A) Perform legal policy mapping*: The UHI law was analyzed, and 10 legal policies and 23 related legal rules were extracted as shown in Table III. To understand the main elements in the legal policy and their relationships to each other the legal policy model was suggested. For example, article (41) identified three important legal policies as shown in Fig. 7.

#	Act No.	Subject	Issuing Date	Issuing Authority
1	No.2 of 2018	The universal health insurance system law	Jan. 2008	The Parliament
2	Bylaw-No.909 of 2018	The executive regulations of the universal health insurance system law promulgated by law No. 2 of 2018	May.2008	The Prime Minister
3	No.707 of 2018	Setting criteria for targeting those below the poverty line in applying the provisions of the Universal Health Insurance Law	April 2018	The Prime Minister
4	No.2257 of 2020	Devolution of some medical assets in the governorates of Port Said and Luxor to the Public Health Care Authority in preparation for their inclusion in the Universal health insurance system	Nov. 2020	The Prime Minister
5	No.2273 of 2020	Determinants of patients with chronic diseases and tumors and controls for their exemption from Universal health insurance premiums	Nov. 2020	The Prime Minister

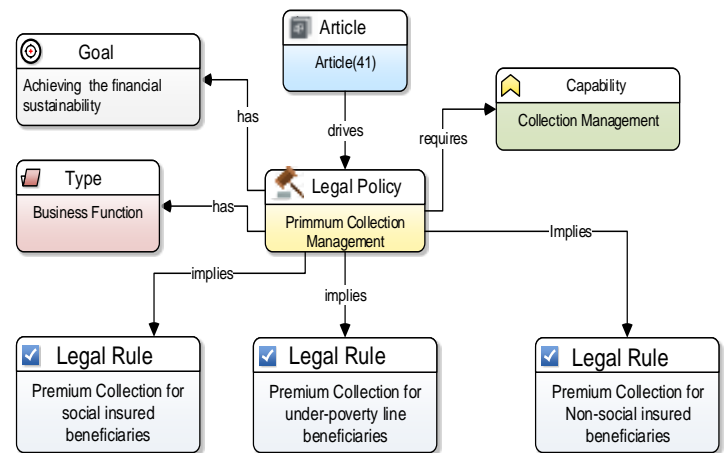

Fig. 7. Model of Premium Collection Management Policy.

3) *Phase (B) Perform legal rule mapping*: The legal policy catalog listed below in Table III was analyzed versus the UHI law to extract and model the related legal rules, Fig. 8 represents a sample legal rule model that represents “Premium Collection for Social Insured Beneficiaries”. Each extracted legal rule was modeled to provide a visualized artifact that can be easily understood by different business and IT stakeholders.

TABLE III. LEGAL POLICY CATALOG OF THE UHI PROJECT

Policy ID	Policy Name	Type	Ref. Article	Req. capability	Goal	Legal Rules
LP_01	Premium Collection Management	Business Function	41	Collection Management	Collection of Financial resources required to achieve financial sustainability	<ul style="list-style-type: none"> Premium Collection for social insured beneficiaries Premium Collection for under-poverty line beneficiaries Premium Collection for Non-social insured beneficiaries
LP_02	Premium calculation	Business Function	41	Collection Management	Collection of Financial resources required to achieve financial sustainability	<ul style="list-style-type: none"> Premium calculation for public employees Premium calculation for private-sector employees Premium calculation for Self Employed Premium calculation for pensioner premium calculation for pension entitled premium calculation for beneficiaries under the poverty line
LP_03	Board of Directors structure of UHI authority	organization structure	5	Program Management	Defining the structure and responsibility of the authority management	<ul style="list-style-type: none"> UHI authority board of directors Duration of the board
LP_05	Disability injuries policy	Business Function	13	Beneficiary management	Defining the process of issuing a disability certificate	<ul style="list-style-type: none"> disability certificate issuing responsibility disability certificate notification responsibility
LP_06	Co-payment policy	Business Function	table (3)	<ul style="list-style-type: none"> Health Service Management Collection Management 	Define the beneficiaries' contributions for health services	<ul style="list-style-type: none"> co-payment value for home visits co-payment value for medicine co-payment value for scans co-payment value for medical tests co-payment value for inpatient services
LP_07	Military recruits handling policy		53	Beneficiary management	Managing the services for the military people	<ul style="list-style-type: none"> Military recruits handling procedures
LP_08	UHI website and Database	Technical Function	57 - bylaw	IT Management	Building a website and DB for UHI Authority	<ul style="list-style-type: none"> building a website and defining access rights
LP_09	National Social Insurance Authority responsibility	Technical Function	57 - bylaw	IT Management	Feeding the authority's database with the necessary data for all those subject to the registered social insurance laws and their families.	<ul style="list-style-type: none"> feeding the authority's database with social insured people and their families
LP_10	work injuries policy	Business Function	12	Beneficiary Management	Regulate the work injury treatment process	<ul style="list-style-type: none"> work injury notification procedures work injury treatment

TABLE IV. LEGAL POLICY / CAPABILITIES MATRIX

Policy Name	Business capability
Premium Collection Management	Collection Management
Premium calculation	Collection Management
Board of Directors structure of UHI authority	Program Management
Disability injuries policy	Beneficiary management
Co-payment policy	Service Management
Military recruits handling policy	Beneficiary Management
UHI website and Database	IT Management
National Social Insurance Authority responsibility	IT Management

1) Phase (C) identify the correlation between legal policies business architecture:

a) *Develop legal Policy/Capabilities Matrix:* Table IV. depicts legal policy/capabilities matrix.

b) *Legal Rule/Business Process Matrix:* Table V depicts legal rule/business process matrix.

TABLE V. LEGAL RULE / BUSINESS PROCESS MATRIX

Legal Rule	Business Process
Premium Collection for social insured beneficiaries	Manage accounts receivable Funds
disability certificate issuing responsibility	Authorize Medical Service
co-payment value for home visits	Manage Rate setting
Military recruits handling procedures	Manage Treatment plan
Feeding the authority's database with social insured people and their families	Manage Integration with external entities
work injury notification procedures	Manage Treatment plan

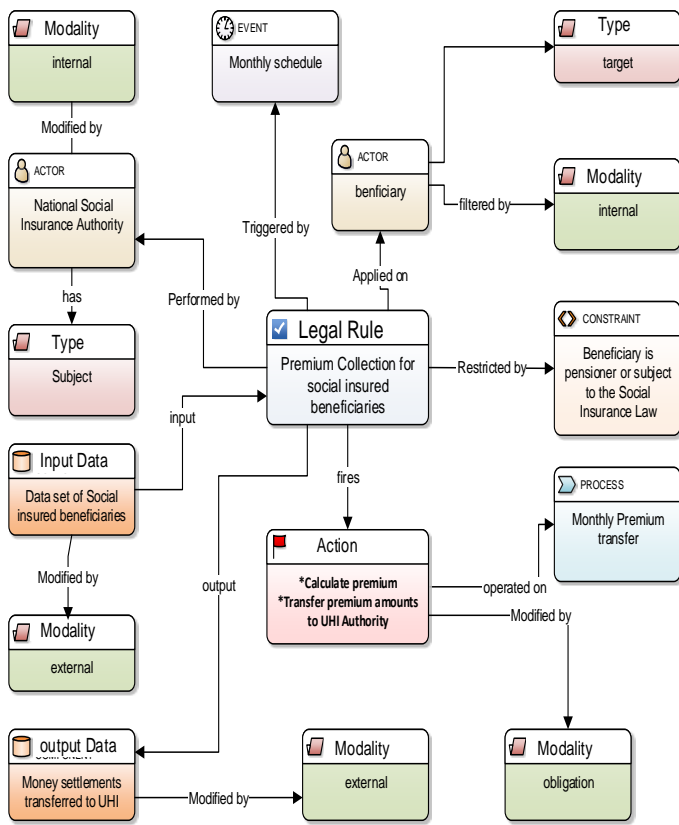

Fig. 8. Legal Rule Mode: Premium Collection for Social Insured Beneficiaries.

c) Stakeholder Mapping: By analyzing the legal policy and rules catalogs several system use cases can be identified in terms of obligations and rights as illustrated in the below Fig. 9.

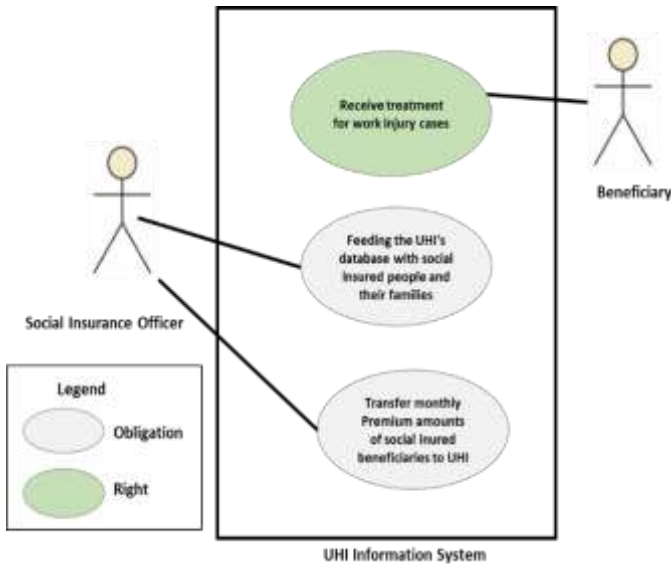

Fig. 9. A Legal Use Case Diagram of the UHI Project.

2) Phase (D) Legal Policy/Information systems Correlation:

a) Data Concepts Extracted from the Law: By analyzing the legal policy and rules catalogs the data concept catalog that is related to the IS was created, the most important data concept related to our extracted above policies is the beneficiary, and by analyzing the legal rule's actions and constraints we deduced that the beneficiary data should be segmented based on the following features shown in Fig. 10.

b) Application Interaction Matrix: By classifying the data concepts as internal or external to the UHI authority, the external data concepts define an integration requirement. Moreover, analyzing the actions related to the legal rules can also identify integration requirements. Following these procedures, the following integration requirements were identified as below in Fig. 11 and Table VI:

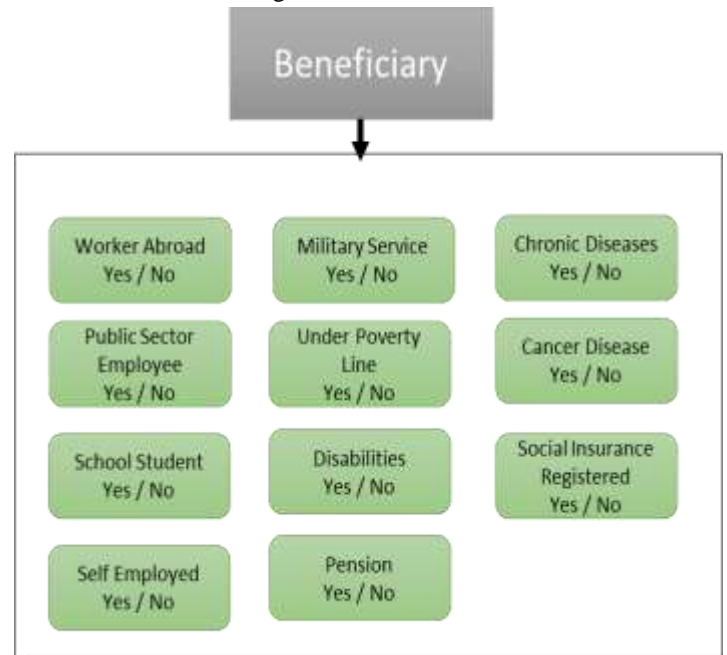

Fig. 10. Beneficiary Segmentation Features.

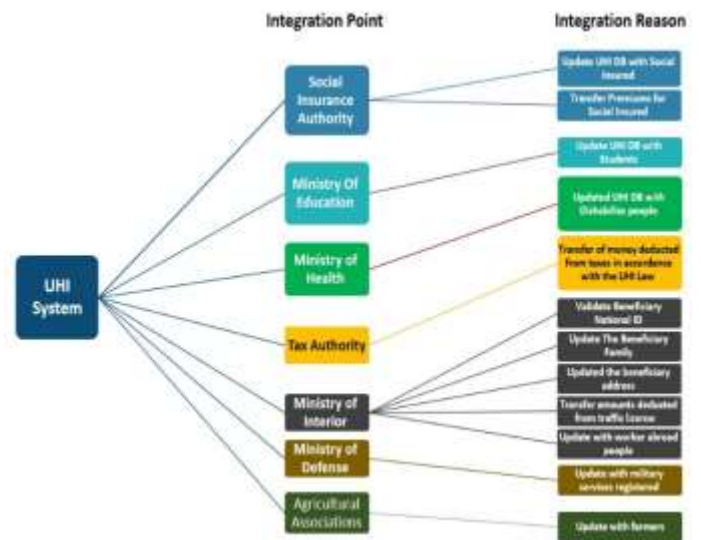

Fig. 11. Application Interaction Diagram.

TABLE VI. APPLICATION INTERACTION MATRIX

#	Target System (External Systems)	Integration Reasons
1	Social Insurance Authority	<ul style="list-style-type: none">• Update UHI DB with Social Insured• Transfer Premiums for Social Insured
2	Ministry of Education	<ul style="list-style-type: none">• Update UHI DB with Students
3	Ministry of Health	<ul style="list-style-type: none">• Updated UHI DB with Dishabilles people
4	Tax Authority	<ul style="list-style-type: none">• Transfer of money deducted from taxes under the UHI Law
5	Ministry of Interior	<ul style="list-style-type: none">• Validate Beneficiary National ID• Update the Beneficiary Family• Updated the beneficiary address• Transfer amounts deducted from traffic license• Update with worker abroad people
6	Ministry of Defense	<ul style="list-style-type: none">• Update with military services registered
7	Agricultural Associations	<ul style="list-style-type: none">• Update UHI system with farmers and their families
8	Ministry of Social Solidarity	<ul style="list-style-type: none">• Update UHI System with under-poverty-line people and their families

3) Phase (E) Legal Policy / Technology architecture correlation: The following technology requirements were extracted based on the legal policy catalog and the regulatory compliance requirements catalog was updated as following Table VII:

TABLE VII. SAMPLE OF REGULATORY REQUIRMENTS CATALOG

#	Requirement	Type	Rational	Architecture Domain
1	The system and servers should operate at 24/7 uptime.	availability	The system provides healthcare services	Technology
2	all changes to a financial database must be recorded in a trace file with before and after values	Audit Tracing	Enable financial transactions tracing	Technology
3	All communications between the UHI system and Social Insurance System	Communication	Respond to system integration requirements	Technology
4	Keep a record of all transactions for 5 years	Data Retention	Mandated by law	Technology

V. DISCUSSION

As presented above, in the introduced case study, the UHI law was the prime source of information that the technical committee depended on for extracting the high-level specifications of the digital transformation solution required for the UHI program. EA frameworks lack a detailed methodology for analyzing and modeling laws, thus our proposed law architecture framework suits these types of problems where the

core business processes and services are highly regulated by laws. The law architecture framework offers the ability to visualize what decoupling and divesting laws and how it impacts various aspects of the public ecosystem. This was illustrated through the use case as the legal policies and rules were extracted from the UHI law, in addition to the relationship between these rules and business capabilities, processes, IS, data concepts, and technical specifications based on the proposed LADM that represents the heart of the proposed law architecture framework. The application of the proposed framework supported the UHI program in extracting the regulatory compliance requirements from the law and supported the design of regulatory-compliant system.

Law architecture does not stand alone in a public enterprise. Several complementary or ancillary frameworks or disciplines may exist within a public enterprise. Each of these frameworks may have its focus. The success and maturity of law architecture are influenced by its ability to integrate and align with each of these disciplines and frameworks. Another limitation in our proposed framework is the LADM proposed for extracting the legal rules and policies and their correlations with other artifacts in the public enterprise model is a manual task. This is because ambiguity exists in the laws that require the investigation and validation of legal experts.

VI. CONCLUSIONS

In recent years, there have been various contributions to deal with law compliance problem, None of the previously surveyed work in the state of the art section takes an (i) generic approach to law compliance management, (ii) seeks to integrate with EA frameworks, (iii) allows declarative modeling of policies and rules while separating these two concepts and, (iv) introduces a new concept and formal definition for the law architecture and, (v) supports for traceability by a set of links to establish between legal policies and enterprise models. Our claim through this work is that our proposed framework allows for achieving these goals and overcomes these limitations:

- Domain-independence: a solution to the problem of IS requirements engineering to comply with all applicable administrative laws.
- Domain-variability: a solution that takes into account the variability of possible legal policies and rules applied in different public sector services.
- Flexible-integration: a solution that takes into consideration the integration with other EA frameworks to achieve a law-compliant public enterprise model.
- Machine-readable: a solution that can be easily translated into an ontology model.
- Knowledge-gap: a solution that covers the knowledge gap between the technical architects and the legal experts.

Finally, the applicability of our proposed framework is shown and validated through a case study. Subject matter experts of the legal domain also evaluated the extracted legal policies and rules during the implementation of the case study.

VII. FUTURE WORK

In this paper, we did not cover all components of the proposed law architecture framework, future work will include a detailed description of other framework components such as compliance management and ontology representation of the framework metamodel. Moreover, the capability of our framework to integrate with other EA frameworks will be investigated.

ACKNOWLEDGMENT

The activities described in our case study were supervised by Dr. Khaled El-Attar, Vice Minister - The Egyptian Ministry of Communications and Information Technology, as part of the Universal Health Insurance program implementation. We also dedicate this work to the deceased Prof. Hawaf Abdel-Hakim for his kindness, help, and assistance.

Abstract—Microorganisms is a Year 6 Science subject that primary school students find considerably less attractive because of the enormous facts that require them to have good imaginary skills to understand. Only limited applications are available on smartphones as tools to learn subjects, especially Science, Technology, Engineering and Mathematics (STEM). Since the young generation is very much into current technology, there is a need to develop an application to gain students' interest and improve their understanding of microorganisms. Therefore, a microorganism learning application that combines augmented reality (AR) and gamification called Microorganisms was developed. The Microorganisms prototype includes two modules; learning and training. The learning modules use AR technology that scan marker images to display a digital layer of microorganisms in three dimensions (3D). Meanwhile, the training module is represented through gamification consisting of quiz questions, a timer, and a score. The application was designed using Agile methodology and developed using various software such as Unity, Autodesk 3ds Max, Vuforia, and Firebase. Ten respondents, nine students and one teacher in a primary school, assessed the prototype through experimental testing. The results showed that, on average, the user satisfaction value was 4.6 out of 5. Thus, the Microorganisms application based on AR and gamification can be considered a good learning tool for primary school students to learn about micro-organisms.

Keywords—Augmented reality; digital game-based learning (DGBL); game; learning tool; microorganisms; usability testing

I. INTRODUCTION

Students have been learning the Science subject from a young age, not only as a requirement in school but also for student comprehension. Microorganisms are one of the sub-topics that Year 6 students learn in primary school. The students need to realise that microorganisms, such as viruses, are tiny and can only be seen through a microscope and cannot be seen with the naked eye. This concept becomes more difficult for students to understand and appreciate the design and structure of the microorganism itself. Most students and even parents consider that the Science subject or field is not easy to understand [1]. Moreover, scientific notes are dense with writing and facts, which causes students to lose interest in learning and understanding the topic of microorganisms. Thus, it is essential to create a learning tool that can grab students' attention and realise that Science is an exciting subject to learn. Factors that can motivate students to learn include presenting the content in various ways, such as sound, visualisation, and

animation [2]. Specifically, it is more stimulating for the students to get to see the microorganisms in 3D.

Augmented reality (AR) is a current technological medium that offers a unique opportunity that combines the physical and virtual worlds [3]. AR works interactively and in real-time, aligns real and virtual objects [4]. Many applications relating to education have applied AR in their design. For example, the AR Marine Scientific program aims to create awareness of marine environments among lower-grade primary school students. It was identified that the application could help low academic achievers improve their learning performance [5]. Besides, AR (as a learning supplement) has also been used in research to evaluate and compare Biology students learning via AR and printed books, in which it was found that both methods indeed helped enhance the learning of Biology [6]. Furthermore, some AR applications include a game element to attract learners' attention. Gaming is significantly related to the young generation, which generally consists of avid gamers. Therefore, a good learning tool that combines AR technology and gamification in the application design may help students learn better [7].

Thus, this research aims to design and develop an application as a learning tool to learn the microorganism topic, especially for primary school students, with the integration of AR technology and gamification in the design. First, this research paper discusses the current tools in the market for learning the Microorganism topic and the AR applications that have been developed by other researchers in a similar area, followed by the present research methodology, including the framework and the development of the Microorganism application prototype. Sections 3 to 6 discuss the process of evaluating the application, Microorganisms. Finally, the paper reviews the evaluation results and discusses the development of the Microorganisms application.

II. LEARNING TOOL FOR MICROORGANISMS

Learning Science subjects can be frustrating for some people because they cannot see or imagine how certain scientific phenomena work. Hence, many learning tools have been created to help enhance learning activities, especially science subjects or topics. Some tool designs may suit particular aims and can be used by others facing similar issues in learning.

One study compared the learning performance between students learning biology using an AR application and a

printed book [6]. Their study showed no difference in understanding and remembering factors between the students in both categories. However, the students that used the AR application showed a better learning attitude than the students who used printed books. However, the study gave no detailed explanation of the application design.

Meanwhile, another work [8] proposed a visual aid for students and practitioners to learn about antimicrobials in Microorganisms in the form of a video. The support was aimed at adult learners, and based on the result analysis, the tool indeed helped improve user understanding. Moreover, the video presentation is an excellent method to assist students in learning the topic. Nevertheless, it can still be improved by using 3D or even four dimensions so that the organism could be seen from a different angle.

Another study created a learning tool for Microorganisms specifically to learn the mushroom structure. The study applied AR technology to display the design in 3D [9]. Based on the evaluation process, it was identified that the tool offered a reasonable satisfaction rate among users. Nevertheless, the application focused on AR and did not include any game element in the design. Also, the application content is not similar to the primary school syllabus in Malaysia. Still, it can be used as a reference for local students to learn the topic beyond that covered in school.

Applications with AR features have been developed since the 2000s. Many AR applications help students to improve their learning performance, especially in subjects considered challenging or less interesting; for example, ATHYNOS, a serious AR game for children with Dyscalculia, was developed to help them learn mathematics. ATHYNOS was identified to be able to help students with calculation disorders and, based on the evaluation results, the students took less time to understand the subject [10]. Another application was also designed and developed to learn Kanji, considered one of the most challenging writing systems. Called Dragon Tale, the adventure game with AR features was designed to help students learn Kanji interactively [11]. Similar research also aimed to help students in Thailand to learn the same writing system [12]. Hence, the study designed an AR application that improved Kanji skills by more than 41%.

According to some studies [6], [8], [9], a learning application should consider including multiple media to attract students' attention, such as video, audio, graphic, text and animation. The lengthy and dense text should be avoided as much as possible. The element of 3D that is activated through AR features can be one of the fun factors in learning [13]. It is also essential to assess the student's comprehension; thus, questions or quizzes should be attached at each lesson in the application [6], [8], [14]. Since gaming is very much connected to the young generation, the assessment can be presented in a game where students can compete with other players. The current problem is identified based on real scenarios at local schools where students are having a tough time learning the subject. Since there are limited learning materials that suit the syllabus, a research project is conducted to develop a learning application for primary school students to learn Microbiology.

III. METHODOLOGY

The research methodology was divided into three main phases: 1) Conceptual, 2) Design and Development, and 3) Evaluation. The conceptual phase involved the process of analysing the current problems and project requirements. The second phase, Design and Development, comprised designing the application and developing the prototype. At the same time, the last phase involved evaluating the prototype and verifying the application design. The overall research method was adapted from the agile methodology that is usually applied in software development. In mobile software engineering, this methodology is essential since the software is constantly changing and evolving based on users' immediate needs [15]. Table I shows the phases and research activities for this study.

In phase 1, current issues are identified and based on past studies, the essential elements are recognised. Thus, the elements that are included in the application are multimedia like text, graphic, audio, video and animation in 3D. The application also includes AR and gaming feature as fun factors to draw students' interest.

In phase 2, the application is design and developed using multiple software and briefly describe in the following subtopic. While in phase 3, the process of evaluation is discussed concisely in Section IV.

A. Framework

There are two modules in the Microorganisms application, learning and training, which are indirectly interconnected. The student can browse through the learning modules or choose to answer questions in the training modules at any time. The learning module is aimed to represent the content of Microorganisms in 3D with the support of Augmented Reality technology. Five topics were included in the learning modules: Fungi, Bacteria, Viruses, Protozoa, and Algae. Students can choose any topic to learn by clicking on the listed buttons labelled with the topic's name. In addition, a button labelled AR is also included in each topic to represent the content of the specific topic in 3D. The student must scan a specialised marker to activate the AR function. Besides, a video presentation of each topic is also included in the learning module.

TABLE I. RESEARCH ACTIVITY

Phase	Research Activity	Output
1. Conceptual	Analyse the current problem Get initial information from primary school teachers and parents Analyse similar studies	Component
2. Design and Development	Design the proposed framework Identify software requirements Develop the application prototype	Application prototype
3. Evaluation	Functional testing Usability testing	Verified application framework

The training module is aimed at testing student knowledge on the same topics as the learning module. In the training module, some questions are grouped into four difficulty levels to imitate the gamification structure. The students are given a time limit to answer the questions, and at the end of the training session, the student's individual score is displayed together with their ranking. Fig. 1 shows the application framework for Microorganisms.

The application prototype for Microorganisms was designed based on an application framework. Adobe Photoshop and Unity software were used to create the application interface design. Meanwhile, 3D models for the Augmented Reality modules were developed using Autodesk 3ds Max software. The Firebase database was used to store user data and the scores obtained in the training module. The languages used to program the application were C# and PHP. Fig. 2 to Fig. 9 shows the interface design for Microorganisms.

B. Prototype

The application prototype for Microorganisms was designed based on an application framework. Adobe Photoshop and Unity software were used to create the application interface design. Meanwhile, 3D models for the Augmented Reality modules were developed using Autodesk 3ds Max software. The Firebase database was used to store user data and the scores obtained in the training module. The languages used to program the application were C# and PHP. Fig. 2 to Fig. 9 show the interface design for Microorganisms.

Fig. 2 shows the main page of the application that consists of three buttons, Masuk (Login), Tetapan (Settings), and Keluar (Exit) buttons. Users need to select the login button to go to the category selection page. Users can also choose the settings button to set the voice settings and see the how-to-play guide while pressing the exit button to stop the application.

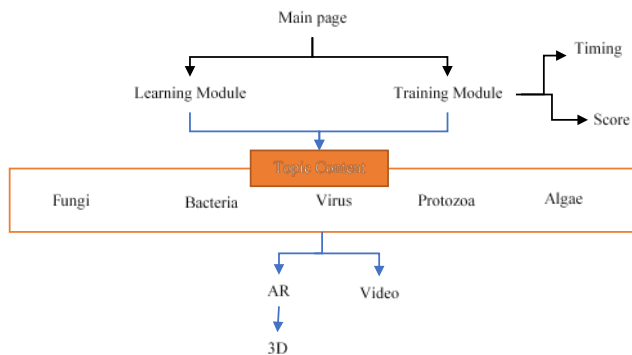

Fig. 1. Application Framework.

Fig. 2. Main Page.

Fig. 3 shows the category page where users can select the Belajar (Note) button to view notes related to Microorganisms or the Kuiz (Quiz) button to answer quizzes. Users are also allowed to return to the main page by clicking the home button at the top of the page.

Fig. 4 shows the Notes page where the users can select the Fungi, Bacteria, Viruses, Protozoa, and Algae buttons to view notes related to the chosen type of microorganism. There are also buttons for Jenis (Type), Proses Hidup (Processes), Kegunaan (Uses), Keburukan (Disadvantages), and Pencegahan (Prevention). Users can also view the 3D model in AR by clicking on the AR button. There is also a back button to return to the category selection page.

Fig.5 shows a video page with similar buttons in the Notes page to allow users to view related video descriptions in video format. There is also a back button to return to the category selection page.

The application can access the users' camera to allow users to scan the designed marker. Fig. 6 shows the page that displays the 3D model where users can select the Fungi, Bacteria, Viruses, Protozoa and Algae buttons to view 3D models related to the chosen type of microorganism. There is also a back button to return to the Notes page.

Fig. 6. 3D Model in Augmented Reality.

Fig. 7 shows the game level where users have to answer the quiz questions in order to move to a higher rank.

Fig. 7. Level of Difficulties in the Game.

There is a score on the left side of each question. All questions are multiple-choice, like in Fig. 8. There is a time limit to answer each question.

Fig. 8. Example of Quiz.

Fig. 9 shows the scoreboard page to displays the five highest user scores in ascending order.

Fig. 9. Scoreboard.

IV. EVALUATION

Evaluation was conducted via two sets of questionnaires to obtain feedback from the users of the Microorganisms application. The testing process involved ten respondents, consisting of nine students and one Science teacher. The questionnaire consisted of three parts: to test the function of the application and a non-functional variable, usability.

A. Functional Testing

In functional testing, Microorganism was tested to identify any problems in operating the application. The functions in the learning modules, including browsing the content using the buttons, the scan markers to test the AR function, and watching the 3D and video content, were tested. Meanwhile, in the training modules, the testing was done by browsing through the game questions of different difficulties, answering some questions, and getting feedback and the game score. Functional testing was done via a simple walkthrough method to ensure that all features such as the buttons, notes, video, 3D model, and AR marker worked well. Four significant phases were included in the functional testing, as described in Table II, while Table III shows one of the detailed procedures in the functional testing. The functional testing procedure was adapted from a past study [16]. Each team member in the project did the testing. No issue was found in all four phases of functional testing. The status column in Table II indicates a pass to show that the application features are working well.

TABLE II. PHASES IN FUNCTIONAL TESTING

Phase	Description	Process	Status
1	Display notes and video	Manual	Pass
2	Display 3D model	Manual	Pass
3	Play game	Manual	Pass
4	Display scoreboard	Manual	Pass

TABLE III. EXAMPLE OF DETAILED FUNCTIONAL TESTING PROCEDURE IN PHASE 2

Criterion	Description
Objective	To ensure the 3D module works well. It tests whether an application can display a 3D model of the microorganism and respond correctly to user interactions.
Pre-requirement	Markers for AR for users to scan.
Testing Procedure	<ol style="list-style-type: none"> 1. Install the application on a mobile device. 2. Run the application. 3. Select the "Login" button – The application displays the learn and quiz menu page. 4. Select the "Learn" button – The application displays the learning notes page. 5. Select the "AR" button available on each type of microorganism – The application displays the camera mode. 6. Scan the marker image as a target image – The application displays the model and name of the microorganism.
Exit steps	<ol style="list-style-type: none"> 1. Press the home button. 2. The application returns to the main page. 3. Press the "Exit" button.

B. Usability and Effectiveness Evaluation

Ten respondents were asked to evaluate the application and then answer a set of questions using a Likert scale to assess the usability of the Microorganisms application. According to [17], responses from five to ten participants are enough in experimental evaluation. The testing was conducted via an online medium to obtain feedback from the respondents about the usability of Microorganisms. Then, .apk files were uploaded onto Google Drive and the URL distributed to the respondents. Feedback from the respondents was collected via Google Forms online questionnaire. The usability evaluation was done to ensure that the application is in line with what users want by observing how users use the application. There are ten questions in total, with the items adapted from a past study [18]. Based on the descriptive analysis, the total mean value for usability was 4.26 and 4.56 for effectiveness. The detail of the usability and effectiveness result is shown in Table IV.

TABLE IV. USABILITY AND EFFECTIVENESS RESULT

No.	Factor	Item	Mean
1	Usability	User-friendly	4.3
2	Usability	Clear instruction	4.5
3	Usability	Easy to use	3.9
4	Usability	Button works well	4.2
5	Usability	Attractive interface	4.4
6	Effectiveness	Easy to understand	4.4
7	Effectiveness	AR is interesting	4.5
8	Effectiveness	Questions in quizzes are understandable	4.5
9	Effectiveness	Enjoyable	4.8
10	Effectiveness	Suitable	4.6

V. DISCUSSION AND CONCLUSION

The initiative to begin the research project came from a teacher in a local primary school who had trouble teaching the microorganism topic. The teacher had problems showing the details of the microorganism to students since the school had no lab equipment. Reference books were the only resource and non-interactive, so it wasn't easy to attract students' interest in learning the topic. Thus, Microorganisms' application was developed as a learning tool to help the students understand the topic and the teacher to teach the subject. It was purposely developed in a mobile platform since most of the students' parents have mobile gadgets that the students can use not only at school or with the teacher but anywhere. The teacher specifically prepared the content of the notes, and the representation of the notes was redesigned by the researcher with the teacher's approval and verification.

To make the notes more interesting, visualising the topic can be a good method to apply [19]. Thus, features of AR and 3D models were added to the mobile application. These features have been identified to hold students' attention in the subject matter [11], [12], [20], [21]. The researchers argued that AR with 3D models creates new experiences and provides new teaching methods, learning, and research [13], [21].

Hence, the AR feature with a 3D model was designed as part of the application to grasp students' attention and interest to learn the topic. Since the topic is part of Science, Technology, Engineering and Mathematics (STEM), the application can also be considered as one of the initiatives to expose students to STEM concepts based on real-world situations.

Designing for a generation exposed to current technology and addiction, gamification has now become a compulsory element in learning tools [22]. Many learning tools that integrate gaming elements in their content aim to increase enjoyment in learning and measure student comprehension of the subject [10], [11]. Also, some studies emphasised the vital role of games in knowledge acquisition and content understanding [14], [22]. The study found that many learning tools have succeeded in delivering knowledge by incorporating gaming into their devices. Consequently, Microorganisms was developed with AR and layering of 3D models, with game element integration.

The process of designing and developing Microorganisms took seven months, while another three months were required to evaluate its features, usability, and effectiveness. The evaluation of the application features, known as functional testing, was done via a simple walkthrough method, while the evaluation of usability and effectiveness was done via an online questionnaire. Based on the results of the assessments, the Microorganisms application received good feedback from all respondents, with high mean values for all items. Therefore, this application can be used in class as a learning tool for teachers to teach their students the same topic.

There are some limitations to this research project; firstly, many respondents are negligible due to an imbalance in the number of students and teachers. In the future, the number of respondents will be increased to balance between both types of users (student and teacher). Secondly, the set of questions used to evaluate Microorganisms' usability is simple, so the researchers were unable to obtain detailed feedback from the respondents that could have further enhanced the application's design.

VI. FUTURE WORKS

Based on the discussion above, this research will continuously improve the diverse representation of the microorganism notes, adding more gamification elements, such as group competitions, and setting the application in an iOS platform. At the same time, future research will focus more on the importance of suitable methods and sufficient respondents to evaluate the application. The proper method of evaluation will uncover a significant or insignificant aspect of any application [23], [24], [25].

Abstract—The advancement of technology has led to the development of an artificial intelligence-based healthcare-related application that can be easily accessed and used to assist people in lifestyle intervention for preventing the development of non-communicable diseases (NCDs). Previous research suggested that users are demanding a more emotional evocative user interface design. However, most of the time, it has been ignored due to lack of a model that could be referred in developing emotional evocative user interface design. This creates a gap in the user interface design that could lead to the ineffectiveness of content delivery in the NCD domain. This paper aims to investigate emotion traits and their relationship with user interface design for lifestyle intervention. Kansei Engineering method was applied to determine the dimensions for constructing emotional evocative user interface design. Data analysis was done using SPSS statistic tool and the result showed the emotional concepts that are significant and impactful towards user interface design for lifestyle intervention in NCD domain. The outcome of this research shall create new research fields that incorporate multi research domain including user interface design and emotions.

Keywords—Emotion; Kansei; non-communicable diseases; lifestyle intervention; user-interface design

I. INTRODUCTION

Most technologies in the healthcare domain user interface design are equipped with a clear and simple interaction approach that includes a text and button. However, the new display technology paradigm has shifted to touch-screen or semi-transparent display, allowing a new approach for visual human-machine interaction which more complex and efficient. The emergence of the new display technologies and artificial intelligence (AI) resulted in the adaptation of devices interface navigation that depending on the user's behaviour [1]. Recently, the chatbot has seemed to be a potential tool in communicating the context of healthcare effectively and improved patient education and treatment compliance[2] with an abundance of technologies that have been developed to assist people on a daily basis. However, affective interaction principles are not able to be realized yet [3]. Previous research showed that users are demanding for more emotional evocative user interface design [4]. Nevertheless, most of the time, it has been ignored due to the lack of a model that could be referred to in developing user interface design (UID) that is

emotionally evocative[5]. This creates a gap in the user interface design that could lead to the ineffectiveness of content delivery by the personal healthcare application.

Assessment of emotion related to UID is vital for the utmost user experience and effectiveness in using the application to achieve the desired usage objectives. Researchers are focusing mainly on how to design and redesign UID by examining the possible UID cognitive features such as design colour, characteristic, size, contents and messages [6]. The process of redesigning UID has been however carried out on a trial-and-error basis, which led to difficulties in selecting the most suitable design that can increase usage efficiency. Although the emotional embedded design is preferable by users, there are inadequate studies done on this topic.

To improve the human factor in interacting with a machine, the existing methodology namely Kansei Engineering (KE) is capable of guiding UID designers in developing UID that is in line with the complexity of dimension in a lifestyle intervention and user experience-based application design. Thus, in the UID context, various dimensions in a lifestyle intervention can be mapped to establish a joint representation of an optimum function of lifestyle intervention. Since KE is effective enough in addressing all dimensions needed for the user interface design, this paper proposed Emotional Evocative User Interface Design for Lifestyle Intervention in Non-communicable diseases (NCDs) domain using KE.

This paper is organized as follows: In Section II we present a brief overview of our research including advice and recommendation in avoiding the development of NCDs, the criteria of chatbot UID in smartphone and an overview of Kansei Engineering. Section III follows with details of our pilot study that utilize chatbot interfaces to evaluate the relationship between chatbot UID and user's emotion trait. Finally, we conclude in Section IV with a discussion on the result investigation and determined the significant emotions for the lifestyle intervention for NCDs development.

This research is fully supported by the National Defence University of Malaysia (UPNM) under Short Grant UPNM/2020/GPJP/ICT/6. The authors fully acknowledged UPNM and Ministry of Higher Education Malaysia (MOHE) for the approved fund, which made this research viable and effective.

II. RELATED WORK

A. Non-Communicable Diseases

Non-communicable disease (NCD) cases are a global health problem that continues to rise globally. The pandemic Covid-19 that is forcing people to be at home when there is no need to go out contributed to less exercise and overeating, causing the increase of NCD developments[7]. The development of NCDs do not result from germs and viruses, but individual risky behaviours such as tobacco use, alcohol consumption, unhealthy diet and inactive lifestyle [8],[9],[10]. Therefore, it is important to undergo a regular health screening to help to identify any early signs of chronic disease to reduce the socio-economic burden on an individual [11] and turn it to reduce morbidity and mortality as well as improve health and prevent disease [12], [11], [13].

A healthy lifestyle is classified into two categories [14], which are non-modified (age, family history) and modified (no obesity, healthy diet, physical activity and no smoking) variables that contribute to having a longer life with good health [13], [15]. This study utilised modified variables to measure user's emotion for lifestyle intervention compliance including food and nutrition intake. According to the previous research, healthy eating is based on the right amount of nutrients (protein, fat, carbohydrate, vitamins and minerals) and proportions of foods recommended by the food pyramid for daily requirement [16]. Meanwhile, the best amount of food serving depends on the types of exercise done by an individual. For instance, higher intensity activity increases energy expenditure and fuel for muscles. Besides, physical activity can balance energy by changing appetite and cutting food intake [17]. According to WHO, adults aged between 18 to 24 should do at least 150 minutes per week for mild physical exercise or at least 75 minutes per week for intense physical activity or both physical activities[18].

With the advancement of technology, lifestyle intervention can be done using the application to assist the users in their lifestyle. Nowadays, technology is widely used as a healthcare tool in spreading awareness and promoting health since it is effective, convenient, and cost-effective. Recently, several chatbots such as Quro, Shihbot and Mandy have been used in public health to reduce the burden of low and middle-income countries[19]. Since a decade ago, smartphones have been gaining popularity with mobile health (mHealth) applications used to conduct lifestyle interventions in gaining better health at a lower cost [20]. However, most of the applications are not considering the user's emotion during the designing and development phase that creates a gap in the established UID. Therefore, an emotional embedded user interface design for lifestyle intervention to prevent NCDs development should be developed to ensure the effectiveness of the applications.

B. Significance of Emotion in Lifestyle Intervention Compliance

Emotions are one of the essential properties of human-to-human interaction and complex process that consists of feeling, behaviour and psychology influenced by surrounding[21]. According to Legg et al., physicians ability in determining the current patient's emotion will improve the

level of compliance to the instruction given [22] due to the patient's satisfaction and adherence to treatment influenced by the level of understanding towards the instruction of lifestyle interventions. Anger, frustration and irritation due to negative experience caused by inappropriate health service providers will lead to non-adherence behaviour by the patients[23]. Legg et al. also emphasized that anxious emotions (worry and nervousness) trigger difficulty for individuals to understand instruction given by health providers and impede people's decision making[22].

Emotional issues cannot be ignored and should be taken into consideration while implementing any type of lifestyle intervention and more research is needed in this area [22]. In addition, Lockner & Bonnardel also highlighted the importance of studying emotions especially in the context of UID [24]. Therefore, it is vital to determine the emotional expression of an individual before implementing any lifestyle intervention to avoid the development of NCD effectively. As a result, people will be able to comply with instruction provided by the healthcare provider and lead a healthy lifestyle [23].

C. Kansei Methodology

Kansei Engineering is the combination of technology between Kansei and engineering realms, which is frequently used for product development that includes components such as desired need, emotion or sense [25]. Kansei can be utilised to establish a new product design based on users' evaluation of a product emotionally. Kansei integrates the product based on knowledge of what the users feel. Thus, Kansei is useful in influencing implicit users' insight related to the product design element and incorporating these insights with a new product[26]. Recently, people have shown interest in the application of Kansei in various fields such as industrial products, healthcare, education and e-commerce[27]–[29]. Furthermore, Kansei has been proven successful in measuring human emotions toward services and products such as in designs of eyewear, popup box and e-commerce websites desired by users[30], [31]. In the realm of information security, Kansei is utilised to design information security-related UID [32].

Kansei expresses human's feeling towards artefact, situation, or environment. Kansei refers to an external process that is tacit or known as a function of the brain at a higher level. This means that Kansei cannot be measured directly but can be measured partially or indirectly through a quantitative method using a self-reporting system like Semantic Differential (SD) scale, Different Emotional Scale (DES) or free labelling system. The measurement is done using Kansei Checklist, a form of a questionnaire that includes emotional keywords or known as Kansei Words (KW). KW is a word representing a user's emotions [6]. Commonly, the selection of KW is done based on the literature review and experts' advice. Normally, Kansei is used to measure the emotion of a user towards a product design. In this study, Kansei was applied using a quantitative method with KW, a form of questionnaires distributed to participants to evaluate related evocative user interface design based on users' insight towards artefact.

In this work, we proposed that Kansei can be utilised as a methodology to measure users' emotion in a chatbot design where the result can serve as a guideline on how to design a UID that can be associated with emotional evocative user interface design focusing on a lifestyle intervention for NCD. In this study, a chatbot was used as the UID. Generally, a chatbot can be used to spread awareness, promote health and act as a medium of interaction in lifestyle intervention to ensure a healthy lifestyle practice towards preventing the development of NCD.

D. Emotion Evocative User Interface Design (UID)

The most important factors in designing chatbot UID for lifestyle intervention are: 1) to make sure that the chatbot interaction with the target user is pleasant and comfortable to be used emotionally, 2) the chatbot could use a similar approach in understanding the target user like the one used by the health provider and 3) to create a relationship with target user to use the chatbot continuously. The dependency on technology has increased in people's daily activities whether in education, entertainment, business, or healthcare. Hence, the use of technology in assisting individuals in lifestyle modification for NCD intervention is convenient and accessible as smartphones are easily acquired today. Previous studies have shown the significance of technology in lifestyle intervention, which can help people with lifestyle modification and motivation [33], [34].

To increase emotional evocative user interface design in chatbot, user preferences are used as a guideline in designing UID and are the main concern of designers [35], [36]. Researchers have suggested that gender, age preference and emotion factors have to be included in the technology that addresses user's feelings, process and behaviour [37]. Moreover, embedded culture in UID affects product development [38], [39]. Thus, the influence in designing the users' interface and understanding attraction depends on how the users use the technology.

Before starting to develop the chatbot UID, it is important to decide the personality of the bot. According to Pricilla et al., the personality should be developed based on the bot's function, target audience, and type of task that the bot must complete [35]. Creating the right personality for the bot will boost the user experience and interaction. Besides, female-gendered chatbots have a huge effect on gaining trust for both women and men because female bots are perceived to be friendlier and trustworthy [36].

To provide a good user experience, the bot may also need to support rich interactions such as audio, pictures, and maps. Suggestion criteria in designing chatbot followed by user preference, gender, age and culture preferences include typefaces[37], colour [38], emoticon[1], avatar[5], tone[5] and voice[5].

1) *Typefaces*: People's impressions of books, packages, signs, and screen interfaces are affected by typeface elements. The typefaces used have a huge impact on how users view a chatbot and appreciate the emotion evoked while reading the contents. Fig. 1 shows two types of typefaces based on the finding by Candello et al. that stated, a robot-like typeface

(OCR) was more identified as a machine in a chat, rather than script typefaces (Bradley). Typefaces (Bradley) were less perceived as human in a chat. These show that script typefaces give an impression of more human like emotional conversation and have higher ratings of trust than robot-like speech.[37] Besides, the author suggested, designers can select different typefaces based on target users' familiarity with chatbots to give a favourable first impression. People who have had less experience with chatbots need additional elements or content reinforcement in order to view chatbots as less emotionless machines and designers' role in decreasing the typeface bias are vital.

Typeface 1: A robot-like typeface (OCR-A neutral typefaces such as Helvetica and Georgia)

abcdefghijklmnop
qrstuvwxyz

Typeface 2: Mimics handwriting (Bradley)

abcdefghijklmnop
qrstuvwxyz

Fig. 1. Type of Typeface [37].

2) *Colour*: Colours are also associated with other feelings and emotions. Colours not only affect our attitudes and perceptions toward a product but are also correlated with variations in UI trusting behaviour. Most studies agree that blue is perceived as a cold colour, while red is perceived as a warm colour. The author in [38] believes that the warmth of the user interface has a positive effect on trusting behaviour. However, pleasant colours and a joyful atmosphere in a chatbot should be surrounded by cheerful and lively design settings for a more positive effect. The colours design and atmosphere of a chatbot can result in a positive effect on user's attitudes toward it, which in turn influences compliance to the advice given by the chatbot in having a healthy lifestyle.

3) *Emoticon and Gifs*: Emojis are defined as the typographic display of a facial representation that used to express communication feelings and emotions[39]. Emojis have the ability to change the tone of a message. Furthermore, emojis are added with text and other platforms such as stickers and GIFs to expand and complement the text's expressive message. Unlike plain text, which is informative and brings the meaning of a message within the text, emojis are richer in terms of meaning that show stronger emotional behaviour. For example, the text "That not funny" and "That not funny 😞💔" convey different meanings. The first sentence sounds serious whereas the second one looks sad and heartbroken[1].

4) *Avatar*: An avatar may incorporate "joy-of-use" into the conversation and inspire the user with friendly encouragement and the right answers to promote a positive

work climate. A character's trustworthiness is also important in natural communication. As a result, each character's exterior appearance, speech characteristics, gesture, and general movement can vary. Fig. 2 shows alarm messages which require immediate actions. The red colour and the fireman avatar was representing the warning and alert towards the situation[5].

Fig. 2. Avatar for Alarm Message [5].

This criterion is a significant element in measuring users' emotional trait towards interaction with a chatbot using all the senses of vision, hearing, sensitivity and scent that resulted in a reaction established and stored in the human brain by experiencing all the impressions. Thus, this created a reaction of human behaviour towards the design of a chatbot. In this study, we proved that the data gathered using Kansei Engineering methodology are capable of providing a guideline to UID designers in developing UID that is able to address the emotion complexity dimension for NCDs lifestyle intervention and user experience-based application design. Thus, in the UID context, various dimensions in NCDs can be mapped to establish a joint representation of an optimum function of NCDs lifestyle intervention from the perspective of chatbot design.

III. EMOTIONAL EVOCATIVE USER INTERFACE DESIGN FOR LIFESTYLE INTERVENTION IN NON-COMMUNICABLE DISEASES

Emotional evocative UID can be realized if there are enough data gathered to explain the relationship between design and how it will affect user emotion in a particular domain. Emotion embedded UID will enable the optimum joint representation for lifestyle intervention to avoid NCDs development. Communication using chatbot has the potential to deliver message according to user's need if the chatbot design considers the emotion that capable to increase the positive effect on user's attitudes. This study adopted a model proposed by [40] to determine the emotional trait that will increase the adherence to instructions related to lifestyle intervention to prevent the development of NCDs. However, in this study, some modifications were made to this model to the suitability of the study scope. This study was conducted in four phases, which were 1) Identifying instrument of lifestyle intervention in NCD 2) Emotional measurement 3) Emotional Conceptualisation and 4) Design Requirement Formulation. This paper reports the result of a pilot study performed to

determine the reliability of the research methods and test the subject recruitment strategy.

For this study, the process for determining emotion assessment for chatbot interface for NCDs lifestyle intervention is shown in Fig. 3. The first phase was the process of identifying the artefact of the chatbot application interface from the Google App store and journals. The chatbot UID is defined as a visual layout design of artefacts that can interact with users [41].

Based on the findings, 8 out of 15 chatbots were selected using a matrix approach. The matrix approach is used to validate a specimen by checking the features of design and values that make up the appearance of each specimen [31]. Table I show the extraction of chatbot UID with the corresponding category, item and value, respectively.

A. Methodology

In the second phase, 71 KW was synthesised from a literature review and models including Panas-X that connected to the lifestyle intervention domain. In addition, a Kansei Affinity Cluster (KAC) was adopted for the process of synthesising KW and the confirmatory phase of KW. It was recommended that the researcher choose and pick only certain words that are important to the study [42]. Therefore, based on the 71 KW discovered, the words were filtered and selected based on the KAC model since KAC words are very suitable for representing emotions in chatbot UID. The result of this selected process was 16 KW. Finding from this process is as shown in Fig. 4.

After the KW was determined, Kansei Checklist was developed to evaluate emotions and was represented as a form of a questionnaire that consists of KW. The developed Kansei Checklist is shown in Fig. 5.

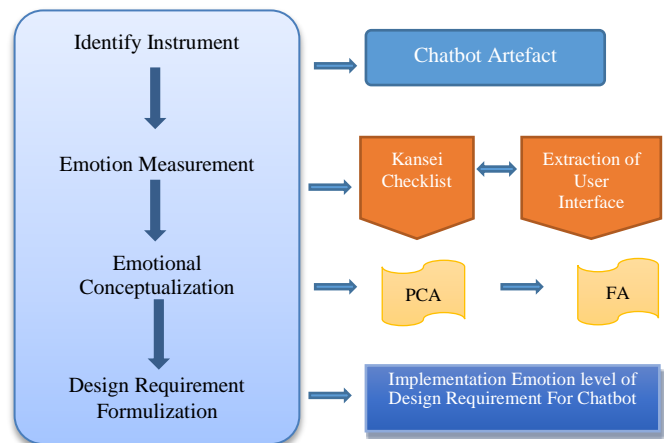

Fig. 3. Process for Emotion Assessment for Chatbot Interface using KE [40].

Frustration, Disgusting, Irritating, Annoying,
Concern, Painful, Stressful, Joyful, Cheerful,
Energetic, Satisfaction, Exciting, Exhausting,
Hopeful, Panic, Lively

Lively	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	Not Lively

Fig. 5. The Kansei Checklist.

To conduct the evaluation experiment, KW was assembled into a 5-point Semantic Differential (SD) scale to form a checklist. Ten participants were recruited based on different demographic factors to evaluate KW appeal for eight artefacts that were selected in Phase 1. The samples of the artefact are as shown in Fig. 6. The artefacts' categories were made

according to the literature review obtained. However, not all categories and items were included in this pilot evaluation process due to the limitation on the allocation of timeframe and process delivery.

This evaluation was made by the selected participants with interest in lifestyle intervention using chatbot to prevent development of NCDs. The process was conducted in a close environment to prevent the emotion changes of the participants between five to six hours.

In this study, the demographic factors included sex, race and age in between 18 and 30. In this study, 10 smartphones were given to all subjects to show the artefacts simultaneously by the facilitator. The participants were asked to give a score based on their feelings on the Kansei Checklist for each sample product chatbots (artefacts).

B. Result

Result analysis started by determining the Cronbach's alpha of Kansei Checklist. Cronbach's alpha is a convenient test used to reach a reasonable reliability standard [50]. Cronbach's alpha reliability commonly ranges from 0 (very unreliable) to 1.0 (perfect reliability). The nearer the Cronbach's alpha to 1.0, the higher is the internal consistency of the scale item. Based on Cronbach's alpha rules of thumb recommended value; above 0.9 is excellent, above 0.8 is good and above 0.7 is acceptable[51]. This value also relies on the number of items that affect whether the scale reliability will be higher or lower. Therefore, in this study, Cronbach's alpha was performed in SPSS Statistics using Reliability Analysis.

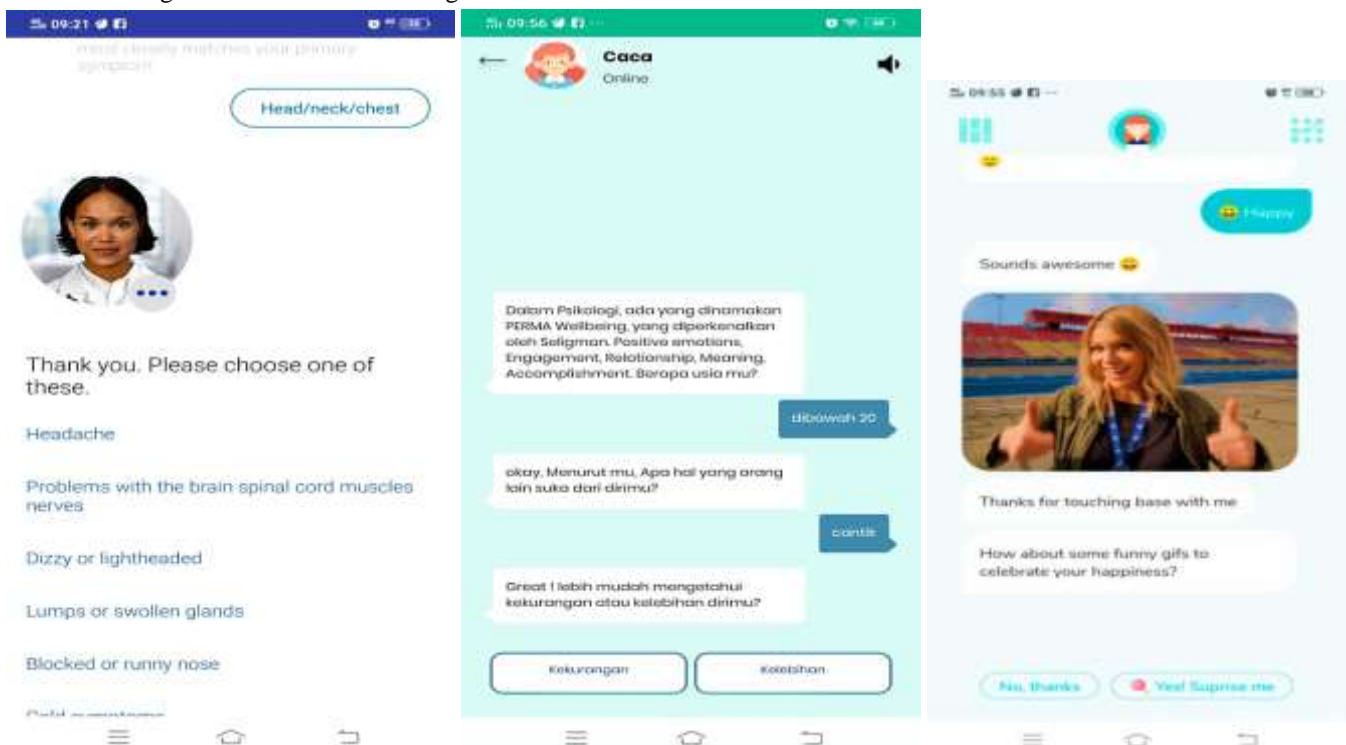

Fig. 6. The Kansei Checklist.

TABLE I. EXTRACTION OF CHATBOT UID

Category	Item	Value
Timing [40],[43]	Appear of notification	Seconds, Minutes, Hours
	Speed of reply	Fast, Medium, Slow
	Appear of location box	Above, Below, Centre, Right, Left
Typography[37]	Font Type	Regular, Italic, Bold
	Font Size	Small, Medium, Large
	Font Colour Reply	Red, Blue, Green, White, Black, Grey, Others
Emoticon[39],[44]	Type of emoticon	Unicode, Graphic
Colour[45]	Colour of header	Red, Blue, Green, White, Black, Grey, Others
Size[46]	Size of screen box	Half, Full
Button [47]	Size of button reply	Small, medium, large
	Colour of button reply intensity	Light, Dark
	Shape of button reply	Round, Rectangle, Oval, Square
Profile Picture [5]	Location of button reply appear	Centre, Right, Left, Down, Up
	Frame of Avatar	Oval, Round, Square,
Media[48]	Type of Avatar	Robot, Human, others
	Image	Less, More
	Gif	Yes, No
Animation [49]	Motion path of text	Appear, Fade, Fly-in, Float in, Wipe
Voice tone	Type of conversation	Robotic, Natural

TABLE II. EXTRACTION OF CHATBOT UID

Cronbach's Alpha	Cronbach's Alpha for Standardized Items	Number of Items(N)
0.771	0.757	128

Based on Table II, the alpha coefficient for 128 items was 0.771, which indicated that the items have high internal consistency. Meanwhile, the Cronbach's Alpha standard was 0.757. Alpha coefficient values between 0.60 and 0.70 have been shown to be acceptable in exploratory research, whereas range values between 0.70 and 0.95 are known to be satisfactory to a good degree of reliability [52]. Thus, it can be concluded that the reliability of the Kansei checklist was verified.

Then, the analysis was performed using principle loading analysis (PCA). PCA is an exploratory data analysis method that requires a technique to reduce a large dataset to a small set, but still maintains the amount of information in a large set[53]. There are three types of PCA namely PC Loading, PC Score and PC Vector. In this study, PC Loading was used, which represented the evaluation of how KW affects specimens. Fig. 7 shows the result of PC Loading for Component 1 and Component 2.

Fig. 7. PC Loading for Pilot Study.

From Fig. 7 above we observed that a good distribution of KW existed on both axes, which indicates an efficient evaluation. Based on a previous study, the loading can range -1.0 to 1.0. Furthermore, loading closer to -1 or 1 means that the component is highly influenced by the variable. While loading close to 0 means that the variable has a lower influence on the component [54].

In this loading, plot "Concern", "Hopeful", and "Exciting" have a large positive PC loading on component 1 (x-axis), whereas "Exhausting" has a moderate negative loading, making this component to be marked as an "Attractiveness". This study assumed that chatbots with a high score on component 1 of the PC axis would have a greater sense of attraction and vice versa.

Meanwhile, "Stressful" and "Disgusting" have a large positive PC Loading on component 2 (y-axis) near to 0; so, this component was marked as a "Hostility". This study assumed that chatbots with a higher score on component 2 of the PC axis would tend to feel hostility and vice versa.

Then, Factor Analysis (FA) was conducted to identify significant KW variables for the chatbots that reflect adherence of people in the chatbot features in a lifestyle intervention. The result was used to refine the outcome of PCA. FA is a technique of data reduction to describe ambiguity in terms of unobserved explanatory variables named factors [55]. Table III shows the result of FA after varimax rotation.

Based on this table, the first factor indicates the majority contribution with 28.109%, followed by the second factor with 24.216%. The majority of factors represented both variables. Therefore, as can be observed in this table, both Factor 1 and Factor 2 have a dominant KW affect, representing 28.109% and 52.325% = of the variability. Meanwhile, the third and fourth-factor contributions were 19.36% and 15.243%, respectively. Thus, Factor 2, Factor 3 and Factor 4 were seen with 52.325%, 71.693% and 86.936% of variability, respectively.

TABLE III. CONTRIBUTION AN ACCUMULATED CONTRIBUTION

Factor	Contribution (%)	Accumulated Contribution (%)
1	28.109	28.109
2	24.216	52.325
3	19.368	71.693
4	15.243	86.936

The results of factor loading after rotation of the varimax are shown in Table IV. In chatbot design, variables with a higher score are considered as important factors. This study defined 0.7 as the standard score. However, a slightly lower score can be also known as a significant concept[56].

Factor 1 consisted of “Disgusting”, “Painful”, “Frustration”, “Stressful”, “Panic”, and “Irritating”. These variables were labelled as the concept of “Hostility”. Factor 2 consisted of “Satisfaction”, “Hopeful”, “Concern” and “Lively”. These variables were labelled as the concept of “High-spirited”. Factor 3 comprised “Cheerful”, “Exhausting” and “Concern”, which were labelled as the concept of “Complicated”. Factor 4 consisted of “Energetic”, “Annoying” and “Exciting”. These variables were labelled as the concept of “Hyperactive”. This study reflected the common procedure in KE using representative terms for naming each factor group, the one that could effectively define the factor group. There is nothing right or wrong in naming group factors, except that the name must match the variables in factors.

TABLE IV. FACTOR LOADING FOR KW

Variable	Factor 1	Factor 2	Factor 3	Factor 4
Disgusting	0.908	0.125	-0.209	
Painful	0.896			
Frustration	0.796		-0.414	-0.324
Stressful	0.794	-0.1	-0.116	0.439
Panic	0.68	-0.381	0.32	0.156
Irritating	0.668	-0.602	-0.356	0.124
Satisfaction		0.923	0.101	
Hopeful	-0.204	0.847	0.408	
Concern	-0.158	0.748	0.226	0.485
Lively	0.43	0.697	0.228	0.27
Cheerful	0.206	0.295	0.835	
Exhausting	0.387	-0.117	-0.816	
Joyful	-0.34	0.336	0.792	
Energetic	0.238	0.297	0.134	0.842
Annoying	0.209	-0.41	-0.431	0.754
Exciting	-0.177	0.471	0.405	0.704

From the experiment results, we determine that the concept of emotion in Chatbot UID is structured by four variables as evident from the outcome of FA, which was Hostility, High-Spirited, Complicated and Hyperactive. However, it can be concluded that Factor 1 and Factor 2 were more relevant concepts of Kansei for Chatbot due to the

52.325% of data variance. Thus, to obtain an optimal outcome, two factors were used namely Hostility and High-spirited, which were very significant emotion concepts. Whereas the other two factors were also significant, which were Complicated and Hyperactive, but have a poor impact to be used in designing the chatbots that include targeted emotions as supporting elements.

C. Discussion

This paper has described our research to establish emotions evocative chatbot UID in the healthcare domain. This finding will be useful in future research concerning the use of KE in the measurement of emotion, which integrates the user's subjective perception in a UID. In this study, we had extracted 16 KW related to lifestyle intervention from previous studies and eight chatbots artefacts have been identified using multilinear techniques. For this pilot study, the significant KW has been chosen using FA. Participants were recruited from different demographic factors that include a variety of analysis and a more precise relationship to reflect the specific regional field of NCDs. FA revealed more detailed findings compared to PCA. However, PCA illustrated a larger picture of the emotion structure, where it is shown that emotion was strongly affected by the first PC, which was “Attractiveness”, whereas the second main component “Hostility” has a poorer effect. From this pilot study, it has been determined that the significant emotions for designing UID chatbot for the lifestyle intervention in NCDs domain are hostility and high-spirited. These emotions will be the pillars in guiding the chatbots' design requirement that could influence emotion level for NCDs lifestyle interventions.

Based on the extraction of chatbot UID that has been chosen, the results show that evaluation using the Kansei Engineering method have revealed that two significant factors which are “Hostility and “High-spirited” as likely to have strong healthcare awareness and influences to individual's behaviour in using a chatbot. An individual is comfortable, pleasant and confident to comply with the chatbot guidance and instruction when supported with these two emotional factors. In this study, we selected UID from the applications in the Google App store as our artefacts since many applications are related to the healthcare domain and free to access.

IV. CONCLUSION AND FUTURE WORK

As a conclusion, this paper has conceptualised emotion assessment in UID for lifestyle intervention especially NCDs domain using KE methodology. The results were presented as a pilot study to determine the reliability of its data collection towards a small number of participants.

The next step is to perform activities with a larger group of participants to obtain more comprehensive data to determine emotion assessment in the NCDs domain for lifestyle intervention using Kansei Engineering method. The result could be utilised to create the guidelines on the representation of emotions towards the design of chatbot in the lifestyle intervention for NCDs domain. The guideline can be used by developers and software designers in designing emotionally evocative chatbot to guide lifestyle intervention and contribute to reducing the risk factor in developing NCDs. The most

important factor in designing a chatbot for lifestyle intervention is to make sure that chatbot interaction is pleasant and comfortable to be used emotionally and users have a tendency to share and follow the instructions guided by the chatbot to prevent the development of NCDs. This is to ensure that the users are comfortable and willing to cooperate upon receiving instructions of any lifestyle intervention in NCDs.

This research was able to offer insight into people's attitudes, sensitivity, and knowledge of lifestyle interventions for preventing NCD development issues. As a result, the findings of this study are recommended to be used as a foundation for future research into the relationship between emotion and UID using a chatbot or other conversation agent interfaces as an artefact. Nevertheless, a thorough investigation involving comprehensive evaluation and measurement of emotion is needed to expand the research findings and to extend more promising results.

ACKNOWLEDGMENT

This research is fully supported by the National Defence University of Malaysia (UPNM) under Short Grant UPNM/2020/GPJP/ICT/6. The authors fully acknowledged UPNM and the Ministry of Higher Education Malaysia (MOHE) for the approved fund which makes this research viable and effective.

Exploring the Socio-economic Implications of Artificial Intelligence from Higher Education Student's Perspective

Sarah Areef¹, Lobna Amouri², Nahla El-Haggar³, Aishah Moneer⁴
Computer Department, Imam Abdulrahman Bin Faisal University
Community College, Dammam, KSA

Abstract—As a result of the instability of oil prices, the economic prospects of the Gulf region are increasing their focus on new technologies. Thus, Saudi Arabia has demonstrated a strong commitment towards the development and implementation of Artificial Intelligence (AI) technologies as alternative sources for revenue and growth in line with globalisation, development, and the vision 2030. This paper examines the impact of AI in the Saudi Arabia community, especially for social and economic evolution. Special focus on the use of smart cars and smart cameras to monitor intelligently traffic, public services and national security is explored. A total of 424 participants from Eastern Province took part in this study. Analysis and discussion of the obtained results are also presented. The findings showed that 75.71% of participants mostly highly agreed about the AI economic impact leading to an increase in both government and business financial incomes. Whereas only 59.84% of participants mostly highly agreed about the social impact of AI as they are worried about AI ethical concerns, job loss and the changing workforce.

Keywords—Artificial intelligence; Saudi community; data analysis; social efficiency impact; economic productivity impact

I. INTRODUCTION

AI is based on the use of big data, artificial learning and robot technology applications that will have far-reaching implications for the economy (Clark, 2020) [1], jobs, social fabrics and culture sectors (Elsaadani et al., 2018) [2]. For the last few decades, the energy sector's presence in the Saudi economy has decreased dramatically, from almost two-thirds of GDP to 43 percent by 2015 ((Elsaadani et al., 2018) [2] (Stephens et al., 2019) [3]). The Kingdom's government has responded with a series of contiguous strategies based especially on economic diversification that aimed to expand non-oil industries to ensure sustainable development, recruitment and to decrease the dependency of the public sector on jobs. According to Accenture analysis (Elsaadani et al., 2018) [2], the common point between all these strategies is the determined and exhaustive adherence to AI. This analysis demonstrated that AI has the capacity to considerably increase economic development rates by contributing \$215 billion in annual gross value added (GVA) to the economy of Saudi Arabia by 2035. So far, the main idea beyond the Kingdom's

Vision 2030 national growth strategy is the technology sector (in government, business, services, industry, healthcare, education) which is rapidly empowered by AI. So far, the Traditional Economic Growth model shown in Fig. 1 demonstrates that capital, labour factors and new technologies are the key drivers of economic growth. Nevertheless, according to Accenture analysis, the new growth model treats AI as a new factor of economic growth rather than simply another technology-based productivity enhancer.

The objectives of the study are:

- To study the Saudi Arabia community's acceptance and willingness to deal with AI.
- To compare the future situation of Saudi Arabia's community in an AI scenario to a scenario without AI.
- To explore the AI impact on health, security, privacy (ethical considerations), safety, employment, education as well as public services of Saudi Arabia's population.

The remainder of this study is structured as follows: Section II explores a literature review about the implication of AI on social and economic development. Section III introduces the suggested methodology. Section IV clarifies the results and discussion. Finally, Section V illustrates conclusions, future work and limitations.

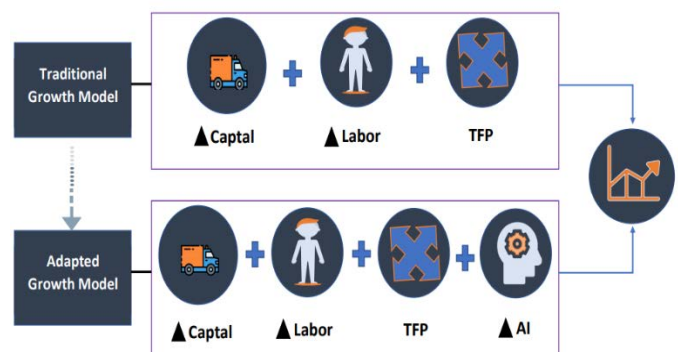

Fig. 1. Economic Growth Model (Elsaadani et al.,2018).

II. LITERATURE REVIEW

This section present synthesizes the existing research papers that treated first with the AI applications for smart cities (smart cars and cameras). Then, we introduced a literature review on the social and economic AI implications at the national and international level.

A. AI Applications in Smart Cities

A. Beg, et al. (2020) [4] analysed transportation vulnerabilities and emergency response systems; proposed a smart, autonomous UAV-enabled solution; and demonstrated the system in a simulated environment. Various traffic control and police system conditions were taken into consideration in the simulation: traffic light abuses and accident detection, mobile speed traps and automatic alerts, crowds.

Impedovo, et al. (2020) [5] studied 21 peer-reviewed papers that contributed to the broad range of artificial intelligence applications and demonstrated that under a more resource-efficient management and economy than ordinary cities, smart cities work. As such, advanced business models around smart cities have grown, leading to the development of smart companies and organisations that rely on advanced technologies.

S. Hoofar, et al. (2020) [6] presented a new approach to supporting smart cars by exploring Vehicle Ad Hoc Networks (VANETs), which are intelligent interconnected vehicle networks that can provide real-time traffic parameters such as the type, speed, direction and location of each vehicle. The studied intelligent transport system is commonly used in various applications such as traffic flow control, automatic parking systems and security compliance.

B. Social AI Impact

The researchers in [7] demonstrated that AI has unfavourable effects on disadvantaged segments of populations, and the effects on individual AI applications can vary. Some other researchers in [8] examined what type of human labour will be a replacement versus a complement to emerging technologies in the field of AI. Besides, researchers in [9] studied the impacts of rapid progress in artificial intelligence technologies on society. They discussed one such potential impact: the issue of machine learning system accidents, identified as unintended and harmful actions that could result from poor design of real-world AI systems. Researchers in [10] have examined the effect of the use of AI in medicine at three levels. For clinicians, mainly by quick, precise interpretation of images; for health systems, through enhancing workflow and the ability to minimise medical errors; and for patients, through enabling them to access their own health-promoting data. They also argued the existing limitations of using AI in medicine including bias, privacy and security, and lack of clarity, along with the potential directions for these applications. While researchers in [11], [12] [13], [14] and [15] used AI to build various systems for people with disabilities and aged persons who require support in their everyday lives or in recovery from emergency situations.

The proposed systems identified vital signs (Body Temperature, Blood Pressure, Blessing, Heart Pulse Rate, and Consciousness) as well as location/attitude monitored by the

sensor network. Besides, researchers in [16] focused on AI-based learning by trying to analyse and investigate how AI can be fruitfully exploited by universities in Saudi Arabia. In addition, they centralised on challenges of teaching/learning procedure and advantages in the implementation of Information and Communication Technologies (ICT) in a classroom, leading to delegate an academic committee to an AI-based context. The researchers in [17] created a short questionnaire and circulated it to four expert groups in 2012/2013. For instance, they detected that there was, in some areas, concern over high-level artificial intelligence growing up in a few decades and addressing its serious dangers for humanity. In other areas, these concerns have been overlooked or deemed science fiction, what the likelihood that the best experts allocated to high-level machine intelligence coming up within a given time frame, which threats they have seen in this growth, and how rapidly they have seen them evolve.

C. Economic AI Impacts

Approximately 47% percent of the all jobs in the U.S. are at risk from computerisation, according to Frey and Osborne (2013) [18]. Author (2015) [19] argues, however, that automation and technological advancement have not led to the obsolescence of human labour. Automation and labour are highly complementary, particularly for staff who are adaptable, innovative, and solution oriented.

E. Ernest, et al. (2019) in [20] demonstrated how AI has produced widespread worry of job loss and further increases in unfairness. The authors called, through the paper, for a reasonable outlook on the opportunities and risks from AI. For this, they discussed how skills policies and new ways of digital economy regulation are necessary to prevent further increases in market concentration, ensure adequate data protection and privacy and help redistribute the gains of productivity growth by combining wealth sharing, capital taxes and a decline in working time.

On the other hand, G. C. Allen (2019) in [21] addressed China's political thinking towards AI and national security and highlighted that China's leadership claims that being at the forefront of AI technologies is vital to the future of global military and economic-power rivalry.

M. Uzun (2020) in [22] addressed growing awareness about the negative impacts of AI among countries and proposed a solution modelling universal norms, international institutions and policies that ensure beneficial discovery of AI in order to provide a strategic equilibrium between major powers, international economic stability, and equitable economic control at national and international levels. Besides, O. Hassan (2020) in [23] described how the new mega-city Neom, currently under construction in Kingdom of Saudi Arabia, is targeting to integrate robotics and AI into various aspects of citizens' lives in order to generate earnings from key economic sectors for the future. The authors discussed also that this transition from an economy based on oil to AI targets to secure the survival of the Saudi community and meet the growing challenges of constructing a state around oil.

III. METHODOLOGY

This current study was prepared at the Computer Department of the Community College of Dammam, which is a college in Imam Abdulrahman Bin Faisal University that provides diploma graduates for both female and male students. All participants that took part in questionnaires answered closed-ended items which are likely to receive short answers. A Likert scale which is a close-ended, forced-choice scale is used in the questionnaire to provide a series of answers. This study used a 4-point Likert scale ranging from S.A (Strongly Agree), A (Agree), D (Disagree) and S.D (Strongly Disagree) to explore the participants' acceptance and willingness to deal with AI. Six criteria were used to develop the questionnaire including acceptance, security, ability, increase productivity, approval, and efficiency. A set of items were prepared for each domain according to five demographic profile items given at the beginning of the questionnaire. The demographic profile items include gender, identity, age-category, education, and standard of living. Besides, the conducted questionnaire explores the effect of specific AI applications in Saudi Arabia on social and economic developments. As well as, AI applications were discussed that include utilising smart cars and smart cameras for intelligent monitoring of traffic, public services, and national security.

A. Participants

A total of 424 participants took part in the questionnaire. The participants include students and teachers of Imam Abdulrahman Bin Faisal University, some other faculty members and employees in public and private sectors working outside the university. The groups we asked were categorised referring to the following criteria:

- Gender: Male or female.
- Identity: Saudi, non-Saudi.
- Age-Category: from 15 to 34 years, from 35 to 60 years.
- Education: High School Degree, Undergraduate Degree, Postgraduate Degree.
- Standard of living: Low, Moderate, High.

B. Data Collection

The conducted questionnaire is a cross-sectional one as collecting information from the respondents was conducted over a single period which was from 28 of February 2020 to 6 March 2020. It was prepared using the Google Forms tool and shared with participants by means of a link (see Appendix A). The sharing process took advantage of the best mobile messaging applications like WhatsApp, Viber, Snapchat and Facebook messenger that offer a superior substitute to email and text messaging thanks to built-in social networking characteristics and improved security. The questionnaire was appropriately configured to describe the views, concerns, obstacles and ideas of the participants in order to identify the measures needed to further strengthen the actual condition of AI in Saudi Arabia.

C. Data Analysis

Several steps were taken to analyse the data. Data was collected in an excel file and pictures were sorted out; percentages of the answers were calculated and studied thoroughly. The percentage for each item was determined using the mathematical formula 1, out of a total of 424 respondents who answered the questionnaire.

$$S_{i,j} = \frac{\text{Frequency of answers in each scale}_{i,j}}{\text{Total number of respondents}} * 100 \quad (1)$$

Where i is the number of items from 1,2,3,4...16 and j is the number of scales from 1 to 4. Note that the scale number 1 refers to scale Strongly Agree (S.A), 2 refers to Agree (A), 3 refers to Disagree (D) and 4 refers to Strongly Disagree (S.D).

The mean score ($M_{i,j}$) was also calculated for each item, to describe the strength of each one. In fact, weights (w) were assigned for each Likert scale. The larger number (4) was assigned to the most positive scale (S.A), 3 was assigned to (A), 2 to (D) and 1 to (S.D). The standard deviation was then applied to estimate the dispersion of each item relative to its mean. In fact, a second mean ($M_{0i,j}$) with the newest weights (W) (1, 4, 9 and 16) was explored to calculate the standard deviation $STDEV_{i,j}$. The mathematical formula 2, 3 and 4 represents respectively the first mean ($M_{i,j}$), the second mean ($M_{0i,j}$) and Standard Deviation $STDEV_{i,j}$:

$$M_{i,j} = \sum_{i,j} S_{i,j} * w_1 ; w_1 = w_j = 4, 3, 2, 1 \quad (2)$$

$$M_{0i,j} = \sum_{i,j} S_{i,j} * w_2 ; w_2 = w_j^2 \quad (3)$$

$$STDEV_{i,j} = \sqrt{M_{0i,j} - M_{i,j}^2} \quad (4)$$

Respectively, the mean score (M_c) and the standard deviation $STDEV_c$ were also calculated for each criterion c , where c is from 1 to 6 as shown in formulas 5 and 6. Then we used equations the formulas 7 and 8 to calculate the mean score (M_d) and the standard deviation $STDEV_d$ for each domain d , where d is from 1 to 2.

$$M_c = \frac{\sum M_{i,j} \text{ for each criterion}_c}{\text{Number of items for each criterion}_c} \quad (5)$$

$$STDEV_c = \frac{\sum STDEV_{i,j} \text{ for each criterion}_c}{\text{Number of items for each criterion}_c} \quad (6)$$

$$M_d = \frac{\sum M_c \text{ for each domain}_d}{\text{Number of criterion for each domain}_d} \quad (7)$$

$$STDEV_d = \frac{\sum STDEV_c \text{ for each domain}_d}{\text{Number of criterion for each domain}_d} \quad (8)$$

IV. RESULTS AND DISCUSSION

This section demonstrates and recognises the beneficial effects of adopting AI on the social domain and on specific criteria such as acceptance, security, ability, approval and efficiency. In addition, it identifies the advantages of AI in the economic domain to find out its effect on increasing the competitiveness of the Saudi community by using smart cars as well as implementing AI in working areas (companies, universities, hospitals...) to explore factors influencing the Saudi community's satisfaction with AI.

A. Demographics Profile Results

Table I shows the results of the questionnaire’s items regarding respondents’ demographic profile where the size of the sample is 424 Saudi community members. The demographic results signify 85% of the respondents to be female while 15% were male respondents. This can be explained by the fact that the college was originally a girl’s college, and the boy’s branch has recently been added, in addition to the lack of awareness between the sexes about the impact of artificial intelligence on society. According to the item “Age-Category”, most of the respondents (373 or 88%) of the sample population fall with 15- 34 years category while 51 respondents were between 35-60 years, representing 12% of the total sampled population. As for the item “Education”, the majority of the respondents (260 or 61%) have an Undergraduate Degree and 157 (37%) respondents have Postgraduate Degree. The remaining 7 (2%) of the total sampled population have a High School Degree. As for the item “Standard of Living”, most of the respondents (336 or 79%) have a Moderate Standard of Living, 73 of the respondents have a High Standard of Living representing (17%), and 15 of the respondents have a Low Standard of Living representing 4% of the total sampled population.

TABLE I. RESPONDENTS’ DEMOGRAPHIC PROFILE

Demographic Information’s	Options	Frequency	Percentage (%)
Gender	Male	63	15
	Female	361	85
Identity	Saudi	348	82
	Non-Saudi	76	18
Age-Category	15-34	373	88
	35-60	51	12
Education	High School Degree	7	2
	Undergraduate Degree	260	61
	Postgraduate Degree	157	37
Standard of Living	Low	15	4
	Moderate	336	79
	High	73	17

B. Analytical AI Impacts on Social and Economic Domains based on Item

The conducted questionnaire is a cross-sectional one as the collection information from the respondents was conducted over a single period of time, which was from 28 of February 2020 to 06 March 2020. It was prepared using the Google Forms tool and shared with participants by means of a link. The sharing process took advantage of the best mobile messaging applications like WhatsApp, Viber, Snapchat and Facebook messenger that offer a superior substitute to email and text messaging thanks to built-in social networking characteristics and improved security. The questionnaire was appropriately configured to describe the views, concerns, obstacles and ideas of the participants in order to identify the measures needed to further strengthen the actual condition of AI in Saudi Arabia.

Table II provides the analytical breakdown of the impacts of AI on social and economic domains on the Saudi community. Also, it illustrates the feedback obtained from

respondents regarding the social and economic criteria factors affecting the satisfaction of the AI Saudi community.

There are 14 items for the social domain classified as 6 items for acceptance, 2 items for security, 3 items for ability, 2 for approval, and 1 item for efficiency. Also, there are 2 items for the economic domain that examine the productivity criterion. The mean score for each item was used to describe the strength of each one. In the social domain, there are 4 items’ mean scores higher than 3 and 1 item for the economic domain. The obtained result demonstrates that some respondents highly agree about the impact of AI on security, approval, efficiency and productivity items.

Furthermore, 9 items’ mean scores are higher than 2 in the social domain and 1 item in the economic domain. Thus, most respondents mostly agree about the impact of AI on acceptance, security, ability and approval’ items. On the other hand, there is only 1 item’s mean score lower than 2 in the social domain in relation to being photographed without people’s knowledge. The result could be explained by the fact that the Saudi community is so far considered as conservative families. Fig. 2 and 3 provides the graphical interpretation of the information provided in Table II.

Fig. 2. Means and Standard Deviation for each Item.

Fig. 3. Means and Standard Deviation for each Criterion.

TABLE II. PERCENTAGE DISTRIBUTION OF SOCIAL AND ECONOMIC DOMAINS FACTORS AFFECTING SATISFACTION OF AI SAUDI COMMUNITY

Domain	Criteria	Items	S.A%	A%	D%	S.D%	Mi	STDEVi
Social	Acceptance	1.Do you accept to be controlled by smart cameras while shopping, driving, walking, getting a public service (bank, ministry, school, university, hospital)?	19.1	37.97	27.83	15.09	2.611	0.960
		2.To you accept that your personal information will be saved including your face patterns, your actions, your movements, your car number?	8.49	17.69	42.45	31.37	2.033	0.911
		3.Do you think that using smart cameras could increase the efficiency of social services (like booking ticket using face patterns only in airports)?	28.77	49.06	16.75	5.42	3.012	0.82
		4.Do you accept to be photographed without your knowledge	3.07	5.66	32.55	58.73	1.531	0.739
		5.Do you accept being surveyed almost completely by government authorities?	15.75	41.75	28.07	14.62	2.583	0.92
		6.Do you accept boarding in a smart car and not driven by a human being?	15.09	38.68	34.43	11.79	2.571	0.885
	Security	1.Do you think that using smart cars in Saudi Arabia is much secure than traditional driving?	31.84	56.13	8.96	3.07	3.167	0.709
		2.Do you think that using smart surveillance cameras in Saudi Arabia could release a secure life better than your actual life?	14.62	234.43	41.04	9.91	2.538	0.86
	Ability	1.Do you think that the smart car is better than human being driver?	19.1	47.41	26.65	6.84	2.788	0.828
		2.Do you think that using smart cars will reduce the accident rate in Saudi Arabia?	20.52	38.21	36.56	4.72	2.745	0.833
		3.Do you think that smart cameras are able to work continuously (while raining, winding, a troubleshoot in electrical power)?	17.45	38.44	37.26	6.84	2.665	0.842
	Approval	1.Do you agree about using artificial intelligence generally in Saudi Arabia	26.42	47.41	21.7	4.48	2.958	0.812
		2.Do you think that the advantages of artificial intelligence are more than its disadvantages?	36.08	51.89	8.49	3.54	3.205	0.738
	Efficiency	1.Do you think that smart cameras will collect data efficiently?	31.6	45.28	19.1	4.01	3.045	0.816
	Total Distribution for Each Scale			20.55	39.29	27.27	12.89	
Economic	Increase Productivity	1.Do you think that using smart cars increases people's productivity?	64.62	33.02	0.94	1.18	3.615	0.572
		2.Do you think that using smart cameras in working areas (companies, universities, hospitals...) could increases employee's productivity?	11.56	42.22	39.86	6.37	2.59	0.775
	Total Distribution For Each Scale			38.09	37.62	20.4	3.77	

C. Analytical AI Impact for each Social Criterion

- Generally, the research found that the total respondents mostly agreed the AI social impact is 59.84% which is the sum of S.A (20.55%) and A (39.29%). This result will be detailed below among different social criteria.

Acceptance criteria: The research found that the Saudi community (the respondents) agreed most highly upon item 3 that using smart cameras could increase the efficiency of social services (like booking tickets using face patterns only in airports had an average of $m= 3.12$ ($STDEV= 0.82$) . The most commonly agreed upon acceptance of controlling by smart cameras while shopping, driving, walking, getting a public service (bank, ministry, school, university, hospital had an average of $m=2.611$ ($STDEV = 0.960$) and monitoring and tracking the personal information and behaviour without knowledge) had an average of $m= 2.39$ ($STDEV = 0.872$). Also, the most commonly agreed upon approval of completely surveyed by government authorities, showed an average of $m= 2.583$ ($STDEV = 0.92$). Onboarding in a smart car and not driven by a human being, had an average of 2.571 ($STDEV = 0.885$) and the agreement of saving the extracting personal features which include face patterns, actions, movements and car number, showed an average of $m= 2.033$ ($STDEV= 0.911$).

- Security criteria: The research found that the Saudi community agreed most highly upon item 1 with an average for using smart cars being much secure than traditional driving with an average of $m= 3.167$ ($STDEV=0.709$). They mostly agreed upon item 2 with an average $m= 2.538$ ($STDEV=0.86$) for using smart surveillance for cameras in Saudi Arabia to release a secure life better than your actual life.
- Ability criteria: The research found that the Saudi community mostly agreed upon item 1 with an average of $m= 2.788$ ($STDEV=0.828$) for the ability of the smart car to do better than a human being driver. They mostly agreed upon item 2 with an average of $m= 2.745$ ($STDEV= 0.833$) for the ability to use smart cars to reduce the accident rate in Saudi Arabia. Also, they mostly agreed upon item 3 with an average of $m= 2.665$ ($STDEV= 0.812$) for the ability of smart cameras to work continuously (while raining, winding, a troubleshoot in electrical power).
- Approval criteria: The research explored that the Saudi community agreed most highly upon item 2 with an average of $m= 3.205$ ($STDEV= 0.738$) for approving that the artificial intelligence has a great advantages on Saudi society more than its disadvantages and they mostly agreed upon item 2 with an average of $m= 2.958$ ($STDEV=0.812$) for utilising artificial intelligence generally in Saudi Arabia.
- Efficiency criteria: The research revealed that the Saudi community agreed most highly upon item 1 with an average of $m= 3.045$ ($STDEV= 0.816$) for the efficiency of using smart cameras for collecting data for approving that artificial intelligence has great

advantages on Saudi society more than its disadvantages. They mostly agreed upon item 2 with an average of $m= 2.958$ ($STDEV=0.812$) for utilising artificial intelligence generally in Saudi Arabia.

D. Analytical AI Impact for Economic Criterion

- Increasing Productivity: The research found that the Saudi community agreed most highly with an average of $m= 3.615$ ($STDEV=0.572$) for increasing people’s productivity by using smart cars. They mostly agreed upon item 2 with an average of $m= 2.59$ (0.775) for increasing employee’s productivity by using smart cameras in working areas (companies, universities, hospitals, etc.). Thus, the total respondents that agreed most highly the economic AI impact is 75.71% which is the sum of S.A (38.09%) and A (37.62%).

E. Overview of AI Impact on Domains

In Table III, generally, the research found that the Saudi community agreed most highly about the impact of AI upon the economic domain and specifically for the criteria “increasing people’s productivity” by using smart cars and implementing AI in working areas (companies, universities, hospitals...) with the total average $m=3.102$ ($STDEV=0.673$). Besides, the research found that the Saudi community mostly agreed with the impact of AI on the social domain, with the total average $M=2.82$ ($STDEV=0.816$). Specifically, for each criterion of the social domain, the respondents agreed most highly about the impact of AI upon the approval representing a total average of $m= 3.081$ ($STDEV= 0.775$) and upon the efficiency criteria of using smart cameras for collecting data with a total average $m= 3.045$ ($STDEV= 0.816$). The respondents most commonly agreed on the impact of AI upon the security that represents a total average $m= 2.853$ ($STDEV= 0.784$), upon ability representing the total average of $m= 2.733$ ($STDEV= 0.834$), and acceptance representing the total average $m= 2.39$ ($STDEV= 0.872$). Furthermore, Fig. 5 and 6 explore the analytical AI impacts on social and economic domains based on demographic profile. Fig. 5 shows firstly, that the “standard of living” highly influences the respondents' point of view upon the implication of AI on social and economic development as the least scales starting from mostly agree to agree were obtained for that demographic property. This result could be explained by the fact that most respondents have a “moderate standard of living” so that they have a fear of losing their jobs because of AI development.

TABLE III. AI IMPACT ON DOMAINS

Domain	Social					Economic
Feature s	Acceptan ce	Securit y	Abilit y	Approv al	Efficien cy	Productivi ty
Mc	2.39	2.853	2.733	3.081	3.045	3.102
STDEV c	0.872	0.784	0.834	0.775	0.816	0.673
Md	2.82					3.102
STDEV d	0.816					0.673

Secondly, the figure demonstrates also that the “age category” has a strong implication on the respondent’s approval criteria as most of the questionnaire participants being between 15 and 34 years old, they have a great curiosity to discover and explore all new AI technologies. As well as Fig. 6 demonstrating that the demographic property “education” has the highest scale (highly agreed) upon AI economic impact, whereas the same property has the least Likert scale (mostly agree) about AI social impact. The result could be explained by the fact that the higher the education level, the higher the respondents’ awareness about the influence of AI on society criteria including employment, security, privacy, and poverty.

Generally, from the research results shown in Fig. 4, 5 and 6, it is clear that almost all respondents are fully in support of the intervention of this technology in their life and their feedbacks reveal that AI has a greater impact on the economic domain than the social domain.

Fig. 4. AI Impacts on Social and Economic Domains.

Fig. 5. Distribution of Relation’s Perspective between each Domains’ Criteria and Demo- Graphic’s Profile.

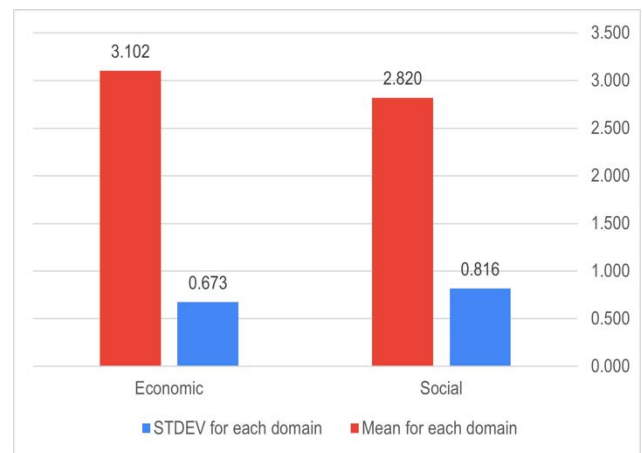

Fig. 6. Distribution of AI Impact on the Relationship between Social, Economic Domains and Demographic’s Profile.

V. CONCLUSION, FUTURE WORK AND LIMITATIONS

As Saudi Arabia continues to diversify away from oil dependence, the Kingdom has adopted a series of procedures considered to be adherent to AI technology. In this paper, the AI implications upon social and economic development have been presented. A special focus on the use of smart cars and smart cameras to monitor intelligently traffic, public services and national security has been studied. Understanding how the Saudi community is reacting during this economic pattern change is a significant challenge for social/economic experts and policymakers. The work outlined in this paper has resulted in evidence-based work, considerable worries of social AI implications, including ethical concerns, job loss and the changing workforce.

Responses also indicate that there is not enough general knowledge of AI, including what it can help accomplish in business and society and the consequences of not implementing it. Therefore, there needs to put in place adequate mechanisms to help companies and government negotiate the social and economic implications of AI. Several issues may be further investigated to highlight the concerns, behaviours and problems of the numerous participants’ demographic profile so that we could enhance the social and economic impact of AI in Saudi Arabia.

A. Limitations

The number of participants in this study is acceptable. Nevertheless, the participation rate could not be calculated for the online questionnaire as the prediction of adherent number for each mobile messaging application is impossible. Furthermore, the questionnaire takes only 2–3 minutes, and we tried to encourage participants through several ways of official communication. The male contribution was lower than expected due to the difficulty to contact them, as the college was originally devoted to females. Finally, there is no local data addressing matching rate or demographic profile distribution of AI impacts upon social and economic development in Saudi Arabia to compare with.

ACKNOWLEDGMENT

This paper is published under the socio-economic Implications of Artificial Intelligence project, as a part of Smart Campus implementation in Imam Abdulrahman bin Faisal University, Community College (CCD). The authors would like to special thanks to the Computer Department for supporting this work by giving the authorisation to share the survey through all students and faculty members.

Abstract—In the last few years Internet-of-Things (IoT) technology has emerged significantly to serve varied purposes including healthcare, surveillance and control, business communication, civic administration and even varied financial activities. Despite of such broadened applications, being distributed, wireless based systems, IoTs are often considered vulnerable towards intrusion or malicious attacks, where exploiting the benefits of loosely connected peers, the attackers intend to gain device access or data access un authentically. However, being resource constrained in nature while demanding time-efficient computation, the majority of the classical cryptosystems are either computationally exhaustive or limited to avoid attacks like Brute-Force, Smart Card Loss Attack, Impersonation, Linear and Differential attacks, etc. The assumptions hypothesizing that increasing key-size with higher encryption round can achieve augmented security often fail in IoT due to increased complexity, overhead and eventual resource exhaustion. Considering it as limitation, in this paper we proposed a state-of-art Generalized Feistel Network assisted Shannon-Conditioned and Dynamic Keying based SSPN (GFS-SSPN) Lightweight Encryption System for IoT Security. Unlike classical cryptosystems or even substitution and permutation (SPN) based methods, we designed Shannon-criteria bounded SPN model with Generalized Feistel Network (SPN-GFS) model that employs 64-bit dynamic key with five rounds of encryption to enable highly attack-resilient IoT security. The proposed model was designed in such manner that it could be suitable towards both data-level security as well as device level access-credential security to enable a “Fit-To-All” security solution for IoTs. Simulation results revealed that the proposed GFS-SSPN model exhibits very small encryption time with optimal NPCR and UACI. Additionally, correlation output too was found encouragingly fair, indicating higher attack-resilience.

Keywords—Internet-of-Things; dynamic programming; lightweight encryption; generalized Feistel network; substitution and permutation network

I. INTRODUCTION

The exponential rise in advanced software computing and low-cost hardware has broadened the horizon for industries to provide more-efficient and productive systems, serving healthcare, monitoring and surveillance, home-automation, smart-city planning and management, business communication, smart-factory, etc. Amongst the major such innovations the recently evolved IoT technology has gained wide-spread momentum to serve major aforesaid application

environment. With low-cost, decentralized communication and control ability, IoT has become one of the most sought-after technology to meet the major aspects of human activities and expectations [1]. Contemporarily, it not only enables optimal decision making, productivity but also facilitates luxurious life signifying accomplished human objectives in modern era. In general, the inception of IoT can be hypothesized to be with machine-to-machine (M2M) communication systems that later evolved as internet enabled query driven systems or services [1]. Architecturally, IoT systems comprise multiple distributed (autonomous) nodes and a sophisticated software computing enabled data-processing unit, where the first collects the real-world data, while the later executes query driven tasks or instructions to meet expected demands [1]. Interestingly, in early days of evolution, though no sophisticated communication platforms were defined; however, the contemporary IoT eco-systems operate over certain wireless channel with unavoidable network dynamism and uncertainty [2]. Undeniably, in the era of IoT-ecosystem(s), the interaction between human and machines is more frequent and increase with high-pace. This is because the machines getting smarter and capable to perform many human tasks on the basis of certain targeted instructions provided. This as a result has been broadening the horizon of IoT systems across industries as well as socio-scientific periphery [1][2]. Putting a glance around, one can find that IoT has been applied in varied critical purposes as well including healthcare, finance, manufacturing, research, surveillance etc.; however, being operated over certain unpredictable network condition its reliability and data-infra-procedural (DIP) safety always remains questionable. Ironically, with increase in high-pace IoT demands, the events of security breaches too have increased severely. The security breaches in IoT can be at the different level, i.e., device level, infrastructure level, network level (say, channel) and data level [3][4][6][38]. Such security breaches can cause detrimental impacts in terms of financial loss, data-loss, tack-manipulation and procedural destruction [2]. Consequently, such IoT-security breaches can have adverse impact on major aspects of human life and its decision systems [5].

Recalling the typical architecture of the IoT systems that encompasses Low-power Lossy (sensor) Networks (LLNs), gateways, transmission channel and data-warehouses or storage possessing undeniably security related vulnerabilities. Typically, the poorly interfaced nature of IoT devices and their inferior connection, especially operating online can undergo

security breaches and resulting losses [5-7]. On the other hand, attack probability gets increased manifolds over channel where different man-in-the middle attack (MITM), linear and differential attacks, impersonation, etc. are more common. Similarly, once compromising the security access level of IoT devices due to poorly configured setup or keys, an intruder can manipulate the device and its functioning, thus obstructing overall performance [7]. However, looking into depth it can be found the key reason behind such attack possibility is poor encryption systems with limited keying capacity and inferior cipher-space [8]. Such limitations are common in IoT systems where to meet computational efficiency demands; authors often apply lower-sized keys with smaller round of encryption. In fact, the threat of higher computation due to large key size and more complex confusion or cipher randomness limit efficacy of such systems [8]. It indicates the need of a robust (say, attack-resilient) and lightweight encryption system for IoTs [5][6]. An interesting fact that majority of the classical security systems employ different encryption modalities to perform device (access-level) security and data security; however, such systems under real-time (hardware) realization imposes significantly large computational overheads and resource (power and memory) exhaustion. Practically, the methods addressing IoT-network security or access-level security are different than the one used for data-security. Approaches pertaining to the data security predominantly consider attack-resilience, irrespective of the cost of computation (over large data size) and allied hardware realization [9]. On the contrary, the security measures designed towards access-control focus on retaining large key-size and encryption rounds to enable attack-resilience [10-12]. In sync with above inferences, to cope up with contemporary or even NextGen IoT ecosystems, designing a robust and "Fit-To-All (FTA) lightweight encryption system is inevitable [12]. Such security models are required to retain higher attack-resilience even at reduced computational cost, time, and hardware utilization.

Considering above the potential approaches available, despite of the different cryptosystems or crypto-algorithms like AES [13], RSA [14], DES [18], Huffman Coding, Homomorphic encryption etc. IoT demands more effective and more specifically lightweight solution [12][15-17][19]. Majority of these encryption methods focus on increasing key-size and corresponding encryption rounds to retain higher level of attack-resilience; however, fail in hardware realization due to significantly large computational overheads, memory and power exhaustion [21]. Similarly, a few researches suggested to use multi-factor authentication (MFA) by strategically amalgamating multiple cryptosystems to achieve IoT-security [1][11][13][14][17][19][32]. Such approaches often fail when delivering resource efficient and computationally efficient performance, especially with hardware realization [11][20]. Unlike classical cryptosystems, in the last few years lightweight encryption systems [12][13][16-18][33] have emerged as a potential solution for IoT security. The ability to retain higher level of confusion in cipher even at the significantly lower computation enables lightweight encryption system a viable solution towards IoT-security. Amongst the major approaches towards lightweight encryption based IoT-security, SPN-based algorithms are well-known [15][21]; however, retaining higher level of confusion even at reduced

encryption cycle and relatively lower key-size has remained a challenge [8][22]. Most of the existing SPN encryption models employs 64, 128 and even larger size keys which operate over tens of encryption rounds to achieve higher cipher-confusion [23-28]. Unfortunately, these all approaches turned inferior due to higher demands of gate-elements (GE), power consumption and computational time [21][33][37]. Moreover, such methods mainly focused on retaining higher level of confusion (in cipher), irrespective of the fact that doing arbitrarily it may impact bit error rate or correlation performance. This as a result can impact different IoT-enabled services such as healthcare sector, device access control, etc. which are highly sensitive to the single-bit and /or pixel changes. In such circumstance, developing a robust lightweight encryption system with conditional confusion (say, limit constrained confusion in SPN) with lower key-size and minimum encryption rounds can be of great significance [29][30]. Undeniably, SPN based lightweight encryption methods have gained wide-spread attention towards IoT security; however, have always been criticized for limited S-box generation [29][34]. Moreover, their suitability with single key assisted encryption [30] has also been under suspicious lens. It indicates the need of dynamic keying concept with improved S-box function so as to yield better cipher at the end. Furthermore, the efficacy of Feistel Network towards SPN realization [31] too has broadened the horizon for further improvement in lightweight encryption based IoT systems. The hypothesis that "the strategic implementation of SPN with improved FN architecture [31][37] can enable improved lightweight encryption system for IoT" can be considered as the key driving force behind this research.

In sync with above stated problem and allied scopes, in this research paper a state-of-art new and robust Generalized Feistel Network assisted Shannon-Conditioned and Dynamic Keying based SPN Lightweight Encryption System for IoT Security. Our proposed lightweight encryption model, GFS-SSPN intends to improve attack-resilience or cipher generation while retaining lower key size and even significantly small encryption rounds. Architecturally, GFS-SSPN model employed SPN with Generalized Feistel Network (GFN) to perform block-cipher based encryption for IoT device security. Here, being a block-cipher based encryption, our proposed GFS-SSPN model considered 64 bits key size with merely five encryption rounds to perform data encryption. The overall proposed model encompassed dynamic programming based "Dynamic Key Generation and Expansion System", 64-bit block-cipher encryption and decryption. The proposed GFS-SSPN was designed in such manner that it retained higher level of confusion even at the reduced key-size and encryption rounds that enable to resilient to the major IoT attacks like Smart Card Loss Attack, Brute-Force Attack, Impersonation Attack, Linear and Differential attack etc. Unlike classical approaches the use of Shannon criteria for SPN-GFS encryption enabled quality-preserving encryption thus helping GFS-SSPN to have sufficient correlation and possibly minimum bit-error rate at the decryption. It enables it to be used for broad IoT applications including access-control, sensitive data logging and actuation control, telemedicine etc. [38]. The performance assessment in terms of NPCR, UACI, correlation and execution time exhibited that the proposed

GFS-SSPN model exhibits optimal performance even with significantly small key-size and encryption round. Additionally, the use of GFS enabled reduction in decryption programming and hence can be visualized as reduced hardware utilization or allied power exhaustion.

This research paper is organized as follows: Problem formulation is provided in Section II, which is followed by the system model in Section III. The results and discussions are presented in Section IV and conclusion and future scope of this research are presented in Section V.

II. PROBLEM FORMULATION

Most of the classical security systems hypothesize that increasing key-size, encryption rounds and eventual cipher-randomness can help achieving optimal security; however, fail in addressing the resulting complexity and resource (i.e., power, memory, etc.) exhaustion. Additionally, these approaches undergo significantly large delay as well thus making it unsuitable towards realistic IoT-ecosystem. Undeniably, existing IoT-security systems employed cryptosystem(s) whether as standalone architecture or multi-factor authentication [35]. It eventually imposes computational overheads and complexity, thus making it inappropriate for IoT systems. To alleviate such issues, developing a lightweight encryption system has always been the dominant solution. However, retaining optimal key-size, number of rounds etc. has always remained challenge for industries, as any inappropriate design could cause loosely-coupled systems or channel inviting attacker to intrude it. Despite of the fact that the majority of the lightweight encryption methods developed so far are mainly focused towards multimedia data security in IoT systems [6]. On the contrary, a complete IoT ecosystem needs security system to ensure device-level security as well as data-level (within channel) security. To cope up with such demands, designing a "Fit-To-All" solution is must. Considering it as objective, in this paper a state-of-art new and robust Lightweight encryption-based block-cipher technique is proposed for IoT-systems. In GFS-SSPN the key goal is focused on retaining a lightweight encryption solution with smaller key-size, very small encryption and allied computational cost. Moreover, realizing the fact that IoT-systems encompass varied applications including access-control, data-logging, query-based data-retrieval, financial transactions, telemedicine information exchange etc., we focused on retaining optimal data quality along with uncompromising security. This as a result can enable a Fit-To-All solution for both access-control security as well as IoT-data security.

Literatures reveal that SPN based lightweight encryption is more hardware-friendly and computationally efficient towards IoT-security system; however, majority of the related work have applied large key-size with single key-based encryption. Additionally, such approaches have considered higher number of encryption-rounds to introduce encryption. Despite of the lightweight computation ability such approaches are often criticised for higher computational cost and delay that confines its suitability for IoT systems. It indicates the need of a solution employing lower key size with minimum encryption round of computation. Moreover, reduction in programming cost and

allied overhead can help reducing memory consumption or allied gate-element exhaustion. Towards data-quality centric IoT systems, maintaining optimal cipher quality with minimum possible error too is equally significant. Considering these facts as scope or motivation, in this research we designed a novel Generalized Feistel Network (GFN) assisted Shannon-Conditioned and Dynamic Keying based SPN (SSPN) lightweight encryption system for IoT security. As the name indicates, GFS-SSPN model encompasses Shannon-Conditioned SPN encryption system which is employed over GFS encryption structure for plaintext encryption. Architecturally, GFS-SSPN employs 64-bit key which is executed over merely five rounds of encryption to generate the cipher results. Unlike major classical SPN models where authors mainly focus on introducing randomness, without considering its detrimental impact on the cipher generated and eventual decryption results, our proposed SSPN model is designed in reference to the Shannon-condition. Here, Shannon condition states that for an arbitrarily selected input, if one flips the i th bit, then likelihood that the j -th output would be changed must be one half has been taken into consideration, which is also called Strict Avalanche Condition for SPN. This approach can enable sufficiently large confusion in cipher, while maintaining higher association between input plain text and the cipher generated and hence would be advantageous towards error-free decryption. The proposed SSPN model has been applied with GFS architecture that enables its implementation as block-cipher model by partitioning input data into multiple chunks. This method not only helps in enhancing computational efficiency (i.e., time) but also reduces the separate program demands for decryption. It can be vital towards resource efficient and delay-resilient encryption for IoT. Recalling the overall architecture, SSPN model can enable higher confusion with optimal randomness and resource as well as delay efficiency while preserving data-quality. Here, SSPN helps achieving optimal S-box and P-box generation, while GFS would enable dynamic key management of keying. In the proposed model, SPN block cipher has been applied in iterative and alternating rounds of substitution and permutation (say, transposition) while ensuring that it fulfils the demands of Shannon's Confusion and Diffusion characteristics to ensure higher attack-resilience. To achieve it, a novel dynamic key management has been developed to assure that the cipher has been processed in pseudo random manner. To introduce higher level of confusion and security-structure the proposed key-expansion block is implemented over five rounds, where in each round it intends to meet above stated Shannon's Confusion and Diffusion (SCD) conditions. Cumulatively, these approaches can be robust enough to retrieve attack-resilient encryption even at the reduced cost and time. Here, to introduce a non-linear layer for better lightweight encryption, the proposed model applied S-Box. The proposed S-box has been applied in such way that it enables optimal diffusion over each round and thus making it more imperceptible and hence higher attack-resilient. Being a block-cipher concept, it splits 64-bit data into four chunks and performs five rounds of key generation and encryption that introduces sufficiently large randomness in cipher to avoid any attacks including SCLA, Brute-force, impersonation, linear and differential attacks etc.

III. SYSTEM MODEL

As discussed in the previous section, our proposed lightweight encryption-based block-cipher model amalgamated SSPN and GFS optimistically designed to cope-up with high parallelism so as to achieve better time-efficiency. In the proposed model, complete input block is split into four equally partitioned 16-bit blocks. Noticeably, unlike classical SPN based approaches, we improved the overall structure by introducing numerous enhancements such as Shannon-Conditioned SPN, GFN, Dynamic Keying, etc. To enable our proposed GFS-SSPN model for swift computing IoT security system, unlike classical Feistel Network (CFS) which partitions the input into two-equal blocks, we applied GFS which split it into multiple equal blocks for further encryption. This mechanism at first helped SSPN to achieve time as well as computationally efficient parallelized encryption. Moreover, the use of GFS helps reducing additional programming cost that makes it hardware and power efficient when realized in real-world. Before discussing the proposed lightweight encryption model, a snippet of the proposed SPN model, in sync with Shannon criteria is given as follows:

A. Shannon's Confusion and Diffusion Theory

Being an SPN based encryption the proposed GFS-SSPN model applied two consecutive methods, confusion and diffusion for encryption. A snippet of these mechanisms is given as follows:

1) *Confusion*: Typically, in encryption system domain, confusion mechanism states that "each binary bit of the cipher must rely on varied other fractions of the key, representing obscured connection between the two (i.e., cipher and key). Functionally, it hides the associations in between the plaintext and the key applied, and consequently avoids any possible security breaches due to key-loss, such as SCLA or linear and differential attacks. Confusion makes it difficult for attacker to extract key and hence can alleviate any unauthorized retrieval of the original data from cipher. Functionally, for an efficient encryption model with single bit change or manipulation entire cipher bits must be changed. This approach enhances the level of ambiguity of the cipher and hence helps in retaining higher attack-resilience.

2) *Diffusion*: Unlike confusion, diffusion states that in case a single bit is manipulated in input plaintext, then nearly half of the bits in the cipher might be statistically changed. Similarly, if a single bit is manipulated in the cipher then the half of the plaintext bit would change. Since, a single bit may have only two-states, approximately half of the bit can have their state manipulated. In our proposed GFS-SSPN encryption scheme, the predominant concept behind diffusion is to hide the relationship between the input plaintext and the corresponding cipher which make it difficult for attacker(s) to get access of the plaintext. Diffusion is further accomplished because of the increased level of randomness in the plaintext over the different rows and columns. Functionally, it is accomplished by performing transposition. A snippet of the Shannon

Condition of SPN, being applied in the proposed GFS-SSPN lightweight encryption model is given as follows:

Typically, Shannon condition for SPN encryption defines confusion as the process for transforming the associations or the relationship between the key and the cipher as complex as possible. It enables depletion or reduction in the native statistical structure of the input plaintext over cipher. In our proposed SSPN model, such complexity is introduced by perform repetitive substitutions and permutations function, where in substitution, a part of bits in each block is replaced or substituted with other parts following the Shannon criteria of substitution. Permutation on the other hand indicates the mechanism of changing the bit's order as per certain mathematical approach, also called transformation rules. In GFS-SSPN model to achieve high non-linearity, the input bits are distributed across the structure of the cipher text which makes it difficult to detect either key or the plaintext data. In sync with the Shannon condition for SPN, for any randomly selected input, if one changes the i th bit, probability that the j -th output would be changed remains the half. This condition is also known as the Strict Avalanche Condition. It states that it is important to assure that flipping of a definite set of bits must change each output bit in cipher with the probability of minimum one-half. A vital purpose of the use of confusion was to inculcate such randomness that an attacker to identify the key, despite the fact that the one has the significantly large plaintext-cipher pairs generated with the same key. Therefore, each bit of the cipher depends on the entire key in the different ways on the varied bits of the key. In other words, manipulating a single bit can change the entire cipher text. Thus, implementing the Shannon conditioned SPN (say, SSPN) we developed a state of art new Dynamic Keying and Expansion (DKE) mechanism over with GFS over five consecutive rounds. Here, we designed DKE in such way that it ensures the Shannon condition where the cipher gets manipulated in pseudo random manner. The proposed DKE assisted encryption with GFS-SSPN model was applied over five consecutive rounds so as to induce higher confusion and hence attack-resilience, where in each round of computation it follows the Shannon's criteria of confusion and diffusion. The detailed discussion of the overall system implementation is given in the sub-sequent sections.

B. System Implementation

For system implementation, to maintain lower computational cost and allied (possible) hardware resource exhaustion, we designed GFS-SSPN as a 64-bit block cipher model. In this approach we considered 64-bit key to perform encryption of each block encompassing 64-bit input plaintext. Additionally, to perform GFS-SSPN encryption we applied only five round of encryption. In this process, each encryption-round is performed over DKE function which helps in generating confusion and diffusion matrix over different rounds of encryption. Though, maintaining higher encryption round can introduce higher randomness; however, at the cost of increased computational overhead, delay and resource exhaustion. Therefore, to design the proposed encryption model suitable for IoT-applications, we maintained only five round of encryption, while to introduce higher cipher randomness and minimum correlation we introduced a state-of-

art new Dynamic Keying and (key) Expansion concept in which each split of input 16-bit was processed for GFS-SSPN over five rounds, where each round gave rise to a new set of keys for encryption. Thus, performing keying expansion over each round of computation finally we obtained a concatenated 64-bit key to be used for decryption. Architecturally, in GFS-SSPN, at first the input of 64-bit was split into four equally chunks, which was possible by the use of GFS architecture. In other words, by applying the proposed GFS architecture as shown in Fig. 1, we applied SSPN over each chunk of 16-bits. To further enhance randomness in cipher, we split each 16-bit data into four distinct sub-parts each of 4-bits size. To further introduce higher confusion and diffusion over consecutive rounds of encryption, the proposed GFS model applied logical XOR function over each round of confusion and diffusion to result cipher results per block. To achieve the overall implementation our proposed model applies three key functions.

- 1) Multi-round Dynamic Keying, Expansion and Update.
- 2) Block-Cipher Encryption and Cipher Generation, and
- 3) Block-Cipher Decryption.

The detailed discussion of each functional component is given in the subsequent sections.

1) *Multi-round dynamic keying, expansion and update:* In sync with the real-world IoT systems where each node can be assumed to act like a key generator as well as decoder, it becomes vital to minimize cost caused by key generation and update. To enable lightweight encryption, in GFS-SSPN model different mathematical models by using varied logical functions like XOR and XNOR has been developed. Here, our proposed DKE model serves dual purpose; first it acts as a key generation and expansion (KGE) unit while secondly it helps concatenating cipher iteratively. To achieve key generation and expansion, GFS-SSPN applied GFS assisted encryption. In GFS-SSPN, GFS is applied over five encryption rounds, where each round employs distinct key to perform substitution and permutation tasks. Realizing the fact that the proposed model intends to apply minimum (here, only five) round of encryption which is undeniably lower than the classical AES, RSA, ECC, Diffie-Hellman, etc. kind of encryption systems or even many existing SPN based encryption model, our proposed model intended to introduce a concept of dynamic keying. Unlike classical SPN methods or other cryptosystems that apply merely single key to perform encryption, GFS-SSPN to introduce higher randomness or confusion in cipher, we applied dynamic keying concept. In the GFS-SSPN, we estimated a set of keys over each round and thus, we retrieved a final concatenated key of 64-bits. Noticeably, to retain higher attack-resilience a lightweight encryption model requires maintaining sufficiently large key size k_t which can prohibit any intruder to perform 2^{k_t-1} encryption so as to gain key

information for data access or retrieval. Our proposed model applied 64-bit key to perform bit-permutation instruction-based encryption for the 64-bit block sized input data. We applied 64-bit's cipher key k_c as the input of the proposed DKE function to perform a SSPN confusion and diffusion task, as per Fig. 2. In this manner, it provides five distinct keys one for each round of encryption.

In DKE (Fig. 1) we implement the mathematical approach suggested by Barreto et al. [68]. The Khazad cipher model as proposed in [68] applied Broad-Trial-Mechanism (BTM) to perform multiple linear and non-linear transformation to perform encryption. On the contrary, we applied GFS architecture which enabled a definite relationship and inter-dependency between the input bits and the output cipher in a predefined complex manner. As depicted in Fig. 1 the 64-bit input k_c is equally-split into four equal-blocks, each of 16-bits. Moreover, to perform SSPM, we split each 16-bit block into 4-bit chunks, which were later processed for substitution and permutation as depicted in Fig. 2. Thus, performing DKE over each 16-bit input, our proposed model obtained a matrix of 4-bits each. Noticeably, each block of 16-bits generated four 4-bits chunks to be processed for further GFS enabled SSPN. The detail of the proposed SSPN model is given in the subsequent section.

a) Shannon Constrained SPN (SSPN)

As depicted in Fig. 1, once estimating the 16-bits data post DKE, we performed the initial substitution of the chunks of k_c (1).

$$Km_{i \in \{1,2,3,4\}f} = \prod_{j=1}^4 Kn_{4(j-1)+i} \quad (1)$$

The above derived model (1), enabled estimation of a 16-bits output for each DKE block, applied over all four 16-bit blocks. Once estimating the 4×4 matrix from each 16-bit input (i.e., post DKE), we performed circular shifting which helped us to generate four different keys.

Now, estimating all four keys for $Km_{i \in \{1,2,3,4\}f}$ as depicted in Fig. 1, we concatenated these keys and retrieved a set of keys Kc_{if} for round of computation using (2).

$$Kc_{if} = f(Km_{if}) \quad (2)$$

To further introduce higher confusion and diffusion over the consecutive SSPN layers, we applied a state-of-art new Transformation coder containing two different functions, say, "Linear (LF)-Non-Linear Function (NF)", as depicted in Fig. 2.

To enable a computationally efficient SSPN implementation, we applied a predefined transformation coder, encompassing two distinct functions, LF and NLF, as given in Table I. Though, in GFS-SSPN k, we applied LF and NLF transformation coder as predefined value; however, different other transformational values can also be assigned for the different test cases or custom encryption demands.

Fig. 1. Proposed Dynamic Key Generation and Expansion.

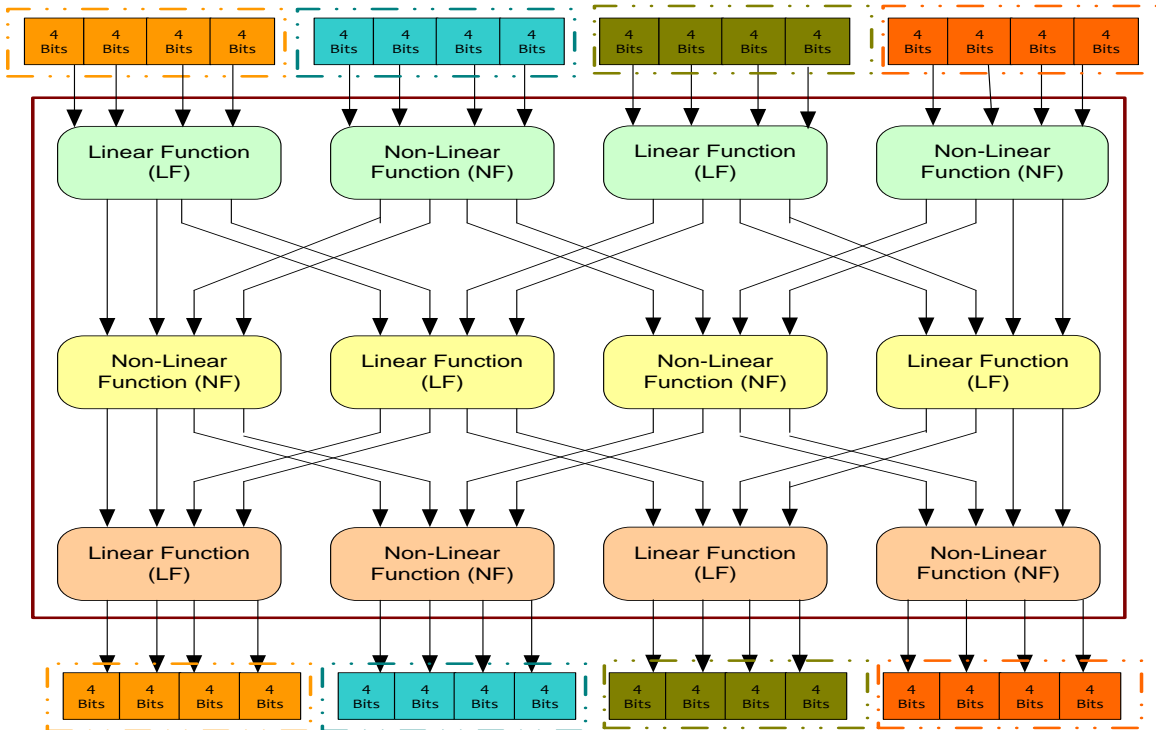

Fig. 2. SSPN Implementation.

TABLE I. TRANSFORMATION CODER

$k_{n,i \in \{1,2,3,4\}}$	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
$LFP(k_{n,i \in \{1,2\}})$	3	F	F	0	4	1	E	B	A	F	7	8	6	8	1	1
$NLFP(k_{n,i \in \{1,2\}})$	9	D	4	4	F	2	3	E	D	2	6	E	7	C	2	7

Thus, with the different inputs, we applied transformation coder (Table I) values. This as a result enabled distinct keys per 16-bit blocks. Estimating the outputs from the DKE model, we obtained 4×4 matrix which was later processed for the ‘‘circular-Shifting’’. This mechanism re sampled the input 4×4 matrix, per 16-bit of input and eventually estimates four distinct keys, as per the equations (3-6). The matrix generated for each 16-bit block is given in equations (3-6).

$$K_{Mat1} = \begin{bmatrix} Kc_1f_1 & Kc_1f_2 & Kc_1f_3 & Kc_1f_4 \\ Kc_1f_5 & Kc_1f_6 & Kc_1f_7 & Kc_1f_8 \\ Kc_1f_9 & Kc_1f_{10} & Kc_1f_{11} & Kc_1f_{12} \\ Kc_1f_{13} & Kc_1f_{14} & Kc_1f_{15} & Kc_1f_{16} \end{bmatrix} \quad (3)$$

$$K_{Mat2} = \begin{bmatrix} Kc_2f_1 & Kc_2f_2 & Kc_2f_3 & Kc_2f_4 \\ Kc_2f_5 & Kc_2f_6 & Kc_2f_7 & Kc_2f_8 \\ Kc_2f_9 & Kc_2f_{10} & Kc_2f_{11} & Kc_2f_{12} \\ Kc_2f_{13} & Kc_2f_{14} & Kc_2f_{15} & Kc_2f_{16} \end{bmatrix} \quad (4)$$

$$K_{Mat3} = \begin{bmatrix} Kc_3f_1 & Kc_3f_2 & Kc_3f_3 & Kc_3f_4 \\ Kc_3f_5 & Kc_3f_6 & Kc_3f_7 & Kc_3f_8 \\ Kc_3f_9 & Kc_3f_{10} & Kc_3f_{11} & Kc_3f_{12} \\ Kc_3f_{13} & Kc_3f_{14} & Kc_3f_{15} & Kc_3f_{16} \end{bmatrix} \quad (5)$$

$$K_{Mat4} = \begin{bmatrix} Kc_4f_1 & Kc_4f_2 & Kc_4f_3 & Kc_4f_4 \\ Kc_4f_5 & Kc_4f_6 & Kc_4f_7 & Kc_4f_8 \\ Kc_4f_9 & Kc_4f_{10} & Kc_4f_{11} & Kc_4f_{12} \\ Kc_4f_{13} & Kc_4f_{14} & Kc_4f_{15} & Kc_4f_{16} \end{bmatrix} \quad (6)$$

Now, once retrieving the values of the key-matrix ($K_{Mat1}, K_{Mat2}, K_{Mat3}$ and K_{Mat4}), to obtain the keys for each 16-bit block, we transformed these metrics into four distinct arrays of 16 bits as derived in (7-10). These 16-bits arrays provided the encryption key per round. Noticeably, in (7-10) the operator $\#$ represents the concatenation function.

$$Key_1 = a_4 \# a_3 \# a_2 \# a_1 \# a_5 \# a_6 \# a_7 \# a_8 \# a_{12} \# a_{11} \# a_{10} \# a_9 \# a_{13} \# a_{14} \# a_{15} \# a_{16} \quad (7)$$

$$Key_2 = b_1 \# b_5 \# b_9 \# b_{13} \# b_{14} \# b_{10} \# b_6 \# b_2 \# b_3 \# b_7 \# b_{11} \# b_{15} \# b_{16} \# b_{12} \# b_8 \# b_4 \quad (8)$$

$$Key_3 = c_1 \# c_2 \# c_3 \# c_{10} \# c_{11} \# c_{12} \# c_{16} \# c_{15} \# c_{14} \# c_{13} \quad (9)$$

$$Key_4 = d_{13} \# d_9 \# d_5 \# d_{11} \# d_7 \# d_3 \# d_4 \# d_8 \# d_{12} \# d_{16} \quad (10)$$

Thus, estimating the four distinct keys; Key_1, Key_2, Key_3 and Key_4 , we performed XOR logical function as per (11) to achieve the final encryption key.

$$Key_{Fused} = Key_1 \oplus Key_2 \oplus Key_3 \oplus Key_4 \quad (11)$$

2) *Lock-Cipher encryption and cipher generation*: Once estimating the complete 64-bit of encryption key (11), we performed plaintext encryption. To perform encryption, we applied the schematic given in Fig. 3. As depicted in Fig. 3, the input 64-bit plaintext was equally split into four 16-bit blocks (i.e., $Px_{0-15}, Px_{16-31}, Px_{32-47}$ and Px_{48-63}). Subsequently, executing bit-permutation instruction over each 16-bit block (each round), GFS-SSPN exhibited bit-wise swapping so to reduce traceability. To achieve it, we performed bit’s order alteration, where the sub-blocks of 16-bit block were changed. Subsequently, we performed bitwise XNOR logical operation between the round key Key_i and the input plaintext Px_{0-15} . This process was repeated four rounds in K_i to Px_{48-63} and eventually the corresponding outputs Ro_{11} and Ro_{14} were obtained. Now, estimating the output from XNOR logical operator (Fig. 3) we fed the results to the DKE component which generated two distinct outputs Ef_{l1} and Ef_{r1} . Now, once estimating the values of Ef_{l1} and Ef_{r1} , we took Ef_{l1} and Px_{32-47} , and performed bitwise-XOR to estimate Ro_{12} . Similarly, the bitwise-XOR between Ef_{r1} and Px_{16-31} gave rise to Ro_{13} . We applied equation (12) to estimate encrypted cipher outputs.

$$Ro_{i,j} = \begin{cases} Px_{i,j} \odot K_i ; & j = 1 \text{ and } 4 \\ Px_{i,j+1} \oplus Ef_{li} ; & j = 2 \\ Px_{i,j-1} \oplus Ef_{ri} ; & j = 3 \end{cases} \quad (12)$$

Thus, the above discussed transformations were performed in such way that for each consecutive round, Ro_{11} turned out to be Px_{16-31} , while Ro_{12} became Px_{0-15} , Ro_{13} as Px_{48-63} . Similarly, Ro_{14} became Px_{32-47} . This process was performed for all rounds by using (12). The outputs of the final round were concatenated as per (13) to generate the cipher output.

$$CT = R_{51} \# R_{52} \# R_{53} \# R_{54} \quad (13)$$

3) *Block-Cipher decryption*: As already stated, unlike classical SPN based encryption or other cryptosystems, our proposed GFS-SSPN lightweight encryption model applied GFS assisted SSPN, and therefore, it avoids any additional programme for decryption. The use of GFS enabled decryption in the same way as performed towards encryption using the different logical functions, as discussed above. This characteristic enabled significantly lower computational overheads and resource exhaustion. Thus, implementing the above discussed methods, we performed block-cipher encryption for the different set of inputs characterizing a small size authentication credential or a large plaintext data to be communicated over the IoT-centric LLNs channels or even to be stored on local memory [70]. The detailed discussion of the overall simulation results and allied inferences is given in the subsequent sections.

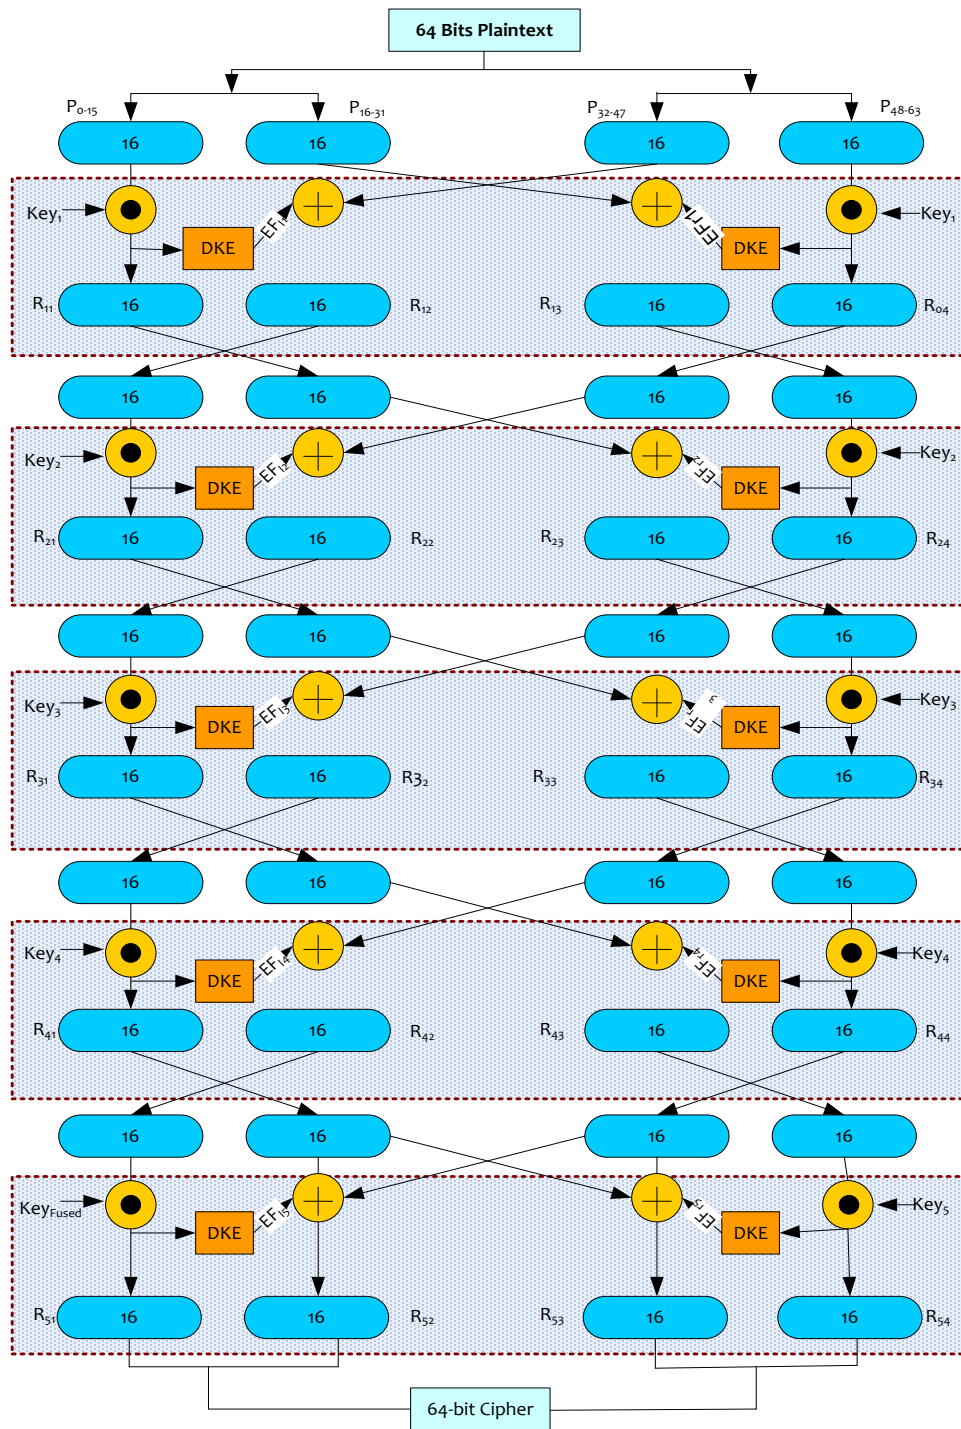

Fig. 3. Proposed Block-Cipher Encryption.

IV. RESULTS AND DISCUSSIONS

As stated, and discussed in details, the predominant emphasis of this research was to contribute a state-of-art new and robust lightweight encryption system or the block-cipher technique for IoT security. Zeroing down the belief that whether a device level or the data level security in IoT, maintaining seamless and attack-resilient cipher is must, the proposed work focused on introducing sufficiently large and optimal randomness (say, confusion) in cipher. On the other

hand, to retain computational efficacy and optimality, we considered block cipher method with 64-bit key and merely five round of encryption. In sync with hypotheses that maintaining or applying higher encryption rounds can enable higher randomness in cipher, unlike classical methods, we applied different state-of-art logical functions implemented over GFS assisted SSPN to perform encryption. In other words, we strategically implemented GFS with Shannon-Conditioned SPN to perform encryption using 64-bit key and only five

round of encryption. Noticeably, the key purpose of using GFS was to assist block-cipher generation, while SSPN was targeted to accomplish encryption with sufficiently large confusion or randomness. Moreover, the use of GFS enabled reduction in programming cost as it avoided any separate decryption program like other classical SPN methods or cryptosystem algorithms. Noticeably, unlike conventional SPN methods, the use of Shannon-conditioned SPN not only intended to achieve optimal confusion and diffusion, but also intends to support optimal decryption at the receiver without bit-loss. This is the matter of fact that not much significant works are done towards lightweight encryption based IoT security, especially by using SPN and/or Feistel network. A few efforts employing technologies have mainly focused on multimedia data security [6]; however, the use of higher encryption key and rounds make them computationally exhaustive. On the other hand, a few methods, targeting hardware efficient lightweight encryption too are found limited and exhaustive due to bit-by-bit encryption and supplementary tool/programme-based randomness insertion (in cipher). In our research we tried to alleviate such limitations and designed GFS-SSPN in such manner that it could retain higher confusion even with minimum encryption round and lower key-size. The use of dynamic keying concept over the multiple rounds helped accomplishing an untraceable keying strategy, where SSPN helped in maintaining sufficiently large randomness as well as associations with the input plaintext. This as a result intended to achieve high attack-resilience.

Repeating the structural details, our proposed GFS-SSPN model encompassed three key components including Dynamic Key Generation, Expansion and Update (DKE), GFS-SSPN encryption and GFS-SSPN decryption. Being a bloc-cipher method, the proposed model at first split 64-bit input into four equal blocks of 16-bit each. Subsequently, applying an initial key value, with input 16-bit plaintext we perform SSPN that eventually performs logical operations and generated each round output. The outputs obtained for each 16-bit blocks were processed for the different logical operations and flipping, circular rotation etc., that eventually generated 64-bit keys (16-bit key per block, which were concatenated together to result a final 64-bit key for encryption) over five round of encryption. Thus, with the final generated key, we performed GFS-SSPN encryption followed by decryption. The overall proposed GFS-SSPN model was developed using C-programming language which was simulated over *DEV C++* compiler. We simulated the proposed lightweight encryption system onto a central processing unit (CPU) with 8 GB RAM, and Intel-i5 processor. To assess performance of the proposed GFS-SSPN model, we examined its efficacy in terms of encryption time, correlation, NPCR and UACI. To be noted, as already stated IoT-ecosystem encompasses the different activities including data logging, device access, live streaming, etc., and hence for both device level security as well as data level or network level, ensuring plaintext (say, data) security is must. Retaining minimum encryption time, negligible or very small correlation between the cipher and key is must. Moreover, there are many IoT applications such as data-streaming, access-credentials, telemedicine in healthcare etc., where maintaining higher NPCR and suitable UACI is must. Considering this fact, we examined the proposed of the proposed GFS-SSPN model in

terms of encryption time, correlation, NPCR and UACI. The performance assessment has been performed under two broad umbrellas; first quantitative assessment and second, the qualitative assessment. Here, quantitative assessment discusses empirical simulation outputs and allied inference, while qualitative assessment discusses different attack-resilience. The detailed discussion is given as follows:

A. Quantitative Assessment

This section primarily discusses some of the key empirical analysis outcomes in terms of correlation, encryption time, etc.

1) *Correlation*: Realizing the fact that to ensure high attack-resilience and imperceptibility in cipher, it is must to retain minimum correlation between cipher generated, original text and the encryption key. There are many IoT-attack conditions such as linear and differential attack analysis, impersonation etc., where the attacker often exploits cipher details to retrieve the key information and allied original data. To avoid such problems, retaining minimum or negligible correlation is must. On the other hand, correlation being the statistical dependency between the two different variables requires to be maintained as minimal as possible so as to alleviate any attack conditions, as stated above. To assess performance of the proposed GFS-SSPN model, we obtained correlation coefficient value γ between the cipher text and the original text using (1). Noticeably, for any encryption-based security system maintaining γ near zero is considered as an ideal condition.

$$\gamma_{x,y} = \frac{cov(x,y)}{\sqrt{D(x)}\sqrt{D(y)}} \quad (14)$$

In (14), the parameter $cov(x,y)$ signifies the covariance, while the variance for x and y are given as $D(x)$ and $D(y)$, respectively. Typically, the distribution of the variance of any single dimension random variable can be estimated as per (15).

$$D(x) = \frac{1}{N} \sum_{i=1}^N (x_i - E(x))^2 \quad (15)$$

In (15), $D(x)$ states the variance for x . Now, to calculate covariance in between x and y , we used (16) as given below.

$$cov(x,y) = \frac{1}{N} \sum_{i=1}^N (x_i - E(x))(y_i - E(y)) \quad (16)$$

In (16), the parameters $E(x)$ and $E(y)$ signifies the targeted values for x and y , respectively. Here, the expectation values for x is obtained as per (17).

$$E(x) = \frac{1}{N} \sum_{i=1}^N x_i \quad (17)$$

In (18), N presents the total number of bits in the data, while x signifies the N -dimensional vector. Noticeably, the component x_i presents the i -th value of the original plaintext. To assess the performance, we simulated proposed model with the input plaintexts of different sizes (here, we call sample(s)). The results obtained towards the correlation outputs between input sample and resulting cipher is given in Table II.

TABLE II. CORRELATION ANALYSIS

Input Samples	Original data	Cipher data
1	0.9919	0.0076
2	0.9971	0.0072
3	0.9829	0.0036
4	0.9801	0.0060
5	1.0000	0.0071
6	0.9672	0.0129
7	0.9721	0.0131
8	0.9408	0.0083
Average Correlation	0.9790	0.0082

The average correlation obtained over a total of 8 different samples encryption reveals that the proposed GFS-SPNN model accomplishes the minimum correlation coefficient of 0.0082. This is significantly small that it can enable seamless encryption for attack-avoidance. In above depicted results (Table III), we considered the different samples of varied sizes for encryption. Table II presents the correlation results between the original test and the cipher data obtained post GFS-SSPN. Observing the results, it can easily be inferred that post-encryption the correlation value significantly decreases. It indicates minimum correlation signifying high attack-resilience.

2) *Number of Changing Pixel Rates (NPCR)*: In addition to the correlation performance, we examined the efficacy of the proposed lightweight encryption system in terms of other statistical performance variables such as the number of pixels changing rate (NPCR) and unified averaged changed intensity (UACI). Typically, those encryption algorithms or methods which hypothesize that merely including randomness in cipher can enable attack-resilience often under a detrimental effect called avalanche effort or plaintext sensitivity [39-41]. Though, the use of Shannon criteria of SPN alleviated such problem, however, maintaining higher changes or sensitivity over encryption is must. In this relation, we measured NPCR performance signifying the total number of characters which are different in cipher than the equivalent plain-text (say, w_1 and w_2). Mathematically, NPCR was estimated as per (18), where its value is often presented in the form of percentile (%).

$$NPCR = \frac{\sum_{i=1}^l W(i)}{l} \times 100 \quad (18)$$

In (18), the variable l states the length of the text to be encrypted, and

$$W(i) = \begin{cases} 0, & \text{if } E_1(i) = E_2(i) \\ 1, & \text{if } E_1(i) \neq E_2(i) \end{cases} \quad (19)$$

In majority of the lightweight encryption models, the ideal NPCR is hypothesized to be near 99.6%. In this reference our accomplished average performance with NPCR=99.63% affirms suitability towards a real-time IoT security system.

TABLE III. NPCR PERFORMANCE OVER DIFFERENT PLAINTEXT SAMPLES

Input Samples	NPCR (%)
1	99.60
2	99.483
3	99.21
4	100.00
5	100.00
6	99.63
7	99.52
8	99.62
Average NPCR	99.63

3) *Unified Averaged Changed Intensity (UACI)*: UACI represents the difference of the mean values between the cipher texts. Typically, the 100% of UACI states that both texts are completely different in amplitude. Mathematically, we used (20) to estimate the UACI performance.

$$UACI = \frac{100}{l \times 95} \sum_{i=1}^l |E_1(i) - E_2(i)| \quad (20)$$

In (20), l represents the text-length, while $E_1(i)$ and $E_2(i)$ signify the symbol value of the cipher texts. For a single text encryption method, (i.e., a unit plaintext is processed at once), $E_i(i)$ can be applied for UACI estimation. The UACI values for the different samples are given in Table IV.

TABLE IV. UACI RANDOMNESS ASSESSMENT

Input Samples	UACI (%)
1	35.77
2	38.32
3	43.81
4	45.00
5	44.00
6	41.06
7	44.87
8	43.31
Average UACI	42.01

4) *Encryption time analysis*: In sync with IoT systems or allied applications, maintaining minimum encryption time is must. As already discussed, IoT system often performs delay-resilient real-time communication and therefore whether to get access of system or data, or even transmits the data, achieving minimum encryption time is inevitable. Taking into consideration of this fact, we examined encryption time (in ms) performance over the different samples. Table V presents the encryption time results by the proposed GFS-SSPN lightweight encryption system. Noticeably, we used (21-23) to estimate the encryption and decryption time (ms) [35].

$$Encryption\ Time\ (ms) = \frac{\text{Time required to encrypt i-th data}}{\text{Total number of data}} \quad (21)$$

$$Decryption\ Time\ (ms) = \frac{\text{Time required to Decrypt i-th data}}{\text{Total number of data}} \quad (22)$$

$$Execution\ time = Encryption\ time\ (ms) + Decryption\ time\ (ms) \quad (23)$$

TABLE V. EXECUTION TIME

Plaintext Input Samples	Execution Time (ms)
1	1.67
2	6.02
3	6.31
4	9.82
5	6.98
6	11.41
7	12.14
8	23.28
Average Exec time (ms)	9.70

To be noted, the sample sizes (in bits) considered in this study were varied (here, increasing order) from 1 to 8. The initial sample size we considered for sample-1 was 256 bits, while we kept increasing the size from 1 to 8 samples. In sync with increasing data volume, the encryption and decryption time too increased. However, the average time for execution (including both encryption as well as decryption) was 9.70 ms. This time is sufficiently small to accommodate real-time encryption purposes. To be noted, typically the time efficiency of an algorithm depends on computer's efficacy as well. Since, the proposed model was simulated over Intel i5 processor, execution over superior CPU configuration can yield even more affirmative results.

5) *Inter-Model performance assessment:* This is the matter of fact that the proposed GFS-SSPN lightweight encryption model exhibited significantly well towards delay-resilient and quality-sensitive encryption for IoT. Undeniably, the performance outcomes in terms of correlation, NPCR, UACI and execution time (ms) is encouraging; however, to validate efficacy of the proposed model towards IoT ecosystem we performed an inter-model performance assessment. In this approach we compared the performance of the proposed GFS-SSPN model with the other state-of-art existing methods. Factually, a very few researches have addressed lightweight encryption based IoT security system, and a few researches applying this method are developed for multimedia data security to be used in IoT applications [6]. Researchers [20][21] [40][41] emphasized their lightweight encryption model towards image data security over IoT platforms [6]. Furthermore, these authors have applied different random inputs to assess respective performance; and therefore, comparing performance over the same data is difficult. Considering this fact, we examined relative performance as average performance by the different algorithms.

Authors [21] developed a dynamic structure based lightweight encryption system for image encryption for IoT communication. Unlike our proposed model, authors designed a lightweight encryption concept with forward and backward chaining blocking concept (FBC) that in conjunction with a permutation block performed encryption. Though, similar to our approach authors too suggested applying multi-layered dynamic keying concept to introduce higher randomness and hence high attack-resilience. Noticeably, their proposed cipher

layer comprised a binary diffusion matrix, S-box and P-Box, in sequence. Authors [15][42][43] affirmed their efficacy backed by a binary diffusion matrix, substitution and permutation table. Considering about the NPCR performance by [43], the highest NPCR obtained was 50.10, while UACI for the same algorithm was obtained as 99.64. In sync with the inference in [39][41], for a robust lightweight encryption model retaining maximum possible NPCR (near 100%) is must. Therefore, [43] fails in delivering the expected performance. Murillo-Escobar et al., [39] too designed a lightweight encryption model using Chaotic map based symmetric text-cipher generation [36]. Though, authors applied 128-bits key, the use of two logistic maps with optimized pseudorandom sequences were considered for encryption, made it too computationally exhaustive. Authors employed single round of permutation diffusion to reduce overhead of encryption. A snippet of the recent approaches and their corresponding performance is given in Table VI.

Noticeably, the work proposed by Murillo-Escobar et al. (2014) applied 128-bit key. On the contrary we employed only 64-bit key for encryption. A snippet of the different lightweight encryption models and their configurations is given in Table VII.

Table VI presents some of the key lightweight encryption systems and allied functional architectures like block size, key size and number of encryption rounds. Observing the overall results, it can be found that the proposed GFS-SPNN model employs minimum key size (here, 64) with minimal encryption rounds (here, five) and even retains optimal performance. Though, a few works like KHAZAD [68][29][52], etc. applied low encryption round; however, retained 128 as key size. Similarly, the approaches employing 64-bit of encryption key have applied higher encryption round to retain higher confusion or randomness in cipher. The comparative assessment also reveals (Table VI) that most of the existing lightweight encryption models for IoT have applied SPN as encryption technologies. Though, a few works like [29][45][60] and [67] applied FN assisted SPN for encryption; however, the key size used were 128 or 256 bits. These approaches can easily be visualized to be highly computationally complex and exhaustive, demanding higher gate element (GE) for hardware realization. Another lightweight encryption models such as SPARX [49], LAX [49], Chaskey [52] and LEA [57] employed SPN with ARX-based S-boxes for encryption. However, these approaches demanded higher key-size (128 minimum) that makes them computationally as well as resource exhaustive.

TABLE VI. RELATIVE PERFORMANCE ANALYSIS

Technique	NPCR (%)	UACI (%)	Correlation	Encryption Time (ms)
[43]	50.1029	99.6460	-	-
[39]	98.85	33.31	-	140 ms for 1126 symbols or characters
GFS-SSPN	99.63	43.01	0.0082	6.70 ms

B. Qualitative Assessment

In addition to the above discussed performance assessment, to assess attack-resilience of the proposed GFS-SSPN lightweight encryption system we performed qualitative assessment. In this method we examined the robustness and attack-resilience of the proposed lightweight encryption system

in IoT-ecosystem [70]. In real-world IoT communication environment, an attacker can intercept the cipher stored (using SCLA), communicated (Linear and differential attack or impersonation) etc. and can attack the same to retrieve the targeted content or credential. Functionally, a cipher can be stated to be breached in case the attacker gets access or

becomes able to retrieve the secret key. The encryption method applied in the proposed model was robust enough to alleviate the different kinds of attack-vulnerability. In this reference, we examine its robustness theoretically.

1) *Differential and linear cryptanalysis*: The proposed GFS-SSPN block-cipher model employs DKE component that functionally applies different linear and non-linear mathematical functions, substitution a permutation, along with cyclic flipping concepts to introduce higher randomness in cipher without using large key or higher encryption rounds. This approach strengthens it to avoid any cryptanalysis or linear and differential attack probabilities. Moreover, as discussed above, the correlation in between the plaintext and the ciphertext is significantly low exhibiting higher imperceptibility that can be vital to avoid any linear attacks in IoT-ecosystem. Moreover, GFS assisted confusion and diffusion over five consecutive rounds too strengthened the proposed model to achieve higher attack-resilience. Additionally, since the (each) round transformation is maintained uniform which enables treating each bit similar and hence facilitates resilience to the differential attack. The results obtained in terms of NPCR and UACI, as discussed above reveals that the proposed block-cipher model can have sufficient resilience to avoid any kind of differential attacks probability over IoT ecosystem.

2) *Weak key combination*: In major operating conditions, users make a common mistake by keeping poor or weak key combination that helps attacker to get easy access to the ciphers. On contrary, the cipher information where the non-linear operations usually rely on the key value maps the block cipher in such manner that it causes detectable weakness. On the other hand, looking into the proposed security model where it avoids using the same (actual) key in the cipher (due to multiple round key manipulation and/or exchange by XORing the actual key followed by DKE for five rounds). It makes our proposed GFS-SSPN model robust enough to avoid any kind of week-key attack probability.

3) *Related keys combination trial attack*: The attack can be made with the help of certain partially known or unknown keys as well. The related keys primarily depend on either slow diffusion or possessing symmetry in key expansion block, as discussed in the previous section. In our proposed security model, we crafted the key expansion mechanism in such manner that it retains fast computation and non-linear diffusion, especially for the cipher key difference in comparison to the round keys that makes significant confusion to assess related key for credential level or under transit data attack.

4) *Square-attack*: To assess efficacy of a security model, different attack modules are applied to investigate attack-resiliency by the proposed approach. Some of the key approaches applied in cloud-sensitive security models are the RS-Analysis and Square Attack. Considering Square Attack condition, it is capable enough to retrieve one byte of the last key combination and intends to retrieve or recover rest of the

keys by repeating the attack iteratively. Let, such repetition be eight times, then also to achieve above stated information, the attacker needs to identify 28 keys precisely by 28 plaintexts which is equivalent to 216- S-box lookups. This becomes highly complicate and thus the proposed model can avoid such attack efficiently.

5) *Interpolation attack*: In general, such kinds of attacks primarily rely on the generic architecture of the cipher components which could generate certain rational expression with relatively low complexity. However, as already discussed the S-box expression of the proposed security system with diffusion characteristics strengthen it to avoid such limitations and thus makes it impracticable enough to avoid attack.

The above-mentioned relative performance assessment (Table VIII and Table IX), affirms suitability of the proposed GFS-SSPN lightweight security model towards realistic IoT ecosystems.

V. CONCLUSION

This paper primarily focused on designing a state-of-art new and robust dynamic programming assisted lightweight encryption system for IoT security. Unlike classical cryptosystem-based approaches which often undergo increased computational overhead, latency and more importantly resource exhaustion, this research contributed a state-of-art new lightweight encryption system. The proposed model intended to exploit efficacy of both SPN with GFS, where the first enabled optimal confusion and diffusion (in cipher) while the later enabled reduced computation with significantly smaller decryption cost. Additionally, towards "Fit-To-All" IoT security solution for both device-level security as well as data-level security, the proposed model employed Shannon Criteria based SPN (SSPN) which helped in error-free decryption. On the other hand, the use of GFS enabled block-cipher encryption helped in enhancing computation time as well as cost. Architecturally, the proposed GFS-SSPN model employed 64-bit dynamic keying with five rounds of encryption which retained minimal computation and allied cost. It can be vital towards resource efficient hardware realization. A key notable contribution of the proposed model can be the use of dynamic keying concept was derived by processing four 16-bit inputs by means of the SPN followed by cyclic rotation and concatenation. The use of 64-bit key with merely five round of encryption helped maintaining minimal computational overheads and time, which can be vital for IoT security systems. The overall proposed GFS-SSPN model was realized as block-cipher model and hence unlike bit-by-bit encryption it reduced computational overhead and delay significantly. Moreover, the use of predefined transformation coder for SPN (substitution purpose) enabled time-efficient confusion and diffusion process to assure IoT-centric efficacy. Noticeably, being the Feistel Network based Shannon Conditional GFS-SSPN based lightweight encryption model avoided distinct decryption program and therefore can be more resource and computationally efficient. In this reference, the

proposed GFS-SSPN model was examined with the different inputs' credentials, often in plaintext to perform encryption. To assess performance by the proposed GFS-SSPN model, different plaintext samples were taken into consideration where performance in terms of correlation, encryption time, NPCR and UACI confirmed superiority over the existing approaches, including other lightweight cipher models as well as symmetric key cryptographic concepts. The depth analysis revealed that the correlation in between the original plaintext and the encrypted cipher was significantly low 0.006, while it maintained NPCR of 99.6% and UACI of 27%. The encryption time observed was near 2.6 ms which is fairly in sync with major IoT systems and allied real-time encryption demands. The overall results affirmed that the proposed system can be well suited for IoT security system, where it can be applied as a device middleware to safeguard access-level security, while the same can be applied to encrypt the input to ensure attack-resilience during transmission. Qualitative assessment too revealed that the proposed model can be effective enough to alleviate the attacks of MITM type, SCLA, Interpolation as well as linear and differential attacks. Though, GFS-SSPN model exhibited satisfactory performance and efficacy towards IoT security, computationally efficient performance etc. Considering the hardware compatibility, the proposed system is developed using C programming language. However the power and resource profile could not be examined. In feature authors can implement the proposed method in a hardware efficacy so as to examine the power and resource utilization for real word realization.

Abstract—Cloud computing is an emerging technology that has been used to provide better healthcare services to the users because of its convenient and economical features. Noted that the healthcare services required fast and reliable data sharing at anytime from anywhere for better monitoring and decision making in medical requirements. However, the privacy and integrity of electronic healthcare record become a significant issue during data sharing and outsourcing in Cloud. The data privacy of clients/patients is important in healthcare services where exposure of the data to unauthorized parties is unexceptional. In order to address this security loophole, this paper presents a Cloud-based Secure Healthcare Framework (SecHS) to offer safe access to healthcare and medical data. Specifically, this paper enhance the Ciphertext Policy Attribute-Based Encryption (CP-ABE) scheme by adding two more modules which aims to provide fine-grained access control and offer privacy and integrity of data. It facilitates encryption and hashing schemes. The proposed framework is compared with existing frameworks that used CP-ABE scheme. It shows the SecHS offers better features towards securing the healthcare services data. Optimistically, data security requirements such as privacy, integrity and fine-grained access control are required to effectively proposed for assuring data sharing in the Cloud environment.

Keywords—Cloud computing; privacy and integrity; fine-grained access control; Ciphertext Policy Attribute-Based Encryption; electronic health record

I. INTRODUCTION

Cloud technology offers an innovative computing method for delivering IT services efficiently. Cloud technology able to enhance the quality of services (QoS) in numerous fields, including healthcare and medical services[1],[2]. Basically, in the healthcare services, electronic health record (EHR) has been widely used to improve storing, accessibility, sharing and realized a collaboration of medical data among medical practitioners. The EHR includes patients' data, laboratory results, medication lists, diagnostic tests, physical assessments, and historical observations. Due to most of these records are crucial and confidential, it is recommended by the Health Insurance Portability and Accountability Act (HIPAA) [3],[4] for ensuring the data and documents are safe and protected.

Cloud adoption in healthcare services has gained many attentions as mentioned in [1], [5]–[7] and it offers superfluous

benefits to the hospital and medical organization. The healthcare services through Cloud computing is expected to reduce execution cost hence might improve the services delivery. Furthermore, the resource management and system administration (infrastructure) can be effectively monitored through Cloud computing makes healthcare service is easy to maintain [8]. However, despite all the advantages, security is one of the most important challenges in Cloud computing. Particularly, the systems that have been used by the healthcare practitioner or end-users are vulnerable to many security issues. It is due to the medical data is confidential and data leaked by the irresponsible entity are unacceptable. Moreover, according to [9], [10], [11] the fact that the data is stored in the Cloud and can be resided anywhere and beyond the geographical boundary might cause the users to lose control over their own data. Other security concern includes the issue of the healthcare and medical organizations that need to have a clear agreement including security concern with the Cloud Service Provider (CSP). This involves security and access control procedures. There is very often where the Cloud users are not given a thorough explanation of their security concerns and needs in renting the Cloud services from CSP. Therefore, the need for data integrity and privacy mechanism which offer fined-grained access control are a necessity in order to provide better security services to both Cloud users and CSP.

This study proposed a Secure Healthcare Framework (SecHC) in Cloud computing using Ciphertext Policy Attribute-Based Encryption (CP-ABE). It aims to provide secure access to healthcare and medical data in the Cloud environment. In this framework, the patient's data is encrypted under Symmetric Encryption Scheme and the access policy in CP-ABE is embedded with the ciphertext. The contribution is summarized as follows:

- Provide a fine-grained access control by implementing the CP-ABE scheme which suited for a Cloud-based electronic health record system.
- Model security analysis related to security requirements in the Cloud environment includes privacy, integrity and fine-grained access control.

The remaining paper organization is as follows. Section 2 discuss on related work. In section 3, a simulation is conducted to proof the weakness of existing work. The proposed secure

*Corresponding Author

healthcare framework is provided in Section 4. Section 5 discussed the feature and security requirement analysis against other frameworks. Lastly, Section 6 provides a conclusion.

II. RELATED WORK

The area of healthcare and medical in Cloud computing is commonly implemented and realized. There are several approaches and techniques are used in securing the Cloud-based healthcare system in the data sharing process.

A. Healthcare and Medical in Cloud

The rapid development of Cloud computing nowadays has transformed the way of healthcare provider and even medical practitioners such as doctors and hospitals, to provide a quality and affordable service to their clients. This transformation is motivated by two major factors which are the business commanding to reduce costs and to convalesce the quality of care [12]-[14]. From the business side of view, the providers can lower their operational expenses to compensate for the increasing costs of infrastructure, administrative and pharmaceutical. Simultaneously, they also must handle requests from the government to increase the quality of healthcare and delivered a common healthcare operating standard [15], [16].

Meanwhile, on the patient side, the provider must offer a service that provides instant and top-quality access because nowadays, a patient is acquainted with the 24/7 accessibility of services especially from the online retailers and financial institutions. Furthermore, currently, the users are interested to involve in managing their own healthcare so the need for a system that could provide diagnosis, information, and treatments is in demand [3], [14]. For example, a patient would like an internet-based service from the healthcare providers that provide a platform for them to converse or consult the healthcare professionals all the time especially before, during and after any health-related procedures. This situation shows that a dire need of healthcare providers to transform themselves from a traditional to a Cloud environment to tackle the business and patient needs of an agile environment and to revolutionize their IT infrastructure.

Although the implementation of Cloud computing in healthcare sectors may seem beneficial and positive, it also fosters many detrimental situations and challenges. Despite the emergent trends of using Cloud computing as the platform to promote healthcare, the anxiety over the security and privacy of confidential information in the Cloud are intensifying over the years [17]. Data leakage and loss, phishing, hijacking of account or service, and unidentified risk profile are an example of the threats that impend the privacy and integrity of Cloud data.

Furthermore, the healthcare organizations have discovered that the existing mechanisms such as Secure Socket Layer protocol (SSL) and Transport Layer Security (TLS) protocol are not sufficient to secure EHR in Cloud because it only protects the privacy during data transmission [3][18]. Apart from it, according to [3], dishonest employees of the CSP can easily overrule a particular role with the authorization to retrieve and read the healthcare data beyond their privileges. Thus, to avoid any infringements of sensitive data by

fraudulent employees and to prevent medical data from other security threats, a secure mechanism must be designed and developed to enhance the data privacy and integrity of EHR in Cloud computing.

Recently, numerous security mechanism has been proposed by researchers to protect medical data in Cloud such as encryption schemes and access control schemes [10][19]. Such schemes permit the data owner to manage the data by restricting access to specific users for a specific file with limited privileges. Fig. 1 shows example of mechanism used to secure EHR in cloud. In this figure, data owner is defined as a patient stored the records in the cloud server and the record can only be accessed and downloaded by authorized physicians. This mechanism helps the healthcare and medical organization to protect the security and privacy of cloud data.

Fig. 1. Securing Electronic Health Record in Cloud [12].

B. Securing Healthcare and Medical Records in Cloud

In medical and health organizations, allowing end-users to control access to the data stored in unreliable cloud servers by using encryption schemes is an effective method to prevent data leakage, ensure safe transmission and secure from any other security threats. According to [20][21], the encryption algorithm permits end-users to encrypt data and ensure only user with the key can decrypt the data. However, this traditional encryption scheme is incapable to satisfy one-to-many encryption which is crucial in the cloud sharing scenario. One-to-many encryption permitting the data owner to encode the data once and it can be decoded or decrypted by several users that have a decryption key.

To deal with this issue, a control access mechanism that supports one-to-many encryption should be implemented to prevent unauthorized access to the Cloud. The author [21] proposes a scheme to support one-to-many encryption using Attribute-Based Encryption (ABE). This scheme is based on a novel patient-centric framework for controlling access to Patient Health Records (PHR) stored in semi-trusted cloud servers.

Meanwhile, authors [13][14][15][16][18][22] proposed another variant of ABE which is CP-ABE scheme wherein the CP-ABE scheme, data owner are allowed to specify the

authorized users to access the data, by enclose the access policy to the ciphertext. In order to generate private keys associated with set of user's attributes, ABE schemes rely on reliable and trusted authorities.

In order to achieve confidentiality and authenticity simultaneously, an efficient and improving CP-ABE scheme has been introduced by [15] and [20]. They used a signature scheme to verify the authenticity of data and the owner of the data. In the meantime, authors [13] and [18] proposed a scheme to enhance the efficiency of the decryption process. They used the Attribute Bloom Filter technique to assess whether an attribute is in the access policy and locate the exact position in the access policy if it is in the access policy. This technique will reduce the decryption time. However, this technique will cause a trade-off in terms of increasing computation overhead.

Besides, authors [21] also construct a scheme used CP-ABE which offers not only fine-grained access control but also providing integrity by checking the access policy of the users before they can access healthcare data. Their works also aimed to offer fast decryption by adding some redundant components to a ciphertext before the decryption stage. However, their works are not sufficient to secure the process of sharing data in the Cloud environment due to the failure to provide a fully hidden policy within the CP-ABE. The same issue applies to the researchers [23] where they proposed a privacy-aware s-health access control system that offers partially policy hiding. In the system, only the attribute value is hidden while the attribute name is sent to the Cloud with ciphertext in a readable form. This will cause data security to be compromised in the event of an attack where the attacker can find out and learn about the policy which leads to privacy leakage.

In addition, Zhang et. al., [17] proposed a privacy-preserving scheme using CP-ABE with efficient authority verification. They preserve the privacy of the data authority identification phase by determining whether the user is authorized or not. Apart from it, a study by [24] proposed a scheme using CP-ABE which successfully achieved high security by hiding the entire access policy of the EHR. However, they overlooked the additional computational cost and decryption time is high due to the newly introduced scheme on verification of the matching process.

Thus, the above literature review indicates that many works have been done to provide additional security towards the security mechanism provided by the CSP. However, according to [17], it still insufficient to protect medical and healthcare records and reduce the risk of threats in the Cloud environment. This is because there are many issues arise such as multi-authority, hidden policy and constant size ciphertext which need to be studied.

C. Framework of Health Data in Cloud

Generally, a framework is built to simplify a complex technological process. It is usually consisting of a few elements, or entities which will be integrated to become a useful process. In medical and healthcare organizations, several frameworks have been proposed to ensure administration of patients, data, staff and operations are running smoothly. For

example, a security framework focusing on data delivery of patient care has been developed by Zhang et al. [25]. In this framework, Zhang has introduced three main components: data collection, secure storage and secure usage model as shown in Fig. 2. The aim of this framework is to provide a safe interaction between healthcare professionals and patients based on security needs and patient privacy in the EHR Cloud.

The first component is collection and integration of various data from various departments in organizations. These components are responsible to make sure all the data is available and safe to be used. Hence, this component needs to verify the data in term of confidentiality, integrity, and ensuring nonrepudiation as well as HIPAA compliance.

The second component is the secure storage that consists of two entities which are secure storage server and access control engine. Data is stored as ciphertext in secure storage server and only authorized user is permitted to access the data. Meanwhile access control engine use role-based and attribute-based method to grant access to the user. As a result, user that does not match the attribute will be denied the access to patient's data in Cloud Storage.

The last component is secure usage model. This component's role is to provide a safe data access by using two methods: signature and verification. Medical practitioners will sign EHR using appropriate signature algorithm before sending it to Cloud storage. Then, user will verify the authenticity of the data by using digital signature verification.

Apart from that, the work proposed by [26] introduces a framework that offers privacy of health data and provides access control to the data in Cloud. There are four entities in this framework are S-Health Authority, S-Health Cloud, Data Owner, and Data User as shown in Fig. 3.

In this framework, S-Health Authority is responsible for system initialization and authorization where it uses attribute-based access to permit authorized user to store or access data in Cloud. Meanwhile, for data owner they manage their EHR by performing encryption process to secure the record. They stored the ciphertext and its access policy in the S-Health Cloud. To enhance the security, they partially hide access policy to prevent untrusted entities take advantages of the access policy.

Fig. 2. Security Framework Focusing on Data Delivery of Patient Care [25].

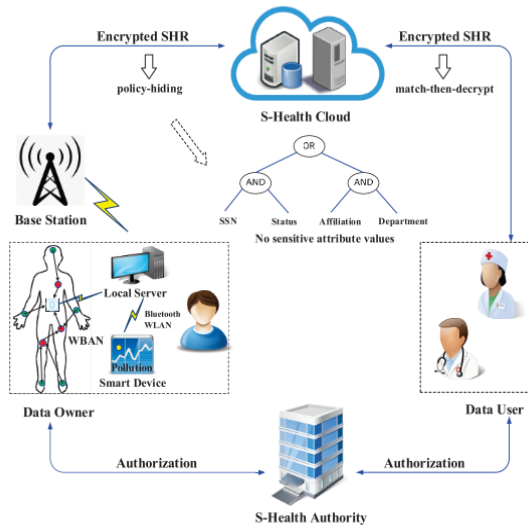

Fig. 3. Framework of the Privacy-Aware S-Health Access Control System [26].

In addition, to make the process efficient, they implement match-then-decrypt procedure in the decryption phase. In this phase, data user will use to his secret key to check whether his attributes match the underlying access policy, and then decrypt the encrypted EHR only if the matching is successful.

Using this framework, the system achieved security requirement by offering fine-grained access control using CP-ABE scheme. They also provide confidentiality using encryption algorithm and offer data privacy using hidden access policy.

However, both frameworks proposed by [25] and [26] can be improved by incorporating other mechanisms such as hashing algorithms which are used to ensure data integrity. In addition, to ensure the privacy of data, fully hidden access policy must be implemented to solve user distrust issues.

III. PRELIMINARIES WORK

This section describes the preliminaries related to the proposed work by [21]. In Zhang's work, they used CP-ABE to provide fine-grained access control to the health data in Cloud storage. The proposed solution was successfully delivered data verifiability and fast decryption by providing the validation of decrypted message. However, the access policy was sent to the Cloud together with the ciphertext in a readable form which led to the data privacy leakage.

In this preliminaries work, a simulation of transferring a file that contained an access policy using FileZilla Tool is conducted. To transfer the file from a client to a server, a File Transfer Protocol (FTP) without encryption is used as shown in Fig. 4.

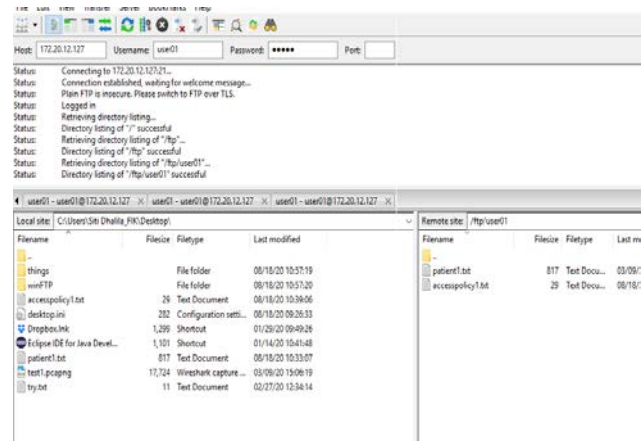

Fig. 4. Transferring a File using FTP in FileZilla Tool.

While transferring a file in FileZilla, Wireshark tool is execute by running a passive attack to sniff the packet as shown in Fig. 5.

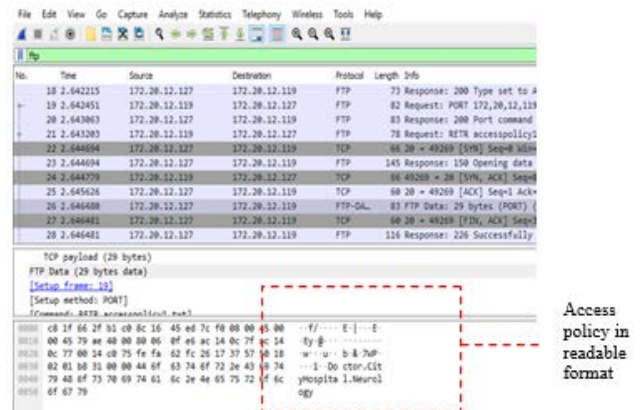

Fig. 5. Packet Sniffing using Wireshark.

In this simulation, because of the access policy was sent in a readable form, the attacker can read packet and gain the information in the access policy. Based on the simulation, it is necessary to provide a framework that can help user to secure their data than preserve the privacy of an access policy.

IV. ENHANCEMENT OF CIPHERTEXT POLICY ATTRIBUTE-BASED ENCRYPTION (CP-ABE) SCHEME

This section describes in detail on how the ciphertext policy attribute-based encryption (CP-ABE) scheme has been utilized to design the proposed framework; called as SecHC. The proposed framework provides security components in order to ensure the healthcare and medical data can securely exchange among healthcare organizations through Cloud environment. The SecHC framework (Fig. 6) have four entities involved are Data Owner, Data User, Attribute Authority and Secure Health Cloud.

Fig. 6. Cloud-based Secure Healthcare Framework (SecH).

The general framework for CP-ABE scheme has four modules are (i) setup, (ii) key generation, (iii) encrypt and (iv) decryption. The data owner in CP-ABE scheme is been set to some access policy before it been encrypted. Data owners then outsourced the encrypted data along with access policy to the Cloud storage. If the receiver satisfied the defined access policy, the data then will be decrypted. Even though ciphertext attribute-based encryption is a prominent access control scheme however it suffers from privacy preservation of policy. It is because the defined policy is appended to the ciphertext in readable format which can lead to user's information leakage. So, the adversaries can learn confidential information from readable access policy. To address the issue, this work enhance Ciphertext Policy Attribute-Based Encryption (CP-ABE) scheme by adding other components to secure the healthcare data for designing the Secure Healthcare Framework (SecHC). The proposed framework provides security and integrity of data using encryption and hashing scheme. It also provides a policy hiding scheme to ensure access control with privacy-preserving.

Specifically, two more modules have been added in encryption phase namely hashing and policy hiding while for decryption phase, the added module is hashing verification. In the encryption phase, the hashing module is to ensure there is no tampering data while maintaining the data integrity. In the policy hiding module, the access policy will be hidden from the unauthorized users that might be led to privacy leakage. Meanwhile in the decryption phase the hashing verification is introduced which is to verify the authenticity of the access policy. This module aims to accelerate hashing verification thus reducing the time for decryption. Each of the functions is described as follows.

A. Setup Algorithm

The setup algorithm involves a security parameter as an input and produces a public parameter key and a master key as the outputs. Both will be utilized as the input in the key generation algorithm. In this setup algorithm, Bilinear Pairing will be used to create a public key which generated by Attribute Authority.

B. Key Generation

The key generation algorithm is executed by the Attribute Authority. It will take input users' attributes, public parameters, and master key then perform an operation to the inputs to generate a secret key. Later, this secret key will be employed by the data user to decrypt the ciphertext.

C. Hashing

This is the new module introduced in SecHC. The hashing algorithm used a mathematical function to generate a hash value from the input by the user. It used to verify the integrity of a file after it has been transferred from one place to another. In this module, the attributes of access policy will be hashed using the MD5 algorithm. According to [27], MD5 is very efficient and it operates faster than other algorithms. Then, after the hashing process, the hashed value will be sent to the Cloud along with ciphertext.

D. Encryption

In the encryption phase, the algorithm takes the inputs from the Data Owner to be encrypted and produce a ciphertext. Advanced Encryption Standard (AES) is used as an encryption algorithm to converts data into unreadable forms. The data owner will outsource the ciphertext along with the hashed value in the Cloud to be shared with the other users.

E. Access Policy Hiding

In traditional CP-ABE, the access policy is sent along with the ciphertext to the Cloud in readable form. Therefore, anyone who accesses the ciphertext can learn about the access policy which leads to weak policy privacy. Hence, to overcome this issue, an access policy hiding scheme is proposed and developed in SecHC to provide fully hidden access policy. In this module, the Logical Connective Operator is used to hide the attribute names and its values into meaningless values. Then, this meaningless value will be sent to Cloud along with ciphertext and hashed value.

F. Extracting Hidden Access Policy

Data Users need to extract the hidden access policy before he/she can access and download the file from Cloud. In this module, reverse process of hidden access policy from meaningless value to the access policy will be performed.

Then, after extracting the access policy, hashing verification will take place.

G. Hashing Verification

Hashing verification scheme is used to determine the authenticity of ciphertext and access policy. This module is to ensure the transferred ciphertext is not corrupted. In this module, the user needs to perform a calculation (hashing verification algorithm) to access policy. If the hash value of access policy (before and after downloaded from the Cloud) is the same, then the transferred file is an identical copy. So, the user can proceed to the decryption module. But if the values are not the same, the process will be ended.

H. Decryption

The decryption module is taking place after the hashing verification process produced the authentic hashing value. The decryption scheme takes a public parameter, secret key (associated with the user's attributes) and ciphertext as input and produces the message.

V. COMPARISON WITH OTHER FRAMEWORKS

In this section, a comparative analysis of the proposed scheme with some typical CP-ABE schemes has been conducted. By considering the characteristics of the proposed scheme satisfied, only selected schemes [21][26][28][29] that are strongly relevant to the proposed scheme for comparison is discussed.

Based on findings reported in Table I, a comprehensive comparison according to important features is presented including policy hiding, privacy-preserving, data integrity, and fine-grained access control.

By comparing the proposed framework with the schemes by the authors in [21][29] it definitely a different strategy is used for improving CP-ABE. In [21], the enhancement of CP-ABE scheme only achieves partly hiding policy which leads to failure to protect the privacy of the data. However, they accomplish to offer integrity using a hashing scheme. Yet, their scheme can be improved in terms of decryption procedure which focuses on the decryption test.

TABLE I. COMPARATIVE SUMMARY BETWEEN SCHEMES

Technique	Hidden Policy	Privacy-Preserving	Integrity	Fine-grained Access Control
CP-ABE [26]	Partial	√	X	√
Improvised CP-ABE [21]	Partial	X	√	√
CP-ABE [28]	No	√	X	√
Improvised CP-ABE [29]	Partial	X	√	√
SecHC CP-ABE scheme	Fully	√	√	√

Meanwhile, in [29], their CP-ABE scheme focused more on the decryption phase where they introduced KeyGen.out, Decrypt.out, Decrypt.user. Their scheme is designed to broadcast encryption techniques and used outsourcing techniques to realize policy-hide, direct revocation, and secure delegation simultaneously. However, their scheme failed to provide a fully hidden access policy and unable to keep it private.

Meanwhile, in SecHC framework, the proposed CP-ABE scheme capable of supporting fully hidden access policy using data hiding technique, provide integrity using hashing scheme and provision fine-grained access control. Most of the researchers have improvises the CP-ABE scheme except the authors in [26] and [28] which cause them unable to achieved hidden policy and provide data integrity.

VI. DATA SECURITY REQUIREMENT ANALYSIS OF SecHC FRAMEWORK

Particularly, in medical and healthcare organizations, sharing information in the Cloud environment has raised many security problems related to security requirements such as confidentiality, integrity, privacy and so on. Thus, the SecHC framework is developed to meet and satisfy the security requirement for the Cloud environment. The analysis of security requirements is described as follows.

A. Data Privacy

The proposed framework is fully privacy-preserving. It protects users' privacy by using the encryption algorithm. The proposed framework adopted the encryption algorithm in CP-ABE scheme to provide data privacy in a secure health Cloud. The electronic health record's privacy is achieved when the user uploads the encrypted record with hidden policy to the cloud.

B. Data Integrity

In the proposed framework, the hashing algorithm is used to protect the accuracy and consistency of data from any modification, deletion or fabrication. To achieve data accuracy, only correct and trustworthy data must be stored in the Cloud while consistency can be attained when outsourced data is not tampered, changed or maliciously deleted. Based on the framework, the medical and health record will be encrypted, and the access policy will be hashed. This hashing process is to ensure there is no modification that has been made on ciphertext stored in Cloud. If there is any modification on ciphertext, the user could not perform the decryption process. This process proves that the proposed framework offers to protect the integrity of data in a secure health Cloud.

C. Fine-Grained Access Control

In a healthcare Cloud, all users do not have the same privileges to retrieve medical data. This privilege depends on the degree to which a user is involved or specialized in treatment. Therefore, this framework ensures a different user will have different access privileges which defined by access policy imposed by attribute authority. The CP-ABE scheme used in this framework helps us achieve fine-grained access control. This means that all the attributes must be matched with

the user access policy structure to be able to access the required information.

VII. CONCLUSION

In the ever-increasing era of a data breach, Cloud computing is required to provide a security solution to protect sensitive information and transactions. This solution can prevent a third party from eavesdropping or tampering with the data while it is being transmitted. In this work, the Secure Healthcare Framework (SecHC) is designed by enhancing the Ciphertext Policy Attribute-Based Encryption (CP-ABE) scheme. It can further promote the Cloud privacy and integrity to both users and providers in the healthcare and medical organizations. The SecHC framework supports privacy and integrity of healthcare and medical data and offers fine-grained access control strategy. It is provided by using combination of prior and new components in the CP-ABE scheme. Such components offer a fully hidden access policy and provide fast decryption. Analysis of security requirements shows that this framework satisfies the privacy and integrity of healthcare data. In the near future, let the proposed framework to handle the real healthcare and medical data over the Cloud environment.

Abstract—e-Learning is appropriate when the learners are grouped and facilitated to learn according to their learning style and at their own pace. Elaborate researches have been proposed to categorize learners based on various e-learning parameters. Most of these researches have deployed the clustering principles for grouping eLearners, and in particular, they have utilized K-Medoid principle for better clustering. In the classical K-Medoid algorithm, predicting or determining the value of K is critical, two methods namely the Elbow and Silhouette methods are widely applied. In this paper, we experiment with the application of both these methods to determine the value of K for clustering eLearners in K-Medoid and prove that Silhouette method best predicts the value of K.

Keywords—Clustering; e-learning; elbow method; k-means; k-medoid; machine learning; silhouette method

I. INTRODUCTION

The educational systems nowadays are slightly moved from Traditional Teaching Method to Electronic Teaching Method. There are a variety of tasks that can be performed in e-learning, such as; assignments, quizzes, and so on. These activities are used to assess the learner's performance. To facilitate appropriate e-learning activities by grouping users into a possible number of groups, Clustering is the Machine Learning (ML) technique that is used to group the related objects. There are numerous existing methods available for cluster analysis in the field of Data Analytics. Determining the optimal number of clusters in a data set is a fundamental problem in partitioning clustering, such as K-means clustering, which allows the user to define the number of clusters K to be generated. The possible number of clusters is rather arbitrary and is determined by the method used for measuring similarities and the parameters used for partitioning [1]. There are many clustering algorithms used for the group the similar objects in many domains such as the Medical domain, Education domain, Governance domain, etc. The clustering algorithm is the most suitable one to group users based on the learners preferred learning activities in e-learning.

The existing methods mainly focus on the majority of learning activities based on the learner's style. This could be improved further by grouping the users based on their learning activities. The main objective of this paper is to identify the optimal number of groups by using cluster validation methods. If we identify the possible number of groups of learners, we can easily enhance their learning abilities according to their preferred learning activities.

The flow of organization of work is as follows: This paper introduces a different method for identifying the value of K. Then it elaborates two major method such as Elbow and Silhouette method. The paper experiments with data using both methods. It further denotes the best method for identifying K values in K-means along with the eLearners.

A. Choosing the Optimum Number of Cluster

The optimum number of clusters obtained by using the following two methods such as *Elbow* and *Silhouette methods* [2][3].

1) *Elbow method*: The number of clusters (K) in the Elbow method ranges from 1 to n. We calculate WCSS (Within-Cluster Sum of Square) for each value of K. In a cluster, WCSS is the number of squared distances between each point and the centroid. The plot looks like an Elbow when we plot the WCSS with the K meaning. The WCSS value will begin to decrease as the number of clusters grows. When K = 1, the WCSS value is the highest. When we examine the graph, we can see that it will shift rapidly at a point, forming an elbow shape. The graph begins to travel almost in the same direction as the X-axis [2][3]. The optimal K value or the optimum number of clusters corresponds to this point.

Algorithm

Step 1: Compute clustering algorithm (e.g., K-means clustering) for different values of K. For instance, by varying K from 1 to N clusters.

Step 2: For each K, calculate the total Within-Cluster Sum of Square (WCSS).

$$\sum_{k=1}^K \sum_{i \in S_k} \sum_{j=1}^p (x_{ij} - \bar{x}_{kj})^2 \quad (1)$$

Where S_k is the set of observations in the K^{th} cluster and \bar{x}_{kj} is the j^{th} variable of the cluster center for the K^{th} cluster.

Step 3: Plot the curve of WCSS according to the number of clusters K.

Step 4: The location of a bend (knee) in the plot is generally considered as an indicator of the appropriate number of clusters.

2) *Silhouette method:* This method calculates the similarity of an object to its own cluster called *cohesion*, when compared to other clusters is called *separation*. The Silhouette value, which is a value in the range [-1, 1], is the comparison's means; a value close to 1 indicates a close relationship with objects in its cluster, while a value close to -1 indicates the opposite [2][3]. A model that produces mostly high Silhouette values from a clustered collection of data is most likely acceptable and reasonable.

Algorithm

Step 1: Choose the K from 1 to n clusters.

Step 2: For each k, calculate the Silhouette value.

Let $C(i)$, be the cluster to which the i^{th} data point has been allocated.

Let $|C(i)|$, be the number of data points allocated to the i^{th} data point in the cluster.

Let $a(i)$, indicates how well the i^{th} data point is allocated to its cluster.

$$a(i) = \frac{1}{|C(i)|-1} \sum_{C(i), i \neq j} d(i, j) \quad (2)$$

Let $b(i)$, be the average dissimilarity to the cluster nearest to it, but not its own

$$b(i) = \min_{i \neq j} \left(\frac{1}{|C(i)|} \sum_{j \in C(i)} d(i, j) \right) \quad (3)$$

The Silhouette Coefficient $S(i)$ is given by:

$$S(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))} \quad (4)$$

Step 3: Plot the curve of Silhouette value according to the number of clusters K.

Step 4: The location of the highest point is taken as the suitable number of clusters.

B. Flow Chart of Elbow and Silhouette Method

Fig. 1 portrays the flow chart of *Elbow* and *Silhouette* method to identify the optimum number of clusters.

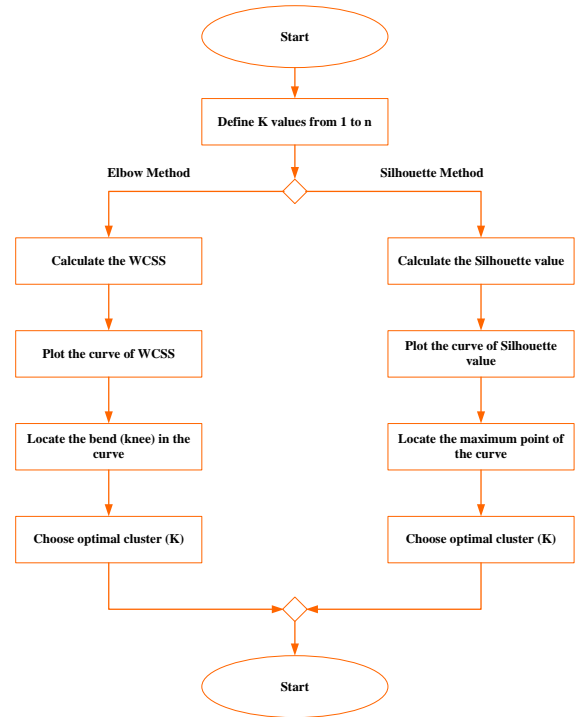

Fig. 1. Flow Chart of Elbow and Silhouette Method.

C. Comparison of Elbow and Silhouette Method

Table I contrasts the comparison between *Elbow* and *Silhouette* methods.

TABLE I. COMPARISON BETWEEN ELBOW AND SILHOUETTE METHOD

Elbow method	Silhouette method
It is more of a criterion for making decisions.	The Silhouette is a validation metric used in clustering.
The WCSS is a metric for clustering compactness, and it should be as low as possible.	This approach is useful for determining the consistency of clustering, or how well an object fits into its cluster.
The Elbow method is not computationally demanding.	The Silhouette method is the most computationally demanding.
Sometimes we don't get a clear elbow point on the plot, in such cases it's very hard to finalize the size of the cluster.	Based on the Silhouette we can identify the cluster size.

II. RELATED WORKS

In cluster analysis, especially in the field of Data Analytics determining the optimum cluster number is a major challenge. Many methods are used to find optimal clusters among Elbow and Silhouette methods which are frequently used.

H Humaira et al. [4] proposed the method of the identifying size of the clusters using the Elbow method for the K-Means Algorithm. However, this approach lacks comparison with another method called Silhouette.

Integration K-Means Clustering method and Elbow method for identification of the best Customer profile cluster were suggested by M A Syakur et al. [5]. This approach is used to determine the best number of clusters with the elbow method and it will be the default for characteristic process based on the case study.

Mohammad Khalil et al. [6] applied a Clustering pattern of engagement in Massive Open Online Courses (MOOCs): the use of learning analytics to identify student groups. This research is used to predict the learners' engagement in MOOCs by choosing optimal clusters.

Brahim Hmedna et al. [7] proposed a method, how does a learner prefer to process information in MOOCs? Using the K-Means clustering algorithm, this study discovered that the majority of learners favour active learning styles.

Towards an optimal personalization strategy, MOOCs were suggested by Alaa A.Qaffas et al. [8]. Using K-Means clustering, this approach was used to increase the retention rate and quality of learning in MOOCs.

MOOC Video Personalized Classification Based on Cluster Analysis and Process Mining was suggested by Feng Zhang et al. [9]. They suggest a process model for a group of students that represent the students' overall video-watching behaviour. Then, based on the video watching data of the students involved, it suggested using the process mining technique to mine the process model of each student cluster. Finally, the method is used to measure the difficulty and importance of a video based on a process model.

Mohammad KHALIL et al. [10] introduced a Portraying MOOCs Learners: a Clustering Experience Using Learning Analytics. The study used Clustering Analysis to group the students into suitable profiles based on their participation in a university-mandated MOOC that was also accessible to the public.

Delali Kwasi Dake et al. [11] applied a K-means clustering algorithm to analyze students' clusters for centered project-based learning. K clusters of 20 are used in this study. The findings show that the K-means clustering algorithm is good at grouping learners based on similar performance characteristics.

Analysis of University Students' Behavior Based on a Fusion K-Means Clustering Algorithm was proposed by Wenbing Chang et al. [12]. They proposed a new algorithm based on K-means and clustering by quick search and find the density peaks (K-CFSFDP), which improves data point distance and density.

Abdallah Moubayed et al. [13] proposed a model for Student Engagement Level in an e-learning Environment: Clustering Using K-means. This study recommends that students be clustered using the K-means algorithm based on 12 engagement metrics divided into two categories: interaction-related and effort-related.

Using Self-Organizing Map and Clustering to Investigate Problem-Solving Patterns in the Massive Open Online Course: An Exploratory Study proposed by Youngjin Lee et al. [14]. This study suggests that combining self-organizing map and

hierarchical clustering algorithms in a clustering technique can be a useful exploratory data analysis method for MOOC instructors to classify related students based on a large number of variables and analyse their characteristics from multiple perspectives.

Prerna Joshi et al. [15] proposed a model for Prediction of Students Academic Performance Using K-Means and K-Medoids Unsupervised Machine Learning Clustering Technique. The K-mean and K-Medoids grouping algorithms were used in this study to examine students' consequence information.

Yaminee S. Patil et al. [16] suggested a technique K-means Clustering with Map Reduce Technique. This research article identified the implementation of the K-Means Clustering Algorithm over a distributed environment using Apache Hadoop.

Xin Lu et al. [17] proposed a method Improved K-means Distributed Clustering Algorithm based on Spark Parallel Computing Framework. This research identified, a density based initial clustering center selection method proposed to improve the K-means distributed clustering algorithm.

Literature review reveals that the authors have mostly focused on evaluating learner's performance by clustering techniques based on their learning styles, learning activities, and e-learning tools. The existing approaches lack in choosing an optimum number of cluster size K to group the learners. Hence, this research proposes an algorithm to identify optimum numbers of cluster size K to group the learners based on their preferred e-learning activities.

III. RESEARCH OBJECTIVES

- 1) To identify learners preferred e-learning activities using PCA.
- 2) To find correlation coefficient for selected e-learning activities using Pearson Correlation.
- 3) To identify an optimal number of clusters using Elbow and Silhouette method.
- 4) To select best method for choosing optimal cluster size.
- 5) To group the learners based on their preferred e-learning activities with optimal cluster size.

IV. PROPOSED ARCHITECTURE OF CHOOSING OPTIMAL CLUSTER

The purpose of finding optimal number cluster is to extract the most possible number of groups with learner's preferred e-learning activities. The course teacher can implement those selected activities to learners based on the clusters, which helps the learners to enhance their learning abilities. Fig. 2 portrays the process to find an optimal number of groups with the help of *Elbow* and *Silhouette* method. It has been classified in the following stages:

Stage 1: Identify learners preferred e-learning activities.

Stage 2: Apply cluster validation to fix the cluster size.

Stage 3: Identify the possible number of clusters using Elbow and Silhouette method.

Stage 4: Select the method which is suitable to group the learners based on their preferred learning activities.

Stage 5: List the optimal cluster to group the learners.

Stage 1: Identify learner's preferred e-learning activities: In the first stage, identify the learners' preferred e-learning activities by using Principal Component Analysis (PCA) and compute the correlation coefficient using Pearson Correlation.

Stage 2: Apply cluster validation to fix the cluster size: In the second stage, validate cluster size by using appropriate cluster validation methods. Identifying possible number cluster size is a big challenge.

Stage 3: Identify the possible number of clusters using Elbow and Silhouette method: These two methods are used to identify the size of the cluster known as Elbow and Silhouette method. In the Elbow method by calculation value of WCSS the cluster size is fixed. Similarly, in the Silhouette by calculation of Silhouette Value the cluster size is fixed.

Stage 4: Select the method which is suitable to group the learners based on their preferred learning activities: Apply the data set in both methods and list the possible number of clusters. Let K1 be the number of cluster sizes identified by the Elbow method. Let K2 be the number of cluster sizes identified by the Silhouette method. Choose a suitable method by comparing both the cluster size (K1 and K2) and give the highest priority by choosing cluster size which one is bigger (either K1 or K2).

Stage 5: List the optimal cluster to groups the learners: Finally, the most possible cluster size (Kn) is identified by using Stage 4. Use this cluster size to identify the possible number of learners groups according to their preferred e-learning activities.

V. PROPOSED ALGORITHM OF IDENTIFICATION OF CLUSTER SIZE USING ELBOW AND SILHOUETTE METHOD

Input: S : Data Set

Output: K : Number of cluster size

1: Let S be the given set of preferred e-learning activities.

$$S = A_{ij} \quad (5)$$

2: Compute the sum of activities based on learner wise.

$$S = \sum_{i=1}^n \sum_{j=1}^m A_{ij} \quad (6)$$

3: Apply the cluster validation methods

Elbow method:

$$\sum_{k=1}^K \sum_{i \in S_k} \sum_{j=1}^p (x_{ij} - \bar{x}_{kj})^2 \quad (7)$$

Where S_k is the set of observations in the K^{th} cluster and \bar{x}_{kj} is the j^{th} variable of the cluster center for the K^{th} cluster

Silhouette method:

$$S(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))} \quad (8)$$

4: Choose an appropriate method to fix cluster size

$$K = \begin{cases} \text{Choose Elbow Method if } K1 > K2 \\ \text{Choose Silhouette Method if } K2 > K1 \end{cases} \quad (9)$$

5: List the optimal cluster size

6: End

VI. RESULTS AND DISCUSSION

The optimal number of cluster size was implemented with the following e-learning activities such as Continuous Assessment (CA), Assignment, Test, Practical, Seminar, and Course Work.

Step 1: Preferred e-learning activities

Table II listed the preferred e-learning activities of 70 users and their performances. These preferred e-learning activities are identified through PCA and compared with the Pearson Correlation to find a correlation coefficient with each attribute.

Step 2: Compute the sum of activities based on learner wise.

Compute the sum of selected activities for each learner. Table III listed the sum of e-learning activities of 70 users and their performances.

Step 3: Apply the cluster validation methods

Graph 1 portrays dataset of 70 users and their performance with their preferred e-learning activities.

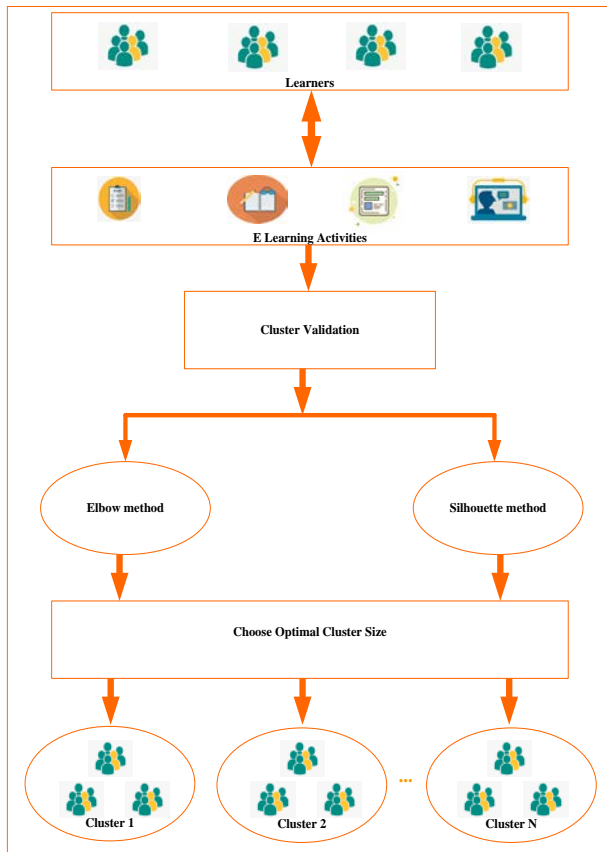

Fig. 2. Architecture of Choosing Optimal Cluster.

Graph 1. Dataset of 70 users and their Performance.

Elbow method – Graph 2 portrays optimal numbers of cluster size identified by using Elbow method. The graph shows the possible optimal number of cluster $K = 5$.

Graph 2. Elbow Method: Optimal Number of Cluster.

Silhouette method – Graph 3 portrays optimal numbers of cluster size identified by using Silhouette method. The graph shows the possible optimal number of cluster $K = 10$. The Silhouette Score for cluster size $K = 2$ to 15 are as follows:

- Silhouette Score for 2 Clusters: 0.5742
- Silhouette Score for 3 Clusters: 0.6004
- Silhouette Score for 4 Clusters: 0.5982
- Silhouette Score for 5 Clusters: 0.6091
- Silhouette Score for 6 Clusters: 0.6034
- Silhouette Score for 7 Clusters: 0.5960
- Silhouette Score for 8 Clusters: 0.6094
- Silhouette Score for 9 Clusters: 0.6185
- Silhouette Score for 10 Clusters: 0.6518
- Silhouette Score for 11 Clusters: 0.6248
- Silhouette Score for 12 Clusters: 0.5981
- Silhouette Score for 13 Clusters: 0.5995
- Silhouette Score for 14 Clusters: 0.6061
- Silhouette Score for 15 Clusters: 0.6047

Graph 3. Silhouette Method: Optimal Number of Cluster.

Step 4: Choose appropriate method to fix cluster size

From Step 3, the appropriate method for validating cluster size for given data set is Silhouette method. This can be achieved by comparing cluster size of both the methods.

Step 5: List the optimal cluster size

The most possible number of cluster size is $K = 10$. The possible number of learners' groups is also 10, according to their preferred e-learning activities.

The paper experiments data with two cluster validation methods such as Elbow and Silhouette method. These two methods are frequently used to validate cluster size. The cluster size return by Elbow method for the given data set is 5 ($K=5$). The cluster size return by Silhouette method for the given data set is 10 ($K=10$). Naturally when the cluster size increases, the learning abilities of the each learner is identified in depth. Based on their learning abilities, we can optimize and predict e-learning activities for each user. Finally this paper concludes that Silhouette method is the optimal method for validating cluster size for the given data set.

VII. CONCLUSION AND FUTURE WORK

In this paper, we have illustrated that determining optimal value for K to cluster eLearners using K-Medoid algorithm is essential. Further, we have experimented the Elbow and Silhouette methods to compute the optimal value for K . To decide the suitable method among these two, sufficient experiments were conducted, and the results of the experiments were investigated carefully. The results were indicative that the Silhouette method best suits to fix the optimal value for K . This paper is focused in estimating K value for K-Medoid based clustering of eLearners, computing the optimum value for k , number of clusters to be formed can also be done in other clustering methods which are applied in eLearners groupification, which is suggested by the authors as a future enhancement.

Abstract—In the world and in Peru, Acute Respiratory Infections are the main cause of death, especially in the most vulnerable population, children under 5 years of age and older adults. Pneumonia is the leading cause of death of children in the world. 60.2% of pneumonia cases affect children under 5 years of age. Thus, prevention and timely treatment of lung diseases are crucial to reduce infant mortality in Peru. Among the main problems associated with this high is percentage the lack of medical professionals and resources, especially in remote areas, such as Puno, Huancavelica and Arequipa, which experience temperatures as low as -20°C during the cold season. This study develops an algorithm based on computational neural networks to differentiate between normal and abnormal lung sounds. The initial base of 917 sounds was used, through a process of data augmentation, this base was increased to 8253 sounds in total, and this process was carried out due to the need of a large number of data for the use of computational neural networks. From each signal, features were extracted using three methods: MFCC, Melspectrogram and STFT. Three models were generated, the first one to classify normal and abnormal, which obtained a training Accuracy of 1 and a testing accuracy of 0.998. The second one classifies normal sound, pneumonia and other abnormalities and obtained training Accuracy values of 0.9959 and a testing accuracy of 0.9885. Finally, we classified by specific ailment where we obtained a training Accuracy of 0.9967 and a testing accuracy of 0.9909. This research provides interesting findings about the diagnosis and classification of lung sounds automatically using convolutional neural networks, which is the beginning for the development of a platform to assess the risk of pneumonia in the first moment, thus allowing rapid care and referral that seeks to reduce mortality associated mainly with pneumonia.

Keywords—Algorithm; classification; computational neural networks; lung sounds; mortality; pneumonia

I. INTRODUCTION

Pulmonary diseases in the new pandemic context are a public health concern. Pneumonia, for example, is evolving rapidly and its complications threaten the lives of the population, especially in low-income countries such as Peru[1],[2]. The Ministry of Health recognizes Acute Respiratory Infections (ARI) as a constant concern in Peru, caused by viruses, bacteria and fungi. Among ARI, pneumonia is consistently the leading cause of death in children and older adults in the world. In Peru, 60.2% of pneumonia cases occur in the 0-5 age group, and it is the leading cause of death[3].

Prevention of pneumonia complications is a priority to reduce mortality in children, especially in the most remote areas of the country.

Peru is a country with a diversity of weather and regions. There are more than 30 cities, with altitudes ranging from 2000 to 5100 meters above sea level[4]. Populated centers that endure extreme temperatures, even below -20 degrees Celsius, in departments such as Puno, Huancavelica, Arequipa, Junin, Pasco and Cuzco, among others[5]. In cold weather seasons, vulnerability, remoteness and limited access to medical services cause ARI, especially pneumonia, to be the main cause of death for many years, being an unfortunate constant[6].

Pneumonia, when detected in early stages, responds to antibiotic treatment with good results, when there are no medical or viral complications. Mortality associated with this disease is due to late diagnosis and complications associated with viruses, bacteria or comorbidities([7],[8],[9],[10]). For this reason, WHO created a program for the control of respiratory infections aimed at community workers, which did not have the desired impact due to the imprecision in evaluating and calculating some clinical data, such as respiratory frequency for example [11], [12].

Accurate diagnosis of pneumonia depends on medical expertise and requires evaluation of various clinical features; shortage of expertise and appropriate diagnostic tools hinders timely treatment[13].

The diagnosis of pneumonia provided by a health specialist is made with the chest X-ray and clinical data, but in rural areas of Peru these resources are not available, and even more health professionals to perform them, which is why 2 out of 3 deaths from pneumonia are out-of-hospital because of the mobilization of the patient for a diagnosis from one population center to another, which brings complications that increase the possibility of death in the patient [14].

One of the most important clinical data to be considered by the health specialist is the result of pulmonary auscultation. However, this is subjective and depends on the training and skill of the health personnel in charge. The health personnel must have the ability to recognize the different sound patterns, our research quantifies these values eliminating subjectivity to have a reliable classification of abnormal sounds to support the health personnel or community agent at the first level of care

that allows a diagnosis at the first moment in the most vulnerable, distant and in need areas[15].

The most common pulmonary sounds are crackles for pneumonias and wheezing in case of bronchitis. According to the sound analysis, the sounds are located between 100-1000 Hz, which is the frequency range we will cover for this study [16]. On the other hand, the acoustic stethoscope has a frequency response that attenuates the frequency components of the sound signal that the human ear is not particularly sensitive to, thus the analysis of sound in a wider frequency range can benefit the follow-up and evolution of cases[16].

This study details the creation of an initial algorithm for the classification of lung sounds from the characteristics of the audio signals, as a first step in the development of an automatic model that will further aim to classify them automatically and continuous learning, being this the first approach to algorithms of such kind by means of the definitions and characteristics of the sounds in general[15].

This research develops, by means of convolutional networks, the evaluation of lung sound using an automatic algorithm that with clinical data will allow assessing the risk of pneumonia at an early stage.

This research aims to contribute to this problem, proposing a mobile tool that through the use of Deep learning techniques can classify whether a patient is going through a pulmonary process or pneumonia from clinical data and the capture of lung sounds classifying them with convolutional neural networks. This project is based on computational neural network models for the classification of lung sounds, and identification of wheezing, hoarseness, or crackles for an effective analysis of support in those places where there is no medical personnel for timely diagnosis. In this way, artificial intelligence provides by means of learning the capacity of automatic classification based on artificial neural networks through the use of computational servers for the respective calculation[17]. The system could help non-expert technicians, such as health assistants or community workers, to detect pneumonia in low-resource settings where specialized personnel are not available to interpret ultrasound images.

II. POPULATION AND SAMPLE

A. Sample

In this investigation a public sound base was used, 2 research groups from Portugal and Europe, which has classifications and clinical data of 126 patients from which a total of 920 sounds were collected. The equipments used for sound collection are electronic stethoscopes:

- AKG C417L Microphone (AKGC417L).
- 3M Littmann Classic II SE Stethoscope (LittC2SE).
- 3M Litmann 3200 Electronic Stethoscope (Litt3200).
- WelchAllyn Meditron Master Elite Electronic Stethoscope (Meditron).

It is worth mentioning that due to the audio recording by the aforementioned equipment directly on the patients, the sounds captured have those emitted by the lungs and have

some noise coming from the heart or any other sound that exists in the body or external at the moment of the capture.

The sounds have a duration from 10 seconds to 90 seconds, captured by specialists and classified into five main ailments:

- Bronchiectasis
- Bronchiolitis
- COPD: Chronic Obstructive Pulmonary Disease
- Healthy
- Pneumonia
- URTI: Upper Respiratory Tract Infection

The use of convolutional neural networks for this research requires a large amount of data. The database used had a limited amount of them in some cases of classification because of this the process of data augmentation was used to obtain a base with better characteristics that support a better classification.

The Data Augmentation process has been carried out using three sequential processes. Fig. 1 presents the spectrogram of a normal sound at the beginning of the process.

Noise Addition: This process involves the addition of noise which means white noise to the sample. White noises are random samples distributed at regular intervals with a mean of 0 and a standard deviation of 1. In order to achieve this, we will use numpy's normal method, generate the above distribution and add it to our original sample. The following factors were used.

- Noise addition amplitude 0.005.
- Noise addition amplitude 0.007.

In Fig. 2 we can observe the effect of the Noise Addition on the normal sound shown in Fig. 1.

Time Shifting: This is the process of moving the acoustic wave to the right by a given factor along the time axis.

To accomplish this, we used numpy's roll function to generate time shifts. The following factors were used:

- Time shifting de factor $\text{sample_rate}/10$
- Time shifting de factor $\text{sample_rate}/5$.

In Fig. 3 we can observe the effect of the Time Shifting on the normal sound shown in Fig. 1.

Fig. 1. Mel Spectrogram of Normal Sound.

Fig. 2. Mel Spectrogram of Noise Addition with Amplitude of 0.005 for Normal Sound.

Fig. 3. Mel Spectrogram of Time Shifting on a Normal Sound with a Factor Sample_rate/5.

Pitch Shifting: An implementation of the pitch scale used in musical instruments. It is a process of changing the pitch of the sound without affecting its speed. We will use the `pitch_shift` function of `librosa` again (example in the Fig. 4). It samples the waveform, sampling frequency and number of steps through which the pitch should be shifted. The following factors are used:

- Pitch shifting de factor +2.
- Pitch shifting de factor +1.
- Pitch shifting de factor -1.
- Pitch shifting de factor -2.

Fig. 4. Mel Spectrogram of Pitch Shifting de Factor -2, on a Normal Sound.

With this process, the data ended up increased by a factor of 9, as follows Table I shows the original data and the final data after the complete process.

In Table I, we can see in the first column, the initial classification followed in the second column by the number of data originally in the database. In the third column, the amount of data obtained after the data augmentation process. In the last two columns we see the classification that was performed, with

the classification between healthy and sick and in the last one the identification of healthy, pneumonia, and some other disease. Each base and classification has its respective model, based on the characteristics of the pulmonary sounds.

TABLE I. TABLE OF DATABASE ANALYSIS AND ITS CLASSIFICATION FOR EACH MODEL DEVELOPED

Pulmonary Sounds				
Classification by disease	Original number	Data Aumentation	Dichotomic classification	Classification Pneumonia and others
Healthy	35	315	Normal	Normal
Pneumonia	37	333	Abnormal	Pneumonia
Bronchiectasis	16	144	Abnormal	another disease
Bronchiolitis	13	117	Abnormal	another disease
COPD	793	7137	Abnormal	another disease
URTI	23	207	Abnormal	another disease

III. METHODOLOGY

The objective of this study is to model by means of convolutional neural networks, the classification of normal and abnormal sounds. To this end, the general process we used for the design of the study was based on a sequential process consisting of three main parts schematized in Fig. 5.

Fig. 5. Classification Process Flowchart.

The procedures shown are:

- Data Augmentation process, to achieve a more solid base, our original base had 917 sounds and our final base of the process has 8253 sounds, which we finally worked with, thus allowing an adequate classification and model. This process was explained in the population and sample section [17].
- Feature extraction process, for this process 3 methods were used: MelSpectrogram, STFT and MFCC, the sound features were combined and utilized to generate 3 models[7].
- Modeling process, after the features were extracted they were classified in three ways, the first to classify Normal and Abnormal sound, the second to classify Healthy, Pneumonia or other diseases, and the last one to allow classification by disease.

The feature extraction process is performed by 3 methods:

- Melspectrogram: is a nonlinear transformation of the Short Time Fourier Transform (STFT) on the Mel scale, a scale based on the human perception of tones.
- STFT: is a sequence of Fourier transforms of a windowed signal that provides time-localized frequency information for situations where the frequency components of a signal vary over time. As a general

rule, a narrow window width generates better resolution in the time domain, but generates poor resolution in the frequency domain and vice versa. Visualization of STFT is often done through its spectrogram, which is an intensity plot of the STFT magnitude over time. In the present work, a window length of 2048 and an offset length of 512 were used. Once the STFT is obtained, it is transformed to the Mel scale by applying a bank composed of multiple triangular band-pass filters, for this work 128 filters were used.

- MFCC: Concerning the field of sound signal processing, the analysis is usually completed with the calculation of the logarithm of the energy of each frequency band and with the calculation of the Direct Cosine Transform, obtaining the Mel Frequency Cepstral Coefficients (MFCC).

Fig. 6. Mel Frequency Cepstral Coefficients (MFCC).

The anomaly classifier using the convolutional neural networks that we have used is summarized in Fig. 6. For each classification, different variations of the convolutional neural network (CNN) architecture were performed, but all share certain similarities. For all models, the structure of the convolutional network was as follows: an input layer with dimensions of 256 x 256, followed by 7 convolutional layers with a 3x3 kernel and RELU activation function whose filters had dimensions of 32,64,128,256,512 and 1028 respectively, 7 layers of Max Pooling, 7 layers of dropout of 20%.

Next follows the final convolutional layer which has a GlobalAveragePooling2D type with softmax activation function followed by a fully connected 4 neuron and softmax activation function. Finally, an output layer that varies depending on the classification required, 2 dimensions for dichotomous classification, 3 dimensions for pneumonia classification and others, and 6 dimensions for complete classification. The Process is in the Fig. 7.

The Modeling process starts after the extraction of features given by the previous methods, with this data 3 classifications are modeled which are:

- Model 1: classification of normal and abnormal sound.
- Model 2: classification between normal sound, pneumonia and other diseases.
- Model 3: classification by disease and wellness, which would allow a finer classification.

Statistical Analysis

To evaluate the classification models of each of the 3 models selected for analysis in this paper, we have considered

some measures to validate their prediction or effectiveness[18], [19].

Among the measures to evaluate each model are:

Training Accuracy, this measure assesses the accuracy of the model that has been designed on the training set.

Testing Accuracy, this value represents the accuracy of the model performed on the test set, which is different from the one used for training.

Accuracy is the measure that quantifies the number of positive class predictions that actually belong to the positive class.

To remember, this measure quantifies the number of positive class predictions made from all positives in the data set.

F1-score, combines the measures of accuracy and completeness to return a more general measure of model quality.

Support, is the amount of data you have to evaluate the model.

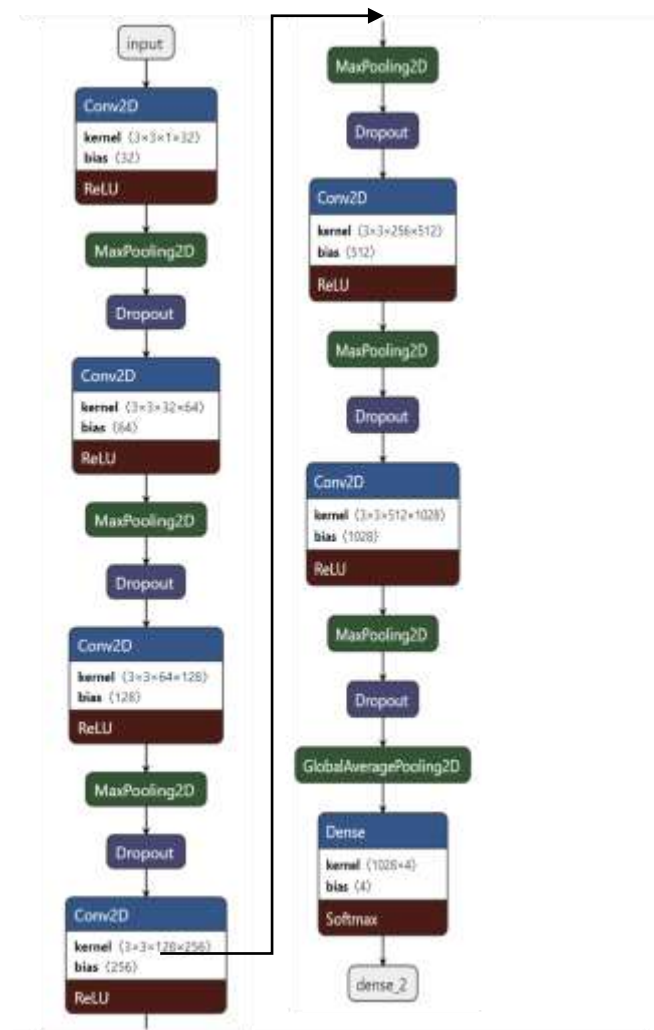

Fig. 7. Convolutional Neural Network Structure for Classification.

Confusion matrix, within the field of artificial intelligence, it is important to measure the power of statistical classification. The confusion matrix allows the visualization of the performance of an algorithm used in supervised learning, observing clearly in absolute values or percentages the way in which the model has classified the subgroups that we seek to model.

Receiver Operating Characteristic or ROC curve is a graphical representation of sensitivity against specificity for a binary classifier system according to varying discrimination threshold.

These measures will help us to assess and estimate the predictive ability of the classification on the set selected by the convolutional neural networks.

IV. RESULTS

This study was formulated to demonstrate the feasibility of an automatic design software based on convolutional neural networks in order to categorize pulmonary sounds depending on the extraction of the aforementioned features. We have detailed the variables that will support us in the evaluation of each model or classification set. In the following, we will show the results of the best model for each subgroup.

Model 1: classification of normal and abnormal sound.

For this model we work with a classified database based on the output of the data augmentation process, the details of the database conformation are shown in Table II.

For the MFCC feature extraction method. A training accuracy of 1 and a testing accuracy of 0.998 were obtained.

The details of the classification report are shown in Table III.

The confusion matrix based on percentages is detailed in the graph (Fig. 8).

For this model, we obtained an ROC curve of 1 for each classification.

Model 2: Classification between normal sound, pneumonia and other diseases.

For this model we work with a classified database based on the output of the data augmentation process, the details of the database conformation are shown in Table IV.

TABLE II. REGRESSION MODEL 1 RESULTS

Description	Number of samples	Percentage
Healthy	315	3.82
UnHealthy	7938	96.18
Total	8253	100

TABLE III. NORMAL (HEALTHY) AND ABNORMAL (NONHEALTHY) MODEL 1 CLASSIFICATION REPORTS

Description	Precision	Recall	f1-score	Support
Healthy	0.9981	1.0000	0.9991	1588
UnHealthy	1.0000	0.9524	0.9756	63

Fig. 8. Confusion Matrix in Percentages for Healthy or unhealthy Classification.

TABLE IV. REGRESSION MODEL 2 RESULTS

Description	Number of samples	Percentage
Healthy	315	3.82
Pneumonia	333	4.35
Others	7605	91.83
Total	8253	100

For the MEL feature extraction method. A training Accuracy of 0.9959 and a testing accuracy of 0.9885 were obtained.

Classification report of wellness, pneumonia, and other illnesses is described in Table V.

TABLE V. WELLNESS, PNEUMONIA, AND OTHER ILLNESSES CLASSIFICATION REPORT OF MODEL 2

Description	Precision	Recall	f1-score	Support
Healthy	0.9492	0.8889	0.9180	63
Pneumonia	0.9683	0.91044	0.9385	67
Others	0.9915	0.9967	0.9941	1521

The confusion matrix based on percentages is detailed in the Fig. 9.

Model 3: Classification by disease and wellness, which would allow a finer classification

Fig. 9. Confusion Matrix in Percentages for the Classification of Wellness, Pneumonia, and other Ailments.

For this model we work with a database classified from the output of the data augmentation process, the details of the conformation of the database are shown in Table VI.

TABLE VI. REGRESSION MODEL 3 RESULTS

Description	Number of samples	Percentage
Healthy	315	3.82
Pneumonia	333	4.35
URTI	207	2.51
COPD	7137	86.48
Bronchiolitis	117	1.42
Bronchiectasis	144	1.74
Total	8253	100

For the MFCC feature extraction method. A training Accuracy of 0.9967 and a testing accuracy of 0.9909 were obtained.

The details of the classification report are shown in Table VII.

TABLE VII. NORMAL (HEALTHY) AND ABNORMAL (NONHEALTHY) MODEL 3 CLASSIFICATION REPORTS

Description	Precision	Recall	f1-score	Support
Healthy	1	0.9524	0.9756	63
Pneumonia	0.9692	0.9423	0.9545	67
URTI	0.8511	0.9756	0.9091	41
COPD	0.9958	0.9951	0.9954	1428
Bronchiolitis	1	1	1	23
Bronchiectasis	1	1	1	29

The confusion matrix based on percentages is detailed in Fig. 10 as follows.

The models presented in the results are based on the extraction of features provided by the methods explained, as part of the convolutional neural network that we have applied. These results have been applied taking as a sample the database after the data augmentation process, and the random division of the training and testing set.

Fig. 10. Confusion Matrix in Percentages for the Classification by Health and each Disease.

For each case, we have provided tables showing the distribution of the sample in the respective categories within the models and results, where the values for each sub-classification are also described.

V. DISCUSSION

In this research, model 1, which classifies normal and abnormal sounds by means of convolutional neural networks, obtained precision values for normal sounds of 0.998 and precision values for abnormal sounds of 100.

Other studies in the literature have pursued similar objectives, some of which are discussed below.

In 2017, Aykanat [20], their research aims to improve audio data analysis through machine learning in order to classify respiratory sounds. They are based on auscultation, a non-invasive process for the diagnosis of pulmonary anomalies. In terms of materials, the Thinklabs One electronic stethoscope was used. They classify their information into 4 sets: (1) healthy versus pathological classification [17 930 clips], (2) rale, rhonchus and normal sound classification [15 328 clips], (3) singular respiratory sound type classification [14 453 clips] and (4) audio type classification with all sound types [17930 clips]. The acquired database is utilized in the highest quality format and in a real environment. In addition, they process their raw data, without filtering, amplification and with a single instrument and software adapted to the hospital environment. The spectrograms used are in 28x28 grayscale (to reduce storage and post-processing memory). They have a classification of healthy and pathological (1) with an average accuracy of 86% using Convolutional Neural Networks. Our research uses similar techniques, with better results, also using sufficient amount of data, but our approximations are higher than those detailed in this analysis.

Tracey [21] in 2011 researches on a low-cost cough monitoring system for drug-resistant tuberculosis (TB) patients (MDR), which could be used in places with poor access to specialized laboratories, the validation of the system algorithm, based on other research, is presented. The cough detection algorithm implements an image analysis of the MFCC through machine learning algorithms and compares the performance of manual diagnosis of cough audios and diagnosis by Neural Networks such as: Multilayer perceptron (MLP), Support Vector Machine (SVM) and Sequential Minimal Optimization (SMO). Its samples consist of 30 audio files corresponding to 10 random patients and a recording time of 30 minutes. In addition, a total of 13 429 cough frames and 43 925 non-cough frames were used to train the Neural Network. The algorithm designed with SMO classifies events as cough and non-cough. Moreover, it presents a sensitivity of 81%, which in the validation with 28 patients with MDR TB yields a promising recovery due to the indication of cough in the patient. The designed algorithm proposes an improvement in cough detection by estimating an empirical filter for environmental noise. Each recording file contains a number of frames used to train the neural network. It consists of two known and manually diagnosed patients. To reduce the CPU load in the training, the "divide and conquer" clustering method was used. If we compare with the present research we focus on pulmonary sound, the amount of sound samples they contain

are not comparable with those used in our study, it is worth mentioning that our analysis also has higher accuracy results than those indicated in the aforementioned research.

In 2019, Tariq[17] used the same database as the one presented in this paper and a similar methodology, but the results we obtained and the data augmentation processes are different. As their research in medicine and advanced technologies is associated with more accurate care and treatment, so the research aims to evaluate the degree of accuracy of Deep Learning and 2D Convolutional Neural Networks (CNN) using lung spectrogram data. The methodology is based on three steps: (1) normalization for information cleaning; (2) data augmentation, for training; and (3) CNN model, as identifier and classifier through libraries on MEL spectrograms. As a result of the 2D CNN (3) we obtain a model called lung disease classification (LDC) with 7 classifications: Asthma (0), bronchiectasis (377), COPD (10 205), Healthy (455), LRTI (26), Pneumonia (481) and URTI (403). Additionally, an accuracy of approximately 83% for original data and 97% for augmented and normalized data. The data augmentation methods expanded the original data by approximately 95%, which serves as a useful baseline for training. They do not specify the database format and do not prioritize the use of resources such as GPU or data storage. Accuracy increases significantly according to the normalization and data augmentation technique to the point of reaching 97% of their previous research. Our research uses the same data, without data normalization but uses data augmentation at 900%. This makes the results work better for model building, achieving a positive accuracy of 0.998 and a negative accuracy of 1.0.

VI. CONCLUSIONS

We can conclude that the highest classification found is with respect to the classification of normal and abnormal, with classification values of normal of 0.998 and abnormal of 100, which gives a high probability of success in implementing this technique in an automatic classification. The second finding is the one shown in the second model, where we reached model accuracy values of 0.9959 and 0.9885, this gives us evidence of an acceptable classification of the recognition of pneumonia over other ailments, since this is the primary interest of the study.

It is important to mention that in this work every model has been provided with a training and testing set. Also, the analysis of our experts showed that the sounds of the mentioned base are normal heterogeneous sounds of child and adult, trachea and lung that are captured by the digital stethoscope, commercial, captured in normal conditions of attention which leads to environmental noise, which could negatively influence the design of each model, but even so, the models are acceptable and we obtain from the analysis an adequate and significant value that encourages us to continue analyzing this method but now for sounds of patients with ailments such as COVID, during the pandemic in order to develop a tool for the first level of care in vulnerable areas with scarce resources.

This research is the proof of concept for the development of a complete system for the first level of care that supports the diagnosis through the automatic classification of sounds

between normal and abnormal, in conjunction with clinical data, is the first step as part of a process that we are starting in favor of reducing the gaps in health. Although there are recent studies that work with neural networks for classification, our study aims to achieve a better understanding of the differences between these sounds to achieve with an adequate result the discrimination of these, as part of a study to implement an automatic platform for remote and remote locations to assess the risk of pneumonia at the point of care so that we can work on low-cost tools to reduce child mortality in times of cold and highland areas of Peru.

ACKNOWLEDGMENT

We want to thank the Image Processing Research Laboratory.

(INTI-Lab) and the Universidad de Ciencias y Humanidades.

(UCH) for their support in this research, the National Fund for.

Scientific, Technological and Technological Innovation (FONDECYT), according to the research: "SAMAYCOV: "Desarrollo de un dispositivo electrónico portátil a bajo costo para evaluar riesgo de neumonía basado en sonido pulmonar anormal en pacientes con sospecha de COVID-19 en zonas vulnerables". CONVENIO 054-2020-FONDECYT"; for the financing of this research and the Electronics Laboratory of the UCH for assigning us their facilities and being able to carry out the respective tests.

Cost Effective Hybrid Fault Tolerant Scheduling Model for Cloud Computing Environment

Hybrid Fault Tolerant Scheduling

Annabathula.Phani Sheetal¹, K.Ravindranath²

Koneru Lakshmaiah Education Foundation

Green Fields, Vaddeswaram, Guntur-522502, Andhra Pradesh, India

Abstract—Cloud computing provides flexible and cost effective way for end users to access data from multiplatform environment. Despite of support by the features of cloud computing, there are also chances of resource failure. Hence there is a need of a fault tolerant mechanism to achieve undisrupted performance of cloud services. The task reallocation and duplication are the two commonly used fault tolerant mechanisms. But task replication method results in huge storage and computational overhead, when the number of tasks is increasing gradually. If the number of faults is high, it incurs more storage overhead and time complexity based on task criticality. In order to solve these issues, we propose to develop a Cost Effective Hybrid Fault Tolerant Scheduling (CEHFTS) Model for cloud computing. In this model, the Failure Occurrence Probability (FoP) of each VM is estimated by finding the previous failures and successful executions. Then an adaptive fault recovery timer is maintained during a fault, which is adjusted based on the type of faults. Experimental results have shown that CEHFTS model achieves 43% reduced storage cost and 13% reduced response delay for critical tasks, when compared to existing technique.

Keywords—Cloud computing; failures; fault tolerant; critical tasks; scheduling; fault recovery; overhead

I. INTRODUCTION

Cloud computing is one of the new areas of technology that has emerged recently. On-demand resource sharing can be accomplished by utilizing internet and cloud services [1]. The primary goal is to offer services or distribute resources at the request of the customer with the lowest possible cost. There is a huge amount of heterogeneous resources [2], a vast user base, and a great range of application tasks in the cloud computing system. They have to deal with numerous individual activities, as well as big data. In terms of finance and science, cloud computing is a very valuable service [3]. A difficult challenge arises when deadlines are imposed on the jobs, since the required resources may be unavailable due to failures [4].

Along with missing project deadlines, fault tolerance is an important cloud computing aspect. It is designed to handle real-time tasks even if a failure occurs. Due to the higher storage overhead of taking backups, it is vital to use alternative approaches that have a high resource utilization ratio. Even though cloud features are attractive and a fault

tolerant technique is required to guarantee uninterrupted cloud service functioning [5].

Both internal and external factors contribute to some of the flaws. The two most often utilized fault-tolerant strategies in cloud computing are task reallocation and duplication. In task reallocation, a task is reassigned after a fault occurs. This method boosts the overall system resource usage. However, failing to meet the deadline constraints [6] of jobs could cause the response time to be prolonged. The rise in the amount of electricity consumed while making resource allocations causes resource requests to fail in data centers.

Both traditional application components and new traditional application components may be heterogeneous in their component composition, composed of scientific techniques. With virtualization technology, these components have their own specialized execution environment. Workflows can also be implemented and run in cloud environments that offer an ever-growing resource pool [7] that you pay just for what you use. On-demand cloud resources can thus be acquired and shared on workflows. Clouds serve as a favored scientific process execution environment due to these characteristics.

However, processes that operate in the clouds face obstacles, because the complexity and dynamics of processes and cloud breakdowns occur more frequently. Failures tend to stop continuous implementation and have considerable impacts on the performance of processes, particularly for big, long-run workflows. It is crucial that scientific workflow scheduling fault tolerants be achieved in order to provide consumers with flawless experience.

Due to the time-consciousness of many scientific procedures, their successful completion does not depend exclusively upon the correct results but also on the time when those results are available. For a workflow that must complete the working phase and generate the computer results, a deadline is specified for the workflow. Failures lead to deadline conscious workflows that cannot be concluded on time without an appropriate faults-tolerant schedule. In that circumstance, QoS is badly damaged, although beyond the deadline[8] the results may be acquired. Therefore, it is required and crucial to plan a defect tolerant workflow since processes can be successfully completed before the deadline.

This paper is organized as follows. Section 2 presents the motivation and objectives. Section 3 presents the proposed methodology. Section 4 presents the simulation results. Section 5 presents the conclusion.

II. MOTIVATION AND OBJECTIVES

In fault-tolerant workflow scheduling [6], task replication method is used. Here duplicate multiple copies of tasks [9] can execute simultaneously. But it results in huge storage and computational overhead, when the number of tasks is growing. Moreover, it did not present the strategy for finding the exact number of duplicate copies.

The Power, memory, and other network elements were addressed in order to enhance the reliability of resources. In task scheduling, the VM with the greatest level of reliability is picked. Hussein El Ghor et al. [8] has presented two scheduling algorithms. The first approach uses energy-efficient fault-free scheduling and the second approach provides essential slack time for fault recovery. The proposed model is limited in handling small group of tasks that cannot improve the performance levels.

Redundancy is a common way to protect against errors that can be done quickly or in space. Any additional resources required to perform the identical duplication or resilience replication process are designated as spatial redundancy. When considered in depth, an example of spatial redundancy may be parallel execution. There are considerable space expenses when you simultaneously run many jobs on different resources. In the case of redundancy, the task that was missed with respect to initial resources does not have to be redone because the clock was reset.

With Fault Tolerance Algorithm utilizing Selective Mirrored Tasks Approach (FAUSIT), they proposed a selective mirrored task method to ensure the correct balance between parallelism and topology for applications. DAG-based application fault tolerance is dealt with by limiting the number of make spans and minimizing computation costs.

For important jobs or tasks with permanent failures, the dynamic fault-tolerant workflow scheduling [10] uses spatial re-execution (SRE) and temporal re-execution (TRE) schemes in unison. However, as the number of issues detected for important operations is greater, the SRE strategy consumes more disc space. If the number of faults for non-critical tasks is excessive, then it has an adverse effect on time complexity. Additionally, the backups' odds of failure are not examined.

In FESTAL [11], for each primary task, a backup task is created and VMs are allocated for both. When the primary task is completed successfully within the execution time, then the execution of back task is terminated. But in this approach also, it results in huge storage and computational overhead [12], when the number of tasks becomes high. The performance levels are not satisfactory as the model causes overhead in the system.

In [13], a fault tolerant technique to ensure task completion deadline, has been proposed. But it does not check the types of tasks and storage overhead also is more that improves the delay levels in the system.

In [15], a trust based scheduling technique is proposed. For selecting the trusted computation service, set-based particle swarm optimization (S-PSO) and for selecting the storage service, ser covering problem (SCP) tree search are applied. The task scheduling concept in [16] is built on trust mechanisms. This model uses the Bayesian cognitive technique to determine the trustworthiness of computer nodes by examining the trust relationships that exist between them.

A research paper [17] outlines a trust-based Meta heuristic workflow scheduling technique called TMWS. The manual offers strategies and procedures to avoid the hazards associated with workflow scheduling.

Hence the fault tolerant algorithm should meet the following objectives:

- To reduce storage overhead.
- To reduce time complexity.
- To reduce the chances of backup VM failures.
- To meet deadline of critical tasks.
- To reduce the response delay.
- To reduce the fault recovery time.
- To increase the CPU utilization.

In order to solve these issues, we propose to develop a cost effective hybrid fault tolerant scheduling scheme for cloud computing.

III. COST-EFFECTIVE HYBRID FAULT TOLERANT SCHEDULING (CHFTS) MODEL

A. Overview

In this paper, Cost-effective Hybrid Fault Tolerant Scheduling (CHFTS) model is proposed. Figure 1 shows the block diagram of the CHFTS model.

The CHFTS model uses previous failures and successful executions to calculate the VM failure occurrence probability (FoP). The anticipated execution time (EET) is estimated for each job T_i . At this point, the projects with deadlines of less than one week are classed as high-priority activities. The designation of some VMs as fault-tolerant based on FoP. A fixed number of primary and backup VMs are assigned to each task. A recovery timer is initiated if a failure occurs in any VM. A notification will be delivered to the failed VM, and the VM will continue execution from the point in time that the failure occurred.

B. System Model

Virtualization divides each server in the Cloud system into a series of heterogeneous virtual machines (VMs). The fact is that a VM is an essential component of a cloud system.

Suppose that a cloud system offers a set of VM resources, as given by.

$$VM = \{VM(1), \dots, VM(k), \dots, VM(k)\}$$

to users.

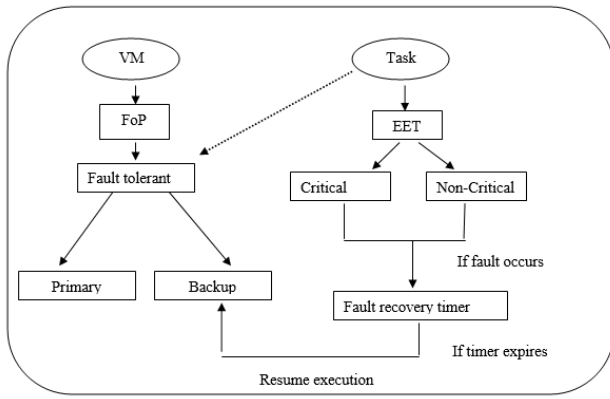

Fig. 1. Block Diagram of CHFTS Model.

The model represents the system structure, as seen in Figure 2. Processing capacity and cost per hour are particularly important for selecting VM(k) because of processing capacity and cost per hour, respectively (k). Users can access an endless number of VMs on cloud computing platforms that utilize virtualization. In addition, all VMs are hosted in one cloud data center to provide consistent bandwidth for all the VMs.

C. Fault Model

If a task is incomplete because of internal or external issues, it may be considered as a task failure.

Faults may occur during the execution of scientific work flows in cloud computing environments. There are various reasons behind these faults. The most common reason for task failure is the failure of corresponding VM. The other reasons for faults include unavailability of enough resources, resource overloading, delayed execution time etc.

There are two cases of faults that may occur in cloud, during execution. The first one is a permanent fault and other one is a temporary fault. In temporary faults, the faults may be recovered within short span of time whereas in permanent faults, the faults cannot be rectified until the failed element is repaired or replaced. Fail-signal or acceptance test is a fault detection mechanism, commonly used.

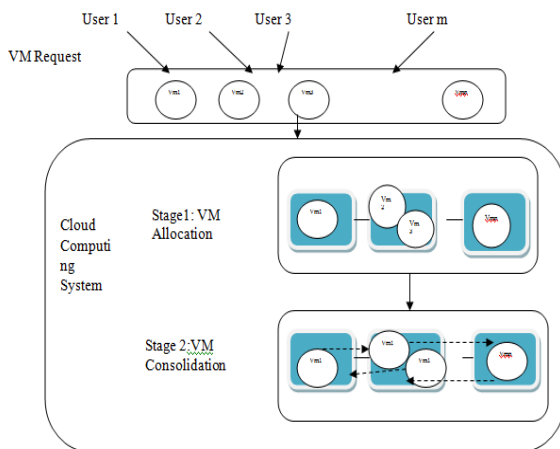

Fig. 2. System Model.

Due to task failures, the make span time of work flows will be increased and the service-level agreement (SLA) will be violated. Re-execution is one of the commonly used less expensive fault tolerant technique, which improves the reliability of workflows. Re-execution can be implemented in two methods: Spatial re-execution on other resources (SRE) and Temporal re-execution on the same resources, after fault recovery (TRE).

1) Estimation of FoP: The exponential probability density function for a specified mean time (M) between failures, is given by.

$$f(t) = \frac{1}{M} e^{-t/M} \quad (1)$$

Then, the probability of a failures, that occurs before time Δt for a VM is given by.

$$P(t \leq \Delta t) = \int_0^{\Delta t} \frac{1}{M} e^{-t/M} dt = 1 - e^{-\Delta t/M} \quad (2)$$

Hence the probability of successful completion during the time Δ , is given by.

$$P(t > \Delta t) = 1 - P(t \leq \Delta t) = e^{-\Delta t/M} \quad (3)$$

Let T_c be the computation time for a subtask executing on a VM and ϕ be the computation interval between two check points.

Then, the average number of attempts (NoA) required to finish T_c is given by.

$$NoA = \frac{T_c/\phi}{P(t > \Delta t)} = \frac{T_c e^{\Delta t/M}}{\phi} \quad (4)$$

The number of success is given by

$$NoS = \frac{T_c}{\phi} \quad (5)$$

Hence the number of failures NoF, during Δt is given by

$$(ie) NoF = NoA - NoS \quad (6)$$

$$\frac{T_c e^{\Delta t/M}}{\phi} - \frac{T_c}{\phi} = \frac{T_c}{\phi} (e^{\Delta t/M} - 1) \quad (7)$$

Hence

$$FoP = NoF / T_c, = \frac{1}{\phi} (e^{\Delta t/M} - 1) \quad (8)$$

Note: It is assumed that only single failure occurs during one computation interval.

D. Estimation of Expected End Time (EET)

Let $P(k)$ is considered as processing capacity of VM_k , $k=,1,2...K$.

Let $S(t_i)$ and $W(t_i)$ be the workload size of given input task t_i .

If and only if all the input data has been received from all prior tasks, then the task is started (t_i).

start time of t_i is signified by Eq. (9).

$$T_{start}(t_i) = \max_{t_j \in pre(t_i)} \{T_{end}(t_j)\} \quad (9)$$

Note that if $t_i=t_{entry}$, then $T_{start}(t_i)=0$. Then, the transmission time is computed by,

$$T_{trans}(t_i) = S(t_i) / BW \quad (10)$$

where BW is the bandwidth between two VMs.

Then, the execution time is given by,

$$T_{exec}(t_i, VM(k)) = W(t_i) / P(k) \quad (11)$$

Thus, the end time of task t_i is given by.

$$T_{end}(t_i) = T_{start}(t_i) + T_{trans}(t_i) + T_{exec}(t_i, VM(k)) \quad (12)$$

Hence the make span of workflow is given by.

$$makespan = T_{end}(t_{exit}) \quad (13)$$

E. Fault Tolerant Scheduling

Let {FVM} be the set of fault tolerant VMs with maximum FoP.

The type of each task is categorized into CRITICAL and NON-CRITICAL based on the values of EET. (ie) The tasks with shorter EET are considered as CRITICAL and others are considered as NON-CRITICAL.

For each task, a pair of VMs $\langle VM_p, VM_b \rangle$ from the k VMs, are allocated, where VM_p and VM_b are primary and backup VMs. If there is a fault occurs in VM_p , then a fault recovery timer (T_{FR}) will be started.

Case-1: If the task is a critical task, then T_{FR} is fixed such that.

$T_{FR} < EET-FOT$, where FOT is the time of fault occurrence.

Case-2: If the task is a non-critical task, then T_{FR} is fixed such that.

$T_{FR} < (EET-FOT) * \mathcal{D}$, where \mathcal{D} is a scaling factor ranges between (2, 4).

The total cost of the Hybrid Fault Tolerant Scheduling Model is calculated as.

$$CC = NoS * \min(NoA) + \frac{T_{End}-T_{exec}}{\text{count}(VM)} + \Delta t * \varphi \quad (14)$$

If the fault cannot be recovered within T_{FR} , (ie) If fault recovery time (FRT) is more than T_{FR} , then immediately, a notification will be sent to VM_b , which will resume the execution from that point.

Algorithm - Fault Tolerant Scheduling

Input : List of VMs and Tasks

Output: fault tolerant scheduling

1. **foreach** VMj
 2. Estimate FoP_j using (5)
 3. If FoP_j >= Max(FoP), then
 4. Include FoP_j in {FVM}
 5. End if
 6. **End for**
 7. **foreach** task t_i
 8. Estimate EET_i using (11)
 9. **if** EET_i <= EET_{min}, **then**
 10. Type(t_i) = CRITICAL
 11. **else**
 12. Type(t_i) = NON-CRITICAL
 13. **end if**
 14. **end For**
 15. **foreach** incoming task t_j
 16. Allocate (VM_p, VM_b) ∈ {FVM}
 17. **if** fault occurs at time FOT, **then**
 18. **if** Type(t_i) = CRITICAL, **then**
 19. Set $T_{FR} < EET-FOT$
 20. **else**
 21. Set $T_{FR} < (EET-FOT) * \mathcal{D}$
 22. **end if**
 23. **if** FRT < T_{FR} , **then**
 24. Resume t_j at FRT
 25. **else**
 26. Send notification to VM_b
 27. Resume t_j at VM_b
 28. **end if**
 29. **end if**
 30. **end For**
-

Special outcomes of this approach

1) Since fault free VMs are selected, the chances of faults are less.

2) It does not result in huge storage since the VMs are allocated only when the fault is not recoverable (permanent fault) within a time span.

3) The time critical tasks will be executed within their deadlines since the tasks are migrated to backup VM, within the deadline.

4) The non critical tasks can be executed in the same VMs if the fault is recovered within tolerable time span (which is an even multiple of its deadline).

5) If the task could not be recovered beyond the tolerable time span, then only the non critical task are migrated to backup VMs, thereby reducing the storage overhead significantly.

6) Since the execution of tasks starts in the backup VM only from the time of fault, the time complexity will be less.

IV. EXPERIMENTAL RESULTS

The proposed CEHFTS model is compared with the Spatial-Temporal Re-Execution method (SRE) [10]. The NASA workload [14] has been used as the emulator of Web users requests to the Access Point (AP). This workload represents realistic load deviations over a period time. It comprises 100960 user requests sent to the Web servers during a day. Table 1 shows the experimental parameters assigned in this work.

TABLE I. EXPERIMENTAL PARAMETERS

Parameter	Value
Work load	NASA traces
Resource Utilization Thresholds	$U^{low-thr} = 20\%$ and $U^{high-thr} = 80\%$
Response Time Thresholds	$RT^{low-thr} = 200ms$ and $RT^{high-thr} = 1000ms$
Scaling Intervals	$\Delta t = 10min$
Desired Response Time	$DRT = 1000ms = 1s$
Fault rate	1 to 2
Configuration of VMs	Medium and Large
Maximum On-demand VM Limitation	$MaxVM = 10VM$
Task and Resources Scheduling Policy	Time-Shared

A. Results for Critical Tasks

In this section, work flows with strict deadlines are considered (critical tasks) and allocated to VMs. The FoP of each task is increased in terms of fault rate. The performance metrics response delay, percentage of missed deadlines, CPU utilization and storage overhead of server are considered for evaluation.

Table 2 Performance Results of CEHFTS and SRE schemes for fault rate of critical tasks.

Figure 3 shows the response delay measured for the critical tasks when the fault rate is increased from 1 to 2. Since in the case of time bound critical tasks, backup VM migration is mostly supported, the response delay will be high. Hence, CEHFTS has the delay in the range of 1.4 to 2.8 seconds whereas SRE has delay in the range of 1.7 to 3.1 seconds. However, in case of CEHFTS, the failed tasks are resumed when the recovery time is less than EET. Hence it has 13% reduced response delay, when compared to SRE scheme.

TABLE II. SHOWS THE PERFORMANCE RESULTS OF BOTH CEHFTS AND SRE SCHEMES FOR VARYING THE FAULT RATE OF CRITICAL TASKS

Fault rate (Critical)	Response Delay (sec)		% of Missed Deadlines		CPU Utilization (%)		Storage cost of Server	
	CEHFTS	SRE	CEHFTS	SRE	CEHFTS	SRE	CEHFTS	SRE
25	1.472	1.782	18	25	57	47	150	270
50	1.573	1.893	26	32	52	43.1	178	356
75	2.069	2.245	31	38	45.3	38.2	287	452
100	2.275	2.628	35	44	44.2	34	368	628

Fig. 3. Response Delay for Critical Tasks.

Figure 4 shows the missed deadlines for the critical tasks when the fault rate is increased from 1 to 2. Since in the case of time bound critical tasks, if the recovery time is higher than EET or if the fault is permanent fault, the chances of deadline miss are high. As depicted from the figure, CEHFTS has the missed deadlines in the range of 18% to 41% whereas SRE has missed deadlines in the range of 25% to 47%. However, in case of CEHFTS, the failed tasks are resumed when the recovery time is less than EET. Hence it has 19% reduced missed deadlines, when compared to SRE scheme.

Fig. 4. Missed Deadlines for Critical Tasks.

Fig. 5. CPU Utilization (%) for Critical Tasks.

Figure 5 shows the CPU utilization for the critical tasks when the fault rate is increased from 1 to 2. In case of permanent failures, the CPU utilization of primary VMs will be affected for the critical tasks. As it can be seen, from the figure, the utilization of CEHFTS reduces from 57% to 41% and the utilization of SRE reduces from 47% to 33%. However, CEHFTS has 18% higher CPU utilization than SRE scheme, since it minimizes the use of backup VMs.

Fig. 6. Storage Cost for Critical Tasks.

Figure 6 shows the storage cost of servers in case of critical tasks. Since in case of time bound critical tasks, if the recovery time is higher than EET or if the fault is permanent fault, the tasks are migrated to backup VMs, leading to increased storage cost. As depicted from the figure, CEHFTS has cost in the range of 150 to 470 whereas SRE has cost in the range of 270 to 840. However, in case of CEHFTS, the failed critical tasks are resumed when the recovery time is less than EET. Hence it has 43% reduced storage cost, when compared to SRE scheme.

B. Results for Non-Critical Tasks

In this section, work flows with elastic (flexible) deadlines are considered (critical tasks) and allocated to VMs. The FoP of each task is increased in terms of fault rate. The performance metrics response delay, CPU utilization and storage overhead of server are considered for evaluation.

Table 3 Performance Results of CEHFTS and SRE schemes for fault rate of non-critical tasks

TABLE III. SHOWS THE PERFORMANCE RESULTS OF BOTH CEHFTS AND SRE SCHEMES FOR VARYING THE FAULT RATE OF CRITICAL TASKS

Fault rate (Non-critical)	Response Delay (sec)		CPU Utilization (%)		Storage cost of Server	
	CEHFTS	SRE	CEHFTS	SRE	CEHFTS	SRE
25	2.672	3.582	52	45	120	165
50	3.573	4.813	46	42.7	138	228
75	5.069	7.145	44.2	36.4	187	280
100	5.755	7.628	41.5	33.1	228	355

Figure 7 shows the response delay measured for the non-critical tasks when the fault rate is increased from 1 to 2. Since in case of non-critical tasks, the fault response timer is set as high, the response delay will be higher than that of critical tasks. Hence, CEHFTS has the delay in the range of 2.6 to 6.4 seconds whereas SRE has delay in the range of 3.5 to 8.3 seconds. However, in case of CEHFTS, the failed tasks are resumed when the recovery time is less than EET. Hence it has 25% reduced response delay, when compared to SRE scheme.

Figure 8 shows the CPU utilization for the non-critical tasks when the fault rate is increased from 1 to 2. In case of permanent failures, the CPU utilization of primary VMs will be affected for the non-critical tasks also. As it can be seen, from the figure, the utilization of CEHFTS reduces from 52% to 40% and the utilization of SRE reduces from 45% to 30%. However, CEHFTS has 16% higher CPU utilization than SRE scheme, since it minimizes the use of backup VMs.

Figure 9 shows the storage cost of servers in case of non-critical tasks. Since, if the fault is permanent fault, the tasks are migrated to backup VMs, leading to increased storage overhead. As depicted from the figure, CEHFTS has cost in the range of 120 to 270 whereas SRE has cost in the range of 165 to 472. However, in case of CEHFTS, the failed non-critical tasks are resumed when the recovery time is less than EET. Hence it has 35% reduced storage cost, when compared to SRE scheme.
