

Fig. 9. Storage Overhead for Non-critical Tasks.

V. CONCLUSION

In this research, a new hybrid fault tolerant scheduling approach, called Cost Effective Hybrid Fault Tolerant Scheduling (CEHFTS), is proposed for cloud computing. For this model, the prior failures and successful executions are used to estimate the VM failure probability (FoP). Estimated anticipated execution time (EET) is calculated for each task. At this point, the projects with deadlines of less than one week are classed as high-priority activities. An adaptive fault recovery timer is kept running until a fault occurs, which is then increased as a function of the various fault types. Experiments are conducted for critical and non-critical tasks by varying the fault rate. Experimental results have shown that CEHFTS model achieves 43% reduced storage cost and 13% response delay for critical tasks, when compared to existing technique. Future work focus on grouping the tasks based on its type and requirements so that the CPU utilization and battery power can be further reduced. The task deadline and time scheduling can still be improved to enhance the performance levels.

Abstract—Clustering is a predominant technique used in image segmentation due to its simple, easy and efficient approach. It is very important for the analysis, extraction and interpretation of images; which makes it used in multiple applications and in various fields. In this article, we propose a different image segmentation technique based on the cooperation between an optimization algorithm which is the Cuckoo Search Algorithm (CSA) and a clustering technique which is the Fuzzy C-means (FCM). The clustering method we propose goes through two major steps. In the first step, CSA explores the entire search space of the specified data to find the optimal clustering centers. Subsequently, these centers are evaluated using a new objective function. The result of the first step is used to initialize the FCM algorithm in the second step. The efficiency of the suggested method is measured on several images selected from the BSD300 database and we compare it with other algorithms such as FCM optimized by genetic algorithms (FCM-GA) and FCM optimized by particle swarm optimization (FCM-PSO). The experimental results on the different algorithms used in this paper show that the proposed method improves the segmentation results, based on the analysis of the best values of fitness, MSE, PSNR, CC, RI, GCE, BDE and VOI.

Keywords—Clustering; classification; image segmentation; fuzzy c-means; cuckoo search algorithm

I. INTRODUCTION

Segmentation is an important step in extracting qualitative information from the image. It is done via dividing the image in question into regions with homogeneity according to a predefined criterion (gray level, color, intensity, texture, etc.). Several segmentation approaches have appeared in recent years. Some of them seek to delimit homogeneous regions by their contours (contour approach) while others seek to find homogeneous regions (region approach).

The segmentation process represents a crucial step in computer vision systems, as features and decisions are extracted and made from its output. The first image segmentation algorithms were developed in the 1970s. Since then, many techniques and methods of segmentation have been experimented to try to improve the results. Nevertheless, until today, no classical image segmentation algorithm can provide perfect results on a wide variety of images.

Several segmentation techniques exist and four main categories can be distinguished: segmentation by classification [1- 3], by regions [4], by contours [5], and finally segmentation

by region-contour cooperation [6]. Clustering is considered among the most used image segmentation algorithms. The latter is a field of machine learning belonging to unsupervised learning. Clustering is mainly used to group populations into communities with similar common criteria. It is a data mining task that aims at dividing the elements of a set into groups, i.e. to establish a partition of this set. Each group must be as homogeneous as possible, and the groups must be as heterogeneous as possible. However, classical clustering methods converge to the local optimum and require a prior initialization of cluster centers. Therefore, unsupervised classification is studied as an optimization domain, i.e., finding a partition of the data that optimizes a given feature.

The image processing system presented has a multidisciplinary aspect. Its applications can be found in various fields like medical imaging [7], video analysis [8], and remote sensing [9]. In the literature, we do not find a technique to generalize it to image segmentation. Each method is used for a given type of image and in a well-defined computing context to know its performance and efficiency. Therefore, the different techniques proposed for image segmentation have asserted their defects and limitations. Researchers then found new, more flexible and efficient strategies to solve the segmentation problem, using metaheuristic approaches that now occupy an increasing place in the clustering framework for image segmentation. Metaheuristics are a set of algorithms that allow finding the fastest and most efficient solution for several optimization problems for which no more efficient classical method is known. They are iterative, i.e. starting from a single solution considered as a starting point, the search consists in moving from one solution to a neighboring solution by successive moves in a neighborhood constituted by the set of solutions by examining the fitness function.

The growing interest in metaheuristics is justified by the development of machines with enormous computational capacities, which has allowed the design of more and more metaheuristics that have proven to be quite efficient in addressing many problems like image segmentation. Thus, metaheuristics is a generic approach which operating principle is based on general mechanisms independent of any problem. Metaheuristics are stochastic and can therefore avoid being trapped in local minima. They are mainly guided by chance; however they are often combined with other algorithms in order to accelerate their convergence.

Metaheuristics are classified into two broad classes: single solution metaheuristics and solution population metaheuristics. Population-based optimization methods improve a population of solutions over time. The advantage of these methods is to use the population as a factor of diversity. Furthermore, single-solution optimization methods are called trajectory methods, i.e., they allow a trajectory to be described during the search process. In the literature, there are several algorithms based on a population of solutions employed to increase the quality of segmented images, like: evolutionary algorithms [10], genetic algorithms [11], PSO algorithm [12], ABC (Bee Colony Algorithm) algorithm [13], the SCA algorithm (Sine Cosine Algorithm) [14], the cuckoo search algorithm [15] and others. The operation of metaheuristics is progressive and iterative. The initial step is often chosen randomly and the stopping step is often fixed using a stopping criterion. All metaheuristics rely on the balance between search intensification and diversification. Otherwise, we will see a convergence towards local minima through too long an exploration due to lack of intensification or lack of diversification.

Several different methods have been devoted to unsupervised automatic classification. However, the evolution towards metaheuristics has given, in some difficult cases, very good results. In order to help improve the efficiency and performance of clustering-based image segmentation methods, we used a metaheuristic called "Cuckoo Search Algorithm" which was described by authors in [16]. This metaheuristic is an iterative stochastic method for solving many optimization problems. This method has been very successful in the optimization community; its good performance in different applications and the possibility of hybridization with other metaheuristics have contributed to this craze. In particular, this algorithm is based on the Cuckoo Search, which is inspired by the fascinating life style, habitat and reproduction of a bird species called cuckoo. It is also based on the parasitic behavior of this species combined with levitating flight-like movement logic specific to certain bird and fly species.

In the literature, there are several metaheuristic algorithms that have been used in the field of image segmentation, but the reasons for the choice of the cuckoo search are due to the use of two fundamental mechanisms:

- Intensification, which refers to the exploitation close to the optimal solution found.
- Diversification, which refers to the efficient exploration of the totality of the research field.

To solve the problem of image segmentation and improve the quality of segmented images for use in various applications. In this paper, we propose a new image segmentation method based on the hybridization of FCM clustering and CSA algorithm, which focuses on the issue of finding the optimal cluster centers in the first step and starting the FCM clustering operation in the second step. Our method can not only search for the optimal solution in the global range, but it can also exercise the accuracy of the local optimization ability of FCM algorithm. We also compared the proposed technique with other existing clustering-based segmentation algorithms, such as FCM-GA and PSO-GA. The experimental results showed the efficiency of our hybrid algorithm on the

different types of images used in our work and proved its performance by making a visual and statistical analysis of the different results obtained.

The fundamental contributions of this document can be mentioned by the following points:

- The creation of a clustering approach based on the cooperation between the FCM and CSA algorithms.
- The fixation of the number of clusters k and consequently of the center of each cluster.
- The use of CSA operators to generate the initial centers and then the FCM starts with the generated centroids.
- The proposed method has been tested by several evaluation criteria well recognized in this field.
- The results obtained confirmed the robustness and performance of the proposed method compared to other algorithms.

In the next sections, we will first present a description of the workings of the CSA and FCM algorithms, in order to exploit the advantages of CSA to optimize the FCM clustering problem. In addition, the results achieved by our approach will be compared to other well-known image segmentation methods in the literature.

The structure of this document is as follows: Section 2 lists the related work. Section 3 presents the background used. The description of our approach is provided in Section 4, while the discussion of the obtained results is presented in Section 5. Last, the conclusion is displayed in Section 6.

II. RELATED WORK

Data mining refers to the set of algorithms and methods used to explore and analyze large computer databases in order to detect in these data: unknown rules, associations and trends (not fixed a priori) and particular structures, restoring in a concise way, the essential information useful for decision support. It uses advanced statistical methods such as data partitioning (gathering data in homogeneous packets), and regularly employs artificial intelligence mechanisms or neural networks. In other words, clustering allows to group objects with similar properties into several homogeneous classes so that the intersection of the formed classes in pairs gives an empty set and the union of all classes gives the initial data set. Note that the degree of overlap between classes and the multidimensional nature are the most important difficulties in solving a classification problem. Knowing that, data elements from different clusters have minimal similarity [17]. Clustering is classified as the main unsupervised learning problem; thus, the clustering process can be hard or fuzzy. The hard method assigns each object a single label, e.g., K-means is the most popular classification technique [18] for hard clustering; while in fuzzy classification, an object can simultaneously belong to several classes [19], e.g., FCM which is widely used for image segmentation by fuzzy classification [20]. Fuzzy methods can be easily converted into hard methods.

The use of FCM standard for image segmentation has limited performance because the result is strongly dependent

on the initial cluster centers. As a result, the algorithm quite often falls into locally optimal solutions and misses global solutions. Another disadvantage of FCM is its high sensitivity to image artifacts, such as noise and intensity inhomogeneity. In the literature, many bio-inspired techniques, such as Algorithm (GA), Whale Optimization Algorithm (WOA), Ant Colony Optimization (ACO), Differential Evolution and also PSO, were proposed in addition to FCM to reduce its weaknesses [21].

Recently, other metaheuristic approaches have been employed to address several optimization problems and can open new perspectives and improve image segmentation. Some of these approaches are:

In [22], the author described an algorithm for fireflies based on fuzzy classification. This algorithm has two phases. In the first phase, an optimal value is identified of the number of predetermined clusters, and then the result of the first step is input to the FCM algorithm to perform the cluster segmentation operation. The results obtained show promising results compared to the traditional FCM algorithm.

In [23], the author introduced a new method for liver segmentation using the whale optimization algorithm (WOA). The proposed technique starts by dividing the image into a predefined number of classes. The clustering process of this method converts the prepared image into a binary image and after multiplication by the WOA segmented image. This technique is tested using a database of MRI images. The results demonstrate the robustness of the technique suggested by the authors.

Based on a metaheuristic algorithm called Grey Wolf Optimizer, the authors in [24], proposed a new algorithm for satellite image segmentation. This algorithm has been modified to work as an automatic clustering algorithm. This technique has been evaluated on satellite images and shows an efficient accuracy with a shorter computation time.

In [25], the author used a clustering strategy for fish image segmentation using the Salp Swarm Algorithm (SSA). This method is used to cluster the image pixels to produce compact and quasi uniform super pixels. The results of the experiments conducted by the proposed model show the performance and efficiency for different cases compared to the work.

In this work, we introduce a new clustering-based approach to image segmentation. This technique is performed by hybridizing the FCM algorithm and the CSA algorithm which was proposed by the researchers in [16]. The CSA is a recent optimization algorithm based on artificial intelligence, which has shown its robustness and efficiency on a large number of optimization problems. Many researchers have proven the efficiency of Yang's CS algorithm in different applications, such as face recognition [26], neural network training [27] and engineering design [28]. The CSA has also been used in clustering problems and as examples we can cite [29]. Although the CS algorithm is simple and very efficient and also has few parameters, it sometimes falls into the local optimum during the search. Therefore, many researchers have been working to improve the performance of this algorithm, and thus they have proposed improved versions of the CS

algorithm [30, 31]. In our paper, a hybrid algorithm between CSA and FCM is introduced for image segmentation using clustering technique. On the proposed method, the initial step size is randomly calculated without being designed in advance. In addition, to reduce local extremes and improve the variety of cuckoos, the pa value changes non-linearly with iterations. To judge the efficiency and the performances of our proposal, we have tested it on several images of different types and compared it by several classical clustering algorithms or metaheuristics.

III. BACKGROUND

A. Fuzzy C-Means Algorithm

FCM is a clustering technique, developed by Bezdek in 1981. In image processing, FCM consists in finding the exact membership of a pixel to a cluster. Each pixel is initially assigned a value that corresponds to its degree of membership in each cluster. This degree varies between 0 and 1: this is the fuzzification. We apply the chosen fuzzy rule; this rule manages the defuzzification of the system by assigning each pixel to a single class, namely the one to which it has the highest degree of membership. The concept of this operation is as follows: Each of the N pixels belongs to each of the C classes with a membership coefficient U ; the set of membership degrees is stored in the FCM matrix U . This algorithm is often used in fuzzy image segmentation.

- Principle of the FCM algorithm

The FCM algorithm [32] is a fuzzy segmentation technique applicable to different types of images. To partition the image, we need to minimize the criterion of the sum of intra-class distances generalized to the fuzzy case and given by the following formula:

$$J_{FCM}(V, U, X) = \sum_{k=1}^K \sum_{i=1}^N U_{ki}^m d^2(x_i, v_k) \quad (1)$$

Under the following constraints:

$$0 < \sum_{i=1}^N U_{ki} < N \quad (2)$$

$$\sum_{i=1}^K U_{ki} = 1 \quad (3)$$

Where:

- $m \in]1, +\infty[$ is a parameter that characterizes the degree of fuzziness,
- K : represents the number of classes,
- N : represents the number of pixels to be classified,
- V is the feature vector of the center of gravity of the index class K .
- $d(x_i, v_k)$ characterizes the distance between a pixel x_i and the center of gravity of the class v_k

$d(x_i, v_k)$ is the Euclidean distance given by the following formula:

$$d(x_i, v_k) = \sqrt{\sum_{j=1}^D (x_{ij} - v_{kj})^2} \quad (4)$$

The basic idea of FCM classification is to assign to each vector x_i a degree of membership u_{ki} , to each class centered in v_k . The algorithm minimizes a certain error between classes by iteratively computing the degree of membership and the class centers using previously denoted relations. The update v_k and u_{ki} presented by the following expressions:

$$u_{ki} = \sum_{l=1}^K \left(\frac{\|x_i - v_k\|}{\|x_i - v_l\|} \right)^{\frac{-2}{m-1}} \quad (5)$$

The function to update the centers is:

$$v_k = \frac{\sum_{i=1}^N u_{ki}^m x_i}{\sum_{i=1}^N u_{ki}^m} \quad (6)$$

The FCM is based on the update of the membership function during the iteration of the algorithm. The FCM thus makes the partition examine by minimizing the fitness function J_{FCM}

The FCM algorithm is as follows:

Algorithm 1: FCM

Fix: $c, m, \text{iterMax}$ and stop criterion ε

Initialize randomly the cluster centers $v_k, k=1, \dots, c$.

For $t \leftarrow 1$ to iterMax **do**

 Update the membership function u_{ki} according Eq. (5)

 Compute the cluster centers v_k with the formula Eq. (4)

 Compute the objective function according Eq. (1)

if $|J^t - J^{t+1}| < \varepsilon$ **then**

break

end if

end for

- Cluster validity Indices

Verification of the results obtained by the clustering algorithm is an essential part of the clustering process. The most important method of cluster validation is based on internal cluster validity indicators. Clustering will be good if the clusters are maximally separated from each other and if the objects within the clusters are increasingly close (compact) to the center of gravity. Thus, this operation separates data objects into different clusters with the goal of maximizing intra-cluster similarity and minimizing inter-cluster similarity. To evaluate the quality of the partitions of clustering algorithms, we will use the validity indices which are numerous and very well known in the literature. In our paper, we will implement two indices [33] to examine the new objective function used in this paper, which are:

- The Subarea Coefficient (SC) measures the ratio of the sum of cluster compactness and cluster separation:

$$SC = \sum_{i=1}^c \frac{\sum_{k=1}^n (u_{ik})^m \|x_k - v_i\|^2}{n_i \sum_{j=1}^c \|v_j - v_i\|^2} \quad (7)$$

- The Partition Coefficient (PC) determines the amount of overlap between clusters:

$$PC = \frac{1}{n} \sum_{i=1}^c \sum_{k=1}^n (u_{ik})^2 \quad (8)$$

A clustering approach is considered better and efficient if the PC values are high while the SC values are low.

B. Cuckoo Search Algorithm

The metaheuristic methods are a new generation of powerful and general approximate methods that consist of a set of fundamental concepts. Among of which we find the Cuckoo Search algorithm which is a very recent meta-heuristic, inspired by the parasitism of cuckoo birds by laying their eggs in the nests of other birds, other species created by the authors Yang and Deb in 2009. This algorithm aims at breeding high quality solutions for optimization problems. In Cuckoo Search, an egg refers to a solution of the optimization problem at hand. A cuckoo egg refers to a solution just generated, and a nest means a set of possible solutions. It is based on the aggressive cuckoo breeding strategy complemented by a behavior called Levy flights [34]. The latter is a class of random walks in which the jumps are determined according to the Levy distribution which is based on a power law with infinite variance and a mean of the type [35].

$$Lévy(\beta) \sim y = X^\beta, (1 < \beta \leq 3) \quad (9)$$

The use of the Levy flight by CSA optimizes the search, this process is carried out as follows: the new solutions are generated by a random walk of Levy around the best solution obtained until now, which accelerates the global search.

The fitness function is a function that gives each solution in the search space a numerical value to show its quality. In our treatment, a better quality nest will give us access to new generations. Thus, the quality of a cuckoo egg is necessarily related to its ability to produce a new cuckoo.

Yang and Deb incorporated the Levy flight present in relation (10) to get a new solution $X(t+1)$ generated at each cuckoo i :

$$X_i(t+1) = X_i(t) + \alpha \oplus Lévy(\lambda) \quad (10)$$

Where $\alpha > 0$ is the displacement step size.

Generally, $\alpha = 1$.

The Levy flight represents a random walk whose random steps are defined from the Levy distribution given in the following equation:

$$Levy \sim u = t^{-\lambda} \quad (11)$$

In general, the CSA steps are summarized in Algorithm 2 presented as follows:

Algorithm 2: CSA

Input: Nest population $x_i=(x_{i1}, \dots, x_{iD})$ T for $i= 1, \dots, Np$

Output: Best Solution ($xbest$)

Begin

Generate initial population of host nests ()

eval=0

While (*stopping condition not met*) **do**

For $i=1: Np$ **do**

if ($f_j < f_i$) **then**

$x_i = x_j$;

$f_i = f_j$;

end

if ($\text{rand}(0,1) < pa$) **then**

 Init_nid ($xWorst$);

end

if ($f_i < f_{min}$) **then**

$xbest = x_i$;

$f_{min} = f_i$;

end

end for

end while

end begin

IV. THE PROPOSED METHOD

This paper proposes a new image segmentation technique using CSA and FCM algorithms. The CSA has strong overall optimization capability and a hybridization of FCM and CSA has improved performance over traditional FCM clustering. In the approach we propose, the CSA is used to find the optimal clustering of data taking into account a new objective function of having initial cluster centers. Then the centers found by CSA are used as input for the FCM algorithm. The process of the proposed technique treats the populations as host nests and then the sum of the population gives a better solution to each generation. In other words, the better cuckoo egg is considered to be the optimal solution and will be passed on to the next generation. In our paper, the image segmentation technique is performed on a clustering method that forcefully depends on the cluster center. However, the processing is initiated by generating the cluster centers randomly and after integrating the CSA to refine the location of the class center. Then, CSA updates the class centers to minimize the fitness function of FCM to find near-optimal centers.

A. Fitness Function

The new objective function proposed in this paper to evaluate the quality of clustering results is presented as follows:

$$fitness = \frac{intra_{cluster} + SC}{PC} \quad (12)$$

The parameters of this function are presented by:

- SC is the subarea coefficient determined by equation (7),
- PC is the partition coefficient presented in equation (8).
- The intra_cluster [36] is computed using the equation given below:

$$intra_{cluster} = \frac{1}{N} \sum_{i=1}^N \sum_{j=1}^c \|x_i - z_j\|^2 \quad (13)$$

The primary objective of our proposed method is to provide a cooperative technique to globally improve the performance of image segmentation results and overcome the limitations of FCM alone. For this purpose, we use the CSA algorithm to minimize the function shown in equation (12) to get the near-optimal initial cluster centers. Then, these centers are applied as initial inputs to the FCM. However, for the fitness function to be minimized, it must have the term value (intra_cluster + SC) low and the parameter value PC high.

The proposed approach can be summarized in the following points:

- The CSA finds the near-optimal centroids, after this stage, FCM algorithm operation starts with these cluster centers generated by CSA.
- The performance of the image segmentation results is evaluated by a fitness function given by equation (12).
- The role of CSA is to search for the optimized centroids
- The use of FCM on the input image by the optimal centers generated by CSA.
- The clustering is done by merging the results and gives the final segmented image.

The main steps of the hybrid algorithm of our method are presented in Fig. 1.

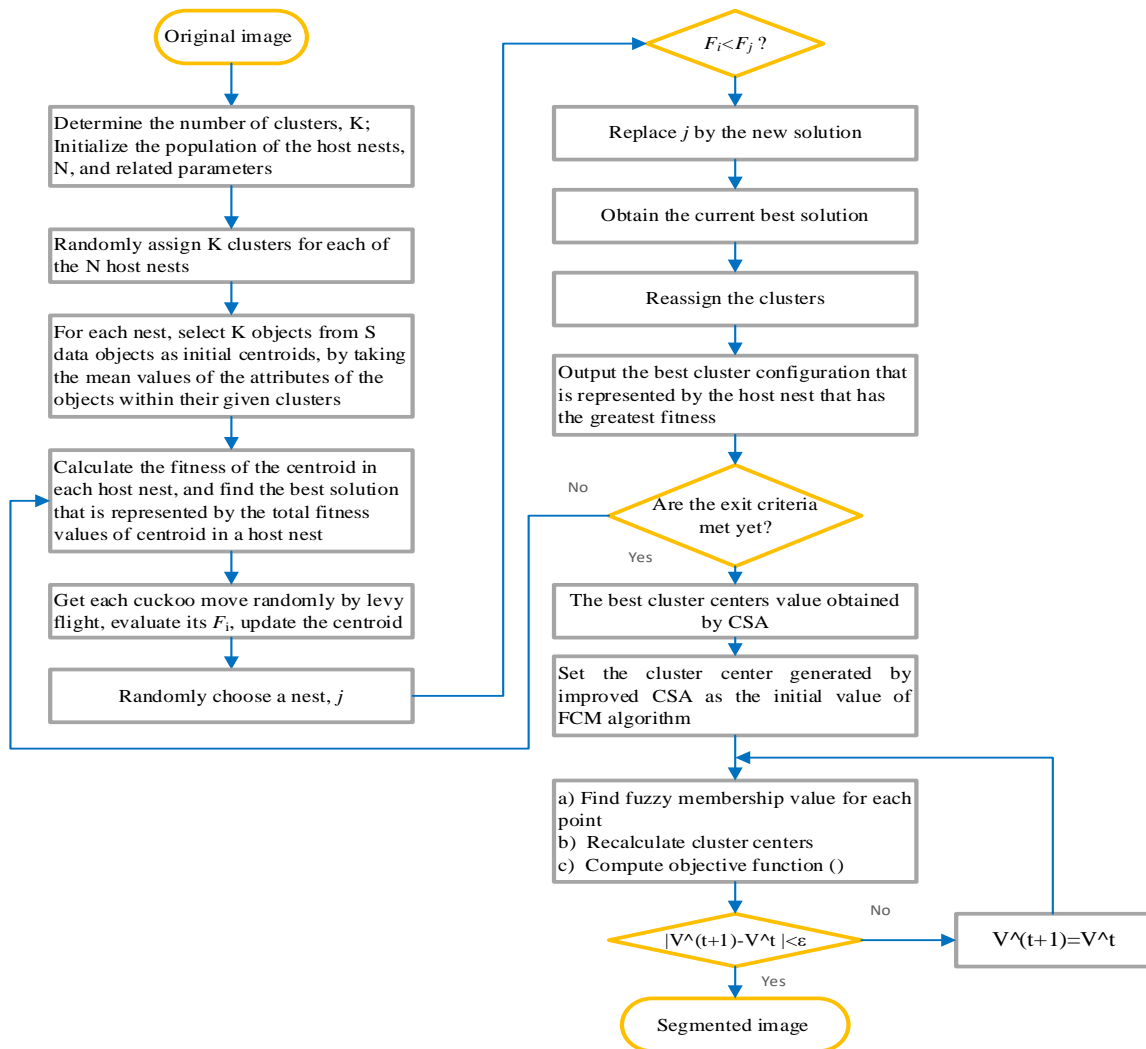

Fig. 1. The Clustering Flowchart of the Proposed Approach.

V. EXPERIMENTAL RESULTS AND DISCUSSIONS

For a better segmentation of images, it is necessary to minimize the fitness function. The minimum value of fitness corresponds to segmentation with a minimum distance between pixels belonging to the same region. So to evaluate the proposed approach and better experiment the performance and robustness in image processing, especially image segmentation, we have performed several tests on different reference images. Furthermore, we compared the proposed method with other existing clustering-based segmentation techniques that perform well, such as: FCM based on genetic algorithms [37], FCM based on particle swarm optimization [38] and the standard FCM algorithm. The algorithms used in the experiment are implemented in the MATLAB 2014b platform and run on a computer containing the following configuration: a 4th generation Intel Core (TM) i5 processor at 2.5 GHz, 4G of RAM and running Microsoft Windows 10 64 bits. The effectiveness of various image clustering approaches is analyzed and discussed by different evaluation indices to examine the quality of image segmentation. These are mean square error (MSE) [39], peak signal to noise ratio

(PNSR)[40], Rand Index (RI)[41], global coherence error (GCE)[42], boundary displacement error (BDE)[42], information of variation (VOI)[42], and correlation coefficient (CC)[43].

The FCM, FCM-PSO, FCM-GA, FCM-CSA algorithms are implemented in their original versions. Thus, the parameters have to be adjusted for each algorithm, in order to get the best matching values that can produce good image segmentation results with a short execution time.

First, we perform a series of experiments based on the modification of the number of clusters k , to search for good image segmentation results based on the evaluation parameters mentioned above. Then and in order to optimize the results obtained by CSA, we will apply the fraction $P_a = 0.25$ which allows us to have the optimal solution. In order to approach the best image segmentation, we followed practically to choose the value of each parameter. The experiments show that the choice of cluster number k is influential on the quality of the segmented image i.e. the choice of k is dependent on the image to be segmented; therefore, to present the performance of the proposed technique and the measures of the evaluation criteria

of the algorithms used in this article, we will focus on the choice of cluster number k which is equal to 4 on several images selected from the BSD300 database [44]. Table I shows the best values of the parameters that were optimized for the algorithms used in this paper (npop is the population size and MaxIt is the number of iterations).

TABLE I. THE VALUES OF THE PARAMETERS USED IN THE EXPERIMENT

Algorithm	Parameter	Value
GA	pc, pm	0.7, 0.3
	Mutation rate	0.02
	npop, MaxIt	50, 100
PSO	$C_1, C_2, V_{max}, V_{min}$	1.49, 1.49, 3, -3
	npop, MaxIt	50, 100
	Pa	0.25
CSA	npop, MaxIt	50, 100

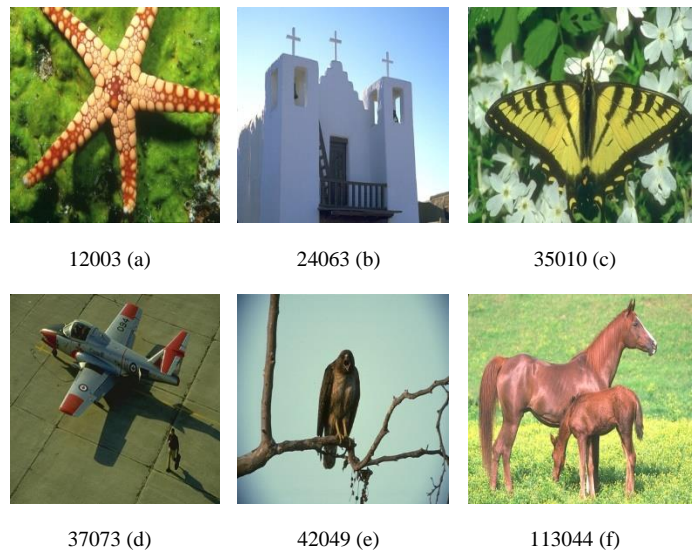

Fig. 2 shows reference images that are selected from the Berkeley 300 database (BSD300).

The image segmentation results of the different used algorithms are shown in Fig. 3.

Fig. 2. Examples of Original Images of the Berkeley 300 (BSD300) Segmentation Base.

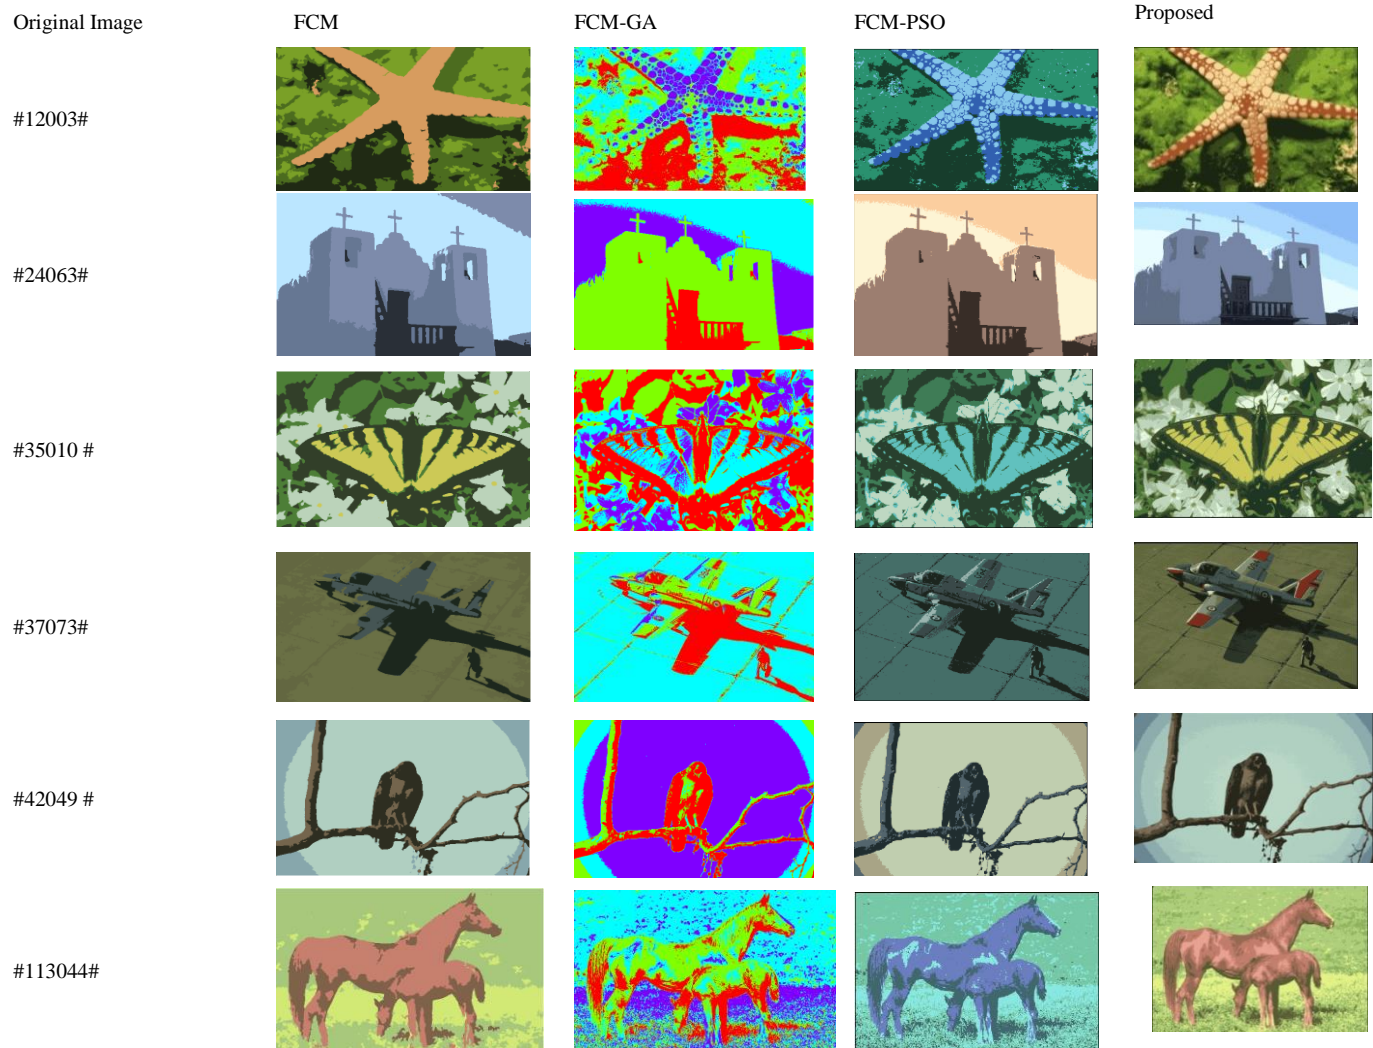

Fig. 3. Experimental Results of Clustering using different Algorithms.

The results obtained by the various techniques are analyzed and discussed on the basis of the excellent fitness values, MSE, PSNR, CC, RI, GCE, BDE and VOI measures.

A clustering technique is considered to be effective and good performance to evaluate the result of the segmented image if the PSNR metric value is large and the MSE value is small as well as the CC parameter value is high. The MSE, PSNR and CC parameter values of the segmented images are measured by the algorithms used in this paper. From the results shown in Fig. 4, 5 and 6, we can see that the MSE values obtained by the proposed approach are very small. On the other hand, the PSNR values obtained by our method are very high, while the correlation coefficient values are high, which clearly show that the proposed approach with the use of the objective function proposed in this paper, can generate correct segmentation results compared to other comparison algorithms.

According to the obtained results, we can conclude that the proposed hybrid algorithm shows good performance and gives better results, because the image segmented by the proposed approach generates well detailed segmentation results, the different regions of the image are visible.

Fig. 4. MSE Values Obtained by the Four Methods.

Fig. 5. PSNR Values Obtained by the Four Methods.

Fig. 6. Correlation Coefficient Values Obtained by the Four Methods.

In order to examine and present the effectiveness of the proposed technique, we compared the segmentation results obtained by different test images with all the algorithms used in this paper. We also evaluated the performance of the segmented image results using four well-recognized image segmentation evaluation indexes in the literature: PRI, VOI, GCE, and BDE which are mentioned earlier. Furthermore, the experiments show that the segmented image result is of good quality and closer to the ground truth, if the value of RI is larger, and the values of VOI, GCE and BDE are smaller.

According to the results displayed in Fig. 2, we can say that our approach gives better results compared to other methods, knowing that each of the segmented image results is related to its content and the number of classes we choose. For the comparison experiments, the value of the parameter K (number of clusters) was changed several times for the segmentation of different images. From the experiments performed on the different algorithms, we can see that the objects in each image can be identified or not depending on the image content and the choice of K. And according to these experiments, we chose the number of clusters equal to 4 for all the selected images in the Berkeley 300 database in order to properly present the performance of our approach and clearly visualize the quality of the segmented image, as well as the measures of the evaluation indices of the methods used.

In the BSD300 database, each image corresponds to several field truth segmentations, which leads to a segmentation result corresponding to several performance index groups. Therefore, the average value of several performance index groups is generally considered as the final performance index of the segmentation result.

Table II shows a comparison of the various evaluation criteria values using the clustering method on the different techniques used in this paper for each test image. From this table, we found that the performance varies depending on the image. But our method of cooperation between FCM and CSA achieves better results than the other algorithms. It is clear that the proposed approach generates well-detailed segmentation results; the different regions of the image are visible and gives satisfactory results as it obtains the best values of RI, VOI, BDE and GCE.

TABLE II. STATISTICAL PARAMETERS OF IMAGE SEGMENTATIONS. THE BEST VALUES ARE IN BOLD

	METRIC	FCM	FCM-GA	FCM-PSO	PROPOSED
(a)	RI	0.6992	0.7531	0.7910	0.8673
	VOI	3.3652	2.4731	2.5537	1.8596
	GCE	0.4320	0.3378	0.3051	0.2434
	BDE	14.4953	14.3853	13.2981	12.2113
(b)	RI	0.7419	0.7531	0.7542	0.7875
	VOI	2.9940	2.5493	2.4433	2.1532
	GCE	0.2315	0.2278	0.2015	0.2064
	BDE	13.7532	13.2016	12.1931	12.0124
(c)	RI	0.7431	0.7415	0.7476	0.7882
	VOI	2.8315	2.8003	2.5821	2.0020
	GCE	0.4153	0.4051	0.3451	0.2603
	BDE	14.3156	14.0251	12.7328	12.0031
(d)	RI	0.6851	0.7631	0.7542	0.7558
	VOI	3.0420	2.8749	2.2074	2.1306
	GCE	0.5003	0.4207	0.4008	0.3120
	BDE	12.7892	12.7112	12.1005	12.1106
(e)	RI	0.7427	0.7462	0.7752	0.7882
	VOI	2.2732	2.2653	2.2124	2.2007
	GCE	0.4167	0.4054	0.3921	0.2521
	BDE	13.9821	12.7629	12.2368	12.0701
(f)	RI	0.7591	0.7698	0.7834	0.7899
	VOI	2.6210	2.3521	2.2750	2.0193
	GCE	0.3281	0.2872	0.2645	2.5698
	BDE	13.9823	12.8902	12.3482	12.331

We also note that the values of RI, VOI, GCE and BDE obtained by our technique are better than those obtained by the other techniques. In detail, we notice that the values of VOI, GCE and BDE of our algorithm are smaller, and the RI value is larger than that obtained by the other methods.

Based on the results of the statistical calculations presented in the previous Fig. 3, 4 and 5 and the values of the parameters of the evaluation indices, indicated in Table II applying the different image segmentation techniques used in this paper, it can be seen that the quality of the segmentation image varies from one method to another depending on the optimization algorithm used to improve the classical FCM method. In summary, the cohesion within clusters is very high by our clustering technique compared to other clustering methods. The clustering technique used in this paper which is based on the FCM optimized by CSA gives good values in terms of cluster quality measures according to the experimental results. Therefore, the detailed analysis of these results on several reference and real images shows the robustness and high efficiency of our method in terms of accuracy and reliability.

VI. CONCLUSION

FCM is the most widely used clustering algorithm in classification problems, especially in image segmentation because it is efficient and simple. However, FCM has the limitation of being sensitive to prior values and often falls into local optima. To overcome this drawback we proposed a new

image segmentation method that relies on the optimization of segmentation by cuckoo search. CSA has a strong global optimization capability and hybridization of FCM with CSA will give an increased performance compared to traditional FCM clustering. Our method has been used on various images, and despite their complexity, the segmentation performed by FCM gives quite good results, and with the help of CSA, it makes a jump and gives us the optimal solution. The performance of the method has been evaluated based on the best values of the cluster evaluation indices and the values of the fitness function used in this paper. We also compared the proposed technique with other existing clustering-based segmentation algorithms such as FCM-GA and PSO-GA. The results indicate that a perfect initialization of the classes gives better results by the proposed algorithm. The experimental results showed the efficiency of our method on the different types of images used in our work and proved its robustness by making a visual analysis of the different results obtained.

Nevertheless, our approach requires the knowledge of the number of classes and it relies on the Euclidean distance to measure the similarity between an observation and the center of a class which makes it usable only to detect spherical classes. To overcome these drawbacks, I propose as a perspective of this work, to apply other hybrid methods based on recent metaheuristics for image segmentation in order to improve the quality of classification and reduce the execution time.

Abstract—The Support Vector Machine is one of the artificial intelligence techniques that can be applied to forecast the stability of cantilever retaining walls. The selection of the right Kernel function is very important so that the Support Vector Machine model can make good predictions. However, there are no general guidelines that can be used to select Kernel functionality. Therefore, the Kernel function which consists of Linear, Polynomial, Radial Basis Function and Sigmoid has been evaluated to determine the optimal Kernel function by using 10 cross-validation (V-fold cross-validation). The achievement of each function is evaluated based on the mean square error value and the squared correlation coefficient. The mean square error value is closer to zero and the squared correlation coefficient closer to the value of one indicates a more accurate Kernel function. Results show that the Support Vector Machine model with Radial Basis Function Kernel can successfully predict the stability of cantilever retaining walls with good accuracy and reliability in comparison to the various other Kernel functions.

Keywords—Cantilever retaining wall; kernel function; prediction; stability; support vector machine

I. INTRODUCTION

Cantilever retaining walls were introduced by the Burlington and Quincy Railroad in the 1880s. This retaining wall is constructed using reinforced concrete to withstand high tensile strength. It consists of two main parts namely, the walls, and the base made of reinforced concrete. Typically, the height of this wall ranges from 2.5 m to 6.0 m and is usually in the shape of either an inverted L or T. Its size is wider and flatter, and its construction cost is cheaper because the building materials are less compared to gravity walls [2]. The walls can be built on the construction site or pre-cast concrete that has been made in the factory can be used and only installed on the construction site which saves more time and energy. For heights exceeding 6 m, the use of prestressing techniques will be used. The wall part of this cantilever retaining wall is built protruding out of its large and solid site.

The cantilever retaining walls are very widely used in geotechnical engineering practice. Therefore, engineers play an important role in ensuring the construction of cantilever retaining wall is stable and safe. The stability of cantilever

retaining walls involved the checking of stability in terms of overturning, sliding, and bearing capacity. However, trainee engineers may find it difficult to get optimum stability results because of the lack of experience on the behavior of cantilever retaining walls. A prediction method using conventional mathematical models is utilized to estimate the stability of the cantilever retaining walls.

The development of studies on non-linear data analysis is growing with the revolution of the artificial intelligence (AI) methods. AI method is a great and versatile computing tool for solving complex problems, series, and its ability in identifying irregular arrangements and clusters of data. This method is popular for prediction and is able to predict the data that is non-linear, and not uniform. Among the AI methods introduced are artificial neural networks (ANN), adaptive neuro-fuzzy inference systems (ANFIS) and support vector machines (SVM).

The support vector machine (SVM) is the latest machine learning technique after neural network machine. Boser, Guyon and Vapnik introduced the SVM method in 1992 at the Annual Workshop on Computational Learning Theory. SVM is a new generation of statistical learning method which aims to recognize the data structures. It contains algorithmic learning using statistically based theories [4, 22, 15]. Learning is done by using input data and output data as the desired target this is known as supervised learning.

The SVM model has been extensively used in several fields of study for classification and prediction. Initially, SVM was developed to solve the classification problem, after which the use of SVM was extended for regression [27]. SVM regression is considered a nonparametric technique because it relies on kernel functions. According to Li et al. [6], SVM was developed as a regression device and is recognized as support vector regression (SVR). SVM is also worked to reduce overfitting and decreases the expectations of machine learning errors [26]. Smola and Scholkopf [23] stated that SVM is a method that can overcome overfitting and will result in good performance. In summary, it can be agreed that SVM is a technique that can make classifications and predictions with maximum accuracy by using the machine learning theory.

SVM method can solve regression and pattern recognition problems effectively and can also be used to make predictions and stability assessments [28]. According to Lu et al. [7], SVM has many advantages when utilized to solve small samples, nonlinear, and high-dimensional pattern recognition problems when compared to other algorithms.

II. LITERATURE REVIEW

In the last decade, the use of SVM to solve problems that cannot be solved using traditional methods in geotechnical engineering has been deeply investigated. The SVM model can improve the weaknesses found in traditional models such as ease of overfitting, single consideration factor, and inability to make predictions with long periods. Several previous studies have found that SVM is a potential method and has become the most desired in recent studies because of its ability to solve nonlinear and time series regression problems.

In the geotechnical field, reviews show that SVM is used effectively to predict soil shear strength, landslides, slope stability, deformation displacement, etc. Ly and Pham [8] proposed the use of the SVM model to predict soil shear strength using physical properties of soil as input parameters. The results of the study found that the SVM model showed good performance for soil shear strength prediction with an R value of 0.9 to 0.95. It was found that the three parameters that most influenced the prediction of soil shear strength were moisture content, liquid limit, and plastic limit. Shi et al. [21] used the SVM method to predict the deformation of the surrounding rock in the shallow-buried tunnels. The research indicates that the method of SVM produces good accuracy when utilized in making rock deformation predictions around shallow-buried tunnels. Besides, SVM is also an easy method to implement. Ramya and Vinodhkumar [18] used the SVM technique to predict the minimum factor of safety (FOS) based on upper and lower bound theorems for slope stability. The study confirmed that SVM has the capability to calculate the FOS with an adequate degree of exactness and suitable to use for the prediction of the stability of slopes. Rachel and Lakshmi [16] introduced the SVM prediction model to predict landslides by predicting rainfall data sets using big data concepts. The study summarizes that SVM is proven to be an effective technique for predicting landslides by first predicting rainfall. Samuil and Sitharam [20] compared the SVM and ANN on the liquefaction susceptibility of soil under earthquake. The research proves that SVM can produce good performance for the prediction of soil liquefaction susceptibility under earthquakes. Samui [19] investigated the effectiveness of the SVM method when compared with the ANN method to predict the frictional capacity of driven piles in clay. The results showed that SVM gave better performance than the ANN method. However, not many previous studies have been found on the use of the SVM method for predicting the stability of retaining walls. Mohamed et al. [10] used SVM to predict the external stability of segmental retaining walls reinforced with backfill with residual soil and geogrid. The results proved that the SVM based on the Radial Basis Function method and based on the specific data selection can predict the external stability factor of segmental retaining wall with a good accuracy. Cheng and Wu [3] studied the efficacy of the Evolutionary Support Vector Machine Inference Model

(ESIM) to forecast wall deformation in deep excavations. ESIM is a model that uses the SVM method and fast messy genetic algorithm (FMGA). The study found that the ESIM model successfully predicts wall deflection and deformation.

SVM provides two properties that are not found in other learning algorithms, namely the process of maximizing margins and the transformation of non-linear input space into feature space using the Kernel method [4]. Many experts have known that the capabilities of SVM are exactly correlated with Kernel function. The Kernel function transforms a data set into a hyper-plane [13]. Additionally, kernel variables need to be calculated accurately because it determined the structure of high dimensional features when the final solution was performed. Commonly, the types of Kernel functions found in the SVM model are Linear, Polynomial, Gaussian or Radial Basis Function (RBF), Laplace, Sigmoid, Exponential, etc. [9]. The Linear Kernel used when data is linearly separable. The Polynomial Kernel is well suited for problems where all the training data is normalized. The RBF and Laplace Kernel used when there is no prior knowledge about the data. The Sigmoid kernel used as the proxy for neural networks [24].

An accurate prediction model can be obtained by using the optimal Kernel functions. However, there are no general guidelines that can be used to select Kernel functionality. Based on the previous studies, it was found that most of the research conducted until recently has focused on the advantages of the SVM models. Very few studies were conducted to obtain the right Kernel function. Nanda et. al [12] conducted termite detection studies using different Kernel functions in support vector machines and found that Polynomial Kernel has produced the best accuracy. Hong et. al [5] compared the effectiveness of four Kernel functions in a support vector machine in a landslide mapping study. Findings emanated from the research indicated that the SVM-RBF model is the most suitable for landslide susceptibility assessment.

Therefore, this study intends to compare the Kernel function model between Linear, Polynomial, Radial Basis Function (RBF), and Sigmoid in their ability to predict the cantilever retaining walls stability and suggest the optimal Kernel function among them. Only four types of Kernel functions were selected since it was most frequently used compared to other Kernel functions and produced satisfactory results.

III. METHODOLOGY

The Statistica software was used to develop SVM models using data mining methods. According to Thuraisingham [25], Radhakrishnan et al. [17] and Mohammed and Wagner [11], data mining is a process of answering all questions and identifying information, forms and trends found in large quantities of data. Furthermore, in the use of data mining, there are various techniques that can be used to help make decisions. In this study, machine learning techniques have been used for SVM model making predictions. SVM model prediction is performed using input and output data. The data used for this study were 280 different designs of cantilevers retaining wall designs. The input parameters used for prediction contains walls of various heights, slope angles, and surcharges. On the

other hand, the output parameters involve the external stability of the retaining wall i.e., the safety factor (FOS) for sliding, overturning, and bearing capacity. The output parameters are applied as a target for the model prediction.

A. Kernel Function Selection

The selection of the right Kernel function is very essential so that the SVM model can make a good performance. Basically, SVM is employed as a quadratic optimization to solve the case of linear classification. Applying Kernel functions which are presented into the combined type of the optimization model can easily expand linear to nonlinear SVM via of functional mapping [14]. SVM uses a technique called the Kernel trick to provide a bridge from linear to nonlinear. The equation of Kernel trick is shown in equation (1).

$$K(x, y) = \langle f(x), f(y) \rangle \quad (1)$$

Where K is the Kernel function, x and y are n-dimensional inputs, and f is a map from n-dimension to m-dimension space.

In this study, Kernel function consisting of Linear, Polynomial, Radial Basis Function (RBF) and Sigmoid function was evaluated to determine the best Kernel function by using 10 cross-validations (V-fold cross-validation). Based on the mean square error value (MSE) and the squared correlation coefficient (R^2), the achievement of each function is determined. The MSE measures the differences in values between the target data and the predicted data in the existing predicted models. The MSE value is closer to zero and the R^2 value is closer to the value of one indicates a more accurate Kernel function. The equations of MSE and R^2 for the performance evaluation of the prediction model are shown in equation (2) and equation (3) as follows:

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_i - \tilde{y}_i)^2 \quad (2)$$

Where n is the total of data points, y_i is the target data, and \tilde{y}_i is the predicted data.

$$R^2 = \frac{(\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}))^2}{\sum_{i=1}^n (x_i - \bar{x})^2 \sum_{i=1}^n (y_i - \bar{y})^2} \quad (3)$$

Where n is the total of predicted data, x_i is the target data, y_i is the predicted data, \bar{x} is the average of target data series, and \bar{y} is the average of predicted data series.

B. Optimum Parameters Selection

The Epsilon-RBF model was used to obtain the optimum model parameters such as gamma, capacity, epsilon, and Nu parameters. The optimal use of parameters in the Kernel function will produce an accurate prediction model [1]. The most common method used to obtain optimal model parameters is through the 10-cross-validation method (V-fold cross-validation). The cross-validation method is used in SVM to check the overfitting of data and it gives more correct predicted results.

C. Model prediction

All machine learning algorithms must be tested and validated to select those with the highest performance and prediction accuracy. After obtaining the optimal model parameters, the data set was randomly divided by 70% for the

training and 30% for the testing. To speed up training time, a selection of training data was used. Only training data close to the boundary was used. Data far from the boundary were eliminated to shorten training time.

SVM algorithm attempt to predict a target data or known as a dependent variable using features, which is the dependent variable. Prediction is implemented by mapping an independent variable to a dependent variable known as a process mapping function. The process of a mapping function for an SVM is a boundary that distinguishes two or more classes.

After getting all the prediction output, root mean squared error (RMSE) and regression square was computed for every model and compared. The root mean squared error (RMSE) can be obtained from equation (4).

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \tilde{y}_i)^2} \quad (4)$$

Where n is the total of data points, y_i is the target data, and \tilde{y}_i is the predicted data.

IV. RESULT AND DISCUSSION

Kernel functions consisting of Linear, Polynomial, Radial Basis Function (RBF) and Sigmoid function were evaluated in the SVM model analysis. The results show that the Kernel function plays an important role in producing a good SVM model. The Kernel functions have the advantage of converting nonlinear input space to linear feature space. Table I and Table II show a comparison of the prediction performance of the SVM model based on MSE and R^2 values for the external stability safety factors using four different Kernel functions. The RBF kernel was found to produce the best prediction accuracy for the external stability factor of cantilever retaining wall, with the MSE value being closest to zero and the R^2 value being closest to one. This finding seems to be agreed with the study conducted by Hong et. al [5], where the RBF Kernel showed better performance than other Kernel functions. Followed next by the Linear, Polynomial, and finally the Sigmoid function which produces the least accurate prediction. Therefore, the Radial Basis Function (RBF) was chosen to be applied to the SVM model for all the external stability safety factors of the cantilever retaining wall.

TABLE I. THE PERFORMANCE OF THE SVM MODEL BASED ON MSE VALUES USING FOUR KERNEL FUNCTIONS

External Stability	Linear	Polinomial	RBF	Sigmoid
FOS for sliding	2.071	7.156	0.396	684.920
FOS for overturning	12.844	37.771	2.187	1930.534
FOS for bearing capacity	0.089	0.153	0.050	6.832

TABLE II. THE PERFORMANCE OF THE SVM MODEL BASED ON R^2 VALUES USING FOUR KERNEL FUNCTIONS

External Stability	Linear	Polinomial	RBF	Sigmoid
FOS for sliding	0.955	0.840	0.992	0.264
FOS for overturning	0.914	0.747	0.987	0.264
FOS for bearing capacity	0.708	0.478	0.716	0.479

A. SVM Model Prediction

Prediction of the cantilever retaining wall stability using the SVM model was performed by implementing the RBF Kernel and the optimal gamma, capacity, epsilon, and Nu parameters. The prediction accuracy of SVM model was compared based on the RMSE and R^2 values. Table III shows a comparison of RMSE and R^2 values for the external stability safety factors. It can be clearly observed that the prediction of the cantilever retaining wall stability using the SVM model with RBF Kernel function for safety factor of overturning is more accurate because it produces an RMSE value that is closer to zero and an R^2 value that is closer to one.

TABLE III. THE PERFORMANCE OF THE SVM MODEL USING RBF KERNEL FUNCTION BASED ON RMSE AND R^2

External Stability	RMSE	R^2
FOS for sliding	0.172	0.9985

FOS for overturning	0.044	0.9992
FOS for bearing capacity	0.236	0.9766

The prediction results in terms of the comparison of target with predicted output for the safety factor of sliding, overturning, and bearing capacity are shown in Fig. 1. It seemed that the target together with predicted output values were mostly overlapping for safety factors of sliding and overturning because of a very good prediction result of R^2 which is 0.99985 and 0.9992, respectively. The most significant difference of target and output values can be seen at the FOS for bearing capacity.

Fig. 2 presented the R^2 plot for a safety factor of sliding, overturning, and bearing capacity. The results proved that the SVM based on the RBF Kernel function can predict the cantilever retaining wall external stability with a good accuracy and reliability because the R^2 value greater than 0.97. The graph shows the dots were scattered close to the 45° line.

Fig. 1. Comparison of Target with Predicted Output for a Safety Factor of (a) Sliding, (b) Overturning, and (c) Bearing Capacity.

Fig. 2. Regression Square (R^2) Plot for a Safety Factor of (a) Sliding, (b) Overturning, and (c) Bearing Capacity.

V. CONCLUSION

SVM model prediction based on four Kernel functions, namely Linear, Polynomial, Radial Basis Function (RBF) and

Sigmoid were applied successfully to predict 280 data sets of external stability factors for cantilever retaining walls. The perfect prediction result was for RBF Kernel if compared with the other Kernel function because of the good R^2 for the output value. SVM model prediction based on RBF Kernel was able to predict the cantilever retaining wall stability with good accuracy and nearly to the target data. The prediction of the external stability of the cantilever retaining wall using the SVM model has successfully produced an accurate prediction by performing nonlinear regression for high-dimensional data sets.

As a conclusion, the results of the study can contribute to researchers for the current literature, especially in the field of retaining walls stability with the SVM approach. The optimal solution found in this study is that the right Kernel function has been obtained for the SVM model by producing the best prediction accuracy for the external stability of the cantilever retaining wall. The SVM is a technique that can solve complex problems with the application of appropriate Kernel functions. This study can help to forecast the stability of cantilever retaining walls used in civil engineering problems quickly and accurately. Prediction model developed provides advantages to geotechnical engineers in producing a more stable, and safe cantilever retaining wall.

Abstract—An outlier is a data observation that is considerably irregular from the rest of the dataset. The outlier present in the dataset may cause the integrity of the dataset. Implementing machine learning techniques in various real-world applications and applying those techniques to the healthcare-related dataset will completely change the particular field's present scenario. These applications can highlight the physiological data having anomalous behavior, which can ultimately lead to a fast and necessary response and help to gather more critical knowledge about the particular area. However, a broad amount of study is available about the performance of anomaly detection techniques applied to popular public datasets. But then again, have a minimal amount of analytical work on various supervised and unsupervised methods considering any physiological datasets. The breast cancer dataset is both a universal and numeric dataset. This paper utilized and analyzed four machine learning techniques and their capacity to distinguish anomalies in the breast cancer dataset.

Keywords—Anomaly; machine learning; outlier detection; minimum covariance determinant

I. INTRODUCTION

Anomalies can detect a fault in a system or a network, abnormalities in healthcare data, or fraud [1]. The fast growth in the amount, dimension, and complexity of data in the dataset has made it compulsory to automate the outlier detection in analytical processes. Those analytical results can then be used in decision-making processes by various algorithms to identify the health condition [2]. Description of these anomalous values can provide a better and new understanding of the dataset. Using different examples can visualize the whole phenomenon in a better way for the researchers. Particularly in healthcare, this could be used to develop good knowledge about the patient's health condition and complications, whereas in the case of predicted value, it does not focus only on the data description but also the future assumption about numerous states of a patient's health condition. That could help healthcare employees to treat the patient in an improved way by detecting the disease correctly. These outliers must not be considered an error or noise. Still, these are also important with respect to train the existing detection models and prepare to predict the new data added to the dataset.

Undoubtedly, the anomaly detection procedure depends on an effective definition of data point that must be considered an anomaly [3]. Anomaly detection approaches usually undertake two things, namely, (1) anomalies are rare and minor in

amount, and (2) anomalies are dissimilar in some sense or another from other normal data. The presence of multiple kinds of outliers or anomalies further results in complicating the operational definition. According to the occurrence, data points can be subdivided into anomalous concerning neighboring data points (local anomalies) or the entire dataset (global anomalies). It is challenging to differentiate between classes from which the anomaly belongs. The dissimilarity is still convenient for reminding the data scientists that anomalies can differ from both the data point and each other. A vast variety of technology is present in the healthcare system. However, the application of both machine learning and physiological data-set still needs some attention and in its early stages. Adding to the already problematic and challenging work of health care specialists is the scarcity of employees in the public healthcare field. To enhance the massive burden of healthcare specialists, it requires analyzing the minor units of physiological data collected, and it also helps improve patient care facility. Faulty events in the healthcare sector and minor medical errors may increase the chances of accidental deaths. Anomaly detection is a vital task, especially in the healthcare sector, where errors are rare. This paper has tried to better understand a patient's safety by predicting anomalous behaviors in breast cancer data through different anomaly detection techniques and errors in predicting the disease. Whether anomaly detection techniques are instigated to identify that patient is sick, look after the health conditions through sensors that can be wearable, or support another patient care-related work, these processes are vital components of the automated patient care system.

Nevertheless, what is considered by the system as an anomaly is often challenging to define? In most cases, choosing the proper machine learning techniques to implement depends on both investigation and the variability of the outliers present in the dataset. For example, there exist numerous works where the neural network has been used in healthcare-related problems. At the same time, some researchers have utilized clustering approaches and the multi-layer perceptron [4], [5]. Undoubtedly, choosing the algorithm depends partly on both the type of dataset and the dataset's size. Classifying an ideal machine learning model [6] for a particular problem relies on either or not the ground truth labels for data exist. In labeled data, supervised methods are suitable, while unsupervised methods allow analyzing the unlabelled data.

Nevertheless, it must be momentarily stated that semi-supervised anomaly detection approaches provide yet another vital option comprised of datasets labeled and comparably large amounts of unlabelled datasets. While countless models can be effectively adjusted to process the anomaly detection problems, the present study focuses on the subsequent four approaches: Local Outlier Factor (LOF), Isolation Forests (IF), Minimum Covariance Determinant (MCD), and One-Class SVM. The reason to choose these approaches are (1) their extensive occurrence in the area of machine learning and anomaly detection works fundamentally, and (2) because they comprise both supervised and unsupervised techniques. In the following subdivided sections, the techniques are briefly described.

II. RELATED WORKS

A. Local Outlier Factor (LOF)

The LOF technique was first presented by Breunig et al. as per the name recommends [18]. The technique primarily evaluates the separation between each of the data points concerning its neighborhood. This technique partially depends on the k-nearest neighborhood of the data point. Though other approaches classify outliers in a binary manner, LOF can also generate the degree of outliers of a data point. This local outlier density calculation is summarized with k-nearest neighbors. Data points in comparatively lower density zones are classified as outliers or assign a higher degree of outliers.

B. Isolation Forest (IF)

Isolation forest is an unsupervised type of machine learning technique for outlier detection implemented based on isolating anomalies instead of the most popular techniques of profiling normal points [19]. In this type of detection technique, the outlier is isolated by randomly partitioning them by selecting a random feature at a time. As a result, the outliers are more manageable to isolate than normal data. However, the node with the regular data needs time to isolate and requires many partitions.

C. Minimum Covariance Determinant

The input variables in the Gaussian distribution can deal with normal statistical methods to identify the outliers or anomalies. For example, suppose a dataset has two input variables. Minimum Covariance Determinant (MCD) is a detection technique that deals with those datasets to form the multi-dimensional Gaussian distribution [20]. Information of this distribution can be cast off to detect entries far from the distribution. Thus, the Minimum Covariance Determinant (MCD) technique is a vastly robust detector of multivariate location and scatter.

D. One-Class SVM (OC-SVM)

One-class SVM is a kind of unsupervised learning technique formally based on the classical Support Vector Machine (SVM) [21]. It is an algorithm where the training is only done with regular data or the dataset's negative data. Generally, this algorithm classifies the boundary with these training data subsets and can classify data point that does not belong to that boundary.

Fig. 1 and 2 shows the example features of various anomaly detection techniques on a 2D dataset. For every dataset, 15% of samples are produced as uniform random noise. This ratio is the value assigned to the nu parameter of One-Class SVM and the contamination boundary for other anomaly detection techniques. Considering a manually generated dataset, it tries to visualize the different outlier detection models for better understanding.

Outliers are generally the data points that do not comply with (other data points) general behaviors of the dataset. If the outliers are graphically represented, they fall typically somewhat apart from the regions consisting of normal data points. Outliers typically show variability in the dataset, errors present in measurement, or a novelty.

Fig. 1. Scatter Plot Showing the Graphical Representation of Outliers using Isolation Forest and LOF.

Fig. 2. Scatter Plot Showing the Graphical Representation of Outliers using MCD and One-Class SVM.

Random forest was a detection technique implemented by Leo Breiman [7]. It is an unsupervised learning technique and uses a Gini index classification of the anomalous data point. Many of the trees are generated randomly in this approach, selecting features, and then the most popular one is voted out. Outlier detection was implemented with machine learning techniques by Hadi et al. [8]. It is a supervised technique based on the regression analysis model trained by the training subset and predicts the outliers' test subset. Accordingly, Ramaswamy et al. come with a partition-based supervised technique capable of handling the numeric dataset [9]. It is a proximity-based algorithm. Pawlak et al. use the roughest methodology to derive the outlier from the numeric dataset [10]. It is a supervised detection algorithm based on the model of soft computing. Peterovskiy et al. proposed a fuzzy approach based on kernel function, a supervised learning technique that requires no separate training data [11]. It is capable of handling the numeric type of dataset. The class represents the degree of membership is used to classify the outliers from the normal data point. A trendy outlier detection technique known as Local Outlier Factor (LOF) was introduced by Kriegel et al. [12]. It is a density-based detection technique. It is a supervised learning technique that can process datasets with both numeric and categorical data.

Benjamin Nachman et al. introduced an approach to find outliers using density estimation [13]. A density-based outlier

detection technique uses conditional probability density to classify outliers in the dataset containing categorical and numerical data.

Bo Tang et al. introduced an outlier detection algorithm based on the Local Density of data [14]. It is a density-based detection technique that calculates outlier in a dataset containing both numerical and categorical data. Duan et al. proposed (LDBSCAN) a clustering-based model and used Euclidian distance as a proximity measure [15]. It is capable of the handle only numeric datasets. Kriegel has discussed many subspace-based detection algorithms that consider the subspace of the feature set [16]. All these works are generally based on a subset of the different existed detection techniques. Rank Based Detection Algorithm (RBDA) (2011) was introduced by H. Huang et al. [17]. It is a rank-based model that uses the density of the data points to identify the outliers. Our paper will provide an analysis of four popular detection techniques with different analytical measures.

III. MATERIALS AND MODEL IMPLEMENTED

A. Approaches Involved

Outlier detection is significant and essential in data mining, which can be used to preprocess the dataset, increasing the final result's accuracy. If the database is vast, then it always consists of some abnormal dataset. These data points are known as outliers which are irrelevant from the regular data points. Therefore, these data points must be removed from standard data in data mining. Hence, outlier detection, also known as anomaly detection, is required to classify the outliers to improve the data quality.

1) *Local Outlier Factor (LOF)*: LOF is a type of score that tells either a data point is an outlier or not [18]. Initially, let us start with the basic introduction of a parameter k , determined by calculating the distance between a point, say, p , and its k th nearest neighbors. This detection algorithm works by considering the neighborhood density of a specific data point to its k nearest neighbor. This density of the data points is then considered to determine the relative densities. Now choosing the correct value of k is a bit tricky, for selecting a too-small value of k it will focus more on local data, i.e., concentrated more on neighborhood points giving erroneous result in terms of noisy data, and for a large value of k it will completely miss out the local outliers. Breunig et al. introduced a LOF detection algorithm to understand the algorithm more precisely, which consists of three important terms discussed below:

a) *k-Distance*: The term k -distance can be defined as a distance is between the data point from its k th neighborhood data point. Let us assume k has a value of 4; k -distance will be the distance from a point to its 4th nearest neighbor data point.

Reachability Distance: To determine the reachability distance, the k -distance has been used. The reachability distance is a measure to calculate the maximum distance between two data points and the k -distance value of the second point. Mathematically,

$$reach_dist = \max\{-distance(p, q), distance(p, q)\} \quad (1)$$

Suppose p is a k -nearest neighbor of point q , then $reach_distance(p, q)$ can be defined as k -distance of q or the distance between these two points.

b) Local Reachability Distance (lrd): This value of reachability distance calculates another key concept called local reachability distance (lrd). To determine the value of lrd first step, calculate all the $reach_distance$ of k -nearest neighborhood points and find the mean of these values; use the inverse of this mean will be the lrd. Here, for densities, the higher the distance between the points lesser will be the density. Local reachability distance can be represented as:

$$lrd(p) = 1 / \left(\frac{mean(reach_distance(p,n))}{k} \right) \quad (2)$$

Parameter $lrd(p)$ represents the distance from a point to its nearest neighbors. Each point's lrd and the neighbor's lrd are then related. Through this, the ratio for each point is determined, and calculates the average. The LOF is determined by calculating the average ratio of lrd of a particular point by its neighbor's lrd. Lastly, the density of that data point is correlated with the density of its nearest neighbors. Less density of a data point than its neighbors indicates that point as an outlier.

2) Isolation forest: A feature is chosen randomly at once in an isolation forest from a subset of the dataset. It then isolates each data point until they are entirely isolated from one another [19]. This algorithm is based on the idea that anomalous data points are easier to isolate than normal data points. The detection algorithm enables building all the possible collections of isolation trees (Itree). Those Itrees are made considering all random subsets of data points and assigning each Itree with an outlier score that sums up an outlier score for each dataset's data points. The most important part of this algorithm is building the Itree. The process that comprises choosing a random subset of the whole dataset and then selecting one random feature at a time separates each point until they are entirely isolated. It is required to conduct a binary search operation to predict a new data point's anomalous behavior for that point. That operation must follow top to bottom order. Then assign the anomaly score to that data by calculating the total path length to reach the data point. Then determine the collective outlier score of the data point from the outlier score of individual Itree. The required mathematical equation to compute the outlier score is given by:

$$S(p, m) = 2 \frac{-E(h(p))}{c(m)} \quad (3)$$

Where $S(p, m)$ is the outlier score of the data point p and m is the sample size, $h(p)$ gives the average depth to reach the point p from the Itree. $c(m)$ is the average value of $h(p)$. Now, if outlier score, i.e., when $E(h(p)) \ll c(m)$ indicates the point to be an anomalous point and if outlier score, when indicates a regular point. The points with a value close to 1 are outliers, and values close to 0.5 are normal.

The whole detection process can be sub-divided into two stages- the training stage and the evaluation stage. In the training

stage, the building of Itree is done by recursively separating every data point up to a precise height is reached, which is approximately the average depth of Itree. Then, each test data point's outlier score is set from the expected path distance $E(h(p))$ in the evaluating stage. Finally, the value of $E(h(p))$ is determined by passing the test data point through Itree, a part of an isolation forest.

3) Minimum Covariance Determinant (MCD): Robust estimation of the multivariate mean ($\hat{\mu}$) and covariance ($\hat{\Sigma}$) in MCD, searching data subset from the h data points is concluded in MCD [20]. The robust estimate must comply with a minimum determinate value the covariance matrix. where h data point must lie between $\frac{k+p+1}{2}$ to k . The MCD is based on Mahalanobis Distance (MD) [21] and given by:

$$m^2 = (x - \hat{\mu})^T \hat{\Sigma}^{-1} (x - \hat{\mu}) \quad (4)$$

When the determinate covariance is equal to zero, then the inverse of the covariance ($\hat{\Sigma}$) will not exist, and also, the value of m will be undefined in the case of ($h < p$). So, it must be necessary to have more observation than the number of variables to determine the value of m for the dataset. It is complex and costly to implement exact MCD instead; fast-MCD is very popular in practice. Fast-MCD starts with randomly choosing a subset from observation equal to $p+1$ from dataset x [22]. The subset x_n of real dataset x , simultaneously calculating their Mahalanobis Distance m_n for k number of observations with subsequent mean and variance $\hat{\mu}$ and $\hat{\Sigma}$, respectively. Then the number of h observations are separated from a whole new subset of the dataset x , having the lowest value of MD m_0 . The value of h is determined by-

$$h = \left\lfloor 2 \left[\frac{k+p+1}{2} \right] - k + 2\alpha \left(n - \left\lfloor \frac{k+p+1}{2} \right\rfloor \right) \right\rfloor \quad (5)$$

The value of the parameter α always lies between 0.5 and 1, representing the desirable robustness. Equating a lower value of α may cause in increasing the robustness but also cost inefficiency and resulting in a potentially large outlier set. Then all x_i and m_i is computed for all k number of observations each time choosing a new subset of h , unless the subset at the present iteration is the same as the previous iteration, the process will repeat. At that point, the local minimum value of determinate of covariance is attained. This algorithm repeats itself up to a maximum number of the subset of x . x_{Mcd} is then defined by a subset of h observation with the lowest value of covariance determinate. The robust estimation is calculated by:

$$\hat{\mu}_{Mcd} = \frac{1}{h} \sum_{i=1}^h x_{Mcd_i} \quad (6)$$

$$\hat{\Sigma}_{Mcd} = c_0 \frac{1}{h} \sum_{i=1}^h (x_{Mcd_i} - \hat{\mu}_{Mcd}) (x_{Mcd_i} - \hat{\mu}_{Mcd})^T \quad (7)$$

To handle correctly comparatively small sample of a scalar consistency factor (c_0) is introduced in the equation of estimation, following the estimate of m_{Mcd} . Then the threshold value of m_{Mcd} is calculated, which indicates the data point as an outlier when it falls beyond that threshold. A popular approach is followed to do so introduced by Dovoedo and Chakraborty [23]. In this approach, the first step is to transform the value of each x_{Mcd} to Robust Mahalanobis

Distance (r_{Mcd}) [20] outliers, to limit the distance distribution in the range of zero to one.

$$r_{Mcd} = 1 - \frac{1}{1+m_{Mcd}} \quad (8)$$

Then on the second step, some regular multivariate sample of k observation is simulated with $\hat{\mu}_{Mcd}$ and $\hat{\Sigma}_{Mcd}$. Finally, the outliers of those simulated k observations are determined and $\hat{\epsilon}_{Mcd}$ percentile is being used from these simulations to limit the outliers. The user-defined value $\hat{\epsilon}_{Mcd}$ lies between zero to one. More reliably, the detect outlier is needed to implement a robust estimation to resist a possible outlier set. The robust MCD estimator is more helpful to deal with the multivariate dataset. The distance called robust distance [20] is used to flag anomalies. The robust distance is given by-

$$RD^2 = (x - \hat{\mu}_{Mcd})^T \hat{\Sigma}_{Mcd}^{-1} (x - \hat{\mu}_{Mcd}) \quad (9)$$

It is more reliable to define a precise hypersphere capable of covering all regular data points, and the points out of this distance from the origin are termed outliers.

4) *One-Class Support Vector Machine (OCS)*: A One-Class SVM is a type of unsupervised machine learning technique [24]. The One-Class SVM is only trained with regular points or negative examples. It automatically develops learning boundaries of those negative points and can successfully estimate the classification of any data that belongs outside that defined boundaries and identify them as outliers. The training stage of any unsupervised machine learning technique is challenging, and so with the One-Class SVM. Crucial parameter ν in this detection technique controls the amount of outlier or contamination one user expects to identifies as outliers. The gamma is another parameter used to calculate the smoothing of boundary lines.

In One-Class, SVM defines an optimized boundary used to differentiate regular data from the anomalous data points in higher dimensionality by maximizing the difference between regular and anomalous points. For example, in One-Class SVM, a hyperplane [25] is defined as a separate anomalous and regular data point from the origin.

The objective function to generate a hyperplane for One-Class SVM is given by-

$$\min_{w, \xi, \rho} \frac{1}{2} \|w\|^2 + \frac{1}{\nu n} \sum_{i=1}^n (\xi_i - \rho) \quad (10)$$

$$\text{Subject to: } (w \cdot \phi(x_i)) \geq \rho - \xi_i, \xi \geq 0 \quad (11)$$

Where w is weight vector, ξ is represented slack variables, ρ is the distance between origin and hyperplane, $\phi(x_i) \rightarrow F$ is feature space mapping for input dataset x . The regularization parameter is represented by ρ , which controls the boundary around regular data and leaves a fraction of data classified as anomalous. The main objective is to attain a hyperplane with less distance from the origin, which calculates the optimized value of w & r so that some miss-classification allows for few data points. Moreover, the hyperplane-based One-Class SVM has a low-performance ability. So, to overcome this, another approach is developed where a hypersphere is constructed aiming to separate regular and anomalous point by a sphere of

radius R , center C , and feature space F [26]. the objective function is given by-

$$\min_{R, \xi, C} R^2 + \frac{1}{\nu n} \sum_{i=1}^n \xi_i \quad (12)$$

$$\text{Subject to: } \|\phi(x_i) - C\|^2 \leq R^2 + \xi_i \quad (13)$$

Here the main issue is to reduce the value of R of hypersphere and to compute this. It has to determine the value R & C so that most data points have a comparative Euclidean distance to radius R so that some miss-classifications are allowed.

B. Model Implemented

To analyze the different outlier detection techniques, make a baseline algorithm performance and compare it with other algorithm's performance. We developed the baseline performance by fitting a linear regression for the given dataset. The evaluation of method performance is then carried out by training a particular algorithm on the training data subset. The Mean Absolute Error, Root Mean Square Error, and model score [26] are determined based on the algorithm's prediction on the test dataset. Then we fit the dataset with each of the detection algorithms after defining them. The previously fitted algorithm predicts the anomalous and non-anomalous data points. The anomalous data points are dropped from the training part of the dataset. Then the remaining data points are fitted on the detection algorithm, and finally, the prediction on the test part of the dataset is analyzed.

This is the analytical model use to analyze breast cancer data. Four different outlier detection techniques are used to detect outliers. The various analytical measures are used to analyze the predicted outcomes. Then a classifier is called a decision tree classifier. The proposed algorithm is given below:

Input: Breast cancer dataset.

Output: Analysis and classification of data.

Step 1: Prepare the breast cancer dataset.

Step 2: Prepare a Base performance using the linear regression technique.

Step 3: Apply different detection methods to identify outliers.

Step 4: Analyze the results with different analytical measures.

Step 5: ROC value and the precision rank of different detection are measured.

Step 6: Out of the above outlier detection, the best one is used to detect the outlier from the breast cancer dataset, and using the confusion matrix as a classifier, the prediction of breast cancer has been made.

IV. RESULT AND DISCUSSION

A. Data Description

The breast cancer dataset is considered is downloaded from the data world repositories. The breast cancer dataset contains information about the women who are likely to have cancer. The dataset consists of a total of 11 attributes, namely sample id, clump thickness (1-10), uniformity of cells (1-10),

marginal adhesion (1-10), single epithelial cell size (1-10), bare nuclei (1-10), bland chromatin (1-10), normal nucleoli (1-10), mitoses (1-10) and finally the class attribute. The dataset consists of 698 instances. The dataset also comprises 10 feature attributes and one class attribute. The original dataset is split into training and test dataset. The training dataset is 70% of the total dataset, i.e., 488 instances, and the test data is 30% of the entire dataset, i.e., 210 cases.

B. Analytical Measures

The different detection algorithms' performance is evaluated by some analytical measures like Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Model Score of each detection algorithm [27],[28],[29]. The measurements are described in the following Table I.

TABLE I. ANALYTICAL MEASURES

Evaluating Measures	Description	Formula
Mean Absolute Error (MAE)	It helps to evaluate the mean error in the prediction set, not considering its direction. It indicates the error between prediction and actual observations.	$MAE = \frac{1}{n} \sum_{i=1}^n y_i - \hat{y}_i $
Root Mean Square Error (RMSE)	It is a type of quadratic grading method that uses to determine the average magnitude of the error.	$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2}$
Model score	It takes input as a feature matrix and probable target values. Then both predictions made on the feature matrix are compared with the target to attain a score.	mdl.fit (X_train, y_train) mdl.score(X_test, y_test)
Precision	It is the ratio of the true anomalies present with the total number of anomaly candidates.	$Tp / (Tp + Fp)$ where Tp is the number of true positives and Fp is the number of false-positive cases.

Both MAE and RMSE are the average error of the prediction made by the detection algorithms. This error measure works on negatively oriented scoring, which implies the lowest values are better values. For considering larger errors, RMSE is much useful. The more excellent value of RMSE does not mean the larger value of variance in the errors. Using the MAE value, we can always bound the values of RMSE.

- The RMSE error values are either greater than or equal to MAE, i.e., $RMSE \geq MAE$.
- When the prediction errors are calculated from the same test dataset, then the difference in MAE and RMSE will be the highest. In that respect, the total squared error will always equal $(MAE^2 \times n)$, where n is the data in the test dataset. Thus, RMSE is less than or equal to the absolute squared error's square root, i.e., $RMSE \leq [MAE^2 \times n]$.

Finally, RMSE is more beneficial for penalizing a large number of errors, but both are equally important.

TABLE II. EVALUATING RESULTS OF OUTLIER DETECTION TECHNIQUES

Analytical Measures	Anomaly Detection Approaches			
	Isolation Forest	MCD	OC-SVM	LOF
ROC (Training dataset)	0.9833	0.9864	0.9838	0.8863
ROC (Test dataset)	0.9804	0.9832	0.88	0.8123
Precision	0.8888	0.9028	0.8880	0.9164
Model Score	0.802	0.835	0.814	
Computation Time	0.3	0.3	0.3	<0.1

C. Result Analysis

The evaluating results are tabulated in Table II, representing the ROC and the precision of the different algorithms and the algorithm's model score.

Fig. 3 and 4 represent the MAE and RMSE of the different outlier detection techniques. The figure shows the performance analysis of different detection algorithms; we can derive that the best performing algorithm is Minimum Covariance Determinant (MCD). It has lower MAE and RMSE values of 0.241 and 0.371 than other detection algorithms. It also has a higher prediction accuracy rate of 84%.

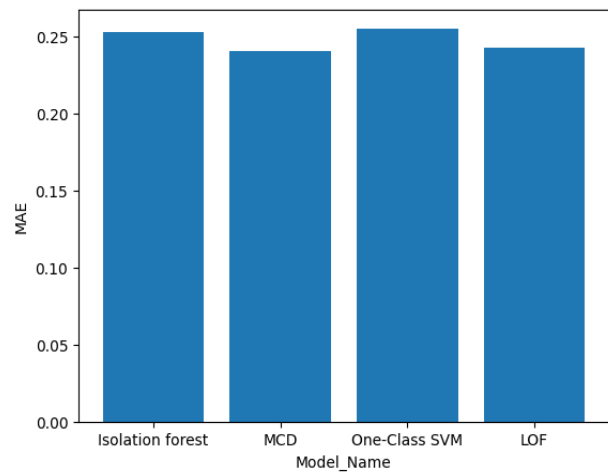

Fig. 3. Mean Absolute Error of Different Detection Algorithm.

Fig. 4. Root Mean Square Error of the Different Detection Algorithm.

V. CONCLUSION

This paper discussed the details of the four most popular and versatile outlier detection algorithms. It is a performance analysis-based study where various analytical measures are considered to derive a final result. The breast cancer dataset was considered in our research from multiple datasets available in the real world. The detection algorithms considered are also very diverse. The MAE and RMSE are used for analyzing the performance of different algorithms. Also, the model score of all the algorithms is calculated. The returned value of the model score is measured as these algorithms' accuracy to predict the test dataset after training the model with the training dataset. The slight variance in both the error values can make a lot of difference in analyzing algorithms' performance with the particular dataset. The inclusive conclusion observed that the algorithm that produced a minor error in predicting the test dataset is Minimum Covariance Determinant (MCD) with MAE and RMSE of 0.241 and 0.371. MCD also has the highest accuracy among the other algorithm.

Abstract—Nature-inspired algorithms in computer science and engineering are algorithms that take their inspiration from living things and imitate their actions in order to construct functional models. The SOS algorithm (symbiotic organisms search) is a new promising metaheuristic algorithm. It is based on the symbiotic relationship that exists between different species in an ecosystem. Organisms develop symbiotic bonds like mutualism, commensalism, and parasitism to survive in their environment. Standard SOS has since been modified several times, either by hybridization or as better versions of the original algorithm. Most of these modifications came from engineering construction works and other discipline like medicine and finance. However, little improvement on the standard SOS has been noticed on its application in cloud computing environment, especially cloud task scheduling. As a result, this paper provides an overview of SOS applications in task scheduling problem and suggest a new enhanced method for better performance of the technique in terms of fast convergence speed.

Keywords—Cloud computing; cloud resource management; cloud task scheduling; symbiotic organisms search; entrapment; convergence speed

I. INTRODUCTION

The term "cloud computing" refers to a fully centralized, scalable, on-demand computing network with distributed virtual infrastructure, storage, and pay-per-use services[1][2][3]. Resource management in infrastructure as a service (IaaS) is one of the most important challenges of cloud computing especially cloud task scheduling. Task Scheduling is an optimization problem that falls into the NP-hard class[4][5][6]. Therefore, using conventional search algorithms to find an optimal mapping between tasks and resources in a short period of time becomes almost impossible.

Many metaheuristic algorithms have been proposed to solve optimization problems in recent decades. Metaheuristic research around the world has resulted in optimization techniques that have proved to be superior to conventional gradient-based approaches[7][8][9][10]. Almost all metaheuristic algorithms have the following features in common: nature-inspired, probability distributions, do not need significant gradient information, and many parameters that must be tailored to the problem at hand. Several metaheuristic algorithms that mimic the actions of insect or animal classes in

nature have been developed using a combination of deterministic rules and randomness[9][11]. Many of the optimization problems that can be formulated are extremely nonlinear, with multimodal objective landscapes and a series of dynamic, nonlinear constraints[12][13][14].

Optimization algorithms are intelligent self-learning algorithms derived from the observation and mimicking of intelligent processes and actions observed in nature, usually based on swarm intelligence[9][15]. The optimization problems that have piqued interest in metaheuristic approaches range widely in complexity, from single to multi-objective, continuous to discrete, constrained to unconstrained and large-scale global optimization problems. Therefore, solving these problems is not always easy due to their complicated behaviour[1][9][16][17][18]. Studies of swarm behavior can perhaps be regarded as a field of artificial intelligence (AI), is saddled with the responsibilities of collecting information about the behaviour of organisms in self organized environment. Symbiotic Organisms Search algorithm (SOS) is an SI(Swarm Intelligence)-based recently developed metaheuristic algorithm that was inspired by nature[19]. The SOS algorithm mimics the collaborative behavior observed in nature among individuals. Symbiotic relationships between paired organisms in an ecosystem define cohabitation behavior of different species which include mutualism, commensalism, and parasitism. Symbiosis is a close relationship between organisms that last over a period[20][21][22][23]. Overview of the relationship among distinct species is depicted in Fig. 1.

Mutualism is the interaction between two species with mutual benefit, which means that both benefit from the relationship. Commensalism happens when one species forms a bond with a different species, with one species gaining while the other is unaffected. When two species form a relationship in which one benefits and the other hurts, it is referred to as parasitism. Both mutualism and commensalism operations focus on creating new species for the next generation by allowing the search procedure to find solutions to the problems within the solution search space, thereby improving the algorithm's exploratory capability. The parasitism phase, on the other hand, focuses on increasing exploitative capability by allowing the search process to escape entrapment at local optimality.

Fig. 1. Vector Illustration of Symbiosis.

The optimization analysis group and other similar domains have been paying considerable interest to the algorithm because of its deployment simplicity and consistency.

Furthermore, in comparison to other alternative algorithms or competitors such as GA, ACO, PSO, and DE, the SOS algorithm has drastically risen in its area of application to several optimization realms but little in cloud computing environments. Therefore, this paper provides a comprehensive analysis of the standard SOS algorithm, its basic concepts and structures, variants, and hybrid implementations for addressing constrained, unconstrained, single objective, multiple objectives, large scale global optimization problems, and practical oriented real world optimization problems in a cloud computing setting. This paper's major contributions are as follows:

- A comprehensive review of the traditional SOS algorithm.
- A look at SOS varieties and hybridization strategies.
- Identification and presentation of the different applications of the SOS algorithm in task scheduling problems within cloud computing context.

The rest of the paper is structured as follows: Section 2 introduces the fundamental concept and summarized work on standard SOS algorithm; Section 3 presents a review of research works on SOS algorithms, including variants and hybrid versions of the regular algorithm, while Section 4 concludes the study and provides viable future directions.

II. SYMBIOTIC ORGANISMS SEARCH ALGORITHM (SOS)

Cheng and Prayogo [19] developed a framework for simulating the symbiotic relationship between species in an environment, using it to solve mathematical and engineering design problems. Three distinct search processes govern the next possible solution, which are modeled after three basic symbiotic interactions: mutualism, commensalism, and parasitism.

A. Mutualism Phase

This is the first stage which entails selecting organisms based on their fitted values. In this phase, two organisms Z^i and Z^j (where $i \neq j$) are selected to interact with each other. The two distinct organisms benefit from one another. The mathematical formulations of these procedures are presented as in (1) and (2).

$$Z^{i_new} = Z^i + \mathfrak{r}(0,1) \times [Z^{best} - M_v \times B^{f-1}] \quad (1)$$

$$Z^{j_new} = Z^j + \mathfrak{r}(0,1) \times [Z^{best} - M_v \times B^{f-2}] \quad (2)$$

The joint relation vector between Z^i and Z^j denoted by M_v and benefit factor (B^f) are evaluated using the mathematical formulars in equations (3), (4), and (5) respectively.

$$M_v = \frac{z^i + z^j}{2} \quad (3)$$

$$B^{f-1} = 1 + \text{round}(\mathfrak{r}(0,1)) \quad (4)$$

$$B^{f-2} = 1 + \text{round}(\mathfrak{r}(0,1)) \quad (5)$$

The new species Z^{i_new} and Z^{j_new} are created by sculpting their structure from M_v and B^f matching to the existing population's fittest species (Z^{best}). However, while M_v specifies the mutual bond between different species, B^f denotes the degree of value gained by each species as a result of their interaction. $\mathfrak{r}(0,1)$ denotes a vector of uniformly distributed random numbers ranging from 0 to 1. The fitness values of these new species Z^{i_new} and Z^{j_new} are each evaluated and compared with their respective predecessor to select the next generation of the ecosystem. If the fitness values of the new species are better than their predecessor, then they automatically move to the next generation otherwise they are rejected, and the old species remain. Note that worst fitness values are rejected and replaced.

B. Commensalism Phase

In this phase, only one organism Z^i can increase his or her fitness value. This is achieved by randomly select organism Z^j which is neutrally affected in their relationship. The commensalism relationship between these two organisms is established using the mathematical equation as in (6).

$$Z^{i_new} = Z^i + \mathfrak{r}(-1,1) \times (Z^{best} - Z^j) \quad (6)$$

So, the beneficial contribution of organism Z^j to organism Z^i is computed using $(Z^{best} - Z^j)$ as in (6). Similar to the mutualism process, the newly created organism (Z^{i_new}) can only substitute its predecessor (Z^i) if and only if its fitness value is higher; otherwise, (Z^i) is retained.

Algorithm 1 below outlines the processes of the standard symbiotic organism search (SOS) algorithm.

Algorithm 1: Pseudo-code of Symbiotic Organism Search algorithm

```

Define input variables, objective function, and problem dimension.
//Population size (ecosize), maximum iterations (Maxitern)
Initialize population with respect to population size(ecosize)
Identify the best organism in the ecosize ( $Z^{best}$ )

Start SOS Looping:
  While itern<maxitern
    For i = 1: ecosize
      Mutualism Phase
      Select species  $Z^i$  and  $Z^j$  ( $i \neq j$ )
      compute the common vector ( $M_v$ ) as in (3) and the Benefit
      factor ( $B^{f-1}$  and  $B^{f-2}$ ) as in (4) and (5)

      Using (1) and (2) to create the new species
       $Z^{i\_new}$  &  $Z^{j\_new}$  and assess their strengths.
      If the strengths of the new species are better, then
        replace the predecessors

      Commensalism phase
      Select species  $Z^j$  randomly ( $i \neq j$ )
      Using (6) to create new species  $Z^{i\_new}$  and assess
      its strength
      If the strength of the new species is better, then
        replace the predecessor.

      Parasitism Phase
      Select species  $Z^j$  randomly ( $i \neq j$ )
      Produce parasite vector  $Z^p$  by amending  $Z^i$ , assess the strength
      If the strength of the parasite vector ( $Z^p$ ) is better,
      then replace  $Z^j$  with  $Z^p$ 

    End for
    Update best species  $Z^{best}$  of the existing population
  End while

```

C. Parasitism phase

The phenomenon of parasitism can be best described by the interaction between a mosquito and human. Once the human is

bitten by mosquito, the process create parasite in the human body. The parasite present in the human host reproduces itself and overwhelms the human host through disease infection which may lead to death. On the contrary, if the human body has better immunity, then it protects itself and the parasite gets eliminated from the body.

The human host is harmed in this type of interaction, while the anopheles mosquito, which is the parasite carrier, remains unharmed, the plasmodium parasite thrives and replicates within the body system. The parasitism interaction between two organisms Z^i and Z^j with ($i \neq j$) is introduced in the SOS model as follows:

If Z^i is assigned to the anopheles' mosquito which is selected randomly from the search space, fine-tuned its dimension to create an artificial vector or (parasite vector) denoted by Z^p . Similarly, the organism Z^j is equally selected randomly from the search space and serves as host to Z^p . The parasite vector, Z^p , tries to replace the host Z^j in the ecosystem. If Z^p has a higher fitness value than Z^j , Z^p replaces Z^j otherwise, Z^j gains immunity, fights back, and eliminate Z^p from the ecosystem.

The mathematical formulation of selection of species guided by their strength is as in (7) and (8): -

Randomly select Z^j with $i \neq j$

Create a parasite vector Z^p from Z^i using a random number.

If $f(Z^p) > f(Z^j)$ then

$$Z^j \leftarrow Z^p \tag{7}$$

else

$$Z^{j_new} = Z^j \tag{8}$$

III. THE MOST RECENT SOS VERSIONS FOR TASK SCHEDULING PROBLEMS

So far, different implementations of SOS have been introduced due to various type of task scheduling optimization problems. Therefore, it is critically important to examine the enhanced and improved variants of the SOS algorithm as they contribute to task scheduling issues in the cloud. Fig. 2 shows the classification of variant symbiotic organisms search algorithm. Some of the modified SOS algorithms considered in this review are highlighted in Table 1.

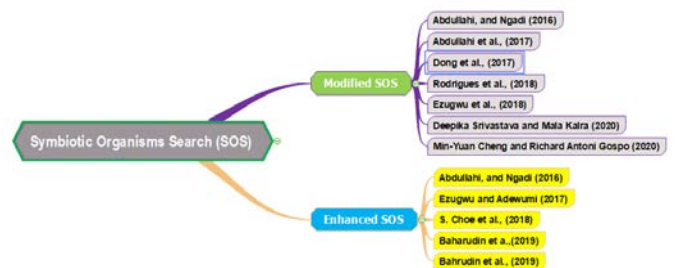

Fig. 2. Taxonomy of Variant Symbiotic Organisms Search Algorithm.

TABLE I. THE SUMMARY OF LITERATURES ON MODIFIED SYMBIOTIC ORGANISM SEARCH (SOS) ALGORITHMS

S/N	Authors	Title	Objectives	Modified technique	Benchmarked Technique	Journal/Conference	Publishers	Remarks
1	Abdullahi, and Ngadi (2016)	Symbiotic Organism Search optimization-based task scheduling in cloud computing environment	Minimizing makespan	DSOS	PSO	Future Generation Computer Systems	Elsevier	T-test analysis of the proposed method revealed that DSOS performs significantly better than PSO, especially for large search spaces.
2	Abdullahi et al., (2017)	“Chaotic symbiotic organisms search for task scheduling optimization on cloud computing environment”	Minimizes cost and makespan	CSOS	SOS, PSO	6th ICT International Student Project Conference	UTM/RUG/15H99 RMC Universiti Teknologi Malaysia.	The key idea is to incorporate a chaotic map, which enlarges the search space and provides diversity, to avoid premature convergence of SOS at early stages of the optimization process.

A. Modified SOS

Modified symbiotic organism search technique is one in which either one or two of the operators are improved to enhance the efficiency of the algorithm in order to optimize fast convergence time while avoiding entrapment at the local optimal region[15][21]. In most cases, either the mutualism or commensalism phases, or both, are strengthened by adding a random weighted reflective parameter or converting continuous outcomes to discrete results among approaches.

A symbiotic organism search optimization-based task scheduling technique has been proposed in the work of [24] to schedule a collection of independent tasks in a cloud computing environment. The proposed technique used various types of distributions to gain insight into the proposed method's performance trend. In addition, to account for the finite nature of cloud resources, a discrete version of SOS was introduced. To assess the suitability of the proposed approach, four types of data set were used in the experimental setup: regular, left-skewed, right-skewed, and uniform distributions. Furthermore, the performance of DSOS over SAPSO improves with increasing search space. According to [25], an investigation to a scheduling issue using a unique chaotic SOS algorithm to save time and expenses has been presented. The key idea is to perform a chaotic map, which expands the search area and generates diversity, to prevent the SOS algorithm from prematurely converging in the early stages of the optimization process.

In the work of [26], an optimized SOS algorithm for use in workflow-scheduling problems has been suggested. The proposed algorithm selects three steps of the SOS algorithm without regard to the population's pre-defined symbiotic relationship. Following the selection of solutions, a special method is selected to assign each solution to a symbiotic relationship. The proposed algorithm's performance was tested using twenty standard samples of the workflow-scheduling problem, and it was found to be more effective than the standard SOS. In another study, Improved Symbiotic Organism Search-Based Approach for Cloud Job Scheduling has been presented by [27]. The technique presents a discrete algorithm based on Improved Symbiotic Organism Search (ISOS) for scheduling independent tasks with the sole aim of mapping of various tasks to the best available cloud resources so as to minimize makespan and computational cost. Experimental results show a better performance of the improved technique over the benchmarked PSO algorithm.

According to [28] a reconstructed mathematical model for cloud task scheduling with additional approximate end time to the proposed design has been presented. By implementing a cloud task scheduling protocol based on the SOS (CTS-SOS) process, a continuous search space is obtained. The CTS-SOS algorithm more accurately optimizes and schedules time, and it effectively reduced the makespan, improved the efficiency of processing operations, and increased customer loyalty. Furthermore, the results of the simulation using CloudSim toolkit shows that the CTS-SOS algorithm outperform Round

Robin and ACO algorithms. Another similar work proposed an SOS algorithm for scheduling unrelated parallel machines with sequence-dependent startup times [29]. The technique developed a new solution of representative and decoding procedure to enhance the capacity of SOS algorithm for heterogeneous parallel machine scheduling problems. The problem of minimizing makespan in the scheduling of unrelated parallel machines with sequence-dependent initialization times has been solved using the proposed technique.

SOS 2.0: An Evolving Solution to the SOS Algorithm has been presented by [30]. The proposed technique integrates self-parameter updating (SPU) method into the search process to enhance its exploration capability. Furthermore, a chaotic map for generating chaotic behaviour was adopted to enhance its exploitation process thereby providing faster convergence. The combination of SPU and chaotic sequence provide adequate balance between local and global search process as well as avoiding premature convergence. The experimental result shows that SOS 2.0 performed better than the basic SOS and other several improved techniques.

B. Hybrid Symbiotic Organisms Search Algorithm

The modified/improved versions of SOS are faced with some challenges related to solving some complex optimization problems that needs extra synergy to resolve. Since there is no single technique that can address all optimization problems, the hybridized algorithms are more likely to be better in dealing with complex optimization issues and as such can produce a better result. The main aim of hybridizing two or more optimization techniques is to harness the complementary benefits of the techniques involved to produce a better solution[29][31][32]. Current literatures on the usage of SOS to address a variety of complex optimization and real-life problems have shown that the implementation of the SOS algorithm needs additional effort to produce high-quality performance. Table 2 highlight the summary of the literatures on hybridized SOS algorithm, while Table 3 presents analysis of some of the performance metrics used to measure the algorithms performance.

An optimization algorithm for task scheduling in cloud computing environment using hybrid symbiotic organisms search technique has been presented in [31]. The proposed technique integrated the Simulated Annealing (SA) method with the basic SOS. The SOS employs fewer control parameters and is highly flexible, has excellent exploration and convergence capabilities. The proposed technique employs SA's systematic reasoning ability to find better solutions on the local region identified by SOS, thereby enhancing SASOS's exploitative ability. Furthermore, a fitness function was introduced to increase the degree of resource utilization thereby minimizing makespan while optimizing the degree of imbalance among the virtual resources. The result of the experiment indicates a better performance of the hybridized technique (SASOS) over the basic SOS algorithm.

TABLE II. THE FOLLOWING IS A SUMMARY OF THE LITERATURES ON HYBRID SYMBIOTIC ORGANISM SEARCH (SOS) ALGORITHMS

S/N	Authors	Title	Objectives	Hybridized Technique	Benchmarked Technique	Journal/Conference	Publishers	Remarks
1	Abdullahi, and Ngadi (2016)	Hybrid Symbiotic Organisms Search Optimization Algorithm for Scheduling of Tasks on Cloud Computing Environment	Minimizing makespan, optimizing job scheduling, and reducing the degree of imbalance between virtual machines	SOSSA	SOS	PloS one	PLOS	In a cloud computing world, the proposed hybrid algorithm (SOSSA) has been shown to outperform the current standard SOS algorithm in terms of task scheduling.

An improved task scheduling algorithm for cloud computing using hybrid symbiotic organisms search technique has been presented by [32]. The proposed technique combines the Simulated Annealing (SA) and Chaotic local search (CLS) with SOS optimization technique to improve the convergence rate as well as to avoid being trapped at the local optimal region. Simulation results show that the hybrid SOS outperforms SOS, SA-SOS, and CLS-SOS in terms of convergence speed and makespan.

A soft sets-based symbiotic organisms search algorithm for resource detection has been built in a cloud computing environment [33]. The proposed technique tackles the uncertainty problems of resource selections in cloud computing environment. Furthermore, the hybridized approach incorporates the capabilities of the underlying approaches to efficiently handle tasks that must be performed during cloud resource discovery. As compared to the PSO, SOS, and PSOSA algorithms, the algorithm performed well in terms of finding a large number of good global solutions while minimizing resource collection time, search accuracy, search depth distribution, and the ability to escape premature convergence.

For global optimization problems, a Quasi-Oppositional-Chaotic Symbiotic Organisms Search algorithm has been developed by [34]. For a higher standard of performance and faster convergence, the technique combines Quasi-Opposition-Based Learning (QOBL) and Chaotic Local search methods with traditional SOS. QOBL is used for population initialization and generation hopping, while CLS is used to target the new best population. The results of the experiments show that QOCSOS achieve a better global optimum solution with remarkable convergence speed as compared to the original SOS.

In another study, [35] presents an efficient search algorithm for a multi-objective task scheduling problems based on symbiotic organisms search with a chaotic optimization strategy in a cloud computing environment. The proposed technique employed chaotic strategy to generate initial ecosize (population) as well as using its chaotic sequence to replace the random sequence based component of the SOS phases. This process ensures diversity among species for global convergence. Furthermore, the approach guarantees optimum cost-makespan trade-offs. Therefore, the CMSOS algorithm outperformed the other algorithms in terms of Pareto fronts for task execution time and cost.

The analysis of Table 3 shows that more work needs to be done on Symbiotic Organism Search (SOS) algorithms to improve its convergence speed so as to enhance its performance in cloud task scheduling issues. This can be achieved by modifying the mutual features parameter that exist between two distinct species and by taking into cognizance the contribution of each species in the relation measured by equity rather than equality in the ecosystem. By this improvement, it will enhance equitable allocation/mapping of task to heterogenous VMs as well as balance the search process between local search and global search. This modified technique named G_SOS is in its incubation stage awaiting further improvement and implementation.

IV. CONCLUSION AND FUTURE WORK

Many metaheuristic algorithms have been proposed to solve optimization problems in recent decades. Thus, metaheuristic research around the world has resulted in optimization techniques that have proved to be superior to conventional gradient-based approaches. Symbiotic Organisms Search algorithm (SOS) is a recent SI-based metaheuristic algorithm that was inspired by nature[19]. The SOS algorithm mimics the collaborative behavior observed in nature among distinct species in ecosystem. Though, there have not been any review work on symbiotic organism search algorithm based on task scheduling problems. The modified and enhanced versions of SOS are faced with some challenges when solving some complex optimization problems that needs extra synergy to resolve. Therefore, these algorithms, modified or enhanced, can still be improved by looking inward to the features of the basic (SOS) algorithm.

ACKNOWLEDGMENT

I would like to appreciate the Nigerian Tertiary Education Trust Fund (TETFund) in partnership with Kogi State Polytechnic Lokoja for their support of this work.

Abstract—Sarcasm (i.e., the use of irony to mock or convey contempt) detection in tweets and other social media platforms is one of the problems facing the regulation and moderation of social media content. Sarcasm is difficult to detect, even for humans, due to the deliberate ambiguity in using words. Existing approaches to automatic sarcasm detection primarily rely on lexical and linguistic cues. However, these approaches have produced little or no significant improvement in terms of the accuracy of sentiment. We propose implementing a robust and efficient system to detect sarcasm to improve accuracy for sentiment analysis. In this study, four sets of features include various types of sarcasm commonly used in social media. These feature sets are used to classify tweets into sarcastic and non-sarcastic. This study reveals a sarcastic feature set with an effective supervised machine learning model, leading to better accuracy. Results show that Decision Tree (91.84%) and Random Forest (91.90%) outperform in terms of accuracy compared to other supervised machine learning algorithms for the right features selection. The paper has highlighted the suitable supervised machine learning models along with its appropriate feature set for detecting sarcasm in tweets.

Keywords—Machine learning; detection; sarcasm; sentiment; tweets

I. INTRODUCTION

Sarcasm detection in opinion mining is an essential tool with various applications, including health, security, and sales [1, 2]. Several organizations and companies have shown their interest in studying tweets data to know people's opinion towards popular products, political events or movies. Millions of tweets are posted every day, which increase the content of twitter tremendously.

However, microblogging social media (i.e., maximum 140 characters in every tweet) and containing informal language essentially makes it quite tricky to understand users' sentiment and perform sentiment analysis. Additionally, sarcasm poses a challenge in sentiment analysis and causes the misclassification of people's opinions. Hence, it leads to reduced accuracy of sentiment analysis. People use sarcasm to mock or convey contempt through a sentence or while speaking. People apply positive words to reveal gloomy feelings. In recent days, sarcasm or irony is very common in social media, although it is challenging to detect.

The cutting-edge approaches of opinion mining and sentiment analysis are prone to unsatisfactory performances while analyzing social media data. Maynard and others [3] proposed that detecting sarcasm during sentiment analysis might significantly improve performance. Consequently, the necessity for an effective method to identify sarcasm arises.

In this paper, we propose an effective method to identify a sarcastic tweet. Our strategy considers the various types of sarcasm indicating features such as Lexical-based Features, Sarcastic-based Features, Contrast-based Features, Context-based Features, and detects the sarcastic tweets using multiple supervised machine learning models based on extracted features. We suggest an effective machine learning model and feature set to better perform sarcasm detection in sentiment analysis and get better accuracy, which is explained at the end of the evaluation and the result analysis parts of this paper.

The main contributions are as follows:

- 1) To detect sarcasm, we use a set of machine learning classification algorithms along with a variety of features to identify the best classifier model with significant features, which leads to recognize of the sarcasm in tweets to get better performance of sentiment analysis.
- 2) We propose the right set of features that lead to better accuracy, which is presented in the result analysis part of this paper.
- 3) Analysis results present that Decision Tree (91.84%) and Random Forest (91.90%) outperform the accuracy compared to Logistic Regression, Gaussian Naive Bayes, and Support Vector Machine for the different features set up.

The remainder of this paper is arranged as follows: Section 2 explains the literature review, and Section 3 demonstrates the sarcasm recognition process. Section 4 illustrates our findings, and Section 5 concludes this work.

II. LITERATURE REVIEW

Many research articles and publications motivated us to work with this topic; a few of them are discussed here in detail. The authors, Sana Parveen, Sachin N. Deshmukh [4], suggested a methodology to recognize the sarcasm on Twitter using Maximum Entropy and Support Vector Machine (SVM). Firstly, they created two datasets from collected

Twitter data. One dataset has sarcastic tweets and another dataset without sarcastic tweets in training data. Penn treebank is used to tag POS with each word. Maximum Entropy and SVM are used to classify tweets after features extraction related to sentiment, syntactic, punctuation, and pattern. Finally, they got more accuracy for Maximum Entropy than SVM. The authors, Anukarsh G Prasad, Sanjana S, Skanda M Bhat, BS Harish [5], suggested a technique based on the slang and emojis used in tweets to identify sarcastic and non-sarcastic tweets. They took into consideration slang and emoji values according to the slang and the emoji dictionary. Afterward, these values are used to classify sarcasm, applying Random Forest, Gaussian Naive Bayes, Gradient Boosting, Logistic Regression, Adaptive Boost, Logistic Regression, and Decision Tree. They suggested an effective classifier using slang and emoji dictionary mapping to produce the most satisfactory performance. A new technique was suggested by Sreelakshmi K, Rafeeqe P C [6] using context incongruity to define sarcasm on Twitter. To recognize the irony, they considered various features such as linguistic, sentiment, and context features. Both the sarcastic and non-sarcastic tweets are collected and pre-processed. They used Simple Vector Machine (SVM) and Decision Tree as a sarcasm classifier and produced a satisfactory level. A significant study from the linguistic sector tells us that lexical factors such as adjectives and adverbs, interjections, and punctuations play a considerable role in sarcasm detection [7]. In sentiment analysis, many researchers used machine learning methods such as Maximum Entropy, Naïve Bayes, and Support Vector machine because these algorithms tend to outperform the other algorithms in text classification [8,9]. Buscaldi and others (2012) [10] addressed the features which lead to the sarcasm classification. It also provides an in-depth description of how the different features contribute to the classification. Barbieri F. And Saggion H.'s work (2014) [11] dealt with the automatic detection of sarcasm on Twitter data. They divided the results of the classification of tweets into sarcastic or non-sarcastic classes. They do it depending on frequency (the gap between rare and common words), written-spoken (written-spoken style uses), intensity (intensity of adverbs and adjectives). And also, analyze structure (length, punctuation, emoticons, links), sentiments (the gap between positive and negative terms), synonyms (common vs. rare synonyms use), and Ambiguity (a measure of possible ambiguities). Based on the features mentioned above, they proposed a classification algorithm and claimed 71% accuracy on irony detection. The authors, David B. and Noah A. S. (2016) [12], improved the classification method by adding the history of tweets and author profiles, which helps in the classification process. The article presents accuracy for different contexts ranging from 70% and

upwards. Parmar and others (2018) [13] pointed out a few of the present challenges to classify sarcastic tweets, such as the nature of the collected tweet, the presence of uncommon words, abbreviations, and slang, that are more informal and no predefined structure for sarcasm identification in Twitter. Ren, Y., Ji, D., and Ren, H. suggested two distinct context-augmented neural models for detecting sarcasm in the text [14]. Prasad and others [15] examined numerous classification approaches in which they noticed that Gradient Boost (GB) showed the best performance. Another study stated a novel method for identifying sarcasm in tweets by combining two classification techniques, Support Vector Machine with N-gram features [16]. Karthik Sundararajan and others proposed a sarcasm detecting approach and irony type using Multi-Rule Based Ensemble Feature Selection Model [17]. Siti Khotija, Khadijah Tirtawangsa, Arie A Suryani suggested a context-based method to detect sarcasm in tweets based on Long Short-Term Memory (LSTM) [18]. According to another paper, classifier's performance is vital in sarcasm predictions in opinion mining [19].

Moreover, the nature of classifiers can also play an essential role in sarcasm detection. However, in tweets, limited studies have approached the efficiency of sarcasm detection methods with valuable features. Hence, this study investigates the principal sarcasm classifiers, classification performance, and the selection of features that dominate such performance.

Besides, the paper drives motivation from numerous works, as mentioned earlier, and intends to produce better performance in sarcasm detection.

III. PROPOSED METHODOLOGY

The structure of suggested methodology is depicted in Fig. 1 and mainly consists of three modules such as tweet pre-processing, feature engineering, and sarcasm recognition modules.

A. Tweets Dataset

Twitter's streaming API was used to collect tweets. To obtain sarcastic tweets, we request the API for tweets having the hashtag "#sarcasm". Similarly, for no sarcastic tweets, we collected tweets regarding different topics and eliminated ones that include any hashtag indicating sarcasm. We collect a total of 76799 tweets having two categories, sarcastic (37583) and non-sarcastic (39216) tweets. 0(zero) is used to indicate non-sarcastic tweets, while 1(one) for sarcastic tweets. The dataset contains two columns as Label and Tweet. The Label column has 1 or 0 to present, whether it is sarcastic or not while the Tweet column has tweets.

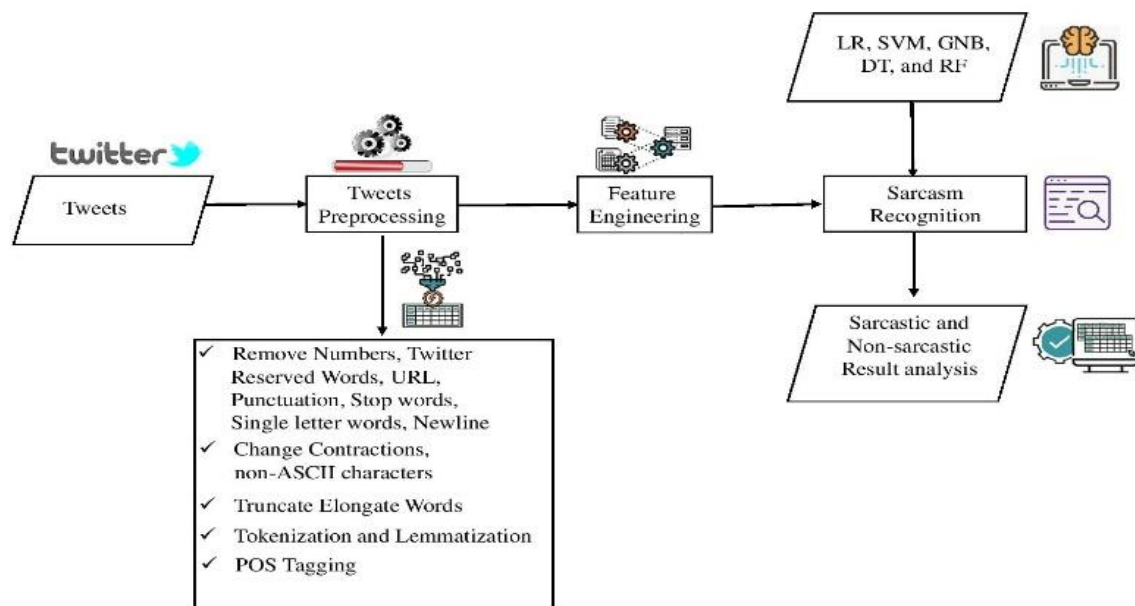

Fig. 1. Proposed Methodology.

B. Tweets Preprocessing

1) *Noise removal*: We have removed numbers, newlines, non-ASCII characters, twitter preserved words, a single word tweet and some common string literals to speed up the feature mining process.

2) *URLs removal*: URLs (Uniform Resource Locators) in the tweets are references to a location on the web but do not provide any additional information. They are removed in the pre-processing phase of the sarcasm detection process.

3) *Stop words removal*: One of the significant forms of pre-processing is to filter out useless data referred to as stop words. Stop words include mainly articles (a, an, the), prepositions (in, of, to, and so on), along with other very commonly used words. They, indeed, don't have any contribution to detect sarcasm in the sentence. Therefore, they are removed before further processing of data. For example, after removing common words from "I don't know how to swim", we have "know and swim" words remaining.

4) *Truncated elongated word*: Tweets contain repeated characters in a word such as goooooood, loooove, moooove and many more styles. These words usually indicate sarcasm in tweets. We did not apply this preprocess step while counting the number of repeated letter segments and vowel repetitions in the tweet. However, we get the base word for these words, for instance, good, love, move, respectively, to extract other features.

5) *Punctuation removal*: Punctuations such as "#\$%&'()*+,-./:;<=>@[\\]^_`{|}~" are discarded before extracting features from tweets, though some special punctuations, for example, ?, !, ... are preserved which sometimes indicate sign of sarcasm.

6) *Replace contraction and acronym*: Contractions are n't, aren't, wasn't, can't, couldn't, haven't, won't, shan't, shouldn't and many more. We replaced all of them with their

full form so that we can analyze a single word. Moreover, we use forms of common acronyms used in tweets such as hella, lhh, lmao, jk and so on.

7) *Normalization*: To normalize tweets, we apply tokenization and lemmatization steps. Tokenization helps to create words list from tweets while lemmatization finds the base form of any provided word, for instance, made to make and loved to love. The base form of a word, in most cases, supports identifying tweet sentiment.

8) *POS Tagging*: It is the method of matching a word to its morphological class, which supports learning its role inside the sentence. Necessary parts of speech counted in POS Tagging are Noun, Verb, Adverbs, and Adjectives. Part-of-speech taggers essentially take a series of words as input and produce a list of tuples as output, where every word is connected with the relevant tag.

C. Feature Engineering

Being a modern form of communication, sarcasm is used for various purposes that fall in prevailing in three categories:

1) *Irony as wit*: when used as a wit, sarcasm is applied to be funny; the person applies some particular sorts of speeches, favors to exaggerate, or adopts a distinct tone from that when he speaks usually. In social networks, voice tones are transformed into particular kinds of writing: use of uppercase letter words, ellipsis, letter repetition, quote repetition, question marks, interjections, and exclamation, as well as some sarcasm-related emoticons.

2) *Irony as whimper*: when used as a whimper, sarcasm is used to reveal how annoyed or irritated the person is. Consequently, it stimulates to explain how wicked the circumstance is, using exaggeration and highly positive feelings to express a negative state.

3) *Irony as an escape*: it attributes to the circumstance when the person wishes to pretend to give a precise answer. Hence, it makes the presence of sarcasm. In this case, the person applies perplexing sentences, unusual words, some common expressions, and slangs.

We extracted four sets of features based on the assumption mentioned above: Lexical, Sarcastic, Contrast, and Context-based.

4) *Lexical-based features*: We extract seven lexical or textual-related features. They are Noun, verb, adverb, adjective having a higher impact in a tweet than any other parts of speech. We count them individually according to individual tweets. Moreover, intensifiers such as absolutely, amazingly, awfully, ridiculously, bloody, excessively, outrageously, strikingly, tremendously and so on, are sometimes used to show exaggeration in the tweet to express negative feelings through positive intensifiers and vice versa. Therefore, we also count the number of positive and negative intensifiers present in every tweet. Lastly, the whole tweet's sentiment is calculated, which reveals the overall polarity of the tweet.

5) *Sarcastic-based features*: Generally, people tend to make complicated sentences or use rare words to make them vague to the listener or reader to get a definite answer in other events. Indeed, when people use sarcasm as avoidance, they intend to hide their actual feeling or sentiment by hiding them in fun. Therefore, we derive the following features. People sometimes try to convey the irony message through punctuations, such as exclamation, question marks, and repeated ellipsis. Hence, we count the number of exclamations, question marks and repeated ellipsis. Additionally, interjections are 'ha-ha', 'ho-ho', 'ho-ho-ho', 'oh', 'ouch', 'ow', 'shh', 'super' 'kidding', 'ah', 'aha', 'aww', 'nah', 'yay', 'uh', 'bah', 'bingo', 'boo', 'bravo', 'brilliant' and many more. People use them to express their feeling in different ways, which help to identify sarcastic tweet. Words like looove, goooood, mooove having repeated letters more than three or equals to three also probable indications of mockery tweets and repetition of vowels also denote the same thing. So, we count the number of repeated letter segments and vowel repetition in the tweet. It is worthy to note here, we extract this feature before removing repeated letters. On the other hand, people apply the uppercase word, for instance, GOOD, AWESOME and part of the word as uppercase, for example, gOOD, aWESome, to reveal their irony feeling. We find their number as well. We compute the number of laughter namely 'lol', 'lhh', 'jk', 'wow', 'kidding', 'ha ha', 'ha-ha', 'haha', 'rofl', 'roflmao', 'lmao', 'wtf'. Emoji are the facial emotions such as laughter created by typing a series of keyboard symbols, which are normally used to convey the author's attitude, feeling, or intended tone. In particular, sarcastic Emoji are sometimes used with sarcastic or ironical statements (e.g., ":P"). We consider not only rare sarcastic words but also very common words used in sarcastic tweets.

Sarcastic slangs as examples of 'ayfkmwts', 'fubar', 'kyso', 'lhh', 'lmao', 'stfw', 'stf', 'roflmao', 'rofl' are used in the tweet, and we take into consideration them too. We calculate the number of repeated quotes in the tweet as letter repetition. Besides, hashtags also contain emotional content.

In many cases, they are employed to ambiguate the tweet's real purpose carried in the message. Accordingly, we also calculate the sentiment score of hashtags. Finally, we calculate polarity summation (+1 for positive whereas -1 for negative polarity) for n-grams such as bigrams and trigrams.

6) *Contrast-based features*: We then outline four features that interpret whether there is a contrast between the various elements. By comparison, we indicate a negative element's coexistence and a positive one within the identical tweet. We calculate emoji polarity flip, polarity flip of sentiment, the number of positive and negative words. Before counting positive and negative words, we convert the following word of a negation word (e.g., "not", "never", etc.) into antonym, then find the number of positive words and that of negative words.

7) *Context-based features*: For context-related features, we find the number of users mentions and hashtags included in the tweet. People tend to express their feelings by applying various types of hashtags and sometimes use user mention as well.

D. Sarcasm Recognition

Usually, supervised machine learning models and lexicon-based approaches are used in opinion mining and text classification. The former includes various techniques such as K-Nearest Neighbor, Support Vector Machine (SVM), Linear Regression, Logistic Regression (LR) [20], Gaussian Naive Bayes (GNB)¹, Decision Tree (DT), Random Forest (RF), Neural Networks, Linear Discriminant Analysis (LDA) and so on. The latter has two strategies: a dictionary-based approach and a corpus-based approach.

However, for sarcasm detection in our proposed approach, we use five machine learning classifiers, such as Support Vector Machine, Logistic Regression, Gaussian Naive Bayes, Decision Tree and Random Forest, to examine which one performs better with our extracted features.

We commonly need two sets of data in machine learning-based classification, such as training data and test data sets. The classifier uses training data set to learn from the data and build the model, while the test data set is applied to validate the classifier's performance. In our case, we use the 10-fold cross-validation technique to split the dataset into training and test sets. Cross-validation is a method to evaluate predictive models by splitting the dataset into a training data set for training the model and a test data set to evaluate it.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. Evaluation

We have evaluated the effective classifier and feature set depending on three metrics: precision, recall, and F1-score.

¹ <https://iq.opengenus.org/gaussian-naive-bayes/>

Precision: Precision presents the ratio between the True Positives and all actual Positives in the dataset. Additionally, precision indicates the number of Positive class predictions which belong to the Positive class. It denotes TP (True Positive) divided by the sum of TP (True Positive) and (FP) False Positive.

Recall: Recall presents the percentage of correctly identifying the True Positive class. It denotes TP (True Positive) divided by the sum of TP (True Positive) and (FN) False Negative.

F1-score: F1-score presents the weighted or Harmonic average of Precision and Recall. Hence, it takes into consideration both False Positive and False Negatives. The formula denotes it: $(2 * \text{Precision} * \text{Recall}) / (\text{Precision} + \text{Recall})$.

1) *Evaluating effective sarcasm classifier:* We have evaluated five machine learning classifiers depending on precision, recall and F1-score to investigate which outperforms. According to Table I, Random Forest shows the highest precision, and Naïve Bayes presents the lowest value for precision. Regarding Recall and F1 metrics, the Decision Tree classifier performs better than other classifiers, 91.72% and 91.67%, respectively. Overall, the Decision tree outperforms different classifiers.

2) *Evaluating of effective feature set:* We have evaluated four feature sets with three popular classifiers, such as Support Vector Machine, Decision Tree and Random Forest. Here, also we have investigated three metrics: precision, recall and F1-score. According to our evaluation presented in Table II, the Sarcasmic feature set produces consistently better values for precision, recall and F1 than other feature sets. In contrast, the context-based feature set shows the lowest values in all cases.

B. Results

This section is explained in three separate subsections as follows:

- Investigation of the accuracy metric depending on various features.
- Explanation of our observation for various feature combinations.
- Analysis of the variation in classification accuracy for adding categories incrementally.

We have used accuracy metric to perform results analysis.

Accuracy: Accuracy indicates the ratio between the total number of accurate predictions and the total number of possible predictions in test data. It is calculated as the sum of TP (True Positive) and TN (True Negative) divided by the sum of total Positives and Negative classes.

1) *Performances of each set of features:* According to the given Table III and Fig. 2 above, it is clear that sarcasmic features in our study have a much better contribution in sarcasm detection in tweets than any other features such as lexical, contrast, and context features. For the rest of the

feature sets, lexical features have better accuracy than contrast-based features, while context-based features have far less impact on sarcasm detection. Decision Tree performs consistently better in terms of classification technique, and it reaches around 80 percent accuracy for sarcastic features merely. Logistic Regression shows the lowest accuracy for lexical and sarcastic features, while contrast and context features are less useful for the Random Forest technique. As sarcastic features produce far more accuracy, it is worthy to note that the proper selection of sarcastic feature set can increase the accuracy instead of selecting any other features.

TABLE I. EVALUATION OF EFFECTIVE SARCASM DETECTION CLASSIFIER. RESULT SHOWS THAT THE DECISION TREE OUTPERFORMS OTHER CLASSIFIERS

Classifiers	Precision	Recall	F1-score
LR	72.12	42.43	53.43
SVM	90.06	85.93	85.36
GNB	63.43	84.18	72.35
DT	91.62	91.72	91.67
RF	91.9	91.5	90.33

TABLE II. EVALUATION OF EFFECTIVE FEATURE SET ALONG WITH VARIOUS CLASSIFIERS. RESULT SHOWS THAT THE SARCASMIC FEATURE SET PRODUCES CONSISTENTLY BETTER VALUES FOR PRECISION, RECALL AND F1 THAN OTHER FEATURE SETS

Classifiers	Features	Precision	Recall	F1-score
SVM	Lexical	58.85	62.79	60.75
	Sarcasmic	77.83	68.05	72.61
	Contrast	60.99	35.68	45.02
	Context	0	0	0
DT	Lexical	64.68	60.77	62.67
	Sarcasmic	82.57	77.72	80.07
	Contrast	57.71	74.76	65.14
	Context	55.59	37.5	44.79
RF	Lexical	56.69	53.31	54.95
	Sarcasmic	80.19	74.98	77.5
	Contrast	39.04	41.73	40.34
	Context	21.93	20.36	21.11

TABLE III. ACCURACY (%) ON EVERY FEATURE SET. OUR ANALYSIS SHOWS THAT SARCASMIC FEATURES ARE USEFUL TO OBTAIN HIGHER CLASSIFICATION ACCURACY THAN OTHERS

Classifier	Lexical Features	Sarcasmic Features	Contrast Features	Context Features
LR	51.10	63.83	51.10	51.10
SVM	60.33	74.90	57.39	51.10
GNB	59.83	62.19	59.56	49.96
DT	64.59	81.08	60.87	54.79
RF	57.25	78.71	39.65	25.61

Fig. 2. Graphical view of Accuracy (%) on Every Feature Category. We Observe that Sarcastic Features are Dominating to get Higher Sarcasm Detection Accuracy.

2) *Accuracy for various feature combinations:* As of Table IV and Fig. 3 mentioned below, sarcastic (S) and contrast (C) based features together show the highest accuracy for DT and RF than the other feature combinations. The analysis result shows that lexical (L) and sarcastic feature combinations achieve more accuracy than sarcastic and context features. Mainly, GNB produces the highest accuracy for lexical and sarcastic features set. For all classification techniques, contrast and context (Cx) features together represent the lowest accuracy. As explained, except for lexical and sarcastic feature sets, it is found that the sarcastic and contrast features combinedly are the minimal feature set which leads to getting higher accuracy than the remaining combination sets. Although the Decision Tree classification technique has consistently higher accuracy than random forest and others, it exhibits lower accuracy for lexical and sarcastic feature combinations. Naïve Bayes and Logistic Regression are stabilized with almost 63% accuracy, while accuracy for SVM fluctuates between around 58% and 87%. Overall, the Decision Tree produces maximum accuracy, nearly 91% for the minimal sarcastic and context-based feature set.

TABLE IV. ACCURACY (%) FOR COMBINED FEATURE SETS. SARCASTIC (S) AND CONTRAST (C) BASED FEATURES TOGETHER SHOW THE HIGHEST ACCURACY FOR DT AND RF THAN THE OTHER FEATURE COMBINATIONS

Classifier	L + S	S + C	S + Cx	C + Cx
LR	63.83	63.83	63.83	51.10
SVM	79.34	86.59	74.90	57.39
GNB	67.95	63.44	62.63	60.32
DT	82.79	90.99	81.86	64.54
RF	84.66	89.81	79.38	57.21

Fig. 3. Accuracy for Various Category Combinations. Sarcastic (S) and Contrast (C) based Features Produce the Highest Accuracy for DT and RF than the other Feature Combinations.

3) *Accuracy for incrementally added category:* Depending on our findings as of Table V and Fig. 4, we observe that the sarcastic-based features dominated the accuracy metric. We fixed them as a base feature set and added feature sets incrementally to understand how accuracy changed with more feature sets. The addition of two (sarcastic, context) and three (sarcastic, contrast and lexical) feature sets show almost similar accuracy. Therefore, it is observable that lexical features with sarcastic and contrast features have far less impact on accuracy. It is not necessary to add more features to get better accuracy at all. Analysis results reveal that Decision Tree (91.84%) and Random Forest (91.90%) exceed the accuracy compared to Logistic Regression, Gaussian Naive Bayes, and Support Vector Machine for the different features selection.

C. Discussion

Looking at the values obtained in our sarcasm recognition experiments, it seems that the sarcastic feature set has more contribution to sarcasm detection in tweets among the four feature sets. In fact, this feature set's accuracy is constantly more excellent than other feature sets with all classifiers, and the Decision Tree shows maximum accuracy (approximately 81%) for the sarcastic feature set.

TABLE V. ACCURACY (%) FOR THE INCREMENTALLY ADDED FEATURE SETS. WE FOUND THAT THE SARCASTIC BASED FEATURES DOMINATED THE ACCURACY METRIC, AND ANALYSIS RESULTS REVEAL THAT DECISION TREE (91.84%) AND RANDOM FOREST (91.90%) PRESENT HIGHER PERFORMANCE

Classifier	S	S + C	S + C + L	S + C + L + Cx
LR	63.83	63.83	63.83	63.83
SVM	74.90	86.59	86.59	88.48
GNB	62.19	63.44	64.16	68.53
DT	81.07	91.04	91.51	91.84
RF	78.71	89.81	90.60	91.90

Fig. 4. Accuracy for the Incrementally Added Category. Decision Tree and Random Forest Classifiers show Better Accuracy along with the Sarcastic Feature Set.

Now turning to the experiment on different feature set combinations. We analyzed four distinct combinations to see which combination outperforms others. We combined the sarcastic feature set with lexical, contrast and context-based feature-set separately and contrast and context together for this experiment. We found higher accuracy (around 90%) for the sarcastic and contrast-based feature set. It appears that adding more features does not increase the model performance and feature selection is the central part of the efficient classification.

Lastly, we performed tests to observe which classifier outperforms if we increase the features, considering the sarcastic feature set as the base feature set. According to our observation, all feature sets' accuracy is not far more significant than other feature combinations. Hence, it is not always practical to add more feature sets to get better accuracy. However, the Decision Tree presents overall higher accuracy in all cases.

V. CONCLUSION AND FUTURE WORK

In this paper, we have suggested an improved model for detecting sarcasm in sentiment analysis. According to results, sarcastic features are more dominating than other features in sarcasm detection in tweets. Results show higher accuracy with sarcastic-based features for all classifiers we have used in our study. Moreover, the Decision Tree presents the highest accuracy (around 81%) with sarcastic-based features. Combining contrast-based features with sarcastic features increases the accuracy at approximately 90% for the Decision Tree. Therefore, it seems that it is not enough to add more features to obtain high accuracy. Though, the selection of the suitable feature set is the central part of the effective classification. Finally, we have evaluated all classifiers with incrementally added features, and findings reveal overall higher accuracy for the Decision Tree. We will study how to apply our proposed approach to improve sentiment analysis and opinion mining performances in future work. Additionally, we are also interested in context and pattern-based sarcasm detection in sentiment analysis.

Evaluation of Agent-Network Environment Mapping on Open-AI Gym for Q-Routing Algorithm

Abstract—The changes in network dynamics demands a routing algorithm that adapts intelligently with the changing requirements and parameters. In this regard, an efficient routing mechanism plays an essential role in supporting such requirements of dynamic and QoS-aware network services. This paper has introduced a self-learning intelligent approach to route selection in the network. A Q-Routing approach is designed based on a reinforcement learning algorithm to provide reliable and stable packet transmission for different network services with minimal delay and low routing overhead. The novelty of the proposed work is that a new customized environment for the network, namely Net-AI-Gym, has been integrated into Open-AI Gym. Besides, the proposed Q-routing with Net-AI-Gym offers optimization in exploring the path to support multi-QoS aware services in the different networking applications. The performance assessment of the NET-AI Gym is carried out with less, medium, and a high number of nodes. Also, the results of the proposed system are compared with the existing rule-based method. The study outcome shows the Net-AI-Gym's potential that effectively supports the varied scale of nodes in the network. Apart from this, the proposed Q-routing approach outperforms the rule-based routing technique regarding episodes vs. Rewards and path length.

Keywords—Reinforcement learning; environment; agent; network; Net-AI-Gym; Q-routing; rule-based routing

I. INTRODUCTION

The collaboration of entities either in the form of computing devices or the people or be it any things through some specific form of connectivity and set of communication protocols forms a network [1]. Examples of networks may include computer networks [2], social networks [3], the network of things as the Internet of Things (IoT) [4]. The adoption of machine learning is a requirement to bring automation in the process of routing.

A. Machine Learning Models

The machine learning models learn to perform a specified task(T). The machine learning models (MLM) are broadly classified into three categories as i) Supervised learning Model (SLM), ii) Unsupervised Learning Model (USLM), and iii) Reinforcement Learning (RL) model, as shown in the Fig. 1. The selection of the MLM depends upon the type of task(T) to be performed by the machine. Whereas the learning experiences (LE) in different MLM comes from the different sources of the data. In the SML, the 'LE' comes from the input

and output mapping of the data. The USML gains the 'LE' from the pattern of the data.

B. Reinforcement Learning

The RL Model is a goal-oriented ML approach, where the 'LE' for performing a 'T' comes by interacting with the uncertain and dynamic environment. The RL enables the computer to make a sequence of such decisions that ensure to maximize their cumulative rewards (CR) automatically even if the computer is not explicitly programmed to complete the 'T.' Fig. 2 illustrates the architectural diagram of the typical RL context.

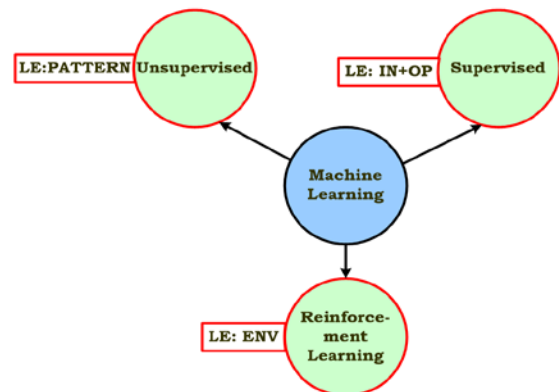

Fig. 1. Classification of Machine Learning Models

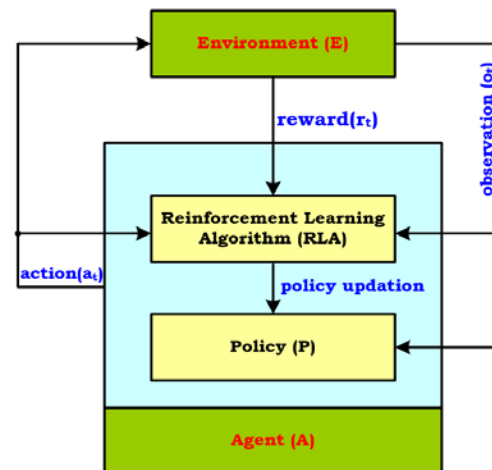

Fig. 2. Architectural Diagram of Typical RL Context.

The 'E' in RL is partially observable Markov decision process (POMDP). The mathematical modeling of any problem as an RL model takes a set of attributes (Sa) as a core building component for building the intuition of $\forall E \in S$. The attribute set $S_a = \{AE-R, MP, MP-MC, MRP, MDP, BE\}$, where, AE-R= agent and environment relationship, MP=Markov process, MP-MC= Markov process and Markov chain, MRP= Markov rewards process, MDP = 'Markov decision process, and finally, BE=Bellman equation.

C. Agent-Environment Relation (AE-R)

Basically, in RL Model, the 'A' is a software component that takes intelligent decisions based on the learning by an iterative cycle of gaining reward and penalty. The 'E' mimics the representation of the problem through a simulated environment to which the 'A' interacts. Another construct, namely 'state' (S), is the 'A' at a definite time step in the 'E.' The process that cannot be changed arbitrarily or randomly is a part of the 'E.' In simplification, action is any decision which the model wants it to learn, and the State is useful in choosing action. The 'A' cannot change the rewards arbitrarily. However, while designing the 'A,' it is assumed that as a part of its functions of taking action under the particular State, the agent knows how the computation of reward takes place in the environment. In some context, though the 'A' may have complete exposure or awareness of the 'E' yet, the 'A' finds it hard to maximize the 'R.' Therefore, the AE-R is the representation of the boundary or the limit of the 'A' control, not the knowledge of the 'A.'

D. Markov Property (MP)

The two intrinsic properties that define the Markov property are i) Transition (T): the process of changing one State to another state, ii) Transition probability (TP): The probability by which the agent can move from one State to another. Therefore, the Markov property states that "Future is independent of the past if present is given." The MP is expressed as in (1).

$$P[S_{t+1} | S_t] = P[S_{t+1} | S_1, \dots, S_t] \quad (1)$$

Where, $S[t]$ =current state of 'A' and $S[t+1]$ = next state. The intuitively meaning is that the current state includes information of the past states. Whereas, the state transition probability (STP) is expressed as in (2).

$$STP = P_{s \rightarrow s'} = P[S_{t+1} = s' | S_t = s] \quad (2)$$

The STP formulates a STP matrix (STPM) where, \forall Row \in STPM, represents the probability of moving next state.

$$\begin{bmatrix} p_{11} & p_{12} & \dots & p_{1n} \\ p_{21} & p_{22} & \dots & p_{2n} \\ \dots & \dots & \dots & \dots \\ p_{n1} & p_{n2} & \dots & p_{nn} \end{bmatrix}$$

The sum of each row \in STPM, $\sum R = 1$.

E. Markov Process and Markov Chain (MP-MC)

MP is a memoryless random process such that the sequence of the random states $\{S[1], S[2], \dots, S[n]\}$ with a Markov property, so the environment, $E: \{State(S), STPM\}$.

F. Markov Reward Process (MRP)

To understand the MRP, it is essential to understand the rewards concept and the different nature of the task. The agents receive a +ve or a -ve numerical value on acting as some state(S) in the 'E,' whereas the sum of such rewards is called return(G) which is expressed in the equation below as in (3):

$$G_t = \sum_{i=t+1}^T r_i \quad (3)$$

Another essential aspect is the type of task. It is either episodic or continuous. In the episodic task, every time the process initiates from the start-state (S_s) and ends at the terminating-state (S_t), and once it researches the S_t , it is said to be completing one episode (E_t). Again, the process restarts from the S_s to S_t , where every E_t is independent of others. Once the agent research the destination node from the source node in the routing case, it completes one E_t . In contrast to the episodic task, the continuous task (C_t) does not have any terminating state (S_t). Therefore, the return (G) can be easily calculated, whereas the value of 'G' in C_t yields infinity. Thus, to resolve the problem of infinity return (G), the concept of discount

factor (γ) comes into the picture.

The factor ' γ ' basically regulates the immediate reward (R_i) and the future rewards (R_f) and the range of ' γ ': $\{0,1\}$ to avoid R^∞ in the C_t . The value '0' of ' γ ' indicates higher importance to the R_i , whereas the value '1' indicates higher importance. Therefore $\gamma = 0$, in practice no learning condition and $\gamma = 1$, will keep hunting infinitely the R_f , so for all practical purpose ' γ ' is taken as: $0.2 \leq \gamma \leq 0.8$. Therefore, the equation (3) with discount factor(γ) is normalized as in equation (4).

$$G_t = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \quad (4)$$

The Agent (A) operates in the environment and gets rewards for each operation, and the prime goal of the 'A' is to maximize the cumulative reward by taking the most suitable action for the current observation. Therefore, the success rate of the 'A' is decided based on its reward, which shows how well the action being taken. In the existing literature, various research works have been conducted based on RL to solve network-related problems. However, none of the existing research works have introduced a suitable networking environment to evaluate the RL agent. In this paper, the evaluation of a customized environment, namely Net-AI Gym, is carried out with an RL agent algorithm designed based on the Q-Learning approach for network routing. The proposed study also considers a rule-based algorithm to be evaluated in the Net-AI Gym environment to carry out performance assessment in terms of reward VS episode and path length. The remaining sections of this paper are organized as follows: Section II provides a brief discussion on the types of networks and their characteristics. Section III presents the formulation of routing problems in the network. Section IV presents related work for analyzing the existing literature regarding the application of RL to network routing. Section V discusses the Environment Setup and processes involved. Section VI discusses the performance analysis and model validation, and finally, the overall contribution of the proposed work is concluded in Section VII.

II. TYPES OF NETWORK AND CHARACTERISTICS

Networks have become progressively ubiquitous. The network is a system of interconnected devices intended to share digital information. According to the characteristics, communication networks are usually divided into different categories: wired or wireless, energy limitation, network topology, and node mobility. These characteristics have a significant influence on RL-based routing optimization. Fig. 3 highlights the different types of networks based on wired and wireless network types.

In general, the typical characteristics of the network that usually affect the protocol design are based on several factors such as network is infrastructure-based or no infrastructure-based, centralized or distributed, node mobility, variation in network topology, node's energy consumption, link quality, bandwidth, the accuracy of data transmission, and application-specific requirements such as, time sensitivity and reliability-based requirements. The RL-based routing protocol has been gradually extended and improved as the network develops. Thus, 1 RL-based routing protocols have the capability of addressing various network issues.

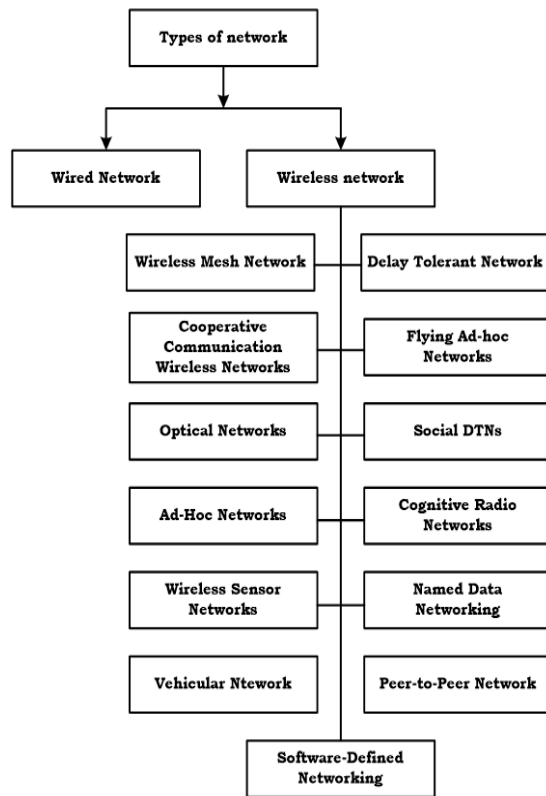

Fig. 3. Types of Networks.

III. FORMULATION OF ROUTING PROBLEM

The typical network 'NW' is a set of nodes(N), whereas a typical graph(G) is a set of vertices(V). In the case of NW, the 'N' is connected by links(L), whereas in the case of G, 'V' is connected by edges(E). Therefore, the mapping of a set: Network (NW) = {Node(N), Link(L)} → Graph(G) = {Vertex(V), Edge(E)}, so NW (N, L) is mapped to G (V, E). Whereas the Route(R) in an NW and a Path (P) in G is defined

as a way to move from the source node (Ns) to the destination node (Nd) in the NW and origin vertex (Vi) to another vertex (Vj), so {R (NW): Ns→Nd} → {P(G): Vi→Vj}. In the Network (NW), the link(L) is either one way or two ways, i.e., either Vi→Vj or Vj→Vi. Fig. 4 illustrates a real-world network as a mathematical model of an NW.

Fig. 4. Mapping Real-world Network (NW) to a Mathematical Model as Graph(G) of Machine Learning Models.

Therefore, in a nutshell, the network routing problem (NRP) is to obtain an optimal path (Po) between Vs. and Vd through intermediate nodes (Vk) under the constraints of weight (Wij) assigned to the link between Vi and Vj. The numerical value of Wij depends upon a set of parameters (Ps) with explicit and implicit relation between various properties of the chosen network such that Ps={Time(T), Cost (C), distance(D), Energy(E), Bandwidth (BW), Signal Strength (SS)}. Generally, in any network delay is induced or experienced due to the traffic condition of congestion, along with it if the nodes and links fail, the network topology dynamically changes; therefore, finding Po in such changing dynamics is a computationally expensive task because the complexity O(N²) of computation is exponential with the number of nodes(N/V).

IV. REVIEW OF LITERATURE

This section discusses the existing literature regarding the application of RL to network routing. A recent work carried out by Guo et al. [5] developed a quality-of-service (QoS) aware secure routing technique in software-defined Internet of Things (SD-IOT). This scheme exploits SDN's exclusive characteristics and considers the routing path planning under malevolent attacks to achieve QoS. A few research literature on underwater sensor network (UWSN) specific RL-based routing congestion control techniques [6]. In this approach, the next forwarder nodes are selected based on the current buffer state, location, and remaining energy of the one-hop neighbor nodes. The adoption of RL based routing scheme is considered for magnetic induction communication in UWSN [7]. In this study, the authors have derived the iterative formula of the Q-table by considering distance and energy path metrics. The RL-based routing scheme to the Mobile Ad-hoc Network (MANET) is considered by [8]. A routing algorithm is designed to select the next hop for packet forwarding based on the joint mechanism of stochastic approximation, function approximation, and RL. The authors in the study of [9] used RL's Q-learning approach to design an efficient and enhanced gradient-oriented routing strategy for balancing energy

consumption and QoS in Wireless Sensor Network (WSN). RL-based opportunistic routing scheme is suggested by [10] to support high-dimension data streaming in the application of multi-hop wireless networks. The application of Q-learning for Unstructured Peer-to-Peer Networks is considered by [11]. A load-balancing intelligent routing is devised to improvise query search efficiency for both intragroup and intergroup peers and reduce loads of queries under higher churns and heavy network workloads. A concept of a multi-agent RL scheme is introduced by [12] to devise an optimal routing scheme for the underwater optical WSN. In this approach, nodes' link quality and remnant energy are considered to develop an efficient routing algorithm suitable to dynamic communication environment and prolong network service duration. Also, Q-value initialization and the variant learning rate are devised to boost the routing algorithm's convergence. Some existing studies have implemented an RL-based routing scheme in Cognitive Radio Networks (CRNs). The authors in [13] examined the routing issue in energy harvesting in a multi-hop CRN communication scenario. RL-based route selection mechanism is developed considering the various factors affecting routings, such as the number of hops, the node's distance, energy consumption during the communication process, and remnant energy. Various routing schemes have been introduced in the context of unmanned aerial vehicle (UAV) communications in complex network environments [14-16]. However, such schemes are associated with bottleneck issues. In this regard, the use of RL for routing algorithms in UAV applications has gained wide attention. The researchers in the study of [17] suggested a Q-learning-based load balancing routing technique to handle relay traffic in UAV communication. The presented technique estimates network load through the queue status obtained from the ground-vehicular nodes. A reward function control is also implemented for quick learning feedback of the reward values under a dynamic communication environment. In [18], a global routing scheme using where each mobile node participates in the route discovery process. The presented global routing protocol is compared with the local routing protocol, where each intermediate node performs routing then based on its energy profile. Both these approaches are designed based on the Q-learning approach of RL. The concept of RL is adopted in routing optimization at the network level for minimizing interferences and delay in channel switching [19]. The routing decision is carried out based on past events and predicted routing decisions of primary users. An RL agent is devised into the cross-layer approach towards assisting the transfer of channel information to the network layer. In [20], adopted deep RL mechanism to address sampling problems and optimal route selection in the highly complex and dynamic network communication scenario. A hierarchical routing scheme based on Q-learning is presented by [21] to enhance message delivery rate performance with less delay and hops in Vehicular Ad-hoc networks (VANET). Here, a network region is divided into different grids, and the presented routing scheme discovers the next optimal grid towards the end-point or target point. It also finds a vehicle moving towards the next optimal grid for communicating data transmission. The authors in [22] presented a collaborative RL model to design a tree-based routing scheme that captures the network's dynamic

characteristics, such as several nodes and uncertain traffic, to provide QoS-aware services in Cloud Content Delivery Networks. In [23], the authors have used RL for network traffic engineering. The presented techniques learn to select critical traffic flows in the matrix and reconstruct optimal routes based on flow information in the matrix to balance link utilization in the network. In [24], RL-based intelligent routing is developed to provide a complete view of the network and fast data forwarding process in SDN-enabled networks. In [25], Cluster-oriented cooperative Scheduling scheme using RL to improve vehicular networks' communication efficiency and reliability.

V. OPEN-AI: GYM AND NETWORK ENVIRONMENT SETUP

With the appropriate function approximation, the methods like Q-Learning and policy gradients may provide better performance even under challenging environments. The popular benchmark for RL includes 1) Arcade Learning Environment (ALE), and 2) RL Lab (RLL).

Recently, Open-AI-Gym is the most popular benchmark with the following essentials into it:

- Combines best elements of ALE and RLL and having a diverse collection of tasks (Environment) with a standard interface.
- OpenAI-Gym provides the episodic setting of RL, where the agent experiences are broken down into a series of episodes.
- The agents' initial State is randomly sampled from distribution in each episode. The interaction proceeds until the environment reaches a terminal state.
- The goal in episodic RL is to maximize the expectation of total reward per episode and achieve a high level of performance in a few episodes as possible.
- OpenAI does not include an agent class.

Process: Function of -Open-AI Gym

1. Sample environment state [return first observation]:

Ob0 = env.reset()

2. Agent chooses first action:

A0=agent.act(Ob0)

3. Environment returns observations:

Info =env.step(A0)

Ob1, Rew0, Done0

4. Reward and a Boolean flag indicates

- if the episode is complete

A1=agent.act(Ob1)

Env.step(A1)

Ob2, Rew1, Done1

[A99 =agent.act(O99)]

Info= env.step(A99)

Ob100, rew 99, Done99

5. Done 99 = = True →Terminal

Design assumptions in OpenAI-Gym include i) the Only environment but no agent, ii) Emphasis on the sample, not just final performance, iii) Encourage peer review, not competition, iv) Strict versioning of environment, v) Monitoring by default.

OpenAI-Gym is a collection of partially observable Markov decision processes (POMDP), and the current environment consists of i) Algorithms, ii) Atari, iii) Box2D, iv) Classic Control, iv) Mujoco, v) Robotics, and vi) Toy text. It does not consider any environment explicitly for a network; therefore, a custom environment for the network is created as SimpleNetwork with a different number of nodes.

VI. Q-ROUTING MODEL VALIDATION WITH RULE-BASED ROUTING

This section presents outcome analysis and performance assessment of the proposed Q-routing on the customized OpenAI Gym environment, namely, Net-AI Gym [26]. The development and design of the proposed system are carried out on the numerical computing platform, and scripting of the proposed technique is done in Python. Different case studies have been considered to evaluate the stability and consistency of both Net-AI gym and Q-routing scheme in the performance analysis.

A. Case:1 Network with 6-Nodes

In this scenario, a network with six nodes is being considered.

Table I presents test case one with a network scenario with six nodes.

TABLE I. NETWORK SCENARIO-1: 6-NODES

Observation space	Discrete (6)
Action space	Discrete (6)

In this scenario, a network with six nodes is being considered. The agent will be examined with various networks containing various nodes. Both rule-based algorithms, as well as Q learning algorithms will be tested. The networks are designed in such a way that they simulate the actual internet.

Fig. 5 shows the network deployment scenario. The network contains six nodes. Randomly two nodes are selected and made into source and destination. The Net-AI gym platform has a unique reward system where if the agent tries to transfer the packet from one node to another, the packet will be dropped if the nodes are not connected. Every transfer agent will get a negative reward. However, the agent will get a positive reward when the packet reaches its destination. So in a way, the reward shows the throughput of the system.

Fig. 6 shows how the throughput is increasing over some time. After many episodes, the throughput starts increasing. The graph clearly shows the increase in the throughput and hence the reward. The agent initially takes some random moves to explore the network.

In Fig. 7 shows an analysis of the proposed Q-routing scheme concerning Epsilon Vs; the episode with six nodes network. The epsilon represents the probability of the agent taking up random moves. As can see, as the episodes progress,

epsilon decays down. This means, in the initial episodes, the agent may take more random moves; the probability of it reduces as the episodes progress.

Fig. 8 shows an analysis of the proposed Q-routing scheme concerning Episodes Vs. path length. The path length of 0 represents that the packet is lost. The path length of 2 is optimal. If we can observe the epsilon plot and the path length plot together, path length reduces to optimal length when epsilon decay below 1% which means the agent stops exploring.

Fig. 5. An Environment with 6- Nodes Network.

Fig. 6. Network with Node=6, Episodes vs. Rewards.

Fig. 7. Network with node=6, Epsilon Vs. Episode Define Episode.

Fig. 8. Network with Node=5, Episode vs. Pathlength.

B. Case:2 Network with 50-Nodes

In this scenario, a network with fifty nodes is being considered. Table II presents test case one with a network scenario with six nodes.

TABLE II. NETWORK SCENARIO-2: 50-NODES

Observation space	Discrete (50)
Action space	Discrete (50)

However, when the network is with higher nodes, as shown in Fig. 9, the study comes across a different type of result. The probability of dropping is much more compared to a smaller network. As it can be observed, the agent will start delivering packets only after 1000 episodes.

Fig. 9. An environment with 50- Nodes Network

This indicates that the more significant nodes, the more time the agent will take to learn the correct path. This is as expected.

As shown in Fig. 10, 11, and 12, even though the epsilon decay is much similar to that of the lower node network, if we observe the path length graph, the agent takes a very long time to find any let alone the longer path. This is because the network contains many gateway nodes. Due to which there will

be many nodes connected to a common node. This exactly happens in a real-world network scenario. The gateways are usually connected to a high number of other nodes and national links. Very rarely will any node be connected directly to a significant network. As it can be observed, the optimal path length here is 4. Even with 50 nodes, the optimal path length is only 4. This is true even in a real-world scenario.

Fig. 10. Network with node=50, Episode vs. Rewards.

Fig. 11. Network with node=50, Episode vs. Epsilon.

Fig. 12. Network with node=50, Episode vs. Pathlength.

C. Case:3 Network with 100-Nodes

In this scenario, a network with fifty nodes is being considered. Table III presents test case one with a network scenario with six nodes.

TABLE III. NETWORK SCENARIO-3: 100-NODES

Observation space	Discrete (100)
Action space	Discrete (100)

Fig. 13 shows a network environment with 100 nodes. The study has adopted the monte Carlo method here to evaluate the algorithm. A different case study has been considered to see how the algorithm performs with an increasing number of nodes. The scalability of the network routing algorithm is an essential aspect.

In Fig. 14, the 100-node network takes around 2000 episodes to learn the optimal path. As shown from graph trend, till episode 2000, there is no reward at all. Only after the algorithm learns the route, it starts to perform.

Fig. 15 shows an analysis of the proposed Q-routing scheme concerning Epsilon Vs; an episode with a 100 nodes network. The epsilon represents the probability of the agent taking up random moves. As can see as the episodes progress, Epsilon decay is the same as usual. The same rule works here as well.

Fig. 13. An Environment with 100- Nodes Network.

Fig. 14. Network with node=100, Episode vs. Rewards.

Fig. 15. Network with node=100, Episode vs. Epsilon.

Fig. 16 shows an analysis of the proposed Q-routing scheme concerning Episodes Vs. path length. As shown from the path length plot, the algorithm finds a suitable path after 2000 episodes. Even after epsilon decay fall below 1%, the algorithm has not found a path yet. Even if the algorithm does not explore, the algorithm finds a path in the network. Also, it can be analyzed based on the closer analysis that the optimal path length here is 3, and it has been earlier; there is no relationship between optimal path length and the number of nodes.

Fig. 17 demonstrates a comparative analysis for all three case studies of different network sizes. As it can be observed, once the algorithm learns, then the performance is the same on all the networks. However same is not true with rule-based methods.

As it can be seen in Fig. 18, the rule-based method never settles for a single path. This is due to the dynamic nature of the network. Connections and the weights keep changing. Hence, the path length also keeps varying.

Fig. 19 shows an analysis of Episodes vs. Pathlength for the proposed Q-learning scheme. In contrast to the path length plot of the rule-based method, the Q learning method always follows the optimal path after some time since it can predict the changes in the network before they can occur.

Fig. 16. Network with node=100, Episode vs. Pathlength.

Fig. 17. Comparison Scenario-1, Two and, 3.

Fig. 18. Rule-Based: Episodes vs. Pathlength.

Fig. 19. Q-Learning Based: Episodes vs. Pathlength.

From the comparative analysis in Fig. 20, it can be analyzed that the rule-based method exhibited higher throughput. However, the Q-routing method is highly efficient once it learns the policy. Hence, in the long run, Q learning produces higher throughput compared to the rule-based method. Based on the overall analysis it can be observed that the proposed system offers a good scope for solving network related problem with RL agent algorithm, which can be well evaluated in the proposed customized Net-AI-Gym environment. The proposed system is found to be scalable to

both small network and large network as it perform well in all the three cases of network with different number of nodes. Based on the comparative analysis the proposed Q-learning algorithm outperform the rule-based algorithm in terms of episode vs. reward which shows the stability and efficiency of proposed system to address routing related problem.

Fig. 20. Rule-Based vs. Q-Learning (Episodes vs. Reward).

VII. CONCLUSION

In this paper, the evaluation of the newly designed environment on the Open-AI Gym, namely Net-AI-Gym, is performed for agent algorithm based on the Q-learning is evaluated. The scalability limitation of network routing protocols using rule-based methods is being overcome with the RL-based Q-routing protocol. The performance validations between rule-based and RL-based Q-learning are carried out, and it is being found that the Q-learning performs better than rule-based routing protocols concerning episodes Vs. Rewards. The self-validation test for scalability for varying nodes provides a consistent result. However, the constraints of space optimization are planned as future research work. This is the first of its kind of work, custom-developed for routing protocol on the newly designed environment. In the future work, the proposed work can be extended towards improving the performance of the system and evaluation of RL algorithm on the customized Net-AI Gym environment with different technique dealing with a complex, high-dimensional state space.

Abstract—Nearly 30% of the people in the rural areas of Bangladesh are below the poverty level. Moreover, due to the unavailability of modernized healthcare-related technology, nursing and diagnosis facilities are limited for rural people. Therefore, rural people are deprived of proper healthcare. In this perspective, modern technology can be facilitated to mitigate their health problems. ECG sensing tools are interfaced with the human chest, and requisite cardiovascular data is collected through an IoT device. These data are stored in the cloud incorporates with the MQTT and HTTP servers. An innovative IoT-based method for ECG monitoring systems on cardiovascular or heart patients has been suggested in this study. The ECG signal parameters P, Q, R, S, T are collected, pre-processed, and predicted to monitor the cardiovascular conditions for further health management. The machine learning algorithm is used to determine the significance of ECG signal parameters and error rate. The logistic regression model fitted the better agreements between the train and test data. The prediction has been performed to determine the variation of PQRST quality and its suitability in the ECG Monitoring System. Considering the values of quality parameters, satisfactory results are obtained. The proposed IoT-based ECG system reduces the health care cost and complexity of cardiovascular diseases in the future.

Keywords—Internet of things (IoT); electrocardiogram (ECG) monitoring system; ECG signal parameters; cardiovascular disease; logistic regression model

I. INTRODUCTION

IoT concept can be utilized in versatile areas such as intelligent health care system, intelligent agriculture, environmental impact predictions, automation industries, etc. [1, 2, 3, 4]. World Health Organization (WHO) [5] mentions

that the uncertainty of health conditions is a widespread problem for aged people. Aged people need to check their health conditions very frequently, especially for senior cardiovascular patients. Existing cardiovascular diagnosis systems need to be improved, including modern technology to detect the heart condition in a low cost, accurate and timely manner [6, 7]. Considering the heart-related issue, electrocardiogram (ECG) monitoring used extensively in rural hospitals and health research centers [8].

Rather than IoT, Cyber-Physical systems (CPS) can be considered as data-centric technology. CPS integrates innovative functionality processes that facilitate communication, computation, and control through IoT [9]. Moreover, it contributes to an advanced intelligence system that significantly affects social life [10]. CPS concept can be activated through Micro Electromechanical Systems for networking in monitoring, computing, and controlling the physical world.

The work concentrates on developing a portable heart monitoring system in the corporation of Electrocardiogram (ECG) technology [11]. Three heart rate detection sensors are utilized to make the device that generates analog data from ECG signals. Moreover, the analog data are converted into CSV format by Arduino microcontroller. The collected data is transmitted to the cloud through a local server, processed into P, Q, R, S, T ECG parameters, and analyzed by the machine learning algorithm. The ECG monitoring process detects ECG signals incorporating non-intrusive sensors, and the signal obtained from sensors transmits through the smartphone by wireless transmission methods, such as Zigbee or Bluetooth [12, 13]. Steady heart rate detection and an immediate heartbeat monitoring system are viable parameters for heart

disease. Experimentation indicated that cardiovascular disease could be treated, controlled, and prevented in a steady data monitoring process using ECG signals [14, 15].

A wearable ECG monitoring gadget-based system has been designed to associate with IoT and cloud service architecture for monitoring heart disease in this study. The sensors placed in the human chest records different ECG data through Arduino, and these data are transmitted to the IoT cloud without any delays. The HTTP and MQTT servers are put in the IoT cloud to provide users with quick and timely access to ECG data. The acquired data is stored in a non-relational database that can continuously improve data storage velocity and flexibility. In addition, a graphical user interface, accessible via the internet, is developed for the availability of cardiovascular-based data for medical experts to analyze the patient's heart conditions. The proposed IoT cloud-related systems in this work ensure the effectiveness, reliability, and accuracy of the data collected.

In addition to that, the measured heartbeat and ECG report of the patient obtained from this intelligent information system can be sent quickly through the text message, web server, and mobile application. The LIVE monitoring option of the webserver can be used by nurses and patient relatives for emergency cases. This process can be used for rural people at an affordable cost.

The features of the system are below:

- It will be a handy tool because it displays all the data and information collected solely from the internet. As a result, it minimizes the stress and pressure of the patient's relatives who work outside the home.
- Doctors can increase diagnostic accuracy by being connected to the health care system via IoT since they have all the relevant patient data at their fingertips. In a nutshell, it allows for continuous and remote patient monitoring.
- Doctors and family members may conduct their jobs without fear because they can track the patient's health status from anywhere. It also gives alerts anytime when a specific health parameter exceeds the optimal limit. Additionally, by getting a warning, doctors and family members can take the appropriate action and saves lives in the emergency.
- Rather than visiting or spending time at hospitals, most older people choose to stay at home with their loved ones. But, on the other hand, people suffer from a variety of diseases because of their stressful lifestyles and become very weak at old age. Furthermore, this project will benefit ICU patients.

II. MATERIALS AND METHODS

A. Proposed System

The following components are used to run the project:

- 1) Arduino MEGA ATmega2560
- 2) Sensors

- a) ECG AD8232
- b) Heartbeat sensor MAX30100
- 3) Wi-Fi module ESP8266 A1 Cloud Inside
- 4) Jumper wires
- 5) Breadboard
- 6) Laptop/ computer.

In the middle of the devices, an ECG monitoring system is used. First, the patient will press their finger against the heartbeat sensor, and the IR sensor's ray will count the beats from the blood flow. Then, the H-Beat button will be pushed and waited for 20 seconds after counting the beats from the blood flow. Finally, the outcome will be transmitted, and the heartbeat rate will be displayed on a laptop screen or a mobile screen utilizing a web page or a mobile app. This complete process is depicted in Fig. 1. Next, the ECG sensor will be affixed to the patient's chest, and the patient will press the 'ECG' button to activate the function. Therefore, the ECG graph, signal, or digits will be generated.

B. Electrical Components Control Unit

An Arduino Mega 2560 microcontroller board [16, 17] is utilized to complete the project. A 16 MHz crystal oscillator, 54 digital input/output pins, 4 UARTs, 16 analog inputs, a USB connection, an ICSP header, a power jack, and a reset button are included on the board. The ATmega2560 board is powered through a USB or an external power supply. The source of energy is automatically selected. Two power adapters are used. One is a 9v battery, and the other one is a 5v laptop USB. Heartbeats, ECG, and Wi-Fi sensors are getting 3.3v from those power sources. If more power is driven in the sensors, they may get damaged. Registers are used to minimize the source voltage and avoid damages.

C. Hardware and Software Implementation

Arduino is the system's central control unit. A heartbeat sensor, an ECG sensor, and various manual buttons are available on the input side. The Arduino com port displays the output. The Wi-Fi Module allows to transfer of data to the cloud, and once the data is uploaded, the results can be reviewed by signing in to the server using a computer or smartphone. The block diagram (Fig. 2) describes the complete hardware process.

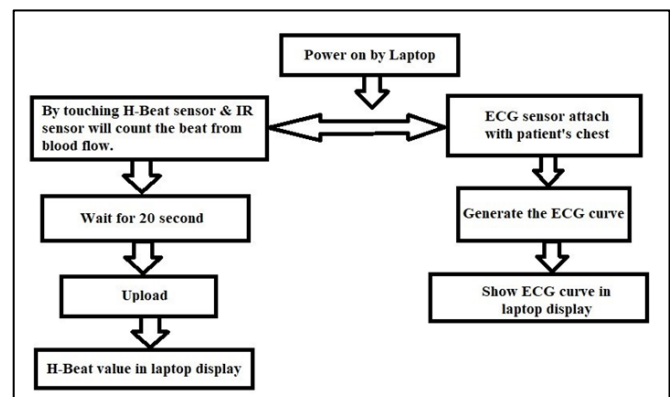

Fig. 1. Working Flow Diagram.

Fig. 2. Design of the IoT Device-based ECG System.

The software and hardware parts are merged in software implementation. Necessary code was written to command the hardware. In the coding section, the Arduino pin 2 (SDA and SDL) is used to initialize the cardiac bit sensor pin. Two other buttons are initialized in pin GND and 3.3v. ECG sensors LO+ and LO- are initialized in Arduino pin 10, 11. Additional controls are initialized in pin OUTPUT to A0, GND to GND, and 3.3v to 3.3v. The ECG and Heartbeat values are both zero at the beginning. The Wi-Fi cloud module contains an auto-configuration method. Wi-Fi modules RX and TX are initialized in Arduino pin 9 and 8, CH_EN and VCC are connected in Arduino pin 3.3v. Another pin named GPIO_0 is used for uploading the program to the Wi-Fi module.

In the beginning, combining two different sensors, programs are launched simultaneously and get the output result in the COM3 port of the Arduino. In the heartbeat approach, the hardware is employed to read the heartbeat. First, the heartbeat is counted for 20 seconds. At which point the heart bit pin raises high, the value is calculated. While taking data, the heartbeat is estimated for 60 seconds or 1 minute. Lastly, the heartbeat data is uploaded to the cloud. The command line for the ECG method is the same as the heartbeat method. If the ECG count is less than 50, then count the ECGs and send analog or digital data to the cloud, which is subsequently sent to the MQTT web server and displays the ECG result. The analog ECG data is uploaded and converted to digital data using the loop approach. ECG data is uploaded when it scores greater than 80, and for a lower score, an ERROR message is shown.

Wi-Fi module ESP8266 is connected to Arduino for uploading the MQTT program [18]. ESP8266 GPI 03 pin is connected to GND. After uploading the program, the RX, TX, and GPIO_0, the pin is unplugged. The RX and Tx pin of ESP8266 is connected to TX pin 8 and RX pin 9 of Arduino. After doing all these procedures, the project runs, and it transmits the sensors data to the cloud. The cloud visualizes the result on the MQTT box.

D. MQTT Box Site Implementation

REST has proven to be one of the most important advancements for Web applications [19]. REST stands for Representational State Transfer, and it is a technique of composing hypermedia applications. Structures for constructing RESTful Web administrations are currently

included in every significant development dialect. The hardware of the project is related to a program to implement and visualize the website. On the webpage, it shows the current value. A web front interface was used in the MQTT box. For this purpose, we downloaded the MQTT box and installed the software. When the heartbeat is measured, data is uploaded into the cloud server, and then it transmits the result to the MQTT box to show real value on the website according to date and time. The ECG result is shown using a web service that calls data from the server and generates it using Arduino code.

To design and test the MQTT communication protocol, a developer's helper application was used. MQTT Box for ECG Monitoring System boosts the MQTT process. Apps for Mac, Linux, and Windows are also available for MQTT Box. In the ISM database, the cyber-level serves as the significant information hub [20]. To deploy cyberspace, information is extracted from each source and compiled. With massive data, a specific analyzer is employed to extract data that gives a better sense of each patient's ECG data monitoring status.

III. EXPERIMENTAL ANALYSIS AND RESULTS

A. Dataset Configuration and Analysis

We created a dataset to train the Gradient Boosting Model (GBM) [21, 22, 23]. Approximately 2000 samples were collected from volunteers. In addition, related information like age, 'P,' 'Q,' 'R,' 'S' and 'T' were also collected. Table 1 shows a tiny part of our dataset.

Exploring the relationship among different variables, some concise analyses were done to measure the mean, median, count, minimum, maximum, standard deviation, and quartile value of the dataset, which have been described in Table 2.

TABLE I. DATASET CONFIGURATION

Record No	Age	P	Q	R	S	T
1	21	91.6	100.0	100.0	100.0	90.0
2	23	100.0	100.0	100.0	100.0	100.0
3	30	100.0	100.0	100.0	100.0	100.0
4	25	100.0	100.0	100.0	100.0	100.0
5	20	78.5	100.0	80.0	100.0	100.0

TABLE II. DATASET MEASUREMENTS

	R. N	Age	P	Q	R	S	T
Count	20.00	20.00	20.00	20.00	20.00	20.00	20.00
Mean	10.50	29.85	97.06	96.26	95.26	96.51	97.66
Std	5.92	8.86	5.88	7.57	8.33	7.15	4.50
Min	1.00	18.00	78.50	76.19	76.19	76.19	85.00
25%	5.75	22.75	98.43	98.43	93.53	98.43	98.63
50%	10.50	28.50	100.00	100.00	100.00	100.00	100.00
75%	15.25	36.25	100.00	100.00	100.00	100.00	100.00
Max	20.00	45.00	100.00	100.00	100.00	100.00	100.00

B. Exploring Attributes type Cleaning the Dataset

The model used the parameters described in Table 3.

Drawing Box Plot, many attributes have been found containing outliers or extreme values (Fig. 3). All the observations along with outliers were deleted. After that, some robust statistics were utilized to calculate the different features of this dataset. However, the entire dataset was considered to estimate various measures. The dataset contained no null values and needed not to treat with any null values.

C. Dependent and Independent Variables

Quality is dependent on the target variable, and all other variables are independent variables. From these target values, a heart condition was measured (Table 4). There are six distinct quality values through analysis, and these are 14, 1, 1, 1, 2, 1. Grouping the quality, we found that most of the heart is in 14, 2 & 1, indicating the condition as good. We found two lousy quality hearts in our dataset, and three people were close to a tragic situation.

TABLE III. DATASET PARAMETERS

S.N.	Column	Non-Null Count	Data Type
1.	Record No	20 not_null	int64
2.	Age	20 not_null	int64
3.	P	20 not_null	float64
4.	Q	20 not_null	float64
5.	R	20 not_null	float64
6.	S	20 not_null	float64
7.	T	20 not_null	float64

Fig. 3. BOX Plot of Dataset.

TABLE IV. QUALITY VALUES FOR GOOD OR BAD HEART CONDITION

Mean value	Quality value
76.13	1
80.00	2
82.35	1
92.85	1
93.75	1
100.00	14

Fig. 4. Quality Wise Pie Chart.

Fig. 5. Investigation of Variables Correlation and Covariance

D. Dataset Visualization

A quality-wise Pie-Chart was drawn that describes the percentage ratio of the six qualities. In the chart, yellow indicates quality 14, red, green, blue, and orange indicate quality 1 and 2. According to the values mentioned in Fig. 4, it can be concluded that 70.00% sample's heart condition was excellent when collecting data.

Another measurement was run to investigate the correlation and covariance of different variables with the target variables. The outcomes identify variables responsible for various heart conditions. The correlation result is mentioned in Table 5 and covariance in Table 6.

After sorting the significant correlations, we found that 'Q' (ECG, Q - parameter), 'S' (S - parameter), 'T' (T - parameter) & 'P' (P - parameter) have some moderate correlation, comparing with other attributes. On the other hand, 'R' (R - parameter included angina) has a significant positive correlation with Q (Q - parameter included angina).

TABLE V. CORRELATION VARIABLES

	R. N	Age	P	Q	R	S	T
R. N.	1.0000	0.4431	0.1777	0.0657	0.1772	0.0408	0.2775
Age	0.4431	1.0000	0.4338	0.1623	0.2878	0.1383	0.1095
P	0.1777	0.4338	1.0000	-0.2135	0.2052	-0.2072	0.1713
Q	0.0657	0.1623	-0.2135	1.0000	0.8460	0.9893	0.4546
R	0.1772	0.2878	0.2052	0.8460	1.0000	0.8372	0.3474
S	0.0408	0.1383	-0.2072	0.9893	0.8372	1.0000	0.5011
T	0.2775	0.1095	0.1713	0.4546	0.3474	0.5011	1.0000

TABLE VI. COVARIANCE VARIABLE

	R. N	Age	P	Q	R	S	T
R. N.	35.000	23.236	6.1802	2.945	8.735	1.726	7.389
Age	3.236	78.555	22.594	10.888	21.256	8.760	4.371
P	6.180	22.594	34.533	-9.498	10.046	-8.703	4.530
Q	2.945	10.888	-9.498	57.285	53.345	53.515	15.485
R	8.735	21.256	10.046	53.345	69.405	49.846	13.027
S	1.726	8.7607	-8.703	53.515	49.846	51.072	16.118
T	7.389	4.3712	4.530	15.485	13.027	16.118	20.251

E. Comparison among Significant Variables and Target Variables

Comparing among significant variables and 'R' variables, the relationship between the variables can be virtualized. The correlation of the 'R' variable with other variables is shown in Table 7. 'Q' type makes an essential factor for having heart disease because most cases with 'R' I have chest pain. Two 'R' variables raise to level 120 – 150 among the age range 40 – 60. Fig. 5 represents the change of various parameters. From the findings, it can be concluded that people who have heart disease have maximum high blood pressure, and cholesterol is very high. Par's plot shows the distribution of single variables depicted in Fig. 6.

TABLE VII. CORRELATION WITH OTHER VARIABLES

R	1.000000
Q	0.846016
S	0.837237
T	0.347479
Age	0.287883
P	0.205213

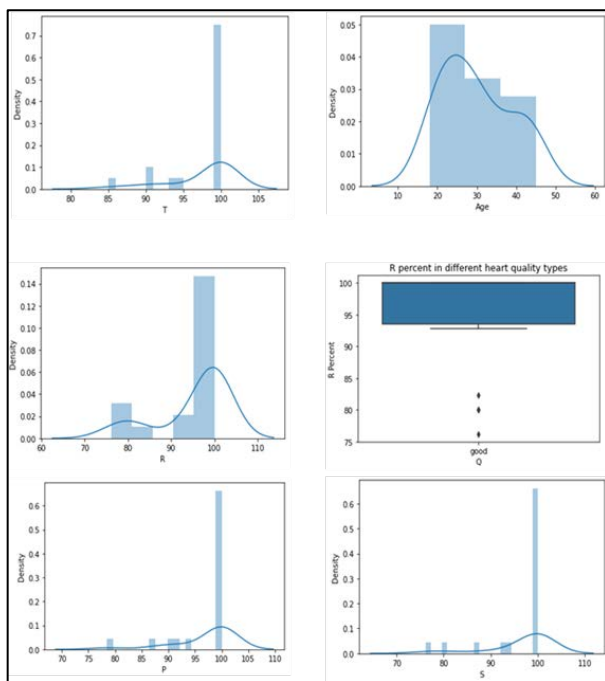

Fig. 6. Change of Various Parameters.

F. Heartbeat Result Analysis

The heartbeat result was analyzed by an automatic blood pressure system to see if the heartbeat sensor is functional or not (Fig. 7). For further processing, data were collected from five different persons of a specified age range. The information was listed along with a particular day and time.

G. ECG Report Analysis

Three electrodes are inserted on the patient's chest at first. The red electrode is implanted on the right side of the chest. The green electrode is situated on the left side of the chest, whereas the yellow electrode is located under the green electrode. Then the ECG push button is pressed. The value is converted into a curve and uploaded to the webserver and virtualized through mobile app and website. Arduino com port result is shown in Fig. 8. The key feature of the measured ECG is depicted in Fig. 9. ECG_PQRST data from the device is mentioned in Table 8.

Fig. 7. Pair Plots among the Variables.

Fig. 8. Heartbeat Result Analysis.

Fig. 9. Arduino com Port Result.

TABLE VIII. ECG_PQRST DATA FROM THE DEVICE

Record No	Age	P	Q	R	S	T
1	21	91.6	100	100	100	90
2	23	100	100	100	100	100
3	30	100	100	100	100	100
4	25	100	100	100	100	100
5	20	78.5	100	80	100	100
6	22	100	82.35	82.35	87.5	100
7	24	90	100	100	100	90
8	45	100	100	100	100	100
9	43	100	80	80	80	85
10	26	100	100	100	100	100
11	19	100	76.19	76.19	76.19	94.54
12	18	93.75	93.75	93.75	93.75	93.75
13	34	100	100	100	100	100
14	35	100	100	100	100	100
15	30	100	92.85	92.85	92.85	100
16	41	100	100	100	100	100
17	40	100	100	100	100	100
18	44	100	100	100	100	100
19	29	87.5	100	100	100	100
20	28	100	100	100	100	100

H. ML (Machine Learning) Intercept and Coefficients

A statistical tool known as linear regression predicts the future value of heart condition measurement parameters (P, Q, R, S, T) by analyzing the past. The technique uses the least square method to draw a straight line that minimizes the difference between current values and resulting values. The best fit line associated with the n points (S1, T1), (S2, T2), (Sn, Tn) has the form $y = mx + b$. Using the formula and we have got the intercept value which is 14.319164821638992.

From the analysis, the coefficient value for S is 0.962445, for T is -0.173491. For age, the value was 0.162937, where a positive sign implies that the response variable increases when the predictor variable rises. In contrast, a negative sign suggests that the response variable drops when the predictor variable increases.

I. Prediction

The score of one variable is predicted based on the scores of a second variable. The criterion variable is the variable that forecasts and is denoted as Y. The variable on which the predictions are based is the predictor variable and abbreviated as X. The project used only one predictor variable: Y. The projections of Y are evaluated when it is plotted as a function of X from a straight line. This complete process of prediction is listed in the Table 9.

In Fig. 10 indicates a positive association between X and Y. If Y is forecasting based on X, the greater the value of X may provide an accurate prediction of Y. The regression line in the figure is made up of the expected score on Y for each possible value of X.

Fig. 10. The Key Feature of the Measured ECG.

TABLE IX. PREDICTION

S. N	Actual	Predicted
2	100	98.10267
5	82.35	84.76861
17	100	100.3838
19	100	97.7768
12	100	98.75442

Fig. 11. Prediction Plot.

The error for a point is the difference between the actual value and the predicted value. From our analysis, the mean absolute error value is 1.633702533697678, and the mean squared error is 3.2181888486775514. Thus, the accuracy percentage is 93.5434261396096.

The bar diagram below (Fig. 12) shows the relationship between actual and predicted plots. For example, in Fig. 11, the blue indicates true, and the orange represents the expected value.

Fig. 12. Relationship between Actual and Predicted Data.

J. Cost Analysis

In developing countries, hospitals buy a lot of new medical equipment. Famous hospitals import medical equipment from other countries. As a result, hospital administrators pay a significant amount of money to bring the equipment to provide the best possible service to their patients.

The project described in this article is not costly. Every component is inexpensive and of good quality. As a result, it is affordable to everyone without causing financial hardship. The list of devices selected for ECG monitoring system purposes is listed in Table 10.

TABLE X. COST ANALYSIS

Components	Unit Price
Arduino Mega 2560	800/-
Heartbeat/Pulse sensor (MAX30100)	750/-
ECG sensor (AD8232)	1250/-
Esp8266 A1 cloud Wi-Fi module	180/-
CP2102 USB 2.0 to TTL UART Module	180/-
Male-Female Jumper Wires	100/-
400 Tie Points Breadboard White	100/-
Total	3360/-

IV. CONCLUSION

We have created and executed an ECG monitoring system that is entirely based on current IoT technologies. The IoT-based ECG monitoring system is constructed based on the proposed design. IoT-based healthcare platform links with smart sensors affixed to the human body for health monitoring. We talked about IoT-based patient monitoring systems in this article. Smartphones or gadgets use intelligent technologies, and we have discussed the advantages, disadvantages, and opportunities. Continuous remote monitoring is required for observing the medical patient. Our research work provides the ability to monitor patients via web app services and mobile massage services continuously. This research also contrasted the early medical system to modern health monitoring. The work will bring change in medical science and be a blessing for rural areas. The research work has proved its benefits already. We are planning for the further

development of the project by promising that one day every people of our country will get immediate medical treatment with the help of our project.

Design of a Plastic Shredding Machine to Obtain Small Plastic Waste

Witman Alvarado-Diaz¹, Jason Chicoma-Moreno², Brian Meneses-Claudio³, Luis Nuñez-Tapia⁴

Image Processing Research Laboratory (INTI-Lab)
Universidad de Ciencias y Humanidades
Lima, Perú

Abstract—One of the biggest environmental problems in the world is the excess of plastic waste. Although it is true, around the world there are companies that are responsible for recycling plastic waste, since 42% of plastics that are generated worldwide have a single utility. In Peru, the culture of recycling is not promoted, each year approximately each person uses 30 kilos of plastic and that only in Metropolitan Lima and Callao 46% of plastic waste is generated nationwide. In view of this problem, this article will design a plastic shredding machine to obtain small plastic waste to help people to be dedicated to the recycling industry in an automated way, it would also generate jobs since it requires a staff in charge of the machine and it will also be extremely useful to reduce plastic pollution in the environment, which due to COVID-19 is increasing. Through the design of the plastic waste shredding machine, the plastic will be selected by color and type of plastic composition, whether it is Polyethylene Terephthalate (PET), High Density Polyethylene (HDPE), Low Density Polyethylene (LDPE), Polychloride vinyl (PVC) or Others (Plastic Mix), then it will go through the shredding process to become small plastic waste, which could be turned into filament for 3D printer.

Keywords—Automation; pollution; filaments; recycling; plastic waste

I. INTRODUCTION

One million plastic bottles are bought every minute and 500 billion bags are used per year. Eight million tons end up in the oceans every year, threatening marine life [1]. The great problem of plastic is inherent to its usefulness: most of the products made of this material have a very short useful life and are usually easily disposed of [2], for this reason there are many companies that are in charge of recycling plastic to give them different applications. 42% of the plastic used in the world is destined to the packaging of food and manufactured products. In other words, single-use plastics that barely spend a few minutes in the hands of consumers [3]. If no action is taken, by 2050 there will be about 12 billion tons of plastic waste distributed in landfills and the ocean [4].

Plastic in Peru represents 10% of all the waste generated in the country, since 2015 we have had a huge growth in plastic [5]. On average in Peru, approximately 30 kilos of plastic are used per year per citizen [6]. Each year, there are about 3 billion plastic bags, almost 6 thousand bags per minute. In Metropolitan Lima and Callao, 886 tons of plastic waste are generated per day, representing 46% at the national level [6] due to the fact that the population in Peru grows towards the cities, 75% live in urban areas, and this means more garbage

production [7], causing, in recent years, several districts such as Comas and San Martín de Porres were declared in sanitary emergency because their garbage collection systems collapsed [8]. According to the ex-Minister of the Environment Muñoz Fabiola, she indicated that in other countries there are no sanitary landfills and that absolutely everything is valued [9].

The quarantine generated by COVID-19 in the world presented positive effects at the environmental level: improvements in water and air quality and less pollution of the ozone layer [10]. The sanitary measures that are now being faced by the COVID-19 causes the index of plastic material to increase the figure spontaneously. The plastics that stand out the most for their use are gloves, masks, alcohol gel containers and plastic bags; There are also the Polyethylene due to the increase in delivery. There are no exact figures, but organizations estimate that household waste grew by 30% to 40% [11].

In Peru, a biodegradable plastic is one that degrades to carbon dioxide (CO₂), methane (CH₄), water and biomass by the action of microorganisms, contains a minimum of 50% volatile solids, has limited concentrations of dangerous chemicals and its degradation is carried out in a reasonable time: 90% degradation in 6 months in the presence of oxygen (O₂) and 2 months in the absence of O₂ [6]. These are the measures that are being taken in Peru to reduce plastic pollution, but even so the culture of recycling is not a common measure that the Peruvian citizen has in mind, it is that only 3% of Peruvians recycle the garbage they generated daily [12].

The objective of the research work is to design a plastic Plastic Shredding Machine to obtain small plastic waste, in such a way that it allows people dedicated to the recycling industry to obtain waste in an automated way and will also be very useful to reduce plastic pollution in the environment. For the development of the design, SolidWorks software was used for the mechanical part that makes up the Shredder machine and an Arduino UNO programmable board that will allow the machine to work in an automated way.

In section II, the methodology will indicate the mechanical, electronic and design of the Plastic Shredding Machine. In Section III, the mathematical calculations, the formulas that were considered for the design of the Plastic Shredding Machine will be placed. In Section IV, the results that are generated according to the tests carried out on the design of the Shredder will be presented. In Section V the discussion will be presented, where the importance of this work with respect to

other works carried out will be indicated. Finally, in Section VI, the conclusion and recommendation of the design of the Plastic Shredding Machine will be presented.

II. RELATED WORKS

Plastic waste shredding machines are of great importance as mentioned below in some studies. For example: In [13], the authors identified that when shredding disposable plastic, the small pieces can be used to make new plastic products, that is why they proposed the development of a plastic waste shredding machine, likewise, the shredding machine was designed with a traditional method of use scissors to cut materials in a small way and from the scraping used by rabbits when digging, some of the blades have sharp curved edges to attract the plastic towards the teeth of the cutting blades. The performance of the machine is 27.3 kg/h and the efficiency is 53% for all types of plastic and 95% for the type of polyvinyl chloride plastic, concluding that the machine could be very useful in a situation in which considerable plastics have to be crushed and also efficient in the crushing of large sizes.

In [14], the author identifies that the PUCP (Pontificia Universidad Católica del Perú) works with 3D printing technology in various areas of the University and that printed material is increasing since it cannot be discarded because they are highly polluting, that is why they proposed the design of a recycling machine oriented to the production of ABS plastic filaments for 3D printing in the PUCP, thus using an Arduino UNO programmable board to control the DC motors, a servo motor and a touch screen, it also uses the Autodesk Inventor 2017 software to design the mechanical part of the system. The result was that the designed system has the capacity to produce at least 0.5kg of ABS per hour, concluding that, by having an interchangeable nozzle extrusion system, a system is obtained capable of manufacturing not only filaments of 1.75, 2.85 and 3.00 mm in diameter as it was determined in the beginning, but also other variants that are in this range of values.

Finally, in [15], the authors identified that most of the PET bottles produced are not recycled, on the contrary, new bottles are produced every time, thus increasing waste, which is why they proposed to carry out the design and construction of a plastic Shredder for the recycling and management of plastic waste, generated in the area of the Petroleum Training Institute, Effurun, Nigeria, thus using a crushing chamber made of a rigid and thick 0.610mm steel plate, also a 0.22mm steel hopper where plastic waste accumulates while shredding is carried out with a base of the shredder casing that has a wire mesh used to regulate the type and size of the shredded plastic waste. Obtaining as a result 98.44% of crushing efficiency, with a crushing rate of 0.575kg/s, concluding that the crushed plastic waste has a size that ranges between 10mm and 20mm and the results obtained reveal that the performance of the machine it is satisfactory.

III. METHODOLOGY

A. Mechanical Part

Since the shredding machine will be in constant friction from the cuts of the plastic material, it must be made of a durable material. For this, suitable materials were chosen for the mechanical assembly of the Shredder.

- Aluminum
- Stainless steel
- Close type pulley
- Bearings

Aluminum will be used for the case of the Plastic Shredding Machine, which is also a lightweight and durable material. The blades of the plastic waste shredding machine will be made of stainless steel to maintain the durability of the friction when making the cuts, the shaft that will hold the blades will also be made of stainless steel, which will be supported by rolling bearings for mobility shredding machine.

B. Electronic Part

The electronic part is composed of a DC motor, which will be an important factor through of its force it will allow to crush the plastic waste that is placed in the machine, for this, the power of the motor must be considered. For this project, the DC motor that we will be using has GGM geared motors of the helical coaxial type in DC with powers from 120W M6 with 3.0 N.m (30kg.cm).

It will also have an Arduino UNO board to work together with a driver module and be able to control the DC motor, in such a way that the shredder has an automatic function.

C. Design

To arrive at the result of the design that will be presented in the article, a preliminary study was made which consists of the durability of the product, its efficiency, and its sustainability over time. Mention will be made of the design of the different parts that make up the crushing machine.

The most important evaluation criteria for the "Crushing and Classification" module were selected in the conceptual phase, which were:

- Ease of manufacture
- Ease of assembly and disassembly
- Reliability
- Ease of maintenance
- Low noise and vibration level
- Inexpensive and affordable spare parts
- Recirculation of material
- Under weight
- Little wear on the cutting elements

1) *Metal sieve or sieve in the shape of a half moon*: The classification of the material already crushed has the appropriate size. To fulfill this function, a metal sieve or a crescent-shaped sieve is used as shown in Fig. 1. Since, thanks to its geometric shape, it does not allow the accumulation or waste of plastic material at any point. Likewise, thanks to its reduced distance to the cutting elements, it allows the

recirculation of material not conforming to the appropriate size to reintegrate it in the crushing process.

2) *Storage module*: The most important evaluation criteria for the "Storage" module, as shown in Fig. 2, were selected in the conceptual phase, which are:

- High storage capacity
- Under weight
- Ease of Manufacturing
- Ease of downloading material
- Ease of Installation
- Safety for the operator

3) *Shredding module*: This module allows the size reduction process to be carried out through the cutting elements, which reduce the plastic material that enters the feed hopper to the appropriate size.

Off-center blades provide the optimal solution to "push" parts into the cutting chamber in the same way that they allow for return. This configuration allows for even distribution of cutting force and simple scissor cutting for greater energy savings, as well as quiet operation and high cutting performance. The geometry of the cutter blades as shown in Fig. 3, allows them to be changed without the need for adjustments, in addition to reducing downtime due to blade change problems.

Fig. 1. Half-Moon-Shaped Sieve for the "Crushing and Classification" Module".

Fig. 2. Storage Module.

Fig. 3. A) Staggered Blade Design B) Blade Design.

4) *Crushing shaft design*: In this section, the construction of the crushed sleeper is carried out, which is subjected to bending and torsion loads created by the power transmission of the pulley, the cutting forces, and the weight of the elements it contains, as shown in Fig. 4.

Fig. 4. Isometric View of the Crushing Shaft.

The mechanical part is an important factor, because the machine will be in constant friction that is why durable materials should be considered as mentioned above, which together with the electronic part manage to crush the plastic in such a way that the machine is efficient and not present complications in its operation.

IV. MATHEMATICAL CALCULATIONS

A. Mathematical Calculations

To start the calculation and selection of the different components of the crusher, it is necessary to know the resistance to cutting of the plastics most used in industries. Table I shows the tensile strength values of different materials. It is also necessary to know the resistance to shear of the selected materials, which through of a mathematical formula is the values as shown in Table II.

TABLE I. TENSILE STRENGTH VALUES

Material	kg/cm ²
Polyethylene (PE)	110 – 375
Polypropylene (PP)	500
Polystyrene (PS)	350 – 600
PVC	350 - 630

TABLE II. CUT RESISTANCE

Material	kg/cm ²
Polyethylene (PE)	88 – 330
Polypropylene (PP)	400
Polystyrene (PS)	280 – 480
PVC	280 - 504

With the values already exposed, the resistance to shear cutting will be calculated, through of the following formula [16]:

$$\tau = \frac{4}{5} \times \sigma \text{ (kg/cm}^2\text{)} \quad (1)$$

Where:

τ = Resistance to shear cutting (kg/cm²).

σ = Tensile strength (kg/cm²).

In Table III, the values of charpy impact resistance and melting temperature are shown.

TABLE III. IMPACT RESISTANCE AND MELTING TEMPERATURE

Material	Charpy impact resistance (kg/cm ²)	Melting temperature (°C)
PET	3.6	170 – 270
PVC	15	80
PP	4 – 20	160 – 270
PS	3 – 12	105 – 270
PE	18	70 – 120

As mentioned above, polypropylene was chosen, which has higher impact resistance than other thermoplastic polymers. To calculate the force required to generate the failure of the polypropylene, the work required to perform the failure of the material must first be calculated, which is calculated using Equation 2 [16].

$$\partial w = \partial W^{el} + G_c \times l \times \partial a \quad (2)$$

Where:

∂W = Work required to break the material (Joule).

∂W^{el} = Elastic energy change (Joule).

G_c = Energy absorbed per unit area (Joule/m²).

l = Length of the material cut by the blade (length of the cutting edge) (m).

∂a = Advancement of the fracture during impact (m/s).

Also, Fig. 5 shows how the material will be cut, the so-called scissor cut, which is essentially a shear cut that offers greater energy savings.

Fig. 5. General Structure of Shear or Scissor-Type Cutting.

Based on Fig. 6, Newton's second law is implemented, which allows us to relate the movement of the body with the forces acting on it through equations 3 and 4, which are written in their tangential and normal components.

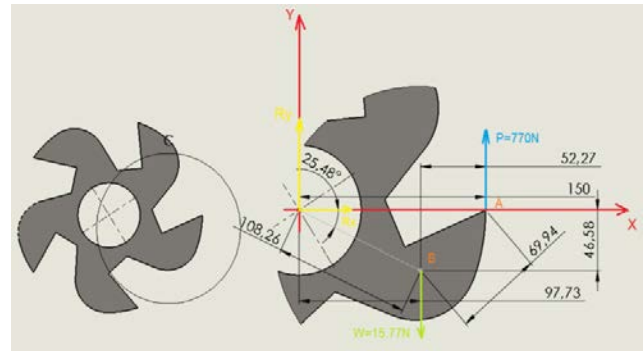

Fig. 6. Center of Mass of the Blade Holder.

$$\sum F_t = m \times a_t \quad (3)$$

$$\sum F_n = m \times a_n \quad (4)$$

Where:

m = Mass of the element (kg).

F = Forces on the element (N).

a_t = Tangential acceleration (m/s²).

a_n = Normal Acceleration (m/s²).

Tangential acceleration and normal acceleration are defined by equations 5 and 6.

$$a_t = r \times \alpha \quad (5)$$

$$a_n = r \times \omega^2 \quad (6)$$

Where:

r = Radius (m).

α = Angular Acceleration (rad/s^2).

ω = Angular speed (rad/s).

And finally, Equation 7, which refers to the sum of the moments around a point, will be applied to determine the reactions and the angular speed of the body; it should be considered that this is a non-centroid movement, since the axis of rotation does not coincide with the center of mass of the body, for this reason the system of external forces is not reduced to a couple $I\alpha$, in the same way we consider that the rotation is constant, therefore the angular speed (ω) is constant and the angular acceleration (α) is zero.

$$\sum M_0 = I \times \alpha \quad (7)$$

Where:

M_0 = Moments of a point (Nm).

I = Moment of inertia ($kg \times m^2$)

Through equations 3 and 4 the force summations will be carried out.

V. RESULTS

In the article, a complete study was elaborated on the efficiency of the plastic crushing machine that will have a sustainability in time with the role that it is exercising. With this, the purpose of reducing pollution by plastic waste would be fulfilled, since it would fulfill its main role, which is to obtain small plastic waste. Inside the shredding module, the shaft formed by the blades is placed as shown in Fig. 7. The container where the small parts of the plastic shredded by the blades accumulate is shown in Fig. 8.

The design of the plastic waste shredding machine would have an approximate efficiency of 85%, because it does fulfill the main job that is shredding plastic, but that missing percentage is since the blades are not strong enough for the plastic bottles additionally.

Fig. 7. Shredder Module.

Fig. 8. Storage Module.

In Fig. 9, the implementation of a plastic shredder machine that generates filaments for 3D printers is observed, where the motor will help in the rotation of the blades and thus crush the plastic bottles with the help of an extruder generate filaments that are used a lot in 3D printers. In addition, the power source to feed the system is also identified in the lower part of the motor, so this would be a more complete project.

Fig. 9. Plastic Shredding Machine that Generates Filaments for 3D Printers.

VI. DISCUSSION

The articles made about shredding machines share the same purpose, which is to reduce plastic waste that pollutes the environment over the years. The design of a shredding machine does not require a microcontroller as mentioned [13], since to carry out the crushing function only a good mechanical part is needed, that is why it adapts to the work carried out by [15], since the machine when shredding plastic does not require any programming. On the other hand [14], it indicates that it is necessary to use an Arduino UNO since it will give one more function to the shredding machine, therefore, it is necessary to indicate what function it will perform the shredding. Although it is true, each job has a specific efficiency, and they are of great importance for those people who are dedicated to the recycling business. It should be noted that these works serve as a basis for other projects that are intended to be carried out.

VII. CONCLUSIONS

It is concluded that the plastic crushing machine works efficiently, this would confirm that the use of this system will help reduce the pollution generated by the plastic, since by

crushing the plastic bottles it allows them to be recycled faster than traditional recycling.

It is concluded that the crushing machine has a structure that is not strong enough to push and bring the plastic towards the blades, due to this it has difficulty in crushing some plastic bottles. Although, it is capable of crushing Technopor, it is a more porous and structured alloy of small balls.

It is concluded that the use of metal blades is strong enough to crush plastic bottles, initially plastic blades were considered for the crusher, but they could not crush the plastic bottles.

It is concluded that the use of the Arduino UNO board helps a lot to control the motors that are part of the shredder machine, and its programming is more user-friendly unlike other microcontrollers.

As work in the future, a heating system will be placed as shown in Fig. 9, which will be of great help to obtain filaments for 3D printers that are used by various professionals, for example, in the biomedical field. This would be making the most of the plastic shredded by the machine.

It is recommended to consider that the blades to be incorporated into the structure of the crushing machine can withstand the force generated by the motor when the machine is in operation. It is also necessary that the blades are staggered on their shredding axis as it allows the cutting to be more efficient.

An HC-CSO Algorithm for Workflow Scheduling in Heterogeneous Cloud Computing System

Jai Bhagwan¹, Sanjeev Kumar²

Department of Computer Science & Engineering
Guru Jambheshwar University of Science & Technology
Hisar, India

Abstract—Many scientists are using meta-heuristic techniques for dynamic workflow task scheduling in the area of cloud computing systems to get optimum solutions. Many swarm intelligent algorithms have been designed so far which are having many limitations as some get trapped in local optima, a few are having low convergence speed, some are having poor global search facilities, etc. Still, there is a requirement of designing a new algorithm or modification of existing algorithms to overcome the limitations of the existing techniques. A new Hybrid Cat Swarm Optimization algorithm named H-CSO was designed inspired by the HEFT algorithm and the initialization problem of the Cat Swarm Optimization was overcome. Still, that algorithm has a limitation of getting stuck in local minima. To overcome this algorithm a part of the Crow Search Algorithm has been integrated into H-CSO and described in this paper. After simulation, it was found that the new hybrid algorithm named HC-CSO outperforms CSO and H-CSO.

I. INTRODUCTION

Information Technology has been reshaped by the evolution of cloud computing technology via big storage facilities, high-performance computing, and other hardware and software services. The current technology includes the evolution of computing eras where computers were connected via the internet that took the form of distributed computing. This further transformed into cluster computing, cluster to grid computing, and then cloud computing [1]. The major aim of cloud computing technology is to provide high-performance computing services at the minimum cost. The cloud technology shifted the users' data from client machines to network-abled machines which are having high-powered processors and hardware parts. Cloud computing provides services in the form of Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS) [15]. Any end-user can pick up the services as per his requirements. The main benefit of the cloud is that it doesn't include geographical boundaries to provide the services to the end-users [2]. This means that the users need not to know the physical locations of the service providers and computing datacenters. Cloud technology is flexible because a user can increase the number of services and drop whenever it is required due to the pay-per-usage policy. Various cloud service providers are Amazon Web Services, Microsoft, Google, Rackspace, salesforce.com, etc. The cloud system

can be classified into four categories such as private cloud, public cloud, community cloud, and hybrid cloud [3].

The performance of the cloud can be improved at various levels such as network level, scheduling level, database level, etc. After studying various research papers, it can be seen that numerous algorithms have been designed for workflow task scheduling, load balancing, energy consumption management, etc. in cloud computing. Workflow task scheduling is one of the major areas where a lot of improvement is required. Task scheduling can be of two types static and dynamic scheduling. In static scheduling, the execution times of the tasks are pre-estimated or known but in the case of dynamic scheduling, it is not known. This era is of dynamic task scheduling. So, dynamic task scheduling algorithms are required to be improved. The optimization techniques play an important role to improve the cloud scheduling problem nowadays. A few famous techniques are Ant Colony Optimization, Particle Swarm Optimization, and Cat Swarm Optimization, etc. Cat Swarm Optimization belongs to Swarm Intelligent (SI) family [4]. The algorithms used in this paper are as under:

1) *Cat swarm optimization*: This is an intelligent algorithm originally developed in the year of 2006. This algorithm is inspired by the behaviour of the original cat which is having to two modes known as seeking (resting mode) and tracing (attacking mode). Here, N numbers of cats are generated randomly and each cat denotes a solution, its position, a flag, and fitness value. M dimensions in the search space represent the position, and each dimension in the search space is having its self-velocity. The flag is used to identify that the cat is in either seeking mode or in tracing mode and this flag is set by a parameter known as Mixing Ratio (MR). After finding the fitness, the best cat is stored in the memory at each iteration and finally, the best solution or cat is identified at the end of the final iteration. The two modes of Cat Swarm Optimization are described below [1][21]:

i) *Seeking mode*: This mode represents the resting mode of a cat and four parameters play an important role in it: SMP (Seeking Memory Pool), SRD (Seeking range of the Selected Dimension), CDC (Counts of Dimension to change), and SPC (Self Position Consideration). In SMP, one position is selected by a cat randomly for moving to the next position. Let's say, the SMP is set to 10, now for every cat 10 new random positions will be generated and one among them will be

selected randomly for movement. SRD and CDC will decide the randomization of the new positions. How many dimensions need to be mutated that is decided by the CDC factor which is in the interval between [0 to 1]. The amount of mutation is defined by SRD for the dimensions selected by CDC. The Boolean value SPC will consider the candidate cats for the next iteration from the current position. Let's assume, if SPC is true then for each cat SMP-1 candidates will be generated instead of SMP because the current position will be decided from them. Seeking Mode steps are given as:

a) Generate S Copies of Seeking Cat_k equal to the SMP value.

b) For each copy, change at a random dimension of Cats as per CDC by applying SRD operator as:

$$Cat\ nD_{new} = (1 + rand * SRD) * Cat\ nD_{old} \quad (1)$$

Where, $Cat\ nD_{old}$ is the current position and $Cat\ nD_{new}$ is the next new position, n is the numbers of Cats and D is the dimension, rand is a random variable between [0, 1] interval.

c) Evaluate fitness of all candidate/ changed Cats and find Best Cats (Cat_{Best,D}).

d) Replace the position of S Cats by picking up the Best Cats randomly.

ii) *Tracing Mode*: This mode follows the tracing behaviour of real cats.

a) At first, velocity values are computed and assigned to all the dimensions of a Cat_k position by the following equation 2.

$$V_{K,D} = V_{K,D} + (c1 * r1 * (X_{Best,D} - X_{K,D})) \quad (2)$$

Where, $V_{K,D}$ is the velocity, c1 is an acceleration coefficient, r1 is a random variable between [0, 1], $X_{Best,D}$ is the best cat position, $X_{K,D}$ is the current cat position and D is the dimension.

b) If velocity is going beyond the upper range set it within the range.

c) Update the position of the Cat_k by using the following equation 3.

$$X_{K,D} = X_{K,D} + V_{K,D} \quad (3)$$

2) *Crow search algorithm*: Crow family is treated as one of the most intelligent bird groups. Their brain is considered slightly lower than a human being, based on their body-to-brain ratio. Crow is a very well famous thief as to watches other bird's food and steals it after the victim bird leaves its place of food. This intelligent behaviour of the crow can be used to solve and optimize real-world problems. The CS Algorithm can be described with the help of a pseudo-code in Fig. 1 [22].

Crow Search Algorithm	
1.	Randomly initialize the positions of a group of N crows, fl (flight length), r_1 , r_2 and max. iterations
2.	Evaluate the position of all the crows
3.	Initialize the memory of every crow in the group
4.	While itr < itr _{max}
5.	For i = 1 to N
6.	Randomly choose one of the crows to follow, let it be Crow _j
7.	Define the awareness probability
8.	If $r_j \geq AP_{i,itr}$ Then
9.	$x_{i,itr} = x_{i,itr} + r_1 * fl_{i,itr} * (m_{j,itr} - x_{i,itr})$ (4)
10.	Else
11.	$x_{i,itr}$ = a random position of a crow in search space
12.	End If
13.	End For
14.	Check the fitness of new positions
15.	Evaluate the new position of the crows
16.	Update the memory of crows
17.	End while

Fig. 1. Pseudo-Code of Crow Search Algorithm.

First of all, the positions of all crows in a group and other parameters have been initialized. N is the number of crows, r_1 and r_2 are random variables between 0 to 1. After evaluation of the positions of all crows, the memory of each crow is initialized. As described earlier, the behavior of the crow is to chase a bird to steal its food. So, a random crow from the search space is selected say it be a Crow_j. Crow_i will follow it and will steal its food whenever the Crow_j will leave its place after hiding its food. If the random variable r_j will be greater than awareness probability the position of the current Crow_i will be updated by using equation 4 otherwise the position will be updated randomly from the search space. Flight Length (fl) of the crow will decide the local or global search. If the fl is less than 1 then it will work for local search otherwise the global search will take place. Then the new positions or solutions will be stored in the memory and this process will be continued till the termination condition will not be satisfied [22].

In this paper, the limitation of getting stuck in the local minima of the H-CSO algorithm has been improved by integrating the local search part of the CSA. The details are given in the coming sections.

The rest of the paper is structured as follows: Section II covers the related work. In Section III, the proposed methodology is described. Section IV is having a description of the simulation setup and simulation results and discussion are covered in Section V. Section VI is summarizing the conclusion and future scope. In the end, the research papers' references are given.

II. RELATED WORK

Existing work in the area of workflow and task scheduling can be found in the following literature review: In [1] the scientists proposed multi-objective Cat Swarm Optimization based on the Simulated Annealing technique. The Simulated Annealing (SA) technique is incorporated in the local search of the proposed algorithm and the SA is enhanced by the Orthogonal Taguchi approach. The parameters like execution time and execution cost are considered for performance

measurement. The proposed technique worked better as compared to Multi-Objective Ant Colony Optimization, Multi-objective Genetic Algorithm, and Multi-Objective Particle Swarm Optimization. The authors [2] proposed a Multi-Objective Cat Swarm Optimization algorithm and after comparison with the existing Multi-Objective PSO technique, the proposed approach was found better in the account of energy consumption, execution cost, and execution time. The researchers in [3] introduced a Cat Swarm Optimization-based technique for workflow scheduling. The results were compared with PSO (Particle Swarm Optimization) and found that the CSO reduces the processing cost, made a good load balance, and gave the optimum results in less iteration. In [5] a Hybrid Particle Swarm Optimization algorithm using the Hill-Climbing technique was proposed by the scientists. The proposed algorithm was found effective in terms of makespan after experiments. The scientists [6] introduced a Binary Hybrid Particle Swarm Optimization and Gravitational Search algorithm for load balancing of virtual machines (VMs). The experimental results showed that the proposed algorithms worked better than the existing Binary PSO load balancing algorithm in terms of load balancing. In [7] the researchers offered a new HPSOGWO algorithm that is a combination of Particle Swarm Optimization and Grey Wolf Optimization. The idea behind this algorithm was to improve the exploitation of PSO and exploration of GWO for making the better strength of the proposed algorithm. The results concluded that the HPSOGWO is better than standard PSO and GWO variants concerning solution stability, convergence speed, and quality. The authors in [8] proposed an IPSO (Improved Particle Swarm Optimization) algorithm to improve the allocation of large-length tasks. The introduced algorithm outperformed despite Ant Colony, Honey Bee, and Round-Robin algorithm in accounts of load balance, makespan, and degree of imbalance. In [9] authors presented a Particle Swarm Optimization based technique for workflow scheduling and found that the Particle Swarm Optimization based technique saved the cost equal to 3 times as compared to BRS (Best Resource Selection) algorithm. Also, the presented technique balanced the load efficiently. The authors of the paper [10] proposed a PSO (Particle Swarm Optimization) based scheduling technique for independent tasks. The proposed technique was improved using a load balancing strategy. The newly introduced method was compared with Improved PSO, Round-Robin, and existing load balancing techniques. The experimental results showed that the proposed technique is better than the above said three algorithms for resource utilization and makespan. The scientist [11] introduced the MPSO (Modified Particle Swarm Optimization) algorithm for the reduction of cost as compared to the existing Particle Swarm Optimization algorithm. The simulation results showed that the proposed technique worked better. In paper [12] the authors modified Particle Swarm Optimization by modifying the parameters like MIPS and Bandwidth for effective load balancing. The simulation results showed that the proposed model resulted in a reduction of execution time. The researchers of the paper [13] compared a

task scheduling strategy based on Ant Colony Optimization with FCFS and RR (Round-Robin). The simulation results proved that the ACO outperforms traditional FCFS and Round-Robin algorithms. The authors [14] developed a hybrid optimization technique using Flower Pollination and Grey Wolf Optimization. The PEFT algorithm was used for the initialization of the proposed method for workflows. The simulation resulted that the proposed method is effective as compared to Flower Pollination with Genetic Algorithm in terms of cost and reliability. In [16] the researchers designed an Improved Social Learning Optimization Algorithm by introducing the Small Vector Position method for task scheduling problems. After simulation, it was found that the proposed approach worked well as compared to GA and PSO-based techniques. In the paper [17], the researchers proposed an Adaptive Cost-based Task Scheduling technique to scheduling the tasks between virtual machines at minimum cost. The simulation results concluded that the proposed technique is performing well in terms of communication cost, execution time, CPU utilization and execution cost rather than cost-efficient task scheduling. In [18] research paper, the scientists implemented a Dynamic Adaptive Particle Swarm Optimization algorithm to enhance the efficiency of Particle Swarm Optimization for better makespan, resource utilization. The authors also proposed an algorithm named MDAPSO. DAPSO and MDPSO worked better than the original Particle Swarm Optimization. The authors of [19] research paper proposed an Improved Particle Swarm Optimization based technique to solve workflow scheduling problems in cloud systems. The proposed method worked better as compared to existing state-of-art methods. In [20], the scientists proposed a cloud scheduling model named Task Scheduling System. The proposed Genetic Algorithm-Chaos Ant Colony Optimization worked better than ACO and GA algorithms in respect to cost and convergence speed.

From the above study, it is found that the ACO, PSO, and CSO algorithms are optimizing the scheduling of independent as well as workflows tasks. The ACO algorithm is performing well for local searching; the PSO and CSO algorithms are good for global searching and get stuck in local optima easily. Various researchers integrated a few techniques and formulae in these algorithms to improve the performance of the cloud. But, these techniques are old. The CSO algorithm is a good performer among the ACO and PSO; the H-CSO is better than the CSO.

So, a new method is required to integrate into the H-CSO so that its limitation of getting trapped in local optima can be overcome. Hence, the local searching part of the Crow Search Algorithm has been integrated into the H-CSO algorithm. The details are indicated in the proposed methodology section.

III. PROPOSED METHODOLOGY

From the related work, it is learned that a single algorithm could not be able to give better results for workflow task scheduling.

Proposed Algorithm

Input (Tasks (T₁, T₂, T₃ ... T_n), Virtual Machines (VM₁, VM₂, VM₃ ... VM_m))

Output (Optimal Makespan and Cost of n Tasks on m VMs)

BEGIN PROCEDURE

1. Initialize fl (flight length), r_k, velocity factor V_k, c, γ_{max}, Coefficient c1, MR flag, and no. of iterations
/* Calculate Rank of Workflows Tasks in DAG using HEFT Algorithm */
2. Feed workflows in HEFT
3. **For** Each Task in DAG **Do**
4. Calculate average execution time of all VMs
5. **If** Task t_i is the last Task **Then**
6. Rank value of t_i = its average execution time
7. **Else**
8. rank_u(t_i) = WAv_g_i + Max t_j ∈ succ (t_i) (CAvg_{i,j} + rank_u(t_j))
 Where WAv_g_i is average execution cost
 Succ (t_i) is set of immediate successor of task t_i
 CAvg_{i,j} is average communication cost
9. **End If**
10. **End For**
11. Assign Tasks to VMs according to HEFT Rank
12. **If** Solution not Optimized **Then**
13. Generate a set of Crows by the Population generated by HEFT of Size N
14. **While** No. of Iterations not Exceeded **Do**
15. **For** K=1 to N
16. Update the positions by the following equation : // Do local search
17. $X_{K,D} = X_{K,D} + r_K * fl_{K,D} * (M_{L,D} - X_{K,D})$
 Where, X_{K,D} is current position of Crow_k, r_k is uniformly distributed random number [0, 1]
 fl_{K,D} is flight length (less than 1 i.e. 0.5) of the Crow_k at current iteration
 M_{L,D} is present best location of Crow_k in Dimension D
18. Feed the population generated by Local CSA in H-CSO // Do local and global search as given below
19. Assign the velocity V_k to each Cat
20. According to Mixing Ratio (MR) flag Distribute Cats to Seeking and Tracing Modes
21. **If** current Cat_k is in Seeking Mode **Then**
22. Generate S (SMP) Copies of Cat_k and Spread them in D Dimensions where each Cat has a velocity (V_{k,D})
23. Evaluate the Fitness value of all Copies and Discover Best Cats (X_{BEST,D})
24. Replace Original Cat_k with the Copy of Best Cats (X_{BEST,D})
25. **Else If** current Cat_k is in Tracing Mode **Then**
26. Compute and Update Cat_k velocity by following equations:
27. $\gamma = \gamma_{max} * \exp\left(-c * \left(\frac{itr}{itr_{max}}\right)^c\right)$
 Where, γ is a weight factor calculated by Self-Motivated Inertia Weight method
 γ_{max} and c are constant factors greater than 1, both are set as 2.
28. $V_{K,D} = \gamma * V_{K,D} + \left(c1 * r1 * (X_{BEST,D} - X_{K,D})\right)$
 Where, D = 1, 2, 3, ..., M.
 c1 is acceleration coefficient, r1 is random number in the range of [0, 1]
29. Update the position of every dimension of Cat_k by using following equation:
30. $X_{K,D} = X_{K,D} + V_{K,D}$
31. Evaluate Fitness of all Cats and find out Best Cats (X_{BEST,D}) with Best Fitness
32. **End If**
33. Update Best Cats (X_{BEST,D}) in Memory
34. **End For**
35. **End While**
36. **End If**
37. return (Optimal Solution)

END PROCEDURE

Fig. 2. Pseudo-Code of Proposed HC-CSO Algorithm.

Many scientists advised improving the existing algorithms. The H-CSO algorithm is a combination of the HEFT, Cat Swarm Optimization algorithm, and Self-Motivated Inertia Weight useful in overcoming the velocity outrange problem of the standard CSO. As said earlier, this H-CSO algorithm gets trapped in local minima in the case of a large search space and complex workflows' tasks environment. A few limitations of the H-CSO algorithm are described below in short:

1) The H-CSO algorithm is having only a good global searching capacity.

2) The H-CSO algorithm gets trapped in local minima due to a large number of cats is always residing in seeking Mode as compared to tracing mode.

3) Due to a lack of balance between seeking and tracing modes, optimal results could not be got using the H-CSO algorithm.

In the proposed algorithm named HC-CSO, a local search part of a well-known Crow Search Algorithm is integrated into the H-CSO for avoiding it getting trapped in the local optima. The working of the HC-CSO algorithm is described as:

First of all, the initialization of various parameters takes place then pre-processing of workflows tasks is executed with the HEFT method as shown in the pseudo-code of the proposed algorithm. After the pre-processing of workflows, the tasks are assigned to available VMs. If this solution is getting optimized at the very first stage then the algorithm is stopped and returns the optimized schedule otherwise the initial solution generated by the HEFT algorithm is fed to the CSA algorithm. Here, a number of N Crows are generated using the population obtained by the local Crow Search Algorithm. Then, the population got from the local CSA is fed to the H-CSO algorithm. Now, N numbers of Cats are generated and velocity value V_k is assigned to each cat for further processing. In the next phase, the cats are randomly distributed into the seeking and tracing mode as per the Mixing Ratio (MR) rate and flags are set to each cat. If the current Cat_k is found in the seeking mode as per flag value, this mode gets executed otherwise the tracing mode gets executed. The position and velocities of the cats in the tracing mode are updated using the equations given in the pseudo-code in Fig. 2 and the best cats get stored in the memory in the form of solution. This process is continued until the termination condition is not matched and finally an optimal solution is returned in the form of better makespan and cost. The proposed algorithm has both the best local and global searching capacity, so the results could be reached at an optimum level. The proposed algorithm is also useful to avoid the premature convergence of the H-CSO method. The pseudo-code of the proposed algorithm named HC-CSO has been described step by step in Fig. 2.

IV. SIMULATION SETUP

The simulation environment has been created in the CloudSim tool for simulating the different workflows used in this paper. Various experiments were carried out over a computing machine having the configuration as Processor – Intel® Core™ i3-5005U at a speed of 2.0 GHz, RAM – 4.0 GB, HDD – 1 TB, and OS – Windows 10.

A. Parameters

For simulation, a PowerDatacenter has been designed having the configuration as RAM – 25 GB, MIPS per VM – 1000 MIPS, Storage – 1 TB, Bandwidth – 50000 bps. Rest configurations of the heterogeneous cloud environment are depicted in Table I. The scheduling policy was set as Time Shared. The parameters of the CSO, the H-CSO and, the proposed HC-CSO are also summarized in Table I.

TABLE I. SIMULATION PARAMETERS

PowerDatacenter	
Parameters	Values
Number of Hosts	1
System Architecture	x86
VMM	Xen
OS	Linux
Number of Cloudlets	1000 in Each Workflow
Cloudlets Length Type	Random
Numbers of VMs	10, 20 and 30
CPU (PEs Number)	1
RAM per VM	512-1024 MB
Bandwidth	1000-1500 bps
Processing Elements per VM	500 – 1000 MIPS
Image Size	10000 MB
Policy Type	Time Shared
Standard CSO and H-CSO	
No. of Cats	100
Iterations	300
Weights (C1)	1.5
r1 and r _k (Random Variables)	[0, 1]
Mixed Ratio Percentage	Random Range [0, 1] i.e. 0.2-0.3
HC-CSO (Proposed Algorithm)	
No. of Cats	100
Iterations	300
Weights (C1)	1.5
r1(Random Variable)	[0, 1]
Mixed Ratio Percentage	Random Range [0, 1]
fl (Flight Length)	0.5

B. Cost Plan

The cost plan (in Indian Rupees) of workflow scheduling is depicted in Table II.

TABLE II. COST PLAN

Resource	Processor	RAM	Storage	Bandwidth
Size	500-1000 MIPS	512 MB	Unlimited	1000 bps
Cost	Rs. 3.0 per processor	Rs. 0.05 per MB	Rs. 0.1	Rs. 0.1 per MB

C. Cloudlets

Cloudlets are called tasks to be submitted for execution on virtual machines. In this paper, the scientific workflows named CyberShake, Montage, Inspiral, and Sipt have been used to test the proposed algorithm along with others. Each workflow is having 1000 tasks.

D. Performance Metrics

There are several performance metrics like Makespan, Processing Cost, Waiting Time, Response Time, Energy Consumptions, and Resources Utilization, etc. to test the performance of the algorithms. In this paper, makespan and cost are used to measure the performance of the proposed algorithm, and these parameters are given in the coming topics.

1) *Makespan*: Makespan [23] is referred to the maximum time taken for finishing the last task in a group. It is the most widely used metric to measure the performance of a scheduling algorithm. A lesser makespan decides that the algorithm is efficient enough. The makespan is computed by the given equation 5.

$$\text{Makespan} = \max (CT_i)_{ti \in \text{tasks}} \quad (5)$$

Where, CT_i is the completion time of task $_i$

2) *Processing cost*: Processing Cost is along with makespan is another important performance metric because cloud service providers want to give efficient services at the minimum costs in this competitive environment. The processing cost can be measured by equation 6.

$$\text{Total Cost} = \frac{MF+CF}{2} \quad (6)$$

Where, MF is Movement Factor

CF is Cost Factor

$$MF = \frac{1}{\text{No. of Hosts/Datacenters}} \left[\sum_{x=1}^{VMx} \left(\frac{\text{Number of Migrations}}{\text{Used VM}} \right) \right] \quad (7)$$

$$CF = \sum_{x=1}^{VMx} \left(\frac{\text{Processing Cost} * \text{Memory of Tasks}}{VM * \text{Datacenter}} \right) \quad (8)$$

3) *Fitness function*: Equation 9 is depicting the fitness function which is used by meta-heuristic techniques to check that the solution is optimized or not at various levels in the form of makespan along with computation cost.

$$F_X = \frac{1}{\text{Datacenter} * VMj} \left[\sum_{i=1}^{DCi} \sum_{j=1}^{VMj} \frac{1}{VM} \frac{CPU \text{ Utilized}}{CPU_{ij}} + \frac{\text{Memory Utilized}}{\text{Memory}_{ij}} + \frac{\text{Makespan Utilized}}{\text{Makespan}_{ij}} + \frac{\text{Bandwidth Utilized}}{\text{Bandwidth}_{ij}} \right] \quad (9)$$

Equations 7 and 8 help in the calculation of the total processing cost represented in equation 6.

V. SIMULATION RESULTS AND DISCUSSION

Four scenarios and a set of 10, 20, and 30 virtual machines have been set in CloudSim for simulation. To evaluate the performance of the proposed algorithm HC-CSO, the simulation results were compared with standard CSO and H-CSO. The makespan results concerning all scenarios are displayed in Table III. The results shown in Table III are the average of the results retrieved by the proposed algorithm HC-CSO along with other algorithms which were executed several times.

Simulation results of the proposed algorithm HC-CSO, H-CSO, and standard CSO for the scientific dataset

Cybershake_1000 are displayed in Fig. 3. Southern California Centre collected data and made the CybeShake workflow to analyze seismic hazards. For execution, this workflow requires almost near to lower CPU power and memory. It can be seen that at the x-axis 10, 20, and 30 VMs are being displayed and makespan at the y-axis. The results express that the HC-CSO outperforms other algorithms better local search after adding the Crow Search Algorithm and a better balance between seeking and tracing mode.

It is seen in Fig. 4 that the experiment carried out with the Montage_1000 dataset needs less memory and CPU power as compared to other workflows. The Montage dataset is having astronomical images collected and stored by NASA. The graph tells that the group of 10, 20, and 30, VMs as well as makespan, are shown at the x-axis and y-axis correspondingly. The results depiction tells the proposed algorithm HC-CSO performed efficiently as compare to other algorithms due to better convergence in less number of iterations.

TABLE III. MAKESPAN EVALUATION (IN SEC)

Scenarios	VMs	CSO	H-CSO	HC-CSO
Scenario - 1 CyberShake_1000	10	4603.23	4520.45	4413.65
	20	3693.52	3500.27	3425.29
	30	2401.29	2350.15	2220.15
Scenario - 2 Montage_1000	10	2310.70	2270.09	2210.43
	20	2021.13	1982.05	1813.58
	30	1308.28	1219.01	1187.67
Scenario - 3 Inspirial_1000	10	52300.41	50940.98	49859.35
	20	40350.03	39241.18	37174.27
	30	23975.57	22548.23	20140.03
Scenario - 4 Sipht_1000	10	32820.02	31107.81	30740.41
	20	25203.13	23293.24	22980.37
	30	19113.29	18279.02	18033.13

Fig. 3. Makespan Comparisons for CyberShake_1000 Tasks.

Fig. 4. Makespan Comparisons for Montage_1000 Tasks.

Fig. 5 is demonstrated the experimental results of the proposed algorithm named HC-CSO along with other algorithms like CSO and H-CSO for the dataset Inspiral_1000 which is related to the physics field and used to analyze the gravitational waves. This dataset needs high powered CPU and a large amount of memory for execution. The results concluding here that the proposed algorithm performed better than other algorithms because the HC-CSO algorithm has both capabilities of global and local searching as well as the algorithm also manage the velocities outrange. This capability of the proposed algorithm manages under-loaded and overload machines effectively by task migration. In this graph, the numbers of VMs are being displayed at the x-axis and makespan at the y-axis.

Fig. 5. Makespan Comparisons Inspiral_1000 Tasks.

Fig. 6 is displaying the results of the Sipt_1000 workflow processed with the proposed HC-CSO algorithm and others.

Fig. 6. Makespan Comparisons for Sipt_1000 Tasks.

For displaying the 10, 20, and 30 sets of VMs and makespan, the x-axis and y-axis are being used respectively. The Sipt dataset is used to represent sRNA-encoding genes

of several bacteria and it has been released by the HIB (Harvard International Bioinformatics) Centre. This dataset requires huge memory and a high computational CPU. For the processing of this dataset, the proposed algorithm HC-CSO again worked well as compared to standard CSO and the H-CSO because the proposed algorithm chooses the most appropriate VM instead of high or low power due to better properties of local as well as global searching and the HC-CSO also avoids unnecessary diversity. The proposed algorithm could not trap in local minima due to Crow Search Algorithm local searching property.

In the last, it is concluded that the HC-CSO algorithm is giving better results in the form of a better makespan for all scenarios in comparison to standard CSO, and H-CSO. For all the scenarios, HC-CSO works better than CSO and, H-CSO because of the better pre-processing of tasks by HEFT, a good balance between seeking and tracing modes due to the Crow Search algorithm. The HC-CSO algorithm along with the Crow Search Algorithm searches the VMs at a local and global level very carefully to optimize the results in the minimum number of iterations. The SMIW method restricts the Cats to go outside the search space.

Table IV is summarizing the evaluation of the processing cost for the execution of all scenarios designed for simulation.

TABLE IV. COST CONSUMPTIONS (IN INDIAN RUPEES)

Scenarios	VMs	CSO	H-CSO	HC-CSO
Scenario - 1 CyberShake_1000	10	484.53	459.43	447.89
	20	601.43	590.29	567.78
	30	703.47	668.13	640.25
Scenario - 2 Montage_1000	10	181.83	167.53	159.13
	20	191.19	184.19	173.19
	30	198.13	190.89	169.17
Scenario - 3 Inspiral_1000	10	3663.48	3629.55	3413.42
	20	3759.37	3685.87	3543.65
	30	5430.17	5217.58	5130.71
Scenario - 4 Sipt_1000	10	2811.93	2759.19	2645.13
	20	2973.87	2918.13	2703.29
	30	3353.29	3109.24	2999.43

Fig. 7. Cost Comparisons for CyberShake_1000 Tasks.

For the first scenario having CybeShake_1000 dataset, a group of 10, 20, and 30 VMs along with processing cost are demonstrated at the x-axis and y-axis respectively in Fig. 7. The graph is expressing that the proposed HC-CSO algorithm is consuming minimal costs as compared to other algorithms. This is because the proposed algorithm has faster convergence and the positions of the workflows tasks on various VMs are updated smartly.

Fig. 8. Cost Comparison for Montage_1000 Tasks.

Fig. 8 is summarizing the processing cost consumption for the proposed algorithm HC-CSO, H-CSO, and standard CSO algorithms while working on 10, 20, and 30 VMs for the Montage_1000 dataset. The x-axis and y-axis of the graph are demonstrating the VMs and computing costs respectively. The proposed algorithm works better than H-CSO and CSO because the workflow tasks are migrated effectively for under-loaded virtual machines irrespective of their computing capacity.

Fig. 9. Cost Comparison for Inspiral_1000 Tasks.

The processing cost results are being depicted in Fig. 9 for the Inspiral_1000 dataset. It can be seen VMs and Processing at the x-axis and y-axis respectively in the graph. The HC-CSO algorithm consumes less cost while executing the Inspiral_1000 dataset with all sets of VMs in comparison to other algorithms, this is because; the proposed algorithm makes an effective balance between seeking and tracing modes due to CSA integration. The VMs were picked up for execution of tasks irrespective of their MIPS, RAM, and bandwidth.

Fig. 10. Cost Comparisons for Sipt_1000 Tasks.

Fig. 10 is describing the results of processing cost obtained by the proposed HC-CSO, CSO, and H-CSO algorithms with various groups of virtual machines for the Sipt_1000 dataset. The VMs and processing cost can be seen at the x-axis and y-axis correspondingly in Fig. 10. Again, for the Sipt_1000 workflow; the proposed algorithm outperforms CSO and H-CSO in terms of computing cost. It is because the global and local searching properties of the proposed algorithm are balanced and the overloaded VMs loads are migrated to other VMs very smartly in the minimum time.

With these results, it can be specified that the proposed HC-CSO algorithm is better than other algorithms like CSO and H-CSO in respect of makespan and processing cost. The reason behind this is the good combination of global and local due to CSA. The Self-Motivated Inertia Weight factor integration overcomes the velocity outrange problem of Cats at tracing mode. The proposed algorithm chooses the virtual machines which are idle, under-loaded, or overloaded for workflow tasks migration among different VMs irrespective of their computing power, RAM, and Bandwidth.

VI. CONCLUSION

In the current technological era, cloud computing is one of the important emerging technologies used to store a large volume of data and other computing services in various science and technological fields. For computing facilities, various heuristic and meta-heuristic techniques have been developed. In this paper, an intelligent workflow scheduling algorithm named HC-CSO has been proposed to solve the workflow task scheduling problem. The proposed algorithm is a combination of H-CSO and the Crow Search algorithm. The H-CSO algorithm is an integration of HEFT and SMIW methods. The HEFT algorithm pre-processed the workflows tasks and initialized the proposed HC-CSO algorithm with these tasks. This process saves time and optimizes the results in a fewer number of iterations. The proposed HC-CSO algorithm didn't get trapped in local optima due to the good local searching capacity of the CSA. Velocity outranges cause to push the Cats outside the search space and affects the performance of the algorithm. The Self-Motivated Inertia Method overcame this problem.

The proposed HC-CSO algorithm outperformed CSO and H-CSO in terms of makespan and computing cost with all four scenarios having four scientific datasets CyberShake, Montage, Inspiral, Sipt, on a group of 10, 20, and 30 VMs. This is because the proposed algorithm chose the best VM among a group of VMs using its perfect global and local searching capacity for workflows task scheduling. The proposed approach is a generalized algorithm and will perform well with all types of scientific datasets despite a particular one.

In the future, the proposed algorithm can be tested at a wide scale to reduce makespan, cost and, other parameters in the cloud system and many other fields. The efficiency of the proposed algorithm can also be tested for independent tasks. A new technique can also be developed to enhance cloud performance.

Department of Statistics, Mathematics and Insurance, Faculty of Commerce, Assuit University, Assut, Egypt¹

Abstract—Predicting the frequency of insurance claims has become a significant challenge due to the imbalanced datasets since the number of occurring claims is usually significantly lower than the number of non-occurring claims. As a result, classification models tend to have a limited ability to predict the occurrence of claims. So, in this paper, we'll use various data level approaches to try to solve the imbalanced data problem in the insurance industry. We developed 32 machine learning models for predicting insurance claims occurrence {(under-sampling, over-sampling, the combination of over-and under-sampling (hybrid), and SMOTE) × (three Decision tree models, three boosting models, and two bagging models) = 32}, and we compared the models' accuracies, sensitivities, and specificities to comprehend the prediction performance of the built models. The dataset contains 81628 claims, each of which is a car insurance claim. There were 5714 claims that occurred and 75914 claims that didn't occur. According to the findings, the AdaBoost classifier with oversampling and the hybrid method had the most accurate predictions, with a sensitivity of 92.94%, a specificity of 99.82%, and an accuracy of 99.4%. And with a sensitivity of 92.48%, a specificity of 99.63%, and an accuracy of 99.1%, respectively. This paper confirmed that when analyzing imbalanced data, the AdaBoost classifier, whether using oversampling or the hybrid process, could generate more accurate models than other boosting models, Decision tree models, and bagging models.

Keywords—Machine learning; classification; insurance; imbalanced data problem; resampling methods

I. INTRODUCTION

The use of machine learning techniques and the transformation of the insurance market into a new level of digital applications are the insurance industry's current challenges. There are two types of insurance: life insurance and non-life insurance. Non-life insurance, specifically auto insurance, is the subject of this study.

A variety of variables influence automobile insurance pricing [1]. And these factors would affect the cost of a client's insurance policy. Credit history is an example of one of these factors; studies indicate that people with poor credit are more likely to file claims, commit fraud, or miss payments, putting the insurance company in a financial bind. Another factor to consider is the client's location; studies have shown that densely populated areas with heavy traffic have a higher rate of accidents, resulting in a higher number of claims. This would result in a significant rise in the customer's insurance premium. However, it is unjust for a good client to pay more simply because of where they live; this creates a problem for the

consumer because if the insurance premium is raised, he will be unable to afford it, resulting in the insurance provider losing these clients. So, necessitating the creation of an appropriate method for evaluating the risk each client poses to insurers.

As a result, insurance rates should be adjusted based on a client's skill and other personal information, making car insurance more accessible to consumers. Where insurance companies should customize a custom premium for each customer because this will help the insurers to adjust to any situation and manage any loss. Since It would be unreasonable to expect a client with a good driving record to pay the same insurance premium as a client with a poor driving record; as a result, the model should classify which clients are unlikely to file claims, lower their insurance costs, and raise insurance costs for those who are likely to file claims.

Data imbalanced problem are more likely to arise in the case of insurance data since the number of occurring claims is usually significantly lower than the number of non-occurring claims. And one of the major problems with machine learning techniques is that they are affected by the data set's unequal binary class distribution. In other words, when the data is unbalanced, certain machine learning techniques will simply ignore the small class and allocate the majority of the unseen cases to the common class, resulting in high overall model accuracy. Nonetheless, the performance of the prediction models for the small class will be substantially reduced. To solve this problem, we will use resampling techniques, such as Over-sampling, under-sampling, the combination of over-and under-sampling (hybrid), and the synthetic minority over-sampling technique (SMOTE), to improve the classification efficiency for imbalanced data.

We used a large dataset given by a large automotive company based in Egypt. In this study, we apply data-level approaches that could reduce overfitting caused by data imbalance. And we built 32 machine learning models for predicting the occurrence of auto insurance claims ((under-sampling, over-sampling, hybrid of over-and under-sampling, and SMOTE) × (three Decision tree models, three boosting models, and two bagging models) = 32). And we compared the models' accuracy, sensitivities, and specificities to better understand the built models' prediction efficiency.

The following is the structure of this paper: Section II presents the previous studies. Section III explain the data collection, machine learning models, and data-level approaches. Section IV compared the results of the built thirty-

two prediction models. Section V presents concludes. Section VI presents the future work.

II. RELATED WORK

Over the last decade, many researchers have used machine learning algorithm to forecast the occurrence of auto insurance claims. And while machine learning models are efficient at predicting. But when the data is unbalanced, machine learning techniques will simply ignore the small class and allocate the majority of the cases to the common class, resulting in high overall model accuracy. Nonetheless, the performance of the prediction models for the small class will be substantially reduced. The following studies show a lack of using the resampling methods to solve the unbalanced data problem except for the study of [1] that only used the oversampling method.

In the study of machine learning approaches for auto insurance big data [1], they built eight classifiers to predict the occurrence of the claims using big insurance data, including XGBoost, J48, RF, C5.0, CART, K-NN, logistic regression, and naïve Bayes algorithms, and they handled the heavy imbalanced data using the over-sampler method. The RF model performed the best among the eight models. And [2] used two competing methods, XGBoost, and logistic regression, to predict the frequency of motor insurance claims. This study shows that the XGBoost model is slightly better than logistic regression. Furthermore, a model for predicting insurance claims was developed by [3]; they built four classifiers to predict the claims, including XGBoost, J48, ANN, and naïve Bayes algorithms. The XGBoost model performed the best among the four models. Another example of a similar and satisfactory solution to the same problem is the thesis "Research on Probability-based Learning Application on Car Insurance Data" by [4], which used only a Bayesian network to classify either a claim or no claim. And the [5] research also aims to look at data mining techniques for creating a predictive model for auto insurance claim prediction. And they compared three ML methods for predicting claims. Their findings showed that the best predictor was the neural networks.

In summary, despite the relevance of the imbalanced data problem in the insurance industry, there is a lack of comprehensive comparison among the prominent resampling approaches as a strategy to deal with it. The purpose of this study is to investigate the impact of the unbalanced data problem on the performance of machine learning models. This paper solves the unbalanced data problem with several resampling approaches and compares them while utilizing various machine learning classifiers to fill in the gaps in the literature.

In comparison to prior studies, the following are the novel innovations and vital procedures of this study:

- Applying and comparing several resampling algorithms, including the Random Over Sampler, Random Under Sampler, SMOTE, and the hybrid.
- Applying several machine learning models, such as three Decision tree models, three boosting models, and two

bagging models, to compare the performance of resampling methods.

- Measuring the effectiveness of implemented machine learning models utilizing various performance measures such as Accuracy, Sensitivity, and Specificity.
- Demonstrating how resampling affects the performance of classifiers.

III. METHODS

A. Data Collection

Our dataset is progressive record keeping, which usually updates over time to reflect the updated status of a particular customer, which means that provided data is the snapshot of some particular date, where all the records show the updated status of each customer. This dataset is updated on changes in circumstances of the customer, such as marital status, age, etc. The sample auto insurance claims dataset was collected between 2014 and 2018.

The data used in this study is real-life data obtained from an Egyptian car insurance firm; we end up with 81628 claims in the dataset, each of which is a car insurance claim. In total, there are 5714 claims that occurred, and 75914 non- occurred claims, suggesting that the data is heavily unbalanced. And as we mention, the performance of classification algorithms is greatly affected by imbalanced data. So, we apply four resampling techniques to solve the problem of data imbalance. Each claim comprises 17 features. Table I provides Attributes of the data.

B. Data Preprocessing

Numeric values are allocated to categorical variables. For example, instead of male or female as the gender of the insured, the "Male" component would be (1), and "female" would be (0). After this phase, we can apply our data to all machine learning models.

C. Machine-Learning for Auto Insurance Claims Occurrence:

1) *Decision trees*: A decision tree D , in more formal terms, is made up of two kinds of nodes:

- A leaf node that represents the response variable's given class/region.
- A decision node that defines a test on a single attribute (predictor variable) with one branch and subtree for each test outcome.

Using a recursive divide and conquer method, a decision tree can be used to classify an observation by beginning at the top decision node (called the root node) and going down through the other decision nodes until a leaf is encountered.

The following models are the most well-known methodology for constructing decision trees [6,7,8].

- a) CART algorithm.
- b) C5.0 algorithm.
- c) C4.5 algorithm.

TABLE I. ATTRIBUTES OF THE DATA

No.	Description	Descriptive statistics
1	Representing the age of the insured.	Min. :18.00 Mean :44.84 Max. :81.00
2	Represent the Value of the car in Egyptian pounds.	Min. :75000 Mean :304003.5 Max. :6610100
3	Represent the car age in years.	Min. :0.000 Mean :10.298 Max. :28.000
4	Represent the car type.	Such as Mercedes, BMW, and Toyota, etc.
5	Represent the car use.	Commercial:30148 Private: 51480
6	Represent the insured education level.	High School :12244 Bachelors :32856 Masters :16325 PhD :7347 Other :12856
7	Represent the annual Income of the insured In Egyptian pounds.	Min. :0 Mean :61572 Max. :367030
8	Represent the number of dependants for the insured.	Min. :0.0000 Mean :3.000 Max. :5.0000
9	Represent the Marital status	Married:48977 not married:32651
10	Represent the insured's occupation.	The job of the insured
11	Represent the claim frequency.	Min. :0.0000 Mean :0.8007 Max. :5.0000
12	Represent if the insured license was revoked before.	No:71880 Yes:9748
13	Represent The insured gender.	MALE:38365 FAMLE:43263
14	Represent the Distance to work in km	Min. :5.00 Mean :33.42 Max. :142.00
15	Represent where the insured live urban vs. rural area.	Urban:66118 Rural:15510
16	Represent the number of Years on job for the insured(yoj).	Min. :0.00 Mean: 10.47 Max. :23.00
17	Claim occurred or not. (the target variable)	non occurred: 75914 occurred: 5714

2) *Bagging trees*: Bagging, or bootstrap aggregation, is an ensemble meta-algorithm. This algorithm increases the model's consistency and accuracy while also reducing overfitting. In classification, it weights the output to ensemble into a single output. Leo Breiman suggested bagging in 1996 [9] as a way to improve classification results.

The following are the two most common bagging algorithms:

- a) Bagged CART.
- b) Random forest.

3) *Boosting*: Boosting is an ensemble technique that, like training, creates several individual models sequentially. Each new model attempts to correct the errors of the previous group of models. Boosting, like bagging, can be used to improve any supervised machine learning algorithm. Boosting, on the other hand, is most effective when weak learners are used as sub-models. As a result, boosting has historically been used on shallow decision trees. By shallow, I mean a decision tree with a limited number of levels of depth or a single split. Boosting's aim is to bring together a group of weak learners to form a strong ensemble learner [10,11,12].

The following are the two most common bagging algorithms:

- a) AdaBoost.
- b) XGBoost.
- c) Stochastic Gradient Boosting.

D. A Data-level Approach and Imbalanced Data

The imbalanced data problem exists in many datasets; as a result, classifiers models are biased against the minority class and are unable to predict it accurately [13]. In contrast, most machine learning models perform better when applied with balanced datasets [14,15,16,17].

Analysis of our database shows that they are extremely imbalanced, and the two forms of insurance claims are not balanced, with 93% (n=75914) of the auto insurance claims occurred, and those non-occurred were 7% (n=5714). As a consequence, the imbalanced data problem must be addressed. Many techniques have been developed to resolve the problem of unbalanced data. One of the most successful approaches for addressing unbalanced data is using a sampling-based approach, either Random Over Sampler [18], Random Under Sampler [19], and SMOTE [20].

We will use the ROSE and the ovun.sample function incorporates more conventional class inequality solutions, such as over-sampling the minority class, under-sampling the majority class, or a combination of over-and under-sampling. And also, we will use the DMwR package to apply SMOTE as a resampling method.

1) *Over-sampling technique*: This technique increases the weight of the minority class. It's important to note that the technique of over-sampling is typically used more than other methods.

a) *Random over sampler*: Random Over-Sampling is a technique based on bootstrap that supports the binary classification task in the presence of unbalanced classes by generating synthetic examples from a conditional density estimation of the two classes [21]. It handles both continuous and categorical data by randomly replicating samples from the minor class [22]. As a result of this process, the dataset grows in size. The argument is that no new samples are generated by a random over-sampler, and the variety of samples remains constant. Since the sample size grows, the oversampling technique takes longer to construct a model and can cause

overfitting because it duplicates samples from a minor class. [23,24].

b) *SMOTE*: SMOTE is similar to random oversampling. However, it does not regenerate the same instance. It creates a new instance by appropriately combining existing instances, thus making it possible to avoid the disadvantage of overfitting to a certain degree. Moreover, SMOTE is an oversampling technique that produces new minority samples by combining two minorities and one of their K nearest neighbours [25]. This approach is a statistical technique for creating new instances to increase the number of minority samples in a dataset. This algorithm takes characteristic features for the target class and its closest neighbours, then produces new samples by combining the characteristics of a specific case with those of its neighbours.

2) *Random under sampler*: Under-sampling is one of the simplest techniques to dealing with the problem of unbalanced data. It balances the majority and minority classes. The process of under-sampling includes arbitrarily deleting examples from the majority class in the training dataset, referred to as random under-sampling [26]. By reducing the amount of data, under-sampling can save time when building a model, but it comes at the cost of losing information [27,28].

3) *Hybrid methods*: There are several benefits and drawbacks of over-sampling and under-sampling. Combining these two strategies will add the strengths of these two methods to a new method [26].

E. Development of Prediction Models and Prediction Performance Evaluation

This study built thirty-two prediction models ((under-sampling, oversampling, the combination of over-and under-sampling (hybrid), and SMOTE) × (three Decision tree models, three boosting models, and two bagging models) = 32). The accuracy, sensitivity, and specificity of each model are used to compare the prediction performance of the established models.

This study randomly divided the data into a training dataset and a test dataset at a ratio of 7:3. The hyperparameters are tuned using a 10-fold cross-validation that was performed only on the training dataset to get the best performance for each machine learning model. And the test dataset was used to evaluate the prediction performance. The Data-level Approaches must only be applied to the training set while the test set still unbalanced. We used R version 4.0.2 to conduct all analyses.

F. Evaluation Methods

Evaluation methods are essential in comparing and selecting the best model because they are assessing the efficiency of classifiers [1].

Table II shows the Evaluation methods used in this study. Where TP is the number of true positives, the number of false positives is FP, the number of true negatives is TN, and the number of false negatives is FN.

TABLE II. EVALUATION METHODS

Accuracy	Referred to the overall correctly prediction	$\frac{(TP + TN)}{(TP + FP + TN + FN)}$
Sensitivity	Referred to the correct rate of predicting the occur claims	$\frac{TP}{(TP + FN)}$
Specificity	Referred to the correct rate of predicting the non-occur claims.	$\frac{TN}{(FP + TN)}$

IV. RESULTS AND DISCUSSION

To show the difference between the ability of the machine learning classifiers to predict the insurance claims occurrence before and after handling the unbalanced data problem, we compared all applied models on the unbalanced data and also on the balanced data created by different resampling techniques. We measure the performance of models on the testing data using accuracy, sensitivity, and specificity.

A. Comparing the Performance of the Built Machine Learning Models

Tables III, IV, and V show the accuracy, sensitivity, and specificity respectively of the thirty-two prediction models, as well as Fig. 1.

Table III shows the Accuracy of each machine learning technique on unbalanced data and balanced datasets generated by four different resampling models. And we must consider that only if the data is balanced will Accuracy be a valuable metric, while when the data is unbalanced, the Accuracy would be meaningless. Because when the data is unbalanced, most machine learning techniques will simply ignore the small class and allocate most of the unseen cases to the majority class, resulting in high overall model accuracy and high specificity, while the sensitivity of the models will substantially be reduced. The AdaBoost classifier achieved 99.4 % accuracy by using the oversampling, which is the highest of all other classifiers. And the lowest accuracy outcome goes to the C5.0 with 74.84% by using the under-sampling.

Table IV refers to the Sensitivity of the machine learning models. Sensitivity relates to the ability to predict the occurrence of claims. We can note that the Sensitivity for all ML models with the unbalanced data is lower than the Sensitivity for balanced data created by different resampling methods because the occurred claims represent a small class with only 7% in our data. Therefore, before solving the unbalanced data problem, machine learning techniques will simply ignore the small class (occurred claims). Thus, resulting in very low Sensitivity in the case of the unbalanced data. While the Sensitivity is improved after applied the resampling methods. This refers to the effectiveness of using the resampling methods to handle the unbalanced data problem in the insurance industry. And the highest Sensitivity goes to the AdaBoost classifier with 92.94% using the oversampling, while the lowest one goes to the AdaBoost model with 0.46% using the unbalanced data.

TABLE III. THE ACCURACY OF THE DEVELOPED MODELS

Models	Unbalanced	OVER	UNDER	HYBRID	SMOTE
Decision trees models					
C5.0	0.9393	0.9426	0.7484	0.9822	0.8441
C4.5	0.9432	0.96	0.794	0.9544	0.8117
CART	0.9441	0.7791	0.7586	0.8076	0.8316
Bagging models					
Bagged CART	0.939	0.928	0.7487	0.9044	0.8266
Random forest	0.94	0.978	0.7807	0.9806	0.8533
Boosting models					
AdaBoost	0.9385	0.994	0.7516	0.9919	0.8689
XGBoost	0.9386	0.8786	0.7951	0.8715	0.8641
Stochastic Gradient Boosting	0.9396	0.7865	0.7648	0.796	0.8461

TABLE IV. THE SENSITIVITY OF THE DEVELOPED MODELS

Models	unbalanced	OVER	UNDER	HYBRID	SMOTE
Decision trees models					
C5.0	0.1422	0.8415	0.7768	0.8878	0.8098
C4.5	0.1268	0.713	0.6333	0.8633	0.8064
CART	0.1463	0.7098	0.7024	0.6707	0.8
Bagging models					
Bagged CART	0.161	0.1904	0.7309	0.3873	0.6499
Random forest	0.0456	0.8223	0.7244	0.8428	0.8064
Boosting models					
AdaBoost	0.0046	0.9294	0.7175	0.9248	0.8109
XGBoost	0.1139	0.7744	0.7153	0.795	0.8337
Stochastic Gradient Boosting	0.1162	0.7358	0.7585	0.7289	0.7722

Table V refer to the Specificity of the machine learning models. Specificity refers to the ability to predict non-occurred claims. We can note that the Specificity for all models with unbalanced data is highest than the Specificity for balanced data created by different resampling methods because the non-

occurred claims represent the majority class with 93% in our data. Therefore, before solving the unbalanced data problem, machine learning techniques will allocate the most unseen cases to the majority class (non-occurred claims). This is resulting in very high overall model Specificity in the case of the unbalanced data. But our objective is to detect MINOR class more accurately than MAJOR class; therefore, we are interested in Sensitivity more than Specificity. SO, we need to resample the dataset to force algorithms to identify both classes with equal importance. And the highest Specificity in the dataset belongs to AdaBoost classifiers with 99.93% using the unbalanced data, and the lowest one goes to the C5.0 model with 74.65 % using the under-sampling.

Last but not least, from Tables III, IV, V, and Fig. 1, we can conclude that using the resampling methods is very effective for handle the unbalanced data problem in the insurance industry, because the best results are achieved after applied the data-level approaches.

And the best models are AdaBoost with the over and hybrid methods, then the C5.0 model with the hybrid method, and then the random forest model with the hybrid method. Where AdaBoost with the over and hybrid methods achieved a sensitivity of 92.94%, a specificity of 99.82%, and an accuracy of 99.4%. And a sensitivity of 92.48%, a specificity of 99.63%, and an accuracy of 99.19%, respectively. And the C5.0 model with the hybrid method has a sensitivity of 88.78%, a specificity of 98.79%, and an accuracy of 98.22%. Then there's the random forest model with the hybrid method, which has a sensitivity of 84.28%, a specificity of 98.96%, and an accuracy of 98.06%.

TABLE V. THE SPECIFICITY OF THE DEVELOPED MODELS

B. Variables Importance for Auto Insurance Claims Classification in the AdaBoost with the Oversampling

The importance of the variables of the final model (AdaBoost with the oversampling) is presented in Fig. 2.

Fig. 2. The Importance of Variables in the AdaBoost Classifier with Oversampling-based Claims Occurrence Prediction Model.

V. CONCLUSION

This study specifically established models for improving the classification efficiency of imbalanced data by using oversampling, under-sampling, the combination of over-and under-sampling, and SMOTE as resampling approaches. ((under-sampling, oversampling, a combination of over-and under-sampling (hybrid), and SMOTE) × (three Decision tree models, three boosting models, and two bagging models) =32)

for predicting auto insurance claims occurrence. According to the findings of this analysis, the AdaBoost model with over and hybrid could generate more accurate models than other boosting models, Decision tree models, and bagging models, then the C5.0 model with the hybrid method, and then the random forest model with the hybrid method.

VI. FUTURE WORK

Further research is required to compare the accuracy using various datasets from various fields to prove the prediction efficiency of an AdaBoost classifier with resampling methods to solve the imbalanced data problem. And Future work may be done in the following directions: Using hybrid machine learning classifiers to improve comparison and performance. And also, use different feature selection approaches to enhance model results and gain a deeper understanding of the important features.

Abstract—High dimensionality is one of the main issues associated with text classification, such as selecting the most discrepant features subset for classifier's effective utilization is a difficult task. This significant preprocessing stage of selecting the relevant features is often called feature selection or feature filtering. Eliminating the non-relevant and noise features from the original feature set will drastically reduce the size of the feature set and the time complexity of the classification models and also improve or maintain their performance. Most of the existing filtering method produced a subset with relatively high number of features without much significant impact on running time, or produced subset with lesser number of features but results in performance degradation. In this paper, we proposed a new bi-strategy filtering approach that integrates Information Gain with t-test that selects a subset of informative features by considering both the score and ranking of respective features. Our approach considers the results' disparity produced by the benchmark metrics used in order to maximized and lessen their advantage and disadvantage. The approach set a new threshold parameter by computing V-score of the features with minimum scores present in both the two subsets and further refined the selected features. Hence, it reduces the size of the features subset without losing much informative features. Experiment results conducted on three different text datasets have shown that the proposed method is able to select features that are highly discrepant and at the same time achieves a significant improvement in terms of classification accuracy and F-score at the cost of a minimum running time.

Keywords—Dimensional reduction; feature filtering; feature selection; t-test; information gain; V-score

I. INTRODUCTION

In this emerging era of computing and internet technology, especially the emerging of social media, text analytic becomes more cumbersome[1]. As a result, both the size of features and instances of a textual dataset has been increasing rapidly. The increasing size of the text data results in diverse research problems to text analytic tools, such as machine learning. Text classification is one of the pronounce problem associated with text analytics [2][3], and currently is becoming one of the most vital research direction in the field of machine learning.

Text classification or documents classification is the problem of assigning unlabeled text instances to one or more predefined labelled classes or categories [4] [5][6][7]. Text classification has been utilized in various application domains [8], e.g. spam filtering [9], Sentiment Analysis [10], Natural

Language Processing [11][12] Information Retrieval, Text Mining and so on.

One of the most crucial steps of the preprocessing of text data is the presentation of text documents into vector space via Bag_of_Word (BOW) [13][14][15]. The final product of this task is associated with two main issues, a vast number of features representation, and the presence of irrelevant and noisy features which general termed high dimensionality[15]. These issues can cause a lot of problems for the Text classification task, which is known to be intrinsically high dimensional [4] [5]. Classification in a situation that involves high number of features or high-dimensional space can become infeasible or very difficult due to computational complexity expensiveness [16][17]. However, feature reduction approach is considered as a dimensional reduction problem. The huge features generated introduces the so-called "dimensionality curse" with thousands of features that increase the computational complexity of a classifier [18][19][20][21][22]. Curse of dimensionality is a popular known problem for machine learning models [23]. When it arises in text classification, it seriously worsens the performance of the classifier in terms of classification accuracy and running time [5][24].

The main goal of dimensionality reduction is to reduce the number of features without worsening the performance of the classifier [14] [19]. As the key way to overcome this problem, feature selection (FS) technique can be applied to filter out irrelevant, redundant and noisy features and selects the most informative subset of features from the original features set [1][19]. This task will aggressively reduce the original vectors space representation of features into lower-dimensional vector representation [25][26][27]. Moreover, the properties of the informative features in the original feature set would be unaltered in the processes of dimensionality reduction. Feature selection (FS) approach ranks the original features according to some criterion evaluation (scores) and selects the top-ranked features to form an informative subset [27], which retains a good degree of discriminating capability in separating documents of various categories [28][29]. In contrast to the feature selection, feature extraction approach transforms the text documents on to a new lower-dimensional space from their original high dimensional feature instead of selecting a features subset from the original features set [30][31] [15].

Generally, feature selection methods [32] are broadly grouped into filter methods, wrapper methods[33], and embedded methods [34][35][27]. Filter methods [36] are independent that they do not interact with classifier when constructing an informative features subset. They rely on metrics for evaluating and ranking the importance of a feature prior to the classification. The methods can attain quick feature sorting to effectively filter out a high number of non-relevant or noise features [27]. They select features subset by considering the usefulness of a feature according to evaluation metrics [35][28][27][37]. Filter methods usually have good computational efficiency but sacrifice classification accuracy to some extent. Information Gain [38], Chi-Square [39], Fisher Score [40], ReliefF [41], *t*-test [4] are among the few filter based methods. Wrapper methods are dependent on classifiers that they frequently interact with the classification algorithm in order to construct a subset of informative features [13][35][27]. They evaluate a particular feature subset by training and testing a given classifier. The methods are tailored to a particular classifier [42]. These methods have bad computational efficiency but result in high classification accuracy, and they are not usually favoured in text classification task [43]. Heuristic Search Algorithms (HSA) and Sequential Selection Algorithms (SSA) [44][45][46] are common examples of classical wrapper methods. Embedded Methods integrate classifiers with feature selection technique during the training phase and optimally search feature subset by designing an optimization function [35][44][47]. Like wrapper methods, embedded methods frequently interact with the classifier but have computational efficiency better than wrapper methods, and are also tailored to a specific classifier [43]. Selection-Perceptron (FS-P)[48], Support Vector Machines (SVM-RFE) [49], Lasso (L1) and Elastic Net (L1+L2) based models [50][51] are some few examples of embedded based methods.

This paper is based on filter FS approach, and goal of this research work is to propose a new approach that selects more informative features from the original features set which help classification model to achieve good performance with regard to both time complexity and classification accuracy. The main point of view is on dimensional reduction, to reduce the number of features and processing time without sacrificing the classification accuracy. The features are exposed to double filter-based evaluation metrics (IG and *t-test*), in which at the final output, are obtained, only the discriminate features that highly contribute to the classification task, and produce a lower dimensionality subset base on features' respective rank and score. The approach blends the concepts of intersection and vector magnitude to select a subset of refined informative features by considering both the score and ranking of respective features. An experiment conducted with three distinct text datasets has shown that the proposed approach produces acceptable results by achieving a recorded performance of 67.65%, 54.74%, and 80.16%, and running time of 7464ms, 4689ms, and 29806ms on 20NewsGroups, NewsCategory, and Reuters-21784, respectively. This shows that the method retains most of the informative features when compared with other chosen methods.

The remaining body of this paper is systematically partitioned as follows: In Section 2, related works are presented. The proposed approach and the Filter-based feature selection methods employed explicitly by the approach, namely IG and *t*-test are discussed in Section 3. Properties of the datasets used and experimental set up are devoted to Section 4. Experiment results and discussion are systematically placed in Section 5. Finally, the study ends with a conclusion and highlights of possible future work which are given in Section 6.

II. RELATED WORKS

There are large number of research works on filter-based feature selection metrics to remove irrelevant and noisy features in text classification problem. The primary aim is often to reduce the feature dimensionality so as to minimize the processing time without sacrificing or improving the classification accuracy. In an effort to reduce the computational complexity, some numerous current works hybridized multiple scoring metrics to select most informative features. Results discrepancy is among the top challenges in hybridization approach as different results would be obtained when applying different evaluation metrics on the same dataset [38], and this issue can result in selecting noncontributory features. In this section, we will briefly present some review of those works, and lastly, we will summarize the drawbacks of the existing methods.

Lewis [52] uses mutual information (MI) to measure the importance of a feature, thus proposed a new scoring metric known as Mutual Information Maximization (MIM) that computes the relevancy between n features and classes. Liu and Setiono [39] proposed an algorithm that computes the score of each feature and selects relevant features based on chi-square score. The algorithm calculates the numeric attribute intervals and selects features according to the statistical data characteristics. A comparative study by Mladenic and Grobelnik [53] on a different dataset was conducted, and only for the Multinomial Naïve Bayes (NB) model upheld Odds Ratio over a wide variety of evaluation metrics been compared. For feature filtering, Bi-Normal Separation (BNS) has previously been described to be outstanding in ranking terms. Forman [54] improve an existing scoring metric for features by substituting IDF with BNS. The new method, TF-BNS scales the magnitude values and rank features by computing the BNS score of every feature. Empirical evaluation of text classification tasks using Support Vector Machine (SVM) shown significantly better performance in terms of F-measure and accuracy. Uguz [55] applies IG to ranked terms in a given document according to their importance in the initial stage of his proposed framework. Vinh et al. [56] proposed a new approach for selecting feature by normalizing well known MI (Mutual Information) measurement and used it to assess the potentiality of the features. Despite the competitive results achieved, the proposed approach could not conceal the highly correlated features influence the classification outcomes. Azhagusundari and Thanamani [57] developed a feature selection method based on IG for selecting the discriminant features from a give original set. The authors used IG to build a discernibility matrix which could be used to select the optimal subset of

features from the set of original data. Experimentally they showed their method obtained comparative classification accuracy on comparison with the original dimensionality. A greedy feature selection method using mutual information is introduced by Hoque and et al. [58]. The method blends feature–feature and feature–class MI to select the optimal feature subset. Wang et al. [4] use the concept of term frequency and developed a new feature scoring metric approach based on t-test, the method measures the diversity of the distributions of a feature between the particular category and the entire dataset. Experiment results indicate that the proposed method is marginally better than IG and chi-square method in terms of micro-F1 and macro-F1. Rehman et al. [5] proposed a novel function metric for feature ranking named Normalized Differences Measure (NDM), which evaluate the rank of a term by considering the term's relative document frequencies in both positive and negative classes. Zhou et al. [37] proposed a feature selection algorithm that uses segmented term frequency to compute the frequency of a document. Moreover, the impact of the same feature term to the classification under the dissimilar frequency of term is deeply considered. The algorithm uses the resultant terms' frequencies to give scores to each available feature and selects those features that are above a defined threshold. When Compared with six different FS methods, the empirical result demonstrated that the proposed method could able to increase classification accuracy on a textual dataset.

All the works mentioned earlier are single FS methods that consider only a single strategy for the selection of an informative subset of features. Consideration of multiple strategies altogether is impossible with a single feature selection method. In view of that, the hybridization approach has received significant attention in the field of dimensional reduction currently. The methods combined different FS methods considering various aspects of the features into single. Tsai and Hsiao [59] combine multiple methods for dimensional reduction to figure out more informative features for stock prices prediction task. The method integrates decision tree, PCA, and genetic algorithm as search methods, and utilizes the concept of an intersection, union, and multi-intersection approaches to filter out irrelevant variables. An intermediary method of union (OR) and Intersection (AND) approach named modified union is presented by Bharti and Singh [60]. The authors applied union (OR) and intersection (AND) on k -top selected ranked features, and on remaining unselected features subset, this merges the feature subsets into a single subset and further select the most relevant features. The feature filtering methods used in the study are document frequency (DF) together with term variance (TV). To exploit the advantages of two different FS methods, a hybridization of cluster-based and the frequency-based approach is presented by Nguyen and Bao [13]. The proposed method termed FCFS on comparison with its counterpart achieved the best performance in terms of micro-F1. To tackle the problem of results discrepancies, a new feature selection approach that combines the computed scores from multiple FS methods into one is proposed by Rajab [61]. The proposed method normalizes and computes vector score (V-Score) magnitude of each feature using the scores produced based on IG and Chi-square function metrics, and selects the top-ranked features.

Kamalov and Thabtah [62] proposed a method that selects optimal features from sets with ranking features produced by three different ranking strategies. The authors used vector scores (V-Scores) to stabilize the scores obtained from three methods (IG, Chi-square, and inter-correlation) and assign a new rank to each feature. To further remove non-relevant and noise features from feature subsets produced by two different evaluation functions, Li et al. [27] consider the application of union approach on the lowest rank feature subset produce by Fisher score and IG methods.

Many studies have investigated the strength of several filtering methods and their combination in the literature. Forman [32] empirically studied and compared twelve different evaluation metrics for feature selection on a text classification problem, and they finally revealed that BNS with IG has the minimum correlated failure so as mark best backup choice. The impact of integrating five methods for FS was investigated by Thubaity et al. [63]. The study employed IG, Chi-square, NGL, GSS, and RS methods on Arabic textual dataset. Union (OR) and intersection (AND) approach were utilized to integrate the scores produced from various FS methods employed to a single sorted feature set. Results Analysis showed there was no any improvement recorded in terms of classification accuracy when more than three FS metrics were integrated, while a small improvement was noticed for integrating two to three FS metrics. Vora and Yang [64] present a comparative study on ten different filtering methods namely Fisher Score, Chi-square, Gini Index, Laplacian Score, IG, mRmR, CFS, FCBF, Kruskal-Wallis, and RELIEFF. Experimented on five different text dataset, the authors found that combination of Kruskal-Wallis, Gini Index with SVM classifier lead the race as it achieved competitive classification performance but takes longer processing time, while IG and Chi-2 are projected as methods with a large number of similar features have been selected.

III. MATERIAL AND METHOD

This section presents a brief discuss on the information gain and t-test algorithm since both are useful for the proposed approach that will be explained in sub-section C.

A. Information Gain Algorithm

Gain (IG) [38][65], is an information theoretical and entropy-based method which is widely used in the field of dimensional reduction [43] [37]. IG is previously used to determine attribute use in splitting instances in decision tree-based models [66] and currently is applied to select the informative features subset in a given set of features. The method computes and assigns score to each feature considering the variation between entropy obtained based on presence or absence of term in a given category [37]. High information gain or high score indicates the discriminating capability of a feature and ranked top. The entropy of discrete random variable X is formulated as:

$$H(X) = -\sum_{x_i \in X} P(x_i) \log(P(x_i)) \quad (1)$$

x_i denotes a specific event of the variable X , $P(x_i)$ denotes the probability of an event (x_i). The general formula for computing IG of a given feature t is given as:

$$IG(t, c) = \sum_{c \in \{c_i, \bar{c}_i\}} \sum_{t \in \{t_k, \bar{t}_k\}} P(t, c) * \log \left(\frac{P(t, c)}{P(t) * P(c)} \right) \quad (2)$$

where $P(t, c)$ is the probability of class c and occurrence of the feature t . $P(t)$ is the probability of class containing feature t , $P(c)$ is the probability of class c . \bar{t}_k and \bar{c}_k denote feature not present, and class not present, respectively. Let N represent the total number of documents in a given dataset, and N_s with indicated subscripts values represents counts of documents. Using Maximum Likelihood estimates (MLEs) of probabilities, equation (2) can be expressed as:

$$I(t, c) = \frac{N_{11}}{N} \log_2 \left(\frac{NN_{11}}{N_1 N_1} \right) + \frac{N_{01}}{N} \log_2 \left(\frac{NN_{01}}{N_0 N_1} \right) + \frac{N_{10}}{N} \log_2 \left(\frac{NN_{10}}{N_1 N_0} \right) + \frac{N_{00}}{N} \log_2 \left(\frac{NN_{00}}{N_0 N_0} \right) \quad (3)$$

In information theory logic, a term/feature contains about the class, if the distribution of a term is equivalent in the class as it is in the whole collection, then $I(t, c) = 0$. IG attains its optimal value if the term is a perfect discriminator for class membership if the term exists in a document if only the document is in the class.

B. Student Statistical Test Algorithm

Statistical Test (t -test) is a statistical-based method which is commonly used to evaluate if the means of two groups are statistically different from each other by computing a ratio between the mean difference of two groups and the variability of the two groups [4][67]. Presently, t -test is widely used as an evaluation function to select significant features that contribute to classifying instances. The method computes score of feature by measuring the distinct distributions of the term in relevant category and documents collection [68]. The formula for calculating t -test is given as:

$$t - test(t_i, c_k) = \frac{|tf_{ki} - \bar{t}_i|}{m_k \times s_i} \quad (4)$$

$$S_i^2 = \frac{1}{N-K} \sum_{k=1}^k \sum_{j \in C_k} (tf_{ij} - \bar{t}_i)^2 \quad (5)$$

$$m_k = \sqrt{\frac{1}{N_k} - \frac{1}{N}} \quad (6)$$

Each class's specific scores obtained from (4) are combined to find the final score as follows:

$$t - test_{avg}(t_i) = \sum_{k=1}^k t - test(t_i, C_k) \quad (7)$$

where S_i denotes the standard deviation within a category, C_k denotes the k^{th} category, N_k is the number of documents in k^{th} category, k is the total number of categories, tf_{ki} denotes the average TF of term t_i in category k , \bar{t}_i denotes average TF of term t_i in the corpus. N is the total number of documents.

However, when the score is less than the defined threshold, it indicates that the feature has lower discrimination ability; otherwise, the feature will contribute in the classifying instances and will be selected.

C. Proposed Approach

Considering the problem of result discrepancy produced when two filtering methods are combined, and the risk of

losing informative features, an approach is proposed named new bi-strategy feature filtering approach which hybridizes IG with t -test to remove indiscriminate features by taking into consideration both feature ranking and vector score magnitude (V -score). The approach applies IG and t -test metrics independently to compute scores and assign the computed scores to each feature in the original features set, let say D_1 and D_2 . The top-ranked features that are greater than a predefined threshold K_1 are considered as significant features and are selected, new subsets of features S_1 and S_2 , which are based on IG and t -test are generated independently. Next, a feature with minimum IG score from S_1 and a feature with minimum t -test score from S_2 that are present in both S_1 and S_2 are selected and their V -scores are computed. The minimum V -score among the two computed V -scores is set as the new threshold K_2 . The approach further refines the features subsets by selecting a feature only if it is present in S_1 or S_2 and its V -score is greater than the new defined threshold K_2 otherwise it is an indiscriminate feature and will be neglected.

V -score of a given feature is computed using the concept of vector magnitude proposed in [61] that is, summing the squares of a vector's coordinates and taking the square root of the summation, it is formulated as:

$$V_{score} = \sqrt{(IG_{score})^2 + (t - test_{score})^2} \quad (8)$$

NB: The values of the scores produced by IG is different from that of t -test. So, we have to normalize the scores first before computing V -score so as to uniformly transform them into equivalent scale.

Let us consider Table I below, which contains few samples extracted from 20NewsGroups. It shows generated ranking of each feature based on the chosen filter methods. It can be seen that there are presence of discrepancies in the output. This issue arises due to the different theoretical strategy used by distinct filter methods to compute the score of each feature in the given dataset. IG ranked "Thanks" the lowest while t -test ranked it the highest, there is high assurance for IG method to eliminate this particular feature when a threshold is defined despite it has been selected by t -test method as the most informative feature. Therefore, both methods fall into the problem of losing informative features, likewise the existing hybrid filtering methods. Nevertheless, the proposed approach mitigates such issue by considering both the ranking and score of each feature. The approach sets a new thresholds base on computed V -score and further refines the features subset.

TABLE I. RANKING PRODUCED BY IG AND T-TEST FILTER METHODS

Framework of the proposed approach is based on the following algorithm 1:

ALGORITHM 1: PROPOSED BI-STRATEGY FILTERING APPROACH “MIN_MAX_V-SCORE”

INPUT:

- D : Set of documents with N features
- c : Set of label classes
- K_j : Initial threshold

OUTPUT:

- SL : Subset of selected features

FEATURE_SCORING(D, c)

```

1.  $L_1 \leftarrow [], L_2 \leftarrow []$ 
2.  $T \leftarrow$  EXTRACT TREMS IN DOCUMENTS ( $D$ )
3. For each  $t_i$  in  $T$  do:
4.    $A(t_i, c) \leftarrow$  COMPUTE(SCORE( $t_i, c$ )) using
     eqe(1) through eqe(3)
5.   APPEND( $L_1(A(t_i, c), t_i)$ )
6.    $A(t_i, c) \leftarrow$  COMPUTE(SCORE( $t_i, c$ )) using
     eqe(4) through eqe(7)
7.   APPEND( $L_2(A(t_i, c), t_i)$ )
8. End For
9. SORT( $L_1$ ), SORT ( $L_2$ )
10. Return  $L_1, L_2$ 

```

Begin

```

1.  $L_1, L_2 \leftarrow$  FEATURE_SCORING( $D, c$ )
2.  $FS1 \leftarrow k_1 \% \{L_1\} = \{t_1, \dots, t_q\}$ 
3.  $FS2 \leftarrow k_1 \% \{L_2\} = \{t_1, \dots, t_n\}$ 
4.  $j \leftarrow q$ 
5. For  $t_i$  in [SORT.descend( $FS1$ )]
6.   Normalise ( $t_i$ )
7.   If  $t_i \in \{FS1\} \cap \{FS2\}$ 
8.      $V_{score}(1) \leftarrow$  COMPUTE( $V_{score\_of\_t_i}$  using
       eqe (8))
9.     Break
10.  For  $t_j$  in [SORT.descend( $FS2$ )]
11.    Normalise ( $t_j$ )
12.    If  $t_j \in \{FS1\} \cap \{FS2\}$ 
13.       $V_{score}(2) \leftarrow$  COMPUTE( $V_{score\_of\_t_j}$  using
        eqe(8))
14.      Break
15.   $k_2 \leftarrow$  MIN( $V_{score}(1), V_{score}(2)$ )
16.  APPEND [ $SL, \{FS1 \cap FS2\}$ ]
17.  For  $t_i$  in [ $\{L_1 \cup L_2\} - \{SL\}$ ] do
18.    If  $V_{score}(t_i) \geq k_2$ 
19.      APPEND[ $SL, (t_i)$ ]
20.  End For
21. Return  $SL$ 

```

End

A summarized flowchart of the proposed methodology is depicted in Fig. 1. The process begins with the raw datasets as input. After relatively balancing the all unbalanced datasets, then original features set is constructed using TF-IDF. Next step is the initial features subsets formation using IG and t-test filter methods to compute and assign a score to all features and a sequence of high ranked features will be selected. Next,

we employed the proposed BI-strategy filtering approach to further refined the initial features subsets and generate the new informative features subset. Lastly, we validate the new approach by recording the Classification accuracy and f-score of the selected classifiers.

Fig. 1. Flowchart of the Proposed Methodology.

D. Experiment and Datasets

In this sub-section, summary of the datasets used and the experimental process adapted are briefly explained. The classification algorithms employed are also presented. Lastly, the section ends with a discussion on classifiers and implementation requirements.

1) *Dataset*: To evaluate the proposed approach in this experiment, the well-known three text benchmark datasets widely used for multi-class classification task is selected. Two of the datasets (Reuters 21578 and News Category) are unbalanced while the other one (20newsGroups) is balanced. We believed that both the datasets are highly dimensional with large number of samples, and also diversity amount of classes is considered. The summary information of the datasets is display in Table II.

TABLE II. SUMMARY OF THE DATASETS USED

Dataset	#Instances	#Features	#Classes
20news Groups	18846	173451	20
News Category	140597	1268350	36
Reuters-21578	11367	16578	90

The 20NewsGroups approximately comprises of 20,000 documents gathered from the collection of Usenet Newsgroups [69], and it consists of relatively balanced 20 distinct categories, each category contains around 1000 documents. The Reuters-21578 comprises of 21578 documents gathered from Reuters newswire, and it consists of unbalanced 135 categories with each document is associated with at least one categories (multi-label) [70][60]. Before importing the dataset into our experiment, we assigned only one category label to each document by stripping out all country names on the list and selecting the first topic left. Moreover, any document that is not associated with any topic was also eliminated from the dataset. This significantly reduced the number of categories and documents to 90 and 11367. The News Category comprises of around 150, 000 samples gathered from Short News Category, and it consists of unbalanced 41 categories with each document is associated with at least one categories (multi-label). We combined some few categories that can be naturally merged together, such as 'CULTURE & ARTS', ARTS & CULTURE', and 'ART'. We finally reduced the number of categories to 36.

2) *Experiment settings*: In the initial phase of the experiment, all English letters are converted into lowercase, stop words are removed, and words having non-characters are filtered. After then, roots of English words are found by applying porter stemmer algorithm [71]. And lastly, feature extraction is performed using TF-IDF weighting [72]. NB: all the three datasets are randomly divided into 60% training and 40% testing.

To validate the proposed filtering approach and its effectiveness on classification models, two existing benchmark methods for feature filtering are selected for comparison, namely IG and t-test. The selection is based on the fact that the proposed method is a hybrid of the selected methods. Besides the new approach, three other existing hybrid filtering approaches include Union (OR) approach, Intersection (AND) approach and Vector Magnitude (V-score) approach proposed in [61] are also selected. The initial threshold value K_l is based on the number of features been ranked in the original set and was set as 60% for both IG and t-test, any feature below the predefined threshold is low scored feature and will be disregarded otherwise will be qualified for further selection evaluation. Jaccard Similarity Coefficients (JCC) is used in this study to measure the similarity of features been selected by different benchmark filtering methods.

Five different well-known classification methods are used for validation purpose in this study. The selection is based on the positive recommendation of the methods in terms of text multi-class classification. The selected methods including Support Vector Machine (SVM) [18][22], Naïve Bayes (NB) [73], Decision Tree (DT) [38], Random Forest (RF)[74][18], and Ridge Regression (RR) [75][76]. All these models will be used to record the classification accuracy and performance of the stated filtering methods. Default values of most of the parameters associated with the classification methods are retained. For SVM and NB, multi-class SVC with kernel function and MultinomialNB are adapted while for RF number

of estimation was set to 100 when executed on 20News groups and Reuters 21578 datasets and set to 20 on News Category dataset, respectively.

Because of space limit, the performance of the classification methods will be reported using two standard recognized metrics widely used for text classification in literature, namely, Accuracy and F1-score. Accuracy is the percentage of the documents that are classified correctly in the given entire documents dataset. F1-score is the representation of harmonic mean of precision and recall. Accuracy and F1-score were computed using the following equations.

$$accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (9)$$

$$f - score = \frac{2 \times P \times R}{P+R} \quad (10)$$

Where, 'TP' = True Positive (documents correctly classified as positive), 'TN' = True Negative (documents correctly classified as negative), 'FP' = False Positive (documents incorrectly classified as Positive), 'FN' = False Negative (documents incorrectly classified as Negative), and 'P' and 'R' are precision and recall values and are computed using the following equations.

$$precision = \frac{TP}{TP+FP} \quad (11)$$

$$recall = \frac{TP}{TP+FN} \quad (12)$$

In this study, all the implementations for the experiment are conducted on Python (V3.8.2) environment, which is installed on a computer with Windows 8 (OS). Other minimum required conditions for the experiment include Intel(R) Core™ i5 processor4300m@2.60GHz/8GRAM/64 GB.

IV. DISCUSSION OF RESULTS

Table III shows a brief description of the chosen filtering methods based on the formulation and strategy adapted. As it can be seen that all the selected hybrid filtering method were formulated by integrating information theory and statistical theoretical based benchmark methods (IG and t-test), the reason behind the selection of this two benchmark methods is by considering the Jaccard Similarity Coefficients between them which is very low compared to other methods. The average percentages of features reduced by different methods in all the three datasets are displayed in Fig. 2. From the figure, it can be seen that the percentage reduction differences in terms of feature dimensions between the proposed method (PM) and existing methods (IG, TS, UA, IA, VS). PM, UA, and IA reduced the number of features by 52.07%, 19.2% and 60% on 20NewsGroups Dataset, where as 48.08%, 26.53%, and 53.48% on NewsCategory Dataset and finally 45.25%, 28.86% and 51.15% on Reuters-21578 Dataset respectively. While IG, TS and VS reduced the features by 40% in all the three datasets, this is because a fixed threshold K_l was defined in all the experiments. The figure reveals in all the three datasets, the proposed method comparatively reduces the feature dimensions, with IA and UA achieved the highest and lowest percentage of features been reduced in all the datasets.

TABLE III. A BRIEF DESCRIPTION OF THE EXISTING AND PROPOSED FILTERING METHOD(S) EMPLOYED FOR THE EXPERIMENT

Method	Acronym	Description	Strategy
Information Gain	IG	Selects top-ranked k features based on IG scores: {K%(IG)}	Single
t-test	TS	Selects top-ranked features based on t-test score: {K%(TS)}	Single
Union Approach	UA	Selects features from hybrid of IG and TS based on Union (OR) approach: {K%(IG)} U {K%(TS)}	Hybrid
Intersection Approach	IA	Selects features from hybrid of IG and TS based on intersection (AND) approach : {K%(IG)} ∩ {K%(TS)}	Hybrid
V-Score	VS	Selects features from hybrid of IG and TS based on V-score: {K%(VS)}	Hybrid
Proposed Approach	PM	Selects features from hybrid of IG and TS based on modified V-score: {K ₂ %VS({K ₁ (IG) U K ₁ (TS)})}	Hybrid

The proposed approach could not beat IA method in terms of feature reduction because we seriously take into

	Running Time (ms)	7676	7901	7880	7942	7676	7899

In Table IV, accuracy results and running times are summarized for different chosen filtering methods on 20 Newsgroups dataset. Both the methods showed good performance with all the classifiers except with DT. The average classification accuracy, when filtering methods (IG, TS, UA, IA, VS and PM) were applied are 67.54%, 68.09%, 67.20%, 65.51%, 66.90%, and 67.65%. However, from the average score, we notice that the accuracy by different filtering methods is basically at the same level across all the classifiers with TS achieved the highest accuracy score followed by our method with no much significant difference. As can be seen from the table, in terms of running time, the proposed approach and IA marked the lowest as they achieved an average running time of 7464ms and 7425ms, thus supersede TS and the other methods. In particular, our method shows competitive performance on 20NewsGroups dataset.

The classification performance on NewsCategory dataset is shown in Table V. the average classification accuracy for the filter methods are 54.29%, 54.40%, 54.50%, 51.14%, 54.46%, and 54.75%. We notice the average accuracy of the proposed approach is comparatively little bit higher than that of the other filter methods compared. From the table, it can be seen that in most cases, our approach achieved a lower running time (4689ms averagely) but a little bit higher than IA (4635ms averagely). However, the overall comparison on NewsCategory dataset shows our method achieved significant performance.

Table VI reports the classification performance on Reuters-21578 dataset. It shows that the accuracy by different filtering methods is roughly similar. The average accuracy for the filter methods are 79.78%, 79.87%, 75.72%, 80.00%, and 80.16%. Compared with the other filter methods, the average accuracy of the proposed method is comparatively higher. The lowest average running time is achieved by IA as 29865ms and then followed by our method as 29806ms upon all the filter methods.

In general, the performance of the filter methods reported on each dataset is roughly at the same level across all the five classifiers. On 20NewsGroups dataset, we observed that TS recorded the highest classification accuracy with a slice

difference than that of our method, but the running of our method is significantly lower than that of TS. While on NewsCategory and Reuters-21576 datasets, our method recorded the highest classification accuracy with lower running time. IA generally recorded the lowest running time upon all the classifiers but sacrificed their performance. This indicates that the method filters out some informative features, thus reducing classification capability. On the other hand, IG, TS, UA, and VS achieved competitive performance but the running time is significantly high, and this indicates the presence of noise and irrelevant features in the final subset produced which need to filter out so as to reduce the time complexity. We also observed that the best accuracy results were obtained with the Ridge classifier and SVC classifier, whereas the results that are obtained with DT are comparatively bad. Generally, the proposed method achieves acceptable performance on all datasets, which indicates that this kind of filter method can not only reduce the size of the features set but also ensure that informative features are retained so that the performance of a classifier is not sacrificing.

Despite work done to balance the two unbalanced datasets used in this experiment still, the datasets are relatively unbalanced. Therefore using accuracy metrics to evaluate the performance could be misleading. In order to further verified the validity of the proposed approach, Fig. 3, 4 and 5 shows the performance results based on F-score of the chosen classifiers when the proposed and existing filter methods were applied on the three datasets selected. Examining both the figures, we can see that the results obtained are in line with accuracy results obtained in Tables IV, V, and VI. The information depicted in Fig. 3 shows the approach recorded the highest F-score after TS with a relatively small difference. Moreover, in Fig. 4 and 5, the proposed approach attains the highest F- score with a minimal gap. Therefore, we conclude that the proposed method achieves the best classification performance in terms of the highest F-score on most of the cases. Although the proposed approach, does not always give the highest result on all the datasets such as with 20NewsGroups, but the F-scores results are still acceptable.

Fig. 3. Performance of the Existing and Proposed Filtering Method(s) in Terms of F-Score on 20 News Groups Dataset.

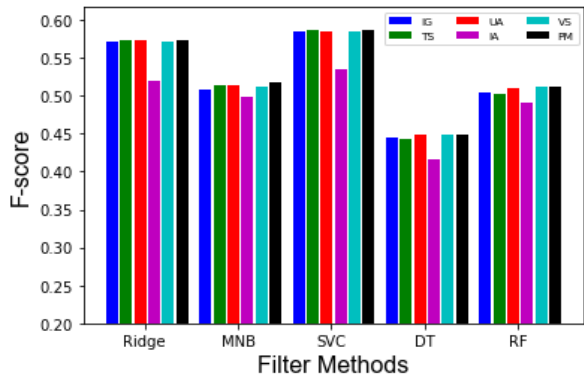

Fig. 4. Performance of the Existing and Proposed Filtering Method(s) in Terms of F-Score on News Category Dataset.

Fig. 5. Performance of the Existing and Proposed Filtering Method(s) in Terms of F-Score on Reuters-21578 Dataset.

V. CONCLUSION AND FUTURE DIRECTIONS

Filter-based Feature selection is one of the dimensional reduction techniques, and it is an important preprocessing step of any text classification problem. Selecting the most informative features is one of the main problems faced in building a robust classifier due to performance degradation and time complexity. Reducing the dimension of features by removing irrelevant and noise features as well as retaining the relevant features will significantly reduce the classifiers' computational complexity. There have been a quiet number of works done in the literature to address this problem. The

common filtering methods select features by considering a single theoretical approach. Recently, a hybrid approach that combines multiple filtering methods based on different theoretical approach receives more attention. These methods produce a discrepancy in the result that makes combining features subsets produced into a single subset and selecting significant features a difficult task. In this paper, we propose a novel Bi-strategy fileting approach that uses the combined scores of IG and t -test to produce refined features subsets by setting a new threshold. The method filters out common features with low V-scores from the considered subsets of features without sacrificing classifier's performance. First, two subsets with high ranked features based on IG and t -test are produced. This is done by defining the initial threshold K_1 . Then the method identified a feature with minimum IG and t -test scores that are present in both subsets produced and compute their V-scores. The minimum V-score is set as the new threshold K_2 , and it is used to further filter out insignificant features from the IG and t -test subsets.

In order to validate the performance of the proposed method, the study presents a comparison based on accuracy and F-score of the filtering approach with that of benchmark methods include IG, t -test (TS), and existing hybrid subsets merging approaches include Union (UA), Intersection (IA) and V-score (VS) using five classification algorithms. The experiment is conducted using three different text datasets, 20Newsgroups, NewsCategory, and Reuters-21578. Results in Fig. 2 show that our filter method produces a subset with features that is higher than that of IA in number but smaller than that of IG, TS, UA, and VS. It is the fact that our method ignored irrelevant and noisy features and at the same time retained much more informative features, unlike IA. Further experiment results showed that with the small size of features subset produced, our approach achieved a significant improvement in terms of accuracy and F-score of the classifiers used at the cost of a minimum running time. Lastly, a conclusion is reached that the proposed approach achieved a competitive performance even though it does not always give the highest result in most cases, but the results are still acceptable.

In future work, there is a need to investigate the following task: (1) To develop and in-cooperate a feature hashing method as the next step to our method that will consider the correlation between features. (2) To develop a method that has the capability to automatically determine optimal threshold parameter(s) between significant and non-significant features without any domain expert involvement.

An Ontological Framework for Healthcare Web Applications Security

Mamdouh Alenezi

College of Computer and Information Sciences
Prince Sultan University, Riyadh
Kingdom of Saudi Arabia

Abstract—The current era of digitization and transformation causes various issues and advantages both at the same time in the healthcare sector. The beneficial advantages are exceptionally good but the issues that are gardening the business of attackers is a serious issue and requires effective prevention. Current statistics and attack vector analysis portray that technical breaches have the most common and highest priority in numbers. This type of information opens a need to prevent and develop an effective model that helps to exerts and healthcare practitioners in security management. In order to achieve this desired goal, we adopt and apply an ontology-based approach of security and development methodology and provide a model that effectively produces systematic secure pathways to design healthcare web applications. The conceptual framework discussed in the study has many effective and beneficial advantages namely, it gives a unified pathway to future developers; the model also attains focus on requirement identification during development and portrays its significance.

Keywords—Security; web application; healthcare; digitization; requirement

I. INTRODUCTION

The era of digitization led to the whole concept of businesses and services on a virtual platform. This type of transformation creates an exceptionally beneficial environment of working. It is unified that digitization has various beneficial and good effects for current businesses and services but there are also some adverse effects available that tell us about the possibility of exploitation and digital systems and the impact of harm after exploitations. It is very significant and necessary to investigate and facilitate models that reduce the possibility of exploitation in systems.

This type of exploitation possibility and attack situations raise the requirement of a solid and secure fundamental concept of security in web application security. These types of exploitations and attacks pose some serious harm and defects in the web application that cause serious harm for hosting organizations and businesses [1]. Any type of exploitation and vulnerability creates an adverse reputation situation for business because users do not want a type of interruption or loss of data during the use of web application and if it causes then the reputation of the application and its owner gets affected. Now, it is frequently shown that this type of exploitation possibilities and issues appeared only because of any type of flaw and vulnerability in the application.

Most of the time these vulnerabilities and flaws are overlooked by the development team because of the deadline and hurry issue [2]. Further, many of the organizations do not identify which factors need attention for security or which not. However, from some previous years, many researchers and experts are paying attention to factors that need considerable attention for security in software and web application and in this proposed article we are also paying attention to them. Web application security is something that associates the whole development functionality of it when we talk about its security. Security is something that can only be achieved by systematic security towards development in web applications [3]. Producing a secure development and development towards systematic security is something that demands an appropriate equipped team and laboratory.

To make this development and its system more clear and efficient SHIELDS discusses a secure development project that discusses various security models and models them towards web application security. This project opens a door for repositories that effectively help secure development by providing the best expert practices and their processes. This type of project is effective and systematic but unable to give foundation security functionality in web applications. The development of security is something that demands implementation from the basic level of development phases. To make it possible discussing and providing an artifact-based approach that gives an effective result is required.

The proposed paper tries to present a systematic step-wise framework based on the secure development of healthcare web applications from an ontology perspective. Ontology is nothing but a novel systematic idea or concept that has some exceptionally effective potential to portray solid and effective results. The proposed model in the paper associates security factors from basic development phases and tries to manage them systematically further. The proposed model in the paper is a conceptual ontology-based model that aims to provide effective and secure development for web applications.

II. MATERIALS AND METHODS

A. Relevant Literature Analysis

Semantic analysis and its tools provide support to ontology-based security modeling and help them in achieving their goals. The concept of ontology makes them very specific and conceptual [4]. Searching the ontology-related literature for security perspective is not so hard due to its wide adaptation.

However, it is surprisingly challenging for authors to get a relevant healthcare web application development-based ontology approach. After a long and exhausting literature search, we could not find any specific literature based on ontology that talks about artifacts and other functional security attributes of development phases. To summarize other studies that associate the ontology concept effectively and discuss it towards security in various other parts similar field, we discuss some literature below:

In order to secure the software by adopting the ontology concept, researchers proposed a model by associating the SecEval framework and managing it towards software security [1]. The researchers combine the developed model with software engineering approaches and produce some effective results as an outcome. This literature motivates authors of the proposed work to choose the ontology for web application security.

As the next relevant study, we find an article that extensively manages various factors of the possible risk that cause bad influence on software security and manage them through various models discussed in the paper [2]. This type of model manages the risk and provides long serviceability as well as security in software. The result discussed in the paper has potential and good efficiency.

Further, as a case study, a research study associates ontology-based security modeling for user perspective and models their possible threads and its perspective [3]. Moreover, to facilitate software development security a study summarizes the facts of security modeling from an ontology perspective and gives an extensive analysis of them [4]. The results discussed in this article are effective and sensitive.

Furthermore, to provide development knowledge security and management the relevant study talks about various contexts-based security artifacts and their features respectively [5]. This type of model provides a contextual ontology approach that produces effective results.

The above-discussed literature discusses various perspectives and previous use of ontology. We try to understand their work properly and then portray an appropriate model that has novel utilities and working processes. It is very significant to adopt ontology in secure healthcare web application development because there is no specific work available currently that talks about web application security in healthcare or normally about any web application context.

B. Needs for Ontology-Based Model

Healthcare is a sector that deals with sensitive and huge amounts of data. It is a challenging and crucial task for experts to manage and secure the whole healthcare data management and web application properly due to its complexities. The digitization era forces healthcare services to be digitized via various online platforms and web applications. In such situations, it is very important to apply security strategies and processes efficiently. Before discussing the proposed model and idea it is an important job to talk about the origin of the idea and its need in a relevant field.

Healthcare web applications are applications that get penetrated frequently by attackers in current situations. Due to the sensitivity and value of health information, it is very normal and frequent for attackers to target and exploit healthcare web applications for valuable information breaches. A survey about healthcare data breach victims tells that the amount of victims from 2005 to 2019 is 249.09 million. Further, 157.40 million are affected only in the last few years [6]. Now, if we look beyond the reported attack scenario of data breach attacks the total number of attacks implemented and registered with governing bodies are 2216 from all around the 65 countries of world, and 536 breaches are from the healthcare industry in all of them. This type of statistics portrays the severity of the healthcare sector and gives an understanding that healthcare is the most targeted and sensitive field for attacks [7].

Moreover, there are a lot of breach-related statistics for healthcare web applications are available like: a report published by IBM in 2019 shows that the average revenue loss caused by attacks in all the fields and world is around 3.92 million dollars and if we look at the healthcare field specifically then the cost of a breach was 6.45 million dollars [8]. These statistics are automatically sufficient to portray the sensitivity and thread on healthcare web application security. Managing these issues and problems of healthcare is the most prioritized and immense demand of the situation.

To understand the previous healthcare records and breach statistics, we provide Table I and Fig. 1 which contain data related to previous year records and the data breach counts. This table portrays that healthcare data attacks are increasing day by day. The increasing use of web applications for providing health services creates a sensitive condition for security measures because of the complex nature of healthcare it is very challenging to manage every possible security measure on web applications. Attackers attain these loopholes as their weapons and target the system effectively and exploit the system on a large scale.

TABLE I. PREVIOUS ATTACK STATISTICS

Breach Year	Count	Amount of Data (In Millions)
2010	199	5.530
2011	200	13.150
2012	217	2.800
2013	278	6.950
2014	314	17.450
2015	269	113.270
2016	327	16.400
2017	359	5.100
2018	365	33.200
2019	505	41.200
Total	3033	255.18

Fig. 1. Graphical Attack Illustration.

Table I and Fig. 1 portray data summarized and associated by HIPPA [9, 10]. The summarized information about the number of breach incidents and the number of breach records is totally surprising because these are officially registered and known cyber-attacks implemented on healthcare organizations. The amount of breach records is very high and significant because health is something that is totally and directly connected to the life of humans. A breach in this type of data can cause some serious life-threatening situations to the patients. Therefore, it is an immense need to manage web application security and attain security for healthcare.

Moreover, after understanding the attack statistics in healthcare it is a significant job to remediate its issues. To identify issues, it is necessary to find the loopholes first for healthcare breach incidents. To make it simple, we portray the various sources of breach registered and identified by experts in the following Table II. The following table represents the specific counts of breach incidents executed by any specific source that gives a clear point-wise understanding of healthcare loopholes and helps the experts to prepare preventive measures.

In Table II, it is clearly described and represented that technical issues are the most common and frequent exploit creators in healthcare. However, if we look at both Tables I and II comparatively then the data analysis tells that web application vulnerabilities cause maximum issues and exploits in healthcare in need of an instant solution. Thus, it is evident that technical faults cause and create issues in the current era and attackers grab these issues as an advantage and inject applications of healthcare very frequently on a large scale.

All in all, the whole statistics and attack data represented in this paper portray the current serious and sensitive situation of healthcare web application management as well as it also poses the need and requirement of functionality-based security measures that pillar the security of healthcare digitization from the deep down bottom. That is why the proposed article effectively aims to apply an ontology-based model that gives additional affectivity and conceptual understanding to the experts about how to build healthcare web applications.

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar.

C. Adopted Ontology-Based Idea

As stated in the introduction ontology is something that portrays conceptual systematic steps that help in producing a secure and systematic manner of process and development methodology. In the development context of healthcare web application ontology adaptation is a novel that is why it is important to draw a proper connection between ontology concept and healthcare web application development. Developing a context-based model for effective security and efficiency in any type of process can only be achieved from ontology ideas [2].

Ontology ideology and concept are universally adopted and used in various fields like new mobile communication development and real human-machine interaction, etc. [11-15]. Ontology is nothing but simply a conceptual relationship of two ideas on one platform. This type of approach helps experts to relate the real live world issues into machine scenarios and portray or solve them through machines. Following figure 2 portrays the adopted ideology of ontology and tries to portray an overview of working.

TABLE II. SOURCE BASED ATTACK STATISTICS

Year	Technical Issues & Causes	Human Error & Disclosure	Theft	Miss Handling
2010	8	8	148	10
2011	17	27	136	7
2012	16	25	138	8
2013	25	64	150	13
2014	35	76	143	12
2015	57	101	105	6
2016	113	129	78	7
2017	147	128	73	11

Fig. 2. Adopted Ontology Concept.

Fig. 2 illustrates the adopted concept for effective security measures in healthcare web application security. The core part of the figure represents the healthcare web application and its development and the outer layer of the figure portrays the ontology-based security management methodology that is going to be implemented on the healthcare web application development. Another issue that causes problems during development is the extensive and huge amount of information available on various online and offline resources that are adopted and used by developers during development steps to make their work easier. But did not identify that these adopting concepts are perfectly developed for their field or not. Development is a phase that demands only specific customized steps and utilities developed specifically for relevant processes; any other approach or utility can cause issues. Hence, the adopted concept for developing a more effective and secure model in healthcare web applications development is facilitated effectively by the proposed model in the article. The developed model based on this approach is discussed in the next section.

Moreover, the adopted methodology works on a conceptual ideology that tells about combining ontology-based security management with the classical widely adopted development phases for making it more systematic and secure without moving to a secure development process. There are various secure development ideologies available that are complex and very costly in implementation for organizations. In this type of situation, the proposed model by adopted ideology can produce some effective and good results and portray normal security managed overview of the healthcare web application.

III. PROPOSED MODEL

Modeling a systematic conceptual model for healthcare web application development by associating an ontology-based approach is a challenging task. There are various development guidelines and best practices are available but still it is hard for developers and designers to adopt them specifically for their development scenario [16]. This type of condition was created just because of the complexity and quick demand for applications in healthcare. The competitive market of web application development creates a challenging and risky culture of quick releasing in web application development. Business always tries to release their product or software quickly and this situation creates negligence in various fundamental aspects of designing.

Further, to tackle these situations in healthcare and provide them a systematic basic security model it is very important and necessary to portray the ontology ideology of concept development. Developing a concept before totally addressing it is the basic demand of any new approach. Concept-based models as proposed in this paper open a door for researchers to attain new ideas and develop their own by associating existing. In order to do this in the proposed article, we provide a classical development step-based model with ontology-based security management which is unique on its own.

Therefore, Fig. 3 portrays a five-step combined systematic model of healthcare web application development that associates classical development steps and ontology-based security management functionality. The proposed model

associates idea initiation to facilitate the phase of the web application with a blend of ontology-based security management. The conversation is something that can be referred to as comparative analysis in cybernetics [17] and managing the security always demands conversation in-between outcome and previous steps.

By focusing on this concept, a model is created that comparatively analyzes the requirement, design, and required the desired outcome of the developer to the same platform for producing effective results. The proposed model in this paper has five steps as Idea Understanding; Requirement Identification; Design & Code; Classification of Potential Possible Threats; Facilitate. All these steps are treated as classical none extra specific steps that demand extra from the developer or business.

As described and displayed in Fig. 3 the model has five fundamental steps for healthcare web application development. These steps work systematically one by one. We try to make it simple and non-complex because complexity is something that creates confusion as well as develops a lack of interest from the developer's side for the development process. Further, it is very important to understand the step-by-step working process of the proposed model that is described in the next heading of this paper.

A. Working Process of Proposed Model

A brief description of every step in the proposed model is described and discussed below.

a) *Idea understanding*: It is a step that initiates ideas about development. In this phase, the developer, coder, and owner of the web application discuss functionality and ideas about how the web application is going to be after development and what kind of functions the owner demands.

b) *Requirement identification*: After discussing and analyzing the idea of a web application it is necessary to identify which type of process, utilities, and qualities need attention during the development and design of the application. The requirement identification phase associates these demands and prepares a proper concept of relevant development for the systematic development of the application.

Fig. 3. Proposed Ontology-based Security Assured Model.

c) *Design and Code*: This is a step where developers design and code the application by associating identified requirements and prepare a systematic application according to them.

d) *Classification of Potential Possible Threats*: This is a step that is responsible for prevention from exploits in the system. It is a step that analyzes three perspectives and then compares the current development scenario. If the scenario was compatible according to the demand, then it's okay otherwise it again starts the loop from the requirement identification process. The whole phase description and internal working process are displayed in the following Fig. 4.

e) *Facilitate*: After comparing and classifying various threats and other issues of development when the whole cycle gets systematic without any interruption the proposed model allows developers to facilitate the developed healthcare web application in the industry.

Fig. 4. Classification Phase of Proposed Model.

All in all, after discussing the concept, model, and working flow it is clear that the described model is the first initial step to facilitate healthcare web application development through an ontology-based approach. The proposed model portrays only the conceptual modeling of the idea and requires proper mathematical experimentation and validation in the future.

IV. DISCUSSION

The current healthcare digitization process demands various advanced requirements and utilities [18]. At the same time, increased attack vectors and processes created a situation where every type of post-developed prevention mechanism for breach attacks in healthcare gets destroyed by attackers. Now to tackle these situations experts and researchers believe that pre-security measures during the fundamental development phases can play a key role in healthcare security. Therefore, to facilitate this idea, and believe the authors of the proposed articles portray a conceptual model of healthcare systematic development by attaining a focus on security factor from the ontology-based approach.

V. CONCLUSION

In this rapid era of digitization healthcare services demand a new, novel, and fast development approach with a blend of security measures. To achieve this desired goal, we find that it is challenging and brainstorming work for them to facilitate the security measures after the development of healthcare web applications. Therefore, they think from different perspectives and manage the goal by applying ontology ideas and development phases at the same platform. This type of combination gives exclusive power to the authors about discussing and managing systematic development and security both at the same time for healthcare web applications. The proposed article portrays a model for ontology-based secure healthcare web application development. The proposed model has five simple but effective phases which aim to give a systematic secure development pathway to the healthcare web application developers. The proposed model has various beneficial advantages for healthcare web application security and portrays a pathway for future researchers to facilitate systematic development.

A Proposal to Improve the Bit Plane Steganography based on the Complexity Calculation Technique

Cho Do Xuan

Information Assurance Department
FPT University, Hanoi
Vietnam

Abstract—The video steganography technique is being studied and applied a lot today because of its benefits. In particular, the video steganography technique using Bit-Plane Complexity Segmentation (BPCS) has increasingly proven its effectiveness compared to other methods. In this paper, based on the theoretical basis of the BPCS method, we propose a new method to improve the efficiency of the steganography process. Accordingly, our improvement proposal in this paper is improving the complexity formula of the bit planes. Our new formula not only has improved the steganographic thresholds in the bit planes to find more planes hiding secret information, but also has ensured the amount of information hidden in the video and their safety. The experimental results in the paper have not only demonstrated the effectiveness of our proposed method but also provided a new mechanism for digital image analysis in general and video steganography techniques in particular.

Keywords—Steganography; video steganography technique; bit-plane complexity segmentation (BPCS); complexity formula

I. INTRODUCTION

A. Introduction to BPCS Method

In the study [1], Kawaguchi et al. presented an image steganography method based on the BPCS technique. The characteristic of this method is the use of images or video frames as the message vessel. Accordingly, the image is divided into bit planes based on the depth value of the image. With each bit-plane, we can divide it into noise-like blocks or informative blocks, then replacing noise-like by the blocks of secret information that have similar noisy property will not change the image quality. The process of embedding information in video using BPCS technique includes the following steps [1]:

1) *Determining the noise-like block.* Fig. 1 illustrates an example of the noise-like block. To determine noise-like block, the study [1] proposed Black-White border method. Accordingly, in Black-white border, the complexity is determined by the length of the border of the Black-White regions in blocks horizontally and vertically. For example, a black pixel surrounded by 4 white pixels has a border length of 4. The longer the block has the border length, the higher the complexity. Based on the above definition, we have the following formula to determine the complexity of a block with size $2n * 2n$ [1]:

$$\alpha = \frac{k}{2 * 2n * (2n - 1)} \quad (1)$$

Where:

- α is the complexity of the block.
- k is the number of borders in contact between 2 regions.
- $2 * 2n * (2n - 1)$ is the number of borders that are in contact maximum possible with the block. It is the number of borders in the chessboard.

2) *Identifying complexity threshold:* The process of identifying the complexity threshold to determine how much complexity is, the region is noise, and how much complexity is, the region is informative. To do that, the researchers tested on blocks of size $8 * 8$. The use of blocks $8 * 8$ is to match the complexity of the current method. For blocks $8 * 8$, the average value of α is 0.5, the informative blocks have α in between 0 and 0.5 and only accounted for $6.67 * 10^{-14} \%$. From these values, one normally choose a complexity threshold as $\alpha_0 = 0.3$ for block $8 * 8$ [1].

3) *The conjugation property.* This property ensures the safety of the information that needs to be hidden in the noise-like regions. Accordingly, when information is divided into appropriate blocks and is calculated complexity, if it is an informative block, it will be conjugated to be a block with higher noise for embedding information. The conjugation property is stated as [1]: With a block P with complexity α , there exists only a block conjugate of P denoted P* has complexity is $\alpha' = 1 - \alpha$. This block is an XOR result between P and the block W_c (alternating black and white blocks starting with white pixel).

4) *Canonical gray coding:* This is the process of processing images to embed information. Accordingly, suppose that b_i and g_i are respectively the i -th bit of the PBC and CGC codes with n -bits of data we have [2].

$$b_0 b_1 \dots b_{n-1} \text{ and } g_0 g_1 \dots g_{n-1}$$

The formula for switching between two coding systems is:

$$g_i = \begin{cases} b_0 & \text{Where } i = 0 \\ b_{i-1} \text{ xor } b_i & \text{Where } i > 0 \end{cases} \quad (2)$$

$$b_i = \begin{cases} g_0 & \text{Where } i = 0 \\ b_{i-1} \text{ xor } b_{i-1} = g_0 \text{ xor } \dots \text{ xor } g_i & \text{Where } i > 0 \end{cases}$$

Fig. 1. Examples of Bit Planes for Determining the Noise-like Block.

B. The Problem of Improving the BPCS Method

Based on the process of processing and embedding information, it can be seen that improving the BPCS method is based on two main methods [2, 3, 4, 5]:

- Improvement in the pre-processing process. This is an improved method to be performed at the pre-processing step. The characteristic of this method is the modification of the input data (namely the image used for embedding) in order to make embedding more efficient. Some of the approaches are: Use of Gray coding; handling the vessel to increase the image sharpness; randomizing input data.
- Improving the embedded algorithm. The approaches usually focus on two main improvement methods: i) Improvement of complexity threshold. This approach mainly refers to 2 improvement methods: the complexity threshold for each bit plane and the Dynamic Threshold; ii) Improvement of the formula. There are 2 formulas currently used as Run-Length Irregularity and Border Noisiness.

C. Contributions of the Paper

Our research is presented as follows: the urgency of the research problem is presented in Section I. In Section II, we present the process of researching, surveying, and evaluating related works. In Section III, we present our surveys and reviews of problems of proposing improvements for BPCS. This review and survey help us have a basis to propose our new method in the paper. Finally, in Section IV, we present the experimental method to evaluate and compare the effectiveness of our proposed method with other methods. The practical significance and scientificity of our paper include:

- Proposing improvements for video steganography techniques based on the approach about the calculation formula. Accordingly, we propose a new calculation formula to evaluate the complexity of the frames. Details of the proposed algorithm and its feasibility assessment are described in section III.C of the paper.
- We conduct experiments, evaluate, and compare to see the effectiveness of our approach with other research directions. The experimental results in section IV.B.2 proved the correctness of our method. At the same time, the research results in the paper also provide a new approach to calculating the complexity of the image in order to serve for the analysis of digital images in general and hiding information by the BPCS method in particular.

II. RELATED WORKS

A. BPCS Technique and Some Improvements

The study [5] proposed the Modified BPCS technique by combining hybrid cryptography algorithms between RSA and DES to create noise for secret messages. Piyush and Paresh [6] proposed a combined method of cryptography, steganography, and multimedia data hiding. In this method, the authors used a reference database to provide higher security levels. First, the authors used the DES algorithm to encrypt the message, then using a modified bit encoding technique to save the cipher in the image. For each byte of data, one cover pixel will be edited. The study [7] combined the AES cryptography algorithm and the BPCS steganography algorithm to hide a large amount of data in image. In the study [8], the authors proposed applying the BPCS method and FPGA model to ensure information security for secret information. In the study [9], the authors proposed combining the BPCS method with the Huffman cryptography algorithm to improve the quality of hiding information.

In the study [10], the authors proposed a method of combining BPCS with fuzzy logic techniques. This study applied the principles of fuzzy sets to classify the bit-plane into three sets: informative, partly informative, and noise region. This is expected to classify the bit-plane in a more objective approach. Finally, the Mamdani fuzzy inference is used to make decisions on which bit-plane will be replaced with a message based on the classification of bit-plane and the size of the message that will be inserted. This helps improve the message capacity of the images. The research could improve BPCS steganography techniques to insert a message in a bit-plane with more precision. Thus, the container image quality would be better. Seeing that the PSNR value of the original image and the stego-image is only slightly different. In addition, the studies [11, 12, 13, 16] listed some video steganography methods, difficulties, challenges as well as the advantages and disadvantages of video steganography techniques. Besides, Spaulding et al. [14] presented the BPCS steganography method with the embedded zerotree wavelet (EZW) lossy compression. This method used the DWT coefficients to represent pixels of the original frame. Therefore, the BPCS steganography can be applied to DWT coefficient sub-bands containing different features. Similarly, Noda et al. [15] proposed a video steganography technique using the BPCS and wavelet compressed video.

On the other hand, Sharma et al. [17] presented a number of research and evaluation results of the effectiveness and safety of BPCS and LSB techniques. The research results showed that in the BPCS technique, all the data was embedded in a complex noisy blue plane. The embedding capacity of BPCS techniques and LSB techniques is high. On comparison, it is found that the LSB steganography and LSB using the secret key perform the best on the basis of PSNR. According to the entropy and correlation point of view, the best results are shown by the status bit and BPCS steganography techniques.

B. Some Studies of Combining Encryption with Steganography

In the study [18], Shifa et al. proposed a method of combining the AES encryption with LSB steganography

technology in order to distribute and exchange keys. The experimental results show that the LSB model combined with AES encryption has a good effect on the speed and impact degree on the message vessel. In the study [19], Dhall proposed the first method of using Quantum Cryptography to increase the security of the application. Saha [20] et al. published a steganography method based on Exploiting Modification Direction using the hashed-weightage Array. Kait [21] applied the BPCS technique as a technique to noise information in order to ensure data security using FPGA implementation. In addition, the studies [22-26] proposed to apply some common steganography techniques such as Discrete Cosine Transform (DCT), LSB, Least Significant bit Matched Revisited (LSBMR), DWT to protect data in communication applications.

III. EVALUATING AND RECOMMENDING IMPROVEMENTS OF BPCS

A. Improvement on Complexity Threshold

With basic BPCS, we usually choose only one complexity threshold for the whole bit-plane. The study [3] proposed a method to apply the complexity threshold for each bit plane. Accordingly, the authors demonstrated that the complexity threshold from the low bit plane will gradually decrease to zero. Usually, at the highest bit planes, no change will be made here because changing the bit here will strongly affect image quality. On the contrary, the lower bit planes have a higher threshold to increase the ability to embed information.

The study [3] proposed improvement direction for the BPCS algorithm based on Dynamic Threshold. This method makes some adjustments to the threshold setting. These threshold values have no default values. They can be adjusted manually according to the actual conditions. This algorithm can avoid the analyzer from detecting the existence of secret information using complex statistical analysis of the entire graph, thus further enhancing the security of steganography. The basis of the Dynamic Threshold improvement method is based on the Chaos theory. Accordingly, the Chaos theory is a type of behavior controlling nonlinear dynamical rule. In this research, the authors used the logistic mapping method to create chaos series according to the formula:

$$ak+1 = \mu * ak*(1 - ak), k= 0,1,2. \quad (3)$$

The moving value is in the range [0, 1] and μ is a control parameter or a split parameter. When $3.5699456... < \mu \leq 4$, logistic maps operate in a chaotic state [3]. The generated data stream is disordered and it is similar to random noise. Processing the obtained chaos series, mapped to {0, 1} and {-2, -1, 0, 1, 2}.

B. Improving the Formula Determining the Complexity

To assess whether the blocks are complex or not, the studies are based on the complexity of the black-and-white border region. However, it is not always the best approach. For example, blocks with periodic patterns like the chessboard will be recognized for complexity in this way as shown in Fig. 2 $\alpha_a = 1$ and $\alpha_b = 1/2$.

Fig. 2. Example of Blocks with Large α but those are not Complicated.

1) *Determining the noise-like block:* The Run-Length Irregularity is the histogram of the lengths of both black and white pixels in a row or a column [2]. Assume that:

- $h[i]$ is the frequency of runs of i pixels either in black or in white.
- n is the length of the sequence of pixels.
- h_c to measure the irregularity of a binary pixel sequence.

$$P_i = \frac{h[i]}{\sum_{j=1}^n h[j]} \quad (4)$$

The value $h_s \in [0; 1]$ and denoted by:

$$h_s = \sum_{i=1}^n h[i] \log_i p_i \quad (5)$$

If the size of the block is $n \times n$ and r_i and c_j are respectively the i -th row and j -th column of a block, then the run-length irregularity β of a block is defined with \bar{X} which is the mean of all the elements of X .

$$\beta = \min\{\widehat{H_s(r)}, \widehat{H_s(c)}\}$$

$$\widehat{H_s(r)} = \{\widehat{h_s}(r_0), \dots, \widehat{h_s}(r_{n-1})\}$$

$$\widehat{H_s(c)} = \{\widehat{h_s}(c_0), \dots, \widehat{h_s}(c_{n-1})\}$$

If according to the definition, the smaller row and column averages are taken as the value of the run-length irregularity β . As shown in Fig. 3, they are both periodic in row or column. The result is that every run-length irregularity β is 0, so they are simple and cannot be used for embedding information. The run-length irregularity β is only useful in rows or columns. If the block is frequently in other directions, there will be nothing to do with it.

Fig. 3. Examples of Blocks with Large β but those are not Complicated.

2) *Border noisiness*: If the data is embedded on the boundary of the noise region and the informative region of the block in the image, then the noisy regions would grow. As a result, the image will be evidently changed. Border Noisiness is based on the difference between adjacent binary pixel sequences in a block. In a similar way, if the block size is $n \times n$ and r_i and c_j are respectively the i -th row and j -th column of a block, then the *Border Noisiness* γ of a block is defined as follows [2]:

$$\gamma = \frac{1}{n} \min\{E_f[P_x(r), E_f[P_x(c)]]\} \quad (6)$$

Where $\rho(x)$ is the number in the binary string X and

$$P_x(r) = \{\rho(r_0 \oplus r_1), \dots, \rho(r_{n-2} \oplus r_{n-1})\}$$

$$P_x(c) = \{\rho(c_0 \oplus c_1), \dots, \rho(c_{n-2} \oplus c_{n-1})\}$$

$$E_f(X) = \frac{1 - V(X)}{\max_X\{V(X)\}} \cdot \bar{X}$$

Where: $X = \{x_0, \dots, x_{m-1}\}$, $V(X)$ is the variance of X , and \bar{X} is the mean of X .

Border Noisiness is used to check if many black and white pixels are well distributed over a block along with both horizontally and vertically. Although blocks in Fig. 3(a) and 3(b) both have large run-length irregularity β ($a = 0.745$, $b = 0.694$), their Border Noisiness are 0.294 and 0.048 respectively. Therefore, they are not complicated according to Border Noisiness and are not suitable for embedding data.

C. Our Proposal

We noticed that there is no exact formula or judgment about the definition of complexity for an information block. The black-white border is just one of many formulas to determine this complexity. This formula is simple, useful, and gives the best results. But it still has some shortcomings. Therefore, we propose a novel method to calculate complexity. This method is quite similar to the Black-white border but it exploits another aspect that is the number of black and white regions in the block (the Black-white border uses the number of black and white borders). This formula is based on the assumption that the higher the number of black-and-white regions a block has, the higher the complexity of the block is and vice versa. From the above assumption, we propose the formula for calculating the complexity for a block of size $2n * 2n$ as follows:

$$\partial = \frac{k}{2n * 2n} \quad (7)$$

Where: k is the number of black and white regions in the block; $2n * 2n$ is the maximum number of black and white regions that a block of size $2n * 2n$ can receive. To verify this assumption and to show the better aspects of this formula than the previous formulas, we will conduct a comparison with some blocks (see Fig. 4 and Fig. 5, 6).

From Fig. 4(a) we calculate the following values: $\alpha = 0.42$; $\beta = 0.198$; $\partial = 0.04$.

Fig. 4(b) gives the following values: $\alpha = 0.42$; $\beta = 0.123$; $\partial = 0.156$.

Fig. 4(c) gives the following values: $\alpha = 0.58$; $\beta = 0.745$; $\partial = 0.14$.

Fig. 4(d) gives the following values: $\alpha = 0.285$; $\beta = 0.694$; $\partial = 0.14$.

With the naked eye, we can see which are informative blocks with clearly divided black and white regions. However, with the original formula, these images give high results, in contrast to the Border Noisiness formula and the formula that we proposed. Fig. 5 below is an example that shows a weak point of Border Noisiness. On the other hand, the proposed way still indicates that these are informative blocks.

From Fig. 5(a), we calculate the following values: $\alpha = 1$; $\beta = 0$; $\partial = 1$.

Fig. 5(b) gives the following values: $\alpha = 1$; $\beta = 0$; $\partial = 0.07$.

Can be seen that: Although giving good results with the previous blocks, but up to the chessboard block, the proposed method still gives high results. But for stripe block, it still gives low results in contrast to the Black-white border. Through the above examples, we can see that our proposed method gives better results than the original algorithm. Next, to evaluate the feasibility of the complexity formula, we will conduct the experiment of embedding information using the BPCS method and evaluate the embedded results based on measures.

Fig. 4. Examples of Noise Blocks.

Fig. 5. Example of Informative Blocks showing the Weakness of Border Noisiness.

IV. EXPERIMENTS AND EVALUATION

A. Evaluation Criteria

To conduct experiments and evaluations, we use a number of criteria to evaluate as follows.

1) *Peak signal-to-noise ratio*: The Peak signal-to-noise ratio (PSNR) is a measure of the difference between the original image and the stego image. Comparing the results of two algorithms should be based on the same codecs and the same data content. The simplest way is defining through the mean squared error (MSE) used for 2-dimensional images with size $m \times n$ where I and K are the original image and the stego image [4].

$$MSE = \frac{1}{N^2} \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} (C_{ij} - R_{ij})^2 \quad (8)$$

PSNR is defined by [4]:

$$PSNR = 10 \log_{10} \frac{(2^b - 1)^2}{MSE} \quad (9)$$

2) *Embedding capacity*: Embedding capacity is the maximum amount of data that an image can be successfully embedded by a steganography algorithm. This criterion depends on the input image data and the number of embedded bits [4].

$$bpp = \frac{\text{hidden bits}}{\text{total bits}} \quad (10)$$

B. Experiment And Evaluating Formula Improvement Methods

1) *Scenario and experimental data*: To evaluate the effectiveness of our proposed formula, we will do experiments on some images with a resolution of $512 * 512$, which is the resolution commonly used for hiding information. Fig. 6 below presents the images used to hide information.

2) *Experimental results*: Table I below shows the distribution of thresholds. From there, we select a complexity threshold that balances image quality and memory capacity.

Through the statistics in Table I and Fig. 7, we can see that with the proposed formula, blocks $8 * 8$ usually have a value in the range from 0 to 0.2. This proves that the majority of blocks have threshold values from 0 to 0.2. The distribution diagram is similar to that of the classic formula. The only difference is that the equilibrium threshold is 0.2 and the threshold of the classic formula is 0.5. With classic formula, the threshold will be selected from 0.3 to 0.5 so we can speculate that the threshold of the improved formula is from 0.12 to 0.2. With this range, we can also see the ability to hide is about 50%. With the selected complexity threshold of 0.14, the experimental process will proceed as follows. Specifically, to test the maximum ability to hide information, we will use 3 images in Fig. 6 as vessels, and then we check the maximum ability to hide information on each photo to give the results of the ability to embed. Besides, to test PSNR, we will embed the

Beagle.png image (Fig. 8) to produce the results and calculate PSNR between the original image and stego image.

Fig. 6. Three Experimental Images.

TABLE I. THRESHOLD DISTRIBUTION OF THE IMAGES IN FIGURE 6

Capacity	Baboon.png	Peppers.png	Jet.png
0.05	92.85%	64.59%	60.56%
0.1	80.74%	52.48%	48.44%
0.15	56.52%	44.41%	40.37%
0.2	40.37%	24.22%	12.11%
0.25	20.18%	0.08%	0.08%
0.3	0.04%	0.00%	0.00%

Fig. 7. Distribution Diagram of the Thresholds Calculated by the Classical Formula [1].

Fig. 8. Beagle.png

3) *Experimental results*: From the results in Tables II and III, it can be seen that the ability to hide information of improved BPCS, which we propose, is much better than classic BPCS with a complexity threshold of 0.4. The ability to hide information will increase by about 10% to 15% of the image capacity. Although this ability increases significantly, when compared to the PSNR index, it is not much different from the original algorithm. Although the PSNR index decreases by about 0.01, increasing the ability to hide information brings great benefits. This can be seen as a valuable improvement. Here we can increase the complexity threshold to 0.15 or 0.145 in exchange for a higher PSNR depending on the intended use.

TABLE II. COMPARING THE ABILITY TO HIDE INFORMATION OF EACH METHOD

Capacity	BPCS [1] $\alpha = 0.4$	BPCS [our proposal] $\delta = 0.14$
Baboon.png	3503297 bit = 55.68 %	3810240 bit = 60.56 %
Peppers.png	2612544 bit = 41.52 %	3048192 bit = 48.45 %
Jet.png	1821056 bit = 28.94 %	2540160 bit = 40.37 %

TABLE III. COMPARING IMAGE QUALITY AFTER HIDING INFORMATION

Capacity	BPCS [1] $\alpha = 0.4$	BPCS [our proposal] $\delta = 0.14$
Baboon.png	53.43	53.42
Peppers.png	53.44	53.43
Jet.png	53.44	53.43

V. CONCLUSION

Applying the BPCS steganography technique to hide secret information or protect vessels is one of the best current approaches. In this paper, based on the procedure and the mathematical basis of the BPCS steganography technique, we proposed an innovative method to improve the quality of hiding information. The experimental results, which we performed in Tables II and III, proven that the method of improving the complexity calculation algorithm in bit planes gave good results not only for the ability to hide information but also to ensure the image quality. The research results will allow having many criteria to select the bit planes based on calculating their complexity for hiding information. At the same time, our computation proposal will also provide a new way for problems related to analyzing digital images in the face of the diversity and rapid development of the multimedia field. In the future, we will apply many other improved methods, especially the applying of different thresholds for each plane bits, in order to increase the capacity to hide information as well as image quality when hiding.

Multiplicative Iterative Nonlinear Constrained Coupled Non-negative Matrix Factorization (MINC-CNMF) for Hyperspectral and Multispectral Image Fusion

Priya K¹, Dr. Rajkumar K K²
Dept of Information Technology
Kannur University
Kerala

Abstract—Hyperspectral and Multispectral (HS-MS) image fusion is a most trending technology that enhance the quality of hyperspectral image. By this technology, retrieve the precise information from both HS and MS images combined together increase spatial and spectral quality of the image. In the past decades, many image fusion techniques have been introduced in literature. Most of them using Coupled Nonnegative matrix factorization (CNMF) technique which is based on Linear Mixing Model (LMM) which neglect the nonlinearity factors in the unmixing and fusion technique of the hyperspectral images. To overcome this limitation, we are going to propose an unmixing based fusion algorithm namely Multiplicative Iterative Nonlinear Constrained Coupled Nonnegative Matrix Factorization (MINC-CNMF) that enhance the spatial quality of the image by considering the nonlinearity factor associated with the unmixing process of in the image. This method not only consider the spatial quality but also enhance the spectral data by imposing constraints known as minimum volume (MV) which helps to estimate accurate endmembers. We also measure the strength and superiority of our method against baseline methods by using four public dataset and found that our method shows outstanding performance than all the baseline methods.

Keywords—Hyperspectral data; multispectral data; minimum volume; nonlinear mixing model; spectral variability; spectral image fusion

I. INTRODUCTION

Hyper-spectral (HS) images are enriched with high spectral resolution than conventional images. Therefore, the energy collected by hyper-spectral sensors is partitioned into several narrow wavelengths. Due to the partitioning of several narrow wavelengths band, the energy received by each band is limited. This makes the HS image to be easily influenced by many kinds of noise. This high signal-to-noise ratio reduces the spatial resolution of hyper-spectral image. So, it is mandatory to increase the spatial quality of the HS image. The fusion of high quality spatial data with the hyper-spectral image that possess high spectral resolution is one of the good approach for HS image enhancement [1].

Many existing traditional or multispectral sensors can capture images that have higher spatial resolution with lower spectral resolution compared with hyper-spectral sensors.

Therefore, data fusion with hyper-spectral (HS) and multispectral (MS) image is one good approach to increase the spatial quality of hyper-spectral image. This HS-MS fusion approach fuses the spectral data of low-spatial resolution hyper-spectral image (LR-HSI) with the spatial data of high-spatial resolution multispectral image (HR-MSI) of the same scene. Thus, generated a high-spatio-spectral resolution hyper-spectral image (HR-HSI) [2]. Some important HS-MS fusion problem is component substitution (CS), multiresolution analysis (MRA), Bayesian probability, Spectral Unmixing (SU). But recently, the Spectral Unmixing (SU) based HS-MS fusion become a trending attention in this area due to its straightforward description in the fusion process. In spectral unmixing a simple and effective method namely linear mixing models (LMM) are widely used in most of the literature [3].

In HS - MS data fusion approach, both LR-HSI and HR-MSI data are unmixed into spectral (endmember) and spatial (abundances) data [4]. Next, the high-spatial data of HR-MSI are fused with high-spectral data of LR- HSI using some constrained optimization techniques. Coupled Non-negative Matrix Factorization (CNMF) algorithm is a promising HS-MS data fusion approach based on unsupervised unmixing. Therefore, LMM based CNMF method yields the high-spatial-resolution HSI without any prior knowledge [5]. However, two main factors spectral variability and nonlinearity are still obstructing the performance of LMM method. The variation in spectral signature due to illumination, topography, atmospheric effects of the material are considered as spectral variability [6]. This variation of spectral signatures may cause significant errors during the spectral unmixing process. So, it is necessary to pay a considerable attention in spectral variability during the hyper-spectral unmixing process [7].

In this article, a multiplicative iterative nonlinear constrained coupled nonnegative matrix factorization (MINC-CNMF) algorithm is proposed. This MINC-CNMF algorithm aims to enhance the spatial as well as spectral quality of HSI along with considering the nonlinearity of the image. For this achievement, a multiplicative iterative algorithm is used alternately to update the endmember, abundance and outlier term that accounts for nonlinearity. This fusion algorithm enhances the spatial quality of hyperspectral image, but to

improve the spectral data we add minimum volume constraints to the simplex. This minimum volume (MV) of simplex controls the quality of spectral data. The simplex formed by connecting the endmembers selected for this process. The iterations continue until the algorithm reaches the convergence condition. Finally, the fusion image is created as a product of endmember and abundance with the outlier term. Thus, obtain high spatial and spectral quality fused image [8].

The MINC-CNMF algorithm is experimented on various synthetic data sets to evaluate the reconstruction quality in both spatial and spectral wise. This proposed method also compares with many other baseline algorithms available in literature to determine the performance of our fusion result. The main contribution the MINC-CNMF algorithm is that, 1) improve the accuracy for the extraction of spatial information from the MSI image, 2) improve the visual effect of the HSI image without any other distortion in the image, 3) propose an efficient image fusion algorithm that consider the nonlinearity effects in the image.

The succeeding sections of this paper are arranged as following order. In Section 2, a detailed study is done about the various spectral unmixing based fusion work that is related to our paper and identified the proper research gap in the literature. Then we proposed and formulated a model for MINC-CNMF algorithm in Section 3 followed by implementation of the same algorithm in Section 4. The details of experimental results and discussion are given in the Section 5, which also include the dataset and quality measures used for the performance evaluation. Finally, in the Section 6 conclusion and future enhancement of the work is explained.

II. RELATED WORK

Yokoya *et.al* in 2012 [16] proposed a coupled NMF (CNMF) algorithm which fuse HS and MS data based on unsupervised unmixing. Compared to other existing unmixing based fusion CNMF is straightforward and easy for mathematical formulation and its implementation. This method also minimizes the residual errors during unmixing process. Finally, this method results better local optimal solution and produce high-resolution hyperspectral image. Simoes *et.al* in 2015 [17] proposed a hyperspectral super resolution method, termed as HySure. This modal formulates data fusion as a convex optimization problem by adding an edge-preserving regularizer. This method uses vector total variation (VTV) regularizer to promote piecewise-smoothness to the image.

Lin *et.al* in 2018 [18], proposed an unmixing based fusion problem by incorporating two regularization terms such as sparsity and sum-of-squared-distances (SSD) regularizer. This method uses ℓ_1 -norm regularization to promote sparsity with well-known SSD regularizer to yield a fused image with high quality data. Therefore, this method upgrades the existing CNMF fusion performance by adding these regularization terms with two convex subproblems. Therefore, this algorithm with biconvex optimization is so called a convex optimization-based CNMF (CO-CNMF) algorithm. But as the noise level increases the CO-CNMF algorithm would degrade its performance rapidly. Therefore, it is necessary to add image denoising or smoothing constraints with the fusion method.

Yang *et.al* in 2019 [19], proposed an algorithm incorporating total variation and signature-based (TVSR) regularizations, into the CNMF method. Therefore, this algorithm is referred to as TVSR-CNMF. The total variation (TV) regularizer ensures the image smoothness to the abundance information. The signature-based regularizer provide high-fidelity signature reconstruction. Therefore, this method enhances both spatial and spectral quality of the fused data irrespective of high noise level in environment.

Borsoi *et.al* in 2019 [20], presented an unmixing based fusion algorithm that deals the spectral variability between images captured at different time instants. For this implementation, Generalized LMM (GLMM) that considers the variability of spectral signature by using individual scaling factor of each spectral band. This method divides the high-resolution images into subspace components and then represents the variability of the spectral signatures in each subspace separately. Then solve and combine each subproblem to obtain high fused data. Therefore, this algorithm is called HS-MS image Fusion with spectral Variability (FuVar). Due to the consideration of more complex spectral variability this method creates some difficulty to obtain an optimization solution.

Yang *et. al.*in 2019 [21], proposed an unmixing based fusion method by imposing sparsity and proximal minimum-volume regularizer. The minimum-volume regularizer control and minimize the distance between center of mass and the endmember at each iteration. Thus, it redefines the fusion method at each iteration until reaches the simplex volume to minimum. The algorithm is called SPR-CNMF and it reduced the computational complexity. This method also controls the loss of cubic structural information and thus improves the fusion performance by yielding high-fidelity reconstructed images and also shows good performance at high noise-level.

HS-MS image fusion is becoming an ever-increasing demand for the resolution enhancement of HS imagery. In this paper we analysed the literature based on several spectral unmixing based fusion methods. From the comprehensive and recent overviews of fusion models and associated spectral unmixing algorithms it is identified that unmixing-based fusion methods provide good and stable performance and estimated high-fidelity in the reconstructed image. The CNMF also shows a good classification capability in HS-MS fusion. Due to this reasons, CNMF is one of the very promising fusion methods based on spectral unmixing. The various algorithm based on CNMF models was introduced by imposing some constraints to the standard CNMF, to get better quality fused image. Even though all these methods had established well desired outcome, but most of the CNMF method are based on linear mixing model that means it does not consider the non-linearities of the image.

The LMM based method does not consider the nonlinear data in the image such as specific or localized areas of the image, the areas at the edges or boundary of heterogeneous regions. This property implies that, LMM assume only limited number of pixels. Due to this limited number of pixels assumptions, there occurs a lack of obtaining information during the unmixing process. Therefore algorithms based on

LMM are found difficulty for the accurate estimation of endmembers and their abundances fractions. So, in our work, we are planning to modify the CNMF algorithm by adding some regularizer for improving the image quality and also an additive term for considering the non-linearity of the image. Thus, improvement the performance and robustness of unmixing based image fusion algorithm.

III. PROBLEM FORMULATION

Let $Y_h \in \mathbb{R}^{L_h \times N_h}$ be an observed LR-HSI with L_h bands and N_h pixels, and $Y_m \in \mathbb{R}^{L_m \times N_m}$ be an observed HR-MSI with L_m bands and N_m pixels, with $L_m < L_h$ and $N_h < N_m$. Then data fusion of L_h band from LR-HSI, Y_h and N_m pixels from HR-MSI, Y_m to yield the desired high spectral and spatial resolution hyper-spectral image, $Z \in \mathbb{R}^{L_h \times N_m}$ [9].

$$Z = EA \quad (1)$$

The observed Y_h and Y_m can be represented as spectrally and spatially degraded version of fused image Z . This is represented as,

$$Y_m \approx DZ + R_m \quad (2)$$

$$Y_h \approx ZB + R_h \quad (3)$$

Where, $B \in \mathbb{R}^{N_m \times N_h}$ is a point spread function (PSF) which is used to blur the spatial quality of referenced hyper-spectral image to obtain LR-HSI, Y_h . $D \in \mathbb{R}^{L_m \times L_h}$ is a spectral response function (SRF) which is used to spectral downsampling of referenced hyper-spectral image to obtain HR-MSI, Y_m . The matrix R_m and R_h denote as residual noise are generally assumed as zero-mean Gaussian noises, but here this residual term R_m and R_h are consider as an outlier nonnegative matrix to accounts the nonlinearity effects [10].

The CNMF algorithm is a coupling of two NMF algorithm, which factorize a matrix into a product of two nonnegative matrices called endmembers and abundances. The CNMF algorithm starts from NMF by unmixing both hyper-spectral image Y_h and multispectral image Y_m [11]. That means CNMF simultaneously unmix both Y_h and Y_m by using NMF to estimate E and A , with the constraints. Then fuse the required data by using CNMF to obtain high quality image [12].

By the Eq. (1), (2) and (3) the cost functions of NMF unmixing for Y_h and Y_m , are defined as,

$$\|Y_h - EA_h\|_F^2 \quad \text{and} \quad \|Y_m - E_m A\|_F^2 \quad (4)$$

where $\|\cdot\|_F^2$ denotes the Frobenius norm. The squared Frobenius norm are commonly used to minimize the cost function in hyper-spectral unmixing [10].

Then the CNMF method fuse the data from Y_h and Y_m to reconstruct the high spatial-spectral resolution hyperspectral image $Z = EA$ [13]. Therefore, the objective function CNMF can be defined as,

$$\text{CNMF}(E, A) = \|Y_h - EA_h\|_F^2 + \|Y_m - E_m A\|_F^2$$

subjected to, $E, A \geq 0$ (5)

The CNMF method has an ill-posed problem by nature, which means it may have more than one solution to the objective function. This ill-possedness problem of CNMF can be solved by adding some constraints or regularization term into spectral signature and/or fractional abundance.

A. Constrained CNMF Method

In this model we extend the standard LMM by considering the residual term R which accounts all possible nonlinear effects in the image. This additional term R gives the measurement of errors or novelty that deviates from the overall distribution of original sample data [14]. Therefore, the NMF unmixing for Y_h and Y_m , are defined as,

$$\|Y_h - (EA_h + R_h)\|_F^2 \quad \text{and} \quad \|Y_m - (E_m A + R_m)\|_F^2 \quad (6)$$

Then the objective function CNMF for Eq. (6) can be redefined as,

$$\text{CNMF}(E, A, R) = \|Y_h - (EA_h + R_h)\|_F^2 + \|Y_m - (E_m A + R_m)\|_F^2 \quad (7)$$

The symbol approximation (\approx) in Eqs. (2) and (1) indicates that it aims to obtain the minimum dissimilarity between both referenced and estimated image. The measure of dissimilarity between referenced image Y and estimated image $EA+R$ can be represented as, $D(Y|EA + R)$ [14]. Then this measure of dissimilarity on both hyperspectral Y_h and multispectral image Y_m in CNMF (E, A, R) method can be represented as:

$$\min_{E,A,R} \text{CNMF}(E, A, R) = D(Y_h|EA_h + R_h) + D(Y_m|E_m A + R_m) \quad \text{subjected to, } E, A, R \geq 0 \quad (8)$$

This additional term R itself is not enough to amounts the ill-posed problem of CNMF, so we further incorporate some priors to E and A based on its physical considerations. To reduce volume of the simplex a signature-based minimum volume (MV) constraint is imposed into our problem. To reconstructs the fused image, $Z = EA + R$, the objective function of our constrained CNMF method will be as following:

$$\min_{E,A,R} \text{CNMF}(E, A, R) + \alpha \phi_{MV}(E)$$

subjected to $E \geq 0, A \geq 0, R \geq 0$ (9)

where CNMF (E, A, R) is unconstrained CNMF method, $\alpha > 0$ are the parameters to control the MV constraints thus strengthen the spectral quality and this MV constraints are calculated as,

$$\phi_{MV}(E) = \sum_{i=1}^p \sum_{j=i+1}^p \|e_i - e_j\|_2^2 \quad (10)$$

$\phi_{MV}(E)$, is a well-known regularizer which minimize the volume of the simplex in hyper-spectral imagery, this minimum volume simplex is capable of estimating high-fidelity spectral signature [15].

IV. PROBLEM OPTIMIZATIONS

This proposed MINC-CNMF algorithm alternatively solved through the following convex subproblems until convergence:

$$R^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E^k, A^k, R) \quad (11)$$

$$A^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E^k, A, R^k) \quad (12)$$

$$E^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E, A^k, R^k) + \alpha \phi_{MV}(E) \quad (13)$$

where k indicates the number of iterations. This algorithm initializes E^0 with ATGP, A^0 with FCLS and outlier R^0 as a random matrix. Then updated each term (E, A, R) by using multiplicative updated rule [47]. Therefore, this algorithm starts with a given initial value (R^0, A^0, E^0) , then proceed in the order as $(R^k, A^k, E^k) \rightarrow (R^{k+1}, A^k, E^k) \rightarrow (R^{k+1}, A^{k+1}, E^k) \rightarrow (R^{k+1}, A^{k+1}, E^{k+1})$ where k is the current iteration stage. These steps repeated until it meets the convergence condition.

The method is implemented by extracting endmember E from LR-HIS, abundance matrix A from HR-MSI and the outlier R_h and R_m is estimated from observed HSI and MSI. After this, the outlier term R for final high resolution HR-MSI uses a low resolution Outlier Active Function (OAF) $S \in \mathbb{R}^{L_h \times N_m}$ that estimate the outlier matrix $R = R_h S R_m$. Consequently, the high spectral-spatial resolution fused image Z can be produced as follows,

$$Z = EA + R \quad (14)$$

This fused image Z cover all the information of ground truth image without any distortion in spectral and spatial information. The Algorithm 1 shown below summarized the proposed unmixing based fusion MINC-CNMF algorithm.

V. EXPERIMENTS AND PERFORMANCE ANALYSIS

To evaluate the performance of the unmixing based fusion method using our MINC-CNMF algorithm we conducted our experiment on four public dataset and then measured the quality of fusion method by using various quality measures. At last, the strength and superiority of our algorithm were evaluated by conducting experiments on four hyper-spectral datasets. We also compare the quality of our fusion methods with baseline fusion methods includes CNMF [16], HySure [17], CO-CNMF [18], TVSR-CNMF [19] and FuVar [20].

Algorithm 1: MINC-CNMF algorithm

Input:

LR-HSI $\rightarrow Y_h$

HR-MSI $\rightarrow Y_m$

Initialize:

$k=0$ and (R^0, A^0, E^0)

Step 1 : First unmix Y_h using nonlinear NMF unmixing algorithm by $\|Y_h - (EA_h + R_h)\|_F^2$

Optimize E, A_h and R_h as follows

$$R_h^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E^k, A_h^k, R_h) \quad A_h^{k+1} =$$

$$\arg \min_{E,A,R} \text{CNMF}(E^k, A_h, R_h^k)$$

$$E^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E, A_h^k, R_h^k) + \alpha \phi_{MV}(E)$$

Step 2 : Subsequently, unmix Y_m using same unmixing algorithm by $\|Y_m - (E_m A + R_m)\|_F^2$

Optimize E_m , A and R_m as follows

$$R_m^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E_m^k, A^k, R_m)$$

$$A^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E_m^k, A, R_m^k)$$

$$E_m^{k+1} = \arg \min_{E,A,R} \text{CNMF}(E_m, A^k, R_m^k) + \alpha \phi_{MV}(E_m)$$

Step 3: Repeat step 1-2 until convergence or predefined terminating condition is satisfied.

Step 4: Optimize the outlier R by using OAF $S : R = R_h S R_m$

Step 5: Reconstruct Z from E, A and R: $Z = EA + R$.

Output:

Fused HS image Z with high spatial-spectral dimension.

A. Dataset

Experimented and evaluated the proposed MINC-CNMF algorithm by using four real dataset such as Washington DC mall, Neon, Pavia University, Indian Pines. The first dataset is Washington DC Mall dataset is a well-known dataset captured by HYDICE sensor. This dataset contains image of size 1278×307 pixels. Due to large size of the image, we crop it to a 240×240-pixel size and that is selected for experiment which possesses 191 bands with 0.4 to 2.5 μm spectral range [16].

The second dataset is NEON Data, this dataset provides information on the National Observatory Networks San Joaquin Experimental Range field site. The image was collected over the San Joaquin field site located in California. The image selected for this experiment consists of 500×500 pixels with 107 bands with 0.4 to 0.85 μm spectral range [23].

The third HS dataset is Pavia University captured by the reflective optics spectrographic imaging system (ROSIS-3) over the University of Pavia, northern Italy in 2003. It consists of 610 × 340 pixels with 103 bands with 0.430 to 0.838 μm spectral range. The image select for this experiment is 560×320 pixel size [17].

The fourth HS image dataset AVIRIS Indian Pines is captured by AVIRIS sensor over the Indian Pines test site in northwestern Indiana, USA, in 1992. The image consists of 512×614 pixels. The selected image for experiment consists of 350×360 pixels size and 192 bands with wavelength range from 0.4 to 2.5 μm [16].

The high resolution ground truth images from these datasets were used as referenced image. The observed LR-HSI and HR-MSI are the input data for image fusion. These observed input data were generated by degrading spatial and spectral data from the referenced image according to Wald's protocol [22]. The observed LR-HSI Y_h is created by down sampling the ground truth image Z with a spatial blur factor $\omega = 6$ in both horizontal and vertical directions, respectively. The observed MSI Y_m , was produced with uniform spectral response functions corresponding to Landsat TM bands 1–5 and 7, which cover the 450–520, 520–600, 630–690, 760–900, 1550–1750, and 2080–2350 nm regions, respectively [10].

B. Quality Metrics

The strength of our fused images are measured by using four quality metrics: Spectral Angle Mapper (SAM), Signal-to-Reconstruction Error (SRE), Root-Mean-Square Error (RMSE), Peak Signal to Noise Ratio (PSNR), Universal Image Quality Index (UIQI). Using these metrics, the performance of our hyper-spectral image fusion algorithm is compared and also evaluated the quality of the estimated image by comparing it with ground truth HSI [8].

1) *SAM*: SAM identifies the spectral distortion between the estimated spectra E and a ground truth spectrum \hat{E} with n number of pixels. It measures the spectral similarity between the estimated and reference spectra by calculating the angle difference of the vectors between them as follows:

$$SAM(E, \hat{E}) = \frac{1}{n} \sum_{j=1}^n \arccos \left[\frac{E_j^T \cdot \hat{E}_j}{\|E_j\|_2 \cdot \|\hat{E}_j\|_2} \right] \quad (15)$$

The arccosine is defined as the inverse cosine function of the given value. If higher the spectral similarity between estimated spectra E and a ground truth spectrum \hat{E} , SAM values is closer to zero. That means, SAM value near to zero indicates high spectral quality [17].

2) *SRE*: The SRE measure the quality of reconstructed image based on the accuracy of estimated abundance data. Therefore, using this result, we can determine the quality and robustness of the proposed algorithm. The SRE is measured as follows,

$$SRE = 10 \log_{10} \left(\frac{\frac{1}{n} \sum_{i=1}^n \|\hat{A}_i\|_2^2}{\frac{1}{n} \sum_{i=1}^n \|\hat{A}_i - A_i\|_2^2} \right) \quad (16)$$

where the number of pixels is denoted as n , and \hat{A}_i and A_i are the abundance vectors of the estimated and original at the i^{th} pixel. Larger the SRE value, higher the spatial quality of the image [24].

3) *RMSE*: The result of RMSE gives the average difference between the original and estimated abundance map and so this result indicates the quality of the image as well as unmixing algorithm. That means, this matrix measures the spatial quality between the reference abundance \hat{A} and estimates abundance image A , is defined as:

$$RMSE(\hat{A}, A) = \frac{1}{\lambda_h n_m} \|A - \hat{A}\|_F^2 \quad (17)$$

Where, λ_h and n_m are the number of bands and the pixels in each of the band. The ideal value of RMSE is equal to zero and it can be achieved when $\hat{A} = A$ which signifies that there is no deviation. Smaller the RMSE value, better the quality of image [20].

4) *PSNR*: PSNR measure the reconstruction quality of spatial data in band wise. PSNR is the ratio between the signals to the residual errors. The PSNR of the l^{th} band is defined as

$$PSNR = \frac{1}{\lambda_h} \sum_{l=1}^{\lambda_h} PSNR_l \quad (18)$$

where $PSNR_l$ measures the spatial quality in the l^{th} spectral band, is defined as:

$$PSNR_l = 10 \cdot \log_{10} \left(\frac{\max(A^l)^2}{\|\hat{A}^l - A^l\|/P} \right) \quad (19)$$

where A^l is the pixel value of the l^{th} abundance band in the image. Higher the PSNR value, better the spatial quality of the estimated image [16].

5) *UIQI*: UIQI determines the similarity between the original and the estimated images by calculating the average correlation between the both images. The A_i denotes the image at the i^{th} band and \hat{A}_i denotes the original image at the corresponding band, then the correlation between $A^{(l)}$ and $\hat{A}^{(l)}$ are calculated as,

$$Q(A^l, \hat{A}^l) = \frac{\sigma_{A^l \hat{A}^l}}{\sigma_{A^l} \sigma_{\hat{A}^l}} = \frac{2\mu_{A^l} \mu_{\hat{A}^l} - \mu_{A^l}^2 - \mu_{\hat{A}^l}^2}{\sigma_{A^l}^2 + \sigma_{\hat{A}^l}^2} \quad (20)$$

Where, μ_{A^l} and $\mu_{\hat{A}^l}$ denote the mean vectors, σ_{A^l} and $\sigma_{\hat{A}^l}$ denote the variances and $\sigma_{A^l \hat{A}^l}$ is the covariance of both images respectively. The UIQI measure the average correlation Q over all the bands as follows,

$$UIQI(A^l, \hat{A}^l) = \frac{1}{\lambda_h} \sum_{l=1}^{\lambda_h} Q(A^l, \hat{A}^l) \quad (21)$$

The UIQI value range from $[-1, 1]$. When both images are similar, $A = \hat{A}$, then the value of $UIQI(A^l, \hat{A}^l) = 1$. For the final result, the overall UIQI of the estimated HSI can be computed by averaging the UIQI value of all bands [17].

C. Regularization Parameter

The regularization parameter controls the minimization of optimized problem, thus guarantees reconstruction of hyperspectral image with high spatial-spectral resolution. The original CNMF problem is reformulated into the regularized or constrained CNMF by incorporating minimum volume constraints to enhance the spectral quality during the enhancement of spatial quality by fusion. For regularizing this constraint a parameters α imposed into the problem. According to the comparative analysis of the existing literature study, the values of this parameter are set empirically in the range $\{1e-5, 1e-4, 1e-3, 1e-2, 0.01, 0.05, 0.1, 0.15, 0.2, 0.25, 0.3, 0.35, 0.4\}$ to obtain the best result [20].

The results obtained on our proposed method with this parameter α for set of above ranged values are observed in four selected datasets. It shows that when the α value exceeds 0.0015, the value of SAM and RMSE increases rapidly. Similarly, when the value of parameters α is below 0.0001, the RMSE value also starts rising. Therefore, the performance metrics provide better values in between 0.0015 and 0.0001. Other performance measures such as SRE, PSNR, and UIQI are also shows higher value in these ranges in all our four datasets. So, we set $\alpha = 0.00001$ (1e-4) to achieve better performance [20].

D. Performance Analysis of Fusion Algorithm

Many fusion algorithms are introduced in recent years to enhance the hyper-spectral image by fusion. But majority of these unmixing based fusion algorithms enhance the quality of either spectral or spatial information. Out of these existing algorithms our MINC-CNMF algorithm improves the quality of both spectral and spatial data in the hyper spectral image. In addition to this, enhancement is also considered the nonlinearity in the image during fusion by unmixing process. In this work our plan to enhance the spatial quality of LR-HSI. For this purpose, we extracted the high spatial quality of multispectral image and fused with high LR-HSI which having high spectral quality. The LR-HSI and HR-MSI are obtained by spatial and spectral down sampling of ground truth HSI.

In this paper, we proposed a MINC-CNMF algorithm for fusing the high quality spectral and spatial data of LR-HSI and HR-MSI by enhancing the both data without any distortion. The visual effect of our proposed algorithm on four datasets is presented in Fig. 1. Form Fig. 1 it is found that our proposed

algorithm gives better visual effect compared to other fusion method.

Then the performance capability of this proposed algorithm against various baseline algorithm are tested using the quality measure such as SAM, RMSE, SRE, PSNR and UIQI and the result are shown in the Table I. The result shown in Table I indicates that our proposed algorithm show superiority over all the baseline fusion methods. The less SAM value indicates that estimated fused image has less spectral distortion. The reduced value of RMSE shows the high reconstruction fidelity to the referenced image. The high PSNR value shows the good spatial quality of estimated image. Similarly, the higher value of SRE and UIQI shows much better performance of fusion algorithm. The performance of all these quality measures are shown in Fig. 2.

Fig. 1. The Ground Truth, HR-MSI, LR-HSI and our MINC-CNMF Algorithm Images of Four Dataset (a) Washington DC Mall, (b) NEON, (c) Indian Pines and (d) Pavia University.

TABLE I. PERFORMANCE VALUES OF DIFFERENT QUALITY MEASURES ON THE FOUR DATASETS (BEST VALUES ARE MARKED AS BOLD CHARACTER)

Fig. 2. The Performance of Four Quality Measures on our Proposed MINC-CNMF Algorithm.

VI. CONCLUSIONS

In this paper, we proposed an unmixing based fusion algorithm to enhance the LR-HSI using a multiplicative iterative nonlinear constrained coupled nonnegative matrix factorization (MINC-CNMF) algorithm. This algorithm enhances the quality of both spectral as well as spatial dimension of the image to the standard CNMF. In addition, this algorithm also considered the nonlinear factors in the image by considering the outlier data heterogeneous area, pixel illuminations, tiny spots in the image. This MINC-CNMF spectral unmixing based fusion algorithm updates each parameter by using a popular update method namely multiplicative update rule, which update the endmember signatures, abundances and the outlier matrix iteratively until it reaches the stopping criteria as explained in the algorithm implementation.

We experimented our fusion by unmixing method on four real-world dataset and analyze the performance of our methods on various quality measures such as SAM, SRE, RMSE, PSNR, UIQI. Then we compare the effectiveness of our MINC-CNMF algorithm with the existing methods. From the results produced by all the above method it is found that the proposed algorithm gives better fused image with high quality spatial and spectral dimension and consume less computational processing time than all other existing methods. This work mainly focused on exploring both spatial and spectral information by considering nonlinear effects in the hyper-spectral image. In future work, to furthermore improve the accuracy of unmixing performance by introducing some more constraints or prior information about endmembers and abundance to this modal.

ACKNOWLEDGMENT

The authors would like to express the gratitude to all the reviewers for their helpful comments and suggestions to improve the quality of paper.

Optimal Operation of Smart Distribution Networks using Gravitational Search Algorithm

Surender Reddy Salkuti

Department of Railroad and Electrical Engineering, Woosong University
Daejeon, Republic of Korea.

Abstract—This paper proposes a methodology for an optimal operation of smart distribution network considering the network reconfiguration, distributed generation (DG) units allocation and optimally placing the shunt capacitors for reactive power compensation. In this work, the total power losses minimization objective is considered. By optimizing this objective, it can also result in the reduction of voltage deviation. The proposed problem is solved using evolutionary-based gravitational search algorithm (GSA). Simulation studies are performed on 33 bus radial distribution system (RDS). Simulation results reveal that there is a drastic reduction in the power losses by utilizing the network reconfiguration, DG allocation, and reactive power compensation.

Keywords—Distributed generation; renewable energy; meta-heuristic algorithms; network reconfiguration; smart grid; reactive power compensation

I. INTRODUCTION

Distribution system is the most important component of current smart power system, and it aims to provide the electricity to its customers in an efficient, reliable, economic, and environmentally friendly way while satisfying all the operating constraints of the system. It can be observed that during the last few years, there is a rapid expansion of power systems due to the drastic increase in the load demand which leads to high power losses and poor voltage regulation. To overcome this increased load demand and economic benefits, renewable energy has been introduced to the power system. In recent years, distributed generations (DGs) are emerging as an important alternative solution for the enhancement of smart power distribution systems [1]. Along with this, reactive power compensation and optimal network reconfiguration (ONR) are considered as the tools for the enhancement of smart power distribution systems.

Various objectives considered for the optimal reconfiguration of smart systems include investment and operational cost minimization, active power loss minimization, enhancement of reliability, etc. Several researchers proposed various approaches to handle the distribution networks include optimal network reconfiguration (ONR), optimal allocation of DG, and simultaneous optimization of both ONR and DG allocation. ONR is an approach to change the configuration of distribution system by changing the opening/closing status of the sectionalizing (normally closed) and the tie (normally open) switches of the network, so that the radiality and connectivity are well maintained [2]. The distribution networks need to be expanded to meet the increasing demand, however, it is a big

issue as it is associated with various economic and environmental factors. In this situation, ONR is a viable solution to this problem [3, 4]. ONR problem is a highly non-linear, complex, mixed-integer, large-scale, combinatorial, non-differential, and constrained optimization problem.

The author in [5] proposes an approach for the economic operation of distribution networks by considering the curtailment costs. A multi-objective-based ONR is proposed in [6] for the minimization of loss and enhancement of voltage profile. A day-ahead ONR model is proposed in [7] for smart distribution networks including the renewables-based DGs and storage systems by considering voltage deviations and operating cost minimization objectives. The author in [8] proposes an approach for calculating the daily profit and risk of RDSs by considering the uncertainties of power outputs from the DG units and electricity prices. An analytical optimization approach is proposed in [9] for optimal investment of DG units along with capacitors to minimize interconnection costs of renewable sources and to enhance the voltage profile of the system. An approach for simultaneous ONR and optimal DG allocations in a RDS by considering the voltage stability improvement and active power loss minimization objectives has been proposed in [10]. Simultaneous and optimal allocation of RESs and reconfiguration in RDSs with reliability enhancement and cost of power losses minimization objectives are solved by using the information gap decision theory has been proposed in [11]. The ONR and supply restoration approach based on the improved genetic algorithm (GA) has been proposed in [12]. Multi-criteria based ONR of RDS considering reliability, stability improvement, and loss minimization objectives have been proposed in [13].

The above literature review revealed that there is a need for simultaneous optimization of ONR, reactive power compensation, and optimal allocation of DG units. To address the complexity and computational burden involved with the loss minimization objective, it uses the gravitational search algorithm (GSA). The work presented in this paper is as follows: Distribution load flow (DLF) analysis of the radial distribution system (RDS) has been presented in Section 2. The proposed optimal network reconfiguration (ONR) approach has been presented in Section 3. In Section 4, gravitational search algorithm (GSA) is described. In Section 5, 33 bus RDS is used to demonstrate the proposed approach and analyze the results for the considered test system. Finally, conclusions are drawn from the proposed study are reported in Section 6.

II. DISTRIBUTION LOAD FLOW (DLF)

Load flow analysis is a tool for steady-state analysis of the distribution network in both operational and planning stages. In the literature, several researchers use conventional approaches like Fast Decoupled, Newton Raphson load flow approaches to address static and dynamic distribution network problems [14]. However, these load flow approaches are inefficient due to high resistance to reactance (R/X) ratio of the distribution line and its radial structure, which has resulted in the development of special load flows for the RDSs [15]. Most of the load flow calculations are based on forward-backward sweep methods. The load flow approach presented in this paper is based on an iterative approach which is based on the receiving end voltage of the RDS. Here, an effective power at each bus is calculated after the formulation of the adjacent node and adjacent branch matrices. Fig. 1 depicts the equivalent circuit of a line in a RDS [16].

Fig. 1. Equivalent Circuit of a Branch in RDS.

The current in the branch (ab) connected between the sending end (a) and receiving end (b) can be expressed by [16],

$$I_{ab} = \frac{|V_a| \angle \delta_a - |V_b| \angle \delta_b}{R_{ab} + jX_{ab}} = \frac{P_b - jQ_b}{(|V_b| \angle \delta_b)^*} \quad (1)$$

Where,

$$P_b = \sum_{i=1}^{N_b} P_{D,i} + \sum_{l=1}^{B_b} P_{loss,l} \quad (2)$$

N_b represents all the nodes beyond node b and B_b represents all the branches beyond node b. $P_{D,i}$ is power demand at node i , and $P_{loss,l}$ is active power loss in the branch l . From equation (1), the active power (P_b) can be calculated by [17],

$$P_b = \frac{|V_a| |V_b| \sin(\delta_a - \delta_b) + R_{ab} Q_b}{X_{ab}} \quad (3)$$

From equation (3), the voltage at the receiving end can be determined by,

$$|V_b| = - \left[|V_a| \left(\frac{R_{ab}}{X_{ab}} \sin \delta - \cos \delta \right) \right] + \left[|V_a| \left(\frac{R_{ab}}{X_{ab}} \sin \delta - \cos \delta \right) \right]^2 - 4Q_b \sqrt{\left(\frac{R_{ab}}{X_{ab}} + X_{ab} \right)} \quad (4)$$

Where $\delta = \delta_a - \delta_b$. The angle δ_b can be expressed by,

$$\delta_b = \delta_a - \tan^{-1} \left[\frac{P_b X_{ab} - Q_b R_{ab}}{|V_b|^2 + P_b R_{ab} + Q_b X_{ab}} \right] \quad (5)$$

The real and reactive power losses in a branch (ab) can be determined by [17],

$$P_{loss,ab} = \frac{R_{ab}(P_b^2 + Q_b^2)}{|V_b|^2} \quad (6)$$

$$Q_{loss,ab} = \frac{X_{ab}(P_b^2 + Q_b^2)}{|V_b|^2} \quad (7)$$

III. PROBLEM FORMULATION

Integration of renewable power generation along with ONR is performed to achieve optimum power losses in the system. As mentioned earlier, minimization of total power loss (P_T^{loss}) in the RDS is selected as a primary objective of ONR problem [18, 19]. However, the problem is also carried out with the objectives of voltage profile improvement, loadability and power quality enhancement, minimization of total network cost and emissions, economic and reliable operation. Real and reactive power losses in a branch connected between the nodes/buses a and b can be expressed by,

$$P_{a,b}^{loss} = \left(\frac{P_{a,b}^2 + Q_{a,b}^2}{|V_a|^2} \right) \times R_{a,b} \quad (8)$$

$$Q_{a,b}^{loss} = \left(\frac{P_{a,b}^2 + Q_{a,b}^2}{|V_a|^2} \right) \times X_{a,b} \quad (9)$$

Then total power losses (P_T^{loss}) in the entire RDS can be expressed as [20],

$$P_T^{loss} = \sum_{a=1}^{N_B} \left(\frac{P_{a,b}^2 + Q_{a,b}^2}{|V_a|^2} \right) \times R_{a,b} \quad (10)$$

Where N_B is number of buses in the RDS.

The power loss minimization objective can be expressed by [21],

$$f = \text{minimize } (P_T^{loss}) \quad (11)$$

In this work, optimization is performed, by considering the network reconfiguration, reactive power compensation by using the shunt capacitors, and by optimally allocating the DG units [22], then there is a minimization in the voltage deviation in the system. This voltage deviation can be expressed as,

$$\Delta V = \left(\frac{V_1 - V_a}{V_1} \right) \quad a = 1, 2, \dots, N_B \quad (12)$$

The above problem is solved by considering the following constraints.

A. Equality Constraints

These constraints are expressed as [23],

$$P_D = P_G^{Grid} + \sum_{i=1}^{N_{DG}} P_{DG,i} \quad (13)$$

$$Q_D = Q_G^{Grid} + \sum_{i=1}^{N_{DG}} Q_{DG,i} + \sum_{j=1}^{N_{RC}} Q_{RC,j} \quad (14)$$

B. Inequality Constraints

These constraints for the RDS are DG power limits, bus voltage, and branch current limits.

1) *DG power constraints*: The real and reactive power generations from DG units [24] are limited by,

$$P_{DG,i}^{min} \leq P_{DG,i} \leq P_{DG,i}^{max} \quad (15)$$

$$Q_{DG,i}^{min} \leq Q_{DG,i} \leq Q_{DG,i}^{max} \quad (16)$$

2) *Bus voltage constraint*: Lower and upper voltage limits of buses in the RDS are expressed as [25],

$$V_{Bus,i}^{min} \leq V_{Bus,i} \leq V_{Bus,i}^{max} \quad i = 1, 2, \dots, N_{Bus} \quad (17)$$

3) *Bus voltage constraint*: The current in each branch ($I_{b,k}$) is limited by,

$$I_{b,k} \leq I_{b,k}^{max} \quad k = 1, 2, \dots, N_{Br} \quad (18)$$

4) *Power flow constraint*: Power loss in each feeder (P_i) is limited by,

$$P_i \leq P_i^{max} \quad \text{for } i = 1, 2, \dots, N_F \quad (19)$$

Where N_F is number of feeders in the system.

5) *Capacitor constraint*: The capacity of shunt capacitor (C_k) is limited by,

$$C_k^{min} \leq C_k \leq C_k^{max} \quad \text{for } k = 1, 2, \dots, N_{Cap} \quad (20)$$

Where N_{Cap} is number of capacitor banks. C_k^{min} and C_k^{max} are minimum and maximum values of discrete controls of k^{th} capacitor banks.

The above problem is solved by retaining the structure of radial network. From an optimization perspective, these problems are considered as highly non-linear, highly constrained, mixed-integer, high dimension, and multi-modal optimization problems with a large number of local optimum solutions. So, determining the global solution is a complex optimization problem is challenging, which provides ample opportunity for further research. The distributed generators (DGs) can be wind energy generators, solar PV, biomass, small hydro, etc.

IV. GRAVITATIONAL SEARCH ALGORITHM (GSA)

GSA has been developed by E. Rashedi et al. in 2009 [26] by using Newton's law of gravity and motion. The gravitational force (F) can be expressed as,

$$F = G \frac{m_1 m_2}{r^2} \quad (21)$$

Where G is gravitational constant. m_1, m_2 are masses of the objects 1 and 2; r is distance between centers of masses. In this GSA, agents are represented as objects and their performance is measured by their masses. Let a system has N_m number of masses and the position of i^{th} mass (X_i) can be expressed as,

$$X_i = (x_i^1, x_i^2, \dots, x_i^d, \dots, x_i^n) \quad i = 1, 2, \dots, N_m \quad (22)$$

Where n is size of search space, x_i^d is position of i^{th} mass in d^{th} dimension. The flow chart of GSA is presented in Fig. 2. For detailed description of GSA, the reader may refer [26]-[29].

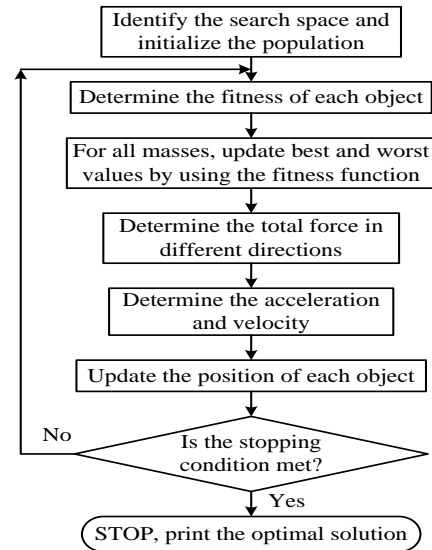

Fig. 2. Flow Chart of GSA.

V. RESULTS AND DISCUSSION

In this work 33 bus RDS is used for the analysis and explanation of network reconfiguration. The base voltage and base MVA for 33 bus is considered as 12.66 kV and 100 MVA [30]. In this test system, a maximum of three DG units are incorporated and the maximum size of DG is 2000 kW. In this paper, 3 case studies are considered, and they are:

- Case 1: Optimal operation with only reconfiguration.
- Case 2: Optimal operation with only reactive power compensation.
- Case 3: Optimal operation with only DG allocation.
- Case 4: Optimal operation with reconfiguration, reactive power compensation, and DG allocation.

This test system data has been taken from the [31, 32]. This test system has 33 buses, 32 lines, and bus 1 is assigned as the substation bus. In this test system, the active and reactive power demands are 3715 kW and 2300 kVAR. Single line diagram (SLD) of 33 bus system is depicted in Fig. 3. This system has 5 open tie switches which form the loops in the system and they are 33 to 37. This system has 32 sectionalizing switches marked as 1 to 32 which are normally closed and they are shown in Fig. 3.

A. Case 1

As mentioned earlier, a similar analysis can be made for a 33 bus RDS. Initial and final configurations of the system are depicted in Fig. 3 and 4. A comparison of node voltages before and after the reconfiguration is shown in Fig. 5. A comparison of various other parameters before and after reconfiguration is shown in Table I. Under the base case condition (i.e., before the network reconfiguration), the switches 33 to 37 are opened and the system power losses are 202.6592 kW. The minimum voltage has occurred at bus 18 and its value is 0.9038 p.u.

Fig. 3. Initial Configuration of a 33 Bus RDS.

Fig. 4. Final Configuration of a 33 Bus RDS for Case 1.

Fig. 5. Comparison of Node Voltages before and after Reconfiguration (Case 1) for a 33 Bus RDS.

TABLE I. SIMULATION RESULTS FOR 33 BUS RDS BEFORE AND AFTER THE NETWORK RECONFIGURATION

	Before network reconfiguration	After network reconfiguration
Tie switches opened for reconfiguration	33, 34, 35, 36, 37	7, 9, 14, 32, 37
Power loss (kW)	202.6592 kW	150.8846 kW
Reduction in power loss (%)	-	25.55 %
Minimum voltage (p.u.)	0.9038 pu at bus 18	0.9378 pu at bus 32

From Fig. 5, it can be seen that the voltages at node numbers 5 to 18 and 26 to 33 have drastically improved and at several other nodes, the voltage is improved to a reasonable extent. Though there is a decrease in voltages at some nodes, it is to a reasonable extent. From Table I it can be seen that there is a reduction in active power loss of 25.55%. The minimum voltage after reconfiguration is found to be 0.9378 p.u.

B. Case 2

In this case, reactive power compensation is used to reduce active power losses further. Table II presents the simulation results for 33 bus RDS for reactive power compensation using differential evolution (DE) and GSA.

TABLE II. RESULTS FOR 33 BUS RDS FOR REACTIVE POWER COMPENSATION USING DE AND GSA

	Reactive power compensation using DE	Reactive power compensation using GSA
Bus number and reactive power compensation (kVAr)	552.4 kVAr at bus 6	550.4 kVAr at bus 6
	560.5 kVAr at bus 28	562.8 kVAr at bus 28
	545.9 kVAr at bus 29	548.5 kVAr at bus 29
Total compensation	1658.8 kVAr	1661.7 kVAr
Power loss before the compensation	202.6592 kW	202.6592 kW
Power loss after the compensation	142.52 kW	140.83 kW
Power loss reduction	29.68%	30.51%
Minimum voltage	0.9794 pu at bus 33	0.9798 pu at buses 17 and 33

Active power losses before reactive power compensation is 202.6592 kW. In this paper, GSA is used for determining the optimum size of the capacitor at the potential candidate bus. In this work, it is considered that a maximum of 3 capacitors can be placed for the reactive power compensation. By using GSA, the total compensation required for this system is 1661.7 kVAr, and it is placed at buses 6, 28, and 29 with the compensation values of 550.4 kVAr, 562.8 kVAr, and 548.5 kVAr, respectively. The SLD of 33 bus RDS for Case 2 after incorporating the shunt capacitors is depicted in Fig. 6.

Fig. 6. SLD of 33 Bus RDS for Case 2 after Incorporating the Shunt Capacitors.

Fig. 7. Comparison of Node Voltages before and after Reconfiguration for a 33 Bus RDS.

The active power loss obtained in this case is 140.83 kW which resulted in the reduction of 30.51% compared to the case without any compensation. The results obtained with GSA are also compared with DEA, and the results are reported in Table II. Voltage profile of RDS has been improved after incorporating the shunt capacitors. Comparison of node voltages before and after the reconfiguration for 33 bus RDS is depicted in Fig. 7. Minimum voltage after installing the capacitors is found to be 0.9798 p.u.

C. Case 3

In this case, proposed optimization problem of RDS is solved by optimally allocating the DG units at various buses in the system. Table III presents the simulation results for Case 3. In this case, DG of 835.8 kW is placed at bus 8, 1105.6 kW is placed at bus 23, and 1084.9 kW is placed at bus 29. Hence, the total size of DG is 3026.3 kW. By optimally placing the DG units, the system power losses have been decreased to 84.62 kW from the base case loss of 202.66 kW. Therefore, in this case, there is a loss reduction of 58.25% compared to base case losses. Fig. 8 depicts the improved voltage profiles for case 3. The minimum voltage obtained in this case after DG allocation is 0.9742 p.u. which has been occurred at bus number 17, whereas in the base case, the minimum voltage occurred is 0.9038 p.u. at bus number 18.

TABLE III. SIMULATION RESULTS FOR 33 BUS RDS FOR CASES 3 AND 4

	Case 3	Case 4
Tie switches opened for reconfiguration	33, 34, 35, 36, 37	7, 9, 14, 32, 37
Bus number and DG size (kW)	835.8 kW at bus 8	822.4 kW at bus 13
	1105.6 kW at bus 23	1150.5 kW at bus 23
	1084.9 kW at bus 29	983.2 kW at bus 30
Total DG size (kW)	3026.3 kW	2956.1 kW
Bus number and reactive power compensation (kVAr)	---	560.5 kVAr at bus 6
	---	565.2 kVAr at bus 28
	---	540.8 kVAr at bus 29
Total compensation (kVAr)	---	1666.5 kVAr
Power loss (kW)	84.62 kW	55.98 kW
Power loss reduction	58.25 %	72.38 %
Minimum voltage	0.9742 pu at bus 17	0.9802 pu at bus 17

Fig. 8. Comparison of Node Voltages for the base Case, Case 3, and Case 4 for 33 Bus RDS.

D. Case 4

This case considers network reconfiguration, DG allocation, and reactive power compensation simultaneously for minimizing the system power losses. Table III presents the simulation results for Case 4. The opened tie-switches for ONR are 7, 9, 14, 32, and 37, and the system configuration for case 4 after the ONR has been depicted in Fig. 9. The total optimum DG size obtained is 2956.1 kW. The buses 13, 23, and 30 are placed with DG units with capacities of 822.4 kW, 1150.5 kW, and 983.2 kW, respectively. Here, the shunt capacitors are placed at buses 6, 28, and 29 with the reactive power compensation of 560.5 kVAr, 565.2 kVAr, and 540.8 kVAr, respectively.

Fig. 9. Final Configuration of a 33 Bus RDS for Case 4 after Incorporating the Shunt Capacitors and DG Units.

The total optimum reactive power compensation required for Case 4 is 1666.5 kVAr. The obtained optimum loss is 55.98 kW which is 72.38% less when compared to base case power loss (i.e., 202.66 kW). The voltage profile obtained in this case has been depicted in Fig. 8. From this figure, it can be observed that the voltage profile obtained in this case is better than all other cases studied in this work. Final configuration of a 33 bus RDS for Case 4 after incorporating the shunt capacitors and DG units has been depicted in Fig. 9. Minimum voltage occurred in this case after the ONR, DG allocation and reactive power compensation is 0.9802 p.u. at bus number 17, which has been improved from 0.9038 p.u. (i.e., base case).

VI. CONCLUSIONS

This paper proposed an approach for the optimal allocation of distributed generations (DGs), shunt capacitors along optimal network reconfiguration using the meta-heuristic-based gravitational search algorithm (GSA). Here, the minimization of total active power losses is considered as an objective function, which will also enhance voltage profile in the system and hence reduces voltage deviation. The proposed problem has been implemented on the standard 33 bus radial distribution system (RDS). The obtained results show the improved voltage profile and reduced power losses in the system. The proposed work can also be extended to unbalanced RDSs and the optimal allocation of electric vehicles (EVs) can also be studied. Optimal allocation of energy storage systems (ESSs) along with FACTS devices such as D-STATCOM is scope for future research.

Visakhapatnam, Andhra Pradesh – 530045

Abstract—A Stroke is a health condition that causes damage by tearing the blood vessels in the brain. It can also occur when there is a halt in the blood flow and other nutrients to the brain. According to the World Health Organization (WHO), stroke is the leading cause of death and disability globally. Most of the work has been carried out on the prediction of heart stroke but very few works show the risk of a brain stroke. With this thought, various machine learning models are built to predict the possibility of stroke in the brain. This paper has taken various physiological factors and used machine learning algorithms like Logistic Regression, Decision Tree Classification, Random Forest Classification, K-Nearest Neighbors, Support Vector Machine and Naïve Bayes Classification to train five different models for accurate prediction. The algorithm that best performed this task is Naïve Bayes that gave an accuracy of approximately 82%.

Keywords—Stroke; machine learning; logistic regression; decision tree classification; random forest classification; k-nearest neighbors; support vector machine; Naïve Bayes classification

I. INTRODUCTION

According to the Centers for Disease Control and Prevention (CDC), stroke is the fifth-leading cause [1] of death in the United States. Stroke is a non-communicable infection that is liable for around 11% of total deaths. Consistently, over 795,000 individuals in the United States experience the ill effects of a stroke [2]. It is the fourth significant reason for death in India.

With the advancement of technology in the medical field, predicting the occurrence of a stroke can be made using Machine Learning. The algorithms present in Machine Learning are constructive in making an accurate prediction and give correct analysis. The works previously performed on stroke mostly include the ones on Heart stroke prediction. Very less works have been performed on Brain stroke. This paper is based on predicting the occurrence of a brain stroke using Machine Learning. The key components of the approaches used and results obtained are that among the five different classification algorithms used Naïve Bayes has best performed obtaining a higher accuracy metric. The limitation with this model is that it is being trained on textual data and not on real time brain images. The paper shows the implementation of six Machine Learning classification algorithms. This paper can be further extended to implementing all the current machine learning algorithms.

A dataset is chosen from Kaggle [3] with various physiological traits as its attributes to proceed with this task.

These traits are later analyzed and used for the final prediction. The dataset is initially cleaned and made ready for the machine learning model to understand. This step is called Data Preprocessing. For this, the dataset is checked for null values and fill them. Then Label encoding is performed to convert string values into integers followed by one-hot encoding, if necessary.

After Data Preprocessing, the dataset is split into train and test data. A model is then built using this new data using various Classification Algorithms. Accuracy is calculated for all these algorithms and compared to get the best-trained model for prediction.

After training the model and calculating the accuracy, an HTML page and a Flask application are developed. The web application is for the user to enter the values for prediction. The flask application is a framework that connects the trained model and the web application. After proper analysis, the paper concludes which algorithm is most appropriate for the prediction of stroke.

II. LITERATURE SURVEY

In [4], stroke prediction was made on Cardiovascular Health Study (CHS) dataset using five machine learning techniques. As an optimal solution, the authors used a combination of the Decision Tree with the C4.5 algorithm, Principal Component Analysis, Artificial Neural Networks, and Support Vector Machine. But the CHS Dataset taken for this work had a smaller number of input parameters.

In [5], stroke prediction has been carried out from the social media posts posted by people. In this particular work, the authors have used the DRFS method to find the various symptoms associated with stroke disease. The usage of Natural Language Processing to extract the text from the social media posts adds up to the overall execution time of the model which is not desirable.

In [6], the authors have performed the task of stroke prediction by using an improvised random forest algorithm. This was used to analyze the levels of risks obtained with the strokes. As suggested by the authors, this method is said to have performed better when compared to the existing algorithms. This particular research is limited to very few types of strokes and cannot be used for any new stroke type in the future.

Research paper [7] shows that the model was trained using Decision Tree, Random Forest, and Multi-layer perceptron for stroke prediction. The obtained accuracies for the three methods were quite close, with slight differences. The calculated accuracy for Decision Tree was 74.31%, Random Forest was 74.53%, and Multi-layer perceptron was 75.02%.

This paper suggests that Multi-layer perceptron is more accurate than the other two methods. Accuracy score was the only metric used for calculating the performance that might not always give favorable results.

Research carried out in [8] shows the implementation of machine learning model to predict heart stroke. They used various machine learning techniques like Decision tree, Naïve Bayes, SVM to build the model and later compared their performance. They obtained a maximum accuracy of 60% from the used algorithms which is pretty less.

In [9], the authors have used different data mining classification techniques to predict the possibility of a stroke. The dataset was taken from the Ministry of National Guards Health Affairs Hospitals, Kingdom of Saudi Arabia. The three classification algorithms used were C4.5, Jrip and Multi layers perceptron (MLP). With these algorithms, the model obtained an accuracy of around 95%. Even though the paper claims to obtain an accuracy of 95%, the time taken for training and predicting is higher as the authors have used a combination of complex algorithms.

Research carried out in [10], suggests the usage of three different algorithms to predict the possibility of stroke. These algorithms are Naïve Bayes, Decision Tree, and Neural Networks. This paper concluded that the Decision tree has the highest accuracy (about 75%) of the other two algorithms. But this model could not suit the real-world examples based on the values obtained from the confusion matrix.

In [11], the researchers have performed stroke prediction on Cardiovascular Health Study (CHS) dataset. They proposed a novel automatic feature selection algorithm that selects robust features based on their proposed conservative mean. They have combined this method with the Support Vector Machine algorithm for better efficiency. But this resulted in the generation of a number of vectors that tend to reduce the performance of the model.

Research in [12] proposes the prediction of thrombo-embolic stroke disease using Artificial Neural Networks. The method used for prediction was the Back-propagation algorithm. This model was able to get an accuracy of around 89%. But Neural Networks need more time to be trained and require higher processing time because of the complex structure with increasing number of neurons.

III. SYSTEM METHODOLOGY

To proceed with the implementation, different datasets were considered from Kaggle. Out of all the existing datasets, an appropriate dataset was collected for model building.

After collecting the dataset, next step lies in preparing the dataset to make the data more clear and easily understood by the machine. This step is called as Data preprocessing. This

step includes handling of missing values, handling imbalanced data and performing label encoding that are specific for this particular dataset.

Now that the data is preprocessed, it is ready for model building. For model building, preprocessed dataset along with machine learning algorithms are required. Logistic Regression, Decision Tree Classification algorithm, Random Forest Classification algorithm, K-Nearest Neighbor algorithm, Support Vector Classification and Naïve Bayes Classification algorithm are used. After building six different models, they are compared using five accuracy metrics namely Accuracy Score, Precision Score, Recall Score, F1 Score and Receiver Operating Characteristic (ROC) curve.

The comparison of the models gives the best model in terms of the accuracy metrics to proceed with the deployment phase. For deploying the model, an HTML page is developed to make it user-friendly for the user to enter the input parameters and get the result. The parameters entered by the user are sent to the model using a flask application which is basically a python framework that links the web application and the model together. The model takes the input parameters, predicts the output and returns the result to the flask application. Now this flask will display that result on the web page for the user to check the result.

The flow chart of the proposed system's methodology is in Fig. 1.

Fig. 1. Proposed System's Flow Chart.

IV. IMPLEMENTATION

The implementation of this project is as follows.

A. Dataset

The dataset for stroke prediction is from Kaggle [3]. This particular dataset has 5110 rows and 12 columns. The columns have 'id', 'gender', 'age', 'hypertension', 'heart_disease', 'ever_married', 'work_type', 'Residence_type', 'avg_glucose_level', 'bmi', 'smoking_status' and 'stroke' as the main attributes. The output column 'stroke' has the value as either '1' or '0'. The value '0' indicates no stroke risk detected, whereas the value '1' indicates a possible risk of stroke. This dataset is highly imbalanced as the possibility of '0' in the output column ('stroke') outweighs that of '1' in the same column. Only 249 rows have the value '1' whereas 4861 rows with the value '0' in the stroke column. For better accuracy, data pre-processing is performed to balance the data. The dataset discussed above is summarized in Table 1.

TABLE I. STROKE DATASET

Attribute Name	Type (Values)	Description
1. id	Integer	A unique integer value for patients
2. gender	String literal (Male, Female, Other)	Tells the gender of the patient
3. age	Integer	Age of the Patient
4. hypertension	Integer (1, 0)	Tells whether the patient has hypertension or not
5. heart_disease	Integer (1, 0)	Tells whether the patient has heart disease or not
6. ever_married	String literal (Yes, No)	It tells whether the patient is married or not
7. work_type	String literal (children, Govt_job, Never_worked, Private, Self-employed)	It gives different categories for work
8. Residence_type	String literal (Urban, Rural)	The patient's residence type is stored
9. avg_glucose_level	Floating point number	Gives the value of average glucose level in blood
10. bmi	Floating point number	Gives the value of the patient's Body Mass Index
11. smoking_status	String literal (formerly smoked, never smoked, smokes, unknown)	It gives the smoking status of the patient
12. stroke	Integer (1, 0)	Output column that gives the stroke status

B. Data Preprocessing

Data Preprocessing is required before model building to remove the unwanted noise and outliers from the dataset, resulting in a deviation from proper training. Anything that interrupts the model from performing with less efficiency is taken care of in this stage. After collecting the appropriate dataset, the next step lies in cleaning the data and making sure that it is ready for model building. The dataset taken has 12 attributes, as mentioned in Table I. Firstly, the column 'id' is dropped because its existence does not make much difference in model building. Then the dataset is checked for null values and filled if any found. In this case, the column 'bmi' has null values filled with the mean of the column data. After removing the null values from the dataset, the next task is Label Encoding.

C. Label Encoding

Label encoding encodes the string literals in the dataset into integer values for the machine to understand them. As the machine is usually trained in numbers, the strings have to be converted into integers. There are five columns in the collected dataset that have strings as their data type. On performing label encoding, all the strings get encoded, and the entire dataset becomes a combination of numerals.

D. Handling Imbalanced Data

The dataset chosen for the task of stroke prediction is highly imbalanced. The entire dataset has 5110 rows, of which 249 rows are suggesting the occurrence of a stroke and 4861 rows having the possibility of no stroke. The graphical representation of the imbalance is in Fig. 2. Training a machine-level model with such data might give accuracy, but other accuracy metrics like precision and recall are shallow. If such imbalanced data is not handled, the results are not accurate, and the prediction is inefficient. Therefore, to get an efficient model, this imbalanced data is to be first handled. For this purpose, the method of undersampling is used. Undersampling [13] balances the data wherein the majority class is undersampled to match the minority class. In this case, the class with a value as '0' is undersampled for the class with the value '1'. So after undersampling the resulting dataset will have 249 rows with value '0' and 249 rows with value '1'. The graphical representation of the output column in the resulting dataset is as shown in Fig. 3.

Fig. 2. Before Undersampling.

Fig. 3. After Undersampling.

V. MODEL BUILDING

A. Splitting the Data

After completing data preprocessing and handling the imbalanced dataset, the next step is building the model. The undersampled data is split into training and testing data for better accuracy and efficiency for this task keeping the ratio as 80% training data and 20% testing data. After splitting, various classification algorithms are used to train the model. The classification algorithms used for this purpose are Logistic Regression, Decision Tree Classification algorithm, Random Forest Classification, K-Nearest Neighbors Classification, Support Vector Machine and Naïve Bayes Classification.

B. Classification Algorithms

1) *Logistic regression*: Logistic Regression [14] is a supervised learning algorithm used for predicting the probability of the output variable. This algorithm is the best fit when the output variable has binary values (0 or 1). As the output attribute in the dataset has only two possible values, Logistic Regression is opted. After performing this algorithm on the dataset, the accuracy obtained is 78%. Efficiency of this algorithm can also be found by using various other accuracy metrics like precision score and recall score. Those two scores obtained in this case are equal, having a value of 77.6%. The F1 Score obtained with this algorithm is 77.6%. The Receiver operating characteristic (ROC) curve for Logistic Regression is 78% as shown in Fig. 4.

Fig. 4. ROC Curve for Logistic Regression.

2) *Decision tree classification*: Decision Tree classification [15] is to solve both Regression and classification problems. This algorithm is also a supervised learning method wherein the input variables already have their corresponding output variable. It is a tree-like structure. In this algorithm, the data continuously splits according to a particular parameter. A decision tree has two parts: Decision Node and Leaf node. The data splits at the former node, and the latter is the node that gives the outcome. In this case of stroke prediction, the decision tree classification algorithm obtained an accuracy of 66%, which is less than that obtained using logistic Regression. Similar to logistic Regression, the precision and recall scores are the same and equal to 77.6%. The F1 Score obtained with this algorithm is 77.6%. The Receiver operating characteristic (ROC) curve for Decision Tree Classification is 66% as shown in Fig. 5.

3) *Random forest classification*: The following classification algorithm chosen is Random Forest Classification [16]. Random Forests are composed of multiple independent decision trees trained independently on a random subset of data. These trees are generated at the time of training, and the outputs are obtained from each decision tree. For the final prediction from this algorithm, a method called "voting" takes place. This method means that each decision tree votes for an output class (in this case, the two classes are: 'stroke' and 'no stroke'). The random forest chooses the class with the maximum number of votes as the final prediction. The accuracy obtained by training the model using this particular algorithm is 73%. The precision and recall scores are 72% and 73.5%, respectively. The F1 Score obtained with this algorithm is 72.7%. The Receiver operating characteristic (ROC) curve for Random Forest Classification is 73% as shown in Fig. 6.

Fig. 5. ROC Curve for Decision Tree Classification.

Fig. 6. ROC Curve for Random Forest Classification.

4) *K-nearest neighbors classification*: Another algorithm used for classification is K-Nearest Neighbors (KNN). It is also a supervised learning technique. KNN [17] is a lazy algorithm that would not train immediately on giving the dataset. Instead, it stores the dataset, and at the time of classification, it acts on the dataset. The working principle of KNN is to find similarities between the new case (or data) and available data and then map the new case into the category that is most similar to the available categories. The accuracy obtained is 80%. Precision and recall scores are 77.4% and 83.7%, respectively. The F1 Score obtained with this algorithm is 80.4%. The Receiver operating characteristic (ROC) curve for KNN is 80% as shown in Fig. 7.

Fig. 7. ROC Curve for KNN.

5) *Support vector machine*: It is a supervised learning technique that can be associated with learning algorithms to analyze the data for both classification and regression. Support Vector Machine (SVM) [18] scales relatively well to high dimensional data. For this particular dataset, the algorithm obtained an accuracy of 80%, with precision and recall score being 78.6% and 83.8%. The F1 score is 81.1% for this algorithm. The Receiver operating characteristic curve (ROC) for Support Vector Classification is 80% as shown in Fig. 8.

Fig. 8. ROC Curve for Support Vector Machine.

6) *Naïve bayes classification*: It is also a supervised learning technique. A Naïve Bayes classifier [19] assumes that the presence of a particular feature in a class is unrelated to the presence of any other feature. It is based on Bayes Theorem.

This algorithm follows the principle that 'every feature or attribute classified is independent of one another.' With this algorithm, the accuracy obtained was 82%, with the precision score being 79.2% and recall score being 85.7%. The F1 Score obtained with this algorithm is 82.3%. The Receiver operating characteristic (ROC) curve for Naïve Bayes Classification is 82% as shown in Fig. 9.

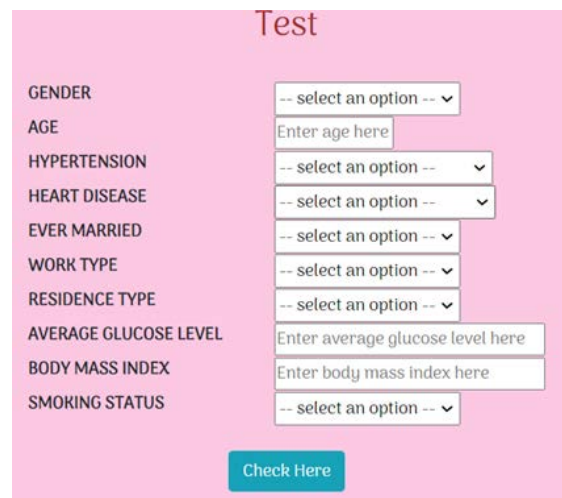

Fig. 9. ROC Curve for Naïve Bayes Classification.

After model building, it can be concluded that Naïve Bayes has performed better when compared to other algorithms. So, the model trained using Naïve Bayes classification is dumped using pickle. The next task is to develop a web application and a flask application to enter the input parameters.

The web page is built using simple HTML code. This application has an input form that will take the entered input values from the user to predict the occurrence of stroke. When the user clicks on the 'Check Here' button, the entered parameters are given to the flask application. A part of the HTML page is shown in Fig. 10.

The flask application which is basically a python code is the bridge between the web page and the trained machine learning model as shown in Fig. 11. The input values are sent to the flask application which in sends the values to the model for prediction.

The figure shows a web form titled 'Test' with a pink background. It contains several input fields and dropdown menus for user input. The fields are: GENDER (dropdown), AGE (text input), HYPERTENSION (dropdown), HEART DISEASE (dropdown), EVER MARRIED (dropdown), WORK TYPE (dropdown), RESIDENCE TYPE (dropdown), AVERAGE GLUCOSE LEVEL (text input), BODY MASS INDEX (text input), and SMOKING STATUS (dropdown). A 'Check Here' button is located at the bottom right of the form.

Fig. 10. Input Form in HTML Code.

```
from flask import Flask, request, render_template
import numpy as np
import pickle

model=pickle.load(open('stroke_model.pkl','rb'))

app = Flask(__name__)
@app.route('/')
def home():
    return render_template("home.html")
```

Fig. 11. Flask Application Linking the Model and Web Page.

Once the machine learning model gets the input parameters, it predicts the output. The obtained result then is reflected back on the web page through the flask application for the user to see the prediction.

VI. CONCLUSION

Stroke is a critical medical condition that should be treated before it worsens. Building a machine learning model can help in the early prediction of stroke and reduce the severe impact of the future. This paper shows the performance of various machine learning algorithms in successfully predicting stroke based on multiple physiological attributes. Out of all the algorithms chosen, Naïve Bayes Classification performs best with an accuracy of 82%. The comparison of accuracies obtained from various algorithms is as shown in Fig. 12. Among all the precision, recall and F1 scores obtained, Naïve Bayes has performed better. The comparison of Precision score, recall score and F1 score is as shown in Fig. 13, Fig. 14 and Fig. 15.

Fig. 12. Comparing the Accuracies of ML Algorithms.

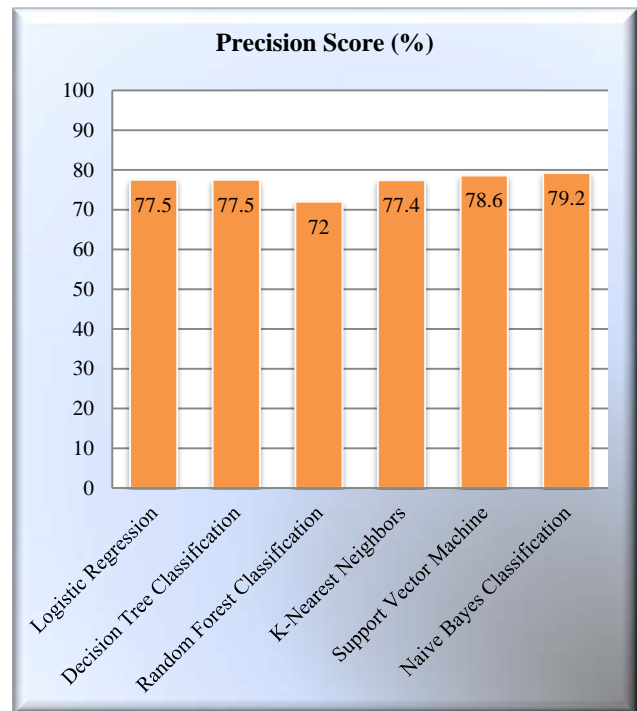

Fig. 13. Comparing the Precision Scores of ML Algorithms.

Fig. 14. Comparing the Recall Scores of ML Algorithms.

Fig. 15. Comparing the F1 Scores of ML Algorithms.

This paper suggests the implementation of various Machine learning algorithms on the dataset taken. This project can be further extended by training the model using Neural Networks. The comparison of the performance can be done by taking more accuracy metrics into consideration. This work is limited to textual data, which might not always be accurate for stroke prediction. Collecting a dataset consisting of images such as Brain CT scans to predict the possibility of stroke would be more efficient in the future.

Abstract—Retinal vessel segmentation is an active research area in medical image processing. Several research outcomes on retinal vessel segmentation have emerged in recent years. Each method has its own pros and cons, either in the vessel detection stage or in its extraction. Based on a detailed empirical investigation, a novel retinal vessel extraction architecture is proposed, which makes use of a couple of existing algorithms. In the proposed algorithm, vessel detection is carried out using a cumulative distribution function-based thresholding scheme. The resultant vessel intensities are extracted based on the hysteresis thresholding scheme. Experiments are carried out with retinal images from DRIVE and STARE databases. The results in terms of Sensitivity, Specificity, and Accuracy are compared with five standard methods. The proposed method outperforms all methods in terms of Sensitivity and Accuracy for the DRIVE data set, whereas for STARE, the performance is comparable with the best method.

Keywords—Retinal images; blood vessel detection; and segmentation; segmentation; hysteresis thresholding; cumulative distribution function introduction

I. INTRODUCTION

Retinal images are the fundamental diagnostic element to identify various ophthalmic diseases for medical experts. It can be captured using a specialized camera, fundus camera, with low power light capable of simultaneously illuminating and capturing the interior part of the eye [1]. The image captured by a fundus camera includes the retina along with the optic disc, macula, fovea, posterior pole, etc. [2].

A critical component of the retina is the blood vessels which are broadly categorized to retinal arteries and veins. The retinal artery carries oxygen and nutrients. It is through the optic nerve that the retinal artery enters the eye and then splits to superior and inferior branches [3]. The abnormalities in the structure of blood vessels lead to several ophthalmic diseases. In general, the abnormalities are due to the variations that occur in blood

vessel attributes such as its tortuosity, vessel width, diameter, bifurcation, etc. These abnormalities are identified by the ophthalmologist using a detailed analysis of vessel color, shape, and contrast [2], [4].

When Intra Ocular Pressure (IOP) is higher than normal, it leads to ocular hypertension. As a consequence of this situation, the retinal artery narrows considerably and may cause the bursting of blood vessels [5]. When a blockage occurs to the arteries carrying oxygen to the nerve cells, it leads to retinal artery occlusion, which may cause vision loss [6]. Changes in the structure of blood vessels may lead to bleeding or leakage of fluid and vision distortion. This situation, diabetic retinopathy, arises in the retinal vessels due to diabetes [7]. The obstruction of blood flow occurs when blockages are present in arteries or veins of the retina and lead to the narrowing of blood vessels or blood clots. This is normally known as eye stroke in ophthalmology [8].

In the early days, ophthalmologists faced difficulties in diagnosing these ophthalmic diseases as manual extraction may contain a human error. Also, the entire process of vessel extraction is time-consuming. Hence, blood vessel segmentation using medical image processing techniques has become significant for an ophthalmologist for accurate diagnostics.

Several blood-vessel segmentation algorithms for retinal images have been developed in recent years [2], [9]–[12]. The segmentation algorithms can be broadly categorized into algorithms which comes under pattern recognition techniques [10], [12], vessel tracking approaches [13], [14], model-based approaches [15], [16], hardware implementation [17], [18] and hybrid approaches [19], [20]. Further sub-classification is possible for pattern recognition (PR) techniques and model-based methods. The model-based methods can be categorized into region-based models and edge-based models [2]. On the other hand, PR techniques are divided into supervised and unsupervised algorithms based on the classification

methodology [2]. In supervised learning, prior model has to be trained using a set of reference images whereas in unsupervised learning, there is no need of prior training of samples. In the last decade, researchers proposed several deep learning models, specifically convolutional Neural Network models, for the segmentation of blood vessels. Compared to classical machine learning approaches, these methods are resource demanding.

A comprehensive review of the topic reveals the limitations of existing models in terms of recognition accuracy and algorithm complexity. This motivated the authors to explore the area. In this paper, a novel retinal vessel segmentation framework based on unsupervised learning is proposed to accurately extract blood vessels from fundus images. Vessel extraction is achieved by combining different segmentation steps from well-established unsupervised algorithms. The vessel detection step is constructed from an unsupervised coarse-to-fine vessel segmentation method developed by Câmara Neto et al. using an adaptive threshold [20]. The threshold is based on the cumulative distribution function of vessel intensity values [10]. The vessel extraction is carried out using the hysteresis thresholding technique [11]. The proposed vessel segmentation framework is compared with a set of state-of-the-art methods and is found to have the edge over them.

The paper is articulated as follows. Section 2 gives a comprehensive review of blood vessel segmentation algorithms developed in recent years. Section 3 describes the proposed methodology followed by experimental results discussed in section 4. Section 5 concludes the paper.

II. LITERATURE REVIEW

In this section, descriptions of prominent retinal vessel segmentation algorithms using conventional and Convolutional Neural Network (CNN) based approaches are discussed, highlighting their methodologies and merits.

Coye developed a novel vessel segmentation algorithm for retinal images in 2015 [21]. RGB retinal images are converted into LAB color space and enhanced using the CLAHE algorithm in the proposed algorithm. Background exclusion is carried out using an average filter followed by thresholding using the IsoData algorithm on the improved image. Further, isolated pixels are removed using morphological operations.

A retinal vessel segmentation algorithm from color fundus images using an ensemble classifier is developed by Zhu et al. in 2016 [22]. They have used a 36-dimensional feature vector for each pixel. These feature vectors are then given as input to the Classifier and Regression Tree (CART) classifier. Ultimately, an AdaBoost classifier is constructed by iterative training for vessel extraction. The authors have experimented with their algorithm on the Digital Retinal Images for Vessel Extraction (DRIVE) database, and average values of accuracy, sensitivity, and specificity of 0.9535, 0.8319, and 0.9607, respectively, are reported [22].

Orlando et al., in 2017, developed a segmentation algorithm for retinal blood vessels via a discriminatively trained fully connected conditional random field model. A structured output support vector machine is used to automatically learn the parameters. The authors carried out their experiments on images from DRIVE, Structured Analysis of Retina (STARE), Child

Heart and Health Study in England (CHASE_DB1), and High-Resolution Fundus (HRF) databases and claimed that the proposed method outperforms other existing methods based on sensitivity, F1-score, G-mean, and Matthews correlation coefficient [12].

A simple retinal vessel segmentation algorithm was developed by Dash et al. (2017) [23]. The extracted green channel from the retinal image is initially enhanced using the CLAHE algorithm in this algorithm. The enhanced image is then segmented using mean-c thresholding. Morphological cleaning is carried out on the segmented image to obtain the final segmented blood vessels. The authors carried out their experiments on DRIVE as well as CHASE_DB1 databases and claimed 0.9555 and 0.9540 accuracy, respectively.

Jiang et al. (2017) proposed a retinal vessel segmentation algorithm that mainly comprised of capillary detection and venules detection [9]. In this algorithm, the input retinal image is converted to gray scale by extracting its green channel. A morphological top-hat operation is performed on the extracted image to obtain characteristic features for the classification of vessels and non-vessels, followed by empirical intensity thresholding. This leads to venules detection. For capillary detection, centerline candidate pixels are highlighted using the first-order derivative of the Gaussian filter by rotating it at different angles with a variation of 180. In their work, instead of rotating the filter, the image itself is rotated in order to avoid the loss of image information. After applying the filter, a connectivity check is performed to remove low connective components. Finally, the extracted venules and capillaries are combined and denoised using morphological erosion. The authors obtained an accuracy of 95.88% for single database tests and 95.27% for cross-database tests on experiments carried out with images from DRIVE and STARE databases.

A coarse-to-fine algorithm for vessel segmentation was developed by Câmara Neto et al. (2017) [10]. In this method, a vessel segmentation algorithm is proposed in which coarse vessels are detected using intensity thresholding, and vessel refinement is carried out using the principal curvature method. In the coarse vessel segmentation stage, the preprocessed retinal image is divided into two categories- tissue intensities and vessel intensities using an intensity threshold which is obtained by maximizing the distance between the extreme intensity values of an image and its cumulative distribution function (CDF). Further, an adaptive threshold is used for the final segmentation of vessels which are refined using curvature analysis and vessel reconstruction. Balanced accuracies of 0.7819 and 0.8702 are reported by the authors for images from DRIVE and STARE databases.

In 2018, Oliveira et al. proposed a retinal vessel segmentation algorithm by combining multi-scale analysis provided by stationary wavelets and multi-scale fully convolutional neural network [24]. This method used rotation operation for data augmentation as well as prediction. The authors carried out their experiments on DRIVE, STARE, and CHASE_DB1 databases and reported accuracies of 0.9576, 0.9694, and 0.9653, respectively.

Dash and Bhoi (2018) [25] reported a study on thresholding, founded on the variational minimax optimization

algorithm, to segment retinal blood vessels. In this algorithm, gamma correction is applied on the extracted green channel of the fundus image, which is then enhanced using the CLAHE algorithm. On this enhanced image, thresholding is carried out and followed by morphological cleaning to obtain the final segmented blood vessels. The authors claimed that the experiments carried out on DRIVE and CHASE_DB1 databases give an average accuracy of 0.957 and 0.952, respectively.

In 2018, Wang et al. proposed a vessel segmentation algorithm that used Hessian-based linear feature filtering at preprocessing stage followed by fuzzy entropic thresholding. The authors reported an F1 score of 66.15% for their proposed method [26].

A vessel segmentation algorithm that used Gray-level Hit or Miss Transform (GHMT) with multi-scale, iteratively rotated multi-structuring elements to extract blood vessels from retinal images was proposed by Pal et al. in (2019) [11]. The vessels extracted using GHMT are further post-processed using hysteresis thresholding. The authors claimed that their method gives an average accuracy of 94.31% for images from the DRIVE database.

Preity and Jayanthi introduced Multi-threshold along with morphological operations for vessel segmentation [27]. Preprocessing was carried out using AHE, CLAHE, and average filter, followed by segmentation using a variant of the Otsu method followed by post-processing using morphological operations. Average accuracy of 95.3% was obtained using the DRIVE database.

An adaptive segmentation algorithm was used to extract retinal blood vessels by Kabir (2020) [28]. Anisotropic diffusion was applied on grayscale fundus images, followed by top-hat transformation to enhance the image. Local-property-based intensity transformation was introduced on sub-images, and finally, vessels were segmented using k-means clustering from all sub-images. 95.29% and 95.47% accuracies were obtained on DRIVE and STARE databases, respectively.

Jadoon et al. (2020) proposed a vessel extraction algorithm in which the CLAHE algorithm is applied on the green channel of fundus images, followed by the top-hat operation [29]. Prominent vessels are obtained using Frangi as well as high boost filters. The entire vessels were obtained using Isodata thresholding. 95.32% and 94.98% accuracies on DRIVE and STARE databases are reported.

Alhussein et al. (2020) used hessian along with intensity transformation information for blood vessel segmentation from fundus images. On CLAHE enhanced image, Wiener and morphological filter were applied to denoise it [30]. Thick and thin vessel enhanced images were obtained separately by using Eigenvalues of the hessian matrix at two different scales. Otsu and Isodata thresholding were applied to extract thick and thin vessels from the respective enhanced images. Accuracies of 95.59% and 95.01% on DRIVE and CHASE_DB1 databases were respectively reported.

In [31], a multi-scale convolutional neural network for retinal vessel segmentation was proposed. The network consisted of two consecutive convolution structures. After each convolution layer, ReLU was used as the activation function.

Once features are extracted from convolutional layers, feature maps were added and connected with a fully connected layer. The proposed network consisted of three fully connected layers. Softmax function was used for classification and the loss function used was cross-entropy. The network was implemented using Anaconda and TensorFlow. The training process took about 18h to complete. The proposed methods were evaluated on DRIVE and STARE databases with sensitivity, specificity, accuracy, and AUC values of 0.843, 0.980, 0.951, 0.979 on DRIVE and 0.823, 0.978, 0.956, and 0.974 on STARE databases, respectively.

In [32], a novel multi-label classification scheme for retinal vessel segmentation by a local de-regression model (LODESS) designed for multi-labeling was proposed. CNN classifier was designed for multi-label classification and learning of multi-label neighborhood relations. The proposed CNN model consisted of an encoder with max-pooling layers and a decoder with upsampling and convolutional layers. A focal loss function was used to solve the imbalanced classification problem. The algorithm was built on the Keras library with NVIDIA Titan X Pascal GPU. The network was trained for 20 epochs, and a standard stochastic gradient descent optimizer was used for training. Experiments were conducted on DRIVE and STARE databases. Accuracy, sensitivity, specificity and F1 scores of 0.952, 0.776, 0.979 and 0.813 on DRIVE and 0.970, 0.812, 0.990 and 0.855 on STARE databases were reported.

In [33], retinal vessel segmentation using a cross-connected convolutional neural network (CcNet) was proposed. Features from different layers were fused using a cross-connected structure. There were primary and secondary paths in the network, with each convolutional layer in the primary path connected with all layers in the secondary path. Each cross-connection from the primary to the secondary path was processed by a convolution, ReLU, and max-pooling module (CRM) in order to reduce the network parameters. The outputs of the primary path concatenated with each output of the secondary path. ReLU is the activation function used for the last layer. Green channel images were given as input to the network, and a pre-training step was used to accelerate the convergence of the network. The parameters of these pre-trained modes were employed as the initial values of the final trained model. CcNet was trained using the ADAM optimization method. GeForce GTX 1070 was used to accelerate the computation using the Caffe toolkit. Based on the experiments carried out on DRIVE and STARE databases, sensitivities of 0.7625 and 0.7709, specificities of 0.9809 and 0.9848, accuracies of 0.953 and 0.963, and AUC values of 0.968 and 0.970 were obtained, respectively.

Retinal vessel segmentation by making use of deep supervision with historically nested edge detector (HED) and smoothness regularization from CRFs was proposed in [34]. The network, known as Deeply Supervised and Smoothly Regularized Network (DSSRN), was an end-to-end network for a pixel to pixel segmentation that combined FCN and CRF strengths. Five staged HED network was used, and the segmented results from each layer and the last fuse layer were connected to mean-field CRF. The learning rate was initially set to 10^{-8} , momentum and weight decay parameters were set to 0.9 and 0.0002, respectively. The model was implemented on

NVIDIA GTX Titan X GPU using the Caffe framework. Training model on a single GPU took 12h for completion, whereas testing of one retinal image required only 0.3s. Accuracy and sensitivity values of 0.954, 0.763 on DRIVE, 0.960, 0.742 on STARE and 0.959, 0.782 on CHASE_DB1 databases were obtained respectively.

Based on the review, it is clear that even though various algorithms exist, the majority are computationally expensive. Moreover, the results obtained can be further enhanced. So, there is a requirement for a better method with maximum true positive values and minimal false negative values. This motivated the development of a new unsupervised framework for retinal vessel segmentation. The following section describes the proposal.

III. PROPOSED METHODOLOGY

A novel blood vessel segmentation framework that combines a coarse-to-fine vessel extraction algorithm with hysteresis thresholding is proposed in this section.

Retinal vessel extraction, in general, is carried out in multiple steps. For thresholding-based methods, the last steps include thresholding for classification of pixels and post-processing for fine-tuning/denoising. We have carried out an extensive experimental study of chosen retinal vessel segmentation algorithms [10], [11], [21], [23]. Based on the study, the proposed model is built.

The separation of vessel intensities from the tissue intensities as proposed in [10] is found to give a relatively good result. Also, the thresholding technique used by Pal et al. in their work [11] is simple, efficient, and convincing. The use of hysteresis thresholding ensures that final vessel segmentation is not based on a single threshold. Based on these observations, a novel retinal blood vessel segmentation framework is proposed by obtaining vessel intensities as described in [10], followed by the application of hysteresis thresholding [11].

The working of the proposed algorithm is as follows. Let, I denote the green channel of the input retinal image. In order to make the vessels in I brighter than their background non-vessels, I is inverted.

$$I_c = (L - 1) - I \quad (1)$$

where L is the number of possible intensity values.

I_c is then smoothed using a Gaussian filter to remove noise and further enhanced using morphological top-hat operation.

$$I_E = I_g - (I_g \circ S_e) \quad (2)$$

where I_g denotes the Gaussian smoothed image, the symbol \circ denotes morphological opening operation, and S_e , its structuring element, respectively.

The enhanced image, I_E , further undergoes contrast enhancement such that the top and bottom 1% of all the pixel values in I_E are saturated [10]. From this contrast-enhanced image, I_{CE} , vessels are extracted using a threshold defined based on the cumulative distribution function (CDF) of pixel intensities in I_{CE} . The idea behind the selection of CDF for threshold computation is that vessels constitute approximately

12% of total intensities in an image and the CDF becomes smoother when vessel pixels are reached [10].

$$I_{CDF}(x) = \sum_{n=0}^x P_n \quad (3)$$

where $x \in [0, (L-1)]$ and

$$P_n = \frac{\text{no. of pixels with intensity } n \text{ in } I_{CE}}{\text{total number of pixels in } I_{CE}} \quad (4)$$

where $n = 0, 1, 2, \dots, (L - 1)$.

From the CDF, the threshold is computed as follows.

$$\tau = \operatorname{argmax}_x \left\{ \frac{|I_{CDF}(x) + \Delta I_{CDF} * (1-x) - 1|}{\sqrt{1 + \Delta I_{CDF}^2}} \right\} \quad (5)$$

where

$$\Delta I_{CDF} = I_{CDF}(L - 1) - I_{CDF}(0) \quad (6)$$

The vessel intensity image is then extracted based on the threshold, τ , as follows:

$$I_{CE} \in V \text{ if } (I_{CE} > \tau) \quad (7)$$

From this vessel intensity image, vessels are segmented using hysteresis thresholding. Unlike most of the thresholding schemes, which uses a single global threshold or local threshold, hysteresis thresholding uses two threshold values, say T_1 and T_2 . All the pixels in V whose intensity values are greater than or equal to T_1 have been considered as vessel pixels, and all the pixels whose intensity values are less than T_2 , considered as non-vessel pixels. Also, for each pixel whose intensity values lies in between T_1 and T_2 , it is considered as a vessel pixel if at least one of the pixel in its 8-neighborhood has an intensity value greater than or equal to T_1 [11]. The working of hysteresis thresholding for vessel segmentation is mathematically expressed as follows.

$$S_v(x, y) \begin{cases} 1, V(x, y) \geq T_1 \\ 0, V(x, y) \leq T_2 \\ 1, (T_2 < v(x, y) < T_1) \text{ and} \\ \quad \exists i |\phi_i(x, y) \geq T_1 \end{cases} \quad (8)$$

where $\phi(x, y)$ denotes the 8-neighborhood of pixel with coordinate positions (x, y) . Fig. 1 depicts the working principle of the proposed methodology. The algorithm for the proposed framework is as follows.

Proposed Algorithm

- Read input fundus image.
 - Extract the green channel and invert it.
 - Smooth the inverted image using a Gaussian filter.
 - Enhance the smoothed image using morphological top-hat operation.
 - Apply contrast enhancement.
 - Detect retinal blood vessels from the contrast-enhanced image
 - Threshold-based on CDF of pixel intensities are used.
 - Final retinal vessels are extracted by applying Hysteresis thresholding.

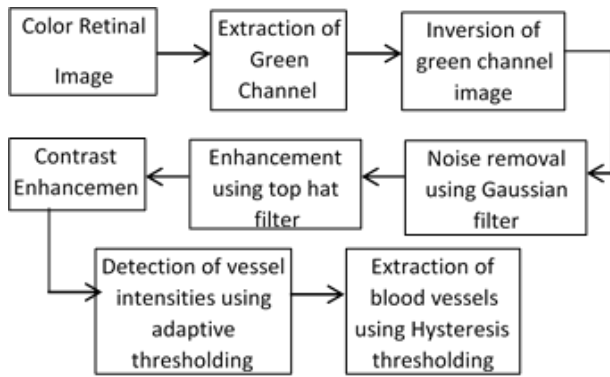

Fig. 1. Working Principle of the Proposed Methodology.

IV. EXPERIMENTAL SETUP

In this section, details of the data sets used, values of various parameters, and matrices for performance evaluation are described.

A. Data Sets

1) *Digital Retinal Image for Vessel Extraction (DRIVE)*: DRIVE is a well-known publicly available fundus image database used for comparative studies on retinal blood vessel segmentation algorithms [35]. The images in the database are obtained from a Diabetic Retinopathy (DR) screening program in the Netherlands with a population that comprised 400 subjects within the age group 25-90 years. From the photographs of these subjects, 40 images are randomly selected, among which 7 showed signs of mild early diabetic retinopathy, and the remaining had no signs of DR. Canon CR5 3CCD camera with a 45° field of view (FOV) is used for capturing the images. Each image in the database has a size of 584x568. The database is divided into two sets – training and testing set. Both the sets contain 20 images each, along with a corresponding mask that describes the FOV. Vasculature's single manual segmentation is available for the training set, whereas the testing set contains two manual segmentations – one is used as gold standard/ ground truth and the other for comparison of an algorithm's performance with that of a human observer.

2) *Structured Analysis of Retina (STARE)*: The STARE database is based on the STARE project initiated by Michael Goldbaum, M.D. in 1975, at the University of California, San Diego, funded by the U.S. National Institutes of Health [36]. The project is contributed by more than 30 people from the field of medicine, science, and engineering. The dataset consists of 400 raw images of size 700x605. The images are captured using the TopCon TRV-50 fundus camera at 35° FOV. For each image in the database, a list of diagnoses and diagnosis codes are also provided. Expert annotations of features visible in the database are also presented in a tabular format. For the blood vessel segmentation task, 20 images with manually segmented vasculature from two experts are provided. The database also contains artery/vein labeling of 10 images by two experts and 80 images with ground truth for optic nerve head detection.

B. Values for Various Parameters

The first parameter to be fixed is the sigma value for the Gaussian filter, used to remove noise from the inverted green channel image. The sigma value is fixed to 0.45, and a filter of size 3x3 is used as suggested in [10]. As far as the enhancement process is considered, the structuring element selected for the top hat filter is a disk with a radius of 6 [10]. For hysteresis thresholding, different combinations of threshold values are tried, and an optimum threshold value is fixed as $T_1 = 0.7$ and $T_2 = 0.2$ respectively. If the value of T_1 is reduced, it may lead to an increase in false-positive values. On the other hand, if the value of T_2 is increased, it may lead to decrease in true positive values.

C. Performance Evaluation Measures

“Sensitivity,” “specificity,” and “accuracy” are three performance evaluation measures considered for the study. These are powerful measures generally used to evaluate segmentation results. Based on the manually segmented vessels and the one obtained by applying a segmentation scheme, the numbers of pixels classified as true positive (TP), true negative (TN), false positive (FP), and false-negative (FN) are computed. From these values, the following formulas are derived [37].

$$Sensi = \frac{TPOS}{TPOS + FNEG} \quad (9)$$

$$Speci = \frac{TNEG}{TNEG + FPOS} \quad (10)$$

$$Accur = \frac{TPOS + TNEG}{TPOS + TNEG + FPOS + FNEG} \quad (11)$$

V. RESULTS AND DISCUSSION

Twenty images each from the DRIVE and STARE databases are selected for the experiments. The output of blood vessel segmentation is analyzed quantitatively using the performance evaluation measures – sensitivity, specificity, and accuracy.

In order to assess the merit of the proposed work, it is compared with the following algorithms: (i) Coye (2015): enhancement using CLAHE algorithm followed by segmentation using IsoData thresholding technique [21]; (ii) Jiang et al. (2017). : segmentation is carried out in two steps – venules detection and capillary detection [9]; (iii) segmentation technique which uses conditional random field model for discriminative feature extraction developed by Orlando et al. [12]; (iv) segmentation using mean-c thresholding [24] and (v) segmentation via variational minimax optimization thresholding [25].

Among the algorithms considered for implementation, each has its enhancement technique which precedes segmentation. These algorithms are applied on the green channel of color (RGB) retinal image and use the CLAHE algorithm for enhancement. The above algorithms are unsupervised methods except the one proposed by Orlando et al. [12], which is a supervised method.

Table 1 gives the list of methods used for the experimentations. The average, best and worst performance of the segmentation algorithms given in Table 1, based on

sensitivity, specificity, and accuracy on images from the DRIVE database, is given in Table 2.

From Table 2, it is clear that based on both sensitivity and accuracy, the proposed method outperforms the other methods for images from the DRIVE database. Based on specificity, though the proposed framework performs well, the supervised method based on the conditional random field [12] gives the highest value. Table 2 reveals that when the best performance of each algorithm is considered, the proposed method dominates the existing methods based on accuracy. For specificity, it performs closer to the method giving the best result. Also, it is evident that the worst performance of the proposed algorithm is more comparable to its average performance in terms of performance evaluation measures. The worst performance evaluation highlights the fact that for images where other methods fail to give a satisfactory result, the proposed method gives better results, which is a significant achievement.

In Table 3, the average, best and worst performances of the segmentation algorithms for images from the STARE database are given.

Methods that perform satisfactorily with the DRIVE dataset are found to give a poor performance with the STARE dataset. This is basically due to the difference in the quality of images.

From Table 3, it is clear that Method 1, which is a supervised method, shows good performance in identifying blood vessels with accuracy (high sensitivity and accuracy). The proposed method is better in terms of specificity, and overall performance is very close to Method 1. The performance of the other four methods is relatively poor.

Analysis of best and worst performance highlights the fact that variation of the performance of the proposed method with respect to images is low, which is a preferred quality.

From Table 3, it is clear that Method 1, which is a supervised method, shows good performance in identifying blood vessels with accuracy (high sensitivity and accuracy). The proposed method is better in terms of specificity, and overall performance is very close to Method 1. The performance of the other four methods is relatively poor. Analysis of best and worst performance highlights the fact that variation of the performance of the proposed method with respect to images is low, which is a preferred quality.

Table 4 gives a comparison of the proposed method with other state-of-the-art retinal vessel segmentation algorithms in terms of sensitivity, specificity, and accuracy on images from the DRIVE database. From Table 4, it is evident that the proposed method produces better results compared to other state-of-the-art methods.

Fig. 2 and Fig. 3 show the segmented vessels obtained using each algorithm for sample images from DRIVE and STARE databases, respectively.

The proposed framework fuses the merits of different works and is tested based on images from standard test databases. A possible challenge that may affect the algorithm is the quality of real-time input fundus images. We can correlate image statistics with input parameters by mapping image statistics with the parameters in such cases. It requires extensive experimentation and theoretical modeling and is not considered in the present study.

VI. CONCLUSION

In this paper, a novel retinal vessel segmentation algorithm by performing vessel detection using an adaptive thresholding technique followed by hysteresis thresholding for final vessel segmentation is proposed. Vessel detection is carried out with an adaptive threshold that depends on the cumulative distribution function of image intensity values. This method is capable of detecting almost all vessel intensities within a retinal image. The detected vessel intensities are then extracted using hysteresis thresholding. The combination of the detection and extraction stage using the two approaches led to the development of an innovative idea for the extraction of retinal blood vessels.

Experiments carried out with the DRIVE and the state databases establish the merit of the proposed algorithm. The algorithm extends help to the ophthalmologist in an easy diagnosis of retinal diseases as the extracted vessels can identify changes in normal vessel structures and indicate the presence of abnormalities, if any. This opens scope for further research for a better segmentation algorithm. The present study can be further extended by incorporating the influence of image quality on the algorithm and making it suitable for all types of images.

Abstract—The development of high-tech progression around the world, with the attentions of governance body and private companies towards well-organized setup access control measures within the organization. The importance of these exceedingly essential perception, this article is proposing an integrated approach with the assimilation of IAM (identity access management) as an authentication tool and PAM (privileged access management) as a restricting accessing control measure in terms of an active directory. Originally the experimental setup organized within the Prince Sattam Bin Abdulaziz University, and it is analyzed using the real-time data which is available within the university database. We found that the proposed mechanism can be a vital method for protecting governance data or key business-oriented data from the unauthorized or adversarial attack. We also reviewed and compared other access control methods and find that the integrated method is relatively have an advantage to deal accessing task in any premier organization.

Keywords—Identity management; governance framework; privileged access management; security; privacy

I. INTRODUCTION

These days, propagation of the communication within the organization or outside world is very common. It is also very necessity to engage proper protocol to address effective and innovative things to manage secure access control over the system. The covid-19 disease outbreak has led to an inevitable rise with the use of digital technology nationwide subject to socioeconomic distancing requirements including territorial lockdowns, individuals and organizations now have to adjust a changing method of working as well as residing[1]–[5]. A rise in digitalization is leading industries as well as educational institutions to switch to work online. Governance and the management of identity will become relevant. They will require design and regulatory analysis. Online workers will likely increase in size, rising job distribution issues, teamwork, motivation, work overload, and present aspects. With rapid intensification in digital occurrence, tracking among the workplace and technostress problem will turn out to be prevalent[6]–[8]. Information technology (IT) improves companies' ability to compete in the 21st century's intensely competitive global marketplace has become increasingly evident. However, the actual practice of information technology count on profoundly on efficient and adequate IT governance. The flow of communication within the

organization and outside is inviting many security and privacy challenges among the user. The restriction of the adversarial attack is highly required and build such type of mechanism which can deal to provide a framework and use proper access among the authorized user[9]–[11]. To ensuring such type of mechanism our intension to encourage to develop an essential tool or any type of integration approach, concerning these technological enhancements, this article is going to optimized with the integration of the identity access management framework (IAM) and privileged access management (PAM) as an active directory which is demonstrated on the Fig 1. The architecture of the system incorporates as a managerial way such as life cycle manager, compliance manager, password manager and the layout of the system demonstrated such as identity intelligence, dashboards, reporting console, analysis console. This system is performed governance console including policy model, identity warehouse, role model, workflow engine, risk model, IT security, 3rd party provisioning, IT services management and mobile device management with the fronted communication in terms of external world.

Integrating as an active directory is necessary for almost all applications and contexts to organizations which can adapt within and across applications, systems, and boundaries. For instance, active directory can apply. One of the principal problems to be tackled is uncertainty. If an integrated framework is restricted or expensive, the development of trustworthy environments through adequate security and privacy policies and practices, a user-friendly interface, and commitment to user education and knowledge is another significant challenge for its successful implementation. Due to the organization's rapid growth and the application that they are using, the user will have to memorize all his credentials for each application[12]. Moreover, a crucial component of such an operation is digital identity management with privileged access management. Today public and private sector organizations vary dramatically in their approach to active directory designing their means of generating, checking, sorting, and using digital identities through their network and the internet. In our increasingly interconnected economies, the lack of shared policies and methods creates privacy, protection, and efficiency problems and hampers an organization's ability to deliver convenient service to customers. Besides, improving user conveniences is one of the

*Corresponding Author

significant advantages of active directory. Effective integration may reduce the inconveniences and inefficiencies caused by the need to keep track of various identities, passwords, and authentication requirements when used through organizations. Similarly, more functional user interfaces will boost accessibility and increase online services for registration and log-in processes. Finally, protection and privacy enhancement by minimizing the flow of data during transactions, only requesting, transferring, and storing what is needed, security and privacy are improved, and effective integrated approach can minimize the transactional details needed by multiple device users and reduce the security and privacy risks.

The significant contribution of the proposed study is provided a hybrid approach between the identity and access management and privileged access management to protect highly confidential access data within the organization or outside world. The incorporating this mechanism is validated that using these types of hybrid mechanism can be a better option to handle things and restrict some adversarial attacks

into the entire system. The adjustment between IAM and PAM, by describing a general project management methodology for IAM environments, we attempt at shutting down this research gap. It not only provides a generic high ranking research method, but also incorporates specific methods for the handling of attributes of quality. This fulfills the demand for the measurement of ABAC's quality evaluation and at the same time provides an interconnected process-oriented approach which is applicable to large-scale IAM scenarios.

The organization of the articles is as follows: Section 2 highlights literature background of the hybrid approach as a well-defined context about access control, Section 3 proposed an integrated methodology which provides a highly trusted architecture to deal with control access about the user within the organizations, Section 4 discussing optimization of proposed mechanism with advantages as well as disadvantages and finally Section 5 concludes with future work.

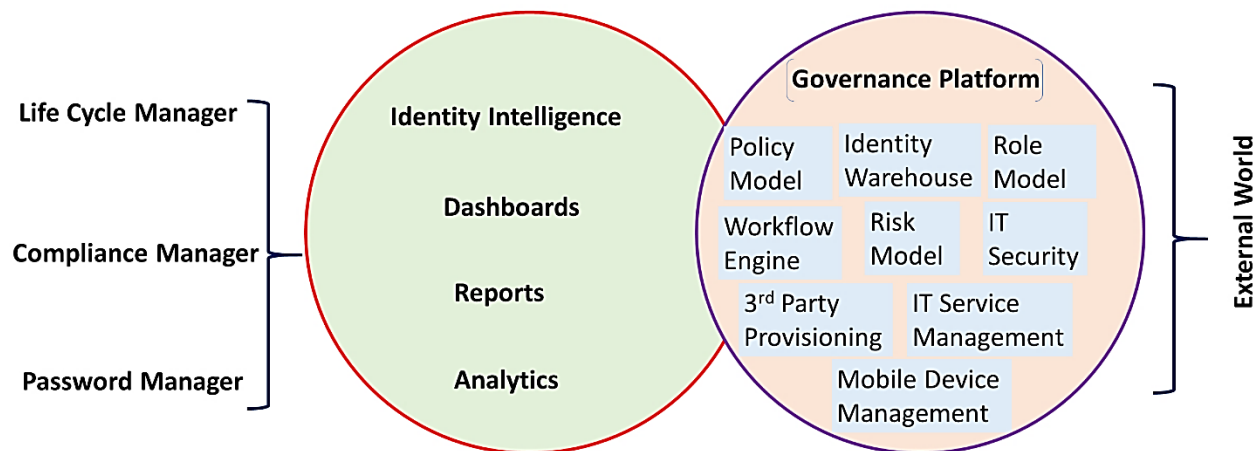

Fig. 1. Integrated Conceptual Design.

II. PRELIMINARIES

The intention of the governance and organizational setup is to improve control access methodologies within the institution from the external world. This requires due to day-by-day new threads coming to unauthorized access within the organization and stealing valuable secret data to destroy business as well as economic consequences around the world. Concerning these thread and new epidemical policies during covid-19, its hand to mouth to control adversarial data theft about the organization. So, it is required to provide an architecture to address these shortcomings, the adaptation of the identity and access management with integration of privileged access management is quite favorable option to adjust governance as well as business companies to fight back and control these valuable data and any miss happening things within the organization or institution. Identity management (IdM) is in a position to perform such functions as management, maintenance, discovery, management, enforcement of policies, exchange of information and substantiation. Identity and access management (IAM) formalizes the use and management of the same identity for all application areas and

guarantees simultaneous security[13]. The software is being utilised to validate devices, users or services as well as deny or allow access to data or other infrastructure components. In the event that the application is accessed, the system or service does not have to authenticate all its identity shops or authentication mechanism. Rather, the identity checking process can be customized such reliable identity provider, which actually decreases the volume of work among application. Management of identity and access simplifies management of transmitted distributed projects. IAM are utilised in whole business (B to B) or even amongst a private innovativeness with cloud provider within a company or outside the enterprise[14]. IAM has a broader organizational area to identify entities, cloud objects and manage admittance to resources oriented predetermined policies [15], [16]. Identity and access management are a number of functioning zones. Identity managing and provision, federated identity management, validation administration, compliance management and authorization management [17] are all functioning zones. These functioning zones ensure the secure and effective integration of authorized users at clouds. The service provisioning markup language (SPML) is an XML-

related framework which is used to manage identity. It enables communication on resources, users and services amongst officialdoms. One of SPML's failings, this employs multiple symmetric cryptography from innumerable providers which lead to a range of marginal applications (APIs). Since APIs not the identical provider, interacting with each other is difficult. Authentication management is the second industries application of IAM. This ensures secure management of credentials including passwords as well as digital documentations [18].

Federated identity management is the third operational field of IAM. The said identity management validates cloud facilities using the selected ID provider of the organization. Management of federated identities guarantees privacy, integrity as well as non-repudiation. It therefore ensures the confidence here between mobile application as well as the identity provider by transferring certified public keys from public key infrastructure (PKI). The fourth main activity is the management of authorizations. After authentication process, authorization management decides whether such an authenticated entity is permitted to perform an application. Compliance management is the last functioning zone of IAM. This ensures that the resources of an association are secured and accessible under the current policies and regulations [19]. In the field of cloud security, Identity management plays an important role. Privacy as well as compatibility are the major problems with current solutions to identity management, particularly in public cloud environments [10], [11], [18]. Currently, IAM systems are effective mechanisms for reducing cloud-based risks. Many institutions provide an IAM system to ensure information through the influence of each user's access authorization [20]–[22]. SailPoint, IBM, Oracle, RSA as well as Core security are the most popular IAM system providers. SailPoint's identity management approach is capable of handling passwords, compliance control, data access management, requests for access, automated delivery, as well as Single Sign-On [9]. Purpose of effective in web access requesting, providers to ensure, single sign-on company, multi-factor authentications, access control, privileged identity, and compliance of user-activity are available through the IBM identity and access management Suite. Oracle identity & access management offer four keys cloud security mechanisms. [23] explained an identity management system, and its functions, including security roles to prevent various scams and instances of identity theft. A distinction is presented between the conventional and new scope of identity management. As a prerequisite for the current IT period, an identity management framework is given. [24] reported that most emphasis on identity security has centered on securing customer information in the area of virtualization. However, as they use cloud services, users usually leave a trail, as well as the subsequent verification of accounts can potentially contribute to the leakage of confidential personal information. In the meantime, cyber criminals can do damage to cloud service providers by the use of fake identities. The author is introducing a credibility framework and developing a prestige identity management model for information computing to address these issues. Throughout the model, anonymous sources are created based on a credibility identity to ensure that aliases are untraceable,

as well as a framework is suggested to measure user credibility, that enables cloud providers recognize malicious users. Investigation verifies that perhaps the template will guarantee that data centers are accessed anonymously by consumers and also that cloud providers efficiently determine the reputation of users thereby infringing consumer privacy. [25] addressed and offers the efficient assessment model of IT administration that could be used in specific, by organizational management throughout the HEI. In addition, this research identifies the variables that lead to successful IT accomplish a specific objective upon that domain's published studies. The suggested model needs to be evaluated in future projects by someone else by empirical research.

Privileged access management offers an automatic credential managing as well as sessions managing solution for secure accessing control, audit, notification with logging for all privileged accounts. The methods are intended to control localized or domains shared admin privileges; a client's account and admin account, a customer's service, network device, operating system, application (A2DB) accounts and database. IT businesses can reduce privileged risks and meet assessment of progress by increasing the authority and ownership over authorized credentials. The benefit of approach, although, requires on all such situations of usage and even on the presence of resources on site, virtualized or cloud environments. Ecosystems also require to take account of advance reliability, breaking glass, disaster recoveries, as well as stint to recover when the application itself faults or underlying equipment part from connections to web access which could trigger a breakdown happens. Privileged information security used as a SaaS platform (software as a service) can only run in the clouds or allow special supervision nodes to drive as well as combine policies as well as events. These systems are fully maintained by PAM manufacturer as well as share data centers at multi-tenant installation with other PAM customers. Although nearby few PAM implementations at cloud utilizing SaaS at the moment, the trend implies that companies acquire assurance in the storage of PAM cloud credentials, administration tools and policies. This approach is determined by personal suppliers and system integrators, who offer economic services related on financial PAM capabilities as well as with no required skills by consumers.[26] explained in his article, amongst the most complex issues for device integration of 4G generation communication. Which is very complex in terms of safe multimedia delivery in current and future networks. This incorporation implies that in order to deliver their facilities to users, multiple service and network providers would have to collaborate. Such multi-domain setting poses a major threat to the consumer that has an agreement with the consumer and even just a restricted numeral of carriers and service providers confidence. [27] suggested about the model of digital identities. Confidence management should create and check the confidence to provide lead to increased results for online transactions such as reactants between the purchase and sale of products and services, improved retention and loyalty, expanded credibility, etc. Author discusses the need and value of confidence managing in the digital world, along with the different models and strategies required to mitigate confidence. For the existing options, a qualitative analysis was

presented. In view of the large-scale emergence of the digital world and electronic firms, the research seems to have a lot of significance. [28] Characterizes a case of developing a stable identity management system as well as its organizational structure in accordance with the VAHTI protection guidelines of the Finnish government. The construction project was about to be conducted in compliance with the directives for government protection, while adopting the management structure of the supplier itself. [29] referred the goal of his article is to examine how or when integrated knowledge management of a seaport terminal operation can be efficiently shared between the most advantageous and cost-effective great skills, to potentially boost their access control, a road haulier as well as a rail operator. The automated exchanging of characteristics depends on the standardization of the participating actors among information technology. In this analysis, compatibility is accomplished through an existing simple object access protocol. His research paper adds to previous studies by creating a cost comparison that identifies the characteristics affecting four principles (from low advantage/low cost to high advantage/high cost) data cultivation, committed sharing of data, opportunistic exchange of information, as well as preventing sharing of information.

III. MATERIAL AND PROPOSED METHOD

The idea behind to integration or hybrid approach of the IAM and PAM are to facilitate secure ecosystem about the end user within the organization or outside the organization. Nowadays, there are so many malicious, adversarial threads available in the world to make highly risk and easily destroy organization with stealing credential, informative data. The key objective of this project is to clarify that identity management and governance are central to good cybersecurity, and role-based access control is among the essential characteristics of identity and access management (RBAC). Role-based access control enables device users to delegate positions[30]. Moreover, permissions are required to execute specific functions across these roles. This implies that users are not explicitly granted authorizations but rather obtain them through their allocated profession function or responsibilities, meaning whether someone enters the business, switches offices, goes on leave, or leaves the company, their access rights are easy to handle and stay in charge. Instead of addressing user access rights at a granulated level, operator access rights are combined into several positions across different systems[31]. This means that you mechanically have one set (combination) of defined access rights if your effort in the Finance team, which is different from if you work in the marketing team. Organizations minimize both the difficulty of granting user access rights and the related costs by role-based access management. It offers the ability to evaluate access rights in order to ensure compliance with different legislation, as well as to refine processes such that new workers can be up as well as successively work from the beginning, as it is already defined that the new member of staff would access systems, all based on his or her position in the company. The market advantages are various. This also increases productivity, in addition to the apparent improvement in security across the company, resulting in smoother onboarding and off-boarding processes

and enforcement, as an organization has a higher degree of control and understanding of who has access to what and why, as well as decreasing directorial work, IT care and creating price savings.

A. Integration Methods

In numerous systems of government, digital identity management initiatives and processes have been developed in order to deal with identity-related risks, compliance, and operational gaps. In order to stay one step ahead of the competition, companies must regularly evaluate their identity solutions' abilities. An increase in the number of password-related breaches has made the issue of IAM access rights even more critical. To safeguard data from internal and external threats, the several organizations still have yet to implement mature capabilities that enable them to effectively manage privileged access, even though the frequency of the compromise of privileged accounts has increased. Compounding the risk of compromise has been added to the equation. This type of organization has invested in a product, but it hasn't implemented the processes as well as governance to make it work. Other organizations may have well-established processes, but they are missing the necessary supporting technologies that would be required for addressing privileged access threats at an enterprise scale. Identity governance and PAM solutions have been implemented by some organizations, but few have combined the two. For many companies, this could lead to the inconsistent application of processes and policies across silos of tools, which would result in incorrect reporting and failed audits.

In order to better manage both privileged as well as nonprivileged user access requests, authorizations, accreditations, provisioning, and restoration, organizations should implement Identity Governance and PAM. The importance of the proposed approach as shown in the Fig. 2 using cloud identity platform's component is that it makes it possible to integrate with and govern a wide variety of enterprise applications as well as directories, whether they are in the cloud, on-premise, or a combination of both. Creating a service account is typically required, which must be set up for each application to gain access to identity information.

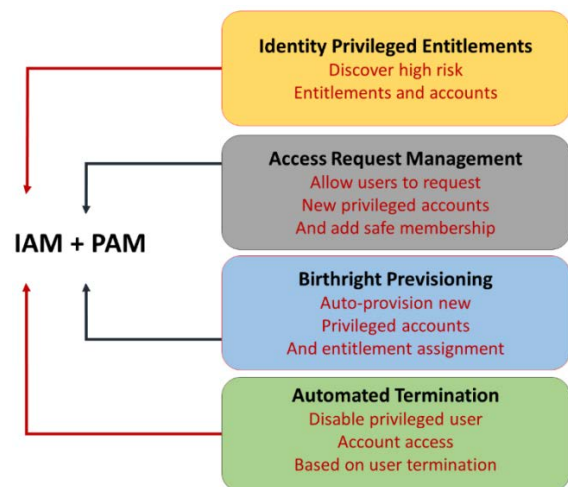

Fig. 2. Integrated Approach.

B. Session Flow within the Optimised System

The proposed incorporation of the hybrid approach is significantly organized as shown in the Fig. 3. Where it is described the conceptual session flow within the organization. The implemented mechanism is targeting to achieve better connection-oriented way within the organization to tackle users accessing policies and its managing session to accomplishing the task. In the session flow operation, some sort of the protocol handler is incorporated to setup its goal and provide accessing things according to user’s authorization skills. In which the used protocol handlers are listed as follows:

1) *Secure connection:* Communication lines prior among each node are optimised securely. This can be validated in the Fig. 3 where it is demonstrated very well how the transformation happen within the entire system. Our optimised system has taken care secure communication and tracing each activity with the monitoring capacity easily.

2) *Launch application locally:* Initially the optimised setup launched with locally installed server to administering each activity. The incorporated adjustment was quite well to reach desired outcomes.

3) *Session recording:* The additional process is inbuilt in the optimised setup which is known as session recording concept. This feature is enabling to monitoring task within the university setup and this can provide real proof about the adversarial attacks or miss use within the organization very well. Utilising this mechanism gives freedom to know who want to access our setup then it can be possible to take immediate action against the happened activities.

4) *Terminating session:* The administration of the entire setup can easily terminate suspected activity within the university accessing lines. The incorporation the whole process it can be easily seen that each process is providing distinguished outcomes to handle security a privacy within the system to integrate IAM and PAM.

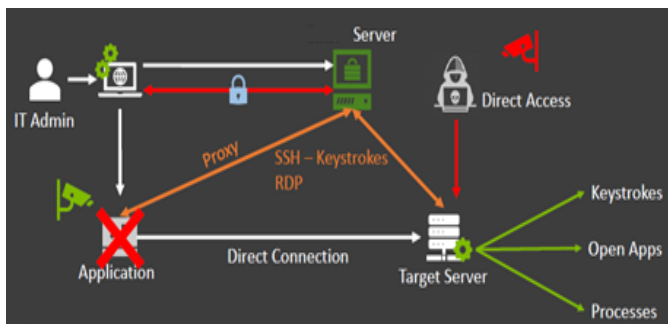

Fig. 3. Session Flow Diagram within the Applied Mechanism.

C. Implementation with Hardware and Software

The implementation of the integrated approach is needed appropriate hardware and supporting software utilities to successfully run proposed thought. The proposed integrated method is needed highly equipped hardware resources which are illustrated in Table 1 very well. The required supporting software is also defined very well in the Table 2. The

collectively incorporation among the hardware and software utilities produced an integrated mechanism which can be easily used among the organizations as well as any universities for the security and safety from the external world or adversarial attacks.

TABLE I. HARDWARE SPECIFICATION FOR THE IMPLEMENT

VM Name	CPUs >=2 GHz	RAM (GB) >=4 GB	Storage Space (GB) >=100 GB	OS Advance Version	Comments
Server Node 1	8	16	500	Windows Server 12 or Higher	
Server Node 2	8	16	500	Windows Server 12 or Higher	
Database Cluster	8	16	1000		It entails if customer does not have present DB
Site Connector	2	4	100	Windows Server 12 or Higher	

TABLE II. COMMUNICATING PORT FOR THE IMPLEMENTATION USING SOFTWARE

Application/Process	Traffic Types	Port	Sources	Destination
Discovery	Microsoft DS SSH RPC Port Range Epmap	445 22 49152- 65535 135	Secret Server IP	Work Stations
Web Server	HTTP HTTPs	80 443	IT Admin IP	Secret Server
Active Directory Syn	NTLM LDAP LDAPS Kerberos	445 389 636 88	Secret Server IP	Active Directory
Remote Changer password	Oracle Telnet NTLM LDAPS MS SQL SSH LDAP Sybase Kerberos	1521 23 445 636 1436 22 389 5000 88	Secret Server IP	Work Stations
Database	TCP/UDP SQL Connections	1433	Secret Server IP	Database Cluster
Load Balancer	HTTP HTTPs	80 443	Load Balancer IP	Secret Server IP
RADIUS Server	RADIUS	1812	Secret Server IP	RADIUS Server
Email	SMTP	25	Secret Server IP	Email Server
Rabbit MQ	MQTT	5672	Secret Server IP	Rabbit MQTT

IV. DISCUSSION TOWARDS OPTIMIZATION

The integrated mechanism for the optimization towards security and safety from external world within the organization and universities is very necessary. Discussing an integrated method which is the highly acceptable due to achievement of the various factors including major access controls mechanism incorporated with hybrid approach of IAM and PAM. The incorporation of this method reflected as a better mechanism which gives three-way access control mechanism as shown on Fig. 4. The first one is endpoint privilege managing. This managing administration gives very least privileged as well as credential theft protection within the organization to remain safe and protected towards external things. The second one is core privileged access security managing. This managing administration is provided remotely vendor access, risk-based credential security, protection of session management attacks and protection of least privilege server with domain controller. The third one is application access managing. This managing administration is illustrated tools, secret managing applications, containers and other develops. These all protection is coming from the optimization of IAM and PAM in a certain degree of integration methods as mentioned in the proposed section. During incorporating and implementation it seems some advantages to explore which is quite justifiable to integrate these applications.

A. Benefit of the Integrated Methods

One integrated identity and access management (IAM) and privilege access management (PAM) implementation can resolve this issue and make it possible for businesses to reliably respond to incidents and help facilitate regulatory compliance. When used, it can be used to automate use cases that involve the management of privileged accounts in the real world, proposing a unified, policy-driven approach to IAM across all users.

- Discover privileged accounts in addition passwords installed by the IAM solution in the PAM program.
- Implement a single, set of policies IAM solution for all users.
- Supplying fresh privileged accounts automatically by role-based access provisioning or IAM application authorization policies.
- Utilize user profile characteristics including title, consulting firm including profile to allow sufficient access to privileged accounts.
- Automation of periodic accounts access checks.
- Automation and implementation of duties segregation (SOD) strategies on privileged and non-privileged accounts.
- Modularizing privileged accounts abortions based on player separation or termination incidents as per the active directory solution.
- Excludes the doubt as to who is permitted to receive privileged or restricted information.
- We've developed better security on both the outside and inside of the organization.
- The efficiencies created by autonomous systems reduce costs, freeing companies to focus on building and protecting their networks.
- To stop the breach from happening, implement a process to avoid hackers from breaking in will save both time and money.
- Enforcing new and existing security policies with the system for the easiness.

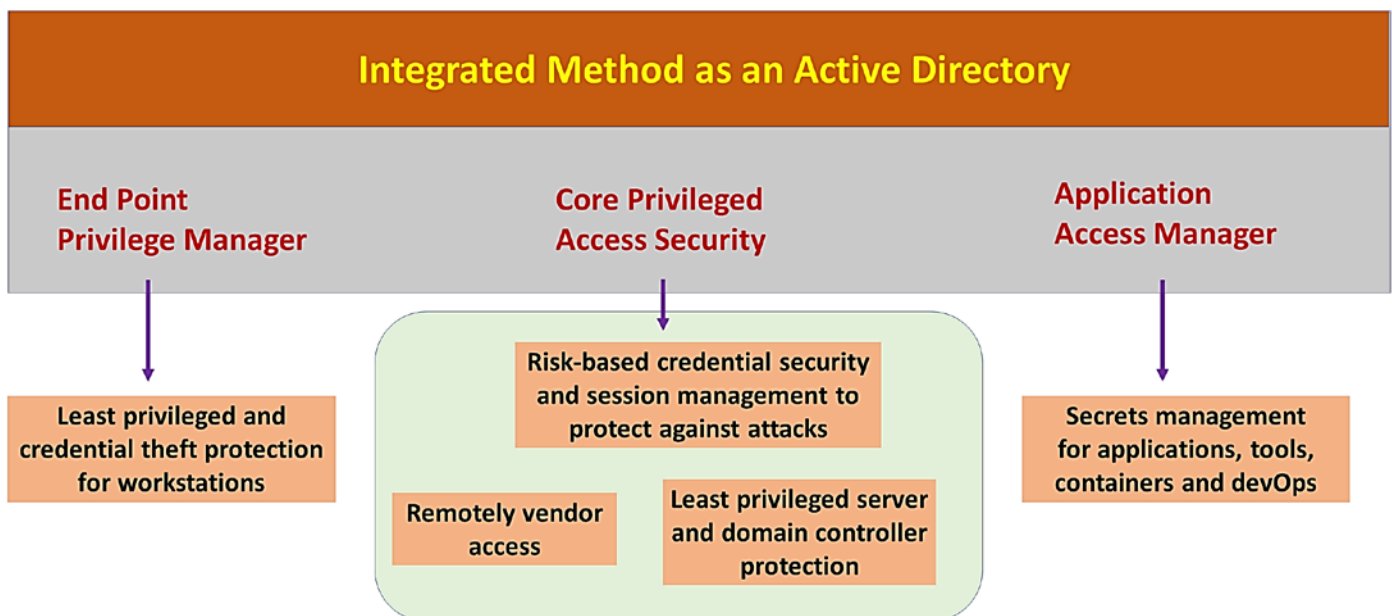

Fig. 4. Outcomes of Applied Integrated Mechanism.

B. Limitation of the Integrated Methods

Protecting identity and restricting access control is the key reason for using an integrated method. The system is controlled by only passwords. This is to say that the employee access code is only has some value when they have the ability to affect it. Regardless of the size of the enterprise, installing and configuring an integrated method can be expensive and time-consuming. For security purposes, it needs to be incorporated with the current security systems. To the extent possible, many enterprises are depending on IT security experts to develop and enforce the relatively better framework such as two factor or three factor authentications to eliminate interruptions for staff and company operations.

V. CONCLUSION

The emergence of the technological advancement around the world a well-organized governmental as well as business oriented smart control measure focuses within the organization. The emphasis of these highly required concept, this article is proposed an integrated approach with the incorporation of IAM as an authentication tool and PAM as a restricting accessing control measure. This method is enhanced the secure accessing policies among the governance as well as business organization to know each activity and record the adversarial attack from the proposed system. The whole experimental setup implemented within the Prince Sattam Bin Abdulaziz University, Saudi Arabia and it is analyzed using the real-time data which is available within the university database. We found that the proposed mechanism can be a vital method for protecting governance data or key business-oriented data from the unauthorized or adversarial attack which is always a challenging task in any premier organization. Using this integrated method, we believe that there will be so many controls within the governance body or business companies which can help a lot to restrict any miss happening being a large company. This article is just an initiative towards the better digitized system in terms of cyber security to employ at public as well as private corporate system to enrich trusted ecosystem for the people of kingdom of Saudi Arabia.

For the future work, we are still thinking to incorporate some cryptographic based strong authentication setup and integrate with effective privilege access control measure which can give highly trusted and relatively better outcomes for the governance system or business-oriented institutions.

ACKNOWLEDGMENT

We thank the Deanship of Scientific Research, Prince Sattam Bin Abdulaziz University, Alkharj, Saudi Arabia for help and support.

Dorsal Hand Vein Extraction in Uncontrolled Environment

Nisha Charaya¹, Anil Kumar², Priti Singh³

Department of ECE
Amity University, Gurgaon
Haryana, India

Abstract—Biometrics is an inseparable part of our day to day life. A major development in this area has been observed in past few decades. Over the recent years, dorsal hand veins have emerged as a promising biometric attribute due to its universality, stability and anti-forgery characteristics. However, detecting the veins of different thickness under different illumination is a challenging task. The traditional vein extraction approaches based on thresholding does not find their applicability in these situations. This paper presents a hybrid approach for vein segmentation for these hand images. The proposed approach is a combination of two techniques, i.e. repeated line tracking and maximum curvature points. The technique has been tested over Bosphorus hand vein dataset which contains 1575 images of different age groups captured under different illumination conditions. From the results, it is evident that this technique is suitable to extract vein pattern from all types of images. Further, these images have yielded an accuracy of more than 98% when subjected to feature extraction and classification steps.

Keywords—Biometrics; security; forgery; hand vein; vein segmentation; vein extraction; thick veins; unclear veins

I. INTRODUCTION

With the advances in technology and implementation of automation everywhere, security has been put at stake and needs to be ensured before bringing a new technology into practice. Starting from minor to major, all the activities in our lives has become automated with the help of biometrics. Attendance marking systems in offices, online transactions in banks and door opening at home; everything has become fast and automatic. But this automation requires a perfect, accurate and precise method to identify a person [1][2]. The technique to identify or verify a person with the help of physiological or behavioral attributes is known as biometrics. Iris, veins, fingerprints, and face are examples of physiological biometrics whereas voice, gait and DNA are examples of behavioral biometrics. A biometric system is user-convenient as compared to the traditional methods as it doesn't require be kept with safety or crammed all the times [3].

Hand-veins are seeking researcher's attention due to its attracting characteristics of user convenience and anti-forgery. Under the human skin, there is vein pattern which consists of various networks of blood vessels. The structure of vascular pattern in human body parts is diverse and stable over time [4]. Further it is present beneath skin which cannot be visible directly with bare eyes of humans. Related to other biometric

features, vein pattern are very difficult to recognize. Still its characteristics like uniqueness, contactless, universality and anti-forgery are strong enough to hide the challenges in its use. One of the main challenges in vein pattern based biometric system is to acquire images of vein pattern quickly without involving harmful and expensive devices which has been resolved by the near infra-red cameras.

Another major challenge is extracting the vein pattern from the images captured under poor illumination, with different hand postures and for people of different age group [5]. The thickness of hand veins vary with age and it gets affected due to some common diseases like diabetes and hypertension. In addition to these, irregular shading, optical blurring and skin scattering are some unavoidable factors which deteriorates the vein recognition and overall accuracy of the system. Though a lot of significant work has been contributed by researchers, yet an effective technique which can extract vein pattern from all types of images needs to be devised. This raises the need for finding a vein detection technique which is capable of extracting veins of varying thickness from the unclear images acquired from hands kept in different postures.

In this paper, a hybrid approach for the same is presented which is a merger of two techniques i.e. repeated line tracking method and maximum curvature point's method. The repeated line tracking method is based on tracing the dark lines by examining the cross section profile. It has proved to be effective for unclear images but faces issues for thick/thin veins. On the other hand, maximum curvature point method detects the vein based on the points having maximum curvature. This method is quite satisfactory for detecting the veins of different thickness but fails when the images are unclear. As the former one is suitable for unclear images while the latter is for thick/thin veins, so a combination of these two is proposed which has proved to be efficient for detecting veins from all types of hand images.

The main objective of this paper is to devise a vein extraction technique which can detect the veins of varying thickness from unclear images acquired in uncontrolled environment.

The rest of this paper is organized as follows. Section II discusses related work on this topic. The general methodology is described in Section III. Section IV depicts the proposed method and Section V contains simulation results. Finally, Section VI concludes the paper.

II. LITERATURE STUDY

The generalized and most basic way to detect vein pattern is by identifying the dark lines. It is done by thresholding method. A suitable threshold is selected and all the pixel values are compared with the threshold. Based on the comparison, it is categorized as background or vein. The most common thresholding method is OTSU's thresholding which has been adopted by many researchers to extract vein pattern [6]. However, the traditional method fails for images captured in uncontrolled environments in different hand postures.

Apart from thresholding, some different concept has also been devised to detect the vein patterns. The repeated line tracking method has been implemented by Miura (2004) to extract the finger veins which was able to extract veins in the presence of irregular shading [7], [8].

In 2007, Zhao applied local dynamic threshold method for vein segmentation which was based on extracting the veins by calculating mean and variance of the points in the neighborhood [9].

Zhong, Shao and Liu (2018) adopted the curvature point algorithm to extract the veins in an uncontrolled environment which was earlier deployed by Miura(2005) to extract finger vein pattern[10][11]. This algorithm is based on the concept that, in each grey profile of the grey image the distribution of grayscale values is a concave curve and the curvature value of point on the vein is greater than zero. So, the veins can be extracted by finding the pixels whose curvature values are greater than zero. The curvature point used deeper data features, which largely eliminated the effects of noise and retained more venous details [4].

Li (2010) used a local dynamic thresholding named NiBlack to segment the vein image[12]. To overcome the effect of uneven surfaces which leads to dark regions in DHV image, Shang-Jen Chuang (2017) applied global-local threshold algorithm [13].

BELEAN (2017) applied Hough transform (VP-HT) to determine the line segments in hand vein image. This technique is based on a global description of image features [14].

The majority of the methods for DHV recognition are devised on the basis of geometrical strategies and thresholding. However, optical blurring, hand vein postures and skin scattering are the major issues which may result into irregular shadings that may degrade the accuracy of recognition. A comparative analysis of existing techniques is depicted in Table 1 which clearly shows the lack of a technique that can extract vein pattern from thick/thin veins and unclear images acquired in uncontrolled environment.

All the techniques have their own significances but none of them can be used globally to extract vein pattern from all type of hand vein images due to their own applicability to particular images.

TABLE I. COMPARATIVE ANALYSIS OF EXISTING VEIN SEGMENTATION TECHNIQUES

Year	Authors	Technique Used	Remarks
2004	Miura , Nagasaka, and Miyatake	Repeated line tracking	Tested on finger veins, not suitable for thick veins
2007	Zhao et. al	Local dynamic thresholding	Not suitable for uncontrolled environment
2010	Li, Liu, and Liu	NiBlack thresholding	Not suitable for noisy images acquired in uncontrolled environment
2012	Li, Wang, and Jiang	OTSU thresholding	Not suitable for noisy images acquired in uncontrolled environment
2017	Shang-Jen Chuang	Local-global thresholding	Not suitable for noisy images acquired in uncontrolled environment
2017	Bellean et al.	Hough transform	Not tested for noisy and thick veins images
2018	Zhong, Shao and Liu	Curvature Point Algorithm	Not validated for non-uniform and unclear images

Extraction of vein pattern is an essential requirement for designing a hand vein based human authentication system. So, a poorly extracted pattern cannot result into an accurate biometric system. This raises the need for a global method of vein detection which can be used for all kind of hand images that are acquired with different postures, ages and illumination.

To achieve this, a new vein detection technique is proposed in this paper.

III. GENERAL METHODOLOGY

A general biometric system is comprised of several components as shown in fig 1. The sensor element collects the unprocessed biometric data from an individual that may be in the form of an image, video, audio or some other signal. This unprocessed data is passed through the pre-processing block where it is refined, improved and made ready to be processed and utilized [15]. The feature extraction block gathers a unique set of features to represent the signal. The extracted feature set is labeled with user identity and stored in the database during user enrolment phase. The matching block is responsible for performing comparison between the data presented for identification and the stored data. As an outcome of comparison, a matching score is generated. The decision block categorizes the presented data as identified or unidentified based on its matching score value.

Image pre-processing specifically vein extraction plays an important role in the overall system performance. The images captured in uncontrolled environment contain noise due to variation in illumination, optical blurring and bone shadows [4]. Also, it is challenging to extract veins from all types of images with different hand postures and varying vein thickness. So, it becomes mandatory to pre-process the images.

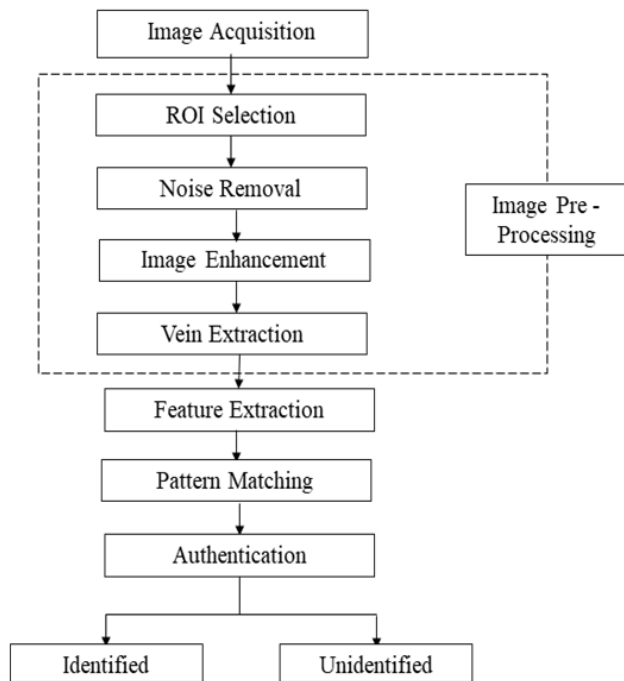

Fig. 1. Flow Chart of Hand vein based Authentication System.

For this, the images acquired by near infra-red camera are first converted to gray scale images. After this, histogram equalization is performed to make the image uniformly illuminated. Noise is removed by the application of median filter and the images are enhanced by morphological ‘open’ operations. Once enhanced hand image has been obtained, it is used to extract the region of interest (ROI) for further processing.

The ROI is a small area selected and extracted out of whole image for further processing. The size of image and the number of images in a database is very large which makes it time consuming to process the complete data as well as its memory requirements are larger. For these reasons, a particular small region is selected out of the whole image from which the features are extracted and stored for database creation and matching purpose. Generally, the ROI is selected around the centre of image so that it is present in all the images and is not affected by the position and placement of hand. In this work, ROI is extracted from the segmented hand image and is chosen such that the most affected and corrupted area is removed from the image and all the important information is retained. It comes out to be a rectangular or square region which is equidistant from all the margins in all directions. Once the region of interest is obtained, the proposed method is employed to extract the vein pattern from the selected regions.

IV. PROPOSED METHOD

Vein segmentation is an important and essential step in hand vein based authentication system as the system performance is directly dependent on it. The proposed technique of vein detection is a combination of two techniques i.e. repeated line tracking method and maximum curvature point method. The dorsal hand images are passed through

them one by one and the resultant images are obtained. Finally the resultant images obtained by the two methods are overlaid upon each other to get the vein pattern extracted.

A. Repeated Line Tracking Method

The repeated tracking of dark lines is performed to facilitate extraction of hand-vein patterns using non-uniform images. The hand veins are extracted from the non uniform images based on tracking the veins in all directions starting from a seed pixel. The line-tracking operation is initiated from any pixel in the captured image. The current position of a tracking pixel is called as the “current tracking point”, and it is moved along the dark line pixel by pixel. The vein appears as a valley in its cross sectional profile as shown in fig 2. The depth of valley is affected by the shading in the image but still it can be detected. It makes this method a robust method that can be used for extracting veins from non-uniform images. The depth of the cross-sectional profile around the current tracking point is checked to decide whether this point lies on a dark line or not. If this cross sectional profile resembles a valley, the tracking point is on a dark line. Further, the cross section profile is observed for different angles and the one with deepest profile is retained to provide the direction of tracking. After this, the current tracking point is updated with the closest pixel in that direction. If a valley is detected again at the updated tracking point, the tracking is continued in the direction of deepest valley and this result in extraction of a vein or part of a vein. Else if valley is not detected in any direction, this means that the updated pixel is not on a dark line and a new tracking operation is started at some other position. This tracking process is depicted in fig 3 showing current tracking point, direction and the cross section profile. A single line tracking operation will yield only a part of veins, so to gather and recognize all the hand veins, tracking is performed at various random starting positions across the whole image.

Sometimes, a tracking operation may also track a region of noise but there are more chances of tracking a dark line which represents a vein. A matrix named the “locus space” is created to store the number of times that each pixel has become the current tracking point. The size of the locus space is determined by the number of pixels in the captured images. Matrix elements are obtained by recording the total count in which the pixel has become the current tracking point against each pixel. Therefore, a frequently tracked element of the locus space has a higher value. The hand veins are obtained as chains of these high value positions in the locus space.

Fig. 2. Cross-sectional Profile and Pixel Position [9].

Fig. 3. Detection of Dark Line by Repeated Line Tracking [9].

The steps considered in recognizing the hand veins using repeated line tracking strategy is portrayed below:

Step 1: Discovering the starting point to move-direction attributes and start line tracking.

Step 2: Recognition of tracking direction by examining cross-sectional profile and updating tracking position along the dark line.

Step 3: Update count against a pixel in locus space whenever a pixel gets traced.

Step 4: Repeat step 1 to step 3.

Step 5: Acquiring the vein pattern via locus space.

This method has the advantage of quick processing and minimized computational time while extracting the vein pattern from unclear dorsal hand images with non-uniform illumination.

B. Maximum Curvature Point Method

The width of hand veins varies with several conditions like temperature, blood in the veins, physical conditions etc. Also with ageing, the vein thickness increases which produces difficult in tracking. To combat these issues, the maximum curvature points technique is employed to inspect the curvature of image and highlight center-lines of veins. The center-lines are determined by probing the position wherein the curvatures of a cross-sectional profile of a vein are locally maximal. These points are connected with each other to obtain the vein pattern.

The algorithm is processed with three steps which involve:

- Mining of centre positions of veins.
- Connecting centre positions.
- Image labelling.

The algorithm checks the cross-sectional profile of a hand vein image. As the vein is darker than its surroundings, the cross-sectional profile of a vein appears like a dent. It appears as a concave surface with large curvature. The curvature is large even for a thin vein. Therefore, even the thin veins get recognized by obtaining local maximum curvature points. Each local maximum position is assigned with a score which is larger for a deeper profile.

The curvature $C(z)$ of a cross sectional profile $P_H(z)$ can be represented as:

$$C(z) = \frac{d^2 P_H(z)/dz^2}{\left\{1 + \left(\frac{dP_H(z)}{dz}\right)^2\right\}^{3/2}} \quad (1)$$

Where, $P_H(z)$ is obtained from the intensity of a pixel, $H(x,y)$ in any direction and z represents a direction in profile. $P_H(z)$ is related to $H(x,y)$ by a mapping function T_{rs} [10].

The sign of $C(z)$ is observed to determine the nature of curvature. The curvature is concave for a positive sign and convex for a negative sign of $C(z)$. The points, where local maxima are obtained for a concave area, give the centre positions of the veins. All such points are stored as z'_k and a score is assigned to them. The assigned scores determine the probability that these points are on the veins. The score for any centre position is calculated as:

$$S(z'_k) = C(z'_k) \times W_r(k) \quad (2)$$

Where, $W_r(k)$ represents the width of concave region containing z'_k [10].

The centre positions of veins are joined together based on score values to obtain veins from group of points. The profiles are analyzed in all four directions to acquire the vein pattern. The vein pattern so obtained is binarized by thresholding method.

The hand veins recognized by the two methods are overlaid upon the original image and stored in the vector form represented as J . Each hand vein region is then subjected to feature extraction and classification for mining significant features and matching process respectively.

V. SIMULATION RESULTS

The proposed technique has been implemented in MATLAB and tested over Bosphorus Hand database.. The database comprises of 1575 images including both left and right hand images captured under different postures and 219 are captured with a time drop of several months.

The database comprises 642 subjects having 6 images for a person, which contains three right-hand images and three left-hand images. The images are of different illumination condition and different postures.

Moreover, 276 subjects with three left-hand images only. Amongst total 918 subjects, 160 poses hand images with time drop of several months.

The proposed method has been tested for vein detection in normal hand images, images with thick veins, rotated hand images and translated hand images. The simulation results for the same are shown in figure 4-6.

The resultant images obtained from maximum curvature point method shown in fig 4, contains dark patches due to irregular shading. While repeated line tracking fails to extract vein pattern from thick vein images as shown in fig 5. From the simulation results shown in fig 6, it is observed that the proposed method can successfully detect vein pattern from all kind of images which can be further used for feature

extraction and classification steps to develop the complete authentication system.

Fig. 4. Veins Extracted by Maximum Curvature Points Method for (a) Normal Image (b) Rotated Image (c) Translated Image (d) Thick Vein Image.

Fig. 5. Veins Extracted by Repeated Line Tracking Method for (a) Normal Image (b) Rotated Image (c) Translated Image (d) Thick Vein Image.

Fig. 6. Veins Extracted by Proposed Method for (a) Normal Image (b) Rotated Image (c) Translated Image (d) Thick Vein Image.

VI. CONCLUSION

It is evident from the results that the proposed method can efficiently detect the vein pattern from thick veins and unclear images acquired in uncontrolled environment. This method can be used as a global method of vein segmentation for all kind of images. The vein pattern so produced when further tested for matching purpose by using convolutional neural network (CNN) for feature extraction and deepCNN for classification yields overall accuracy of above 98% for all type of images. However, this approach needs to be validated over practical noisy images and can be extended to the design of dorsal hand vein based biometric system.

Abstract—This paper proposes an ensemble model for wind speed forecasting using the recurrent neural network known as Gated Recurrent Unit (GRU) and data augmentation. For the experimentation, a single wind speed time series is used, from which four augmented time series are generated, which serve to train four GRU sub-models respectively, the results of these sub-models are averaged to generate the results of the proposal ensemble model (E-GRU). The results achieved by E-GRU are compared with those of each sub-model, showing that E-GRU outperforms the sub-models. Likewise, the proposal model (E-GRU) is compared with benchmark models without data augmentation such as Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), showing that E-GRU is much more precise, reaching a difference of around 15% with respect to the Relative Root mean Square Error (RRMSE) and 11% with respect to the Mean Absolute Percentage Error (MAPE).

Keywords—Wind speed forecasting; recurrent neural networks; gated recurrent unit; ensemble GRU; data augmentation

I. INTRODUCTION

Earth's natural greenhouse effect makes life possible as we know [1]. However, human activities, such as the burning of fossil fuels and deforestation, have intensified the natural phenomenon, causing global warming [2], and due to this problem, the exploitation of renewable energies such as solar, wind, thermal energy and others have emerged as excellent alternatives for its solution.

Regarding wind energy, this is harnessed through the use of wind machines or wind motors capable of transforming wind energy into mechanical rotational energy usable for the production of electrical energy. Thus, the prediction of wind speed time series has become an essential task in wind energy farms, this helps in the planning of energy production [3] among others.

In models based on deep learning, the problem of overfitting [4], [5], [6] is usually presented due to the lack of data. Various solutions have been suggested in the literature, such as the use of dropout layers, regularization and data augmentation.

In this work an ensemble model for wind speed forecasting is proposed, it is based on the recurrent neural network known as Gated Recurrent Unit (GRU), where despite having enough historical data for the training phase [7], a data augmentation process is used with the sole objective of improving the precision of the model results, thus it is used the data augmentation technique proposed by Flores et al (2021) "in press" [8]. GRU is used instead of Long Short-Term Memory (LSTM), due to the antecedents such as [9], [10], and others where GRU presents slightly better results than LSTM.

The proposal ensemble model (E-GRU) consists of four GRU sub-models, for which four different augmented time series have been generated from a single wind speed time series. The final result is the average of the four sub-model predictions. The idea of using an ensemble model arises from the need to take advantage of the default and excess predicted values with respect to the observed or original data.

The main contribution of this study is a novel ensemble model (E-GRU) for wind speed time series forecasting based on recurrent neural networks as GRU and data augmentation.

The content of the work has been organized as follows. In the first section, the problem and the respective solution are described. In the second section, the theoretical bases are described, which are the basis of the paper's proposal. In the third section, the methodology followed for the implementation of the proposal is described. In the fourth section, the results achieved are described and discussed. In the last section, the conclusion reached at the end of the study is presented, as well as future work.

II. BACKGROUND

This section briefly describes some theoretical bases that are important for understanding the content of the paper.

A. Recurrent Neural Networks (RNN)

Just like Deep Neural Networks (DNN), Convolutional Neural Networks (CNN), RNNs are part of the fundamental architectures of Deep Learning, which specialize in working with sequential data, hence their use in natural language processing (NLP) as well as in time series regression.

The best known RNN is probably Long Short-Term Memory (LSTM) known to overcome the vanishing gradient problem in RNNs. Several variants are generated from LSTM, including Gated Recurrent Unit (GRU), which, as mentioned above, for certain case studies, especially in time series, presents better results than LSTM.

The GRU architecture is shown in Fig. 1

Fig. 1. GRU Architecture.

From Fig. 1, to estimate h_t it is necessary the following equations:

$$r_t = \sigma(W_r x_t + U_r h_{t-1} + b_r) \quad (1)$$

$$z_t = \sigma(W_z x_t + U_z h_{t-1} + b_z) \quad (2)$$

$$\tilde{h}_t = \tanh(W x_t + U(r_t \odot h_{t-1}) + b) \quad (3)$$

$$h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \quad (4)$$

Where:

W_z, W_r, W, U_z, U_r, U Matrices of parameters

b_r, b_z, b Vectors of parameters

σ Element-wise sigmoid function

\odot Element-wise multiplication

B. Data Augmentation

Data augmentation arose to solve overfitting problems in image classification [11] models like CNN and others. Many of these techniques consisted of zooming, rotation, flipping, etc. Later, the concept was transferred to time series classification, here techniques such as time-warping, rotation, scaling, jittering, etc. emerged.

This work uses the technique proposed in "in press" [8] which is based on two basic techniques such as time-warping and jittering. The first one allows to increase the length of the original time series and the second one makes the synthetic data generated with the first one non-linear. Thus, this technique works with two parameters, the block size and the sub-block size, the first indicates the number of synthetic items to insert between each pair of the original time series and the second the number of linear synthetic items in each synthetic block. Fig. 2, shows a graphical view of this data augmentation technique.

Original time series

Parameters for data augmentation

synthetic block size=17 sub-block size=6

Linear synthetic values

Random non-linear synthetic values

Fig. 2. Data Augmentation based on Time-warping and Jittering [8].

III. METHODOLOGY

The methodology followed for the implementation of the proposal is described below.

A. Time Series Selection

The selected daily wind speed time series is the same that was used in the work "in press" [7], and was obtained from the repository of the National Aeronautics and Space Administration (NASA) using Power Data Access Viewer with latitude: -17.6851 and longitude: -71.3515. This corresponds to a point in Ilo city in Peru that has enormous potential for wind energy.

This time series ranges from 1981-01-01 to the present, however, for the purposes of experimentation in this study, the years 1981-2016 will be used for training and the years 2017-2020 for testing.

B. Time Series Imputation

The selected daily wind speed time series does not present NA values, so the application of any data imputation technique was not necessary at this stage.

C. Data Augmentation

In this phase, the data augmentation technique based on time-warping and jittering proposed in [8] was configured according to Table I.

TABLE I. PARAMETERS OF DATA AUGMENTATION TECHNIQUE

Time series	Augmented time series	Block-Size	Sub-Block Size	Augmented ítems	Total
1981-2016	TS-1	6	3	78888	92037
	TS-2	6	3	78888	92037
Ítems 13149	TS-3	6	4	78888	92037
	TS-4	6	4	78888	92037

As can be seen in Table I, the first two augmented time series (TS-1 and TS-2) have the same parameters as well as the third and fourth (TS-3 and TS-4), but due to the randomness of the data augmentation technique different items are generated for each synthetic block, this can be seen in Fig. 3.

Fig. 3. Augmented Time Series for 9-first Original Items.

D. Ensemble Model Implementation (E-GRU)

At this stage, the ensemble model is implemented. Here the four sub-models have the same characteristics, which are detailed in Table II.

TABLE II. HYPERPARAMETERS OF EACH SUB-MODEL

Sub-Model	Hyperparameters	Values
GRU GRU GRU GRU	Hidden neurons	160
	Epochs	100
	Optimizer	adam
	Drop rate	0.2
	Activation function	ReLu
	Layer 1, 2, 3 y 4	(40,40,40,40)
	Batch size	40

The tools used for implementation of proposal model are Google Colab and tensorflow 2.4.1

E. Evaluation

For the evaluation of the predicted days, it is necessary to extract those corresponding to the original data since these also include predicted synthetic values. For this process, the value of the block-size parameter of the data augmentation technique is considered, which we will call z ; the predicted time series begins to be traversed and the predicted value located after the z value is extracted, then z new positions are traversed and the next value is extracted, and so on until reaching the last predicted value.

The model is evaluated through three regression metrics, these correspond to the Root Mean Square Error (RMSE), Relative RMSE (RRMSE) and Mean Absolute Percentage Error (MAPE), which are estimated through equations (5), (6) and (7) respectively.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (P_i - O_i)^2}{n}} \quad (5)$$

$$RRMSE = \frac{RMSE}{\frac{1}{n} \sum_{i=1}^n O_i} * 100 \quad (6)$$

$$MAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{(O_i - P_i)}{O_i} * 100 \right| \quad (7)$$

A graphical version of the proposal model (E-GRU) can be seen in Fig. 4.

Fig. 4. Proposal Ensemble Model.

IV. RESULTS AND DISCUSSION

After experimentation, this section shows and describes the results achieved.

A. Results

According to Table III and Fig. 5, it can be seen that the ensemble proposal model E-GRU on average surpasses all the sub-models.

Regarding the RMSE, on average E-GRU is superior to all sub-models. However, for the forecast horizon of 500 days, GRU-1 (0.0284) slightly exceeds E-GRU (0.0288), this is the horizon where E-GRU reaches its worst performance.

According to RRMSE on average and in all prediction horizons, E-GRU outperforms all sub-models. It is important to highlight that according to the RRMSE achieved, E-GRU and all the sub-models can be classified as excellent since they present RRMSE < 10% [12], [13].

With respect to MAPE, like the previous metrics, on average E-GRU outperforms all sub-models. However, it is important to highlight that GRU-1 for the horizons of 50 and 100 predicted days, manages to surpass E-GRU.

According to Fig. 6, the importance of the ensemble process in the proposal can be appreciated. The data predicted by the sub-models closely approximates the original data by default and excess, and the average operation of the ensemble model makes it much closer to these, making E-GRU more accurate than the sub-models.

Likewise, it is important to highlight the importance of each sub-model, thus in Fig. 6 for the point enclosed in the circle, GRU-4, the worst of the sub-models according to Table III, is the only one that contributes to improving the proposal model precision.

TABLE III. SUB-MODELS VS MODEL RESULTS

Model/ Sub-Model	Predicted Days						Avg

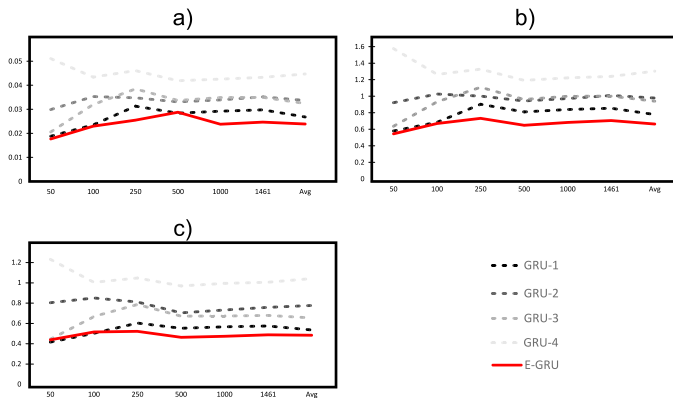

Fig. 5. Comparison of Metrics: Sub Models vs Proposal Model. a) RMSE, b) RRMSE and c) MAPE.

Fig. 6. Comparison of First 10 Predicted Days for Sub Models and Proposal Model.

According to Table IV, in reference to the average and all the prediction horizons it can be seen that the ensemble proposal model E-GRU far exceeds the results of the benchmark models (LSTM and GRU). Here it is important to highlight that the architecture of the LSTM and GRU models is four-layer and use the same hyperparameters as the sub-models of ensemble proposal model, but they do not use data augmentation.

Regarding the RRMSE, there is an average difference of approximately 15% between the results of the ensemble proposal model (E-GRU) and the benchmark models. Likewise, with respect to MAPE, the percentage difference is approximately 11%.

B. Discussion

In this part, the results achieved by the ensemble proposal model E-GRU are compared with those achieved by other state-of-the-art models in the prediction of wind speed time series.

Here, according to Table V, the high precision of the models proposed by Qureshi et al [14] and Flores et al [7] can be highlighted. In the first case, the authors use an architecture based on Deep Neural Networks and Meta Regression with Transfer Learning (DNN MRT), reaching an RMSE = 0.0953. In the second case, the authors use an architecture based on the recurrent neural network GRU including data augmentation, reaching an RMSE = 0.0876.

The E-GRU proposal model uses the same GRU architecture of [7] for each sub-model as well as the same data augmentation technique, the fundamental difference is that instead of using a single augmented time series, it uses four augmented time series, which are different due to the randomness of the technique and also work with different values for the sub-block size parameter.

The results show that the proposal ensemble model manages to surpass the state-of-the-art models including the techniques proposed in [14] and [7].

V. CONCLUSION AND FUTURE WORK

According to what is observed in the Results and Discussion section of this paper, it can be concluded that the proposal model allows to improve the results of the state of the art in relation to wind speed forecasting. Likewise, it is important to highlight the importance of the data augmentation process, since all the sub-models implemented for the ensemble proposal model E-GRU present excellent results according to the RRMSE evaluation. Thus, the main advantage of the proposal model with respect to the state-of-the-art models for wind speed prediction is its high precision, and the simplicity of model implementation and each of its respective sub-models.

As a future work, it should be noted that the main weakness of the proposal model lies in the computational cost involved in training 4 GRU models with 92,037 items each. Thus, the minimum amount of synthetic and historical data

could be analyzed to obtain satisfactory results. On the other hand, it could be experimented with time series with characteristics different from those of wind speed.

ACKNOWLEDGMENT

Relative Merits of Data Mining Algorithms of Chronic Kidney Diseases

Harsha Herle¹, Dr. Padmaja K V²

Electronics and Instrumentation Engineering, Department
RV College of Engineering, Affiliated to VTU, Bengaluru, India

Abstract—Early prediction of Chronic Kidney Disease in human subjects is considered to be a critical factor for diagnosis and treatment. The use of data mining algorithms to reveal the hidden information from clinical and laboratory samples helps physician in early diagnosis, thus contributing towards increase in accuracy, prediction and detection of Chronic Kidney Disease. The experimental results obtained from this work, with subjected to optimal data mining algorithms for better classification and prediction, of Chronic Kidney Disease. The result of applying relevant algorithms, like K-Nearest Neighbors, Support Vector Machine, Multi Layer Perceptron, Random Forest, are studied for both clinical and laboratory samples. Our findings show that K - Nearest Neighbour algorithm provides the best classification for clinical data and, similarly, Random Forest for laboratory samples, when compared with the performance parameters like, precision, accuracy, recall and F1 Score of other data mining analysis techniques.

Keywords—*Ultrasound images; support vector machine (SVM) k-nearest algorithm (K-NN); multilayer perceptron algorithm (MLP); random forest (RF); clinical data*

I. INTRODUCTION

In recent years more than two million people across the globe suffer from Chronic Kidney Disease (CKD) like Kidney stone, kidney transplant, blockage of urine, congenital anomalies, cyst, bacterial infection, dialysis or cancerous cells, to stay alive, of which at least only 10% of the patients need treatment to live with high health care costs [1]. Due to the increase in cost, only 2 million people are capable of receiving treatment for CKD, representing 12% of the global population [2-3]. Within developed countries, only 20% of patients are treated for CKD, and under developed countries, on an average one million die from untreated kidney failure due to financial constraints [9]. CKD can be detected using either X-rays, Ultra Sound (US), Computer Tomography (CT) and MRI or laboratory samples for medication. This work focuses on applying data mining techniques for kidney stone detection using Ultra Sound (US) technique and laboratory samples collected from database, for further treatment by medical doctors.

In detecting the CKD, the laboratory samples obtained from standard database UCI machine learning repository is subjected to data cleaning or preprocessing of the data samples and for further classification, the labels are converted to numbers. The database contains 25 attributes of which serum creatinine, blood ureas, hemoglobin, hypertension remains important in this work and others are out of the scope for our analysis [3].

Once the CKD is detected, the next step is to focus on detecting the kidney stone using US technique. The US technique has more advantages like non-ionising nature, portability, low cost and also in giving the details of real-time monitoring of patient's vital internal organs. US image is recorded by incisive technique, where a high frequency signal of order greater than 1MHz is penetrated into the human body with the help of a transducer. The US waves reflected from kidney tissues are received by transducer and displayed on a computer screen either in two-dimensional (2D) or three dimensional (3D). The obtained US images contain background information and labels that require crossing out and to enhance the quality of US image. Further, the US wave was subjected to speckle noise -multiplicative type of noise that appear as dark and bright spots resulting in trouble analysis and diagnosis interpretation. In reduction of speckle noise in US images, a method termed as speckle denoising is carried out for analysis, preprocessing and interpolation of US images [5]. In removal of speckle noise from US images many algorithms exists and differ in their basic methodologies. Preprocessing filters like, spatial and wavelet filters have proved its efficiency, in-terms of statistical parameters like increased Signal to noise ratio (SNR), Peak Signal to Noise Ratio (PSNR), decrease in Mean Squared Error (MSE), Mean Absolute Error (MAE).

Moreover in US image, the Region of Interest (RoI) is retained and other portions are removed using segmentation techniques. Segmentation is the logical implementation to find the RoI against the characteristic of the US images, thus its features are expected to find the region where kidney stone may be present. Feature extraction method aims at reducing the input data by finding the features from several input patterns, resulting in an input vector consisting of appropriate image properties, which will be given to data mining techniques for further classification.

In classification phase, the input image is classified into abnormal or normal classes depending on the statistical parameters of features obtained from clinical and laboratory data samples. Generally, classification phase is further categorized into unsupervised and supervised classification, where, in supervised classifier, the algorithm iteratively arrives at predictions on the training data and is validated by the teacher, often coined as learning with teacher. Conversely, in unsupervised learning, algorithms are left to their own devices to determine and present the interesting structure in the data, hence does not necessitate training phase for classification. The supervised learning, further classified into,

artificial/logical, Perceptron based, statistical based, and Support Vector Machines (SVM).

This work focus on statistical analysis of clinical and laboratory data samples, where data mining algorithm, K-Nearest Neighbors algorithm, SVM, Multi Layer Perceptron (MLP) and Random Forest (RF) and are used to evaluate the performance of the classifier against different parameters like sensitivity, precision, Recall and F1 score. The experimental results validated the above statistical parameter in estimating the best machine learning algorithm for CKD. Upon classification of kidney stone US images, a Graphical User Interface (GUI) is developed to assist medical doctors about the presence or absence of Kidney US images.

The preceding section in the paper foresees the literature review carried out to find the problem of interest. The research methodology for the problem defined is well stated. The description of constituent blocks and its mathematical relations are well explained and derived. Finally experimental results demonstrate the effectiveness of best suitable algorithm for kidney US Images with conclusion drawn towards it.

II. RELATED WORK

The medical imaging plays a prominent role in detection and diagnosis of diseases related to human subjects, have wide range of scope, thereby researchers and scientists have contributed significantly over decades [6]. To begin with, the laboratory data samples obtained are subjected to transformation and preprocessed or data cleaned for replacing the missing values using data mean method. The data samples are applied to classifiers to evaluate the performance of the algorithms to detect the presence of CKD in human subjects. Upon detection of CKD, the next step is to find the presence of kidney stone using US images.

The raw US image is obtained from the radiologist, unwanted details like anatomical information, are removed by binary threshold method. The US images are subjected to removal of speckle noise either using statistical or classification of model. The main objective in statistical modeling is to remove the noisy images by obtaining the statistical features from training data and later obtain the parameters of interest. Initially, statistical filters such as Weiner filter [20], adaptive filters in spectral domains, finds applicable in removal of additive noise [7]. In order to address the multiplicative noise, Jain mode is proposed [8] that works by taking the logarithmic of the image is obtained, later multiplicative noise is converted to additive noise, and Weiner filtering is applied. This process is tedious, time consuming and depends on the size of the image. A region based segmentation method is applied to kidney along with Gabor filter, resulting in reduction of speckle noise and smoothen the image signal, along with histogram method to improve the quality of the image [9]. The experimental results demonstrate reduction of speckle noise up-to to 85%, focusing on only few parameters. Thresholding methods like soft thresholding, Visu-Shrink, hard thresholding, Sure-Shrink, Bayes sure shrink and Bayes thresholding for speckle reduction were also applied for kidney US images [10]. The Visu shrink method is based on wavelet shrinkage and uses over smooth images. The Bayes shrink gives promising results in Mean

squared Error (MSE) over visu shrink, all these methods are based on soft thresholding, with the input value is shrunk to zero by the amount of thresholding. In hard thresholding, the input is retained to same value, if it is greater than threshold, else retained to zero [11]. After preprocessing, the next step is to extract the features from US images followed by applying data mining techniques to detect into normal or abnormal using Graphical User Interface (GUI) developed.

The most prominent work involves detection of absence or presence of kidney stones. The US images were segmented using intensity threshold variation that helps in identifying multiple classes to classify the images as stone, early stone stages and normal, [13]. Other methods in feature extraction can be intensity histogram features and Gray Level Co-Occurrence Matrix (GLCM) features. The kidney US images were classified into four different groups like Normal (NR), Bacterial Infection (BI), Cystic Disease (CD) and kidney stones (KS). Thus create the database for classified kidney US image for further pathological studies [12-13].

In classifying the abnormalities in kidney, statistical methods like GLCM or Run Length Matrix (RLM) are used along with SVM, reaching an accuracy of 85.8% [21]. Increased in classification accuracy up-to 98.8% can be reached by applying two level set segmentation methods with Artificial Neural Network (ANN) architecture [14]. Intensity histogram and Harlick features were used as feature extraction for segmented Region of Interest (RoI) Kidney US images A two level of classification methods is proposed, of which in the first method, a lookup table based approach was used to classify the US images into normal and abnormal, followed by second stage, where an SVM with MLP was used to classify the presence of stone or cyst in the kidney with promising experimental results reaching an accuracy up-to 98.14%. SVM was used to classify the Kidney US images for early detection of CKD for classifying the training and testing results and to evaluate the performance of SVM with accuracy of 97.6%. The prominent features were extracted from abnormal kidney US images and classified using SVM algorithm reaching accuracy up-to 83.74% [15]. Likewise, the US images were subjected top adaptive median preprocessing method and segmented using K-Means method. GLCM features were extracted and meta-heuristic SVM classifier is used to classify the US images to detect the renal calculi, and have performed better in noisy images exhibiting detection accuracy of 98.8%.

Further, the other machine algorithms like K-NN is used in classification for normal and cyst Kidney US images, with experimental results predicting up-to 92% for normal images and 85% for Cystic images [16]. In addition to this, several machine algorithms like, Logistic Regression, Elastic Net, Lasso Regression, Ridge Regression, SVM, Random Forest, Neural Network, K-NN Elastic Net were applied for kidney US images, of which K-NN alone gives prediction accuracy of 85% [17]. Extending further, a new decision support system was developed to predict and classify CKD using Artificial Neural Network, K-NN, decision tree, Random Subspace, Linear Discriminate Analysis (LDA), of which K-NN alone gives 78% prediction accuracy [19]. Recently, Hybrid classification algorithms play a prominent role in classification of US kidney images, were subjected to SVM-

KNN together, reaching the prediction accuracy up-to 99.6% [17]. Recent advancements in US imaging have revealed the way to increased interest in removal of the speckle noise from the medical images using different algorithms, without reducing much of the diagnostic information [20].

Data mining techniques are applied for laboratory data set consisting of 361 CKD patients. SVM, MLP, Radial Basis function (RBF), Probabilistic neural network (PNN) were applied to these data samples with PNN emerging as the best algorithm that can be used for physicians for further treatment [4].

Of the literature reviewed in this work, the kidney US images are subjected to preprocessing method like Median, Adaptive median, Weiner filter to remove salt and pepper noise, Neigh SURE shrink method to remove speckle noise. The resultant images were applied with GLCM and histogram method for feature extraction. This current work focus data mining technique like SVM, MLP, RF and KNN for the preprocessed Kidney US image to increase the classifier performance. Further the kidney US Images were subjected to data augmentation methods like rotations of US kidney images to enhance the number of images, thereby contributing to increase in overall classification accuracy. The experimental results of both clinical and laboratory data are compared to estimate the optimal data mining algorithm for early diagnosis.

III. RESEACRH METHOD

Fig. 1 shows the block diagram for estimating optimal data mining technique for CKD, using both clinical and laboratory samples. The laboratory data sample obtained from UCI machine learning repository consists of 400 CKD Indian patients and contains 11 numerical and 14 attributes that are categorized. The obtained datasets are preprocessed or data cleaned. The data sample are then passed to different data mining techniques to find the optimal classifier algorithm with respect to accuracy, precision, recall and F1 score. All the preprocessing methods, classification and detection area are carried out in sklearn machine learning API using python programming environment. Upon detection of CKD using laboratory data sets, the next step is to use the same classifiers to detect the presence or absence of kidney stone using Ultrasound Imaging technique.

The raw image is obtained from the radiologist, and unwanted anatomical information are removed using binary threshold method. The resultant noisy image is then filtered to suppress the Salt and Pepper noise, speckle noise using Median, Adaptive Median, Weiner and Neigh SURE shrink filtering method. The preprocessed image is segmented by threshold method and morphologically operated to detect RoI in kidney, and then the statistical features are extracted from normal and abnormal images to classify the kidney abnormalities. If the abnormalities are detected, then the Centroid of the abnormal image is estimated to find the area of kidney abnormal region. The detected abnormalities will provide information for medical doctors, to take the medication to next level. All the preprocessing methods, classification and detection of centroid area for kidney stone detection are carried out in image acquisition tool box in

MATLAB® 2018a version simulation environment for image resolution of 256×256 using high end computers.

A. Preprocessing

In preprocessing the laboratory samples, data sets are subjected to interpolation, transformation and scaling, where interpolation method includes mean, median or most frequent values. Data transformation, method converts label to number and scaling is a process to normalize the values in the data set. Likewise, for Kidney US images, the acquired image undergo different preprocessing stages to increase the quality of images [39]. The acquired images are prone to speckle noise, salt and pepper noise, which requires to be filtered out. In this work, Neigh SURE shrink, median, adaptive median, Weiner filter are used to remove the both the noise and un-sharp masking for sharpening. Entropy based segmentation is used for finding the RoI and morphological operations like erosion and dilation are also used for finding the final segmented image.

1) *Median filters*: Median filters are non-adaptive filters that adjust the coefficients based on data within a rigid moving window, and summons between the quality of speckle noise suppression and the potential to preserving image details. They are linear statistical filter which works with the principle of replacing the current pixel value in US images into the median value in a neighborhood. [19-20].

2) *Adaptive median filers*: This filter works with the three step methodology of which the primary step is to detect the noise, in US images, secondly, adaptively estimate the window size based on the number of noise pixels within the window. Finally, determine the weight of each non-noise point in filtering window and filter off noise points by means of weighted median filtering algorithm. This method is advantageous compared to other preprocessing filters, as it preserves the edges of its high frequency parts of an image. [25].

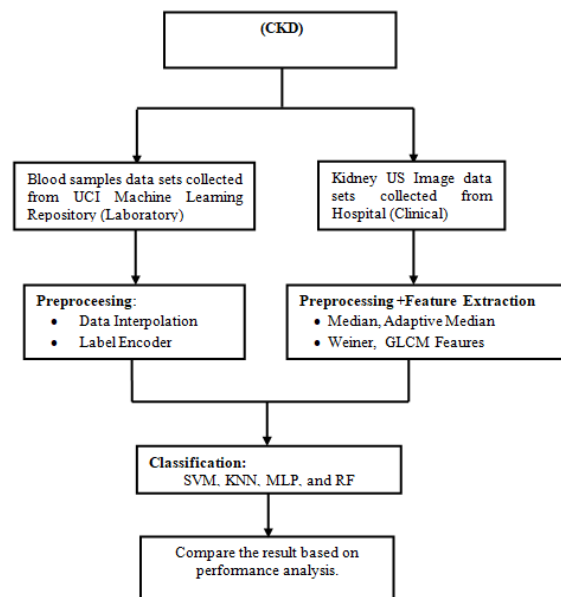

Fig. 1. Block Diagram for Estimating the Optimal Data Mining Algorithm for CKD.

3) *Weiner filters*: Another common preprocessing filter that finds application in US image is Weiner filter that works on the principle of blurring and removal of additive noise simultaneously by performing best possible substitution between inverse filter and noise smoothing [18] and is optimal in terms reduction in Mean Square Error [22].

4) *Neigh SURE shrink filters*: Neigh SURE shrink is the adaptive filter based method works on the principle of thresholding technique, combining both soft thresholding and hard thresholding, and only deals with binary values. In this method, a fixed threshold value is considered based on the window size, $[W_s]$ and variance value, is calculated using the equation 1,

$$\sigma^2 = \frac{\text{median}(|w_s|)}{0.6745} (w_s \in \text{subband LL}) \quad (1)$$

The smooth or low frequency components are approximated from father wavelet and high frequency components are resembled from mother wavelet. A 3x3 sized window is moved all over the image to be filtered, where the surrounding pixel value is averaged over the central pixel. Mean and variance is applied over the decomposed image to reduce the speckle noise from US image reduction in speckle noise is based on the thresholding value, when the pixel value crosses the threshold value then that pixel value becomes 1 or 255 and if the pixel value is below the threshold value then that pixel value becomes 0. The Neigh Shrink uses a suboptimal universal threshold and identical window size in all wavelet subbands, whereas the improved version of it determines an optimal threshold and neighboring window size for every subband by the Stein's unbiased risk estimates [23] as given in equation 2.

$$(T^s, k^s) = \arg \min_{T,k} \text{SURE}(w_s, \rho, k) \quad (2)$$

Where ρ is the threshold, k is the window size and s denotes the sub band [24].

B. Feature Extraction

Feature extraction primarily focuses on reducing the input data by determining the distinguishable features from numerous input data samples. The output of feature extraction stage results in an input vector consists of significant image properties, which will be fed into classifier to classify normal and kidney stone US images. In medical imaging analysis, texture is an important feature that provides the spatial distribution of pixels gray level in a region. Textural characteristics of particular image is extracted, to perform the identification of object regions, using many diverse algorithms like fractal based methods, Markov random field and Gabor filter. Harlick features often coined as Gray level co-occurrence matrix (GLCM) is a statistical feature extraction method, represented in the form, $N_g \times N_g$, where N_g is number of gray levels, Within MATLAB, GLCM is represented in the form of a matrix where number of rows and columns are equal to number of gray levels, G in the image. GLCM gives spatial relationships between pixels $P(i,j)$ [26].

Of various features, this work focuses on homogeneity, contrast, correlation, and energy. Another prominent feature extraction method, is Gray Level Run Length Matrix

(GLRLM), can be used to extract the higher order statistical features in a US kidney images. Unlike GLCM, the GLRLM is a two dimensional matrix of $N_g \times R$ element in which each element $P(k, l|0)$ gives the total occurrence of runs having length k of gray level L in a given direction, with R representing the longest run. All the seven statistical features namely, Short Runs Emphasis, Long Runs Emphasis, Gray Level Non Uniformity, Run Length No uniformity, Run Percentage, Low Gray level Runs Emphasis, and High Gray level Runs Emphasis are used in this work. [21].

C. Data Mining / Classifier

The principle behind the classification stage is to categorize the input image into normal or abnormal class depending on the features extracted, based on statistical parameters. The data mining techniques like SVM, KNN, MLP and RF are used in the present work for classification of clinical and laboratory data samples.

1) *Support Vector Machine (SVM)*: SVM classification is a non probabilistic linear binary classifier that analyzes the input data and predicts one of the two classes it belongs to, that are separated by hyper plane, constructed using structural risk minimization principle. The SVM is independent of the dimensionality of the feature space that outperforms as compared to other classifiers with minimum training samples. [27].

2) *K- Nearest Neighbour (KNN)*: Another important classifier used in clinical and laboratory data samples, K-NN classifier that classify the datasets according to majority of its neighbors belongs to. Selection of number of neighbours is elective and user defined. [17].

To select the K , for the data sets, the KNN algorithm is executed several times for different values of K , the optimal value of K is chosen so that number of errors is reduced. Euclidean distance is one of frequently used method for distance measures to find the K-NN and is given by,

$$\text{Euclidean} = \sqrt{\sum_{i=1}^k (x_i - y_i)^2} \quad (3)$$

The minimum distance between the training and test samples gives best classification of the test samples.

3) *Multilayer Perceptron Algorithm (MLP)*: Another significant class of classifier algorithm is MLP, consists of an input layer, one or more hidden layers, and the output layer, of which the output in different stage is activated either using linear or non-linear activation function. This algorithm is sub classified into two stages, wherein the feed forward stage, the output is estimated by weightage average of inputs and bias. In the backward stage, the errors are minimized by updating the weights [28].

4) *Random Forest (RF)*: Random forest algorithm works with the principle of creating the decision trees on data samples obtained, accumulate the prediction from each of the samples, and provides the optimal solution through voting. It is an ensemble method which is better than a single decision tree because it reduces the over-fitting by averaging the result.

Generally RF consists of many decision trees, and the features are randomly selected from the optional features, thus allowing the tree at each node to grow without trimming. RF algorithms reaches high accuracy even for a portion of the data is missing in the data samples [29].

IV. RESULT AND DISCUSSION

During the preprocessing stage for all the 400 laboratory samples, the patient ID is removed from the dataset and missing predictor attributes/variable values are replaced using data interpolation method. For the categorized attributes like Hypertension, Coronary Artery Disease, Appetite, Pedal Edema, Pus Cells, Pus Cells Clumps, Diabetes Mellitus, and Anemia, the digitizing label encoder was also applied. The resultant data sets are further subjected to data mining techniques as mentioned above. Each data attribute contains distinct and unique features that also help in classification of CKD, which was shown in Table I.

TABLE I. ATTRIBUTES DESCRIPTION USED IN THE ANALYSIS (PRED-PREDICTOR, NUM-NUMERICAL, NOM-NOMINAL, TAR-TARGET)

Sl.N O.	Dataset Attributes	Class	Type	Misssing	Distinct	Unique
1	Age	Pred	Num	9	76	16
2	Blood Presure	Pred	Num	12	10	3
3	Specific Gravity	Pred	Nom	47	5	0
4	Albumin	Pred	Nom	46	6	1
5	Sugar	Pred	Nom	49	6	0
6	Red Blood Cells	Pred	Nom	152	2	0
7	Pus Cells	Pred	Nom	65	2	0
8	Pus Cells Clumps	Pred	Nom	4	2	0
9	Bacteria	Pred	Nom	4	2	0

24	Anemia	Pred	Nom	1	2	0
25	Class	Tar	Nom	0	2	0

The next step is to use the mentioned-preprocessing filters for speckle noise reduction, applying for both normal and kidney stone US images of clinical data samples. The different spatial filters like, Median, Adaptive median, Weiner are used in estimating statistical parameters. Further, for the different noise variance (NV) varying from 0.01 to 0.08, the statistical parameters like Peak Signal to Noise Ratio (PSNR in dB), Signal to Noise Ratio (SNR in dB), Root Mean Square Error (RME) and Mean Absolute Error (MAE) are estimated for both normal and abnormal kidney images.

Further, for the US images, the experimentation begins with removal of background and labels associated with kidney images for both normal and kidney stone US Images, followed by enhancing the contrast and sharpening the quality of image for better performance as shown Fig. 2.

Fig. 2. (a) Normal Kidney Image. (b) Removal of Background and Label of Kidney Images. (c) Contrasted Image and Sharpened Image.

Table II represents statistical analysis of noise variance for different filters used in preprocessing of US images. The NV values from 0.01 to 0.08, for different filters, the statistical parameters like PSNR, SNR, MAE and RME are calculated and only the optimal values are provided in Table II. For Kidney stone US images, the adaptive median filter with NV value of 0.01 gives PSNR as 33.51dB and SNR of 18.01dB as compared with other filters. Likewise, the same method was applied to normal kidney US images and results are tabulated. The presence of kidney stone decreases the PSNR and SNR as compared to normal US images with the variation in RME and MAE.

Fig. 3 shows the preprocessed normal US images, from (a-c), and kidney stone US images from (d-f). It is evident that the speckle noise is reduced relatively better using median filter, but image is blurred and artifacts are introduced, as compared with other filters. In case of Adaptive filter, maximum speckle noise reduction is observed, and the edges features are well preserved. In Weiner filter, image is subjected to over enhancement, resulting in reduction in speckle noise, but posing diagnosis problems. Likewise, the same US images are also subjected to Neigh SURE Shrink wavelet filters with haar, db4, sym-8, and for decomposition levels 2 and 4.

From Fig. 4, for decomposition level-4, Wavelet Neigh SURE shrink along with haar, db-4, sym8, increases the contrast resolution that leads to superior visual quality. This, in turn, enhances the quality of kidney stone boundaries, reducing the speckle noise, increasing the SNR, when compared to decomposition level-2, thus, improving the image quality for further diagnosis. Likewise, comparing the decomposition level 2 and level 4, it is observed that decomposition level 4 improves the PSNR and SNR.

TABLE II. STATISTICAL ANALYSIS OF NV AGAINST DIFFERENT PREPROCESSING FILTERS

Kidney Stone US image					
Filter	Noise variance	PSNR in dB	SNR in dB	RME	MAE
Median	0.01	31.73	16.23	6.60	1.49
Adaptive Median	0.01	33.51	18.01	5.38	1.70
Weiner	0.04	31.85	16.35	6.51	2.58
Normal Kidney US image					
Median	0.01	30.84	18.50	7.31	3.74
Adaptive Median	0.01	33.70	21.36	5.26	2.76
Weiner	0.05	35.29	23.29	4.21	2.24

Fig. 3. (a-c) Results of Median Filter, Adaptive Median, Weiner Filter for Normal US Image (d-f) Results of Median Filter, Adaptive Median, Weiner Filter for Kidney Stone US Images.

Fig. 4. Preprocessing Filters of Kidney Stone US Image, (a-b) Sys8 Level 2 and 4 Decomposition, (c-d) db4 Level 2 and 4 Decomposition, (e-f) Haar Level 2 and 4 Decomposition.

In Table III, it is observed that Neigh SURE shrink with sym8 for decomposition level 4 of kidney stone images, PSNR is found to be 41.82dB and SNR of 26.36dB, along with reduction in RME and MAE respectively. The presence of kidney stone in US images reduces PSNR and SNR values, compared to normal kidney images. Comparing Tables II and III, the increase in PSNR and SNR, reduction of RME and MAE can be observed. In Conclusion, sym8 Neigh SURE shrink filter is a far superior filter that can be employed in US Image preprocessing method.

TABLE III. STATISTICAL ANALYSIS OF NV AGAINST DIFFERENT WAVELET FILTERS

Kidney Stone US image					
Neigh SURE shrink	Decomposition Level	PSNR in dB	SNR in dB	RME	MAE
db4	4	41.62	26.12	2.11	1.34
Haar	4	41.33	25.83	2.18	1.37
sym8	4	41.86	26.36	2.03	1.30
Normal Kidney US image					
db4	4	41.70	29.36	2.09	1.46
Haar	4	40.10	27.75	2.51	1.72
sym8	4	42.21	29.87	1.97	1.39

Fig. 5 depicts the GUI developed using MATLAB, to detect the presence/absence of the kidney stone in US images Upon GLCM and GLRLM feature extraction, the next step in image processing is to classify the kidney US Images into normal and kidney stone US images. The normal and kidney stone US Images together are used in training and validation process for classification. A data mining/Classifier performance measure is based on accuracy, precision, recall and F-1 Score, i.e. number of sample that can be into normal or abnormal classes, hence this work proposes the application of SVM, KNN, MLP and RF classifier for the classification US images with tenfold cross validation to train and validate the classifiers.

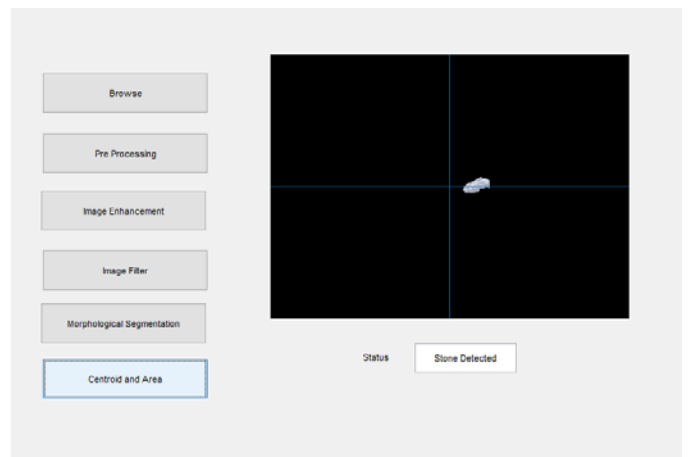

Fig. 5. RoI along with Graphical User Interface (GUI) to Detect the Presence of Kidney Stone.

True positive, True Negative, False Positive and False Negative are the confusion matrix features that are used for measuring the accuracy, precision, Recall, and F-1 Score of the classifier system. All these parameters are characterized by below relation.

$$\text{True Positive (TP)} = \frac{\text{Number of Image with kidney stone}}{\text{Total Number of kidney Images}}$$

$$\text{True Negative(TN)} = \frac{\text{Number of Images without kidney stone}}{\text{Total number of kidney Images}}$$

$$\text{False Positive(FP)} = \frac{\text{Number of Images falsely detected as kidney stone}}{\text{Total Number of kidney Images}}$$

$$\text{False Negative(FN)} = \frac{\text{Number of Images having kidney stone but not detected}}{\text{Total Number of kidney Images}}$$

$$\text{False Negative(FN)} = \frac{\text{Number of Images having kidney stone but not detected}}{\text{Total Number of kidney Images}}$$

$$\text{Accuracy} = \frac{(TP + TN)}{(TP + TN + FP + FN)}$$

$$\text{Recall} = \frac{TP}{TP + FN}$$

$$\text{Precision} = \frac{TP}{TP + FP}$$

$$\text{F1 Score} = \frac{TP}{TP + \frac{1}{2}(FP + FN)}$$

Table IV depicts the classifier category of clinical and laboratory samples using different data mining techniques. From Table IV it is observed that, the KNN algorithm yields better results of 100% precision, accuracy against other classifier for clinical sample or kidney US images. Subsequently increase in accuracy precision, Recall and F-1 Score are also noticed in below table. Likewise, for laboratory samples, RF algorithm reached maximum accuracy of 100% along with other performance parameters against different data mining techniques.

TABLE IV. PERFORMANCE EVALUATION FOR CLINICAL AND LABORATORY DATA SAMPLES

Performance Evaluation (%)				
Clinical data sets- US images				
Classifier	Precision	Recall	F1 Score	Accuracy
Support Vector Machine	0.77	0.62	0.58	0.62
K Nearest Neighbour	1.0	1.0	1.0	1.0
Multi Layer Perceptron	0.58	0.57	0.56	0.57
Random Forest	0.88	0.87	0.87	0.87
Laboratory data sets- Blood sample				
Support Vector Machine	0.61	0.61	0.57	0.61
K Nearest Neighbour	0.88	0.88	0.88	0.88
Multi Layer Perceptron	0.83	0.71	0.70	0.71
Random Forest	1.0	1.0	1.0	1.0

Furthermore, the experimental results obtained from the work are compared with the results obtained from similar works and are tabulated as depicted in Table V. By optimal selection of nose variance value from the results obtained, it is observed that the machine learning algorithm KNN when applied to US images reaches a maximum accuracy, whereas the Random Forest algorithm yields an accuracy of 87%. Extending further, for the laboratory samples, the experimental results obtained for Random forest with that of enhanced decision tree algorithm, with KNN reaching an accuracy of 88%. Of all the comparative analysis carried out, it is evident from the experimental results that KNN best suits for detecting the Kidney stone using US technique.

TABLE V. COMPARATIVE ANALYSIS OF DATA MINING METHODS FOR CKD

Ref.No.	Kidney category	Feature Extraction	Classifier	Accuracy (%)
A. Clinical Data samples				
[30]	Normal, abnormal	PCA	SVM, KNN	84, 89
[21]	Normal, abnormal	Gradient features, GLCM	SVM	85.8±3.1
[31]	Normal, abnormal	Statistical features GLCM	SVM	85.7
[32]	Normal, abnormal	GLCM	ANN	87.5
[33]	Normal, abnormal	Gobar features	ANN	87.06

This work	Normal, abnormal	Physiological and Clinical Attributes	RF,KNN	100,88.0

V. CONCLUSION

The main focus of this work is to find the optimal data mining algorithms for both clinical and laboratory data sets. This work also characterizes the NV parameter varying from 0.01 to 0.08 against the statistical parameters like SNR, PSNR, RME and MAE for different preprocessing filters like spatial and wavelet filters for US images, and find the best filter can be used for preprocessing the US Images. From the experimental results it is evident that, sym8 decomposition level 4, provide increased SNR (29.87dB), PSNR (42.21dB), with reduction in RME (1.97) and MAE (1.3921) as compared other filtering methods. Further, morphological operations like erosion and dilation were applied to segment the filtered US image. By applying entropy based segmentation and morphological operations, feature extraction, RoI and exact area of kidney stone can be located for kidney stone US image. In classifying clinical and laboratory data sets different data mining techniques such as SVM, KNN, MLP and RF are used. The RF and KNN reaches good accuracy up to 100% for laboratory and clinical data sets against other techniques discussed above.

The notable limitation of this work is direct comparison of experimental result obtained with result obtained from similar work is beyond scope of this work, as kidney US Images obtained vary between hospitals. To author knowledge this is the first work to use NV from 0.01 to 0.08 against statistical parameters. Further increase in noise value may not directly improve the PSNR, SNR or decreases in RME and MAE.

This work recommends the use of KNN for kidney US Images and RF for laboratory samples that can be used for physicians in order to eliminate diagnostic and treatment errors. To assist the medical doctor for further treatment, a GUI was developed, that helps in detection of kidney stone and its area with minimum effort.

Comparing the Balanced Accuracy of Deep Neural Network and Machine Learning for Predicting the Depressive Disorder of Multicultural Youth

Haewon Byeon

Department of Medical Big Data
College of AI Convergence, Inje University, Gimhae 50834, Republic of Korea

Abstract—Multicultural youth are more likely to experience negative emotions (e.g. depressive symptoms) due to social prejudice and discrimination. Nevertheless, previous studies that analyzed the emotional aspects of multicultural youth mainly compared the characteristics of multicultural youth and those of the other youth or identified individual risk factors using a regression model. This study developed models to predict the depressive disorders of multicultural youth based on the Quick Unbiased Efficient Statistical Tree (QUEST), Classification And Regression Trees (CART), gradient boosting machine (G-B-M), random forest, and deep neural network (deep-NN) using epidemiological data representing multicultural youth and compared the prediction performance (PRED PER) of the developed models. Our study analyzed 19,431 youths (9,835 males and 9,596 females) aged between 19 and 24 years old. We developed models for predicting the self-awareness of health of youths by using QUEST, CART, G-B-M, random forest, and deep-NN and compared the balanced accuracy of them to evaluate their PRED PER. Among 19,431 subjects, 42.9% (5,838 people) experienced a depressive disorder in the past year. The results of our study confirmed that deep-NN had the best PRED PER with a specificity of 0.85, a sensitivity of 0.71, and a balanced accuracy of 0.78. It will be necessary to develop a model with optimal PRED PER by tuning hyperparameters (e.g., number of hidden layers, number of iterations, and activation function, number of hidden nodes) of deep-NN.

Keywords—Quick unbiased efficient statistical tree; gradient boosting machine; deep neural network; classification and regression trees; balanced accuracy

I. INTRODUCTION

South Korea has shifted to a multicultural society at a very rapid pace over the past 30 years. As a result, the number of multicultural youth has been increasing rapidly. The Ministry of Education (2019)[1] reported that the number of multicultural youth students was 137,225 people (2.5% of all students) in 2019, which is a 200% increase // an increase by 200% from 67,806 people in 2014. Particularly, the total fertility rate (TFR) decreased to 0.918 as of 2019 [2] due to the low fertility trend in Korean society, and the proportion of children with multicultural backgrounds in the school-age population is predicted to increase continuously [1].

Nevertheless, most of the policy interests targeting multicultural families (MUC-fam) in Republic of Korea have emphasized employment and welfare aspects, and there are not enough surveys on the mental health of MUC-fam [3,4]. In

addition, studies conducted on multicultural youth have mainly focused on academic achievement or school adaptation, and emotional characteristics such as depression have been studied rarely [5].

Multicultural youth are more likely to experience negative emotions (e.g. depressive symptoms) due to social prejudice and discrimination [6]. Moreover, a national survey (epidemiological survey) [7] reported that the youth in low socioeconomic status such as low household income experienced a depressive disorder more. It was also implied that the multicultural youth were more likely to be exposed to negative emotionality since the proportion of MUC-fam in rural areas was higher than that in cities and only 9.7% of multicultural households made KRW 30 million or more per year. Above all, Byeon (2014)[8] revealed that approximately 15% of multicultural youth aged between 19 and 24 years old experienced social discrimination and children of international marriage families born in South Korea and immigrant children of international marriage families had difficulties in social adaptation due to the social characteristics of MUC-fam and rapid changes in adolescence. Since multicultural youth are highly likely to have multiple factors associated with a depressive disorder (e.g., sociodemographic factors and personal characteristics), they are believed to experience a depressive disorder more than the other youth. Nevertheless, previous studies [9,10,11,12] that analyzed the emotional aspects of multicultural youth mainly compared the characteristics of multicultural youth and those of the other youth or identified individual risk factors using a regression model.

It is necessary to develop a prediction model based on big data to grasp the characteristics of a depressive disorder because emotional issues are induced by multidimensional factors such as stress, social support, and environment. In recent years, machine learning (Mach Learn) has been widely used in various fields as a means to overcome the limitations of the Mach Learn regression model. This study developed models to predict the depressive disorders of multicultural youth based on quick unbiased efficient statistical tree (QUEST), classification and regression trees (CART), gradient boosting machine (G-B-M), random forest, and deep neural network (deep-NN) using epidemiological data representing multicultural youth and compared the prediction performance (PRED PER) of the developed models.

II. METHODS AND MATERIALS

A. Source of Data

This study analyzed the raw data of the National Survey of MUC-fam on MUC-fam residing in South Korea in 2012 jointly conducted by the Ministry of Health, Welfare and Family Affairs (MHWFA), the Ministry of Justice (MJ), and the Ministry of Gender Equality (MGE). The National Survey of MUC-fam was carried out to grasp the living conditions and welfare needs of MUC-fam to develop policies customized for MUC-fam [2]. This national survey consists of economic level, general characteristics, marital life, employment, health and health care. The National Survey of MUC-fam was conducted July 20 to October 31, 2012, and targeted all 154,333 marriage immigrants by using the status of foreign residents and the basic status of MUC-fam by the Ministry of Public Administration and Security (MPAS). The selection criteria for MUC-fam were based on the MUC-fam Support Act: this study targeted (1) families composed of marriage immigrants and South Korean citizens and (2) those composed of foreigners who obtained South Korean citizenship by acknowledgment or naturalization and South Korean citizens who obtained Republic of Korean citizenship by naturalization, birth or acknowledgment. This study analyzed 19,431 youths aged between 19 and 24 years old (9,835 males and 9,596 females) among the children of marriage immigrants (MI).

B. Measurement of Variables

A depressive disorder, the outcome variable, was divided into “experienced a depressive disorder” and “did not experience a depressive disorder” based on the question, “Have you ever felt sad or despair that lasted two weeks or longer in a row in the past year?”, of the Diagnostic and Statistical Manual of Mental Disorders-five [13], a diagnostic criterion for major depressive disorder. Explanatory variables included gender, education, residence area (rural or urban), economic activity (yes or no), social discrimination experience (yes or no), career counseling experience (yes or no), Korean language education experience (yes or no), the experience of using a support center for multi-cultural families (yes or no), level of Korean reading (good, average, or poor), level of Korean writing (good, average, or poor), level of Korean listening, level of Korean speaking, and experience of Korea society adaptation training (yes or no) by referring to previous studies [9,10,11,12] related to a depressive disorder.

C. Developing Models for Predicting a Depressive Disorder:

QUEST

QUEST [13] selects a significant variable among variables entered first, performs a quadratic discriminant analysis based on the selected variable, and selects a predictor for reducing the variable selection bias. The variable selection is made (1) by ANOVA F-statistics for continuous variables and (2) by choosing the various with the smallest probability as a classification variable for categorical variables using the chi-square test. It is characterized by selecting a threshold by finally conducting quadratic discriminant analysis for the classification variable selected in this process [14].

The QUEST algorithm for predicting and classifying variables is performed by the following procedure [15]. First,

the significance probability (p-value) of an ordinal or continuous predictor is calculated by the F-test of ANOVA. Second, when a categorical predictor is selected, the p-value of the cross-validation is calculated in the contingency table of predictor and target variables. If the p-value is smaller than the adjusted Bonferroni's threshold, the corresponding variable is selected as a classification variable. If there are more than 3 categories, it is replaced with a binary classification based on two-means clustering. Third, if a separation variable cannot be selected by the above two procedures, the p-value of the Levene F-test is calculated for an ordinal or continuous classification variable, and it is compared with the adjusted Bonferroni's threshold to finally select the variable corresponding to the p-value as the classification variable. This procedure is repeated until the condition is fully satisfied. For data composed of categorical variables, if the categories of outcome variables are three or more, the two-mean clustering consisting of two categories is performed. At this time, quadratic discriminant analysis is used to find the optimal threshold of explanatory variables, and child nodes are formed by finding explanatory variables that classify the outcome variables best.

D. CART

CART measures impurity using the Gini Index (Gini impurity) and performs a binary split in which only two child nodes are formed from a parent node [16]. The Gini impurity refers to the probability that two elements randomly extracted from n elements belong to different groups. When the decrement of the Gini Index is calculated, the predictor and the optimal threshold that decreases the Gini Index most are selected as child nodes, as the final step.

E. G-B-M

G-B-M is a Mach Learn algorithm that creates a strong learner (S-learner) by combining weak learners (W-learner) of decision trees (Decis Tree) by using an ensemble technique [17]. This method generalizes models by generating models for each step and optimizing the loss function (loss-func) that can be arbitrarily differentiated, like other boosting methods. Even if the accuracy is low, a model is created, and the error of the generated model is complemented by the next model. Through this process, more powerful learner), than the previous a learner, is created. The basic principle is to increase accuracy by repeating this process. The concept of G-B-M is presented in Fig. 1.

Algorithm	Gradient boosting algorithm.
Input:	Input data $(x, y)_{i=1}^N$ Number of iterations M Choice of the loss-function $\Psi(y, f)$ Choice of the base-learner model $h(x, \theta)$
1:	Initialize \hat{f}_0 with a constant
2:	for $t = 1$ to M do
3:	Compute the negative gradient $g_t(x)$;
4:	Fit a new base-learner function $h(x, \theta_t)$;
5:	Find the best gradient descent step-size p_t $p_t = \operatorname{argmin}_p \sum_{i=1}^N \Psi[y_i, \hat{f}_{t-1}(x_i) + p h(x_i, \theta_t)];$
6:	Update the function estimate: $\hat{f}_t \leftarrow \hat{f}_{t-1} + p_t h(x, \theta_t);$
7:	end for

Fig. 1. The Concept of G-B-M.

F. Random Forest

Random forest is a decision tree-based ensemble method that generates a large number of random samples (Rand Sam) from a training dataset through bootstrapping (random sampling with replacement of the same size from a given data), learns an independent Decis Tree for each sample (Eac Sam) set, and creates a final model by synthesizing the results. The structure of it is presented in Fig. 2.

G. Deep-NN

Deep-NN is an algorithm composed of an composed of independent variables, an composed of dependent variables, and two or more hidden layers between them. Independent node (Ind node)s are arranged in each layer of the input layer, the hidden layer, and the output layer. A group of nodes in each layer is connected by weighted neurons (connecting lines) (Fig. 3).

This study used H2O's deep-NN among various deep learning types. H2O's deep-NN is based on a multi-layer feedforward artificial neural network (A-NN) that is trained with stochastic gradient descent (Grad Des) using back-propagation (Back-propag). This study set two hidden layers with ten nodes in each layer (20 nodes in total) and five epochs (number of iterations). This study used the Rectifier Linear Unit (ReLU), default value, as the activation function of deep learning (Fig. 4).

H. Validation of the Models

This study developed models for predicting the subjective health of youth by using QUEST, CART, G-B-M, random forest, and H2O's deep-NN and compared the balanced accuracy of them to evaluate their PRED PER. Balanced accuracy is an index that considers sensitivity and specificity and presents the same value as the area under the curve (AUC), indicating the accuracy of a classification model. This study used 10-fold cross-validation (Cro-Valid) to validate the developed models.

Fig. 2. Structure of Random Forest Model [18].

Fig. 3. Layers of Deep-NN [19].

Fig. 4. The Concept of Rectified Linear Unit Activation Function [20].

In this study, a model containing randomness, such as random forest, was developed while fixing the seed to “435435”. This study defined the model with the highest accuracy as the model with the best PRED PER by comparing the PRED PER of these models. When the accuracy of multiple models was the same, the model with high sensitivity was defined as the model with the best PRED PER. All analyses were performed using R version 4.0.4 (Foundation for Statistical Computing, Vienna, Austria).

III. RESULTS

The general characteristics of subjects by depression experience are presented in Table I. Among 19,431 subjects, 42.9% (5,838 people) experienced a depressive disorder in the past year. The results of chi-square test showed the highest level of education, gender, economic activity, Korean language education experience, level of Korean speaking, Korean writing level, level of Korean listening, Korean reading level, Korea society adaptation training experience, career counseling experience, social discrimination experience, and experience of using a support center for MUC-fams were significantly (p<0.05) different between multicultural youth with a depressive disorder experience and those without a depressive disorder experience.

TABLE I. CHARACTERISTICS OF SUBJECTS BASED ON EXPERIENCE OF DEPRESSIVE DISORDER, N (%)

The balanced accuracy of five models (QUEST, CART, G-B-M, random forest, and H2O's deep-NN) for predicting a depressive disorder of multicultural youth is presented in Fig. 5. The results of our study confirmed that H2O's deep-NN had the best PRED PER with a specificity of 0.85, a sensitivity of 0.71, and a balanced accuracy of 0.78. The normalized importance of variables was analyzed using H2O's deep-NN. The major predictors of multicultural youth's depressive disorder were social discrimination experience, gender, level of Korean speaking, Korean writing level, and level of Korean listening (Fig. 6). Among them, social discrimination experience was the most important factor in predicting a depressive disorder (Fig. 6).

Fig. 5. Comparison of Balanced Accuracy of 5 Models for Predicting Depression, (%).

Fig. 6. Importance of Variables (Impor Var) in the Depression.

IV. CONCLUSION

Our study compared the balanced accuracy of models for predicting the depressive disorder of multicultural youth and confirmed that H2O's deep-NN was the model with the best PRED PER among QUEST, CART, G-B-M, random forest, and H2O's deep-NN. On the other hand, tree-based Mach Learns such as QUEST and CART had relatively low balanced accuracy compared to other Mach Learn methods. These results agreed with da Krauss et al. [21], which showed that the

prediction accuracy of deep-NN was better than gradient-boosted-trees or random forest. On the other hand, Grolinger et al. [22] reported that H2O's deep-NN had worse PRED PER than support vector regression and took longer computation time. These results imply that the most optimal algorithm with the best PRED PER may vary depending on the data type. Therefore, more follow-up studies are needed to compare the performance of Mach Learn and deep-NNs using various datasets with different characteristics.

Currently, various open-source platforms (e.g., Torch, MXNet, TensorFlow, Caffe, Theano, and H2O) have been developed for deep learning. Among them, the H2O platform provides access to Mach Learn algorithms through common development environments (e.g., Python, R, and JAVA), big data systems (e.g., Hadoop and Spark), and various data sources (e.g., SQL, NoSQL, HDFS, and S3). This study developed a model to predict the depressive disorder of multicultural youth using the defaults of the H2O platform (i.e., number of hidden layers, number of iterations, number of hidden nodes, and activation function). It was confirmed that the balanced accuracy of predict the depression was superior to that of other Mach Learn algorithms. It will be necessary to develop a model with optimal PRED PER by tuning hyper-parameters (e.g., number of hidden layers, number of iterations, number of hidden nodes, and activation function) of H2O's deep-NN.

Our study developed a model for predicting the depressive disorder experience of multicultural youth using H2O's deep-NN and found that social discrimination experience, gender, level of Korean speaking, Korean writing level, and level of Korean listening were related to the depressive disorder of multicultural youth. Among them, social discrimination experience was the most influential factor in predicting a depressive disorder. Consequently, it is required to prepare a legal system that can help multicultural youth overcome discrimination and prejudice and give attention to them at the social level.

Abstract—Cloud Server (CS) is an untrusted entity in cloud paradigm that may hide accidental data loss to maintain its reputation. Provable Data Possession (PDP) is a model that allows Third Party Auditor (TPA) to verify the integrity of outsourced data on behalf of cloud user without downloading the data files. But this public auditing model faces many security and performance issues such as: unnecessary computational burden on user as well as on TPA, to preserve identities of users from TPA during auditing, support for dynamic updates etc. Many PDP schemes creates computational burden either on TPA or Cloud User. To balance this overhead between TPA and User, this paper proposes Privacy-Preserving Dynamic Provable Data Possession (P²DPDP) scheme, which is based on ODPDP scheme. In ODPDP scheme, user relieves the burden by signing a contract with TPA regarding verification of his outsourced data. But this scheme generates computation overhead on TPA. To reduce this computation overhead of TPA, our P²DPDP scheme uses Indistinguishability Obfuscation (IO) with one-way function such as message authentication code to make a lightweight auditing process. P²DPDP scheme uses Rank-based Merkle Tree (RBMT) to support dynamic updates in batch mode which greatly reduces computation overhead of TPA. ODPDP lacks privacy which is maintained in P²DPDP using ring signature technique. Our experimental results demonstrate the reduced verification time and computation cost compared to existing schemes.

Keywords—Public auditing; ring signature; Indistinguishability Obfuscation; Rank-based Merkle Tree (RBMT)

I. INTRODUCTION

With the rapid development of cloud computing, many individuals or small-scale organizations started outsourcing their data on untrusted CS. This paradigm even though, proved to be a boon, has brought many security challenges with it. The user is not having physical ownership of data since outsourced data may be stored at any server. This outsourced data may get damaged unintentionally because of disk crashes or natural disasters. Sometimes CS may delete infrequent data intentionally to create space for new users. These incidents or data loss are not reported to cloud users to maintain reputation [1]. Provable Data Possession (PDP) is a technique that allows any user to check the integrity of data blocks outsourced on CS without downloading the entire data file. Many researchers have proposed cryptographic techniques using homomorphic authenticators [2]-[12]. Cloud users can check the integrity of outsourced data on their own but this frequent task creates an additional burden on the cloud user in terms of time and

computation cost. So, researchers have proposed solution in which user can delegate auditing work to TPA having expertise and skill. TPA generates a challenge message and CS has to produce the proof based on recent data. This proof is verified by TPA. This model has many security challenges since CS is one of the untrusted entities and TPA even if trusted, curious about auditing work.

Integrity checking during dynamic update operations of data is a major challenge in the PDP model. Authenticators have to be recalculated during insertion, deletion, and modification operations on data because most of the authenticators are calculated based on indices of files. Researchers have proposed dynamic auditing schemes using Merkle Hash Tree (MHT) [24]. MHT is a hash-based data structure used for data verification. Another data structure used for dynamic data updates are Index Hash Table (IHT) [5],[6] Dynamic Hash Table (DHT) [18]. These techniques need some additional information to store which may increase storage and computation cost. Guo et al. [21] proposed Multi-leaf-authenticated (MLA) scheme for dynamic data using Rank based Merkle Tree (RBMT). This scheme authenticates multiple leaf nodes at once without storing height and status value. With this scheme, multiple dynamic update operations can be performed in batch mode.

In auditing model, TPA is one of the trusted entity but still curious and may compromise data and user privacy. During auditing, TPA may infer user information who have signed the blocks. Researchers have given multiple approaches to address this issue. Some privacy-preserving protocols [39],[40] are proposed based on aggregate signature [14] or hash-based commitment [15] but auditing is not mentioned in these schemes. Huang et al. [18] proposed privacy-preserving scheme using group signature and blockchain. Tian et al. [20] also proposed a privacy-preserving scheme that addresses data privacy using random masking to blind the data proof. Identity privacy is preserved using a modification record table to record operation information. Different variations of signature algorithms, such as blind signature, random sampling, ID-based privacy, and attribute-based signature are used by multiple researchers during auditing [22]-[28]. Attribute-based signatures are based on attribute-based cryptography [16],[17]. Ring signature is another variation of group signature in which ring or group is formed with multiple users. User sign the blocks and share it among the group members. Verifier determines that block is signed by one of the group members

*Corresponding Author

but can't reveal who has signed the block. Certificateless authentication [29],[30] is one of the cryptographic techniques for authentication. Some authors proposed privacy-preserving integrity verification scheme [31],[32] using certificate-less ring signature which greatly reduces the computation cost during auditing. Li et al. [19] proposed integrity checking of group shared data using certificateless signature. Ni et al. [33] proposed lightweight ID-P²DPDP scheme in which privacy is achieved through zero-knowledge proof.

Many of the above auditing schemes are based on homomorphic authenticators which incur high computation cost and time during auditing. There is a need to propose a lightweight auditing process which can create a little burden on TPA as well as on cloud user. Indistinguishability Obfuscation (IO) is a modern cryptographic technique that uses one-way function for implementation of different cryptography constructs [35]. Researchers [36]-[38] proposed an efficient public verification scheme using IO combined with one-way function MAC which makes this scheme lightweight by generating very little burden on TPA. Tu et al. [13] proposed user-focus auditing which try to reduce the overhead of user by pre-generating challenges for TPA before auditing. Guo et al. [21] also proposed outsourced auditing scheme in which after each verification, TPA generates an audit data log which is checked later by the user. These schemes reduce the burden of verification on user. There is no need for a user to be available during verification, as per his convenience he can check the audit log.

Most of the auditing schemes create computational burden of tag generation and verification either on TPA or user. If we try to reduce the burden of TPA, it will increase the burden on user or vice-versa. Zhang et al. [36] scheme reduces the computation overhead of TPA but cloud user is actively involved in auditing process. Guo et al. [21] scheme proposes auditing scheme where user is not involved in auditing process but it creates computation burden on TPA because of Efficient Homomorphic Verifiable Tags (EHVT).

The remainder of this paper is described as follows: Section II describes related work, problem identification and contributions by authors. Section III elaborates basic building blocks of P²DPDP scheme. Section IV explains the P²DPDP scheme. Section V discusses the evaluation of P²DPDP scheme in terms of security and performance.

II. RELATED WORK, PROBLEM IDENTIFICATION AND RESEARCH CONTRIBUTION

A. Related Work

A good number of solutions have been proposed by many researchers [1]-[10] for integrity verification of outsourced data. In most of these schemes, cloud user and TPA are actively involved during verification phase. This may create an additional burden on cloud users as well as on TPA. Guo et al. [21] proposed ODPDP scheme which relieves user's verification overhead by migrating frequent auditing tasks to TPA. In this scheme, a contract takes place between user and TPA regarding the frequency of verification task. TPA generates challenges based on this contract. After each verification, a log file is generated at TPA which contains an

audit data log. User as per his convenience can check the log and make sure the integrity of his data as well as working of TPA. This scheme greatly reduces the overhead on user side. This scheme uses Multi-Leaf Authentication (MLA) solution with RBMT for dynamic data updates which greatly reduces storage cost as well as allows verification of multiple dynamic operations in batch mode.

To minimize the burden of TPA in terms of computations, it is necessary to develop a verification scheme which is lightweight in terms of computation. Zhang et al. [36] proposed lightweight auditing technique using IO and one-way function MAC. This greatly reduces the computation overhead of TPA during verification since TPA has to just calculate MAC each time and verify it with the received proof from CS. In this scheme, during outsourcing data at CS, a user has an additional overhead of generating circuit (audit program), obfuscating with MAC key, and send it to CS. But this is only a one-time cost to generate obfuscated program since it would not change along with the modification of public parameters and challenge message. This scheme uses Merkle Hash Tree (MHT) to support dynamic data updates on file.

In auditing model, generating privacy-preserving auditing technique is a major challenge because of the curious but trusted nature of TPA. Thokcham [34] proposed a privacy-preserving auditing technique using CDH based ring signature. This ring signature scheme is unforgeable and completely anonymous. Any ring member can sign a message using his private key and public keys of other members. So not every member needs to be present during the signing process. Using this scheme, anyone can check whether a signature is generated by a valid member of the group but at the same time not revealing the user's identity who has signed that message. Thus, preserving the identity privacy of user during verification from TPA.

ODPDP scheme reduces user overhead but increases burden on TPA in terms of computation. The computation cost on TPA in ODPDP during auditing is $(l+s+1)Exp_G + 2Pair$. Where l is number of challenged blocks, s denotes number of sectors per block, Exp_G is exponentiation operation on group G and $Pair$ is pairing operation. Compare to ODPDP scheme, Zhang et al. [36] scheme create less burden on TPA during auditing i.e., $2 Hash_{Z_p}$ where Hash is hashing operation on Z_p . It means TPA has to compute only 2 hash functions for verification. So proposed P²DPDP scheme modifies the ODPDP by using IO and MAC proposed by Zhang et al. scheme instead of EHVT of ODPDP for integrity verification. ODPDP scheme not proposing any solution for identity privacy. We extend this scheme by using CDH based ring signature to achieve identity privacy proposed by Thokcham [34]. P²DPDP also uses RBMT of ODPDP which allows verification of multiple dynamic operations in batch mode compared to MHT in Zhang et al. [36].

B. Problem Identification

To balance the computation overhead between user and TPA, this paper proposes Privacy-Preserving Dynamic Provable Data Possession (P²DPDP) scheme for cloud storage. In this scheme, the main purpose of using IO is to reduce the computation burden of TPA while maintaining security. Since

TPA only needs to validate the commitments generated by CS, user's data will not be revealed to TPA which preserve data privacy during auditing process. To avoid the continuous involvement of user during auditing process, Cloud user and TPA sign a contract which includes starting address of the block, the frequency at which auditor launches a challenge, and number of challenged blocks. TPA verifies the outsourced data based on contract and generates a log file which can be verified by user as per his convenience. For the support of dynamic updates, RBMT is used that can perform multiple update operations in a batch way. P²DPDP support user groups and preserve identity privacy by using CDH based ring signature scheme.

C. Research Contribution

Specifically, the contribution of our scheme P²DPDP is as follows:

- Guo et al. [21] proposed ODPDP scheme which uses Effective Homomorphic Verifiable Tag (EHVT) for integrity verification and RBMT for dynamic data processing. To make the auditing process lightweight and to reduce computation overhead of TPA, we modify the integrity verification scheme of ODPDP by using indistinguishability obfuscation of Zhang et al. [36].
- Guo et al. [21] scheme not offering a solution for identity privacy during auditing. We extend this ODPDP scheme to achieve group user privacy using CDH based ring signature.
- We describe a concrete P²DPDP scheme to be secure and lightweight by modifying ODPDP scheme. Experimental results certify the performance of our scheme.

III. PRELIMINARIES

This section introduces cryptographic building blocks used in P²DPDP scheme such as IO for integrity verification, MLA for dynamic updates and CDH based ring signature scheme for privacy-preserving.

A. Indistinguishability Obfuscation (IO)

Indistinguishability obfuscation is a notion that obfuscates any two distinct (equal size) programs that implement identical functionalities but computationally indistinguishable from each other [35].

Assume $\{C_l\}$ is a circuit class with security parameters l . A uniform PPT algorithm iO having input l , circuit $C \in \{C_l\}$ and outputs a circuit C' is called indistinguishable obfuscator if the following conditions are fulfilled:

1) For all security parameters l , Circuit C , and input x , we have probability as:

$$\Pr[C'(x)=C(x)]=1, \text{ where } C'=iO(l,C) \quad (1)$$

Equation (1) satisfies the completeness property of IO. It states that circuit C' must behave exactly same as circuit C if C' is generated by an independent invocation of iO on C .

2) For any (not essentially uniform) PPT adversaries D , for all security parameter $l \in \mathbb{N}$, for all pairs of circuits $C_0, C_1 \in C_l$, there exists a negligible function Negl such that if $C_0(x) = C_1(x)$ for all inputs x , then.

$$|\Pr[D(iO(l, C_0))=1] - \Pr[D(iO(l, C_1))=1]| \leq \text{Negl}(l) \quad (2)$$

Equation (2) satisfies the indistinguishability property of IO. It states that the secrets embedded in obfuscated program cannot be extracted by D .

Zhang et al. [36] proposed integrity verification using IO and one-way function MAC.

B. Multi-Leaf Authentication (MLA)

ODPDP scheme [21] proposed MLA for dynamic updates. This scheme uses RBMT instead of MHT to support authentication of indices of leaf nodes. In RBMT, no need to store height value as in MHT. Each node contains only two fields (r, h) where r is the rank of a node which is the number of leaf nodes reachable from node ω and h is a hash value of that node. Mainly, the rank of a leaf node is 1 i.e., $r=1$. The second element h is defined as in (3):

$$h = \begin{cases} H_2(m_i), & \text{if } \omega \text{ is the } i\text{th leaf node} \\ H_1(r || \omega.\text{left}.h || \omega.\text{right}.h), & \text{if } \omega \text{ is a nonleaf node} \end{cases} \quad (3)$$

where H_1 and H_2 be a secure collision-resistant hash function and $||$ denotes concatenation. The outsourced file F is divided into n blocks such as $F = \{f_1, f_2, \dots, f_n\}$. The i^{th} element f_i is bind to the i^{th} leaf node of RBMT by storing the hash value of f_i at node ω_i using H_2 in (3). Thus, leaf nodes are already sorted from left to right by their indices. For each non-leaf node, $\omega.\text{left}.hash$ and $\omega.\text{right}.hash$ indicates the hash value of the left node and right node respectively calculated using H_1 in (3). RBMT can be constructed for given n data blocks. A Merkle root h_{root} is sufficient to check the integrity of dynamic updates in a tree because of the dependency of all data blocks. Fig. 1 shows the RBMT constructed over 14 data blocks. In Fig.1, when multiple leaf nodes are challenged using MHT such as ω_3 and ω_7 , the proofs generated are $\Omega_3 = \{\omega_{26}, \omega_{22}, \omega_{15}, \omega_4, \omega_3\}$ and $\Omega_7 = \{\omega_{26}, \omega_{21}, \omega_{17}, \omega_{18}, \omega_7\}$. During verification using MHT, some repeated and unnecessary nodes have to be retrieved and processed that incur large computation costs. But using MLA solution, if multiple challenged nodes are $(3,7,8,10,13)$, the corresponding multi-proof \sqcup_p is:

$$\sqcup_p = \{\omega_3, \omega_7, \omega_8, \omega_{10}, \omega_{13}, \omega_{16}, \omega_{18}, \omega_{19}, \omega_{21}, \omega_{22}, \omega_{23}, \omega_{24}, \omega_{25}, \omega_{26}\}$$

where every necessary node appears just once which reduces computation cost as well as support multiple updates in batch mode.

C. CDH based Ring Signature Scheme

To achieve privacy during auditing, Thokcham [34] used CDH based ring signature which is one of the unforgeable and anonymous technique. No centralized entity is involved i.e., no concept of group manager. This scheme comprises two algorithms: Ring_sign and Ring-verify.

Fig. 1. RBMT Authentication Tree.

Ring-sign: This algorithm takes as input given message M . For a size of ring n , each group member chooses a secret key $Sk = x_i$ which belongs to Z_p and public key $Pk = g^{x_i}$.

- Signer t uses global parameter $d, u_0, u_1, \dots, u_l \in G_1$ of l random elements.
- Signer t will choose random $r_i \in Z_p$ for all other members of the group and generates $s_i = g^{r_i}$. Signer t again computes signature on behalf of group

$$s_t = (d \cdot \prod_{i=1, i \neq t}^n Pk_i^{r_i} (u_0 \cdot \prod_{j=1}^l u_j^{m_j})^{-r_{n+1}})^{1/x_t} \quad (4)$$

In (4), signer t computes signature s_t using his private key X_t with different parameters such as: public keys of n group members PK , the global parameter d, u_0, u_1, \dots, u_l , message M divided into l elements (M_1, \dots, M_l) , random number r . Final signature is $\sigma = (s_1, s_2, \dots, s_{n+1})$.

Ring-verify: As per (5), verifier verifies the signature using received ring signature σ , message M , and public keys PK of all members. The verifier checks the following equality.

$$\prod_{i=1}^n e(s_i, Pk_i) \cdot e(s_{n+1}, u_0 \prod_{j=1}^l u_j^{m_j}) = e(g, d) \quad (5)$$

In (5), using public keys PK , signature $(s_1, s_2, \dots, s_{n+1})$, and received message M , recomputes $\prod_{i=1}^n e(s_i, Pk_i) \cdot e(s_{n+1}, u_0 \prod_{j=1}^l u_j^{m_j})$. This recomputed part is verified using global parameter d and g .

IV. PROPOSED SCHEME

A. System Model

The framework for our P²DPDP scheme is as shown in Fig. 2. It consists of three entities: Cloud User, CS, and TPA.

- Cloud User: Cloud user is one of the members of user group who can share a file in a group. Users can check the integrity of shared files through an audit log generated by TPA.
- CS: an entity having the capability of computation and storage at its end. It is having the responsibility to maintain and manage outsourced files.

- TPA: an external entity that works on behalf of users and expertise in verifying the integrity of outsourced data.

The workflow for P²DPDP scheme from Fig. 2 is as follows:

- 1) Any cloud user from a group outsources data file on CS. Before outsourcing, user calculates the tag for each block, signs the blocks using a ring signature scheme.
- 2) The user constructs RBMT tree using hash values of file blocks. User generates circuit for auditing program, obfuscates it, and sends to CS. Shares MAC key to TPA as well as sign a contract with auditor regarding verification activity.
- 3) Based on the frequency mentioned in the contract, TPA generates challenges and performs auditing activity. During an audit, using CDH based ring signature, TPA verifies group signature using public keys of all members in a group.
- 4) Generates log file for each activity.
- 5) Users can check the log entry at any time to verify the integrity of an outsourced file.
- 6) For dynamic updates, user sends the update command uc to the TPA.
- 7) TPA updates the RBMT tree according to uc and sends updated proof to CS for verification. If verification successful, CS sends signed proof to user.
- 8) User verifies proof and if successful, send updated data blocks u_i to CS. CS updates data blocks accordingly.

B. Design Goals

To achieve privacy-preserving during integrity verification of outsourced data, proposed scheme P²DPDP should satisfy the following design objectives:

- 1) *Public verification*: to allow an external auditor to verify the integrity of outsourced data without downloading the data file.
- 2) *Privacy-Preserving*: data or user identity must not be revealed to TPA during auditing.
- 3) *Data Dynamic Support*: integrity verification process must support dynamic updations on outsourced data such as insert, delete and modify operations.
- 4) *Lightweight*: verification process must create minimum communication and computation overhead on user and TPA.

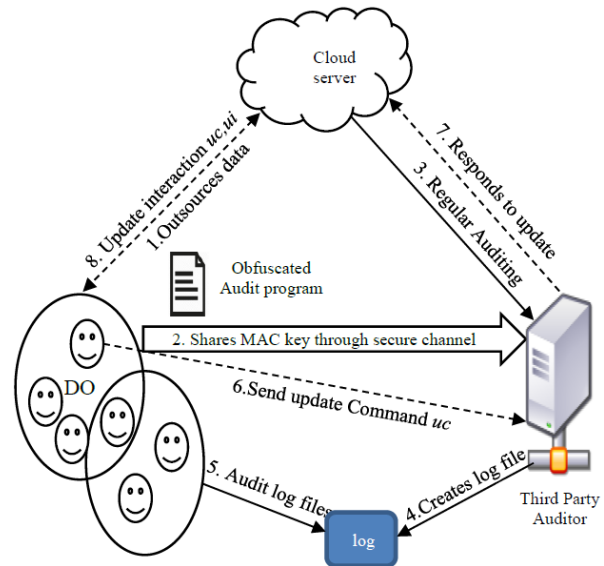

Fig. 2. Architecture of P²DPDP Scheme.

C. P²DPDP Scheme

Our proposed P²DPDP scheme works in four phases: Setup, Store, AuditData, and AuditLog.

Setup: Let G and G_T be two multiplicative groups produced by g with order p contains bilinear map $e: G \times G \rightarrow G_T$. User

U selects a signing key pair (ssk, spk) , α, v where $\alpha \rightarrow Z_p$ and $v = g^\alpha \in G$. U picks random elements u_1, u_2, \dots, u_s and fixes pseudorandom permutation, function key $\pi_{key}(\cdot)$ and $f_{key}(\cdot)$ respectively. The secret and public parameters are $sk=(\alpha, ssk)$ and $pk=(v, spk, u_1, u_2, \dots, u_s)$. Group members randomly select private key as $x_i \in Z_p$ Using key generation of CDH based ring signature scheme and $Pk_i = g^{x_i} \in G$ as a public key.

Store: Initially according to (6), U divides the file F into blocks n and sector s as in.

$$F = \{f_{i,j} \mid 1 \leq i \leq n, 1 \leq j \leq s\} \quad (6)$$

Tag Generation:

U chooses random element name for file and computes file tag as

$$\tau = \text{name} \parallel n \parallel u_1, u_2, \dots, u_s \parallel \text{sig}_{ssk}(\text{name} \parallel n \parallel u_1, u_2, \dots, u_s)$$

and data tag as in (7).

$$\sigma_i = (H(i \parallel \text{name})) \cdot \prod_{j=1}^s u_j^{f_{ij} \alpha}, i \in [1, n] \quad (7)$$

In (7), User calculates data tag for each block i of file F using random elements of each sector u_1, u_2, \dots, u_s and hash value of block number and file name. Here H is any secure hash function. U generates processed data M as $M = \{M, \phi\}$ where

$$\phi = \{\sigma_i, \tau\}_{i \in [1, n]}$$

Constructing RBMT:

U first calculates hash values for each block of file F using H_2 .

$$h_i = H_2(m_i) \text{ where } 1 \leq i \leq n$$

Then generate tree TR using RBMT on ordered hash values. Each leaf node w_i stores the corresponding hash value h_i .

Ring Signature Generation:

U has to sign a block on behalf of a group using CDH based ring signature scheme. U randomly chooses $u_0, r_i \in Z_p$ and compute signature for all other group members except U denoted by j in (8).

$$S_i = g^{r_i} \text{ for } i = \{1, 2, \dots, n+1\} \setminus \{j\} \quad (8)$$

Where, n - number of members in a group

j - serial number of the member in the signature who

is signing it

U computes signature for every member using respective random number r of that user. Then computes $h = H(\phi \parallel T)$ where T is a timestamp. U again computes S_j using (4).

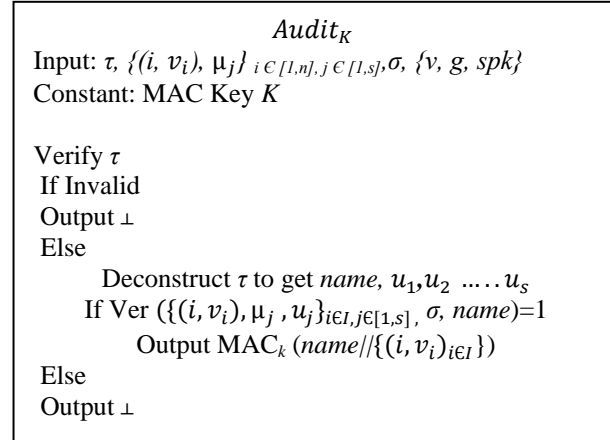

The signature at time T is

$$\phi^T = (S_1, S_2, \dots, S_{n+1}) \quad (9)$$

U outsources M and ϕ^T calculated as in (9) on CS. In (9), S_1, S_2, \dots, S_{n+1} is the signature generated for n users by U on behalf of group at time T .

Outsourcing Auditing Task:

During this task, U chooses a MAC key k and passes it to TPA using a secure network. U also produces a circuit **Audit_k** as described below.

This circuit is similar to auditing program which generate the MAC using embedded MAC Key K based on given input. Uniform PPT algorithm iO proceeds with audit circuit **Audit_k** as input and generates public parameter P as $P = iO(\text{Audit}_k)$.

$\text{Ver}(\{(i, v_i), \mu_j, u_j\}_{i \in [1, n], j \in [1, s]}, \sigma, \text{name})$ in circuit denotes checking of (10):

$$e(\sigma, g) = e(\prod_{i \in [1, n]} H(i \parallel \text{name})^{v_i} \cdot \prod_{j=1}^s u_j^{\mu_j}, v) \quad (10)$$

- U outsources RBMT tree TR with signature $\text{Sig}_{ssk}(TR)$ to TPA. If verification is successful, TPA accepts TR else rejected considering the malicious author.

Agreeing Parameters:

- All group members need to sign on a public parameter $P_{pub} = \{q, h_{root}\}$ where q is the number of data blocks and h_{root} is a Merkle root of TR .
- Contract CT is established between U and TPA as

$CT = \{BI, Fr, b\}$, where

BI- block index from which auditing work will start.

Fr- Frequency at which TPA launches a challenge.

b- number of challenged data blocks for checking.

AuditData Protocol: This protocol mainly deals with checking the integrity of outsourced data and log generation by TPA.

Auditing Phase:

- TPA generates a challenge message $Q^{(b)} = \{b, K_1^{(b)}, K_2^{(b)}\}$ using data blocks b to be audited. TPA

Generates pseudorandom permutation and function keys $\{K_1^{(b)}, K_2^{(b)}\}$ respectively and send to CS.

- CS computes $i = \pi K_1^{(b)}(\xi)$ and $v_i = f K_2^{(b)}(\xi)$ where $\xi \in [1, b]$ and b is the size of I (Input blocks to be audited). Based on public parameters and corresponding σ_i calculated using (7), $\tau, f_{i,j}$ and b , CS computes:

$$\sigma^{(b)} = \prod_{i \in I} \sigma_i^{v_i}, \mu_j = \sum_{i \in I} v_i f_{i,j} \text{ and}$$

$$PRF^{(b)} = P(\tau, \{(i, v_i), \mu_j\}_{i \in I}, \sigma^{(b)}, \{v, spk\}) \quad (11)$$

Equation (11) shows the proof PRF calculated by CS for challenged blocks b . PRF is calculated by executing audit circuit $Audit_K$ i.e. $P = iO(Audit_K)$ using input parameters $file\ tag\ \tau, \{(i, v_i), \mu_j\}, \sigma, \{v, g, spk\}$. CS send this $PRF^{(b)}$ and $Sig_{sk_{CS}}(PRF^{(b)})$ to TPA for verification.

- Using CDH based ring signature process, TPA verifies the group signature based on input signature ϕ^T , public keys $(Pk_1, Pk_2, \dots, Pk_n)$ of all members in a group, F^T and public parameter u_0 . TPA first calculate $h = H(\phi || T)$. Then verifies signature using (5).
- To verify the integrity of data, TPA computes $i = \pi K_1^{(b)}(\xi)$ and $v_i = f K_2^{(b)}(\xi)$ and compare MAC with $PRF^{(b)}$ calculated by CS using (11).

$$PRF^{(b)} = MAC_k(\text{name} || \{(i, v_i)_{i \in I}\}).$$

Log Generation:

After every audit, either successful or fail, TPA creates a log record of his auditing work.

$$L^{(b)} = \{t, Q^{(b)}, PRF^{(b)}, Sig_{sk_{CS}}(PRF^{(b)})\}$$

and saves in his local file Log_File .

AuditLog Protocol:

- U generates challenge using random subset B of file block indices and sends it to TPA. For each $b \in B$, TPA finds challenge $Q^{(b)}$, proof $PRF^{(b)}$ from his log file. Computes i, v_i from $Q^{(b)}$. TPA generates multi_audit proof \sqcup_p using h_{root} of TR and generates the proof of appointed log for subset B using (12).

$$PRF^B = \{ \sqcup_p, i, v_i, PRF^{(b)} \} \quad (12)$$

In (12), B indicates the challenge generated by U during $AuditLog$. Elements i, v_i denotes the challenge retrieved through log file for blocks b and $PRF^{(b)}$ indicates proof retrieved from log file for blocks b . \sqcup_p is a multi-audit proof generated from RBMT.

- TPA send a signed proof with his signature $Sig_{sk_{TPA}}(PRF^B)$ to U for verification. After verifying the signature, U computes new PRF as.

$$PRF_{new} = MAC_k(\text{name} || \{(i, v_i)_{i \in B}\})$$

- U compares if $PRF_{new} = PRF^B$. If matched, verification of outsourced data is successful else verification fails. U also verify \sqcup_p using h_{root} of TR .

D. Support for Dynamic Updates

P^2DPDP scheme support three types of update operations such as: deletion, insertion, and modification on blocks. If we perform these updates one by one, it will incur a large computation overhead at the auditor side to generate and verify the hash tree. To reduce this overhead, P^2DPDP is based on a MLA scheme using RBMT proposed by ODPDP which can handle updates in batch instead of one by one.

Initially, U computes all the hash and tag values of the new file block in $Store$ phase, generates the RBMT tree, and set public parameter as $P_{pub} = \{q, h_{root}\}$. U sends the update command uc to CS and TPA. U also generates audit circuit same as basic scheme but with modified verification function $VerD(\{(i, v_i), \mu_j, u_j, \sigma, name\}_{i \in I, j \in [1, s]})$ which consists of checking following equation:

$$e(\sigma, g) = e(\prod_{i \in I} H(\sum_{j=1}^s m_{ij})^{v_i} \cdot \prod_{j=1}^s u_j^{\mu_j}, v)$$

After receiving uc command, TPA updates leaf nodes, other affected nodes and generate an updated tree TR^* and its Merkle root h_{root}^* . TPA then sends the updated signed proof up to CS. CS verifies up by executing the audit circuit. U can also later check the correctness of up. If verification is successful, U sends updated information ui to CS and CS updates the processed data.

V. EVALUATION

In this section, P^2DPDP scheme is evaluated by showing correctness proof, security analysis, performance and experiment analysis.

A. Correctness Proof

$Audit_K$ is an audit circuit generated by U during $Store$ phase. Upon execution of this audit circuit, CS generates MAC based on challenge, block tag σ and using global parameters. Audit circuit contains verification function which denotes the realization of (10). Correctness proof for (10) is as follows:

$$\begin{aligned} e(\sigma, g) &= e(\prod_{i \in I} \sigma_i^{v_i}, g) \\ &= e(\prod_{i \in I} (H(i || name) \cdot \prod_{j=1}^s u_j^{f_{ij}})^{v_i}, g) \\ &= e(\prod_{i \in I} (H(i || name)^{v_i} \cdot \prod_{i \in I} \prod_{j=1}^s u_j^{f_{ij} v_i}), g) \\ &= e(\prod_{i \in I} (H(i || name)^{v_i} \cdot \prod_{j=1}^s u_j^{f_{ij}}), v_i) \end{aligned}$$

B. Security Analysis

Storage Correctness:

Theorem 1: If the CS successfully passes the verification from an auditor, then data outsourced on CS must be intact.

Proof: Assume user U outsourced data at CS using $Store$ protocol. But due to some problems, data at CS accidentally corrupted or deleted. With P^2DPDP scheme, malicious CS can't pass its verification. We prove this by game sequence as below:

- 1) Based on a contract signed between U and TPA, TPA generates a challenge using $AuditData$ Protocol.
- 2) For the challenged blocks, CS computes i, v_i . Using

- 3) Public parameters and (k_1, k_2) , CS computes \overline{PRF} and send to TPA.
- 4) TPA computes $i = \pi k_1(\xi)$ and $v_i = f k_2(\xi)$ where $\xi \in [1, c]$ and c is the size of I (Input blocks to be audited).
- 5) Using MAC_k , TPA calculates PRF and compares it with \overline{PRF} .
- 6) CS wins if TPA passes the verification even if $PRF \neq \overline{PRF}$.

But in above game, it's very difficult for malicious CS to cheat auditor because of HMAC scheme during verification.

Liability:

Theorem 2: An honest auditor can demonstrate that he did his work correctly in case of any disputes.

Proof: To prove the liability of the auditor, we consider two situations: when an auditor is honest or an auditor is dishonest. Consider first the auditor is honest. As per the contract between auditor and User, the auditor generates a challenge $Q^{(b)}$. User can reconstruct the challenge since the contract consists of number of data blocks to be audited. User can check the value of PRF by recalculating (11). Honest auditor generates a log file named Log_File which is the evidence for all the auditing work completed by auditor. So honest auditor can prove his liability by this Log_File.

Compare to this, if the auditor is malicious and not doing his work properly, user can use AuditLog Protocol to verify the behavior of auditor. By regenerating challenge, user can check the AuditLog file anytime and auditor can't deny his misbehavior.

Privacy-Preserving:

Theorem 3: From the server's response to the challenge message, TPA not able to infer any information such as data and identity of user.

Proof: During verification, user U first generates an audit circuit (which is nothing but an auditing algorithm program which is supposed to be originally executed by TPA). U obfuscates this circuit by embedding MAC key K and send to CS. For each verification, CS computes the inputs based on the challenge message and executes the obfuscated program. CS generates the MAC tag and sends it to TPA. TPA has to only verify the MAC tag to check the integrity of outsourced data. TPA needs to calculate i and v_i based on challenged blocks using the HMAC scheme. So, it is computationally infeasible for TPA to infer any information or user data using P^2DPDP .

P^2DPDP uses CDH based ring signature scheme to share any data among group members. In this scheme, user who want to share a file, computes signature on this data with his own private key using (4). During verification, TPA can verify the

signature with public keys of all users. Using this scheme, TPA can check whether the signature is computed by a valid user of group or not but scheme can't reveal individual user identity to verifier. Thus because of CDH based ring signature scheme and IO, P^2DPDP proved to be privacy-preserving.

C. Performance Analysis

We first evaluate the performance of P^2DPDP scheme which shows the privacy-preserving, lightweight auditing process. Also, we compare the performance of P^2DPDP with existing schemes.

The main important functionalities which we have considered for this work are: public auditing, dynamic data operations, privacy-preserving, and group support. Table I shows the functionality comparison of P^2DPDP scheme with existing schemes.

To evaluate the performance of P^2DPDP scheme, we evaluate the communication cost between CS and TPA during the proof generation and verification phase of *AuditData* protocol. Communication cost between the user and CS is not important since user uploads the data entirely to CS initially and user can verify the integrity of outsourced data during *AuditLog* protocol. During proof generation, TPA generates a challenge message $\{k_1, k_2\}$ for b number of blocks where k_1 and k_2 are transformed keys of HMAC. After receiving challenge message, CS generates proof PRF by calculating HMAC through the obfuscated program. So, communication overhead for proof generation is bH where H is any secure hash operation. After generating the proof PRF using HMAC, CS sends it to TPA. During verification, TPA checks the integrity of outsourced blocks using MAC key and verify

$$PRF = MAC_k(\text{name} || \{(i, v_i)_{i \in I}\})$$

So TPA has to calculate only HMAC. TPA also verifies the user signature by verification algorithm of CDH based ring signature. Using (5), TPA verifies the users n . So, the total communication overhead during verification is $H_{Z_p} + n$ where H_{Z_p} is hashing operation into Z_p .

User can check the integrity of outsourced data or performance of TPA during *AuditLog* protocol. So total Communication overhead during *AuditLog* is also H_{Z_p} . Table II shows the comparison of P^2DPDP scheme with the existing scheme. Fig. 3 shows the comparison between ORUTA, CORPA, and our P^2DPDP scheme for communication overhead in KB with respect to group size.

We can't compare this cost with ODPDP scheme since it doesn't support user groups. The comparison demonstrates the noticeable and constant performance of communication cost between CS and TPA during auditing in P^2DPDP scheme.

TABLE I. THE COMPARISON OF AUDITING FUNCTIONALITIES

Scheme	Third-Party Auditor	Dynamic Data Operation	User Group Support	Privacy Preserving
ORUTA [5]	Homomorphic Authenticators (HA)	Index Hash Table	Ring Signature	Homomorphic Authenticable Ring Signature (HARS)
Tian et al. [20]	Homomorphic Verifiable Authenticators (HVA)	Dynamic Hash Table	Group Signature	Random Masking
ODPDP [21]	Efficient HVA	Rank Based Merkle Tree (RBMT)	NA	NA
CORPA [23]	HA	Merkle Hash Tree (MHT)	Group Signature (GS)	HA+GS
Thokcham and Saikia[34]	Vector Commitment	MHT	CDH based Ring Signature	CDH based Ring Signature
Zhang et al. [36]	Indistinguishability Obfuscation (IO)	MHT	NA	NA
Proposed Scheme P ² DPDP	Indistinguishability Obfuscation (IO)	Rank Based Merkle Tree (RBMT)	CDH based Ring Signature	CDH based Ring Signature

TABLE II. COMMUNICATION COST

Scheme	Proof Generation	Proof Verification	
		AuditData	AuditLog
ORUTA [5]	$(s+nb)E+nbM+bsM+sH$	$(2s+b)E+(2s+b)M+nM+bH+(n+2)p$	NA
ODPDP [21]	$(2q+s+1)E$	$(b+s+1)E+2p$	$3E$
CORPA [23]	$H+M$	$2E+P+bE+bM$	NA
Proposed Scheme P ² DPDP	bH	$H+n$	$H+n$

s : Total no. of sectors
 n : Total no. of users in a group
 b : No. of challenged blocks
 q : Total no. of blocks
 E : Exponentiation operation
 M : Multiplication Operation
 H : Hash Operation
 P : Pairing Operation

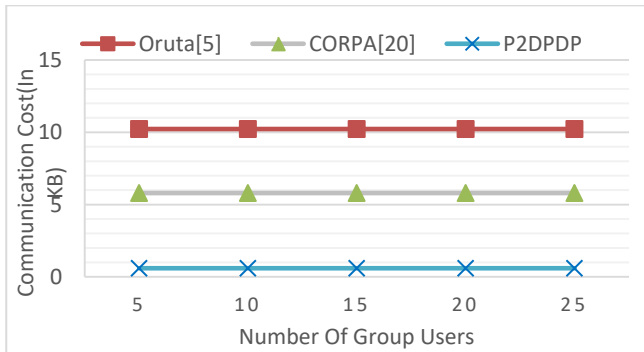

Fig. 3. Communication Cost w.r.t. Group Size.

D. Experimental Results

This section proves the performance of P²DPDP system in terms of different experiments. We deployed our P²DPDP scheme on a system comprising Windows 8.1 with an Intel Core i5-5200U CPU functioning at 2.20 GHz, 4.0 GB RAM. Python is used for module implementation of P²DPDP scheme. The hash algorithm is instantiated using SHA256. Fig. 4 shows the impact of number of users in a group on verification time during AuditData protocol. It shows that verification time is independent of the number of users. By creating a group of 25 users, we have compared the results with Oruta and CORPA

scheme. We have not considered ODPDP scheme for comparison since it doesn't support user groups. All results are average of 5 runs. For 20 users in P²DPDP scheme, the Verification time is 0.15 seconds. While Oruta, and CORPA are 2.24, and 1.75 seconds respectively. Result proves the effectiveness and lightness of our scheme because of reduced and constant verification time at auditor side during AuditData protocol. Since our P²DPDP scheme is based on ODPDP scheme, it is mandatory for us to compare results with this scheme. In both the schemes, verification is performed during AuditData and AuditLog protocol. Initially we compare the results of both schemes during AuditData where TPA performs audit based on contract and generate log entries. Fig. 5 shows the proof generation and verification time in seconds with respect to challenged data blocks during AuditData protocol.

To compare the results with ODPDP scheme, in P²DPDP scheme, the block size is kept fixed i.e., 16KB. Total outsourced data is 1GB. Fig. 5(a) shows the constant proof generation time in P²DPDP scheme as compared to ODPDP. Fig. 5(b) shows the gradual increase in proof verification time as number of challenged blocks is increasing in P²DPDP as compared to ODPDP scheme. Fig. 6 shows the performance of P²DPDP during AuditLog. It presents the computation time and communication cost required by user to verify the past work of TPA under the number of checked log entries.

Fig. 4. Impact of Number of Group users on Verification Time.

Fig. 5. (a) Proof Generation Time during AudiData Protocol w.r.t. Challenged Data Blocks; (b) Proof Verification Time during AudiData Protocol w.r.t. Challenged Data Blocks.

Fig. 6. (a) Computation Time for user to Check Log Entries w.r.t. Number of Checked Log Entries; (b) Communication Cost for user to Check Log Entries w.r.t. Number of Checked Log Entries.

For experiments, we have analyzed the computation time of our scheme up to 100 log entries. As expected, computation time is increasing linearly with number of checked log entries. But computation time of P²DPDP scheme is reduced as compared to ODPDP scheme.

Fig. 6 shows the communication cost during AuditLog protocol. Result shows that P²DPDP scheme is giving better performance in terms of communication cost compared to ODPDP.

VI. CONCLUSION

In most of the previous auditing scheme, Cloud user and TPA are actively involved during verification process which may create additional burden in terms of time and cost. This paper proposes P²DPDP scheme for cloud storage in which there is no need of user during verification process. TPA generates challenges based on the contract signed between TPA and user. TPA also generates log which can be audited by user as per his convenience. P²DPDP scheme also create the light-

weight verification process so as to reduce the computation burden of TPA using new cryptographic technique, Indistinguishability Obfuscation and MAC. P²DPDP support and manages user groups using CDH based ring signature scheme. CDH based ring signature is anonymous scheme which preserves the identity of users from TPA during auditing. P²DPDP scheme supports dynamic updates in batch mode using MLA solution proposed by ODPDP scheme which is based on RBMT.

Security analysis and experiments show that P²DPDP scheme is secure, lightweight and privacy-preserving. Communication cost during auditing between CS and TPA is almost constant and reduced compared to Oruta and CORPA since TPA has to just calculate MAC and compare it with MAC received from CS. Verification time is also reduced and constant compare to existing schemes. Experimental results reveal that verification time is independent of number of group users. Results of AudiLog protocol shows that P²DPDP scheme is performing better in terms of communication time and cost as compared to ODPDP scheme. CDH based ring signature generates certificates which need to be processed during verification leads to increase computation time. In terms of future work, we plan to modify P2DPDP scheme using certificateless signature schemes to reduce computation time.

Classification Model Evaluation Metrics

Željko Đ. Vujović

Boulevard Save Kovačevića 20/6
81000 Podgorica
Montenegro

Abstract—The purpose of this paper was to confirm the basic assumption that classification models are suitable for solving the problem of data set classifications. We selected four representative models: BaiesNet, NaiveBaies, MultilayerPerceptron, and J48, and applied them to a four-class classification of a specific set of hepatitis C virus data for Egyptian patients. We conducted the study using the WEKA software classification model, developed at Waikato University, New Zealand. Defeat results were obtained. None of the four classes envisaged has been determined reliably. We have described all 16 metrics, which are used to evaluate classification models, listed their characteristics, mutual differences, and the parameter that evaluates each of these metrics. We have presented comparative, tabular values that give each metric for each classification model in a concise form, detailed class accuracy with a table of best and worst metric values, confusion matrices for all four classification models, and a type I and II error table for all four classification models. In addition to the 16 metric classifications, which we described, we listed seven other metrics, which we did not use because we did not have the opportunity to show their application on the selected data set. Metrics were negatively rated selected, standard reliable, classification models. This led to the conclusion that the data in the selected data set should be pre-processed to be reliably classified by the classification model.

Keywords—Classification model; classification models; evaluate classification models; worst metric values; four-class classification; metric classification; reliable classified classification models; detailed class accuracy

Subject areas—Artificial intelligence and machine learning; software engineering

I. INTRODUCTION

A specific set of data on the hepatitis C virus, consisting of 1385 instances described with 29 attributes, was considered [12]. The goal is to classify these instances into four classes, which represent hepatitis diseases: class a - Portal fibrosis, class, b - Little sepsis, class, c - A lot of sepsis, and class d - Cirrhosis.[6] This paper challenges this classification. Sources in the literature suggest that classification into five classes would be better: class a-liver inflammation, class b-fibrosis, class c-cirrhosis, class d – end-stage disease (ESLD), and class e-cancer [15].

The initial assumption is that standard, generally accepted classification models, BayesNet, NaiveBayes, Multilayer-Perceptron, and J48, are suitable for such a classification. These models exist in the WEKA software and, as such, have been applied to the selected data set. Unsatisfactory results were obtained. Available instances are classified very poorly.

That was the reason, motive, and incentive to consider why this is so? These four models were chosen at random. In this introduction, we give their generally accepted definitions.

A Bayesian network is defined as a system of event probabilities, nodes in a directed acyclic graph, in which, the probability of an event can be calculated from the probabilities of its predecessors in the graph. The nodes in the network are variable. They can be concrete values, randomly given, latent values, or hypotheses. They are characterized by the distribution of probabilities. Probability is a quantity that touches a presented state of knowledge or a state of belief. In Bayesian opinion, the probability is assigned to a hypothesis. In frequency thinking, the hypothesis is tested without assigning a probability. The result of Bayesian analysis is Bayesian inference. It updates the previous probability assigned to the hypothesis because more evidence and information have been obtained [3], [16].

Naive Bayesian classifiers are based on naive assumptions of the mutual characteristics of independence. In this way, each distribution obtained can be independently estimated as a one-dimensional distribution. This alleviates the problems arising from the "curse of dimensionality". The "curse of dimensionality" is the problematic nature of the number of variables, which can be collected from a single sample. An example of this is the need for data sets that are scaled (arranged) exponentially with many characteristics [3],[14] [16], [18].

A multilayer perceptron is defined as a system composed of a series of elements (nodes - "neurons") organized into layers. Layers process information so that they react dynamically to external inputs. The input layer has one neuron for each component, which exists in the input data. Communicates with hidden layers in the network. The entire processing of input data takes place in hidden layers. The input data are weighted (measured) by appropriate coefficients. The neuron accepts them, calculates their sum, and processes it with an activation function. It processes the processed data in a "forward" process. The last hidden layer is connected to the output layer. The output layer has one neuron for each possible output.[3], [14] ,[16], [18].

J48 is a machine learning model based on the decision tree. It was created using the ID3 algorithm (Iterative Dichtomizer 3), developed by the WEKA project development team. The decision tree presents and analyzes decision-making situations when one type of decision is derived from another type of decision. This facilitates understanding of selection problems, assessment of available versions of the decision,

and coverage of uncertain events, which affect outcomes and versions of the decision [3],[14],[16],[18].

The first idea was to consider the metrics used to evaluate the classification models used. 16 metrics used by WEKA software were reviewed, described, and explained [4]. In addition, it was stated that there are, in addition to the above, the following metrics: False discovery rate, [21] Log Loss, [22] Barrier score, [23] Cumulative gain chart, [24] Lift curve, [25] Kolmogorov-Smirnov test, [26]. These metrics were not considered because they were not contained in the WEKA software, which was used. Therefore, they could not give their ratings of the classification model on the selected data set.

The research made a significant contribution to the interpretation of the 16 mentioned metrics, elements, and parameters that each of them uses to evaluate the classification models.

A significant contribution is also the question: why did the metrics negatively evaluate the classification models used on the selected data set?

As a result of this research, other questions arose. Is the number of attributes per instance of the observed data set too large? How many attributes are needed (optimal) and what are those attributes? Is it necessary to pre-process the data of the observed set? What are the techniques for pre-processing data in a set?

Unobtrusively, the question arose as to whether the four classes for the classification of instances of the observed set were correctly determined?

II. METRICS

1) Accurately classified instances are the sum of true positive (TP) and true negative (TN).

2) Incorrectly classified instances are the sum of false positives (FPs) and false negatives (FNs).

3) Kappa statistic - Cohen's Kappa coefficient (k) is a measure of how many instances are classified model of machine learning, matched the data marked as the basic truth, controlling the accuracy of the random classifier as measured, expected accuracy. The accuracy of the Random Accuracy is $1/k$. Here k is the number of classes in the data set. In the case of binary classification $k = 2$, so the accuracy is 50%.

$$K = \frac{(p0 - pe)}{(1 - pe)}$$

$p0$ - total accuracy of the module, pe - random accuracy (random accuracy of the model).

In the problem of binary classification $pe = pe1 + pe2$; $pe1$ - the probability that the predictions agree randomly with the actual values of class 1 - "good"; $pe2$ - the probability that the predictions agree randomly with the actual values of class 2 - "accidentally". The assumption is that the two classifiers (model prediction and actual class value) are independent. In this case, the probabilities $pe1$ and $pe2$ are calculated by

multiplying the share of things in the class and the share of the predicted class.[2],[20].

4) Mean Absolute Error is the mean value of the absolute values of individual prediction errors of all instances in the test set. Each prediction error is the difference between the actual value and the predicted value for the instance.

The mean absolute error (MAE) E_i of an individual model and is calculated by the formula:

$$E_i = \frac{1}{n} \sum_{j=1}^n \left| P_{(ij)} - \sum_{j=1}^n |P_{(ij)} - T_j| \right|$$

where $P_{(ij)}$ is the value predicted by the individual model i for record j (of n records); and T_j is the target value for record j . For a perfect prediction, $P_{(ij)} = T_j$ and $E_i = 0$. Thus, the index E_i ranges from 0 to infinity, and 0 corresponds to the ideal [14] [28].

5) Root mean squared error (RMSE) - The root mean square error is relative to what it would be if a simple predictor was used. Taking the square root of the relative square error, the error is reduced to the same dimensions as the predicted size.

The root mean square error (RMSE) E_i of an individual model and is calculated by the formula:

$$E_i = \sqrt{\frac{1}{n} \sum_{j=1}^n (P_{(ij)} - T_j)^2}$$

Where $P_{(ij)}$ is the value predicted by the individual model i for record j (of n records), and T_j is the target value for the record j . For a perfect prediction, $P_{(ij)} = T_j$ and $E_i = 0$. Thus, the index E_i ranges from 0 to infinity, and 0 corresponds to the ideal.[27].

6) Relative absolute error (RAE) is the total absolute error and normalized by dividing by the total absolute error of the simple predictor (ZeroR classifier). The relative absolute error E_i of an individual model is evaluated by the equation:

$$E_i = \frac{\sum_{j=1}^n |P_{(ij)} - T_j|}{\sum_{j=1}^n |T_j - \bar{T}|}$$

Where $P_{(ij)}$ is the value predicted by the individual model i for record j (of n records); T_j is the target value for record j , and \bar{T} is given by the formula:

$$\bar{T} = \frac{1}{n} \sum_{j=1}^n T_j$$

For a perfect prediction, the counter is 0 and $E_i = 0$. Thus, the index E_i ranges from 0 to infinity, and 0 corresponds to the ideal.

A good prediction model produces a near-zero ratio. A bad model (one that is worse than a naive model) will produce a ratio greater than one x100%.[27].

7) Root relative squared error (RRSE) reduces the error to the same dimensions as the predicted size. Relative square error is the total square error divided by the total square error of a simple predictor. The root of the relative square error E_i of an individual model j is calculated by the formula:

$$E_i = \sqrt{\frac{\sum_{j=1}^n (P_{(ij)} - T_j)^2}{\sum_{j=1}^n (T_j - \bar{T})^2}}$$

Where $P_{(ij)}$ is the value predicted by the individual model i for record j (of n records). For perfect prediction, the counter is equal to 0 and $E_i = 0$. The index E_i ranges from 0 to infinity, and 0 corresponds to the ideal [28].

8) Confusion matrix for a binary classifier (Fig. 1). Actual values are marked True (1) and False (0), and are predicted as Positive (1) and Negative (0). Estimates of the possibilities of classification models are derived from the expressions TP, TN, FP, FN, which exist in the confusion matrix [10].

Class designation		Actual class	
		True (1)	False (0)
Predicted class	Positive (1)	TP	FP
	Negative (0)	FN	TN

Fig. 1. Confusion Matrix for the Binary Classification Problem [7].

TP (True Positive) - The data point in the confusion matrix is True Positive (TP) when a positive outcome is predicted and what happened is the same.

FP (False Positive) - The data point in the confusion matrix is false positive when a positive outcome is predicted, and what happened is a negative outcome. This scenario is known as a Type 1 Error. It is like a boon in bad foresight.

FN (False Negative) - The data point in the confusion matrix is false negative when a negative outcome is predicted, and what happened is a positive outcome. This scenario is well known as a Type 2 Error and is considered as dangerous as a Type 1 Error.

TN (True Negative) - The data point in the confusion matrix is True Negative (TN) when a negative outcome is predicted and what happens is the same. The results of the binary classification shown in Fig. 2.

Confusion matrix for four-class classification (Fig. 3). Four-class classification is a problem of classifying instances (examples) into four classes. Case of four classes: class A, class B, class C, and class D [13],[17].

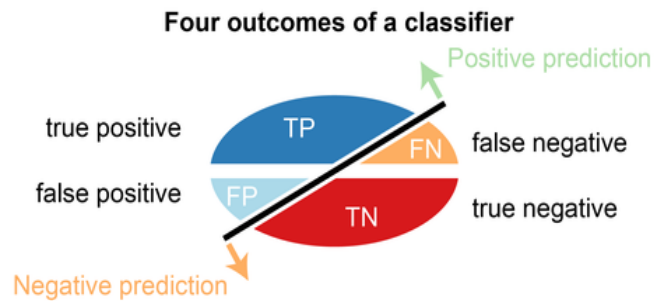

Fig. 2. Elliptical Representation of Four Binary Results of the Test Set Classification [7].

		Actual value			
		A	B	C	D
Predicted value	A	100	0	0	0
	B	80	9	1	1
	C	10	0	8	0
	D	10	1	1	9

Fig. 3. Confusion Matrix for the Four-class Classification Problem [8].

9) Accuracy is calculated as the sum of two accurate predictions (TP + TN) divided by the total number of data sets (P + N). The best accuracy is 1.0, and the worst is 0.00 (Fig. 4) [19].

Fig. 4. Two ellipses show how accuracy is calculated [7],[11].

10)TP Rate - True Positive Rate (Sensitivity or Recall) is calculated as the number of accurate positive predictions (TP) divided by the total number of positive (P). Also called Sensitivity or Recall (REC). The best TP Rate is 1.0 and the worst 0.0 (Fig. 5) [19].

Fig. 5. Two Ellipses Show How the Sensitivity is Calculated [7].

11)FP Rate - False Positive Rate is calculated as the number of false-positive predictions (FP) divided by the total number of negatives (N). The best false positive rate is 0.0 and the worst is 1.0. It can also be calculated as 1-specificity (Fig. 6) [19].

Fig. 6. Two Ellipses Show How the False Positive Rate - FPR is Calculated [7].

12) Precision is calculated as the number of correct positive predictions (TP), divided by the total number of positive predictions (TP + FP). The best accuracy is 1.0 and the worst 0.0 (Fig. 7) [19].

Fig. 7. Two Ellipses Show How Precision is Calculated [7],[11].

13) True Negative Rate – TNR (Specificity) - is calculated as the number of correct negative predictions (TN) divided by the total number of negatives (N). The best specificity is 1.0 and the worst 0.0 (Fig. 8) [19].

Fig. 8. Two Ellipses Show How Specificity (SP) is Calculated [7].

14) F-Measure or F-score is a measure of the accuracy of the test. It is calculated, based on precision and reminders, by the formula:

$$F-Score = \frac{2 \times precision \times recall}{precision + recall} [7],[11],[19]$$

15) Matthews Correlation Coefficient (MCC) - is the correlation between the predicted classes and the basic truth. It is calculated based on the values from the confusion matrix.

$$MCC = \frac{TP}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

MCC is generally considered a balanced measure, which can be used even if the classes are of very different sizes [7],[11],[19].

16) ROC Area - Receiver Operating Characteristic Area - The ROC curve is a graph that visualizes the trade-off between True Positive Rate and False Positive Rate (Fig. 9)

For each threshold, we calculate True Positive Rate and False Positive Rate and plot them on one graph. The higher the True Positive Rate and the lower the False Positive Rate for each threshold, the better. Better classifiers have more curves on the left. The area below the ROC curve is called the ROC curve AUC score, a number that determines how good the ROC curve is [11].

The ROC AUC Score shows how good the model is in ranking predictions. Indicates the probability that a randomly selected positive instance is ranked higher than a randomly negative instance [7],[19].

17) PRC Area (Precision-Recall Curve Area) It is one number that describes the capabilities of the model. The PR AUC Score is the average of the precision scores calculated for each reminder threshold [0,0, 1,0]. The PRC curve is obtained by combining Positive Predictive Value and True Positive Rate (Fig. 10). For each threshold, Positive Predictive Value and True Positive Rate are calculated and the corresponding point of the graph is plotted. Preferably, the algorithm has high precision and high sensitivity. These two metrics are not independent. That is why a compromise is being made between them. A good PRC curve has a higher AUC. Research has shown that PRC is graphically more informative than ROC graphs when estimating binary classifiers on unbalanced sets [5],[9],[19].

Fig. 9. ROC Curve [1],[5].

Fig. 10. Precision-Recall Curve [9].

III. EXPERIMENTAL RESULTS

The best and worst values of each general metric are used to measure the accuracy of the classifier. Metrics are in rows and values are in columns of the table.

Summary of the accuracy of the four representative classifiers expressed by general metrics. Metrics are listed in the rows of the table, and their values, for each classifier, in the columns of the table. A special number is the total number of instances, which is the same for each classifier.

The detailed accuracy of each of the four representative classifiers for each of the predictions of the class is expressed by the values of eight different metrics. Metrics are in the columns of the table, the names of the classifiers in the rows of the table, separately for each class. For each class, the weighted value of each of the eight metrics is shown. This value is the average that results from multiplying each component by a factor that reflects its significance.

TABLE I. METRICS SUMMARY

	Bayes Net	Naïve Bayes	Multilayer Perceptron	J48
Correctly classified instances	318	362	368	350
Incorrectly classified instances	1007	1023	1017	1035
Kappa statistic	-0,0287	0	0,0206	0,0029
Mean absolute error	0,3763	0,3748	0,3718	0,3751
Root mean squared error	0,4393	0,4329	0,5466	0,5814
Relative squared error	100,382%	99,9999%	99,2009%	100,0671%
Root relative squared error	101,4822%	100%	126,2575%	134,2938%
Total number of instances	1385	1385	1385	1385

TABLE II. TABLE OF BEST AND WORST METRIC VALUES FOR DETAILED CLASS ACCURACY

	The Best	The Worst
TP Rate	1,0	0,0
FP Rate	0,0	1,0
Precision	1,0	0,0
Recall	1,0	0,0
F-Measure	1,0	0,0
MCC	+1,0	0,0
ROC Area	0,9	0,5
PRC Area	1,0	0,5

Comparative table of four confusion matrices for all four representative classifiers. In the rows, the number is provided for each class, and in the columns the actual value of the class.

Comparative table of Type I and Type II error values for each class and each representative classifier. There are types of errors in the rows, and their size in the columns.

IV. DISCUSSION

The average value of correctly classified instances is 25.24%, and incorrectly classified instances 73.68% (Table 1).

Landis and Koch proposed the following standards for the kappa coefficient: ≤ 0 = poor, $.01 - .20$ = insignificant, $.21 - .40$ = fair, $.41 - .60$ = moderate, $.61 - .80$ = substantial, $.81 - 1$ = almost perfect [29]. In line with the above proposal, BayesNet and NaiveBaies have a poor kappa coefficient, and multilayer perceptron and J48 are negligible. It is concluded that the values of the kappa coefficients show that the instances, classified by the machine learning model, do not match the data marked as the basic truth. MAE values: 0.3763 for BaiesNet, 0.3748 for NaiveBaies, 0.3718 for MultilayerPerceptron, 0.3751 for J48 are closer to the lower limit (ideal) than the upper (worst). We, therefore, appreciate that they are acceptable (Table 1).

Anthony Ladson gave a model performance table based on the efficiency coefficient. For the case of model performance validation, the values of the efficiency coefficients describe the classification as follows: $E \geq 0.93$ - excellent, $0.8 \leq E < 0.93$ - good, $0.6 \leq E < 0.8$ - satisfactory, $0.3 \leq E < 0.6$ - transient, $E < 0.3$ - bad [30]. Based on this, values of 0.4393 for BayesNet, 0.4329 for NaiveBayes, 0.5466 for MultilayerPerceptron, and 0.5814 for J48 are in the transient group (Table 2).

Relative absolute error (RAE) can have values from 0 to infinity. Ideally, it should have a value of 0. Based on this, it is concluded that the values of 100.3802% for BaiesNet, 99.999% for NaiveBaies, 99, 2009% for MultilayerPerceptron, and 100.0671% for J48 are approximately the same as in the naive model (ZeroR classifier). The root of the relative square error (RRSE) can have a value from 0 to infinity. Ideally, it should have a value of 0. RRSE values: 101.4822% for BayesNet, 100% for NaiveBaies, 126.2775% for MultilayerPerceptron, and 134.2938% for J48 rate NaiveBayes

as a naive model, and BayesNet, MultilayerPerceptron and J48 worse than naive (Table 1).

Analysis of the detailed accuracy of the classes (Table 1 and Table 2) shows very significant results. Based on the tables of best and worst metric values for detailed class accuracy, we conclude:

1) TP Rate has extremely poor values, close to the worst, for all rated models and all classes. The exception is NaiveBaies, which has the best value of 1,000 for class 4, but the same NaiveBayes has the worst value of TP Rate, 0,000, for classes 1,2, and 3. Relatively good value of TP Rate, 0,577, showed MultilayerPerceptron for class 2. Weighted values TP Rates are consequently poor.

2) FP Rate for NaiveBayes has an optimal value of 0.000 for classes 1,2 and 3, as opposed to class 4 for which it has a maximum value of 1000. BayesNet, MultilayerPerceptron, and J48, as well as a weighted value for all four models, and all four classes are extremely bad.

3) Precision has values below a level satisfactory for all four models.

4) Recall, has the same values as TP Rate. The question is why are they separated for display in a separate column?

5) The F-Measure has values that are below levels that meet all rated models and all four classes.

6) MCC showed unsatisfactory values, which are at the level of random prediction, for all evaluated models and all classes.

7) The ROC Area showed values for all models and all classes that are on the verge of bad.

8) The value of the PRC area, for all models and all classes, is below the level that is the worst.

The metrics of detailed assessment by classes unequivocally show that the evaluated models, applied in a presented way, do not satisfy (Table III). This means that new research is needed and the answer to the question: why do metrics of detailed accuracy give poor estimates of the models used?

By comparative analysis of the confusion matrix for all four classification models and all four classes, we see that the predictions of true positive results (TP) are not good enough

REFERENCES

(Table 4). Type I and type II errors are relatively high. The goal of modeling is to reduce these errors to minimum values.

Separate consideration of type I and type II errors for the four applied models shows that NaiveBayes has a type I error value equal to 0, for class d, and type II errors for classes a, b, and c (Table 5). These data further problematize the use of this model. For the other three models, the type I and type II errors are, on average, 2.5 times larger than exactly predicted.

V. CONCLUSIONS

In this paper, we have considered in detail the 16 metrics for the evaluation of classification models, which exist in WEKA software, version 3.4.1., Developed at the University of Waikato, New Zealand. The consideration is in line with the initial assumption of the paper that classification models are suitable for solving the classification problem applied to a specific set of hepatitis C virus data for Egyptian patients.

In addition to the above 16 metrics, we found in the literature that there are other metrics: False discovery rate, Log Loss, Barrier score, Cumulative gain chart, Lift curve, Kolmogorov-Smirnov plot, and Kolmogorov - Smirnov statistics. We did not describe them because we were unable to demonstrate their application to the data set we selected. These metrics remain for display in a later review paper.

All metrics considered negatively evaluated the classification models, which we used. This has led to doubts because these are models that are generally accepted as standard and reliable. Why, metrics, do they rate them negatively on a selected data set? Is the number of attributes in the selected data set too large? How many attributes are needed and what are those attributes? Is it necessary to pre-process the data of the selected set?

The special significance of this paper is that it highlights the multitude of metrics used to evaluate each classification model. It emphasizes the diversity of these metrics and the parameters they measure to better understand the model and its features.

New questions and problems, which arose from this paper, are: What are the techniques for pre-processing data in a data set, and how should discretization, purification, reduction, and discussion of data be performed in a specific hepatitis C virus data set for Egyptian patients?

We suggest that the classification be performed in five classes, as provided in the latest professional literature: class a-inflammation of the liver, class b-fibrosis, class c-cirrhosis, class d – end-stage disease (ESLD), and class e-cancer.

Abstract—The aggregation of mobile nodes without the use of a base station is known as Mobile Ad Hoc Networks (MANETS). In nature, the nodes are moving. These networks are not connected and thus subject to security attacks due to their mobility. There are several mechanisms proposed to prevent mishaps while routing of the packets in such networks methods: The methodology outlined in Mobile Ad Hoc Networks to protect against various types of assaults is based on a recent method known as Cooperative Bait Detection Scheme. Its implementation scenario demonstrates that in the event of Sybil assaults, the packet delivery ratio and performance are low on the network. Our goal is to propose a cluster-based methodology to improve delays, packet delivery ratio, and other performance assessment criteria. Improved Cooperative Bait Detection recommends a disjointed multipath technique to avoid attacks. Until date, the dropped packet delivery ratio has been the key to preventing collaborative and Sybil assaults. In the Hybrid Cooperative Bait Detection Scheme, nodes are verified in two stages: first, on the basis of packet delivery ratio, and then, in the second stage, the exact cause of performance decline is explored to check node behavior. In order to improve security, certifying procedures must be used to clustered networks. For malevolent entities, the false accusation algorithm provided certificate revocation and blocking approaches. An algorithm is proposed that remembers false accusations for a set period of time in order to increase the number of normal nodes in the network and hence improve the system's performance. Results: With the help of NS2 simulation, the clustering approach was evaluated by considering several Sybil-attack network scenarios. When the proposed work is compared to other ways such as Cooperative Bait Detection Scheme, Improve Comparative Bait Detection Scheme, and Hybrid Comparative Bait Detection Scheme, the results show that Packet Delivery Ratio and performance are improved for Sybil attackers over the internet. In conjunction with Certifying authority, the Cluster Head in the network identifies and prevents false complaints. The results of the comparison using several performance parameters reveal that the new strategy outperforms the existing ones. As the number of normal nodes in the system grows, the system will be able to work at its best, preventing various types of attacks.

Keywords—Mobile Ad Hoc Networks; cooperative bait detection scheme; cluster; cluster head; certifying authority; certificate revocation

I. INTRODUCTION

The AdHoc Mobile Network is a less dependable wireless network for the infrastructure. [1]. Since the 1980s wireless mobile systems have been in use. We saw their developments in wireless systems of the first, second, and third generations.

With the assistance of a centralized support structure like an access point, wireless networks function. These access points help wireless users to maintain connections from one area to the other with the wireless system. The existence of a permanent support structure inhibits wireless solutions' adaptability [2]. So Bluetooth provided a new sort of wireless system called ad hoc mobile networks to develop wireless networks (MANETS).

Mobile Ad Hoc Networks (MANETS) is the aggregation without the base station of mobile nodes. The nodes are moving in nature. Due to its mobility, these networks are not wired yet vulnerable to security assaults. There are several mechanisms proposed to prevent mishaps while routing of the packets in such networks. MANET is free to roam in any direction and consequently regularly changes its connections to other devices. The goal of connecting "everywhere and every time," mobile Adhoc networks can make true. Wireless ad hoc mobile network is usually shown as Fig. 1.

A. Misbehaving Nodes in MANETS

A mobile node might be dubbed a selfish or misbehaving node to gain from other nodes. This node produces its own network connection certificate and attempts to communicate with other genuine network nodes [3]. It also acts like denying or not responding to other nodes to forward data packets to preserve its battery power.

B. Blocking of Misbehaving Node

With an unsafe node, secure communications between network nodes are interrupted. MANETS utilizes weighted bunching strategies to construct geography. Hubs inside the organization structure a bunch that is a group head (CH) along with certain group individuals (CM)[4]. Security is the critical need of MANET in light of the versatility of the hubs [3].

Fig. 2 shows the MANET working using the clustering approach. For overall study it finds that there is the number of activities in mobile Adhoc network but due to its ad-hoc nature number of unknown activity can occur which causes the problem in the network that indirectly affects the working and throughput. So it is expected to protect the adhoc network by detecting the unknown activity so can improve the performance without affecting the network communication.

The following section gives a detailed overview of each attack with the proposed approach to detect the malicious activity.

Figure - Mobile Ad Hoc Network

Fig. 1. MANET Environment.

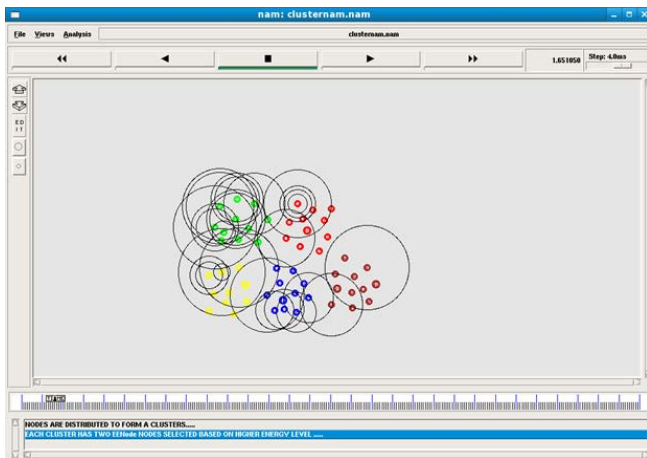

Fig. 2. MANET Working with Clustering.

Section II gives the details of MANET attacks and related works. Section III discusses the proposed approach use in-network to secure communication between the nodes. Section IV shows the simulation outcome followed by the conclusion and future scope.

II. RELATED WORK AND CLASSIFICATION

This session gives a details overview of attack and review in mobile adhoc network.

A. Data Traffic Attack

DATA traffic attacks either in nodes that discard data packets or in data packets that hold forwarding. A couple of forms of assaults are picked for dropping victim packets, while others drop them altogether independent of sender nodes. This can increase service end to end and decrease service value. It can also lead to considerable loss of data. Moreover, few nodes might be completely out of the way save for a redundant path near the irregular node.

B. Control Traffic Attack

MANET is naturally susceptible to attack because of its primary features, like open medium, conveyed hubs, self-governance for network investment (can connection and leave the organization as indicated by its will), absence of focal position (which can force net wellbeing on the organization),

disseminated coordination and communitarian activities [6]. Because of these reasons, the present routing protocols in MANET cannot be used. MANET has many different routing protocols with their individual characteristics and set of legislation [7]. The DYMO is a fast light routing technology created for Multi-Hop networks that depend upon the cooperation of each individual Node in defining the genuine routing table. But they all rely on confidence in networked nodes [14]. The first stage for a successful attack is that the node is a network component. Since there are no constraints on network membership, the hostile node can be connected to and disrupted by capturing routing tables or by dodging lawful routes.

In addition, if the node can determine itself as the quickest route to any target, it may spy on the network using unsafe routing protocols. That is why the protocol for routing must be maximally safeguarded [17]. Similar assaults are not CONTROL assaults and may be mitigated in physical security mechanisms, especially for jamming assaults.

A recent method known as Cooperative Bait Detection Scheme is the basis of the methodology described in [3] Mobile Ad Hoc Networks to defend against various forms of assaults. Its implementation scenario reveals that the delivery ratio and performance of the packet are low in the event of Sybil assaults on the network Improved Cooperative Bait Detection suggests disjoint multipath strategy to prevent assaults. Dropped Packet delivery ratio is the key for implementation to prevent collaborative and Sybil assaults till now.

In Hybrid Cooperative Bait Detection Scheme two stage verification of nodes is done where node which found malicious in first stage on the basis of packet delivery ratio, later stage exact cause of performance drop is investigated to check behavior of the node [3].

III. PROPOSED WORK

The below session explain the proposed work use in the simulation approach with malicious activity detection to improve the throughput of the overall network.

It is required to apply certifying mechanisms to clustered networks so as to enhance security measures.

Our goal is to propose a cluster-based methodology to improve delays, packet delivery ratio, and other performance assessment criteria.

The fundamental goal of our proposed work is to combine a cluster-based certificate blocking mechanism with a better false accusation algorithm, which will be discussed later in this section.

Therefore, we updated the CBDS method with the proposed approach to the clustering system. The number of hops of all nodes from the destination is considered [22]. The node receives the packet and only transfers it from that dedicated path in accordance with the CBDS scheme, otherwise, the packet will be discarded. As explained earlier this is carried out before clustering is done by integrating the CBDS algorithm with the proposed false accusation algorithm.

A. Algorithm Design

Assumptions and Abbreviations

CA=Certifying authority

CH= Cluster Head

WL= Warned List

BL= Blocked List

CH=Cluster Head

NN = Number of Nodes

SNi = Specific Node,

SCK = Specific Cluster,

MAX = Number of maximum nodes per cluster,

PD = Packet Data,

NBi = Buffer of Specific Node,

SNTCi = Specific node's trust counter (Initially set to 0 for each node),

SNTSi = Specific node's trust status (Initially set to 'F' for each node)

TV = Threshold Value (Set default is 0.8)

k = Used for Cluster Number

count = Used to count number of nodes in cluster

Algorithm

Initialize

k = 0

count = 0

Step 1: Cluster formation

for i = 1 to NN

{

Find out degree of each node ();

Find out power status of each node ();

}

while (making cluster by putting every node in to any one cluster)

{

if (SNi = = max (degree of node and power status of node))

{

Add SNi into SCi

Set count = count +1

}

if (count > MAX)

{

k++

Set count =0

}

}

Step 2: Detection of suspected nodes

while (SNTCi < TV)

{

if (SNi sends accusation message against node M = True)

{

CA updates WL and BL

}

else

{

CH sends recovery packet to CA

CA broadcast this information

SNTCi = SNTCi + 0.2

}

}

Step 3: Process for suspected nodes

Send Testing packet data RREQ to the node with TTL=1

if (receives response)

{

if (SNTCi < TV)

Set SNTSi as 'F'

}

else

{

Set SNTSi as 'D'

Go to step 4

}

Step 4: Detection of false accusation ();

Step 5: Send accusation message for time t

False accusation algorithm proposed certificate revocation and blocking techniques for malicious entities. An algorithm proposed remembers false accusation for certain amount of time to achieve increased number of normal nodes in the network and hence improves performance of the system.

B. Environment used in Proposed Approach

The network environments of 1000 m * 1000 m with various numbers of nodes are seen in Table I below. In addition, the suggested phenomenon was tested against malevolent situations in which the intruders were infected by a variety of legal nodes. In existence, the CUs became movable, where they could at any moment break from their network or combine. In addition, 802.11 was the underlying MAC layer standard, although the routers' transmission range was restricted to 250 m [14]. To quantify the protection, during the handoff and communication process, the malevolent nodes or CUs were inserted into the environment using the probability distribution.

TABLE I. PARAMETERS USED IN AD HOC NETWORK FOR SIMULATION

Simulation Time	1000 seconds
Number of nodes	50
Number of Malicious Nodes	0,5,10,15,20 (Scenario)
Network Size	1000 m X 1000 m
Transmission Range	250 m
Maximum Speed	1 m/s – 10 m/s
Mobility Model	Random Way Point
Traffic Type	CBR
Number of Source Destination Pairs	30 %
IFQ Size	NS2 Default
Channel Bandwidth	2 Mbps

C. Parameters

In our experimentation, there are multiple inputs and output attributes. The input features are the number of nodes and the time of arrival. The proposed algorithm would follow all scheduling requirements such as overall performance, packet transmission rate, reduced return time, minimum waiting time, minimum power usage, and minimum end-to-end delay in multiple cases of arrival time [12]. The algorithm will then be implemented to test the proposed process. In each case of our experiment for the assessment of results, we consider different performance measurements; some of the normal performance parameters are,

1) *Throughput*: It is a network computing efficiency parameter for the supply of packets of data from the source to the destination. This attribute reflects network performance and is crucial.

2) *End to end delay*: It is defined as the total amount of all plausible delays made due to buffering when the task of the route discovery process is ongoing and completed.

3) *Packet delivery ratio*: it gives the ratio of the total amount of packets delivered to the total amount of packets lost. This parameter signifies the efficiency of transmission.

Evaluate the proposed approach, namely improve energy-efficient resource allocation (IEERA) in cognitive radio networks using clustering. The other variables that influence this are transfer & propagation delays, transmission delays, interface queue, etc. output in various network scenarios in

terms of node movement rate, multicast group size, resource assignment group number [13]. The number of multi-cast destinations is calculated between 5 and 20 radio nodes in this simulation. The amount of traffic is 10 packets per second.

D. Energy Efficiency

Energy performance is one of the key problems in the architecture of wireless sensor node MAC protocol. In MAC-layer protocols, diverse sources contribute to energy conservation. The first energy waste source is a crash, triggered by two or more sensor nodes concurrently transmitting. The need to re-transmit a broken packet increases the consumption of electricity. The second explanation for energy depletion is lazy listening. When you hear traffic that is not being sent, a sensor node enters this mode. In many sensor network implementations, this energy-consuming silent channel monitoring can be high. The third source of energy waste is overheard when a sensor node collects packets for other nodes.

Energy Efficiency= Energy utilized by node / Total energy of the node

E. Congestion Control

Congestion takes place when traffic approaches the combined or total potential of the underlying networks. Therefore, more modern methods to eliminate, track and overcome congestion must be built-in special con-side rations. When designing certain strategies for maximal performance, the finite resources of the WSN need to be considered. Diverse techniques, including protocols for routing aided by congestion detection and control mechanisms and complex protocols for congestion control, have been adopted in the last few years.

IV. SIMULATION AND RESULTS

Cluster-based bait detection system performance review of the proposed system model in the Ad hoc Network is tested and contrasted with Boost DSR, CBDS, and HCBDS routing system based on some parameters successful the stable routing protocol applied in the presence of Sybil attack.

The clustering strategy with the help of NS2 simulation and assessed by taking into consideration various Sybil-attack network situations. The outcomes of the planned work is compared with Cooperative Bait Detection Scheme), Improve Comparative bait detection Scheme & Hybrid Comparative bait detection Scheme approaches indicate that PDRs & performance are being enhanced for Sybil attackers over the internet as compared to other existing approaches. Cluster Head in the network detects and prevents fake allegations in association with Certifying authority. The comparative result with different performance parameters shows that the proposed approach gives a better outcome as compare to the existing ones. As the number of normal nodes in the system is increased the system is able to perform at its best with achievable prevention to different kind of assaults.

Performance Analysis of proposed system model namely Cluster basted is evaluated and compared with conventional DSR and CBDS based on parameters like false positives, detection rate, energy consumption, packet loss rate. Following is some Performance analysis of cluster-based approach with proper procedure.

A. False Positives

The False Positives Sum is the ratio of legal nodes considered unsafe to the total legal node numbers. We contrasted the architecture proposed with the DSR, CBDS, HCBDS system in the terminology of positives that are false, this time gripping all the frameworks together with our model of optimization, and incorporating nodes that are malicious into the network [12]. The incidence of false positives with increased speed of node movement is shown in Fig. 3. From the diagrammatic representation, it is clear that the rate of false positives decreases to a far bigger degree in our Cluster-based system compared to the other scheme. In reality, our proposed methodology better analyses the overall possible cause of an event of packet drop, and then a decision is made on the trustworthiness of the node. Overall, the statistic indicates that with an increase in growing node speed the false positive rate increases. On similar lines, Representation indicates a false positive rate along with the growing density of the node in the network, keeping the moving speed is 4 m / sec at the node is rigid. With an increased count of a node in the architecture, the source/destination number pairs are also increasing, because due to collisions, more packets are lost in the network. The number of false positives in the Cluster-based scheme is smaller relative to numerous other schemes, which considers every packet drop as an activity that is malicious [28], because the frequency of each packet drop is measured before making any judgment on the behavior of nodes and its multipath strategies.

In Fig. 3 shows the false Positives versus node Moving Speed with moving velocity and thickness on bogus positives where the x-pivot addresses the no of hubs use in-network and the y-hub addresses the False Positives rate.

B. Detection Rate

The rate of detection with rising moving nodes under the Cluster-based scheme and the other device is shown in Fig. 2. In our Cluster-based system, the detection rate is higher, as every decision is unbiased. The detection rate is the number of true malicious nodes found in the scheme relative to the total number of malicious nodes. The other plan considers every parcel drop as malevolent and the related hub is viewed as malignant and consequently more real hubs are vindictive. As the insights show, the recognition rate for our Cluster-based plan is higher than for the other plan. Moreover, the identification rate with developing hub thickness is displayed in Fig. 2. The quantity of information associations inside the organization is additionally developing with the expanding hub thickness, which implies that more parcels are dropped on the organization because of crashes. The other scheme considers packet drops to be misbehavior of valid nodes. Therefore the detection rate in our Cluster-based scheme is higher again than in other schemes, as shown in the figure.

In Fig. 4 shows the Detection Rate vs. Node Speed with moving velocity and thickness on identification rate where the x-pivot addresses the no of hubs use in-network and the y-hub addresses the Detection rate.

(a) False Positives vs. Node Moving Speed.

(b) False Positives vs. No Node Density.

Fig. 3. Effect of Node Moving Speed and Density on False Positives.

(a) Detection Rate vs. Node Speed.

(b) Detection Rate vs. Node Density.

Fig. 4. Effect of Node Moving Speed and Density on Detection Rate.

C. Energy Consumption

Fig. 5 shows the energy consumed under the Cluster-based system and CBDS schemes at rising node speeds. The goal of this experiment is to show that the total costs of processing and communication in the Cluster-based scheme are higher compared with the method i.e. the CBDS and other schemes. Packet transmission and receipt absorb most node resources. There is a novel energy-efficient secure routing protocol for the ad-hoc network with a Mobile sink [26]. Our Cluster-based plan doesn't build the quantity of traded messages; rather it utilizes existing directing bundles to trade data like line status and association status (already required according to routing Protocol standards). In addition, the data path continues to convey true malicious nodes.

D. Packet Loss Rate

In the cluster-based system and CBDS schema, the packet loss rate is shown in Fig. 6. The packet loss rate in our cluster system is less than in the CBDS scheme, as is seen in the figure. In reality, in the cluster-based routing path system more trustworthy nodes are chosen which leads to reduced packet losses and greater packet delivery ratios. For the CBDS & Other systems, genuine node isolation is possible, which leads to a greater drop in packets since transmission nodes to the destination are not available. In addition, the data path remains true malicious nodes, which provide them more possibilities of dropping vital data packets.

Fig. 5. Energy Consumption.

Fig. 6. Packet Loss Rate.

E. Packet Delivery Ratio (PDR)

PDR of Conventional DSR routing protocol. PDR is the presence of Sybil attack, partially secure CBDS routing protocol and proposed Cluster-based System, is shown in Fig. 7. The percentage data loss in DSR & CBDS under Sybil Attack is increased more than the Cluster-based routing protocol in all scenarios.

Fig. 7. Performance Analysis of Packet Delivery Ratio using DSR, CBDS, HCBDS & Clustering.

F. End to End Delay

The end-to-end delay performance of the conventional DSR, CBDS, HCBDS & clustering is the results are shown in Fig. 8. The CBDS, HCBDS producing over average end-to-end delay compared with clustering produces. From the results, it concludes that the model is flooding a minimum number of delays as compared to other.

Fig. 8. Performance Analysis of End to End Delay using DSR, CBDS, HCBDS & Clustering.

V. CONCLUSION AND FUTURE WORK

Among other things, Sybil assaults are known as the most dangerous Adhoc network attacks. While several mechanisms exist for protecting Adhoc networks from such attacks, there are significant limitations and several drawbacks in the conventional approach. In addition, during the path discovery process, DSR does not detect malicious nodes and hence cannot send all data packets to the target during Sybil attacks. Many conventional approaches are inefficient to detect malicious activity. In addition, the delivery ratio of packets (PDR) under these attacks may decrease with an increase of

malicious nodes. Therefore, a new Clustering mechanism was proposed to protect ad hoc networks.

An advanced version of DSR with Clustering is first used to find and protect the malicious nodes that lead to attacks when a network is built using an NS-2 simulator. Additional encryption was done twice to boost security. It guarantees confidentiality to ahead and back. Whenever topology changes, all authenticated neighbors obtain the new neighborhood key and will be supported. In conclusion, all of these mechanisms prevent attacks of Sybil, and the proven growth in performance and an improved Packet Delivery Ratio are especially worthy of attention.

By looking at the result, the proposed system showed improved performance in terms of packet delivery ratio and output compared to the CBDS, HCBDS processes. This proposed work increases the number of normal nodes in the network and hence improves the performance. In the future, we can focus on the detection of different attacks with their performance analysis.

In future work we intend to investigate:

- 1) Varying density evaluation in the clustered network.
- 2) Other parameters of packet losses like MAC layer information.
- 3) Performance of our method under different security threats in the mobile ad-hoc network.

Abstract—Existing primary education is not organized properly to fulfil the demand of fourth industrial revolution (IR 4.0) which causes lack of engagement in learning materials, lack of spatial ability and motivation towards learning by young age students. Students especially from initial education level tend to learn from seeing rather than reading or memorizing. In this context, technology like augmented reality and virtual reality bears such visual power in lieu with interactivity and engaging characteristics by bringing virtual and real world together. In addition, flexible presentation mechanisms in lieu with tagging and tracking technology with various degree of freedom provide the effective ground of augmented reality and virtual reality to integrate with current primary education or initial level of education. In this context, this research presents comprehensive and critical reviews in the previous research in terms with several aspects such as methods, research design and experimental validation. Each of the aspects is demonstrated with adequate advantages and disadvantages to design the integration of augmented reality and virtual reality with primary education methodology. In addition, this research illustrates extensive critical explanation for various challenges to integrate augmented reality and virtual reality with primary education to make students motivated towards education, effective activity and memorization with visualization. The overall investigation proposed in this research is expected to fulfil the future demand for Fourth Industrial Revolution (IR 4.0).

Keywords—Augmented reality; virtual reality; adaptive and collaborative learning; fourth industrial revolution

I. INTRODUCTION

Education is a continuous learning process which should include not only traditional class activities, learning process should be creative and interactive to meet the demand of fourth industrial revolution (IR 4.0) so that students will not feel demotivated towards learning. Besides, way of acquisition of education should be through discussion, research, training which should be fun and interesting. However, current initial level of education system seems to abandon the main idea about education and learning process to lean towards memorizing and rote learning. Traditional primary education is based on two-dimensional materials and does not provide any of these opportunities. Children aged from 5-11 are the ones who goes to primary schools and considered to be future hope, are losing their hope from learning. As a result, dropout rates are growing day-by-day and students are lacking behind

in lieu with not being able to show their creativity. To keep the children focused, motivated, creative and to keep their enthusiasm alive, changes needs to be brought in the way of delivering education to the children which demands to opt for technology integration with primary education. To integrate technology with primary education, researchers need to take account more on visualization and boosting engagement of students. Technology with such visualization power as well as interactivity is Augmented Reality, which bring virtual and real world together by putting digital information on the world. Existing research has been engaged in finding ways to integrate augmented reality with education system and achieved positive results. However, most of them were integrated with college or higher studies. Previous research on augmented reality with education medium and positive results so far gained by the previous research encourage this research to depict critical and comprehensive reviews to integrate augmented Reality with primary education system.

Augmented Reality and virtual reality is an advanced technology which connects virtual and physical world around us by superimposing digital information like sound, images or objects which can be seen with the help of regular handheld devices like mobile phones, tablets, laptops. All the positive characteristics of augmented reality make it dynamic and perfect combination for technology-based education system. Students from primary education tend to learn things by visualizing not reading or memorizing them. Augmented Reality is perfect medium in this context which provides a great deal of visualization with digital information as well as let students interact with the system so that contents can be taught in groups. AR in classroom is expected to be helpful to capture student's attention towards the learning and make them feel more engaging with other students and teacher as well [1] due to some factors, i.e. enhance environment and help with discovery-based leaning and increased student's spatial ability and motivate them towards learning. This research aims to illustrate various methods in terms with integrating AR technology with primary education level.

For the opportunities provided by augmented reality and virtual reality, AR has been used in college and higher education level in the previous research. The results from their researches illustrates that augmented reality and virtual reality has shown a promising result, better understanding of the

subject, boost engagement among students with course material, improve of interest and attention in classroom which can play motivating factors to mix augmented reality in primary education. This research presents critical and comprehensive reviews of using augmented reality in the exiting research towards using augmented reality in primary education. Section 2 presents core research background, Section 3 demonstrates comprehensive and critical reviews based on existing methods, Section 4 illustrates existing research based on frameworks, Section 5 depicts experimental validation by the previous research, Section 6 describes observation and discussion and finally, concluding remarks are presented in Section 7.

II. CORE BACKGROUND STUDY

Existing education system is not structured properly to meet the demand of fourth industrial revolution (IR 4.0) and its hampering society in a lot of ways, i.e. students are not feeling motivated, not curious about learning, tired of memorizing and reading books when they cannot grasp and there is no alternative to it. Education sharpens the way to future and it's important to work for the betterment of education. But it's not easy to improve education system in a short time where all issues need to address properly for proper structured education methodology and will provide solutions to most of the problems as well as will not become outdated within a short period of time. Making education better with technology, researchers are continuously conducting researches and they have come up with the technology called Augmented Reality [2]. For the last few decades research has been going on the possibilities of Augmented Reality in education system and most of the researches have been conducted on higher level of education to teach different subjects and measuring its success based on some key factors, i.e. students motivation towards learning, engagement with materials, concept understanding, visualization for enhancing spatial abilities, grasping deeper understanding of abstract and difficult topics [3]. The result of the research was positive and successful in terms of achieving the satisfactory level of students and teachers. Augmented Reality has provided students with new techniques of visualizing course materials, new way of interacting with course materials within the class, changing their perspective of learning and increasing their interest to the courses.

Augmented reality and virtual reality have all the characteristics needed to improve our current education system and give education the pace it needs to be mixed with the technology. Existing research showed how to implement augmented reality with education system to improve education's current situations. In Turkey it is very difficult to achieve good results in Ottoman Turkish reading but with AR technology they have found that students have less difficulty and performed well in terms of performance [30]. Medical Subjects need much deeper understanding and they are facing problems especially in generating real life scenarios but using Miracle [5], an AR system it was possible to make real life scenarios and provide students with an interactive virtual human body where they can explore for their better understanding. Similarly, there are a lot of augmented reality applications which are being used to taught different subjects

to students in different countries. Augmented Reality are used in medical education [6,7], science [8,9], engineering [10,11], object detection [12,13,14], motion modelling [15,16,17], face modelling [18,19], analysis of aerial images [20,21,22] etc. and a few mentionable Augmented reality applications are Elements 4D, Experience Chemistry teach chemistry, Anatomy 4D, Human Heart 3D and Corinth Micro Anatomy teach human anatomy, CARE an Augmented Reality application built to teach Science, Technology, Engineering and Math parts. ARVe - Augmented Reality applied to vegetal field [23], FreshAir™ teach discovery-based learning [24], Construct 3D to teach math (geometry) to college students [25], AR Physics to teach physics to college students [26]. All these AR applications are really making some differences to engaging students and their motivation. However, all of these existing AR applications are for college or higher-level study materials.

Augmented reality has also been used in primary level education but the usage is really few, yet the results are positive. Augmented Reality Popup Book application which was used to teach English Language and the course material were built according to English curriculum [27]. Realitat3 is an augmented reality system consists of six applications: skeletal apparatus, water cycle, plant development, frog metamorphosis, solar system and the senses. All these AR applications are being used to teach primary school students to improve their efficiency (academic achievement), usability and motivation [28]. Again, researcher in [27] explored the possibility of augmented reality application in teaching English to primary school children. Research in [29] was conducted to discover the geometrical disadvantages of technology for implementing augmented reality in education, the result illustrates positive feedback and promising output. The application was one mouse per children and it teaches math to students. Research in [1], opt for different methodologies to figure out which will work best for integrating augmented reality with primary education system. Other business applications which were built for primary education, i.e. Math alive teaches math's up to 3rd grade students, Animal Alphabet AR Flashcards are built to learn letters, Zookazam or Bug 3D to teach about animal species. However, there are few applications which can be incorporated with the curriculum provided for primary education level children. Existing experimental results for various AR applications are remarkable to prove enough that AR can not only be incorporated with primary education system but also it is well acceptable by teachers, students, parents as well. In addition, existing usage of augmented reality has showed better engagement with learning contents, more attentive and faster learning.

III. REVIEW BASED ON METHODS

Although currently we are living in three-dimensional era, however two dimensional materials is still provided to use for education which is failing us to provide quality education to keep our pace with modern era. To keep up pace with modern era we need to embedded technology with education and many countries are doing so, and the result indicate positive and better impact on learning. Researcher has been doing so many experiments and testing many approaches to integrate

technology with education for quality education so that they could find the optimal and best solution possible to integrate Augmented Reality with education system. However, finding organized procedure which can help us to integrate technology with our education system as well as work smoothly with our existing educational system is not an easy task but with hard work and depth research, researchers have also come up with some effective procedures which have shown how fun and amazing education can be with help of augmented reality. Existing methods in this context are shown in Fig. 1.

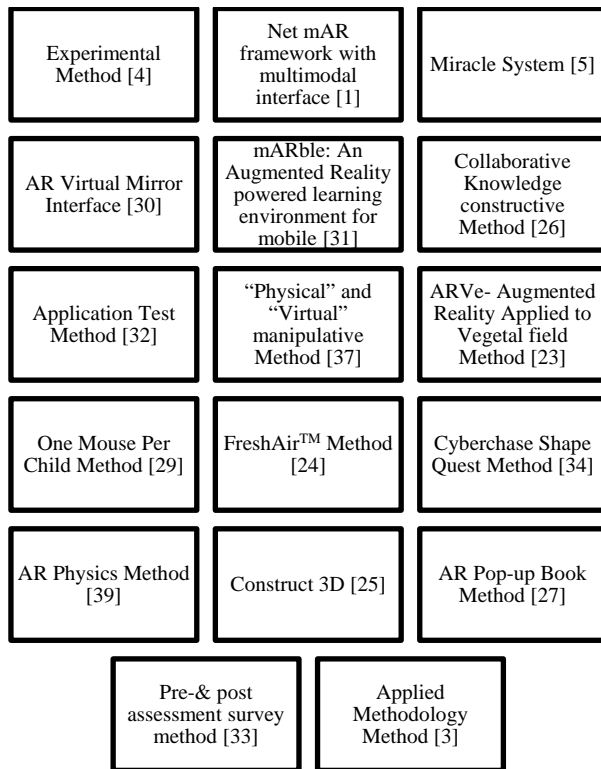

Fig. 1. Existing Learning Methods using Augmented Reality.

Augmented reality is highly praised due to its visualization capacity and interactive capacity with the system [1]. Researcher in [1] proposed multimodal interface model as mobile augmented reality framework using these dynamic characteristics of augmented reality. Their proposed system is built for mobile version in hope of increasing interactivity which will boost the engagement of students with the learning materials and increased the accessibility of augmented reality based educational material through application. However, their proposed method is still no acting as hypothesis as their proposed method is not implemented. Weakness of multimodal interface model can be improved by Construct 3D, a collaborative learning method.

Construct 3D method was introduced to overcome its drawback and flows of multimodal interface model which was theoretical hypothesis. Construct 3D method is based on the interactivity characteristics and have modified the characteristics by creating various interactive model to teach students about geometry and increase their spatial ability [25]. Construct 3D method also increased student’s interaction with system and for various model of interactivity in lieu with

providing more engagement with course materials. However, construct 3D method was designed to teach geometry only to students. To overcome the disadvantage of construct 3D method, AR mirror interface method was introduced. AR mirror interface model was proposed to study the affordance of augmented reality in education, proposing a less expensive and more user interactive tool [30]. Although, AR mirror interface model was successful to fulfil its purpose, AR mirror interface model required more engagement of students to teach some subjects than tradition educational methodologies. To fill the gap created by AR Mirror interface another method was introduced Realitat3.

Realitat3 is a method proposed for increasing interaction between system and user while keeping the affordance in AR system which consists of six AR games: skeletal apparatus, water cycle, plant development, frog metamorphosis, solar system and the senses. Realitat3 introduced AR gaming for educational purpose and more engagement while keeping student motivated, interested towards learning [28]. However, Realitat3 method is not able to teach all subjects by games which can be overcome by collaborative knowledge construction method using AR.

Collaborative knowledge construction method integrated augmented reality to help learners to develop skills and knowledge effectively, enabled co-located learners to be involved in knowledge construction by exploring the outside environment and interacting with each other through the guidance of AR-supported information [26]. However, software usability or learners perceived as learning effectiveness of the AR system needs to improved more for collaborative knowledge construction method using AR. To overcome this issue, research in [5] came up with Miracle System.

Research in [5] explored the possible areas of integrating augmented reality with medical study to give medical students a better way to learn medical studies. They focused on the visualization power of augmented reality as medical subjects especially Anatomy which needs figure to get a better understanding. Anatomy is a topic where students are taught the internal structures of human body so that they can have a deeper knowledge about human body and how organs work. To match with anatomy characteristics research in [5] introduced Miracle system which displays anatomical structures of the user’s body to a monitor and they have also proposed a gesture-based interaction to get real life experience. However, their proposed research was only for anatomy study and focused on a small number of important organs of the abdomen. For the usage of large screen and in order to solve the portability issue research in [31] proposed a portable augmented system called mARble.

Research in [31] proposed mARble which was an augmented reality powered learning environment for mobile proposed to make augmented system portable and affordable to use. As most of the students carry smartphone with them and now smartphone have enough computing power to carry out the operations of augmented reality. They tried to make students smartphone alternative of their books. They aimed for portability and making it as an alternative of books to teach

basic medicine courses. Using their system medical students performed better than those who were taught using books. Their performance was measured in terms of “the hedonic qualities simulation (HQ-S), identification (HQ-I) and attractiveness (ATT)”. However, their proposed system was used only for teaching basic courses in legal medicine which is the drawback of their method and solved by research in [27].

Research in [27] introduced AR pop-up Book to solve the content issue which was faced by most of the previous research methods. They integrated augmented reality with the book we read where users need to scan the image with the smart phone and augmented contents will appear on their mobile screens. They used AR pop-up Book to teach physics to the students which also needs deeper understanding. AR pop-up books help the students to bridge the gap between the digital and physical world. However, drawback of their method was that their proposed method was tested with 5 students only, so the results gained by AR pop-up Book may not be same for large number of users. In this context, research in [32] came with the solution by proposing Applied Test Method.

Applied Test Method experimented how augmented reality can be used in education with large number of participants [32]. Research in [32] proposed Applied Test Method to display real time results on screen, designed for educational purposes, interactive features like reactive to plain paper notebooks. However, their proposed methods provides some concerns towards privacy and ethical concerns, social acceptance concern of being constantly photographed, videotaped. Even though Applied Test Method was designed for education, however, it seems that Applied Test Method lacks effectiveness when used with high-achieving students which indicates little impact on high-achieving students. To solve this weakness, research in [33] introduced Pre-& Post Assessment Survey Method.

Research in [33] worked with how augmented reality can provide quality education in terms with delivering lessons to the students. They proposed Pre-& Post Assessment Survey

Method where they gathered students, teachers’ feedback with traditional and augmented reality based educational system. They took an assessment before and after use of augmented reality and analyzed results. According to their survey, they were able to achieve better understanding level for spatial concepts and make learning more effective and interactive. However, they implemented their research on students who were in grad 6 to 8 only. To investigate more about the spatial ability improvement with augmented reality, research in [34] proposed Cyberchase Shape Quest method.

Research in [34] introduced Cyberchase Shape Quest Method to improve spatial ability with augmented reality. Their goal was to utilize augmented reality to teach geometry as this particular subject needs more spatial ability to grasp the problem. With their proposed method they saw students became engaged with spatial memory, visualization for seeing the content and planning to solve the given task which showed that their method was more interactive, engaging and efficient. However, their method can only teach students about geometry which is a major drawback. To solve this problem, research in [4] introduced Experimental Method. Experimental method was introduced to overcome the issue and crisis defined by other methods. In this method, research in [4] tends to select a study group to gathering their feedback after using the system and monitor the results. So far experimental method gives the best output with positive result and great motivation to leaning [4]. Previously, many methods were tested to integrate AR with educational methodology to have a positive and good impact on engaging students, boosting their interactivity. Existing concerns by the researchers proves that augmented reality can be integrated with primary education system for improved and adaptive learning technique. However, existing almost all the methods needs further investigation due to the lack of experimentation on larger number of users, portability issues, user friendliness, higher engagement of the students. Previous research methods with advantages and disadvantages for integrating augmented reality to improved existing education methodology are mentioned in Table I.

TABLE I. PREVIOUS PROPOSED METHODS WITH ADVANTAGE AND DISADVANTAGE

Method Name	Advantage	Disadvantage
Experimental method [4]	So far best output with positive result and great motivation to leaning.	The experiment was conducted on 60 students and limited words. The result might be different for large group of students and syllabus
Net mAR framework with multimodal interface [1]	Using Multimodal Interface, usability of application increases as people can interact with the app.	Only theoretical method proposed.
Miracle system [5]	(a) Displayed anatomical structures on user's body, (b) New concept for gesture-based interaction.	Their method was used for only anatomy of small number of important organs of the abdomen.
AR Virtual Mirror Interface [30]	(a) Studied affordance and contains of AR technology in formal education, (b) Showed AR virtual mirror is less expensive and more users can interact with it, (c) Showed how to improve AR to integrate with national curriculum of UK Primary education	(a) Students using AR were less engaged than those using traditional resources, (b) Only used to teach science
mARble: An Augmented Reality powered learning environment for mobile[31]	Performed better than text book in terms of "the hedonic qualities simulation (HQ-S), identification (HQ-I) and attractiveness (ATT)	Applicable only for basic course in legal medicine.
AR in education [35]	(a) AR system detected students' locations and working status, (b) Provided task reminders, (c) Offered alternatives to refocus students' attention, (d) Enhance students' recognition of community of learners	(a) Students often felt overwhelmed and confused when they were engaged in a multi-user AR simulation. (b) Students require applying and synthesizing multiple complex skills in spatial navigation, collaboration, problem solving, technology manipulation, and mathematical estimation.
Collaborative knowledge construction [26]	(a) Helped learners to develop skills and knowledge effectively. (b) Enabled co-located learners to be involved in knowledge construction by exploring the outside environment and interacting with each other through the guidance of AR-supported information.	Software usability needs to be improved for effectiveness of the AR system.
Application Test Method [32]	(a) Displayed real-time result. (b) Designed for educational purposes, interactive features reactive to plain paper notebooks.	Causes privacy and ethical concerns in lieu with social acceptance of being constantly photographed, videotaped, and analyzed, less effectiveness when used with high-achieving students.
"Physical" and "Virtual" manipulative [37]	Showed that students motivation can be increased through AR technology. (b) Children who cannot yet think symbolically, AR play vital role in that context.	AR experiences may allow students to view virtual content and other people in the same mixed-reality space.
ARVe - Augmented Reality applied to Vegetal field [23]	(a) Used for students with cognitive disabled, (b) Provided feedback from the students, teachers and parents.	Worked only in the basis of visualization and matching.
Case Study of AR in Primary School [28]	An evaluation of the educational contents was made from the point of view of efficiency (academic achievement), usability and motivation	Depends on work which was conducted between 1993 and 2007
One Mouse Per Child [29]	(a) The system can be implemented even with different environment condition with minimal equipment, (b) established statistically relevant results and observed that the software proved most beneficial for the students with the lowest initial results.	Only teaches math to primary school children.
FreshAir™[24]	Navigated the pond environment and observed virtual media information overlaid on the virtual pond	The system was built for outdoor study, there was no indication how it will integrate with indoor technology.
Cyberchase Shape Quest [34]	While using the application students engaged their spatial memory, visualization & planning skills.	Focused only on geometry.
AR Physics [39]	(a) Initial step toward understanding learners' knowledge construction process by using AR System, (b) Learners knowledge construction behaviors were qualitatively identified according to adaptive three-category coding scheme.	Focused only in the performance on learners' knowledge construction of elastic collision of physics.
Differentiate between learning theories [36]	Showed how they selected different teaching method for augmented reality application.	Provided theoretical view with no experimental justification.
Construct 3D [25]	(a) Run on heterogeneous and hybrid setups. (b) System was built for mobile platform and collaborative.	(a) Their laboratory set up cannot be fully implemented in the schools or colleges, (b) They only aimed for geometry.
AR Pop Up Book [27]	Helped students to bridge the gap between digital and physical world.	Experiment was conducted on only 5 students
Pre- & post assessment survey method [33]	Better understand spatial concepts and make learning more effective and interactive	This research is done only in grad 6-8
Applied methodology [3]	Showed different types of AR application in educational environment	No option to reproduce study.

IV. REVIEW BASED ON FRAMEWORKS

Embedding AR in education to provide quality education is considered as challenging tasks and researcher is still trying to find an optimal solution for which they tested and proposed many methods [39,40]. To prove those methods, they used some framework by which they intend to support their work which has proved to have better result in outcome. To support Multimodal Interface method researchers in [1] proposed Net mAR Framework which is divided into five phases, i.e. Phase 1: Conceptual Features to be applied on the application, Phase 2: Focus more on the software and hardware requirement to develop application, Phase 3: Prototype Development, Phase 4: Application Reliability Testing, Phase 5: Final Application. Advantages of the framework are motivating students in learning as well as helping them to retain the information longer, benefit the educator explaining more complex subjects to students and improve student's memorization capability through visualization [1]. However, drawback of the framework have is being a theory. To overcome this drawback, another framework was introduced for collaborative augmented reality system.

Collaborative augmented reality framework was based on collaborative construct 3D method which builds for collaboration of a large number of students and supports various teacher-student interaction scenarios. Collaborative augmented reality framework had hybrid hardware setups and provided a natural setting for face to face collaboration of teachers and students, projection walls were established techniques for semi-immersive group environment, and single projector display are affordable for classroom use [25]. Having all the advantages, collaborative augmented reality framework also comes with disadvantage. Due to the number of available AR sets significantly restricts the use in large groups and the screen is shared between the active user and the observer. To overcome these drawbacks AR Virtual Mirror Interface with socio-cultural theory framework can be used as remedy.

AR Virtual Mirror Interface with socio-cultural framework was built for affordance of AR virtual mirror and its advantage over head mounted system which describes the potentiality of AR in primary education [30]. In that research, framework needs four steps to implement, i.e. AR Sessions and recordings of the sessions, class teacher interview, data analysis, comparing teacher dialogue across AR and Traditional teaching sessions. Again, AR Virtual Mirror Interface with socio-cultural framework had issues like need to train teachers so that they do not fell out of script while teaching with new technology and limited observation time. To surpass this challenge, another framework is being proposed named as collaborative knowledge constructive framework.

TABLE II. PREVIOUS FRAMEWORKS WITH ADVANTAGES AND DISADVANTAGES

Previous Frameworks	Advantages	Disadvantages
Quasi-Experimental Design framework [4]	(a)Academic Achievement shows pre-& post-test scores differ significantly. (b) Material motivation questionnaires show that motivation of the students was high in positive direction. (c) Fears of student towards the Ottoman Turkish Lesson were decreased.	(a) Obtained data are limited to the study group and miracles group, (b) AR integration was not fully developed.
Net mAR Framework [1]	(a) Motivated students in learning as well as helping them retain the information longer. (b) Benefited educator in explaining more complex objects to students, (c) Improve memorization through visualization	Still in theoretical phase, not in deployment.
AR Virtual Mirror Interface with socio-cultural theory framework [30]	(a) Affordance of AR virtual mirror and its advantage over head mounted system, (b) Describes the potentiality of AR in primary education.	(a) Need to train teachers so that they do not fell out of script while teaching with new technology, (b) Students less engaging with AR as some of them holding AR tiles and others are observing, (c) Limited time
Framework for mARble [31]	(a) Students using mARble showed better performance than textbook, (b) Improved learning rates.	Only Basic medical content were provided.
Collaborative knowledge constructive framework [26]	(a) Provided great possibilities for supporting face-to-face collaborative learning, (b) Enhanced social interactivity between or among group learners, (c) AR group learners performed significantly better in terms of their post-test scores.	(a) While constructing relations between single theoretical concepts or distinguished concepts from each other, it would confront obstacles regarding the topic of elastic collision and need support from their partners, (b) Other dimensions such as the argument and social modes dimensions needed to be analyzed.
Discovery based learning framework [38]	Showed benefits of AR in educational environments.	Limited by a number of factors, i.e. First, identified empirical studies are only informal investigations with a low number of participants. The significance of the ascertained benefits of AR applications may be unclear in these cases.
Framework for ARve [23]	Safe and highly portable	Required further experimental validation.

Collaborative knowledge constructive framework consists of various steps, i.e. Mobile AR in education, collaborative knowledge construction, enhancing learners understanding of elastic collision and momentum with technology, AR Physics system comparison with traditional 2D Physics, data analysis [26]. Collaborative knowledge constructive framework gave great possibilities for supporting face-to-face collaborative learning, enhancing social interactivity between or among group learners. AR group learners performed significantly better in terms of their post-test scores with disadvantages like while constructing relations between single theoretical concepts or distinguished concepts from each other, it would confront obstacles regarding the topic of elastic collision and need support from their partners. To overcome this challenge Quasi-Experimental Design framework was introduced.

Quasi-Experimental Design framework was based upon experimental method which takes a few steps to complete, i.e. research design, study group selection, data collection from the groups and finding representation. Material motivation questionnaires showed that motivation of the students was high in positive direction and fears of student towards the Ottoman Turkish Lesson were decreased [4]. Like all other framework, Quasi-Experimental Design framework also has some drawbacks, i.e. obtained data are limited to study group and AR technology was not fully developed. Previous frameworks with advantages and disadvantages for integrating augmented reality to improved existing education methodology are mentioned in Table II.

V. REVIEW BASED ON EXPERIMENTS

Augmented Reality is going to make education fun, increase student's motivation and will help them to improve their academic results as well. Having said that framework is the proof of the working methods, previous research conducted experiments to see if those methods or frameworks to validated their research, even if they have given some theoretical methods and frameworks, they proposed experimental steps so that if anyone implemented that framework they would know how to measure success or outcome of the experiments [41,42]. Research in [4] formed study groups, trained them with course materials, then conducted pre- & post-test to see their methods effectiveness. They used academic and motivation questionnaires to measure the success of augmented reality. From their experiment with AR, pre-test result average was 29 and post-test result average was 56.4, which illustrates significant improvement with the help of augmented reality and states that augmented reality can help students to improve their results and increase motivation as well.

Augmented Reality can provide a great way for students to interact with the provided courses material and boost the engagement of students in classroom and keep them concentrated in the topic. Research in [30], tried to prove that by proposing a method called AR Virtual Mirror Interface. For

their experiment they used web camera, AR tile, AR virtual mirror to set up the environment and by this system they taught students to prove the effectiveness of their research. They used several steps to run the experiment, i.e. AR sessions where they took AR sessions led by AR experienced teacher, own class teacher and recorded data. In the data analysis session, they used NUD*IST Quantitative analysis software to find results, they also recorded teachers interview to see teacher's reaction towards the system and use of Augmented reality in education.

Research in [32] conducted experiment to find AR contribution in improving education and integrate the technology in formal education. They made AR application to investigate how it could help students in discovery-based learning. To build their system environment, they used presentation devices, stimulus devices, tagging of known objects and computational estimators. Tagging of physical objects is what makes a device recognized a specific object in the real world. In their research, tagging of physical objects was accomplished with a system of GPS sensors, magnetic sensors, accelerometers, digital cameras, wireless sensors, digital compasses, and ultrasonic sensors. In their research, accuracy of a tagging system depended on the sensitivity of the various components where data processing components of AR systems required large amounts of RAM. Image capture was performed with a binocular or monocular lens. By analyzing their result, they found that highly accurate GPS position tracking to within 3 centimetres and accurately displayed results to users.

Research in [23] conducted their experiment to state the effectiveness for implementing augmented to visualize books. They built their system to integrate with primary school and used video projector, web cam, AR Book, webcam to scan the QR code from the AR book, and sent the findings to the video projector for visualization. In their application, participants had to complete several tasks, i.e. matching fruits, flower, seeds and leaves. Then they recorded the time to complete the task and analyzed the results. Their system was also compatible for handicapped students. Using their system 90 % of the parents considered it positively for their teaching aspects. 97% of K-2 up to K-5 students finished 4 stages with fast and less training. Their results illustrate that augmented reality has great potentiality to be used in primary education.

Research in [28] proposed Realitat3 which consist of an AR engine and several AR applications, i.e. skeletal apparatus, water cycle, plant development, frog metamorphosis and solar system. They used camera calibration, marker detection and calculation of marker position and orientation (pose estimation). They tried to find out how AR games can be used to deliver education and increase student's spatial ability. 21 Students participated in their research experimentation and 95% confidence level was gained using their proposed research. Previous research experimentation for integrating augmented reality to improved existing education methodology are mentioned in Table III.

TABLE III. PREVIOUS RESEARCH EXPERIMENTATION

Previous research methods	Parameter Used	Numeric Results
Experimental Method [4]	Academic & Motivation questionnaires'	Academic result has been increased. Average Pre-Test Score: 29, Post- Test Score: 56.4.
AR Virtual Mirror Interface with socio-cultural theory [30]	Teacher question in AR sessions clarifying the relationship between elements on the screen, Teacher question in AR sessions: children turns to hold a tile, Teacher questions in the traditional teaching sessions, Teacher interviews	96% agreement between AR & traditional teaching transcript.
Four Step Research Approach [42]	Benefits of AR	Identified 14 different benefits of AR in education and among them 20% benefits were accounted for Improved learning curve and increased motivation
Application Test Method [32]	Accuracy of a tagging system	(a) Highly accurate GPS position tracking to within 3 centimetres. (b) Accurately displays results to users.
ARVe - Augmented Reality applied to Vegetal field [23]	Accuracy to consider positivity among users.	(a) 90 % of the parents considered it positively for their teaching aspects. (b) 97% of K-2 up to K-5 students finished the 4 stages with fast & less training
Realitat3 [28]	Number of participants and confidence level.	(a) 21 Students participated in the research, (b) 95% Confidence level using application
FreshAir™ [24]	Pre-field trip training and post-field trip discussion	70 students were participated in the study
Cyberchase Shape Quest [34]	Number of usages	The game has been downloaded more than 500,000 times

VI. OBSERVATION AND DISCUSSION

Human have evolved by adapting new methods or new ways of living in the context of fourth industrial revolution, still we are doing same in every aspect of our life except for our existing education system. To keep our pace with fourth industrial revolution (IR 4.0) we need to identify the problems we are having with our education and how to integrate them with the help of technology. Augmented reality and virtual reality have proved to be a technological tool which is expected to improve current educational barrier. This research presents how previous research integrated augmented reality

and virtual reality with education and observed some problems with their methods, framework and experiment.

From the review based on the method illustrates that augmented reality and virtual reality has really been showing its capability to provide quality education and fulfil the purpose with some drawbacks. In some of the methods, i.e. Experimental Method [4], Miracle System [5], mARble [31], One mouse per children [29], AR pop-up Book [27], Pre-& Post Assessment Survey [3] researchers experimented their method for only a small proportion of population which gives them expected result but it cannot be said that the result will be the same when the experimentation for validation will be for large population. Again, in some of the methods, i.e. case study of AR in primary School [28], differentiate between learning theories [8] are only theoretical hypothesis with no experiment done. In review based on methods, i.e. Experimental Method [4], Miracle System [5], mARble [31], One mouse per children [29], Cybershape Chase Quest [34], AR physics [39] content was created for particular topic or based on small portion of the topic. In Construct 3D [25] method, proposed system setup was not idle for implementation as their setup was costly or not affordable for all. Again, in the basis of review based on methods, i.e. FreshAir™[24] proposed system was environment oriented like indoor based augmented reality system which cannot be used in outdoor and outdoor based system cannot be implemented with indoor. In some reviews for the method illustrates that users found the system confusing causes less engagement for the participants or students.

Review based on framework showed same possibility with drawbacks. In Experimental Method Framework [4], AR was not fully developed to be integrated with education system. Net mAR Framework [1] was only in conceptual theory not implemented yet. In AR Virtual Mirror Interface with socio-cultural theory [5] framework, to integrate augmented reality with education researchers need to teach teachers about the system so that they do not fell out of script while teaching. In other review based on framework, i.e. mARble [31], AR Virtual Mirror Interface [30], Application test method [32] illustrate that Augmented reality teaching materials was not fully developed which can only help to teach some particular subjects efficiently and deeply. In addition, sometimes there are some ethical problems, lack effectiveness when using with high-achieving students.

Review based on the experiment showed clear scenarios of augmented reality in education system in terms with validation. Based on the experimental results of some methods showed promising results, i.e. by using Experimental Method [4], academic results have been improved by 27.4 % and using AR Virtual Mirror Interface [30] 96% agreement has been reached between AR and traditional teaching transcript. Based on the four step research approach experiment mentioned in research [42], 14 benefits of AR found in education among them 20% benefits were accounted for improved learning curve and increased motivation. With ARve experiment [23], 90% parents were satisfied with the usage of Augmented Reality. In addition, Realitat3 [28] received 95% confidence level among students.

Augmented reality and virtual reality has been used by different countries by different method. So far, in Chile and India Desktop application has been used to teach math to primary school student. In London also AR application was used to teach science subject, AR games are used to teach and improve spatial ability of primary school students. Spain used AR to teach geometry to primary school students. All of their efforts were fruitful and have illustrated improvements in engaging students with class material, boost activity, increased motivation, and memorization with visualization. To use augmented reality in primary education system AR books and AR application need to be used together as AR book will help them to teach history, literature subjects where AR Application with AR Games can teach them science, math and other subjects as well. In this way AR can be implemented in all the subjects to teach at primary level while making students motivated towards education, boost their engagement with class materials.

VII. CONCLUSION

This research focused on integrating augmented reality and virtual reality into primary education to overcome current challenges of traditional educational method. This research illustrated thorough advantages and disadvantages for various methods to integrate augmented reality with primary education in the context of fourth industrial revolution (IR.0). Comprehensive reviews by this research show that if it is possible to integrate augmented reality and virtual reality with higher level of education, it can be integrated with primary education as well. Besides, demonstrated critical reviews by this research not only analyzed key points for the integration of augmented reality with primary education but also depicted hardware requirement to make overall research design for integration portable, cost effective, affordable which will help students to engage with the system easily. Although, augmented reality and virtual reality has been used by some countries, this research recommends to use AR books and AR application together as AR book can be used to teach one category of subjects such as history or literatures types of subjects and AR application can be used to teach science or math related subjects. This hybrid methodology is expected to improve students' motivation and engagement in class materials. Demonstrated reviews by this research are expected to play significant role in developing adaptive and collaborative education environment to fulfil the demand of fourth industrial revolution (IR 4.0).

ACKNOWLEDGMENT

The authors would like to thank Universiti Kebangsaan Malaysia for providing financial support under the "Geran Universiti Penyelidikan" research grant, GUP-2020-064.

Dept. of Electrical Engineering
Faculty of Engineering, Minia University
Minia, Egypt

Abstract—The construction of photovoltaic power plants (PVPPs) in the right place is an important task when planning the development of the power system and choosing investors. In this paper, the technical, environmental, the economic feasibility of installing a 50kW solar power plant in different places in the New Valley Governorate in Egypt has been presented using RETScreen Expert software. The input data used in the current study are obtained from the database of the Surface Meteorology and Solar Energy Dataset of NASA. In general, five sites for the construction of 50 kW power stations were assessed which represent the five administrative regions of the New Valley governorate. The study is based on annual electricity production, greenhouse gas (GHG) emissions, and financial analysis. With the proposed PV power plant, up to 100 MWh of electricity can be produced and a minimum of 43.3 tons of GHG emission can be prevented from the exhaust into the local atmosphere annually. The obtained results from the RETScreen program proved the viability of installing the proposed 50kW photovoltaic power plant in any of the proposed locations. This study could give a piece of important information and feedback that can be utilized as a database for upcoming investments in the photovoltaic generation projects in Egypt.

I. INTRODUCTION

Renewable Energy is the energy that can be extracted and derived from renewable natural resources or that cannot be exhausted or developed (sustainable energy). There are several fundamental differences between renewable energy sources (RES) and fossil fuels, which include "coal, natural gas, and petroleum" or "nuclear fuel that can be used in nuclear reactors". Usually, new and renewable energy does not generate harmful wastes such as carbon dioxide or harmful gases or increase the danger regarding global warming, compared to what can happen when burning fossil fuels or harmful atomic waste and waste from nuclear power reactors. Renewable energy can be produced from the sun and wind. And water [1]. It can also be produced from tidal movements and waves, or geothermal energy, in addition to some productive trees and agricultural crops.

Renewable energy has several advantages and benefits, direct or indirect, summarized in the following points: Renewable energy is not running out; It can also provide clean

energy free of waste; it aims to protect human health; it can preserve the natural environment; it has Low production cost; it can improve human livelihood and reducing poverty; it can secure new job opportunities. Moreover, renewable energy has extra advantages like Reducing harmful gaseous and heat emissions and their dangerous consequences; Reducing greenhouse gas emissions and harmful heat and their dangerous consequences [2]; Reduced numbers and risks of natural disasters resulting from global warming; Not to form acid rain that harms all crops, agricultural products, and all different life forms; offering a significant reduction in the formation and accumulation of harmful waste in all its forms (gaseous, liquid and solid); Protecting all living organisms, especially the endangered species; Protecting groundwater, seas, rivers, and fisheries from the risk of pollution; Contribute to ensuring food security; In addition to increasing the productivity of agricultural crops as a result of eliminating chemical and gaseous pollutants [3].

The sun is one of the largest sources of light and heat on the face of the earth, and this energy is distributed over the parts of the earth according to its proximity to the equator, and this line is the area that receives the largest share of that energy, and the thermal energy generated by the sun's rays is used by converting it into (energy Electricity) by panels (solar cells). There are also two methods of collecting solar energy. The first one is that the sun's rays are focused on a collector employing convex mirrors. The collector usually consists of several tubes containing water or air [4]. The sun's heat heats the air or turns water into steam. The second method, in which a level plate collector absorbs the sun's heat, uses the heat to produce hot air or steam.

The geographical location of the Arab Republic of Egypt is between latitudes 22 and 31.5 north, and as a result, Egypt is located in the depth and value of the global sunbelt. As a result, Egypt has been considered one of the world's richest countries with solar energy [4]. Where the Ministry of Electricity and Energy conducted a lot of research and studies to determine and clarify the characteristics of solar radiation in the Arab Republic of Egypt, which resulted in updating information, data, and statistics that were provided by meteorological stations and centers and adding many new stations and modern measuring devices. According to the various economic events and developments that Egypt has gone through during the modern era and their clear impact on the projects implemented

in the field of renewable energy, and as a result of the flexibility of adequate strategies to keep pace with the changes and developments. Events, its renewable energy strategy has been implemented and adjusted to target 20% of the total production of energy during 2022 [2, 5, 6]. The energy sector in Egypt (electricity, renewable energy, and petroleum) has prepared a study for the optimal combination of technically and economically for energy production until 2035 in cooperation with the European Union through the Technical Support Program for the Restructuring of the Energy Sector in Egypt (TARES) [6]. The project included several parts, the most important of which was supporting the sustainable and integrated energy strategy in Egypt until 2035.

This study includes a set of scenarios for the energy mix with different assumptions to assess the impact of the introduction of renewable energies in different proportions to the electricity generation mix from a technical and economic perspective, to choose the optimal scenario. In October 2016, the Supreme Council of Energy approved the Egyptian Energy Strategy until 2035 and chose Scenario (4-B) as the reference for energy planning in Egypt during the coming period [7], which aims to reach the percentage of renewable energy contribution to 42% of the total amount of electricity production by 2035.

RETScreen simulation program is a clean energy management software that is used for energy efficiency studies and feasibility assessment of renewable energy cogeneration projects and performing the required analysis for energy performance [8]. This program empowers professionals and decision-makers to quickly point out, evaluate and optimize the viability of renewable clean energy projects from the technical and financial sides. RETScreen software also makes it easy for managers to estimate and verify the real performance of their projects and helps them to obtain supplementary energy savings/production opportunities. RETScreen program has been utilized in many research papers. In [9] the feasibility study of a 100MW photovoltaic power station at Bati, Ethiopia has been conducted and the results showed that 2365.3 tCO₂ will be reduced to be exhausted into the environment. In [10], the assessment of solar energy potential in Algeria has been evaluated. In this study, 61 different sites have been evaluated and the results showed that the southern regions of the country have a great solar energy potential. In [11], the pre-feasibility study of nine small-scale hydropower plants in Turkey has been evaluated, and the obtained results were compared with those reported in State Hydraulic Works of Turkey. It was observed that RETScreen is capable of performing pre-feasibility studies of these small hydropower plants within a relatively short period concerning the time taken by other classic methods. In [12] cost, financial, and risk analysis for a 100 kW wind power plant, containing two 50kW wind turbines, that is planned to be installed on Taşlıçiftlik Campus in Tokat has been accomplished using RETScreen software program. In [13] an environmental and economic assessment of a grid-connected PV system established in a public institution in Brazil using the RETScreen program, the results proved that

the project is environmentally viable but still needs tax remuneration to attract investors in the country. In [14] RETScreen Expert software has been utilized to implement Measurement and Verification analysis to evaluate the energy effectiveness of an existing building in Korea based on the collected data of 12 years of gas consumption. In [15] an economic analysis based on RETScreen to evaluate the case of transition from grid electricity to PV power plants for a domestic building existing in Ado ekiti, Nigeria. The results showed that the PV system is more economic than depending on the grid electricity and the cost of energy is relatively cheap. The RETScreen software has been used in evaluating the technical potential and economic feasibility of different renewable generation projects in different countries [16-18]. Taking into consideration the great dependency on RETScreen simulation software in performing feasibility studies of renewable energy sources, the authors are motivated to evaluate the technical and economic performance of the planned PV power plants in Egypt.

The New Valley is the largest and least densely populated governorate in Egypt. Its capital is Kharga and includes the southern half of the Egyptian part of the Libyan Desert. It is bordered to the north by the governorates of Minya, Giza, Matrouh, and to the east by the governorates of Assiut, Sohag, Qena, and Aswan, and to the south by the borders with Sudan and to the west by the border with Libya. The New Valley Governorate is characterized by the presence of vast land areas that can be used in the establishment of various projects in all industrial, service, agricultural, and tourism fields. The New Valley Governorate is considered one of the best governorates in Egypt in terms of solar radiation intensity. The average annual number of hours of sunshine per day ranges from 9 hours to approximately 11 hours in the southern desert of Egypt, which means greater investment opportunities in the domain of different solar energy applications [4, 19]. Therefore, we find that there is a trend, whether personally by farmers, to operate many water wells with solar energy or by government agencies recently. Fig. 1 presents the Global Horizontal Irradiance (GHI) that appears in all regions of Egypt [20].

In this paper, a study of the potential of a PVPP installation in New Vally is carried out. In general, five sites for the construction of 50 kW power stations were assessed according to their technical potential. The selected locations represent the five administrative regions of the New Vally governorate. The analysis of the feasibility of the project is carried out using the RETScreen software, taking into account the peculiarities of electric power production at the proposed power plant, economic feasibility, and reduction of greenhouse gas emissions.

The Rest of the paper is organized in the following manner: Section II introduces the climatic conditions in the proposed sites; Section III provides the technical specifications of the PV module used in this study; Section IV presents the obtained results and discussion; and finally, Section V is conducted for the conclusion and future work.

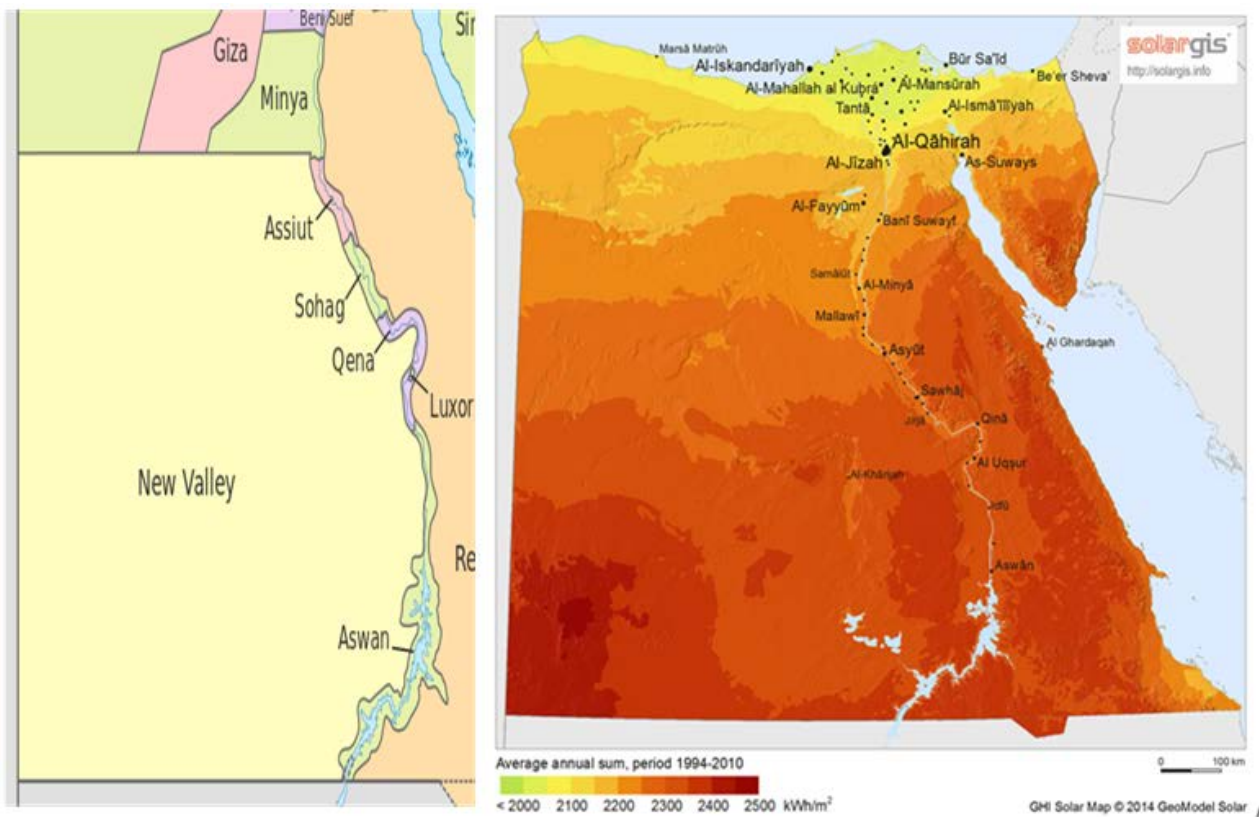

Fig. 1. Global Horizontal Radiation in Egypt.

II. CLIMATIC CONDITIONS OF THE PROPOSED REGION

From Cairo to the far south, Egypt receives radiation exceeding 6 kWh/m²/day, and the days on which clouds appear for most hours of the day are less than 20 days a year, and the total radiation increases from north to south, reaching a value of 5 kWh/m²/day "near the northern coast and exceeding 7 kWh/m²/day at the farthest point in southern Egypt, while the number of hours of sunshine exceeds 4000 hours annually. These numbers are among the highest in the world. The New Valley Governorate is considered one of the best governorates in Egypt in terms of the intensity of solar radiation and the average number of hours of sunshine. In the next subsections, the meteorological data of the five administrative regions of the New Valley governorate are presented.

A. Solar Radiation Intensity

The mean value of the solar radiation on the selected region for all months of the year is displayed in Fig. 2. From the shown figure, it has become clear that during the summer months the greatest value of the solar radiation is observed in Frafra while during winter the greatest value of the solar radiation is obtained in Paris and Kharga regions. The average, greatest, and least values of the solar radiation in the five locations are presented in Fig. 3. From this figure, it is noticed that Frafra region is characterized by the greatest and least values of solar radiation in New Valley. The mean value of the solar radiation in Paris and Kharga is the best within the five locations. Fig. 4 shows the variation of the mean value of the solar radiation, calculated by the mean value of the solar radiation over the five regions, over the year. It is obvious from

the figures that the least solar radiation value is 5.88 kWh/m²/day, and it is found in Frafra and the greatest solar radiation value is 6.28 kWh/m²/day, and it is found in both Kharga and Paris.

B. Air Temperature

The manners of air temperatures have been presented in Fig. 5, 6, and 7 for the different locations. The monthly values of the air temperature over the selected sites are shown in Fig. 5, while the greatest, least, and average values of the air temperature in the proposed regions are shown in Fig. 6. It is obvious from the figures that the greatest air temperature value is 33.4°C and it is found in both Kharga and Paris. The least air temperature value is 11.3°C and it is found in Frafra. The lower values of air temperature were detected during winter months while the greater values in winter as expected.

Fig. 2. The Monthly Values of Solar Radiation of Different Locations.

Fig. 3. Long-Term Average Solar Radiation.

Fig. 6. Long-Term Averaged, Maximum and Minimum Air Temperature.

Fig. 4. The Total Variation in All Seasons of Global Solar Radiation in the New Valley.

Fig. 7. The Total Variation in All Seasons of Air Temperature in New Valley.

C. Relative Humidity

The behavior of relative humidity can be discussed in Fig. 8, 9, and 10. It is obvious from the figures that for climatic conditions and relative humidity one can find that Frafra has the highest relative humidity 41.5%, the lowest relative humidity found in both Dakhla and Balat and equals 38.4%. The higher values of relative humidity were detected during winter months and lower in summer months as prospective.

Fig. 5. The Total Monthly Variance of Air Temperature At Different Locations.

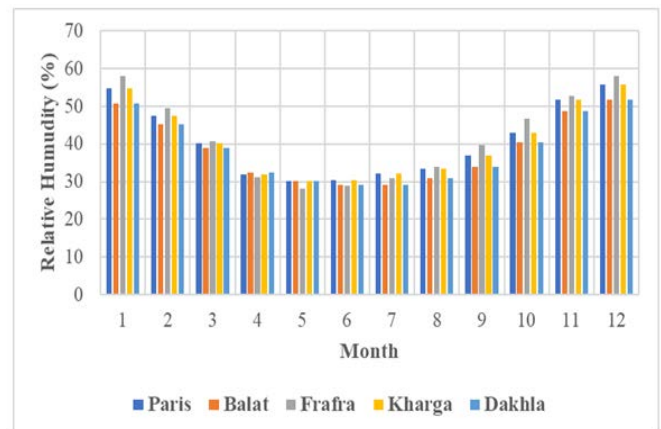

Fig. 8. The Monthly Values of Relative Humidity (%) in Different Locations.

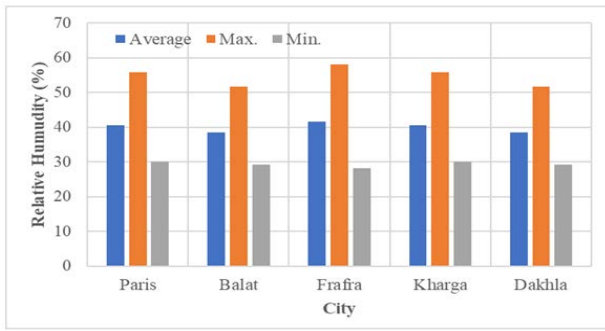

Fig. 9. Long-Term Averaged, Maximum, and Minimum Values of Relative Humidity (%).

Fig. 10. The Total Variation in All Seasons of Relative Humidity (%) in New Vally.

III. PV MODULE SELECTION

The appropriate type of the photovoltaic module was chosen according to the proportion of the energy generated to the unit and its surface area (power/surface area 350w mono solar power spandrel with a number of units equal 143 unit). The required PV module specifications are provided in Table I [21]. 143 units needed to establish the required 50 kW station. In our work, the fixed axis position of the modules will be chosen to reduce the initial cost 60kW inverters are selected with 95% efficiency.

TABLE I. SPECIFICATIONS OF THE CHOSEN PV MODULE

Model:	350w mono si-solaria power spandrel
Electrical Specifications	
Power P_{max}	350 W
Efficiency	17.3%
Open Circuit Voltage (V_{oc})	47.0V
Short Circuit Current (I_{sc})	9.6A
Max Power Voltage (V_{mp})	39.0V
Max Power Current (I_{mp})	9.0A
Temperature Performance	
Coefficient of P_{max}	-0.40% /C
Coefficient of V_{oc}	-0.30% /C
Coefficient of I_{sc}	+0.05% /C
Mechanical Specifications	
length	1495 mm [58.8in]
Width	1350 mm [53.1in]
thickness	11.5 mm [0.45in]
Weight	52 Kg [114lbs] approx

IV. RESULTS AND DISCUSSION

In this study, a 50kW PV power plant is proposed in the five locations and feasibility analysis of installing such a power plant in the New Vally region is assessed. The feasibility study is accomplished using RETScreen software. RETScreen Which means Clean Energy Management Software (usually abbreviated to RETScreen) is a package of programs for clean energy, improved and developed by the Canadian government that is an Excel-based software tool for making analyzes of clean energy projects, which helps decision-makers know both financial and technical feasibility in the field of energy efficiency, renewable energy and cogeneration (integrating heat and power generation) [8]. Conventional energy projects can also be designed and compared to more conservative alternatives. The program has the access to database of NASA and the values of the solar radiation on the horizontal surface, air temperature, relative humidity, and other meteorological data are applied to the RETScreen software [8, 22]. The program output is the annual total of energy produced from the proposed plant, the annual reduction of the GHG emissions thanks to the installed power plant in the selected locations.

A. Renewable Energy Production

The total annual power produced (MWh) is obtained from the RETScreen program as an output. Fig.11 shows the amount of energy produced in the five stations. The maximum energy amount is 100 MWh produced at Paris station. The minimum energy amount is 95 MWh produced at Balat station.

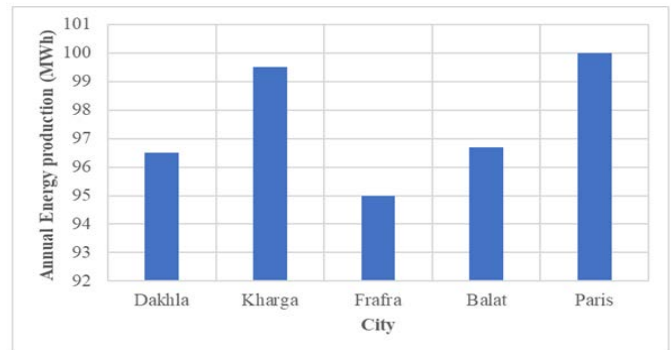

Fig. 11. Annual Energy Production of Different Stations.

B. Greenhouse Gases Reduction

One of the essential issues for validating the best-case study location is the Greenhouse Gases (GHG) Reduction. So, the model estimates the overall percentage and annual reduction in the amount of greenhouse gas emissions that would be incurred if the proposed case were implemented. The calculation is dependent on emissions of both the base case and the state systems selected on yearly basis. The units are given in CO2 equivalent annually per year (tCO2/yr). The annual GHG emission reduction thanks to the installation of the proposed 50kW PVPP in the five sites is presented in Fig. 12. According to this figure, it is noted that Kharga station has the highest rate of preventing greenhouse gases by 45 tons of CO2 can be prevented to reach the atmosphere. On the other hand, the Frafra station has the lowest rate of preventing greenhouse gases by 43.3 tons of CO2 can be prevented to reach the atmosphere.

Fig. 12. Annual Reduction of GHG in the Selected Locations.

C. Economic Feasibility Analysis

RETScreen has been utilized to determine a series of economic indicators such as simple payback period (SPP), internal rate of return (IRR), benefit to cost ratio (BCR), net present value (NPV), annual life cycle saving (ALCS), years of positive cash flow (YPCF), and energy production cost (EPC) for each project (50kW PV power plant). These indicators are explained in detail in the following subsections. The initial economic parameters, like the growth rate of energy cost, the rate of inflation, plus the cost of the main components of the PV power plant, are taken following the data given in Table II [13, 14].

TABLE II. FINANCIAL PARAMETERS THAT ARE USED IN THE STUDY [22, 23]

Parameter	Value
Project life	25 years
Inflation rate	2.5%
Discount rate	5%
Reinvestment rate	9%
Fuel cost escalation rate	0.0%
Debt interest rate	7%
Debt term	20 years
Electricity export rate	0.1\$/kWh

a) *Internal Rate of Return (IRR)*: Through IRR, companies can learn the feasibility of investment of the projects in the long term as it is one of the methods of capital budgeting. It is the discount rate at which the present value result is equal to zero, and it is usually explained by the expected profits that an investment decision generates [5]. In general, If the rate exceeds the capital value for the project, this will represent an added value for the project. IRR is calculated as given in equation (1):

$$InitialInvestment = \sum_{t=1}^N \frac{C_t}{(1 + IRR)^t} \quad (1)$$

where C_t denotes the Net of cash inflow during the period called t , IRR is defined as the internal rate of return, N represents the lifetime of the project, and t represents the number of time intervals.

b) *Simple Payback Period (SPP)*: A measure of the project's liquidity. It refers to the period of time during which the initial cost is recovered from the cash receipts, and this method is based on the fact that the more investment value is recovered in a shorter time, the more acceptable the investment or the paid-back capital period, which is one of the capital budgeting tools that the investor or financial manager relies on to implement an investment project. The higher the recovery period of the invested money in a shorter time, the better the investment in this project and vice versa.

c) *Years of Positive Cash Flow (YPCF)*: It refers to the movement of money in or out of a business, enterprise, or financial product. It is usually measured over a specific, limited period of time. It indicates that the company's core business activities are thriving. It provides an additional measure of an indication of the company's profitability potential.

d) *Annual Lifecycle Saving (ALCS)*: It is a nominal annual saving with an equation, with the exact value of the NPV discount rate and the project life, the value of ALCS is calculated.

e) *Net Present Value (NPV)*: It is defined as the present equivalent value of future payments. One of the tools that companies use to evaluate investment projects (long-term projects); The method of working the net present value depends on ensuring that the project being evaluated generates cash flows above the value invested in the project [5, 23]. The financial flows of the coming years can be transformed to the net present value by the next equation:

$$NPV = \sum_{t=0}^N \frac{C_t}{(1 + r)^t} \quad (2)$$

where C_t is annual cash flow, r represents the annual interest rate of annual interest, and t represents the current year.

f) *Benefit-Cost Ratio (BCR)*: An indicator used in the field of cost-benefit analysis that attempts to arrive at the total value of money needed by the project. The higher the ratio is more than 1, the better the project, and the safer investment in it:

$$BCR = \frac{Discounted\ value\ of\ fringe\ benefits}{The\ value\ of\ the\ additional\ costs} \quad (3)$$

g) *Energy Production Cost (EPC)*: Energy production cost per kilowatt-hour for generated electricity. This value is equivalent to the electricity export rate required to make a net present value (NPV) equal to zero.

The variation of the aforementioned economic factors concerning the location of the PVPP is presented in Fig. 13. If the value of IRR equals to or greater than the required return rate value, the study will be passed. The IRR values of all sites are shown in Fig. 13(a). The greatest value of the internal rate of return (IRR) is 20.5% found at Paris station while the minimum IRR value is 19.4% found at Frafra station. For SPP which equal to the period of time during which the initial cost is recovered from the cash receipts. The values of SPP and

YPCF for all locations are shown in Fig. 13(b). The greatest value of the simple payback period is 5.3 years found at Frafra station while the minimum value is 5 years found at Paris station. For YPCF which indicates how long the project will take to recoup its initial investment. The maximum value of YPCF is 9.638 years found at Paris station. The minimum value of YPCF is 9.119 years found at Frafra station.

The values of NPV and ALCS of all sites are shown in Fig. 13(c). ALCS can be calculated using the discount rate, the NPV, and the life of the project. ALCS has a maximum value equal is 6.358 years found at Paris station. The minimum value of ALCS is 5.83 years found at Frafra station. The maximum value of net present value is 89.605 million USA\$ found at Paris station while the minimum value of NPV is 82.28 million USA\$ found at Frafra station. Positive NPV values ensure project feasibility. From the shown values in the figure, we can see that all the values are positive which ensures that all five stations are potentially feasible.

All the available values of BCR are greater than one so that it is an indicator for profitable and better projects. The values BCR for all locations are illustrated in Fig. 13(d). The greatest value of BCR is 2.9 at Kharga and Paris stations while the minimum value of BCR is 2.8 at Dakhla, Balat, and Frafra stations. The generating unit's production cost known as Energy Production Cost (EPC) is one of the outputs of the RETScreen program. The value EPC of all sites is shown in Fig. 13(e). The minimum value of EPC equals 3.7 cents/kilowatt hour in Kharga and Paris stations while the maximum value EPC equals 3.9 cents/ kilowatt hour in Frafra station.

Fig. 13. Economic Indicators Varied According to the Location of the Photovoltaic Power Plants.

V. CONCLUSION

This paper presented a comprehensive study of the potential of a PVPPs installation in New Vally governorate, Egypt. For completing this study, five sites have been assessed for installing the same power plant with a capacity of 50 kW. This study has been accomplished to have a map for solar energy projects that will increase the international investment in the underutilized and superabundant environmentally friendly energy source in southwestern Egypt. After analyzing the meteorological conditions in the region it was obtained that the minimum solar radiation in the studied area is 5.8 kW/m²/day and obtained in Frafra station, while the maximum solar radiation is 6.04 kW/m²/day in the Kharga and Paris stations. The amount of annual energy produced from the

proposed PV power plants in the suggested locations ranges from 95 MWh at Frafra station to 100 MWh at Paris station, which ensures the small variation in the output of the PV power plant regarding the location in the New Valley governorate. From the environmental side, it has been found that the 50kW PV power plant located in Kharga oasis has the highest rate of reduction in the greenhouse gases emissions with 45 tons of CO₂ that can be prevented to reach the atmosphere annually, in addition, it has been found that the PV power plant located in Frafra oasis has the lowest annual greenhouse gases reduction by 43.3 tons of CO₂. From the financial point of view, it was concluded that the installation of a solar PV power plant in any of the proposed places is economically feasible, and the cost of energy produced by solar power plants ranges from 3.7 to 3.9 cents per kWh. All the proposed sites are fully recommended for the installation of PV projects from all the accessible indices, but the proposed PV power plant located in Paris is considered to be the best choice because of the high energy exported to the grid utility. The payback period of the PV project in Paris is also the shortest compared to other sites.

It is recommended that solar photovoltaic power plants may be installed in Paris to acquire new experiences and endorse the PV technology in the regional environment. Based on the results obtained in this study, the authors in their future work are looking forward to studying the impact of the integration of such PV power plants into the distribution network in Paris on the power quality indicators in the distribution network.

Augmented Reality Adapted Book (AREmotion) Design as Emotional Expression Recognition Media for Children with Autistic Spectrum Disorders (ASD)

Tika Miningrum¹, Herman Tolle², Fitra A Bachtiar³
Faculty of Computer Science, Brawijaya University
Malang, Indonesia^{1,2,3}

Abstract—One of the Autism Spectrum Disorder (ASD) characteristics is their difficulty understanding other people's emotions. Their lack of skill of understanding emotion includes expression and appropriate emotional response for a certain situation. This paper proposes an adapted book that helps therapists and parents guide ASD children to learn facial emotional expression. The adapted book combined with video, animation, and Augmented Reality increases children with ASD at recognizing emotional expression. This research uses *User-Centered Design* (UCD) approach to design the AR Adapted Book application and design the social story to be observable in school and family environment. Based on usability testing tried on the application, the result shows that AREmotion has an average score of 82.73 percent, and the learnability aspect has the highest score of 86.7 percent. This preliminary usability testing proves that the design of the AREmotion application is ready to use in real implementation for children with ASD.

Keywords—Autism Spectrum Disorder (ASD); adapted book; Augmented Reality (AR); User-Centered Design (UCD)

I. INTRODUCTION

Recognizing facial emotional expression is an important part of daily life to build an excellent interpersonal relationship [1]. Yet, not all people, in general, can easily recognize other people's facial emotional expressions. People with ASD (Autism Spectrum Disorder) have difficulties recognizing facial expressions [2]. Autism is a developmental and neurobiological disorder that has powerful effects on children's growth and influences their communication skills and social interaction in daily life [3]. People with ASD spreads all over the world, and the people with ASD total number is not small. The World Health Organization (WHO) stated that one of 160 children is a child with Autism Spectrum Disorder [4]. This estimate is the average result of a population in a certain period in all studies that have been carried out. Since the time of their growth, children with ASD have a problem in some social interaction area, i.e. (1) The development of their interpersonal relationship is blocked. (2) The spontaneous willingness to share hobbies and interests is lacking. (3) A significant disruption in body language, eye gazing, and facial expression when they do social interaction [5]. There is bad impact if ASD children do not study about facial emotional expression. They will grow up with lack of empathy and they find difficulty to give appropriate reaction to other people emotional expression. To avoid those

problems, a therapy is needed for ASD children so they can studying recognize other people expression in early stage.

A therapy, treatment, and guidance performed by therapist, parents, shadow teacher is needed to train the children with ASD to be able to learn how to interact socially. Parents and professionals, especially in Indonesia, stated that they need more coordination to give education, therapy, and care to children with ASD [6]. Children spent most of their time with family. This situation puts parents and family in the crucial role to treat the children with ASD very carefully. The treatment should be done correctly as every growth of children with ASD could inhibit the children growth phase. As a result, the children are in a high risk to be isolated from society. The isolation is due to their studying ability, lack of communication skills, and social stigma of children with ASD [7]. To overcome the described problem, a medium is needed to help therapists and parents to be able to take care of ASD Children in correct manner, especially so that the therapy for ASD children becomes more easily yet effective in treating the children.

There are various methods can be used to conduct a therapy for children with ASD. One of the therapies is using the sketch from drawing or art. Sketch art is a psychotherapy medium for children in general [8]. In case either normal children or children with ASD have difficulties or disruption, sketch art can be used so they can communicate in a non-verbal manner [9]. In general, therapists for ASD use a flashcard with sketch art or an illustration book as a supporting medium in learning and recognizing facial emotional expressions.

Previously, various technology has been developed to increase the quality of education and learning process of children with ASD. The research entitled The Impact of Technology on People with ASD [10] stated that there are four categories in learning with technology for people with ASD. The categories are conceptual skill (cover the subtopics: language, mathematics, colors, money, science, and programming), practical skill (subtopics: health, transportation, and daily life), social skill (subtopics: interpersonal relationship, communication, emotion) and general skill. The researcher explained that the most recent examination focused on utilizing technology to increase children's social skills with ASD. The study also emphasized that user needs, experience, and comfort are very important

considerations in developing technology for children with ASD. The method for developing development designs based on user needs is User Centered Design (UCD).

One technology incorporated used in children ASD therapy is Augmented Reality (AR). Augmented Reality is a technology that visualizes virtual objects generated by a computer, and the virtual object resides in a real-world environment to give an interactive experience to the user. The virtual object consists of 2D or 3D objects, video, animation, and audio. Augmented Reality technology can be applied to many fields such as entertainment, advertising, education, and medicine [11]. Using AR in education, students will experience new things and give more exciting and interactive ways during the learning process [12]. However there are a lot of research about AR technology with positive findings that explained on systematic review that Augmented Reality Technology for ASD patients show that 56 % social skill learning using AR [13]. The study also state that social skills, cognitive skills, and communication skills can be improved by using AR-based learning. Most of AR learning implementation is carried out on children and adolescents with ASD on age range of 3-14 years old.

Previous research carried out innovation in interactive media by combining game books and Augmented Reality on tablet device to learn expression to children with ASD [14]. User with ASD confronted with choosing expression that match with scenario story that presented according the real environment, the game book was developed with mobile based technology. The author believed that the game book application would improve social skills of ASD children. The limitation of this research was they did not explain how to develop the application and social story on the game book, and it was not explained either how significant the used of application for the development of ASD children.

Previous research discussed ARSFM (Augmented Reality Self Facial Modeling) [15]. This research aimed the goal to help children with ASD to improve their social skills. The ARSFM used a mask with facial emotional expression to train their ability to recognize facial expressions. The result from the research, there was a significant difference between baseline and follow-up lines. The AR technology is implemented on a personal computer, not free to move while using the application. Furthermore the research using ARVMS (Augmented Reality Based Video Modeling Storybook), to teach social skills for children with ASD by understanding the expression and emotions of other people in the social environment [16]. ARVMS learning system has 2 layers : the first one is static image layer, and the second one contains videos. The system has 20 videos that focus on social interaction. These studies also confirmed that augmented reality can help children with ASD to improve their social skills through expression. Several limitations in this study undeveloped technology based on User-Centered Design principles in order to comply the requirement of ASD children learning process. The research also did not include how they started make the design from early stage and there is no assessment of the application using usability testing after the application was developed.

The current study proposed an Augmented Reality Adapted Book that combines static sketch in flashcards and adapted books as a tool for children with ASD. Each of these two combination tools is a common tool used by the therapist to help ASD children learn facial emotional expression. This research started by conducting an observation. The process of designing the adapted book's story and the application uses the User-Centered Design (UCD) approach. This technique will assist in the development process, to ensure the design meets the needs of children with ASD. After that, ASD's therapists will evaluate it by assessing the usability level of the developed application.

The hypothesis in this research is augmented Reality with virtual objects, i.e., animation, audio, and video, can help ASD children increase their ability to recognize facial emotional expressions. Comfortability and enjoyment experience in using the application will be aimed by using the User-Centered Design (UCD) principle to develop a technology on a handheld device. This research also hopes to help parents and therapists guide children with ASD in learning facial emotional expression. Therefore, people with ASD need special attention and special treatment to become people who can recognize and distinguish other people's facial emotional expressions.

II. MATERIALS AND METHODS

To comply with a request of ASD children's facial emotional recognition application developments, it should be designed as its requirement list. End user and stake-holder's experience are one of the important part so the product agrees with the requirement, the goals, and learning process for ASD children. Three special needs teachers was involved in the process of iteration to made AREmotion application. The iteration is based on User Centered Design, and from this step the research gets feedback from end user or stakeholder. The feedbacks influence the design so a user friendly application can be developed for ASD children [19]. Indirectly, UCD is a continual process a combination of direct identification, development, and brainstorming processes by involving several people or professionals from several disciplines to produce a product or media according to user needs [17].

To be more precise, this research used UCD for design and develop the AR application. There are four steps insist: 1) Specify the context of use to store user information, 2) Specify user requirements to gets information and start the product modification by inputting feedback that collected from previous step, 3) Design and development, 4) Evaluation of the design as an assessment in order to improve the design, so end user can comfortably interact with the application and the application can help them learning something. The methodology diagram is presented in Fig. 1.

In the development process of the AREmotion application for children with autism, 2 literacy sessions were carried out. This iteration process applies to the process of making stories in the adapted book (ARBook) and the development of the AREmotion application as a whole accompanied by a special needs teacher. In the evaluation phase, usability testing was carried out, which was carried out on the therapist for children with autism. Evaluation is an effort to find out whether the

overall design of the AR application developed in this study is easy enough before being used/implemented for special users, namely children with ASD.

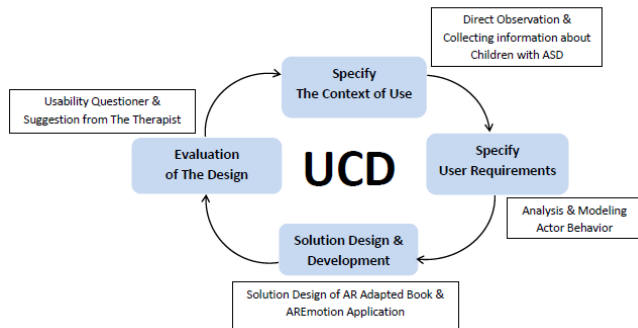

Fig. 1. UCD Process in AREmotion Application Development.

A. Understanding and Specify of Context of use

In the first phase, to understand and specify the context of use, direct observation is made on a Special Needs School. The teachers at the school were asked and interviewed to get some information about ASD children. Other information collected from the interview is: a general picture of ASD children's activity, their social interaction with school peers, and learning methods and therapy applied for them. The collected data will be used as a reference when designing the story and illustration on the adapted book. The information gathered from the interview, explained in Table I.

TABLE I. INFORMATION ABOUT ASD CHILDREN ACCORDING TO SPECIAL NEEDS TEACHER

No	Information
1.	In the studying process, ASD children often need a familiar guide (parents/teacher/therapist/shadow teacher)
2.	ASD children experience difficulties in understanding the abstract concept of social interaction, i.e., facial emotion recognition.
3.	It is often hard for ASD children to focus on their studies.
4.	Therapy and learning methods for ASD children rarely use an updated technology.
5.	ASD children are more interested in visual objects such as pictures, photos, and videos.

B. Understanding and Specify user Requirement

After getting information about therapy and the learning process, the next step is modeling the actor's behavior, as explained before using the case diagram. The diagram in Fig 2 shows that the main actor in this research is children with ASD. The children will interact with the application in four different use cases. The first use case is viewing the animation through Augmented Reality. The second is viewing the video footage menu for human emotion and expression. The third is finding the multiple-choice to answer the problem on ARBook through AR marker. And the last is checking the notification 'True' or 'False' on their answer through augmented Reality.

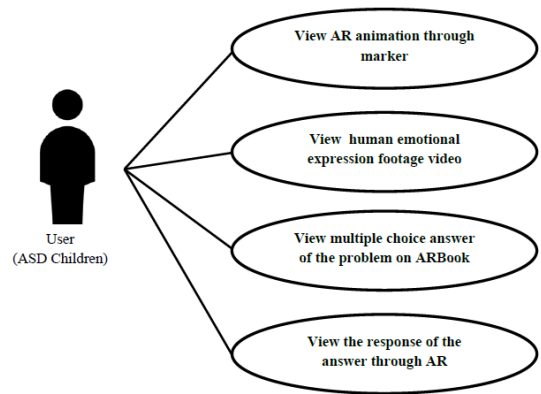

Fig. 2. Use Case Diagram for AREmotion Application.

III. DESIGN AND DEVELOPING OF AREMOTION APPLICATION

A. Design of Adapted Book (ARBook)

1) *Design of the story of adapted book:* The first design of storybooks that the researcher used is related to the book titled "A guide to producing written information in easy read" [18]. This book suggests using simple words, clear fonts, and sentences with less than 15 words, using pictures that are easy to understand and support the target sentences, and the images are made in the possible largest size.

After showing the first storybook's design to the ASD special needs teachers, they suggested dividing each expression into different categories. Every category contained some actions (in this field, the researcher made a limit in 3 actions in every category), and in 1 action would consists of 5 to 6 sentences.

In the second step, there are 18 accumulated stories divided into three parts. Each part contains six human expressions: happy, sad, angry, scary, disgust, and shocked. The therapist suggested a choice of word in every sentence the researcher made. Then, in the last step in developing the adapted book, the researcher formulated a flow to make a story for Autistic Spectrum Disorder (ASD). Here are the lists:

- Use time sequence story method
- Every story have to explain detailly
- Every sentence use 2 to 5 words only
- Give an illustration picture in every sentence
- The sentences must relate to the illustration picture
- Illustration picture must be in sequence
- Instead of abstract words, the explanation uses a concrete word. Take, for example, a dark sky, and there is a dark sky on the illustration.
- Avoid using the word like "want" and "will."
- Show familiar story for children

- Use variable character, such as curly hair, straight hair, bright-dark skin, to show there are many ethnics and race (SARA) in Indonesia.

After arranging the sentences, an illustration made from each of the sentences and dividing a page of the Augmented Reality adapted the book into three layout sections, as shown in Fig. 3.

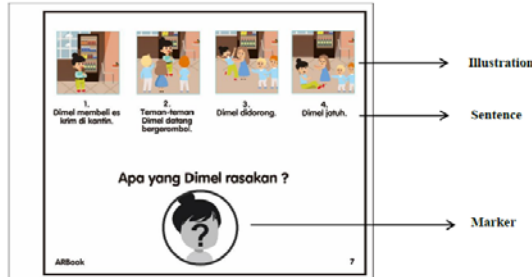

Fig. 3. Three-Section Layout on AR Adapted Book.

2) *Illustration design*: The adapted book illustration was made sequentially according to the formula list in Section III (A). Each page on the adapted book is divided into three layout sections, i.e., illustrative layout, sentence or narrative layout, marker layout. The illustrative layout contains pictures that visually explain the sentences beneath it on the narrative layout and marker layout allocated for the camera to detect the marker on that area.

3) *Marker ARBook design*: There are 18 different markers on each page designed on an Augmented Reality adapted book (ARBook). Every marker was made to suit facial expression on the adapted book pages. The marker can show the multiple-choice answer to the problem story in the adapted book.

B. Design of Augmented Reality Object on ARAnimasi

1) *ARAnimasi's character design*: A digital sketch was used in the process of designing and editing the animation character. The character was made and grouped into two categories, male character, and female character. When the animation showed, the upper body of each character will pop out. The illustration described in Fig. 4. While designing the sketch, it focused on facial features such as the shape of the eyes, eyebrow, and mouth which is described in Fig. 5. The shape of the facial feature is used to differentiate facial emotional character on each animation sketch.

Fig. 4. Sketch of Head, Upper Body, and Hand of Animation Character.

Fig. 5. Various Shape of Mouth, Eyes, and Eyebrow of Animation Character.

2) *ARAnimasi's marker design*: On the ARAnimasi menu, there is 12 flashcard-shaped marker choice with emotion animation object on augmented Reality. The ARAnimasi marker consists of two gender groups, male and female. Each group contains six emotional expression animations (angry, sad, happy, afraid, nauseous, and surprised). The design of the ARAnimasi's marker can be seen in Fig. 6.

Fig. 6. ARAnimasi Markers.

IV. SYSTEM IMPLEMENTATION

A. Tools and Technology

The development of the AREmotion application using Unity and Vuforia. Vuforia was chosen because this platform provides Augmented Reality SDK for image recognition ability to recognize the marker [19]. Every marker in the AREmotion application is saved in the Vuforia account. The engine that is used in the AREmotion application, Unity3D, all of the process is in PC. The result of the Unity3D engine is in the form of a smartphone application with Android systems.

Every animation and character in the ARAnimasi menu was drawn in Adobe Photoshop and Crazy Talk Animator. Wavepad was used for recording and balancing audio. The Adobe Premiere was used for the final rendering of the animation video. AREmotion application was used in the smartphone. The mobile device specification used was 2 GB RAM, 16GB internal memory, 16 MP camera to detect the markers, and the operating system Android 6.0 (Marshmallow).

B. System Overview

AREmotion is a combine application of adapted book and mobile Augmented Reality, which runs in smartphone with platform Android. AREmotion divided into three menus. They are video, ARAnimasi, and ARBook. The first menu is "video", consists of video footages with kinds of expression gesture like sad, happy, angry, afraid, disgust and shock. The second menu is "ARAnimasi", consists of a marker flashcard with six child expressions (for girls and boys) in AR is shown in Fig. 8(left). The third menu is "ARBook", which consists of questions in the form of a story/storybook, with the answers in AR is shown in. 8(right).

Fig. 7. Augmented Reality Adapted Book.

The AR adopted book's physical form is printed in the size 21cm x 16cm, as shown in Fig. 7. There are two menus in the book that is ARAnimasi and ARbook.

Fig. 8. Flashcard of ARAnimasi (Left) and Marker Sample of ARBook (Right).

C. Features Overview

In this study, there are two designs Augmented Reality, ARAnimasi dan ARBook. Fig. 8 shows an example of the ARAnimasi. Fig. 9 shows a menu containing 5 seconds animation video supported by clean audio to express human emotion. For example, there is the sound of someone's crying in the video. It is to show the children the expression of sadness.

Fig. 9. Marker Sample of ARAnimasi Menu.

Fig. 10 shows an example of the ARBook menu design when the smartphone camera is ready to detect the marker. While Fig. 11 shows, there is a multiple-choice answer organized as a UI AR button with slight animation from the detected marker. Animation of the answer pops out for 3 seconds, and it played automatically when the smartphone camera detects the marker. Fig. 12 shows the design of augmented Reality that pops out when the user chooses the correct answer and wrong answer.

Fig. 10. Example of ARBook Menu Design.

Fig. 11. Multiple Choice Interface.

Fig. 12. The Interface of Right Answer (Left) and Wrong Answer (Right).

V. RESULT AND ANALYSIS

The usability of AREmotion is tested on three therapists as the respondent. The therapist tested the usability by experiencing the AREmotion end fill out the questionnaire. Usability is a method that aims to measure whether the application media that has been built is in accordance with user needs. Usability testing can verify whether the applied design has worked well because there is an interaction how the user can cognitively assess the questions on the questionnaire, as the implementation of the interaction with the designed application [20].

There are 17 statements related to five categories of usability in the questionnaire, i.e., efficiency, learnability, errors, memorability, and satisfaction [21]. Each statement in the questionnaire is evaluated by the respondent using the Likert Scale. The respondent gives marks or rates from 1 to 5 to each statement [22]. Table II shows the Likert Scale which describes the symmetrical scale assessment of the respondent's level of agreement or disagreement [20], and Table III shows the questionnaire and all respondents's rates.

TABLE II. LIKERT SCALE DESCRIPTION

Score	Description
1	Very Disagree
2	Disagree
3	Neutral
4	Agree
5	Very Agree

TABLE III. USABILITY QUESTIONNAIRE STATEMENT AND RESULT

No	Statements	Score					Sum
		1	2	3	4	5	
Learnability							
1.	I think children with ASD can easily recognize the menu on AREmotion (Augmented Reality Adapted Book).	0	0	0	2	1	13
2.	From my point of view, AREmotion (Augmented Reality Adapted Book) is simple and easy to learn	0	0	0	3	0	12
3.	In my opinion, text on AREmotion (Augmented Reality Adapted Book) can be read easily	0	0	0	0	3	15
4.	It seems that the graphic display on AREmotion (Augmented Reality Adapted Book) screen is familiar to children with ASD.	0	0	0	2	1	13
5.	I think the icon on the AREmotion (Augmented Reality Adapted Book) media cognizable by ASD children.	0	0	0	3	0	12
Efficiency							
6.	In my opinion, AREmotion (Augmented Reality Adapted Book) can introduce human basic emotional expression to ASD children.	0	0	0	1	2	14
7.	I think the media has simple and easy use features.	0	0	0	3	0	12
8.	It seems that AREmotion (Augmented Reality Adapted Book) does not run at a slow speed.	0	0	3	0	0	9
Memorability							
9.	From my perspective, the animation object on the media is easily recalled by children with ASD.	0	0	0	3	0	12
10.	I think children with ASD can remember how to use AREmotion (Augmented Reality Adapted Book) media.	0	0	0	3	0	12
11.	In my opinion, ASD children recalling the variety of human facial emotional expressions more accurately when they learn it through AREmotion (Augmented Reality Adapted Book).	0	0	0	1	2	14
Error							
12.	In my opinion, children with ASD will not be making many mistakes when they use AREmotion (Augmented Reality Adapted Book)	0	0	2	1	0	10
13.	I think when children make some mistake in using the application, they will easily correct it.	0	0	2	1	0	10
Satisfaction							
14.	In my opinion, children with ASD use AREmotion (Augmented Reality Adapted Book) media comfortably.	0	0	1	1	1	12
15.	From my perspective, the animation on AREmotion (Augmented Reality Adapted Book) is running well.	0	0	0	2	1	13
16.	It seems to me that audio from AREmotion (Augmented Reality Adapted Book) heard by ASD children	0	0	1	2	0	11
17.	In my opinion, AREmotion (Augmented Reality Adapted Book) has an interesting design	0	0	0	3	0	12

Based on the result in Table III, the sum of each category will be calculated. Table IV and Table V show the calculation process.

TABLE IV. THE TOTTALLING SORE FOR EACH CATEGORY

No	Category	1	2	3	4	5	Sum
1.	Learnability	0 x 1	0 x 2	0 x 3	10 x 4	5 x 5	65
2.	Efficiency	0 x 1	0 x 2	3 x 3	4 x 4	2 x 5	35
3.	Memorability	0 x 1	0 x 2	0 x 3	7 x 4	2 x 5	38
4.	Errors	0 x 1	0 x 2	4 x 3	2 x 4	0 x 5	20
5.	Satisfaction	0 x 1	0 x 2	2 x 3	8 x 4	2 x 5	48
SUM		0 x 1	0 x 2	9 x 3	31 x 4	11 x 5	206

TABLE V. PERCENTAGE OF USABILITY SCORE

No	Category	Sum x Likert Score	Maximum Score	Result
1.	Learnability	65	75	$(65/75) \times 100\% = 86.7\%$
2.	Efficiency	35	45	$(35/45) \times 100\% = 77.8\%$
3.	Memorability	38	45	$(38/45) \times 100\% = 84.4\%$
4.	Errors	20	24	$(20/24) \times 100\% = 83.3\%$
5.	Satisfaction	48	60	$(48/60) \times 100\% = 80\%$
SUM		206	249	$(206/249) \times 100\% = 82.73\%$

AREmotion (AR Adapted Book) has a usability score in a total of 82.73 %.

VI. CONCLUSION

This paper focused on analyzing the design and developing the application augmented Reality adapted book (AREmotion) for children with Autism Spectrum Disorder (ASD). The primary participant in this research is therapist and ASD children. The therapist was involved in designing the application using the User-Centered Design (UCD) approach.

The adapted book's story design was based on a simple consecutively event concept explained in 2-5 sentences and illustration embedded in each sentence. There are three main menus on AREmotion, i.e., ARAnimasi consists of emotional expression animation video in augmented Reality, video emotion menu consists of a group of human emotional expression footage video, and the last menu is ARBook that consists of story problem series about emotional expression for ASD children includes the answer in augmented Reality.

In this initial research work, the application's design is tested on the therapist to en-sure that this application is efficient, easy, and understandable before children with ASD use it. Usability testing on AREmotion has 82.73%, and the highest score among all categories is learnability, with an 86.7% score. The result shows that the AREmotion application can be used as educational media for children with ASD when learning about facial emotional expression. The next step of this research is evaluating the usage of AREmotion to help children with ASD recognize emotional expression through this innovation.

Kenitra, Morocco

Abstract—The emerging new technologies, such as autonomous vehicles, augmented reality, IoT, and other aspects that are revolutionising our world today, have highlighted new requirements that wireless communications must fulfil. Wireless communications are expected to have a high optimisation capability, efficient detection ability, and prediction flexibility to meet today's cutting-edge telecommunications technologies' challenges and constraints. In this regard, the integration of deep learning models in wireless communications appears to be extremely promising. However, the study of deep learning models has exhibited inherent vulnerabilities that attackers could harness to compromise wireless communication systems. The examination of these vulnerabilities and the evaluation of the attacks leveraging them remains essential. Therefore, this paper's main objective is to address the alignment of security studies of deep learning models with wireless communications' specific requirements, thereby proposing a pattern for assessing adversarial attacks targeting deep learning models embedded in wireless communications.

Keywords—Adversarial attacks; deep learning; wireless communication; security; robustness; vulnerability; threat

I. INTRODUCTION

Wireless communication represents an exciting and evolving field of study. It has significantly contributed to the development of telecommunications and had been at the source of LTE and 5G network implementations, and it continues today to lead advancement in 6G generation development. Nevertheless, this field of study has recently encountered several challenges to meet emerging telecom technologies' requirements. The necessity of optimisation and adaptability is crucial today to guarantee highly efficient wireless communications [1]. In this context, the researchers have immediately turned to the rapidly growing techniques of artificial intelligence, especially the deep learning models that have received considerable interest for their reliability in computer vision and object detection.

Deep Learning models have revolutionised many fields of study. Their expressivity and generalisation potentials have shown impressive outcomes in several areas, including wireless communications [2]. The latter have utilised deep learning models in the radio frequency spectrum and have harnessed their adaptability and flexibility to improve the wireless communication capacity. An obvious application of Deep Learning in Wireless Communications is spectrum estimation and detection and modulation classification. These two functionalities contribute significantly to enhancing the

transmission quality while handling the channel effects encountered at the receiver [3,4].

However, several research studies have revealed that Deep Learning models contain inherent vulnerabilities that an attacker could eventually harness to perform malicious actions compromising wireless communications systems. Nevertheless, researchers usually opt for different hypotheses and follow different methods when testing adversarial attacks, rendering confronting, and comparing the latter challenging and complicated since the platform used in literature while testing adversarial attacks are not standardised. Whereas some researchers hypothesise a scenario where the attacker possesses complete knowledge of the system, known as white-box attacks, others deal with attacks where the attacker's knowledge is constrained, known as grey-box attacks. This disparity in assumptions provides a complex platform to make an accurate comparison of attacks on various algorithms.

Since no unified scheme has been developed for assessing attacks robustness, we have proposed a framework to analyse and evaluate the robustness of adversarial attacks in the context of wireless communication [27-30]. This paper aims to provide a standardised and unified platform for comparing different adversarial attack strategies against wireless communication systems. Through our study of adversarial attacks in literature, we have derived a list of criteria that we have considered to evaluate the complexity of the attack and its impact on the target system to obtain a global view of its robustness.

In this paper, we will extensively review the work devoted to studying the particularities of adversarial attacks targeting wireless communications to propose a pattern designed to evaluate the robustness of these attacks while incorporating the specifications related to this field of study.

First, we will introduce the applications of deep learning models in wireless communications. Then we will discuss the theoretical aspect of these attacks as well as the different factors involved in their identification and classification. Afterwards, we provide a review of the work highlighting certain particularities of wireless communications that could impact adversary attack success. Finally, we will elaborate on a pattern being proposed to evaluate the adversarial attacks' robustness in the context of wireless communications.

II. RELATED WORKS

A new research field has been conducted to extensively study the security of deep learning models and adversarial attacks leveraging their flaws [5]. Adversarial learning addresses the empirical evaluation of adversarial attacks by testing them in the physical world to experience them in a realistic scenario [6]. This research field is similarly focused on studying the theoretical aspect of these attacks by proposing a taxonomy for their classification and a threat model to describe the different aspects of the attack. However, the multiple suggestions carried out towards assessing adversarial attacks have mainly focused on attacks targeting computer vision or object detection models. Few works have addressed adversarial learning in the wireless communications context [27-30]. Indeed, the latter presents certain specificities to be considered in the study of attacks targeting the models they employ. Hence, it is necessary to adapt threat models and methods for evaluating adversarial attacks' robustness to wireless communication's technical and functional specifications.

III. DEEP LEARNING APPLICATION IN WIRELESS COMMUNICATIONS

Wireless communications represent an essential field of study for developing networks and meeting innovative technologies' specific requirements. The evolution of telecommunications stems from this research field since it has brought LTE and 5G networks to the surface. It is also contributing significantly today to waveform design for 6G emerging networks. Wireless communications have been based on classical probabilistic and analytical methods. However, such an approach involves several limitations regarding channel modelling, interference handling, traffic management, error detection and correction, and security [7].

Wireless communications have evolved systems built on deep learning models to overcome the complexities encountered in earlier network generations. Wireless Communications leverage the expressiveness and capacity for generalisation of Deep Learning models toward addressing detection, classification, optimisation, and prediction problems and consequently guarantee quick, reliable, and secure communications.

A. Deep Learning for Communication Systems

The primary purpose of wireless communication is to ensure a message's reception in an optimal state by deploying resources efficiently. The transmission mechanisms deployed by wireless communications are handled through independent blocks, each dedicated to the specific functionality of the data transmission process, as shown in "Fig. 1". Conventional approaches have focused on enhancing each block's functionality separately, thereby failing to achieve a proper optimisation of the overall system. Nevertheless, deep learning models flexibility currently provides the ability to address the optimisation needed for different blocks in parallel [8].

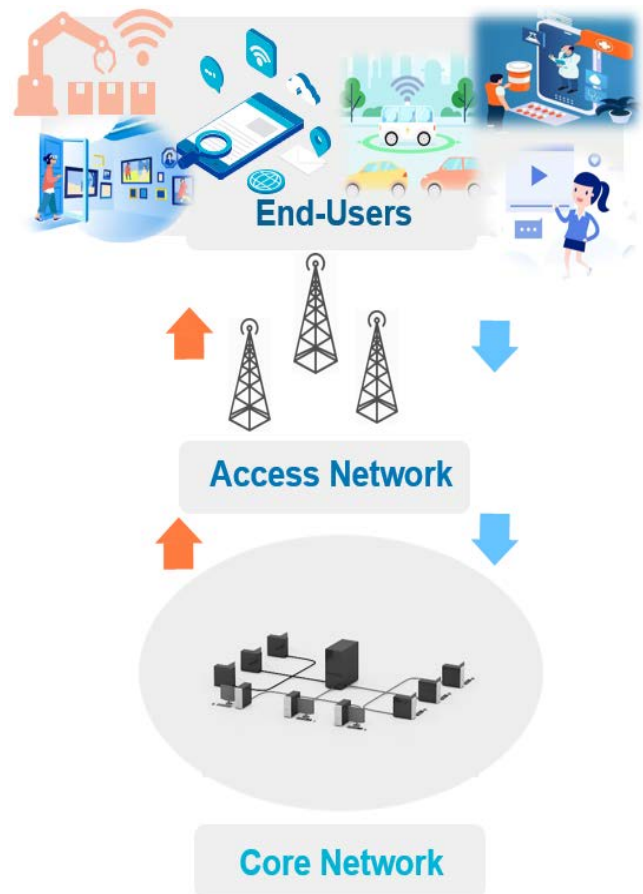

Fig. 1. Wireless Communication Architecture.

Moreover, Deep Learning in the end-to-end communication process has been employed significantly in implementing MIMO techniques. This technology involves integrating multiple antennas during the transmission and reception of signals to boost the spectrum's performance. Moreover, the implementation of multiple antennas appears to be computationally expensive and challenging in system optimisation. Thus, the use of Deep Learning in innovative studies [9,10] regarding the MIMO technique has overcome these challenges. The application of deep learning models has proven to be important when managing multiuser communication systems as well. These techniques could be applied to optimise the spectrum's exploitation for multiple users, yet they remained restrained by channel interferences.

Accordingly, an emerging technique known as Non-Orthogonal Multiple access NOMA has contributed to solving this trade-off by improving spectrum efficiency while minimising interference [11]. Currently, a new approach is also being considered for addressing these three issues in a synergistic scheme. It involves dealing with both emitter and receiver as one system designed as a single autoencoder [12], requiring a comprehensive optimisation.

B. Deep Learning for Spectrum Estimation, Detection, and Classification

Wireless communications have employed Deep Learning models' powerful capabilities in adaptability and flexibility to arm their systems with cognition. Cognitive radio could learn from collected data to adjust dynamically and rapidly the spectrum to performance and throughput demands. Among the crucial tasks that cognitive radios need to carry out, we cite signal detection and classification, although it is complex for classical feature-based algorithms that lack the flexibility to accommodate different types of signals. Deep learning model-based systems can overcome such problems since they have a high generalisation ability to classify and detect several types of signals, as shown in "Fig. 2".

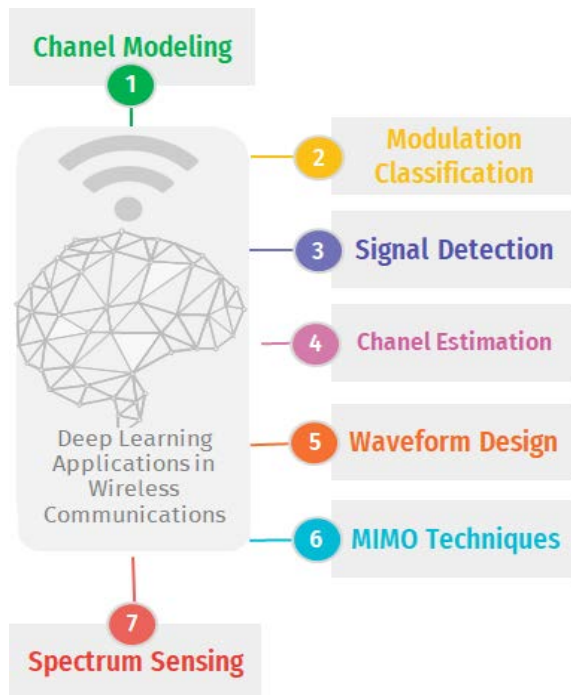

Fig. 2. Deep Learning Applications in Wireless Communications Systems.

1) *Channel modeling and estimation:* Channel modelling becomes essential to enhance the communication system's performance. For instance, autoencoders require a training phase approaching as closely as possible the real channel conditions. However, because of the channel effect, performing an efficient autoencoder training enfold several complexities. Hence reliance on GAN [13] to approximate interferences, noise, and multi-path effects to depict a channel model representing accurate and realistic behaviour [14].

2) *Signal detection:* Signal detection and classification is crucial functionality in wireless communications. It allows the control of system components and provides an up-to-date overview of the communications and events occurring in the system. Indeed, it ensures reliable detection of spectrum users and arising events, such as identifying interference sources for immediate response. Nevertheless, the spectrum is often shared for multiple simultaneous applications (TV, GSM, LTE, Radar, Etc.), which is challenging when identifying the wide variety

of waveforms used. The conventional general and specialised detection methods lack scalability and depend on the SNR for signal detection and classification. Therefore, detection using these methods is difficult to perform, especially when the SNR these to noise ratio is low [15].

3) *Consequently,* many studies consider employing CNN models that have proven their high performance in object detection and recognition, specifically in computer vision. O'Shea et al. [16] have examined the application of CNN models for signal detection and classification in the radio frequency spectrum. Their study utilised Gradient-Weighted Class Activation Mapping (Grad-Cam) for spectral event localisation and have achieved high performing results.

4) *Modulation classification:* O'Shea et al. [17] have evaluated the performance of CNN models in modulation classification by experimenting with channel effects such as multi-path fading to test the accuracy rate obtained under real-world conditions. Following the study carried out on a dataset of 11 types of modulations often used in wireless communication, the results obtained by CNN models vastly exceeded those produced by SVM or Naive Bayes, even for all used SNR ratios.

Although deep learning delivers considerable potential advantages, most recent studies have shown that they contain many vulnerabilities that attackers can harness to perform malicious manipulations [18]. Many researchers have recently examined the security of deep learning models. Some have considered the practical aspect by testing these attacks in the physical world, particularly in computer vision and object detection, while others have focused on studying the theoretical aspect of adversarial attacks. In the following section, we will present the taxonomy of these attacks and the different classifications proposed for their study.

IV. THREAT MODEL

Recently, several research studies have focused on scrutinising the security of Deep learning models. Experiments conducted in a variety of fields of study have shown that these models are vulnerable. Their high flexibility potential and their adaptability have contributed considerably to their weakness [19]. Today, several types of attacks have been tested to reveal the security flaws of deep learning models. Indeed, an attacker potentially poisons the model by introducing malicious data during the training phase to affect its behaviour to the new input data. The attacker could also severely compromise the model even in the prediction phase through carefully designed inputs to exploit its inherent flaws to mislead it into producing inaccurate results [20]. All these considerations have motivated researchers to explore deep learning models' security using conventional security approaches, especially the study of their confidentiality, integrity, and availability (CIA). In this regard, a group of researchers, namely Barreno et al. [21], have developed a taxonomy dedicated to the security of these models, providing a comprehensive classification of adversarial attacks by highlighting the opponent's goals, his knowledge of the targeted system, his capabilities and the strategy he may employ to carry out the attack as illustrated in "Fig. 3".

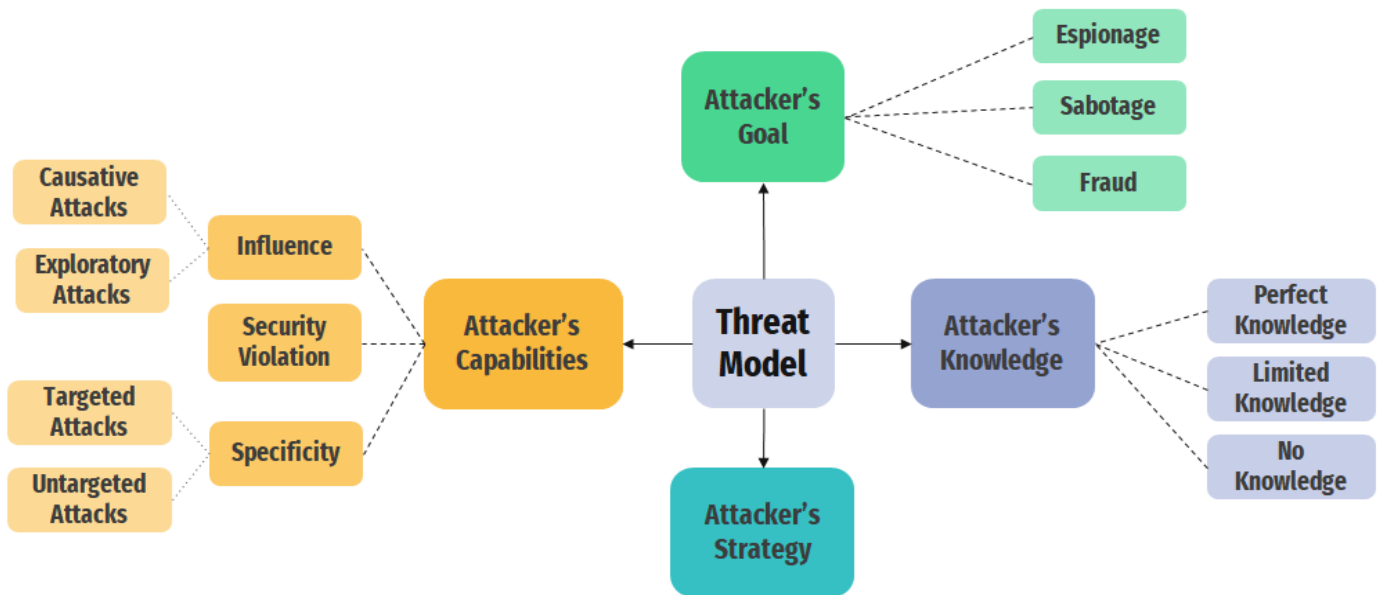

Fig. 3. Adversarial Learning Threat Model.

A. Attacker's Goal

While the same motivations might not necessarily guide attackers, their aims tend to converge around three main axes: espionage, sabotage, or fraud [22].

1) *Espionage*: In this context, the attacker seeks to derive sensitive information by exploiting vulnerabilities in the system. The leakage of sensitive information can compromise the confidentiality and the privacy of the system since the received information can be utilised to plan more advanced attacks and consequently cause very severe incidents.

2) *Sabotage*: The attacker can obstruct the system by either disabling important functionalities or by denying normal operations. Usually, this occurs when the adversary attempts to flood the model with incorrectly classified examples to increase the working time on false positive, or he can just as easily overload the system with a massive number of requests that require more computation time.

3) *Fraud*: Fraud in the Deep Learning system refers to the adversary's action of causing misclassifications or inaccurate predictions. In this case, the attacker takes advantage of existing vulnerabilities in the system to inject malicious inputs in the dataset or even modify the model's behaviour, and in this way, he causes severe damages.

B. Attacker's Knowledge

Regardless of the adversary's goals, the complexity of the attack he intends to carry out depends significantly on his knowledge of the targeted system. Papernot et al. [23] have elaborated a classification of the attacker's knowledge that can be represented in the following three levels:

1) *Perfect knowledge level*: in this scenario, the attacker knows everything about the model and the training dataset and can carry out white-box attacks. Nevertheless, this scenario

remains unrealistic because it is almost impossible to have perfect knowledge about the target system.

2) *Limited knowledge level*: This scenario is more realistic and practical; nevertheless, it presents a range of possibilities: 1) Limited Knowledge attacks with surrogate model: when the attacker has limited knowledge of the model, he can use an alternative model with features similar to the targeted system's model's features in order to craft effective attacks, 2) Limited knowledge attacks with the surrogate dataset: when the adversary has no access to the training data he can use substitute dataset with similar characteristics to carry out efficiently the attacks.

3) *Oracle or no knowledge*: In this case, the attacker has no prior information about the training set, the model, or its features; he can perform black-box attacks.

C. Attacker's Capabilities

Besides factors seen in the previous sections, the opponent's means and potentials contribute largely to determining the attack's success [24]. The adversary's potentials could be categorised according to the following three main axes:

1) *Influence*: The attacker can compromise the targeted system using either a causative attack to introduce malicious data into the algorithm's training set or by exploiting the model's weaknesses by introducing specific inputs, often called adversary examples. The causative attack influences the model's behaviour contrary to the exploratory attack, where the adversary does not affect the model's behaviour [25].

2) *Security violation*: The security infraction committed by the adversary relies on the actions taken to compromise the targeted system. The attacker can cause integrity violations by crafting false-negative inputs that bypass the model without altering the usual tasks. However, the adversary causes an availability violation when he conducts false positives, leading

to a denial of service. Moreover, the adversary can also perform privacy violation attacks that aim to derive sensitive information about the users of the targeted system, the training dataset, or the features of the model [26].

3) *Specificity*: This characteristic determines how much the adversary is specific while performing the attack. Indeed, when the attacker has intentions to mislead the model for specific instances, he can perform targeted attacks, whereas, if he chooses to compromise the predictions or the classifications carried out by the model for a broad range of inputs, he must implement indiscriminate attacks [22].

D. Attacker's Strategy

An attack strategy can be elaborated by leveraging the model's vulnerabilities and flaws by considering the attacker's goals, knowledge of the targeted system, capabilities, and potentials. Therefore, the attack strategy in question is nothing more than an optimisation problem aiming to minimise the model performance by carefully crafting efficient and imperceptible perturbations to achieve its malicious objectives successfully [21].

V. EVALUATING ADVERSARIAL ATTACKS IN WIRELESS COMMUNICATION

The study of adversarial learning in Wireless Communications presents new aspects beyond the scope of the examination of attacks targeting computer vision. Indeed, the adversarial attacks must be meticulously studied in this context. In the following paragraphs, we will examine the types of attacks targeting wireless communication systems. Then we will highlight important metrics that must be considered while assessing their robustness [27].

A. Type of Adversarial Attacks

Adversarial attacks in Wireless communications could be classified into two categories:

1) *Direct Access Attacks (DAC)*: This category of attacks exploits the direct access to the classifier's input dataset to carry out malicious actions. The results obtained in [27] for this type of attack have shown that for symbol energy and jamming signal ratio E_s/E_j of 30db, the FGSM attack produces a higher degradation than the one caused by the addition of AWGN Gaussian noise.

2) *Over the Air Attacks (OTA)*: In computer vision, the attack reliability depends on selecting the perturbations that lead the model into misclassifications while remaining imperceptible to human eyes. Similarly to computer vision, Self-protect attacks are also interested in misleading the classifier while guaranteeing information transmission to the receiver with a defined modulation.

B. Metrics to Evaluate Adversarial Attacks in Wireless Communications

Besides, the evaluation of attacks and their success rates in Wireless Communications must adopt additional metrics aligned with signal transmission performance measures. Therefore, it is essential to consider the Bit Error Rate (BER) computation and the ratio of perturbing noise and modulated

signal to estimate the opponent's attack's success rate, among other metrics.

1) *Frequency offset*: Before classifying the wideband signal, the systems initially identify the frequency of the signals and the time of transmission to convert these signals back to the baseband. Nevertheless, such operations may induce errors, as shown in [13], especially in centre frequency estimation, leading to frequency offset. The authors in [13] have noticed that raw-IQ-based AMC model accuracy dramatically decreases after adding frequency offsets. This encouraged Flowers et al. to examine frequency offsets' impact on adversarial attacks' success rate. The obtained results for 10 and 20 dB SNRs showed that even the most minor errors in frequency offset estimation could reduce the effect of adversary examples by increasing the model's accuracy by approximately 10%.

2) *Time offset*: To estimate transmission start and end times, the system employs an energy detection pattern that utilises a specific threshold of frequency power to determine the signal's existence in each instant. Incorrect evaluation of this threshold can result in false alarms or delays in the estimated transmission start time. In [28], the authors studied the impact of these parameters on the model accuracy rate. Indeed, in the absence of adversarial examples, the time offset does not significantly affect the model's accuracy rate. However, under adversarial conditions, they have noticed that translating the time-offset by four samples enhances the model accuracy rate by 20% for an E_s/E_j ratio of 12 dB. Thus, they have concluded that the time offset can considerably reduce adversarial perturbations' impact on modulation classifier.

3) *Multiple antenna usage*: In [29], the authors have examined a wireless communication system in which the transmitter emits signals to receivers using several different modulation types. The receiver identifies the modulation types using a deep learning model classifier. In this context, an opponent can potentially introduce adversarial noise by employing multiple antennas to mislead the classifier and decrease its accuracy. They have demonstrated that using multiple antennas could enhance the opponent's attack robustness using a technique used in previous work [30] known as the maximum received perturbation power MRPP. They have evaluated this attack by emulating two different scenarios. In the first one, they have attacked while using adversaries operating in separate locations with only a single antenna. In the second scenario, they have performed the Elementwise Maximum Chanel Gain EMCG attack involving a single opponent yet with multiple antennas. These two scenarios have applied different techniques for power allocation. Kim et al. [29] also considered the opponent's attack on modulation classifiers while maintaining two essential requirements: 1) the perturbations introduced to the signal must be conceived to drive the targeted model to misclassify the modulations; 2) the power of the perturbations must not exceed maximum permissible levels so that they remain imperceptible to the receiver. The experimental findings indicated that the use of

multiple opponents would not degrade the classifier's performance significantly as a single adversary had employed the same antenna power [31]. The reason behind the obtained results is the lack of coordination and collaboration between multiple opponents in the second case since they do not focus on the same adversarial goal. The authors have demonstrated in their study the efficiency of EMCG attack. The EMCG attack associated with Gaussian noise gives the weakest results proving that Gaussian Noise's presence makes the adversarial perturbations detectable by the signal receiver.

VI. THE PROPOSITION OF ASSESSMENT PATTERN OF ADVERSARIAL ATTACKS ROBUSTNESS FOR WIRELESS COMMUNICATION

Considering the results obtained in the study of adversarial attacks in the context of wireless communications, we will propose in this section a pattern to evaluate attack robustness, as shown in "Fig. 4". This pattern is inspired by our previous

works [32] related to adversarial examples robustness assessment in computer vision. It is more adapted to the specificities of wireless communications.

The process is initiated by evaluating the attacker's knowledge of the targeted system. Attacks requiring complete knowledge of the targeted system are the least robust, while those designed with limited knowledge of the target system are proven to be the most robust. Afterwards, the attacker's potential and capabilities are analysed. Indeed, we have extensively detailed through Kim et al.'s [30] experience the impact of this factor in enhancing the robustness of the opponent's attack. In the previous section, we have already demonstrated that the adversary can improve the attack robustness by maximising the used antenna's power or increasing the number of antennas employed to carry out the adversarial attack.

Fig. 4. Adversarial Attacks Robustness Evaluation Pattern.

Subsequently, the focus is on investigating the specificity of the attack. Attacks aiming at specific targets appear to be more robust than those seeking to introduce errors into the model without focusing on a specific target. Further, we analyse the imperceptibility of the perturbations introduced into the targeted system. Indeed, this parameter remains highly relevant to the attack's success rate. Further, we analyse the imperceptibility of the perturbations introduced into the targeted system. Indeed, this parameter remains highly relevant to the attack's success rate. It has been demonstrated in the studies conducted by [33] that as long as the crafted perturbations are perceptible, it is highly probable that they will be detected. This could be achieved in the context of wireless communications by keeping the power of the perturbations below the maximum permissible thresholds and thereby fooling the model without disrupting the signal transmission to the receiver.

In addition, the proposed pattern also involves examining the channel effects of Additive White Gaussian Noise, sample time offsets, and centre frequency offsets on the receiver. As in [34], researchers have shown that adding AWGN would significantly impact the adversarial examples compared to the model's accurate input data. In the presence of AWGN, the success rate of the adversarial attack is significantly reduced due to the identified sensitivity of adversarial examples to additive white Gaussian noise. Therefore, it is essential to include channel effects in the assessment process of adversarial attacks to match conditions that reflect a realistic scenario perfectly.

Finally, the pattern concludes with an estimation step of the attack's impact. To this end, we have proposed an analysis, including the adversary's objective and damaged components in the targeted system. Indeed, if the attacker fails to carry out malicious actions, we consider the attack with no impact on the target system. However, if it allows unauthorised access to the system by the adversary, then the attack has a significant impact on the confidentiality of the target system, yet its impact remains limited. Nevertheless, when the adversary carefully designs malicious perturbations to reduce model confidence in its predictions by diminishing its accuracy rate, then the impact is higher than the previous case. On the other hand, if crafted perturbations alter the model's output or influence its behaviour regarding the input dataset, then the impact is considered high since the attack affects target system integrity [35].

VII. DISCUSSION

The approach we proposed in the previous section is designed to guarantee several advantages, including evaluating adversarial attack robustness according to several metrics, such as the type of attack, its specificity, its imperceptibility, and its impact. Indeed, we have considered analysing the adversary's knowledge and capabilities since they directly affect the attack's success rate. As far as the attacker is familiar with the components of the system, he can perform attacks causing tremendous damage. This feature allows the attacker to design imperceptible adversarial examples to carry out the attack and increase its specificity by targeting precise targets. In addition, We have included the attack's adaptability as an essential

criterion for estimating its robustness. Indeed, the latter considerably affects the adopted attack strategy flexibility and therefore increases the challenge of the adopted defensive mechanism to mitigate the vulnerabilities of the targeted system. Moreover, we have conducted a comprehensive study of the attack's impact through an in-depth examination of the opponent's goal. Accordingly, we have developed a framework standardising the study and the assessment of different types of adversarial attacks. Our process provides the significant advantages of adaptability and generality since it can be applied to different models and can be tailored to different attacks and strategies that attackers may adopt in wireless communication systems.

VIII. CONCLUSION

Recently, growing attention in the scientific community has been dedicated to adversarial attacks. Throughout their studies, researchers have adopted several methods and established different hypotheses. This has made evaluating these attacks challenging since the platforms used in the experimentations are not standardised. Therefore, the proposed work suggests a unified method for evaluating adversarial attacks targeting deep learning models in wireless communications. This work has highlighted essential security aspects of the deep learning model used in wireless communications. In the different sections, we have explored the theory behind adversarial attacks as well as their practical application in the physical world. We have also examined the different studies carried out in this direction to draw a set of characteristics specific to wireless communications that greatly influence the success rate of the opponent's attack. At the end of this article, we have proposed a pattern devoted to evaluating adversarial attacks' robustness. Finally, the proposed model is designed to highlight the different characteristics of the attacks to provide an exhaustive evaluation that approximates the scenarios that can be encountered. Our future work will focus on implementing this framework using various Deep Learning models and different attacks to test its reliability in assessing adversarial attacks robustness in wireless communication systems.

Abstract—The classification application is an important procedure for selecting the feature. The classification is mainly based on the features extracted from the object. You can select the best feature using the following three methods: wrapper selection, filter and embedded procedure. All three practices have been implemented by single or combined two approaches. As a result, there is no important feature in the classification process. This problem is solved by the proposed integrated global analysis of sensitivity. Each feature is selected in a classification based on the sensitivity of the feature and the correlation from the target vector in this integrated sensitivity and correlation approach. Likewise, the GSA approach uses a variety of filtering techniques for ranking attributes and optimization using particle swarm technique. Then, the optimum attributes are trained and tested using the Random Forest Classifier grid search via MATLAB software. In comparison to the existing method, wrapper-based selection, the performance of our integrated model is measured using sensitivity, specificity and accuracy. The experimental results of our proposed approach outweigh the sensitivities by 93.72%, 94.74% and the accuracy of 89.921% and 90% where, wrapper selection approach as sensitivity by 89.83% and the accuracy of 93%.

Keywords—Feature selection; feature sensitivity; feature correlation; global sensitivity analysis; classification

I. INTRODUCTION

In a period of large amounts of large amounts of data, social media, health care, bioinformatics, online training and other media are omnipresent. The machine learning methodology depends greatly on useful basic data from a large data pool. Redundant information degrades learning process performance. It is a critical task to determine useful data and remove redundant information. The process for discovering knowledge is used to gather promising information in large data pools. Pre-processing data steps are sub-processed, such as data cleaning, data inclusion, processing and information reduction. A feature is a quantifiable characteristic of a particular process. Feature selection (FS) is the process of selection from a certain dataset for the most important features. In many cases, FS can further enhance the performance of a learning model [1]. A number of features can be used to classify many machines. Real world data has numerous unimportant, superfluous and noisy features. Deleting these characteristics by FS decreases storing and computer costs while preventing important information loss or trying to learn performance degradation. The general approach to FS is shown in Fig. 1.

FS brings numerous benefits as the system's classification increases predictability, knowledge, usability and broad capacity. It also reduces computer systems' complexity and storage, offers a rapid and effective method for knowledge discovery, and plays a critical role. [2] In literature, the majority of FS methods can be classified as wrappers, filters, embedded or hybrid as illustrated in Fig. 2.

Wrapper methods making wise the quality of the selected features by predicting a predefined, learning algorithm. A traditional method takes two different steps, as shown in Fig. 3, according to a particular learning algorithm. (1) a sub-set of features will be searched and (2) the selected feature will be evaluated. [3] Wrapper repeats (1) and until certain stop criteria have been met (2). The search feature set first generates an inferior set of features, but the algorithms studied are then used as black boxes for quality evaluation. For example, the required number of features or the enhanced learning efficiency is achieved iteratively. When a selected function is returned the sub-set of functions provides maximum performance.

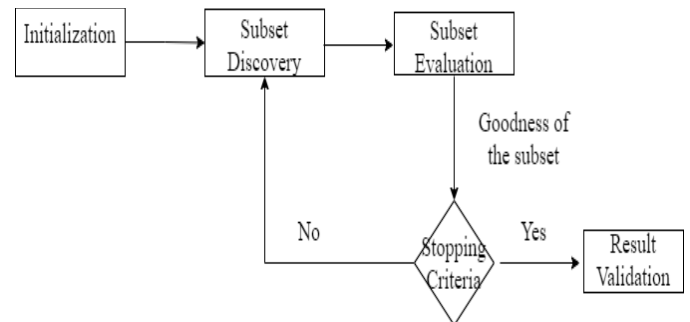

Fig. 1. Basic Feature Selection Process.

Fig. 2. Classification of FS Approaches.

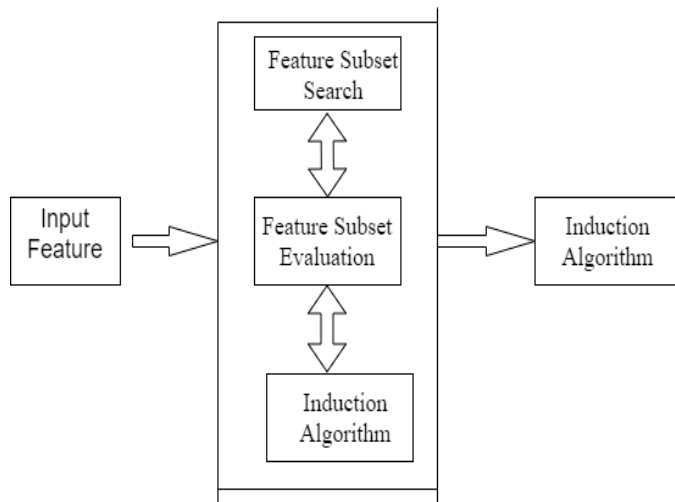

Fig. 3. Wrapper Feature Selection Working Principle.

In the majority of investigators, the selection of supervised features uses the filter evaluation framework [4]. No learning algorithms are available for the filters. You rely on data properties to measure the importance of its features. In general, filter methods are computationally effective rather than wrapping. However, because the feature selection phase is not governed by any certain algorithm, the selected features cannot be optimal for algorithms for the study. There are two steps to a typical filter method. In the first step, the importance of features is classified by certain criteria for feature assessment. The evaluation process may be one-size-fits-all or multivariate. Low quality features are filtered out in the second phase of the typical filter method. Examples are filter methods [5-9]. A typical FS filter technology diagram is shown in Fig. 4.

Fig. 4. Filter based Feature Selection Method.

The last type of feature selection is called embedded methods in Fig 4, a compromise that includes the selection of functions for model learning between the filtering and the wrapping methods [10]. Therefore, these approaches are worthy of wrappers and filter (1) because they need to interact with the classification algorithm; and (2) because they do not require an iterative evaluation of the functional sets. The major integrated approaches are the regulation model that can be adapted to the study model by minimizing fitting mistakes and

forcing less coefficients (or exact zero). The official outcome will then be returned, both the regularization model and the chosen functions. In this article we focus on new FS technologies based on a global sensitivity approach.

The paper is organized accordingly: Section II covers the existing related works and its shortcomings. Section III details the work of the proposed methodology. Section IV describes implementation and the results are discussed. Section V summarizes its performance to conclude this document. The future improvement work was suggested in Section VI.

II. RELATED WORKS

A mixture of several methodologies can be considered hybrid techniques to select features (e.g., filters, wrapper, and embedded). The main goal of many traditional approaches for selection is to solve problems of instability and interruption. Hybrid methods are examples of [11-12]. A small data disturbance, for example, can lead to completely different selection results in small, high-dimensional data. The results are consistent and therefore the integrity of the selected functions is managed to improve by combining several selected subassemblies from different methods.

Table I shows the comparative analysis of various existing feature selection techniques in the classification cardiovascular diseases. The support vector machine was preferred as classifier by most algorithms. It is due to the classification of the binary class. Due to the hierarchical arrangement of data only few works were suggested by the random forest classifier. The wrapper selection technique allows the three filter techniques to be highly precisely designed. This is due to the attribute's selection process. The attributes are selected according to the classifier's performance. On this basis, the current Cleveland data set classification technology is selected for the wrapper feature. You can use the grey-wolf optimization algorithm [13] to choose a feature from the dataset here. The selected characteristics were then given training and variable classified. It can achieve 89.83% higher grading rates. However, the wrapper selection algorithms have the following problems.

The wrapper method depends entirely on the grading option. With a different classification, the result can vary.

The classification efficiency determines the selection of fitness and variables.

These disadvantages have been overcome through the proposed global classification based on sensitivity analysis. The following Section III provides a brief explanation of the proposed approach.

TABLE I. COMPARATIVE STUDY OF DIFFERENT METHODS OF EXISTING FEATURE SELECTION

Author	Type	Technique	observations
Subanya and Rajalakshmi [13]	Wrapper selection	Artificial bee colony algorithm on heart diseases dataset SVM classification is performed Only 7 features were used.	<ul style="list-style-type: none"> • Fitness is not defined. • The results do not verify their identification nature • accuracy is the only measure.
Shah et al. [14]	Wrapper selection	Selection of features: mean fishing score and accuracy Reduction of feature: principal analysis component. Radial base kernel-based classification Vector support machine support	<ul style="list-style-type: none"> • Computational time high due to multiple feature extraction. • Cleveland datasets have minimal accuracy when compared to other datasets such as Hungary and Switzerland.
Chiroma et al. [15]	Wrapper selections	Rule based algorithm like Prism is used for feature selection and classification Wrapper algorithms like decision tree, LibSVM, K-nearest neighbor were used. Wrapper algorithm utilized forward selection and backward elimination algorithm	<ul style="list-style-type: none"> • Cleveland's f-score is a minimum of the other dataset. • As with prism, the algorithm of the Cleveland wrapper can also produce better results.
Moorthy and Gandhi [16]	Wrapper selection	Combination of ANOVA and whale optimization is used. Classification: naïve bayes, SVM and K-NN	The whale optimization algorithm for Cleveland data sets in any classification type can achieve greater precision. Compared to others, SVM produced Cleveland's best results in classification. However, it used all the classification attributes.
Wang and Li [17]	Wrapper selection	Immune system artificial	The best sonar and cardiac statolog result are produced. It can be as accurate as the Cleveland data set approach.
Saqalin et al. [18]	Filter selection	Selection of the feature: fisher score, selection forward and selection backward. Reduction feature: coefficient of mathematical correlation Classification: SVM based on radial basis	Cleveland's 81 percent data set is less accurate. The Switzerland heart disease dataset produced the best result. Less feature reduces the performance of the classification.
Garate Escamila et al. [19]	Filter selection	Chi-square and Principal Component analysis is used for feature selection. Classifier: six machine learning algorithms is used	<ul style="list-style-type: none"> • Random forest produced the best classification result. • Processing time is high for more attributes.
Gupta et al. [20]	Filter selection	Correlation and Squared correlation are used for feature selection. Random forest classifier is best among many classifiers	Able to achieve high classification rate. The number of features is high.
Ayon et al. [21]	Filter selection	Feature selection: Correlation Classifier: logistic regression, and many machine learning algorithms	Five- fold SVM based classification produced the best result. Real time features require modification
Muhammad et al. [22]	Ensemble Selection	Feature selection: LASSO, Relief, mRMR Different classifiers.	Proposal is made based on the analysis. Optimization techniques can improve the results further.

III. PROPOSED METHODOLOGY

This work introduces efficient approaches to select features such as integrated sensitivity and correlation and a global hybrid feature sensitivity analysis. We're using the data set for cardiac disease in Cleveland [23] here. It consists of 76 variables, 14 of which were only selected for use. Of the 14

attributes, 13 are predictors, and the final attributes are the target. In studies, 270 cases, 120 of which were categorized as CHD patients and 150 cases as CHD-free patients, were considered for the elimination of missing-value cases [14]. The characteristics and range of values are explained in Table II.

TABLE II. CLEVELAND HEART DISEASE DATASET [23]

Features	Description	Ranges
age	Age (in years)	29-77
sex	Gender	1: male; 0: female
Cp	chest pain type	0-3
Trestbps	resting blood pressure	94-200
Chol	serum cholesterol in mg/dl	126-564
Fbs	Fasting blood sugar	0-1
Restecg	resting electrocardiographic results	0-2
thalach	maximum heart rate achieved	71-202
Exang	exercise induced angina	0-1
Oldpeak	ST depression induced by exercise relative to rest	0-6.2
Slope	the slope of the peak exercise ST segment	0-2
ca	number of major vessels (0-3) colored by flourosopy	0-4
thal	3 = normal; 6 = fixed defect; 7 = reversable defect	0-3

A. Feature Sensitivity

The first stage uses the sensitiveness approach to identify the sensitivity to output variations in a particular model for each input factor. The results from the feature sensitivity analysis are highly dependent on the factors to be carefully selected. We have here classified their significance in determining the CHD risk. Ranks have been determined using functional sensitivity in a learned classification algorithm. After removing the least preferred characteristics, design was gradually trained according to these rankings. This phase continued until compared with the previous one the model performance deteriorated. In this approach, we examine the model, in order to analyze the differences between the characteristics of the development of the learning model.

The sensitivity of the i^{th} feature $\text{Sen}(M, m_i)$ is determined by a condition that differs between the original and the deformed data set by adding very little noise (known as μ) in the developed model.

$$\text{Sen}(M, m_i) = \frac{1}{N} \sum_{v_k} | \text{RFOutput}_k(M_{(m_i+\delta)}) - \text{RFOutput}_k(M) | \quad (1)$$

In the $\text{RFOutput}_k(M)$ and $\text{RFOutput}_k(M_{(m_i+\delta)})$, the inputs k are the output, with the original input data set M , and then the result with a noisy input ($X(x_i + \delta)$) is the very small noise δ to i^{th} . All sensitivities were measured individually with a single sensitivity. μ was randomly selected in the range [a1, 0.0010].:

B. Feature Correlation

We analyze the characteristics of model prediction outcomes and evaluate them. When changes were affected by features in the input for the preview performance, features were deemed correlated. This means that the value of the property is increased when training the model if a feature improves its severity. In addition, the relating characteristics can be compared if the size of the increase greatly affects the other features. Selection of features Correlation sees the class and value-based correlation of the subfunctions as an ideal set of characteristics:

$$\text{CFS} = \max_{s_i} \frac{k r_{cf}^-}{\sqrt{k+k(k-1)r_f}} \quad (2)$$

Where $(r_{cf})^-$ the average correlation of all the features is equal to r_f^- the average correlation of all features-class.

In this study, we analyzed features for category relationships and evaluated if they were correlated with the results of classification predictions mainly during the feature correlation analysis stage. If any of the features affects the possibility that the correlation will contribute to the output, the features were considered to be correlated.

Fig. 5 shows the flow diagram for our proposed integrated sensitivity model and correlation. The flowchart begins with the data pre-processing where missing data is processed using a data imputation method followed by min-max standardization. Any negligible input features can reduce the output of the classifier. It is therefore very difficult to select from a collection of features for the prediction mission an exact and rigorous set of attributes. Feature selection is made through the combination of feature sensitivity and functional correlation in the presented design. Each approach will evaluate the rating of features and then measure the value of the response variable by using the amount from both approaches. Functions are selected first in order to increase 1 to 13, and then in the second scenario, in order to reduce 13 to 1. This can be used to calculate and check the optimal feature subset. Random forest models are generated after the input rating with different number of features in order to estimate heart disease. A novel integrated feature selection result is linked in comparison with existing classification models like naive Bayes, decision tree, regression analysis and support vector machine.

The following is a pseudocode for feature selection based on sensitivity analysis:

Input: X = x1, x2, x3, ...xi.... xn /* features of Cleveland dataset
#Choose the feature subset based on sensitivities
#Assess all feature sensitivities
Rank the characteristics according to their sensitivities
#Add the features according to their rank to the feature subset
Output: Xs /* Chosen feature sub-set */

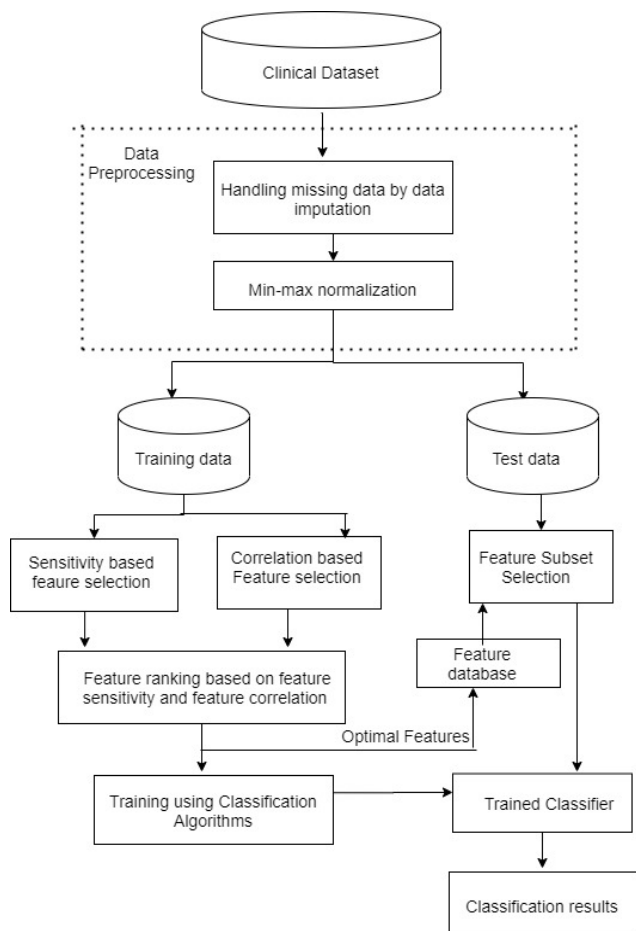

Fig. 5. Flowchart of Integrated Feature Sensitivity and Correlation Approach.

C. Global Sensitivity analysis - Particle Swarm optimization Feature Selection

This proposes an optimized filter technique for the classification process feature selection as shown in Fig. 6. There have been two phases in which to select classification attributes. The very first stage is based on a global analysis of feature sensitivity. In the second stage, a wrapper optimization determines the predominate attribute from the first phase. Due to this multi-stage functions selection, the framework developed can be used to apply every type of machine learning application. The purpose of the approach proposed is to attain the following objectives.

- 1) The method proposed does not depend on the first phase ranking of the selection of features.
- 2) Larger data sets can offer greater precision.

The importance of the attribute is determined by three individual filtering approaches:

- 1) The coefficient of correlation of the input vector to the objective output is calculated by Pearson. The correlation values are -1 and 1. The classification depends on the negative correlation approach. The attribute is listed below and the negatively correlated attribute is higher. Each ranking of attributes is performed on this basis.

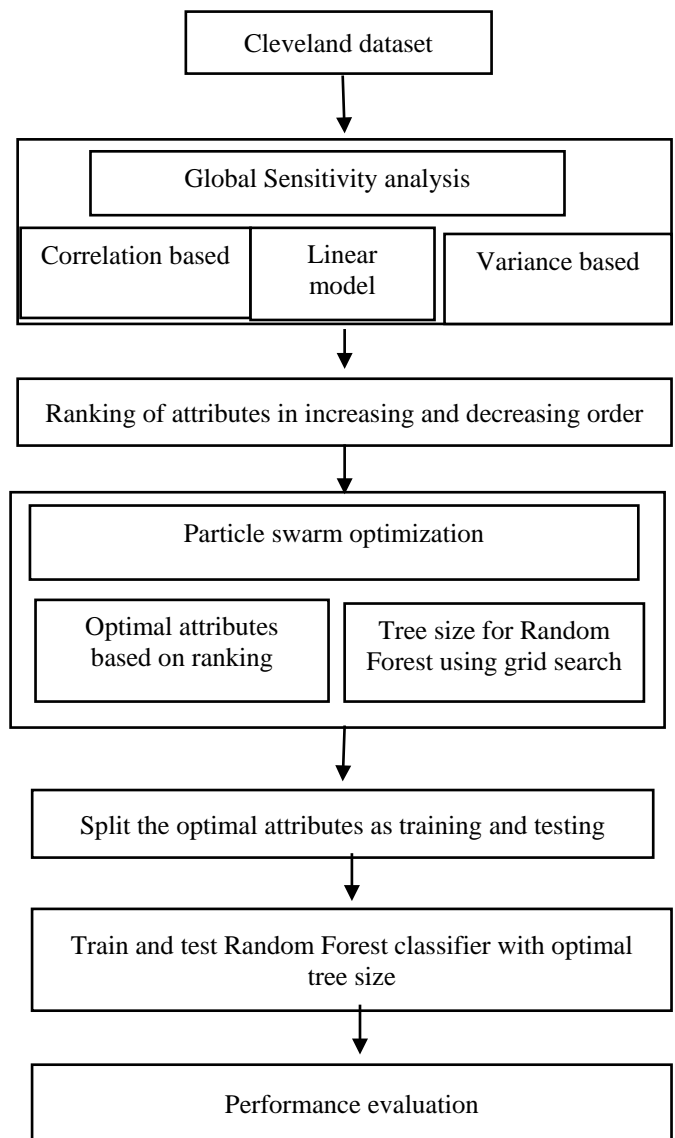

Fig. 6. Flowchart of GSA-PSO Feature Selection.

2) *Linear model fitting*- The value of the attribute is determined by the minimum average vector input error. Input attributes X1 to Xn and destination Y are included in this data set.

3) *Variance based*- The variance between the input and the target vector is calculated in order to determine its importance. Two steps for determining the difference. First, it calculates the medium of the attribute. The significant difference is also used to calculate the difference between the single attribute and its mean value.

D. Classification Methods

1) *Random forest*: The Random Forest (RF) as a supervised method of learning has been introduced recently to engineering practice [23–25]. This RF procedure combines two powerful ML techniques, bootstraps [26] and a random subspace [27]. It is therefore excellent to generalize this technique, as it adds the results of several decision-making

bodies, but computer cost is substantial. N arbitrary samples and trainings are derived using the bagging technique in this algorithm. Bootstrap sets are used to decide trees. Each node tests a feature and the leaf nodes are the output labels. The solution is achieved by combining all of the outputs [28-29], as follows: The solution is:

$$m = \frac{1}{n_{tree}} \sum_{i=1}^{n_{tree}} m_i(x) \quad (3)$$

Where y = the mean output of the total ntree amount; $m_i(x)$ = the prediction of the individual tree for the vector input x .

Fig. 10 illustrates the RF model comparison with other learning models. Fig. 11 shows the RF model comparison to the Proposed RF FSFC.

Pseudocode for feature selection based on GSA-PSO feature selection is given below:

Inputs: Cleveland dataset with thirteen attributes (Mn) and two classes (Pn)
Begin GSA
CR=corr(Mn,Pn) /* GSA based on Correlation*/
LM=fitlm(Mn,Pn) /*GSA based on Linear fit Model*/
VM=Var (Mn,Pn) /* GSA based on Variance-based*/
End GSA
#Ranking of attributes in increasing and decreasing order
Begin PSO /*Particle Swarm optimization*/
#Optimal attributes based on ranking
#Find Tree size for random forest using Grid search
End PSO
#Simulate the model with train and test/* Split the optimal attributes as training and testing*/
#Evaluate the model Performance

E. Optimization of the Feature and Size of the Tree by Particle Swarm

The optimal attribute and tree size is determined for the random forest classification via an optimization approach. The best solution for the problem is to solve the fitness function. The fitness focus is to prevent the rate of errors in the random forest classification. The fitness function is given with the following equation 5.

$$FitnessFunc_{GSA-PSO} = \text{minimum}(\text{error rate of RandomForest}) \quad (4)$$

This is achieved by finding the optimum attribute through the grid search algorithm based on a global sensitivity analysis and the best tree size between 10 and 130. By minimizing the classificatory error rate on the search algorithm, the optimum tree can also be determined. The common fitness function for optimizing the algorithm is therefore used.

IV. IMPLEMENTATION, RESULTS AND DISCUSSIONS

With the MATLAB Software R2018a, the proposed method is presented in Windows 10. The selection of characteristics based on integrated sensitivity and correlation is computed and the selection of characteristics calculated using the Global Particle Swarm Optimization Sensitivity analysis. And the approaches are compared on the basis of accuracy, sensitivity, specificity and time. The Table III shows an integrated selection of sensitivities and correlation functions. Therefore, the sensitivity of properties is determined by Equation 1 and the correlation between properties is calculated by Equation 2. The higher the sensitive value and the lower the sensitive one. And the less correlated feature is higher. In the case of the calculation of a total function range, features of the same rank will be given priority.

By combining the ranking of these techniques and identifying the importance of each attribute in classifying the data set, the integrated feature selection procedure by feature sensitivity and correlation is performed. Table III shows the general classification of these two methods for each attribute. Likewise, in order for the importance of attributes to be determined during the grading process, there was a combination of rankings with Pearson's correlation and variance-based tests as shown in Table IV. There have been sensitivity analyses.

The classified attributes were arranged in two ways in an increasing and decreasing order to determine the optimized attributes for the classification process. The ranking of lower to higher attributes is indicated by the increasing order. Lower order indicates the ranking of the higher to lower attributes.

The Cleveland dataset is used for random classification based on the above optimal attributes. The classification system is trained to increase order formats with the optimal attributes of 1 to 13 percent and 70 percent of the data. The remaining 30 percent data is then used to test and evaluate trained classifiers.

The greater ranking of an integrated method that allows patients with 93.72% sensitivities effectively to identify cardiac diseases compared with the control patient with 83.28% specificity. The overall precision of the increased order rating is 89.921%.

TABLE III. RANKING OF ATTRIBUTES WITH INTEGRATED FEATURE SENSITIVITY AND CORRELATION

8	thalach	522.9148	-0.4217	0.0079882	2	2	5	9	2	12
9	Exang	0.219978	0.4368	0.0053868	11	13	6	30	12	2
10	Oldpeak	1.343646	0.4307	0.010847	5	12	8	25	11	3
11	Slope	0.378481	-0.3459	0.063453	8	3	7	18	4	10
12	ca	1.042272	0.3917	6.2486e-06	7	11	2	20	6	8
13	thal	0.373645	0.3440	0.00095231	9	10	4	23	7	7

The reduction of ranking classifications is also trained, and all its attributes are tested using the random classification using 70% of data and 30% of data. In comparison with normal patients in the lower classifications, it can also efficiently detect cardiac patients. Its total precision, however, is 78.32%.

Table V and Fig. 7 shows the comparison between the two approaches proposed by the use of performance assessment in increased and decreasing order.

TABLE V. COMPARISON OF THE INTEGRATED FSFC APPROACH TO PERFORMANCE ASSESSMENT

Method	Increased order ranking (%)	Decreased order ranking (%)
Accuracy	89.921	78.32
Sensitivity	93.72	80.23
Specificity	83.28	78.47

Fig. 7. Comparison of the Integrated FSFC Approach to Performance Assessment.

TABLE VI. COMPARISON OF GSA APPROACH PERFORMANCE ASSESSMENT

Method	Increased order ranking (%)	Decreased order ranking (%)
Accuracy	90.00	73.33
Sensitivity	94.74	69.23
Specificity	81.82	76.47

Performance evaluation comparison of GSA approach

Fig. 8. Performance Evaluation Comparison of GSA Approach.

Similarly, with 94.74% sensitivity, 81.82% specialty and the overall accuracy for the increased ranking classifier is 90.00%, the GSA method. And with a sensitivity of 69.23 percent, 76.47 percent are declining and 73.33% are indicated in Table VI and Fig. 8 for the total accuracy of the classifier.

The performance evaluation shows that the higher rankings can effectively classify heart disease by having higher precision compared to decreasing order precision.

This means that in the Cleveland dataset, the classification of patients with normal and heart disease is best determined by the increasing order.

Then, the proposed integrated approach and global sensitivity analysis approach is compared to the existing wrapper selection method with the same Cleveland data set, using a grey wolf optimization support vector machine classifier.

In addition, our approaches, when compared with the existing wrapper selection performance, are shown in Table VII and Fig. 9 compared with the current wrapper 93% above the wrapper selection by precise determination of cardiac diseases with high sensitivity at 93.72% and 94%.

TABLE VII. PERFORMANCE COMPARISON BETWEEN GSA AND EXISTING WRAPPER SELECTION

Method	GSA analysis (%)	Integrated sensitivity and correlation analysis (%)	Existing wrapper selection GWO-SVM
Accuracy	90.00	89.921	89.83
Sensitivity	94.74	93.72	93
Specificity	81.82	83.28	91

Performance comparison between Proposed approaches and Existing Wrapper selection

Fig. 11. Comparison of RF Accuracy based on Sensitivity and Correlation.

V. CONCLUSION

The purpose of the features is assessed based on an integrated approach to sensitivity and correlation and a global sensitivity analysis based on optimization. The integrated sensitivity and correlation of properties are implemented in two phases as follows:

- 1) The first stage is to rank each attribute based on feature sensitivity analysis between the vector and the target.
- 2) The second phase consists of classifying each attribute by a correlation between the vector function and the variable objective.

The global sensitivity analysis is similarly conducted in two phases:

- 1) The first step is a classification based on different sensitivity analyses of each attribute.
- 2) The second Phase defines a more sensitive grading attribute based on the optimization of particle swarm.

The proposed approaches assess the ranking of the random forest classifier's trees and the reduced order ranking with optimum dimensions. It then uses its accuracy, sensitivity and specificity to assess its performance. The lower to higher classification produced the best results for heart disease patients. This classification helps to avoid the least classified features.

By comparing the performance with the wrapper selection-based classification, our proposed approaches integrated feature sensitivity and feature correlation outperforms it with the accuracy 89.921% and the sensitivity with 93.72% and also the global sensitivity analysis outperforms the wrapper selection by finding heart diseases accurately with the accuracy 90% and high sensitivity of above 94% as compared to existing of 93%.

The integrated approach to feature sensitivity and correlation and the global approach to sensitivity play a significant role in choosing the best classification feature especially in comparison to each feature selection procedure.

VI. FUTURE ENHANCEMENT

With the aim of reducing calculation times for the selection of attributes and improving the performance of the learning model, the results from our suggested approaches can be further strengthened.

Abstract—In early 2015 the United States Department of Energy conceived of a consortium of collaborative bodies based on shared expertise, data, and resources that could be targeted towards the more difficult problems in energy materials research. The concept of virtual laboratories had been envisioned and discussed earlier in the decade in response to the advent of the Materials Genome Initiative and similar scientific thrusts. To be effective, any virtual laboratory needed a robust method for data management, communication, security, data sharing, dissemination, and demonstration to work efficiently and effectively for groups of remote researchers. With the accessibility of new, easily deployed cloud technology and software frameworks, such individual elements could be integrated, and the required collaboration architecture is now possible. The developers have leveraged open-source software frameworks, customized them, and merged them into a platform to enable collaborative energy materials science, regardless of the geographic dispersal of the people and resources. After five years in operations, the systems are demonstratively an effective platform for enabling research within the Energy Material Networks (EMN). This paper will show the design and development of a secured scientific data sharing platform, the ability to customize the system to support diverse workflows, and examples of the enabled research and results connected with some of the Energy Material Networks.

Keywords—Energy materials research; cloud computing; virtual laboratories; data management; consortium; network

I. INTRODUCTION

The Energy Materials Network (EMN) is a United States Department of Energy (DOE) and Office of Energy Efficiency and Renewable Energy (EERE) network of consortia formed to accelerate the process of materials discovery, characterization, scale-up, and commercial deployment focused on solving the nation's toughest materials challenges in the energy sector. Building on the working concepts of High-Throughput

Experimentation [1] and the Materials Genome Initiative [2], the EMN was envisioned to be a coordinated resource network for advanced materials R&D, enabling industry and university access to world class materials capabilities at the National Labs. The concept of the EMN can be defined broadly as a virtual laboratory. The concept of virtual laboratories has been around for over a decade but has primarily been centered on the concept of supporting educational activities for remote students [3]. Unlike these virtual laboratory ideas, this concept is not a reference to a simulated environment but is centered around extending research accessibility in the real world. However, the key points that make it ideal for educating remote students, can make it equally beneficial for bringing together geographically remote resources of expertise and equipment to advance research. Bridging that expertise and equipment allows specific capabilities in each remote lab to be leveraged efficiently and provide cost saving measures in reduced equipment purchases and travel. Additionally, a virtual laboratory can still operate effectively in a changing world where environmental conditions demand social distancing and limited travel.

To facilitate this kind of research structure requires a common communication and data sharing platform for the collaborations to function efficiently. A major underpinning of the EMN strategy is the data and tool collaboration framework referred to as the Data Hub. The Data Hub is the means for capturing data, tools, and expertise developed at each of the EMN consortia facilities (called nodes) such that they can be shared and leveraged throughout the EMN and in future programs. The EMN Data Hub infrastructure facilitates accelerated learning and materials development through the establishment of data repositories, distribution of data to the greater scientific community, and development of data informatics tools. The Data Hub must also address certain challenges with creating any viable repository; data quality,

result duplication, provenance, relevance, data standards, security, and access [20].

Each Data Hub supports collaborative materials science through the establishment of accessible, searchable data resources for its EMN consortium. The Data Hubs host materials data associated with each consortia's technical portfolio, and integrate data of heterogeneous data types, sizes, and sources, including materials experimental results, theoretical and simulation data from computation, remote automated data acquisition from multiple sources, and performance and characterization benchmarking data. The Data Hubs enable robust data workflows from consortia resources and define metadata and standards for each technical area. Perhaps most importantly, the EMN Data Hubs are collectively managed by each consortiums Data Team, a group of data experts representing each member lab that focuses on coordinated development efforts, thereby increasing opportunities for data analytics and data outreach (see Fig. 1). It cannot be understated that establishing useful data hubs for materials science takes a team effort and lots of coordination and communication to facilitate development that crosses so many technical, data, and data source boundaries.

Developing a data archiving and collaboration platform that can consolidate experimental and theoretical data along with analytics tools presents many challenges. Due to the limited

development resources available, EMN Data Hubs needed a software framework that is not only customizable within the needs of each technological domain of a particular EMN, but one that can be utilized across all the EMNs. The Data Hub must house a variety of heterogenous instrumentation data, which would need to be not only archived, but contextually searchable requiring developing both standards of metadata elements along with means to facilitate metadata capture. To allow for programmatic access by analytic tools and to facilitate automated data uploads, an Application Programming Interface (API) would either need to be available or constructed for any Data Hub. Since the system would be supporting active projects and not just public release of data, any Data Hub would need project level security to restrict access to protected datasets.

This article discusses the architecture of the EMN Data Hubs with respect to both implementation, operations, and collaboration details, with an emphasis on showcasing capabilities and data available now on several of the EMN Data Hubs. The article will discuss the data governance concerns and the EMN Data Hub approach to data security and data accessibility, including efforts for standardized metadata for materials science datasets. Finally, there is a discussion of the ongoing virtual laboratory development efforts across the EMN's and the important research being conducted within them.

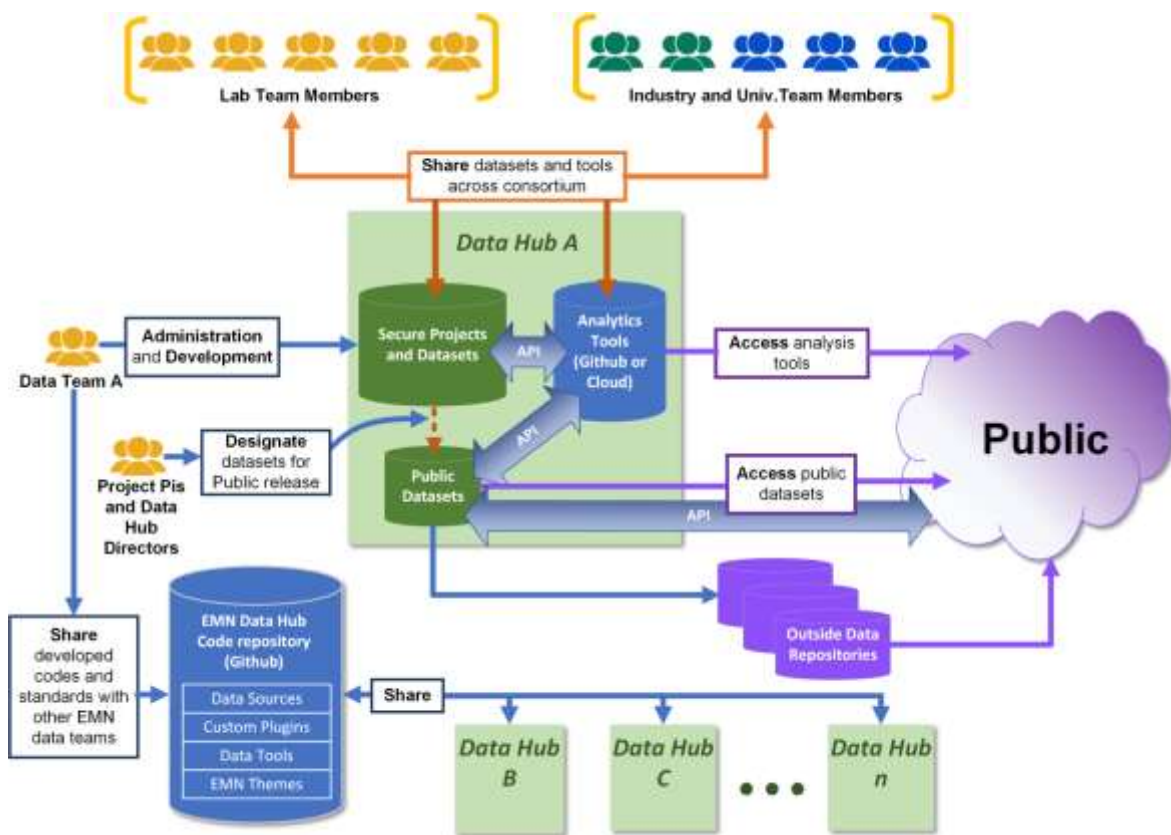

Fig. 1. EMN Data Hubs Collaboration Workflow. Not only do the Researchers Share Data and Resources Across the Platforms, but the Developers can Share Code and Administrative Resources Allowing for a More Efficient Development to Support Multiple Data Hubs. EMN Researchers from Across the National Labs, Industry and Academia Leverage the Collaborative, Virtual Lab Capabilities of the EMN Data Hubs. Each EMN Supports a Data Team, Made up of Data Experts Responsible for the Development and Operations of the Data Hub and Developed Resources are Shared among Data Team Members. Data is Released to the Public through a Managed Data Release Process.

II. COLLABORATIVE SCIENCE

From writing and publishing papers to experimental research, a vast majority of science is done as a collaborative effort. Some work is done in isolation, but often that piece is only part of a larger collaborative effort. While many ubiquitous modern technological elements can improve remote collaborative efforts (e.g. Dropbox, Google Drive, Teams, Slack, Figshare, etc.), there are often limits or pitfalls with many of those that had to be addressed for the EMN Data Hubs so that it could facilitate more efficient remote collaboration. The EMN Data Hubs were also able to facilitate the varied workflows and processes that researchers would normally use in more traditional collaborations. Many of these aspects were a result of the creation of EMN data teams, comprised of senior scientists, data architects and software engineers, to customize and refactor the basic software platform to meet each EMN's needs.

One of the basic research workflows needed by all the EMNs is round-robin experimentation (see Fig. 2), and a good example of this workflow can be found in one of the initial DuraMAT projects studying of hydrophilic and hydrophobic coatings.

Sharing data while the research under way is only one aspect of the collaborations that must be addressed. In any project there are often many ancillary documents and information that the working group will need to access. Constantly emailing documents and information, when project personnel changes, can be an onerous process, often requiring additional time by project leads to make sure the correct and complete information is distributed appropriately. In many cases, there have been established repositories within the Data Hub for both project level and EMN level information covering topics such as benchmarks, data standards and formats, tutorials, other data sources, and supporting research papers.

Fig. 2. Round-Robin Experimentation Workflow to Support the Anti-Reflection Anti-Soiling Project on DuraMAT. This Demonstrates How The Dispersed Resources Can Work In Concert Through The Collaborative Platform: Group 1 Performs Synthesis of Coating Material On glass. Group 2 Creates the Initial Baseline Measurements along with Soiling and Wash Cycles through in-Situ or Interim Processes. Group 3 Performs Any Additional Measurements Plus Analysis of Data. The Process Repeats Itself with Subsequent Samples. Data is managed through the Data Hub, Providing each Link in the Chain Access to the Project's Data. All Plots and Images; S.L. Moffitt, R.A. Flemming, et. al. [8].

III. THE EMN DATA HUB INFRASTRUCTURE

The purpose of the EMN Data Hubs is to build up a meaningful data resource from the research being done across each of the EMN nodes. The Data Hubs are designed to enable multiple levels of data governance, so that data can move from private, team-based sharing to public availability within the same infrastructure. Each Data Hub also enables the design of consortium-specific customizations for managing, analyzing, and visualizing the data types common to that consortium. The Data Hubs are hosted in the Amazon Web Services (AWS) cloud and are based on the open-source Comprehensive Knowledge Archive Network (CKAN) platform, which has a plug-in architecture for customizations.

The CKAN platform provides a project and dataset architecture, where resources within datasets can be either files or links to other internet resources. In addition, data teams have implemented several cloud resources as part of the Data Hub environment, to further the availability and manageability of materials data beyond being just a data repository.

There are currently seven EMN Data Hubs:

- LightMat (data.lightmat.org)
- DuraMAT (datahub.duramat.org)

- HydroGEN (datahub.h2aws.org)
- ChemCatBio (datahub.chemcatbio.org)
- ElectroCat (datahub.electrocat.org)
- H-Mat (data.h-mat.org)
- HyMARC (datahub.hymarc.org)

Fig. 3 shows a diagram of the Data Hubs and the cloud resources used in the Data Hub environment. At the Application level, it illustrates the Data Hub web front-end applications, which make use of a centralized authentication service. This allows researchers working within multiple EMN consortia to have a single account across all the Data Hubs they work in. CKAN also enables API accessibility to the data within the Data Hubs, so that researchers and developers can create applications, such as Python analysis and data harvesting methods that work programmatically with the Data Hub repository. The CKAN level is where the CKAN server is located, along with the CKAN database and file system. The cloud architecture enables the incorporation of other custom applications, such as a centralized sample management system, various EMN-specific materials databases, and distributed databases and big data storage.

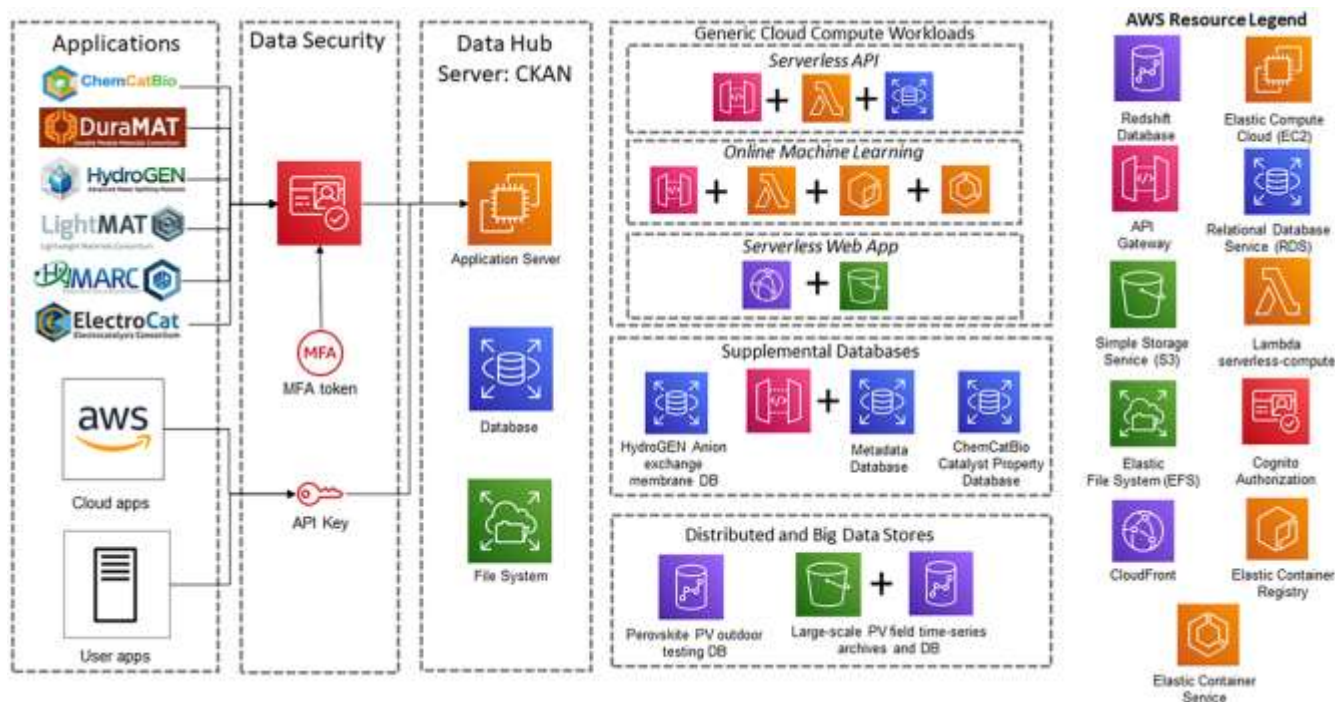

Fig. 3. EMN Data Hub Architecture. The Deployment Location of these CKAN Platform (Columns 2 and 3 on Left) was a Critical Decision that allowed for the Expansion of the Capability through Access to Easily Available, Utility Scale (Cloud) based Storage and Analysis Resources. This Extension of the basic Deployment by Integrating Automated Serverless Processing and Databases Provided the Capability for Sample Tagging and Tracking. Integrated Custom Designed Material Databases and Administration Tools were deployed as Separate Apps from the Main CKAN Deployment. Leveraging the Available Big Data Applications Allowed for Deployment of Cloud-based Time-Series Databases, Large Scale Archives, and Machine Learning and Deep Learning Resources as Ancillary Elements to the Data Hubs.

IV. DATA GOVERNANCE

As part of data governance, the seven Data Hubs managed by multiple institutions desired to adopt a common set of policies and terms. A governance team comprising of the Data Hub representatives, the legal team of the institutions and the DOE's Assistant Chief Counsel for Intellectual Property jointly worked on the language for the terms and agreement document and privacy policy. A common set of terms and agreement (<https://data.lightmat.org/terms>) and privacy policy (<https://data.lightmat.org/privacy>) was adopted by all the Data Hubs, and is available on each Data Hub or from a data team member. This governance team determined that three tiers of data could be hosted on the Data Hub. The Public-Unlimited Rights data is the most open data where data and metadata can be viewed by the public without restriction. This tier of data could be downloaded, but within some of the datahubs, this would require user authentication, so that essential metrics could be gathered on who is downloading data thereby allowing notification when a new version of the data became available. The Embargoed-protected data tier consists of data and metadata that are government sponsored and limited to authorized Non-Disclosure Agreement (NDA) or Cooperative Research and Development Agreement (CRADA) members until the embargo period ends; not to exceed five years. The embargoed-protected data will automatically become public-unlimited after the period. Finally, the Restricted-Proprietary level consists of government or non-government sponsored data that is limited to authorized NDA or CRADA members for a standard maximum of 5 years, unless terms of the agreement specify a longer period. At the end of the period, the data must be removed or released to the public.

All registered users are required to accept the terms and agreement before logging into the Data Hub. Users must also register with the Data Hub to submit data, but most Data Hubs do not accept submissions from outside of the consortium. It is the data producer's responsibility to provide metadata, upload data that accurately represents their work, and ensure that the data can be reproduced. The data producers are responsible to ensure that no personally identifiable information or classified information is uploaded. It is also the responsibility of the users to acknowledge the author, institution and DOI's on any publication related to data downloaded from the Data Hub.

Some of the Data Hubs also require an administrative review of datasets prior to the dataset being made public, to ensure accuracy and completeness. Each Data Hub has its own streamlined process for making a dataset public, which typically includes a committee review and approval. Additional supporting documentation is often required before the dataset is made public, to help understand and utilize the data. Data can be made public on a Data Hub with or without a publication; each Data Hub has an account on OSTI.gov to request a Data Object Identifier (DOI) for a new public dataset. A DOI is an example of a persistent unique identifier (PUD) and is important especially for scientific data because the unique persistent identifier is utilized and referenced in publications; therefore, as a publication will persist, so should the data that supports the research findings.

Today, there are many general-purpose data hubs pertaining to different areas of research, which elevates the importance of data governance for the EMN consortia and others [20]. Considering the growing number of such data repositories and in support of scientific data discovery and re-usability, instead of attempting to host all data, one goal of the EMN Data Hubs is to ensure there exists integrations and linkages to other external databases, datasets, and related resources that pertain to a particular public EMN dataset [21]. The Data Hubs allow external links to reference each dataset; the dataset DOI helps ensure these linkages persist for publications and other references. In some cases, the developers have consolidated dataset hosting on the EMN Data Hubs, as well as provided multiple ways to access and analyze data from the Data Hubs.

A. Data Security

The EMN Data Hubs are hosted on the Federal Risk and Authorization Management Program (FedRAMP) certified AWS cloud platform. The servers running the Data Hub application are secured via 2-factor authentication, follow network security standards and best practices, and have been vetted against DOE Cyber Security compliance rules. Data within the Data Hub is stored on secured AWS file storage, that is only accessible by the Data Hub servers. Users must be pre-approved by the Project PI for access to a private project and must use their authentication credentials to access project-specific data. Only datasets that have been marked public are available for view and download by others outside of the consortium. The security for the platform is scalable and capable of handling everything from low level to proprietary or embargoed data.

B. Data Accessibility

A backbone of modern scientific discovery is sound data management practices with a chief goal of free and easy access to data, following the FAIR (Findability, Accessibility, Interoperability, and Reliability) guiding principles for scientific data stewardship [4][21]. The EMN Data Hubs help users adhere to the best practices for data science. When possible, data should be non-proprietary, unencrypted, uncompressed, and easily interoperable by machines and humans. Typically, this means simple ASCII or UTF-8 encoding and CSV format for datasets, or simple text (.txt) format for all other relevant information. The Data Hubs provides additional support to the users with resources for applying best data management practices including:

- Documentation of metadata standards.
- Data source generation information for the discovery, reuse, and citation of scientific data.
- Consistent and reusable procedures for data release.
- User tutorials and workflow documentation.

These resources are available within the public domain on the Data Hubs. The platform enables programmatic accessibility to the data via an API and each registered user is provided an API key. This API key can be used within scripts to programmatically query and download any data to which the user has access.

V. METADATA FOR MATERIAL SCIENCE DATASETS

Metadata is the basic information that defines the criteria by which data was acquired or computed (e.g., the 2 θ setting of an X-Ray Diffraction instrument), thereby providing context to the underlying data. Experimental metadata can be elusive to capture, most often residing in researcher notebooks. Experience has demonstrated that many instrumentation manufacturers either do not capture important metadata criteria in a data file, or they bury it in proprietary binary formats, accessible only through their analysis platforms. Metadata is an important element in the Data Hubs since it enables the means to verify the accuracy of the data and provide the information needed for reproducibility, discovery, and reusability. Datasets must include all applicable metadata, data dictionaries, schemas, and technical specifications as appropriate. Discipline-specific metadata standards should be used whenever possible [5][6][7].

The EMN Data Teams view metadata as a central component of the Data Hubs, and early in the development process they focused on defining and refining community metadata definitions. This process was done iteratively, in close collaboration with the materials researchers within the EMN and at other institutions [21]. The Data Hubs have been designed to support multiple metadata types and methods, including both pre-defined metadata choices and user-defined tagging methods. This metadata can then be used for querying through both the web interface as a navigation tool, and via the API.

The Data Hub developers enabled collection of metadata in the Data Hubs using multiple methods to increase flexibility in acquiring this important information. One method utilizes predefined interactive CKAN pages with dynamic forms which are filled out by researchers when they create a new dataset or resource. This same process can be performed through the API, where a programmer can provide the predefined metadata as part of an API call. In another method, metadata templates are defined for specific materials data types, and users upload a completed template file when they add new data. This method has its advantages in that new metadata for a given dataset is within a single file and is quickly accessible. Additionally, a metadata plugin for CKAN was developed, which defines both dataset-level and resource-level metadata in JSON formatted files and used as part of the deployment configuration of CKAN. These JSON files are loaded when CKAN is started, and the web front-end uses these configuration files to create a dynamic user-input form. This method is useful in that metadata is archived as part of the internal key-value store of CKAN and can be referenced and searched directly in API calls.

VI. THE EMN DATA HUBS

The following section highlights examples of the EMN consortia and the materials research they focus on. Each EMN has produced unique and valuable datasets, and most have also developed custom data tools and models to explore and understand the underlying materials phenomena within their datasets. As part of the overarching design of the EMN Data Hubs, these tools have been engineered to be reusable across

most, if not all, the Data Hubs, enabling each of the consortia to leverage this tool development work for their own data.

A. The DuraMAT Consortium

DuraMAT is an EMN virtual laboratory focused on studying and improving the materials, reliability, and manufacturing of PV modules. This includes everything from the PV module framework to solder to encapsulants. The types of projects can include lab experimental studies, long term time-series studies of modules in the field and under accelerated testing and designing new data tools to explore and improve the understanding of the PV degradation modes. The projects in DuraMAT follow several different workflows and utilize both automated data harvesting and upload through the Hub's native API and web-based manual processes. The Data Hub is very adept at supporting a variety of experimental methods and workflows including key data management solutions that provide the dissemination of critical raw and processed time-series data to support internal collaborations and public research.

A critical DuraMAT project involves looking at degradation effects seen in PV modules, but these processes can take months or years in the field to see the cumulative damage (see Fig. 4). It was important for the Data Hub to be able to archive large, accelerated testing, time-series datasets for internal project members and to easily disseminate the information to outside researchers, stakeholders, and the public. Not only was the gathered data important, but the accelerated testing process and instrumentation would provide significant advancements in the field. With increased manufacturing levels of PV, combined with new technologies, packaging, and production methods; understanding long term degradation effects can be critical in determining PV and system component reliability. This understanding is pivotal to all stakeholders in the PV supply chain and a small savings at the PV system level could mean billions of dollars in savings overall [9][10]. By combining many of the stress factors as they occur in the natural environment, rather than sequentially, Combined-Accelerated System Testing (C-AST) can accurately provoke failure modes seen in the natural environment, reduce test time, and number of samples in parallel test. It can also help avoid costly over design by minimizing test failures not seen in the field [8]. Experiments in the C-AST system can accurately reproduce stress failures seen in the field over a longer time. Notable failure effects seen during the process were solder bonds, light-induced degradation, backsheet cracking, corrosion, and cracking of photovoltaic cells [9].

Fig. 4. Example Images [13]. A Few of the known Degradation Modes Found in PV Modules in the Field. These Modes and others are Targeted for Reproduction by C-AST Protocols. From Left to Right: Corrosion, Polyamide Backsheet Cracking, Edge Seal Failure, Delamination, Snail Trails.

During operation, the C-AST system produces a great deal of time-series data containing environmental chamber recipe data, chamber monitoring data, module monitoring data, current-voltage (IV) measurements, and electroluminescence (EL) imaging. Both the raw and processed data is extracted from the C-AST databases using automated API processes and is hosted within the DuraMAT Data Hub.

Most analysis of environmental effects on PV modules and many other physical processes have relied on the Koppen-Geiger (KG) classification of climates zones. The KG classifications are based on seasonal variations in precipitation and temperature and do not target all the climate factors that can possibly affect PV degradation. This makes using the KG model directly more difficult to ascertain true impacts of climate on PV modules. A key DuraMAT study was to re-examine the environmental climate factors and tune the models to be looking at those various climate factors known as contributors of PV degradation and rebuild the model and map to help advice improvements in PV array development, deployment, and costs (see Fig. 5).

The specific stressors used in this new climate model are based on mean module temperature, mean module temperature rate of change, extreme low ambient temperature, specific humidity (relative to damp heat), UV exposure, and wind loading [10]. The model and associated maps now provide a better insight into expected performance characteristics and expected failure and degradation modes in geographic zones. All the data and maps are available via the Data Hub to the public. Researchers can use an interactive web app, supplied through the DuraMAT Data Hub, to enter latitude and longitude coordinates to see PV climate stressors for any location in the US.

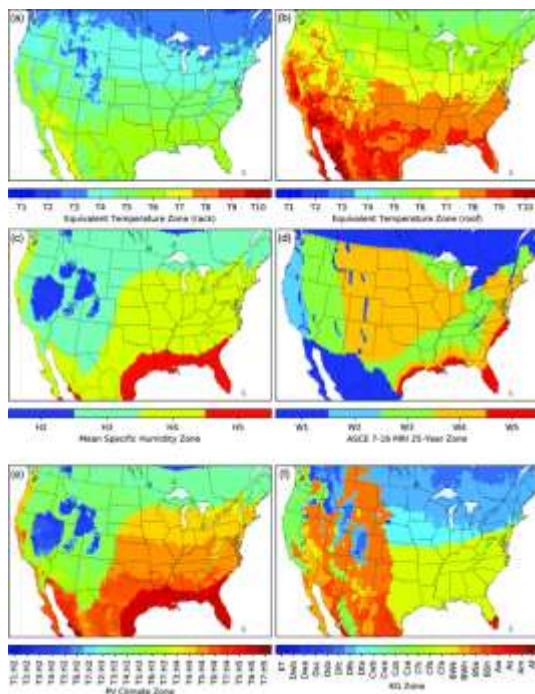

Fig. 5. Photovoltaic Stressor Climate Zones. (a) Temperature Zones for Continental United States (b) Specific Humidity Zones. (c) Wind Zones. (d) Combined Temperature and Humidity Zones. (e) Comparative Koppen-Geiger Temperature Zone [12].

B. The HydroGEN Consortium

The Hydrogen GENERation (HydroGEN) consortium is focused on accelerating the foundational R&D of innovative materials for multiple advanced water-splitting technologies to enable clean, sustainable, and low-cost hydrogen production. The consortium uses a collaborative, multi-lab, and theory-guided R&D approach to address the critical research gaps identified for the following technology readiness level (TRL) for water splitting pathways:

- low temperature electrolysis (LTE), including polymer electrolyte membrane (PEM) and anion-exchange membrane (AEM) electrolysis,
- high temperature electrolysis (HTE), including oxygen-conducting (o--SOEC) and proton-conducting solid oxide (p-SOEC) water electrolysis,
- solar thermochemical (STCH).
- photoelectrochemical (PEC) water splitting hydrogen production.

Within HydroGEN, a host of collaborative experimental, benchmarking, and round-robin data is being produced and archived within the Data Hub. Experimental data comprise materials characterization (e.g., x-ray diffraction, x-ray photoelectron spectroscopy, Raman spectroscopy, microscopy, stagnation flow reactor), device performance (e.g., voltage-current electrolysis, PEC photocurrent-voltage, solar-to-hydrogen efficiency), and materials durability (e.g., thermal gravimetric analysis, membrane conductivity, current or voltage vs. time).

In addition to the experimental data, there is structural modelling data that provides critical insights to a STCH water splitting material. $BaCe_{0.25}Mn_{0.75}O_3$ (BCM) material is of interest for solar thermochemical Hydrogen (STCH) generation. The BCM polytype structures from density functional theory (DFT) data is hosted on the Data Hub (<https://datahub.h2awsm.org/dataset/metadata/bcm-structures>) and provides explicit structure models for both the 12R (ground state) and 10H (metastable at ambient temperature) polytypes of BCM. These explicit structure models can be used for further electronic structure calculations and comparisons with experimental data [11].

The first principles materials theory (FPMT) for advanced water splitting pathways, a computational modeling capability (hosted by NREL), which produced these BCM data, supports the mission of the consortium by providing computational materials data for STCH water splitting. Access to the data and this modeling capability on the Data Hub, will allow researchers to accelerate the selection of suitable materials for synthesis, characterization, and optimization for water splitting.

The HydroGEN Data Hub also has public plenary presentations and breakout summaries from the three annual Water Splitting Technologies Benchmarking and Protocols Workshops. This is a national community effort with international engagement and participation in all four advanced water-splitting technologies. Presentations, discussion summaries, and action items obtained from the breakout groups

(e.g., high-level roadmaps for each advanced water-splitting technology, technoeconomic analysis, and protocols) are currently publicly available on the Data Hub (<https://datahub.h2awsm.org/dataset/2021-water-splitting-technologies-benchmarking-and-protocols-workshop>) (<https://datahub.h2awsm.org/dataset/2019-water-splitting-technologies-benchmarking-and-protocols-workshop>), (<https://datahub.h2awsm.org/dataset/2018-water-splitting-technologies-benchmarking-and-protocols-workshop>).

The 36 developed test protocols are still being finalized and will be published on the Data Hub soon. The development of standard test protocols and benchmarking of advanced water-splitting materials are one of HydroGEN's most important consortium cross-cutting activities and is critical to accelerate materials discovery and development.

As more experimental, computational, and benchmarking data are added to the data hub, along with the metadata that are being developed for the different water splitting technologies and the tools that help with the batch uploading of datafiles and data visualization, the HydroGEN Data Hub is an invaluable, central, searchable advanced water-splitting materials data source for the entire advanced water-splitting hydrogen production community.

C. The HyMARC Consortium

The Hydrogen Materials Advanced Research Consortium (HyMARC) addresses the scientific gaps to advancing solid-

state hydrogen storage materials. HyMARC focuses on the basic understanding, synthesis development, protocols, characterization tools, and validated computational models to accelerate exploration and discovery of materials that meet industry requirements for hydrogen storage, carriers for distribution of hydrogen from production to storage, or user facilities.

The HyMARC Sorbent machine learning (ML) application is a great example of a standalone data tool developed for the consortium and accessible through the Data Hub (see Fig. 6). In some cases, a standalone tool is the better solution than embedding the tool within the Data Hub framework. Internal linkages to the Data Hub data make it work seamlessly and make it easily accessible to consortium researchers and the public. The Sorbent web application interacts with a ML model and is centrally hosted with the model, code, and data storage, to help accelerate discovery of optimal hydride design (<https://sorbent-ml.hymarc.org/>). The public sorbent ML application can be extended to host high throughput runs of the model and or interactive dataset models; to provide a pre-computed visualization with varying input parameters.

Additional details concerning the input values to these ML codes could be needed by the researchers and public and can be explored within the HyMARC Data Hub projects. The work (<https://datahub.hymarc.org/dataset/machine-learning-ready-metal-hydrides>) provides any needed information on the seeding data [17] supporting the interactive tool.

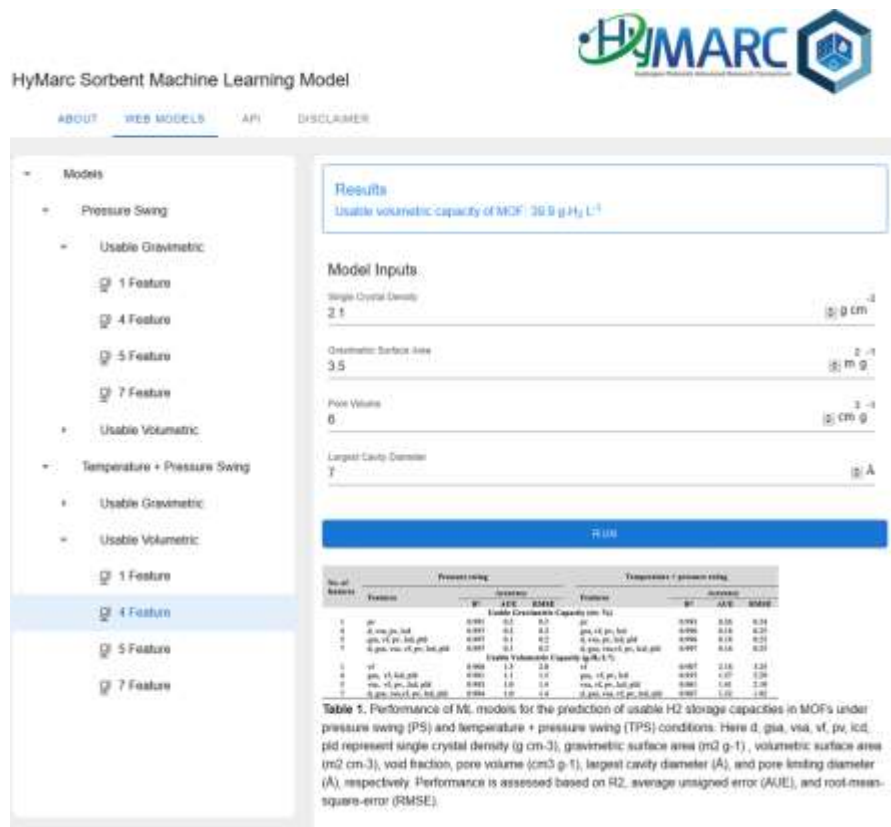

Fig. 6. An Example of the HyMARC Data Hub's Ancillary Application Capability. Built using Modern Web Technologies and Hosted on a Serverless Cloud Platform, a Public Machine Learning Application for Prediction of Usable H₂ Storage Capacities of MOFs Varying Input Parameters.. Interactive Dataset Models could Provide a Pre-Computed Visualization with

D. The ElectroCat Consortium

The ElectroCat (Electrocatalysis) consortium focuses on fuel cell energy conversion devices by accelerating the development and deployment of non-platinum group metal (PGM-free) catalysts. With a systematic approach using high-throughput, combinatorial methods, potential catalysts can be synthesized and analyzed rapidly and comprehensively. This results in an accelerated development of PGM-free catalysts, reducing fuel cell costs, by utilizing more abundant materials, thereby increasing U.S. competitiveness in manufacturing fuel cell electric vehicles (FCEVs) and other applications. The consortium has pooled electrocatalysis knowledge from several national laboratories, with an overarching goal of refining and streamlining the hardware and software tools necessary to model, analyze, and optimize PGM-free catalyst and electrode structure and performance. These tools have become enduring capabilities and will grow the publicly available dataset as a resource on the ElectroCat the Data Hub.

Of particular importance is the Unmix X-Ray Diffraction (XRD) data tool, which is a prime example of a custom CKAN embedded tool. This tool gives researchers the ability to perform component analysis on experimental x-ray diffraction spectra to estimate the contributions of each of a set of reference spectra, thereby determining a percentage distribution of each reference material within the experimental sample. Unmix XRD provides a form of automated Rietveld analysis for thin-film and powder x-ray diffraction spectroscopy. By providing a series of reference patterns in addition to an experimental spectrum, Unmix XRD determines the percentage of each reference pattern present within the spectrum. Reference patterns may be provided by the user or determined automatically from a diverse selection of the National Institute of Standards and Technology Inorganic crystal structure database of powder diffraction spectra (see Fig. 7).

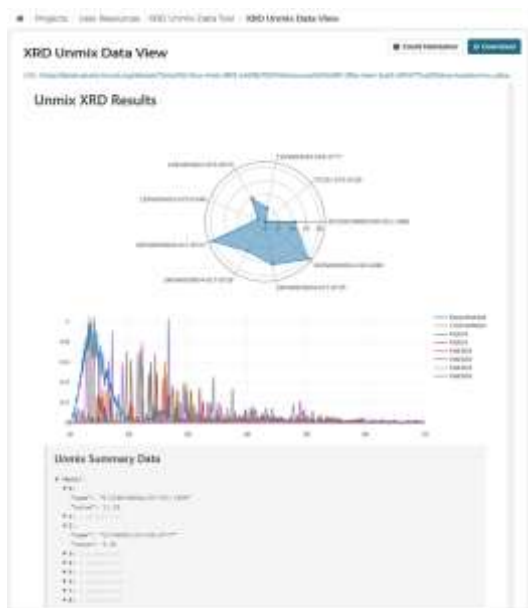

Fig. 7. The Unmix XRD Tool, which Enables the Researcher to Analyze XRD Data and Estimate the Relative Contributions of a Set of Reference Material Spectra. The Result is an Estimate of the Percentage of each Reference Material in the Experimental Sample.

This tool takes input from a reference spectra set, and any number of XRD experiment result files, performs non-negative least squares fit, and outputs a heatmap showing each "sample" (experimental file) and how much of each of the references were present within each sample. The second output file is a csv file of the same data. The Unmix XRD data tool is designed and built with modern front-end web application technologies and may be decoupled from the CKAN framework. In addition to the web application, Unmix XRD runs a lightweight compute process on the Data Hub servers, leveraging AWS Cloud resources whenever possible.

E. The ChemCatBio Consortium

The Chemical Catalysis for Bioenergy (ChemCatBio) Consortium aims to accelerate the development of catalysts and processes for next-generation biomass conversion processes. Through faster maturation of catalytic technologies, ChemCatBio ultimately intends to speed a transition to a circular economy for fuels and chemical products. It accomplishes this mission through a range of core catalytic technology projects including catalytic upgrading of biochemical process intermediates, catalytic fast pyrolysis, upgrading of one- and two-carbon intermediates (e.g., methanol and ethanol), and CO₂ utilization. These projects are accompanied by a set of enabling capabilities such as synthesis and characterization, cost analysis, deactivation studies, and theoretical modeling. ChemCatBio includes researchers from six DOE national labs, along with a network of advisors and research partners from industry and academia. In order to accomplish its mission with a geographically distributed team and large datasets, structured data management is critical. The ChemCatBio Data Hub offers this structured data-sharing resource, as well as a platform for specific data and tools developed by ChemCatBio.

Two ChemCatBio tools that use the Data Hub platform include CatCost™ and the Catalyst Property Database. CatCost is a free, public estimation tool designed to help catalyst researchers understand the cost of producing their materials at industrial scale. It was developed by ChemCatBio and released in 2018 (<https://catcost.chemcatbio.org>), in both spreadsheet and web app versions. Both versions of CatCost use the Data Hub extensively, including to store the version history for the spreadsheet downloads and the web app's libraries of materials, equipment, and spent catalyst information. CatCost development has continued since its initial release, using the resources of the Data Hub to provide continuity and support. The Catalyst Property Database (CPD) is a structured, searchable database of catalyst property information, designed to accelerate literature searching, collaboration, benchmarking, and data science applications in catalyst research, and ultimately to make the process of catalyst discovery faster. It currently contains density functional theory-computed adsorption energies for intermediates on catalytic surfaces. An initial release of the CPD was published in 2020 (<https://cpd.chemcatbio.org>) and it is under active development to allow external user uploads, establish curation procedures, offer user training, and add user-requested features. As CPD development progresses, data structures offered by the Data Hub guides development and helps ensure reliability.

VII. CONCLUSIONS

The need to meet the rapid changing landscape of scientific research and the ability to handle data efficiently and effectively is becoming more critical each year and has created a need for developers to create these collaborative data hubs to support more than just the searching and sharing of publications [21]. A simple internet search will reveal most data hubs are designed to support searchable publication repositories. Some focus on data archives, modeling and simulation, or are focused on education [17][19]. Other hub platforms are engineered to provide informatics, Machine Learning (ML) and Artificial Intelligence (AI) analysis resources, and reporting. Research teams working on pathogen surveillance are designing and deploying similar systems to the EMN data hubs, sharing the concepts of open data, structured sharing, extensibility, discovery, and data standards [18] all designed to meet research needs and follow FAIR principles of data management and discovery [4]. But what makes the EMN data hubs unique is that they can provide those same capabilities, but with a strategic focus to support ongoing experimental data sharing, secured experimental projects, analysis, and research team communication making them more analogous to a virtual laboratory.

The EMN Data Hubs have been in operation for nearly five years. Each has successfully been able to provide their community with a platform to support the acquisition and dissemination of project data, securely within project teams, and to the public. There are more users, data, visualization tools, and data analytic tools coming online in the Data Hubs every month. The EMN Data Hubs have demonstrated that the cloud is the most suitable platform to provide needed accessibility, disseminate the unique capabilities of a virtual laboratory, and make available a myriad of cloud services and workloads to the community. From web applications and API hosted on the Data Hub infrastructure, to cloud native workloads tailored to specific analytics, the platform on which these Data Hubs are built ultimately enables their EMN to host robust tools for open, reproducible, and on-demand compute workloads for data science, machine learning, and visualization.

With resources and time often at a premium for research organizations, a centralized virtual laboratory like an EMN demonstrates how to maximize the potential of available instrumentation and expertise across a dispersed set of resources. The Data Hub is the binding element of the EMNs, facilitating easy, yet secure communications and data sharing for all the projects and consortium members. While each of the Data Hubs contain elements that are unique to them and the supported EMN, the baseline architecture of the platform enables software re-use and efficient development processes across all the consortia. With a careful eye to modularity and templated deployment, a Data Hub built on these ideas can be quickly deployed and be highly scalable and agile to meet the needs of a distributed research team. As recent world events have shown, there is sometimes a need to avoid travel or direct interaction, and a research consortium built around a virtual laboratory Data Hub can still allow the researchers to continue to perform well; saving time, money, and possibly lives.

VIII. FUTURE WORK

The Data Hubs are always in active development and continue to grow in capability and data resources. Several development thrusts are underway to improve the Data Hub operability and improve the overall user experience. The importance of metadata capture cannot be understated but neither of the current two methods to upload metadata, web user interface (UI) and API, provide a robust validation process (see Fig. 8). Development of a metadata service layer is in progress that will enable more robust metadata curation and validation. This metadata-as-a-service will integrate with the existing CKAN architecture. This service will provide agility to modify existing metadata, reduce developer workload, and easily add new metadata as capabilities change and grow in the future, while still meeting guidelines for community standards [21].

As the Data Hub data repository features have matured, how data tools are developed and hosted is becoming more of a focus of the EMN data teams. Throughout the development of the data repository, several visualization and data analysis tools were developed to showcase common needs as defined within the EMN scientific domain (see above). Some of these existing tools, by design, are integrated within the CKAN framework, however, all of them could be decoupled from CKAN and hosted in the cloud, as independently accessible, interoperable services. Additionally, while open-source software development is a viable method for community sharing and development, it does not guarantee that the code will remain practical or useable (i.e. easy to install and run) for researchers. A more appropriate solution would be to not only develop a tool as open-source research software, but to host it as a service in the cloud and enable other researchers to run the software on-demand with their choice of dataset.

Fig. 8. PI/Leads May Define Custom Templates Per Experiment to Ensure Consistency and Provide Flexibility, Enabling the Curated Metadata Upload for each Project or Capability/Node.

The work being done, and the data being generated in many of the consortia is helping create extensive libraries of materials characteristics. In some cases, this data is being passed into materials science databases to allow for accelerated

discovery through machine learning and deep learning techniques [14], but there is still more to be done. It is hoped that future work can begin to either build additional large scale material databases for experimental data or merge these libraries into existing systems such as the Materials Project [16]. On a limited scale, some of the Data Hubs are currently leveraging a custom Laboratory Information Management Systems (LIMS) to help automatically assure the gathering and consolidation of all the metadata and data products and it is expected that to be extended to additional consortia partners and institutions soon [15].

The developers are constantly working with the consortium researchers and data team members to look at improvements of the general CKAN UI that can provide a better work environment and experience. There are several issues with project hierarchy and data association that while functional, are not as intuitive to use as researchers would like, and the developers are examining ways to improve them during the next rounds of Data Hub development.

ACKNOWLEDGMENT

The Energy Material Network Data Hubs are a large-scale project across several national laboratories and institutions. Much of the work in design, development, deployment, and operations is handled by the members of the EMN data teams, who we wish to thank for their hard work, insight, and dedication.

This work was authored by the National Renewable Energy Laboratory, operated by Alliance for Sustainable Energy, LLC, for the U.S. Department of Energy (DOE) under Contract No. DE-AC36-08GO28308. A New Approach based on Fuzzy MADM for Enhancing Infrastructure Selection in the Case of VANET Network

Abdeslam Houari¹, Tomader Mazri²

Laboratory of Advanced Systems Engineering, Ibn Tofail Science University
Kenitra, 14020, Morocco

Abstract—The emergence of the 5G mobile network has a huge impact on the evolution of services and functionalities offered to its customers; this latest version of mobile networks will allow the simultaneous connection of a significant number of people and IoT devices, in addition to the improvement of several other features. 5G will serve in a large part of smart cities and especially in the field of intelligent transportation systems (ITS). Vehicular Ad-Hoc Network (VANET) is one of the promising projects on which the ITS is relying on. Its main purpose is to provide communication and information-sharing support for the vehicles in its network. VANET is based on a heterogeneous network architecture composed mainly of two infrastructures, the first one is the cellular infrastructure, and the second is the road infrastructure. This paper proposes a new approach based on Fuzzy multiple attribute decision making (MADM) methods for the selection of the most appropriate infrastructure in the VANET network and consequently enhance the number of executed vertical handover to move from one infrastructure to another without loss of connection.

Keywords—5G; Vehicular adhoc network; internet of things; intelligent transportation system; cellular infrastructure; road infrastructure; fuzzy; vertical handover; MADM

I. INTRODUCTION

Nowadays, improving the vehicle's autonomy level has become one of the major concerns of the automotive sector. This new orientation is dictated by the ever-increasing number of accidents and traffic jams, which have irreversible social, ecological, and economic consequences. For this reason, the automotive sector is gradually turning to intelligent transportation systems (ITS).

VANET (vehicular ad-hoc network) is an important project related to ITS, a specific case of MANET (Mobile Ad-hoc Networks) network in which nodes are smart vehicles. The idea behind it is to connect the vehicles and share data and resources between them to understand their surroundings better and deal with the unexpected events that may occur on the road, such as traffic jams, which are one of the biggest issues for road users. Two main communication modes are provided; vehicles can communicate with each other via the V2V (vehicle-to-vehicle) mode using devices such as AU (application unit) or OBUs (On-Board Units), as they can communicate with the road infrastructure using the V2I (vehicle-to-infrastructure) mode which allows them to communicate with RSUs and Base station installed along the

road to benefit from several services such as internet access. The high node mobility is one of the main characteristics of VANET networks caused by the random movement and high speed of the vehicles, which directly impacts the response time and the topology of the network.

The emergence of 5G mobile networks is highly expected by smart cities and especially intelligent transportation. This new generation of mobile networks is equipped with a set of advanced features, such as higher capacity in comparison to 4G, allowing device-to-device communication and providing a better density of mobile broadband users [1]. As a result, vehicles moving in such a heterogeneous network will benefit from various services offered by both infrastructures. Therefore, the network's right choice is an important step to improve the quality of services (QoS) and the vehicles' efficiency. The heterogeneous nature of the VANET network raises the challenge of service continuity; as a result, the performance of this type of network requires the effective use of a vertical handover process to know the most appropriate infrastructure according to predefined criteria. Generally, the selection process can be composed of three phases: data collection, decision transfer, and transfer execution after conducting a comparative study in the previous work presented at the ISAECT conference [2]. In this paper, we focus on the decision-making step. The decision-making in the VHO process depends on several QoS network parameters and criteria such as network state, capacity, reliability, and others. In order to solve the problem of the multitude of criteria that increases with each network upgrade, the multiple attribute decision-making (MADM) approach is proposed in this study. MADM is considered a promising solution to the network and infrastructure selection problem. It is simple to implement and does not require any particular physical resources. The best-known algorithms of the MADM are the hierarchical analysis algorithms such as AHP (analytic hierarchy process) or the analytic network process (ANP) used in the criteria evaluation and weighting step, as well as VIKOR Saw and TOPSIS for ranking the available choices (networks or infrastructures). In the first part of this article, a presentation of the VANET network is performed, as well as its different characteristics, the modes of communication, the main components as well as the main challenges it faces. The next section describes the cellular infrastructure in the 5G era while detailing the main technologies that characterize it compared to previous generations of mobile networks. The following section is

dedicated to the proposed approach, which explains the implemented system model and the applied methods for ranking the two infrastructures. The penultimate part concerns the simulations performed as well as the discussion of the results obtained. Finally, the article ends with a conclusion.

II. VANET NETWORK

As explained earlier, VANET is a form of MANET network, enabling data exchange communication between vehicles in a specific geographical area and between vehicles and equipment installed at the roadside, known as roadside equipment. Several industries are interested in this project, especially the transport sector, mainly for the safety aspect that it promises to ensure by reducing the number of accidents and traffic jams, positively impacting the ecology by reducing harmful gas emissions from road traffic. In this section, a focus on the different modes of communication supported by the VANET network is highlighted. After that, the main equipment on which it is based are listed; later, we explain the data processing cycle. We end with the main features and challenges it faces.

A. Communications Mode

In a VANET network (Fig. 1), vehicles communicate with each other through the vehicle-to-vehicle mode and with road equipment through the V2I (vehicle-to-infrastructure) mode; this will allow drivers and authorities to benefit instantaneously from different information on road conditions and to take advantage of several other services offered by the network (entertainment applications, games, localization...) allowing drivers and passengers to travel safely and comfortably. There is also another type of communication, which not only interconnects vehicles and infrastructure but also includes cellular networks and other devices, this new mode called Vehicle-to-everything (V2X) is composed of V2V, V2I modes in addition to V2P (Vehicle-to-Pedestrian), and Vehicle-to-Device (V2D).

Furthermore, VANET networks are essentially based on two types of applications, one constituting the core of the ITS, which ensures the improvement of road safety, and the second type of application for the comfort of the driver and his passengers[3].

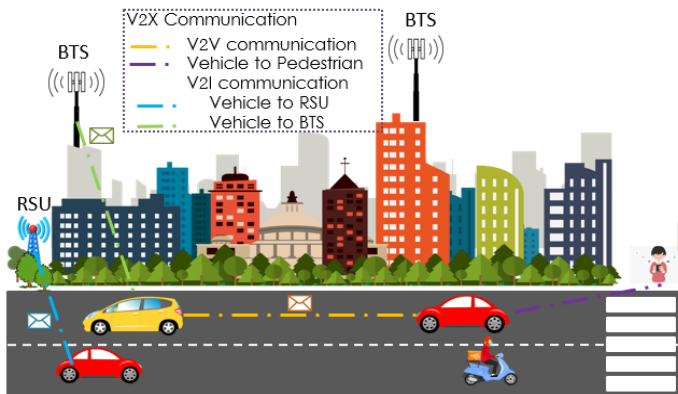

Fig. 1. Communication Modes.

B. Network Architecture Component

The data exchange at the network layer is handled by DSRC/WAVE wireless medium, whose role is to secure data transfer and reduce latency. The resulting communication leads to more reliable information and allows the deployment of safety applications that enhance travelers' safety and make driving more pleasant. Among the main components of the VANET network, there are:

- OBU: Commonly used with the RSU or other OBUs, this device is placed on the vehicle's board. Its role is to share information with the other vehicles. It is also used to retrieve information from the sensors installed in the vehicle. The connection with the RSU and other OBU is established through an IEEE 802.11p wireless link[4].
- AU: The Application unit exploits the communication means provided by the OBU in order to communicate with the network[4]. It is used in various applications; it can be used for security applications and internet access devices such as PDA (personal digital assistants).
- RSU: the road side-unit is a wave device used to extend the range of communication. It is also used to send warning messages on the road to prevent accidents[4].
- Base Station: It is equipment whose role is to connect mobile devices to access a telecommunication network; it comprises a transmission antenna and a reception antenna.

The VANET network vehicles are equipped with a set of sensors enabling them to discover their surroundings better in order to make the right decisions at the right moment. To do this, the vehicle starts by collecting data from its surroundings (location, road conditions, accident, etc.) via the sensors and cameras installed onboard. These data are then stored and processed to retain only the most important ones. Finally, the process ends by transmitting this data to the recipient vehicle belonging to the same network or a completely different network type (Fig. 2).

Fig. 2. Data Collection Process.

C. VANET Features

As mentioned above, VANET network is a specific case of a MANET network with features that differentiate it from other mobile networks, such as:

- **Dynamic topology:** this specificity comes from the fact that the vehicles are constantly changing their position and driving at high speed. They can also move in both directions and join or leave the network at any moment.
- **Frequent disconnection:** this is one of the direct consequences of the network's dynamic topology, making the connection unstable. The link between vehicles can easily be broken, resulting in the loss of the data exchanged.
- **Mobility and prediction:** Although the network's topology is dynamic, vehicles normally follow a mobility model that considers traffic lights, speed limits, road conditions, and driver behavior. However, the vehicle trajectory cannot be predicted in advance[5].
- **Geographical communication:** communication between a source and destination vehicles is possible only if the latter can be reached, a method quite different from those used in other types of networks, which are based more on the vehicle Id.

These different features have led to new challenges in setting up a safe and reliable exchange system that takes into account the heterogeneous aspect of the network and its infrastructure, without forgetting the particularity of the vehicles considered as important storage resources and powerful processing units.

D. Challenges in VANET Network

VANET faces a wide range of challenges (Fig. 3). The most critical ones are data privacy and security, especially as messages are broadcast. Anyone can intercept them, making the network vulnerable to various attacks that threaten road users' safety [6]. Security is an important aspect of any system. Therefore, it must fulfill certain requirements for the system's proper functioning and the continuity of its services. Failure to comply with any of these requirements may lead to irreversible consequences, such as a system crash or data loss.

Fig. 3. VANET Challenges.

Moreover, other requirements are exclusive to VANET networks, such as authentication, data integrity, and confidentiality. Authentication in VANET networks aims to monitor the vehicle's authentication levels. Once connected, the vehicle has a unique identifier, which prevents it from passing for multiple vehicles and usurping other vehicles' identities [7]. The second one is integrity; its role is to ensure that the message's data has not been altered or modified fraudulently during its transmission to the receiving node. For confidentiality, its role is to ensure the reliability of the communication. Sending encrypted messages ensures that only the destination vehicle is authorized to consult their content[7]. The security criterion aims to secure communications between vehicles on the one hand and between vehicles and road facilities on the other hand. One of the most dangerous attacks that vehicles face is the Sybil Attack, which is the subject of several research and studies. one of the recommended ways to prevent this attack is to establish a balance between privacy and non-repudiation[8]. Other dangerous attacks can target vehicles, such as jamming and DOS attacks, which require further research to discover the appropriate security mechanisms and algorithms to protect against them.

In some cases, the communication in an open space leads to the infiltration of malicious nodes that can intercept and corrupt the network's data. One of the major challenges that VANET faces is preventing attackers from accessing information to preserve the reliability of the links set up between vehicles and the loss of data packets on the network. The author in [9] have implemented the Reputation-Based Global Trust Establishment (RGTE) scheme to achieve these objectives. The method adopted is based on statistical laws to circulate only trustworthy information. It also allows the detection of malicious nodes through a dynamic mechanism. However, this method cannot be applied in high mobility vehicles due to packet loss.

Finally, the last major challenge for VANET networks is the link reliability between vehicles in V2V and V2I communications used for traffic data collection. Due to the high node mobility, this problem persists until now. One of the proposals is to deploy a system based on IDS (Intrusion Detection Scheme) for detecting malicious nodes involved in illegal activities. In this scheme, each node is linked to a control system in order to monitor each node and check if the network packet is transferred to the next node. Unfortunately, there is a strong probability that the packets are lost and do not reach their destination, and these nodes are consequently considered malicious even if they are not in reality. Note that this type of system has not yet been implemented and is just at the experimentation phase.

III. CELLULAR INFRASTRUCTURE IN THE 5G ERA

Cellular networks appeared at the beginning of the 1990s, its objective is to provide voice service, using a set of base stations installed in the coverage area, each of these stations cover a smaller area exclusively. The addition of traffic and data processing have been introduced into mobile networks from the second generation onwards. Mobile networks have undergone several evolutions, not just in terms of bandwidth but also in terms of standards and technologies. Several

components constitute this network. Among them, there are two that have remained the same throughout the years. The first is the Radio Access Network (RAN), and the second is the Core Network (CN). The RAN is responsible for wireless signal processing (baseband, passband) from the user equipment (UE). Simultaneously, the CN is responsible for the incoming and outgoing traffic flow's reliable routing to their destinations.

A. Main Components of the Network

During the development of mobile networks, several components have evolved many times. The eNodeB (the evolved node B) represents the base station covering the user equipment in a defined area, through which the user equipment can communicate and reach the remote destination. The other component is the Tracking Area (TA), which manages mobility and optimizes user and system management. In practice the area covered is partitioned into several TAs, and each of them includes a set of enodeBs. The Mobility Management Entity (MME) is one of the most important control components that are part of the LTE network; it acts as a signalling node in an EPC control plane. Finally, the Serving Gateway (SGW) component acts as a router and allows the Transfer of the data flow between the BSs and the Packet Data Network Gateway. A typical architecture of a cellular network can be illustrated as follows (Fig. 4).

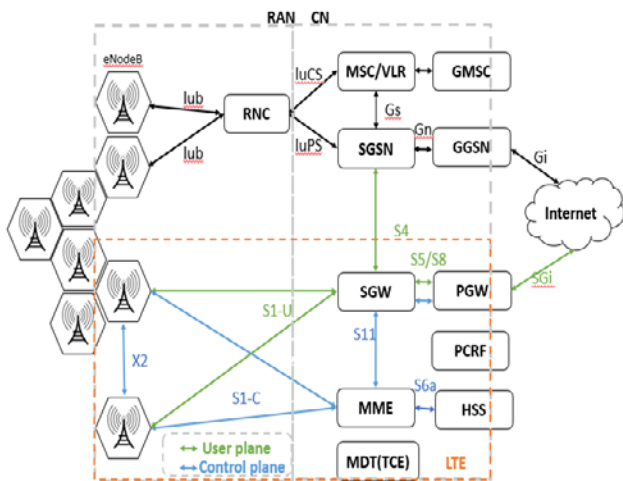

Fig. 4. Cellular Network Architecture.

B. Overview of the 5G

In the case of VANET networks, the data exchange occurs several times and between different actors. The generated data requires special processing, as it contains valuable information on road traffic. Unfortunately, conventional data management systems do not allow the management of a large amount of data in a short period. This new generation of mobile networks promises to solve several problems, including massive data management. Indeed, 5G has started to invade the global market since 2019; several new features will emerge, such as improved response time (estimated at 1ms). 5G will also enable the massive deployment of the Internet of Things (IoT) ecosystem in where networks will satisfy the communication needs of billions of connected devices in a very short time and at a low cost while reducing energy consumption. Several

technologies constitute the pillars of 5G (Fig. 5), enabling it to achieve a level of performance unequaled in the history of mobile networks; the first is the small cell, which is a cellular radio access node with a range from 10 meters to a few kilometers, its role is to increase the data capacity of the network, since, as it is the case with the previous generations, 5G radio waves cannot reach a long-range due to the high frequency used by 5G. The mmWaves (millimeter wave) are localized between 30GHz and 300 GHz; using these waves allows the 5G to reach a high transmission speed. For BeamForming, it is used to steer a radio wave to a specific destination; this is done by tuning the radio waves in order to point in a particular direction. The penultimate technology, which is the Massive mimo, aims to transmit M data flows simultaneously on M transmitting antennas, and each flow is received by N receiving antennas; for this purpose, often several transmitting and receiving antennas are used to improve both the transmission gain and the spectral efficiency. Finally, full duplex is a technology that allows a transceiver to transmit and receive data at the same time, this last technology enables to increase the capacity of the wireless network at the physical layer.

Fig. 5. Triangular Fuzzy Number.

IV. PROPOSED APPROACH TO SELECT THE BEST NETWORK

Roaming between the two infrastructures, road, and cellular is essential for any vehicle belonging to the VANET network qualified as a heterogeneous network. The selection between the two infrastructures is quite an important step. Unlike traditional mobile networks, the nodes' mobility directly impacts the network topology and affects the performance of the used protocols [10]. Also, in urban areas with high towers and a growing number of buildings, the V2X connections can be disturbed due to the phenomenon of channel fading, which is spatially correlated with the number of fixed obstacles locations [11]. In addition, the mobility of vehicles has an impact on the stability of the cluster node due to its effect on the merge and the split of the cluster [12]. As a result, vehicle mobility faces technical and organizational challenges in maintaining connections between vehicles in V2V mode on the one hand and between vehicles and infrastructure (RSU/BS) on the other hand. Moreover, since the vehicle constantly changes

position and moves in and out of the coverages of other vehicles, RSUs, and BSs.

The management of mobility becomes essential to maintain the continuity of shared services and to achieve better QoS in a heterogeneous environment. Hence the importance of using handover strategies and an appropriate network selection scheme. There are two types of handover strategy, the first is horizontal and concerns the data session transmission from one PoA to another in the same network, the second strategy is the vertical handover [13], used when a data transmission session is transmitted from one PoA to another belonging to another network (using a completely different access technology).

A. Choice of Criteria

The selected criteria have been retained since they cover the different aspects that a network should satisfy.

Capacity must be significant to meet the increased demand for bandwidth. In fact, transmitting alerts and information messages requires a moderate capacity since they are transferred occasionally. Nevertheless, autonomous driving systems require a regular exchange with vehicle onboard sensors, in addition to the applications used by road users, which consume a considerable amount of data. For the second criteria, VANET network security faces several challenges, especially with IoT integration, which will increase the number of end-users and connected objects. Different types of attacks have emerged and evolved over time, such as availability and data integrity attacks, which have irreversible consequences on vehicles and people's data and can sometimes lead to road users' death, hence the importance of taking this criterion into account in this study. On the other hand, Coverage is a determining criterion in the infrastructure selection because vehicles will be able to communicate with the infrastructure only if they are within the coverage area of the BS and RSU. Studies have shown that 4G coverage is better than 5G coverage, especially as the latter uses small cell technology. For this reason, during the simulation, the RSU coverage was given an advantage over the 5G coverage. Finally, for the last two criteria, in the VANET context, several constraints slow down the response time (mainly high mobility and dynamic

network topology) and others that affect the reliability of the data exchanged, and what has been noticed in the tests is that improving reliability harms performance and latency and vice versa.

B. MADM Methods

In the context of the heterogeneous environment, there are several types of MADM methods (SAW, GRA, TOPSIS, AHP, MEW) that have proved their efficiency in solving VHO decisions mainly for the simplicity of their implementation. According to researchers, the most efficient methods used in the VHO process are TOPSIS, SAW, and VIKOR[14]. The principle on which they are based is ranking the candidate networks according to their scores. The researchers[15] proposed given weights in order to know the importance of each attribute in the QoS class under consideration. For other researchers, such as [16], they studied using AHP/TOPSIS pair for decision making situation, AHP to calculate the vector weight and TOPSIS for ranking access network, and their results showed the importance of the weights in decision making. Concerning decision-making, algorithms based on intelligent computation are the most performant, using a neural network and intelligent implementation techniques such as fuzzy logic. Indeed,[17] have been interested in the Fuzzy AHP to determine the weight of the evaluation criteria and the Fuzzy TOPSIS for classifying the alternatives. For these reasons, we have included fuzzy logic in the model to ensure the appropriate network selection.

C. System Model

This study focuses on the proposal of a MADM approach to evaluate the two alternatives subject to this paper: cellular and road infrastructure. To do so, we start by identifying the alternatives and the evaluation criteria, and then we build the hierarchy of decisions. The criteria retained to carry out the handover decision are those of capacity, security, coverage, reliability, and latency. Finally, TOPSIS is applied to the weighted matrices to obtain the ranking of the two infrastructures. One thousand iterations covering the different weight vectors have been performed (Fig. 6).

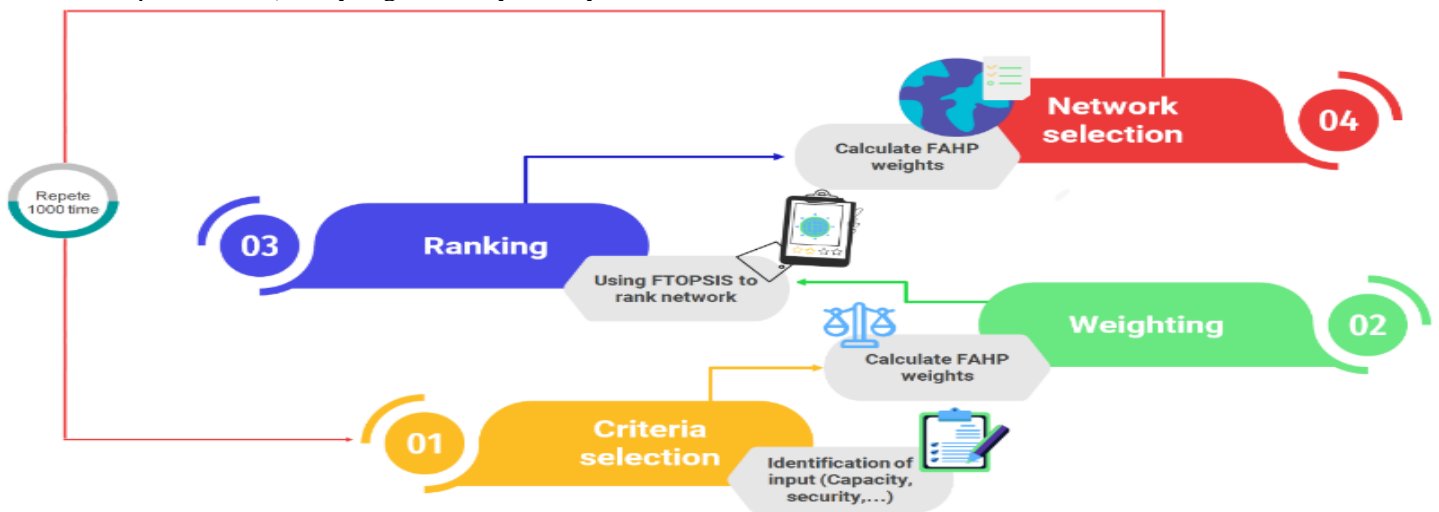

Fig. 6. System Model.

D. Network Selection using Fuzzy MADM Approach

To deal with the uncertainty of human decisions and thoughts, Zadeh [18] introduced the fuzzy set theory to represent the vagueness relative to certain classes of objects mathematically. Its ability to represent vague data is considered an important contribution in the field of mathematics and technology in general.

A fuzzy set (A in X) is characterized by a membership function f which associates for each point belonging to X a real number in the interval [0,1], $f_A(x)$ represents the membership grade of x in A.

$$f_{A(x)} = \begin{cases} \frac{x-l}{m-l}, & l < x < m \\ \frac{h-x}{h-m}, & m < x < h \\ 0, & \text{Otherwise} \end{cases} \quad (1)$$

In this case, TFN (Triangular fuzzy number) will be used in order to present fuzzy relative importance (Fig 7). In the pair-wise comparison the TFNs used are defined by three real numbers expressed as a triplet (l,m,h) with $l \leq m \leq h$ in order to describe a fuzzy event. The choice of TFN is generally related to the number of tuning and classifications (Table 1).

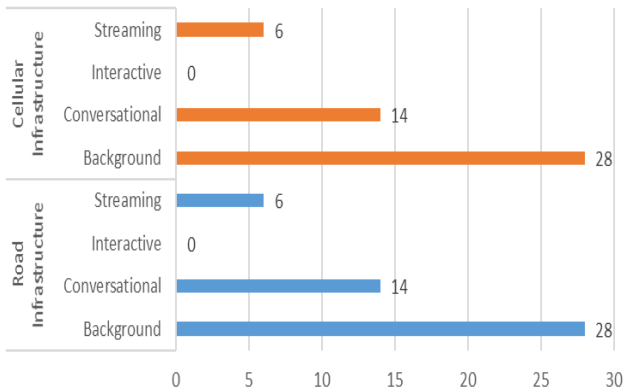

Fig. 7. Number of Vertical Handovers for 1000 Iterations.

TABLE I. MEMBERSHIP FUNCTION OF LINGUISTIC SCALE

Fuzzy Number	Linguistic scales	TFN
$\tilde{1}$	Equally important (Eq)	(1,1,1)
$\tilde{3}$	Weakly important (Wk)	(2,3,4)
$\tilde{5}$	Essentially important (Es)	(4,5,6)
$\tilde{7}$	Very strongly important (Vs)	(6,7,8)
$\tilde{9}$	Absolutely important (Ab)	(9,9,9)

a) AHP: The AHP technique has been introduced to analyze and organize complex decisions. However, research has shown some weaknesses in the AHP Saaty method [19]. FAHP appeared to overcome this deficiency; this new method combines AHP using fuzzy logic and linguistic variables. The most important step in the FAHP process is the generation of the relative fuzzy importance for each pair of factors. Using TFN and through the pair-wise comparison, the following fuzzy valuation matrix is obtained:

$$\tilde{V} = (\tilde{v}_{ij})_{n \times m} = \begin{pmatrix} (1,1,1) & \dots & \tilde{v}_{1m} \\ \vdots & \ddots & \vdots \\ \tilde{v}_{n1} & \dots & (1,1,1) \end{pmatrix} \quad (2)$$

Such as:

$$\tilde{v}_{ij} = (l_{ij}, m_{ij}, u_{ij})$$

Concerning the process of weighing using the fuzzy AHP, we opted for the Bucklet's method [20]. The geometric mean method is used for the calculation and analysis of the resulting vector in the criteria of comparison. From the equation (1), the geometric mean procedure takes the following form:

$$\tilde{r}_i = (\tilde{v}_{i1} \otimes \dots \otimes \tilde{v}_{im})^{1/m} \quad (3)$$

Thereafter the calculation of the weights is given by:

$$\tilde{w}_i = \tilde{r}_i \otimes (\tilde{r}_1 \oplus \dots \oplus \tilde{r}_m)^{-1} \quad (4)$$

The following equation is used to calculate the final resulting vector [21]:

$$\tilde{w}_i^{A/G} = (\tilde{w}_i^{A/C_1} \otimes \tilde{w}_1^{C/G}) \oplus \dots \oplus (\tilde{w}_i^{A/C_m} \otimes \tilde{w}_m^{C/G}) \quad (5)$$

To complete, the fuzzy AHP method is applied to each of the QoS classes and weights are generated for each criterion.

b) TOPSIS: For a system selection requirement, a MADM method called TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) was developed in 1981. It is a ranking technique that is simple to conceive and apply. TOPSIS aims to propose the best alternative that simultaneously has the shortest distance to the ideal positive solution and the farthest distance to the ideal negative solution[22]. the steps of TOPSIS have been detailed in [23] We make the normalized decision matrix of beneficial and non-beneficial criteria:

$$p_{ij} = \frac{x_{ij}}{\sum_{i=1}^n x_{ij}} \quad (6)$$

Concerning the weighted normalized decision matrix, it is calculated as follows:

$$t_{ij} = W_i \cdot n_{ij} \text{ where } \sum_{j=1}^n W_i = 1 \quad (7)$$

The ideal positive and negative solutions are:

$$p^+ = \{v_1^+, \dots, v_2^+, \dots\}, v_j^+ = \max_i(v_{ij}) \quad (8)$$

$$p^- = \{v_1^-, \dots, v_2^-, \dots\}, v_j^- = \min_i(v_{ij}) \quad (9)$$

The distances that separate each Alternative P from the positive ideal solution and the separation of this alternative from the negative anti-ideal solution are calculated as follows:

$$d_i^+ = \sqrt{\sum_{j=1}^M |v_i^+ - v_{ij}|} \quad (10)$$

$$d_i^- = \sqrt{\sum_{j=1}^M |v_i^- - v_{ij}|} \quad (11)$$

E. Finally, we Calculate the Relative Proximity to the Ideal Solution by Applying the Following Formula:

$$0 \leq R_i = \frac{d_i^-}{d_i^+ + d_i^-} \leq 1 \quad (12)$$

a) *QoS Class*: In this study, we have retained three main classes from the IEEE 802.16 Broadband Wireless Access Working Group project: conversational, streaming, interactive, and background class. The distinguishing factor between these classes is the delay sensitivity of the traffic. For example, for the conversational class, it is dedicated to traffic, which is very sensitive to delay, unlike the background class, which is much less delay-sensitive.

The different applications used on the road network are divided into these classes according to their delay sensitivity but also in terms of their need in terms of bandwidth and the level of security required, for this purpose we have ordered each criteria by level of importance for each class by assigning each one a TFN, thereafter we have calculated their weights which we will show in a table in the following section.

V. EXPERIMENTAL RESULT

A. Methodology

The simulations designed for the two infrastructure systems, Road and Cellular based on 5G, involved four application types (background, Streaming, Conversational, and Interactive) that cover different QoS requirements for the user side. For each of the available alternatives, the selected criteria were randomly generated according to the intervals mentioned in Table 3 for the thousand iterations of the experimentation. Finally, each range level was associated with a different vector weight. The criteria weights are calculated for each class of service using the fuzzy AHP method and are listed in Table 2.

TABLE II. ASSOCIATED WEIGHTS FOR EACH QoS CLASS

QoS Class	Capacity	Security	Coverage	Reliability	Latency
Background	0,053	0,403	0,105	0,409	0,030
Streaming	0,097	0,145	0,156	0,316	0,286
Conversational	0,090	0,219	0,197	0,044	0,450
Interactive	0,075	0,177	0,095	0,313	0,340

TABLE III. COMPARISON CRITERIA

Criteria	Capacity (Mbit/s)	Security (%)	Coverage (m)	Reliability %	Latency (ms)
Road Infra.	[10,30]	70	[1,1000]	40	[10,100]
Cellular Infra.	[1000,3000]	50	[1,100]	50	[1,10]

B. Results

The results of the first phase of tests performed on the two infrastructures for the different iterations of each scenario show that the approach adopted ensures an equal distribution of vertical handover decision between the two infrastructures for the different types of applications, except for interactive communications (Fig. 8). In fact, this proves that for V2V and V2I vehicle interactions, the mobile infrastructure is more adapted than the road network for this kind of exchange.

Fig. 8. The Average Number of Infrastructure Selections Per QoS Class.

For the second phase, the simulations showed that the cellular infrastructure exceeded the number of times it was selected, except in background applications, which revealed that vehicles tend to use the road infrastructure to run their programs in this particular case.

The received results demonstrate the potential benefit that 5G has over the other technologies used in VANET's V2X communications. This will have the effect of better managing the different types of communications as well as improving the services offered by each of the stakeholders in the VANET environment.

VI. CONCLUSION AND PERSPECTIVES

This article proposes a new approach based on Fuzzy MADM for selecting the most appropriate infrastructure in a VANET network. The two infrastructures that are the subject of this study are the cellular and the road infrastructure. To conduct this comparative study, five criteria have been considered: capacity, security, coverage, reliability, and latency. We started by presenting the VANET network with its main components, characteristics, and different communication modes. We also introduced the 5G mobile infrastructure, highlighting the main technologies that distinguish it from the previous versions. Then we ended the article by the comparative study while explaining the system model adopted and the different methods used to test and evaluate the two infrastructures, namely the Fuzzy AHP, to generate the weights of the evaluation criteria, and the TOPSIS method was applied to rank the alternatives. The adopted approach also allows us to select better the infrastructure in a shorter delay and less complexity. This approach's advantage for managing vertical handover decision in this type of network characterized by its dynamic topology and its nodes' high mobility has also been demonstrated.

We intend to include vehicle mobility parameters during the tests to have a more realistic simulation in future work. We also plan to test other combinations of MADM methods such as VIKOR and SAW to select the best network and infrastructure.

Abstract—In time-sensitive applications, such as detecting environmental and individual nuclear radiation exposure, wireless sensor networks are employed. Such application requires timely detection of radiation levels so that appropriate emergency measures are applied to protect people and the environment from radiation hazards. In these networks, collision and interference in communication between sensor nodes cause more end-to-end delay and reduce the network's performance. A time-division multiple-access (TDMA) media access control protocol guarantees minimum latency and low power consumption. It also overcomes the problem of interference. TDMA scheduling problem determines the minimum length conflict-free assignment of slots in a TDMA frame where each node or link is activated at least once. This paper proposes a meta-heuristic centralized contention-free approach based on TDMA, a modified particle swarm optimization. This approach realizes the TDMA scheduling more efficiently compared with other existing algorithms. Extensive simulations were performed to evaluate the modified approach. The simulation results prove that the proposed scheduling algorithm has a better performance in wireless sensor networks than the interference degree leaves order algorithm and interference degree remaining leaves order algorithm. The results demonstrate also that integrating the proposed algorithm in TDMA protocols significantly optimizes the communication latency reduction and increases the network reliability.

Keywords—Wireless sensor networks; media access control protocol; scheduling algorithms; meta-heuristics; particle swarm optimization

I. INTRODUCTION

Nuclear energy is an important clean energy source. The probability of radiation releases from nuclear facilities is extremely low due to strictly applied safety measures. But the serious situations that could result from a nuclear accident make it essential to use online detection of radiation [1], [2]. Wireless sensor network (WSN) technology is usually integrated into time-sensitive applications such as online radiation monitoring systems because of its efficiency to deal with low-rate communications, simplicity in construction, reconfigurability, and low cost [3] [4]. An essential role of sensor networks is target coverage, whereas the sensor nodes' function collects data periodically and transmits it to the

destination node in the WSN. This many-to-one communication pattern is known as converge-cast [5], [6]. Although many WSN applications are beneficial, limited resources of WSN cause several challenges that need to be addressed for efficient performance. Energy consumption is the main problem as sensors are usually battery-powered [7], [8]. Minimizing communication latency is a fundamental objective of the alarm-driven WSNs applications or disaster early warning applications [9] - [13]. Communication latency is caused by several factors depending on the design of stack layers of the WSN. To minimize communication latency, the WSN protocols in different layers should overcome the following problems:

- **Transmission interference:** Conflicts are classified into two types: primary and secondary. When a node has several communication tasks in a same time slot, primary conflict arises. When a node switched to a specific transmitter inside the communication range of other communication process considered for it neighbours, a secondary conflict occurred [14]. The existence of a conflict between any two sensors would block these two sensors from transmitting simultaneously [15].
- **The radio transceiver of sensor node:** Sensor nodes use half-duplex transceivers due to hardware limitations as it is impossible for a node to send and receive simultaneously.
- **The topology of WSN:** It is an essential factor as a flat topology results in high latency, and a single-hop-to-sink topology achieves minimum delay, but scalability for its network is limited. The hierarchal or tree-based topology achieves low latency and satisfies power consumption [16].
- **The duty-cycle mechanism:** It controls the listen (transmit or receive) and sleep periods of sensor nodes. This mechanism is executed at the media access control (MAC) layer.
- **Overhearing:** When a node receives data intended for other nodes, it is referred to as overhearing.

Communication latency is affected mainly by the design of the data-link layer and the network layer [17]. The cross-layer strategy is two or more layers communicate to improve the network's overall performance [18]. The cross-layer approach is used here for latency, where the MAC protocol used routing protocol information to determine optimum schedules. MAC protocols conclude mainly in two types; contention-based MAC protocols as carrier sense multiple-access (CSMA) and contention-free MAC protocols as time division multiple access (TDMA) [19]. TDMA protocols are more suitable for heavy traffic conditions to avoid collisions successfully [16] [20]. Interference is an essential factor in determining the TDMA schedule. The sink node organizes the frame's scheduling, whereas time slots are specified to nodes in WSN for data transmission and reception considering interference. The TDMA scheduling remains fixed unless there is no reconfiguration in the WSN [21].

Designing efficient approaches to schedule TDMA transmissions in multi-hop WSNs is an NP-complete problem [22]-[25]. Meta-heuristic optimization algorithms are the most reliable techniques to find near-optimal scheduling that achieve minimum latency for critical WSNs [26] [27].

Eberhart and Kennedy introduced the particle swarm optimization (PSO) approach for swarm intelligence, a meta-heuristic evolutionary technique inspired by bird flocking or fish schooling's social behaviour [28]. A population of random solutions known as particles follows the same idea. These particles fly into a multidimensional search space in the direction of optimum value. Then the PSO algorithm presents a solution to the TDMA scheduling problem and provides the near-optimal schedule off-line, which is then used by the sink node to schedule the sensors in real-time.

This paper aims to discover the best result to the communication latency problem in multi-hop WSNs depending on cross-layer optimization. This paper's primary contribution is as follows:

- Employment of a modified PSO algorithm to optimize TDMA scheduling in a WSN to minimize communication latency.
- Formulation of a fitness function considering communication latency minimization.
- Provision of comprehensive simulation results to demonstrate the advantages of the modified PSO over other relevant algorithms in minimizing the communication latency.

Section II of this article presents a review of related work, and it gives the problem statement. The network model is developed and provided in Section III. The proposed PSO algorithm is discussed in Section IV; also, evaluation metrics are presented in the same section. Section V illustrates the simulation and assessment of performance. Section VI discusses the results, while Section VII concludes this work and suggestions future studies.

II. RELATED WORK

A. TDMA Scheduling Optimization

Several scheduling algorithms for data collection in WSNs have been developed and presented solutions for the aforementioned problems. Each algorithm has one or multi-objective associated with data collection according to its application requirements [29].

Sensor nodes interact via wireless multi-hop routing because of the limited range of radio transmission. One-hop TDMA scheduling is simpler than multi-hop scheduling. There is no requirement for spatial reuse of a time-slot since in one-hop TDMA scheduling, and several nodes can broadcast simultaneously if their receivers are not in conflict [30].

The scheduling algorithms use one of two interference models for evaluation; the protocol model depending on a graphing approach or the physical model depending on the Signal-to-Interference-plus-Noise-Ratio (SINR) as discussed in [25], [31].

Previous research efforts on WSN processing time have focused on a specific problem based on meta-heuristic approaches. Following [15], the authors used the PSO technique to reduce the overall transaction time. The PSO algorithm dealt with it as a graph partitioning problem and maximized the parallel operation of the network's sensors. A multi-objective optimization framework is executed as described in [32], where a genetic algorithm (GA) and PSO algorithm were combined to improve searching for a global optimum. This framework achieved a minimization in latency and a power conservation. TRASA (traffic-aware time slot assignment) algorithm is discussed and presented in [33] to gain minimum scheduling and fair medium access. Scheduling of nodes in different time-slots depends on the node's priority (i.e., a node with a high number of offspring, so it has more data to transmit). There are two versions of TRASA; one slot and many slots. When a node possesses a time-slot, only this time-slot is for this node, and many time-slots are assigned to nodes with high priority to transmit without switching delays. M. Bakshi et al. [25] Proposed an optimum converge-cast schedule in a WSN. They used the SINR model of interference and a TDMA -MAC protocol. The PSO algorithm optimized scheduling in multi-channel and multi-time-slot assignment WSN [11], [34]. This PSO algorithm improved the latency and the length of the frame. The Cross-layer approach, CoLaNet [35], is enhanced as described in [36], as the authors proposed new TDMA scheduling algorithms related to routing to reduce communication latency. They present Rand-LO, Depth-LO, and Depth-ReLO algorithms to improve latency. In the slot scheduling approach, these algorithms demonstrate the necessity of traversing the routing tree. Reference [10] considered the interference degree of sensor nodes in the proposed scheduling methods, IDeg-LO and IDeg-ReLO, and improved the network's latency. [9] Proposed an ETDMA-GA algorithm based on a genetic algorithm and cross-layer approach to obtain optimum TDMA scheduling for minimum latency. They compared the obtained results with [10], [36] and proved that the ETDMA-GA algorithm outperforms Rand-LO, Depth-LO, Depth-ReLO, IDeg-LO, and IDeg-ReLO in terms of average latency and average schedule length.

This paper aims to find the efficient and optimum TDMA schedule for sensor nodes based on routing information. The proposed modified PSO approach schedules sensor nodes efficiently and reduces communication latency for a network.

PSO algorithm has several advantages compared with other meta-heuristic algorithms. For example, its mechanism is more straightforward (few parameters to be adjusted), the computational cost is low, the convergence speed is high, and the quality of solutions [37]. A study comparing various swarm intelligence (SI) approaches used selected thirty benchmark functions that measure these performance approaches'. This study concluded that PSO is a second-best approach next to Differential Evolution (DE); it outperforms or equally performs to the best algorithm in eighteen out of thirty functions [38].

In WSNs, PSO has been used to address several problems such as energy conservation [39], coverage maximization [40], optimal deployment of sensors [41], clustering, clustering head selection, data aggregation [42], and node localization [43].

The PSO algorithm has also been modified to solve a variety of complex optimization problems. For example, it has been used to handle large-scale, constrained, multimodal, multi-objective, and discrete optimization problems, among others [44].

B. Problem Statement

As discussed above in Sections I and II, communication latency is a significant issue in WSN, which imposes challenges in alarm-driven WSN applications such as environmental radiation monitoring networks (ERMNs). This communication latency can be due to transmission interference, network topology, the half-duplex transceiver of the sensor node, duty cycle mechanism, and overhearing. Minimizing the converge-cost is an NP-complete problem, which could be addressed using meta-heuristic optimization algorithms to find a near-optimal off-line solution, which is then used by the sink node in real-time. Compared with other meta-heuristic algorithms, the PSO algorithm has several advantages, including its more straightforward mechanism, higher quality, lower computational cost, and higher conversion speed. The problem that is addressed by this work is the need to minimize the communication latency in ERMNs through optimization of the TDMA scheduling using a modified PSO algorithm.

III. MODELING OF WIRELESS SENSOR NETWORK

A. Network Model and Scheduling Model

The WSN employs static sensor nodes supplied with Omni-directional antennas and single half-duplex transceivers. It has one sink node that contains all information about synchronization between sensor nodes, topology, interference relationships, and determination of each node is parent or child.

A WSN is a graph of vertices (V) and edges (E), $G = (V, E)$ where V represents the sensor nodes and E corresponding to links between nodes. The connectivity model describes the way that the links are connecting nodes. The classical connectivity model based on the unit disk graph (UDG) is adopted. In UDG, any two nodes are considered adjacent if their Euclidean distance is the most [35]. The Euclidean

distance d_{ij} between nodes i and j, denoted by $d(i,j)$, is the least number of hops required to send data from one point to another. The communication range of all nodes is assumed to be the same, and therefore the links in the modeled graph are symmetric. Two matrices describe the topology of the WSN; the symmetric connectivity matrix C_{N*N} , which describes connectivity relations between neighbours as in (1), and the interference matrix I_{N*N} , which represents conflicts between neighbour nodes in the network as in (2)

$$C_{ij} = 1 \quad \text{if} \quad d(i,j) = 1; \quad \text{else} \quad C_{ij} = 0 \quad (1)$$

$$I_{ij} = 1 \quad \text{if} \quad d(i,j) \leq 2; \quad \text{else} \quad I_{ij} = 0 \quad (2)$$

According to these two matrices, the sink node determines the TDMA scheduling, and each node recognizes the time slot assigned to it for transmitting and receiving without interference.

Some constraints restrict the parallel operation of some WSN sensors. Interference between sensor nodes in the WSN forms the primary constraint that decreases successful transmissions. The scheduling algorithm proposed by this paper aims to maximize parallel instead of sequential operation of data transmission. An optimization problem for this solution was modeled.

The normal TDMA scheduling method is used for time-slot allocation for all nodes in the initial phase. For a randomly deployed WSN, the sink node applies a depth-first search [45] algorithm. The sink node constructs a shortest-path routing tree. Then the sink node determines the TDMA schedule and broadcasts it to all sensor nodes in the network. The scheduling technique depends mainly on searching for a first free time-slot for a node; a time-slot is free or suitable for a node if it is not busy with any one-hop or two-hop neighbour nodes. A traversal list, depending on the searching algorithm, orders the sensor nodes in the routing tree.

For each node's traversal list, based on the connectivity and interference matrices, a TDMA scheduling can be deduced as presented in the following slot allocation algorithm[9], [10]:

- 1) The frame length initializes with a size equal to the maximum node interference degree in the network.
- 2) The first time-slot is allocated to the first node in the traversal list for data transmission and all connected nodes for data receiving.
- 3) The sink node schedules the rest traversal list's nodes Similarly. The node's time-slot is for transmission and receiving data.
- 4) If there is no free time-slot for allocation, then an extra time-slot to the frame is added.

B. Optimization Algorithm

PSO algorithm initializes particles randomly and converges to the optimal solution by iterations. Each particle modified its velocity and then updates its position. It depends on its expertise (cognitive) and the expertise of other particles (social) [46]. Every particle has two vectors in the PSO

algorithm: position and velocity. The position vector describes the value and the direction of a particle at all iterations. The position function of a particle changes to a best in each iteration of the PSO algorithm by using (3):

$$\bar{x}_i(t+1) = \bar{x}_i(t) + \bar{v}_i(t+1) \quad (3)$$

Where $\bar{x}_i(t)$ means the position of a particle (i) at iteration t and $\bar{v}_i(t+1)$ presents the velocity of the particle (i) at iteration (t+1). Equation (3) determines the update in a particle's position, which depends mainly on its velocity vector. The velocity vector of the particle (i) at iteration (t+1) is as in (4):

$$\bar{v}_i(t+1) = \omega \bar{v}_i(t) + c_1 r_1 (\bar{p}_i(t) - \bar{x}_i(t)) + c_2 r_2 (\bar{g}(t) - \bar{x}_i(t)) \quad (4)$$

The coefficient ω , known as inertial weight, describes the individual coefficient known as the social coefficient and random numbers [0, 1]. In velocity (2), the equation of velocity (4) contains three parts.

The first part $\omega \bar{v}_i(t)$ keeps the orientation the same as the current velocity of the particle. It tunes exploration and exploitation, which are essential to achieve the exact estimation of a global optimum.

The second part: $c_1 r_1 (\bar{p}_i(t) - \bar{x}_i(t))$ describes the single-particle intelligence by saving in its memory and using the obtained best cost to evaluate and update the particle position. The vector $\bar{p}_i(t)$ is the personal best value of the particle (i) at iteration (t), and it is updated each new iteration if the particle (i) finds a better solution. It affects the final value of the velocity is adjusted using c_1 . The second part keeps a direction in the direction of the personal Best value obtained by a particle.

The last part: $c_2 r_2 (\bar{g}(t) - \bar{x}_i(t))$ describes the population's social intelligence and saves the optimum value obtained by all particles in it. The vector $\bar{g}(t)$ means considering the particles' best solution in search space attracts all particles in the global best solution's direction. The impact of this component can be adjusted using c_2 . These components help in updating the position of a particle in search space. The optimization algorithm evaluates the suitability of population particles depending on a fitness function. The chosen fitness function is related mainly to the aim of optimization. The PSO algorithm structure includes the following steps:

- 1) Initialization: An initial population of particles is generated randomly in the search space with random velocities and positions.
- 2) The algorithm determines each particle's position and velocity as in (3) and (4). Then, according to an evaluation process, it calculates the fitness value for each particle.
- 3) Updating the personal Best and the global Best values, if the fitness value is better than the best fitness value, then change the current value to the new value.
- 4) If it is achieved, the stopping condition will go to step 5; otherwise, go back to step 2.

5) Termination of the algorithm and illustration of the global optimum value is done.

IV. PROPOSED PSO ALGORITHM

The PSO algorithm presented here is modified to suit the time-sensitive application addressed by this work (transmission of data on radiation levels). The flow chart of the modified PSO is illustrated in Fig. 1. After WSN nodes' deployment in a specified area to be monitored, a depth-first search algorithm is applied to the deployed WSN to form a shortest path routing tree. It is possible to produce traversal lists associated with all nodes in this tree and corresponding TDMA schedules considering interference and connectivity between nodes.

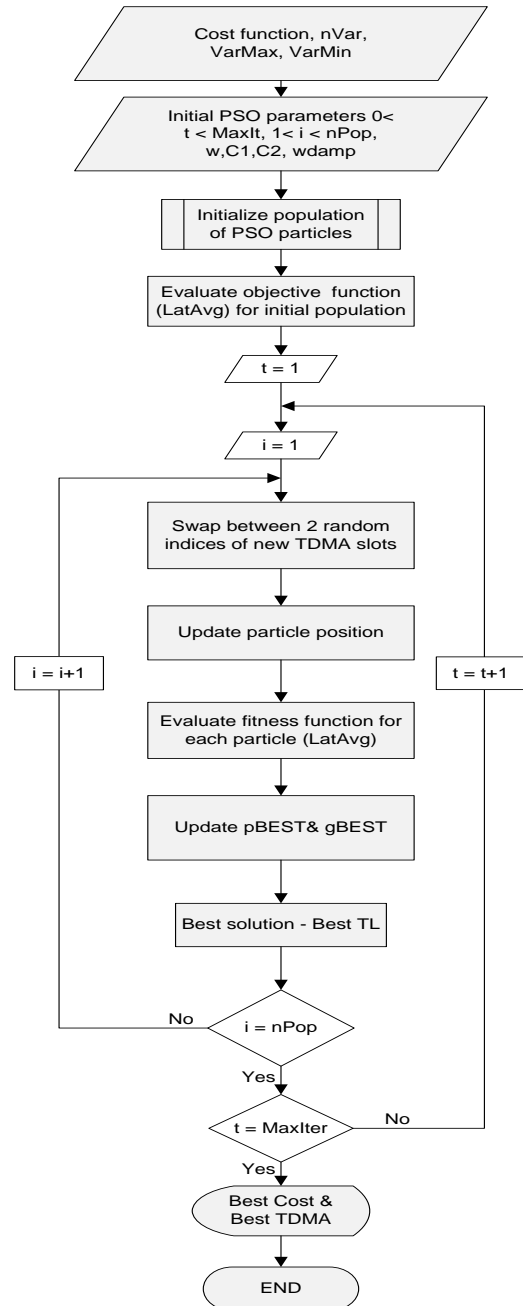

Fig. 1. Flowchart of the Proposed PSO.

A. The Modified PSO Model

The modified PSO re-orders allocated time-slots in the TDMA schedule randomly until optimum scheduling, which reduces the average latency value. The algorithm is as follows:

- 1) Initialization: An initial population of 100 particles (normal TDMA schedules) is generated randomly in the search space with random initial positions.
- 2) The modified PSO algorithm swaps between two random indices of TDMA slots.
- 3) The algorithm determines each particle's position. Then, according to an evaluation process, it calculates the average latency value for each TDMA schedule.
- 4) Keeping personal and global Best values up to date, if the fitness value is better than the best fitness value, then change the current value to the new value.
- 5) If the stopping condition is met, go to step 5; otherwise, go back to step 2.
- 6) Termination of the algorithm and illustration of the optimum value of average latency and its TDMA schedule is done.

The particles in the proposed algorithm are the WSN's TDMA schedules, and their values are optimized by swapping randomly between any two slots, with the children's parent wakes up after it, not before it. As a result, the particle's position is independent of its velocity. Following each TDMA schedule's slot swap, an evaluation is performed to determine the best particle, the TDMA schedule, which has the minimum delay.

B. Evaluation Matrices

The design aim of this paper is to minimize the entire time required to complete a series of tasks based on an optimal time-slot assignment for the TDMA schedule. This objective can be achieved by reducing scheduling length and minimizing average latency. Discussion of these parameters is provided as follows:

- 1) *Average latency and average normalized latency*: The sum of latencies associated all the WSN's nodes defined the average latency, in according to (5):

$$L_{avg} = \frac{\sum_{i=1}^n L_i}{n-1} \quad (5)$$

Where L_i is the latency related to a node (i)

the average latency per link (the node's delay divided by the number of hops along the shortest routing path between this node and its destination) calculates average normalized Latency (L_{norm}) for all sensors in the network and is given by (6):

$$L_{norm} = \frac{\sum_{i=1}^n L_i / h_i}{n-1} \quad (6)$$

Where (h_i) is the sum of hops along the routing path from a source node (i) to the sink node.

- 2) *Schedule length*: The number of time-slots in the derived TDMA frame is used to calculate the schedule length. A minimum TDMA schedule length reduces energy consumption as the sleep period for nodes increases. Increasing the usage of the time slots can decrease the size of the schedule. Most algorithms work to maximize frequent synchronous transmissions and allow spatial reuse by development.

- 3) *Duty cycle*: The ratio between the active mode interval and the whole frame defined the sensor node's duty cycle. Its minimum value results in more power conservation in the sensor node [7]. The duty-cycle is calculated for the TDMA-MAC protocol as the ratio between the total numbers of time-slots engaged with communication to the schedule length.

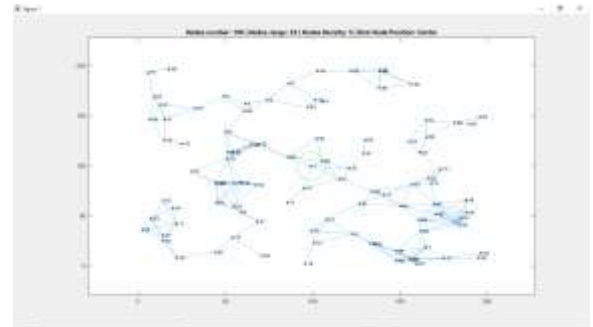

V. SIMULATION AND PERFORMANCE EVALUATION

A. Simulation Setup

A randomly deployed WSN of a hundred sensor nodes on a square area, and each sensor has the same communication range. This work uses randomly generated WSNs of varying densities achieved by adjusting the scale of the deployment area of the network. Fig. 2(a-d) presents examples of randomly generated WSNs with different densities. The density (δ) describes the average number of neighbours per node in the network as in (7) [47]:

$$\delta = \pi * r^2 * \frac{N}{a^2} \quad (7)$$

r is the communication range of a sensor node, N is the number of nodes, and a^2 is the deployment area.

(a) WSN with Density 5.

(b) WSN with Density 10.

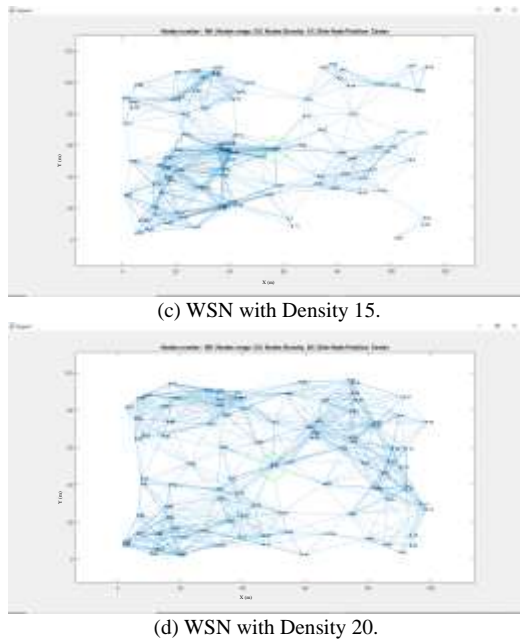

Fig. 2. Randomly Generated WSNs of 100 Sensor nodes with Densities of 5, 10, 15, 20 and Sink Node at Center.

WSN was simulated using numerical simulation of MATLAB in the 1.6 GHz laptop with 4 GB RAM to evaluate the performance of the proposed modified PSO algorithm. Table I presents the simulation setting parameters for the network and the PSO algorithm. The maximum number of particles equals the WSN's TDMA schedules. And these schedules provides using the WSN's traversal lists which equals the WSN's nodes.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Number of sensors (N)	100 static sensors
Sink node	1
Communication range(r)	25m
Position of the sink node	Center, Corner, MiddleEdge
Network density (δ)	5, 10, 15, 20
Network area(a^2)	Change according to δ
MaxIt	30:80 (according to δ)
nPop	100
Inertia Weight(w)	1
C1	1
C2	2

B. Simulation Results and Evaluation

The best TDMA schedule depends on the initial routing tree generated using the DSF- algorithm, and then the sink node broadcasts this best TDMA schedule in the network. So, the problem of collision is overcome. The proposed modified PSO is a centralized contention-free approach that is achieved by the sink node. Experiments were carried out to compare the proposed algorithm's performance to that of other algorithms.

1) *Convergence time and stopping criterion:* The proposed modified PSO algorithm consists of a swarm of particles exploring the search space for searching for a globally optimum solution. The global optimum solution is challenging to determine, so it is essential to decide on the stopping condition and the convergence for the proposed algorithm. These two coefficients are related to the PSO algorithm [28]. The primary requirement for a convergence of PSO is the stability of the state of its particles. A stable condition means that the distance between the current and the particle's previous position is never more significant than a given threshold value ($\epsilon > 0$), or the difference between fitness functions is minimal. The particle convergence time is the minimum number of steps necessary for the particle to reach its stable state. Its value depends on PSO parameters and the convergence level of the fitness function. The value of the convergence time (t) can be calculated theoretically using (8):

$$t = O(-\log \epsilon) \tag{8}$$

As shown in (8), the relationship between the convergence time and the convergence level of PSO is linear. The convergence time can also be computed experimentally by a hundred experiments on the WSN with a particular density and observe the stable state of the fitness function [48]. Simulations for the modified PSO algorithm are performed using various maximum iteration parameters and monitor the fitness function's stability for each WSN density.

The average latency becomes converged as shown in Fig. 3 at iterations 30, 40, 60, 80 for WSN densities 5, 10, 15, 20, respectively, which are the values to them the proposed modified PSO converged. Fig. 3 shows that the maximum iteration number is proportional to the network density; with the increase in the network density, more iterations are needed to fulfil the process optimization.

Fig. 3. A Convergence of the Modified PSO Algorithm.

The elapsed time for execution of the proposed algorithm and give a result is presented in Table II for the WSN with a sink node at the center.

TABLE II. THE ELAPSED TIME THE EXECUTION OF THE MODIFIED PSO ALGORITHM

Elapsed time(sec.)	Node density(δ)			
	5	10	15	20
t	74.968	123.3759	159.732	268.857

2) Average latency and average normalized latency: The next experiment compared the outcomes of the normal (initial), IDeg-LO, and IDeg-ReLO algorithms to the optimal value of average latency and average normalized latency. Fig. 4(a-c) and Fig. 5(a-c) illustrate the results of the simulation

Fig. 4. Average Latency based on the Depth-First Search Routing Tree for Several Scheduling Approaches and Different Sink Node Locations.

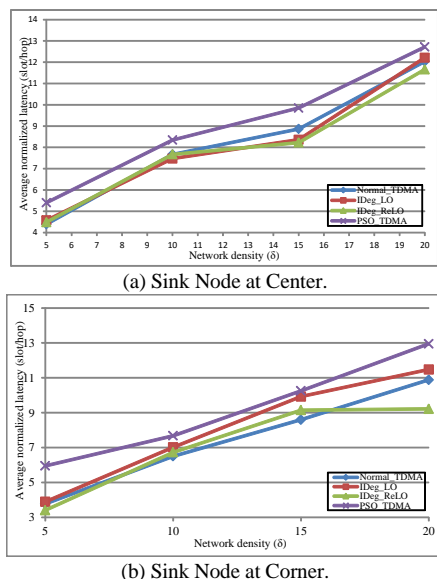

Fig. 5. Average Normalized Latency based on the Depth-First Search Routing Tree for Several Scheduling Approaches and Various Sink Node Locations.

In every situation of network density or sink node placement, the proposed PSO algorithm maximizes the value of average latency and average normalized latency and outperforms existing methods, as shown in Fig. 4 and 5. The gain in average latency reduction of the modified PSO approach compared with Normal, IDeg-LO, and IDeg-ReLO at different densities is averaged and tabulated in Table III.

TABLE III. THE AVERAGE GAIN OF THE MODIFIED PSO IN LATENCY REDUCTION

Sink Node Location	Algorithms		
	Normal	IDEG-LO	IDEG-RELO
Center	14%	29%	17%
Corner	13%	16%	14%
MiddleEdge	8%	31%	23%

The modified PSO from Table III improves the average latency up to 31% better than IDeg-LO and up to 23% compared with IDeg-ReLO.

3) Schedule length: The modified algorithm's schedule length was calculated and compared to other algorithms' results. The outcomes are as follows in Fig. 6.

Fig. 6. Schedule Length used in Modified PSO, IDeg-LO, IDeg-ReLO, and Normal Algorithms.

Fig. 6 shows that the modified algorithm's schedule length is the longest one in approximately all cases of the sink node locations and different network densities. It is more than that of IDeg-ReLO by one time-slot, by two time-slots in the case of IDeg-LO, and by four time-slots over these two algorithms for WSN of density 20 and sink node at MiddleEdge.

4) *Duty cycle*: The duty cycle of the modified algorithm was evaluated and compared with that of the IDeg-LO and IDeg-ReLO. Fig. 7 shows the experiment results in all cases of the sink node locations.

(a) Sink Node at Center.

(b) Sink Node at Corner.

(c) Sink Node at Middle-Edge.

Fig. 7. Duty-Cycle of Modified PSO, Normal, IDeg-LO, and IDeg-ReLO Algorithms with the Three Locations of the Sink Node.

Fig. 7 shows that the modified PSO has a lower duty cycle value than that for the IDeg-LO and IDeg-ReLO, reaching up to a 14.2% reduction value. This value is acceptable in the WSNs' time-sensitive applications.

VI. DISCUSSION

The TDMA schedule has been optimized to remove all possible transmission interferences, which are the leading cause of communication latency in the network. A modified PSO algorithm was developed to provide near optimum interference-free TDMA scheduling, resulting in minimum WSN latency.

The results of simulation and evaluation show that the modified-PSO algorithm outperforms the competition. The modified PSO outperforms IDeg-LO and IDeg-ReLO in minimizing the WSN average latency, respectively, by 31 and 23%. The results show also that the scheduling length of TDMA is the largest in most cases of the WSN. Using the modified PSO, the scheduling length reaches up to 8% over IDeg-LO and IDeg-ReLO addition of time-slots to overcome interference. The value of the duty-cycle using the modified PSO is lower than that of IDeg-LO and IDeg-ReLO at all densities. In middleaged sink node WSN, it scores a reduction of 14.28%. While in a Center sink node WSN, IDeg-ReLO results in a decrease in the duty-cycle value except at a WSN density of 10. The modified PSO is more effective than IDeg-LO and IDeg-ReLO when the sink node is at the corner of the WSN. This efficiency is demonstrated by achieving a reduction in the duty cycle of up to 9%.

The results show also that the value of the duty-cycle depends on the schedule length. The increase in the schedule length results in minimizing the duty-cycle, resulting in more power conservation.

It is also important to note that the results of this work contribute towards a more precise understanding of the relation between the schedule length and the duty cycle as the effect of the sink node location, which is an essential parameter in minimizing latency.

This work confirmed that the simplicity of execution of the algorithm and the fast convergence of the PSO meta-heuristic for optimization of the TDMA-scheduling for WSN communication latency problem; are significant advantages when using WSN in time-sensitive applications. The modified PSO algorithm is executed in the sink node, which has sufficient memory for algorithm implementation. The obtained results are beneficial for the effective design of WSNs for time-sensitive applications. This approach may be used to acquire data from the surrounding environment with minimal latency in a WSN with static sensors. It has applications in the military, climate monitoring, and the supervision and management of nuclear power facilities. This modified PSO may be used in a variety of ways, including adding mobile sensors and underwater, subterranean sensors.

VII. CONCLUSION AND FUTURE WORK

This study proposed a centralized contention-free TDMA scheduling algorithm. It is a meta-heuristic, a modified PSO algorithm that optimizes the latency reduction and the

network's duty cycle. A comprehensive series of simulations was established, and a comparison was made on the performance of the Modified PSO, IDeg-LO, and IDeg-ReLO. This work demonstrated that the Modified PSO algorithm provides a shorter latency than IDeg-LO and IDeg-ReLO algorithms.

The modified PSO algorithm improves the average latency by 31% compared with IDeg-LO and by 23% compared with IDeg-ReLO depending on the routing tree. Additionally, it improves the duty cycle by 14.2% compared with that of IDeg-LO and IDeg-ReLO algorithms. Therefore, the modified PSO approach results in the most acceptable WSN applications because of its simplicity and low computational cost. It is also more suitable for time-sensitive applications as it offers the expected speed of convergence with high quality of solutions.

Future work could be performed to study optimization techniques for calibrating the power consumption to the lowest possible level while ensuring the connectivity and reliability of the transmitted data.

Case Study of Self-Organization Processes in Information System Caching Components

Pavel Kurnikov¹, Nina Krapukhina²
National University of Science and Technology MISiS
IT and Automated Control Systems
Moscow, Russia

Abstract—Most modern Information Systems (IS) are designed with Object-Relational Mapping components (ORM). Such components bring down the number of queries to the database server and therefore increase the system performance. Caching mechanisms in software components are complex dynamic systems of open type. A simulation model of cache-application interaction has been created to assess the critical modes of the system. The authors suggest accumulating the cache elements states during the application run at discrete moments of time and present them as multi-variable time series. This work also suggests a method for reconstruction of phase-plane portrait of the system with multidimensional dynamics of the cache elements states. The article shows self-organization processes in caching components of information systems and illustrates the variability of system states for various initial conditions followed by transition to steady-state conditions. In particular, the paper illustrates dissipative structures as well as deterministic chaos with the complete determinism of queries in simulated information systems.

Keywords—Caching mechanisms; ORM; phase space reconstruction; self-organization; dissipative structures; deterministic chaos

I. INTRODUCTION

Modern Information Systems use caching mechanisms, as the process of their design almost always use the technology for mapping relational data into object model [1]. This technology allows leveling down semantic gaps during system development, but also creates additional expenses in processor resource and memory consumption during the operational phase [2, 3, 4, 5].

Works [6, 7, 8, 9] demonstrated that caching mechanisms in IS are non-linear open-type systems. For instance, article [7] identifies the caching element functioning with the Brusselator model, described through a system of differential equations of high order with non-linear terms. Analytical solution of these systems is not always possible though. The research conducted in work [8] revealed statistical relation between dynamic system running modes and the time for processing user's query. The openness of the system lies in information exchange with the environment. The users working with the IS become sources of "energy", and their actions helps build up structural inhomogeneity of the system. In this case "energy" is the flow of queries to the server that enables modification of the IS. It is inevitable that this process results in cache build-up. Cache release is the zone for dispersion of energy which leads to smoothing the structural inhomogeneity of the system.

Open system of such type can absorb external actions and remain in constant change at the same time.

Caching systems have feedback of both positive and negative types. Input flow of queries from a user can change the inner state of the system. In this case the system can give feedback to the input flow to increase or decrease its force, depending on the inner state of the system. In this regard it is important to take into account the development of processes in the caching system itself, as it is not only the external actions that make it change, but also inner processes that bring the system to self-organization.

In the previous works [4, 9] the authors demonstrated the possibility for extraction of cache system modes while IS model is running and expressing the results as multi-variable time series. Based on the research in works [10-14] the authors suggest using phase space reconstruction methods that are based on Takens embedding theorem [15]. This article aims at giving quality assessment to processes in the observed dynamic system. Attractor reconstruction is made on the basis of changes in caching system variables available for observation in time.

The rest of the paper is organized as follows: Section II briefly describes the caching mechanisms in ORM systems. Section III presents a simulation model of interaction between the caching mechanism and the application. Sections IV and V present the research results and their discussion, respectively.

II. CACHING MECHANISM

Modern ORM frameworks (object-relational mapping) build IS conceptual layer, and then every stored table is assigned an object from the conceptual model. Caching mechanism [16] handles a list of entities, each in one of the following states:

- Detached (from the cache).
- Added.
- Unchanged.
- Modified.
- Deleted.

The object state manager maintains the state of each entity in the cache – detached (from the cache), added, unchanged, modified, deleted and tracks their state transitions.

After the users' interaction with the information in IS the process of transformation of modified entities corresponding with the stored tables of the database is initiated by method SaveChanges. A list of changes is then formed for each entity. This list is formed straight from cache. Next, the list is transformed into a series of algebraic expressions (relational operations with the tables corresponding to the entities) to be realized on the database server [16]. After the transactions are complete, cache mode is synchronized with the new state of the database.

This article uses discrete-event model for simulating scenarios of multiple users interacting with the database via high-level interface [9]. Such a model allows simulating the load of several users on a server and serializes the cache modes in discrete moments of time.

III. DISCRETE-EVENT MODEL

Let us take as R (the data stored in the database) the multitude of stored states of the initial database. ORM creates an entities scheme E (entity schema) from the database scheme (relational schema). Let us assign entity E on the object layer of the application to each object from R . There is a cache vector C for each type of entity. Test on range of entities is defined by predicate formula from range F^E . Transformation between relational and object data is done through bi-direct connection illustrated by formulas 1 and 2.

$$\Delta R_i = \Delta UV(E_i, \Delta^{+/-} E_i), i = 1, \dots, I, \Delta^{+/-} E_i \neq \emptyset \quad (1)$$

where $\Delta^{+/-} E$ is a result of the test from range F^E on entity E_i .

Here the difference in entities state is assessed with *UpdateViews*, which shows how to extract information about the modified state of the stored database [16]. (In Step 1, view maintenance algorithms are applied to update views. This produces a set of delta expressions, *UpdateViews*, which tell us how to obtain delta tables from delta entities and a snapshot of Entities).

In the case when conceptual (entity) level test from F has not modified the entity due to the presence of the modification object in cache, there will be no query to the server. (no update is required).

$$\Delta E = QV(R), \quad (2)$$

here QV – *query views* transforms objects from relational scheme to entities; (The query views express entities in terms of tables).

The general rule which a user uses to work with the common resource C can be presented as:

$$C_i(t_k) = UpdateObjectCache(F_j^E(E_i, t_{k-1}) - F_j^E(E_i, t_k)), \\ j = 1, \dots, J, k = 1, \dots, K \quad (3)$$

This process can be compared to negative and positive feedback. If the list of entities changes received from cache after a certain input test is empty, there will be no query sent to the server. This equals restriction of input flow (negative

feedback). On the other hand, if the result of a certain test run lead to cache flush, that can potentially increase the input flow, and this will result in extra costs for the server.

Let us define a user from range $U = \{u_1, \dots, u_M\}$. A user is defined by a subset of tests $F_{U_m}^E \subset F_E$ which he works with as a full group of disjoint events with probabilities $\langle P \rangle$ as well as a law of test distribution ω and time of work T with the system:

$$U = \langle F_U^E, P, \omega, T \rangle \quad (4)$$

In other words, user U_m is a source of events flow in $[0, T]$. The events flow is an external influence towards the system. Let us set a multi-layer density of probability for intervals between test completion time:

$$\omega_{U_m}(\tau_1, \dots, \tau_K), \tau_k = t_k - t_{k-1}, t_0 = 0, t_K = T \quad (5)$$

where ω_{U_m} is an n -dimensional density function for user U_m defining the law of random vector distribution $\|\tau_k\|, k = 1, K$ for user U_m .

Multi-dimensional random variable is simulated on an ECM with Neumann construction generalized for a multi-dimensional event [17]. The choice of test to be run by a user at the moment of time t_k is made based on a random discrete variable generated in the interval $[0, 1]$:

$$X = \begin{pmatrix} x_1 & \dots & x_L \\ p_1 & \dots & p_L \end{pmatrix}, \sum_{l=1}^L p_l = 1 \quad (6)$$

where $P = \{p_1, \dots, p_L\}$ is a probability vector for a full set of events (tests from range F_U^E) with indexes $\{1, \dots, L\}$.

Test with index x_l where $r_k \in \Delta_l$ will be performed at the moment in time t_k .

$$r \in \begin{cases} \Delta_1, & r \leq p_1 \\ \Delta_l, & p_1 + \dots + p_{l-1} \leq r \leq p_1 + \dots + p_l, (l \geq 2) \end{cases} \quad (7)$$

where Δ_l is a part of a segment $[0, 1]$ with length equal p_l

Server part storing the database is a shared resource for the system. Inner state of the system is cache vector C . This resource is also shared for every user from U .

Let us analyze the dynamics of cache vector C . For this we will inquire the state of vector C at $[0, T]$ every Δt . As a result we have a phase space described by D -dimensional time series X_1, X_2, \dots, X_D where $X_d = (x_{d,1}, x_{d,2}, \dots, x_{d,K})$, $d = 1, 2, \dots, D$, $K = T / \Delta t$, $x_{d,k}$ is the size of d element of cache C at moment in time $k\Delta t$. $D = \dim(C)$. For the systems containing D variables $x_d(t) = [x_{d,1}, x_{d,2}, \dots, x_{d,N}]^T \in \mathbb{R}^D$, $d = 1, \dots, D$ phase space is suggested to be simulated with the method described in work [13]. This approach allows quality simulation of phase space from initial data, and it also has relatively low

calculation complexity compared to the methods described in works [10, 11]. The process involves consecutive calculation of time lapses [18, 19] for each series. Correlation dimensions [20, 21] are found for each variable based on the calculated parameters.

IV. RESULTS

The authors suggest using the previous results [4, 9] for simulating caching mechanisms in the IS. Architecture of the database on the server is illustrated by Fig. 1.

Fig. 1. Database Diagram.

The database consists of 13 tables with multiple links. Three basic tests were taken as functional base: adding data into a table or a set of tables (*insert_data*), removing data from a table or a set of tables (*remove_data*), and getting data from a table or a set of tables (*get_data*). Initial conditions of the model are the number of users working with the system simultaneously. Every user is described by a set of tests which he works with, as well as a function of their distribution in the interval $[0, T]$. A set of tests for each user is a group of disjoint events. Each event is defined by its probability. Another initial condition is the state of cache vector before the run of the model. Initial state of the database was the same for all models described in this work.

Let us look at the model with one user ($U0$) working with one database table ($R7$). Let us identify the set of test for the user ($U0$) as a sub-set $\{insert_data, get_data\}$. Time for modeling was 1000 seconds, Table I.

TABLE I. INITIAL CONDITIONS FOR MODEL 1

Model	Users	Tables	Distribution of basic tests			Time of simulation T, sec
			Insert data	Remove data	Get data	
1	1	R7	0.5	0	0.5	1000

Dynamics for cache size associated with table R7 is shown in Fig. 2.

Fig. 2. Cache Dynamics for Table R7 (Model 1).

Cache dynamics for table R7 is presented by linear growth of space. It is related to the fact that non-linear processes do not occur in single-user mode in the scenario with one object. Additionally, as framework 1 shows obvious domination of *insert_data* and *get_data* tests, each query for an entity is accompanied with caching the object. In 1000 seconds of simulation more than 80,000 queries to cache were executed. The total cache volume reached 11347 bytes. In other words, there is no reaction of the system to external factors, because there is no release of cache and input flow to the database server does not get cut. System does not compensate for these processes and stays in an unbalanced state, meaning there is no self-organization.

Let us simulate a model with three users. The object of the queries is still *table R7*. Let us add test *remove_data* to the *model 1* set of tests. New initial conditions are shown in *Table II*.

TABLE II. INITIAL CONDITIONS FOR MODEL 2

Model	Users	Tables	Distribution of basic tests			Time of simulation T, sec
			Insert data	Remove data	Get data	
2	3	R7	0.3	0.35	0.35	1000

It is worth mentioning that Table II only shows the general distribution of test running in the model during time period T. Fig. 3 illustrates the cache growth dynamics, additionally there are visuals on results of calculations for correlation dimension and time lapse for the simulated attractor. All the calculations were done in RStudio in language R with non-linear Tseries package. Overview of numeral methods for this package is presented in work [22].

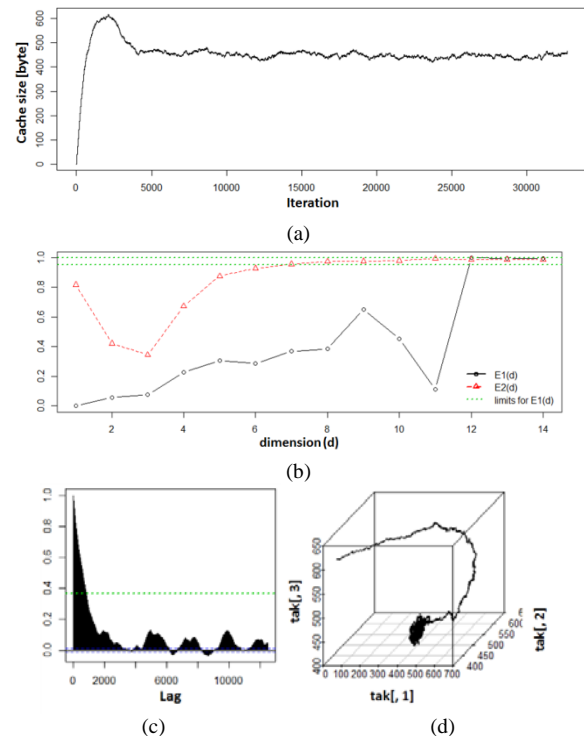

Fig. 3. Simulation Results for 3 users in Accordance with Initial Data for Table II: (a) Cache Dynamics for Table R7; (b) Auto-Correlation Function; (c) Embedding Dimension Calculation; (d) Attractor Visualisation.

Here non-linear dynamics in cache behavior can be seen. This is due to parallel input flows of queries to the system and inner non-linear caching mechanism. Apart from that, this model shows stable increase of allocated memory, as there is a cache release mechanism at work. This mechanism is a zone for information dispersion, and as a result of its work the system structural inhomogeneity is smoothed. Open system of such type processes external influence, but remains in permanent change. Peak memory use in this case only reached 657 bytes. This system is in unstable stationary mode of work.

Let us add another influence to demonstrate the ‘fragility’ of this balance, as shown in Table III. In *model 3* the new external influence to caching mechanism is user *U4* with an only test *get_data*. This time the object of queries will be new table R8 linked to R7 by the key. Time of simulation was kept unchanged. Query *get_data* to object R8 linked to R7 will introduce changes to cache associated with object R7. This will lead to the increase in query flow to the system.

TABLE III. INITIAL CONDITIONS FOR MODEL 3

Model	Users	Tables	Distribution of basic tests			Time of simulation T, sec
			Insert data	Remove data	Get data	
3	4	R7, R8	0.3	0.35	0.35	1000

Cache dynamics for table R7, R8 is shown on Fig. 4.

(a)

(b)

Fig. 4. Simulation Results For 4 users in Accordance with Initial Data for Table III: (a) Shared Cache Dynamics; (b) Attractor Visualisation.

Cyclic transitions of the dynamic system from zone I to zone II are shown in Fig. 4. The system has two attractors. The received data is not stationary as the system is bi-stable. This is an open system, so part of external queries is redirected to cache release, which results in caching mechanism self-regulation.

Let us increase input queries flow to the system by adding new users while keeping the test distribution and query objects the same, see Table IV.

TABLE IV. INITIAL CONDITIONS FOR MODEL 4

Model	Users	Tables	Distribution of basic tests			Time of simulation T, sec
			Insert data	Remove data	Get data	
4	10	R7, R8	0.3	0.35	0.35	1000

Increase in number of users from 4 to 10 affected the total number of completed transactions on the server and queries to cache (Fig. 5a). This did not though change the number of equilibrium conditions of the system (Fig. 5b).

Let us look at the system with two groups of users. Within its group each user will be described by a group of tests it interacts with, as well as a unique function of their distribution in the interval $[0, T]$. Let us also change the objects of the users' queries, see Table V.

(a)

(b)

Fig. 5. Simulation Results for 10 users in Accordance with Initial Data for Table IV: (a) Shared Cache Dynamics; (b) Attractor Visualisation.

TABLE V. INITIAL CONDITIONS FOR MODEL 5

Model	Users	Tables	Distribution of basic tests			Time of simulation T, sec
			Insert data	Remove data	Get data	
5	1-4	R11 – R13	0.35	0.3	0.35	5000
	5	R1 – R4	0.2	0.4	0.4	

Here a group of users U1-U4 interacts with tables R11-R13. User U5 interacts with tables R1-R4.

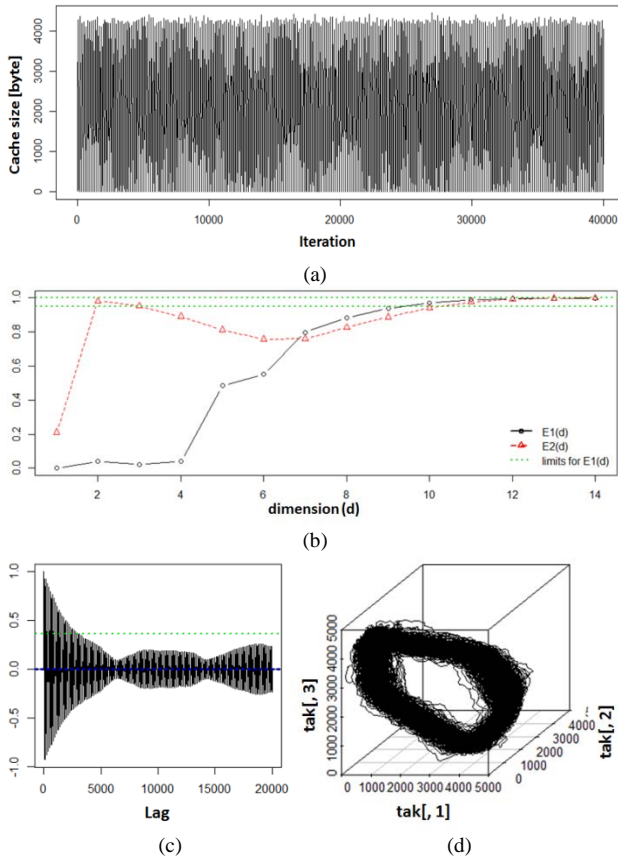

Fig. 6. Simulation Results for 20 users in Accordance with Initial Data for Table V: (a) Shared Cache Dynamics; (b) Auto-Correlation Function; (c) Embedding Dimension Calculation; (d) Attractor Visualisation.

Despite the presence of inquiries to linked entities (R12, R13 and R1, R3, R4), Fig. 6d. shows closed-loop isolated trajectory in phase space corresponding with cyclic movement. This movement is asymptotically stable and in the process of self-organization the system will be attracted to this trajectory regardless of the initial cache state. Despite minor presence of chaotic processes caused by a large number of users interacting with the system, they do not disturb the end cycle. In other words, the system is far from the point of stochastic bifurcation.

Let us introduce additional inquiry objects to the system, as well as new groups of users for running the tests. The time of simulation will be kept unchanged, see Table VI.

TABLE VI. INITIAL CONDITIONS FOR MODEL 6

Model	Users	Tables	Distribution of basic tests			Time of simulation T, sec
			Insert data	Remove data	Get data	
6	1-4	R11–R13	0.35	0.3	0.35	5000
	5	R1–R4	0.2	0.4	0.4	
	6-14	R1, R5, R6	0.25	0.25	0.5	
	15-20	R1, R5, R6	0	0	1	

New groups of users U6-U14 and U15-U20 interact with tables R1, R5, R6, but the latter only accesses the database for information without making any changes.

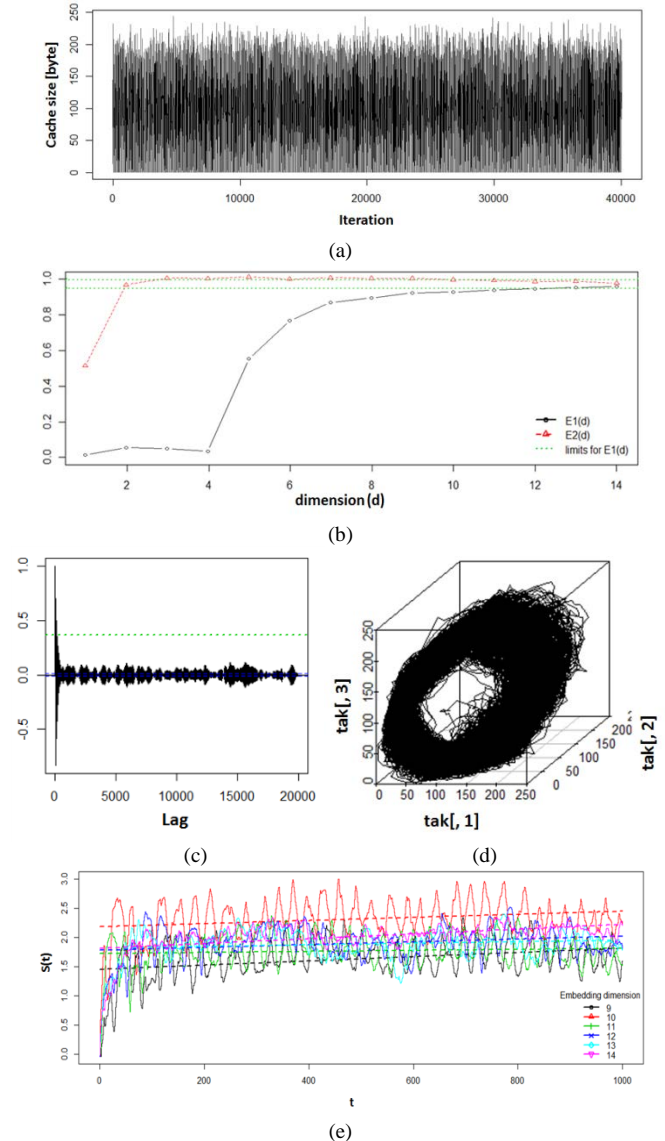

Fig. 7. Simulation Results for 20 users in Accordance with Initial Data for Table VI: (a) Shared Cache Dynamics; (b) Embedding Dimension Calculation; (c) Autocorrelation Function; (d) Attractor Visualisation; (e) Estimating Maximal Lyapunov Exponent.

Information dispersed and injected into the system is strictly compensated, despite minor presence of chaotic

processes caused by a large number of users interacting with the system. This points at dissipative type of the observed system. Fig. 7(e) demonstrates the estimates for maximal Lyapunov exponent [23, 24, 25] for space several special dimensions. Despite the high dispersion of this exponent, it has positive value which is another confirmation for the presence of chaotic processes.

V. CONCLUSION AND FURTHER RESEARCH

A discrete-event model was developed as a result of this research. The model allows simulation of various scenarios for users interacting with the database server through caching mechanisms of object-relative representation. Data on states of each system cache valuable in time were reflected as variables in multi-dimensional time series. Each component of the time series was assigned necessary parameters for phase space reconstruction. Analysis of trajectories data revealed the mode of work for simulated dynamic systems.

The authors demonstrated linear processes of cache dynamics for single user (*U0*) interacting with one database table (*model 1*). With the randomly requested data in test *get_data* and the absence of *remove_data* all the entries were fully cached. In case of collective work of users with the system, combined with non-linear connections in caching mechanism, the latter demonstrates complex non-linear dynamics both on macro- and micro-levels. This is the key element in self-organization process.

Unstable stationary dynamic mode was demonstrated for the system that three users were interacting with (*model 2*). Set of tests and distribution were selected in a way that the model does not show stable increase of allocated memory. It can be described as dissipation of information by the caching mechanism, which leads to the open system of this type processing external influence, while staying in permanent change.

Non-equilibrium of the stationary state of *model 2* was confirmed by the data from *model 3* run, where user *U4* with the sole test *get_data* became the additional external influence on the system. The system demonstrated bi-stable transitions between two attractors I and II, but it still remained in constant self-organization. Adding new users in *Model 4* affected the total number of transactions completed on the server during the simulation time *T*, but it did not affect the number of equilibrium conditions of the system.

Models 5 and 6 demonstrated presence of self-oscillating processes. High load on the caching mechanism was provided by several groups of users simultaneously interacting with most of the objects of the initial database. As a result, the system had stable limit cycle without a stable focus. Observations of *model 5* showed that convergence of phase trajectory does not depend on the initial state of cache. Besides, even though the users in *model 6* had determined behavioral rules, non-linear dynamic system was subject to determined chaos, which was revealed with calculating highest Lyapunov exponent. Despite this, such behavior of caching mechanism is an optimum option for multi-user regime of work with IS due to the system's resistance to initial conditions.

To reproduce a larger number of information systems, one should expand the functional test base of user-application server interaction. Research into self-organization processes in caching components of information systems will allow comparative analysis of function composition at IS development stage and enable choice of a more stable version.

Abstract—This article is a continuation of our previous work on identifying and developing tools and concepts to provide automatic management and derivation of security and privacy policies. In this document we are interested in the extension of the PrivOrBAC model in order to ensure a dynamic management of privacy-aware security policies. Our approach, based on smart contracts (SC) and the WS-Agreement Specification, allows automatic agents representing data providers and access requesters to enter into an access agreement that takes into consideration not only service level clauses but also security rules to protect the privacy of individuals. Our solution can be deployed in such a way that no human intervention is required to reach this type of agreement. This work shows how to use the WS-Agreement Specification to set up a process for negotiating, creating and monitoring Service Level Agreements (SLAs) in accordance with a predefined access control policy. This article concludes with a case study accompanied by a representative implementation of our solution.

Keywords—Access control; privacy; PrivOrBAC; PrivUML; smart contract; WS-agreement

I. INTRODUCTION

Our work is related to the management and development of security and privacy policies. Our goal is to be able to identify security and privacy needs and integrate them early into the design of complex systems. This practice has yet to be widely adopted; generally, security requirements are expressed separately in the form of complementary modules and integrated late into the systems. The principal difficulty which designers encounter concerns the methods and tools used to design functional and security models, as well as to describe the business demands which the system must satisfy. While functional design methods have become increasingly effective so as to allow one to design models formal enough to provide a base of refinement down to code, security design methods are not yet at the same level.

As a first step, we focused our efforts on defining the security policy and modeling tools allowing the integration of privacy protection into the system's design models. It is in this context that we relied on PrivOrBAC [1], an access control model dedicated to the protection of privacy. It is based on the OrBAC model [2] which introduced the notions of organization, context and object views as attributes of access management. Thus, access permission is granted to a role within an organization to perform an activity on an object view in a specific context. PrivOrBAC takes this logic and enriches it with attributes specific to privacy. Access permission in

PrivOrBAC is therefore granted to a role in an organization to perform an activity, justified by a purpose in a specific context, on a granular object view following the consent of its priority. To model PrivOrBAC, we have proposed the new PrivUML metamodel [3] which is an extension of the UML language, and which makes it possible to integrate all the attributes of PrivOrBAC necessary for the protection of privacy into a class diagram. Our implementation of PrivUML under XACML (eXtensible Access Control Markup Language) [4] allowed us to set up a privacy-aware security policy. However, at this level, our solution remains static.

The second part of the article is therefore devoted to automating the management of this policy to make the access control process dynamic. As it stands, any modification to be made in the security policy requires manual interventions, which diverge from the aspirations of complex systems known by their high rates of interactivity and which are therefore penalized by the obligation of human involvement in this type of task. The idea is to put in place intelligent agents capable of replacing human skills. These agents will not only update the security policy, but also manage the entire upstream process responsible for investigating the incoming request and negotiating, creating and monitoring the access agreements in accordance with the policy. It is in this sense that we propose to set up smart contracts managed through the WS-Agreement Specification [5].

We organize the remainder of this article into three sections. The first is dedicated to the presentation of our previous work. We devote the second section to the mechanism for automating the management of our security policy based on smart contracts and the WS-Agreement Specification, and then we present a discussion of our contribution in the third section.

II. PREVIOUS WORK

Our previous work, [3] and [6], focused on providing the means and tools to integrate the principles of privacy protection into IT systems. To achieve our objectives, we have opted, throughout this work, for a certain number of choices which we present in what follows.

1) *PrivOrBAC (Privacy-Aware Organization Based Access Control)*: In OrBAC model [2], the organization is the central component; privileges are not applied directly to subjects, they are assigned to roles within an organization [7]. Permission is granted for a role to perform a subset of activity on a number of views of an organization's objects in a specific

context. PrivOrBAC [1] extends the OrBAC model to covers Privacy management requirements. The first change consists in setting up a hierarchy of views to better manage the granularity of the data consulted. The same view of objects can have different levels of detail from one organization to another. Regarding consent and purpose, they were introduced as new attributes of the context. The organization in PrivOrBAC continues to play its role as a central component which makes it possible to configure the access policy according to the other abstract entities (Role, Activity, View and Context). The role and activity entities behave the same as in OrBAC; privileges are assigned to a role within an organization in order to perform an activity.

2) *PrivUML Metamodel*: In accordance with the MDA approach (Model Driven Architecture), we have defined our CIM model (Computation Independent Model) composed of the pair (ends, means) corresponding to the protection of privacy through the PrivOrBAC access control model. The next step is to go to the second level of MDA which is the PIM (Platform Independent Model). Translating CIM to PIM requires finding the modeling tool capable of integrating all of our Privacy requirements into the model. After a study on the various security modeling tools focused on modeling access control requirements (SecureUML [8], UMLSec [9], PaML [10] and Privacy UML Profile [11]), we noted that none of these tools is completely adapted to our needs. Based primarily on roles and enriched by purpose, they do not, in their current state, allow the PrivOrBAC access control to be modeled. We therefore proposed PrivUML [3], which is an extension of UML enriched by the following concepts:

- The access modalities allowing to express the authorization of access, the refusal or the obligation.
- The hierarchy of object views to control the granularity of the data to be consulted.
- The purpose justifying the access request.
- The explicit consent of the data owner granted on the basis of the purpose.

We have therefore set up a meta-model capable of integrating security policies, meeting privacy requirements, from the design phase of the system. In PrivUML, an access request is refused or accepted with or without conditions to a subject, having a role in an organization, to perform an action justified by a purpose on a specific set of data whose owner has given his prior consent.

III. AUTOMATING OF THE MANAGEMENT AND PROTECTION OF PRIVACY

The work presented in the previous section makes it possible to set up a privacy policy in a static manner. Any new changes require manual updating of this security policy. Complex systems therefore have to dedicate personnel to this task, the cost of which increases according to the volumes of their interactions. This also increases the risk of error and data leaks. Take for example the French Health Management

System (FHMS) which manages all the health information of adherents. Any medical entity not listed in the system must first go through the stage of negotiating a new agreement access, which must comply with the security policy in force, and which will result in updating the security policy of FHMS. The implementation of smart contracts is necessary to ensure automatic management of requests for negotiation and establishment of access contracts. This management method will be piloted by intelligent agents responsible for negotiating contracts as well as updating security policies. In what follows, we will define the notion of smart contract, then we will present the solution chosen for the management of smart contracts, and finally we will explain through a case study how we ensured the automation of management and the protection of privacy in an interactive system based on the elements mentioned above.

A. Smart Contract

The concept of a smart contract first appeared in the 1990s and has evolved over the years. Programmers tend to see it as a solution that replaces traditional contracts and contract law [12]. Another vision of the smart contract considers it as a mechanism to express calculations on a blockchain [13]. The author in [14] defines the smart contract as an automatable and enforceable agreement: automatable, although some parts may require human intervention and control; and enforceable either by legal application of rights and obligations, or by tamper-proof execution of computer code. For our work, we agree with [15] on its definition of the smart contract and consider it as the formalization of an agreement, the terms of which are automatically applied by relying on a transaction protocol, while minimizing the need for an intermediary.

B. Access Agreement

Data providers and consumers operate in a dynamic environment governed by a set of rules, conditions, obligations and guarantees formalized in a contract or access agreement. Several solutions exist for the management of this type of electronic contract, from negotiation to monitoring. Among these solutions we find:

- WSLA (Web Service Level Agreement): this specification, created by IBM in 2003 [16], allows the creation and monitoring of SLA (Service Level Agreement) contracts. WSLA defines a flexible and extensible language to allow consumers and providers of web services to define and specify a set of parameters such as technical-functional descriptions of web services, supplier commitments, etc.
- WSOL (Web Service Offering Language): this specification, based on XML language, allows suppliers to define several service levels or SLOs (Service Level Objectives) for the same web service. A consumer can therefore choose the desired web service and select the SLOs that interest him according to the level of service that suits his needs [17].
- WS-Agreement (Web Service Agreement): this specification defines a protocol and a language for negotiating, renegotiating, creating and monitoring bilateral access contracts (between consumer and

provider) in distributed systems [5]. The WS-Agreement Specification and the WS-Agreement Negotiation Protocol [18] are the only specifications standardized and accepted by a large community [19], [20]. Therefore, our study will be based on this specification to establish the protocol for negotiating and creating smart contracts that frame access agreements.

1) *WS-Agreement Specification*: WS-Agreement is a specification that enables exchanges based on XML language between providers and consumers of web services. An agreement is an XML file created from a template. The agreement and the template have the same structure. An agreement is made up of three sections:

- Name: this section contains the name and ID of the agreement.
- Context: the context contains meta-information about the agreement such as the identifiers of the initiator and the responder of the agreement, the identifier of the template that served as the basis for creating the agreement, references to other agreements, the period of validity, etc.

- Terms: The terms of an agreement include terms of service and, optionally, guarantee terms that define the constraints applicable to the services set out in the agreement. A service term is made up of several sections of Service Descriptions Term (SDT), Service References (SR) and Service Properties (SP). A guarantee term for a service consists of a section describing the scope of the service, a section describing the service level objectives (SLO) and possibly a section describing the business values of the service.

2) *WS-Agreement Negotiation Protocol*: Automating negotiations requires formalizing the definition of each term of the access contract. Much work has been done in recent years to automate contract negotiations in various fields such as connected objects ([19], [21], [22]), cloud computing platforms ([23], [15], [24], [25]) as well as distributed environments ([20], [26], [27], [28]). The WS-Agreement Negotiation Model [18], shown in Fig. 1, consists of three layers: the negotiation layer, the agreement layer, and the service layer.

Fig. 1. WS-Agreement Negotiation Model [18].

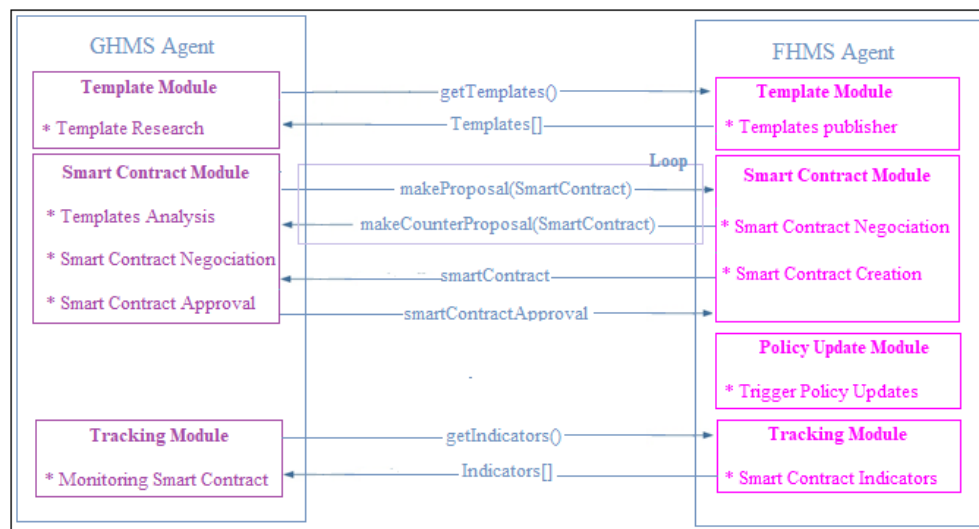

Fig. 2. Protocole De Négociation De Smart Contrat.

The negotiation layer provides a protocol and language for negotiating offers that indicate the willingness of both parties to enter into a subsequent agreement. The negotiation process includes the exchange of negotiating offers and counter-offers until an agreement is reached between the two parties. The agreement layer, on the other hand, provides a protocol and language that provides the basic functionality to create and monitor agreements. Finally, the service layer defines the services offered by the data provider. The execution of the service on the service layer is governed by the agreement layer. Fig. 2 illustrates the protocol for negotiating a smart contract between the French Health Management System (FHMS), as data provider, and the German Health Management System (GHMS) as data consumer.

The consumer agent (GHMS) initiates the negotiation process by requesting the retrieval of the services modeled, described and published by the data provider, FHMS, by calling the public "getTemplates()" method. Once the templates have been received, the consumer agent analyzes them and chooses the one that corresponds to its needs. It then fills in the fields and builds his offer, then sends it to the provider agent via the "makeProposal(smartContract)" method. Upon receipt of this proposal, the provider agent checks the values entered and their compliance with the predefined constraints of contracts creation. In case of invalidity of the proposal made by the consumer agent, the provider agent is responsible for adapting the non-conforming values and making a counter-offer by calling the "makeCounterProposal(smartContract)" method. The negotiation process can see several back and forth between the two agents until a common agreement is reached or the failure following the consumption of all the allowed iterations. The common agreement is reflected in the creation of the smart contract signed by the provider agent and sends it to the consumer agent who in turn signs it and communicates his proof of approval. Then, the provider agent updates the security policy according to the access rules negotiated in the contract. It also provides the consumer agent with the possibility of monitoring his contract.

3) *WS-Agreement Implementation:* Many projects implement the WS-Agreement Specification and Protocol to set up access agreements. Some frameworks, such as WSAG4J [29] and SLA-Framework [30], make it possible to simplify this implementation. WSAG4J is a generic implementation of the WS-Agreement Protocol. It supports common functionality to create and monitor agreements generically and allows users to quickly create and deploy services based on WS-Agreement Specification. WSAG4J follows a declarative approach to support and manage the entire lifecycle of an agreement, from the definition of an agreement template, through the deployment of models in *Factories*, to the management of the agreement. SLA-Framework, as for it, is another implementation of the WS-Agreement Specification. It is an open source project that helps manage the lifecycle of access agreements (negotiation, creation and monitoring agreements). Currently in version V1.1, this framework only supports one-shot negotiation. The core SLA-Framework provides a language and protocol to define and advertise the capabilities of service providers in SLA templates, create agreements based on the templates, and track compliance with agreements at runtime.

C. Case Study

France's national health security organization manages the medical records of all adherents of this state public service. All information relating to an adherent is listed in the French Health Management System (FHMS). This is personal information that the owner has designated as private, for example the Person of Confidence to Contact (PCC) or medical order that describes everything related to the Patient's Care History (PCH). All access to this information is controlled by the system which grants or denies it according to the predefined access control policy. A national or foreign medical entity can therefore issue a request for access to the system to consult all or part of a medical file. These requests are normally issued by entities already recognized by the system, but it is quite possible for a new organization (new private

sector clinic, foreign hospital, new research laboratory, etc.) to request access. In this case, a collaborative access contract is required. Smart Agents, representing consumers and data provider, handle the negotiation and commissioning of the smart contract using the web services responsible for accessing the data. These data concern the personal information of a patient (surname, first name, age, address, telephone number, etc.) as well as all medical information relating to his/her state of health and his/her care path (results of analysis, treatments, chronic diseases, allergies, blood pressure and heart rate measurements, etc.), which are collected by the various portable and implantable sensors of the WBAN (Wireless Body Area Networks) or entered directly by doctors and subsequently stored in the Cloud (Fig. 4) in an encrypted format. The encryption is performed by a local server based on the access control rules specific to each type of data. Fig. 3 shows an excerpt from the access control policy applied to encrypt the PCC and PCH of Mr. Jean Dupont.

Mr. Jean Dupont, a French traveling in Germany, is transported to the emergency room of the K Hospital in the city of Berlin following a serious accident. Dr. Karl Schmidt, who

takes care of him in the emergency department, needs to consult the information on the patient's care path as well as his contact details. Dr. Schmidt connects to the German Health Management System (GHMS) and asks through it to establish a link with its French equivalent (FHMS) in order to retrieve information from Jean Dupont. The GHMS thus sends a request to establish access to the FHMS which in return requests a certain amount of information relating to the requester and the access purpose. Following the sending of this information, the FHMS and GHMS negotiate and enter into a contract which grants the right of access to users attached to the GHMS governed by the access control policy in force in the FHMS. A token is therefore provided by the GHMS to Dr. Schmidt over a fixed period as well as the identifier of the established access contract. The FHMS, for its part, updates its security policy with the attributes relating to the new contract. Dr. Schmidt connects via the token to the PEP of FHMS, which is the user entry point to the system. The PEP transmits the access request to the PDP which studies it based on the input data and access control policies stored in the PAP database and grants Dr. Schmidt access to Jean Dupont's PCH and PCC.

Fig. 3. PCC and PCH Access Control Policy of Mr. Jean Dupont.

Fig. 4. Case Study Illustration.

Bob, a nurse in the emergency department at K Hospital in Germany, can also connect to the PEP thanks to the signed contract covering all staff attached to the GHMS. He made the same request as Dr. Karl Schmidt but did not obtain the same authorizations. According to the access policy in Fig. 3, Bob cannot access the PCC. Although the context (Emergency) and the purpose (Accident) for the access request matches PCC policy, Bob does not have the "Doctor" role and therefore does not meet all the criteria for access. However, he can have read-only access to PCH data in accordance with its policy. Finally, Alice, Jean Dupont's attending physician attached to the FHMS, benefits from permissions to access, read and write to all of his file (PCC and PCH), granted on the basis of her role (attending physician) in organization (H Hospital).

D. Solution Implementation

Fig. 5 shows the sequence diagram of the implementation of our case study.

This sequence diagram summarizes the technical steps taken so that Dr. Karl Schmidt can access Jean Dupont's

medical (PCH) and private (PCC) data. Dr. Karl Schmidt logs into his session in the German Health Management System (GHMS) and formulates a need for access to the French Health Management System (FHMS). The GHMS checks whether a smart contract (SC) already exists and makes it possible to respond positively to the need of Dr. Schmidt. In the case of the absence of a SC or the non-coverage of the need by the existing SCs, the GHMS initiates the automatic process of establishing a new SC with the FHMS as already detailed in the description of Fig. 2. The existence of a SC or the establishment of a new SC triggers the generation of a token by the GHMS which communicates it in addition to the identifier of the SC to Dr. Schmidt. These elements allow the doctor to activate a collaborative session at the FHMS and to formulate an access request to its PEP (Policy Enforcement Point) in which he specifies the attributes necessary to process his request. On the basis of this information, the PEP constructs a XACML request which it transmits to the PDP (Policy Decision Point) to calculate the decision.

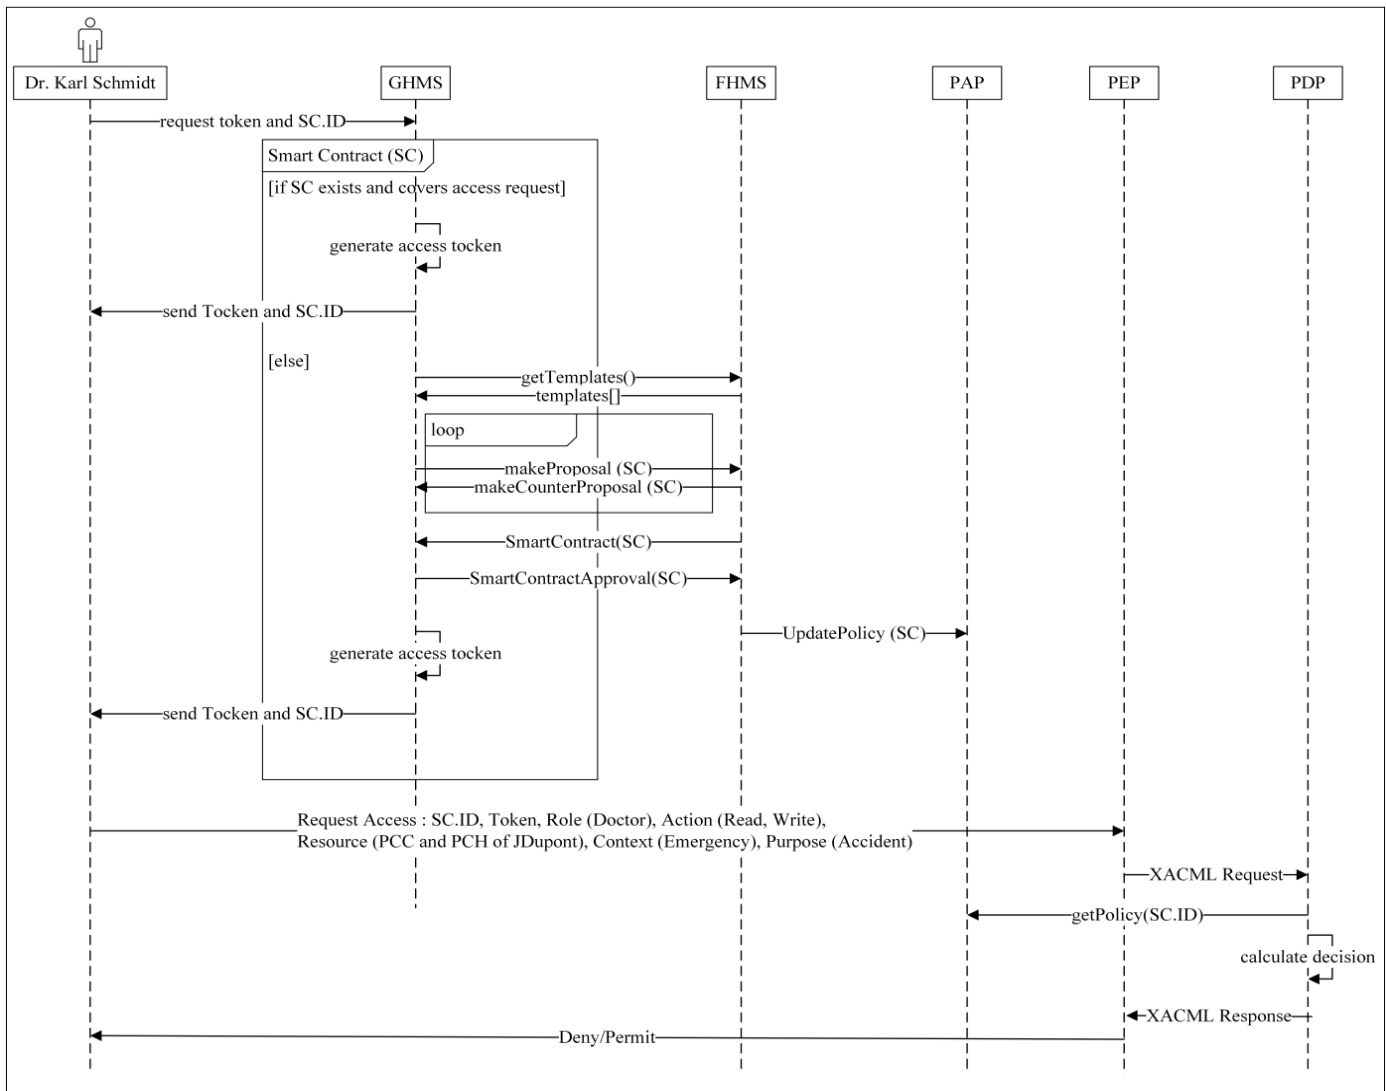

Fig. 5. Negotiation and Establishment of the Smart Contract and Collaborative Access to Data.

Here is an example of a XACML request:

```
<?xml version='1.0' encoding='UTF-8'?>
<Request>

      <AttributeValue>accident</AttributeValue>
    </Apply>
  </Condition>
</Rule>
</Policy>
```

We have therefore seen through this example of an implementation how a subject (Dr. Karl Schmidt) having a role in an organization (Doctor attached to the GHMS) succeeded in exercising an activity (reading and / or writing) on views of objects managed by another organization (PCC and PCH of Jean Dupont, member of the FHMS) in a specific context (Emergencies) and for a specific reason (Accident) following the consent of the data owner (Jean Dupont). This case study and this implementation therefore demonstrates how we were able to implement the process of automating the management of security and privacy policies based on PrivOrBAC using smart contracts and the WS-Agreement Specification.

IV. DISCUSSION

Complex systems allow entities to exchange information even though it is unknown to each other. This type of exchange is generally governed by access contracts negotiated in advance between the providers and consumers of the data. Today, this "static" approach is no longer appropriate. According to [31], Web Services are widely used in the automation of decision making while the use of WS-Agreement asserts itself in the automation of service level agreements (SLA). Automating access negotiation processes and integrating security rules into SLAs seems to be a good solution to make access control dynamic. Stankov et al. [32] consider that SLAs can be used as an instrument to build trust between providers and consumers of services in Cloud Computing platforms even before a relationship is established between them. The WS-Agreement Specification appears to be one of the most promising solutions to achieve this goal. Ludwig et al. [33] use WS-Agreement to negotiate SLA contracts to share resources in Grid Computing. In this same context, Smith et al. [34] also use WS-Agreement and Web Services to set up a security configuration mechanism according to the requirements provided by the user such as the configuration of resources and the quality of service, as well as

security parameters such as the level of encryption and sandboxing. In our work, we use WS-Agreement and Web Services to extend the PrivOrBAC model by incorporating access agreements that cover security rules to protect Privacy.

The WS-Agreement Specification can therefore be combined with access control models to allow data providers and consumers to specify their security rules. This is the case of Li et al. [35] which propose to integrate the attributes and their values in an SLA contract through OrBAC rules. This approach consists in that, thanks to the negotiation protocol of WS-Agreement, the providers and consumers of services exchange offers and counter-offers until an agreement is reached. However, this approach does not explicitly implement the WS-Agreement Specification to eliminate human intervention when discovering services and negotiating terms of the agreement. Our solution, on the other hand, makes it possible to respond to this problem and allows intelligent agents (or connected objects) to discover each other, discover services, negotiate service level clauses as well as clauses related to access security. However, the explicit management of trust based on transaction history and the management of inferences are, among others, two aspects that still needed to strengthen the model and avoid derivation. Indeed, the application of security rules seems to be a good solution to block unauthorized access and even more if these rules are negotiated automatically, but the dynamic reinforcement of these rules throughout the life of the information system is an essential requirement in today's systems.

V. CONCLUSION AND PERSPECTIVES

A. Conclusion

In this article, we first started by explaining our directions in terms of privacy protection. We have given a definition to this concept and we have subsequently explained the approach followed, the choices adopted and the contributions made in our previous work to achieve the integration of privacy protection from the early design phases of complex systems. This integration in its static form is not entirely satisfactory to large organizations equipped with systems with high volumes of interactivity. The most awaited by these organizations is a dynamic administration of security policies and privacy protections. It is in this context that we have proposed in this article an automatic process for managing these policies in interactive systems. Our mechanism is based on the negotiation and establishment of smart contracts through the WS-Agreement Specification. This automation allows a system to autonomously manage access requests from external organizations, negotiate access contracts in accordance with current policies with these organizations, and update these policies with attributes of new contracts. Thus, we have provided the means to convert our integration of security and privacy policies from a static to a dynamic form.

B. Perspectives

We have taken care in our work to offer the various means capable of covering all aspects of privacy protection, ranging from the definition of this concept to the automation of the process guaranteeing it. "Management of inferences" is another aspect that remains to be taken into account. It is true that

PrivOrBAC is a powerful model which allows defining and configuring access controls adapted to different situations, but the risk of inference in this model is not reduced to zero. A user with access to a set of data can always combine them to derive private data that they cannot directly consult. In our case study, suppose that Jean Dupont is HIV positive and he chose to keep this information private. Bob, the nurse at K Hospital, does not have access to Jean Dupont's private data, but can view medical data. Bob can therefore see that Jean Dupont is being treated with a protein called "interferon". This protein is used in the treatment of viral diseases (AIDS, hepatitis, papillomavirus, etc.), in oncology (sarcoma) or in preventive treatment. This information alone does not allow deducing with certainty that Jean Dupont is a carrier of HIV, but by combining it with the results of analyzes on the P24 antigen which are also part of the medical data that Bob can consult, the private data can therefore be revealed. Our perspectives therefore focus on proposing ways to combine with PrivOrBAC to guarantee privacy-aware access control without risk of inference.

Hyperspectral Image Classification using Convolutional Neural Networks

Shambulinga M¹, G. Sadashivappa²

Dept. of Electronics and Telecommunication Engineering
RV College of Engineering, Bengaluru

Abstract—Hyperspectral image is well-known for the identification of the objects on the earth's surface. Most of the classifier uses the spectral features and does not consider the spatial features to perform the classification and to recognize the various objects on the image. In this paper, the hyperspectral image is classified based on spectral and spatial features using a convolutional neural network (CNN). The hyperspectral image is divided into a small number of patches. CNN constructs the high level spectral and spatial features of each patch, and the multi-layer perceptron helps in the classification of image features into different classes. Simulation results show that CNN archives the highest classification accuracy of the hyperspectral image compared with other classifiers.

Keywords—Convolutional neural network; hyperspectral image; classification

I. INTRODUCTION

Latest developments in optics and photonics have made a hyperspectral imaging sensor with better spectral and spatial resolution. The spatial and spectral information is efficiently exploited to identify the materials and objects on the earth surface. The spectral signatures are modelled in such a way that they will differentiate the various objects and materials. It is possible to see the identification of different materials, objects and surface ground cover classes based on their reflectance properties as a classification task, i.e. the classification of image pixels based on their spectral characteristics. Classification of hyperspectral imaging has been used in a broad range of applications, such as agriculture, environmental science, astronomy, surveillance, astronomy and biomedical imaging. However, the classification of the hyperspectral images has its own particular problems, in addition to (i) high dimensionality, (ii) the small number of samples which have been labelled, and (iii) significant spatial variation of spectral signatures.

Much of the recent work on hyperspectral data classification follows the traditional pattern recognition method, which comprises of two distinct steps: first, detailed handcrafted features are obtained from the original data input, and secondly, classifiers like Support Vector Machines (SVM), Neural Networks (NN) [1], maximum likelihood [2], parallelepiped classification, k nearest neighbours [3], minimum distance [4], and logistic regression [5] have been used to learn the extracted features. The “curse of dimensionality” affects the majority of the algorithms mentioned above. Any dimensionality reduction-based classification approaches [6] have been suggested to manage

the large dimension complexity and small training samples of hyperspectral data. Band selection and transformation are the other methods available to deal with dimensionality. In general, statistical learning techniques have been used to solve the large dimensionality and variability of high dimensional hyperspectral data and when few training samples are accessible.

Support vector machine, a popular classification method for hyperspectral data classification, is presented in [7]. SVM is resistant to the Hughes phenomena and has poor sensitivity to high dimensionality. In certain situations, SVM-based classifiers perform better compared to other commonly used pattern recognition strategies in terms of classification accuracy. These classifiers were cutting edge technological tools for a long time.

In recent years, spatial information has become highly relevant for hyperspectral data classification. In terms of efficiency, spatial-spectral classification methods provide substantial benefits. Many new methods aim to bring spatial information into account to deal with spectral signature spatial variability. In [8], applying SVM and a guided image filter, a technique for classifying hyperspectral images has been presented. The guided image filter is used to incorporate the spatial features into the SVM classifier. In [9], the edge-preserving filters such as bilateral filter and guided image filter are included to incorporate the spatial features to the SVM classifier.

However, it is essential to know which features are most relevant for the classification algorithms due to the high diversity of represented materials. The various deep learning models [10,11] have been developed for classification purposes. These models are trained from various levels of features. The high levels features required for training the model are obtained from low-level features. These models automate the extraction of features for any problem compared with any convolutional pattern recognition technique. In addition, deep learning systems tend to match and resolve the classification issue more efficiently with wider datasets and large images with high spatial and spectral resolution. Deep learning approaches have already shown promising results for detecting real artefacts, such as man-made objects or vehicles, as well as for classifying hyperspectral data.

More precisely, a deep learning system for the classification of hyperspectral data with accurate results was used in [12].

In precise, the auto encoder's helps in the design of the deep architecture, which hierarchically extracts the high-level spectral features required for the classification of each pixel in the image. Spectral features were coupled with spatial-dominated information in a separate stage and fed to a logistic regression classifier as input.

In the same way, for the classification of hyperspectral data into various classes, we suggest a deep learning system. Our method, however, is based on a coherent structure that incorporates spectral and spatial information in a single stage, creating high-level spectral-spatial characteristics at the same time.

In specifically, we suggest the use of a Modified Convolutional Neural Network (CNN) that performs the operation of constructing large-level features and a Multi-Layer Perceptron (MLP) which is used for the classification of the image. The evolved framework builds spectral-spatial characteristics at once under this kind of design and, at a similar time, performs real-time predictions of the various classes in the image because of the existence of feed forward network in CNNs and MLPs.

This paper is organized into five sections: Section II gives a brief introduction and background of the convolution neural network. Section III presents the implementation methodology of the convolution neural network for hyperspectral image classification. Sections IV and V discuss the results and discussion of the image classification and conclusion.

II. CONVOLUTIONAL NEURAL NETWORK (CNN): BACKGROUND

Convolution neural network (CNN) is the most standard deep learning algorithm for image classification and image recognition problems. Along with these applications, CNN is widely used to recognize human faces and classify objects.

CNN algorithm takes the input image and extract the features in the learning phase and classify it to various class or

categories. The algorithm sees the input image as an array of a matrix ($h \times w \times d$), and it will depend on the image resolution. CNN consider the ($h \times w \times 3$) matrix for the RGB image and ($h \times w \times 1$) for the grayscale image. In principle, create the CNN model bypassing the input image series through various convolution layers with filters or kernels to extract features, pooling, fully connected layers, and finally applying the softmax function to detect the objects probabilistic value between 0 and 1. Fig. 1 shows the entire CNN follow diagram process.

A. Convolution Layer

The features existing in the input images are extracted through a convolution layer. The relationship that exists between the image's pixels is preserved by taking a small square of input data at the learning phase. The convolution is the mathematical operation given by the multiplication of an image matrix and a filter or kernel. The convolution operation of the image is shown in Fig. 2.

Consider an example of an image pixel whose matrix is 5×5 with values 0 and 1 and the filter matrix or kernel 3×3 . The convolution layer multiplies the image matrix with a filter matrix to provides the convolved feature or feature map. The same convolved operations are shown in Fig. 3 and Fig. 4.

Use the various types of filters or kernel listed in the Table I for convolution operation. These filters can also perform different mathematical calculations like sharpening of the image, blur the image and to detect the edges in the image.

B. Strides

Strides are used in convolution operation, and it determines the shift in the filter kernel matrix by certain number of pixels on the input image. For example, if stride value is 1 in convolution operation, then the filter kernel in convolution is shifted by one pixel at a time on the image matrix. If stride value is 2, then a filter kernel is shifted by two pixels at a time on the image matrix. Fig. 5 shows the operation strides by 2 pixels.

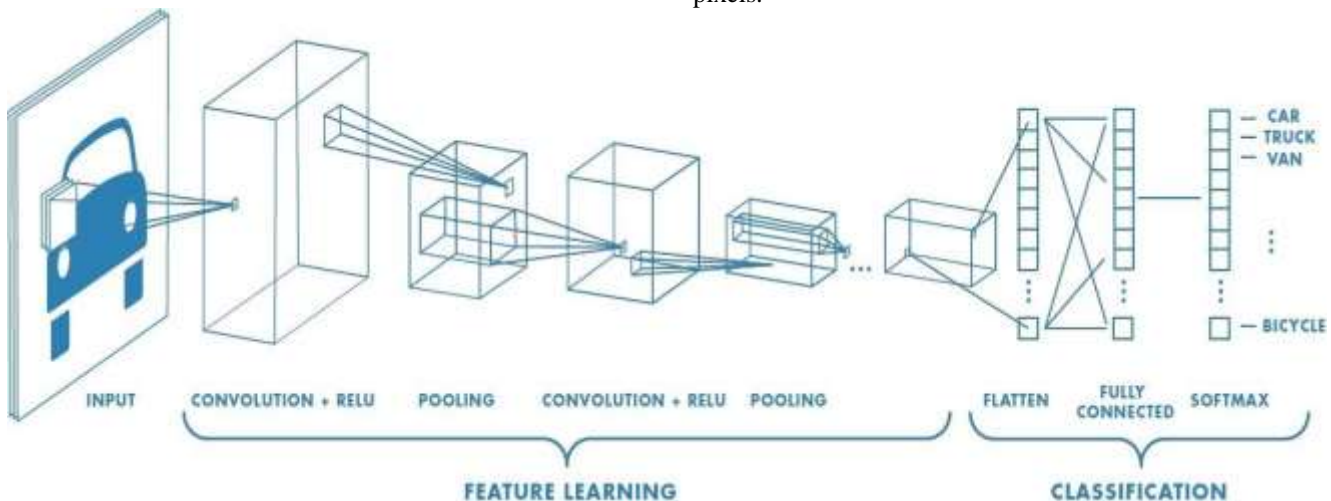

Fig. 1. CNN Flow Diagram.

- An image matrix (volume) of dimension $(h \times w \times d)$
- A filter $(f_h \times f_w \times d)$
- Outputs a volume dimension $(h - f_h + 1) \times (w - f_w + 1) \times 1$

Gaussian blur	$\frac{1}{16} \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$

Fig. 5. Stride by 2 Pixels in Convolution Operations.

C. Padding

In most of the cases, the chosen filter does not fit to the input image. In those cases, the following options are used to fit the input images.

- Zero paddings: input image is padded with zeros to fit the input images.
- Drop a few pixels in the image to fit the input images.

D. Non Linearity (ReLU)

Rectified Linear Unit (ReLU) performs the non-linear computation in convolution network. The output of ReLU is $f(x) = \text{Max}(0, x)$.

The goal of introducing the non-linearity in ReLU is to learn the non-negative linear values in the convolution network. Fig. 6 shows the ReLU operation in CNN.

Fig. 6. ReLU Operation in CNN.

Tanh and sigmoid are the some of the non-linear functions which can be employed instead of ReLU. But the performance of ReLU is better compared to the other two non-linear operations

E. Pooling Layer

The pooling layer decreases the output pixels of the convolution layer and reduces the complexity of large images. The spatial pooling is also called subsampling or downsampling of pixels, and it decreases the spatial dimension of the image by retaining most of the information in the image. Following are three different categories of spatial pooling.

- Max Pooling
- Average Pooling
- Sum Pooling

Max pooling selects the greatest value in the convolved feature value, as shown in Fig. 7. The average pooling selects the average pixel value of all the convolved feature value. The sum pooling selects the addition of all the components in convolved feature value.

Fig. 7. Max Pooling Operation.

F. Fully Connected Layer

The two-dimensional matrix of the pooling layer is converted into a single dimension matrix. This single layer vector is feed into a fully connected layer similar to a neural network. Fig. 8 shows the operation of a fully connected layer. The output feature matrix is converted to vector as x_1, x_2, x_3 . These features are merged to construct a model using a fully connected layer and finally use softmax or sigmoid function to classify the outputs.

Fig. 8. Fully Connected Layer in CNN.

III. METHODOLOGY

The implementation methodology of hyperspectral image classification using the CNN approach is shown in Fig. 9. The hyperspectral image is defined as a 3-D matrix of size $h \times w \times c$, where h and w represent the image's height and width and c represents the spectral channel in the image. The hundreds of channels in the hyperspectral image enhance the calculating time and memory resources of the training and prediction process. On the other hand, using statistical analysis, it is observed that the spectral response variance is minimal for the pixel that belongs to each class.

It means for every channel, pixels with the same class labels have related spectral values, and pixels with different class labels have different spectral values. A dimensionality reduction procedure can be used, based on these properties, to decrease the dimensionality of the input data, to optimize the training and classification processes. PCA is the dimensionality reduction algorithm that reduces the hyperspectral image's

spectral dimensions without losing any image information. After dimensionality reduction, split the hyperspectral image into small patches to compatible with CNN's basic nature. Each created patch contains the spectral and spatial features of a single pixel.

More precisely, square patch of dimension $s \times s$ centred at a pixel $P_{x,y}$ is used to classify the pixel at location (x, y) on the image plane and combine spectral and spatial feature data. Let us denote the class label of the pixel at the given location as $l_{x,y}$ and patch centred at pixel $p_{x,y}$ as $w_{x,y}$. then create a dataset $D = \{w_{x,y}, l_{x,y}\}$ where $x = 1, 2, \dots, w$ and $y = 1, 2, \dots, h$. The patch $w_{x,y}$ is the 3D matrix with size $s \times s \times c$, which has spatial and spectral data for each pixel. Furthermore, this matrix $w_{x,y}$ is split into c matrixes of size $s \times s$, which are given as an input to the CNN algorithm. This CNN develops the large features that encapsulate the pixel's spectral and spatial information. The CNN architecture contains many layers, as shown in Fig. 10. The first layer in CNN structure is the convolution layer with $C_1 = 3 \times c_r$ a trainable filter of dimensions 3×3 . This layer gives C_1 matrixes of dimensions 3×3 . The second layer is also a convolution layer with $C_2 = 3 \times C_1$ trainable filter. The output of the convolution layer is given to flatten layer and fully connected layer. The flow chart for the implementation of hyperspectral image classification using a convolutional neural network is shown in Fig. 11.

IV. RESULTS AND DISCUSSIONS

The Hyperspectral image is used to simulate the proposed algorithm. Indian pines dataset is the hyperspectral image captured at north western Indiana test site using AVIRIS sensors, and its specification is shown in Table II. The overall accuracy, test loss, precision, recall and f1-score are parameters used to analyze the performance of algorithm.

In the simulation, PCA reduces the spectral bands, and 30 principal components are chosen for the classification. After dimensionality reduction, each patch contains $s \times s \times c_r$ dimensions. During the simulation, the patch size s is defined as 5 to consider the nearest 24 neighbours of each pixel. Each patch is given to the CNN architecture for classification.

The classification accuracy obtained for the 5×5 patch is 84.12%, with a simulation time of 1142.26 seconds. The screenshot of the results and the classified image is shown in Fig. 12. The test loss for the same is 47.33%. The precision, recall and f1-score of the individual class is shown in Fig. 12. The patch size s is increased to 7, 9, 11 and 13 to increase the number of neighbours for each pixel.

Fig. 12. Screenshot of CNN Classification with 5 x 5 Patch Size.

Increasing the patch size enhance the classification accuracy and increases the simulation time. The results of CNN classification with different patch size is shown in Fig. 13. The accuracy and computation time of CNN classification is given in Table III. From the table, it can be seen that CNN achieves the highest classification accuracy and computation time for the patch size 13 x 13. No further improvements are observed in classification accuracy for the patch size of more than 13, and in fact, the accuracy of the classifier deteriorates and increases the computational resources. The proposed CNN algorithm for the classification of the hyperspectral image is compared with the Support vector machine classifier as shown in Table IV. Support vector machine uses the spectral features for classification and spatial features are add to SVM output by using guided image filter and bilateral filter.

Fig. 13. Results of CNN Classification with different Patch Size.

TABLE III. ACCURACY AND COMPUTATION TIME OF CNN CLASSIFICATION WITH DIFFERENT PATCH SIZE

Patch Size	5 x 5	7 x 7	9 x 9	11 x 11	13 x 13
Overall Accuracy(%)	84.12	91.10	95.00	97.42	98.28

TABLE IV. COMPARISON OF SVM AND CNN CLASSIFICATION METHODS

Methods	SVM [8]	SVM with PCA [8]	SVM with LDA [9]	SVM with GIF [8]	SVM with PCA & GIF [8]	SVM with LDA and GIF [9]	SVM with BF [9]	SVM with PCA & BF [9]	SVM with LDA and BF [9]	CNN
Overall Accuracy (%)	91.28	88.1	86.53	99.04	98.99	96.37	98.89	98.93	96.53	98.28
Computation Time (sec)	4117.7	568.11	423.58	4118.15	568.25	424.1	4118.03	568.32	424.08	5002.114

Along with SVM, the dimensions of the spectral features are reduced using PCA and LDA. The SVM method along with guided image filter and bilateral filter increases the classification accuracy and SVM method along with PCA and LDA decreases the computational time. CNN algorithm combines both spectral and spatial features at the same time without using guided image filter and bilateral filter. CNN algorithm archives the highest classification accuracy compared to the SVM classification accuracy with increasing computation time. SVM algorithm consumes less computational time compared with CNN algorithm.

V. CONCLUSION

The hyperspectral image is classified using a convolutional neural network. Both spectral and spatial features are considered to classify the image. Spatial features are included in the classification to improve the classification. CNN archives the highest classification accuracy of 98.28% compared to support vector machine classifier and other methods. CNN accuracy depends on the patch size considered for the classification. Patch size indicates the number of spatial features considered for classification. It is observed that the patch size of 13 x 13 is enough to achieve the highest accuracy. CNN consumes more computation time for training and testing compared with other classifiers. The proposed method avoids the usage of an edge-preserving filter to incorporate spatial features into the classification.

Skeletonization of the Straight Leg Raise Movement using the Kinect SDK

Hustinawaty¹, T. Rumambi², M. Hermita³

Department of Informatics^{1,2}

Department of Psychology³

Gunadarma University, Indonesia

Abstract—Biomechanics is widely used as a basis for research in studying disorders of the movement system in the human body. The development of biomechanics has an effect on the field of physiotherapy. Various physiotherapy tests or studies have been developed by researchers to identify and analyze the causes of movement disorders in the human body. Physiotherapy tests performed to detect movement disorders in the human body include: Hawkin Test, Standing Hip Flexion, Standing Trunk Sidebend Test and Straight Leg Raise Test. Straight Leg Raise test is a test to lift one leg straight up in a lying down position. In the medical field, Straight Leg Raise (SLR) movement is very specific for lower lumbar disc herniation and through the use of a device called Kinect which is a color based camera (RGB) and depth camera that can detect movement and track the human skeleton. To get the human body skeleton is through the stages from RGB image acquisition, pose calibration, depth image, skeletonization to feature extraction of the two legs that can form ROM. The result of this study, Kinect is able to track the user's foot frame in SLR pose. Kinect can be relied upon to be used as a tool for detecting and tracking skeletons, and can then be used to measure SLR ROM in real time and analyze low back pain problems and measure effectiveness in physiotherapy.

Keywords—Straight leg raise; range of motion; skeleton; kinect

I. INTRODUCTION

Biomechanics is the study of the use of mechanical forces and includes the interaction effects of forces or systems of movement, nerves, muscles, and forces arising from within and outside the body. Biomechanics is widely used as a basis for research in studying disorders of the movement system in the human body. The development of biomechanics has an effect on the field of physiotherapy. Various physiotherapy tests or studies have been developed by researchers to identify and analyze the causes of movement disorders in the human body in order to increase locomotion in the human body. Physiotherapy tests carried out to detect movement disorders in the human body include: Hawkin Test, Standing Hip Flexion, Standing Trunk Sidebend Test and Straight Leg Raise Test [1].

The straight leg raise test also called the Lasegue test, is a fundamental neurological maneuver during physical examination of the patient with lower back pain aimed to assess the sciatic compromise due to lumbosacral nerve root irritation [2]. The Straight Leg Raise test is used to establish tension in the sciatic nerve to assist in the diagnosis of nerve root compression from the lower lumbar nerve root. Patients can perform Straight Leg Raise (SLR) movements so that the

hip flexion Range of Motion (ROM) is obtained. The test must be done passively and the patient's knee is maintained in full extension and the hip is in neutral rotation. For each test, the doctor records every symptom produced during the test and also the degree of hip flexion. Positive test results require reproduction of foot symptoms that the patient has known between 30° and 70° from hip flexion. Positive contralateral straight leg test results are very specific for lower lumbar herniation. [3][4]. This study describes the clinical markers for Low Back Pain, in which doctors examine and observe the patient's posture and motion and assess range of motion including flexion, extension and rotation. SLR tests should be performed on patients with evidence of sciatica or radicular pain. The SLR test is specifically aimed at detecting lumbar nerve root irritation and positive identification when sciatica is produced between 30 and 60 degrees of foot elevation. The SLR Test is widely used as one of the primary physical diagnostic tests, patients who have low back, lower back and leg pain [5]. But in line with current technological developments, doctors can perform SLR tests with the help of a technology that is using motion capture technology. Motion capture is a terminology used to describe the process of recording motion and interpreting the movement into a digital model using the Kinect sensor that is controller-free gaming and video game platforms by Microsoft. Kinect has an RGB camera, depth sensor and microphone that run on special software devices, which provide the ability to capture motion in 3D, recognize faces and recognize sounds. The depth sensor records 3D video data in any lighting conditions. and can access Kinect depth information, process raw depth images to detect players (users) and find joint positions in 3D and track body skeleton [6]. Kinect technology and tracking markers of human gestures can be developed by several virtual reality applications using Kinect sensors [7]. Research [8] uses Kinect in physical rehabilitation tests to measure a person's ability to walk within a range of 10 meters and to measure the range of motion of the neck, shoulder, elbow, upper thigh, knee joints. Then research using depth images obtained by the Kinect sensor can bring innovative ways to build intelligent fall detection systems that can be used to observe parents at home, and notify guards by raising alarms in the event of a fall event, a fall detection system in real-time scenarios based on the extraction of skeletons from human figures with the help of a Kinect depth sensor[9]. The Microsoft Kinect sensor has the potential to be a low-cost solution for clinical and home-based assessment of movement symptoms in people with Parkinson's disease. The aim of this study is to establish

Kinect accuracy in measuring clinically relevant movements in people with PD, namely a series of movements including standing, reaching in all directions and walking and walking in place, holding hands, tapping fingers, feet, leg dexterity, riding a chair and hand pronation. [10]. In this research combine several image processing techniques with the depth images captured by a Kinect sensor to successfully recognize the five distinct human postures of sitting, standing, stooping, kneeling, and lying.[11].

II. RELATED WORK

A. Kinect Component

Microsoft Kinect is an input device for motion detection and Kinect is a RGB-Depth sensor from Microsoft that uses Light Coding technology PrimeSense, an Apple Inc. company. Light Coding is a technology that can reconstruct a 3-dimensional depth map of the state in realtime and detail. Kinect 640 x 480 pixel depth resolution. Kinect sensors include the following main components, shown in Fig. 1 [12]:

- Camera RGB (color).
- Infrared (IR) emitter and an IR sensor depth.
- Motor Tilt.
- Array Microphone.
- Light Emitting Diode.

Fig. 1. Kinect Component.

B. Kinect for Windows SDK

Kinect for Windows SDK is a programming toolkit for application developers. This allows academics and the community to access the capabilities offered by Microsoft Kinect devices connected to computers with the Windows 7 OS. This SDK is equipped with drivers, APIs for raw sensor streams, skeletal tracking, installation documentation and other resources. This SDK also provides Kinect capabilities for developers who will create applications with C ++, C # and Visual Basic using Microsoft Visual Studio [13].

C. Skeleton

The development of RGB-Depth camera technology, opens new research opportunities in computer science, such as computer vision, games, motion-based control and virtual reality. Research [14] introduces a method for predicting the 3D position of the joints of the human body by extracting image depth information. Then calculate the estimated 3D position of the joints of the body using a search approach based on an average shift with a Gaussian kernel weight. By using a very large training set and various classifications of body parts, body shape, clothing and so on, classification can

be done appropriately. PrimeSense extracts features from joint data from the RGB-D Kinect camera and uses a learning method approach to infer activities that are being carried out by humans.

D. Microsoft API Skeleton

The Natural User Interface (NUI) Skeleton Application Programming Interface (API) provides information about the location of up to two players standing in front of the Kinect Sensor, with detailed information on position and orientation. The data is given to the application code as a set of points called the position of the framework, which forms the skeleton, as shown in Fig. 2. This template is the position when the user is posing. To use skeleton data, an application will display the data when initializing an NUI, then trace the skeleton. The skeleton dataset used in this study is the result of the algorithm which has been integrated by Microsoft into the Windows API operating system. Skeleton data generated by the Windows API divides the skeleton structure into 20 sections as shown in Fig. 2.

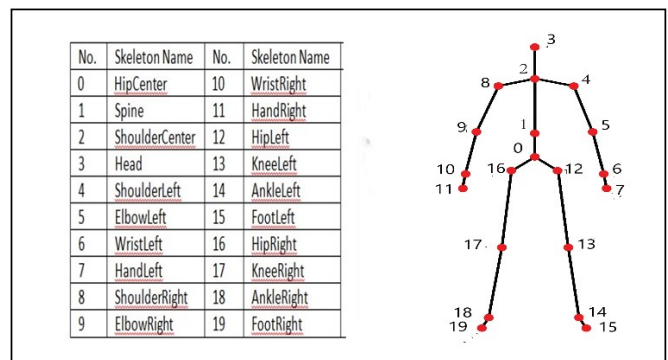

Fig. 2. Skeleton Dataset.

Each skeleton control point is defined by the X, Y, Z coordinate positions expressed in the skeleton space. Skeleton space is defined around the sensor located at the point (0, 0, 0) where the X, Y, and Z axes meet. In units of meters with the midpoint of the coordinates located on the HipCenter skeleton point and depth data (depth) which is the Z axis whose value is the distance between the Kinect device and the object [12].

E. Straight Leg Raise (SLR)

Straight Leg Raise Test is the movement of lifting one leg up straight in the lying position. The movement of lifting the legs straight up slowly will form a hip angle between the legs as shown in Fig. 3. The SLR movement is limited by pain, this test is positive and shows a sciatica of the lumbosacral (spine) [5] [15].

Fig. 3. Straight Leg Raise [1].

III. METHODOLOGY

A. Diagram of the Skeletonization Process Steps

Stages of forming skeleton at the time of the SLR can be described in the flowchart diagram in Fig. 4.

Fig. 4. Diagram of Methodology.

The initial stage is the acquisition and calibration stage. Kinect as an image acquisition device is placed at a height of approximately 3 meters from the floor. The patient in the supine position is the object of image acquisition by a Kinect device that has been equipped with a camera. The image format recorded by the camera is in RGB format. The calibration stage is the alignment stage between the camera position and the patient's body position in a supine pose so that it can be detected according to the expected position standard. The results of calibrated image acquisition are converted into grayscale depth. The second step is tracking the skeleton. Based on the depth data obtained and data on Kinect as machine learning, searching is done to detect humans in visualization of 3-dimensional space and Kinect has the ability to see in 3D through depth sensors that have skeletal tracking capability, namely processing depth images to get the joint position of the human skeleton and optimize the tracking of objects facing the Kinect to be used as a skeleton. skeleton tracking is successful which forms the skeleton in the human hip and the second part of the thighs, calves up to the soles of the feet. The purpose of forming the skeleton of the body part is to make the user or user to observe the movement of the body (legs). The third stage is the detection of skeleton in the SLR movement. This stage is to get the SLR skeleton shape on the lying object. Following are RGB-Depth and Skeleton images in Fig. 5(a) and Fig. 5(b):

(a)

(b)

Fig. 5. (a). RGB-Depth, (b). Skeleton Images.

The skeleton drawing algorithm with the drawBone() method that accepts two joints is tracked and draws a line between the joints. Skeleton drawing between joints can be done as needed. Whenever it requires depicting a joint of the entire human body, sequences need to be carried out, starting from the head to the foot, both from the left and right side of the body. Kinect generates skeleton data in the form of SkeletonStream, which can be set as standard tracking mode (default) or seated tracking mode using SkeletonTrackingMode enumeration during skeleton stream initialization. The process of flow (stream) to capture data skeleton remains the same as used for data streams of color and depth.

B. Skeleton Tracking Coding in Library Kinect

1. Attach and call the *SkeletonFrameReady* event handler
2. Check whether the skeleton frame is active to receive skeleton data.
 - If *SkeletonFrame = null* then returns to the 'Kinect Device Initiation' algorithm
3. Is the skeleton frame active?
 - If *skeletonFrame <> null*
 - Determine the number of skeletons tracked by:
skeletons = new Skeleton
[skeletonFrame.SkeletonArrayLength];
4. Copy the skeleton frame data to local memory
skeletonFrame.CopySkeletonDataTo (skeletons);
5. Draw Bone / skeleton in JointCollection from Head to foot right that is Head – FootRight
SLR skeletonization algorithms in chart box in Fig. 6.

- Draw a Bone / skeleton in JointCollection from the head to the middle chest:
Drawbone skeleton joints. Head-ShoulderCenter,
Drawbon skeleton joints.ShoulderCenter- ShoulderLeft,
Drawbone skeleton joints.ShoulderCenter-ShoulderRight.
- Draw a Bone / skeleton in JointCollection from the left shoulder to the middle of the chest to the right elbow:
Drawbone skeleton joints. ShoulderCenter- ShoulderRight,
DrawBone skeleton joints. ShoulderLeft-ElbowLeft,
DrawBone skeleton joints.ShoulderRight-ElbowRight,
DrawBone skeleton joints ElbowLeft–WristLeft,
DrawBone skeleton joints.ShoulderRight-ElbowRight.
- Draw bone from the left elbow joint into the spine:
DrawBone skeleton joints ElbowLeft–WristLeft,
DrawBone skeleton joints ElbowRight – WristRight,
DrawBone skeleton joints WristLeft – HandLeft,
DrawBone skeleton joints WristRight – HandRight,
DrawBone skeleton joints ShoulderCenter– Spine.
- Draw bone from the spinal joint to the right knee:
DrawBone skeleton joints Spine - HipCenter.
DrawBone skeleton joints HipCenter- HipLeft,
DrawBone skeleton joints HipCenter – HipRight,
DrawBone skeleton joints HipLeft – KneeLeft,
DrawBone skeleton joints HipRight – KneeRight.
- Draw bone from the left knee joint to the right leg:
DrawBone skeleton joints KneeLeft – AnkleLeft,
DrawBone skeleton joints KneeRight – AnkleRight,
DrawBone skeleton joints AnkleLeft - FootLeft,
DrawBone skeleton joints AnklerRight - FootRight.

Fig. 6. SLR Skeletonization Algorithms.

IV. RESULT

After the calibration process is complete and the algorithm detects that the user is a candidate, then the skeleton detection process and accesses any joint information or draws something above the depth image. Test cases were carried out on 10 human objects with different people of different body sizes and height. The picture illustrates the movement of the foot up, and when needed to stop, when used by doctors, the

leg movement stops until the pain center. Images are generated by categorizing in depth images and RGB images and their skeleton in Fig. 7.

Fig. 7. Images of Depth, RGB and Skeleton.

V. CONCLUSION

The results of testing data on human objects that perform successful SLR movements can track the skeleton of both legs. The results of this skeletonization in addition to providing information about the potential of Microsoft Kinect as a tool that can determine the skeleton between the two legs can also later use the skeleton as a basis for calculating the degree of SLR ROM on the SLR test. In this study, there were 4 patients with spinal disorders, it is hoped that in the future more can be done in patients with conditions such as low back pain. In addition, it is also expected to be able to compare manual measurements and SLR ROM measurements in realtime with the help of other than Kinect as an application. Tracked joint position data can aid in the diagnosis of the cause of a lower lumbar disc herniation and can be used to aid psychotherapy training.

ACKNOWLEDGMENT

The authors would like to thank The Directorate of Research and Community Service - Ministry of Research, Technology and Higher Education (DRPM - Kemenristek / BRIN) for financial support of this experiment., Contract number 309/SP2H/LT/DRPM/2021, 18 March 2021.

Abstract—The technological advancement in Intelligent Transport Systems and mobile phones enable massive collaborating devices to collect, process, and share information to support the sales and transportation of agricultural goods (agro-goods) from farmer to market within the Agriculture Supply Chain. Mobile devices, especially smartphones and intelligent Point of Sale (PoS), provide multiple features such as Global Positioning System (GPS) and accelerometer to complement infrastructure requirements. Despite the opportunity, the development and deployment of the innovative platforms integrating Agro-goods transport services with e-commerce and e-payment systems are still challenging in developing countries. Some noted challenges include the high cost of infrastructure, implementation complexities, technology, and policy issues. Therefore, this paper proposes a framework for integrating ITS services in agro-goods e-commerce, taking advantage of mobile device functionalities and their massive usage in developing countries. The framework components identified and discussed are Stakeholders and roles, User Services, Mobile Operations, Computing environment with Machine Learning support, Service goals and Information view, and Enabling Factors. A Design Science Research (DSR) method is applied to produce a framework as an artifact using a six-step model. Also, a case study of potato sales and transportation from the Njombe region to Dar es Salaam city in Tanzania is presented. The framework constructs the ability to improve information quality shared among stakeholders; provide a cost-effective and efficient approach for buying, selling, payment, and transportation of Agriculture goods.

Keywords—Intelligent transport system; stakeholders; mobile phone; agro-goods; information sharing; agriculture supply chain; machine learning

I. INTRODUCTION

The availability and sharing of quality information are of paramount importance to stakeholders involved in the whole process of transportation of agricultural goods (agro-goods) from farms to the markets or buyer locations. Traditional Transport Management Information System (TTMIS) can offer

such solution but has a limitation in achieving maximum efficiency such as the ability for users to access the location of the Transporter instantly, driving behavior of the driver, timely access to weather condition in the position of agro-goods, traffic congestion status with alternative routing in cities and precision in the estimation of the delivery time.

The Intelligent Transport System (ITS) introduction offers vast opportunities that address the limitations observed in TTMIS. ITS mainly utilizes Information and Communication Technologies and sensors to ensure cleaner, efficient and safer road transportation of freights and Passengers [1]– [3]. The ITS allows Information Systems to make decisions that will benefit stakeholders intelligently. However, the requirements for development and deployment vary from one country to another due to different factors such as geographical structure, the way transport infrastructure is planned, the availability of technologies, social and economic differences.

The adoption and use of ITS have increased tremendously, since its inception in Japan and later in the USA and Europe over three decades [4]. The importance of ITS cannot be undermined. The global ITS market counted to 26.68 billion USD in 2019, and it is predicted to reach a 5.8% annual growth rate from 2020 to 2027[5]; but, the COVID-19 pandemic affected the market growth predictions. Significant factors influencing such change include the growing number of road vehicles, lack of traffic data, increasing demand for real-time information exchange in logistics, and advancements in big data, Artificial Intelligence (AI), blockchain, and the Internet of Things (IoT).

The developments and impacts of ITS have been realized high in developed countries [6], especially in transportation services, such as autonomous vehicles and applications to smart cities. There is little focus on Freight Intelligent Transport Systems (FITS) when viewing local contexts in developing countries. Some of the main challenges associated with FITS are the lack of transparency in data sharing to keep a competitive advantage against business rivals [7], [8]. Even

though the adoption of blockchain technology promises to address this challenge as explained by [7], [8], high implementation cost and complexity of the nature of freights in terms of handling requirement parameters such as size, weight, type (hazardous vs. non-hazardous, perishable vs. non-perishable, etc.).

ITS technologies for handling freight transportation include ubiquitous computing, IoT, wireless sensor networks, RFID, GPS, GPRS, GIS, artificial intelligence, and mobile phones. The increasingly mobile phone usage is crediting ITS development. A recent report reveals that out of 7.8 billion of the total world population, 4.88 billion mobile phone users worldwide, having 3.8 billion are Smartphone users. Sub-Saharan Africa recorded 34% smartphone connection in 2017. It is estimated to reach 67% by 2025 [9]. Some of the fueling factors are lower cost of Internet, cheaper devices, and increasing realization of the service provided by smartphones over the regular phone. This increased penetration of mobile phones, especially smartphones as sensors, has changed the way businesses and services are conducted globally. The ubiquity, power, and versatility of smartphone platforms have become valuable data generators in commerce, transport [2], financial services, agriculture [9], and infotainment.

Despite the advantage offered by mobile phone users globally, there is little focus on applying Mobile phone services integrated with ITS and e-commerce platforms the Agriculture Supply Chain (ASC) to improve transport efficiency of agricultural goods between stakeholders. In developing countries like Tanzania, the application of ITS is at its infancy with limited ITS infrastructure, operational standards, and governing policies. Evidently, there are existing e-commerce platforms linking farmers to markets. For example, Tanzania Mercantile Exchange Market (<https://www.tmx.co.tz>), which is government-owned platform; mkilimo (<http://mkilimo.esrf.or.tz>), which uses USSD code; tigo kilimo using USSD, SMS and voice; WeFarm (<https://about.wefarm.com/platform>) focusing on livestock, and Connected-farmer, which aims to improve agri-business efficiency of smallholder farmers. Although the platforms efficiently operate in Tanzania, many available systems lack integration with transport services. Therefore, users still have limitations in terms of the ability to search, acquire, and manage transport information of agro-goods as.

The contribution of this paper is to propose a mobile phone-based framework integrating intelligent transport systems and e-commerce as a practical approach to assist stakeholders in sharing information during the planning and execution of agro-good sales and transportation. The framework uses mobile phones as a multifunctional tool for solving the challenge of scarce technical resources to facilitate information sharing. Also, the paper identifies and analyzes the stakeholders and needs based on their roles in the system. The study further addresses the technological challenges in the limited access and use of transport information for farmers identified in [10]; and removing missing information to link farmers and other stakeholders, information barriers caused by intermediaries in ASC, identified in [9], [11]. The framework will not cover the internal warehousing operations with

assumptions to be handled by Enterprise Resource Planning (ERP).

The rest of this paper compasses the case study as presented in Section II and related work in Section III. Section IV discusses the methodology used in this study, followed by a proposed framework as articulated in Section V. The illustration and evaluation of the framework are described in Sections VI and VII, respectively. Jointly, the conclusion and recommendation are given in Section VII.

II. CASE STUDY

A. Background

In Tanzania, agriculture is the backbone and the leading contributor of the national economy accounting for 28.2% of the GDP in 2018[12]. The total population estimates at 58 million [13], but [14] estimates at 61 million in 2021. About 65% of the entire labor force lives in rural areas and depends on agriculture for daily living. It is also estimated that 80% of the concentrated rural farmers are smallholder farmers. The survey report by [15] indicated that Tanzania produced 68,000 tons of Irish potato in 2019; the production increased by 59% to reach 108,000 tons in 2020. Recent studies show an increased demand for potato consumption in urban areas to process French fries, also known as chips [16], [17].

Road transportation is the primary means for delivering potatoes to the consumers. It is estimated that 75% of the total freights are transported through an estimated 86,472 km road network [18]. In the current practice, the transportation of Potato agro-goods flows from rural to urban. This study focuses on the effective and efficient use of the limited available resource on Potato agro-goods transportation from the Njombe region to the Dar es Salaam region. The selections of the areas rely on the fact that Njombe is the leading producer, and Dar es Salaam is the primary consumer of Irish potato.

In the Njombe region, as a rural area, the study is based on two districts of Makete and Wanging'ombe. Wherein Dar es Salaam, as the urban area, the study concentrated in Ilala, Ubungo, and Kinondoni districts because of the availability of concentrated major potato marketplaces where potatoes from Njombe are delivered. Potatoes will be transported from Njombe rural road network through the highway to Dar es Salaam City with urban roads.

The sales, purchases, and transportation of agro-goods from farmers (in Njombe) to buyers (in Dar es Salaam) require seamless information sharing between stakeholders. Mobile phone technologies and functionalities provide a unique chance to simplify the processes. For example, the Tanzania Communications Regulatory Authority (TCRA) quarterly subscription report [19] recorded 51.2 million mobile network subscribers, 32 million mobile money subscribers, and 28.4 million internet subscribers by December 2020. Such information reveals the stimulating environment for mobile phone use in accessing services. In addition, mobile phones require sharing information with other devices such as vehicle tracking systems, intelligent cameras, etc., to build IoTs. Tanzania has a machine-to-machine (M2M)/IoT management guideline to create a better environment for exchanging

information [20]. The guidelines are vital in using mobile phones to develop an Intelligent Transport System to facilitate agro-goods sales, purchase, and transport.

B. Challenges

In the ASC, the enabling environment and features provided by mobile phones assure services such as seamless linking of farmers to buyers or markets, the provisioning of inputs for farming, and the formal and informal exchange of agricultural information and recommendations [21], [9], [22], [10]. Many existing ICT initiatives focus on market, pest and disease, weather, soil, financial, insurance, and technical advisory information [11]. Despite usefulness, the existing solutions lack transport integration as the fundamental aspect to ensure the movement of agro-goods from one point to another within ASC stakeholders. The transport integration challenges have also been expressed in the paper [10]. The road transportation of agro-goods is currently inefficient due to a lack of information sharing among agro-goods stakeholders. Since Tanzania is characterized by smallholder farmers, lack of information provides middlemen the opportunity to set prices for farmers [23], blocking the market's bargaining power. Also, transporters on their business face a similar challenge of middlemen while linking with buyers. In particular, tracing what, when, why, where, how, and who has transported agro-goods is a severe challenge [11]. Smallholder farmers have to wait for a long time for the transporters to collect small agro-goods from other sources to meet truckload requirements. Hence, delivery time becomes uncertain, and transport charges are becoming higher due to a lack of information sourcing. Besides, data on transport and agro-goods that eventually illustrate the actual demand for goods is inadequate.

III. RELATED WORKS

A. Mobile Phone Usage in Agriculture Supply Chain

In developing countries, mobile phones have contributed to agriculture and rural development by providing access to information, knowledge, services, and market [24], [25], [26]. The mobile phone penetration has further streamlined agro-goods supply and demand. It reduces post-harvest loss through real-time information exchange between agriculture stakeholders, makes delivery more efficient, and forces closer links between farmers and consumers. In Malaysia, the study

by [7] proposed five linking participants and their roles engaging in the physical flow of the pepper agri-food supply chain. At each stage connecting the participants, the third-party logistics (3PL) provider ensures an exchange of agri-food information. Tanzania largely depends on the movement of agricultural goods from rural to urban and involves several stakeholders or Actors. A study by [27] presented a typical chain from Producer, Collection Distribution, Marketing, and Consumption as modified in Fig. 1. A clear description of the Transport Service Client (appear as Transport user) and Transport Service Provider is found in the paper [28]. In the process of developing a framework for accessing market information for farmers, the recommendation for improving ICT connectivity, electrifying rural areas, and increasing awareness of ICT issues were provided [27]. The author posits that minimizing communication costs will motivate rural farmers to purchase mobile phones as an effective tool for accessing marketing information. A survey performed in the Iringa region –Tanzania revealed that mobile phones are not strongly impacting the yields; the agriculture stakeholders positively perceive mobile phone use in agricultural tasks such as accessing information about fertilizer transportation [9]. Hence, call for policy intervention on promoting the use of the mobile phone. While mobile phones, especially smartphones, have become more popular and affordable among agriculture stakeholders in Tanzania [10], [19], their ability to access and disseminate information has positively impacted efficiency, reduced transaction costs, and increased income among ASC stakeholders.

B. Mobile Phone and Freight Intelligent Transport System

Before digging further, it is an excellent reminder to note that agricultural goods (Agro-goods) are agricultural yields for commercial purposes whose source details have come from the farmer and can be perishable or non-perishable. Transportation of perishable goods differs from non-perishable in handling during transport and monitoring parameters such as temperature and humidity, and delivery time. In such a situation, accessing real-time information impacts the value of agro-goods in transport. Mobile phones, especially smartphones, have been the best approach because they provide multiple functionalities using installed sensors to deliver the required information while also interacting with users using mobile applications.

Fig. 1. Information Sharing between TSC and TSP in the Agro-goods Supply Chain (Modified from [7], [27]).

The argument is also supported by [29], posit that smartphone sensors such as Magnetometer, GPS, and accelerometer are critical in developing mobile applications in the Intelligent Transport System environment to capture the compass, location, and speed. Previous studies have complemented GPS-based traffic information exchange between vehicles and infrastructure specifically for road transport performance using GPS and other Intelligent Transport System sensors. In [30], a study demonstrated using GPS data collected from freight trucks for dynamic route planning and visualization using various traffic information such as travel time, route planning, and other congestion indices from the FITS-based application. The vehicle identification, location, and timestamp of record were captured. The study used the floating phone to observe long path trips. A web was developed to fit in more complex logistic business applications and scientific research usage.

In [31], a study identified low information utilization and flow, lack of timely and effective feedback of data, long time, low efficiency, high cost, inadequate security monitoring, and difficulties to meet product quality, food safety, and the market needs are the main challenges to the agricultural goods cold chain transport. The approach to employing an Intelligent Transport System based solution is proposed. The solution combines consumer and driver in the transportation of agricultural goods by designing a mobile phone-based system integrated with RFID and GPS for real-time information sharing to monitor the flow of perishable agricultural products. The author also designed an alarm for temperature and humidity during transportation as key quality variables for perishable agro-goods. A mobile payment Module to facilitate electronic commerce was developed using a two-dimension code to scan the code to transfer payment on goods delivery. With such an approach, tracing the reverse logistics chain is possible as all vendors are captured through the system during the forward chain.

Chapter six of the book [32], contributed by Charalambos A. Marentakis, provides a detailed view of telematics for transportation and agri-food product distribution. In the study, the author gives an ICT tool to offer monitoring and interaction capabilities between vehicle drivers and freight stakeholders from planning to monitoring and reporting need to ensure just-in-time (JIT) delivery, quality preservation, and efficiency. The author posits that the requirements for freight transportation vary depending on the nature of the operation. The author further added that e-commerce, e-business, and enterprise resource planning (ERP) directly influence the transport of agri-food in terms of performance and ability to handle large amounts of data generated through position sensing such as GPS and other sophisticated Information Systems applied in the transportation of agri-food. The author identified some of the requirements such as vehicle location, state of transported goods, including its temperature and humidity, time of arrival and time of departure for loading and unloading points, distance driven, length of the personal break, refueling stations, freight weight, transportation costs as well as vehicle, driver and trailer information. Advanced portable devices such as mobile phones provide features and functionalities for instant data capturing, such as barcode scanning, SMS, proof-of-

delivery, and reconciliation. Also, their ubiquities offer movable information-sharing services among participating stakeholders. The author proposed architecture for telematics applications integrating stakeholders, freight with their particular requirements, position sensing, tachograph operation (speed, stop, and idle), and shared transportation information portal. The author introduces Shipper, Customers, Recipients, Forwarders, Carrier, Vehicle Owners, and Fleet Owners as the users and stakeholders of the system.

A national large and medium agricultural-fresh products management system to monitor the transport of agricultural products considering the number, type, environmental-related temperature and humidity, vehicle speed, routes, locations, and driver information parameters was successfully designed, developed, and tested [33]. The main objective is to minimize the damages of agricultural products caused by transportation flowing from the original point to the destination/sales points/wholesale markets. The system comprises four subsystems focusing on testing environmental-related variables, mainly the temperature and humidity of agriculture products, collecting speed and line of the vehicle, wireless data transmission, and data control center. The study uses GPS for positioning services, GPRS, and the Internet for communication between the vehicle on-board unit (OBU) and the control center. ZigBee wireless network technology was applied for receiving temperature and humidity and communicates to the control center. Although the system met the requirements, the system required enhancement of planning functionalities, optimization functionalities, and emergence assistance services.

C. Existing Freight based Intelligent Transport System Frameworks

While looking for the possibility of the plan and manage co-model freight transport without a centralized system, [28] hypothesize that all transport services providers can publish their information on the Internet in a standardized format. The aim is to allow efficient sharing of accurate information between transport service providers and transport users. To achieve that, the authors argue on the efficient integration of all transport services and users in the transport chain and the lower cost of new connections and accessing the Internet. The ARKTRANS (Norwegian framework architecture for multimodal ITS) methodology to introduce abstraction levels ranging from transport policy, overall concept, logical aspect, and communication aspect together with Rapid Unified Process (RUP) were used. The RUP is used for an architecture-based iterative software development process. The four stakeholders identified were Transport Service Provider, Transport user, Road Network Manager, and Transport Regulator. The identified attributes were based on cost, status, from-to addresses, cargo details, and the reference document to show the Transport User and Transport Service Provider agreement.

In [34], freight brokering system architecture integrates web services and agents combining freight owners and transport services providers using web services integration gateway (WSIG) in JADE, two-layered architecture WS2 JADE RESTful web services were proposed. Users can register and post their products and offers in the public directory

through the virtual platform process. Potential customers can then browse, search and manually inspect the posted products that suit their needs. The available information contains real-time information on transportation and goods. Through employed intelligent services, the system included the provision of transport needs such as optimal transport routes focusing on requirements of the customers and the availability of free transport. The system can also negotiate with transport providers and customers to efficiently choose among the many delivery segments. Each element is covered, and no vehicles travel without cargo on the schedule. The study proposed the Customers, Transporters, and Brokers. Also include Payment, Statistics, and Email-notification service providers.

Also, a step-by-step approach to ITS system architecture for developing countries from scratch while considering limited resources in the countries established in [34]. The author emphasized adopting a framework from developed countries where affordability, compatibility and integration, geopolitics, and technical capabilities are the main identified criteria for building the ITS framework. It is proposed that the list of ITS user services be derived from existing services from developed countries; however, user services may differ in every country depending on the user's needs. Therefore, for countries like Tanzania, broad coverage of mobile networks and the massive availability of users amplify the effort toward implementing such services. The author further proposed to create a common data model, establishing the communication standard, using available communication technologies, and promoting standardization.

IV. METHODOLOGY

The road to the described above is complex and requires extensive multidisciplinary knowledge. Therefore, different documented approaches presented by [4], [35]– [40] were reviewed to establish an appropriate method for the desired framework. As a result, this study adopted Design Science Research. The selection of the Design Science Research Model (DSRM) [40], as inspired by [41], is based on its appreciation to produce new knowledge and seeking for innovations in solving problems. The six steps identified in DSRM are 1) problem identification and motivation, 2) defining the solution's objective, 3) creating the artifact, 4) demonstration, 5) evaluation, and 6) communication.

STEP1: The study used an observation approach, domain knowledge acquired, challenges identified from the case study, the need to use Intelligent Transport System in ASC, and literature reviews. Detailed information is available in sections I, II, and III.

STEP2: Through literature review, different solutions were proposed. For the case study presented in this paper, the objective is to develop a new framework using the mobile phone as a multifunctional tool for developing and managing stakeholders' information sharing systems. Also, the FREIGHTWISE Reference model [39] was extended to identify and analyze the stakeholders based on the roles and type of exchanged information while interacting in the ASC in developing countries. Sections II, III, and V describe more details.

STEP3: The artifact was developed as the main artifact of this study to foster innovation in the new products. The artifact, in this case, means the solution for the challenges, as detailed in Section V.

STEP4: The proposed framework was demonstrated using a scenario context mapping the existing potato agro-goods supply chain from Njombe rural, as the producers of potato, and Dar es Salaam, as main buyers. Section VI provides a detailed demonstration. A descriptive approach using case and scenario was used to illustrate the proposed framework [42], [41].

STEP5: The proposed framework evaluated in section VII. A total 12 experts used to provide opinion based on constructed framework (the artifact) based on challenges presented in the case study. The aim is to gain views on how it addresses the challenges.

STEP6: This paper is communicated to the audience the output of the study.

V. MAGITS FRAMEWORK

A proposed framework, MAGITS, is presented in this section. The MAGITS is abbreviated from a Mobile-based Agro-goods Intelligent Transport System. The framework integrates M-commerce, M-payment, and Intelligent Transport System. The following are primary objectives of the framework:

- 1) To address the existing gap of information sharing among stakeholders,
- 2) To simplifying the current complexity in the transportation of agricultural goods, consider differences in stakeholders' requirements in rural as well as urban transit,
- 3) To reduce the highly technological infrastructure demands through efficient utilization of mobile phones and additional functionalities such as GPS to share information among stakeholders.
- 4) To reduce the transport and intermediaries costs associated with routing through sharing of agro-goods information and easily deployable, readily available,
- 5) To achieve common language and standard information exchange patterns.

The MAGITS framework extends the Freightwise Framework (FWF) components [43]. The MAGITS framework, shown in Fig. 2, has seven components. These components are Main Services, Computing Center, Enabling factors, key performance goals (KPG), Mobile Operations, Operating environment, Stakeholders and their roles, and Information view. The enabling factors comprise the ITS Infrastructure, Policy, Management, Operating environment, Finance, communication viewpoints, and External services. In addition to the stated objectives, the MAGITS framework also uses mobile phone technologies to address the limitation of an on-board support, which was not part of the FWF Reference Model as stipulated in [28], [44], [43].

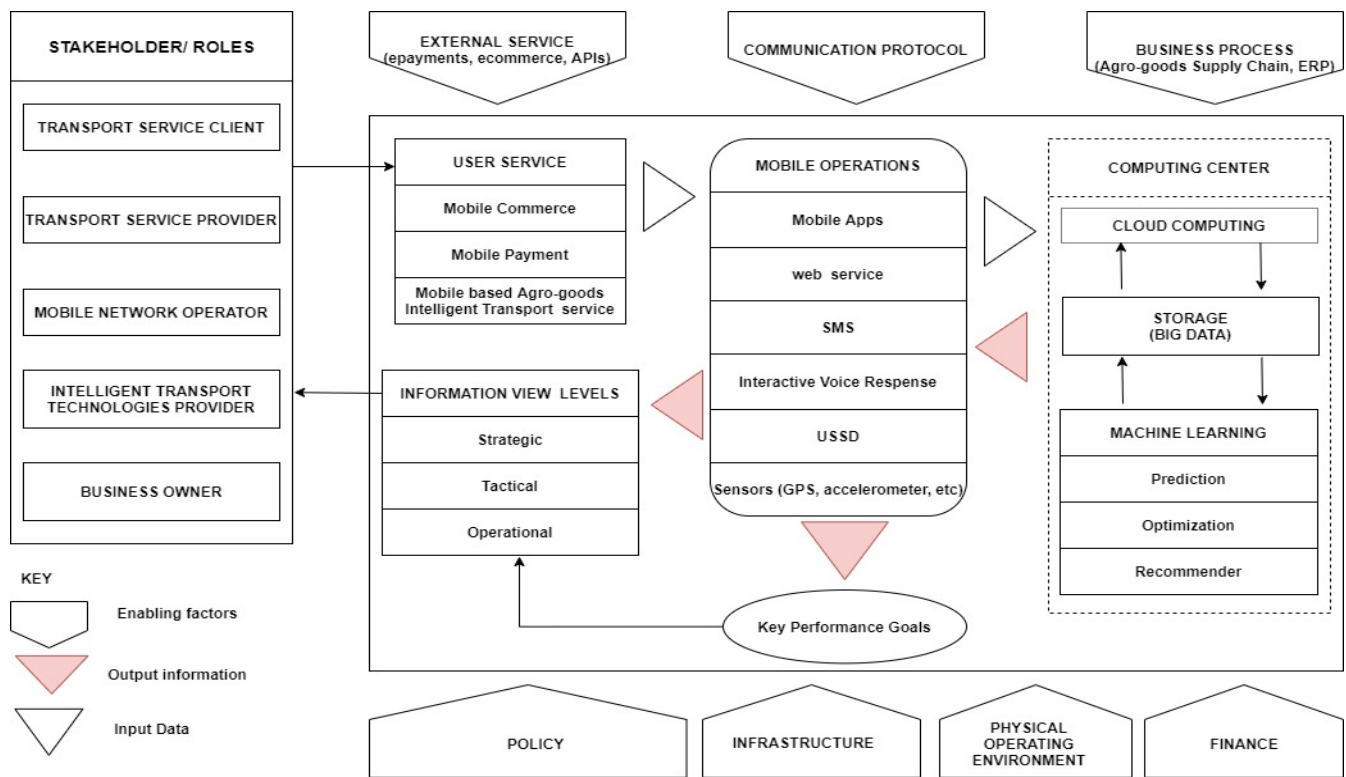

Fig. 2. A View of a Proposed MAGITS Framework.

A. Core Components of the Framework

1) *User services*: The core of the MAGITS framework is the services the stakeholders benefit from accessing and using the Systems developed under the framework. The MAGITS integrates three primary services, Mobile Commerce (M-Commerce), Mobile payment (M-Payment), and Mobile-based Agro-goods Transport Service, as central functions of the system. These services will use an auction-based approach to ensure fairness in the business operation. Based on [46], Researchers propose a most applicable first-price sealed bid as it creates privacy among competing bidders. The services are described in Table 1.

TABLE I. USER SERVICES

No	User Service	Description of service as per framework
1	M-commerce	Sell and buy agro-goods and services using mobile devices such as mobile phone or tablets
2	M-payment	Electronic money transaction for sell and buy of agro-goods or services using mobile devices
3	M-intelligent transport	Using mobile phone to hire and provide intelligent transport services for moving agro-goods between stakeholders in the Agriculture supply chain

2) *Computing center*: This framework component is responsible for capturing, analyzing, processing, storing, and sharing processed information between stakeholders. It ensures the security of information using technologies such as blockchain. The machine learning technology for optimizing and predicting services, big data, and cloud computing technologies provides the environment for accessing and using the platform as a service by reducing the high cost of procuring and maintaining the MAGITS hosting equipment. It also provides a secure mechanism for electronic data interchange (EDI) with external services components using Application Programmer Interface (API) and other decided tunneling approaches.

3) *Mobile operations*: Mobile phones, especially Smartphones, offer important integrated features such as GPS for location identification and WiFi and Bluetooth for wireless communication. These features are critical to ITS services due to the ubiquitous nature of mobile phones and enable stakeholders to access ITS services. For instance, the ITS-enabled sensors installed as the Onboard Unit (OBU) in vehicles wirelessly communicate with mobile phones to share information such as speed, fuel consumption data, mileage, and instant location information. The integration of such information from different ITS components resulting in improving timely delivery, accurate information about clients and providers of transport services, demand and supply optimization, prediction of loss and profit from transport business, tracking and tracing of cargo and vehicles, information of agro-goods to be delivered to the destination,

and transportation costs. Mobile phone-based information systems hosted in computer centers are accessed online through Unstructured Supplementary Service Data (USSD), web, Interactive Voice Response (IVR), and mobile apps to provide a unique environment to support such information lifecycle.

4) *Stakeholders and their roles*: These are institutional entities or persons responsible for operating, managing, using, or maintaining one or more framework services. Each stakeholder in the framework has a role to perform. Some stakeholders have more than one role. For example, a Customer can possess the role of TSC when in need of a transport service to deliver agro-goods to the destination. Table 2 describes the roles of each stakeholder, information to supply and lead to a demand from other stakeholders.

5) *Information view*: Focusing on stakeholders' needs for the MAGITS, the three categories of information flows are Electronic document information flow, payment information flow, and agro-goods information flow. The information flows between partners participating in the services and their processes. Understanding the information flow is critically important in completing the movement of goods from F to C, as defined in Table 2. Through the integration of information flow, the business processes and the depiction of the main objective of the design of any system are realized. It is the responsibility of stakeholders to feed timely and accurate information to the system to achieve actual results and efficient management and as part of sustainability strategy. The framework identified three levels of information: operational, tactical, and strategic. These levels of information assist stakeholders in deciding for their business.

TABLE II. STAKEHOLDER-ROLES AND INFORMATION REQUIREMENTS

Stakeholder	Roles	Information supply parameters	Information demand parameters
Farmers (F) or Producers (P)	Agro-goods producers, sellers, and supply chain initiators	Product Information(Farm-gate Selling Price, Location data, Time of harvest, etc	TSP, TSC, MNO, C
Customer (C)	The purchaser of agro-goods and requires goods to be transported to the desired location	Product information such as quantity in demand, type, delivery location, expected delivery time, Purchasing price, business permits, payment method, etc	F, MNO, RNM, TR, TSC and TSP
Transport Service Client (TSC)	Requires transport service from TSP to move agro-goods from F to C as shown in Fig. 1	Customer's information, product information such as location, quantity, type, payment method and expected delivery time, etc	F, MNO, RNM, TR, TSC and TSP
Transport Service provider (TSP)	Owner of commercial vehicle purpose(Individual/Company) and lease transport service to TSC or direct to C delivery of goods from F to C based on agreed terms	Carriage information such as type, quantity, and transport licensing. Also, vehicle location, current loading information such as FTL or LTL, routing information nearest to the loading point	ITTP, RNM, TR, TSC, MNO, P and C
Road Network Managers (RNM)	Plan, manage and maintain the road network	Route information, road toll charge, and payment models	ITTP, TSC, TSP, P, and C
Transport Regulators (TR)	Road rules enforcement and regulations checker	Law parameters, road charges, and payment approaches	ITTP, RNM, TSC, TSP, P and C
Mobile Network Operators (MNO)	Mobile network provision and mobile-based payment services	Internet charges, connection, and payment approaches	ITTP, RNM, TR, TSC, TSP, P and C
Intelligent Transport Technology Providers (ITTP)	Intelligent Transport System technology and service providers	Location (GPS), weather and communication, Application Programmer Interface (API), OBU, RSUs, etc	MNO, RNM, TR, TSP
Business Owner/System owner	A framework manager. A person or entity who legally owns the system. Responsible for setting the environment for other stakeholders to interact. Responsible for day to day internal management of a system	All information	All information

6) *Key performance goals*: The Key Performance Goals (KPGs) are the overall outputs of the framework. These KPGs directly affect the sustainability of the framework. The key goals of this framework are improving efficiency, increasing safety, reducing carbon emission, and introducing intelligence in agro-goods transport through the collection, store, model (prediction and optimization), and analyzing operational transportation data to improve future transportation investment planning. The lower the KPG rating, the shorter lifetime of a framework. Likewise, the higher the KPG ratings, the longer the sustainability of the framework. The KPGs are achieved due to stakeholder's satisfaction level with the system and services. Performance Indicators (KPIs) are applied to the MAGITS framework to measure its performance, including but not limited to a percentage of uptime of e-commerce per time, percentage of detected overloaded vehicles, average delivery time per trip, number of the shortest routes compared to available routes, rate of carbon emission, improved transport safety, number/amount of electronic toll collection and e-payments per vehicles/time, average transport cost or profit per trip, average loading/unloading time of agro-goods, number of pickup and delivery points per same truck, average available time of tracking and tracing services per vehicle, number of prediction modeling services, number of goods delivered/loss during transportation, and average available time of information among stakeholders.

7) *Enabling factors*

a) *Policy and Governance*: Policies dictate the direction of the business. Therefore, policies in place must harness the integration of Intelligent Transport System with e-commerce and e-payment services to promote the development and deployment of the framework. The policies include how data will be shared between participating stakeholders at lower cost and timely, enabling the usage of services to impact the individual and national economies, strengthening sharing of business information by reducing unnecessary barriers from competing rivals. In addition, the presence of policy support validates the business. It assures participants of recognizing data generated from the system, i.e., electronic payments, contracts, and other e-documents, as legal evidence for business contracts.

b) *Communication Viewpoint*: The two communication types, namely short-range and long-range communication, are identified for this framework, as studied by [47]. The short-range communication protocol, commonly known as a Dedicated Short-Range Communication (DSRC) by IEEE, is a highly reliable, fast network acquisition, high interoperability, and low latency. They are, therefore, suitable to be applied for vehicular data exchange between the Vehicle-to-Infrastructure (V2I), especially roadside units (RSUs) and antennas, Vehicle-to-Vehicle (V2V), and Vehicle's OBUs to loaded cargo using wireless technologies such as ZigBee.

The long-range communication protocol is Cellular-Vehicle-to-Everything (C-V2X) PC5 technology, the cellular-based communication protocol. The detailed study by [48] pointed out two applicable communication protocols for ITS

are 802.11p-based, which contain ITS-G5. The 5G technology offers adaptive application-focused, increased speed, reduced latency (i.e., from 20 milliseconds to approximately one millisecond), and more service-oriented with 99.999 percent reliability. Still, many developing countries such as Tanzania still require more time to overtake the dominance of 3G and 4G in cellular long-range communication technologies.

c) *Business Processes*: The primary business processes are planning, execution and completion. For instance, in FREIGHTWISE[28][43], the planning phase is complete when the Transport Execution plan(TEP) is marked ready for execution. When proof of delivery has been issued, the execution phase is completed. In most cases, the business processes are integrated into the operating business's ERP. The Oasis Universal Business Language (UBL) – 2.3 [49]and ISO TC204 work groups[50] have established the standard documents that facilitate the development of systems related to freight transportation. It is easier for system developers to adopt such agreed design documents as baseline designs to conform to such recognized international standards. The UBL uses the XML standard for exchanging business data.

d) *Finance*: In-depth consideration of the investment cost, revenues, and expenditure must be made during the system's design, deployment, and operationalization. The factors such as payback period, minimizing expenses while increasing revenue, service charges such as internet-service-subscription charges, cost of equipment, labor charges, etc., are essential at every stage of the system lifecycle.

e) *Infrastructure*: In this context, infrastructure contains all physical assets that support the transportation of agro-goods to the consumer. These include roads, OBU, RSU, cameras, sensors, vehicles, agro-goods, Mobile phones, weighbridges, and road toll gates.

f) *Physical Operating environment*: The quality of products and services depends on the operating environment. It involves handling mechanisms in handling agro-goods physical flow to preserve expected quality. The forward physical flow of goods channels from Farmer as Producer/Seller to Collection Center Manager, Distribution Center Manager, and Consumer. Transport Service Provider is involved at each stage to pick up and deliver agro-goods successfully. Each stakeholder in the chain is responsible for preserving the quality of the product and feeding the system with accurate data such as GPS locations to meet the other stakeholders' expectations.

B. *High-Level Layered MAGITS Framework Architecture*

All information will be accessed centrally from the Computing Center using a client-server architecture. The idea is to achieve controlled data flow and reduce the data storage size in the stakeholders' smartphones or tablets and allow coordinated and controlled integration of information whenever needed by stakeholders' or other systems. The general concept of the MAGITS framework considers the use of micro-service architecture using a lightweight approach like application programming interface (API) to communicate different designed services in solving the management of information as the goods move from one point to another. The

advantages of using microservice architecture over typical monolithic architecture. The designed architecture has proven scalable, adaptable, and easy to maintain in the microservice approach, as shown in Fig. 3.

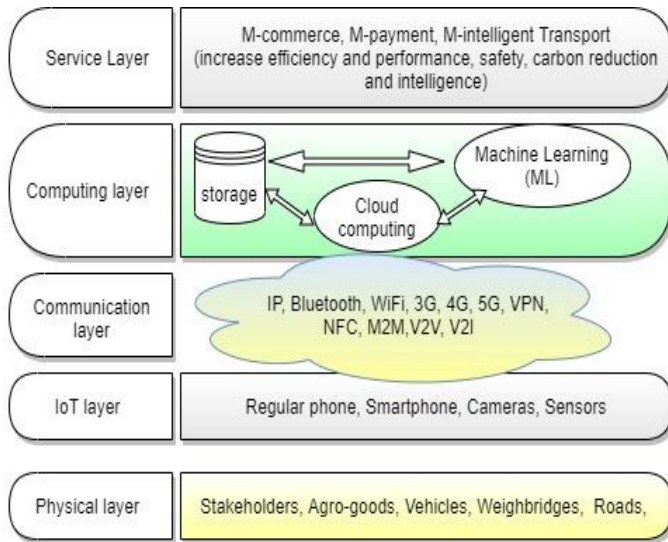

Fig. 3. High-Level Layered MAGITS Framework Architecture have been Defined by [45].

VI. ILLUSTRATION OF THE FRAMEWORK

As described in the methodology, this section illustrates the proposed framework using a descriptive scenario by combining the sales, purchases, payments, and transportations of potatoes in Tanzania. The Transport Service Clients (TSC) and Transport Service Providers (TSP) were selected for this evaluation phase. Fig. 4 illustrates the applicability of the framework. In the process, all stakeholders interact with each other using mobile phone services.

The mobile phone with GPS and mobile app services, such as Android and IOS, qualifies to be installed as vehicle OBU specifically for location serves as an input to the system. Each stakeholder will register in the system. Except for TSP whose locations are changing during transportation, all other stakeholders will register their GPS location. It is crucial in calculating the distance as the parameter for the vehicles. The majority of farmers are smallholders who can afford regular phones. The straightforward approach is for the collection center to register all the farmers located near their collection center using a Smartphone to capture the GPS coordinates of farms and other important information for later use. The essential criteria are that Collection Centers and Distribution Centers must directly connect to the main road to access all transporters. The framework also allows mobile phone information sharing from geographically dispersed smallholder farmers to aggregate potato agro-goods to meet the full truckload (FTL) concept.

The approach is essential for cost-sharing, providing access to markets, and increasing farmers' bargaining power in the markets. From Fig. 4, farmers as an initiator of the chain, feed information including quantity and price about potatoes using the mobile phone.

Fig. 4. Information Sharing Scenario of Potato Mobile-based Agro-goods Intelligent Transport System.

Since the location information was previously captured, the Collection Center will automatically receive notifications about farmers ready to sell using the mobile phone. The Collection Center Manager will confirm the request and advertise to French fryers (Fried Irish potato chips sellers) and other buyers. All buyers will confirm the order through a mobile payment system, where the system will send feedback to the collection center and farmer. The system will automatically publish the successful order to transporters showing parameters such as quantity, pickup location, and delivery location. For a specifically given time interval, each transporter will make a sealed bid for the service by manually filling the cost and expected delivery time.

The system will evaluate submitted offers and send a notification to the buyer to confirm the payment. Using the same payment system for paying transport costs, all parties will receive confirmation about the confirmation of the order. At each payment stage, the system will hold the amount until the buyer confirms the receipt of the potatoes consignment. The system keeps the amount on each payment while generating a secret code and sending it to the buyer's phone. The code will be entered into the mobile phone upon receipt of the order.

The application of Machine Learning (ML) in the proposed framework adds unique achievement to MAGITS. The applications of ML, namely optimization, prediction, and rating, are identified. For instance, each time stakeholders use the system will provide feedback about the service. The combination of rating, questions, comments, demographics, technographic, behavior, and geographic features will be processed using ML recommender modeling techniques to create patterns for decision-making purposes. These patterns aim to improve the system's services, logic, and decision-making. The model, using ML, will use GPS coordinates from smallholder farmers and the location of the nearest road; it is possible to optimize the nearest collection center accessible to the road and share transport to the buyer or markets. The

massive data generated from the use of the framework plays a critical role in predicting the demand and supply of potatoes in Tanzania.

VII. EVALUATION OF THE FRAMEWORK

A total of 12 experts were interviewed to provide expert opinions on the proposed framework, as shown in Table 3. One challenge encountered was the possibility of identifying an interviewee with all the required skills to evaluate the method.

All interviewees were given the paper using the walkthrough approach and establish views on the acceptability of the framework using the challenges as identified in Table 4. The comments were then discussed through a convened online meeting to agree or disagree with the proposed framework. From the discussion, all experts agree on the proposed framework approach to solve the identified challenges and suggest the need for developing web and mobile applications to integrate the proposed service for higher impact to the community, especially marginalized smallholder farmers. Experts also commended the simplicity of the ASC process using a system developed from the framework and suggested more research on the users' acceptability approach. Finally, the experts comment that many more researchers will benchmark this study.

All experts concluded that the framework works best in the presence of smartphones than regular phones.

TABLE III. EXPERTS BACKGROUND

Expert	Area of expertise	Experience in the industry (in years)
1	Agriculture	25
2	Electronic Business	13
3	Information Communication Technology	18
4	Information Communication Technology	12
5	Agri-business	18
6	Agricultural products Transportation	30
7	Information Communication Technology	16
8	Freight Intelligent Transport Systems	4
9	Agri-business	22
10	Smart Cities	5
11	Agriculture Extension Services	16
12	Internet Service Provision	20

TABLE IV. EVALUATE CHALLENGES

Challenge	How framework addresses the challenge?
Stakeholders' involvement	The framework considered all participants involved in the sales, purchase, and transportation of agro-goods.
Context-awareness coverage	Since agro-goods are produced in rural areas then transported to urban areas, the framework has incorporated the environment. The framework has also considered minimum enabling factors required during the design, deployment, and operations.
Resources scarcity	The additional use of mobile phone sensors acting as OBU and Point of Sales (PoS) minimizes the demands for deploying many devices where each performs a single task
Real-time information sharing capability	It is possible for stakeholders accessing and sharing sales, purchases, and payment information in real-time through installed mobile phones. Tracking and tracing of agro-goods loaded vehicles anywhere at any time.
Service demands	The Machine Learning integration in this framework is essential for travel route optimization, sharing of transport and transport cost for smallholder farmers, predicting agro-goods demand, and supply factoring location and time. The framework achieves the KPG indicated in this paper.

VIII. CONCLUSION AND FUTURE WORK

This study provides a unique guide for ASC practitioners linking technology to agro-goods business. It addresses the need for both Information Systems developers during the designers, government authorities in deliver service while seeking income generation, and business managers during investments and operations using limited resources. It also serves as a benchmark for further researchers focusing on developing new products supporting communities based on e-commerce and transportation using mobile phones to monitor and manage the supply chain.

The developed framework for integrating ITS in agro-goods e-commerce in developing countries is inevitable due to the high dependence on agriculture for economic and social survival. The requirements for the framework differ from one place to another, but the proposed framework unifies the high-level needs for successful and sustainable systems. A framework enables the design, implementation, deployment, and ITS in the Agriculture Supply chain in many developing countries from limited available infrastructure, especially mobile phones. For instance, it is possible to obtain traffic and weather information about particular route agro-goods transportation using data collected from other mobile phones located on in-transit vehicles using mobile phone sensors. On the TSP side, there are information limitation challenges that may arise when using the mobile phone as an OBU sensor, such as fuel consumption and break information will not be captured. Nevertheless, some recent vehicle OBU can transmit such data to mobile phones wirelessly using short-range communication such as Bluetooth and WiFi. Further research is required to use mobile phones when installed as OBU, such as power consumption, availability due to changes in environment, and durability.

In terms of Internet service, there is a need for harmonization between different MNOs (defined in Table 2). Therefore, the study establishes a service-focused internet subscription to achieve maximum service availability despite the vehicle in transit changes MNOs. One limitation of the proposed framework is the inability to handle multi-products in the same truck; therefore, the study recommends investigating and suggesting an appropriate ML modeling approach for managing more than one product within a single truck based on type, size, and weight. There is no evidence of Tanzania's framework to researchers' best knowledge. Still, researchers believe that implementing the framework will solve transport challenges of limited-resource many e-commerce platforms globally. This framework also provides the foundation for further research in big data in the transportation of agro-goods in developing countries.

Abstract—This project involves research about software effort estimation using machine learning algorithms. Software cost and effort estimation are crucial parts of software project development. It determines the budget, time and resources needed to develop a software project. One of the well-established software project estimation models is Constructive Cost Model (COCOMO) which was developed in the 1980s. Even though such a model is being used, COCOMO has some weaknesses and software developers still facing the problem of lack of accuracy of the effort and cost estimation. Inaccuracy in the estimated effort will affect the schedule and cost of the whole project as well. The objective of this research is to use several algorithms of machine learning to estimate the effort of software project development. The best machine learning model is chosen to compare with the COCOMO.

Keywords—Software effort estimation; project estimation; constructive cost model; COCOMO; machine learning

I. INTRODUCTION

Problems are created for software professionals, their clients, and stakeholders from the impractical project strategy and budget overruns. Despite many studies and numerous attempts to learn from experience, the problem of inaccurate often happen and has not been solved yet [1]. Software cost, effort, and resources are estimated at the beginning of the development. That information will be used by developers and clients to estimate the budget and time needed to finish develop an application or a system. Techniques and models were invented to assist the developers in estimating budget and effort. However, the problem of inaccuracy in estimation still becomes one of the problems for the developers and stakeholders. Even the emergence of one of a well-established project estimation model in the 1980s, COCOMO model, does not solve the problem of inaccuracy in software project estimation. Therefore, in this research, machine learning algorithms are used to estimate the effort of a software project that is more accurate compared to the COCOMO model. COCOMO model datasets are used to build machine learning models.

Although the COCOMO model has many advantages, it has some weaknesses too. One of it is its estimation varies as time progress [2]. Furthermore, the COCOMO model works depends on historical project data which are not available at all times [3]. COCOMO model cannot be used to estimate in all Software Development Life Cycle phases [3]. A large amount of data required for the COCOMO model to work [4]. A user has to insert input of 15 effort multipliers in order to get output from the COCOMO model. Thus, it will consume a lot of time

for industry that has to estimate a large number of projects. COCOMO has difficulty in learn and identify data patterns [4] which is an important element in the regression model such as COCOMO.

Our main three objectives are to pre-process and analyze the COCOMO dataset. Second, is to apply several algorithms and to predict the output based on the COCOMO dataset and to evaluate the performances of the selected algorithms with the COCOMO method.

An application called SOFREST Estimator is developed to demonstrate how the estimation work and what are the inputs that needed to produce the outcome. The application will require user to insert five inputs about a project, which are number of Lines of Code (LOC), Database Size (DATA), Required Software Reliability (RELY), Execution Time Constraint (TIME) and Main Storage Constraint (STOR). The output of the application will be estimation of effort that needed for that particular project in person-months unit.

This project is significant because it concerns the accuracy in predicting the budget and time needed to develop a whole project. By doing the project cost and time estimation using machine learning, higher accuracy of cost and effort of a software project estimation will be produced since, in machine learning, we build a prediction model by train and test the dataset. By having machine learning as the project cost and effort estimator, money and time can be saved as it will need less human effort. This project will be useful for every software development company for them to estimate the cost and effort of a project. The best algorithm to be used in this project cost and time estimation can be determined based on the highest classification accuracy in machine learning.

II. RELATED WORK

A. Software Project Estimation

Project estimation is an essential part of completing a project. Projects are planned in terms of cost, effort, and budget at the beginning phase of development. Precise effort estimation of software development plays a main task to predict how much workforce should be prepared during the works of a software project so that it can be completed on time and with the budget that planned without ignoring the quality of a software [5]. Accuracy of development cost estimation is a key factor in the success of a construction project and influenced the decision-making by the stakeholders of a software project [6] and to bid a contract with them [7].

The capacity of a budget estimating model is determined by calculating its bias, stability, and precision. Measures of bias, stability, and precision are concerned with the difference in the average between the actual costs and the estimated costs, considering both the degree of variation around the average and the combination with bias and consistency. By far, the most popular evaluation criteria used involve statistics such as mean, standard deviation, and coefficient of variation [6].

Identifying and calculating software metrics are important for various reasons, including estimating programming execution, measuring the effectiveness of software processes, estimating required efforts for processes, reduction of defects during software development, and monitoring and controlling software project executions [8]. An example of the wrong cost estimation that happened recently was in estimating the budget of international arrivals facility that being built at Seattle-Tacoma International Airport in Seattle, Washington, USA. Initially, in 2013 the budget was estimated at US\$ 300 million but then the budget increased up to US\$ 968 million in September 2018 [9]. Research shows that usually projects seem to be unclear at the beginning and become less vague as they progress [10].

One of the software metrics that used to estimate the cost and effort is called lines of code (LOC) metric and is considered basic software metric [11] as it is used in most software project estimation techniques.

B. Project Estimation Techniques

It is hard to quickly and accurately predict the development budget at the planning stage because the documentation is generally incomplete. For this reason, various procedures have been created to accurately predict construction costs with the limited project data available in the early phase [6]. There are three known models that have been used to estimate the project effort, cost and resources which are the Constructive Cost Model (COCOMO), Analogy-based Model, Use Case Points model.

1) *COCOMO Model*: COCOMO (Constructive Cost Model) is a screen-oriented, interactive software package that assists in budgetary planning and schedule estimation of a software project [12]. The intermediate COCOMO model used 15 drivers to estimate the cost of a project. The drivers are classified into four attributes; Product attributes, Hardware attributes, Personnel attributes and Project attributes [7].

Table I shows the intermediate driver of the COCOMO model. Each driver has its own multipliers (refers to Table II) that divided into six categories which are Very low (VL), Low (L), Neutral (N), High (H), Very High (VH), Extra High (XH) [7].

2) *Analogy-based model*: The core of the Analogy-based model is to differentiate the projects that will be estimated with all the software project's former data. Dataset will be from the company itself or that available publicly. The comparison will be carried out to identify which former projects are similar to the current project that its cost and effort will be estimated. Similar projects will be chosen to be

reworked so that the estimated effort of the new project can be identified. Similarity measures, how near the distance between project, will be measured on each type of attribute and using three measurement methods; Euclidean, Manhattan and Minkowski distance [5].

3) *Use-case points model*: Use Case Points (UCP) is a notable size estimate designed mainly for object-oriented projects that use the use case diagram to estimate the size of projects at the beginning development phase. Other software sizing methods that depend on functional requirements, called Function Point, was what encouraged the idea of UCP [13].

TABLE I. INTERMEDIATE COCOMO DRIVERS

Category	Drivers
Product Attributes	Required Software Reliability (RELY)
	Database Size (DATA)
	Product Complexity (CPLX)
Hardware Attributes	Execution Time Constraint (TIME)
	Main Storage Constraint (STOR)
	Virtual Machine Volatility (VIRT)

C. Machine Learning

A computer becomes much more intelligent with their ability that can think by using Artificial Intelligence (AI). One of the subfields of AI is Machine Learning (ML). The computer intelligence is developed through various methods of learning. Thus, there are many types of Machine Learning which are Supervised Learning, Unsupervised Learning, Semi-Supervised Learning, Reinforcement, Evolutionary Learning and Deep Learning [14]. Machine Learning models are build based on learning the dataset using algorithms such as Regression Tree, Linear Regression, Neural Network, Naïve Bayes, Support Vector Machine, K-Nearest Neighbor, Random Forest, etc. The training and testing will be carried out to the dataset to build the ML models.

Previously, ML has offered self-driving cars, speech recognition, systematic web explores, and improved realization of the human generation. Today machine learning is available everywhere that one can possibly use it many times a day without knowing it. A lot of researchers consider it as an excellent way of moving towards human-level as machine learning are advanced to the extent that it can recognize speech like human [15].

Machine learning is a subfield of computer science. It allows machines such as computers to build analytical models of data and find hidden perceptions by learning the data itself. It has been applied to a variety of aspects in modern society, ranging from Deoxyribonucleic Acid sequences classification, credit card fraud detection, robot locomotion, to natural language processing. It can be used to solve many types of tasks such as classification and prediction. Software project estimation is one of the tasks that machine learning is capable of [16].

Machine Learning is important as it is always up to date with the current environment and the model keeps improving its performance itself by learning data or experience. Human efforts and mistakes can be reduced by using Machine Learning.

The traditional software effort performance criterion is not accurate and not satisfying. There were many metrics and a number of techniques in cost estimation have been proposed. Unfortunately, most of them have lacked one or both of two characteristics which are sound conceptual, theoretical bases and statistically significant experimental validation.

Most performance criterion metrics have been defined by an individual and then tested in a very limited environment [17]. So, there is a need design optimization algorithm for correct, precise and reliable effort estimation [18].

Data mining is about acquiring perception in the data in order to detect useful patterns that imply information. Data mining has a record of success in business and more recently in scientific applications. Data mining is usually carried out using process models and employs tens of techniques that span a wide spectrum of interdisciplinary fields including statistics, machine learning, and pattern recognition. The use of data mining in software project prediction has recently gained remarkable popularity inspired by a large amount of error in traditional estimation methods and the continuous

improvements of machine learning algorithms which could help to provide more accurate prediction [7].

Machine Learning has been used to predict the software project cost and effort estimation since late 1980 [6]. Measuring the performance of estimation of machine learning models is accomplished by calculating the metrics including Sum Squared Errors (SSE), Root Mean Square Error (RMSE), Mean Magnitude of Relative Error (MMRE), Mean Absolute Error (MAE), etc.

They are the well-known parameters that are used for the performance evaluation of methods [19]. The evaluation consists of comparing the accuracy of the estimated effort with the actual effort. There are many evaluation criteria for software effort estimation and among them, the most frequent one is the Magnitude of Relative Error (MRE) [20]. Linear regression and Multi-perceptron are the most popular machine algorithms for software development effort estimation [21].

In this research, four Machine Learning algorithms that are used are Random Forest (RF), Linear Regression (LR), Regression Tree (RT) and Support Vector Machine (SVM). Each model's performance was measured by the Mean Magnitude Relatives Error (MMRE). Among the four algorithms, the best one is chosen to build a Machine Learning model that can predict the cost and time of a software project.

D. Literature Analysis

This section contributes to the knowledge of previous studies on software project estimation by using the state-of-art machine learning techniques available. Alongside with the limitation mentioned in the subsection C, most of previous literature studies addressed to measure the project and cost estimation using a single machine learning algorithm which reveals numerous limitations of the particular algorithm. Besides, most previous related work have inadequately present an extensive comparison and evaluation towards their proposed solution. Therefore, this paper aims to extend the evaluation with any other similar machine learning algorithm with four different datasets to further investigate the performance of the most sophisticated algorithm compared to COCOMO model.

III. METHODOLOGY

This research uses an experiment as a methodology to develop the prediction model for software project cost and effort estimation using selected machine learning algorithms. The experiment procedure is illustrated in Fig. 1. There are four selected machine learning algorithms which are Support Vector Machine, Linear Regression, Regression Tree and Random Forest.

A. Data Collection

In this experiment, software project measurement datasets use for developing the prediction model using machine learning. All datasets can be accessed publicly from <http://promise.site.uottawa.ca/serepository/datasets-page.html> and a study conducted by Kaushik et al, 2012. Sources of the datasets are from COCOMO NASA 1, COCOMO NASA 2, COCOMO81 and Kaushik et al. Details of the datasets used in this experiment are tabulated in Table III.

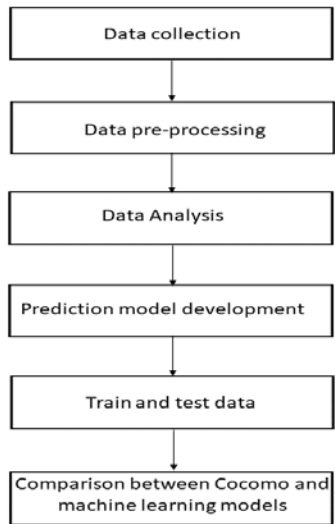

Fig. 1. Methodology.

TABLE III. DATASET USED IN THE EXPERIMENT

Dataset	Attributes	Number of projects
COCOMO NASA 1	17	60
COCOMO NASA 2	24	93
COCOMO81	15	63
Kaushik et al, 2012	16	15

B. Data Pre-processing

The data is pre-processed in order to calculate the effort estimation. In this experiment, the data is imported in r studio. Mice package is used to check the missing values, the datasets contain no missing values. The value of the drivers is in numerical weight converted to numerical values due to avoid bias during constructing the machine learning model. The mode constant is assigned based on the COCOMO predefined values.

C. Prediction Model Development

Four regression machine learning algorithms are used for this experiment.

1) *Linear regression model*: The linear regression model summarizes a relationship between two variables, independent and dependent variables. The practical use of linear regression in this experiment is to find the approximate prediction as a predictive model. The relationship of the prediction and the actuals data is then observed from the best fit line. The best fit line is where the total error prediction is as small as possible.

2) *Support vector machine*: Support vector machine model is a linear model for classification and regression problems. Linear and non-linear problems can be solved by support vector machine model. The aim of this model is to create a hyperplane and separate the data into classes. In support vector machine model, between the data points and the hyperplane we can find maximum margin to reduce misclassifications. Also, it can be used to solve unbalanced data problem.

3) *Regression tree algorithm*: Regression tree is a type of decision tree and it is a method that can create and visualize prediction models from the data. The output of this model is numeric output, and the average value is assigned to the leaves of tree. The decision making in regression tree is easier compared to other method because the undesired data will be filtered and reduces the work on the data as it goes deeper in the tree. The regression tree is used due its ability to reduce ambiguity in decision-making.

4) *Random forest algorithm*: Random Forest model is model made up of many decision trees that each tree depends random vectors values. This model called random because during building trees it uses random sampling for training data points and during splitting nodes it uses random subsets of features considered. Each tree in random forest learns from a random sample of the data points. The random forest is used due to it can produce high accurate classifier.

5) *Metrics*: Mean Squared Error (MSE), the mean squared error or mean squared deviation of an estimator measures the average of the squares of the errors that is, the average squared difference between the estimated values and what is estimated. The lower the value of MSE, the better accuracy.

$$MSE = \frac{1}{N} \sum |Effort_{estimated} - Effort_{actual}| \quad (1)$$

Root Means Squared Error (RMSE). It represents the sample standard deviation of the differences between predicted values and observed values (called residuals).

$$RMSE = \sqrt{\frac{\sum (Effort_{estimated} - Effort_{actual})^2}{N}} \quad (2)$$

Mean Absolute Error (MAE) is the average of the absolute difference between the predicted values and observed value. The MAE is a linear score which means that all the individual differences are weighted equally in the average.

$$MAE = \frac{1}{N} \sum \left| \frac{Effort_{estimated} - Effort_{actual}}{Effort_{actual}} \right| \quad (3)$$

Mean Absolute Percentage Error (MAPE) to measure prediction accuracy as percentage, or also known as the average absolute percent error for each predicted minus actual value and then divided by actuals values. The lower the lower of MAPE, the better the accuracy.

$$MAPE = \frac{100\%}{N} \sum \left| \frac{Effort_{estimated} - Effort_{actual}}{Effort_{actual}} \right| \quad (4)$$

The accuracy of the cost estimation models is evaluated by Magnitude of Relative Error (MRE) and the Mean Magnitude of Relative Error (MMRE). The optimum value of MRE and MMRE is closest to zero.

$$MRE = \left| \frac{Effort_{estimated} - Effort_{actual}}{Effort_{actual}} \right| \quad (5)$$

Mean Magnitude of Relative Error (MMRE) is the measure of predicted effort and actual effort value relative to the actual effort value.

$$MMRE = \frac{\sum_{i=1}^N \frac{|\text{Effort}_{\text{estimated}} - \text{Effort}_{\text{actual}}|}{\text{Effort}_{\text{actual}}}}{N} \quad (6)$$

Min-Max Accuracy is a good metric to see how much they are close that considers the average between the minimum and the maximum prediction. The higher the value of Min-max accuracy the better the accuracy.

Correlation Accuracy is the correlation between predicted and actuals used as an accuracy measure. The Pearson product-moment correlation coefficient is used to measure the strength of predicted and actuals value of the experiment. The predicted and actuals value has similar directional movements when the correlation accuracy is high.

P-Value also known as calculated probability is to determine the significance of the experiments results. The P-Value is lower than 0.05 shows strong prove against the null hypothesis, thus the null hypothesis is rejected. The smaller the P-Value, the stronger the evidence to reject the null hypothesis.

Null hypothesis of this project is, the population correlation coefficient is not significantly different from zero. There is no significant linear correlation between control and experimental values in the population.

Alternative hypothesis of this project is, the population correlation coefficient is significantly different from zero. There is a significant linear relationship between control and experimental values in the population [22].

Vargha and Delaney A (VDA) measure is one of the examples to measure effect size, differentiate between two samples of observations, control and experimental sample. The range of VDA is from 0 to 1. VDA is calculated there is no effect result in a value of 0.50 [23]. Interpretation of A measure:

- A value around 0.56 = small effect;
- A value around 0.64 = medium effect;
- A value around 0.71 = big effect;

Wilcoxon Rank Sum Test is nonparametric test is used to compare two related samples on a single sample to see if their population ranks differ. The null hypothesis is difference between the two samples has equal medians. The alternative hypothesis is there is no difference between the two samples. If the p-value is larger than 0.05, we must accept the null hypothesis because there is enough evidence to conclude. The null hypothesis is rejected, there is sufficient evidence to conclude the sample has no identical distributions [24].

D. Data Training and Testing

Training dataset are 80% and testing dataset are 20% for COCOMO81, COCOMO NASA 1. Training dataset are 70% and testing dataset are 30% for COCOMO NASA 2, and Kaushik et al.

IV. DATA ANALYSIS

In this project, correlation matrix uses to evaluate the correlation of the two variables. The dependent variable is actual effort attribute, while the 15 cost drivers and the line code are independent variable. From Fig. 2, 3, and 4, there are

five attributes that high positive correlation towards actual effort attribute, LOC, DATA, TIME, TOOL and STOR for COCOMO81, COCOMO NASA 1, COCOMO NASA 2. While, other attributes show negative correlations towards actual effort attribute.

Then, the project builds predictive machine learning models with COCOMO81, COCOMO NASA 1, COCOMO NASA 2 and Kaushik et al datasets, using all attributes. The predictive machine learning models are Support Vector Machine, Linear Regression, Regression Tree and Random forest. The result record is in the Table IV. The project evaluates the result and records in a table.

Fig. 2. Correlation of COCOMO81 Attributes.

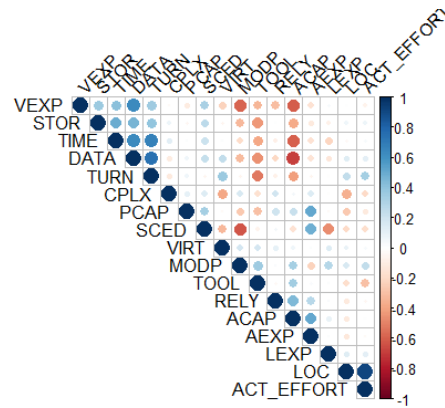

Fig. 3. Correlation of COCOMO NASA 1 Attributes.

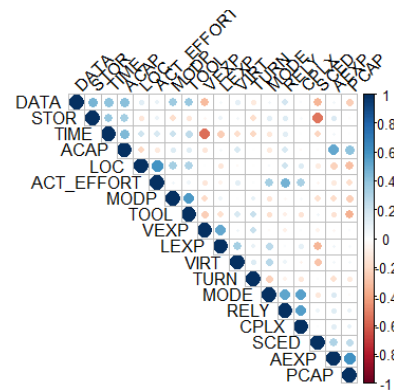

Fig. 4. Correlation of COCOMO NASA 2 Attributes.

TABLE IV. COMPARISON OF MACHINE LEARNING MODELS WITH COCOMO81 DATASET

Algorithm	Support Vector Machine	Linear Regression	Regression Tree	Random Forest
MAE	1002.844	1006.062	943.3075	928.3318
MSE	7675315	6939266	5193249	5769025
MAPE	4.721069	5.151246	4.803107	7.575327
RMSE	2770.436	2634.249	2278.87	2401.880
Min Max Accuracy	0.2742493	0.2647441	0.2758899	0.2895891
Correlation Accuracy	0.8218062	0.5933549	0.7427998	0.8671952
P-value	0.00568	0.03254	0.003628	0.001236
Significant Value	Significant	Not significant	Significant	Significant

Table IV explains the experiment is made on COCOMO81 with training dataset of 80 percent and the testing dataset is 20 percent. Based on the Table IV, Support Vector Machine, Regression Tree and Random Forest are significant due to the p-value which is less than 0.005 except Linear Regression model which p-value is 0.03254.

Table V explains the experiment that made on COCOMO NASA 1 with training dataset of 80 percent and the testing dataset is 20 percent. Based on the Table V, Support Vector Machine, Linear Regression, Random Forest are significant due to the p-value which is less than 0.005. The best MAE value among the four models is Support Vector Machine model which is the lowest, 31.5403163. The second-best MAE goes to Random Forest model with 36.8215429, followed up by Regression Tree with MAE 44.7018519. The worst MAE which has the highest value goes to Linear Regression with 47.7723733.

For the experiment that is made on COCOMO NASA 2 with training dataset of 80 percent and the testing dataset is 20 percent. Based on the Table VI, Support Vector Machine, Linear Regression, Random Forest and Regression Tree models are significant due to the p-value which is less than 0.005.

The experiment is made on Kaushik et al with training dataset of 70 percent and the testing dataset is 30 percent. Based on the Table VII, Support Vector Machine, Linear Regression, Random Forest are significant due to sufficient evidence to reject null hypothesis as the p-value which is less than 0.005; except Regression Tree model which p-value is 0.18 higher than 0.005, fail to reject null hypothesis.

From the evaluation above, Support Vector Machine and Random Forest show consistent and statistically significant between the two variables, predicted effort value and actual effort values; with the four datasets. On the other hand, Linear Regression and Regression Tree show inconsistent result and fail to reject null hypothesis. However, we cannot strongly prove that the statistically significant result of the research hypothesis is correct (100% certainty) and we need to calculate the effect size of the control vs experimental values.

In this research further experiment is to analysis the regression models with selected attributes COCOMO dataset using A measure and Wilcoxon Rank Sum test.

From Table VIII, the project calculates the accuracy metrics of COCOMO NASA 1, train and test Support Vector Machine and Random Forest with all attributes of COCOMO NASA 1, also with 5 selected attributes and one attribute only, LOC. From the result, COCOMO NASA 1, has the highest correlation accuracy compared to other experiments with machine models. There is sufficient evidence to reject the null hypothesis as the p-value of COCOMO NASA 1 is smaller than 5 percent, thus COCOMO NASA 1 is statistically significant. The MMRE of COCOMO NASA 1 is smaller compared to machine learning models' MMRE. The smaller the MMRE indicates the more accurate of the estimation [25].

As for Vargha and Delaney A measure there is no effect of difference between actual effort and the predict value of COCOMO NASA 1 model, to support the statement rank sum p-value is used to measure the distribution between the control and experimental sample. It shows that the p-value of Wilcoxon rank sum test is higher than 5 percent, the null hypothesis is fail to reject, the two samples has identical distributions.

To compare the trained machine learning models with all attributes and machines learning models only with 5 selected attributes, the five selected attributes performance better in producing more accurate results. The correlation accuracy of the five selected attributes have higher relationship between the actual effort and the predicted effort values compared to the all attributes. MMRE of five selected attributes has lower values compared to all attributes, this show that five selected attributes has more accurate estimations between the actual and predicted effort values. For Vargha and Delaney A measure, there are only slight differences between the all attributes and the five selected attributes, Support Vector Machine with all attributes has no effect differences compared to Random Forest model. The rank sum of all attributes and five selected attributes are statistically significant, there are enough evidence to support null hypothesis and to reject the alternative hypothesis.

Then experiment is using only one attribute, LOC. The correlation accuracy of machine models are increased compared to five attributes and all attributes. The p-value of Pearson's correlation also show the models are statistically

significant. The MMRE of Random Forest is lower than Support Vector Machine, 67.6706. The Vargha and Delaney A measure of Support Vector Machine and Random Forest has no effect in difference, this mean the distribution of actual and predicted effort values are identical. The Wilcoxon rank sum test of Support Vector Machine and Random Forest are statistically significant where, there are enough evidences to support null hypothesis and reject the alternative hypothesis since the p-value of both machine learning models is higher than 5 percent.

To conclude, the machine learning models learn and prove that not all attributes are needed to trained and needed. From this experiment, using one attribute, LOC can have closer MMRE towards the COCOMO prediction model, higher correlation accuracy and identical distribution of actual and predicted effort values.

From the Table IX, the project calculates the accuracy metrics of COCOMO NASA 2, train and test Support Vector Machine and Random Forest with all attributes of COCOMO NASA 2, also with 5 selected attributes and one attribute only, LOC. COCOMO NASA 2 has 93 projects and highest number projects compared to other COCOMO datasets. From the result, COCOMO NASA 2 has the lower correlation accuracy compared to experiments with machine learning models that used all attributes. There is no sufficient evidence to reject the null hypothesis as the p-value of COCOMO NASA 1 is larger than 5 percent, thus COCOMO NASA 2 is not statistically significant. The MMRE of COCOMO NASA 2 is smaller compared to machine learning models' MMRE.

The smaller the MMRE indicates the more accurate of the estimation (Malhotra, 2014). As for Vargha and Delaney A measure there is intermediate differences between actual effort and the predict value of COCOMO NASA 2 model, however the Wilcoxon rank sum p-value is used to measure the distribution between the control and experimental sample. It shows that the p-value of Wilcoxon rank sum test is higher than 5 percent, the null hypothesis is fail to reject, the two samples has identical distributions. The COCOMO NASA 2 is still statistically significant according to rank sum test.

TABLE VIII. COMPARISON OF COCOMO NASA 1 DATASET WITH DIFFERENT ATTRIBUTES

Algorithm	COCOMO NASA 1	All Attributes		5 Attributes		LOC Only	
		Support Vector Machine	Random Forest	Support Vector Machine	Random Forest	Support Vector Machine	Random Forest

Significant Value of Rank Sum	Significant	Significant	Significant	Significant	Not Significant	Significant	Significant

In the experiment of machine learning models are using all attributes, there are large differences result obtained from Support Vector Machine models and Random Forest model. The correlation accuracy of the Random Forest is lower than Support Vector Machine however Random Forest has higher MMRE value compared to Support Vector Machine. Moreover, Vargha and Delaney A measure, Support Vector Machine and large difference between the predicted and actual effort values, while Random Forest has closer accuracy of control and experimental sample. The Wilcoxon rank sum test for Support Vector Machine and Random Forest model are statistically significant where there are enough evidence to support null hypothesis and reject the alternative hypothesis, as the p-value of both machine learning is higher than 5 percent.

Then, the experiments are evaluated between all attributes and five selected attributes. The correlation accuracy of the five selected attributes have higher relationship between the actual effort and the predicted effort values compared to the all attributes. However the MMRE of Random Forest for the five selected attributes has higher value compared to Random Forest for the all attributes, while for Support Vector Machine is vice versa.

For Vargha and Delaney A measure, the selected five attributes for both machine learning show medium differences between the actual and predicted effort value. The rank sum of all attributes and five selected attributes are statistically significant, there are enough evidence to support null hypothesis and to reject the alternative hypothesis.

Then experiment is using only one attribute, LOC. The correlation accuracy of machine models drop compared to five attributes and all attributes. The p-value of Pearson's correlation only show the Random Forest model is statistically significant. The MMRE of Random Forest is lower than Support Vector Machine compared to all attributes and COCOMO NASA 2 model. The Vargha and Delaney A measure of Support Vector Machine and Random Forest have small in difference, this mean the distribution of actual and predicted effort values are closely identical.

The Wilcoxon rank sum test of Support Vector Machine and Random Forest are statistically significant where, there are

enough evidences to support null hypothesis and reject the alternative hypothesis since the p-value of both machine learning models is higher than 5 percent.

To conclude, the machine learning models learn and prove that not all attributes are needed to trained and needed. From this experiment, using one attribute, LOC can have closer MMRE towards the COCOMO prediction model, higher correlation accuracy and identical distribution of actual and predicted effort values.

From the Fig. 5, the machine learning model support vector machine and random forest show similar pattern towards to the actual effort, while the calculation of COCOMO deviates at 100, 14, 302, 113, 350 and 339 lines of codes. Support Vector Machine and Random Forest has proximity predicted effort values compared to effort prediction of COCOMO models. Refer to appendices for development of machine learning model.

Fig. 5. Comparison of Actual Effort and Estimated Effort.

V. DISCUSSION

The results of the experiments found clear support that Support Vector Machine and Random Forest algorithms impressively give consistent results with the COCOMO datasets regardless on the number of effort attribute used.

However, the planned comparison in this paper reveals the good performance and increase in the accuracy of Support Vector Machine for estimation of software project effort. Support Vector Machine also able to delivers significantly better results with five important attributes compared to all attributes used to estimate project effort and cost, as some of the attributes are irrelevant to estimate.

VI. CONCLUSION AND FUTURE WORK

To conclude, many existing machine learning algorithms can train predictive models, however, the right and suitable machine learning model are needed to give an accurate estimation. In this research, the five selected attributes with high positive correlation toward actual effort attribute are obtained from the correlation matrix, DATA, STOR, LOC, TIME and TOOL. The five important attributes give better result compared from using all the attributes in COCOMO dataset. Hence, not all attributes in the dataset are relevant to be used to measure the project estimation. Further improvement, during training and testing data, the data is advised to split three parts, 70 percent of training data, 20 percent of testing data, and 10 percent of validation data.

Further improvement of this research on machine learning models is to perform ensemble stacking also known as blending, to ensemble the four machine learning models in order to optimize the predictive model. In development of machine learning model, percentage of accuracy should be included to show the difference percentage between the predicted value and the actual effort value.

Abstract—Higher education models appear to be not entirely designed to support students in facing severe challenges, such as failure in exams and dropping out of school. To solve these challenges, several models of learning styles have been proposed, under the premise that these studies contribute to improving the student's learning experience. This research aims at quantifying the impact of learning styles (learning preferences/dimensions) on students' academic performance from a higher education institution. Ninety-six undergraduate students were surveyed during the 2018-2019 school year and randomly divided into two groups: control (CG) and experimental (EG). The learning preferences of the students were identified using the Unified Learning Style Model (ULSM) instrument. Subsequently, the level of students' knowledge concerning the course was determined employing a pre-test exam. As a following step, the students of the EG consulted the learning objects designed considering different learning styles. The CG attend their lessons in a face-to-face environment; both groups answered a post-test exam to assess their learning. The learning styles' effect on learning objects were designed to cover several learning styles- on academic performance is quantified employing an ANOVA analysis. The results differ from those postulated in previous researches based on the ULSM since there is no statistical evidence that learning styles influence students' academic performance. Therefore, it is necessary to explore other cognitive and affective factors that make the student's learning experience efficient and effective.

Keywords—Learning styles; learning objects; unified learning style model (ULSM); academic performance; higher education

I. INTRODUCTION

According to the National Association of Universities and Institutions of Higher Education of Mexico, in the 2016-2017 school year, there were 2,655,711 students enrolled in public schools [1]. Of these students, the National Polytechnic Institute (IPN) in 2019 [2], in any of its 56 engineering and bachelor's degrees, met the demands of 108,296 students. Of these 66,139 were male students and 42,157 were female students. According to the IPN strategic management program, 13,751 students were enrolled during the 2016-2017 school year in the UPIICSA public institution [3].

However, higher education faces great challenges, and one of these problems is related to school dropout due to various factors, such as: the high failure rate that is mainly observed in subjects considered "difficult", that demand a high level of knowledge, and a lot of dedication on the part of the student. However, the educational models in public institutions do not seem to be designed entirely to help students meet this challenge.

One of the strategies to solve this challenge has been the proposal of various models of learning styles, which classify the way in which a student learns and with it, develop educational materials that serve to facilitate the learning process.

This leads the researchers to think that if students knew how they can learn better, they would notice a significant change in their learning. Moreover, most learning style models capture characteristics in the face-to-face learning context, which made it difficult to identify the learning styles of online learning students. For this reason, The Unified Learning Style Model (ULSM) [4] was proposed to unify the most relevant learning style models, and consequently, to be able to facilitate students learning in the era of web 4.0.

The identification of the way in which students learn can influence their school performance, however, this has been a matter of controversy due to the fact that there have been several studies in favor of the hypothesis that the academic performance of students is given through educational materials designed to suit learning styles, and other studies that contradict this idea.

Due to the aforementioned, this main objective of this research is to determine if the learning objects, which were designed considering the student's learning preferences, are able to impact on their academic performance compared to those students who reviewed the same topics of the learning objects, but in a face-to-face class. For this reason, the students learning style has been classified by means of the ULSM instrument and the Learning Objects (LOs) has been adapted to the detected style, then its influence on academic performance was quantified.

The design and development of personalized LOs that facilitate the retention and understanding of knowledge is considered a fundamental part of solving this problem [5].

On the other hand, there are many criticisms regarding the use of learning styles or preferences due to the fact that some learning styles or preferences are not fully compatible with the use of e-learning systems or based on teaching through the web [4]. In the same way, it warns about the risk that exists when the student is mistakenly pigeonholed in some style [6]. Additionally, most learning style models place students into mutually exclusive groups, for example, a student cannot be verbal and visual at the same time [7]. This leads to ask the question whether or not this nominal classification of having a learning preference is correct or should be considered as a gradual and not dichotomous scale.

II. RELATED WORKS

Reference [8] studied the platforms that use learning styles as personalization criteria, which are also known as adaptive educational systems based on learning styles (Web-based Educational system with Learning Style Adaptation (WELSA)). This study involved 64 graduate students, who were surveyed using the ULSM instrument. Each student was characterized, and adaptation rules were created according to the preferences detected by the ULSM. The results showed that the students whose learning preferences were considered to recommend the courses, achieved a favorable result in their learning, while the students who did not use the recommended course, had an adverse effect.

Similarly, the research by [9] identified the learning styles of 136 engineering students, under the premise that not all students are interested in online learning, in particular, those students belonging to the engineering areas, and that this phenomenon is related to the learning style and their perception of online learning. For this effect, the questionnaire, inventory of learning styles by [10] and the questionnaire, student perception towards online learning adapted from [11] were used. The results revealed that learning styles do not influence engineering students' perception of online learning.

The study by [12] analyzed the effects that arise when equating the teacher's learning style with the student's learning style, and thus, seek a better academic performance of the students. For this purpose, the authors used the learning styles scale of [13], which was applied to instructors and students. The results contradict what was expected; it was already desired that by matching the teacher's learning style and the student's learning style, there would be favorable effects for the students [12].

There have been studies whose objective has been showed to identify the dominant learning style of students, for example, the study directed by [14] which conducted an experiment in a high school applying a survey to 584 students in order to determine the dominant learning style based on the inventory of learning styles of [10]. The results showed that 50.5% of the students were classified as assimilators, which means that the students fluctuate between reflective observation and abstract conceptualization. Additionally, the study concludes that there is no significant difference in terms of learning style and gender, which supports the idea that the learning styles of both men and women have similar preferences.

Likewise, [5] identified the learning preferences of 58 first-year university students using the ULSM instrument. The authors also carried out evaluations on the variables, satisfaction with learning, motivation, time invested in the study, and effort while studying, and identifying the students' preferences in six key aspects: perception, processing, dependence or independence of the field, reasoning, organization and social preferences.

The results showed that after a semester in which students were made aware of their learning preferences, no significant changes were found in the variables evaluated, learning

satisfaction, motivation, time spent studying or effort invested in the study. Furthermore, it is suggested to make changes in study techniques and in the way, students incorporate their learning preferences into their study habits. Finally, the authors concluded that learning preferences are a state and not a trait in students, that is, a trait is associated with stable characteristics, while states are temporary feelings or behaviors of the student at a given time.

Similarly, the study by [15] developed a management system aimed at merging LO, and the consequent adaptation to the student's learning preference. In this study 56 university students participated who were divided into two groups: control and experimental. The ULSM instrument was used to classify students according to their learning style. The proposed system searched the didactic contents for a repository of LOs and then merged LOs according to the learning preferences detected. Subsequently, the LOs fused and adapted to the students of the experimental group were shown.

The authors showed that there are favorable results for the experimental group, when by presenting the merged LOs to the students, it was possible to make the students focus on the subject of study, and avoid the distractions underlying the location of other materials that may or may not be related to their learning preference or of the study subject. A more detailed study by the same authors showed that the fusion of LOs was responsible for improving learning performance that may be related to cognitive load [16].

III. THEORETICAL FRAMEWORK

Learning is a process that has had an innate complexity, without showing a direct and unique solution since there are many factors that affect it, and that cannot be easily controlled [17]. Therefore, multiple ways of studying learning have been proposed, and thus, being able to propose alternatives to make more efficient results. One of the proposed alternatives is to determine the style in which a student learns.

A learning style is defined as "characteristic cognitive, affective, and psychosocial behaviors that serve as relatively stable indicators of how students perceive, interact with, and respond to the learning environment" [18]. Consequently, it is a set of ways by which a person learns as a result of various intrinsic and extrinsic factors, among which the affective and cognitive factors stand out, which may at some point influence the student's performance.

According to literature, 71 different models of learning styles can be identified, however, thirteen models have been recognized as the best results [6] and these are: Allinson's and Hayes Cognitive Style Index (CSI) by [19], Myers-Briggs Type Indicator (MBTI) by [20], Learning Style Inventory (LSI) by [21], Apter's Motivational Style Profile (MSP) by [22], Dunn and Dunn's Model by [23], Entwistle's Approaches to Studying Inventory (ASI) [24], Gregorc's Mind Styles Model and Style Delineator (GSD) [25], Herrmann Brain Dominance Instrument (HBDI) by [26], Learning Styles Questionnaire (LSQ) by [27], Learning Styles Profiler (LSP) by [28], among others.

The huge number of models indicates that being able to identify students' learning styles is not a simple task, because each model considers some particular characteristic of their learning, leaving aside other important features. This led educational researchers to propose an instrument that could unify the cited models to identify the learning styles for each student more accurately.

A. Unified Learning Styles Model (ULSM)

The unified model of learning styles synthesizes the main characteristics of the models mentioned in literature, known as integrative taxonomy [8]. This model integrates learning preferences related to the modality of perception, form of information processing and organization, as well as social and motivational aspects.

Some of the ULSM preferences have a direct corresponding with a dimension of a learning style model, while others represent only a trait that determines a certain style [8].

One of the corresponding dimensions is field dependence or independence, which was based on the learning styles model of [29], including the name and the definition. The opposite case can be observed in the preference regarding attention to details, since it does not have direct correspondence with any of the dimensions of the existing learning styles models [8].

The ULSM includes the following dimensions and preferences: Perception modality and its preferences: visual vs verbal; Information processing and its preferences: abstract vs concrete, serial vs holistic; Experimentation and its preferences: active vs reflective observation, careful vs not careful with details; Field and its preferences: dependency / independence; Reasoning and its preferences: deductive vs inductive; Organization of the information and its preferences: synthesis vs analysis; Motivation and its preferences: intrinsic vs extrinsic, deep vs superficial vs strategic vs resistant approach; Persistence and its preferences: high vs low; Pace and its preferences: focus on one task at a time vs alternating tasks and topics; Social aspects and its preferences: individual work vs team work, introversion vs extroversion, competitive vs collaborative; Coordinating body and its preferences: affectivity vs thought.

The preferences of the perception modality dimension are included from several models of traditional learning styles such as: the Felder-Silverman Learning Style Model (FSLSM) (visual vs verbal dimension) [30], VARK (Visual, Aural, Reading/writing, Kinesthetic) [31], VAK (Visual, Auditory, Kinesthetic), of the Dunn and Dunn model [23] (visual, auditory, kinesthetic, tactile) and of the Riding model (verbalizer / image generator) [32]. Moreover, only visual vs. verbal preference was considered, because kinesthetic or tactile preference is difficult to perceive in an online environment [8]. One of the characteristics that was preserved to identify this dimension was the definition of the Felder-Silverman Learning Style model (FSLSM) which says: "visual students remember better what they see (images, diagrams, graphs, etc.), on the other hand, verbal students rely more on either spoken or written words" [8].

The information processing dimension includes preferences: concepts and generalizations, abstract vs. concrete, practical examples. These preferences were based on Kolb's learning cycle (abstract conceptualization vs concrete experimentation) [21] and Gregorc's model (abstract vs concrete) [25].

The serial vs. holistic preference was inspired by the FSLSM (sequential or global) [30] and by Pask's model (serial or holistic) [33].

From Kolb's learning cycle, the preference of active experimentation vs. reflective observation was taken, which is also described in the FSLSM (active or reflective) [30] and in the Honey and Mumford model (activist or reflector) [27].

According to [8], students who have abstract preference tend to trust contextual interpretation, while students who demonstrate concrete preference rely on immediate experience to capture learning. Similarly, students with a sequential preference tend to understand knowledge linearly, while students who have a global learning preference tend to learn in disorder. Some consider that they perform their learning in large leaps, and that they have the ability to make fast connections between different topics.

The field-dependent vs. field-independent dimension has been based on the model of [29]. This dimension refers to the student's environment and how the environment affects or does not affect their interpretation and the ability to locate information. The meaning is that students who depend on the field have difficulty locating the precise information they need. If this information is hidden or if there is other information superimposed that prevents it from being easily accessible, so they are more oriented towards people. On the other hand, students classified as independent of the field find it easier to recognize and select what is important in their environment, with a kind of abstraction and additionally have an impersonal orientation [8].

The reasoning dimension and its inductive vs. deductive preferences were taken from the first version of the FSLSM. Inductive students prefer to reason from particular facts or situations, and thus, be able to reach a general conclusion. That is, they go from the specific to the general. They also respond better to problem-based learning (fictional or real), as well as inquiry learning. Deductive students prefer to reason from the general to the specific, which is why they prefer the course to begin with the theoretical foundations and with the basic principles and then continue with the applications corresponding to the course [8].

The information organization dimension and its preferences, synthesis vs analysis, had no basis in any previous learning style model. Similar concepts can be found in the Allinson and Hayes model (intuitive or analytical) [19] and in the Riding model (holistic or analytical). A student with a preference for synthesis is the one who has a general image of the topic and who tends to combine different elements to understand something completely. Furthermore, a student with a preference for analysis focuses on each of the parts of a whole, as well as on the basic principles, and therefore be able to build what remains [8].

The motivation dimension and the deep vs. strategic vs. superficial vs. reticent preferences was based on the Entwistle model [24]. From the Grasha-Riechmann model the reticent preference was taken which is similar to the Grasha-Riechmann avoidance concept [34].

The intrinsic vs extrinsic preference does not have a direct correspondence with a learning style model, but it is related to the Entwistle model, as well as the telic (serious) and paratelic (playful) dimensions of [22].

According to [8], the preferences of the motivation dimension have the following characteristics: students with the preference of profound are oriented towards meaning. They try to understand ideas by themselves or by their own means. They generally show interest in the full content of the course. Students with a preference for strategic focus, tend to be achievement-oriented; generally, in a group of students they are the ones who want to obtain the highest grades and they are constantly attentive to the requirements and evaluation criteria. Likewise, they try to guide the work to perceived preferences in teachers.

Students with a superficial preference are oriented towards reproduction, that is, their intention is to pass the different evaluations that are presented to them, by memorizing facts, data and whatever else they need. They generally do not find meaning in the new ideas that are presented to them; they tend not to reflect on the purpose or strategy of a certain action, and they feel excessive pressure as they worry about the work.

Students with the resistant preference show a total disinterest in the course and generally refuse to participate in the learning activities suggested by the teacher. Most of the time they are apathetic students; they do not pay attention to their classes and they are disobedient. Students who are intrinsically motivated learn by the mere fact that their attention will generate a new experience in their life, while those who are extrinsically motivated learn to obtain an external reward which serves as motivation itself [8].

For the persistence dimension, its preferences were based on the Dunn and Dunn model [23] (persistent or non-persistent). In this dimension, students who demonstrate a high persistence preference are those students who are inclined to complete all the tasks that are entrusted to them, sometimes regardless of the cost. They tend to spend a lot of time studying and sometimes, if necessary, they review the study material over and over again. Students who have a low persistence preference tend to take consecutive breaks and rarely return to study material [8].

The pacing dimension includes two preferences, concentrating on one task at a time or alternating between multiple tasks and topics. This dimension was not based on any previous learning style model. Students who demonstrate a preference to concentrate on one task at a time are considered as having linear learning. This means that they will not continue with the learning if they do not complete the current task. Sometimes, they have few changes, or they have no changes and jumps of activity. Students who have the preference to alternate subjects or topics are considered to a certain extent inconstant because they jump from topic to

topic and from subject to subject and this includes jumps from one course to another [8].

The social aspects dimension and their preference to learn alone vs. learning among peers, has been based on the Dunn and Dunn model, and has also been related to other learning styles such as the active or reflective of the FSLSM.

Introversion vs. extraversion preference was based on the Myers-Briggs classification (MBTI). From the Grasha and Riechman-Hruska model [13], the competitive vs. collaborative preferences were taken, which is also related to the autistic domain preference of [22].

Students who have a preference for introversion are those students who tend to avoid social contact and are constantly preoccupied with their thoughts and inner feelings. Extroverted students are constantly involved with social and practical realities of that same nature, instead of worrying about their thoughts and feelings [8]. Students who demonstrate a competitive preference tend to participate in any activity as long as they have competition with someone else. While students who have a preference for collaboration, feel better helping a common goal for all, constantly considering the "win-win" [8].

The coordinating instance dimension of the learning process and its affectivity vs. thought preferences is related to the feeling vs. thought preferences of the Myers-Briggs model (MBTI). Students who demonstrate a preference for affectivity tend to complete tasks based on intuition and their way of feeling, while those students who have a preference for learning thinking, make decisions based on analysis, logic, and reasoning [8].

As mentioned above, the ULSM has only integrated learning style preferences related to the web-based educational context, rather than the context for face-to-face learning. Accordingly, only those preferences related to the context of education 4.0 have been included.

Educational environments for education 4.0 have been enriched by the incorporation of Learning Objects (LOs), which are defined as a set of educational experiences obtained through reflection and experimentation in practice aimed at solving real educational problems, and that are represented in Multimedia Teaching Materials (MTM), in order to avoid memorization of information [35]. LOs are all those digital or non-digital entities that can be reused or referenced during learning with technological support [36]. For this research LOs have been considered as the set of reusable or not reusable multimedia educational materials, and that are intended to facilitate learning for students.

Currently, LOs are used in interactive learning environments, distance learning systems, and collaborative learning environments; and are required by multiple companies to offer online training, such as Oracle company that offers its training courses virtually through what is known as Oracle University, which uses learning objects (texts, videos, illustrations, etc.) to facilitate the learning of the personnel concerned.

IV. METHOD

The study was carried out in a public higher education school with 96 students who had enrolled on the web technologies course of the Industrial Administration career of 2019 scholar year. The age of the students ranged from 20 to 23 years old. It was explained to teachers and students of six groups the objective of the investigation. They both agreed to participate. In each class, the students' total number was randomly divided into two groups: the Control Group (CG) and the Experimental Group (EG).

LOs were designed and developed, including the following dimensions of the ULSM and its respective preferences (learning styles), perception, information processing, field independence, reasoning and organization. The LOs were upload to Moodle platform to be available for the students.

The ULSM instrument was employed to gather the students' preferences. It has been validated through the electronic learning platform, WELSA [8]. Each student's prior knowledge about the course was determined by an evaluation (pre-test) related to the course topic. No statistical difference was found; the details are presented next.

The GC students took all their classes in person, attending their classroom with their teacher. The GE students attended the computer room to take all their course classes using the Moodle platform.

Then, a post-evaluation (post-test) was administrated to the students. This evaluation was carried out to determine the knowledge acquired from the face-to-face or online lessons. The GC students carried out their evaluation on paper, and the EG students through the platform. The questions on both tests were the same. The normality and homoscedasticity of both pre-test and post-test were evaluated. Then, two-way ANOVA (group x dimension) were performed to determine the effect of the dimensions of the ULMS on the students' performance in both groups (CG, EG).

V. RESULTS

The dominant learning style of each student was determined through the ULSM instrument. The results are shown in Table 1.

TABLE I. STUDENTS' LEARNING STYLE ACCORDING TO ULMS DIMENSIONS

Perception dimension	
Kinesthetic	65%
Aural	21%
Visual	6%
Reading/writing	8%
Information processing dimension	
Concrete	86%
Abstract	14%
Holistic	64%
Sequential	36%
Active	50%
Reflective	50%

Field dimension	
Dependent	33%
Independence	67%
Reasoning dimension	
Deductive	26%
Inductive	74%
Information dimension	
Synthesis	66%
Analyze	32%
Motivation dimension	
Deep	44%
Superficial	31%
Strategic	21%
Disinterest	4%
Persistence dimension	
High persistence	51%
Low persistence	49%
Pacing dimension	
Completed one task	70%
Jumped between tasks	30%
Social dimension	
Work in a team	25%
To do it individually	75%
Collaborative	84%
Competitive	16%
Extrovert	48%
Introvert	52%

A. Influence of Learning Styles on Students Performance

The Shapiro-Wilk test showed that the grade obtained in the pre-test of the CG y GE has normal distribution, see Table 2.

TABLE II. THE SHAPIRO-WILK TEST FOR PRE-TEST EVALUATION

Pre-test			
	Statistic	df	Sig
CG	0.972	43	0.376
EC	0.975	53	0.326

($p=0.05$)

Levene's test showed that the grade of the pre-test is homoscedastic, $F(94) = 0.576, p = 0.450$.

The student's t-test showed no difference between the grade of pre-test of EG students and CG students, see Table 3.

Thus, the students in both groups have the same level of prior knowledge.

TABLE III. STUDENT T-TEST OF THE GRADE FOR THE PRE-TEST EVALUATION

Pre-test					
	M	DS	t-value	df	p-value
CG	6.638	1.1479	-1.18	94	0.241
EC	6.337	1.3553			

The post-test evaluation showed that the data are normal, this is shown in Table 4.

TABLE IV. THE SHAPIRO-WILK TEST FOR POST-TEST EVALUATION

Post-test			
	Statistic	df	Sig
CG	0.953	43	0.074
EC	0.976	53	0.347

($p=0.05$)

Also, the grade was homoscedastic, $F(94) = 3.721, p = .057$.

The student's t-test shown that the students who used the LOs (EG) and those who attended the lesson face to face (CG) have not statistical difference in post-evaluation, see Table 5.

TABLE V. STUDENT T-TEST OF THE GRADE FOR THE POST-TEST EVALUATION

Post-test					
	M	DS	t-value	df	p-value
CG	7.2563	1.4840	-1.156	94	0.25
EC	7.5447	1.2148			

Therefore, both groups had the same level of knowledge after reviewing the LOs or attending face-to-face lessons. Thus, the LOs designed based on several learning styles of the ULSM do not influence academic performance.

B. Influence of the Dimensions of Learning Styles on Students Performance

A two-way ANOVA test (group x preference) were carried out to analyze each dimension of the students' learning styles in their performance. The ANOVA showed no significant difference between the interaction of the LOs and preferences: kinesthetic, visual, aural, reading/writing, $F(2.89) = 1.293, p = .279$. Thus, the students with kinesthetic, visual, aural and reading/writing preferences obtained the same performance by consulting the LOs or attending the teacher's lecture.

Likewise, the results have shown no significant difference between the interaction of the LOs and the information processing dimension (abstract vs concrete), $F(1.92) = .254, p = .615$. Therefore, students with abstract, concrete preferences obtained the same performance by consulting the LOs or attending class with the teacher. Also, no statistically significant difference has been found between the interaction of the LOs and the information processing dimension (active vs reflective), $F(1.92) = 1.548, p = .217$. Consequently, students from both groups with active or reflective preferences obtained the same performance. The statistical analysis indicated no difference between the interaction of LOs and the information processing dimension (sequential vs global), $F(1.92) = 2.006, p = .160$. Therefore, students with sequential or global preferences obtained the same grade.

Furthermore, no statistically difference between the interaction of the LOs and the field dependence dimension (dependent or independent), $F(1.92) = .047, p = .829$ was found. A similar result was realized for deductive or inductive

learning, $F(1.92) = .166, p = .685$, for synthesis vs analysis, $F(1.92) = .455, p = .502$; and for individual vs team, $F(1.92) = 1.787, p = .185$.

VI. DISCUSSION

The results have shown that there is no evidence that the individual learning styles and the dimensions of the ULSM influence students' academic performance. Therefore, there was no statistical difference between face-to-face and blended learning which shows that blended learning can be just as effective as face-to-face learning. This is certainly a good choice to meet a challenge of the growing student population demanding quality education [37].

A previous study [14], whose objective was to identify the dominant learning style of students, shows that the majority of students are kinesthetic (65%), with inductive reasoning (74%), with a preference for synthesis (66%), deeply motivated (44%), highly persistent (51%), and who prefer to work individually (75%).

The study of [8] showed that the courses recommended based on students learning styles improve academic achievements. In contrast, our results show that learning styles —included in the LOs — do not affect the students learning performance.

Our results agree with those found in [9], who showed that learning styles do not influence students' perception of online learning. It is also consistent with the study [5], which found no significant difference in learning satisfaction changes, motivation, time spent studying, and effort invested in the study after considering the students' learning preferences. Thus, a learning preference is a state—temporary feelings or behaviors—and not a trait —associated with stable characteristics—in students [5].

VII. CONCLUSIONS

In conclusion, research supports the conjecture that learning styles positively influence students' academic performance. On the other hand, our results argue that student performance does not depend on learning style. Consequently, for future work, it is necessary to explore other psychological, affective, and cognitive factors that could influence the students' learning performance to depict “the big picture” and develop strategies to mitigate their negative impact. In developing countries, online learning can be a solution for many aspirants that are not admitted to public universities in a face-to-face career. However, this strategy will be successful if the challenges such as the failure in exams and the high rate of students drop out are solved.

Application of Expert System with Smartphone-based Certainty Factor Method for Hypertension Risk Detection

Dodon Yendri¹, Derisma², Desta Yolanda³, Sabrun Jamil⁴
Computer Engineering Department
Andalas University, Padang, Indonesia

Abstract—Hypertension is a factor health problem with a high prevalence in Indonesia. The total amount of hypertension nationwide is 34.11%. There are only 1/2 were diagnosed, and the remaining 1/2 are undiagnosed. Certainty factor was needed to prove the certain or not of a fact in a metric form, and it commonly was used in expert systems. This method was perfect for diagnosing something uncertain. This research aimed to build a smartphone-based hypertension risk detection system. This system was built by MPX5500DP pressure sensor components that served for blood pressure measurement, Bluetooth module HC-05 as microcontroller data transmission, Arduino Uno as sensor data processing, and Smartphone as hypertension risk detection interface and database access. Measuring blood pressure on the user's right or left arm was used to test the system. Then the data was sent to the smartphone to be classified and processed by using the certainty factor method implanted in the android smartphone to detect the risk of hypertension and then followed by the selection of symptoms and risk factors of hypertension according to previous experience. The results showed that the success rate of the system in detecting the risk of hypertension was 100%, the mean error of the systolic value of the right arm was 2.092%, and the average error of the diastolic value of the right arm was 2.977%, while the average error of the systolic value of the left arm. 1.944% and the mean error of the left arm diastolic value was 2.800%.

I. INTRODUCTION

Based on the 2018 Basic Health Research, the national hypertension prevalence is 34.11%. In the percentage of 34.11%, half of the people who have hypertension have been diagnosed, and most of them undiagnosed. Data shows that only 54.4% of people diagnosed with high blood pressure take hypertension medication [1]. This explanation tells that most hypertension sufferers are unaware that they are suffering from hypertension [2],[3],[4] and are not getting treatment [4], [5]. Hypertension is one of the big problems in the public health field [6], especially in Indonesia. That expressed because hypertension is a health problem with a high prevalence [3], [7], [8]. The Estimated one in three people will suffer from hypertension in 2025 [4].

Hypertension is a condition where the systolic blood pressure value is ≥ 140 mmHg, or the diastolic value is ≥ 90 mmHg [9]. The increase of blood pressure in a long time can cause kidneys, heart, and brain damage until stroke if it is not

detected early [10] and does not receive adequate treatment [11], [12]. A sphygmomanometer, a tool in the medical world, is used to check blood pressure [13] in humans and, it also a medium that can detect hypertension. The Sphygmomanometer consists of an analog sphygmomanometer and a digital Sphygmomanometer [14]. Analog Sphygmomanometer works manually means to be able to know blood pressure precisely depend on the user's expertise [15]. It works using Korotkoff methods in determining the patient's systolic and diastolic through coronary sound from the stethoscope. While digital A sphygmomanometer works based on oscillometry methods in which to determine systolic and diastolic patients use pressure sensors as transducers that will detect blood pressure and oscillation signal changes due to heart rate [4], [16].

There are many mobile health apps (mHealth apps) available in the market currently. This app is designed to facilitate a wide range of health issues and concern that is intended for use outside of the clinic. The review study also found that researchers and publishers of *mHealth* focused more on individual preventative diseases such as self-management for diabetes [17], [18], [19], gout [20], chronic obstructive pulmonary disease [21], bipolar disorder [22] and bowel disease [23], stroke [24], [25], heart disease [26] and flu [27].

Fitriani et 'al research [28] developed a mobile application for early prediction of diabetes type 2 and hypertension based on the factor data individual risk by integrating iForest, SMOTETomek, and ensemble learning. iForest was used to detect and remove outlier data from the dataset. Meanwhile SMOTETomek was used to balance unbalanced datasets and ensemble learning was applied to predict disease. This study collected risk factor data and sent it to a remote server for diagnosis with the proposed prediction model. The prediction results were sent back to the car application. The weakness of this research was the process of sending data back and forth to get action to prevent individual risk.

Furthermore, Egejuru et 'al [29] developed a cellular-based hypertension risk monitoring system. BP_HRM System developed for users can access the system from distant locations easily. The mobile application was designed using an integrated modeling language and implemented using the Adaptive Neuro-Fuzzy Inference System (ANFIS) and Extensible Mark-Up Language methods with the Java

programming language for layout and mobile content. JavaScript Object Notation was used to implement the system's data storage and retrieval mechanisms. This study had not provided information about the symptoms and factors that caused hypertension.

Based on previous research, we have carried out developmental research in addition to classifying hypertension as well as knowing the symptoms and factors that cause hypertension and the level of risk that will occur.

II. COMMON FACTORS AND SYMPTOMS OF HYPERTENSION

Hypertension is the pressure that pushes a wall of the arteries when the blood pumps into the arteries [30]. Systolic pressure or high blood pressure is given to the walls of the arteries when the heart contracts, whereas diastolic pressure or low blood pressure, the pressure given to the arteries when the heart relaxes. Blood pressure is generally measured in millimeters of mercury (mmHg) [31].

Hypertension referred to as "the silent killer" [32], [33]. Generally, hypertension is asymptomatic [34]. Most people don't feel anything, even though their blood pressure is not normal [18]. It can continue for many years until the sufferer (who does not feel suffering) falls into an emergency and even has heart disease, sexual dysfunction, stroke, or damaged kidneys [35]. Based on the case, some hypertension sufferers do not specific hypertension symptoms, they only get headaches, impaired vision, restlessness, dizziness, fatigue, pain in the chest, and heavy feeling on the nape [36].

Hypertension generally causes the sufferer's unhealthy behavior. Some factors unhealthy behaviors can cause hypertension [8], [37]:

1) *Smoking*: Smoking increases the heart rate [37]. Therefore the muscles - heart muscles need a lot of oxygen. Smoking habits of hypertension sufferers will increase the risk of damage to arterial blood vessels.

2) *Lack of physical activity*: Exercise can help stabilize blood pressure[38], and it is beneficial for sufferer's mild hypertension. Moreover, aerobic exercise can drop blood pressure, although the weight has not dropped.

3) *Excessive salt consumption*: Salt causes a build-up of fluid in the body because it collects fluid inside the cell. It can cause the volume of blood pressure to increase [39]. The people who consume 3.5 grams or less salt had lower blood pressure than the community that consumes about 9-12 grams [40].

4) *Excessive alcohol consumption*: The effect of alcohol can increase blood pressure. Several studies showed a relationship between blood pressure and alcohol intake. The American Heart Association recommends limiting alcohol intake in order to avoid developing hypertension. Women should have no more than 1 drink per day and no more than 2 drinks per day for men [41].

5) *Psychosocial and stress*: Stress or mental tension (depressed, moody, angry, revenge, fear, guilt) can stimulate the kidney glands to release adrenaline hormones and spur the beat heart is faster and stronger than usual. It can cause blood

pressure to increase [42]. If people get stress for a long time, their body will occur pathological changes and organic abnormalities. The Symptoms can be hypertension or stomach ulcers. Table 1 shows the common factors and symptoms of hypertension.

Family History of Hypertension		0.2

III. CLASSIFICATION OF HYPERTENSION

Hypertension has two types Based on the cause. They are Essential hypertension (primary) and Secondary hypertension [43], [44]. Essential hypertension (primary) is a type of hypertension that often occurs in hypertension cases about 95 percent. This type is related to lifestyle factors such as lack of movement (inactivity) and diet [45]. Meanwhile, secondary hypertension, type hypertension seldom in hypertension cases. It is related to medical conditions, such as heart disease or reactions medications.

According to the Sevent's Report of the Joint National Committee on Detection, Evaluation and Treatment of High Blood Pressure (JNC7) 2003 [41], [46], hypertension classified into four categories in Table 2.

TABLE II. CLASSIFICATION OF HYPERTENSION ACCORDING TO JNC7 2003 [41]

Category	TDS (mmHg)		TDD (mmHg)
Normal	<120	and	< 80
Prehypertension	120-139	or	80-89
Hypertension stage 1	140-159	or	90-99
Hypertension stage 2	≥ 160	or	≥ 100

IV. CERTAINTY FACTOR

The certainty factor method is used in facing a problem that the answer is uncertain. This uncertainty is a probability. This method was introduced in the 1970s by Short-life Buchanan. Buchanan used this method when he diagnosed and therapy meningitis and blood infections (Wikipedia). The development team of this method noted that doctors often analyzed existing information with phrases such as almost certain.

This method was almost similar to fuzzy logic because uncertainty is represented by the degree of trust. The difference is in the fuzzy logic's rules [47]. The fuzzy logic does not have a confidence value if it calculates the premise more than one. The fuzzy logic's calculation can see the lower value in AND operator and the highest value in the OR operator. It is different with a certainty factor [48]. It has trust value on each premise and shows the measure of certainty of a fact or rule.

$$CF[h,e] = MB[h,e] - MD[h,e] \quad (1)$$

Description:

$CF[h,e]$ = Certainty factor

$MB[h,e]$ = Measure of belief, a measure of belief or confidence level of the hypothesis (h), if given evidence (e) between 0 and 1.

$MD[h,e]$ = Measure of disbelief, a measure of disbelief, or confidence level of the hypothesis (h), if given evidence (e) between 0 and 1.

There are several combinations of certainty factor against certain premises, namely:

1) Certainty factor with one premise.

$$CF[h,e] = CF[e]*CF[rule] = CF[user]*CF[pakar] \quad (2)$$

2) Certainty factor with more than one premise.

$$CF[A \wedge B] = \text{Min}(CF[a],CF[b]) * CF[rule] \quad (3)$$

$$CF[A \vee B] = \text{Max}(CF[a],CF[b]) * CF[rule] \quad (4)$$

3) Certainty factor with a similar conclusion.

$$CF_{\text{combined}}[CF1,CF2] = CF1 + CF2 * (1 - CF1) \quad (5)$$

This method has advantages such as suitable for measuring something certain or uncertain in diagnosing a disease. In addition, this method only applied one calculation, and it reached out two data therefore its accuracy was maintained.

The planning of the test was needed by getting the best result of the test, both hardware and software testing. Table 3 shows the hardware test design, and Table 4 shows the software design.

TABLE III. HARDWARE TEST DESIGN

No	Hardware	Test Design	Destination
1	blood pressure measuring device	Get error values for measuring tools and digital sphygmomanometers.	Get a comparison of the measurement results of tools and digital sphygmomanometers.

TABLE IV. SOFTWARE TEST DESIGN

No	Hardware	Test Design	Destination
1	Mobile Application	Testing the detection of hypertension risk was successfully obtained from the data obtained	To find out the results of detecting the user's hypertension risk successfully obtained
2	Certainty factor method	Testing the obtained hypertension risk value	To determine the risk value of hypertension obtained

V. ANALYSIS OF RESULT

The expert system implementation shows in Fig. 1 using a blood pressure gauge that is Arduino Uno, MPX5500DP Pressure Sensor, Bluetooth HC-05 module, Arm cuff is an airbag that circles on the user's arm, and Android Smartphone.

1) *MPX5500DP Pressure sensor testing*: This test found out the extended function of the MPX5500DP sensor measuring the user's blood pressure. Testing was conducted by connecting sensors, cuffs, and analog Sphygmomanometers to a hose that has three ends. Once the three components had connected, the air pumped into the cuff until it gets a pressure value to be tested. It consists of the systolic value(s) and the diastolic value (d) read by the embedded software. Once the pressure value is obtained, then it is sent to the app via a serial communication function between Arduino and the android app via Bluetooth. The results of pressure measurements using the system shown in Fig. 2:

Furthermore based on the pressure value obtained, then the value is classified and displayed on the smartphone as seen in Fig. 3.

Fig. 1. Blood Pressure Gauge.

Fig. 2. Measurement of Blood Pressure by the System.

Fig. 3. Pressure Classification Page.

The determining of the system accuracy was conducted by comparing medical devices that had the same function as analog Sphygmomanometers. First, the cuffs were attached to the user's arm, and then performed air pumping through an elastic balloon into the cuff until the air pressure on the cuff reached ≥ 180 mmHg, then the air was released slowly by the mechanic's tool. It took systolic and diastolic values when the pressure drops continuously. Systolic value took if the tool would reach out the first spike in the pressure value, and Diastolic value took the last spike in pressure. After the data obtained, it is sent to the app via Bluetooth, and it is transferred to the smartphone to be classified and processed using the certainty factor method. Furthermore, the same way did test with analog Sphygmomanometers.

Fig. 4 shows the results of a blood pressure measurement from 20 tests using the MPX5500DP pressure sensor and analog Sphygmomanometer.

From the graph in Fig. 7, it can be seen that the measurement results using the MPX5500DP pressure sensor are almost the same as the measurements using an analog Sphygmomanometer.

2) *Blood pressure testing on right arm and left arm:* This test is to find out the system extent implemented to measure the user's blood pressure. This test is performed on the right arm and left arm user. Fig. 5 and Fig. 6 show the comparison of measurement test results of blood pressure on the right arm and left arm from 10 different users using mpx5500DP sensors and analog Sphygmomanometers.

Fig. 4. Blood Pressure Comparison.

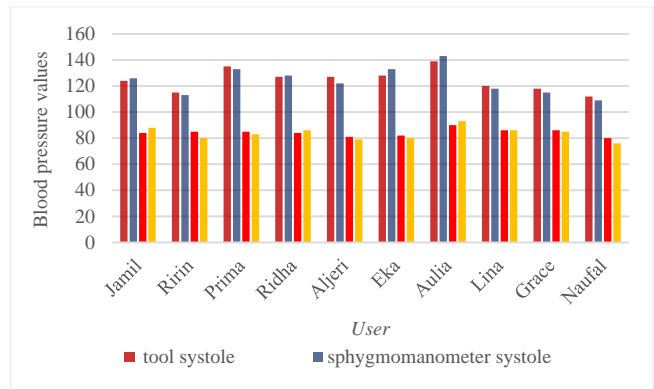

Fig. 5. Blood Pressure Measurement Testing Graph on Right Arm.

Fig. 6. Blood Pressure Measurement Testing Graph on Left Arm.

Based on a graph test performed shows in Fig. 5 and Fig. 6 states that testing using the MPX5500DP sensor and analog Sphygmomanometer provides almost the same results. From the data of blood pressure measurement tests on both arms, the calculation of systolic and diastolic error values of both of them was calculated using the formula:

- $$\text{Average Right Arm Systolic Value Error} = \frac{\text{Number of Right Arm Systolic Error Values}}{\text{Number of Experiments}} \times 100\% = \frac{20.927}{10} \times 100\% = 2.097\%$$

- Average Right Arm Diastolic Value Error =
$$\frac{\text{Number of Right Arm Diastolic Error Values}}{\text{Number of Experiments}} = \frac{29.778}{10} \times 100\% = 2.977\%$$
- Average Left Arm Systolic Value Error =
$$\frac{\text{Number of Left Arm Systolic Error Values}}{\text{Number of Experiments}} = \frac{19.441}{10} \times 100\% = 1.944\%$$
- Average Left Arm Diastolic Value Error =
$$\frac{\text{Number of Diastolic Tool Error Values}}{\text{Number of Experiments}} = \frac{28.009}{10} \times 100\% = 2.800\%$$

From the calculation of the equation above, there was a significant difference in the average value of systolic and diastolic errors in both arms. The difference between them could be caused by several vascular abnormalities in both of a person's arms. The greatest possibility was a blockage of the walls of arterial blood vessels, either due to fat or other plaque, on arms with higher blood pressure. The difference in the average error value of both arms shows the graph in Fig. 7.

3) Accuracy testing: Accuracy testing is performed to determine the capabilities of expert systems embedded in the software using the Certainty factor method. This test shows that the application of the certainty factor method could calculate the hypertension risk for the users based on the symptoms and risk factors of hypertension chose by them.

The Table 5 shows the results of accuracy tests conducted based on one of the system tests as a whole.

Based on Table 3 of the test results above, the percentage value of Hypertension risk was derived from the equation of the Certainty factor method embedded in hypertension risk detection software. The equation of the certainty factor method would process the certainty factor (CF) value according to the symptoms and hypertension factors selected by the user. This is a manual calculation of certainty factor equations to see the accuracy of the methods embedded in the software:

$$CFA = CF1 + CF2 * (1 - CF1)$$

$$CFA = 0,6 + 0,4 * (1 - 0,6)$$

$$CFA = 0,6 + 0,4 (0,4)$$

$$CFA = 0,6 + 0,16$$

$$CFA = 0,76$$

$$\text{Percentage CF} = 0,76 * 100\% = 76\%$$

CF1 and CF2 values refer to Table 2. The results of the calculation of hypertension risk with certainty factor method manually according to the results of detection using the certainty factor method embedded into hypertension risk detection software.

4) Early detection testing of overall hypertension risk: This test was conducted to determine whether an Android-based expert system application has an embedded knowledge base on detecting hypertension risk that supports the system using the Certainty Factor method. The certainty factor method could show a measure of certainty based on facts or rules. That factor method showed the results in the numbers form. The use of blood pressure measurement data had classified an application implanted in a smartphone, then the system processes it by implementing equations (5). The results of the process were stored in Firebase and displayed on android smartphones in real-time. Table 6 shows the results of blood pressure classification testing and early detection of Hypertension Risk levels based on symptoms and factors displayed on smartphones from 10 test cases using the Certainty Factor method.

From Table 4, it can be explained that the system can receive blood pressure values from blood pressure measuring devices and classify them based on the received blood pressure according to the knowledge that has been instilled (based on Table 2).

Fig. 7. Graph of difference in Average Blood Pressure Testing Error on the Right Arm and Left Arm.

TABLE V. HYPERTENSION RISK TEST RESULTS

Name	Blood pressure received		Classification	Symptoms and factors	Risk of Hypertension with Certainty factor
	S	D			
Jamil	123	86	Pre-Hypertension	<ul style="list-style-type: none"> • Headache • Nape Weight • Heart palpitations • Coffee consumption • Stress • Lack of exercise 	76.0 % (True)

TABLE VI. RESULTS OF BLOOD PRESSURE CLASSIFICATION TESTING AND THE EARLY DETECTION OF HYPERTENSION RISK LEVELS

No	Name	Blood pressure received		Classification	Symptoms and factors	Risk of Hypertension with Certainty factor (True/False)
		S	D			
1	Jamil	123	86	Pre-Hypertension	<ul style="list-style-type: none">• Headache• Nape Weight• Heart palpitations• Coffee consumption• Stress• Lack of exercise	76.0 % (True)
2	Ririn	111	71	Normal	<ul style="list-style-type: none">• Headach• Impaired vision• Consuming excess salt• Consuming coffee• Stress• Lake of Exercise	76.0% (True)
3	Prima	140	82	Pre-Hypertension	<ul style="list-style-type: none">• Consuming fatty foods• Consuming coffee• Stress• Lack of exercise• Have a family history of hypertension	52.0% (True)
4	Ridha	128	80	Pre-Hypertension	<ul style="list-style-type: none">• Tired easily• Take Hypertension Drugs• Diabetes Mellitus Lack of exercise	96.46% (True)
5	Aljeri	122	79	Normal	<ul style="list-style-type: none">• Tired easily• Consumption of Hypertension Drugs• Diabetes mellitus• Lack of exercise	80.8% (True)
6	Eka	133	82	Pre-Hypertension	<ul style="list-style-type: none">• Headache• Dizzy• Consumption of Hypertension Drugs• Diabetes mellitus• Consumption of fatty foods• Lack of exercise• Have a family history of hypertension	98.46% (True)
7	Aulia	139	90	Pre-Hypertension	<ul style="list-style-type: none">• Headache• Undergo strenuous activity• Consumption of fatty foods• Excessive Salt Consumption• Stress• Lack of exercise• Have a family history of hypertension	80.8% (True)
8	Lina	120	72	Normal	<ul style="list-style-type: none">• Headache• Dizzy• Excessive Salt Consumption• Lack of exercise	76.0% (True)
9	Grace	106	68	Normal	<ul style="list-style-type: none">• Stress• Lack of exercise	40.0% (True)
10	Naufal	124	80	Normal	<ul style="list-style-type: none">• Dizzy• Impaired vision• Smoker• Lack of exercise	60.0% (True)

And the process of detecting the risk of hypertension continued with the selection of symptoms and risk factors of hypertension according to the user's experience. Meanwhile, the results of the detection were stored in a database and displayed on a smartphone (see Table 1). The percentage value of Hypertension Risk was obtained from the equation using the Certainty Factor method which was calculated based on the hypertension risk or the symptoms of hypertension by examined users. The results obtained from calculating the risk of hypertension with the certainty factor method, were manual system followed the results obtained from applications implanted on Android, and the success rate was 100%. Therefore the built system using certainty factor methods could work properly and provide results as expected.

VI. CONCLUSION

The system built for the blood pressure measurement process using MPX5500DP sensor was done by reading pressure changes on the arm cuff that wore by the user using the certainty factor method can give the following conclusions:

1) The certainty factor method is able to detect the risk of hypertension with the equation $CF(n) = CF(x) + CF(y) * (1 - CF(x))$.

2) The Data hypertension risk detection contains in the Firebase Database Real-time displayed successfully on the smartphone.

3) The blood pressure testing gauges conducted on the right arm of 10 users produced an average error value of 2.092% on systolic value readings and 2.977% on diastolic values.

4) The blood pressure testing gauges conducted on the left arm of 10 users produced an average error value of 1,94% on systolic value readings and 2.8% on diastolic values.

5) The application of calculation hypertension risk implanted in android using the certainty factor method can give success results rate 100%.

6) In the subsequent development of hypertension risk detection software, use different methods such as Machine Learning or other Decision Support System methods.

Using API with Logistic Regression Model to Predict Hotel Reservation Cancellation by Detecting the Cancellation Factors

Sultan Almotiri¹, Nouf Alosaimi², Bayan Abdullah³,
College of Computer and Information Systems
Umm Al-Qura Univeristy

Abstract—The aim of establishing hotels is to provide a service activity to its customers with the aim of making a profit. So, for that the cancellations are a key perspective of inn income administration since their effectiveness on room reservation systems. Cancelling the reservation eliminates the outcome. Many expected factors affect this problem. By knowing these factors, the hotel management can make a suitable cancellation policy. This project aims to create an API that can provide a function to predict if a reservation is most likely to cancel or not. That API can integrate with the hotel management systems to evaluate each reservation process with the same parameters. To do this, the study starts by defining the factors using Chi test, correlation to find the effective variables, and coefficient of the variables in the linear regression. And the results that have been found for the factors are: `is_repeated_guest`, `previous_cancellations`, `previous_bookings_not_cancelled`, `required_car_parking_spaces`, and `deposit_type`. For API function, the intercept and coefficients have been used from the logistics regression model to create a scoring function. Scoring function can be calculated by the sum of the factors multiplied by their coefficients in addition to the intercept. This score is to be evaluated as a probability later using the logistic function.

Keywords—Prediction; API; factors; logistics regression

I. INTRODUCTION

The tourism sector in any region is based on a several of constituents and pillars, among them are the availability of tourist facilities and number and quality of services provided by those facilities. Perhaps the most prominent of these facilities, and the most important, is the hotel sector. In numerous tourism goals, the inn industry is regularly the major financial sector [1]. Hotels are defined as those that provide places for accommodation, meals, and other services for visitors in general. Hence, the presence of hotels in countries has become an indispensable thing. Committing room numbers to the diverse reservations could be a day by day action in inns [2]. In hotels, the revenue Management employments data-driven modelling and optimization strategies to choose What, when, whom to offer, and for which cost, in arrange to extend revenue and benefit [3].

The hotel industry is considered as a basic pillar of tourism because it provides services in the field of economy, because of the means of transportation it pumps and because it is a means of obtaining aid for comprehensive development plans in the world. The aim of establishing hotels is to provide a service activity to its customers with the aim of making a profit. Consequently, the cancellations are a key perspective of

inn income administration since their effectiveness on room reservation systems. By means of the e-commerce increases the chance of cancellation since client can effortlessly compare conditions among lodgings and can cancel his/her reservation [4].

Moreover, Lodging cancellation can cause numerous issues on the hospitality industry in numerous perspectives such as affecting hotel's reputation, since clients can be influenced by others' criticism about the inn [5], [6]. A lodging booking cancellation arrangement can depend on a few variables, such as the rate of the booking and the date of check-in. Cancelled by certain date approach, this type of cancellation approach gives travelers the choice to cancel inn reservations free of charge up until a certain date. Once this date passes, inn cancellation approaches can either: Charge a standard cancellation fee require the complete installment for the reservation. One-night penalty policy, for this sort of lodging room cancellation arrangement, inn charges a cancellation expense proportionate to one night's remain at the inn. The prepaid, nonrefundable hotel reservation policy, this sort of inn booking requires installment for the aggregate of the reservation at the time of booking and is nonrefundable. In truth, exceptionally small is known almost the reasons that lead clients to cancel, or how it can be maintained a strategic distance from.

It is more than common in these days to employ computer programs and services to support management and decision taking. The contemporary algorithms and artificial intelligence (AI) techniques encouraged the involvement of automated decision support systems in every business-oriented information system, especially ERP programs, to analyze problems, detect factors, propose solutions, and help in improving or building new strategies using data-driven approaches.

One of the applications of these services is hotel management application. It started as invoices application which developed to include keeping the reservation information. Later, it added automated reservation services. After many reservations, the data can be analyzed to detect reservation problems' factors and expect results.

Cancelling reservation is one of the most common problems in hotel reservation services. Many expected factors affect this problem like the reservation location, the hotel rate, the price offer, and most importantly, the history of the client and his solemnity. The modern techniques can elicit the question of what these factors are based on data-driven analysis and data mining in the reservation records.

The current state of hotel management and reservation systems is interrelated and cooperative. Almost all reservation systems provide API for the third-party reservation systems which promote the offers and spread the popularity of the hotel. This means we have three main stakeholders in the reservation process: the hotel management, the external reservation promotional, and the client. Although the process is automated, it can be improved by implementing data mining and AI techniques to solve the major problems. We still do not have a concrete API that can evaluate each reservation process to control that process accordingly in the matter of price, payments, and priority.

This study aim to provide a technique that can detect the reasons behind reservation cancelling. These reasons are to be evaluated and weighted where they can be used later to evaluate reservations with similar parameter values. This technique is to be shaped in a ready to implement model that specify the inputs, processes, and output of factor detecting processes. The outputs of this technique is a weighted factor rule that will be added to the factors knowledge base to be checked in later reservations.

A. The Motivation

The importance of the study is derived from its function. Reservation imply the fact that the asset will not be usable until that reservation is over which prevent any exploit of that asset. This is acceptable as the expected outcome of that reservation is granted. However, cancelling the reservation prevents the usability of that asset and eliminate the outcome. In hotels, cancelling reservation have a higher impact as it eliminates the main purpose of the business which is renting the rooms. While there are many consequences for reservation canceling, it is better to avoid that cancel in the first place. We can avoid that cancel, or at least measure the risk of cancellation, by knowing the effective factors that results in cancellation. As knowing hotel cancellation factors can be imperative to make strides overbooking and cancellation approaches, which are two exceptionally critical themes in RM investigate [7].

B. The Contribution

This study aim to create an API that can provide a function to predict if a reservation is most likely to cancel or not. To do this, the study starts to define the factors. And the results that have been found of the factors are is repeated guest, previous cancellations, previous bookings not cancelled, required car parking spaces, and deposit type. The model using these factors show precision of 0.86 while the one that uses all the variables shows an average precision of 0.82.

C. The Paper Structure

First, the paper starts with introduction that introduce the problem and the background. Then, related work that present the current work. After that, the methodology followed by the results discussion. Finally, the conclusion for the paper.

II. BACKGROUND AND RELATED WORK

A. Hotel Cancellation Policies

As is known, all the hotels establish a price and conditions or policies for booking. Some of lodgings make the cancel-

lation access tough by limiting the free cancellation windows and/or by setting higher cancellation punishments. Some hotels put some cancellation fees and consider it as an other revenue [8]. In expansion, cancellation arrangements are outlined to influence travelers' booking behaviors in a way that's more alluring or profitable to inns. Furthermore, some hotels use debit or credit card which tends to decrease the possibility of no appears [9].

There are many indications that the searchers for a hotel continues to search for a suitable hotel even after they have booked a hotel in order to search for another hotel that has better policies and a lower price. In the event that a hotel is found that has suitable policies and has a lower price, the researcher cancels the reservation in the previous hotel and rebook the new one. Cancellation approaches exist for the reason to avoid such "switching" behavior [10].

In [11] inspected the effect of diverse sorts of cancellation confinements on lodging guests' reservation choices. Particularly, the consider explored how cancellation due dates and costs impact the vital booking behavior of deal-seeking travelers, advanced-booking. They found out the cancellation due date influenced participants' behavior whereas the estimate of the cancellation expense had no measurably critical affect. In expansion, there was no noteworthy difference between no cancellation approach and cancellation due date.

This considered in [12] that gives experimental prove on how lodging cancellation approaches are changing in later a long time. The discoveries demonstrate that whereas lodgings are testing with stricter cancellation windows, their cancellation punishments don't appear to end up stricter. There discoveries indicate that in spite of the fact that US inns have as of late fixed their free cancellation windows, there's no clear sign that the cancellation punishments have expanded. They found that together with the tightening of cancellation windows, there appears to be a move toward "standardizing" the cancellation punishments.

Indicated a cancellation policy means choosing the terms and conditions that allow booking to be cancelled, and penalization to the clients who cancel a booking or don't appear up at the concurred date. Such penalization is known to have a non-negligible part in income administration of inn chains. In [13] stated that inns that set extensive penalties for cancellation, especially with it gets closer to the arranged entry date point to play down revenue losses. For occurrence, it has become necessary to request reservations with credit card sponsorship, so that in the event that the customer does not show up, a fee for at least one night will be charged.

Lodging cancellation approaches not only affect Income but it also influences consumer behaviors. This consider [14] confirms the fact that big cities have more Free Cancellation Approaches. The reason is twofold. One reason is due to Competition within the markets in these cities. The other reason dues to the fact that small towns have few high-end hotels Which has permissive policies.

The discovery [14] shows that high-end inns tend to have less-strict approaches because maintaining great relationships with their customers is one of the goals of most high-end hotels. A later industry report demonstrates that the cancellation arrangement is conditional based on diverse variables

such as, the larger part of the sort of clients, the area, and the economy situation. For example, amid the subsidence, the tradition lodgings have tighter cancellation arrangements.

Utilizing the proposition-based theorizing within the setting of cancellation approaches, this study provides a few suggestions that seem have wide suggestions for future investigate. In [15], they introduce a theory about hotel cancellation policies that can Future research examine the effect of these policies. One of the policies that they introduce if the tightening cancellation policy might flag solid demand because the inn anticipates to exchange the room effectively notwithstanding of the restrictive policy or a strict cancellation approach might flag frail request because the lodging does not anticipate to exchange the room, and so endeavors to recoup its losses.

B. Predict Hotel Cancellation using Machine Learning

Inn income administration employments machine learning. The lodging industry endures 20% of income due to cancellation. In Addition, the administration cannot gadget strict arrangements of non-cancellation, as the guests/customers might switch to another inn. The machine learning-based estimating employments a neural network [16].

In [17] the authors proposed a forecasting model that forecast the cancellation in hotels. The forecasting model that they have been used was based on artificial intelligence by using personal name records (PNR). This investigate has been created utilizing genuine booking records provided by a lodging accomplice found in Gran Canaria (Spain) with the point of forecasting future cancellations. There approach for forecasting the cancellation in hotels was using 13 independent variables which is a decreased number in comparison with related investigate. For the result, they used three algorithms which were Random forest with 80% of accuracy, Support vector Machine with 75% and GA for ANN with 79%.

As the cancellation effects the reservation system and the income. In [18] they used a Personal Name Records (PNR) for predict hotel cancellation. Their approach differ from other research by aiming to distinguish those people likely to create cancellations in a short-horizon of time through PNR. Their promising comes about have been accomplished with 80% accuracy for cancellations made 7 days in progress. They used a PNR data from inn found in Gran Canaria (Spain). There method gave accuracy 73% for C5.0, SVM 71% ANN 69% Boosting ensemble 80%. This approach endeavors to forecast individual cancellations likely to be made exceptionally near to the section day, from 4 to 7 days in progress, and which can be considered "critical cancellations".

It is conceivable to construct models to anticipate bookings cancellation probability. These models has never been evaluated in a real environment. Consequently, in this paper [19] the author designed a prototype of the prediction model and transferred it to two hotels. First, they developed a trained model that learns from previous reservations to see a pattern of cancellations over time. From a commercial angle, the model demonstrated its applicability, being above 84% in accuracy, 82% in precision. The framework allowed the residences to predict their net demand, thus making better options for which reservations should be acknowledged and rejected, what construction costs would be, and how many rooms to sell.

As well as, reservation cancellations within the hospitality industry not as it were creating income misfortune and influence estimating and inventory allotment choices. Moreover, in overbooking circumstances, have the potential to influence the hotel's online social notoriety. In [20] authors used data from four resort hotel Property Management Systems (PMS) to predict hotel cancellation. The creators reach the accuracy of 90%.

Furthermore, to overcome the negative affect caused by overbooking and the usage of unbending cancellation approaches to manage with booking cancellations. This paper [21] the author used a real data from four resort hotels of the Algarve, Portugal. The author used Boosted Decision Tree, Decision Forest, Decision Jungle, Locally Deep Support Vector Machine, and Neural Network models to predict hotels reservations cancellation. the author got reached accuracy values above 90%, while models of H2 and H3 reaching 98.6% and 97.4%, respectively.

The online booking system in hotels is one of the most important alluring arrangements within the hospitality industry. Cancellation of inn bookings or reservations through the online framework is as of now one of the issues within the inn administration framework. In [22] the authors used a data set from the paper "Hotel Booking Demand Datasets". That been used XGBoost, Catboost, Light Gradient Boosting Machine, and Random Forest. By using CRISP-DM framework, they got about 0.8725 of accuracy in random forest.

Supervised anomaly detection concept is using to predict hotel cancellation. In [23] the authors used a few classification models such as Decision Tree, Gradient Boost, and XGBoost. Moreover, they reached high accuracy which is 86%. Their result appears that in their circumstance, the decision tree calculation, utilizing data sets with the accurately characterized properties, may be an incredible procedure for making prescient models for booking cancellations. These discoveries too affirm Chiang (2007) articulation "as modern trade models keep on rising, the ancient estimating strategies that worked well some time recently may not work well within the future. Confronting these challenges, analysts ought to proceed to create unused and superior estimating methods".

In this paper [24], they indicated the factors that influence the cancellation behavior. The factors that they found out are lead time, country, and season. The timing of booking is vital, with early bookings showing an altogether higher cancellation likelihood. Moreover, they found out that those who booked through agencies are more likely to not cancel their cancellation while those who booked through online or offline are more likely to cancel. The lead time and country effect the reservations which made through online more than offline. The cancellation probability indicated using cluster adjusted standard errors.

In [25] they use the data from eight hotels with few data from other sources (weather, holidays, events, social reputation, and online prices/inventory). Also, they developed a model to predict reservation cancellation in hotels. Moreover, they indicated cancellation drivers. For the drivers, they found out the most important features are country, deposit type, adults, Stays at Weekend Nights, Distribution Channel and Agent. They got 86% of accuracy for XGBoost model.

We still do not have a concrete API that can evaluate each reservation process to control that process accordingly in the matter of price, payments, and priority. This study aim to provide a technique that can detect the reasons behind reservation cancelling. These reasons are to be evaluated and weighted where they can be used later to evaluate reservations with similar parameter values. This technique is to be shaped in a ready to implement model that specify the inputs, processes, and output of factor detecting processes. The outputs of this technique is a weighted factor rule that will be added to the factors knowledge base to be checked in later reservations. In this study, the factors that influence the cancellation have been found are: is repeated guest, previous cancellations, previous bookings not cancelled, required car parking spaces, and deposit type. These factors evaluated using logistics regression. Later, these factors used in API function. Table I indicates the methodology and the results of related work.

C. Logistics Regression

Logistics regression is a statistical model utilizes to Logistic equation conditional probability. In addition, it uses to model a binary dependent variable. Logistic regression is used to predict the likelihood of an event occurring with additional knowledge of the values of variables that can be explained or for that event. This modeling is widely used in commercial and commercial transactions and is one of the modeling methods most applied in the field of learning, as it is classified within the methods of supervised learning.

In order to know the effectiveness of internal control systems to increase the revenue of hotels [26]. As to know the relationship between two variable, they used logistics regression. that been found out some internal control components have positive effect on revenue in hotels such as controlling activity, information, and communication and observing action have positive and critical impact in determining the results. Moreover, checking action contains a more prominent impact on the outcomes than data communication and control action.

Moreover, to know how auxiliary and organizational components impact hotel's probability of creating service/product, process, organizational and promoting advancements. In [27], the authors used responses from 174 hotels Chi-square test was utilized to test the primary theory. An arrangement of different logistic regression investigations was performed to test the connections between the independent variables. This paper gives bits of knowledge almost the nature and degree of advancements within the inn sector. In spite of the fact that generally considered inflexible and non-innovative, around half of the responding lodgings made at slightest one sort of improvement. Most common are service/product and displaying advancements. A hotel's probability of moving forward depends to a incredible degree on fundamental flexibility (non-chain), having an unequivocal advancement strategy.

III. DATA SET

The dataset used for this project is downloaded from Kaggle website. it contains a variety of hotel reservations information collected based on some potential factors. This data set contains booking information for city and resort hotels. These information such as the date of the reservation, length of

stay, number of adults, children, and/or babies, and the number of available parking spaces, among other things. All personally identifying information has been removed from the data.

The dataset contains 32 columns described in their original project¹ as the following:

- hotel: Hotel (H1 = Resort Hotel or H2 = City Hotel)
- is_cancelled: Value indicating if the booking was cancelled (1) or not (0)
- lead_time: Number of days that between the entering

¹<https://github.com/rfordatascience/tidyuesday/blob/master/data/2020/2020-02-11/readme.md>

date of the booking into the PMS and the arrival date

- arrival_date_year: Year of arrival date
- arrival_date_month: Month of arrival date
- arrival_date_week_number: Week number of year for arrival date
- arrival_date_day_of_month: Day of arrival date
- stays_in_weekend_nights: Number of weekend nights (Saturday or Sunday) the guest stayed or booked to stay at the hotel
- stays_in_weeknights: Number of week nights (Monday to Friday) the guest stayed or booked to stay at the hotel
- adults: Number of adults
- children: Number of children
- babies: Number of babies
- meal: Type of meal booked. Categories are presented in standard hospitality meal packages: Undefined/SC – no meal package; BB – Bed & Breakfast; HB – Half board (breakfast and one other meal – usually dinner); FB – Full board (breakfast, lunch and dinner)
- country: Country of origin. Categories are represented in the ISO 3155–3:2013 format
- market_segment: Market segment designation. In categories, the term “TA” means “Travel Agents” and “TO” means “Tour Operators”
- distribution_channel: Booking distribution channel. The term “TA” means “Travel Agents” and “TO” means “Tour Operators”
- is_repeated_guest: Value indicating if the booking name was from a repeated guest (1) or not (0)
- previous_cancellations: Number of previous bookings that were cancelled by the customer prior to the current booking
- previous_bookings_not_cancelled: Number of previous bookings not cancelled by the customer prior to the current booking
- reserved_room_type: Code of room type reserved. Code is presented instead of designation for anonymity reasons
- assigned_room_type: Code for the type of room assigned to the booking. Sometimes the assigned room type differs from the reserved room type due to hotel operation reasons (e.g. overbooking) or by customer request. Code is presented instead of designation for anonymity reasons
- booking_changes: Number of changes/amendments made to the booking from the moment the booking was entered on the PMS until the moment of check-in or cancellation
- deposit_type: Indication on if the customer made a deposit to guarantee the booking. This variable can

assume three categories: No Deposit – no deposit was made; Non Refund – a deposit was made in the value of the total stay cost; Refundable – a deposit was made with a value under the total cost of stay.

- agent: ID of the travel agency that made the booking
- company: ID of the company/entity that made the booking or responsible for paying the booking. ID is presented instead of designation for anonymity reasons
- days_in_waiting_list: Number of days the booking was in the waiting list before it was confirmed to the customer
- customer_type: Type of booking, assuming one of four categories: Contract - when the booking has an allotment or other type of contract associated to it; Group – when the booking is associated to a group; Transient – when the booking is not part of a group or contract, and is not associated to other transient booking; Transient-party – when the booking is transient, but is associated to at least other transient booking
- ADR: Average Daily Rate as defined by dividing the sum of all lodging transactions by the total number of staying nights
- required_car_parking_spaces: Number of car parking spaces required by the customer
- total_of_special_requests: Number of special requests made by the customer (e.g. twin bed or high floor)
- reservation_status: Reservation last status, assuming one of three categories: Cancelled – booking was cancelled by the customer; Check-Out – customer has checked in but already departed; No-Show – customer did not check-in and did inform the hotel of the reason why
- reservation_status_date: Date at which the last status was set. This variable can be used in conjunction with the Reservation Status to understand when the booking was cancelled or when did the customer checked-out of the hotel.

The second column is the dependent variable in this study, while the other columns represents the independent variables as potential factors.

A. Data Wrangling

Start with 31 proposed variables. These included timestamps, details, and status data. For the timestamps, It can be decided what kind of time variables that should be accepted by understanding the logical scope of the problem. In other words, how would time affect the hotel reservation? and what timestamp are we talking about? If that has been considered, there might be some yearly routine that during some period of the year there would be many cancellations, then it does not need to know which year exactly that has been talking about. In addition, this cannot be observed on daily bases. It is convenient to consider the period on weekly and monthly basis. For this, other timestamps can be drooped.

Now, by talking about dates, considering the arriving date in the reservation, not the reservation date, leaving date, nor status date. The other timestamps might be eliminated too. The details of the reservation include information about the hotel, agency, travelers, reservation type, average daily rate, and meals. Any variable considering this reservation is considered as a potential factor. The status is what we are trying to predict and analyze to find its factor, namely, the calculation status. For this, we can consider all other status as not cancelled. We do not need more details about the status. Based on the criteria above, we will drop the following columns:

- lead_time: Unneeded timestamp
- arrival_date_year: Unneeded timestamp
- arrival_date_day_of_month: Unneeded timestamp
- reservation_status: Unneeded status details
- reservation_status_date: Unneeded timestamp

There are missing data in the children field, country field, agent field, and company field. From the data description in the introduction it can be found that it might be gotten the types that needed from the market segment, distribution channel, and customer type and disregard the agent and company columns. So, these two are just dropped. For the children field and country field, it might be filling the missed data with 0 and 'Not' as mark that it was not inserted.

After cleaning, the dataset contains 33,775 duplicates which is more 30% of the dataset. However, these duplicates are not real duplicates. They might be different in term of year, day, or other removed fields. For this reason, no duplicates might be eliminated.

IV. METHODOLOGY

In order to answer the question of this study, the study starting by making an exploratory data analysis. Then, creating a list of the most effective factors. Finally, evaluating what the study has done by implementing prediction model based on the factors that will be found. The EDA includes having an insight of the statistics of the dataset. This insight will help in detecting if any bias occurs. After that the study will evaluate each factor using chi-square test of independence. To create the list of the effective factors, it will calculate the correlation coefficient between all the variables to understand the relationship between the variables. This process might propose eliminating some unrelated variables. Finally, the remaining factors will be used in creating prediction models, and compare these prediction models with same models which included all the eliminated data. Fig. 1 shows the stages for the methodology.

Fig. 1. Stages.

A. Data Analysis

The dataset has total bookings cancelled about 44,224 (37%). Bookings cancelled in resort hotel are 11,122 (28%). While bookings cancelled in a City hotel are 33,102 (42%). We can see the cancellation in the dataset more than 60% as Fig. 2 shows:

Fig. 2. Bookings Cancellation.

The question of this study is what are the main factors of hotel reservation cancelling? From this question it can be hypothetically derived a sub question for each of the other parameters. However, it can be disregarded some parameters logically or practically during data wrangling. To investigate the dataset statistics, the study starts with exploring the numerical variables. Starting with the numerical variables, the following Fig. 3 the histogram that has been found: There

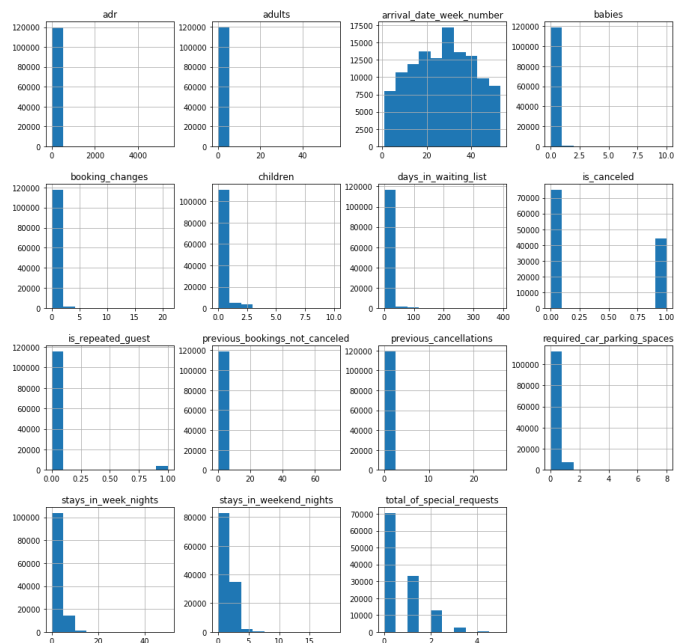

Fig. 3. Histogram of the Variable.

are 15 numerical variables including two of them are Boolean but treated as numerical which are: is_cancelled variable and

is_repeated_guest variable. Numerically, it seems that there are a lot of outliers. Logically, it is understandable that most of the reservation would have adults less than ten for example. it would not consider a reservation for group of 50 is an outlier. This also applies to the average daily rate, babies, and car parking spaces. However, for fields like the booking_changes, previous_booking_not_cancelled, previous_cancellations, stays_in_weeknights, and stays_in_weekend_nights, the concept is the important but not the quantity. This means we might look on the impact of changing booking on the reservation cancellation. This impact would be effective from the first and second change. No need for to look at those of 20 changes. It may combine all more than 5 changes as 5. In other words, the study will decrease the values more than the outlier threshold to the outlier threshold values in these fields. So, by calculating the Outliers based on quartile which is:

interquartile Range

$$IQR = Q3 - Q1$$

threshold range

$$\text{threshold_range} = IQR \times 1.5.$$

It can be seen from Table II the 1.5-based outlier threshold for most of the field is 0. This makes infeasible to use it. According to these results, it can be only used the threshold for stays_in_weekend_nights and stays_in_weeknights fields. For these two fields, we will reduce all outliers to the threshold.

TABLE II. CALCULATING OUTLIERS

Variables	Q1	Q3	IQR	Threshold range
arrival_date_week_number	16.00	38.0	22.00	33.000
stays_in_weekend_nights	0.00	2.0	2.00	3.000
stays_in_weeknights	1.00	3.0	2.00	3.000
adults	2.00	2.0	0.00	0.000
children	0.00	0.0	0.00	0.000
babies	0.00	0.0	0.00	0.000
is_repeated_guest	0.00	0.0	0.00	0.000
previous_cancellations	0.00	0.0	0.00	0.000
previous_bookings_not_cancelled	0.00	0.0	0.00	0.000
booking_changes	0.00	0.0	0.00	0.000
days_in_waiting_list	0.00	0.0	0.00	0.000
ADR	69.29	126.0	56.71	85.065
required_car_parking_spaces	0.00	0.0	0.00	0.000
total_of_special_requests	0.00	1.0	1.00	1.500

B. Factor Extraction

To extract the factors, the study uses chi-square test of independence. For nominated variables, correlation has been used to find the effective variables. After that another test has been added based on the coefficient of the variables in the linear regression.

C. Factors Evaluation

To evaluate the factors, two logistic regression models have been used. One to predict the cancellation based on all variables in the dataset. The other one predicts the cancellation based on the nominated factors. The factorizing process is considered efficient if the precision of the factors model revealed better performance than the all variables model.

Fig. 4. Scatter Plot Matrix.

D. Scoring Function

by assuming that the cancellation process follows a linear equation, the intercept and coefficients have been used from the prediction model to create a scoring function that can calculate the sum of the factors multiplied by their coefficients in addition to the intercept. This score is to be evaluated as a probability later using the logistic function:

$$P(x) = \frac{e^x}{e^x + 1} \quad (1)$$

The result will give the probability of cancellation. If the probability is more than 0.5, the reservation process is more likely to cancel.

E. API Function

The API function is the last function that will use the scouring function to predict if a reservation would likely cancel or not. Its definition would be Boolean cancel (factorsArray). It will return true if the factors indicate probability of cancellations and false otherwise.

V. RESULTS DISCUSSION

For detecting the factors, it can be tried the scatter plot matrix which is used for seeing the connections between combinations of factors. Each scatter plot within the matrix visualizes the relationship between a combine of factors, permitting numerous relationships to be investigated in one chart. Therefore, in this project scatter plot matrix in Fig. 4 has been tried to have an insight about the relationship between the variables:

The scatter plot matrix initially suggests that there might be a relationship between the cancellation and adults' number, babies number. also, it seems that when there are previous cancellations, it is more likely it will cancel, while it might

not cancel with previous uncanceled reservations. There is also relationship with car parking and booking changes.

The study starts by initial evaluation for the factors using chi-square test of independence. The chi test is using for indicating if there is a relationship between tow variables based on the null hypothesis and alternative hypothesis. Null hypothesis assumes that there is no relationship between the two variables while the alternative hypothesis assume there is a relationship between the two variables. So, when the result from chi test less than alpha = 0.05, null hypothesis will be rejected and accept an alternative hypothesis. there are 10 categorical variables. To deal with them, they have been encoded into numerical values. The test shows the following results in Table III:

TABLE III. CHI TEST RESULT

Variable	Chi test result
0	2.78263008e-02
1	2.29104890e-02
2	1.06040302e-01
3	4.42317339e-01

18	5.28838342e-02
19	2.08257569e-02
20	4.67504818e-02
21	2.45671565e-02
22	2.36476367e+01
23	1.77620913e-02
24	2.77362630e-02

The variable number 1 is the ‘is cancelled’ field itself. In general, the test results indicate there is no significant dependency between arrival date month, arrival date week number, stays in week nights, country, market segment, booking changes, and ADR with is cancel variable.

Numerically, the study need to find the correlation between the numerical variables and the dependent variables. Correlation coefficient could be a factual degree of the quality of the relationship between the relative developments of two factors. In the following Table IV the correlation for numerical variable:

The correlation analysis reveals that there is significant correlation at alpha = 0.05 with the following columns: adults, is_repeated_guest, previous_cancellations, previous_bookings_not_cancelled, booking_changes, days_in_waiting_list, required_car_parking_spaces, and total_of_special_requests. At alpha = 0.01, stays_in_weeknights, babies, and ADR are added. The correlation results for the categorical variables in the following Table V:

Based on these results, we will consider the following variables as factors of reservation cancelling: adults, is repeated

TABLE IV. CORRELATION FOR NUMERICAL VARIABLES

guest, previous cancellations, previous bookings not cancelled, booking changes, days in waiting list, required car parking spaces, total of special requests, hotel, country, market segment, distribution channel, assigned room type, deposit type, customer type.

A. Evaluation

The precision defines as the number of true positives divided by the number of true positives plus the number of false positives.

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

For evaluation, two prediction model are created. The one that uses all the variables shows an average precision of 0.82 while the model used the factors shows average precision of 0.85. By exploring the coefficients in the following Table VI and eliminating the insignificant effective variables:

We remain with the following five factors: is_repeated_guest, previous_cancellations, previous_bookings_not_cancelled, required_car_parking_spaces, and deposit_type. The model using these factors show precision of 0.86. The factors are used to create a function that can evaluate these factors and predict if the reservation is more likely to cancel or not. To create this function a scoring function can be started. The intercept and coefficients are rounded to 2 decimal level and used in an equation model. The coefficient values are -0.84, 2.21, -0.76, -6.3, and 2.66. The score is then processed in a logistic function.

Based on the result of the logistic function, the cancel evaluation function returns true if the probability is more 0.5. Otherwise, it returns false. The following Table VII and Table

TABLE VI. COEFFICIENT FOR THE FACTORS

Factors	Coefficient
adults	-0.01
is_repeated_guest	-0.75
previous_cancellations	2.42
previous_bookings_not_cancelled	-0.76
booking_changes	-0.29
days_in_waiting_list	0.0
required_car_parking_spaces	-6.11
total_of_special_requests	-0.37
hotel	0.03
country	-0.0
market_segment	-0.15
distribution_channel	0.6
assigned_room_type	-0.04
deposit_type	2.61
customer_type	-0.37

VIII shows the result from the API function. Based on the result in Table VIII, it seems that there is a probability of cancelling the reservation about 83%. So, the cancel evaluation function gives a true for this reservation.

TABLE VII. EXPERIMENT 1 AFTER USING API

Scoring	7.157
API function result	0.00077
Cancel evaluation function	False

TABLE VIII. EXPERIMENT 2 AFTER USING API

Scoring	1.632
API function result	0.83
Cancel evaluation function	True

Finally, the cancel function can be interfaced in the requested form:
Boolean cancel (factorsArray)

VI. CONCLUSION AND FUTURE WORK

For a future work, it can be considered a data set from hotels in Saudi Arabia. Moreover, API function can be used with the data set that have the same parameters to evaluate it. Because of the unavailability of many data sets that can be used, only this data set was used in this study. Based on the results, the hotel management can consider a good cancellation policy. Furthermore, they can adjust their cancellation policy based on the proprieties that the API function has.

A Technique for Constrained Optimization of Cross-ply Laminates using a New Variant of Genetic Algorithm

Huiyao Zhang¹, Atsushi Yokoyama²

Kyoto, JAPAN

Abstract—The main challenge presented by the design of laminated composite material is the laminate layout, involving a set of fiber orientations, composite material systems, and stacking sequences. In nature, it is a combinatorial optimization problem with constraints that can be solved by the genetic algorithm. The traditional approach to solve a constrained problem is reformulating the objective function. In the present study, a new variant of the genetic algorithm is proposed for the design of composite material by using a mix of selection strategies, instead of modifying the objective function. To check the feasibility of a laminate subject to in-plane loading, the effect of the fiber orientation angles and material components on the first ply failure is studied. The algorithm has been validated by successfully optimizing the design of cross-ply laminate under different in-plane loading cases. The results obtained by this algorithm are better than works in related literature.

Keywords—Laminated composite; classical lamination theory; genetic algorithm; optimal design

I. INTRODUCTION

Composite materials offer improved strength, stiffness, fatigue, corrosion resistance, etc. over conventional materials, and are widely used as materials for applications ranging from the automotive to shipbuilding industry, electronic packaging to golf clubs, and medical equipment to homebuilding. However, the high cost of fabrication of composites is a critical drawback to its application. For example, the graphite/epoxy composite part may cost as much as 650 to 900 per kilogram. In contrast, the price of glass/epoxy is about 2.5 times less. Manufacturing techniques such as sheet molding compounds and structural reinforcement injection molding are used to lower the costs for manufacturing automobile parts. An alternative approach is using hybrid composite materials.

The mechanical performance of a laminate composite is affected by a wide range of factors such as the thickness, material, and orientation of each lamina. Because of manufacturing limitations, all these variables are usually limited to a small set of discrete values. For example, the ply thickness is fixed, and ply orientation angles are limited to a set of angles such as 0, 45, and 90 degrees in practice. So the search process for the optimal design is a discrete optimization problem that can be solved by the GA. To tailor a laminate composite, the GA has been successfully applied to solve laminate design problems [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11]. The GA simulates the process of natural evolution, including selection, crossover, and mutation according to Darwin's principle of "survival of the fittest". The known advantages of GAs are the following: (i) GAs are not easily trapped in local optima and can obtain the global optimum. (ii) GAs do not need

gradient information and can be applied to discrete optimization problems. (iii) GAs can not only find the optimal value in the domain but also maintain a set of optimal solutions. However, the GA also has some disadvantages, for example, the GA needs to evaluate the target functions many times to achieve optimization, and the cost of the search process is high. The GA consists of some basic parts, the coding of the design variable, the selection strategy, the crossover operator, the mutation operator, and how to deal with constraints. For the variable design part, there are two methods to deal with the representation of design variables, namely, binary string and real value representation [1], [4], [12], [13]. Michalewicz [14] claimed that the performance of floating-point representation was better than binary representation in the numerical optimization problem. Selection strategy plays a critical role in the GA, which determines the convergence speed and the diversity of the population. To improve search ability and reduce search costs, various selection methods have been invented, and they can be divided into four classes: proportionate reproduction, ranking, tournament, and genitor(or "steady state") selection. In the optimization of laminate composite design, the roulette wheel [1], [15], where the possibility of an individual to be chosen for the next generation is proportional to the fitness. Soremekun et al. [16] showed that the generalized elitist strategy outperformed a single individual elitism in some special cases.

The data structure, repair strategies, and penalty functions [17] are the most commonly used approaches to resolve constrained problems in the optimization of composite structures. Symmetric laminates are widely used in practical scenarios, and data structures can be used to fulfill symmetry constraints, which consists of coding half of the laminate and considering the rest with the opposite orientation. Todoroki [4] introduced a repair strategy that can scan the chromosome and repair the gene on the chromosome if it does not satisfy the contiguity constraint. The comparison of repair strategies in a permutation GA with the same orientation was presented by Liu et al. [5], and it showed that the Baldwinian repair strategy can substantially reduce the cost of constrained optimization. Haftka and Todoroki [1] used the GA to solve the laminate stacking sequence problem using a penalty function subject to buckling and strength constraints.

In typical engineering applications, composite materials are under very complicated loading conditions, not only in-plane loading but also out-of-plane loading. Most of the studies on the optimization of the laminate composite material minimized the thickness [18], [7], weight [19], [20], [21], and cost and weight [20], [22], or maximized the static strength of the composite laminates for a targeted thickness [7], [8], [23],

[24]. In the present study, the cost and weight of laminates are minimized by modifying the objective function.

To check the feasibility of a laminate composite by imposing a strength constraint, failure analysis of a laminate is performed by applying suitable failure criteria. The failure criteria of laminated composites can be classified into three classes: non-interactive theories (e.g. maximum strain), interactive theories (e.g. Tsai-wu), and partially interactive theories (e.g. Puck failure criterion). Previous researchers adopted the first-ply-failure approach using Tsai-wu failure theory [25], [26], [19], [27], [28], [29], [22], [30], Tsai-Hill [31], [32], the maximum stress [33], or the maximum strain [33] static failure criteria. Akbulut [11] used the GA to minimize the thickness of composite laminates with Tsai-Hill and maximum stress failure criteria, and the advantage of this method is it avoids spurious optima. Naik et al. [34] minimized the weight of laminated composites under restrictions with a failure mechanism-based criterion based on the maximum strain and Tsai-wu. In the present study, Tsai-wu Static failure criteria are used to investigate the feasibility of a laminate composite.

II. CLASSICAL LAMINATION THEORY

A laminate structure consists of multiple laminae bonded together through their thickness. Considering a laminate composite plate that is subject to in-plane loading of extension, shear, bending, and torsion, the classical lamination theory (CLT) is taken to calculate the stress and strain in the local and global axes of each ply, as shown in Fig. 1. Based on fiber orientation, material, and fiber thickness, there are a few special cases of laminate: the set of fiber angles in Fig. 2 only includes 0 and 90, which is called cross-ply laminate.

A. Stress and Strain in Lamina

For a single lamina, the stress-strain relation in local axis 1-2 is:

$$\begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{bmatrix} = \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{bmatrix}, \quad (1)$$

where Q_{ij} are the stiffnesses of the lamina that are related

Fig. 1. Local and Global Axes of an Angle Lamina.

Fig. 2. Model for Cross-ply Laminate.

to engineering elastic constants given by

$$\begin{aligned} Q_{11} &= \frac{E_1}{1 - \nu_{12}\nu_{21}}, \\ Q_{22} &= \frac{E_2}{1 - \nu_{12}\nu_{21}}, \\ Q_{66} &= G_{12}, \\ Q_{12} &= \frac{\nu_{21}E_2}{1 - \nu_{12}\nu_{21}}, \end{aligned} \quad (2)$$

where $E_1, E_2, \nu_{12}, G_{12}$ are four independent engineering elastic constants, which are defined as follows: E_1 is the longitudinal Young's modulus, E_2 is the transverse Young's modulus, ν_{12} is the major Poisson's ratio, and G_{12} is the in-plane shear modulus.

Stress strain relation in the global x-y axis:

$$\begin{bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{bmatrix} = \begin{bmatrix} \bar{Q}_{11} & \bar{Q}_{12} & \bar{Q}_{16} \\ \bar{Q}_{12} & \bar{Q}_{22} & \bar{Q}_{26} \\ \bar{Q}_{16} & \bar{Q}_{26} & \bar{Q}_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x \\ \varepsilon_y \\ \gamma_{xy} \end{bmatrix}, \quad (3)$$

where

$$\begin{aligned} \bar{Q}_{11} &= Q_{11}c^4 + Q_{22}s^4 + 2(Q_{12} + 2Q_{66})s^2c^2, \\ \bar{Q}_{12} &= (Q_{11} + Q_{22} - 4Q_{66})s^2c^2 + Q_{12}(c^4 + s^4), \\ \bar{Q}_{22} &= Q_{11}s^4 + Q_{22}c^4 + 2(Q_{12} + 2Q_{66})s^2c^2, \\ \bar{Q}_{16} &= (Q_{11} - Q_{12} - 2Q_{66})c^3s - (Q_{22} - Q_{12} - 2Q_{66})s^3c, \\ \bar{Q}_{26} &= (Q_{11} - Q_{12} - 2Q_{66})cs^3 - (Q_{22} - Q_{12} - 2Q_{66})c^3s, \\ \bar{Q}_{66} &= (Q_{11} + Q_{22} - 2Q_{12} - 2Q_{66})s^2c^2 + Q_{66}(s^4 + c^4). \end{aligned} \quad (4)$$

The c and s denote $\cos\theta$ and $\sin\theta$, respectively.

The local and global stresses in an angle lamina are related to each other through the angle of the lamina θ

$$\begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{bmatrix} = [T] \begin{bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{bmatrix} \quad (5)$$

where

$$[T] = \begin{bmatrix} c^2 & s^2 & 2sc \\ s^2 & c^2 & -2sc \\ -sc & sc & c^2 - s^2 \end{bmatrix}. \quad (6)$$

B. Stress and Strain in a Laminate

$$\begin{bmatrix} N_x \\ N_y \\ N_{xy} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x^0 \\ \varepsilon_y^0 \\ \gamma_{xy}^0 \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{16} \\ B_{11} & B_{12} & B_{16} \\ B_{16} & B_{26} & B_{66} \end{bmatrix} \begin{bmatrix} k_x \\ k_y \\ k_{xy} \end{bmatrix} \quad (7)$$

$$\begin{bmatrix} M_x \\ M_y \\ M_{xy} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} & B_{16} \\ B_{12} & B_{22} & B_{26} \\ B_{16} & B_{26} & B_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x^0 \\ \varepsilon_y^0 \\ \gamma_{xy}^0 \end{bmatrix} + \begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{11} & D_{12} & D_{16} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} \begin{bmatrix} k_x \\ k_y \\ k_{xy} \end{bmatrix}$$

N_x, N_y - normal force per unit length

N_{xy} - shear force per unit length

M_x, M_y - bending moment per unit length

M_{xy} - twisting moments per unit length

ε^0, k - mid-plane strains and curvature of a laminate in x-y coordinates

The mid-plane strain and curvature is given by

$$\begin{aligned} A_{ij} &= \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k - h_{k-1}) \quad i = 1, 2, 6, j = 1, 2, 6, \\ B_{ij} &= \frac{1}{2} \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k^2 - h_{k-1}^2) \quad i = 1, 2, 6, j = 1, 2, 6, \\ D_{ij} &= \frac{1}{3} \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k^3 - h_{k-1}^3) \quad i = 1, 2, 6, j = 1, 2, 6, \end{aligned} \quad (8)$$

where the [A], [B], and [D] matrices are called the extensional, coupling, and bending stiffness matrices.

III. FAILURE THEORY

A. Failure Process

A laminate will fail under increasing mechanical loading; however, the procedure of laminate failure may not be catastrophic. In some cases, some layers fail first, and the rest are able to continue to take additional loading until all the plies fail. A ply is fully discounted when a ply fails; then, the ply is replaced by a near-zero stiffness and strength. The procedure for finding the first ply failure in the present study follows the fully discounted method:

- 1) Compute the reduced stiffness matrix [Q] referred to as the local axis for each ply using its four engineering elastic constants E_1, E_2, E_{12} , and G_{12} .
- 2) Calculate the transformed reduced stiffness $[\bar{Q}]$ referring to the global coordinate system (x, y) using the reduced stiffness matrix [Q] obtained in step 1 and the ply angle for each layer.
- 3) Given the thickness and location of each layer, the three laminate stiffness matrices [A], [B], and [D] are determined.
- 4) Apply the forces and moments, $[N]_{xy}, [M]_{xy}$ solve Equation 7, and calculate the middle plane strain $[\sigma^0]_{xy}$ and curvature $[k]_{xy}$.
- 5) Determine the local strain and stress of each layer under the applied load.
- 6) Use the ply-by-ply stress-strain and related failure theories to determine the strength ratio.

B. Tsai-wu Failure Theory

Many different theories about the failure of an angle lamina have been developed for a unidirectional lamina, such as the maximum stress failure theory, maximum strain failure theory, Tsai-Hill failure theory, and Tsai-Wu failure theory. The failure theories of a lamina are based on the stresses in the local axes in the material. There are four normal strength parameters and one shear stress for a unidirectional lamina. The five strength parameters are:

$(\sigma_1^T)_{ult}$ = ultimate longitudinal tensile strength

$(\sigma_1^C)_{ult}$ = ultimate longitudinal compressive strength

Fig. 3. Traditional GA Model.

$(\sigma_2^T)_{ult}$ = ultimate transverse tensile strength

$(\sigma_2^C)_{ult}$ = ultimate transverse compressive strength

$(\tau_{12})_{ult}$ = and ultimate in-plane shear strength

In the present study, Tsai-wu failure theory is taken to decide whether a lamina fails, because this theory is more general than the Tsai-Hill failure theory, which considers two different situations, the compression and tensile strengths of a lamina. A lamina is considered to fail if

$$\begin{aligned} H_1\sigma_1 + H_2\sigma_2 + H_6\tau_{12} + H_{11}\sigma_1^2 + H_{22}\sigma_2^2 \\ + H_{66}\tau_{12}^2 + 2H_{12}\sigma_1\sigma_2 < 1 \end{aligned} \quad (9)$$

is violated, where

$$SR = \frac{\text{Maximum Load}}{\text{Load Applied}} \quad (10)$$

The maximum load refers to that can be applied using Tsai-wu failure theory.

IV. GENETIC ALGORITHM MODEL

The genetic algorithm starts with multiple individuals with limited chromosome lengths, in which maybe none of these individuals fulfill the constraints. The GA is assumed to derive appropriate offspring based on the initial population as the GA continues. The traditional way to handle the constrained search of the GA is either to introduce repair strategies or to use a penalty function. Fig. 3 shows the classic flow chart of a GA framework, which includes selection, crossover, and mutation operators. However, GA is originally proposed to solve unconstrained problems; therefore, we suggest a new approach to address the constrained GA search problem in an unconstrained way.

Because of the existence of constraints, the population not only can be sorted by the fitness (obtained by the objective function) but also sorted by the constraint value obtained by the constraint function (assuming a constraint function exists), so the parents of the next generation can be chosen by the

following three approaches. First, the population is sorted by fitness in ascending order, and individuals with smaller fitness are selected. These selected individuals form a group named as a proper group. Second, remove individual which satisfies constraints, and sort population by the difference between the individual's constraint value and the threshold of the constraint in descending order, and individuals with bigger differences are chosen to be the parents of the next generation. The group which forms are called potential group, and an individual from this group is referred to as a potential individual. Third, the population is sorted by fitness from low to high after removing individuals which fail to fit the constraints, select individuals with bigger fitness, and these individuals form the proper group. So the final parents' pool consists of three groups, active group, potential group, and proper group. The number of active individuals, potential individuals, and proper individuals are called, respectively, active number, potential numbers, and proper number.

Each group in the parents' population has its role in the searching process. The problem within traditional GA is premature and has weak local search ability, therefore, traditional GAs are more likely to get stuck in a local optimum. To prevent the GA from experiencing early convergence and to improve the local search performance, the active group is proposed to overcome this problem. As its name suggests, this group would always live in the population. Because both active individual's fitness and constraint value are small, each individual can be treated as an independent gene clip. So their existence enriches the gene clip variety of the mating pool. The offspring of two active individuals are more likely to be active individuals, which can maintain the active group.

For an individual in the potential group, it doesn't satisfy the constraint, however, it's supposed to evolve into a proper individual after multiple generations by modifying its chromosome structure or length. The crossover operation could happen between a potential individual with an active individual, or a potential individual, or a proper individual. The child of an active individual and a potential individual is more likely to be a potential individual, and this active individual could inject a new gene clip into this potential individual, therefore providing a new evolution direction.

A proper individual means a feasible solution, which fulfills all the constraints. However, there are still some drawbacks within it, for example, its fitness is low. The crossover operation could happen between a proper individual and any other individuals.

The mutation operator for an active group is different from the potential group and proper group because their roles in the searching process are different: the target of the potential group and proper group is to obtain a feasible solution; however, the role of the active group is to maintain the variety of gene clips in the mating pool.

Fig. 4 shows the flow chart of the proposed GA. First, the population is divided into three groups, active group, potential group, and proper group by the above-mentioned method. Second, select an appropriate number of individuals from each group as parents, and the various selection scheme can be taken for each group.

The searching process can be divided into two phases according to whether proper individuals are generated or not. During the initial stage, no individual in the population is appropriate, which means the number of individuals in the proper group is zero. Both active group and potential group

are full. After a couple of generations, some proper individuals could be produced. Then, the GA comes to its second phase, the number of proper individuals begins to increase, finally, the number in the proper group reaches its upper bound.

V. EXPERIMENT

First, we formulate a constrained problem by searching the optimal stacking sequence of cross-ply laminate under in-plane loading under the constraint whose strength ratio is not less than two. Each lamina dimensions $1000 \times 1000 \times 0.165mm^3$ is adopted in this experiment, each graphite/epoxy, and glass/epoxy layer is assumed to cost 2.5 and 1 monetary unit, respectively. The other material properties are shown in Table I.

TABLE I. COMPARISON OF THE GRAPHITE/EPOXY AND GLASS/EPOXY PROPERTIES

Property	Symbol	Unit	Graphite/Epoxy	Glass/Epoxy
Longitudinal elastic modulus	E_1	GPa	181	38.6
Transverse elastic modulus	E_2	GPa	10.3	8.27
Major Poisson's ratio	ν_{12}		0.28	0.26
Shear modulus	G_{12}	GPa	7.17	4.14
Ultimate longitudinal tensile strength	$(\sigma_1^T)_{ult}$	MPa	1500	1062
Ultimate longitudinal compressive strength	$(\sigma_1^C)_{ult}$	MPa	1500	610
Ultimate transverse tensile strength	$(\sigma_2^T)_{ult}$	MPa	40	31
Ultimate transverse compressive strength	$(\sigma_2^C)_{ult}$	MPa	246	118
Ultimate in-plane shear strength	$(\tau_{12})_{ult}$	MPa	68	72
Density	ρ	g/cm^3	1.590	1.903
Cost			2.5	1

A. Problem Formulation

In the present experiment, the optimal composite sequences, and the number of layers for a targeted strength

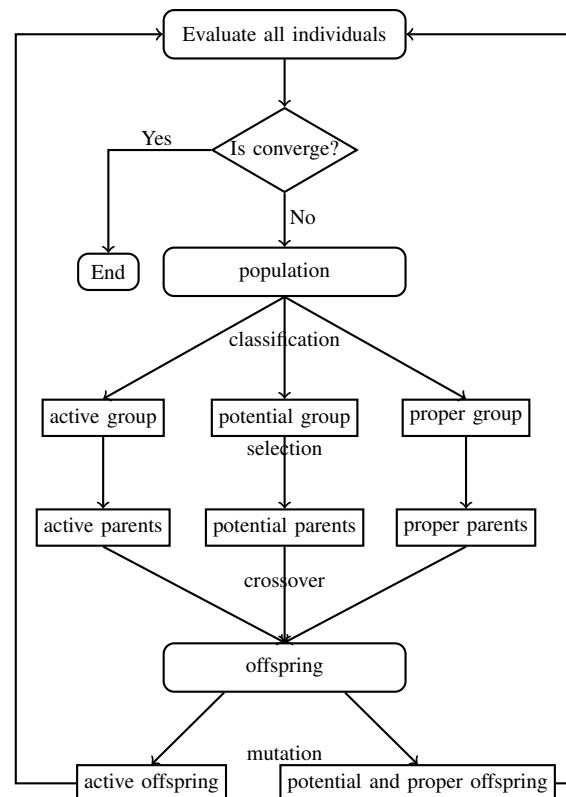

Fig. 4. General Flowchart of Proposed GA Model in which the Parents consist of three Different Groups.

ratio under in-plane loading conditions are investigated. The aim is to minimize the mass of a laminate composite for a targeted strength ratio based on the Tsai-wu failure theory. The design variables are the ply angles and the number of layers. Ply orientation restricted to a discrete set of angles (0, and 90 degrees). The problem can be formulated as the following equation:

Find: $\{\theta_k, n\} \theta_k \in \{0, 90\}$,
 Minimize: weight,
 Subject to: strength ratio.

B. GA Operation

In the present study, floating encoding is adopted to represent a solution for the layup design of cross-ply laminate. Fig. 5(a) shows two parents P_1 and P_2 represent two cross-ply laminates, the corresponding laminates layups are $[0_3/90_7]$ and $[0_6/90_4]$, respectively; Fig. 5(b) shows two offspring of parents P_1 and P_2 are consist of half of each parent’s chromosome; Fig. 5(c) and 5(d) display the offspring after length and angle mutation, respectively.

For the length mutation of chromosome, calculate the chromosome’s strength ratio based on its sequence, if its strength ratio is less than the threshold, then increase its length; otherwise, reduce it. We introduce the term length mutation coefficient to control the length mutation. As shown in Fig. 5(b), the strength ratio of O_1 chromosome is 0.0854, and the strength ratio threshold is five. Suppose the length mutation coefficient takes two, then the corresponding increase length is the multiplication result of length mutation coefficient and the difference between current strength ratio and the threshold: the result is $5 \times (2 - 0.0854)$, round this number to its closest integer, which is 9. So the length of offspring O_1 changes from 10 to 19 after length mutation. For the angle mutation, randomly swap the gene from 0 to 90 in the chromosome, or the otherwise.

Fig. 5. Examples of Crossover, Length Mutation, Angle Mutation Operator for Proposed GA.

Fig. 6. Percentage of Active Individuals from Active Group, Potential Individuals from Potential Group, and Proper Individuals from Proper Group in Parent Population.

C. GA Parameters

Table II shows related GA parameters: the population is 40, and 50 percent is as the mating pool, so the parent population is 20; as shown in Fig. 6, the percentage of active individuals from the active group, potential individuals from the potential group, and proper individuals from the proper group are 0.3, 0.3, and 0.4, which means the corresponding number of these three types of individuals are 6, 6, and 8, respectively.

VI. NUMERICAL RESULTS AND DISCUSSION

To figure out how the number of individuals in each group varies during the GA process, we conduct a one-time experiment and show the number of individuals in each generation with respect of GA generation. Second, to verify its performance and stability, the GA is run one hundred times: the best, worst case, and average results are presented, respectively. Finally, we compare the results with the work in the other literature.

TABLE II. PARAMETERS OF PROPOSED GA MODEL

Parameter	Value
Population	40
Initial length range	[3-15]
Encoding	Integer
Percentage of parent	0.5
Percentage of active group	0.3
Percentage of potential group	0.3
Percentage of proper group	0.4
Selection strategy for active group	Ranking
Selection strategy for potential group	Ranking
Selection strategy for proper group	Ranking
Crossover strategy	One-point
Mutation strategy	Mass mutation
Length mutation coefficient	5
Angle mutation rate	0.1
Crossover rate	0.3

Fig. 7 shows the number of individuals in each group during the one-time GA process. For both active group and potential group, the number of individuals is fixed, and equal to its upper bound from the beginning to the end of the searching process. However, for the proper group, at the initial stage of GA, no individual fulfills the constraint, so the number of proper individuals is zero. As seen from Fig. 7, after forty generations, proper individuals appear, and its population increases very quickly up to its upper bound.

There are two approaches that the GA could obtain a better solution: the first is increasing the length of the chromosome; the second one is adjusting the internal structure of a chromosome. The GA process can be divided into two phases by whether there are proper individuals or not. Fig. 8 shows the GA process in which the dashed vertical line is the watershed between the initial phase and the last phase. In the initial phase, no individual's strength ratio is over the specified threshold, and the main reason that the fitness gets smaller gradually is the increase of chromosome's length; At point 1 on the fitness curve, the fitness suddenly goes up, however, the corresponding strength ratio of point 1, denoted by the point 1' on the generation-strength ratio curve, also increases. it is because of the adjustment of a chromosome's layup. Then GA comes to its second phase. During this phase, the GA already found proper individuals which could satisfy the constraint, so the target in this stage is to improve fitness. This means GA needs to adjust its inner structure, at the point 2 and 3 on the generation-fitness curve, the fitness curves go up, and the corresponding strength ratio of these two points slightly go down, but both of them still satisfy the constraint.

Table III shows the searching results after conducting this experiment one hundred times in two length mutation coefficient cases for glass-epoxy and graphite-epoxy material, respectively. The best, worst case, and average experiment results are showed in this table. For the glass-epoxy material, if the length mutation coefficient takes one, the best and worst sequences are $[0_{40}/90_{26}]_s$, $[90_{24}/0_{38}/90]_s$; the average mass, cost, and the number of layers are 7.83, 123, 123. If we increase its length mutation coefficient, suppose it is five, the number of layers for best and worst cases are 125 and 136; the average mass, cost, and number of layers are 8.55, 131, 131. When graphite-epoxy is taken as the experiment

Fig. 7. Number of Individuals in Each Group as a Function of Generation.

b

TABLE III. THE OPTIMUM LAYUP FOR THE LOADING $N_x = 1e^6$ N WHEN CHANGING THE LENGTH MUTATION COEFFICIENT, THE PERFORMANCE OF THE GA CAN BE IMPROVED WHEN THE LENGTH MUTATION COEFFICIENT IS SMALLER.

Length mutation coefficient	Material	case	Stacking sequence	Strength ratio	Mass	Cost	Layer
1	glass-epoxy	worst	$[0_{40}/90_{26}]_s$	2.010	8.58	132	132
		best	$[90_{24}/0_{38}/90]_s$	2.078	8.12	125	125
		average		2.012	7.83	123	123
	graphite-epoxy	worst	$[0_{09}/90_{14}/0]_s$	2.17	1.41	68	27
		best	$[0_{09}/90_{11}/0]_s$	2.15	1.10	53	21
		average		2.018	1.47	70	28
5	glass-epoxy	worst	$[0_{36}/90_{32}]_s$	2.009	8.84	136	136
		best	$[0_{36}/90_{26}/90]_s$	2.003	8.12	125	125
		average		2.008	8.55	131	131
	graphite-epoxy	worst	$[0_{09}/90_{12}]_s$	2.006	2.20	105	42
		best	$[0_{08}/90_{3}/0]_s$	2.001	1.20	57	23
		average		2.022	1.54	73	29

material, similar experiment results are found. Comparing these two results, we see that a bigger value of length mutation coefficient can improve this GA's performance. This is because the mutation coefficient can control both the convergence speed and search performance, a small mutation coefficient would slow the convergence speed, however, it would lead to small-grained exploitation in the local space.

Table IV shows the optimal cross-ply sequences by the proposed GA and Choudhury and Mondal's [30] study. For the loading case $N_x = 1$ MPa m, the optimal layups are a $[0_{68}/90_{72}]$ cross-ply laminate if glass-epoxy is taken; however, in the present study, a $[90_{24}/0_{38}/90]_s$ glass-epoxy cross-ply laminate is found which significantly reduces both the cost and weight, and it satisfies the constraint. Similarly, if graphite-epoxy is taken, compared with the $[0_{17}/90_{18}]$ cross-ply laminate, an alternative solution is found, its layup is $[0_{09}/90_{11}/0]_s$. For both cases, we can see that the experiment results show that using the present proposed GA can obtain better results.

Fig. 8. The Fitness is the Negation of the Individual's Mass. The Solid Curve is the Fitness of the Best Individual in the Population in Respect to the Generations; and the Dotted Line Denotes its Corresponding Strength Ratio. If no Individuals in the Population Satisfy the Constraint, the best Individual is the one with the Biggest Strength Ratio; if not, the best Individual is the one with the Smallest Mass.

TABLE IV. COMPARISON OF EXPERIMENT RESULTS OF CHOUDHURY AND MONDAL'S [30] AND CURRENT STUDY UNDER IN-PLANE LOADING $N_x = 1e6$ N. THE RESULTS OF PRESENT STUDY IS FROM PREVIOUS EXPERIMENT.

Cross Ply [$0_M/90_N$]	Choudhury and Mondal's study		Present study	
	Glass-Epoxy	Graphite-Epoxy	Glass-Epoxy	Graphite-Epoxy
Material

SR	2.01	2.10	2.078	2.15
weight	9.10	1.84	8.12	1.10
cost	140	87.5	125	53

VII. CONCLUSIONS

In this paper, we reviewed the use of the proposed genetic algorithm framework, classical lamination theory, and Tsai-Wu failure theory for the layup design for cross-ply laminate under different loading cases. The principal applications of this genetic algorithm are in the design of composite laminate material with imposed constraints.

The main contribution of the present work is the genetic algorithm framework for constrained problems since the traditional genetic algorithm is primarily concerned with solving the unconstrained problem, which is not suitable for a constrained case. We deal with these constrained problems by the use of mixing strategies of selection methods instead of adding any punishment terms into the objective function. The performance of this algorithm is heavily influenced by the coefficient of the length mutation. Both for the glass-epoxy and graphite-epoxy material cases, if the coefficient takes a relatively low value, this algorithm can obtain better results than when the coefficient value is high. However, The algorithm converged more quickly with a high coefficient value of length mutation.

This variant of the genetic algorithm provides a new approach to address the constrained search, and this method can be easy to apply in other domains. A drawback of the proposed genetic algorithm is more parameters involving in this GA, which makes fine-tuning more difficult.

Abstract—Many small and large industries use robot arms to establish a range of tasks such as picking and placing, and painting in today's world. However, to complete these tasks, one of the most critical problems is to obtain the desired position of the robot arm's end-effector. There are two methods for analyzing the robot arm: forward kinematic analysis and inverse kinematic analysis. This study aims to model the forward and inverse kinematic of an open-source 4 degrees of freedom (DoF) articulated robotic arm. A kinematic model is designed and further evaluated all the joint parameters to calculate the end-effector's desired position. Forward kinematic is simple to design, but as for the inverse kinematic, a closed-form solution is needed. The developed kinematic model's performance is assessed on a simulated robot arm, and the results were analyzed if the errors were produced within the accepted range. At the end of this study, forward kinematic and inverse kinematic solutions of a 4-DoF articulated robot arm are successfully modeled, which provides the theoretical basis for the subsequent analysis and research of the robot arm.

Keywords—Robot arm; kinematic analysis; forward kinematic; inverse kinematic; open-source

I. INTRODUCTION

A robot arm is made up of a movable chain of links that are linked together by joints. A hand or end-effector that can move freely in space is typically connected to one end, which is fixed to the ground. Robot arms are capable of performing repetitive tasks at speeds and precision well above those of human operators. Robot arms are used in various fields requiring high precision, for instance medical, industry, and some hazardous places. However, controlling the robot arm has been challenging with a higher degrees of freedom (DoF). Position analysis and trajectory planning of robot arm is an essential step in design and control.

Robotics research has gotten much traction over the years, thanks to advances in robot technology and the growing use of robotics in various fields. The robotics researchers have been focusing on more current configurations, intelligent actions, autonomous robotics, and high-level intelligence. All of these areas are related to robot kinematic, both forward and inverse. However, there are no excellent universal algorithms for producing the forward and inverse kinematic of a robot arm, especially finding the correlation between both kinematic models. The problem involves an error in achieving an accurate correlation between the forward and the inverse kinematic of a robot arm [1], [2], [3], [4], [5], [6], [7], [8], [9]. To plan an accurate robot arm's movement, we have to understand the relationship between the forward and inverse kinematic of the actuators to control the robot's resulting position in an accurate manner. Hence, there remains a scope to investigate further and work towards finding better solutions.

This study aims to develop a suitable methodology for solving the forward and inverse kinematic problem for a 4-DoF articulated robotic manipulator with relative ease. A kinematic model with an accurate correlation between the forward and inverse kinematics of a 4-DoF articulated robotic manipulator is developed using MATLAB software. The performance of the developed kinematic model is assessed and evaluated in Robot Operating System (ROS) on Ubuntu. The robot arm assessed in this research is the OpenMANIPULATOR-X robot arm manufactured by Robotis, which is an open-source robotic platform.

A. Kinematic Modeling

Kinematic is a branch of mechanics that studies the motion of bodies and structures without taking force into account. Geometry is used to research the movement of multi-DoF kinematic chains that make up the robot arm's structure. The relationship between the robot arm's linkages and its position, orientation, and acceleration is studied in robot kinematics. Kinematic analysis is an effective method when planning the robot arm's trajectory can be divided into two types: forward kinematic and inverse kinematic.

Forward kinematic refers to using the kinematic equations of a robot arm to compute the position of the end-effector's frame and joint variables relationship. Meanwhile, inverse kinematic is the reverse process that calculates the joint parameters that achieve an end-effector's position. The reverse operation, on the other hand, is much more challenging in general. The reverse operation is, in general, much more challenging. Forward kinematic has a simple and straightforward solution if compared with the inverse kinematic solution, which has many equations with a highly complex form to be solved [10].

In robotics, the inverse kinematic approach uses the kinematic equations to find the joint parameters that give each of the robot arm's end-effectors the desired configuration (position and rotation). Motion planning determines the robot arm's movement so that its end-effectors move from an initial configuration to the desired configuration. Inverse kinematic transforms the motion plan into joint actuator trajectories for the robot arm. Forward kinematic measures the chain's configuration using joint parameters, while inverse kinematic reverses this calculation to find the joint parameters that achieve the desired configuration [11].

B. Mechanism of Robot Arm

A robot arm can be either serial configuration with an open-loop structure or parallel configuration with a closed-loop structure. The joint type for an industrial robot arm can

be revolute or prismatic, and the link type can be rigid or flexible. Furthermore, a hybrid structure comprising both open and closed-loop mechanical chains is possible. The serial robot arm is characterized by the fact that the first joint is always starting from the fixed base and the end of the chain is free to move in space. Several different configurations of the robot arm can be formed due to the revolute and prismatic joints, and the axes of two adjacent joints can be either parallel or orthogonal. Orthogonal joints intersect by 90° with respect to their common normal, and it can be parallel when one axis rotates 90° [12]. Some of the robot arm mechanisms arise from open, closed, and hybrid open and closed kinematic chains.

In addition, the DoF can be defined as the particular motion of links related to any mechanism or machine. When performing a specific task, the DoF often plays an important role. The total number of DoF is always equal to the number of independent displacements of links. The number of DoF permitted by a joint and their characteristics can be determined by the design constraints of the body or link.

C. Articulated Robot Arm

The articulated robot arm is a robot arm with revolute joints and is also called a revolute, or anthropomorphic robot arm. The anthropomorphic resembles the human arm's design, including shoulder, elbow, and wrist joints [13]. The articulated robot arm can range from a simple two-joints structure to systems with 10 or more interacting joints [14]. The configuration of a 4-DoF articulated manipulator is shown in Fig. 1.

Fig. 1. Configuration of a 4-DoF Articulated Robot Arm.

D. Denavit-Hartenberg (D-H) Convention

In the Denavit-Hartenberg (D-H) convention, the link notation can describe the spatial relationship between two relative joints. The frame that connects with another joint has a relationship to the position and geometry with another joint. Fig. 2 shows that the link parameters are α_i and a_i , and the joint offset (d_i) is fixed to provide the manipulator configuration. This configuration achieves a specific posture using n of θ_i [15]. The posture of every configuration or end-effector can be changed if the value of θ_i changes.

Once the link frame has been set, the position and orientation of the i -frame in relation to $i - 1$ are completely

Fig. 2. Definition Parameters of a Robot Arm [15].

defined using four parameters, known as the D-H parameters. The parameters taken are as follows:

- 1) Joint offset, d_i : This parameter is the intersection point's length at the common normal line on the z_i joint axis. The measured value is at a distance between x_i and x_{i+1} , which is measured along z_i .
- 2) Joint angle, θ_i : This parameter is the angle between the orthogonal projection on the common normal line, x_i and x_{i+1} , and the normal plane to the z_i joint axis. The rotation direction is closely related to the parameter value; when the rotation is counterclockwise, it is positive. This parameter is taken at degrees between x_i and x_{i+1} , measured approximately z_i .
- 3) Link length, a_i : This parameter is taken at the distance of the common normal to z_i and z_{i+1} , measured along x_{i+1} .
- 4) Twist angle, α_i : This parameter is the angle between the orthogonal projections on the axis of the joint z_i and z_{i-1} to the normal plane on the common normal line. This value can be obtained from the degree between z_i and z_{i+1} , measured by x_i .

A transformation matrix can be obtained based on the D-H parameters, which define the transformation of the i -frame relative to the $i - 1$ frame. This matrix can be represented as T_i^{i-1} , and can be calculated as,

$$T_i^{i-1} = \begin{bmatrix} c(\theta_i) & -s(\theta_i)c(\alpha_i) & s(\theta_i)s(\alpha_i) & a_i c(\theta_i) \\ s(\theta_i) & c(\theta_i)c(\alpha_i) & -c(\theta_i)s(\alpha_i) & a_i s(\theta_i) \\ 0 & s(\alpha_i) & c(\alpha_i) & d_i \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1)$$

where c and s represent \sin and \cos , respectively. For n DoF consisting of $n + 1$ frames, the sum of the numbers for the transformation matrix is n [16]. The concatenated matrix provides the required transformation from the n frame that corresponds to the end-effector to the 0-frame mounted on the base as follows:

$$T_n^0 = T_1^0 \cdot T_2^1 \cdot T_3^2 \dots T_n^{n-1} \quad (2)$$

E. Closed-Form Solution

A closed-form solution is an expression for an exact solution given with a finite amount of data [17]. If an equation solves a given problem in terms of functions and mathematical operations from a given commonly accepted set, it is said to be a closed-form solution. An infinite sum, for example, will not be considered a closed-form solution. The closed-form solution

can be applied in solving the inverse kinematic of the robot arm. The solution obtained has the advantages of being exact, includes all solution sets, and low computational cost.

II. METHODS

Some considerations should be emphasized to ensure the robot arm can maneuver correctly, including its software and hardware. Accordingly, software should be stable and easy to use to prevent difficulties. Furthermore, hardware plays a role in forming a solid robot arm and able to move as planned. The MATLAB software (MathWorks) has been used to develop the algorithm in this study.

The primary hardware utilized in this study is the OpenMANIPULATOR-X robot arm manufactured by Robotis. The OpenMANIPULATOR-X robot arm is made up of pieces from the DYNAMIXEL-X series and 3D printing. The daisy chain method is adopted by DYNAMIXEL, which has a modular design. It enables users to add or remove joints for their own use easily. Fig. 3 shows the structure of the OpenMANIPULATOR-X robot arm [18].

Fig. 3. Structure of the OpenMANIPULATOR-X Robot Arm [18].

A. Forward and Inverse Kinematic Analysis

Fig. 4 shows the flowchart of the forward and inverse kinematic analysis. Forward kinematic modeling was performed using the Denavit-Hartenberg (D-H) convention method. For inverse kinematic modeling, the closed-form solution method was used to obtain all sets of possible solutions. Next, correlation analysis between the forward and inverse kinematic was performed to determine whether there are any relationship between both kinematic models. Finally, performance evaluation was carried out using trajectory planning and waypoint tracking algorithm in MATLAB and ROS on Ubuntu.

B. Modeling of Forward Kinematic

The D-H convention method used to model the forward kinematic of the robot arm can be divided into three processes. The first process is the configuration analysis of the robot arm to obtain its D-H parameters. Fig. 5 shows the OpenMANIPULATOR-X robot arm's configuration analysis, while Table I shows the D-H parameters obtained after the configuration analysis is performed.

There is an offset between joint 2 and joint 3 on the robot arm, resulting in an offset angle. The offset angle is identified and considered in D-H parameters. Fig. 6 shows the calculation of the offset angle, θ_0 , between joints 2 and 3.

Fig. 4. Flowchart of the Process of Kinematic Modeling.

Fig. 5. Configuration Analysis of the OpenMANIPULATOR-X Robot Arm.

TABLE I. D-H PARAMETERS

Joint	θ_i ($^\circ$)	α_i ($^\circ$)	a_i (m)	d_i (m)
1	θ_1	90	0	0.077
2	$\theta_1 - \theta_0$	0	0.130	0
3	$\theta_3 + \theta_0$	0	0.135	0
4	θ_4	0	0.126	0

Fig. 6. Calculation of Offset Angle, θ_0 between Joint 2 and 3.

The second process in the D-H convention involves the calculation of the transformation matrix. After obtaining the value of the D-H parameters, the parameters will be included in the transformation matrix. Since 4 frames or 4 DoF were used, the limit for the linked matrix is T_4^0 . The transformation matrix equations can be formulated as follows:

$$T_1^0 = \begin{bmatrix} c(\theta_1) & 0 & s(\theta_1) & 0 \\ s(\theta_1) & 0 & -c(\theta_1) & 0 \\ 0 & 1 & 0 & d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (3)$$

$$T_2^1 = \begin{bmatrix} c(\theta_2) & -s(\theta_2) & 0 & a_2c(\theta_2) \\ s(\theta_2) & c(\theta_2) & 0 & a_2s(\theta_2) \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (4)$$

$$T_3^2 = \begin{bmatrix} c(\theta_3) & -s(\theta_3) & 0 & a_3c(\theta_3) \\ s(\theta_3) & c(\theta_3) & 0 & a_3s(\theta_3) \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (5)$$

$$T_4^3 = \begin{bmatrix} c(\theta_4) & -s(\theta_4) & 0 & a_4c(\theta_4) \\ s(\theta_4) & c(\theta_4) & 0 & a_4s(\theta_4) \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (6)$$

After obtaining values for T_1^0 , T_2^1 , T_3^2 and T_4^3 , the next step is to combine them in a sequence to simplify them.

$$T_4^2 = T_3^2 \cdot T_4^3 \quad (7)$$

$$T_4^1 = T_2^1 \cdot T_4^2 \quad (8)$$

$$T_4^0 = T_1^0 \cdot T_4^1 \quad (9)$$

The final process in the D-H convention is to obtain the position vector for the end-effector. After completing the simplification process, the transformation matrix equation is as follows:

$$T_4^0 = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (10)$$

where $p(p_x, p_y, p_z)$ is the position vector of the end-effector while $n(n_x, n_y, n_z)$, $o(o_x, o_y, o_z)$ and $a(a_x, a_y, a_z)$ are orthogonal unit vectors that determine the orientation of the frame for the end-effector. p_x , p_y , and p_z are the values for x , y , and z coordinates of the end-effector.

C. Modeling of Inverse Kinematic

The closed-form solution method involving geometric and algebraic solutions is used to model the robot arm's inverse kinematic. The solution is divided into two processes. The first process is the calculation to get the angle for joint 1. The movement of the robot arm on the $x-y$ surface depends only on the angle of joint 1.

Regarding the $x-y$ surface projection of the robot arm movement, the angle for joint 1, θ_1 can be calculated as follows:

$$\theta_1 = \tan^{-1} \left(\frac{p_y}{p_x} \right) \quad (11)$$

Since θ_1 is the rotational angle for the robot arm's base, the angle range is between -180° and 180° . The quadrant for θ_1 is identified to determine the sign for each trigonometric ratio in a given quadrant. Table II shows the signs for the trigonometric ratio in each quadrant.

TABLE II. SIGNS FOR THE TRIGONOMETRIC RATIO IN EACH QUADRANT

p_x	p_y	Quadrant	θ_1
+	+	1	θ_1
-	+	2	$\theta_1 + 180^\circ$
-	-	3	$\theta_1 - 180^\circ$
+	-	4	θ_1

The second process involves calculating the angles for joints 2, 3, and 4 (θ_2 , θ_3 , and θ_4). For obtaining the solution for θ_2 , θ_3 , and θ_4 , the 3-dimensional (3D) space which is consisting of the x , y , and z coordinate axes, is simplified to a 2-dimensional (2D) surface. The x and y -axis are merged as a new axis and known as the r -axis, as shown in Fig. 7.

Fig. 7. Combination of x and y -Axis as r -Axis.

The x -coordinate and the y -coordinate for the end-effector are combined as r -coordinate using the Pythagorean equation as follows:

$$p_r^2 = p_x^2 + p_y^2 \quad (12)$$

$$p_r = \sqrt{p_x^2 + p_y^2} \quad (13)$$

Fig. 8 shows the projection of the r-z surface for the movement of the robot arm. The r_3 coordinates and the z_3 coordinates can be calculated as follows:

$$r_3 = p_r \quad (14)$$

$$z_3 = p_z - d_1 \quad (15)$$

Fig. 8. Projection of the r - z Surface for the Movement of the Robot Arm.

The range of the total sum of angles for θ_2 , θ_3 , and θ_4 are between -90° and 90° as shown in Fig. 9.

Fig. 9. Maximum and Minimum of the Sum of Angle for Joint 2, 3 and 4.

θ_2 , θ_3 , and θ_4 can be calculated using the following equations:

$$\phi = \theta_2 + \theta_3 + \theta_4 \quad (16)$$

$$r_2 = r_3 - a_4 \cos \phi \quad (17)$$

$$z_2 = z_3 - a_4 \sin \phi \quad (18)$$

$$\cos \theta_3 = \frac{r_2^2 + z_2^2 - (a_2^2 + a_3^2)}{2 a_2 a_3} \quad (19)$$

$$\theta_3 = \pm \cos^{-1} \left(\frac{r_2^2 + z_2^2 - (a_2^2 + a_3^2)}{2 a_2 a_3} \right) \quad (20)$$

$$r_2 = a_2 \cos \theta_2 + a_3 \cos (\theta_2 + \theta_3) \quad (21)$$

$$z_2 = a_2 \sin \theta_2 + a_3 \sin (\theta_2 + \theta_3) \quad (22)$$

$$r_2 = \cos \theta_2 (a_2 + a_3 \cos \theta_3) - \sin \theta_2 (a_3 \sin \theta_3) \quad (23)$$

$$z_2 = \cos \theta_2 (a_3 \sin \theta_3) + \sin \theta_2 (a_2 + a_3 \cos \theta_3) \quad (24)$$

$$\cos \theta_2 = \frac{(a_2 + a_3 \cos \theta_3) r_2 + (a_3 \sin \theta_3) z_2}{r_2^2 + z_2^2} \quad (25)$$

$$\sin \theta_2 = \frac{(a_2 + a_3 \cos \theta_3) z_2 + (a_3 \sin \theta_3) r_2}{r_2^2 + z_2^2} \quad (26)$$

$$\theta_2 = \tan^{-1} \left(\frac{\sin \theta_2}{\cos \theta_2} \right) \quad (27)$$

$$\theta_4 = \phi - (\theta_2 + \theta_3) \quad (28)$$

There are two possible configurations for the robot arm, namely “elbow up” and “elbow down”. Both configurations are considered in the calculation of θ_2 , θ_3 , and θ_4 .

The angle range for θ_2 , θ_3 , and θ_4 is between -90° and 90° , respectively. Based on the configuration of the robot arm in ROS, the angle range for θ_2 becomes 0° and 180° and the angle range for θ_3 becomes -180° and 0° . The angle limit for each joint in ROS ranges between -90° and 90° . Thus, the angle range for θ_2 to be considered in kinematic modeling is between 0 and 90° , while for θ_3 is between -90° and 0° .

Fig. 10. Simulation Procedures for Trajectory Planning and Waypoint Tracking.

D. Trajectory Planning and Waypoint Tracking

The simulation of trajectory planning and waypoint tracking is done using MATLAB software with the help of Robotics System Toolbox, Simulink and Simscape Multibody. Fig. 10 shows the simulation procedure for trajectory planning and waypoint tracking. The first step to be completed is to analyze the data using MATLAB software. This procedure aims to identify and overcome the dependencies of the simulation files. Next, the algorithm includes uploading files related to the robot arm into MATLAB software. After that, the algorithm configures one point or a set of points to be used. The points are obtained from the modeling of the robot arm and incorporated into the algorithm. This step is very important to determine the similarity with the actual robot arm.

The next step is to calculate and form a smooth trajectory. This process runs the trajectory process and uses the points configured in the previous step. Trajectory planning is one of the critical processes in robots, where it involves the smooth movement of the end-effector from the initial position to the target position [18]. When an arbitrary endpoint is given, the algorithm computes the optimal feasible path for the robot arm's movement based on the kinematic constraints.

The final process involves performing inverse kinematic of the points found on the robot arm workspace. There are six values in the weight vector. The first three values are for rotational purposes, and the last three values are for transition purposes. Then, the algorithm configures a number greater than the number of points previously configured to ensure the robot arm's smooth movement. After that, it uses a kinematic solver for each end-effector position and uses the previous configuration to make an initial guess. After completing all the processes, the movement of the robot arm is simulated.

III. RESULTS AND DISCUSSION

A. Modeling of Forward Kinematic

Fig. 11 shows the flowchart of the forward kinematic modeling algorithm. D-H parameters are included in the developed algorithm to obtain the end-effector's coordinate of the robot arm, and the transformation matrix is calculated to obtain the equations for the end-effector's coordinates. Next, random values of the four joint angles are generated by using the "randi" function. This function is able to generate uniformly distributed random integers from the specified interval. Finally, the end-effector's coordinates are calculated by inserting the random values for the four joint angles into the transformation matrix equations. Table III shows the results of the forward kinematic modeling developed.

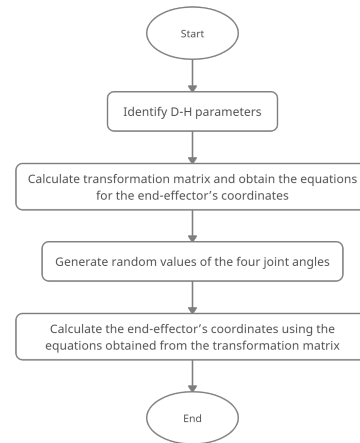

Fig. 11. Flowchart of Forward Kinematic Modeling Algorithm.

TABLE III. RESULTS OF FORWARD KINEMATIC MODELING

Case	Joint Angles (°)				End-Effector's Coordinates		
	θ_1	θ_2	θ_3	θ_4	p_x	p_y	p_z

B. Modeling of Inverse Kinematic

Fig. 12 shows the flowchart of the inverse kinematic modeling algorithm. The coordinates of the end-effector are entered into the algorithm to obtain the joint angles that achieve a particular end-effector position. Next, the angle value for joint 1 is calculated, followed by calculating the angle values for

joints 2, 3, and 4. Finally, all solution sets for the joint angles are obtained.

Fig. 12. Flowchart of Inverse Kinematic Modeling Algorithm.

Table IV shows the set of solutions for joint angles in integers obtained using MATLAB software. Referring to case 1 from the results of the forward kinematic modeling in Table V, a total of 66 sets of solutions can be obtained for the end-effector's coordinates ($p_x = -0.0834$, $p_y = 0.3611$ and $p_z = 0.1744$) including the desired solution set, which is the 65th set of solution ($\theta_1 = 103^\circ$, $\theta_2 = 15^\circ$, $\theta_3 = -5^\circ$ and $\theta_4 = 21^\circ$).

TABLE IV. SET OF SOLUTIONS FOR JOINT ANGLES IN THE FORM OF INTEGER

Solution	Joint Angles ($^\circ$)

63:	103	13	0	17
64:	103	24	-22	28
65:	103	15	-5	21
66:	103	21	-17	27

To obtain more accurate angles with more decimal points, the number of solution sets increases. The number of solution sets increases by about 10 times with the increase of one

decimal point for the joint angles, as shown in Table V.

TABLE V. RESULTS OF INVERSE KINEMATIC MODELING

Case	End-Effector's Coordinates			Joint Angles ($^\circ$)				Number of Solution Sets		
	p_x	p_y	p_z	θ_1	θ_2	θ_3	θ_4	0 DP	1 DP	2 DP

C. Correlation Analysis of Kinematic Modeling

Referring to the forward and inverse kinematic modeling results, as shown in Tables III and V, the solution is precisely the same when comparing the joint angles from the forward and inverse kinematic. The same solution set of joint angles could be obtained using the inverse kinematic model, as applied in the forward kinematic model. Thus, the correlation between the developed forward and inverse kinematic model is said to be accurate.

D. Performance of End-Effector Coordinates

Fig. 13 and 14 display the example of simulation results of trajectory planning and waypoint tracking for the set of solutions for the joint angles. The simulation results show that the solution set of joint angles which produce the most feasible trajectory are $\theta_1 = 103^\circ$, $\theta_2 = 42^\circ$, $\theta_3 = -35^\circ$ and $\theta_4 = 0^\circ$. Furthermore, Table VI depicts the comparison of the end-effector's coordinates obtained from the modeling process in MATLAB and output from ROS. The most significant errors occurred in case 1 and case 5. Errors occur between the end-effector's coordinates obtained from the results of modeling and output from ROS due to the rounding calculations that unavoidable in modeling and the kinematic constraints on the simulated robot arm in ROS as follows:

- 1) Joint Bounds: This constraint is satisfied if the robot configuration vector maintains all joint positions within the bounds specified.
- 2) Cartesian bounds: This constraint is satisfied if the end-effector origin's position relative to the target frame remains within the bounds specified.
- 3) Orientation target: This constraint requires the end-effector orientation to match a target orientation within an angular tolerance in any direction. The target orientation is specified relative to the body frame of the reference body.
- 4) Pose target: This constraint requires the end-effector's pose to match a target pose within a distance and angular tolerance in any direction. The target pose is specified relative to the body frame of the reference body.
- 5) Position target: This constraint requires the end-effector position to match a target position within a distance tolerance in

any direction. The target position is specified relative to the body frame of the reference body.

10	0.1465	-0.2017	0.3691	0.153	-0.194	0.362	4.25	3.97	1.96

IV. CONCLUSION

This study successfully modeled both the forward and inverse kinematic model for the 4-DoF articulated robot arm. Correlation between the forward and inverse kinematic model is analyzed, and the performance of the kinematic model is evaluated on the simulated robot arm. The developed kinematic model serves as a theoretical framework for further research, for instance robot arm trajectory planning, and structural optimization of robot design.

Abstract—In March 2020, the World Health Organization declared the COVID-19 outbreak to be a pandemic. Soon afterwards, people began sharing millions of posts on social media without considering their reliability and truthfulness. While there has been extensive research on COVID-19 in the English language, there is a lack of research on the subject in Arabic. In this paper, we address the problem of detecting fake news surrounding COVID-19 in Arabic tweets. We collected more than seven million Arabic tweets related to the corona virus pandemic from January 2020 to August 2020 using the trending hashtags during the time of pandemic. We relied on two fact-checkers: the France-Press Agency and the Saudi Anti-Rumors Authority to extract a list of keywords related to the misinformation and fake news topics. A small corpus was extracted from the collected tweets and manually annotated into fake or genuine classes. We used a set of features extracted from tweet contents to train a set of machine learning classifiers. The manually annotated corpus was used as a baseline to build a system for automatically detecting fake news from Arabic text. Classification of the manually annotated dataset achieved an F1-score of 87.8% using Logistic Regression (LR) as a classifier with the n-gram-level Term Frequency-Inverse Document Frequency (TF-IDF) as a feature, and a 93.3% F1-score on the automatically annotated dataset using the same classifier with count vector feature. The introduced system and datasets could help governments, decision-makers, and the public judge the credibility of information published on social media during the COVID-19 pandemic.

Keywords—Fake news; Twitter; social media; Arabic corpus

I. INTRODUCTION

The rise of social networks such as Facebook, Twitter, and many others has enabled the rapid spread of information. Any user on social media can publish whatever they want without considering the truthfulness and reliability of the published information, which introduces challenges in information reliability assurance. Twitter is one of the most popular social media platforms. It is designed to allow users to send information as short texts, known as tweets, with no more than 280 characters, and each user on Twitter can follow as many accounts as he or she wants. Nowadays, and with the outbreak of the COVID-19 pandemic, millions of tweets are generated daily, which has caused some adverse effects that impact individuals and society. For example, the spread of misinformation about COVID-19 symptoms may harm people [1]. For instance, it could be anxiety-inducing for a person who experiences COVID-19 like symptoms even if they have not been infected with the virus. The terms fake news and misinformation are closely related and are often

used interchangeably. Authors in [2] defined rumors as: “a hypothesis offered in the absence of verifiable information regarding uncertain circumstances that are important to those individuals who are subsequently anxious about their lack of control resulting from this uncertainty.” Another definition presented in [3] is: “unverified and instrumentally relevant information statements in circulation that arise in contexts of ambiguity, danger or potential threat, and that function to help people make sense and manage risk.”

Detecting fake news in English tweets is an active research area and many studies and datasets have been published during the COVID-19 pandemic [4]. In Arabic, fake news detection is fairly new and has a long way to go to reach the level achieved in other languages, especially English. Therefore, the fight against fake news requires a system that automatically assists in verifying the truthfulness of shared information about the COVID-19 pandemic on social media. Fake news detection is a very challenging task, especially with the lack of available datasets related to the pandemic. An automated fake news detection system is necessary by utilizing human annotation, machine/deep learning, and Natural Language Processing techniques [5]. These techniques help to determine whether a given text is fake news or not by comparing the text with some pre-known corpora that contain both fake and truthful information [6].

In this paper, we address the problem of fake news detection on Twitter during the COVID-19 pandemic period. Our focus is to build a manually annotated dataset for fake news detection from Twitter’s social media platform. We rely on fact-checking sources to manually annotate a sample dataset. The consideration of these fact-checking sources could help in reducing the spread of misinformation [7], [8], [9], [10]. As manual annotation is expensive and time-consuming [11], we also developed a system to expand the manually annotated dataset by automatically annotating a large and unlabeled dataset. We use a supervised learning classification to train and test both the manually and automatically annotated datasets to ensure the quality of our annotation. We use six different machine learning algorithms, four different features with each algorithm, and three pre-processing techniques. The rest of the paper is organized as follows. In Section 2, we cover related work. Section 3 presents our methodology to annotate and automatically detect fake news related to COVID-19. In Section 4, we present the results and discussion. Finally, the conclusion and future work are presented in Section 5.

II. RELATED WORK

Recently, many works have been done to tackle the issue of detecting fake news, rumors, misinformation, or disinformation in social media networks. Most of these studies can be categorized into supervised and unsupervised learning approaches. Moreover, there are fewer works that tackled the problem using semi-supervised techniques.

For the supervised approach, a system based on machine learning techniques for detecting fake news or rumors in the Arabic language from social media during the COVID-19 pandemic is presented in [12]. The authors collected one million Arabic tweets using Twitter's Streaming API. The collected tweets were analyzed by identifying the topics discussed during the pandemic, detecting rumors, and predicting the source of the tweets. A sample of 2,000 tweets was labeled manually into false information, correct information, and unrelated. Different machine learning classifiers were applied, including Support Vector Machine, Logistic Regression, and Naïve Bayes. They obtained 84% accuracy in identifying rumors. The limitations of this research include the unavailability of the dataset, and the fact that it relies on a single source of rumors: the Saudi Arabian Ministry of Health.

Identifying breaking news rumors on Twitter has been proposed in [13]. The authors built a word2vec model and an LSTM-RNN model to detect rumors from news published on social media. The proposed model is capable of detecting rumors based on a tweet's text, and experiments showed that the proposed model outperforms state-of-the-art classifiers. As rumors can be deemed later to be true or false, their model is unable to memorize the facts across time; it only looks at the tweet at the current time. Detecting rumors from Arabic tweets using features extracted from the user and content has been proposed in [14]. The authors obtained rumors and non-rumors topics from anti-rumors and Ar-Riyadh websites. More than 270K tweets were collected, containing 89 and 88 rumour and non-rumour events, respectively. A supervised Gaussian Naïve Bayes classification algorithm reported an F1-score of 78.6%. This research's limitation is that the proposed dataset is not verified using any of the benchmark datasets.

In [15], a supervised learning approach for Twitter credibility detection is proposed. A set of features including content-based and source-based features, were used to train five machine learning classifiers. The Random Forests classifier outperformed the other classifiers when used with a combined set of features. A total of 3,830 English tweets were manually annotated with credible or non-credible classes. The textual features were not studied to examine their impact on credibility detection. Another supervised machine learning approach was proposed in [16] to detect rumors from business reviews. A publicly available dataset was used to conduct rumour detection experiments. Different supervised learning classifiers were used to classify business reviews. The experimental results showed that the Naïve Bayes classifier achieved the highest accuracy and outperformed three classifiers, namely, the Support Vector Classifier, K-Nearest Neighbors, and Logistic Regression. This work's limitation is the small size of the dataset used to train machine learning classifiers.

Detection of fake news using n-gram analysis and machine learning techniques was proposed in [17]. Two different feature

extraction techniques and six machine learning algorithms were investigated and compared based on a dataset from political articles that were collected from Reuters.com and kaggle.com for real and fake news. Another Arabic corpus for the task of detecting fake news on YouTube is presented in [18]. The authors introduced a corpus that covered topics most concerned by rumors. More than 4,000 comments were collected to build the corpus. Three different machine learning classifiers (Support Vector Machine, Decision Tree, and Multinomial Naïve Bayes) were used to differentiate between rumour and non-rumour comments with the n-gram TF-IDF feature. The SVM classifier achieved the highest results. Authors in [19] proposed identifying fake news on social media. They used several pre-processing steps on the textual data, and then used 23 supervised classifiers with the TF weighting feature. The combined text pre-processing and supervised classifiers were tested on three different real-world English datasets, including BuzzFeed Political News, Random Political News, and ISOT Fake News.

An automatic approach to detecting fake news from Arabic and English tweets using machine learning classifiers has been proposed in [4]. The authors developed a large and continuous dataset for Arabic and English fake news during the COVID-19 pandemic. Information shared on official websites and Twitter accounts were considered a source of real information. Along with the data collected from official websites and Twitter accounts, they also relied on various fact-checking websites to build the dataset. A set of 13 machine learning classifiers and seven other feature extraction techniques were used to build fake news models. These models were used to automatically annotate the dataset into real and fake information. The dataset was collected for 36 days, from the 4th of February to the 10th of March 2020.

A large corpus for fighting the COVID-19 infodemic on social media has been proposed in [11]. The authors developed a schema that covers several categories including advice, cure, call for action, or asking a question. They considered such categories to be useful for journalists, policymakers, or even the community as a whole. The collected dataset contains tweets in Arabic and English. Three classifiers were used to perform classification experiments using three input representations: word-based, FastText, and BERT. The authors only made 210 of the classified tweets public.

Two Arabic corpora have also been constructed, without manual annotation. In [20], more than 700,000 Arabic tweets were collected from Twitter during the COVID-19 period. The corpus covers prevalent topics discussed in that period and is publicly available to enable research under different domains such as NLP, information retrieval, and computational social media. They used the Twitter API to collect the tweets on a daily basis, covering the period from January 27, 2020, to March 31, 2020.

The second corpus is presented in [21]. The tweets were collected during the period of the COVID-19 pandemic to study the pandemic from a social perspective. The corpus was developed to identify information influencers during the month of March 2020, and contains nearly four million tweets. Different algorithms were used to analyze the influence of information spreading and compare the ranking of users.

For fake news detection in other languages, there are many corpora that are publicly available to tackle the spread of false information. A multilingual cross-domain fact-checking news dataset for COVID-19 has been introduced in [22]. The collected dataset covered 40 languages and relies on fact-checked articles from 92 different fact-checking websites to manually annotate the dataset. The dataset is available on GitHub. Another publicly available dataset called “TweetsCOV19” was introduced in [23]. This dataset contains more than eight million English tweets about the COVID-19 pandemic. The dataset can be used for training and testing a wide range of NLP and machine learning methods and is available online. A novel Twitter dataset is presented in [24], which was developed to characterize COVID-19 misinformation communities. Authors categorized the tweets into 17 classes, including fake cure, fake treatment, and fake facts or prevention. They performed different tasks on the developed dataset, including identifying communities, network analysis, bot detection, sociolinguistic analysis, and vaccination stance. This study’s limitations are that only one person performed annotation, the analyses are correlational and not causal, and the collected data covered a short period of only three weeks. MM-COVID is a multilingual and multidimensional fake news data repository [25]. The dataset contains 3981 fake and 7192 genuine news contents from English, Spanish, Portuguese, Hindi, French, and Italian. The authors explored the collected dataset from different perspectives including social engagements and user profiles on social media.

Sentiment analysis has also been used in fake news detection has also been facilitated. In [26], the authors used sentiment analysis to eliminate neutral tweets. They claimed that tweets related to fake news are more negative and have strong sentiment polarity in comparison with genuine news. The main issue in using this approach to detect fake news from Arabic text is the lack of Arabic sentiment resources, including sentiment lexicons and corpora [27]. Testing whether emotions play a role in the formation of beliefs in online political misinformation is presented in [28]. The authors explore emotional responses as an under-explored mechanism of belief in political misinformation. Understanding emotions helps in different domains including capturing the public’s sentiments about social events such as the spreading of misinformation on social media [29].

Text classification using machine/deep learning provides a good results over many NLP applications including, sentiment analysis [30], [31], emotion detection [32], hate speech detection [33], sarcasm detection [34], and other applications.

To summarize, most of the existing datasets target the English language, with only a few targeting Arabic. Furthermore, most of the Arabic datasets related to COVID-19 are published without annotation. Datasets that are annotated were annotated automatically and collected during a short period of time. Additionally, not all of these datasets are publicly available. In this research, we address these issues by employing three annotators to manually perform the annotation task.

III. METHODOLOGY

Fig. 1 presents the architecture of the proposed fake news detection system. In the first step of the framework, we collect

data from Twitter using the Twitter Streaming API. In the second step, we perform the extraction of tweets which discuss rumors or fake news topics during the pandemic, annotate a small sample of tweets manually, and develop a system to annotate a large dataset of unlabeled tweets automatically.

In the last step, we store the dataset in a database and use it to accomplish our experiments and analysis. This research intends to build an Arabic fake news corpus that can be used for analyzing the spread of fake news on social media during the COVID-19 pandemic. To address this need, we perform the following four steps: 1) data collection, 2) rumor/misinformation keyword extraction, 3) data pre-processing, and 4) fake news annotation.

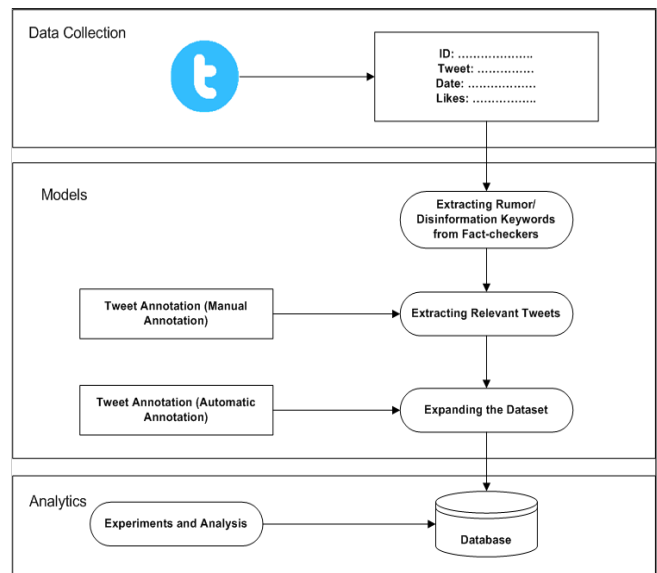

Fig. 1. Fake New Detection Architecture.

A. Data Collection

In this section, we describe the process of data collection from Twitter. In the first instance, we prepared a list of hashtags that appeared during the COVID-19 outbreak, as shown in Table I. Armed with the Tweepy Python library and using Twitter’s API, we proceeded to collect Arabic tweets related to COVID-19 from January 1, 2020, until May 31, 2020. We then searched for tweets containing one or more of the defined hashtags in the tweet’s text. This step allowed us to collect more than seven million unique tweets. After applying some filters such as removing the short and repeated tweets, the remaining tweets are 5.5 million tweets. However, as some of the collected tweets were irrelevant, we decided to keep only those tweets relevant to the COVID-19 pandemic and containing fake news keywords.

B. Fake News Keywords Extraction

To collect a list of keywords relevant to the rumours circulating during the pandemic, we used two sources:

- Agence France-Presse (AFP)¹ with its newly formed health investigation team which have the responsibility

¹<https://factuel.afp.com/ar/CORNA%20COMPILATION%202-20>

TABLE I. LIST OF HASHTAGS USED TO COLLECT THE DATASET

#	Hashtag	English Translation
1	#كورونا	Corona
2	#فيروس_كورونا	Corona virus
3	#كورونا_المستجد	New Corona
4	#كوفيد_١٩	COVID 19
5	#الفيروس_التاجي	Corona virus
6	#الحجر_المنزلي	Home Quarantine
7	#الحجر_الصحي	Quarantine
8	#التباعد_الاجتماعي	Social distancing
9	#كلنا_مسؤول	We are all responsible
10	#ابقوا_في_منازلكم	Stay in your homes

of dealing with large amounts of fake news in various languages and indicating their error or inaccuracy.

- The Anti-Rumours Authority (No Rumours)², an independent project established in 2012 to address and contain rumours and sedition to prevent them from causing any harm to society.

After reading and analyzing rumours and misinformation circulated on social media using the above-mentioned sources, a list of 40 keywords was extracted and used to prepare our dataset, as shown in Table II. These keywords cover a variety of topics associated with fake news, rumours, racism, unproven cure methods, false information. For example, there was a rumour that herbal tea is used to treat COVID-19. Another topic circulated was that Cristiano Ronaldo offered to transform his hotels into hospitals and give free treatment to COVID-19 patients. One alleged that the corona virus targets only those who have yellow-skin and Asian people to reduce population density. Other topics include the conversion of non-Muslims to Islam.

We extracted a corpus of more than 37,000 unique tweets related to rumours and misinformation topics during the COVID-19 pandemic. The tweets were written by 24,117 users with an average of 1.5 tweets per user. Statistical information details about the corpus are presented in Table III.

C. Data Pre-processing

We performed several text pre-processing steps based on the procedure described in [35] in order to sanitize the collected tweets before annotation and classification. Our dataset, which is a mixture of modern standard Arabic and dialectal Arabic, requires further filtering such as removing duplicated letters, strange words, and non-Arabic words. The following is a complete list of the steps performed:

- Removing mentions, hyperlinks, and hashtags.
- Removing non-Arabic and strange words.
- Text normalization.

TABLE II. LIST OF VERIFIED RUMORS AND MISINFORMATION TOPICS

#	Keyword	English Translation
1	شبيكات الجيل الخامس	5G networks
2	العجز الجنسي	Impotence
3	اكتشاف علاج	Discover a cure
4	درجة حرارة ٢٦	A temperature of 26
5	حبس النفس	Holding your breath
6	الغرغرة	Gargle
7	الموز	Banana
8	بخار الماء	Water vapor
9	تشخيص حالتك اونلاين	Online diagnosis of your condition
10	الشاي العشبي	Herbal tea
11	يلقون باموالهم	Throw in their money
12	يرمون اموالهم	Throw in their money
13	محففات الايدي	Hand dryers
14	الساونا	Sauna
15	الرئيس يبكي	The president is crying
16	١٥ دقيقة	Water 15 minutes
17	يصفون	Spit
18	الزندانى كورونا	Zindani Corona
19	الاوغور	Uyghurs
20	الأعشاب	Herbs
21	يدخلون الإسلام	They enter Islam
22	الرئيس الصيني	Chinese President
23	البشرة السوداء	Black skin
24	يعتنون	Embrace
25	توزيع مصاحف	Distributing the Qur'an
26	صدام حسين	Saddam Hussein
27	مستشفيات رونالدو	Ronaldo Hospitals
28	الاذان غرناطة	Call to prayer in Granada
29	الاذان لندن	Call to prayer in London
30	هروب صيني الى اليمن	Chinese escape to Yemen
31	اسلمو	Entered Islam
32	جميع الاديان	All religions
33	تاسوكو	Tasuco
34	أوباما	Obama
35	بيل غيتس	Bill Gates
36	رفع اذان المانيا	Call to prayer in Germany
37	يصلون	They pray
38	متروك للسماء	Up to the sky
39	نقص الأوكسجين	Lack of oxygen
40	المغرب يصدر الكمامات	Morocco exports masks

- Removing punctuations and Arabic diacritics.
- Removing repeated characters which add noise and influence the mining process.

Two libraries were used to perform further pre-processing on the corpus text, including stemming and rooting. The first library is NLTK, which was used to perform stemming on the corpus text using ISRIStemmer4³. The second library is

³<https://www.kite.com/python/docs/nltk.ISRIStemmer>

Tashaphyne⁴, which was used to get the root of each word in the corpus.

IV. CORPUS ANNOTATION

A. Manual Annotation

A sample of 2,500 tweets was manually annotated into fake or genuine classes. We developed a small application to facilitate the annotation process, as shown in Fig. 2. We involved three annotators in the annotation of the sample dataset. Two of the annotators performed annotation while the third was tasked with evaluating their output and resolving conflicts. We requested the annotators to read and understand the list of guidelines and informed them to skip tweets in which there are mixture of fake news and genuine topics and only annotate tweets that have a clear and distinct fake news topic. The following are the guidelines:

- Tweets are generally considered fake if one fake news topic is discussed in the tweet.
- Tweets are considered to not be fake if one fake news topic is discussed in the tweet, and the topic is negated.
- Tweets that contain a mixture of both fake and genuine news are skipped.

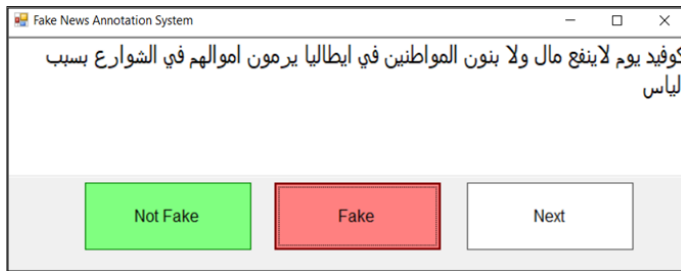

Fig. 2. Fake News Annotation Interface.

The annotation process resulted in a corpus containing 1,537 tweets (835 fake and 702 genuine), after excluding duplicated tweets, tweets that contain mixed fake and genuine news, and tweets where the fake news was meant as sarcasm. Statistical information about the manually annotated corpus is shown in Table III. We used Cohen's kappa coefficient to measure the inter-annotator agreement, obtaining a value of 0.91. Table IV shows an example of some annotated tweets.

B. Automatic Annotation

Initially, we trained different machine learning classifiers on the manually annotated corpus and used the best performing classifier to automatically predict the fake news classes of remaining unlabeled tweets. The outcome of the prediction process is 34,529 tweets (19,582 fake and 19,582 genuine) as shown in Table III.

During the annotation process, the annotators found some tweets containing fake news keywords but carrying sarcasm. In this case, the annotators were requested to annotate them as genuine. Table V shows a sample of such tweets.

TABLE III. CORPUS STATISTICS

Manually Annotated Corpus		
	Fake Tweets	Not Fake Tweets
Total Tweets	835	702
Total Words	20,395	19,852
Unique Words	6,246	7,115
Total Characters	117,630	113,121

Automatically Annotated Corpus		
	Fake Tweets	Not Fake Tweets
Total Tweets	19,582	14,947
Total Words	479,349	463,768
Unique Words	79,383	88,037
Total Characters	2,855,454	2,680,067

TABLE IV. FAKE AND GENUINE TWEETS EXAMPLES

#	Tweet	Class
1	نفسى اكتب اشاعة علي فيروس كورونا اللي تخلي الناس مرزوعة في بيوتها اقول فيها كورونا يسبب الضعف الجنسي حتى لو شفيت منها. I want to write a rumour about COVID-19 that would make people stay in their homes, and say that it causes impotence even if you recover from it.	Genuine
2	ربما مفرك مثل كلام صدام حسين عن كورونا قبل اكثر من عشرين عام. Perhaps fabricated like Saddam Hussein's video about COVID-19 more than 20 years ago.	Genuine
3	تحذير صيني فيروس كورونا يسبب الضعف الجنسي والعقم. Chinese warning: COVID-19 causes impotence and sterility.	Fake
4	كورونا الفيروس مصنع لاصحاب البشرة الصفراء والاسويين لتقليص الكثافة السكانية على الارض والدليل انه لم يصاب اي احد من ذوي البشرة السوداء. COVID-19 is made for yellow-skinned people and Asians to reduce population density, and the evidence for that is that no black-skinned person has been infected.	Fake

V. EXPERIMENTS

In this section, we present the results of the fake news classification after describing the employed feature extraction techniques, experimental setup, classifier model training, and evaluation measures.

A. Feature Extraction

The next step after performing text pre-processing is to prepare the features to build classification models. To accomplish that, we used the following features:

- Count Vector: The text in our corpus was converted into a vector of term counts.
- Word-Level TF-IDF: Each term in our corpus is represented in a TF-IDF matrix.

TABLE V. ANNOTATION CONFUSION

#	Tweet	English Translation
1	بالفيديو ابنة صدام حسين تحسم جدل فيديو والدها عن كورونا.	In the video, Saddam Hussein's daughter resolves the controversy of her father's video about COVID-19
2	اقرا عن بيل غيتس ومسالمة لقاح كورونا ومبلغ ال 75 مليون	Read about Bill Gates, the issue of the COVID-19 vaccine, and the 75 million[dollar] amount

TABLE VI. STATISTICS IN EXPERIMENTAL DATASET

Manually Annotated Corpus			
	Fake Tweets	Not Fake Tweets	Total Tweets
Training	668	562	1,230
Testing	167	140	307
Total Tweets	835	720	1,537

Automatically Annotated Corpus			
	Fake Tweets	Not Fake Tweets	Total Tweets
Training	15,666	11,958	27,624
Testing	3,926	2,989	6,905
Total Tweets	19,582	14,947	34,529

- N-gram-Level TF-IDF: We used unigram, bigram, and trigram models in our experiments. We then represented these terms in a matrix containing TF-IDF scores.
- Character-Level TF-IDF: We represent TF-IDF character scores for each tweet in our corpus.

These features are used to train multiple classifiers in order to build machine learning models with the ability to decide the most probable category for new, unseen tweets.

B. Experimental Setup

This section describes the experimental configurations used to perform the text classification task. We designed a set of experiments aiming to validate and ensure the quality of manually and automatically generated annotations. We also explored fake news detection as a binary classification problem (fake and genuine). The total tweets in our fake news dataset are 1,537 and 34,529 tweets in both manually and automatically annotated corpora, respectively. We divided both datasets into 80% for training and 20% for testing. Table VI shows detail about the manual and automatic annotated datasets.

Six machine learning classifiers were used to perform fake news classification for both datasets: Naïve Bayes, Logistic Regression (LR), Support Vector Machine (SVM), Multilayer Perceptron (MLP), Random Forest Bagging Model (RF), and eXtreme Gradient Boosting Model (XGB). The following are the hyper-parameters used with each classifier:

- NB: alpha=0.5
- LR: with default values
- SVM: c=1.0, kernel=linear, gamma=3
- MLP: activation function=ReLU, maximum iterations=30, learning rate=0.1
- RF: with default values
- XGB: with default values

C. Models Training

Once the numerical form of the textual tweets was complete, the data frame containing the count vector, word-level TF-IDF, n-gram level TF-IDF, and character-level TF-IDF representations for each tweet in our corpus were used to train six different classifiers. We used scikit-learn, a Python library for classifier implementation and prediction of the classes of the unlabeled dataset. K-fold cross-validation was used to select the classifier that provides the highest results and shows

the best ability to generalize. The collection was split into five-folds, four of which were used for training on each iteration, and the fifth for evaluation.

D. Evaluation Measures

The evaluation was carried out using three measures: Precision, Recall, and F1-score as follows:

$$Precision = \frac{TruePositive}{TruePositive + FalsePositive} \quad (1)$$

$$Recall = \frac{TruePositive}{TruePositive + FalseNegative} \quad (2)$$

$$F1 - score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (3)$$

Where:

- True Positive: the number of fake tweets that are correctly predicted as fake tweets.
- True Negative: the number of genuine tweets that are correctly predicted as genuine tweets.
- False Positive: the actual class is genuine, but the predicted class is fake.
- False Negative: the actual class is fake, but the predicted class is genuine.

E. Experimental Results

We present the experimental results on the Arabic fake news dataset. Six machine learning classifiers (NB, LR, SVM, MLP,RF, and XGB) were used to perform our experiments on the manually and automatically annotated datasets. We used count vector and TF-IDF vectorization (word-level, n-gram-level, and character-level) to train the classifiers. Precision, recall, and F1-score are the measures that have been used to evaluate each classifier using 5-fold cross-validation. Bold values indicate which setting yielded the best classification performance of fake tweets.

The results showed that using the LR classifier with the n-gram TF-IDF feature and without applying further pre-processing on the text (such as stemming or rooting) yielded a significantly better classification performance. The classifier gave an 87.8% F1-score classification result with the manually annotated corpus, as shown in Table VII. The same classifier, with the word count feature and without applying stemming or rooting, obtained the best classification performance when applied to the automatically annotated corpus, as shown in Table VIII. It achieved an F1-score of 93.3%.

As shown in Fig. 3, the highest precision value was obtained using the n-gram TF-IDF feature with the LR classifier (87.8%) and the count vector feature with the LR classifier (93.4%) on manually and automatically annotated corpora, respectively. The results obtained using raw text is better than with the corpus text after applying stemming and rooting. We can conclude that performing further pre-processing did not

TABLE VII. PRECISION (P), RECALL (R), AND F1-SCORE (F1) CLASSIFICATION RESULTS (MANUAL ANNOTATED DATASET)

Classifier	Feature Measure	Word Count			TF-IDF (word-level)			TF-IDF (n-gram-level)			TF-IDF (character-level)

enhance the classification results with the text from social media.

As shown in Fig. 4, the highest recall was obtained using the count vector TF-IDF feature with the LR classifier (87.7%), and the count vector feature with the LR classifier (93.3%) on manually and automatically annotated corpora, respectively. The highest F1-score, as shown in Fig. 5 was obtained using the n-gram-level TF-IDF feature with the MLP classifier (87.8%) and the count vector feature with the LR classifier (93.3%) on manually and automatically annotated corpora, respectively.

VI. DISCUSSION

The primary objective of this research was to build a benchmark dataset for fake news in Arabic related to the COVID-19 pandemic. We introduce a new fake news corpus in the Arabic language, collected from Twitter. It is clear from the experimental results that the manually annotated corpus can be used as a baseline for further research in the domain of fake news and misinformation. As there remains no

benchmark dataset for fake news detection in Arabic related to the COVID-19 pandemic, this corpus will help the research community once the dataset is publicly available. The proposed corpus was manually annotated by three annotators to ensure the quality and usefulness of the developed corpus. We used a set of machine learning classifiers to train different machine learning models on the manually annotated corpus. The best model was selected to predict fake news classes of unlabeled tweets (more than 35,000 tweets). The statistical analysis showed lower precision, recall, and F1-score values in the classification of the manually annotated corpus, while the automatically annotated corpus showed improved results. From the results presented in the previous section, we notice that increasing the size of the dataset leads to an improvement in the classification results using precision, recall, and F1-score measures.

The use of machine learning methods to classify the fake news corpus using content-based features gives better results than the user-based features. The corpus can be further expanded using two methods: 1) increasing the number of

Fig. 3. Precision Results.

verified rumour misinformation topics, or 2) performing classification on more unlabeled tweets related to the COVID-19 pandemic. After then, the deep learning approach can be used to enhance fake news classification.

VII. CONCLUSION AND FUTURE WORK

In this paper, we introduced a new Arabic corpus of fake news that will be made publicly available for research purposes on this link: (<https://github.com/yemen2016/FakeNewsDetection>), after preparing the tweets ID's and their associated classes. We explained the collection process of fake news and gave details about how we select rumors and misinformation topics during the COVID-19 pandemic. The classification task was performed using six classifiers (Naïve Bayes, Logistic Regression, Support Vector Machine, Multilayer Perceptron, Random Forest Bagging, and eXtreme Gradient Boosting) to test the possibility of recognizing fake and genuine tweets. We used four feature types: count vector, word-level TF-IDF, n-gram-level TF-IDF, and character-level TF-IDF. We noticed that the achieved performance varies depending on the features and classifiers used. Along with considering the raw text as an input to the machine learning classifiers, we also used two pre-processing methods: stemming and rooting. Both techniques failed to improve the classification results as the corpus text was collected from Twitter, which includes various dialects and language mistakes. Therefore, the stemming and rooting procedures did not produce correct results. The study concluded that we can achieve higher performance with more annotated data.

In the future, we plan to expand our corpus with additional verified rumour and misinformation topics. We also look forward to investigating the performance of new classification methods such as deep learning. In this research, we only

used content-based features to classify and analyze fake news, though user-based features may also be utilized.

Abstract—Probabilistic graphical models are employed in a variety of areas such as artificial intelligence and machine learning to depict causal relations among sets of random variables. In this research, we employ probabilistic graphical models in the form of Bayesian network to detect coronavirus disease 2019 (denoted as COVID-19) disease. We propose two efficient Bayesian network models that are potent in encoding causal relations among random variable, i.e., COVID-19 symptoms. The first Bayesian network model, denoted as BN_1 , is built depending on the acquired knowledge from medical experts. We collect data from clinics and hospitals in Saudi Arabia for our research. We name this authentic dataset DS_{covid} . The second Bayesian network model, denoted as BN_2 , is learned from the real dataset DS_{covid} depending on Chow-Liu tree approach. We also implement our proposed Bayesian network models and present our experimental results. Our results show that the proposed approaches are capable of modeling the issue of making decisions in the context of COVID-19. Moreover, our experimental results show that the two Bayesian network models we propose in this work are effective for not only extracting casual relations but also reducing uncertainty and increasing the effectiveness of causal reasoning and prediction.

I. INTRODUCTION

Over the last two years, the world has experienced events that changed the whole scenario and would be considered as an extremely dark phase when written as history. This is because of the outbreak of a coronavirus disease 2019 pandemic denoted as COVID-19 that results from the family of viruses and causes issues related to gastrointestinal and respiratory diseases. There are different symptoms associated with the COVID-19 including shortness of breath, cough, fever, and fatigue, etc. It is a challenge to detect COVID-19 as these symptoms are also present in other diseases such as the common cold. The testing or detection of COVID-19 depends on the past or current presence of the SARS-CoV-2. If there is no virus, then the patient cannot be declared as a COVID-19 patient. Moreover, there is a presence of fear in people that can lead to psychological responses.

Medical diagnostic errors, on the other hand, can be considered as the leading error of injury and death. The error in diagnosis of the diseases results in the wrong treatment of the patient, which delays the patient's recovery time, give time for actual diseases to spread, and form another reaction from the wrong medications. There is a need for a strong patient

safety culture to improve the quality and reducing the risks associated with the diagnosis and then the treatment of the patient. For coping with all the mentioned above challenging COVID-19 detection issues, Artificial Intelligence (AI) needs to get involved in order to make the process of detecting the virus become accurate and efficient.

Artificial intelligence and machine learning have been widely used in many real-world applications in recent years. It has been reported that machine learning techniques could be used to deliver automated tools that are able to efficiently predict and detect risks. Artificial intelligence is the way that combines large data, intelligent algorithms, and iterative processing. If artificial intelligence is utilized in the right way, it can be beneficial and powerful. In this regard, this research focuses on the detection of COVID-19 utilizing machine learning, namely using Bayesian networks which is the expanded representation of the probability distribution. Bayesian networks are now established as the indispensable tools of artificial intelligence and are vital in the fields of engineering and science.

Probability theory has provided the base for different engineering and scientific tasks. Artificial intelligence and more specifically machine learning are considered as one of the major fields that have used probability for the development of new algorithms and theorems. In terms of the probabilistic graphical models or PGM's, the Bayesian networks are used at a wide-scale [1]. Bayesian networks are the extensive range class of probabilistic models. Initially, Bayesian networks were the type of statistical model that can show the probability distribution at a complex scale. They are well-developed modeling systems that are useful for monitoring, diagnosing, and making predictions even if uncertainties are present.

In this research, we utilize the soundness of probabilistic graphical models to both build a Bayesian network model using expert's knowledge and learn the structure of the Bayesian network model from authentic data. That is, we propose two probabilistic graphical models that are effective in the context of detecting COVID-19. The proposed probabilistic models are potent in encoding causal relations among random variables, i.e., COVID-19 symptoms, and thus can extract the required knowledge in order to reduce uncertainty and increase effectiveness and accuracy of causal reasoning and prediction.

The main contributions of our research are as follows: We build a naive Bayesian network model using experts' knowledge that is potent in dealing with the uncertainty in

Fig. 1. A Causal Bayesian Network Model that was Built based on the Acquired knowledge from Medical Experts, Denoted as BN_1 . The Direction of the Causal Relations in from the Class Variable to Attributes, i.e., top to Down. Each Node in the Diagnostic Bayesian Network Model has Two States, Either 'yes' or 'no'.

diagnosing the arriving patients in a clinic with COVID-19. We name this causal model BN_1 . We collect data from clinics and hospitals in Saudi Arabia for our research. We name this authentic dataset DS_{covid} . We construct the “best possible” Bayesian network model from the dataset DS_{covid} using Chow-Liu tree approach (we refer the readers to [2], [3], [4] for complete information about Chow-Liu algorithm). We name this causal model BN_2 . We have implemented our approaches and evaluate the correctness of BN_1 using the authentic dataset DS_{covid} . Our results show that the naive Bayesian network model, BN_1 , and the learned model using Chow-Liu tree approach, BN_2 , are identical despite using different ways to recover these causal models. In addition, our experimental results indicate that the two causal models, BN_1 and BN_2 , are promising for reasoning under uncertainty, that is, the proposed models not only are capable to detect COVID-19 positive cases but also can be efficiently used make real-time reasoning and predictions.

The rest of this paper is structured as follows. In Section II, we present our coronavirus diagnostic naive Bayesian network model built using Expert Knowledge. In Section III, we present our coronavirus diagnostic Bayesian network model recovered from the collected authentic data. In Section IV, we present implementations of the proposed causal models and show our empirical results. In Section V, we give a brief overview of background information. In Section VI, we present the conclusion and future work of our research.

II. CORONAVIRUS DIAGNOSTIC NAIVE BAYESIAN NETWORK MODEL FROM EXPERT KNOWLEDGE

In this section, we acquire medical knowledge from experts and then build a Bayesian network model that captures the acquired knowledge. The fundamental purpose is to use the developed Bayesian network model to diagnose the condition of arriving patients suffering from one or some of COVID-19 symptoms.

The acquired medical knowledge is as follows: Coronavirus disease (COVID-19) is an acute respiratory disease that can be detected via investigating either exposure risks or clinical signs

and symptoms. Exposure risks for coronavirus disease increase when communicating with a reported case of coronavirus in the last 14 days before onset of symptoms or living/working in a place identified to be suffering of occurrences of coronavirus in the last 14 days. Clinical signs and symptoms may include one or more of the following:

- (1) Patients suffering from fever above 37.5 degrees Celsius,
- (2) Patients suffering from cough,
- (3) Patients suffering from shortness of breath,
- (4) Patients suffering from sore throat or headache,
- (5) Patients suffering from vomiting, nausea, or diarrhea, and
- (6) Patients suffering from Heart failure, chronic renal failure, and immunocompromised patients.

This knowledge needs to be applied to the situation where a patient is presented in a clinic, and we need to assure whether the patient is infected with coronavirus disease or not. Give the set of symptoms that the patient is suffering from, the doctor would like to know the probability that the patient is infected with coronavirus disease. For instance, if the patients suffers from fever, cough, and shortness of breath, what is the chance that this patient is infected with coronavirus disease and must be quarantined immediately? When getting all information from the patient (i.e., by directly asking the patient about what symptoms the patient suffers from), the developed Bayesian network model will give the final judgement, which will significantly help the doctor and significantly reduce the diagnose time.

Therefore, the goal is to transfer this acquired knowledge into a medical network (i.e., Bayesian network model) that can be used to diagnose arriving patients in a clinic. In order to do so, we first have to determine the variables of the Bayesian network model. In the context of the above given medical knowledge from experts, the variables are either symptoms or conditions, i.e., diseases. There are, indeed, fourteen symptoms and a condition, which is the case whether the patient is infected with coronavirus disease or not. The variables in this Bayesian network model are discrete, i.e., their values are either True or False.

TABLE I. CONDITIONAL PROBABILITY TABLES FOR THE CAUSAL BAYESIAN NETWORK MODEL BN_1

Node	Probability Value(s)		Type
INF	$P(in) = 0.01$	-	Prior Probability
LW	$P(l in) = 0.05$	$P(l in') = 0.01$	Conditional Probability
Fe	$P(f in) = 0.1$	$P(f in') = 0.01$	Conditional Probability
Co	$P(c in) = 0.1$	$P(c in') = 0.01$	Conditional Probability
SB	$P(s in) = 0.1$	$P(s in') = 0.05$	Conditional Probability
He	$P(h in) = 0.02$	$P(h in') = 0.01$	Conditional Probability
ST	$P(t in) = 0.02$	$P(t in') = 0.01$	Conditional Probability
Na	$P(n in) = 0.02$	$P(n in') = 0.01$	Conditional Probability
Vo	$P(v in) = 0.02$	$P(v in') = 0.01$	Conditional Probability
Di	$P(d in) = 0.02$	$P(d in') = 0.01$	Conditional Probability
CRF	$P(r in) = 0.02$	$P(r in') = 0.01$	Conditional Probability
IP	$P(i in) = 0.02$	$P(i in') = 0.01$	Conditional Probability
HF	$P(fa in) = 0.02$	$P(fa in') = 0.01$	Conditional Probability
COM	$P(co in) = 0.05$	$P(co in') = 0.01$	Conditional Probability

The structure of the acquired medical knowledge from experts is represented by the qualitative naive Bayesian network model shown in Fig. 1. There are two layers in the proposed Bayesian network model. The edges in this model go from the first layer, the condition or the variable class layer, to the second layer, the attributes or symptoms layer. One should note that give the condition or the class variable in this Bayesian network model, every two attributes are d-separated, i.e., independent.

We obtain the Conditional Probability Tables (CPTs) from medical experts depending on their subjective beliefs that reflect the practical experience they have gained. The assessment of the prior probability of the class variable and the assessment of the probability of each attribute conditional on its parents, i.e., conditional on the class variable, are give in Table I. We use the notation f to indicate a positive response on the node Fe , 'Fever' and f' to indicate a negative response on the node Fe , 'Fever'. The notation $P(f)$ stands for $P(Fe = f)$. Similar notations are applied to each node in the developed Bayesian network model as follows:

- in stands for a positive response on the node INF ;
- l stands for a positive response on the node LW ;
- c stands for a positive response on the node Co ;
- s stands for a positive response on the node SB ;
- h stands for a positive response on the node He ;
- t stands for a positive response on the node ST ;
- n stands for a positive response on the node Na ;
- v stands for a positive response on the node Vo ;
- d stands for a positive response on the node Di ;
- r stands for a positive response on the node CRF ;
- i stands for a positive response on the node IP ;
- fa stands for a positive response on the node HF ; and
- co stands for a positive response on the node COM .

One should note that Table I includes only positive probabilities while negative probabilities can be easily derived from this table. For instance, the probability of heart failure given that the patient has coronavirus disease is 0.02, formally can be

written as $P(fa|in) = 0.02$. One can derive the probability of not having heart failure given that the patient has coronavirus disease, which is $1 - 0.02 = 0.98$, formally can be written as $P(fa'|in) = 0.98$.

The proposed causal model shows that the joint probability can be written as follows:

$$P(INF, LW, Fe, Co, SB, He, ST, Na, Vo, Di, CRF, IP, HF, COM) = P(INF) P(LW|INF) P(Fe|INF) P(Co|INF) P(SB|INF) P(He|INF) P(ST|INF) P(Na|INF) P(Vo|INF) P(Di|INF) P(CRF|INF) P(IP|INF) P(HF|INF) P(COM|INF)$$

The joint probability is the product of class variable prior probability times all conditional probabilities of all other variables. On the other hand, if we want to calculate the probability that a patient has coronavirus disease given that this patient has fever and has communicated with a person who was reported to have coronavirus disease, we would do the following:

$$P(INF|Fe, COM) = P(INF, Fe, COM)/P(Fe, COM)$$

For more information about this inferential equation, we refer the readers to Bayes theorem [4]. The implementation of the proposed causal model in this section and more experiments will be presented in Section IV.

III. CORONAVIRUS DIAGNOSTIC BAYESIAN NETWORK MODEL FROM DATA

In this section, we learn a Bayesian network model from data. We have collected data from clinics and hospitals in Saudi Arabia for our research. We name our dataset DS_{covid} , which contains the data for 60,000 patients. The dataset DS_{covid} is available at https://emadalsuwat.github.io/resources/Covid19_dataset.dat.

The dataset DS_{covid} consists of cases, a.k.a. tuples. Each case represent a unique object in the collection process. Objects or cases are patients in this research context. Each case in our dataset is characterized by fourteen variables. That is, for each tuple in our dataset, there are fourteen cells, a.k.a

data items, that are required to be filled such that each cell corresponds to a defined random variable. The dataset DS_{covid} is a discrete dataset, which means that the answer to each variables is either “yes” or “no”. For example, case #1 contains information about patient #1 in our dataset and so on. If patient #1 has fever, we shall see “yes” in the cell that corresponds to the random variable “Fever” and so on. If the value of a cell in a tuple is missing (i.e., there is no reported information), the cell is left blank.

We construct the “best possible” tree-shaped Bayesian network model from the learning dataset DS_{covid} . We then determine whether or not the best possible tree-shaped belief network learned using the collected dataset DS_{covid} is the naive Bayesian network model. If so, we say that the naive Bayesian network model is the best possible tree-shaped belief network that fits the collected dataset DS_{covid} .

We construct the “best possible” Bayesian network model from the dataset DS_{covid} using Chow-Liu tree approach, which is an approximation of the probability distribution with tree-shaped belief network. In Chow-Liu tree approach, the links are directed away from the root of the tree-shaped Bayesian network model.

Let DS_{covid} be a discrete dataset over variables $\{V_1, V_2, \dots, V_n\}$. Let $BN_2 = (V, E)$ be the Bayesian network model constructed from the dataset DS_{covid} using Chow-Liu tree approach. Let $V = \{V_1, V_2, \dots, V_n\}$ and $E = \{(v_1, v_2) : v_1, v_2 \in V\}$ be the set of nodes and edges, respectively, in the belief network BN_2 . The causal network BN_2 can be learned as follows [3]:

Step 1: For each pair of vertices $(V_i, V_j) \in BN_2$, we calculate the mutual information as follows.

$$MI(V_i, V_j) = \sum_{V_i, V_j} P(V_i, V_j) \log_2 \left(\frac{P(V_i, V_j)}{P(V_i)P(V_j)} \right) \quad (1)$$

Step 2: Construct the mutual information weighted graph, which we denote as G_{MI} , over the set of vertices $\{V_1, V_2, \dots, V_n\}$, where the weight of the edge (V_1, V_2) in G_{MI} is $MI(V_i, V_j)$.

Step 3: Given the G_{MI} graph, build a maximum weight spanning tree, which we denote as G_{SPT} .

Step 4: Direct the resulting maximum spanning tree G_{SPT} . This can be accomplished by selecting any node in the resulting graph as the root of the tree and then set the direction of the remaining edges to point outward from it. We denote the resulting tree as BN_2 .

In this section, we have shown that it is feasible to estimate the Bayesian network model from medical recorders of patients, i.e., from the collected data. That is, the result of the formal steps presented above is the Bayesian network directed acyclic graph. An important point to be mentioned is that one should use Expectation–Maximization algorithm (a.k.a EM algorithm) to estimate the conditional probability distributions of the constructed causal model, BN_2 , from data. For more information about the EM algorithm, we refer the readers to [5]. The implementation of learning the structure of the causal model BN_2 from the collected data using Chow-Liu tree approach as proposed in this section and more experiments will be presented in Section IV.

IV. IMPLEMENTATIONS OF CAUSAL MODELS AND EXPERIMENTAL RESULTS

In this section, we implement our proposed two Bayesian network models, BN_1 and BN_2 , using *HuginTM Researcher* 8.4. We then present some experimental results to show the practical capability of the proposed causal models.

A. Implementation of the Causal Model BN_1

In this subsection, expert knowledge presented in section II can be modeled by the implemented Bayesian network BN_2 shown in Figure 2. The Bayesian network BN_2 consists of fourteen nodes: Infected (INF), Living/Working (LW), Fever (Fe), and so on. Each node has two states: “Yes” or “No”. For instance, if the presented patient has Fever, we choose “Yes” as the answer for this symptom and vice versa.

Fig. 2 shows the running mode of the Bayesian network model BN_1 . The figure is split into two parts: Node List Pane on the left hand side and Network Pane on the right hand side. It is important to point out that we have expanded all nodes getting ready to enter evidence or facts. For instance, if a patients has Nausea, we then just click on the state “Yes” under the node Nausea in the Node List Pane and so on.

One should note that any two variables in the Bayesian network model BN_2 are independent given the state of the hypothesis variable. That is, if the state of the hypothesis variable Infect is given, then any two variables of the symptoms nodes are independent. Another important note is that causality is obvious and clear in the implemented model BN_2 . That is, the class variable, Infect in this case, is the cause of the other variables, i.e., symptoms. Entering information about the state symptoms (either “Yes” or “No”) will increase/decrease the joint probability that the patient has COVID-19 disease.

B. Implementation of the Causal Model BN_2

In this subsection, we use the four steps presented in Section III to learn the structure of the Bayesian network model from data. That is, we use the Chow-Liu algorithm to recover the structure of BN_2 from the collected dataset DS_{covid} . We present the first few lines of the authentic dataset DS_{covid} in Fig. 3. The data file of the dataset DS_{covid} we use in this implementation consists of 60,000 cases, i.e., tuples.

We use *HuginTM Researcher* 8.4 to learn the Bayesian network model BN_2 from the dataset DS_{covid} . We use *HuginTM* implementation of Chow-Liu algorithm with the default significance level at 0.05 [6]. It is important to keep the level of significance at the default setting and not to increase this value in order to reduce the running time of the Bayesian network structure learning algorithm to the best possible running time.

The recovered Bayesian network model from the dataset DS_{covid} is as shown in Fig. 4. When comparing the result of Chow-Liu algorithm, BN_2 , with the result of the original model we built using experts’ knowledge, BN_1 , we observe the following: 1) All nodes have been recovered correctly, 2) All links have been recovered correctly, and 3) There is no missing or misoriented links, i.e., the original and the learned Bayesian network models indicate the same causal

Fig. 2. The Implemented Bayesian Network Model BN_1 .

Fig. 3. The First Few Cases (Tuples) of the Data File of the Authentic Dataset DS_{covid} .

relationships. We thus conclude that Chow-Liu structure learning algorithm was able to perfectly recover the structure of the Bayesian network model BN_2 from the collected dataset DS_{covid} .

C. Reasoning using the Proposed Models

In this subsection, we employ the implemented Bayesian network models, BN_1 and BN_2 , for reasoning under uncertainty. That is, given some symptoms that a presented patient in a clinic suffers from, the medical practitioner can then utilize one of these models to find out the probability that this patients is infected with COVID-19.

Using BN_1 for Reasoning under Uncertainty: Assume that a patient presented in a clinic where this patient has been in contact with a person who has COVID-19 and suffers from Fever and Sore Throat. The medical practitioner employs the

Bayesian network model BN_1 to calculate the inferential (conditional) probability $P(INF = "Yes" | Fe = "Yes", ST = "Yes", COM = "Yes")$, which can be calculated by dividing the joint probability $P(INF = "Yes", Fe = "Yes", ST = "Yes", COM = "Yes")$ by the probability of evidence $P(Fe = "Yes", ST = "Yes", COM = "Yes")$.

The medical practitioner can simply enter the evidence on the nodes "Fever", "Soreth" and "Contact". That is, the medical practitioner chooses the state "Yes" on these three nodes as shown in Fig. 5.

We eventually propagate these pieces of evidence in order to calculate the conditional probability. The conditional probability is calculated by dividing the joint probability by the probability of the evidence. BN_1 can be used to obtain the joint probability as follows: $P(INF = "Yes", Fe = "Yes", ST = "Yes", COM = "Yes") = 8.5916e - 7$.

Fig. 4. The Result of using Chow-Liu Algorithm to Learn the Bayesian Network Model BN_2 from the Authentic Dataset DS_{covid} .

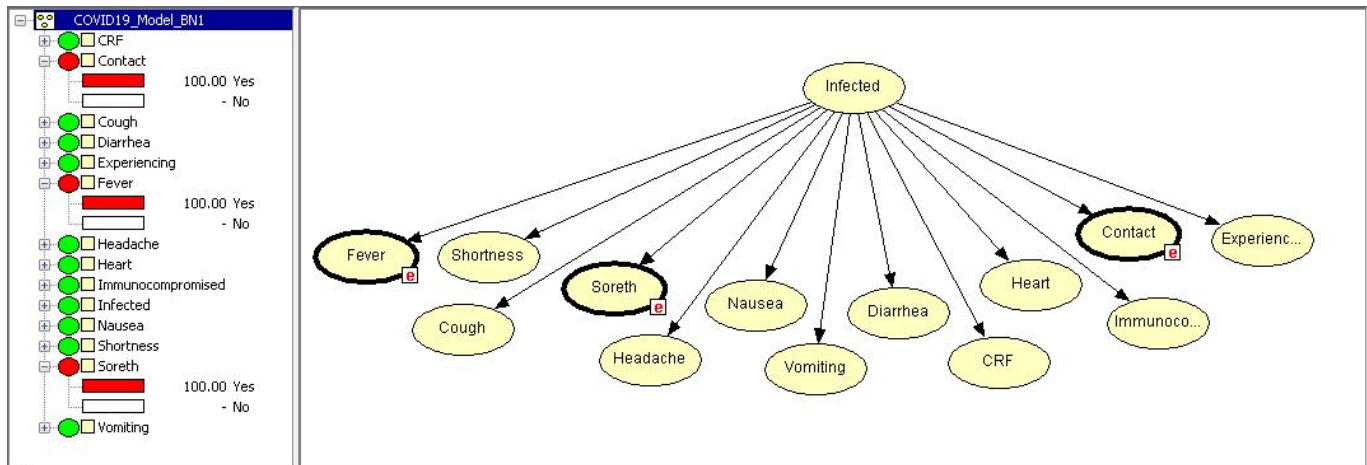

Fig. 5. The Bayesian Network Model BN_1 After Entering the Evidence on the Three Nodes: Fever, Soreth and Contact.

BN_1 also can be used to obtain the probability of the evidence as follows: $P(Fe = \text{“Yes”}, ST = \text{“Yes”}, COM = \text{“Yes”}) = 1.99e - 6$. Thus, the conditional probability can be calculated as follows: $P(INF = \text{“Yes”} | Fe = \text{“Yes”}, ST = \text{“Yes”}, COM = \text{“Yes”}) = \frac{8.5916e-7}{1.99e-6} = 0.432$.

Using BN_2 for Reasoning under Uncertainty: Assume that an arriving patient presented at a clinic suffers from the following symptoms: Fever and Shortness of Breath, and Cough. In addition, the patient has reported that there was a communication with a reported case of coronavirus in the last 14 days before onset of symptoms. The medical practitioner thus employs the Bayesian network model BN_2 to calculate the inferential probability $P(INF = \text{“Yes”} | Fe = \text{“Yes”}, SB = \text{“Yes”}, Co = \text{“Yes”}, COM = \text{“Yes”})$, which can be calculated by dividing the joint probability $P(INF = \text{“Yes”}, Fe = \text{“Yes”}, SB = \text{“Yes”}, Co = \text{“Yes”}, COM = \text{“Yes”})$ by the probability of evidence $P(Fe = \text{“Yes”}, SB = \text{“Yes”}, Co = \text{“Yes”}, COM = \text{“Yes”})$.

The medical practitioner can simply provide the evidence on the nodes “Fever”, “Shortness”, “Cough”, and “Contact”. That is, the medical practitioner selects the state “Yes” on these

four nodes as shown in Fig. 6.

These pieces of evidence are then propagated with the ultimate goal of calculating the conditional probability. The conditional probability is calculated as follows: 1) Employ the Bayesian network model BN_2 to obtain the joint probability. Using the model BN_2 , the joint probability $P(INF = \text{“Yes”}, Fe = \text{“Yes”}, SB = \text{“Yes”}, Co = \text{“Yes”}, COM = \text{“Yes”}) = 4.0411e - 7$. 2) Employ the Bayesian model BN_2 to find the probability of the evidence. Using BN_2 , the probability of the evidence $P(Fe = \text{“Yes”}, SB = \text{“Yes”}, Co = \text{“Yes”}, COM = \text{“Yes”}) = 5.495e - 7$. 3) Calculate the conditional probability as follows: $P(INF = \text{“Yes”} | Fe = \text{“Yes”}, SB = \text{“Yes”}, Co = \text{“Yes”}, COM = \text{“Yes”}) = \frac{4.0411e-7}{5.495e-7} = 0.735$.

we have shown that our implemented causal models are efficient in detecting patients with COVID-19 disease given the set of symptoms they suffer from. It is important to point out that our causal models are an outstanding technique to control the disease. Moreover, these models are great as they enable medical practitioners to take decisions under uncertainty.

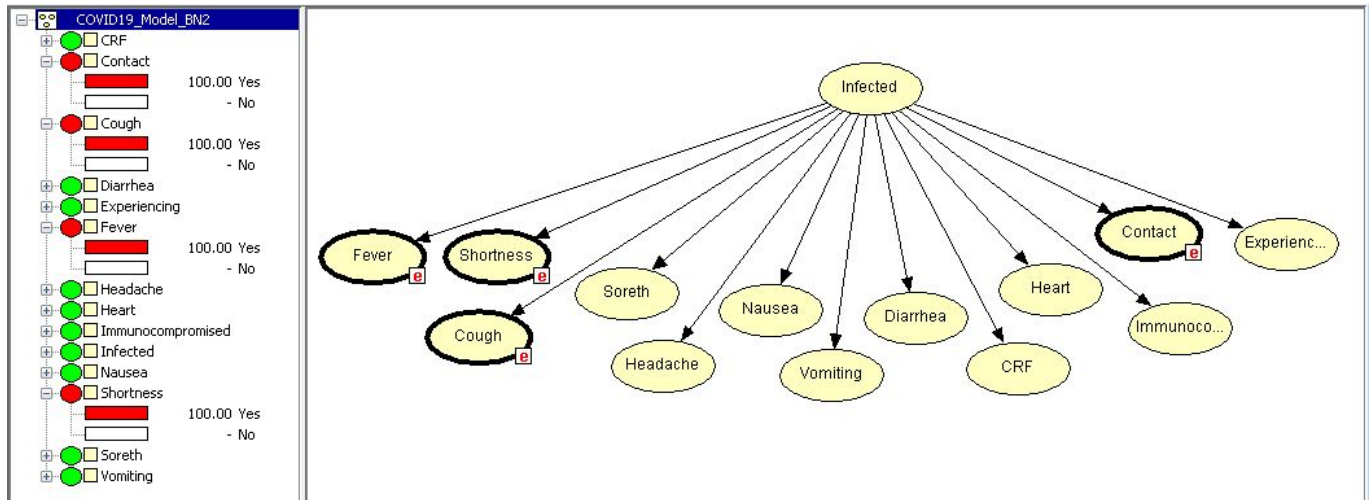

Fig. 6. The Bayesian Network Model BN_2 After Entering the Evidence on the Three Nodes: Fever, Shortness, Cough, and Contact.

V. BACKGROUND INFORMATION

In this section, we will give a brief overview of the use of artificial intelligence, namely Bayesian network models, a favorable tool for decision making. More detailed information about probabilistic graphical models and Bayesian network can be found in [4], [7], [8], [9].

Artificial intelligence is a technology that became prevalent in all different kinds of businesses. However, its use in healthcare has only started in recent years. This increased use is because the technologies have the transforming potential in different aspects of healthcare [10], [11], [12]. Machine learning is a statistical technique for learning the training models with data and for fitting models to data. It is one of the common forms of artificial intelligence. It can be evident from the fact that 63% of corporates that use artificial intelligence were employing machine learning in their corporates and businesses [10]. There are different applications of machine learning in healthcare. For instance, precision medicine- predicting the best treatment method on the basis of the patient attributes and treatment context [10], [13].

The use of probabilistic graphical models has started in 1985 when Pearl (1985) combines the probabilities theories and graphs for obtaining the comprehensible representation of the probability distribution. Further improvements in the specific models can be observed by the research of Lauritzen and Speigelhalter (1988) by Cooper and Herskovits (1992) [1], [14], [4]. The need to overcome difficult and complex problems that exist in the real world has increased the demand for using effective meta-heuristic algorithms that are able to get solutions by performing a momentous search for getting possible solutions.

The probabilistic graphical models have traditionally been used for different purposes. For instance, research indicates the use of probabilistic graphical models for dealing with age estimation of living people [15]. The importance of age estimation of the living individual has been raised because of the civil, criminal, and administrative judicial situations, and it has a significant role in the medicolegal and forensic services all around the globe. Other researchers used the Bayesian

approach for determination of clavicular epiphysis [15]. Moreover, it has been suggested to use probabilistic graphical models for evolutionary algorithm and solving complex problems. The evolutionary computation was performed perfectly using the probabilistic graphical models [15].

The diagnostic is considered as one of the major practices in artificial intelligence. Research shows several probabilistic diagnostic methods that can be implemented in the upcoming medicine research. We refer the readers to [16] for a complete list of possible uses of artificial intelligence in medicine. Another widely use of Bayesian networks other than medical research is detecting spam (a.k.a. spam filtering) [17]. Bayesian networks has also been employed and showed outstanding results in intrusion detection. Recent survey on intrusion detection using machine learning can be found in [18], [19].

Another significant application of Bayesian networks is predicting the type of hematological malignancies [20]. Bayesian networks have helped scientists to model Acute Myeloid Leukemia (AML), which is a subtype of blood cancer. Thus, research has shown that Bayesian network was not only able to model and predict many subtypes of cancer but also help physicians choose the most effective treatment. Bayesian network performance in prediction and reasoning under uncertainty was compared in the literature with other machine learning types. Indeed, Bayesian networks was proved to be a very efficient predictive model in finding probabilistic graphical relationships among random variables. Recently, researchers have employed Bayesian networks to improve screening of COVID-19 cases [21]. The above literature has given model examples that suggests the use of Bayesian networks in healthcare sector for detecting and differentiating between different and complex medical conditions. Previous work for detecting COVID-19 has focused on different machine learning tools except Bayesian networks even though Bayesian networks are very powerful in reasoning under uncertainty [22], [23], [24]. In this work, we explore the feasibility of using the probabilistic graphical models in the form of Bayesian networks to build an effective diagnosis system for controlling and detecting COVID-19 disease. The proposed

Bayesian models are useful in current situation for increasing the speed of diagnosis, which can be helpful in treating and coping with this disease efficaciously.

VI. CONCLUSION AND FUTURE WORK

In this research, we demonstrated the applicability of utilizing probabilistic graphical models in the form of Bayesian networks to detect patients with COVID-19 disease. We proposed two diagnostic Bayesian network models: BN_1 and BN_2 . We implemented the proposed Bayesian network models and conducted our experimental results. Our results indicate this research succeeded in designing and building two effective Bayesian network models to tackle the issue of dealing with arriving patients who may have COVID-19 disease. Our experimental results also show that our proposed Bayesian network models are effective in not only extracting the casual relations but also reducing uncertainty and increasing the effectiveness of causal reasoning and prediction.

In our future work, we aim to extend Bayesian network models we built in this research in order to address more diseases beside COVID-19. In particular, we aim to extend our Bayesian network models to handle rare subtypes of blood cancer as such diseases are very unlikely to get funded or find interested researchers.

Abstract—Global warming and climate change have become universal issues recently. One of the leading sources of climate change is automobiles. Automobiles are the prime source of air pollution in urban areas globally. This has resulted in a problematic and chaotic state in the development of an automatic traffic management system for capturing and monitoring vehicles' hourly and daily passage. With the significant advancement of sensor technology, atmospheric information such as air pollution, meteorological, and motor vehicle data can be harvested and stored in databases. However, due to the complexity and non-linear associations between air quality, meteorological, and traffic variables, it is difficult for the traditional statistical and mathematical models to analyze them. Recently, machine learning algorithms in the field of traffic emissions prediction have become a popular tool. Meteorological and traffic variables influence the variation and the trend of the traffic pollutants. In this paper, an optimized artificial neural network (OANN) was developed to enhance the existing artificial neural network (ANN) model by updating the initial weights in the network using a Genetic Algorithm (GA). The OANN model was implemented to predict the concentration of CO , NO , NO_2 , and NO_x pollutants produced by motor vehicles in Kuala Lumpur, Malaysia. OANN was compared with Artificial Neural Network (ANN), Random Forest (RF), and Decision Tree (DT) models. The results show that the developed OANN model performed better than the ANN, RF, and DT models with the lowest MSE values of 0.0247 for CO , 0.0365 for NO , 0.0542 for NO_2 , and 0.1128 for NO_x . It can be concluded that the developed OANN model is a better choice in predicting traffic emission concentrations. The developed OANN model can help environmental agencies monitor traffic-related air pollution levels efficiently and take necessary measures to ensure the effectiveness of traffic management policy. The OANN model can also help decision-makers mitigate traffic emissions to protect citizens living in the neighborhood of highways.

Keywords—Optimized Artificial Neural Network (OANN); Genetic Algorithm; traffic emissions

I. INTRODUCTION

Global warming and climate change have become universal issues recently [1, 2]. One of the leading sources of climate change is emissions from motor vehicles. Carbon monoxide (CO), nitrogen dioxide (NO_2), carbon dioxide (CO_2), and nitrogen monoxide (NO) are among the significant risk to human health and the environment, which can be emitted by motorized vehicles [3]. Road transport emissions exposure

can increase the risk of lung cancer [4], respiratory and cardiovascular effects [5, 6], pulmonary, chronic diseases [7] and mortality [8, 9]. In 2015 air pollution, in general, are responsible for over 6 million deaths in the world [10, 11]. There is more than 400,000 premature death in Europe [12], and around 7 million worldwide [13].

Automobiles are the prime sources of air pollution in city areas universally. For example, 80.49% of emissions in Beijing, China, were produced by motor vehicles [14]. It was also found that 80% of air pollution in the Lima Metropolitan Area was produced from automobiles [13]. In China, 85% of emissions were from transport [15], while in the United Kingdom was 92% [16], and 75% in Malaysia [17], but in the United States, automobiles are responsible for emitting 57% of air pollution [7]. Many other studies also show that 92% of CO and 65% of hydrocarbon (HC) pollutants were emitted from the transportation activities in Shanghai [18], and 60% of NO_x and PM emissions were from heavy-duty trucks in China [19].

The variation and trend of air pollution strongly depend on meteorological parameters and traffic characteristics [20]. A study conducted in Shiraz, Iran, confirmed that meteorological conditions increase the air pollution level [21]; a similar result was also found in Karaj, Iran [22]. A relationship between air pollution and meteorological condition was studied in Beijing and Nanjing, China. The study reveals that air pollution concentrations depend on meteorological factors [23]. Research in Linfen city, China, shows negative correlations between air pollutants and meteorological parameters [24]. A study was conducted in Penang, Malaysia, to investigate the sources contributing to air pollution concentrations. Five air pollutants were investigated. The result shows that a negative correlation was found between relative humidity with CO , O_3 , SO_2 , PM_{10} , and NO_2 .

A negative correlation was found between wind speed and CO , SO_2 , and NO_2 , but positive relation with PM_{10} and O_3 . Whenever temperature increases, the O_3 , NO_2 , CO , and PM_{10} pollutants increase too, but SO_2 decrease [25]. A study on O_3 variability due to meteorological parameters was investigated in Selangor, Malaysia. The result shows that wind speed, temperature, relative humidity, and wind direction significantly impact O_3 concentrations [26]. [27]

studied air pollution variation due to meteorological in four areas in Malaysia, namely, Petaling Jaya, Cheras, Shah Alam, and Klang. The result reveals that meteorological parameters influenced the seasonal trend of air pollution. Association between air pollution and traffic characteristics has also been investigated. A study was conducted to compare the impact of traffic volume on air pollution levels during COVID-19 in Italy. Data from 2017 to 2018 before COVID-19 and 2020 data during COVID-19 were used. The result reveals that traffic volume significantly impacts PM_{10} , NO_x , NO , and NO_2 concentrations [28].

A study of [29] investigates the exposure of air pollution produced by vehicles on cyclists in Brazil. The research indicates an increase in motor vehicles during peak hours in the morning and evening. The expansion of the vehicle increases the level of air pollution. In addition, air pollution level due to traffic characteristics was studied in Japan [20]. The result indicates that the low speed of the vehicle increases the pollution level. Similarly, traffic volume and congestion increase the emission of air pollution in Kyoto, Japan. It was also found that trucks are the main contributor of PM and NO_x emissions. Furthermore, a study in Kuala Lumpur was conducted to investigate the effect of traffic characteristics on the air pollution level. The study reveals that air pollution level strongly depends on fuel consumption, traffic volume, vehicle speed, and waiting time on the road. The result also shows that lower traffic congestion reduces the level of air pollution in Kuala Lumpur [30].

With the rapid advancement of sensor technology, atmospheric information such as air pollution, meteorology, and motor vehicle data can be collected and stored in databases. Due to the complexity and non-linear associations that exist between air quality, meteorological, and traffic variables, it is difficult for traditional statistical and mathematical models to analyze them [31, 32]. Lately, the usage of machine learning algorithms such as long short term memory, random forest, support vector machine, decision tree, and artificial neural network (ANN) in traffic-related air pollution prediction has become popular [33]. ANN model appeared to be the most used model for predicting traffic emissions because it reduces time, cost, and complexity. It also provides fast and accurate prediction with less error and provides prediction values closer to the observed values [34]. ANN can solve complex multidimensional variables and non-linear problems related to traffic emission concentrations due to meteorological conditions and traffic features [34, 35].

In this paper, an optimized artificial neural network (OANN) was developed to enhance the existing artificial neural network (ANN) model by updating the weights in the network using a Genetic Algorithm (GA). The OANN model was implemented to predict the concentration of CO , NO , NO_2 , and NO_x pollutants produced by motor vehicles in Kuala Lumpur, Malaysia. The remaining structure of the paper is given as follows. Section II discusses the related work on vehicle emissions prediction using the ANN model. Section III presents the methodology used in this study. Section IV presents the result and the comparison with existing machine learning models for evaluation. Finally, the conclusion is discussed in Section V.

II. RELATED WORK

Motor vehicles are producing harmful pollutants that disperse to the atmosphere [33]. These pollutants have significant impact on human health [36]. Several statistical models have been developed for predicting the traffic emissions concentrations at intersection, canyon, street, near the school, and many other locations. However, these statistical models could not predict the emissions rate due to the variability and influence of meteorological variables and traffic parameters [31]. Machine learning models have recently been applied. These models were able to predict the concentrations of emitted pollutants from motor vehicles. ANN has become the most popular model for predicting traffic-related air pollution [34]. These models are highly dependent on the independent variables provided in the study. There is a lack of either meteorological data or traffic data in many studies [37]. Several studies suggested that meteorological and traffic variable influence the trend and variation of traffic pollutants [33], such as relative humidity, temperature, wind direction, and wind speed, [38], traffic volume, vehicle speed [39], types of the vehicle, etc. [40].

The variables mentioned above are needed to predict emission levels. Still, it is not always available [37], for example, prediction of carbon monoxide (CO) concentrations at Jiyan Ave and Shuanglong intersections was conducted by [41] using Gated Recurrent Unit (GRU) neural networks based in the absence of a meteorological dataset. The accuracy of the model's performance was found good with a root mean squared error (RMSE) of 0.088 and mean absolute error (MAE) of 0.056. [42] proposed machine learning algorithms by comparing and selecting the best model with good performance to reduce the effect of Greenhouse gas (GHG) emitted by passenger vehicles on climate change in Canada. Artificial Neural Network (ANN) shows better performance over the other machine learning algorithms with RMSE of 0.442 and MAE of 0.347. This study also lacks the meteorological dataset. ANN was developed by [43] to predict the emission of CO , CO_2 , NO_x , and HC from a liquefied natural gas bus in Zhenjiang, China, without considering meteorological features. The performance of the prediction of CO_2 was unsatisfactory. The MSE value is 52, but the remaining predictions of the contaminants were good. The MSE value for CO 2.23, HC 0.68, and NO_x 9.4. Carbon monoxide was predicted using a Non-linear Autoregressive Exogenous (NARX) based neural network in the absence of traffic data at Shiraz, Iran [44]. The proposed model performed well compared to the previous models with RMSE values of 0.43, R^2 0.31, and MAPE 51.

There are some studies used three datasets, namely, air quality, meteorological, and traffic datasets. ANN was applied to predict the level of NO , NO_2 , O_3 , NO_x , CO_2 , PN_{10} , NH_3 , PM_{10} , $PM_{2.5}$, and PM_1 pollutants from on-road vehicles at the street canyon in Germany. The model have the lowest RMSE for some pollutants, while others have the highest RMSE, which shows that the model has to be improved for predicting these pollutants. The RMSE for NO , NO_2 , O_3 , NO_x , CO_2 , PN_{10} , NH_3 , PM_{10} , $PM_{2.5}$, and PM_1 were 16.017, 5.092, 5.774, 32.820, 0.790, 12,872.74, 13.474, 0.050, 0.013, and 0.010 [45]. [46] proposed an ANN model to predict CO concentration at Subang Jaya Toll plaza, Selangor, Malaysia. Traffic and meteorological variables were used as an input to the model. The model shows good accuracy with

MAE 0.8925, RMSE 1.2736, RAE 21.99, and RRSE 19.40. A comparison with ANN and developed ResNetELF was conducted [47] to predict the CO , CO_2 , NO_x , and HC levels. The ANN performed well with RMSE 0.0930 for CO , 0.080 for CO_2 , 0.0856 for NO_x , and 0.0798 for HC . Furthermore, [48] predict NO , CO , and HC concentrations using the ANN model. The model's performance was found good with RMSE 1.89, 0.97, 1.09 for NO , CO , and CO_2 . Table I presents the variables and size of the dataset used by previous studies. Table II summarizes the performance of the models used in the previous researches.

III. METHODOLOGY

A. Data and Location

In this paper, air quality, meteorological, and traffic datasets were used. The traffic data was obtained from the Ministry of Works, Malaysia, while the air pollution and meteorological datasets are collected from the Department of Environment (DOE), Malaysia. These datasets are set of observations recorded at a specific time for sixteen hours daily for three years (2014-2016). The CO , NO , NO_2 , and NO_x features from air quality and meteorological features such as relative humidity, wind speed, and temperature were used [36]. The traffic dataset consists of traffic volume, the volume of the type of vehicle (taxi and car, bus, van, heavy and light lorries, and motorcycle), time spent on the road, and speed of the vehicle were used [49]. The traffic dataset was collected from the Ministry of Works Malaysia at Jalan Kepong traffic census station located in Kuala Lumpur, Malaysia.

B. Design and Development of OANN Model

An optimized artificial neural network (OANN) was designed and developed to enhance the existing artificial neural network (ANN) model by updating the initial weights in the network using a Genetic Algorithm (GA). An artificial Neural Network (ANN) is an information processing system develop to imitate the human brain's learning and decision-making from experience and examples [50, 51]. The structure of the ANN model consists of input layer, hidden layers, and output layer(s). These layers consist of neurons. These neuron's connection is associated with weight and bias. The neurons have an activation function that determines the neuron's output [52]. The structure of the ANN equation is given below [51]:

$$y = f \left(\sum_{i=1}^n w_i v_i - b \right) \quad (1)$$

Where y is the output of the network, n is the number of neurons in hidden layers, w_i is the weights of the respective neurons, v_i is the input values of the neurons, f is the activation function, and b is the bias. The learning process of ANN improves the model's performance during training by updating the weights in the network. The weights of neurons in ANN define how much influence the input has on the output. The initial weights are randomly chosen [53]. The optimization method has been used to improve and update the weights to efficiently improve the model's accuracy.

Optimization is a process of making something better or finding the best solution, or making a good decision. In this study, a Genetic Algorithm (GA) was designed and developed to optimize the initial weights of ANN to improve its performance in this study. GA works as a process of making changes or finding optimal solutions for the problems. GA works on a

population with a chromosome, and each chromosome has a number of values known as genes [54, 55, 56].

Population in GA represents the entire network's weights (that is, the weights of the input layer to the hidden layer and the weights of the hidden layers to the output layer). Chromosomes represent the weights in one layer (for example, the weights of the input layer to the hidden layer). Finally, Gene represents each neuron's weight (for example, if we have five neurons in the input layer). Fig. 1 illustrates the representations of the GA in the ANN model.

Fig. 1. Representation of GA in an ANN Model.

We will create three vectors. The first vector holds the number of chromosomes per population, the second vector holds the size of the population, and the last vector holds the initial population. There are few processes to generate a new and better population. The processes are given below:

- 1) Select the best parent based on their fitness function.
- 2) The selected parents will be used to produce offspring.
- 3) The production of offspring was performed using crossover and mutation.
- 4) Generated offspring (we create a vector to hold the generated offspring (new population)).
- 5) The algorithm generates new populations (based on how many generations needed).
- 6) One of the best population will be selected.
- 7) The algorithm stops when the optimal solution is found.

Ring pattern was used for selecting parent; for example, if we have ten chromosomes and each chromosome has six genes, the newly generated population will have the same number of chromosomes and genes. If seven chromosomes were found to have the highest fitness value, they would be selected. The remaining three chromosomes will be produced using the ring style. The algorithm will combine the seventh and the first chromosome to produce the eighth one. The first and second chromosomes will be combined to produce the ninth one; we apply a similar way until we get similar

chromosomes in the new generation. An example of initial weight (population) is given in Fig. 2.

Fig. 2. Population in Genetic Algorithm (GA)/Weights in ANN.

The selection of parents was done by calculating the fitness value or function. This was performed using the equation below [57, 58]:

$$f(c) = 2c + 2 \quad (2)$$

Where f is the fitness and c is the chromosome values (genes/weights). An example of a population given in Fig. 2 was calculated in Table III. Based on the table, the first, third, and last chromosomes have the highest fitness values. These parents will be selected to produce new offspring.

TABLE III. FITNESS VALUES CALCULATION

Chromosome	Fitness Function	Parent Selection
0.42 + 0.95 + 0.01 + 0.11 + 0.22 + 0.10 = 1.61	$f(1.72) = 2(1.72)+2 = 5.44$	5.44
0.12+ -0.51 + 0.05 + 0.19 + 0.25 + 0.26 = 0.36	$f(0.36) = 2(0.36)+2 = 2.72$	2.72
0.02 + 0.06 + 0.09 + 0.50 + 0.32 + 0.69 = 1.68	$f(1.68) = 2(1.68)+2 = 5.36$	5.36
0.31 + 0.60 + -0.02 + 0.52 + 0.16 + 0.01 = 1.58	$f(1.58) = 2(1.58)+2 = 5.16$	5.16

As we have discussed earlier, producing offspring was done through crossover and mutation. The crossover is the process of combining two selected parents to produce two offspring [56, 59]. The first half of the first parent and last half of the second parent are selected as the first half of the offspring, while the last half of the first parent and the first half of the second parent were chosen as the second half of the offspring. Fig. 3 shows the producing offspring using the crossover.

Fig. 3. Producing Offspring Using Crossover.

The mutation was achieved by changing the gene's (weight) value from the new offspring [57, 60]; the altered gene was called a mutant. The gene alteration was done randomly by changing the gene with a lower or higher number than the value of the previous gene range between -1 to 1. An example of mutation is presented in Fig. 4.

Fig. 4. Producing Offspring Using Mutation.

After the new population was generated, the algorithm produces new generations (based on how many generations are needed). One of the best generations (optimized weights) will be selected and used as the weights of the ANN model. The flow chart of the Genetic Algorithm (GA) for selecting or producing a new solution has been presented in Fig. 5.

Fig. 5. The Flow Chart of GA for Finding Optimal Solution.

C. Implementation of the OANN Model

The developed OANN predictive model was implemented to predict the concentrations of pollutants produced by motor vehicles. The estimated hourly traffic volume, generated vehicle speed and time spent on the road, standardized pollutants values, meteorological and air quality variables were used to train and to test the developed predictive model for traffic emissions concentrations.

The developed OANN model consists of four layers: one input layer, two hidden layers, and one output layer. The input

layer consists of 12 inputs: traffic volume, taxi and car volume, bus volume, van volume, heavy lorries volume, light lorries volume, motorcycle volume, time spent on the road, vehicle speed, and relative humidity, wind speed, and temperature. The first hidden layer has ten neurons. The second hidden layer has 100 neurons. The output layer has only one output. The output is the predicted values of the pollutants. For OANN prediction model was created for all the four pollutants namely, CO, NO, NO₂, and NO_x. The linear activation function was used from the output layer. The ReLU activation functions were used for the hidden layers.

The weights of the model were optimized using a Genetic Algorithm. Fifty populations were generated, and one of the best populations was selected. The structure of the OANN model has been presented in Fig. 6 and applying the GA in the model was presented in the Fig. 7.

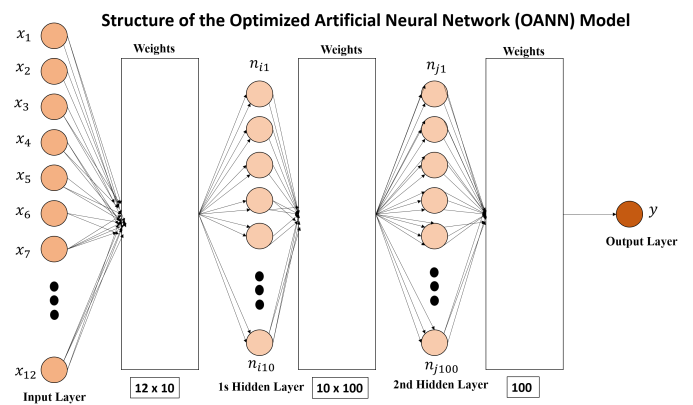

Fig. 6. Structure of the OANN Model.

Fig. 7. GA in an OANN Model.

IV. RESULT AND DISCUSSION

The developed Optimized Artificial Neural Network (OANN) model was evaluated using two main regression metrics, namely, Mean Absolute Error (MAE), Mean Squared Error (MSE), and comparison with Artificial Neural Network (ANN), Decision Tree (DT), and Random Forest (RF) models. MSE is the difference between the actual and predicted values. The MEA calculates and finds the differences between the

measure or predicted value and the observed value. Equation 3 used in this study is given below [61]. MSE is the difference between the actual and predicted values. MSE was calculated using equation four [62].

The n is the number of prediction values, \sum represent the summation (adding all the values), \hat{x}_i is the predicted values, x_i represents the actual values, and $|\hat{x}_i - x_i|$ is the absolute errors.

$$MAE = \frac{1}{n} \sum_{i=1}^n |x_i - \hat{x}_i| \quad (3)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (x - \hat{x})^2 \quad (4)$$

An Optimized Artificial Neural Network (OANN) was developed to predict the concentration of traffic emission in Jalan Kepong area, Kuala Lumpur. The OANN was enhanced by updating the initial weights of the ANN model using GA to improve the accuracy of the existing ANN model. There is a total of 1120 initial weights generated by the model. These weights were from the input layer neurons, first hidden layer neurons, and second hidden layer neurons. There are 12 neurons in the input layer, and they are connected to the first hidden layer. There are ten neurons in the first hidden layer, and they are connected to the second hidden layer. Finally, there are 100 neurons in the second hidden layer, and they are attached to the neuron in the output layer. The generated weights were optimized to improve the ANN model. The GA generated 50 populations/optimized weights, and one of the best populations was selected. Fig. 8 presents the best solution or best population/optimized weights for predicting the concentrations of CO , NO , NO_2 , and NO_x emissions.

Fig. 8. Best Solution/Population/Weights for Predicting the CO , NO , NO_2 , and NO_x Pollutants.

The best set of weights will be selected from the generated 50 population. In Fig. 8 the set of weights was selected after 33 generation for predicting the CO pollutant.

The best set of weights for predicting NO pollutant was selected after 24 generations. Best optimized weights were

selected after 38 generations for NO_2 prediction. The best set of weights was selected after 45 generations for predicting the level of NO_x emissions. Sample of the optimized populations/weights was illustrated in Fig. 9.

best_solution_weights - List (6 elements)

Ind	Type	Size	Value

Fig. 9. The Optimized Weights in The Layers.

The highlighted in yellow colors in Fig. 9 were the optimized weights from the input layer to the first hidden layer, which consist of 12 neurons connected to the first hidden layer with ten neurons. The first hidden layer consists of 10 neurons connected to the second hidden layer with 100 neurons. The second or last hidden layer has 100 neurons connected to the output layer with one neuron. The population with the optimized weights were chosen for prediction of the CO , NO , NO_2 , and NO_x . The set of the optimized weights for the prediction of the CO pollutant was presented in Fig. 10.

Fig. 10. The Optimized Weights in the Network.

The highlighted green color in Fig. 10 were the number of neurons in the layer. While the highlighted in yellow colors were the number of neurons connected to the next layer.

A sample of the total fitness of each generation by GA for predicting CO pollutant has been given. The fitness values of the first set of weights were 10.505416290436793. There are no changes in the fitness values until the seventh generation. In the eighth generation, there is a change from 10.505416290436793 to 10.548116345442276. In the ninth generation, there is a change from 10.548116345442276 to 10.791954330972974. From the tenth generation until the thirty-second generation, there were no changes for the fitness functions. In the thirty-three generation, there is a change from 10.791954330972974 to 10.818411975096184. From thirty-fourth generation until fifty generations there is no change in the fitness value. The highest fitness value of the weights was found in the thirty-three generation.

The developed Optimized Artificial Neural Network model was used to predict the concentrations of CO , NO , NO_2 , and NO_x pollutants emitted by motor vehicles in Jalan Kepong, Kuala Lumpur. Mean absolute error (MAE) and mean squared error (MSE) regression metrics were used to evaluate the performance of the model. Fig. 11 shows the predicted and original values of the pollutants. The prediction of the CO pollutant shows that the model was able to follow the trend of the original values. Similarly, the prediction of NO also follows the trend of the original values with a slightly difference. The OANN model also followed the trends of the original values for predicting the NO_2 and NO_x pollutants.

Fig. 11. Predicted Values and the Original Values of the Pollutants Using OANN Model.

The developed OANN model's performance was compared with ANN, DT, and RF models for evaluation by predicting the concentrations of CO , NO , NO_2 , and NO_x pollutants. The performance of the models was evaluated using mean squared error and mean absolute error. Fig. 12, 13, 14, and 15 present the original or real values with the predicted values for CO , NO , NO_2 , and NO_x predictions. It can be seen that the predicted values of the developed OANN model were able to follow the trend of the real values more than the DT, RF, and ANN models. The ANN model was not able to follow the trend of the real values except for predicting the NO_x pollutant.

Fig. 12. Comparison of Original values and Predicted Values between OANN, ANN, RF, and DT Models for CO Prediction.

Fig. 13. Comparison of Original values and Predicted Values between OANN, ANN, RF, and DT Models for NO Prediction.

Fig. 14. Comparison of Original values and Predicted Values between OANN, ANN, RF, and DT Models for NO_2 Prediction.

Fig. 15. Comparison of Original values and Predicted Values between OANN, ANN, RF, and DT Models for NO_x Prediction.

Table IV presents the comparison of MAE and MSE values between OANN, ANN, RF, and DT for predicting the concentrations of CO , NO , NO_2 , and NO_x pollutants. The result shows the performance of the OANN model for predicting the concentrations of CO was found better than the ANN, DT, and RF models with lowest MAE and MSE values of 0.1155 and 0.0248. The ANN model performed better than RF and DT with the lower MSE values of 0.0441 for the CO prediction. The DT model performed a little better than the RF model with lower MAE and MSE scores of 0.1522 and 0.0446, whilst the MSE and MAE values of RF were 0.0463 and 0.1551.

The comparison of the OANN, ANN, DT, and RF models shows the significant difference of results in terms of MSE and MAE values for predicting the level of NO pollutant. The MAE and MSE values of the developed model were found lowest compared to DT, RF, and ANN models. The MAE and MSE values were 0.1263 and 0.0365, and this shows that the enhanced OANN model was better than the RF, ANN, and DT models. The DT model performed better than the RF and ANN models with lower MAE and MSE scores of 0.1446 and 0.0642. The MAE and MSE values of the ANN model were higher than the RF model, which shows that the RF model was performed better than the ANN model. The MAE and MSE values of the RF model were 0.1450, 0.0644, and for the ANN model were 0.5042 and 0.3040.

The performance of the OANN model is better than the DT, RF, and ANN models with the lowest MAE and MSE values for predicting the concentrations of NO_2 emissions. The MAE and MSE values were 0.1731 and 0.0542. Moreover, the performance of the ANN model was found unsatisfactory with the highest MAE and MSE values of 0.3928, 0.2288 more than RF and DT models for the NO_2 prediction. The RF model performed better than the DT model for predicting the level of NO_2 emissions with a lower MSE value of 0.0810.

Table IV indicates that the OANN model has the lowest MAE and MSE values than the ANN, DT, and RF models for the prediction of NO_x pollutant., this shows that the OANN model performed better than ANN, DT, and RF models. The MAE and MSE scores of the OANN model were 0.2368 and

0.1128. Unfortunately, the DT model has the highest MAE and MSE scores than the ANN and RF models. The MAE and MSE values of the DT model were 0.3178 and 0.2003. However, the RF model performed better than the ANN model with the MAE and MSE values of 0.2872 and 0.1757 for predicting the concentrations of NO_x pollutant. The MAE and MSE values of the ANN model were 0.2928 and 0.1812.

TABLE IV. COMPARISON BETWEEN OANN, ANN, DT, AND RF FOR TRAFFIC EMISSIONS PREDICTION

AP	OANN		ANN		Random Forest		Decision Tree	
	MAE	MSE	MAE	MSE	MAE	MSE	MAE	MSE
CO	0.1155	0.0247	0.1696	0.0441	0.1551	0.0463	0.1522	0.0446
NO	0.1263	0.0365	0.5042	0.3040	0.145	0.0644	0.1446	0.0642
NO_2	0.1731	0.0542	0.3928	0.2288	0.2024	0.0810	0.2007	0.0826
NO_x	0.2368	0.1128	0.2928	0.1812	0.2872	0.1757	0.3178	0.2003

It can be concluded that the developed OANN model achieved the best results in comparison with all models, especially the ANN model for predicting the concentrations of CO , NO , NO_2 , and NO_x pollutants.

V. CONCLUSION

A based Artificial Neural Network (OANN) model was developed to enhance the existing ANN model by updating the initial weights that connect the neurons in the network using a Genetic Algorithm (GA). The OANN model was used to predict the level of pollutants emitted by vehicles in Kuala Lumpur, Malaysia. The OANN model was evaluated using performance metrics and comparison with ANN, DT, and RF models. The result shows the developed OANN model performed better than the existing ANN, DT, and RF models with the lowest regression metrics when compared.

Based on the literature review, the study of [45] predicts the concentration of air pollutants at canyon street. Still, our study predicts the level of air pollutants at the roadside, which is an open space. [46] study was the closest study with our study; the difference is, the study focuses more on the truck vehicles and also used a one-month dataset. Additionally, they predict the concentrations of CO pollutants. Our study added three more pollutants namely, NO , NO_2 , and NO_x . The study of [48] used different variables such as length of the vehicle, vehicle registration, and opacity. The study also has a higher RMSE score than the RMSE values of our study.

The developed OANN model can help environmental agencies monitor traffic-related air pollution levels efficiently and take necessary actions to ensure the effectiveness of traffic management policy. Moreover, the model can help decision-makers mitigate traffic emissions to protect the health of the citizens who are inhabiting very close to highways.

Admittedly, there are some limitations to this study. Firstly, Some studies suggested that different types of fuel have different types of emissions, but the fuel type was not considered in this study. The Jalan Kepong traffic census station was selected, but the other stations were not considered. There are many pollutants emitted by motor vehicles. However, the developed OANN model was limited to predict the hourly CO , NO , NO_2 , and NO_x concentrations. It can be applied to the other traffic pollutants as well. Furthermore, daily, weekly,

monthly, or yearly predictions were not the focus of this research. The prediction using only one type of vehicle was not considered as well.

ACKNOWLEDGMENT

This research is funded by Taylor's University under the research grant application ID (TUFR/2017/004/04) entitled as "Modeling and Visualization of Air-Pollution and its Impacts on Health".

Abstract—Statistics and stochastic-process theories, along with the mathematical modelling and the respective empirical evidence support, describe the software fault-debugging phenomenon. In software-reliability engineering literature, stochastic mathematical models based on the non-homogeneous Poisson process (NHPP) are employed to measure and boost reliability too. Since reliability evolves on account of the running of computer test-run, NHPP type of discrete time-space models, or difference-equation, is superior to their continuous time-space counterparts. The majority of these models assume either a constant, monotonically increasing, or decreasing fault-debugging rate under an imperfect fault-debugging environment. However, in the most debugging scenario, a sudden change may occur to the fault-debugging rate due to an addition to, deletion from, or modification of the source code. Thus, the fault-debugging rate may not always be smooth and is subject to change at some point in time called change-point. Significantly few studies have addressed the problem of change-point in discrete-time modelling approach. The paper examines the combined effects of change-point and imperfect fault-debugging with the learning process on software-reliability growth phenomena based on the NHPP type of discrete time-space modelling approach. The performance of the proposed modelling approach is compared with other existing approaches on an actual software-reliability dataset cited in literature. The findings reveal that incorporating the effect of change-point in software-reliability growth modelling enhances the accuracy of software-reliability assessment because the stochastic characteristics of the software fault-debugging phenomenon alter at the change-point.

Keywords—Stochastic mathematical modelling; discrete time-space; non-homogenous poisson process; change-point; imperfect fault-debugging; software-reliability

I. INTRODUCTION

Today, computer-based software systems are indispensable, and their successful operation depends mainly on software. A fault can be introduced at any point during the software development life cycle (abbreviated as SDLC) due to the deficiency of human-being. A failure is a consequence of a fault. The software development process’s testing phase aims at debugging faults. Software reliability is typically defined as a statistical measure of a software system’s ability to operate failure-free. To quantify software reliability, a number of analytical approaches to mathematical modelling the stochastic-behavior of software debugging phenomenon have been proposed. Non-homogeneous Poisson process (abbreviated as NHPP) models

are widely used in software-reliability engineering to quantitatively express reliability. They are broadly divided into discrete time-space and continuous time-space groups. However, discrete time-space models which adopt the number of executed computer test-run as a unit of fault-debugging period are more suited than their continuous time-space counterparts. Despite the difficulties in formulating them, many studies have highlighted their usefulness [1]–[4].

Several existing NHPP stochastic software-reliability models are based on constant or monotonically increasing fault-debugging rates under perfect and imperfect fault-debugging environments [1], [3], [5]–[16]. In practice, as the debugging grows, a sudden change may take place to the fault-debugging rate as a result of an addition to, deletion from, or modification of the source code. Thus, the fault-debugging rate may not always be smooth and is subject to change at some point in time called change-point [1], [17]–[23]. Many studies argue that considering the change-point concept in imperfect fault-debugging is expected to enhance the software-reliability assessment accuracy due to the stochastic characteristics of software fault-debugging phenomenon changed at the change-point. Thus, the incorporation of change-point provides a notable enhancement in the reliability assessment. However, most of the endeavors are in continuous time-space. Lately, this area has received little attention and few studies have incorporated the change-point concept in developing discrete time-space software-reliability modelling [1], [24], [25]. However, the study of the change-point problem is still very limited in the discrete-time modelling approach. As a result, the paper studies the effect of incorporating a change-point concept in modelling the imperfect fault-debugging phenomenon.

The rest of the paper is structured as follows: Section II reviews related work and models the change-point problem into an imperfect fault-debugging environment through a discrete time-space NHPP based approach. Data analyses and parameter estimation techniques, model validation, comparison criteria, and software-reliability measures are discussed in Sections III and IV, respectively. The descriptive-performance and predictive-capability, and software-reliability evaluation measures based on the proposed modelling approach are shown in Section V. Finally, Section VI concludes the paper and presents future works.

II. SOFTWARE-RELIABILITY MODELLING: A DISCRETE TIME-SPACE APPROACH

In this approach, we model the debugged faults by n computer test-run as a pure-birth counting process $(N_n; n \geq 0)$, [1]–[3] subject to

- No fault debugged at $n = 0$, that is, $N(0) = 0$.
- For any number of computer test-run n_1, n_2, \dots, n_k where $(0 < n_1 < n_2 < \dots < n_k)$. The k random variables $N(n_1), N(n_2) - N(n_1), \dots, N(n_k) - N(n_{k-1})$ are statistically independent.
- For any number of computer test-run n_i and n_j , where $(0 \leq n_i \leq n_j)$, we have

$$Pr[N(n_j) - N(n_i) = k] = \frac{(\lambda_n)^k}{k!} e^{-\lambda_n} \quad (1)$$

here λ be the fault-debugging intensity function.

Accordingly, the NHPP software-reliability model can be formulated

$$Pr[N_n = k] = \frac{(m_n)^k}{k!} e^{-m_n} \quad (2)$$

here N_n be the expected value number of faults whose mean-value function (abbreviated as MVF) is known as m_n .

A. Model Development

In this section, we review some of the well-documented NHPP type of discrete time-space models

1) *Exponential Model* [3], [26]: This model considers that the average number of faults debugged between n^{th} and the $(n + 1)^{\text{th}}$ computer test-run, is corresponding to the current number of undebugged faults after the execution of the n^{th} computer test-run, meets the resulting difference equation:

$$\lambda_n = \frac{m_{n+1} - m_n}{\delta} = b(a - m_n) \quad (3)$$

here a be a fault-content, and the constant b represents a fault-debugging per undebugged faults per test case.

To solve the difference equation (3), we employ the probability generating function (abbreviated as PGF) computational technique, multiply both sides by w^n , and sum over n from 0 to ∞ , we get:

$$\begin{aligned} \sum_{n=0}^{\infty} w^n m_{n+1} - \sum_{n=0}^{\infty} w^n m_n &= \delta b \left(a \sum_{n=0}^{\infty} w^n - \sum_{n=0}^{\infty} w^n m_n \right) \\ \frac{1}{w} \sum_{n=0}^{\infty} w^{n+1} m_{n+1} - \sum_{n=0}^{\infty} w^n m_n &= \delta ab \sum_{n=0}^{\infty} w^n - \delta b \sum_{i=0}^{\infty} w^n m_n \\ \sum_{n=0}^{\infty} w^{n+1} m_{n+1} - \sum_{n=0}^{\infty} w^{n+1} m_n &= \delta ab \sum_{n=0}^{\infty} w^{n+1} - \delta b \sum_{n=0}^{\infty} w^{n+1} m_n \\ \sum_{n=0}^{\infty} w^{n+1} m_{n+1} &= \delta ab \sum_{n=0}^{\infty} w^{n+1} - (1 - \delta b) \sum_{n=0}^{\infty} w^{n+1} m_n \\ (w^1 m_1 + w^2 m_2 + w^3 m_3 + \dots) &= \delta ab (w^1 + w^2 + w^3 + \dots) + \\ (1 - \delta b) (w^1 m_0 + w^2 m_1 + w^3 m_2 + \dots) & \quad (4) \end{aligned}$$

Comparing the coefficients of like powers of w on both sides in (4) and under the initial-condition $m_{n=0} = 0$, yields

$$\begin{aligned} m_1 &= \delta ab + (1 - \delta b) m_0 = a(1 - (1 - \delta b)^1) \\ m_2 &= \delta ab + (1 - \delta b) m_1 = a(1 - (1 - \delta b)^2) \\ m_3 &= \delta ab + (1 - \delta b) m_2 = a(1 - (1 - \delta b)^3) \end{aligned} \quad (5)$$

The closed-form solution, by mathematical-induction, obtained as

$$m_n = a(1 - (1 - \delta b)^n) \quad (6)$$

Accordingly, the fault-debugging intensity function is

$$\lambda_n = \frac{m_{n+1} - m_n}{\delta} = ab(1 - \delta b)^n \quad (7)$$

The equivalent continuous time-space model [27] corresponding to (6) is

$$m_t = a(1 - e^{-bt}) \quad (8)$$

which derived as a limiting case of discrete time-space model substituting $t = n\delta$, $\lim_{x \rightarrow 0} (1 + x)^{1/x} = e$, and taking limit $\delta \rightarrow 0$.

2) *Delayed S-shaped Model* [1], [16]: This model considers that the fault-debugging phenomenon as a two-stage process namely, detection and correction. Accordingly, we have

$$\begin{aligned} \frac{m_{d(n+1)} - m_{d(n)}}{\delta} &= b(a - m_{d(n)}) \\ \frac{m_{c(n+1)} - m_{c(n)}}{\delta} &= b(m_{d(n)} - m_{c(n)}) \end{aligned} \quad (9)$$

Solving the system of difference equation (9), using the PGF computational technique in terms of the initial condition that at $n = 0$, $m_{d(n)} = m_{c(n)} = 0$, we can obtain the closed-form exact solution as

$$m_n \equiv m_{c(n)} = a((1 + \delta bn)(1 - \delta b)^n) \quad (10)$$

An alternate formulation of (9), to obtain it in single stage, is

$$\frac{m_{n+1} - m_n}{\delta} = b_{n+1}(a - m_n)$$

where

$$b_{n+1} = \frac{\delta b^2 n}{1 + \delta bn} \quad (11)$$

Solving (11), using the PGF computational technique in terms of the initial condition that at $n = 0$, $m_n = 0$, we can obtain the closed-form exact solution as

$$m_n = a((1 + \delta bn)(1 - \delta b)^n) \quad (12)$$

It can be noticed that (12) and (11) are same.

Accordingly, the fault-debugging intensity function is

$$\lambda_n = \frac{m_{n+1} - m_n}{\delta} = \frac{\delta ab^2 n}{1 + \delta bn} ((1 + \delta bn)(1 - \delta b)^n) \quad (13)$$

The equivalent continuous time-space model [3], [28] corresponding to (10) or (12) is

$$m_t = a(1 - (1 + bt)e^{-bt}) \quad (14)$$

which derived as a limiting case of discrete time-space model substituting $t = n\delta$, $\lim_{x \rightarrow 0} (1 + x)^{1/x} = e$, and taking limit $\delta \rightarrow 0$.

3) *Inflection S-shaped Model [1], [29], [30]*: The primary assumption of the models mentioned above is that the fault-debugging rate depends linearly upon the number of undebugged faults. In practice, it has been observed that as debugging progress, the fault debugging rate has three possible trends: decreasing, constant, and increasing. To analyze these trends, we interpret the fault debugging rate as a function of the number of executed computer test-run. Accordingly, we have the following difference equation:

$$\frac{m_{n+1} - m_n}{\delta} = b_{n+1}(a - m_n)$$

where

$$b_{n+1} = b_i + (b_f - b_i) \frac{m_{n+1}}{a} \quad (15)$$

Solving (15), using the PGF computational technique in terms of the initial condition that at $n = 0$, $m_n = 0$, we can obtain the closed-form exact solution as

$$m_n = a \frac{1 - (1 - \delta b_f)^n}{1 + \frac{b_f - b_i}{b_i} (1 - \delta b_f)^n} \quad (16)$$

The growth curve's shape is determined by the parameters b_i and b_f and can be either exponential or S-shaped. However, (16) can be rewritten to define a constant fault-debugging rate, as

$$m_n = a(1 - (1 - \delta b_f)^n) \quad (17)$$

An alternate formulation of the model, where the fault-debugging rate per undebugged fault, b_{n+1} , is a non-decreasing S-shape curve that captures the learning-process phenomenon of the debugging-team, as

$$b_{n+1} = \frac{b}{1 + \beta(1 - \delta b)^{n+1}} \quad (18)$$

Substituting (18) in (15) and solving using the PGF computational technique in terms of the initial condition that at $n = 0$, $m_n = 0$, we can obtain the closed-form exact solution as

$$m_n = a \frac{1 - (1 - \delta b)^n}{1 + \beta(1 - \delta b)^n} \quad (19)$$

Setting $b = b_f$ and $\beta = \frac{b_f - b_i}{b_i}$, it noticed that (19) and (16) are identical.

The fault-debugging rate for the above-specified model is a logistic function and $b_{n+1} \rightarrow b$ as $n \rightarrow \infty$. here β is the learning factor, and it represents the skill and experience gained by the debuggers during debugging. If $\beta = 0$, then $b_{n+1} = b$, that is, constant. The fault-debugging intensity function can be obtained as

$$\lambda_n = \frac{m_{n+1} - m_n}{\delta} = \frac{ab}{1 + \beta(1 - \delta b)^n} \frac{(1 + \beta)(1 - \delta b)^n}{1 + \beta(1 - \delta b)^n} \quad (20)$$

The equivalent continuous time-space model [1], [16], [31] corresponding to (19) or (16) is

$$m_t = a \frac{1 - (1 - e^{-bt})}{1 + \beta(1 - e^{-bt})} \quad (21)$$

which derived as a limiting case of discrete time-space model substituting $t = n\delta$, $\lim_{x \rightarrow 0} (1 + x)^{1/x} = e$, and taking limit $\delta \rightarrow 0$.

4) *Imperfect Fault-Debugging Inflection S-shaped Model [29], [30]*: The primary assumption of the models mentioned above is that the debugged fault is perfectly-debugged with certainty. However, due to human-imperfection and software-complexity, the debugging-team incapable to debug the fault-perfectly, and the debugged fault persist, resulting in a phenomenon known as imperfect fault-debugging. As a result, we write

$$\frac{m_{n+1} - m_n}{\delta} = b_{n+1}(a - m_n)$$

where

$$b_{n+1} = \frac{bp}{1 + \beta(1 - \delta bp)^{n+1}} \quad (22)$$

here p is the probability of perfectly debugging the fault.

Solving (22), using the PGF computational technique in terms of the initial condition that at $n = 0$, $m_n = 0$, we can obtain the closed-form exact solution as

$$m_n = a \frac{1 - (1 - \delta bp)^n}{1 + \beta(1 - \delta bp)^n} \quad (23)$$

The equivalent continuous time-space model [1], [32] corresponding to (23) is

$$m_t = a \frac{1 - e^{-bpt}}{1 + \beta(1 - e^{-bpt})} \quad (24)$$

which derived as a limiting case of discrete time-space model substituting $t = n\delta$, $\lim_{x \rightarrow 0} (1 + x)^{1/x} = e$, and taking limit $\delta \rightarrow 0$.

In the following section, the approach is extended to address the concept of the change-point.

B. Model Formulation

In addition to the software-reliability models above, several models assume a constant or monotonically increasing fault-debugging rate. However, in reality, as the debugging progress, the fault-debugging rate function may be changed at some point in time. The change point's position need not be estimated; it can be judged from the plotted graph of the actual software-reliability data or using a change point analyzer tool. To incorporate the change-point concept in (26), both fault-debugging rate and probability of perfect fault-debugging before and after the change-point τ , are subject to change. Accordingly, we write

$$b_{n+1} = \begin{cases} \frac{b_1 p_1}{1 + \beta(1 - \delta b_1 p_1)^{n+1}} & \text{when } 0 \leq n < \tau \\ \frac{b_2 p_2}{1 + \beta(1 - \delta b_2 p_2)^{n+1}} & \text{when } n \geq \tau \end{cases} \quad (25)$$

here $b_1(b_2)$ represent the fault-debugging rates before(after) the change-point, $p_1(p_2)$ represent the probability of perfect fault-debugging before(after) the change-point, and the change-point τ represents the computer test-run number from whose execution onwards change in the fault-debugging rate is noticed.

Substituting (25) in (22) and solving using the PGF computational technique in terms of the initial conditions at $n = 0$, $m_n = 0$ and at $n = \tau$, $m_n = m_\tau$ respectively, we can obtain the closed-form exact solution as

$$m_n = \begin{cases} a \frac{1-\alpha_1^n}{1+\beta\alpha_1^n} & \text{when } 0 \leq n < \tau \\ a \frac{1-(1+\beta)(1+\beta\alpha_2^\tau)(\alpha_1^\tau\alpha_2^{n-\tau})}{(1+\beta\alpha_1^\tau)(1+\beta\alpha_2^n)} & \text{when } n \geq \tau \end{cases} \quad (26)$$

here $\alpha_1 = 1 - \delta b_1 p_1$ and $\alpha_2 = 1 - \delta b_2 p_2$

The proposed modelling approach given by (26) integrates the joint effects of change-point concept and learning of the debugging personnel in an imperfect fault-debugging environment into software-reliability modelling.

III. DATA ANALYSES AND PARAMETER ESTIMATION TECHNIQUES

To evaluate the progress of the debugging-process during the testing phase of the SDLC, reliability trend analysis is employed. Therefore, before applying the model, it is reasonable to decide whether the dataset exhibits software-reliability growth. In other words, assessing reliability is pointless if the software-reliability dataset during debugging does not exhibit growth. The trend tests that are widely adopted with f fault debugging are [2], [11], [33]:

- Arithmetic Average Test.

$$\rho(f) = \frac{1}{f} \sum_{i=1}^f n_i \quad (27)$$

Decreasing values promote reliability growth.

- Laplace Test.

$$v(f) = \frac{\sum_{i=1}^f (i-1)n_i - \frac{f-1}{2} \sum_{i=1}^f n_i}{\sqrt{\frac{f^2-1}{12} \sum_{i=1}^f n_i}} \quad (28)$$

Negative values promote reliability growth.

To estimate the unknown parameters of the software-reliability models, either the maximum likelihood estimate (abbreviated as MLE) or the least-square estimate (abbreviated as LSE) methods is employed. Software reliability dataset can be collected during debugging in the form of ordered pairs $(n_i, y_i), (i = 0, 1, 2, \dots, f)$ where y_i is the cumulative number of faults debugged by n_i computer test-run ($0 < n_1 < n_2 < \dots < n_f$). Table I tabulated the software-reliability dataset used. The dataset had been obtained in twenty weeks of debugging release 1 of Tandem computer project, and 100 faults were debugged [34]. In other words, the dataset consisted of 20 data pairs $(n_i, y_i), (i = 0, 1, 2, \dots, 20; n_{20} = 20; y_{20} = 100)$. To fit and estimate the parameters of the models, all data points have been utilized.

TABLE I. SOFTWARE-RELIABILITY DATASET [34]

n_i	y_i	n_i	y_i	n_i	y_i	n_i	y_i
1	16	6	49	11	81	16	98
2	24	7	54	12	86	17	99
3	27	8	58	13	90	18	100
4	33	9	69	14	93	19	100
5	41	10	75	15	96	20	100

The graphical plot of the dataset reveals a change-point occurs in the 11th week of debugging, that is, $\tau = 11$.

The Likelihood function L for the unknown parameters with the MVF, that is, m_n takes on the form:

$$L = \prod_{i=1}^f \frac{(m_{n(i)} - m_{n(i-1)})^{x_i - x_{i-1}}}{(x_i - x_{i-1})!} e^{-(m_{n(i)} - m_{n(i-1)})} \quad (29)$$

The statistical package for social sciences (abbreviated as SPSS) is applied to estimate the software-reliability model's parameters for quicker and more precise computations.

IV. MODEL VALIDATION AND COMPARISON CRITERIA

The credibility of the stochastic software-reliability model is decided by its descriptive and predictive power capabilities [1]–[3], [5], [8], [16], [35].

A. Goodness-of-Fit Criteria

To test the validity of the proposed modelling approach in (26), we evaluate three goodness-of-fit test indices based on a real software-reliability dataset [34]. The goodness-of-fit test indices adopted for the purpose are [1]–[3]:

- Sum of squared error (abbreviated as SSE). It assesses the dispersion between estimated values \widehat{m}_{n_i} and the actual data y_i of the dependent variable.

$$SSE = \sum_{i=1}^f (\widehat{m}_{n_i} - y_i)^2 \quad (30)$$

- The Akaike information criterion (abbreviated as AIC).

$$AIC = -2\log L + 2N \quad (31)$$

here N is the number of parameters of a model and the likelihood function L for the parameters with the MVF in (29).

- Root mean square prediction error (abbreviated as RMSPE).

$$RMSPE = \sqrt{\sum_{i=1}^f (Bias^2 + Variation^2)} \quad (32)$$

where

$$Bias = \frac{1}{f} \sum_{i=1}^f (\widehat{m}_{n_i} - y_i)$$

$$Variation = \sqrt{\frac{1}{f-1} \sum_{i=1}^f ((\widehat{m}_{n_i} - y_i) - Bias)^2}$$

- Coefficient of multiple determination (abbreviated as R^2).

$$R^2 = 1 - \frac{\sum_{i=1}^f (\widehat{m}_{n_i} - y_i)^2}{\sum_{i=1}^f (y_i - \sum_{i=1}^f y_i)^2} \quad (33)$$

It should be noted that the smaller value of SSE, AIC and RMSE, indicates the better the fit of the model. On the contrary, the larger the value of R^2 indicates better the fit of the model.

B. Predictive Validity Criterion

The predictive validity of the software-reliability model is defined as its ability to predict the future behavior of the debugging process based on its current and past behavior [35]. Suppose we have corrected x_f faults after the execution of the last computer test-run n_f . First, we utilize the software-reliability dataset up to a computer test-run say $n_e (\leq n_f)$ to obtain the MVF, that is, m_{n_f} . Then, put estimated values in m_n to obtain the number of faults corrected by n_f . Next, we compare it with the actually corrected number x_f . Last, his method is iterated for different values of n_e . The predicted relative error (abbreviated as PRE) is given as

$$PRE = \frac{(\widehat{m}_{n_f} - x_f)}{x_f} \quad (34)$$

When the PRE value is positive/negative, the model overestimates or underestimates the future debugging phenomenon. Acceptable values are within the range $\pm 10\%$ [1], [2], [16].

C. Software-Reliability Evaluation Measures

Based on Section II, the following quantitative assessment are derived [1]–[3], [26]:

- Number of residual faults. Let $\xi(t)$ denotes the number of residual faults after the executing of the computer test-run n^{th} , then

$$\xi_n = a_\infty - a_n \quad (35)$$

here a_∞ denotes the number of faults eventually corrected.

- Software-reliability. The probability of no faults debugged between the n^{th} and $(n+n_o)^{th}$ computer test-run, given that x_d faults have been debugged by the n^{th} computer test-run, is

$$R(n_o | n) = e^{-(m(n+n_o)-m(n))} \quad (36)$$

here $n_o (n_o \geq 0)$ is the mission time.

V. DATASET ANALYSES AND MODEL COMPARISON

To validate the proposed modelling approach, we perform the following dataset analyses and model comparisons. First, we use both of the trend tests presented in Section III to determine whether or not the given software-reliability dataset promotes reliability growth. The parameters of the models under comparison [1], [3], [16], [26], [30] including the proposed modelling approach given in (26) are then estimated using SPSS. Then we perform the goodness-of-fit test described in Section IV-A. Based on the obtained results, we conduct a comparative assessments of the models under comparison. Finally, for the proposed modelling approach, we perform the predictive-validity test described in Section IV-B and estimate the software-reliability evaluation measures defined in Section IV-C.

It is worth noting that, while formulating the proposed modelling approach, we set $\delta = 1$ for simplification and $\tau = 11$ by following the stochastic-behavior of debugging phenomenon on the basis of the adopted dataset.

The models under comparison are given below:

- Exponential model [3], [26] given in (6).
- Delayed S-shaped model [1], [16] given in (10).
- Inflection S-shaped model [1], [30] given in (19).
- Imperfect fault-debugging inflection S-shaped model [1], [30] given in (23).
- The proposed modelling approach given in (26).

A. Software-Reliability Trend Analysis

The fitting result of the reliability dataset for arithmetic average and Laplace trend tests are demonstrated in Fig. 1 and 2, respectively. It is quite clear that the arithmetic average and the Laplace trend factor values are decreasing and entirely negative from the beginning, respectively. Negative Laplace factor values indicate that more faults were debugged in the first half of the debugging time, indicating an increase in reliability. Thus, they point to growth in reliability. Consequently, the dataset is suitable for applying software-reliability models.

B. Goodness-of-Fit Analysis

Table II shows the estimated parameters of the models under comparison using the statistical package statistical package for social sciences (abbreviated as SPSS) and their goodness-of-fit test indices. It can be seen that, when compared to all other models using the SSE, AIC, RMSPE, and R^2 indices, the proposed modelling approach has the lowest SSE, AIC and RMSPE values and the highest R^2 value. Therefore, among the models under comparison, the proposed modelling approach outperformed the others. The enhancement in the performance of the proposed modelling approach is attributed to the inclusion of the change-point concept in modelling software-reliability. These results agree with the findings of previously published works [1], [25].

It is worth noting that the proposed modelling approach's estimated value of a is the closest to the number of debugged faults actually present in the software, and the fault-debugging rates $b_2 < b_1$ clearly show a varying trend that first increases and then decreases following the change-point with an S-shaped varying trend. The latter finding is attributed to the presence of imperfect fault-debugging and learning-process phenomena.

Fig. 3 and 4 show the fitting results of the noncumulative and cumulative reliability dataset for the proposed modelling approach. It is quite clear that the proposed modelling approach fits the dataset perfectly.

C. Predictive Validity Analysis

To estimate the proposed modelling approach parameters, the software-reliability dataset is truncated into several parts. It is noticed that the PRE values differ from one truncation to the next. As a result, Fig. 5 depicts the fitting result of the predictive-validity of the proposed modelling approach.

It is noticed that the proposed modelling approach overestimates the debugging-process from the truncated n_e (70% approx.) onwards. Therefore, the dataset is truncated at t_e

TABLE II. PARAMETER-ESTIMATION AND COMPARISON-CRITERIA RESULTS

Models Under Comparison	Parameter-Estimation						Comparison-Criteria			
	a	$b_1(b)$	$p_1(p)$	b_2	p_2	β	SSE	AIC	$RMSPE$	R^2
Model due to [3], [26]	130	.080	—	—	—	—	233	1789	3.449	.986
Model due to [1], [16]	106	.217	—	—	—	—	357	1796	4.329	.978
Model due to [1], [30]	111	.158	—	—	—	1.21	180	1787	3.073	.989
Model due to [1], [30]	111	.158	1	—	—	1.21	180	1787	3.073	.989
Proposed given in (26)	105	.474	1	.357	.675	5.92	35	1780	1.352	.998

— The parameter is not part of the corresponding model.

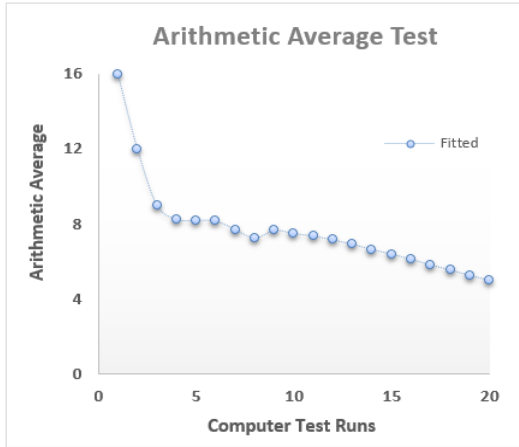

Fig. 1. The Fitting Result of the Reliability Dataset for Arithmetic Average Test Data.

(60% approx.) to obtain the whole dataset. The fitting result of the retrodictive and predictive capabilities is shown in Fig. 6. The points below n_e (marked by the intersection of the horizontal line with the curve) show the retrodictive-capability while the points above n_e show the predictive-capability of the proposed modelling approach.

The proposed modelling approach reveals that about 60% of the debugging-time is enough to predict the debugging-future process's behavior satisfactorily.

D. Software-Reliability Quantitative Measures Analysis

Fig. 7 depicts the fitting result of the number of residual faults for the proposed modelling approach. It is quite clear that the proposed modelling approach fits the dataset perfectly. Following the change-point, every three faults were debugged, one of which was imperfectly debugged according to the parameters' estimated values in Table II. Fig. 8 depicts the fitting result of the estimated software-reliability (three cases: when the mission time is one, two, and three days respectively) for the proposed modelling approach. It is noticeable that the proposed modelling approach reveals that software-reliability

Fig. 8. The Fitting Result of the Estimated Software-Reliability (three cases) for the Proposed Modelling Approach.

monotonically increases after the change-point in all cases.

These types of information provided by the proposed modelling approach enable the developer to decide how best to allocate resources during the software testing and maintenance phases of the SDLC.

VI. CONCLUSIONS

Quantitative measures provided by software-reliability models play a pivotal role in the decision-making process during testing and fault debugging-process. To some extent, the concept of change-point is novel in the discrete time-space software-reliability modelling approach. The NHPP type of discrete time-space software-reliability modelling is well-documented with well-established concepts in the software-reliability engineering literature and can be used to describe the stochastic-behavior of the fault-debugging process.

The proposed discrete time-space NHPP based stochastic software-reliability model integrates the debugger's learning phenomenon with a single change-point under an imperfect fault-debugging environment. The results explained through

a numerical example in the tables and figures provided in Section V are encouraging compared with other well-established models built under imperfect and perfect fault-debugging environments. The conducted numerical example concludes that incorporating the concept of change-point into software-reliability modelling yields the most promising results concerning the descriptive and predictive performances of the proposed modelling approach and software-reliability quantitative measures. As a result, the paper demonstrates a high level of numerical agreement between the results of the proposed modelling approach obtained here and other results presented in the literature.

Finally, the paper shows how starting with fundamental assumptions, the discrete time-space NHPP based modelling approach is becoming more useful with the inclusion of the learning process in debugging and introducing the change-point concept in an imperfect fault-debugging environment. However, we confined ourselves to introducing just a single change-point, and we did not consider the debugging effort expenditures. Hence, it is essential to track and account for the reliability growth concerning the costs spent on software

debugging. Studying the effect of multiple change-point occurrences and software debugging efforts on reliability growth is an ongoing and future research effort.

The Role of Data Pre-processing Techniques in Improving Machine Learning Accuracy for Predicting Coronary Heart Disease

Osamah Sami¹, Yousef Elsheikh², Fadi Almasalha³
Faculty of Information Technology
Applied Science Private University
Amman, Jordan 11931

Abstract—These days, in light of the rapid developments, people work day and night to live at a good level. This often causes them to not pay much attention to a healthy lifestyle, such as what they eat or even what physical activities they do. These people are often the most likely to suffer from coronary heart disease. The heart is a small organ responsible for pumping oxygen-rich blood to the rest of the human body through the coronary arteries. Accordingly, any blockage or narrowing in one of these coronary arteries may cause blood not to be pumped to the heart and from it to the rest of the body, and thus cause what is known as heart attacks. From here, the importance of early prediction of coronary heart disease has emerged, as it can help these people change their lifestyle and eating habits to become healthier and thus prevent coronary heart disease and avoid death. This paper improve the accuracy of machine learning techniques in predicting coronary heart disease using data preprocessing techniques. Data preprocessing is a technique used to improve the efficiency of a machine learning model by improving the quality of the feature. The popular Framingham Heart Study dataset was used for validation purposes. The results of the research paper indicate that the use of data preprocessing techniques had a role in improving the predictive accuracy of poorly efficient classifiers, and shows satisfactory performance in determining the risk of coronary heart disease. For example, the Decision Tree classifier led to a predictive accuracy of coronary heart disease of 91.39% with an increase of 1.39% over the previous work, the Random Forest classifier led to a predictive accuracy of 92.80% with an increase of 2.7% over the previous work, the K-Nearest Neighbor classifier led to a predictive accuracy of 92.68% with an increase of 2.58% over the previous work, the Multilayer Perceptron Neural Network (MLP) classifier led to a predictive accuracy of 92.64% with an increase of 2.64% over the previous work, and the Naïve Bayes classifier led to a predictive accuracy of 90.56% with an increase of 0.66% over the previous work.

Keywords—Coronary heart disease; heart; machine learning; data preprocessing; classification technique

I. INTRODUCTION

The heart is one of the most important organs in the human body. It is a small, muscular pumping organ responsible for supplying other organs in the body with oxygen and other important nutrients [1]. This means that a person's life depends on the efficiency of heart function. Therefore, if the heart does not function well, other organs also cannot function well [2].

People, in light of the difficult economic conditions, seek to secure their basic needs by working long hours daily. This

lifestyle often does not take into account the diet and health of these people to ensure their safety [3]. This type often leads to a risk of diseases such as diabetes, high cholesterol and blood pressure at an early age, and all of these diseases, if not controlled, can lead to coronary heart disease [3].

Heart disease is a term that refers to any problem that can affect the heart and blood vessels [2], such as coronary heart disease, congenital heart disease, and rheumatic heart disease [4], which, according to the National Heart, Lung, and Blood Institute ranks among the most dangerous and common diseases in the world.

In coronary heart disease, a complete or partial blockage of the coronary arteries usually occurs due to blood clotting or the accumulation of fatty plaques on the walls, which leads to the inability of the heart to get enough oxygen [5] and thus it is difficult for the heart to function as efficiently as required.

There are two risk factors for coronary heart disease. The first type is stable and cannot be changed, such as age, gender and family history, while the other type depends on lifestyle such as diabetes, smoking, high cholesterol, high blood pressure, high body mass index, and low exercise [6]. However, the second type of risk factors can usually be controlled, according to experts, by changing our lifestyle and diet, and using certain medications if needed.

In recent years, artificial intelligence techniques have been used extensively in the medical fields in order to improve the efficiency of disease diagnosis/classification in its early stages [7]. Among those techniques stand out machine learning techniques, which are a set of statistical models that help the machine learn from past data [8]. In spite of this, it is often difficult to deal with patient data for diagnosis in the early stages due to reasons such as data volume, missing values and noise in the data. But machine learning techniques and their capabilities have helped process such data [9].

Also, it is noticeable regarding data features that they may be incomplete and huge. The range of some data features is small while the range is large for other data features. The type of data features is combined between categorical and numerical; all of this will affect the accuracy of machine learning techniques in diagnosing and classifying diseases in their early stages, including coronary heart disease. Using different techniques to manipulate the features under the so-called data preprocessing techniques and thus improve the

accuracy of machine learning techniques in early prediction of the disease [10]. This paper is organized as follows: The second section is a review of some relevant work. The third section presents the methodology for this research paper. The fourth section is for presenting, evaluating and discussing the results of the research paper. The fifth section is for conclusion and the sixth section is the future work.

II. RELATED WORK

Recently, there has been an increase in the number of papers dealing with the use of machine learning techniques in predicting serious diseases that may affect people's lives, including coronary heart disease. In [11], the researchers applied a logistic regression technique on the Framingham Heart Study dataset to predict the ten-year risk of coronary heart disease. The researchers used 65% of the dataset for the training set. The accuracy obtained was 84.8%.

The researchers in [12] had a contribution by implementing four machine learning algorithms, namely support vector machine (SVM), neural network, XGBoost, and random forest to predict the ten-year risk of coronary heart disease. The researchers also used the Framingham Heart Study dataset to validate the results. The accuracy obtained was 84.8% for support vector machine, 85.4% for neural network, 86.99% for XGBoost, and 84.9% for random forest.

Also, the researchers in [4] contributed to the literature of this field by using boosting adaptive algorithm on four datasets, namely (UCI Cleveland, UCI Switzerland, UCI Long Beach, and UCI Hungarian) to diagnose coronary heart disease. This approach obtained accuracy (97.16% and 80.14% for Cleveland, 98.63% and 89.12% for Hungarian, 93.15% and 77.78% for Long Beach, 100% and 96.72% for Switzerland) for training and testing set respectively.

In [13], the researchers applied three machine learning algorithms, namely support vector machine, neural network, and Hybrid-SVM on the Framingham Heart Study dataset to predict the ten-year risk of heart attack. The accuracy obtained was 86.03% for support vector machine, 84.7% for neural network, and 94% for Hybrid-SVM. However, these results were better for some of the machine learning techniques used than those used for [12].

In [14], the researchers applied six algorithms, namely decision tree, boosted decision tree, random forest, support vector machine, neural network, and logistic regression on the Framingham Heart Study dataset to predict the ten-year risk of coronary heart disease. The data was divided into 80% training and 20% testing. The researchers used R Studio and Rapid-Miner in their work. The researchers used three techniques to deal with missing values. The first technique is to ignore missing values, and obtained accuracy of 85% for the decision tree, 63% for the boosted decision tree, and 63% for logistic regression. All this while using the Rapid-Miner tool. Whereas, the R studio tool enabled the researchers to obtain the accuracy of 84% for the decision Tree, 85% for the boosted decision tree, and 84% for logistic regression. Analysis of complete case is the second technique used, as the Rapid-Miner tool enabled the researchers to obtain accuracy of 54% for the decision tree, 64% for the boosted decision tree, 65% for the random forest, 69% for the support vector machine, 69%

for the neural network, and 68% for logistic regression. R studio tool obtained accuracy 67%, 81%, 79%, 69%, 67%, and 68% for the decision tree, boosted decision tree, random forest, support vector machine, neural network, and logistic regression respectively. The final technique is to be replaced with the average, and the accuracy obtained while using the Rapid-Miner tool was 62% for the decision tree, 62% for the boosted decision tree, 63% for the random forest, 68% for the support vector machine, 68% for the neural network, and 67% for logistic regression. Whereas, the R Studio tool enabled the researchers to obtain an accuracy of 84% for the decision tree, 84% for the boosted decision tree, 78% for the random forest, 68% for the support vector machine, 71% for the neural network, and 66% for logistic regression.

However, other researchers such as those in [15] applied only one algorithm which is the logistic regression on the Framingham Heart Study dataset to predict the ten-year risk of coronary heart disease. This approach obtained better accuracy of 86.6% than ever.

In [16], the researchers applied the same previous method of logistic regression to the Framingham Heart Study dataset to predict a heart attack. This approach obtained an accuracy of 87%.

Other researchers such as those in [17] applied the neural network algorithm to real data from patient of Paris Hôtel-Dieu University Hospital to diagnose coronary heart disease. Their approach used a different number of input factors (6 to 14). The approach obtained 63% for features (age, diabetes, hypertension, obesity, smoking, family anamnesis of CHD), 76% for features (age, sex, diabetes, hypertension, obesity, smoking, family anamnesis of CHD), 77% for features (age, sex, diabetes, hypertension, obesity, smoking, family anamnesis of CHD, glycaemia, cholesterol total), 81% for features (age, sex, diabetes, hypertension, obesity, smoking, family anamnesis of CHD, TG, cholesterol 0.81 69 79 total, HDL, LDL, glycaemia), 83% for features (age, sex, diabetes, hypertension, obesity, smoking, family anamnesis of CHD, carotid plaque), 87% for features (diabetes, hypertension, obesity, smoking, family anamnesis of CHD, PWV index), 91% for features (diabetes, hypertension, obesity, smoking, family anamnesis of CHD, carotid plaque, PWV index), 93% for features (diabetes, hypertension, obesity, smoking, family anamnesis of CHD, TG, cholesterol, HDL, 0.93 80 92 LDL, glycaemia, carotid plaque, PWV index), 77% for features (age, sex, diabetes, hypertension, obesity, smoking, family anamnesis of CHD, glycaemia, 0.77 53 87 cholesterol total, cGFR), and 77% for features (age, sex, diabetes, hypertension, obesity, smoking, family anamnesis of CHD, glycaemia, cholesterol total, left ventricular hypertrophy)

Those in [18] applied the deep belief algorithm to the KNHANES-6 dataset to predict the risk of coronary heart disease and obtained an accuracy of 82%. However, the researchers applied the genetic algorithm to improve the deep belief network and the obtained accuracy was 74%.

In [19], the researchers applied a logistic regression and neural network to the KNHANES-VI dataset to predict the risk of coronary heart disease. However, this approach obtained accuracy 86.11% for the logistic regression and 87.04% for the neural network. The researchers used a distinct correlation

analysis to improve the accuracy of the neural network to become 87.63%.

In other research such as [20], the researchers applied Naïve Bayes, KNN, random forest, decision tree, SVM, logistic regression, and the ensemble classification approach to the NHANES and Framingham Heart Study dataset, to monitor the risk of chronic diseases. For the NHANES dataset, the decision tree algorithm obtained an accuracy of 97.6%, 96.5% for the ensemble approach, 80.8% for the KNN, 96.4% for logistic regression, 95.7% for Naïve Bayes, 98.5% for random forest, 95.4% for SVM. Whereas, the results for Framingham Heart Study dataset were as follows: The decision tree obtained an accuracy of 90%, 89.3% for the ensemble approach, 90.1% for the KNN, 90% for the logistic regression, 89.9% for Naïve Bayes, 90.1% for random forest, and 90.2% for SVM.

Similarly, the researchers of [21] applied Naïve Bayes, KNN, random forest, decision tree, SVM, logistic regression, neural network, and the ensemble classification approach to the NHANES and Framingham Heart Study dataset to predict Cardiovascular disease. For the NHANES dataset, the decision tree algorithm obtained an accuracy of 97.6%, 96.5% for the ensemble approach, 80.8% for the KNN, 96.4% for logistic regression, 95.7% for Naïve Bayes, 98.5% for random forest, 95.4% for SVM, 98.8% neural network. Whereas, the results for Framingham Heart Study dataset were as follows: The decision tree obtained an accuracy of 90 89.3% for the ensemble approach, 90.1% for the KNN, 90% for logistic regression, 89.9% for Naïve Bayes, 90.1% for random forest, 90.2% for SVM, and 89% for neural network.

In [22], the researchers applied neural network algorithm on the Framingham Heart Study dataset to predict the heart disease. The accuracy obtained was 90% .

Other researchers such as those in [23] applied the k-nearest neighbor (KNN), Logistic regression (LR), linear discriminant analysis (LDA), support vector machine (SVM), classification and regression tree (CART), gradient boosting (GB), and random forest (RF) the Framingham Heart Study dataset to detect the heart disease. The accuracy obtained was 81% for KNN, 83% for LR, 83% for LDA, 82% for SVM, 75% for CART, 83% for GB, and 83% for RF. After that some ensemble techniques were applied and the accuracy was improvement to 86%.

Those in [24] applied k-nearest neighbor, decision tree, random forest logistic regression, and neural network on the Framingham Heart Study dataset to predict the heart disease. The accuracy obtained was 86% for k-nearest neighbor, 77% for decision tree, 86% for random forest, 85% for logistic regression, and 85% for neural network.

Most of previous researchers using either the UCI dataset or Framingham Heart Study dataset, UCI dataset is a good dataset for diagnosis, and prediction heart disease, but this data has some limitations, first limitation is the size of instance of the data is bit small, second limitation the dataset does not include some important features for predict and diagnose heart disease such as LDL cholesterol, HDL cholesterol, smoking or not smoking, diastolic blood pressure, systolic blood presume, number of cigarettes per day, body mass index, and family history of any type of heart disease. This means this data does not fit to diagnose or predict heart disease for smoking patients,

patient with history of blood pressure, obesity patients, and patients with a family history of heart disease. also, Framingham Heart Study dataset is good data for predict heart disease, this data does not contain feature for family history of any type of heart disease. This means this data specific for patient with no family history of any type of heart disease.

Despite this and many other researches, the field is still open for researchers to conduct their experiments in order to improve the accuracy of the machine learning techniques for predicting diseases that pose a risk to human life, including coronary heart disease.

III. RESEARCH METHOD

It is unfortunate to hear that there is an increase in the number of patients diagnosed with coronary heart disease (angina or heart attack) day after day. High blood pressure, high cholesterol, uncontrolled diabetes, smoking, and a diagnosis of cardiovascular impairment and other risks, all increase the chance of diagnosis with coronary heart disease in the future. Therefore, an accurate system needed to help the patient protect him/herself from the risk of coronary heart disease, relying in this on the patient's demographic information, medical history, medical examination, behavior, and laboratory examination.

Many researchers have developed machine learning models using different classification algorithms such as decision tree, Naïve Bayes, SVM, KNN, and neural network. Most of these models were utilizing the Cleveland Heart Diseases dataset to predict coronary heart diseases, but few were using the Framingham Study dataset. This paper uses the Framingham Study dataset to validate the resulting model since it includes features for most of the potential risk factors for coronary heart disease and some of these features are not found in the most common dataset of heart disease namely, Cleveland Heart Disease dataset. In this paper, five machine learning classification algorithms were used such as decision tree, Naïve Bayes, neural network, random forest, and KNN. These five algorithms used the Framingham Heart Study dataset with two events for target (output) features to predict coronary heart disease, as a number of different Data Preprocessing techniques will be used to improve the accuracy of machine learning models for predicting coronary heart disease.

A. Dataset

The Framingham Heart Study dataset is the first long-term epidemiological study concerned with the possible causes of cardiovascular disease that began in 1948 in Framingham, Massachusetts [20]. The Framingham Heart Study dataset identified the prospective risk factors of cardiovascular diseases and their effects [20], [25].

The dataset contains 19 input features divided into demographic features(Age, Gender), behavioral features(Current Smoker, Cigarettes Per Day, Body Mass Index), medical history features(Prevalent Coronary Heart Diseases, Prevalent Angina Pectoris, Prevalent Myocardial Infarction, Prevalent Stroke, Prevalent Hypertensive, Use Blood Pressure Drugs,

Diabetes), medical examination features(Systolic Blood Pressure, Diastolic Blood Pressure, Heart Rate) and laboratory testing features(Glucose, High-Density Lipoprotein, Low-Density Lipoprotein, Total Cholesterol), and two features for prediction (Angina Pectoris, Myocardial Infarction).

B. Data Preprocessing

Data preprocessing is a group of techniques that are applied on the data to improve the quality of the data, such as handling missing values, convert the type of feature and many other techniques [10].

1) *Impute Missing Values By Knn*: knn for missing values working by calculate the distance or similarity to find the most similar case in the dataset and change the missing value with it [26], by applying (1).

$$Dist(X, Y) = \sqrt{\sum_{i=1}^n (X_i - Y_i)^2} \quad (1)$$

Where X_i some known values, and Y_i some values that should predict their values.

2) *Min_Max Normalization*: This method is convert each numerical feature value into new value depending on the minimum and maximum values of the feature [27], by applying (2).

$$\bar{X} = \frac{X - Min}{Max - Min} \quad (2)$$

Where Min is the smallest value in the selected feature, Max is the biggest value in the selected feature, \bar{X} is a new select value after applying normalization, X is a selected value from a numerical feature.

3) *Z-Score Standardization*: This method is convert each numerical feature value into new value depending on the standard deviation and Mean of the feature [28], by applying (3).

$$\bar{X} = \frac{X - \mu}{\sigma} \quad (3)$$

\bar{X} is a new select value after applying standardization, X is a selected value from a numerical feature.

4) *One Hot Encoding*: One Hot Encoding splits the categorical feature into a separate number of features depending on the number of the cases in the original categorical feature, and give 0 for absence and 1 for presence in each new feature [29].

5) *Ordinal Encoding*: In this technique, each case in the categorical feature is converted into integer value [29].

6) *Equal Width Discretization*: This is an easy method that sorting the values of numerical feature and split the range of sorting values into predefined equal-width bins [30] by applying (4) and (5).

$$W = \frac{V_{Max} - V_{Min}}{K} \quad (4)$$

$$Boundaries = V_{Min} + (i * W) \quad (5)$$

Where W is the width of the bin, V_Max is the maximum value in the selected numerical feature, V_Min is the minimum in the selected numerical feature, $i = 1, \dots, k-1$.

7) *Equal Frequency Discretization*: In this method, firstly sorting the values in ascending order. Split the range of sorting values into predefined number of equal-frequency bins by applying $\frac{N}{K}$, each bin has the same number of values [30].

C. Classification Algorithms

Classification is a supervised machine learning model used with a label's output to determine the result of the model from many labels or categorical input data [31]. The classifier model is built for training depending on many known labelled or categorical feature of input data [31]. In the next step, the model tested by using the test set to identify the number of the known target for the model and try to correct the unknown target for the model [31].

1) *ID3 Decision Tree*: Each decision tree contains a root node, leaf node, internal node and branches. In ID3 decision tree, all features set as root node, and after that the features are divided by finding the entropy which it utilizes the measure of the harmony in the data; the values of entropy is between 0 and 1 [7], and information gain is the difference between the feature and the subsets of this feature [7]. Entropy and information gain can be found by applying (6) and (7), and the feature which has the highest information gain value is selected as the root node of the tree [7].

$$Entropy(F) = \sum_{i=1}^C (-P_i \log_2 P_i) \quad (6)$$

$$Gain(F, A) = Entropy(F) - \sum_{i=1}^K \left(\frac{|F_i|}{|F|} Entropy(F_i) \right) \quad (7)$$

Where C is number of outputs, P_i is probability of occurrences each output from all output, K number of spilt data, F feature with some data, F_i spilt data from feature F.

2) *Random Forest*: Random forest is a classification algorithm [32] works by creating many decision trees from the dataset [32]. The features are selected randomly from the training set to build the trees in the random forest [32]. After building each decision tree and find the result of each the tree, applying majority voting to decide the final result of the random forest [32]. In the process of building each decision tree, the randomization is applied to find the value the split node.

3) *K-Nearest Neighbours*: KNN is a lazy supervised machine learning algorithm that used to predict and classify unknown data from known data by measuring the distance between them [33]. The distance metric is using to measure the distance between point from testing data with all the point in training data [33], [34], the distance can calculate by applying (8).

$$Cosine(X_i, Y_i) = \frac{\sum_{i=1}^n X_i Y_i}{\sqrt{\sum_{i=1}^n (X_i)^2} \sqrt{\sum_{j=1}^n (Y_i)^2}} \quad (8)$$

Where X_i some values belong to known output class, and Y_i some values that should predict their output class.

4) *Multilayer Perceptron Neural Network*: Artificial Neural network structure is the same as the brain of human [35]. Multilayer perceptron (MLP) that contains more than one layer(**input layer, hidden layer(s), output layer**) [36].

First, in the neural network before start training from the dataset, the value of weight (w) is randomly assigned [36]. After that, the neural network begin the training [36]. Sigmoid is a non-linear activation function commonly use in feedforward neural networks to find the output [37]. Sigmoid function can be calculated by applying (9).

$$F(X) = \frac{1}{1 + \exp^{-X}} \quad (9)$$

Back Propagation algorithm is commonly used to train Multilayer Perceptron Neural Network In the first step of this algorithm is to compare between predict output (\hat{Y}) and actual output (Y) to find the error between them, this error return to neural network and the weight change depending on this error, and the weight numerical change until the value of (\hat{Y}) become closer to (Y) [36].

5) *Naïve Bayes*: Naïve Bayes is a statistical classification algorithm that works on the basis of Bayes' theory, and Naïve Bayes assumes that each feature is separate, and each variable is distinct in prediction and occurrence [3]. Naïve Bayes uses the prior probability of Bayes theorem to calculate the likelihood of the relationship between each feature in the test data with each target, the target with the highest probability is selected as the result of the model [38]. The probability can be found using (10):

$$P(C_i|F_j) = \frac{P(F_j|C_i)P(C_i)}{P(F_j)} \quad (10)$$

Where $P(C_i|F_j)$ probability of specific class (C_i) appear with specific feature (F_j) from the total of all Features F and Classes C, $P(C_i)$ probability of specific class (C_i) from the total of all classes (C), $P(F_j|C_i)$ probability of specific feature (F_j) appear with specific class (Ci) from the total of all features (F) and classes(C), $p(F_j)$ probability of specific feature (F_j) from the total of all features (F).

D. Stratified KFold Cross Validation

Cross validation is a static method used to test an algorithm by dividing the data set into a training set used to train the model and the test set used to evaluate the model performance [39]. In cross-validation, every point has the same chance of being used in the test [39]. In kfold, the dataset is evenly divided into k number of fields [39]. Stratified KFold means that each fold has the same class naming distribution in the original dataset [40]. For each iteration, one test folds and others are used for training [39].

E. Tool

RapidMiner is a data science software platform developed by the company of the same name that provides an integrated environment for data preparation, machine learning, deep learning, text mining, and predictive analytics [41]. In machine learning, RapidMiner can be used for feature processing, dataset segmentation, model training, model testing, network research, and performance evaluation [41].

IV. RESULTS AND DISCUSSION

In this paper, five machine learning classification techniques used to predict two primary CHD events, namely, angina pectoris (528 yes, 2735 no) and myocardial infarction (308 yes, 2955 no).

A. Performance Evaluation

Performance evaluation is a group of equations used to measure the effectiveness of the classifier or the model [42]. Below is the definition of some essential terms used in the equations of performance evaluation:

1) *True Positive (TP)*: The person is healthy and also predict as healthy [42]

2) *False Positive (FP)*: The person is healthy, but predict as sick [42]

3) *True Negative (TN)*: The person is sick and predict as sick [42]

4) *False Negative (FN)*: The person is sick, but predict as healthy [42]

B. Confusion Matrix

The confusion matrix is used to analyze the ability of classifier or model to identify the classes of the dataset [42]. TN and TP are referred to correct classification, while FN and FP are referred to wrong classification [42]. For the accurate classifier or model, TP and TN are classified more than FN and FP [42], as shown in Table I

TABLE I. CONFUSION MATRIX

	Negative(Actual)	Positive(Actual)
Negative(Predict)	TN	FN
Positive(Predict)	FP	TP

C. Performance Metrics

1) *Accuracy*: Accuracy is an evaluation metric of the total number of predictions the model or the classifier gets right [43]. The accuracy can be calculated by applying (11).

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (11)$$

2) *Precision*: Precision is used to identified is the diagnosis or the predicted result is close to the real result [43]. Precision can be calculated by apply (12).

$$Precision = \frac{TP}{TP + FP} \quad (12)$$

3) *F-Measure*: F-Measure refers to the mean of consistency between Precision and Recall [43]. F-Measure can be calculated by apply (13).

$$F - Measure = 2 * \left(\frac{Recall * Precision}{Recall + Precision} \right) \quad (13)$$

4) *Sensitivity(Recall)*: Sensitivity is true positive rate measure. In other words, the rate of healthy person diagnosis or predict as healthy [43]. Sensitivity can be calculated by apply (14).

$$Sensitivity = \frac{TP}{TP + FN} \quad (14)$$

5) *Specificity*: Specificity is true negative rate measure. In other words, the rate of sick person diagnosis or predict as sick [43]. Specificity can be calculated by apply (15).

$$Specificity = \frac{TN}{TN + FP} \quad (15)$$

D. Algorithms Confusion Matrix

Below Table II, Table III, Table IV, Table V, and Table VI, shown the number of correct predict (**True Positive and True Negative**) and wrong predict (**False Positive and False Negative**) for each algorithm.

H. Discussion

In this research paper, a set of machine learning techniques used to predict two events of coronary heart disease namely, Angina Pectoris (528 Yes, 2735 No), and Myocardial Infarction (308 Yes, 2955 No). Despite the previous researchers used many data preprocessing techniques, the results obtained from this work were very encouraging compared to other studies that use the same data set to calculate accuracy as shown in Table IX.

It is noted that the techniques that have been used to improve the accuracy of machine learning models or classifiers in predicting coronary heart disease have proven effective and thus have achieved better results than previous research.

For example, [20] and [21] used the same data set and obtained by applying the decision tree algorithm a predictive accuracy of 90% to predict coronary heart disease (CHD), while this research paper obtained an accuracy of 91.39%, with a positive increase of 1.39% as shown in Table IX.

Also, this research paper and through the application of the random forest algorithm obtained a predictive accuracy of CHD 92.80%, shown in Table IX, which is higher than the result obtained in the decision tree algorithm in this research paper on the one hand, and on the other hand, higher and better than the results obtained by [20] and [21] and that was 90.10%, with a positive increase of 2.7%.

As for the use of the MLP algorithm in predicting CHD, researchers in [21] obtained an accuracy of predicting the

disease 90%, while this research paper obtained a better accuracy of 92.64%, with a positive increase of 2.64% shown in Table IX.

Regarding the use of the KNN algorithm, researchers in [20] and [21] obtained a prediction accuracy of 90.10%, which is less than the prediction accuracy of the disease obtained in this research paper, which is 92.68%, which was applied to calculate the missing values and equal width discretization, with a positive increase of 2.58% as shown in Table IX.

The application of the Naïve Bayes in this research paper obtained a predictive accuracy of coronary heart disease 90.56% as shown in Table IX, which is better than the predictive accuracy of 89.90% obtained in [20].

After applied data preprocessing techniques, this proposed work obtained accuracy better than previous researches used the same dataset and same techniques, such as, [13] that published in **2018** was obtained accuracy 84.7% for neural network; decision tree was obtained 85%, random forest was obtained 79%, and neural network was obtained 71% in [14] that published in **2017**; [20] that published in **2017** was obtained accuracy 90.1% for KNN, 90.1% for random forest, 89.9% for Naïve Bayes, and 90% for decision tree; the accuracy in [21] that published in **2018** was obtained 90.1% for KNN, 90.1% for random forest, 89.9% for Naïve Bayes, and 90% for decision tree; in **2020** the [22] was obtained accuracy 90% for neural network; [23] that published in **2021** was obtained accuracy 81% for KNN, 75% for decision tree, and 83% for random forest; decision tree was obtained 77%, random forest was obtained 86%, KNN was obtained 86%, and neural network was obtained 85% in [24] that was published in **2021**.

Although the results obtained in predicting coronary heart disease in terms of accuracy were not as significant as it should be, it may contribute to an increase in the number of cases with the correct diagnosis of the disease and at the same time reduce the number of cases that are incorrectly diagnosed with coronary heart disease and thus save lives

V. CONCLUSION

The heart is among the most important organs of the human body, as any problem with it can damage other important organs in the body, such as the brain. All doctors around the world warn of the sharp increase in the number of heart patients, being a serious disease that may lead to serious complications such as heart failure and cardiac arrest, both of which often lead to death if not diagnosed early.

In this paper, the researchers contributed to improving the accuracy of machine learning classification models in predicting two primary coronary heart disease events, namely, angina pectoris and myocardial infarction through the use of a number of feature processing techniques such as normalization, standardization, and discretization. For the purpose of validating the results obtained, the data set of the Framingham Heart Study was used with two main events (angina pectoris and myocardial infarction (heart attack)), due to its containment and after consulting with cardiologists about the most common factors causing coronary heart disease.

After using data preprocessing techniques on the dataset, the accuracy of machine learning algorithms for predicting coronary heart disease improved unevenly. For example, the improvement in accuracy prediction of CHD was 4.2% when using the ID3 decision tree algorithm, 0.14% when using the random forest algorithm, 3.18% when using the KNN algorithm, 2.08% when using the MLP algorithm, and 1.36% when using the Naive Bayes algorithm as shown in Table VII and Table VIII.

However, the best prediction accuracy obtained for the ID3 decision tree algorithm is at 91.39% when applied the equal width discretization method. Whereas, the random forest algorithm achieved a prediction accuracy of 92.80% when applied the equal width discretization and applied normalization methods. The MLP algorithm achieved an improvement in accuracy prediction by 92.64% when using one hot encoding technique. 92.68% represents the predictive accuracy obtained with the KNN algorithm when applied the ordinal coding and standardization techniques. However, all of the predicted values obtained were in the case of a myocardial infarction event. Whereas, the value obtained from Naive Bayes algorithm was 90.65% in the case of angina pectoris and when applied equal frequency discretization. The results obtained confirm the importance of using data preprocessing techniques in improving the accuracy performance of machine learning algorithms for predicting coronary heart disease compared to previous published research with the same objectives.

In the end, the presence of a correlation between some serious diseases such as the occurrence of stroke, high blood pressure, cardiovascular disease and coronary heart disease leads us in the future to predict such diseases and the effect of each of them on the occurrence of coronary heart disease on the one hand, and on the other hand the effect of the occurrence of coronary heart disease, on these diseases, to prevent death. This is because the patient in such cases does not have enough time to go to the doctor to see him and save his life.

VI. FUTURE WORK

In the future work, more data preprocessing techniques and more machine learning classification algorithms can apply to get better results than the ones that obtained in this proposed work.

Machine learning algorithms can be used to analyze big data to forecast coronary heart disease. This means that a huge amount of data means that the prediction will get better because more data means that the result is more accurate.

Sometimes the patient does not have enough time to go to the doctor, so develop a website or smartphones application for the graphical user interface solve this problem, and this site makes the prediction process easier and from the patient's place where the user only enters his risk factors information and the result is presented to him immediately.

Tshwane University of Technology
Pretoria, South Africa

Abstract—The purpose of this research is to perform a comparative numerical analysis of an efficient numerical methods for second-order ordinary differential equations, by reducing the second-order ODE to a system of first-order differential equations. Then we obtain approximate solutions to the system of ODE. To validate the accuracy of the algorithm, a comparison between Euler's method and the Runge-Kutta method of order four was carried out and an exact solution was found to verify the efficiency, accuracy of the methods. Graphical representations of the parametric plots were also presented. Time inference analysis is taken to check the time taken to executes the algorithm in Mathematica®12.2.0. The obtained approximate solution using the algorithm shows that the Runge-Kutta method of order four is more efficient for solving system of linear ordinary differential equations.

Keywords—Euler's method; Runge-Kutta method; System of ODE; Mathematica®; AbsoluteTiming

I. INTRODUCTION

In recent times, computer algebraic system (CAS) have been employed to investigate the use of built-in functions and construction of algorithm to obtain solutions to initial value problems. Scientific problems arises in stem fields as Biology, Physics, Chemistry ,and Engineering [1], Ecology with respect to inverse problems [2]. They also arise in non-stem fields as humanities, virtual art, designs and films [3], [4]. Differential equations recently have been understood, that its application model life realities and numerical methods are used to investigate ODEs. Some problems have been modeled to explore dynamics of music, literature, poetry, prey-predator models, decay radiation, and numerical methods [5], have been used to understand its dynamics in terms of approximation. Some mathematical real life situations modeled by system of ODEs do not have exact solutions, hence, approximation and/or numerical techniques must be used. In this paper, we consider second-order ODEs, convert them to a system of ODEs and compare the exact and numerical solution. This exploration is investigated through evaluation using Mathematica®[6], [7], [8]. Euler's and Runge-Kutta [9], [5], [10] algorithm are implemented with its built-in function. Other researchers have implemented several methods to solve initial value problems and the analysis of the accuracy in areas such as Epidemiology [11], stability and efficiency in system of ODEs [12] but not with the algorithm implemented in this paper and the use of time inference obtained with Mathematica®. The Euler's method has large errors which

is illustrated using Taylor's series expansion. Taylor's series converges within a small range and as a result, if the step size is not relatively small, it diverges. From Taylor's expansion, the first two terms represent the Euler's method. Through this, its imperative enough to know if h is not small enough, the method is not accurate and will not be a good use for practical implementation. The Runge-Kutta method of order four gives a better approximation than the Euler's method but its complicated in computing. However, it converges faster to the exact solution. This procedure explore the comparative analysis between the exact and numerical solution of the ODEs [13],[14]. The algorithm works robustly for obtaining solution to system of first order ODEs [15] and comparing the solution by computation and investigating the absolute timing it takes for each algorithm to compute, hence the algorithm can be applied to biological models. This algorithm will be applied to investigate nonlinear system of ODEs for further studies.

In this paper, we are more concerned about the accuracy of the algorithm and its reliability after comparing the exact solution, Euler's method and Runge-Kutta method on the system of first-order linear ODEs.

II. METHODOLOGY

In this section, we will consider a second-order ODEs by recasting it to system of first-order ODEs. In considering the Euler's method and Runge-Kutta method of order four, this methods investigated by coding an algorithm using the CAS, Mathematica and its built-in function. The approximate solution of both methods would be obtained and compared by the result of algorithm and the built-in function of Mathematica®. For Equation (1) and Equation (2), the explicit formula for the solution can't be obtained for an initial value problem of such form but can approximate the solution using the numerical methods which is based on the tangent line approximation. In this paper, the Euler's method would be used to approximate the system of ODEs with initial conditions. This technique will investigate numerically with the aid of the Mathematica® software.

Fig. 1. (a) Graphical Representation: Exact and Numerical Solution of $x(t)$ (b) Error Plot of $x(t)$ (c) Graphical Representation: Exact and Numerical Solution of $y(t)$ (d) Error Plot of $y(t)$, using the Euler's Algorithm for Example 1.

III. EULER'S METHOD

Consider the initial value problem in

$$\frac{dx}{dt} = f(t, x, y), \quad (1)$$

$$\frac{dy}{dt} = g(t, x, y), \quad (2)$$

with initial condition $x(0) = 0$, and $y(0) = 0$ valid for $a \leq t \leq b$

Let

$$m_k = f(x_k, y_k), \quad (3)$$

$$n_k = g(x_k, y_k), \quad (4)$$

Such that

$$x_{k+1} = x_k + m_k \Delta t \Rightarrow x_{k+1} = x_k + f(x_k, y_k) \Delta t, \quad (5)$$

$$y_{k+1} = y_k + n_k \Delta t \Rightarrow y_{k+1} = y_k + g(x_k, y_k) \Delta t. \quad (6)$$

where $\Delta t = \frac{t_n - t_0}{n}$ is known as the step size. The rule of the thumb to the above algorithm is the smaller the step size (over the increased number of length interval), the more accurate the approximate solution. However, even when extremely small step sizes are used, over a large number of steps the error starts to accumulate and the estimate diverges from the actual functional value which denotes its limitation and the requires more time to compute the approximate solution using the CAS.

IV. RUNGE-KUTTA METHOD OF ORDER 4(RK4)

The Runge-Kutta method are an important family of methods for approximate solutions of ODEs which were developed by mathematics duo C Runge (1856-1927) and M.W Kutta (1867-1944). In this paper, the Runge-Kutta method (RK4)

was considered for a initial value problem (IVP), for a system of the first order ODEs, such that

$$x'(t) = f(t, x) \text{ where } x = x(t) = [(x_1(t), x_2(t), \dots, x_n(t))]^T, \quad (7)$$

$$f \in [a, b] \times \mathbb{R}^n \rightarrow \mathbb{R}^n,$$

$$y'(t) = g(t, y) \text{ where } y = y(t) = [(y_1(t), y_2(t), \dots, y_n(t))]^T, \quad (8)$$

$$g \in [a, b] \times \mathbb{R}^n \rightarrow \mathbb{R}^n,$$

with initial condition $x(0) = x_0$. To implement the RK4 method of solution of $x(t)$ and $y(t)$ of the IVP over the time interval $t \in [a, b]$. The time interval was subdivided into n equal intervals and we selected the step size such that $h = \frac{(b-a)}{n}$ where h is called the step size.

Consider a problem for the implementation of RK4

$$x' = f(t, x, y); x(t_0) = x_0, \quad (9)$$

$$y' = g(t, x, y); y(t_0) = y_0. \quad (10)$$

To obtain the solution through investigation of built-in algorithm of Mathematica[®] 12.2.0, it imperative to note that k 's obtains the solution for $x(t)$ and l 's for solutions to $y(t)$.

Fig. 2. (a) Graph of Exact and Numerical Solution, Euler's Algorithm for Example 1.

V. NUMERICAL EXAMPLES

A. Using Euler's Algorithm

Consider the system of ODE

$$x' = -x + y, \tag{11}$$

$$y' = -x - y, \tag{12}$$

$$x(0) = 0, y(0) = 4, h = 0.1.$$

The exact solution was obtained as $x(t) = 4e^{-t} \sin(t)$, $y(t) = 4e^{-t} \cos(t)$. Results generated using the Euler's algorithm were represented on the Table I

Let $x_1 = 4e^{-t} \sin(t)$, $y_1 = 4e^{-t} \cos(t)$ be the exact solution, and $X_n \Rightarrow x' = -x + y$, $Y_n \Rightarrow y' = -x - y$ be the numerical solution.

TABLE I. RESULTS OBTAINED USING EULER'S ALGORITHM

n	x1	X _n	y1	Y _n
0	0	0	4	4
1	0.361332	0.4	3.60127	3.6
2	0.650627	0.72	3.20964	3.2
3	0.875707	0.968	2.83092	2.808
4	1.04414	1.152	2.46962	2.4304
5	1.16315	1.27984	2.12912	2.07216
6	1.23953	1.359072	1.81182	1.7369
7	1.27964	1.3968608	1.51924	1.42736
8	1.28932	1.3999104	1.2522	1.14494
9	1.27391	1.374412864	1.01091	0.89045
10	1.23824	1.3260166272	0.795064	0.663964

The graphs in Figure 1 represents the exact solution, numerical solution of $x(t)$ & $y(t)$ and the error plots.

Figure 1 (b) and (d) shows that the order of errors observed in the graphs for Figure 1 (a) and (c) are 10^{-2} and 10^0 respectively. For example 1, we observed that the solutions for $x(t)$ yielded better approximations than the solutions for $y(t)$. Although, from a graphical perspective, Figure 1 (c) shows better agreement (between the exact and numerical solutions) as compared to Figure 1

The graph in Figure 2 represents the exact solution and numerical solution of $x(t)$ & $y(t)$

B. Using Runge-Kutta Algorithm

Now, let us consider the system of ODEs from equations in Equation (11)-Equation (12). The exact solution was obtained as $x(t) = 4e^{-t} \sin(t)$, $y(t) = 4e^{-t} \cos(t)$. The results generated by the Runge-Kutta algorithm are represented in the

Table II.

Let $L = 4e^{-t} \sin(t)$, $P = 4e^{-t} \cos(t)$ be the exact solution, and $X_n \Rightarrow x' = -x + y$, $Y_n \Rightarrow y' = -x - y$ be the numerical solution

TABLE II. TABLE II REPRESENT THE RESULT OBTAINED USING RUNGE-KUTTA ALGORITHM.

n	L	X _n	P	Y _n

The graph in Figure 3 represents the exact solution and numerical solution of $x(t)$ & $y(t)$ and error plots.

The same phenomenon we observed under the Euler's algorithm section is also observed in this section. Figure 3 (b) and (d) are error plots having order of magnitudes 10^{-1} and 10^{-1} respectively. However, Figure 3 (a) and (c) shows that the agreement between the exact and numerical solutions for $y(t)$ is better compared to the agreements between the exact and numerical solutions for $x(t)$.

The graph in Figure 4 represents the exact solution and numerical solution of $x(t)$

C. Example 2

Consider the IVP of the form

$$x'' + 2x' + x = 0, \tag{13}$$

$$x(0) = 1, x'(0) = 0.$$

In what follows, we reduce Equation (13) to a system of first-order ODEs

$$x' = y, \tag{14}$$

$$y' = -x - 2y \tag{15}$$

$$x(0) = 1, y(0) = 0$$

The exact solution of the system was obtained as

$$x(t) = e^{-t}(1 + t), \tag{16}$$

$$y(t) = -e^{-t} \cdot t, \tag{17}$$

$$x(0) = 1, y(0) = 0,$$

$$\text{Analytical solution } y(t) = e^{-t}(1 + t). \tag{18}$$

The result generated using Euler's algorithm by comparative analysis is presented in Table III.

We define the following

$$\left. \begin{matrix} x_2 \rightarrow e^{-t}(1 + t), \\ y_2 \rightarrow -e^{-t} \cdot t. \end{matrix} \right\} = \text{Exact solution} \tag{19}$$

and

$$\left. \begin{matrix} X_n \rightarrow y, \\ Y_n \rightarrow -x - 2y. \end{matrix} \right\} = \text{Numerical solution} \tag{20}$$

Fig. 3. (a) Graphical Representation: Exact and Numerical Solution of $x(t)$ (b) Error Plot of $x(t)$ (c) Graphical Representation: Exact and Numerical Solution of $y(t)$ (d) Error Plot of $y(t)$, using the Runge-Kutta Algorithm for Example 1.

Fig. 4. (a) Graph of Exact and Numerical Solution, Runge-Kutta Algorithm for Example 1.

$y(t)$. The error plots for the graph in Figure 5 (b) shows that the approximation is quite good, as the error has order of magnitude 10^{-2} . The error plots for the solutions of $y(t)$ is not quite good (it has dimensions of order 10^0).

The graph in Figure 6 represents the exact solution and numerical solution of $x(t)$

Fig. 6. (a) Graph of Exact and Numerical Solution, Euler's Algorithm for Example 2.

The graph in Figure 7 represents the exact solution, numerical solution of $x(t)$ & $y(t)$, and error plots.

For this section, the error plots for $x(t)$ has order of magnitude 10^{-3} (see Figure 7 (b)). The magnitude of order for the error plots of $y(t)$ still maintains the same value as it was in the section for Euler's algorithm (see Figure 7 (d)).

The graph in Figure 8 represents the exact solution and numerical solution of $x(t)$

E. Example 3

In what follows, we will consider the well-known model of a vibrating particle attached to a stationary wall through a spring

$$mx''(t) + dx'(t) + kx(t) = 0, \quad (21)$$

where m is the mass of the particle, d is the damping factor, and k is the stiffness constant of the spring. Equation (21) is

rewritten as

$$x''(t) + 2\delta x'(t) + \omega^2 x(t) = 0, \quad (22)$$

where $2\delta = d/m$ and $\omega^2 = k/m$. Equation (22) is reduced to the system of first-order ODEs

$$x' = y \quad (23)$$

$$y' = -2\delta y - \omega^2 x \quad (24)$$

$$x(0) = 0.1, y(0) = 0, \delta = 0, \omega = 2\pi$$

From Equation (23)-Equation (24), the exact solution was obtained as

$$x(t) = (0.1 - 2.6963 \times 10^{-34i} \cos[6.28319t] + (3.15475 \times 10^{-17} + 8.22996 \times 10^{-34i} \sin[6.28319t]), \quad (25)$$

$$y(t) = (-0.628319 + 2.38256^{-18i}) ((0 + 0.i) + (1 + 0.i) \sin[6.28319t]), \quad (26)$$

$$x(0) = 1, y(0) = 0.$$

The results generated from the Euler's algorithm is presented in Table V by defining the following: $x3$ to be Equation (25) and $y3$ represented as Equation (26), while the numerical solution of Equation (23) and Equation (24) are represented as (X_n, Y_n) (which were obtained using the Euler's algorithm).

VI. TIME INFERENCE

This section details the time taken by Mathematica® to evaluate the formulated algorithms. An inference can be drawn that Euler's algorithm solves the system of ODEs in less time than the RK4. By computation the average time for each algorithm is represented in Table VII. As seen in Table VII, the Euler's algorithm computes faster although, it does not give an accurate approximation but the RK4 algorithm gives a better approximation despite having a lower computational speed compared to the Euler's algorithm.

TABLE VII. THE COMPUTATIONAL TIME TAKEN IN EVALUATING THE EULER'S AND RUNGE-KUTTA ALGORITHM

	Example 1		Example 2	
	Euler's	RK4	Euler's	RK4
Absolute Timing	0.000553	0.014443	0.001603	0.003870
Average Timing	0.000732	0.002925	0.000684	0.002868

VII. CONCLUSION

In this paper, we considered an algorithm which was simulated using Mathematica® 12.2.0 installed on a 512 SSD, 64 bit laptop. The built-in function of Mathematica® with

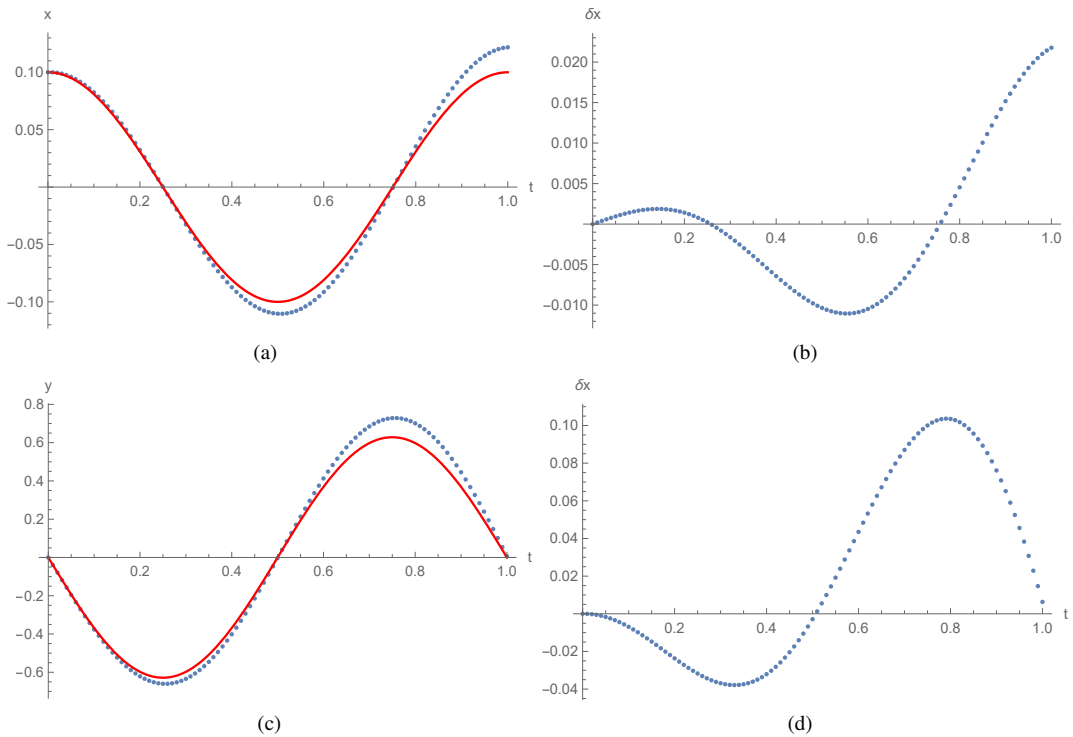

Fig. 9. (a) Graphical Representation: Exact and Numerical Solution of $x(t)$ (b) Error Plot of $x(t)$ (c) Graphical Representation: Exact and Numerical Solution of $y(t)$ (d) Error Plot of $y(t)$ using the Euler's Algorithm in Example 3.

absolute timing was used to generate a better approximation in the three examples considered in preceding sections. The accuracy of this algorithm depends on the system of ODEs under consideration. The algorithm was built to simulate system of ODEs by converting second-order ODE to a system of first-order IVP, with graphical representation of exact and numerical solution. The error plot with the same step size $h = 0.1$ was also graphically illustrated. Considering the parametric plot of example 1, the plot shows that the solution presented by the both algorithm, that RK4 algorithm gives a better approximation than the Euler's algorithm. This was also the case in example 2, the Runge-Kutta algorithm showed that the solution obtained from the exact and numerical solution by comparative analysis obtained accurate result and the same goes for example 3. It has been observed by the results shown in Figure 13, through the parametric plot that the algorithm works well. Table VII shows how the Euler's algorithm computes faster but does not give accurate approximations, like that of RK4 which computes slower but gives better approximation. In future work, we intend to harness the algorithm to solve higher orders of ODE that can be recasted to system of ODEs. We also aim to adopt the algorithms to solve other differential equations such as Lotka-Volterra model, and stiff equations, and investigate the algorithm time taken in execution, using Mathematica®. By investigation, it is shown in Figure 9 that the parametric plot of the system of ODEs using the (Euler's and RK4) algorithms concludes that RK4 algorithm works well and gives better approximation. In Equation (25) and Equation (26), we observed the appearance of complex conjugate values in the exact solution. This was due to the low value of damping ($\delta = 0.01$) used in the equation of motion, describing the particle attached to a stationary wall. This explanation

also covers for the complex values observed in Table V and Table VI. The numerical values in the aforementioned tables showed close approximations, despite the complex part. The values of the complex parts are also negligible as they are really small (having dimensions of 10^{-34} , 10^{-19} and 10^{-18}). Comparing Figure 9 (b) and (d) against Figure 10 (b) and (d), we can observe that the Runge-Kutta algorithm also gave a better approximation to the Euler algorithm. The errors for the Runge-Kutta algorithm was in order 5×10^{-2} while Euler algorithm was in order 1×10^{-1} .

ACKNOWLEDGMENT

The authors wish to thank Tshwane University of Technology for their support and the Department of Higher Education and Training, South Africa.

Maneuverable Autonomy of a Six-legged Walking Robot: Design and Implementation using Deep Neural Networks and Hexapod Locomotion

Hiep Xuan Huynh¹, Nghia Duong-Trung², Tran Nam Quoc Nguyen³, Bao Hoai Le⁴, Tam Hung Le⁵
Can Tho University, Can Tho city, Vietnam^{1,3,4,5}
Technische Universität Berlin, Berlin, Germany²

Abstract—Automatically real-time synthesizing behaviors for a six-legged walking robot pose several exciting challenges, which can be categorized into mechanics design, control software, and the combination of both. Due to the complexity of controlling and automation, numerous studies choose to gear their attention to a specific aspect of the whole challenge by either proposing valid and low-power assumption of mechanical parts or implementing software solutions upon sensorial capabilities and camera. Therefore, a complete solution associating both mechanical moving parts, hardware components, and software encouraging generalization should be adequately addressed. The architecture proposed in this article orchestrates (i) interlocutor face detection and recognition utilizing ensemble learning and convolutional neural networks, (ii) maneuverable automation of six-legged robot via hexapod locomotion, and (iii) deployment on a Raspberry Pi, that has not been previously reported in the literature. Not satisfying there, the authors even develop one step further by enabling real-time operation. We believe that our contributions ignite multi-research disciplines ranging from IoT, computer vision, machine learning, and robot autonomy.

Keywords—Six-legged walking robot; hexapod locomotion; Raspberry Pi; deep neural networks

I. INTRODUCTION AND MOTIVATION

Controlling a multi-legged robot receives a vast research endeavor in the literature. At first, researchers scrutinized the advantages of a legged robot over a wheeled one by investigating the degrees of freedom, mechanical structure, gait generation, and body stabilization on difficult terrain [1]. Then a scheme of the locomotion control approach by mimicking the biological movement of legs and basic motion pattern was investigated. The simulation and modeling were developed on either the eight-legged or six-legged robot. The feedback taken from the environment was collected from motor sensors [2]. By mimicking the physical structure of legged animals, engineers can implement a more stable and faster walking robot. A six-legged walking robot whose kinetic chain of legs based on the biomechanics of the cockroach was prototyped by [3]. The motion mechanisms were controlled by a PLC controller, and the two-degree-of-freedom robot only moved in a straight direction. Another work researched dynamic forward legged locomotion toward a static object using a single monolithic controller. Two virtual quadrupedal robots were used [4]. Another two papers have done intensive experiments and modeling of the robot stability and energy consumption analysis [5], [6]. Many other research articles have strengthened the aspect of sensor-based feedback, and mechanics can be found in [7], [8], [9].

Computer vision on Raspberry Pi is overwhelming on its own field [10], [11], [12]. The tasks can be narrowed to object detection and recognition, home automation, and surveillance, combining camera and software libraries [13], [14]. The idea of real-time face detection deployed on a telepresence robot was proposed in [15], where two Raspberry Pi boards were utilized to achieve real-time detection. They developed a technique to enable real-time detection on a Raspberry Pi and using the result to control the pan and tilt unit of a telepresence robot. The user can either robot's movement by turning or rotating the smartphone or set the robot to follow the face of someone who is at the robot place.

This article aims to bring the two separate research directions into one choir where robot automation, IoT, computer vision, and machine learning operate several complex tasks in real-time. Many contributions of owner work are follows. First, we propose a prototype and mechanical structure of a six-legged working robot. Second, we propose an architecture of convolutional neural networks that work very effectively regarding highly accurate face recognition and be able to deploy on a Raspberry Pi. Third, we implement a complete robot automation solution.

The article is organized as follows. Section (II) briefly presents the background on Haar-like features, boosting technique in machine learning, the cascade of weak classifiers to form a strong one, and convolutional neural networks. These materials help readers understand the underlying techniques that address the tasks of face detection and recognition. Section (III) summarizes several main hardware components used in the experimental robot. Many software libraries, e.g., especially related to convolutional neural networks, are introduced in Section (IV). Our main contributions of this research article are presented in Section (V), where the authors describe the system architecture and its three sub modules, e.g., face detection, owner recognition, and kinematic automation. Section (VI) present the experiments and experimental remarks. And Section (VII) concludes our work.

II. BACKGROUND AND STATE OF THE ART

A. Haar-like Features

Object detection utilizing Haar feature-based cascade classifiers is an effective object detection method [16]. It is a machine-learning-based model where a cascade function is trained from a lot of positive and negative observations. In

our experiments, images of and images without faces are the positive and negative observations, respectively.

Concretely, a general image makes up of pixel in which a person or a computer vision algorithm can recognize many distinctive shapes or patterns, partly depending on the level of contraction. During the creation of a Haar cascade, various parts of the image are cropped and scaled so that we consider only a few pixels that we call a window at a time. We will subtract some of the grayscale pixel values from others to measure the window's similarity to specific common shapes where a dark region meets a light area. If a window is very similar to one of these archetypes, it can be selected as a feature at similar positions and magnifications relative to each other. We expect to find similar features across all images of the same investigated subject.

The problem of determining the face of a person in an image is the problem of binary classification: face or not. To identify faces with Haar features, we apply Haar's features throughout the image, areas that are considered to be most similar to Haar features will be marked. Haar-like featurings is the most basic method of facial recognition. It will add a Haar feature to the whole image. The area that looks like it will identify it as the face. There will be many areas in the image where the algorithm recognizes a face. However, we do not just use a Haar feature but use a lot of features in different image positions and sizes to exclude these areas.

B. Adaptive Boosting

In machine learning [17], [18], we might take random guessing as a default baseline for evaluation reference to other learning models. A learning model is weak when it is slightly better than random guessing, while the strong one accurately classifies elements most of the time. In practice, it may not be competent to entirely rely upon the performance of just one machine learning model. Ensemble learning [19], [20] offers a systematic solution to combine the predictive power of multiple learners referring to learning a weighted combination of base models [21], [22]. The resultant model gives the aggregated output from several models. The aggregation models could be either from the same learning algorithm or different learning algorithms. The objective is to produce a classifier called C , where the output is the prediction confidence. We denote N as the number of observations. Hence, the total error E of classifier C is defined as follows:

$$E(C) = \sum_{i=1}^N \exp(-c_i C(\mathbf{x}_i)) , \quad (1)$$

where $c_i = \pm 1$ for the classification of observation \mathbf{x}_i . Note that we consider binary classification for a simplified discussion. In Equation (1), c_i and $C(\mathbf{x}_i)$ have the same sign if C highly confidently assign sample \mathbf{x}_i with large absolute value of $C(\mathbf{x}_i)$. Consequently, its exponential error $\exp(-c_i C(\mathbf{x}_i))$ contribute very little to the total error $E(C)$ and visa versa.

AdaBoost, short for Adaptive Boosting, is widely used as an ensemble learner. It focuses on classification problems and aims to convert a set of weak classifiers into a strong one. It uses in conjunction with many other types of

learning algorithms to improve performance. Conceptually, AdaBoost iteratively generates a series of classifiers C_m . In each iteration, the classifier is improved by concentrating on the misclassified observations. Therefore, each classifier is more accurate than its predecessor. It is generated as a linear combination of weak classifiers, and their coefficient gives the confidence of these weak classifiers.

Let initialize C_1 to the weak classifier $f_1(\mathbf{x})$ which misclassifies the least training samples. We denote β_1 as its coefficient, and the value is chosen concerning minimize the following error:

$$\begin{aligned} E(C_1) &= \sum_{i=1}^N \exp(-c_i \beta_1 f_1(\mathbf{x}_i)) \\ &= \sum_{c_i \neq f_1(\mathbf{x}_i)} \exp(\beta_1) + \sum_{c_i = f_1(\mathbf{x}_i)} \exp(-\beta_1) , \end{aligned} \quad (2)$$

where c_i and $f_1(\mathbf{x}_i)$ obtain the values of $+1$ or -1 . Then, the difference with respect to β_1 is calculated as follows:

$$\frac{dE(C_1)}{d\beta_1} = \sum_{c_i \neq f_1(\mathbf{x}_i)} \exp(\beta_1) - \sum_{c_i = f_1(\mathbf{x}_i)} \exp(-\beta_1) . \quad (3)$$

We denote N_A as the number of observations that have been accurately classified. Hence, we have

$$\frac{dE}{d\beta_1} = (N - N_A) \exp(\beta_1) - N_A \exp(-\beta_1) . \quad (4)$$

By setting Equation (4) to zero, we solve for β_1 to find the extreme as follows:

$$\begin{aligned} \exp(2\beta_1) &= \frac{N_A}{N - N_A} \\ \beta_1 &= \frac{1}{2} \log \frac{N_A}{N - N_A} . \end{aligned} \quad (5)$$

As previously mentioned, the weak learners should be better than random guessing. Consequently, N_A cannot be less than $N/2$, and the more considerable value of N_A is, the more confidence it indicates. The total error through m iterations is calculated as follows:

$$\begin{aligned} E(C_m) &= \sum_{i=1}^N \exp(-c_i C_{m-1}(\mathbf{x}_i)) - c_i \beta_m f_m(\mathbf{x}_i) \\ &= \sum_{i=1}^N \exp(-c_i C_{m-1}(\mathbf{x}_i)) \exp(-c_i \beta_m f_m(\mathbf{x}_i)) \\ &= \exp(-\beta_m) \sum_{c_i = f_m(\mathbf{x}_i)} v_{i,m} \\ &\quad + \exp(\beta_m) \sum_{c_i \neq f_m(\mathbf{x}_i)} v_{i,m} , \end{aligned} \quad (6)$$

where $v_{i,m}$ is the weights.

Weight is the exponential error that the current weak classifier produces when predicting observation \mathbf{x}_i . Hence, Equation (6) can be split as follows:

$$E(C_m) = \exp(-\beta_m) \sum_{i=1}^N v_{i,m} + (\exp(\beta_m) - \exp(-\beta_m)) \sum_{c_i \neq f_m(\mathbf{x}_i)} v_{i,m} . \quad (7)$$

As we can see in Equation (7), the second summation depends on the classifier f_m . Consequently, the classifier which produces the sum of weights over the accurately classified observations is the largest should be selected.

Assuming that k_m is selected, we differentiate the total error concerning β_m and set the resultant difference to zero, solving for β_m . Then β_m is as follows:

$$\beta_m = \frac{1}{2} \log \frac{\sum_{c_i = f_m(\mathbf{x}_i)} v_{i,m}}{\sum_{c_i \neq f_m(\mathbf{x}_i)} v_{i,m}} . \quad (8)$$

The more accurate observations f_m classifies, the larger its weights are. The higher the weights are, the more confident it gets. The more assured it achieves, the larger β_m is produced.

C. Cascade of Classifiers

We will have a sequence of classifiers, in which each classifier is built using the Adaboost algorithm. Now, let all the windows go through this sequence of classifiers. The first classifier eliminates the most negative sub-windows and passes through the positive sub-window. Here, the classifier is very simple, and therefore, the computational complexity is also very low. Of course, because it is so simple, among the windows that are recognized as faces, there will be a large number of windows that are misidentified (not faces). The windows passed by the first classifier will be viewed as considered by the classifier later: if the classifier thinks it's not the face is removed, if the classifier thinks it's a face, then we pass through and move to the rear class. Later the classifier is more complex, demanding more calculation. People call sub-windows (templates) that the classifier doesn't remove as patterns that are hard to identify. The deeper these patterns get into the sequence of classifiers, the harder it is to identify. Only windows that pass through all the classifiers will decide that face.

D. Convolutional Neural Networks

The high-level general CNN architecture is illustrated in Fig. 1. Input layers are places that raw images are loaded into. The raw images are specified by their width, height, and number of channels. Typically, RGB values of each pixel form three channels. Convolutional layers apply a patch of locally connecting neurons to transform the input data from the previous layer. Consequently, the layer calculates a dot product between the area of the neurons in the input layer and the weights to which they are locally connected in the output

layer. Typically, a convolution is defined as a mathematical operation describing a rule for how to merge two sets of information. Within this work, the authors briefly present the CNN background that leads to the proposed architecture in Section V-B. Further details on CNN and its next-generation investigating transfer learning [23], [24], [25], [26], [27] leaves to interesting readers.

Fig. 1. High-level General CNN Architecture.

III. HARDWARE COMPONENTS

A. Raspberry Pi 3 Model B

The Raspberry Pi (RP) is a small, cheap, single-size, single-chip computer board that comes with CPU, GPU, USB ports, and I/O pins and is capable of performing several functions. Simple as a regular calculator [28], [29]. RP 3 Model B comes with a 64-bit quad-core processor on a circuit board with WiFi and Bluetooth and USB features. It has a processing speed of 700 MHz to 1.4 GHz in which the RAM ranges from 256 to 1GB. The device's CPU is considered to be the brain of the device responsible for executing instructions based on mathematical and logical operations. The board is equipped with Broadcom video core cable, which is mainly used to play video games through the device. RP 3 comes with GPIO (General Purpose Input Output) pins that are essential for maintaining a connection with other electronic devices. These input terminals receive commands and operate based on the device program. An Ethernet port is integrated on this device to establish a communication line with other devices. The board has four USB ports that can be used to connect a keyboard, mouse, or USB 3G connection to access the internet and an SD card added to store the operating system. The power connector is a basic part of the circuit board used to supply 5 V to the board. We can use any source to set the power for the circuit board. However, we prefer to connect the power cable via the laptop's USB port to provide 5 V. HDMI port is used to connect LCD or TV, can support cables versions 1.3 and 1.4. RCA Video port is used to connect the old TV screen using 3.5mm jack without supporting the HDMI port.

B. 32 Channel USB/UART Servo Motor Controller Driver Board

A 32 Servo control circuit can be used with the software on the computer, wireless controller PS2, Android app, Arduino (or other microcontrollers) through UART communication [30]. UART stands for Universal Asynchronous Receiver/-Transmitter. It is a physical circuit in a microcontroller, or

a stand-alone IC. A UART's main purpose is to transmit and receive serial data. The 32 Servo control circuit is capable of simultaneously controlling 32 servos smoothly, from which users can coordinate applications to control systems for robotic arms, industrial production lines, and machines. Servo Controller software and instruction can be found at RTROBOT¹.

Several important technical specifications of the board are summarized as follows. Physical size 63mm x 45mm. Operation voltage 5V. Servo Motor Input Voltage is 4.2V to 7.2V (According to a specific servo). CPU 32bit. Baud Rate (USB) 115200. Baud Rate (Bluetooth UART) 4800, 9600, 19200, 38400, 57600, and 115200. Flash Capacity 16M. Servo Motor Controller the Number Of Simultaneous 32. Max Action Groups 256. Control precision 1us. LEDs are dedicated to CPU power, servo motor power, and wireless remote control.

C. Camera Pi v1.3

Raspberry Pi camera has a built-in 5 Megapixel camera with high light sensitivity, able to shoot well in many different lighting conditions, both indoors and outdoors. A special feature that the camera brings is high-definition photography during movie recording. No additional USB ports are needed for the camera as the camera is securely attached to the CSI socket. This helps limit bandwidth bottlenecks for USB processing chips on Raspberry circuits. The camera cable length has been carefully calculated when it reached the required length while ensuring the speed of image transmission from the module to the RP. The important technical specifications of the Pi camera follow. Resolution 2592 x 1944 (5 megapixels). Lens $f = 3.57$ mm, $f / 2.8$. 65-degree viewing angle. Focus range 0.69m to infinity (at 1.38m). Support 1080p @ 30 fps with H.264 (AVC) codec, 720p @ 60fps and 640x480p @ 60/90 fps. CSI interface. Three dimensions are 25 mm x 25 mm x 10 mm. Weight about 2.8g.

D. Digital RC Servo LD-1501MG Motor

Digital RC Servo LD-1501MG motor is used in complex structured robots such as the humanoid robot, biped Robot, and spider robot due to the outstanding characteristics² compared to the traditional Analog RC Servo MG995 and MG996. RC servos or RC actuators convert electrical commands from the receiver or control system, back into physical movement. A servo plugs into a specific receiver, gyro, or FBL controller channel to move that specific part of the RC model. This movement is proportional, meaning that the servo will only move as much as the transmitter stick on your radio is moved, or as much as the gyro/FBL system instructs it to move. Digital RC Servo LD-1501MG motor has a metal gearbox, fast response speed with strong traction according to manufacturer torque figures up to 17Kg.cm. The important technical specifications of the motor are the following. The operation voltage is 5 to 7.4VDC. No-load current of 100mA, with load \dot{c} 500mA. Speed 0.16sec / 60° at 7VDC. Traction torque of 13Kg.cm at 6VDC; 15KG.cm at 6.5VDC; 17KG.cm at 7VDC. Weight 60g. Dimensions 40 x 20 x 40.5mm. Cable length 30cm. We use 18 motors in the implementation to achieve 4 degrees of freedom of the robot's body, which encourages us to implement complex movement and dancing.

E. Power supply and Low voltage circuit board

The AC power cord (AC) 220V is connected to L and N pins at the input on the power supply (12V, 10A). The 12V output of power adapter, V+ pin, and V- pin, are connected to positive pin (+) and negative pin (-) on the low voltage circuit board. The low voltage circuit board consists of 2 outputs; one output can be adjusted voltage from 1.25 - 32V used to power the servo motor control module, the other output is a 5V USB port used to power the RP. In this case, the appropriate voltage to supply the servo motors is 6 - 6.5V. We can adjust by rheostat on the low voltage circuit board.

F. Mechanic legs

This robot model is inspired by real spiders. However, we can only partially reproduce the movements of spiders on this robot because of the limits of joints on the robot and the complexity of the control. The simple robot model will have fewer joints, so the number of servos (actuators) will be less beneficial, which can include benefits such as reducing the weight of the robot, reducing power consumption and increasing working time. The minimum condition for a robot to move is that each leg must be made up of two or more moving joints. The fact that our robot has three motion joints makes the robot move smoothly and motion control easier. The spider robot model has six legs, each of which consists of three servos (actuators) that are caught in the coal. Each side of the robot consists of three legs that allow the robot to move. The 3D sketch is done by Glovius CAD³.

IV. SOFTWARE LIBRARIES

The Tensorflow library [31] is an open-source library developed by Google and made available to the developer community in 2015. Google Brain has developed the platform for image search, voice recognition, traces data, and many Google services. Keras [32], [33] is an open-source library for neural networks written in the Python language. Keras is a high-level API that can be used in conjunction with deep learning libraries such as Tensorflow, Theano, and CNTK. In this article, we use the Keras library in combination with the Tensorflow library [34]. OpenCV library [35] is a leading open-source library for computer vision, image processing, machine learning, and GPU acceleration features in real-time operation. OpenCV is designed for efficient computing and with a heavy focus on real-time applications. Raspberry Pi uses multiple operating systems: Raspbian, Ubuntu, Windows 10 IoT, and Chromium OS. In this article, the system uses the Raspian operating system⁴ [36], [37] Raspian is the basic and most common operating system and is provided by the Raspberry Pi Foundation.

V. SYSTEM DESIGN

The system architecture can be disintegrated into three sub modules, e.g., face detection, owner recognition, and kinematic automation. The principal task in the face detection module is to detect faces from sequential pictures taken by the Raspberry camera. This task is discussed in Section V-A in more details. Then, only the cropped faces go through the process of owner

³<https://www.glovius.com/>

⁴<https://www.raspbian.org/>

recognition module where (i) the robot owners are recognized, and (ii) robot behaviors and kinematic locomotion are executed. We are going to describe these progress in Section V-B. The last module is more on the kinematics aspect, referred to Section V-C, where the authors discuss how to control the legs in case of owner detection and no owner detection. We have associated several techniques to achieve the harmonic maneuverability of detection, recognition and automation in real-time. The proposed system architecture is illustrated in Figure 2. Our hardware design and implementation of a six-legged walking robot are presented in Figure 3.

Fig. 2. The Overall Software and Hardware Architecture.

A. Module 1: Face Detection

The facial detection system is a computer application that automatically identifies a face and then identifies someone from a digital photo or a video resource. One way to do this is to compare pre-selected facial features from the image and a face database to remove non-face components. Building an automatic control program for spider robots using control signals as a result of the face recognition system with input data is frames cut from the video directly from the camera through the method of using Use the Haar Cascade technique. This RP analyzes the image and returns framed and stored faces for data training later. In general, the method is built on a combination of four components, e.g., Haar features, an integral image, Adaboost, and a cascade of classifiers. The progress of module 1 face detection is illustrated in Fig. 4.

After the faces are detected, they will be manually reclassified to verify faces, to eliminate false positives in the photo set. After the test is stored with the same number of three image files of three team members, these three files will be three data files used to train for the program in the next face recognition.

B. Module 2: Owner Recognition

In this study, the machine learning model used to classify faces is a CNN model, also known as a convolution neural network. The model has two parts: feature learning and classification. We briefly describe them in Section V-B1 and Section V-B2.

1) *Feature learning*: This section includes layers: Conv2D, MaxPooling2D, and Dropout. They extract the image features, learn the image features (during training), reduce the image size, and blur the image. The function of Conv2D is to extract image specifications, learn these specifications (during training). The Conv2D layers use filters to get image features (curves and lines).

The element retained during the training of extracting these properties is not the image channel. If all channels are stored, the data of the model after training will be very large. Besides, adding a new image and predicting will be no different from finding value in the database. So the values stored in this section are mostly kernels. The initial values of the kernels are randomly generated, or we can assign the initial values to them. The kernel matrix values will be updated during the Backpropagation process.

2) *Classification*: This part is two fully connected layers, which consists of 1 dense layer containing 512 nodes and one dense layer consisting of 3 nodes, calculating values and make a classification. Note that the output contains three nodes because we set the number of robot's owners is three. The values stored after training in this part are the weights that are updated during the backpropagation process. The sigmoid activation function is used in the last layer to predict the percentage of an object with an input sample. The class with the highest score will be the final prediction.

We proposed the CNN architecture presented in Fig. 5. We implemented the experimental model in Keras and TensorFlow. The model consists of four convolution Conv2D layers. The first, second, and fourth convolution layers accompany a Max-Pooling2D a Dropout layers. The third convolution layer is just attached to a MaxPooling2D layer. The last two layers are dense. Default Adam [38] is the optimization method. Categorical cross entropy [39], [40] is the loss measurement.

C. Module 3: Maneuverable Automation

A multi-legged robot [41], [42] maintains a tremendous potential for maneuverability over different terrain, particularly in comparison to wheeled robot. It possesses less complexity than a human-like walking robot regarding stability and development effort. A six-legged robot inspired by biology is one of the most common design [43], [44]. It is important to develop a good control mimicking the kinematic behavior of the complex six-legged robotic mechanism. The overall design of our proposed automation is presented in Fig. 7. We use the OpenCV library to process data received from the RP camera. The system selects one frame out of five received frames. The reason is that the robot takes a certain amount of time to complete the current motion, then we perform the identification and send the next control signal. During the experiment, we found that this ratio gives the most natural motion of the robot. When there is a frame, the system will detect the face cut, if any. These cropped faces are then processed by the machine learning model developed on the Keras and TensorFlow library. Next, the system controls the movements of the robot according to the predicted result. The system checks the current rotation angle of each servo motor and finds the appropriate pulse value for the action to be performed. The control signal will be transmitted to each motor, and the robot forms a motion.

We program the robot to perform some basic movements based on the results of the face recognition of the owner. The specific movements of the robot are as follows. If the owner is Hoai Bao, the robot performs the stand-up move. If the owner is Hung Tam, the robot performs the sit-down operation. If the owner is Nam Tran, the robot will move towards the owner. If

Fig. 3. Several Views of the Six-legged Walking Robot.

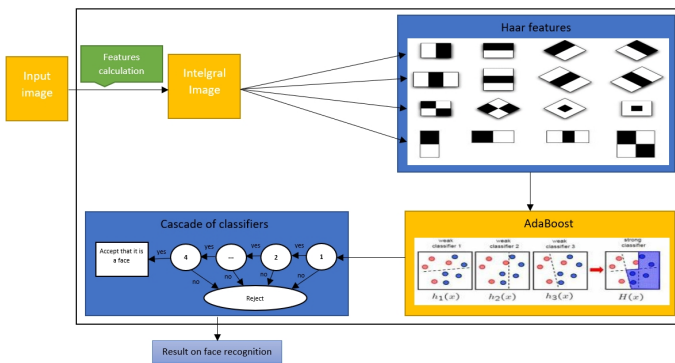

Fig. 4. The Architecture of Module 1: Face Detection.

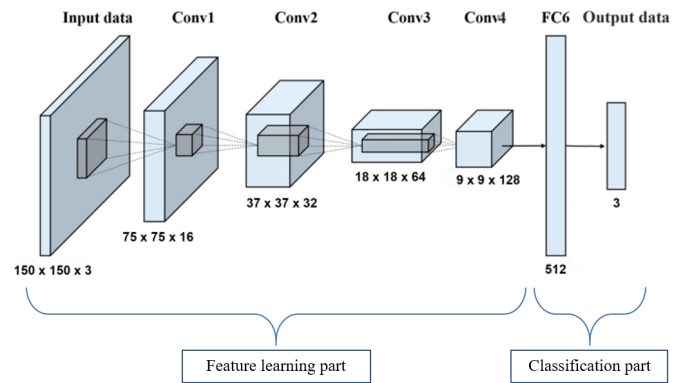

Fig. 5. The Architecture of Module 2: Face Recognition.

one of the three owners is not recognized, keep the previous movement. To control the rotation of the servo motor, we make a change in the pulse value. For LD-1510MG servo motors used in this study, the pulse range is from 500 to 2400 us. Fig. 6 depicts the pulse and sweep angle of the motor.

VI. EXPERIMENTS

A. Hardware and Software Setup

Our six-legged walking robot consists of several hardware components such as one RP 3 model B, one 32 channel US-B/UART servo motor controller driver board, one RP camera

Fig. 6. Motion Angle of a Motor.

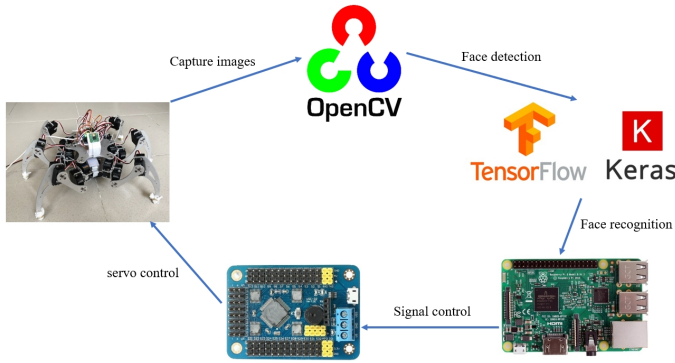

Fig. 7. The Architecture of Module 3: Maneuverable Automation.

v1.3, 18 digital RC servo LD-1501MG motors, one power supply 12V 10A, one low voltage circuit board, mechanic legs, and other components. The hardware connection is presented in Table I. The RP 3 model B is considered the robot brain where most of the controls are calculated from here.

TABLE I. CONNECTIONS OF MAIN HARDWARE DEVICES

Device	Connector Type	Device
Raspberry Pi	CSI - CSI	Pi Camera v.1.3
	RX - TX	32 Channel USB/UART Servo Motor Controller Driver Board
	TX - RX	
	GND - GND	
32 Channel USB/UART Servo Motor Controller Driver Board	GND - GND	Servos
	VCC - VCC	
	heart beat signals	

B. Legs Controller

Each servo motor is then connected to the control circuit. For ease of programming and maintenance, we specify the wiring order as follows: 6 front two-servo motors will be connected to pin 1 to 6 of the motor control module. The six servo motors of the middle two legs will be connected to pin 7 to 12. And the last six servo motors of the rear legs are connected to pin 13 to 18. To check whether the servo motors are correctly installed, we connect the servo motor control module to the computer via the USB interface and use the software⁵ to check the operation of each servo.

In the program, after having information on face recognition, this signal is the input for the control signal for the spider robot. The signals are transmitted except the Raspberry Pi to the servo control circuit by UART communication. Now we need to determine the pulse level for each leg of the robot is the servo. The balance joints smoothly work together, similar to the movements of spiders, in reality, to shape the movements of the spider robots. The control signals are transmitted in the form of pulses with an execution time of ms. Example #1P2500T100 where 1 is the pin position 1, P2500 means 2500 pulses, and T100 is the execution time of 100ms. The simulation of robot moving forward, backward and turning-left is presented in Fig. 8, 9, and 10.

Control angles are calculated manually using RTROBOT control simulation software. We check and select the appropriate pulse width to create motion for 18 robot leg joints.

The settings are saved into a configuration file containing foot control information and pulse value for each motor. Activities are grouped into blocks. The time taken for a moving group is fixed the same by 1 second to avoid control signal congestion. After detecting a face, the RP calls control signals that are pre-configured according to each face we have previously classified. The control signal is executed in series, but the execution speed of the foot joints is fast so that it will see simultaneous movements.

Fig. 8. Simulation of Robot Moving Forward.

Fig. 9. Simulation of Robot Moving Backward.

Fig. 10. Simulation of Robot Turning Left.

C. Face Detection and Image Collection

To apply the Haar recognition method with Adaboost, we use the *detectMultiScale* function to search for faces in the

⁵<https://rtrobot.org/software/>

image. Each image will be scanned in turn, and the program will confirm whether it is a human face or not and determine the number of faces in that frame by sliding the Haar symbols on the image, helping us identify All faces in the photo. The *detectMultiScale* function is a face search, which is part of the *CascadeClassifier* class. The codes are presented in Listing (1).

```
1 cascade = cv.CascadeClassifier(  
2   haarcascade_frontalface_default.xml)  
3 gray = convert_to_gray(imagePath)  
4 faces = cascade.detectMultiScale( gray ,  
5   scaleFactor = 1.1 ,  
6   scaleNeighbor =5, minSize(5,5) , maxSize  
7   (100,100))
```

Listing 1: Detect faces with detectMultiScale function.

The .xml file in Listing (1) contains the classifiers built on the standard database sets that is part of the OpenCV library.

The face detection on video is similar to the image because the video is a series of frames. Then we will capture each frame and save it. The program will read the captured frames again. Then we let the face detection program run on all image data and save all identifiable faces into another folder with the purpose of building data for the training set to be used in the recognition face. The codes in Listing (2) present how images are captured from Pi camera.

```
1 cap=cv.VideoCapture(0)  
2 i=0  
3 while (i!=15):  
4   frame=cap.read()  
5   frame=cv.flip(frame,-1)  
6   cv.imshow("Frame",frame)  
7   name= "%s" %i  
8   name= name + ".png"  
9   i=i+1  
10  cv.imwrite(name,frame)  
11  cap.release()  
12  cv.destroyAllWindows()
```

Listing 2: Images are captured using Pi camera.

Faces after being detected, the image will be manually reclassified to check again to identify faces correctly, removing false identities included in the image file. After the test is stored with the same number of three image files of three team members, these three files will be three data files used to train for the program in the next face recognition. Through experiments with model *haarcascade_frontalface_default.xml* with images containing human faces, the program recognized at a good level.

To increase the data for training, we use the solution augmentation technique to provide more data. *ImageDataGenerator* function is used in the implementation. The codes is presented in Listing (3).

```
1 image_gen = ImageDataGenerator(rescale  
2   =1./255, horizontal_flip = True,  
3   zom_range=0.25, rotation_range=45)  
4 train_data_gen = image_gen.  
5   flow_from_directory(batch_size=1000,  
6   directory="C:\\Test\\Image\\output\\",  
7   shuffle=True,
```

```
target_size=(IMG_HEIGHT, IMG_WIDTH))
```

Listing 3: ImageDataGenerator function for augmentation.

D. Face Recognition

1) *Datasets*: The experimental dataset is a set of images of the face of the robot's owners. This volume is divided into three parts, one part is used to train the machine learning program (training set), the other part is used for validation (validation set), and one part is used to check the accuracy. The original image's resolution taken by Pi Camera is 2048 x 1536. Then face regions are detected and cropped to 150 x 150.

The training set consists of 2250 photos divided into three folders. Each folder contains pictures of a specific person (Hoai Bao, Nam Tran, Hung Tam). These samples were taken from Pi cameras in environments with different light intensity and different angles. Besides, we also use augmentation methods such as: rotating the image with an angle of x degrees (with x being the number of degrees), enlarging the image, zooming the image, flipping the image, or combining many of them to get more photo patterns and to avoid overfitting. The validation set of 750 photos is also divided into three folders. Each folder contains pictures of a specific person (Hoai Bao, Nam Tran, Hung Tam). These images are also taken from the Pi camera. However, they are received at random. These samples will be reviewed after each epoch (number of model training) as one of the model's goodness test metrics. Similar to the validation set, the test set of 741 images is also divided into three folders corresponding to three people who are considered the owners of the robot.

2) *Evaluation Metrics*: Suppose we are solving a binary classification task with a labeled dataset $\mathcal{D} = \{\mathbf{x}_i, y_i\}$. Given a threshold parameter ϕ that guilds our decision rule $g(\mathbf{x})$ and count the number of true positive (TP), true negative (TN), false positive (FP), and false negative (FN). We also define m_+ the total of condition positives, m_- the total of condition negatives, \hat{m}_+ the total predicted condition positives, \hat{m}_- the total predicted condition negatives, and m the total population.

We can compute the sensitivity, also known as true positive rate (TPR) or recall by using:

$$\text{TPR} = \frac{\text{TP}}{m_+} \approx P(\hat{y} = 1|y = 1) . \quad (9)$$

Similarly, we can compute the fall-out, also known as false positive rate or probability of false alarm by using:

$$\text{FPR} = \frac{\text{FP}}{m_-} \approx P(\hat{y} = 1|y = 0) . \quad (10)$$

The true negative rate (TNR) or specificity is defined as follows:

$$\text{TNR} = \frac{\text{TN}}{m_-} \approx P(\hat{y} = 0|y = 0) . \quad (11)$$

The false negative rate (FNR) or miss rate is calculated as follows:

$$\text{FNR} = \frac{\text{FN}}{m_+} \approx P(\hat{y} = 0 | y = 1) . \quad (12)$$

If we work with a dataset for binary classification when the number of negatives is very large or a dataset for multi-class text prediction when a class imbalance exists, considering TPR, FPR, TNR, and FNR themselves is not very informative. Before going further, we define positive predictive value (PPV) or precision as follows:

$$\text{PPV} = \frac{\text{TP}}{\hat{m}_+} \approx P(y = 1 | \hat{y} = 1) . \quad (13)$$

By combining Equation (9 and 13), we can compute F1-score as follows:

$$\text{F1-score} = 2 \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} . \quad (14)$$

3) *Evaluation Results:* Model trained on a 2-core 4-thread laptop, 12GB RAM, Nvidia GTX 950M GPU. The size of each batch is 32 images. Model converges after 10 epochs. The model is then tested on test data to evaluate its final accuracy. The TP, FN, and FP over the test set are presented in Table II.

TABLE II. THE TP, FN, AND FP OVER THE TEST SET

No.	Owner face	TP	FN	FP
1	Nam Tran	247	16	8
2	Hung Tam	247	12	5
3	Hoai Bao	247	15	3
Total		741	43	16

From the evaluation result presented in Table II, we can easily calculate Precision \approx **0.98**, Recall \approx **0.95**, and F1-score \approx **0.96**.

4) *Experimental Remarks:* Model training can be done on Raspberry or regular computers. Because RP is an embedded computer, the hardware configuration and processing speed are relatively limited. Training on Raspberry takes a lot of time. In this case, the training time for one epoch is more than 2 hours (the model used in this topic is ten epoch training) for a training set of 2250 images, and each image size is 150x150. Besides, we have to turn off all the applications so that the training program has enough Ram to execute. However, we still achieved experimental results similar to those done on laptops. During experiments, we also try the VGG-16 model [45], which is very lightweight to compare the prediction accuracy with our proposed CNN model. However, the VGG-16 model cannot fit into RP's memory when loading images. Note that the image's resolution is only 150 x 150.

VII. CONCLUSIONS

Throughout the article, the authors present Haar-like features, ensemble learning, and CNN as the methodology background. We discuss hardware components and mechanical legs, which build a six-legged working robot. The critical contribution is the proposed system design, where three sub modules, e.g., face detection, face recognition, and kinematic

automation, work harmonically in real-time. Therefore, a complete solution associating both mechanical moving parts of a walking robot, IoT hardware components, and software has been adequately demonstrated. The proposed design and implementation has orchestrated several complex tasks. First, we address the task of interlocutor face detection and recognition, utilizing ensemble learning and convolutional neural networks. Second, we develop maneuverable automation of a six-legged robot via hexapod locomotion. And last but not least, we deploy the proposed system on a Raspberry Pi that has not been previously reported in the literature. The experiments are well described to encourage further reproducibility and improvement.

Abstract—The recent advances of Augmented Reality (AR) in healthcare have shown that technology is a significant part of the current healthcare system. In recent days, augmented reality has proposed numerous intelligent applications in the healthcare domain including, wearable access, telemedicine, remote surgery, diagnosis of medical reports, emergency medicine, etc. These developed augmented healthcare applications aim to improve patient care, increase efficiency, and decrease costs. Therefore, to identify the advances of AR-based healthcare applications, this article puts on an effort to perform an analysis of 45 peer-reviewed journal and conference articles from scholarly databases between 2011 and 2020. It also addresses concurrent concerns and their relevant future challenges including, user satisfaction, convenient prototypes, service availability, maintenance cost, etc. Despite the development of several AR healthcare applications, there are some untapped potentials regarding secure data transmission, which is an important factor for advancing this cutting-edge technology. Therefore, this paper also analyzes distinct AR security and privacy including, security requirements (i.e., scalability, confidentiality, integrity, resiliency, etc.) and attack terminologies (i.e. sniffing, fabrication, modification, interception, etc.). Based on the security issues, in this paper, we propose an artificial intelligence-based dynamic solution to build an intelligent security model to minimize data security risks. This intelligent model can identify seen and unseen threats in the threat detection layer and thus can protect data during data transmission. In addition, it prevents external attacks in the threat elimination layer using threat reduction mechanisms.

Keywords—Augmented Reality (AR); healthcare applications; healthcare challenges; AR-based healthcare security issues; dynamic security solution

I. INTRODUCTION

Augmented Reality (AR) stands for the comprehension of modern technology that performs through detection and identification of critical intuition and represents the computer-generated perceptual information (Wikipedia). In recent days, AR is considered one of the prominent advanced technologies for its augmentation prototypes. It enhanced its effectiveness and influenced almost every aspect of life, such as emergency service [2], healthcare management [5][3], industrial implementation, education and training [25][33], design and planning [1][4], and many more.

Therefore, several pieces of research have been undertaken to generate more effective AR prototypes [4] and shown

outstanding achievements [5]. According to Urakov et al. (2019) [6], AR enhances the visualization of the 3-dimensional holographic image through sophisticated glasses. Again, El-hariri et al. (2018) suggested that augmented reality is the visualization process of 3-D imagining data [7]. In some other studies conducted by Vavra et al. (2017) [8] and Kim et al. (2017) [9], augmented reality was described as a projection and interaction-based technology to interact and project computer-generated images in a real environment. Current AR-related research has resulted in several advanced prototypes that promote AR as a prominent technology and call for future research to explore new prototypes and strategies [10][11].

These days, the advancement of AR technology in healthcare has become highly significant with its vast arrays of applications. AR-based healthcare systems are being incorporated with computer vision [6], object detection and identification [18], image processing [10][16], image segmentation [12] and cloud computing technology [14][15]. AR-based healthcare solution has achieved several prominent advancements, such as more secure connectivity and privacy across individual patients [17], more speed while providing quality diagnosis and treatment with more reliability [35]. Besides, wireless services, early diagnosis, real-time monitoring, online consultation, tumor detection, diagnosis specialization, m-health service, and personal assessment are the emerging prototypes of AR-based healthcare solutions, as shown in Fig. 1. Similarly, Medication adherence and rehabilitation treatment have also been enhanced through its utilization. Recently, modern healthcare society introduced an e-health policy to implement prominent augmented devices: AR headset and smart glasses [18]. Therefore, day by day, the popularity of augmented technology in the healthcare system has grown dramatically, and more and more works proposed towards its development.

However, from our empirical observation, it is found that previous review studies have some drawbacks, such as i) a significant number of previous review studies did not present a brief discussion of augmented healthcare applications and their services, ii) few of studies put an effort to provide a comprehensive analysis of the previous works and didn't focus on current limitation of this emerging technology, iii) a majority of them considered only m-health application (medication plan, healthy food guidelines, glucose level monitoring, heartbeat

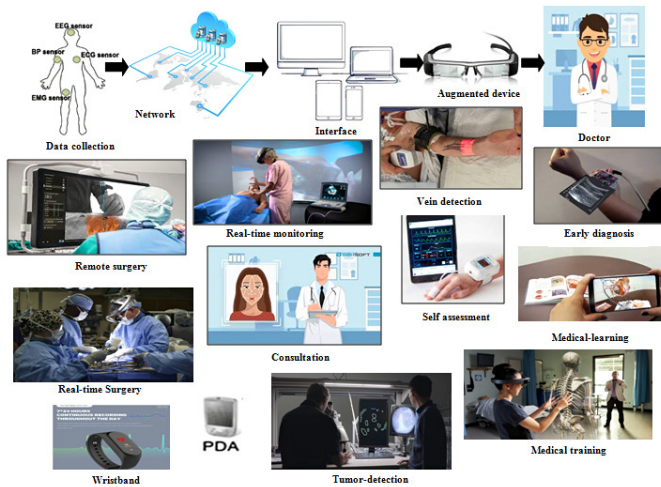

Fig. 1. Current Trends of Augmented Reality in Healthcare Platform.

calculation, etc.) for review/analysis rather than focusing on clinical applications (examines the abnormal joint function, tumor location detection, vein detection, diagnose breast cancer, etc.), and iv) some of the papers addressed recent challenges of augmented healthcare application in short and did not address the possible attacks with proper solutions to mitigate these challenges. Therefore, based on our scientific observation and the author's best knowledge, it can be stated that a comprehensive analysis would be beneficial to identify the limitation and challenges of AR-based healthcare applications. Moreover, this analysis may help to find the solution to these challenges as well as for the further improvement of current applications. This paper aims to investigate the impacts of augmented reality in the healthcare system by addressing above mentioned issues. A brief discussion on augmented healthcare applications (m-health and clinical applications) with their services in the healthcare system is present in this study. Also, a wide range of challenges of the augmented platform in the healthcare system has been demonstrated here with a possible solution against future attacks. Moreover, this paper can be influential in having insights into existing augmented-based healthcare applications. For a further study of AR healthcare solutions, interested readers referred to [23][24][25].

This article has organized as follows: Paper collection and selection for review described in Section 2. Section 3 demonstrates through healthcare applications development prototypes, several augmented mobiles and clinical healthcare applications with services, and current challenges. Section 4 summed up our contribution by addressing several security issues with our proposed intelligent security architecture. Finally, the article concluded with a conclusion and a recommended direction for future research.

II. RESOURCES OF RELATED PAPERS

A. Paper Selection Process

To find the published research articles, we have considered five popular databases in the computer science and health informatics domain for recent development and updated approaches (shown in Fig. 2).

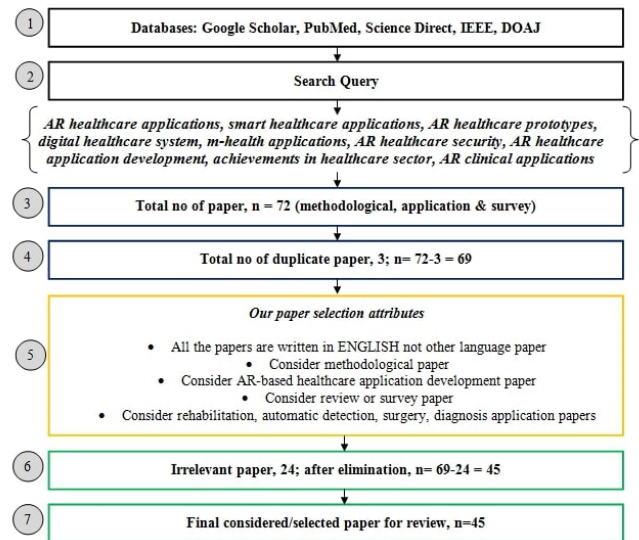

Fig. 2. Related Article Collection and Selection Through Search Query and Predefined Criteria using PRISMA Flow Diagram.

We have considered search queries for searching the relevant papers from the selected database according to the relevancy of our work. For this work, we investigated both peer-reviewed journal and conference articles from 2011 to 2020. Primarily, 72 related articles were found relevant, and after further evaluation, 27 articles have excluded, and 45 articles have finally selected according to our aim. The paper selection process performs following the PRISMA approach. Fig. 2 shows the article extraction and selection process using the PRISMA flow diagram. In Fig. 2, at stage-1, to extract recent publications of augmented and healthcare technology, we considered IEEE, Google Scholar, PubMed, Science Direct, and Directory of open access journal (DOAJ) databases. At stage-2, article searching performs through several keywords such as Augmented Reality (AR) healthcare application, Digital healthcare system, AR-based smart-healthcare applications, AR healthcare application developments, AR-based m-health, recent AR achievements in the health sector, AR healthcare Security, AR clinical application, etc. We added the advanced search option to reveal the most recent articles of our intended domain. Regarding search keywords, we have extracted 72 papers that belong to the methodological approaches, real-life AR healthcare applications development, comparative analysis, survey, and review papers (at stage-3). We performed a manual checking to identify duplicates papers. Three papers have been identified as duplicate and eliminated (stage-4). At stage-5, we set our selection attributes to evaluate the collected papers according to their relevancy with our study aim. Those articles that did not match our selection criteria (Fig. 1, stage-5) did not consider for review. Mostly, those papers that are not written in English and not directly related to the healthcare domain have been marked irrelevant and excluded. After evaluating, 24 articles were removed from the total number (stage-6), and 45 papers were selected for final review (stage-7).

B. Papers Statistics Information

Here, we have categorized the previous articles according to their year of publication, publication database, proposed

TABLE I. CATEGORICAL OVERVIEW OF SELECTED PAPERS FOR REVIEW

No.	Authors	Country	Publication year	Published database	Category	Journal	Conference

category, journal paper, and conference paper. The total number of 45 articles have summarized in Table 1. These articles have been selected based on some predetermined criteria (Fig. 2). From Table 1, the following observation may conclude. First, from 2018 to the present, AR healthcare application has become a serious concern for most the computer scientist and healthcare professionals. Second, the number of comparative analysis and review of AR healthcare applications have dramatically increased in recent days. In contrast, the number of application development articles has decreased due to challenges for ensuring appropriate services and security issues. The detailed statistics of selected articles have shown in the following sections.

1) *Study year and reference database:* Here, we conclude the statistics of the considered articles according to their publication year (2011-2020) and referencing databases (PubMed, Science Direct, DOAJ, Google Scholar, and IEEE), which shows in Fig. 3. Among 45 articles, a significant number of works have published in 2018, 2017, and 2016.

Among five databases, PubMed published ten articles, Science Direct published seven articles, DOAJ published nine articles,

Fig. 3. Number of Articles According to their Publication Year and Referencing Databases.

Google Scholar published thirteen articles, and IEEE published five articles. Moreover, a maximum number of the article we have found for the year 2018. Besides, Google Scholar & PubMed is the more popular database or resource for augmented healthcare domains.

2) *Category of study articles:* To understand the effectiveness of previous works, we analyzed our selected forty-five articles into five categories: methodological, application development, comparative analysis, review, and survey paper. At the same time, we classified these studies into journals and conference publications. Fig. 4 shows that among a total of 45 articles, review, comparative analysis, and methodological papers are maximum in consideration. Among the explained studies, the proposal for methodological studies is ten, six for application developments, eleven for comparative analysis, fifteen for review paper, and three for the survey. The majority of these journal and conference proceedings come from healthcare engineering, computer science, biomedical engineering, and bioinformatics.

Fig. 4. Number of Articles in Each Category with Paper Status.

3) *Country of study articles:* In this study, we considered articles from both developing and developed countries. Figure 5 shows the number of articles according to their country where majority from the USA, Canada, Germany and Brazil and few from UK, South Korea, Greece, Italy, and France. Compared to these countries Australia, India, Bangladesh, Pakistan, and others show less interest in AR-based healthcare research.

III. COMPREHENSIVE ANALYSIS OF SELECTED ARTICLES

After article selection (explain in Section 2), our primary objective is to perform a comprehensive analysis of these 45 selected articles. To do our analysis, here we have considered our research questions regarding how augmented technology facilitated in healthcare domain; identify the recent augmented healthcare applications with services, and current challenges of existing augmented healthcare applications. After exploring these aspects, based on our observation, we proposed a model to mitigate the recent augmented healthcare application's limitation (Section IV-C).

Fig. 5. Number of Articles Per Country.

A. Augmented Reality in Healthcare System

Nowadays, AR technology has attracted significant attention to developing applications that healthcare professionals and patients directly use. Augmented healthcare solutions may apply to a diverse array of fields, including diagnosis, surgery, rehabilitation, monitoring, guidance, education, etc. Generally, AR technology facilitated the healthcare system through its numerous services and platform [29]. The AR service platform refers to a framework that focuses on information acquisition, proper data organization; ensuring data support and providing consistent services, as shown in Fig. 6.

Fig. 6. The Process of Augmented Healthcare Application Services.

1) *Health information acquisition layer:* It refers to collecting healthcare information or patient health reports shared by patients or public health centers or hospitals to make available patient health records to medical specialists or doctors. Generally, healthcare or hospital authority collects these health data and stores them on the hospital database.

2) *Data organization layer:* The data organization layer is the primary layer of the AR-based healthcare application

development process. It benefits transferring real-world information into a virtual environment. This layer extracts the health information from the healthcare database and stores it into a cloud environment to support data preprocessing and model creation. Cloud environment or cloud server refers to data (health data) in the server [27]. Cloud databases provide services for healthcare applications during data examination or visualization. The data preprocessing performed to reduce the noise in MRI and X-ray data. Finally, model creation helps create a visual object for the effective organization of 3-D data [26]. This process allows the generation of a 3-D model from 2-D or 3-D health images or data.

3) *Data support layer*: The data support layer provides services through user registration, data availability, and accessing opportunities. To reduce unknown threats during communication it prerequisites the registration panel. Based on authenticity confirmation, it ensures data availability and accordingly grants access. The authentication process of numerous prototypes ensures through the network interface. Network interface provides the network layer to allow secure communication of the entire prototype of AR healthcare application. Network Layer ensures security through network platforms and network protocols. A network platform is a medium that generates frequencies for communication. Third-generation technology (3G) and fourth-generation technology (4G) are the most popular network platform or network technologies for AR-based healthcare applications. Managing data and ensuring secure connectivity are the prior responsibilities of network protocols. Two widely used protocols are User Datagram Protocol (UDP) and Transmission Control Protocol (TCP). UDP and TCP are responsible for data transmission where UDP is connectionless, reliable, and TCP, errorless.

4) *Service providence layer*: The service providence layer refers to the user interface that allows the extraction of virtual environment data according to availability and accessibility. This layer is also called the process of data collaboration. It helps healthcare specialists overlay the virtually created imagining model on real-time patients' bodies using AR devices. During surgery or diagnosis, on-demand health data accessing is the prime objective of this interface. The majority of healthcare solutions are using smart displays or glass. To detect an object, image, or text projection, Head Mounted Display and Holographic Display device are significant. In recent days, HMD has implemented various healthcare solutions like surgery, diagnosis, assessment, etc. Some prominent functionality of it includes recognizing voice comments, tracking eye movements and gestures movements. At present, powerful and prototype-based HMD devices are OHMDs and OST-HMD. Similarly, a Holographic display is a lighting technology that visualizes a three-dimensional image of objects with better accuracy. Among several holographic displays, HoloLens and Oculus rift is the most used one in healthcare applications. In contrast, smart glass is a wearable, hands-free control system that collects patient's physical information and provides accurate solutions during surgery and diagnosis. It helps to take pictures, record videos, recognize voice instruction, and lessen the requirement of looking on a different screen while examining the medical test report [28]. Smart glasses are being categorized as optical glass and video glass for this study. It is worth mentioning that the majority of AR-based healthcare application uses optical glasses for its augmented functionality.

The most prominent optical glasses are VuFine and Google Glass. Video glasses are called personal media viewers as they provide hands-free convenience. These are categorized into Vuzix, Epson Moverio and Atheer air.

B. AR Healthcare Applications and Services

According to our observation regarding the context of 45 healthcare articles, no standard definition of AR healthcare services has been found. As a result, it gets hard to categorize the healthcare application and their services. However, here, we classified augmented healthcare applications into six categories: including Diagnosis, Surgery, Monitoring, Guidance, Rehabilitation, and Medical Education. We have summarized the available AR healthcare applications and their services as following.

1) *Diagnosis Applications*: Eye Diagnosis, Cancer Diagnosis, Cardiac Diagnosis, Tumor Detection, Vein Detection, and Lung Diagnosis [34] [19] [35] [31] [3] [36].

a) *Services*:

- Identifies the patient's exact eye diseases: Glaucoma, dry eye condition, etc.
- Using a digital contact lens measures blood sugar levels through a multi-sensor for retinal implanted people.
- Used to diagnose breast cancer in sentinel lymph nodes and prostate cancer in prostatectomy specimens.
- To understand cardiac inner and deeper structure.
- Analyzes the heart condition according to normal, murmur and extra-systolic sound.
- Cardiac data examination, prediction and cardiac arrhythmia treatment.
- Identifying skin incision, skull craniotomy and tumor location.
- Provides feedback on lung conditions and is used to diagnose respiratory disease.
- M-application use for vein detection.

2) *Surgery Applications*: Orthopedic Surgery, Cholelithotomy Surgery, Dental Surgery, craniofacial Surgery, HIP Surgery, Urology Surgery, Laparoscopy Surgery [22] [29] [38] [41].

a) *Services*:

- Helps orthopedic surgeon to examine abnormal joint function.
- Identifies the bone structure through 3D computed tomography (CT) data for orthopedic surgery.
- Identify skin incision, skull craniotomy and tumor location for Cholelithotomy surgery.
- Prevents damaging tissues, blood vessels and dental nerves during dental surgery.
- Helps in Endoscopic endonasal transsphenoidal surgery.

- Used for craniofacial surgery applied in treating orbital hypertelorism, hemifacial microsomia, mandibular angle split osteotomy related abnormalities.
- Use for safely HIP placement.
- Enhances urology surgical procedures.
- Provides automatic relevant information to help dental surgeons.
- Used in stone extraction and biopsy procedure.
- Used for treating orbital hypertelorism, hemifacial microsomia, mandibular angle split osteotomy related abnormalities.
- Used for laparoscopy surgery like endophytic tumor surgery.
- Identifies the bone structure through 3D computed tomography (CT) data.
- Reduces blood loss and risk of chronic renal insufficiency.

3) *Monitoring Applications:* Glucose Level Monitoring [42], Insulin Dosages Monitoring [43]

a) *Services:*

- Continuously monitors glucose level, insulin dosages and suggests appropriate foods.
- Helpful for real-time health monitoring and recommending appropriate specialist.
- Automatically connects to the emergency number to seek help or to find defibrillators.
- Measures blood sugar levels through multi-sensor for retinal implanted people.

4) *Guidance Applications:* Grocery Shopping, Medication Plan, Smoking Consequence, Exercise Plan, Medicine Scheduling, Hearing Impaired Guidance [44] [45].

a) *Services:*

- Provides exact guidelines about healthy food.
- Provides information about allergic food, low-fat diets, and general caloric intake.
- Support for medication plan and medication restrictions.
- Helps hearing impaired people for museum visits.
- Shows the consequence of smoking and stimulates the side effects.
- Shows medicine functionality and using procedure.
- Spreads awareness about exercise and make people fit and healthy.
- Recognizes speech commands and provides information on medical needs.
- Provides exact information about drug names and dosages.

5) *Rehabilitation Applications:* Smart Physical Rehabilitation [20] [37][39] [40]

a) *Services:*

- Provides inpatients and outpatient rehabilitation facilities for musculoskeletal, neurological, r-hematological and cardiovascular systems.

6) *Medical Education Applications:* Training, 4D-Visualization [21] [32] [33].

a) *Services:*

- Represents the human organs into 4D anatomies without dissection.
- Helps dental students with both theoretical and practical training.

C. Current Challenges of AR Healthcare Applications

One primal focus of this research is to identify the current challenges of existing AR healthcare applications. Also, we noticed several possible future challenges related to augmented healthcare applications. According to the perspective of our considered articles, here we have conceded eight challenges. Several other challenges might exist in the current AR healthcare application that is beyond our scope of this review.

1) *Challenges with Data security:* Ensure healthcare data security is the most significant aspect of AR healthcare applications. Surprisingly, several exiting applications have no standard security protocols and recently proposed approaches also have a poor security concern. To ensure data security, the implementation of network connection encryption is essential. Providing a complete encrypted or protected data transferring environment for healthcare applications is difficult but adequately needed.

2) *Challenges with Specialized platform:* The majority of augmented healthcare applications have no standard platform and lack appropriate guidelines. The incompetency to provide authentic and accurate services makes it more insecure and complex. Launching a standard and specialized platform that refers to applications package interface (APIs), framework, and appropriate libraries are challenging for modern healthcare platforms. Failure to ensuring a specialized platform may hamper in manages of code, classes, and documentation also.

3) *Challenges with Limited services:* From 2011 to the present, several applications have developed for a limited number of healthcare aspects, for example, diagnosis, treatment, assessment, etc. Yet, more healthcare branches should disclose to provide an effective solution, for example, cardiac surgery, Hematopoietic stem-cell transplantation, etc.

4) *Challenges with Healthcare information accessing interoperability:* The Healthcare Leadership Council (HLC) published several guidelines related to healthcare IT interoperability. For accessing and sharing information, ensuring HLC guidelines are a big concern.

5) *Challenges with Scope of adaptability:* Complex functionality and lack of user guidance make a barrier to healthcare application adaptability. Generally, augmented healthcare application is the reflection of integrated digital components. These integrated digital components might introduce some technical barriers, especially for the healthcare specialist and the end-user. Overcoming the technical obstacle is one of the utmost challenges.

6) *Challenges with Lack of availability:* Several AR healthcare applications launch in the last few years. But a majority of them have been used in the developed country only. High configuration prototypes, training requirements, and cost issues are responsible for these applications limitation in underprivileged countries. Ensuring these applications available for all the country is a challenging issue.

7) *Challenges with Implementation cost:* Furthermore, the development and implementation cost of the AR healthcare device is another vital issue. Due to the high development cost, several healthcare providers disagree to reconstruct their healthcare platform. Therefore, an increased range of implementation costs raises the barrier to introducing modern and digital technology into healthcare solutions.

8) *Challenges with Healthcare device acceptability:* The current augmented platform is committed to providing a user-friendly environment with fluent functionality. But sometimes, issues associated with improving consistency and reducing errors can be more viable. Overcoming this challenge may help to increase the device's acceptability. Developing an application with effective functionalities is a relatively focusable issue for AR technology.

9) *Challenges with Inappropriate prototypes:* Due to inappropriate prototypes, sometimes, unexpected abnormalities such as false recognition, lack of semantic knowledge reduce the effectiveness of augmented healthcare applications. Ensure appropriate prototypes are one of the distinct challenges of healthcare application.

10) *Challenges with Service availability:* Instead of numerous AR applications, providing constant services or long-duration services such as surgery visualization, projection, and interaction for as long as 9-12 hours in a continuous manner is relatively challenging.

11) *Challenges with Real-time geometry awareness:* Real-time geometry awareness is another major issue for researchers and developers. It associates with the process of annotation, tracking location, object detection, and appropriate measurement. Surprisingly, most abnormalities arise during geometry transformation in the augmented application. Therefore, awareness regarding real-time geometry can be a challenging issue for AR platforms.

12) *Challenges with Limited research:* According to the research statistics, it has shown that AR research on the healthcare domain is insufficient due to limited scope, less popularity for healthcare professionals, ambiguous knowledge, and limited resources. Therefore, most healthcare researchers have not shown their interest to research in the healthcare domain, specifically on augmented platforms.

IV. OUR CONTRIBUTION

Section 3 shows that several challenges have existed in the recent augmented healthcare platform. Among several current AR healthcare application issues, ensuring data security is one of the major concerns. Generally, augmented healthcare application provides services through a physical layer with overlaid computer-generated information [30]. Therefore, it is not free from external threats, and cybersecurity risk might introduce on the physical layer. AR healthcare applications should address these external threats and common security vulnerabilities during the development phase. Therefore in this section, we addressed several security requirements and attack terminologies to ensure data security and added a security model that might help prevent threats or network attacks during data transmission.

A. Security Requirements

Security requirements of augmented healthcare applications refer to the property that protects the application platform from unexpected attacks or threats. Figure 7 shows some required security requirements that should focus during application development to ensure application effectiveness and modality.

Fig. 7. Security Requirements of AR Platform.

For example, during the collaboration of virtual objects and real-time data, an intruder may attack. The augmented platform should provide security during virtual and real-time object collaboration. At present, the number of augmented healthcare devices has increased and started to connect with the network. Therefore, the augmented platform should ensure confidentiality to prevent unregistered access to medical information to provide medical data security. However, the assorted number of things can modify data while accessing or transmitting. Healthcare solutions should introduce integrity to ensure

medical information or health data security. Another crucial requirement is resiliency to provide a protective environment if health devices are compromised.

Another major security issue of current healthcare applications is availability. It ensures that data are stored and available in a secure environment and used by the registered authority under secure networks. To increase efficiency and protect patient data from untraceable attacks, ensuring the tracking functionality of all the activities with an authorized detector is essential. Most of the time, lack of awareness about DoS attacks can create opportunities for malicious attackers to hamper data safety while transmitting. Therefore, security awareness should consider sincerely. As we previously mentioned, augmented healthcare devices are wearable technologies to connect to the network anywhere. Hence, deriving a security model for dynamic network topology is highly required.

Designing a dynamic security protocol could increase the security of augmented applications. Surprisingly, augmented Reality Markup Language (ARML) has a lack of security control policy. Lack of security issues and Limited standardization makes it vulnerable, which in turn can introduce security vulnerabilities. In recent days, augmented reality uses computer-aided objects provided by third-party vendors that pave the way for threats such as spoofing, sniffing, data manipulation, and man-in-middle attacks. The AR platform should be aware of these threats and be sure of the authenticity of the generated content during the transmission process to make the application reliable. As augmented healthcare application often uses various unprotected web browsers, it can lead to security breach too.

B. External Attack Terminology

The augmented platform is not free from external attacks. Attackers may introduce several security threats and affect existing and future augmented healthcare applications, devices, and networks. Sometimes these threats are predictable, while some are hard to detect or predict. In this section, we are going to mention several external threats that reduce application and network effectiveness. Fig. 8 shows some attack terminologies that can make systems vulnerable and reduce effectiveness.

For example, by data-stealing or spreading malicious codes during data transmission or communication, intruders may replace original data or make it unreliable. Through unauthorized access, attackers may modify the data and create confusion and reduce network performance. Also, false information may get injected into the network and minimize data reliability, affect the hardware platform by altering program code, information, or reprogramming. Sometimes an attack can be introduced through software platforms such as operating systems or software applications and take advantage of software vulnerabilities that cause buffering, resource destruction or loss.

C. Proposed Data Security Model

Augmented reality-based developed healthcare applications and services are not yet robust but continuing to develop. Therefore, summing up the entire possible vulnerabilities, threats, and attacks associated with augmented medical solutions is difficult. With the expansion of healthcare devices, networks, and applications, several unknown or unseen threats

Fig. 8. Possible Attacks for Security Threats.

may initiate during communication or data transmission, or data storage in the cloud.

A dynamic security protocol is essential to mitigate unseen data threats and provide data transmission security. Therefore, security services should design with dynamic properties. An artificial intelligence-based dynamic mechanism might be capable of identifying these unseen attacks. Here we proposed a security model for AR-based healthcare solutions. The proposed model operates through knowledge-based services. Figure 9 presents the proposed scheme that follows three security layers: threat detection, threat reduction, and data protection.

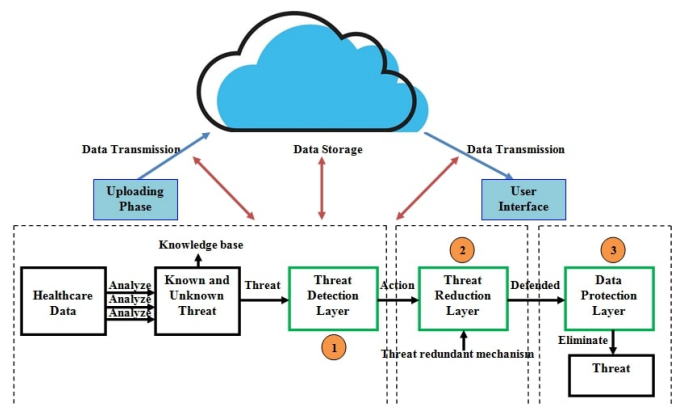

Fig. 9. Proposed Intelligent Security Model.

The threat detection layer is designed to receive healthcare data from healthcare devices and networks and analyzes captured information to identify security threats. Then, to reduce the attack during data transmission, a threat reduction layer is designed. The data protection layer helps protect data by

defending all identified attacks. This security layer performs through dynamic algorithms and provides a shield against attacks. Upon detection, the threat detection layer issues action commands and shares detection experience with the threat reduction layer. The threat reduction layer defends threats using a redundant threat mechanism. Finally, the data protection layer eliminates detected threats and protects valuable data.

V. CONCLUSION

Researchers are vigorously working to invent better technological solutions to enhance the modern health care system throughout the world. The motive of these inventions is to bring a dramatic change in the healthcare sector and reduce the existing complexities. In this paper, we have provided a brief analysis of various AR-based healthcare services and applications. A broad view of the current development strategies regarding present healthcare application architecture and health data processing and accessing procedures have been layout. The article, to some extent, tried to facilitate further development by pointing out several uncovered issues regarding concurrent security requirements and future challenges. The discussion performed in this article on standardization, data availability, service quality, and data protection may help in several ways for future research on AR-based healthcare applications and services. Moreover, this paper also illustrated the importance of augmented reality-based healthcare applications, backed up with present-day market data, which may increase the contribution of several stakeholders for further development.

Abstract—The ubiquitous use of social media has enabled many people, including religious scholars and priests, to share their religious views. Unfortunately, exploiting people’s religious beliefs and practices, some extremist groups intentionally or unintentionally spread religious hatred among different communities and thus hamper social stability. This paper aims to propose an abusive behavior detection approach to identify hatred, violence, harassment, and extremist expressions against people of any religious belief on social media. For this, first religious posts from social media users’ activities are captured and then the abusive behaviors are identified through a number of sequential processing steps. In the experiment, Twitter has been chosen as an example of social media for collecting dataset of six major religions in English Twittersphere. In order to show the performance of the proposed approach, five classic classifiers on n-gram TF-IDF model have been used. Besides, Long Short-term Memory (LSTM) and Gated Recurrent Unit (GRU) classifiers on trained embedding and pre-trained GloVe word embedding models have been used. The experimental result showed 85% accuracy in terms of precision. However, to the best of our knowledge, this is the first work that will be able to distinguish between hateful and non-hateful contents in other application domains on social media in addition to religious context.

Keywords—Social media; religious abuse detection; religious keywords; religious hatred; feature extraction; classifier

I. INTRODUCTION

In the modern age of Information and Communication Technology (ICT), social media platforms seem to be an indispensable part of human lifestyle. Everyday, millions of individuals share their opinions, ideas, thoughts, feelings, experiences through social media services such as Twitter, Facebook, YouTube, Instagram and so on [1], [2]. As the people are not only sharing opinions but also connecting with new people, creating groups and making friendships, so social media has become an important source of information with variety of communities [3]. Moreover, different types of people, even many people who would be speechless previously, now use social media for different purposes in response to the fulfillment of the desires or goals of the mind [4]. Despite

of having such a positive effect on freedom of expression on social media, we can not ignore its negative impacts. Some people either intentionally or unintentionally involved in abusive activities such as spreading false news and videos, trolling, cyberbullying and many more [5].

The people concerned with religion find the social media as useful platforms for sharing religious beliefs, rules and rituals to large audiences. They want to increase affiliations and trust on their religion through different types of activities on social media [6], [7]. During COVID-19 pandemic time, this scenario has increased significantly [8]. However, some people use hate speech against other religions to justify their religion. Furthermore, exploiting people’s religious beliefs and practices, some extremist groups spread provocative and hateful content on social media. Consequently, the falsified and hateful information creates instability among the religious communities since social media news spread so fast by liking and sharing [9], [10]. Moreover, all these religious narrowness increase the likelihood of militant propaganda. As the people are very sensitive regarding religion, so it is essential to restrict the abusers who spread religiously offensive or hate speech on social media.

As religion refers to the ideological identity of a person [11], so expressing hatred by hurting a religion is like hurting a person’s identity. In the literature, there is limited research on detecting religious abuse on social media. In our previous work [12], we addressed the concept of identification of religious abusers on Twitter. We only considered verifying whether abusive activities originated from spamming sources. Besides, there have been many works on social media about hate speech, such as identifying hate speech on Arabic social media [13], [14], which do not mention religious abuses. There is also another similar research in the literature demonstrating hate speech identification on vulnerable communities [15]. Detecting spamming activities in social media [16] is another type of research that is somewhat related to religious abuse detection. However, it should be admitted that not all abusers may use spamming techniques in spreading offensive speech

regarding religion. There has been some more researches on identification of spreading propaganda on social media regarding different issues, like jihadist propaganda [17], [18], [19] and propaganda of COVID-19 deadly virus [20], [21], [22], [23] and then showing how the propaganda is analyzed [24]. Most of these are focused on Arabic social media context and targeted to single community. Therefore, there is a need for identifying abusive/offensive expressions from the posts and comments of every user who expresses religious views on social media.

Each social media has its own policy regarding different abusive activities, but it is still difficult to find out those activities in every user's posts. More specifically, identifying religiously abusive contents on social media are hard due to the noisy data structure. In other words, social media data consists of misspelled user-generated data (as users express freely anything they want without following any rules in writing), jargon, heterogeneity in data with the mixture of texts, urls, videos, emojis and so on [25].

In this paper, we focus on identifying abusive attitudes towards religion on social media. We refer to those activities religiously abusive that represents hatred, violence, harassment and extremist expressions against people of any religion or community, as depicted in Fig. 1 for an example. However, to find abusive contents, first we retrieved social media posts using a predefined set of religious keywords for six major religious beliefs and filtered them in order to remove unwanted information. Then, we labeled the filtered data with lexicon and rule based approaches. After that, we extracted features using traditional and advanced deep learning strategies from the texts after preprocessing. Finally, we fed the dataset into classifiers to identify abusive speech/content. In our experiments, we used Twitter as a social media platform for collecting the dataset. We compared the classical classification models, including Naïve Bayes, Support Vector Machine (SVM), Random Forest, Logistic Regression, and MLP (Multilayer Perceptron) on TF-IDF feature extraction method. We also compared trained word embedding with pre-trained GloVe embedding in terms of LSTM and GRU models. The experimental result shows that we can obtain 85% overall accuracy in state-of-the-art performance in terms of precision.

Fig. 1. An Example of Abusive Speech on Social Media Against Religious Communities.

To the best of our knowledge, this is first work that represents an approach to identify the abusive attitudes towards religion on social media platforms. That is, we can detect

religiously abusive activities on any social media platform. In sum, our contributions are as follows:

- Our proposed approach examines the application of identifying religious abusive expressions on social media platforms.
- We identify abusive behaviour from social media users' posts for major religious beliefs in the world.
- We can use the proposed approach to detect hate/offensive speech on other application domains in addition to religious context.

The rest of the article is organized as follows: Section II represents recent studies in the literature related to this paper. In Section III, we have demonstrated and explained every module of the proposed approach. Then, Section IV represents the experimental procedures including data collection, feature extraction, building classification models and so on. Next, we have shown and discussed experimental results elaborately in Section V. Finally, we have concluded the work with future directions in Section VI.

II. RELATED WORK

People use social media to express their feelings and find emotional gratifications for various reasons [26]. In religious point of view, the use of social media is making a significant contribution to the development of religious values. That is, the linkage between religion and social media has attracted many people over the years, including religious scholars and priests [27]. Despite of these advantages, abusive activities on religion can not be ignored. So, we need to pay attention to the negative impact of using social media in the context of religion. However, research on how to automatically detect offensive remarks from every user's posts and comments is limited in literature. Our previous work [12] highlighted the concept of detecting religious abusers on Twitter. It only showed that the spamming sources were identified as religiously offensive.

Detecting hate speech on Arabic twittersphere is very promising research tread in literature nowadays. Albadi et al. [28] published first publicly available annotated dataset and three lexicons with hate scores in order to detect religious hate speech from Arabic tweets. They classified extracted tweets as hate and not hate speech in terms of lexicon based, n-gram, GRU plus word embedding based, and GRU word embedding with handcrafted features including temporal, user and content features. The experimented result showed that feature based GRU model gave the best accuracy in terms of recall. However, their approach makes a pathway to find hate speech in Arabic tweets but it can not be applicable in many religious contexts such as Hinduism, Buddhism and so on. Besides, the annotated lexicons are unavailable for English contents.

Spreading offensive expressions in many contexts, such as Islamophobia, anti-Africa, and anti-Arab, on social media against people of different groups is not a good sign. Z. Mossie and J. H. Wang [15] were the first to find hatred against minor communities in Ethiopia from Amharic texts on Facebook. They annotated the dataset by the handcrafted method and then clustered the hate words using Word2Vec method. Although their approach successfully identified hate speech against vulnerable groups, but handcrafted features and

annotation tend to the possibility of biasing on any cultural group. There is another research on communal hatred detection that was published by B. Vidgen and T. Yasseri [29]. They identified hate speech in their work on Muslims in terms of non-Islamophobic, weak and strong Islamophobic speech on Twitter. They considered the names of Muslims and Mosques in their analysis. It is not the case that only name of Muslim or Mosque spread Islamophobia, rather the hateful behavior, threats and online harassment against Muslims incite Islamophobia. So, these are also essential to consider.

G. Jain et al. [16] proposed a novel deep learning based approach (combination of CNN and LSTM) to identify spam detection in social media. They considered spamming behavior of user and short text messages in their proposed model. Similar type of research was conducted by N. Sun et al. [30] to find near real-time spam on Twitter. They identified spams in terms of number of tweets issued by a user, number of retweeted, and fake accounts using traditional machine learning models. In articles [13] and [14] we found how deep learning models were used to identify hate speech in Arabic tweets that inspired us to do the work. Although these researches (on spam and hate speech detection) are somewhat related to our work, but it is acknowledged that all abusers may not use spamming tactics or use Arabic language in spreading offensive speech regarding religion. Therefore, we need to establish a model to analyse (lexically, syntactically, and/or semantically) the abusive/offensive behavior of each user when sharing religious views on social media platforms.

III. METHODOLOGY

This section represents our proposed approach that processes religious posts from social media users' activity and then identifies the abusers who spread hatred, violence, harassment, and extremist expressions among different religious communities. It consists of several segments with different functionalities, namely, Information Retrieval, Filtering, Labelling Class Attribute, Text Normalization, Text Vectorization, and Building and Evaluating Classifiers, represented in Fig. 2.

Information Retrieval (IR) is the method of capturing and extracting relevant users' activity from social media platforms. It follows three sequential processing steps. First of all, the social media from which we want to retrieve data needs to provide the required credentials (e.g., access token, consumer key, page id or post id) in compliance with all the terms and conditions. Then, it is necessary to identify the type of data (content language preferences, e.g., English, Japanese, or Arabic) we want to collect through religious search patterns or keywords. Finally, the collected data is transformed into tabular form by selecting different attributes.

Since not all users' activities or social media posts are related to religiously abusive, so only interested of these are considered for further processing. In other words, users' posts that are likely to have an impact on the religious community are filtered out. However, the filtering process follows three phase filtering schemes. In phase one, the information of the best possible impacted posts (or status) are considered, including keeping all unique posts, and posts that have length greater than a threshold. For example, the best impacted post length is between 70-100 in Twitter [31]. The second phase

filters information based on the reputation of the user account, calculated as

$$R = \frac{\text{Number of followers}}{\text{Number of friends} + \text{Number of followers}}$$

If the R (stands for reputation) is small and close to zero, then it is probable to be an abusive account, as the abusers generally tend to get more followers [32]. Phase third of the filtering represents users' activity including the duration of account, date of posts, number of sharing (or retweeting) posts, number of posts issued, and number of likes or dislikes. Thus, the information of the higher activity is kept for future processing steps.

Labelling class attribute defines introducing the class attribute in the filtered dataset. As dataset consists of different types of attributes, so labelling class attribute is created on text data (i.e., religious posts or status of users). At first, text data is cleaned in order to remove unwanted texts or symbols, such as URLs, hashtags, special symbols, and punctuation. Then, generate religious lexicon containing words and phrases with their own polarity scores to be abusive, non-abusive, or neutral. After that, the cleaned texts are attributed as abusive or non-abusive class label using rule-based and generated lexicon-based approaches.

Before feeding the corpus into machine learning models, it is essential to transform the texts into a standard form or normalized form. At the beginning of the normalization, the texts are fragmented into smaller units called tokens, e.g., 'this is religiously abusive' → 'this', 'is', 'religiously', 'abusive'. Then, remove all unwanted words such as 'about', 'above', 'across' from texts with predefined stop word list that is particularly applicable for social media text analytics. At the end of normalization, identical or near identical words (or tokens) are mapped into its base form, called stemming and lemmatization. That is, stemming and lemmatization help to convert the root form of inflected words. For example, the word "followers" and "followings" are transformed to "follow", its root form. Another example is representing of near similar words such as "keywords", "key-words" and "key words" to just "keywords".

After normalization, the textual data in the corpus is mapped into real valued vector form, called text vectorization or feature extraction from texts. That is, it is the process of making textual document into numerical vector form. In Fig. 2, text vectorization is illustrated by feature matrix which is defined as

- **w1, w2, w3,...,wn** represents features (n-grams or words);
- **Doc** represents textual documents (D1, D2, D3,...,Dn) in the corpus where each document indicates a social media post;
- **Class** represents class label attribute; and
- **Each row** represents a text data of a religious post containing feature values in it.

Building and evaluating classifiers is the final stage of the proposed approach where a classification model is built by feeding the feature matrix into it and then evaluate the model

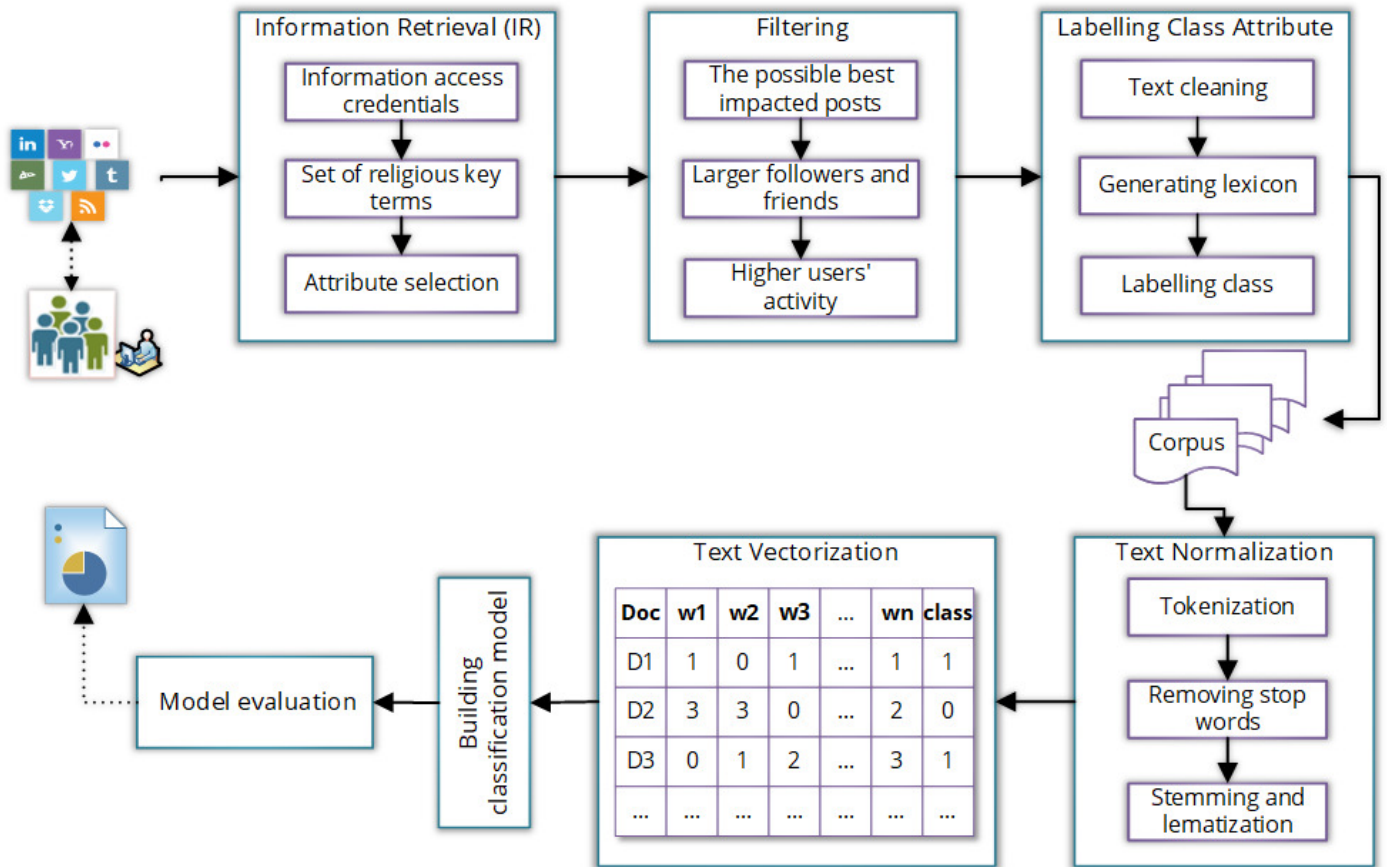

Fig. 2. Overall Architectural Diagram of the Proposed Approach.

with different performance metrics for showing how effectively the machine learning models classify religiously abusive or non-abusive contents.

IV. EXPERIMENTAL SETUP

In this paper, we focused on six major religious beliefs in worldwide¹, including Christianity (31.2%), Islam (24.1%), Secular/Nonreligious/Agnostic/Atheist (16%), Hinduism (15.1%), Buddhism (6.9%), and Judaism (0.2%). We selected Twitter as a social media platform for collecting data in our experimental purposes. We used TF-IDF, trained Word Embedding, and pre-trained GloVe model for feature extraction. For classification, we used different classifiers in the state-of-the-art. However, the overall experimental design flow is demonstrated in Table I.

A. Data Collection

We retrieved total 9,787 publicly available users' Tweet related to English language and letters using Twitter's search API² method with Python Tweepy³ library based on a predefined list of keywords as illustrated in Table II. As the Twitter API search approach returns object with a mix of root-level

attributes, so we highlighted the most fundamental attributes for our experiment. We then removed duplicates and filtered the tweets based on attributes, such as friends, followers, like count, retweets, and total tweet issued. These are demonstrated in the Algorithm 1 and Algorithm 2, respectively. However, after filtering process, we obtained 4,903 tweets for subsequent processing steps.

B. Labelling Class to Tweet Dataset

Before labelling class in filtered tweets, we cleaned the tweets to eliminate hash tags, mentions, and urls because these don't make any significant impact in detecting religious abusive tweets. We then applied ruled based and lexicon based analysis on tweet texts. In order to this, we considered various techniques including position of words, surrounding of words, contexts, parts of speech, phrases, religious slangs (e.g., bible thumper), punctuations (e.g., good!!!), and degree of modifier (e.g., very, kind of). We used VADER (Valence Aware Dictionary and sEntiment Reasoner) Lexicon Tool⁴ which is very effective in finding motifs from texts on social media platforms, especially for microblogging contexts. Using this tool, we calculated different polarity scores of words of a tweet text and then aggregated the scores. We then decided how much close the score for being abusive with a predefined threshold value. However, the Algorithm 3 demonstrates how

Performance evaluation metrics for classification models	<ul style="list-style-type: none"> Accuracy F1-score Precision score Recall score Jaccard Similarity score ROC-AUC score Matthews Correlation Coefficient (MCC) Zero-one Loss

TABLE II. RELIGIOUS BELIEFS WITH RELATED KEYWORDS USED TO COLLECT TWEETS

Religious Beliefs	Keywords
Christianity	Christian, Roman Catholic, Christianity, Apocalypticism, Catholic Church, Baptism, Bible, Bishop
Islam	Quran, Islam, Muslims, Islamic State, Kurdish, Shia, Sunni, Jihad, Wahhabi, Islamphobia
Atheist	Atheist, Atheists, Atheism
Hinduism	Hindu, Bhagavad-Gita, Brahman, Mahabharata, Ma Kali, Ramayana, Durga, Saraswati, Jai Hanuman
Buddhism	Buddhism, Gautama Buddha, Bodhisattva, Buddha, Dalai Lama, Mahayana, Nirvana
Judaism	Judaism, Jews, Jew, Berit

Algorithm 1: Tweet Filtering ($Tweets_{keywords}$)

Data: $Tweets_{keywords}$: All tweets retrieved from religious keywords search approach
Result: Filtered tweets after satisfying different conditions

```

/* Initially set filtered tweet list to null */
1 filtered $Tweets \leftarrow \phi$ 
2  $unique_{tweets} \leftarrow UniqueTweets(Tweets_{keywords})$ 
3 for  $\forall tweet \in unique_{tweets}$  do
4   if  $tweet.followers \geq 100$  then
5     |  $filtered_{Tweets} = tweet$ 
6   else if  $tweet.friends \geq 100$  then
7     |  $filtered_{Tweets} = tweet$ 
8   else if  $tweet.retweet \geq 50$  then
9     |  $filtered_{Tweets} = tweet$ 
10  else if  $tweet.tweet_{like\_count} \geq 1$  then
11    |  $filtered_{Tweets} = tweet$ 
12  else if  $tweet.total_{tweet\_issued} \geq 50$  then
13    |  $filtered_{Tweets} = tweet$ 
14  else
15    |  $filtered_{Tweets} \notin unique_{tweets}$ 
16 return  $filtered_{Tweets}$ 

```

Algorithm 2: UniqueTweets ($Tweets$)

Data: $Tweets$: Set of all tweets retrieved from Tweet API search

Result: Unique tweets after removing duplicates

```

/* Initializing first tweet from Tweets */
1  $uniqueTweets \leftarrow tweet_1 \in Tweets$ 
2 for  $\forall tweet \in Tweets$  do
3   for  $\forall temp \in uniqueTweets$  do
4     if  $tweet \neq temp$  then
5       |  $uniqueTweets = tweet$ 
6 return  $uniqueTweets$ 

```

we can achieve labelling class attributes in the dataset. After including class attributes in filtered dataset, we obtained our corpus for classification.

C. Feature Extraction

In feature extraction, we transformed the texts (from corpus) into feature vector. Before doing that, we preprocessed or normalized the texts in a few consecutive ways. That is, we first removed special characters, numbers and punctuations; then expanded the contractions, lowering case, tokenization and removing stop words with our predefined stop word list; and finally mapped the words to their root form with lemmatization. For feature extraction, we used three different models, i.e., n-gram TF-IDF, trained deep learning based word embedding model, and pre-trained GloVe model. The intention of choosing these three methods is to verify whether the accuracy of the classification improves with feature extraction. However, we obtained different feature matrices for each model and then fed them in the classifiers.

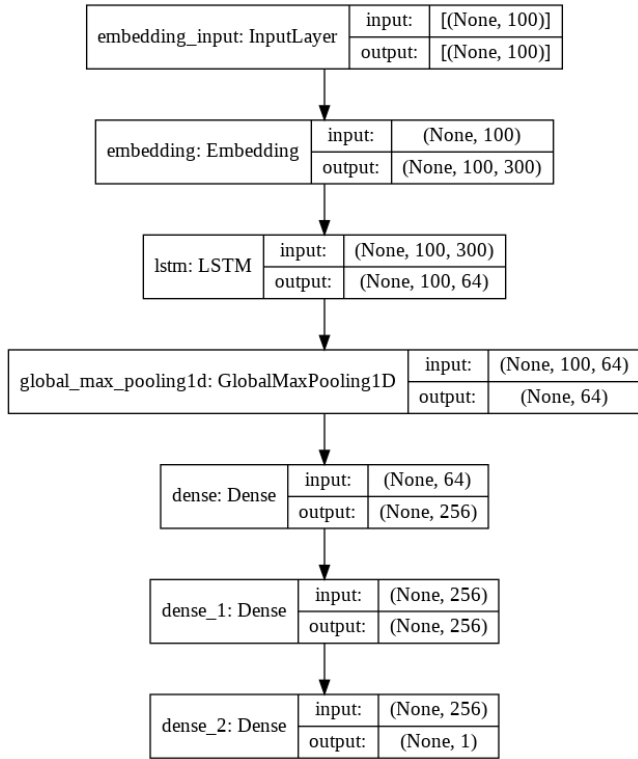

Fig. 3. Visualization of LSTM Model Configuration.

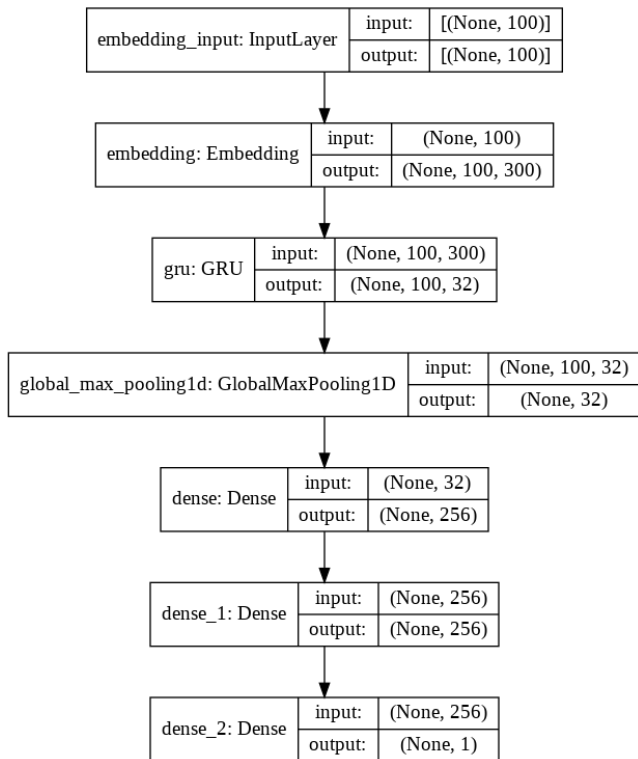

Fig. 4. Visualization of GRU Model Configuration.

Algorithm 3: Labelling Classes($Tweets_{Filtered}$)

Data: $Tweets_{Filtered}$: Set of all tweet texts after applying tweet filtering process
Result: List of class labels
 (0 : non – abusive, 1 : abusive, 2 : neutral)
 associated with each tweet

```

/* Initialize class label list to null
*/
1 labelclass ← ϕ
2 for ∀ texts ∈ TweetsFiltered do
3   scoresaggregated = VADER_Lexicon(texts);
4   if scoresaggregated ≥ 0.05 then
5     | labelclass = 0;
6   else if scoresaggregated ≤ 0.05 then
7     | labelclass = 1;
8   else
9     | labelclass = 2;
10 return labelclass
  
```

D. Building Classifiers

As we focused on detecting religiously abusive contents from texts, so we skipped neutral class labels and considered only abusive and non-abusive classes only. That is, we considered 4,141 (out of 4,903) data samples containing abusive and non-abusive attributes for classification purposes. However, we split the dataset into train and test subsets, where 70% (2,898 samples) were for training and 30% (1,243 samples) for testing. For classification, we used Naïve Bayes, SVM, Random Forest, Logistic Regression, and MLP classifiers on TF-IDF feature matrix. On the other hand, LSTM, and GRU classification models were used on both trained and pre-trained GloVe embedding models because these classifiers are more efficient than the traditional machine learning based classifiers. We have trained all the classifiers more than 100 times with different parameters and then selected the best configuration for the final classification model building. MLP, LSTM, and GRU are neural network based classifiers that may not perform well with predefined parameters for all datasets, rather, depending upon the use case and problem statement, so we emphasized on choosing training parameters that show best performance on test data. The parameters of MLP include: input layer size=total features (i.e., more than 10,000), 3 hidden layers with neurons (125, 125, 125), optimization='adam', learning rate=0.0001, maximum iteration is between 2000-5000, and 1 output layer for deciding whether abusive or non-abusive; on the other hand, the best configuration of LSTM, and GRU networks are shown in Fig. 3 and Fig. 4, respectively. However, we then evaluated the classifiers with various performance metrics (see in Table I).

V. RESULT ANALYSIS AND DISCUSSIONS

As we focused on detecting abusive activities among major religious beliefs of worldwide in social media, so we haven't mentioned how much abusive activities are identified of a particular religion in our experiments. In this section, we have discussed the obtained results in different perspectives.

A. Exploratory Data Analysis

In section IV-A, we demonstrated how we collected tweets with a mix of fundamental attributes using different religious keywords. Among them, the hashtag attribute gives an overview of how religiously relevant datasets we have been able to collect. While retrieving the dataset, we found more than 100 unique hashtags, the most commonly used hashtags are shown in the Fig. 5. It shows that the most occurring hashtags are somehow religiously related, so it can be said that the more occurring religious hashtags, the more likely users have involved in religious tweets.

Fig. 5. Most Frequently Occurring Hashtags in the Collected Tweets.

Users in Twitter share their opinions, ideas and thoughts on diverse religious issues with a large number of audiences. So, taking these opportunities, some users may involve in the harassment of someone, sharing offensive posts or contents, spreading hate speech, and then encourage others to do so. In this paper, we collected many users' tweet (4,903 after filtering) containing both abusive and normal or neutral attitudes. To illustrate the behaviour of the users' tweet, we have shown them using the most occurring unigram, bigram and trigram frequencies Fig. 6, Fig. 7 and Fig. 8, respectively. Fig. 6 shows twenty most frequently occurring unigrams (single words) with their respective frequency counts out of 66,730 unique unigrams. Whereas Fig. 7 shows ten most occurring bigrams (2-adjacent words from a sequence of tokens) with the number of times, they appear sequentially in users' tweet out of 33,350 unique bigrams. On the other hand, Fig. 8 depicts ten most commonly occurring trigrams (3 consecutive words from a sequence of tokens) out of 22,243 unique trigrams on different religions.

We also analysed the number of religious abusers based on the location of tweet users. We found more than 1,500 specified locations that the user provided in their accounts profile. However, Fig. 9 shows ten locations where the highest percentage of abusive tweets were found (as there were 2,067 abusers detected out of 4,141 tweets). The locations indicated

Fig. 6. Most Commonly Occurring Unigrams in users' Tweet on Different Religious Beliefs.

Fig. 7. Ten Most Commonly Occurring Bigrams in users' Tweet on Different Religious Beliefs.

in the figure are categorized by country to visualize the percentage of abusers.

As the text contents on Twitter is limited up to 280 characters, so many users try to attract more audiences to read or engage through posting of different lengths of tweets on it. In our analysis, we considered three different tweet lengths (in total of 4,141 tweets), i.e., '70-140' character limit, '140-280', and less than 70 character limit. These are shown in Fig. 10, where 72.52% of tweets are found within '140-280' character limit, 22% in between '70-140', and then 5.48% in less than 70 character limit. Moreover, the percentage of abusers and normal users in '140-280' length are also higher than that of other character limits. Fig. 10 also shows that the abusive tweets in '140-280' character length are higher than that of other limits, whereas normal or non-abusive tweets in '70-

Fig. 8. Ten Most Commonly Occurring Trigrams in users' Tweet on Different Religious Beliefs.

Fig. 9. The Highest Percentage of Abusers Detected in Different Countries.

140' and '<70' character limit are higher than that of abusive tweets. So, in sum, the most common length of tweets in our dataset are between 140 and 280 characters, which indicates that the users posted long tweets to express their thoughts on

religion.

Fig. 10. Percentage users' Activities in Different Character Limits of Tweets.

B. Evaluating Classifiers

We evaluated the classification models using new unseen testing dataset. As we trained the models more than 100 times with different parameters and selected the best configuration for the final model building, so we evaluated the classifiers with the best performance on testing data (i.e., 1,253 samples with abusive 618, and non-abusive 625). Table III shows a comparative summary of the performance of the classifiers on TF-IDF feature matrix. We can see that SVM shows the best performance compared to other classification models in terms of different classification metrics (except in Jaccard Similarity score). So, the overall accuracy and loss of SVM are 83% and 17%, respectively, which is indeed promising. This means that we have been able to classify 83% correctly of abusive and non-abusive tweets. Table III also indicates that the MLP model shows quite similar performance to SVM except for (0.1-0.4)% marginal difference. However, to illustrate the performance of the models visually, the confusion matrix of each model is presented in Fig. 11. We can see that the number of false positives is higher than that of false negatives in Naïve Bayes and MLP classifiers. On the other hand, false negatives are higher than the false positives in SVM, Random Forest, and Logistic Regression.

As deep learning based feature extraction models are best suited for large features, including millions of parameters [33], so we focused on improving the classification accuracy in terms of trained and pre-trained deep learning models for more than 70,000 n-gram features in our dataset. In Table IV, the performance of LSTM and GRU classifiers are shown on trained word embedding feature extraction model. We can see that the LSTM performs better than that of GRU classifier in all classification metrics. So, we have achieved 84% overall accuracy and 16% loss on trained deep learning word embedding using LSTM. The confusion matrix of the two classifiers is depicted in Fig. 12. It shows that the number of false positives is higher than the false negatives in both LSTM and GRU models.

GloVe embedding is learned in one task and used to solve another identical task. We used this pre-trained embedding

embedding. Now we compare each feature extraction method in terms of classification metrics, as presented in Table VI. The classifier on trained word embedding performs better than the other classification models. That is, LSTM model shows the best classification accuracy (84%) compared to others. The overall accuracy of the classifiers on three feature extraction methods is depicted in Fig. 14. So, if we consider precision, then 85% overall accuracy will be achieved.

VI. CONCLUSIONS

This paper focuses on identifying religiously abusive users on social media. It is the first research devoted to analyse and classify user activities regarding diverse religious beliefs and practices on any social media platform. The main contribution of this research is to establish an approach for detecting religiously abusive activities from users' social media posts. For conducting the experiment, Twitter has been selected as a social media data source. There were many users' activities (approx. 10,000) collected using a set of predefined religious keywords in English Twittersphere. Then the tweets that were redundant in nature and contained less user involvement or attraction were filtered. We then labelled the dataset using

rule based and lexicon based approaches. The labelled dataset (tweet texts) was fed into classifiers after extracting features using three different methods. The performance of the classifiers were evaluated with various classification metrics on test data. The obtained results indicate that SVM model showed 0.832 (83%) accuracy compared to others on TF-IDF, whereas LSTM gave 0.844 (84%) accuracy on trained embedding, and GRU showed 0.836 ($\approx 84\%$) accuracy on GloVe model. However, the LSTM model on trained word embedding showed 85% precision in state-of-the-art performance. Finally, we will be able to use the proposed approach for identification of any hatred/offensive speeches on any social media platform besides religious context.

Although this paper shows the identification of abusive behaviors on different religious beliefs with good accuracy, there are few constraints that were needed to be addressed. Firstly, more train and test data were desirable to take into consideration. Secondly, imbalance class distributions should be used to examine the performance of classifiers (since we used almost balanced class distributions) in experiment. However, in future, we will consider these limitations and explore on user activities of different languages. We will also identify whether the abusive contents are spread by human or social robots. In addition, we want to find the semantic similarity of hate/ non-hate speech on any religion with defined abusive key-terms in users' posts.

Rangamati, Bangladesh

Abstract—The proposed system is designed for automatic detection and classification of fish diseases in freshwater especially Rangamati Kaptai Lake and Sunamganj Hoar area of Bangladesh. Our experimental result is indicating that the proposed approach is significantly an accurate and automatic detection and recognition of fish diseases. This study presents fish disease detection based on the K-means and C-means fuzzy logic clustering method to segment the filtering image. Gabor's Filters and Gray Level Co-occurrence Matrix (GLCM) are used to extract the features from the segmented regions. Finally Multi-Support Vector Machine (M-SVMs) is used for classification of the test image. The proposed system demonstrated a comparison between K-means clustering and C-means fuzzy logic. The proposed methodology gave 96.48% accuracy using K-means and 97.90% using C-means fuzzy logic which is the highest accuracy rate to compare other existing methods. The proposed system has been experimented in the MATLAB environment on infected fish images of Rangamati Kaptai Lake and Sumangan Hoar area. It is a challenging task of fisheries farming in Hoar areas and Lake areas to detect fish diseases initially. The proposed methodology can detect and classify different fish diseases in early stages and also contributes to improved results for fish disease detection.

Keywords—K-means; c-means fuzzy logic; multi-SVM; detection

I. INTRODUCTION

Fisheries play a vital role in social and economic development and deserve the potential for future development in Bangladesh's agricultural economy. This sector represents one of the most prolific and energetic sectors in Bangladesh. It subsidizes 3.65% of the national GDP and approximately one-fourth (23.81%) of the GDP. Bangladesh is considered as one of the most suitable countries in the world for freshwater rural fisheries because of its resources and agro-climatic condition [1]. Fisheries and aquaculture paid 25% of agricultural GDP and 4.4% of national GDP in 2012 [1]. Fish biodiversity of the Rangamati Kaptai Lake and the Sunamganj Hoar area is decreasing day by day, due to territory deprivation and different man-made causes. It also worsens the normal health condition of fish and causes death of the fishes which results in great economic loss. Early detection of infected fish is a necessary step in preventing the spread of the disease. This paper recognizes and identifies the different fish diseases of Rangamati Kaptai Lake and Sunamganj Hoar which impacts the control of disease and maintenance of a strong relationship between living creatures, and the environment of Rangamati and Sunamganj. The prosperity of a fish culture depends on its precise regulation, fish life time, and cultural environment. However, unexpected use of feed and fertilizer are the main

reasons of failures in fish production. Traditional and semi-intensive culture systems are also responsible for the fish disease. Therefore, the search for a more efficient, less expensive, and more accurate method of diagnosing fish disease cases is very important [2]. In this research, we conducted the identification of local freshwater fish using a software based approach. This research also approaches a method for different fish disease detection. Firstly, the pre-processing stage applied on the test image. In the pre-processing stage, the test image is resized [3] then RGB images converted into HIS. The noise filtering technique is also used to remove noise. In the second stage, K-means and C-means fuzzy logic clustering method applied to segment the filtering image. In the third stage, the system extracts the features from the segmented and infected regions using Gabor's Filters and GLCM. In the fourth stage, classification of the test image is done by Multi-SVMs algorithm. The proposed system is tested using different types of fish diseases, especially Tail and Fin Rot, EUS, Red spot, Bacterial gill rot, Parasitic Disease (Argulus), Broken Antennae, and Rostrum. Finally, fish diseases are detected and recognized that can be prescribed in its early stages [4].

This research is designed in six sections. Section II represents some related works and Section III describes the data collection process. Section IV gives a detailed description of the proposed methodology. Section V briefing the experimental results and discussing about the mentioned method and outcomes of the system. Section VI presents conclusions and the opportunity of probable coming work in this area.

II. RELATED WORKS

Some related works associated with the proposed method described here. Waleed, Ahmed, et al. [5] completed a survey on automatic recognition of different fish diseases. They proposed three several categories of fish diseases named Columnaries, Ichthyophthirius (Ich) and Epizootic ulcerative syndrome (EUS) to recognize and identify automatically. They show the effect of several color spaces on CNN ultimate execution using Alexnet. Chacon, Mario I., Luis Aguilar, and Abdi Delgado [6] proposed a method related to an optional defuzzification function, fuzzy operators and an image fuzzification function. The Contextuality of the system is described in three phases, geometric measurements, edge detection and image binarization. On binarization the fuzzy method describes the way to solve indeterminacy on the classification of pixels. The fuzzy edge detection showed how a particular perception could be demonstrated by a fuzzy system. Lastly, fuzzy geometry is an illustration of how to obtain a variable state

below of lighting to gather more consistent measurements. Mohanaiah, P., P. Sathyanarayana, and L. GuruKumar [7] proposed a method that applies GLCM to extract second order statistical texture features. The Four features namely, Inverse Difference Moment, Correlation, Angular Second Moment and Entropy are computed using Xilinx FPGA. The image compression time can be diminished significantly by extracting the features of an image. These features are important in the motion approximation of videos and in real time pattern identification applications. Li, Wei, and Qian Du [8] proposed a system that showed the importance of extracted features using a simple Gabor filter for the NRS classifier. The accuracy of the experimented classifier results compared to conventional pixel-wise classifiers. Specifically, to extract spatial features in the PCA projected domain or a subset of original bands with band selection, a simple two-dimensional Gabor filter was implemented. Traditional classifiers, such as SVM, RLDA and SRC compared with applied classification techniques, i.e., PC-Gabor-NRS and BS-Gabor-NRS. Authors claimed that Experimental results can outperform other classification techniques. Lyubchenko, Valentin, et al. [9] proposed a color based image segmentation by determining the infected areas so that it can detect and diagnose fish diseases. To detect infected and healthy areas of the fish body, they used digital image processing and colored markers. Malik, Shaveta, Tapas Kumar, and A. K. Sahoo [4] proposed a method to segment and classify EUS and Non-EUS infected fish diseases. To enhance the image, they applied segmentation. Again, they collect useful information using different edge detection methods and also applied morphological operation. They used various feature descriptors to extract features to classify the fish disease using PCA. Sankar, M. Muni, et al. [10] proposed an approach to investigate diseased fish using image processing techniques. They applied capturing image sensing techniques for image acquisition and k-means clustering method. They also used edge detection techniques to detect edges and K-means clustering algorithm to cluster the input prawn image and detect diseases.

III. DATA COLLECTION

During the study of the historical 20 endangered fish species, IUCN has been initiating in Kaptai Lake. Among 20 species 16 were found to be available, 4 rarely available, and 34 were not available during the study period. Accessibility of three categories of disapprovingly endangered, threatened, and helpless fishes from Kaptai Lake are presented in considering exposed species, 30% were found accessible, 7% rarely available and 63% were not available during the study period. Available fish landing hubs and marketplaces would be helpful to provide primary knowledge of fish fauna, mostly to know about the fish fauna in the biggest artificial Kaptai Lake, Rangamati, Bangladesh.

In this study, Kaptai reservoir and fishery Ghat in Rangamati and Sunamganj Haor were selected to collect the different types of freshwater fishes. The data were also collected through the interview with fishermen, associated persons and cross-check interviews with informers. After that, the collected data were cross-checked with the landing data from Bangladesh Fisheries Development Corporation fish landing center especially Rangamati and Sunamganj, Bangladesh. Several large diverse fisheries are found in Rangamati town and Sunamganj

Community Based Resource Management Project (CBRMP). Different types of diseases and symptoms are described in Table I. After collecting different types of fishes from Rangamati Kaptai Lake and Sunamganj Haor, we created a database which was uploaded to kaggle.com [11]. We used different types of fish diseases and symptoms of the diseases in our database. In our study, we also used 126 fish species from 39 families initiated in the Sunamganj Haor area [9].

TABLE I. AVAILABILITY OF FRESHWATER FISH SPECIES KAPTAL LAKE AND SUNAMGANJ HAOR

Family	Lacal name	Common name	Scientific name
Schilbeidae	Bacha	Bacha	Eutropiichthys Vacha
Siluridae	Kani Pabda	pabo catfish	Ompok Bimaculatus
Cyprinidae	Mrigel, Mirka	Caurvery white carp	Cirrhinus Cirrhosis
Nandidae	Bheda	Mud perch	Nandus Nandus
Gobiidae	Bele	Tank goby	Glossogobius Giuris
Belonidae	Kaikka	Needle fish	Xenentodon Cancila
Sciaenidae	Poa	Pama	Otolithoides Pama

Pangasidae	Pangas	Yellowtail catfish	Pangasius Pangasius
Cyprinidae	Rui	Rohu	Labeo Rohita
Notopterid	Chital	Humped featherback	Notopterus Chitala

IV. PROPOSED METHODOLOGY

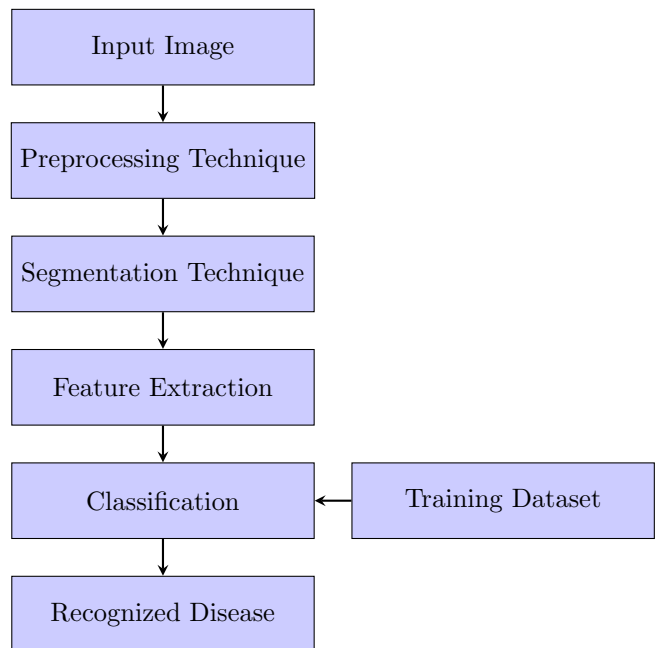

Fig. 1. Block Diagram of the Developed System.

“Fig. 1” describes the proposed block diagram.

A. Input Image

The system required a color image to start the procedure. An affected fish image passed as an input to the system.

B. Pre-processing

Noise Filtering is applied to remove several forms of noises and to filter the redundant information from the images [12]. Contrast Stretching is compulsory when the system needs to intensify or diminish the total number of pixels. Pre-processed results of the input images are shown in “Fig. 2”.

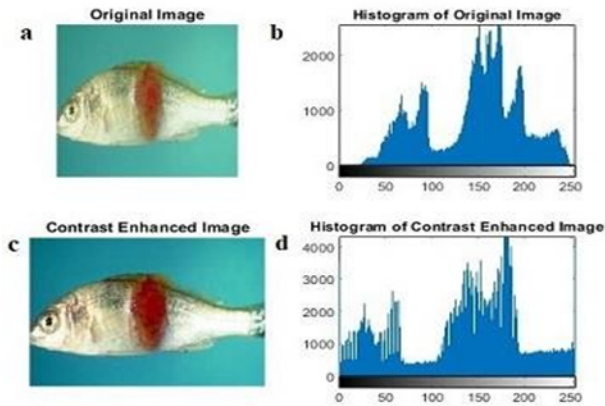

Fig. 2. (a) Input of the EUS Affected Original Fish Image (b) Histogram Result (c) Enhanced Result and (d) Histogram of Enhanced Image.

C. Image Segmentation

Fuzzy C-means (FCM) is a clustering method used to separate data into two or more clusters. We used FCM in our system. Firstly, it picks two initial cluster values from the input image, $I (r \times c)$. The system accesses every pixel as $I (i, j)$, where

$$0 \leq j < c \quad (1)$$

and

$$0 \leq i < r \quad (2)$$

Secondly, the average of median values of each row is calculated. Thirdly, the distance between every pixel of the image and cluster values calculated. Again, the distance between the pixels of the image and averaged medians are measured also. Fourthly, the final fuzzy field smooths the data obtained from cluster values and from averaged medians. Fifthly, the fuzzy rule is applied to segment the image between two clusters. Sixthly, the segmented region is reconstructed by updating cluster centers. Seventhly, steps third to sixth repeated for t times. The whole process is iteratively performed until the difference between two consecutive clusters reaches to a constant position and becomes minimum [13]. Finally, the segmented regions of both clusters for a test image are found.

K-means clustering is an unsupervised learning algorithm that is used enormously. The method is used to define k samples, one for each cluster [14]. The next step is to assign each point of input data into the nearest cluster. After selecting each data point, the first step is completed by re-calculating the new cluster centroid for the k -clusters. An iterative process has been generated until the new centroid reaches the constant state. As a result, the data points separate into k clusters step by step.

D. Feature Extraction

After segmentation, when the area of the interest region is detected then the significant features are extracted. GLCM and Gabor Filter are used to extract feature vectors from input fish disease image like texture. Texture element is extracted from the RGB colored image. The GLCM functions represent texture features of an image. Textures are the features whose focus on the distinct pixels that create an image. Texture features such as statistical feature is used which contains GLCM, grey level histogram, run length matrices and autocorrelation features for texture extraction. GLCM procedures extract 2nd-order statistical texture features [7]. Textural features include entropy, correlation, contrast, homogeneity and energy. The texture is particularly appropriate for this kind of study because of its possessions. The system also used Gabor filter features. The Gabor filters consist of parameters such as standard deviation, orientation and the radial center frequency [8]. The system combined the GLCM feature and the Gabor Filters into one feature set. This combination of the Gabor filters and the GLCM feature generate a better outcome on the fish texture dataset.

E. Classification Using Multi-SVMs

The proposed system used multi-SVMs to classify fish diseases. The extracted features of each fish disease image are stocked in the database. The SVM classifier will calculate the feature number of database images and the feature value of the input image, based on these values the classifier will separate the input image from that category. SVM will compare the test sample feature set to all training samples and select the shortest distance. Support vector machines were initially calculated for binary classification. Several approaches have been proposed where typically the system constructs a multi-class classifier by combining several binary classifiers. The SVM is learned by features given as an input to its training procedure. During training, the SVM identifies the appropriate boundaries in the 2-categories. Features are called according to class associative to a specific class. Using received features, the multi-SVM starts classification steps. The system uses multi-SVM as a two class SVM repeatedly. When the test image is passed to the classifier, it classifies it from the first two classes. After that classified class and a new class used to classify the test image. Similarly, it continued its classification steps until all categories were tested. From this last classification, the test image is classified as the true categorized class [14].

V. RESULT AND DISCUSSION

The proposed method is examined in MATLAB R2018a. The experimented database was uploaded to kaggle.com [11]. The database contains fish disease images of freshwater of Rangamati Kaptai Lake and Sunamganj Hoar area of Bangladesh. The system experimented using different fish diseases such as EUS, Red Spot, Argulus, Tail and Fin Rot, Broken antennae rostrum and Bacterial Gill rot. The system divided the input image into three clusters in both C-means fuzzy logic and K-means. All clusters of both C-means fuzzy logic and K-means clustering are given in “Fig. 3”.

From all of the clusters, one cluster chosen as the segmented cluster based the segmented region. All cluster regions

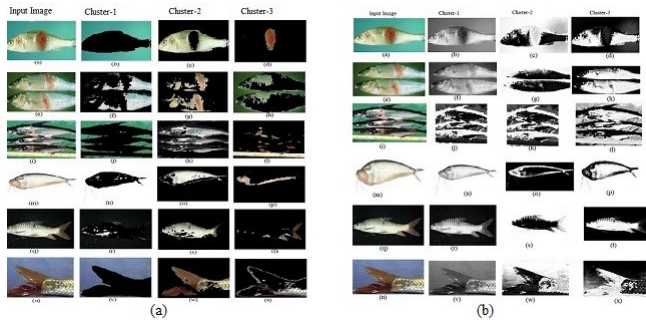

Fig. 3. a. C-means Clusters and b. K-means Clusters.

are calculated and the best cluster region chosen by user input. The segmented output is given in Fig. 4. In “Fig. 4”, the left side portion i.e., (a) represents the segmented image using C-means and the right side portion i.e., (b) represents the segmented images using K-means method.

Table II illustrates the extracted feature of segmented images. The feature extracted using GLCM feature extractor. Combining those GLCM features and Gabor filtered features, passed to the classifier to create the desired classifier.

The results of the Multi-SVM classifier are shown in Table III. The performance of the classifier is calculated by the different procedures and The SVM classifier calculates the feature value of the database and of the test image. The SVM classifier uses that feature values to identify the test image class. Input feature is (1.0e+03) and maximum accuracy of EUS and Broken antennae and rostrum is (98.4127), the

TABLE III. MULTI-SVM CLASSIFIER RESULTS FOR THE FISH DISEASE IMAGES

S/N	Fish Image	Multi-SVM Classifier	Input feature	Maximum Accuracy	Row
1	Img1	EUS	1.0e+03	98.4127	500 iterations
2	Img2	Red spot	1.0e+03	95.2381	500 iterations
3	Img3	Broken antennae and rostrum	1.0e+03	98.4127	500 iterations
4	Img4	Argulus	1.0e+03	95.2381	500 iterations
5	Img5	Bacterial Gill rot	1.0e+03	96.8254	500 iterations
6	Img6	Tail and fin rot	1.0e+03	95.2381	500 iterations

accuracy of Linear Kernel is the highest 500 iteration.

TABLE IV. A COMPARISON BETWEEN K-MEANS CLUSTERING AND C-MEANS FUZZY LOGIC

S/N	Image	Fish disease	Accuracy of K-means	Number of Iteration	Accuracy of C-means
1	Img1	EUS	98.4127	500 iterations	99.25
2	Img2	Red Spot	95.2381	500 iterations	96.50
3	Img3	Broken antennae	98.4127	500 iterations	99.45
4	Img4	Argulus	95.2575	500 iterations	97.23
5	Img5	Bacterial Gill rot	96.8254	500 iterations	98.70
6	Img6	Tail and fin rot	94.7450	500 iterations	96.25

Table IV represents the proportional outcomes of the performance of between K-means clustering and C-means fuzzy logic segmentation. The system gives 96.48% accuracy using C-means fuzzy logic where K-means gives 97.90% accuracy.

VI. CONCLUSION

The paper proposed an image processing based approach and automatically detects different types of fish diseases. The testing of the proposed system has been experienced on the actual infected fish images collected from Rangamati Kaptai Lake and Sunamganj Hoar, Bangladesh. The experimental results indicate that the proposed approach is a valuable approach and can significantly support accurate and automatic detection of fish disease and the proposed combination gave better accuracy after applying the machine learning algorithm. The infected fish images were then classified with an average accuracy rate of K-means clustering and C-means fuzzy logic gives 96.48% and 97.90% respectively. In the future, it will present some guidelines such as establishing a better segmentation system, choosing improved classification algorithms and deep learning algorithms that can apply on different feature descriptors.

Abstract—Providing data services support for large file upload and download is increasingly vital for mobile cloud storage. There is an increase in mobile users whose data access trends show more access and large file sharing. It is a challenging task for Mobile Application Developers to handle upload and retrieve large files to/from a mobile app because of difficulties with latency, bandwidth, speed, errors, and disruptions to service in a wireless mobile environment. Some scenarios require these large files to be used offline, sometimes to be updated by a single user, and sometimes be shared among all other users. The Wireless mobile environment must consider mobile user's constraints, such as frequent disconnections and low bandwidth, which affect the ability to handle data and transactions management. The primary objective of this study is to propose a cloud-based Mobile Sync service (sometimes referred as Mobile backend as a Service) with OpenStack Swift object storage to manage large objects efficiently using two main techniques of segmentation and object chunking with compression in a mobile cloud environment. This work further contributed to a prototype implementation of the proposed framework and provides Application Programming Interface (API) consisting of Create, Read, and Delete queries and chunking operations and a lightweight sync protocol that can manage large file synchronization and access. The experimental findings with object-chunking tested size settings show that the proposed Mobile Sync framework can accommodate large files ranging from 100MB to 1GB and provides a decrease in upload/download synchronization times of 63.203% / 92.987% percent as compared to other frameworks.

Keywords—Mobile cloud computing; mobile backend as a service; large files; distributed systems

I. INTRODUCTION

The development of enterprise mobile services can use variety of cloud computing models. The predominant service models for cloud computing are mainly classified as Infrastructure as a Service (IaaS), Software as a Service (SaaS) and Platform as a Service (PaaS) [1]. With the introduction of a new service model known as Mobile Backend as a Service (MBaaS), making it easy to integrate cloud-based applications with mobile platforms has become possible.

The model of Sync framework offers a cloud server infrastructure to store application data and facilitate easy configuration. The developer needs to do significant work for the application to remain responsive during interruptions in communication due to poor or no network. The Sync framework offers a solution for the unreliable connection problem with customized synchronization and replication processes and

helps synchronize with multiple clients. An intelligent Sync framework allows enterprise data to take offline and facilitate sync operation by syncing data across multiple mobile devices with the backend systems, detect and resolve the conflicts with configurable, standards-based rules, setting precedence based on policies [2] [3]. Ideally, the Sync framework should provide a consistent state at all times (strong consistency). However, the CAP theorem [4] for the distributed systems enforces the Sync framework to guarantee immediate availability and tolerate network partitions to provide a weak form of consistency, commonly known as eventual consistency [5].

Data Services is one of the critical capabilities of an MBaaS platform and provide the following features:

- **Data Management:** A quality MBaaS framework will provide the services to create, save, manage and sync application data and files within the framework itself, in addition to a mechanism for connecting into both public and private systems of record and abstraction layers [3].
- **Online/Offline Workflow:** The mobile apps can operate in online and offline modes, and hence MBaaS can support offline/online database synchronization [6].
- **Sync:** An intelligent MBaaS framework allows enterprise data to take offline, syncing data across multiple devices with the backend systems, detect and resolve the conflicts with configurable, standards-based rules, setting precedence based on policies [2].
- **Caching:** Various caching methods are offered as a part of the MBaaS platforms to reduce latency and boost app performance. The caching can be provided as an inbuilt feature in the framework or at a connection point to systems of record or even cross-platform on-device caching strategies (via client SDKs) [7].

Due to the rising numbers of people making their files shareware accessible via mobile devices, the reliability and efficiency of service for large files is a more crucial feature in mobile file-sharing than previously thought [8] [9]. Developers have to deal with complex issues of latency, speed, timeouts, and interruptions during the uploading and retrieving from mobile apps [10] [11] [12].

Recently, some efforts are focused on finding out the trend

of mobile users to access data on both public and private cloud storage services and several different personal cloud storage systems. One such study in [9] aimed to analyze data access trends in large-scale mobile cloud storage [9].

This research aimed to analyze the database of 350 million HTTP transaction log files from mobile applications to find the trend in how quickly cloud storage is being used for collaborative and large file storage. This study concluded that for retrieving one file in multiple sessions, the average volume was about 70 MB.

An empirical study was conducted by a cloud storage vendor [8], which involved the services of media file uploading, transformations, and storage in the cloud. This research studied a data set of one million mobile applications rendering these services. Their observation examined the statistical information regarding the number of files, including different file sizes and formats, which have been uploaded (from the year 2015 to 2016). Their research showed that the amount of growth files with size 100MB and above is 170%, while files of other sizes increased by 50% year over year. According to this study, it appears that the file sizes are increasing as mobile users make more frequent use of the files or share files and have larger storage requirements (above 100MB).

Some of the mobile operating systems limit the size of the file over which over-the-air (OTA) or app-store downloads are not allowed [13]. For example, Apple's iOS platform [14] limits the Cellular Data downloads to a file size of 100 MB. Android OS limits the size of downloads via cellular data to 150MB [15]. Based on the above studies and mobile operating system guidelines, it can be concluded that a file with a size greater than 100MB is considered a large file.

The rest of this paper is structured in the following manner: Next Section II provides a brief background and problem formulation. Section III analyzes some of the Mobile Sync frameworks in the literature along with support for large objects. Section IV provides the background information of the OpenStack cloud platform and support for large file storage in the Swift module that handles object storage. Section V describes the details of the proposed framework for data services to handle large files. The data management at both mobile Client and Cloud server-side is discussed. Section VI discusses the performance of the proposed Mobile Sync framework, followed by a conclusion and future work in Section VII.

II. BACKGROUND AND PROBLEM FORMULATION

More recently, there has been an exponential growth in mobile devices with requirements for seamless personal data synchronization and availability across devices for mobile users. Different methods, such as Chunking, Deduplication, Segmentation, and Delta-encoding, have been used by cloud storage providers to maximize storage space and reduce transmission time [10]. In addition to custom features, various Mobile Cloud Storage providers have developed and implemented services to incorporate techniques of Chunking, Deduplication, Segmentation, and Delta-encoding. Despite all the efforts, there is still much space for improvement in handling syncing data in the mobile cloud storage, as the sync time is much longer than expected under some circumstances. Executing

data synchronization is a challenging task in a mobile/wireless environment with frequent disconnections.

As commercial storage systems are primarily closed source with encrypted data, the public remains unclear regarding their designs and operating processes. Exhaustive research of the sync protocol of specific frameworks can be time-consuming to determine the cause of sync difficulty and maybe inefficient [16].

Furthermore, while some existing services attempt to integrate multiple capabilities to increase sync speed and efficiency in mobile/wireless environments, whether these strategies are viable is still unclear [11].

Ultimately, as a mobile cloud storage system will need storage and network technologies, storage techniques must be flexible and function effectively in a mobile/wireless environment. Communications in such environments are vulnerable to high delay or interruption due to mobility and changing channel conditions [17].

Although several mobile sync frameworks support mobile customer data replication and management systems, they lack support for large artifacts (more than 10MB to Gigabytes) [11] [17] [18] [19] [20] [21]. The main observation from the literature study in the papers [22] [23] [24] revealed that out of 19, only nine frameworks (47.36 percent) support large objects, including commercial frameworks; additionally, few have limitations (in terms of maximum file upload size, chunking support option, and handling techniques for better performance of large objects). In the case of local storage and updates on the cloud and on other client mobile devices, managing large data and maintaining consistency becomes difficult.

Deduplication techniques, in particular, do not always lead to sync efficiency by reducing redundant data transfers. Reasonable attempts to implement delta encoding algorithms are hampered by the distributed nature of storage infrastructure and may lead to high overhead traffic due to the lack of incremental sync. When synchronizing files across a slow network is necessary, the iterative synch scheme suffers from low throughput [16].

To tackle the above challenges, Chunking, Segmentation, and Compression techniques are suggested to improve the sync performance for large objects in modern mobile cloud storage systems, focusing on Data management for large objects.

III. RELATED WORK AND LARGE OBJECT HANDLING TECHNIQUES IN FRAMEWORKS

Cloud storage providers use different techniques to optimize the storage space and speed up data transmissions [10]. The main techniques used in different synchronization frameworks are Chunking, Bundling, Segmentation, Compression, Deduplication, and Delta-encoding.

- 1) **Chunking:** For each piece of the large file uploaded to the Server, some frameworks will break up the upload into multiple pieces and upload the parts one at a time. The process of dividing the file into several smaller files or sections is called file chunking.

- 2) Bundling: During uploading multiple files together, some frameworks of cloud providers combine them into larger bundles for the sake of efficiency before storing them in the cloud. In file bundling, the transmission latency is reduced because cloud servers have fewer connections to mobile clients.
- 3) Segmentation: This method consists of creating a file that takes in a large object and divides it into smaller, self-contained portions. Because Segmentation allows for virtually unlimited segment uploads in a single object with faster and parallel segment uploads, it is a favorite technique used by Internet service providers and application developers.
- 4) Compression: Prior to transmitting to the cloud, the file data can be compressed. With a bit of overhead of processing, data compression can minimize the traffic and reduce storage requirements [11].
- 5) Deduplication: In the case of an identical copy of a file being uploaded by the user or another user in the cloud storage service, that file can be deduplicated. In such cases, instead of sending the file over the network again, it maintains only a unique link to avoid network traffic and reduce storage requirements. Some frameworks support chunk level deduplication if the provider's data storage unit is a chunk object rather than a file.
- 6) Delta-encoding: This process transmits only the modified portion of a file with Compression. If the previous version of the file already exists on the server, the transmission will contain only the modified parts of the file compared previous version.

A. Analysis of Large Object Support in Frameworks

For mobile cloud services, supporting large file uploading and retrieval is critical as data sizes of sharing content are increasing, and mobile users are accessing or sharing enormous size files [9] [8]. However, only Desktop customers and not mobile apps can use valuable large object services. Open-source and commercial cloud storage services for mobile devices are analyzed for large file object support. The studies are mainly classified into three categories: open source frameworks (Parse Server [25], BaasBox [21], Simba's [11] and Open Data Kit 2.0 [26]), academic research reference frameworks (SwiftCloud [18], QuickSync [16]) and commercial mobile cloud frameworks (Dropbox [27], Google Drive [28], Amazon Dynamo [29], CloudKit [30]).

Table II in the Appendix summarizes the large object support and techniques used to optimize the storage space and speed up data transmissions in the various reference frameworks. Many commercial cloud-based frameworks support large objects, but not every framework addresses large files, unfortunately.

Further investigation on frameworks revealed the various techniques of handling large objects and the maximum files supported with options of resuming uploads if interrupted due to network disconnections. A brief explanation of each framework with respect to handling large files is given below.

In the category of open-source reference frameworks, the Parse Server [25] service platform uses MongoDB as the

backend datastore. It can only handle files up to 10MB in size. The 'ParseFile' is a particular data type that makes it easier for Developers to store application files in the cloud. Parse provides another option with a data type known as 'ParseObject' to upload an array of up to 10MB in bytes or as a series of Streams. Implementing the 'SaveAsync' method, the users can save the file to the Parse framework.

Another MBaaS open-source framework based on the Play framework but does not support large files by default is BaasBox [21]. However, based on the component design architecture, some custom implementations are needed to support uploading and downloading data up to 300MB. It is built on the Play web application framework, which is a lightweight, stateless, open architecture. BaasBox requires configuration modifications for the maximum payload size in POST operations. By default, the value of POST request size is 100KB, which can be changed based on the server configuration. Special HTTP requests known as Body parsers in the Play framework are used for POST or PUT operations.

Simba [11] is a recent framework aimed to expedite the development and deployment of data-centric mobile apps and enable them to store data into the cloud storage. Simba extended the table interface of Izzy [17] but the sync protocol of Simba [11] does not support streaming APIs that can handle large files like Media or Video.

SwiftCloud [18] is another middleware framework that is based on the technique of Conflict-Free Replicated Data Types (CRDTs) with the Riak [31] key store and does not support storing objects over 50MB for performance reasons.

Mobius [7] is an application platform that enables real-time cloud-based data replication and messaging for mobile devices. Mobius is focused on addressing the development challenges of data management and messaging for data-centric mobile apps and does not deal with large files. Also, large size handling is not considered in the case of special CRDT cloud types in libraries like TouchDevelop [32] [33]. On the other hand, high-level ideas of sets and maps enable support for large files, but the storage providers do not support the storage of large objects (greater than 50 MB) for performance reasons.

Open Data Kit 2.0 [26] supports the Android operating system and enables the data to be stored in the cloud and handle offline data management. The default size limit on remote procedure calls in Android service is 1MB. To overcome the limitation of 1MB, the ODK Kit exposes higher-level features using a transport-level interface to developers. Using a client-side proxy, the ODK Kit implements a chunking interface.

Dropbox [27] is a commercial sync service provider, and files uploaded via the dedicated REST APIs can be up to 150MB in size. There is a maximum file size of 150 MB only when uploading with the files put API. Dropbox exposes chunked upload API to upload large chunks of data. A chunk of any size between 150 MB and 4 MB can be chosen. Dropbox has a built-in support to resume uploads if the upload is affected because of network disconnections.

QuickSync [16] is a framework that focuses on addressing the sync performance issues considering the network conditions. The framework integrates Seafile/Dropbox APIs and allows large data up to 180MB. It allows the big files to

be uploaded using the "chunk" API support. The APIs also supports automatic presumable data upload. A chunk of any size between 150 MB and 4 MB can be chosen.

Google Drive [28] is another file sync service provider that provides SDK to upload/retrieve data to/from cloud storage. To achieve resumable uploads, more than 5MB of data can be uploaded by making one request or via multiple requests with Google Drive SDK. In order to make the upload as fast as possible, larger chunk sizes are recommended. The upload request in Google Drive recommends chunk size to be in multiples of 256 KB.

Apple has extended the service of iCloud [32] with Cloud Kit [30], a new way of storing and accessing data stored in iCloud storage. The iCloud storage allowance is dependent on user type (paid or premium subscriptions allow larger storage). There is no explicit description document size limitation and Core Data (iOS local) storage limit. However, uploads depend on the device's or iCloud user storage limit. The operating system (iOS) starts and manages the upload and download of data from devices on the iCloud account. The iCloud app only needs to adopt the lifecycle of document management and need not communicate directly with iCloud servers. There is no need to invoke data upload or download operations in most cases.

Amazon uses DynamoDB [29] as the backend data store for cloud storage, focusing on high availability. Mobile SDKs from Amazon provide the way to interact with cloud services via REST APIs for DynamoDB. DynamoDB allows safe update operation of data even in the face of network partitions or server failures. In the DynamoDB, the total maximum item size is 400 KB, which includes both the name attribute's binary length and value. Suppose the application requires more storage space than that allowed by the Amazon DynamoDB limit. In that case, the developer may try compressing large attributes, or the app may store data in AWS Simple Cloud Storage (S3) [33] and associate the Amazon S3 ID with the Amazon DynamoDB entity using the Amazon object identifier.

The key observation from the study is that out of 19, only nine frameworks (47.36%) support large objects, and a few also has limitations. Because current Mobile Sync frameworks do not support large objects and have restrictions (in terms of maximum file upload size, chunking support, configuration, and large object handling strategies for better performance), this article provides an enhanced cloud-based Mobile Sync framework.

IV. OPENSTACK SWIFT AND SUPPORT FOR LARGE OBJECTS

OpenStack platform (developed by NASA and Rackspace) offers a combination of open-source tools for the management of the core cloud computing services in the areas of computing, identity, storage, networking, and image services. This platform can be customized and integrated with additional packages based on the requirements. The framework proposed in this paper is based on Swift, the object storage of OpenStack. The primary design hierarchy of Swift is based on a *tenant/container/object* structure to efficiently, safely, and cheaply store files.

The flow of request processing in Swift is shown in Fig. 1. When a client submits a request to retrieve an object A, an intermediary proxy server retrieves the object. The proxy is regarded as a stateless single entry point to the storage cluster and allows it to scale to arbitrary clients. The proxy is also responsible for determining the appropriate object server for the client's requested object and eventually returning the response object to the client. Apart from the object catalog, the cluster has a running container catalog that stores data about objects grouped within containers. Alternatively, hash functions are used to locate containers. Swift is based on the Web Server Gateway Interface (WSGI), which allows frameworks to define a pipeline. This pipeline comprises one or more middlewares that can pre-process requests before they reach the main web server component.

With regard to the enterprise architecture, Objects correspond to files and are arranged in Containers, i.e., directories. Tenants form the highest level of hierarchy to set up an organization assigning a set of containers. Swift defines two types of ACLs: tenant-level and container-level. A tenant-level ACL allows administrative access to the tenants. Container level ACLs define the permissions on the container for reading, writing, and listing. OpenStack Swift limits the association of any ACL for objects, and the ACL of a container applies to all objects in it.

This study recommended the techniques of Segmentation and chunking to deal with large object files. The principal goal is to attain faster reading and writing speeds using a low object-to-node ratio with a lesser number of objects having large chunk sizes. In addition to effective data reduction, the method uses effective bandwidth reduction techniques [11] [16].

Using the Chunking Mechanism, large objects can be split into smaller parts of a certain data unit when uploading data to cloud storage services without raising the resulting file size issue (in the user interface of memory-constrained devices). Hence when a user attempts to upload a large file, some frameworks divide the input file into smaller parts and then upload these smaller chunks asynchronously later. The proposed chunking mechanism can handle large object data management and end-to-to-end consistency in a mobile cloud environment [16].

It is also a common technique to decrease network traffic by using chunks [34]. The proposed Mobile sync framework in this article provides data structures that can accommodate both table and object data. A single Table ($Table_{DS}$) can contain several rows (Row_{DS}). In the proposed cloud synchronology design, in the case of a Row_{DS} with one or more objects, the changeset for the sync will only consider the modified chunks. Individual chunks are not versioned.

The technique of Segmentation consists of creating a file that takes in a large object and divides it into smaller, self-contained portions. These smaller segments are then transmitted as one object together. Segmentation allows a nearly infinite object size, with more segments that can be uploaded nearly simultaneously in parallel for quick transfer. The Open Stack Swift [35] supports large object uploads by utilizing this segmentation technique. Such a framework would provide cloud-based services with support for large files of any size, from megabytes to gigabytes, and allow the Developers to

Fig. 1. Request Processing in OpenStack Swift.

```

Fig. 2. Open Stack Swift APIs for Large Object Support.

arbitrarily complex, synchronized large objects to be built and maintained in the cloud.

Fig. 1 and 2 shows the sequence of request in segmentation process of OpenStack Object Storage. While the data is being uploaded, the mobile client can specify how much of it to chunk, and the proxy server will divide it into smaller sections. The different blocks are given internal names according to their position in the cluster. Creation of order lists all object file names also creates a manifest file (see Fig. 2). The proxy reads the manifest file to fetch the parts from the GET request of client. With the integration of OpenStack Object Storage, the proposed Mobile Sync framework can support files that are as large as 5 GB in size.

In addition to the techniques of Chunking and Segmentation, this research also incorporates Compression so that the data will be transmitted to the cloud in a smaller, more compressed form. Google's SPDY [36] with Google Protocol buffers [37] are employed, which uses multiplex to HTTP extensions to save on network overhead and perform better Compression for multiplexing requests over a single connection. Google Protocol buffers provide an expandable serialization mechanism for structured data, which are language and platform-neutral.

V. PROPOSED FRAMEWORK FOR DATA SERVICES TO HANDLE LARGE FILES

A. Prototype Implementation

There are two main modules to the proposed architecture of the Mobile Sync framework: one for executing on the handheld device (Data Service) and the other for data in the cloud. Together, these two modules assist enables mobile application development with the Software Development Kit (SDK) provided by the framework. Fig. 3 shows the basic block diagram of the proposed Mobile Sync framework.

The 'Framework Data Service' (FDS) is a module that connects the mobile apps and the Cloud Data Server by using a custom sync protocol and works as a mediator for transferring data and messages. Each client application is built with the

Fig. 3. Block Diagram of Proposed Mobile Sync Framework.

Framework Data Service API provided by the SDK and talks to the system-wide data service (FDS) via streaming and CRUD APIs. Mobile Local database store consisting of Sqlite and LevelDB, enable FDS to save all the application data and metadata in the local store. For the Mobile client apps that run on mobile devices, the local database is not accessible directly since FDS manages it.

The primary modules used to manage large objects are 'Chunk Data Handler' and handler modules like 'Large Data and Streaming Data', which are included within the framework SDK. These modules use a simplified data storage model for apps to use the chunking process proposed in this research article. 'Mobile Client Data Store' is a local storage module to store tabular data and large app objects in the memory of a mobile device (typically the internal flash memory or the external SD card). On the client-side, the framework integrates SQLite for table and LevelDB for object data (in addition to handling large files).

The data model of the proposed Mobile Sync framework facilitates the storage of data for all client applications and hides the complex details of storing and synchronizing data. A custom Data Model consists of chunk layout support with additional support for larger objects.

The 'Cloud Data Store' is the other main server-side module responsible for data management and interacts with the 'Framework Data Service' (FDS) via the custom Sync Protocol. The primary responsibility of this module is to manage data across multiple mobile clients of the framework and implement the chunking & segmentation method at the server-side. For supporting large files in the cloud, through Object Storage, the framework uses the Infrastructure of OpenStack Swift, which has built-in support for the Segmentation process. The framework API must handle the request and responses from the OpenStack Swift server.

B. Framework APIs

The proposed Mobile Sync framework API is designed in the same way as the well-known CRUD interface, allowing apps to set Table/Object properties, access their data, push new data, and resolve conflicts. The framework provides a streaming API abstraction that allows objects to be written to or read from, making it ideal for dealing with large object. It also allows to read or write only a portion of a huge object locally. Table I lists only the APIs that are specific to chunk processing.

TABLE I. CHUNK PROCESSING APIS IN THE PROPOSED MOBILE SYNC FRAMEWORK.

API	Purpose
UploadObjectChunk[]	Creating chunk
GetChunkObjectRange[]	Retrieving chunk
RemoveChunkObject[]	Remove a chunk
RemoveChunks(table, chunkref)	Removing multiple chunks
UploadManifest[dataptr]	Creating large objects using Chunk
DownloadManifest[]	Retrieving large objects using Chunk
RemoveObjects[objptr]	Deleting large objects

C. Mobile-side Large Objects Handling Method through LevelDB with LSM

This proposed Mobile Sync framework integrates SQLite for the table data structure and LevelDB for the file object storage on the client-side. LevelDB is integrated into the SDK of the proposed Mobile Sync framework for handling large files. LevelDB uses an advanced data structure known as Sorted String Table [38] and Log-Structured Merge (LSM) [39] to handle large workloads with gigabytes of data. LevelDB’s append and update performance meet the throughput criteria for the mobile client-side layer. LevelDB also has atomic snapshot in-like functionality, which is used for synchronization.

Sorted String Table (SSTable) [38] is a valuable and practical data structure for storing key-value pairs in large numbers and high throughput sequential access. SSTable offers flexibility for sequential read/write requests with workloads consisting of data sets that are Gigabytes in size.

The Log-Structured Merge (LSM) [39] architecture adds various new behaviors to the SSTable. Write operations are always fast no matter the size of the data set (append-only) because the LSM permits all write requests directly to the MemTable index. In addition, random reads can be obtained quickly or quickly served from memory (Initially search MemTable and then the indexes in SSTable). SSTable periodically flushes the MEMTables to the disk.

LevelDB architecture uses the SSTable and MemTable processing schemes to form an efficient database engine with powerful algorithms. Many other related products follow the same architecture include Apache Cassandra, Google BigTable, and Hadoop’s HBase.

Fast write operations are allowed in LevelDB regardless of the data-set size, as all write operations are directly executed to the log and the MemTable. The logs of up to 2MB are periodically written to disk assorted string table files (SST) into a database. Each piece of SST data is compressed into single-writable 4K sections. Entries are positioned so that an end-marker block designates the beginning of each data set, and the most recently processed section of the list points to the start of the next. Bloom filters perform lookups more quickly and enable fast search of indexed blocks.

For an improved reading speed, LevelDB breaks SST into sets or levels (see Fig. 4). Each level in LevelDB has ten times the size of the previous one.

D. Server-side Large Object Support with Segmentation

This proposed Mobile Sync framework integrates Cassandra [40] for the table data structure and OpenStack Swift [35]

Fig. 4. Architecture of LevelDB with SSTable and MemTable.

for the file object storage on the cloud server-side.

OpenStack Swift [35] employs the process of Segmentation to enable large file uploads. The goal of the Segmentation process is to create a single file that divides the object into segments. With Segmentation, it is possible to upload a single object of virtually any size while taking advantage of the double uploads and the ability to upload multiple segments in parallel.

Unless the size of an object exceeds the maximum value (5 GB) set for the Swift cluster, each object is considered as a single file and stored in the disk. This restriction of the maximum file size of 5 GB avoids one object taking up all of the storage while half of the disk is empty. If the item to be stored is enormous, it is typically stored in several segments to allow future reassembly.

VI. RESULTS AND DISCUSSION

The proposed Mobile Sync framework is designed for use in large file sync scenarios, from a couple of hundred megabytes up to several gigabytes. Multiple modules serve both the clients and the servers from in same architecture.

The evaluation process discusses the performance of the proposed Mobile Sync framework for the following factors:

- 1) The performance of Application Programming Interface (API) consisting of Create, Read and Delete queries and chunking operations [11] [41] [42]
- 2) The efficiency of Sync Protocol [43] [44] [45].

A. Efficiency of Chunking and Data Access APIs

The Application Programming Interface (API) of the proposed Mobile Sync framework for cloud storage is designed to handle requests from thousands of mobile clients. For evaluating the performance of the cloud storage interface, a Linux Test client is implemented. The prototype included a test application to issue requests of subscriptions for reading or writing to a table data structure exposed by the SDK by generating a configurable number of threads. The test application will then generate required read/write (I/O) requests. Both file object and tabular data sizes can be configured as per the requirement during the API testing. The chunk size for objects and consistency scheme is also configurable.

A series of tests are conducted with an individual API call. A combination API invokes the Create-Read-Delete to carry out the performance testing of exposed APIs from the proposed Mobile Sync framework. Test files ranging in varying sizes from 1MB up to 1 GB are generated for testing. A test

Fig. 5. Latency for Put, Get and Delete APIs in Proposed Mobile Sync Framework.

Fig. 6. Latency for Upload Operation with Different Chunk Sizes in Proposed Mobile Sync Framework.

suite is created for large file reading to analyze if the Mobile Sync framework can handle 1MB to 1GB of data. In addition, testing is also done to delete individual files. The Create-Read test is done with 8MB of the default chunk size. A graphical representation in Fig. 5 shows the latency for Put, Get and Delete APIs in the proposed Mobile Sync framework.

As illustrated in Fig. 5, latency increases with the file size. Upload APIs also took longer than download APIs because the upload operation includes data acknowledgments and processing time. It is observed that the time variation of upload data for a size greater than 500MB is less since the framework sync protocol employs data compression during the optimized transfer of data in the network.

The Delete operation is quicker Mobile Sync framework, as the operation completes instantly by marking objects as deleted, instead of removing them. The objects are permanently removed in the scheduled deletion cycle through configuration. The experimental evaluations show that the proposed Mobile Sync framework APIs can handle reading, and removing large files with excellent efficiency.

The third measurement evaluated the performance of object chunking. A method for modifying the object-to-to-node ratio is achieved by altering the testing file size with varying chunk size [11] [41] [42]. A large file size with a larger chunk size results in a low object-to-node ratio, enabling fast reads and writes. Fig. 7 illustrate the impact of configuring different object chunk size (2MB, 4MB, 8Mb and 16MB) on Upload or Put query for proposed Mobile Sync framework. Having a large chunk size demonstrated to be more effective since the large chunks only require a few partitions but can transmit more data efficiently and quickly. For the proposed Mobile Sync framework chunk size of 16MB is recommended subjected to the

B. Sync Protocol Efficiency

The main goal of the proposed Mobile Sync framework is the efficient synchronization of mobile device data through high-level abstractions. It is, therefore, essential to ensure that the synchronization process is not significantly affected by overhead by the proposed framework. So, it has to be shown that the Sync protocol of the Mobile Sync framework is lightweight. To do so the overhead of synchronization of rows with 1 byte of table data with six scenarios is calculated as follows: First with no data, second with one-byte data, and four other cases with 64 KB, 200 KB, 100 MB, and 300 MB objects. In order to minimize compressibility, random bytes are produced for the payload.

Fig. 7 and Fig. 8 show the overhead of sync protocol for a single message with 1 row and ten rows, respectively, for different payloads.

Fig. 7. Overhead of Sync Protocol for a Single Message with 1 Row with Different Payloads.

Fig. 8. Overhead of Sync Protocol for a Single Message with 10 Rows with Different Payloads.

The test results indicated that the Sync Protocol of the Mobile Sync framework produces a total message overhead of approximately 109 bytes. There is no object in this request but a single row with 1 byte of tabular data. There will be a reduced overhead for per-row baseline requests with the integration of data compression and batch operations of 10 rows turning into one sync request. Thus, with an increase in the payload (table or object) size, the data transfer overhead ultimately becomes negligible.

To sum up, the network overhead is reduced for the batched row or multiple rows operations because of data compression used in sync protocol. By working with single rows instead of

Fig. 9. Comparison of Proposed Mobile Sync Framework with other Frameworks for Upload Data.

Fig. 10. Comparison of Proposed Sync Framework with Other Frameworks for Download Data.

batches, the Mobile Sync framework incurs a little overhead. Hence the sync protocol is lightweight and efficient with batching or group operations. More or less, empirical testing supports the claim that synchronization protocol is lightweight.

C. Performance Comparison with Other Sync Frameworks

The proposed Mobile Sync framework local performance is compared with two other open source mobile frameworks namely ParseServer [25] and BaasBox [21]. A file size of up to 500MB is tested in both Parse Server and BaasBox with the prebuilt virtual machine setup available. Some custom changes are required in Parse Server and BaasBox to support files upto 500MB .

The proposed Mobile Sync framework local performance is compared with two other open-source mobile frameworks, namely ParseServer and BaasBox, with a chunk size of 16MB. Fig. 9 shows latency comparison of Upload API (Put query) for the proposed Mobile Sync framework. The BaasBox upload process is handled by the REST APIs in the Play framework and takes more time than the proposed Mobile Sync framework due to the time taken for HTTP buffer processing and acknowledgment. Also, BaasBox does not support dedicated APIs through the Play framework to handle large files. BaasBox seems to be better in efficiency than the Parse Server framework. Overall the proposed framework reduces synchronization time with object chunking by 65.4% for upload on average when compared ParseServer and BaasBox.

Fig. 10 shows latency comparison of Get API (download query) for the proposed Mobile Sync framework, Parse Server, and BaasBox. The performance of Parse Server is comparatively better than BaasBox for files up to 500MB, and it should be noted that the experiment for download run on mobile with only a single file and no other application running on the device. The latency, which is the measure of response time between the device and a service's Server, must be considered. Since the BaasBox, Parse Server, and proposed Mobile Sync framework run on the virtual network setup in the testing network, the performance is better. The proposed Mobile Sync framework runs better than Parse Server and BaasBox since while downloading, the tests are configured with a chunking feature of 16MB to retrieve data in the device. The download tests are also dependent on the memory available for downloading and processing in the client device, depending on the RAM size. Overall the proposed framework reduces synchronization time with object chunking by 93.7% for download on average when compared to ParseServer and BaasBox.

Delete API performance in the proposed Mobile Sync framework and other two frameworks Parse Server, and Baas-Box is almost identical. These frameworks follow a lazy deletion policy wherein objects are marked deleted and physically removed after the completion of the sync operation.

VII. CONCLUSION AND FUTURE WORK

It is essential to develop Mobile applications to store and access data from backend enterprise systems. Certain usage patterns require storing and access data in large files. Uploading or downloading large files is a complex and time-consuming process for developers because of difficulties with latency, bandwidth, speed, errors, and disruptions to service in wireless mobile environment. In this article different techniques (Chunking, Bundling, Segmentation, Compression, Deduplication and Delta-encoding) for large objects (ranging from hundreds of megabytes to 5GB) in different mobile cloud storage solutions are analyzed. A Mobile Sync framework is proposed with both flexible chunking support and high throughput feature with segmentation technique to store and access large objects for a mobile cloud storage framework. The prototype implementation of the framework supported upload or download larger objects from the cloud storage, with support for tunable chunking configuration at the mobile side and local caching or data transfer only for a part of large objects. The extensive evaluations under the representative data-set show that the Mobile Sync framework works can quickly and effectively store large files and effortlessly keep minimal traffic burden on large workloads with reduced synchronization time. As a future work it is desired to extend the Mobile Sync framework with support for consistency schemes (like Eventual, Strong, Sequential consistency and others).

Abstract—The COVID-19 pandemic continues to impact both the international economy and individual lives. A fast and accurate diagnosis of COVID-19 is required to limit the spread of this disease and reduce the number of infections and deaths. However, a time consuming biological test, Real-Time Reverse Transcription–Polymerase Chain Reaction (RT-PCR), is used to diagnose COVID-19. Furthermore, sometimes the test produces ambiguous results, especially when samples are taken in the early stages of the disease. As a potential solution, machine learning algorithms could help enhance the process of detecting COVID-19 cases. In this paper, we have provided a study that compares the stand-alone CNN model and hybrid machine learning models in their ability to detect COVID-19 from chest X-Ray images. We presented four models to classify such kinds of images into COVID-19 and normal. Visual Geometry Group (VGG-16) is the architecture used to develop the stand-alone CNN model. This hybrid model consists of two parts: the VGG-16 as a features extractor, and a conventional machine learning algorithm, such as support-vector-machines (SVM), Random-Forests (RF), and Extreme-Gradient-Boosting (XGBoost), as a classifier. Even though several studies have investigated this topic, the dataset used in this study is considered one of the largest because we have combined five existing datasets. The results illustrate that there is no noticeable improvement in the performance when hybrid models are used as an alternative to the stand-alone CNN model. VGG-16 and (VGG16+SVM) models provide the best performance with a 99.82% model accuracy and 100% model sensitivity. In general, all the four presented models are reliable, and the lowest accuracy obtained among them is 98.73%.

Keywords—COVID-19; convolutional neural network; hybrid models; chest X-Ray; deep learning

I. INTRODUCTION

The continuous outbreak of the novel coronavirus was first reported in Wuhan, Hubei Province, China. In a preliminary report, it was revealed that the virus shares an 88% serial identity with two coronaviruses derived from bats, similar to SARS. The new coronavirus was preliminarily named nCov-2019. In February 2020, a study group from the International Committee on Taxonomy of Viruses classified the virus as SARS-CoV. Shortly thereafter, the World Health Organization (WHO) formally named the disease caused by the novel coronavirus “COVID-19” [1].

The most common symptoms of this disease are coughing, headaches, fatigue, shortness of breath, loss of smell, pain in the throat, and a high temperature. COVID-19 continues to have a destructive impact on global health and commerce, as

well as individuals’ lives. The number of infections and deaths increases day by day. As of April 18, 2021, the total number of infected persons around the world has reached 141 million with a mortality rate of 3 million.

Therefore, there is a need to cooperate across disciplines and integrate resources to defend against COVID-19 and prevent it from further spread. Because this virus has the ability to spread fast between people, the first and most important step in COVID-19 defense is early detection. The most common method used to detect COVID-19 is the Transcription-Polymerase Chain Reaction (RT-PCR) test. The RT-PCR test usually takes up to 6 hours to produce results [1]. This waiting time is long when we consider the urgent need to test millions of samples and receive the results as fast as possible to prevent those who are infected from spreading the disease to others. Additionally, sometimes patients who have already been exposed to the virus and show severe symptoms could still get false negative results in the (RT-PCR) test [1].

Thus, the development of a fast and efficient alternative is necessary to improve the process of diagnosing COVID-19. One possibility is to exploit the fact that the disease can be diagnosed using chest X-Ray images. In contrast to other types of medical imaging, X-Ray images are available at most hospitals, and have been routinely used in COVID-19 diagnoses thus far. Moreover, they are cost-efficient and quickly produce results [2]. Machine learning and deep learning algorithms are promising in this case. Potential automated COVID-19 detection models can be provided by training such algorithms on chest X-Ray image datasets. These models may aid in producing test results within a few seconds as well as reduce inaccurate results.

This paper addresses the following research question: How would replacing the fully connected layer with a machine learning classifier affect the classification model performance? To answer this question, we examined the efficiency of two types of machine learning models used to detect COVID-19. Using one of the largest available chest X-Ray image datasets, we have built four different models to study and compare between the stand-alone CNN model and hybrid machine learning models with regard to their general effectiveness, giving particular attention to their COVID-19 classifying abilities.

The rest of this paper is structured as follows: Section II provides background and analysis of pre-existing relevant studies. Section III discusses the details of datasets and methodologies used in this study. Section IV presents and discusses

the results of our experiments. Section V concludes the paper by mentioning the most prominent points of this study. Finally, section VI provides ideas that may be implemented in the future.

II. RELATED WORK

Several studies have investigated the use of machine learning techniques to detect COVID-19. Among machine learning algorithms, most researchers used CNN techniques, e.g., Inception (GoogleNet), ResNet (Residual Networks), and DenseNet (Dense Networks), to build the detection models. From the dataset perspective, chest X-Ray images were used more frequently than Computed Tomography (CT) images to develop those models.

Most of the related studies have faced challenges due to a lack of available datasets. Researchers have applied methods such as augmentation and K-fold cross validation to overcome this setback. In [3], the dataset size reached 1,592 images after augmentation, and the authors used the ImageNet dataset and four CNN techniques to build detection models. The accuracy of VGG16 and VGG19 based models were the highest, having achieved a 99.38% accuracy. In contrast, K-fold cross validation was the method used to train the detection models on more data in [4]. In that study, VGG 16 and ResNet50 techniques were used to develop models that distinguish between COVID-19 and pneumonia. The dataset was comprised of 204 images, and their results showed that 89.2% and 80.39% of COVID-19 cases were identified correctly by these techniques, respectively.

In addition to the rarity of available datasets, the quality of obtainable images needs to be enhanced to improve the performance of detection models. To achieve this, the Contrast Limited Adaptive Histogram Equalization (CLAHE) algorithm was applied in [5]. The authors conducted a comparison study to investigate the effect of using CLAHE to enhance covid diagnosis. They compared the detection accuracy of the model when the CLAHE was applied and when the original datasets were used to build the model without applying any image quality enhancement techniques. The accuracy of the developed model increased from 83.00% to 92.00% after the implementation of CLAHE.

Despite COVID-19 dataset challenges, many detection models with acceptable performance have been presented. The transfer learning concept was used to build detection models in previous studies. In [6], the researchers developed a model that detected COVID-19 from chest X-ray images. They used a modified version of VGG-19 by adding a MLP (multilayer perceptron) on top of the VGG-19 model. The accuracy of the model was 96.3%. Additionally, the authors in [7] used seven pre-trained models to develop a deep learning framework that identified COVID-19 cases. Their results showed that VGG19 and DenseNet201 achieved better performance when compared with other models. The accuracy was 90% and the sensitivity was 100% for COVID-19 and 80% for normal images.

Some papers have used hybrid models, meaning they combined multiple models to solve one problem. The authors in [8] used four different types of ensemble learning, feature ensembles, majority voting, feature classification, and class modification, to classify COVID-19 and pneumonia cases.

More specifically, SVM, Bagging Classifier, and AdaBoost were used as classifiers in the models they developed. The accuracy of the combination of Inception V3 and Bagging was 99.36

Table I shows a summary of previous studies that used CNN architectures to build COVID-19 detection models. Along with the performance of detection models, the table illustrates the size of datasets and the CNN technique used.

III. STAND-ALONE CNN MODEL VS. HYBRID MODELS

In this study we have conducted several experiments to investigate the abilities of stand-alone CNN and hybrid models to efficiently and accurately detect COVID-19 in patients. This section presents the datasets and methodologies used in our comparative study.

A. Dataset Collections

As aforementioned, one of the challenges that researchers have faced in previous studies is the limited repository of COVID-19 datasets. Moreover, the datasets that do exist are relatively small. Thus, we used images from four datasets to train and develop our models on COVID-19 cases. For normal cases, we used one dataset. Fig. 1 shows samples of COVID-19 and normal chest X-ray images and Table II illustrates a summary of these datasets.

TABLE I. SUMMARY OF CNN-BASED MODELS FOR COVID-19 DETECTION

Ref.	Dataset size	CNN Technique	Accuracy	Sensitivity	Specificity
A Deep Learning Approach to Detect COVID-19 Patients from Chest X-ray Images [7]	COVID-19 : 295 Normal : 659	Sequential CNN	98.3%	-	-

Fig. 1. Normal and COVID-19 Chest X-Ray Images.

1) *COVID-19 chest X-ray images datasets*: The details of the four COVID-19 chest X-ray image datasets are as follows:

COVID-19_dataset-1: We retrieved this dataset from the Github repository, and it is more popular than any other currently available datasets. It was created and collected by Joseph Paul Cohen, a postdoctoral fellow at Montreal University [13]. The dataset contains 930 images of chest X-ray and CT images of patients with diverse diseases, including both bacterial and viral illnesses, as well as COVID-19 and pneumonia. COVID-19 images alone account for 584 of the dataset's images, with the remainder classified as other. The chest X-ray images are classified into four views, Posterior Anterior (PA), Anterior Posterior (AP), AP Supine, and Lateral.

COVID-19_dataset-2: We obtained the second dataset from the Github repository. It was created by Linda Wang and colleagues from the University of Waterloo in Canada [14]. The dataset contains 238 chest X-ray images, 58 of which are images of patients infected with COVID-19. The COVID-19 images are classified with two views: 32 images are PA and 26 images are AP.

COVID-19_dataset-3: The previous team, Linda Wang and colleagues, created the third dataset as well. This dataset contains 55 chest X-ray images, 35 of which are COVID-19 images and the rest are either Pneumonia or not classified [15].

COVID-19_dataset-4: Dataset 4 is also from the Github repository. It was created by the Institute for Diagnostic and Interventional Radiology at the Hannover Medical School in Hannover, Germany [16]. It contains 243 images of COVID-19 chest X-ray images. Those images include two views: 49 are PA images and 194 images are AP.

2) *Normal Chest X-ray Images Datasets*: The details of the normal chest X-ray image datasets are as follows:

Normal-dataset: We obtained this dataset from the Kaggle website. It was created by Paul Mooney, Developer Advocate at Kaggle [17]. The dataset contains 5,863 chest X-Ray images with two classes, pneumonia and normal. The number of normal images is 1,583 and the number of pneumonia images is 4,273. All images in this dataset were in AP view. To balance our data, we took only 690 normal images from this dataset.

3) *Data Preprocessing*: We converted all images to JPEG format to provide ease by handling only one format type, and to reduce the dataset size to accelerate the training process. Furthermore, we applied normalization to improve image clarity and overall quality. Furthermore, we resized them to 224*224. We tried several rations to split data into train and

TABLE II. DETAILS OF DATASETS USED

Dataset	Medical Images Type	Classes	View	Count of COVID-19 Images	Dataset Size
COVID-chestxray-dataset [13]	X-ray , CT	COVID-19, viral, bacterial, pneumonias	AP, PA, AP Supine, Lateral	504	930
Actualmed-COVID-chest xray-dataset [14]	X-ray	COVID-19 , no finding	PA, AP	58	238
Figure1-COVID -chestxray-dataset [15]	X-ray	COVID-19, pneumonias , no finding	-	35	55
COVID-19-image-repository [16]	X-ray	COVID-19	AP ,PA	243	243
COVID-19-image-repository [16]	X-ray	Pneumonia, Normal	AP	0	5863

test sets. We found that using 60% of data for training the model and 40% for testing it achieved the best performance.

B. Experimental Environment

We used Keras to implement our COVID-19 detection models, which is an open-source library for deep learning applications written in Python [18]. The code was implemented by the Colab environment, a service hosted by Jupyter. The Colab environment provides free access to computing resources, including GPU, which is the most widely used computing technology in artificial intelligence [19]. Additionally, we used TensorFlow as the backend for the machine learning platform [20].

C. Stand-alone CNN Model

As part of our study, we developed a stand-alone CNN model to distinguish between COVID-19 and normal cases. Convolutional neural networks, also known as (CNN), are a specialized kind of neural network used in the computer vision field that contributes to automatic feature extraction and data processing with a known grid-like topology. The CNN architecture has three main layers: convolutional layer, pooling layer, and fully connected layer [21]. The main components of CNN architecture are illustrated in Fig. 2.

Convolutional layer : This layer applies several filters to the input to generate feature maps [21].

Pooling layer : This layer reduces the size of feature maps in terms of reducing the internal dimensions. Max pooling and average pooling are the two operations available in this layer [21].

Fully connected layer : This layer is also called the dense layer. In the fully connected layer, the inputs are connected to the output with a learnable weight and are assigned to the final outputs [21].

Activation function : This is a function used to facilitate knowledge of difficult and complex patterns. It includes sigmoid, tanh, and Rectified Linear Unit (ReLU). The most common is the corrected linear unit (ReLU) [21].

From 1989 to present, improvements have been made in the CNN architecture in terms of number of layers, parameters, and functions. These architectures vary from lightweight to heavyweight structures [23]. From among those architectures, we chose the Visual Geometry Group (VGG-16) architecture to implement our detection models based on information we

Fig. 2. Key Components of CNN Architecture [22].

garnered from the literature review. VGG architecture was proposed by Simonyan and Zisserman in 2014. It includes VGG-11, VGG-11-LRN, VGG-13, VGG-16, and VGG-19. The depth of the layers vary [24].

To develop our detection model, we exploited the principle of transfer learning. We used weights of a pre-trained VGG-16 that were trained on a large dataset called ImageNet. It learned a good representation of low level features like spatial, edges, rotation, lighting, shapes. These features can be integrated to enable the knowledge transfer and act as a feature extractor for new images in different computer vision problems [25].

In our model, we removed the top layer of the pre-trained model to train the model on a new chest X-ray images dataset. For optimization, we used Adam’s algorithm, an effective stochastic optimization method for training deep learning models with a 0.001 learning rate. The number of training epochs was 50 and the batch size for each epoch was 26. The activation function in the hidden layer was ReLU, and sigmoid was used in the last layer because our classification problem is binary. The parameters of our stand-alone CNN model are illustrated in Table III and the model implementation steps are shown in Fig. 3.

D. Hybrid Models

In addition to the stand-alone CNN model, we have developed three hybrid models. Each model consists of a CNN architecture (VGG-16) for feature extraction and one of the following classification algorithms for classification: Support Vector Machine (SVM), Random Forests (RF), and Extreme Gradient Boosting (XGBoost). Fig. 4 shows an illustrative diagram of the proposed hybrid models.

A brief description of the selected classification algorithms follows:

Support Vector Machines (SVM): Essentially, SVM is a classification algorithm which tries to find the plane that separates the classes with the widest margin in the sample space in the most convenient way [26].

Random Forest (RF): RF is a collective classification and regression algorithm that uses decision trees as a classifier. Each decision tree is trained using a random data set derived from the original data set. The majority voting is used for the final classification [26].

Extreme Gradient Boosting (XGBoost): This is a boosting algorithm for classification and regression tree models, which is derived from the gradient lifting decision tree [27].

TABLE III. PARAMETERS OF OUR STAND-ALONE CNN MODEL.

Number of training epochs	50
Batch size	26
Optimization	Adam
Learning rate	0.001
input shape	(224,224,3)
Number of Fully connected layers	2
Number of convolution layers	13
Number of pooling layers	5
Activation function in output layer	Sigmoid

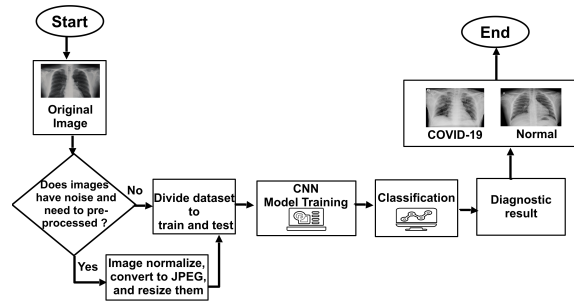

Fig. 3. Implementation Steps of the Stand-alone CNN Model.

We followed several steps to develop our hybrid models, which you can find illustrated in Fig. 5. First, we trained the VGG16 on our dataset. Then, we selected the last max pooling layer, which is the layer that comes after all convolution layers, to extract features. We added a flatten layer after the max pooling layer to handle the dimensionality issues, see Fig. 6. Because we use CNN 16 for the feature extraction part and not for classification, we discarded the fully connected and softmax layers, which are the dense layers after the flatten layer. After that, we used the extracted features to train the classification algorithms and develop models that can distinguish between COVID-19 and normal cases accurately. The number of extracted features is 25,088 features for every single image in the training dataset.

IV. RESULTS AND DISCUSSION

This section outlines the performance metrics we use to evaluate the developed models. Furthermore, it summarizes and discusses the main results of our experiments and presents a discussion related to previous studies.

A. Performance Metrics

We used various evaluation metrics to evaluate the proposed models. These metrics are as follows:

Confusion matrix: This is a technique that summarizes the performance of the classifier used. It presents true positive (TP) and true negative (TN) values, which means the number of correctly rated positive and negative instances. It also shows false positive (FP) and false negative (FN) values, which means the number of misclassified negative and positive instances [28].

Accuracy: Accuracy is the percentage of the test set

Fig. 4. An illustrative Diagram of the Proposed Hybrid Models.

Fig. 5. Implementation Steps of the Hybrid CNN Models.

instances that are correctly classified by the classifier.

$$Accuracy = \frac{TP+TN}{TP+FN+TN+FP} \quad (1)$$

Sensitivity (Recall): Recall is also referred to as the true positive rate, which means the proportion of positive cases that are correctly identified.

$$Sensitivity = \frac{TP}{TP+FN} \quad (2)$$

Specificity: This is the true negative rate. It refers to the proportion of negative instances that are correctly identified.

$$Specificity = \frac{TN}{TN+FP} \quad (3)$$

Precision: Precision is defined as the proportion of the true positives against all the positive results (both true positives and false positives).

$$Precision = \frac{TP}{TP+FP} \quad (4)$$

F1 score: It represents the harmonic mean between recall and precision values.

$$F1score = \frac{2*Precision*Recall}{Precision+Recall} \quad (5)$$

B. Tests Results

In general, the results showed that all of our developed detection models are sufficient, especially the CNN and hybrid (CNN+SVM) models. This finding indicates that both stand-alone and hybrid models could achieve high performances when used to detect COVID-19 cases. Even though all our models are adequate, the CNN+XGBoost model is considered

Model: "sequential"

Layer (type)	Output Shape	Param #
vgg16 (Functional)	(None, 7, 7, 512)	14714688
flatten (Flatten)	(None, 25088)	0
dense (Dense)	(None, 4096)	102764544
dense_1 (Dense)	(None, 4096)	16781312
dense_2 (Dense)	(None, 2)	8194

Fig. 6. The Added Flatten Layer to the VGG-16 Architecture.

the least effective. The values of its accuracy, sensitivity, specificity, precision, and F1-score were 0.9873%, 0.9928%, 0.9874%, 0.9821%, 0.9819%, respectively.

Furthermore, the sensitivity of three models (CNN, CNN+RF, and CNN+SVM) was 100%; however, the CNN+RF model achieved less specificity compared to the two other models. The specificity of the CNN and CNN+SVM models was 0.9964% and it was 0.9855% for the CNN+RF model. Just like the specificity, the accuracy, precision, and F1-score of the CNN and CNN+SVM models were better than those of the two other models. The accuracy, precision, and F1-score of the CNN and CNN+SVM models were 0.9982%, 0.9964%, and 0.9982%, respectively. Also, the accuracy, precision, and F1-score of the CNN+RF model were 0.9928%, 0.9857%, and 0.9929%, respectively. Fig. 7 shows the confusion matrices of the presented models, and Table IV-A summarizes their performances.

Overall, there is not a substantial difference in the performance of our models; all of them are excellent in terms of their ability to detect COVID-19. Besides the stand-alone CNN model, two of the hybrid models, the CNN+SVM and CNN+RF, classified 100% of COVID-19 cases correctly. Nonetheless, there are two main limitations to the generalization of our findings. The first one is the lack of available Covid-19 datasets. The second limitation is that this study focused only on one of the CNN techniques and three machine learning classifiers because of the following constraints: Authors used the Google Colab platform to perform experiments due to the unavailability of powerful computing resources. However, the restrictions in the provided resources that the platform applies prevented them from conducting further investigations. Additionally, this research was not financially supported, and thus researchers only had limited Internet data, and they used personal computers with bounded processing power and memory capacity.

TABLE IV. PERFORMANCE METRICS FOR THE PRESENTED MODELS

	CNN	CNN-RF	CNN-XGBoost	CNN-SVM
Accuracy	0.9982	0.9928	0.9873	0.9982
Sensitivity(Recall)	1.0000	1.0000	0.9928	1.0000
Specificity	0.9964	0.9855	0.9874	0.9964
Precision	0.9964	0.9857	0.9821	0.9964
F1-score	0.9982	0.9929	0.9819	0.9982

C. Discussion Related to Previous Studies

This subsection compares our models with pre-existing models presented in previous studies. These prior models

Fig. 7. Generated Confusion Matrices for a) Stand-alone CNN Model, b) CNN-RF model c) CNN-XGBoost Model, d) CNN-SVM Model

were developed using chest X-ray images and the VGG-16 model as a feature extractor or a classifier. Table V shows the performance for our models as compared to previous models.

In [8], the authors presented a modified CNN based model to detect COVID-19. The model accuracy and sensitivity before modification were 90.19% and 94.16%, respectively. After modifying the last layer of the original model, its performance improved. Its accuracy and sensitivity became 99.52% and 97.93%, respectively. Still, the accuracy and sensitivity of our models are higher. In [5], even though the researchers have used the CLAHE method to enhance their detection model, its performance is still low. Its accuracy was 83%, and then became 92%.

Compared to previous models, a better model has been presented in [3]. Its accuracy was 99.3% and its sensitivity was 99.28%. Our stand-alone model outperformed it. Some factors that lead to that improvement in ours is that the number of COVID-19 images that we used to develop our model is larger compared to these studies, and we have used a balanced dataset as well.

Just like the stand-alone CNN model, our hybrid models outperform those that have been proposed in [8]. Two out of the three classification algorithms that have been used in that paper are different from ours. Authors have selected the following algorithms: SVM, Bagging, and AdaBoost, while we have selected these classification algorithms: SVM, random forest, and XGBoost. As shown in Table V, the SVM is the classifier that leads to developing models with high accuracy in both studies. Our two other algorithms, however, surpassed Bagging and AdaBoost.

V. CONCLUSION

This study addressed some of the challenges of the traditional COVID-19 test method. It exploited the power of machine learning to accelerate the process of detecting COVID-19 and to enhance its efficiency. We investigated the effectiveness of stand-alone CNN models and hybrid machine learning models in detecting the disease. We combined five chest X-Ray images datasets to develop four COVID-19 detection models: a stand-alone CNN model and three hybrid machine learning models. As a comparison to some of the previous studies that have been published in the early few months of the pandemic,

the count of chest X-Ray images that we used to develop our models is considered one of the biggest.

TABLE V. COMPARISON WITH STATE-OF-THE-ART MODELS

Ref.	Model	Accuracy	Sensitivity	Specificity	Precision	F1-Score
[5]	VGG-16	92%	94.92%	92%	-	-
[3]	VGG-16	99.33%	99.28%	99.38%	-	99.28%
[8]	VGG-16	90.19%	94.16%	-	94.12%	94.14%
	VGG-16 & SVM	91.19%	93.15%	-	94.12%	93.63%
	VGG-16 & Bagging	90.19%	92.16%	-	92.22%	92.19%
	VGG-16 & Ada Boot	90.19%	90.10%	-	89.16%	89.63%
Our study	VGG-16	99.82%	100%	99.64%	99.64%	99.82%
	VGG-16 & RF	99.28%	100%	98.55%	98.57%	99.29%
	VGG-16 & XGBoost	98.73%	99.28%	98.74%	98.21%	98.19%
	VGG-16 & SVM	99.82%	100%	99.64%	99.64%	99.82%

Our findings illustrate that all of the four proposed models are effective in detecting COVID-19. The lowest detection accuracy obtained was 98.73% which is the accuracy of the VGG16+XGBoost model. The highest accuracy was 99.82% which is the accuracy of both VGG-16 and(VGG16+SVM) models. Furthermore, one of the most promising findings is that the sensitivity of the VGG-16, (VGG16+SVM), and (VGG16+RF) models is 100%, meaning they have a zero false negative case rate. That means that from all the examined cases, 100% of the COVID-19 positive images were detected. This finding plays an important role in reducing the possibility of spreading the virus to more people.

VI. FUTURE WORK

Several experiments can be conducted to study the effect of different CNN architectures and optimizers on the model's performance. Furthermore, one of the areas that warrants additional study are COVID-19 mutations. It is necessary to develop machine learning and deep learning-based models capable of detecting new versions of COVID-19, such as B.1.1.7, B.1.1.207, P.1 and B.1.525 automatically. Additionally, it is important to build robust models that have the ability to distinguish between SARS, MERS, and COVID-19 accurately.

Abstract—In this paper, we further consider a method for solving the basis pursuit denoising problem (BPDP), which has received considerable attention in signal processing and statistical inference. To this end, a new self-adaptive algorithm is proposed, its global convergence results is established. Furthermore, we also show that the method is sublinearly convergent rate of $O(\frac{1}{k})$. Finally, the availability of given method is shown via some numerical examples.

Keywords—Basis pursuit denoising problem; algorithm; global convergence; sublinearly convergent rate; sparse signal recovery

I. INTRODUCTION

The basis pursuit denoising problem (BPDP) is considered to be an important issue encountered in the fields of signal processing and statistical inference, which is to find a sparse signal $\bar{x} \in R^n$ from linear system $z = A\bar{x}$, and can be mathematically depicted as the following

$$\min_{x \in R^n} F(x) := f(x) + \rho\varphi(x), \quad (1)$$

where $f(x) := \frac{1}{2}\|Ax - z\|_2^2$, $\varphi(x) = \|x\|_1$, $A \in R^{m \times n}$ ($m \ll n$), $\rho > 0$ is a parameter, and the ℓ_1 -norm and ℓ_2 -norm of the vector x are defined by $\|x\|_1 = \sum_{i=1}^n |x_i|$ and $\|x\|_2 = (\sum_{i=1}^n x_i^2)^{1/2}$, respectively. In addition, we denote the solution set of the problem (1) by Ω^* , and $\Omega^* \neq \emptyset$.

Clearly, (1) is an unconstrained convex optimization problem, and some standard algorithms such as the Newton-type algorithms or the conjugate gradient methods to solve it. But, these methods are not suitable for large-scale cases of BPDP, and it even become invalidation as n increases. In recent years, there are a lot of algorithms for solving BPDP have been extensively developed since its appearance. He and Cai et al([1]) introduce a splitting method (MPRSM) for solving Dantzig selector problem, and the BPDP is a special case of this problem. Based on this theory, Sun and Liu et al ([2])further investigate MPRSM for BPDP, and regularize its first subproblem by the proximal regularization. Yang and Zhang ([3]) investigate alternating direction methods for several ℓ_1 -norm minimization, including the basis pursuit problem, the basis-pursuit denoising problems, and so on. Yu et al.([4]) apply the primal Douglas-Rachford splitting method to solve equivalent transformation form of BPDP. In [5], the authors proposed some efficient methods to solve ℓ_1 -norm minimization problems, and are used in BPDP. Zhang and Sun ([6]) presented projection-type method to solve BPDP, its global convergence results of the new algorithm is established. BPDP can be transformed into a smooth optimization problem

by some splitting technique equivalent. some iterative algorithms which can solve smooth optimization problem are applicable to this problem. Xiao and Zhu ([7]) transformed BPDP into a convex constrained monotone equations, and presented a conjugate gradient method for the equivalent the forms. Sun and Tian ([8]) give a derivative-free conjugate gradient projection algorithms for non-smooth equations with convex constraints. Sun et al. ([9]) reformulated BPDP as variational inequality problem, and proposed a novelly inverse matrix-free proximal point algorithm. Base on the same transformation of ([9]), Feng and Wang ([10]) also proposed a projection-type algorithm. Although there are so many ways to solve it, the solving speed and accuracy are still need improved. In the paper, we further consider a new self-adaptive method to solve BPDP, which this method is sublinearly convergent rate, the motivation behind this is for the better numerical performance when the dimension increases.

The rest of this paper is organized below. In Section 2, some related properties are given, which are the basis of our analysis. We present a new self-adaptive algorithm with Armijo-like line search to solve BPDP, and show that this method is global convergence in detail. Furthermore, the sublinearly convergent rate of $O(\frac{1}{k})$ is presented. In Section 3, we give some numerical experiments on BPDP for sparse signal recovery to show availability of the presented algorithm. Finally, some results are described in Section 4.

In the end of this section, we give some notations used in this paper. Use \mathcal{R}^N to denote an N -dimensional Euclidean space with the standard inner product. For vectors $x, y \in \mathcal{R}^M$, we use $\langle x, y \rangle$ to denote the standard inner product. We denote the standard l_1 -norm and l_2 -norm by $\|\cdot\|_1$ and $\|\cdot\|$, respectively.

II. ALGORITHM AND CONVERGENCE

In this section, we will present a new iterative algorithm with Armijo-like line search to solve BPDP, and the global convergence and sublinearly convergent rate of new algorithm is proved in detail. To this end, we give some needed preliminaries which will be used in the sequel.

Definition 2.1: ([11]) Set $f : \mathcal{R}^N \rightarrow \mathcal{R}$ be convex. The subdifferential of f at x is defined as

$$\partial f(x) = \{\xi \in \mathcal{R}^N | f(y) \geq f(x) + \langle \xi, y - x \rangle, \forall y \in \mathcal{R}^N\}.$$

For $F(x)$ involved in (1), we establish quadratic approxi-

mation of $F(x)$ below:

$$Q_L(x, y) := \left[f(y) + \langle x - y, \nabla f(y) \rangle + \frac{L}{2} \|x - y\|^2 \right] + \rho\varphi(x), \quad \forall L > 0. \quad (1)$$

Let

$$p_L(y) = \arg \min_{x \in R^n} \{Q_L(x, y)\}, \quad (2)$$

and (2) can be further written as:

$$p_L(y) = \arg \min \left\{ \rho\varphi(x) + \frac{L}{2} \left\| x - \left(y - \frac{1}{L} \nabla f(y) \right) \right\|^2 \right\}. \quad (3)$$

Next, we recall Lemma 2.1 below, which is fundamental property for smooth function in the class $C^{1,1}$. It will be crucial for the convergence analyses of our algorithm below.

Lemma 2.1: (Lemma 3.2. [12],[13]) Let $f : \mathcal{R}^N \rightarrow \mathcal{R}$ be a continuously differentiable function with constant L_f . Then, for any $L \geq L_f$, one has

$$f(x) \leq [f(y) + \langle x - y, \nabla f(y) \rangle + \frac{L}{2} \|x - y\|^2], \forall x, y \in \mathcal{R}^N. \quad (4)$$

From Lemma 2.1, if $L \geq L_f$, then for any $y \in R^n$, one has

$$\begin{aligned} F(p_L(y)) &= f(p_L(y)) + \rho\varphi(p_L(y)) \\ &\leq [f(y) + \langle p_L(y) - y, \nabla f(y) \rangle \\ &\quad + \frac{L}{2} \|p_L(y) - y\|^2] + \rho\varphi(p_L(y)) \\ &= Q_L(p_L(y), y). \end{aligned} \quad (5)$$

Now, we formally state our algorithm for model (1) as follows.

Algorithm 2.1.

Step0. Choose $\beta > 0$, $\epsilon \geq 0$, some $\eta > 1$, $\gamma \in (0, 1)$, and an initial point $x^0 \in R^n$, and let $k := 0$.

Step1. For $k = 1, 2, \dots$, update the next iterate x^k via

$$(x^k)_i = \begin{cases} (\theta_k)_i + \frac{\sigma}{L_k} & \text{if } (\theta_k)_i < -\frac{\sigma}{L_k} \\ 0 & \text{if } |(\theta_k)_i| \leq \frac{\sigma}{L_k} \\ (\theta_k)_i - \frac{\sigma}{L_k} & \text{if } (\theta_k)_i > \frac{\sigma}{L_k} \end{cases} \quad (6)$$

where $\theta_k = x^{k-1} - \frac{1}{L_k} \nabla f(x^{k-1})$, $L_k = \eta^{m_k} \beta$, and m_k is the smallest integer $m \geq 0$ such that

$$f(x^k) \leq f(x^{k-1}) + \langle x^k - x^{k-1}, \nabla f(x^{k-1}) \rangle + \frac{\eta^{m_k} \beta}{2} \|x^k - x^{k-1}\|^2. \quad (7)$$

Step2. If $\|x^k - x^{k-1}\| \leq \epsilon$, stop. Then, x^k is a solution of (1). Otherwise, go to Step 1 with $k \triangleq k + 1$.

Remark 2.1: By the subdifferential of the absolute value function $|t|$, which be given as follows:

$$\partial(|t|) = \begin{cases} -1 & \text{if } t < 0, \\ [-1, 1] & \text{if } t = 0, \\ 1 & \text{if } t > 0. \end{cases}$$

Combining this with (7), we obtain the following results.

If $(\theta_k)_i < -\frac{\sigma}{L_k}$, then $(x^k)_i = (\theta_k)_i + \frac{\sigma}{L_k} < 0$, i.e., $(x^k)_i = (\theta_k)_i - \frac{\sigma}{L_k} \frac{\partial\varphi(x^k)}{\partial x_i}$, where $\frac{\partial\varphi(x^k)}{\partial x_i} = -1$.

If $(\theta_k)_i > \frac{\sigma}{L_k}$, then $(x^k)_i = (\theta_k)_i - \frac{\sigma}{L_k} > 0$, i.e., $(x^k)_i = (\theta_k)_i - \frac{\sigma}{L_k} \frac{\partial\varphi(x^k)}{\partial x_i}$, where $\frac{\partial\varphi(x^k)}{\partial x_i} = 1$.

If $|(\theta_k)_i| \leq \frac{\sigma}{L_k}$, then $|(\theta_k)_i| / \frac{\sigma}{L_k} \leq 1$. From $(x^k)_i = 0$, one has $(x^k)_i = 0 = (\theta_k)_i + \frac{\sigma}{L_k} (\theta_k)_i / \frac{\sigma}{L_k} = (\theta_k)_i - \frac{\sigma}{L_k} \frac{\partial\varphi(x^k)}{\partial x_i}$, where $\frac{\partial\varphi(x^k)}{\partial x_i} = (\theta_k)_i / \frac{\sigma}{L_k}$. By the above analysis, we have

$$x^k = \theta_k - \frac{\sigma}{L_k} \partial\varphi(x^k),$$

i.e.,

$$\sigma \partial\varphi(x^k) + \nabla f(x^{k-1}) + L_k(x^k - x^{k-1}) = 0. \quad (8)$$

Remark 2.2: Combining (7) with Lemma 2.2, we know that

$$\eta^{m_k} \beta = L_k \geq L_f = \|A^\top A\| \quad (9)$$

for some m . In addition, we know that L_k/η must violate (7), i.e., $L_k < \eta \|A^\top A\|$. Thus, we obtain

$$\|A^\top A\| \leq L_k < \eta \|A^\top A\|. \quad (10)$$

Using $L_k = \eta^{m_k} \beta$ and $\eta > 1$, one has $\beta < L_k$ for every $k \geq 1$. Hence, $\beta < \eta \|A^\top A\|$.

Next, we will discuss global convergence results and sub-linearly convergent rate of the proposed method. To this end, we present some lemmas below.

Lemma 2.2: The sequence $\{F(x^k)\}$ generated by Algorithm 2.1 is non-increasing.

Proof: For any $k \geq 1$, we have

$$\begin{aligned} F(x^k) &= f(x^k) + \rho\varphi(x^k) \\ &\leq f(x^{k-1}) + \langle x^k - x^{k-1}, \nabla f(x^{k-1}) \rangle \\ &\quad + \frac{L_k}{2} \|x^k - x^{k-1}\|^2 + \rho\varphi(x^k) \\ &= Q_{L_k}(x^k, x^{k-1}) \\ &\leq Q_{L_k}(x^{k-1}, x^{k-1}) \\ &= F(x^{k-1}), \end{aligned} \quad (11)$$

where the first inequality is obtained by using (4) with $y = x^{k-1}$, $x = x^k$ and $L = L_k$, the second inequality follows from (2) and (6). Thus, the desired result follows.

Lemma 2.3: For any $x \in R^n$, and $k \geq 1$, we have

$$F(x) - F(x^k) \geq \frac{L_k}{2} \|x^k - x^{k-1}\|^2 + L_k \langle x - x^{k-1}, x^{k-1} - x^k \rangle. \quad (12)$$

Proof: By (5), one has

$$F(p_{L_k}(x^{k-1})) \leq Q_{L_k}(p_{L_k}(x^{k-1}), x^{k-1}). \quad (13)$$

By (6), one has $x^k = p_{L_k}(x^{k-1})$. Combining this with (13), we obtain

$$F(x) - F(x^k) \geq F(x) - Q_{L_k}(x^k, x^{k-1}). \quad (14)$$

Since f and φ are convex, we can deduce

$$\begin{aligned} F(x) &= f(x) + \sigma\varphi(x) \\ &\geq [f(x^{k-1}) + \langle x - x^{k-1}, \nabla f(x^{k-1}) \rangle] \\ &\quad + [\sigma\varphi(x^k) + \sigma\langle x - x^k, \xi^k \rangle], \end{aligned} \quad (15)$$

where $\xi^k \in \partial\varphi(x^k)$. Using (1) with $x = x^k, y = x^{k-1}$, one has

$$\begin{aligned} Q_{L_k}(x^k, x^{k-1}) &= [f(x^{k-1}) + \langle x^k - x^{k-1}, \nabla f(x^{k-1}) \rangle] \\ &\quad + \frac{L_k}{2} \|x^k - x^{k-1}\|^2 + \sigma\varphi(x^k). \end{aligned} \quad (16)$$

Applying (15), (16) and (14), we have

$$\begin{aligned} F(x) - F(x^k) &\geq F(x) - Q_{L_k}(x^k, x^{k-1}) \\ &\geq \langle x - x^k, \nabla f(x^{k-1}) + \sigma\partial\varphi(x^k) \rangle \\ &\quad - \frac{L_k}{2} \|x^k - x^{k-1}\|^2 \\ &= L_k \langle x - x^k, x^{k-1} - x^k \rangle - \frac{L_k}{2} \|x^k - x^{k-1}\|^2 \\ &= L_k \langle (x - x^{k-1}) + (x^{k-1} - x^k), x^{k-1} - x^k \rangle \\ &\quad - \frac{L_k}{2} \|x^k - x^{k-1}\|^2 \\ &= L_k \langle x - x^{k-1}, x^{k-1} - x^k \rangle + \frac{L_k}{2} \|x^k - x^{k-1}\|^2. \end{aligned} \quad (17)$$

where the first equality holds by (8).

Theorem 2.1: Suppose that x^* be an arbitrary solution of (1), and $\{x^k\}$ be sequence generated by Algorithm 2.1. Then, for any $k \geq 1$, one has

$$F(x^k) - F(x^*) \leq \frac{\eta \|A^\top A\|}{2k} \|x^* - x^0\|^2. \quad (18)$$

Proof: Applying Lemma 2.3 with $x = x^*, k = m$, one has

$$\begin{aligned} &\frac{2}{L^m} (F(x^*) - F(x^m)) \\ &\geq \|x^m - x^{m-1}\|^2 + 2 \langle x^* - x^{m-1}, x^{m-1} - x^m \rangle \\ &= \|x^m - x^{m-1}\|^2 \\ &\quad + \langle (x^* - x^m) + (x^m - x^{m-1}), x^{m-1} - x^m \rangle \\ &\quad + \langle x^* - x^{m-1}, (x^{m-1} - x^*) + (x^* - x^m) \rangle \\ &= \langle x^* - x^m, x^{m-1} - x^m \rangle \\ &\quad + \langle x^* - x^{m-1}, x^{m-1} - x^* \rangle + \langle x^* - x^{m-1}, x^* - x^m \rangle \\ &= \langle x^* - x^m, (x^{m-1} - x^*) + (x^* - x^m) \rangle \\ &\quad + \langle x^* - x^{m-1}, x^{m-1} - x^* \rangle + \langle x^* - x^{m-1}, x^* - x^m \rangle \\ &= \|x^* - x^m\|^2 - \|x^* - x^{m-1}\|^2. \end{aligned} \quad (19)$$

Since x^* be a solution of (1), then one has $F(x^*) - F(x^k) \leq 0$. Combining this with (10), we obtain

$$\begin{aligned} &\frac{2}{\eta \|A^\top A\|} (F(x^*) - F(x^m)) \\ &\geq \frac{2}{L^m} (F(x^*) - F(x^m)) \\ &\geq \|x^* - x^m\|^2 - \|x^* - x^{m-1}\|^2. \end{aligned} \quad (20)$$

where where the second inequality is by (19). By (20), we can deduce

$$\frac{2}{\eta \|A^\top A\|} [kF(x^*) - \sum_{m=1}^k F(x^m)] \geq \|x^* - x^k\|^2 - \|x^* - x^0\|^2. \quad (21)$$

Applying (12) with $x = x^{m-1}, k = m$, we deduce

$$\frac{2}{L_m} (F(x^{m-1}) - F(x^m)) \geq \|x^m - x^{m-1}\|^2. \quad (22)$$

By Lemma 2.2, one has $F(x^{m-1}) - F(x^m) \geq 0$, combining (22) with (10), we obtain

$$\frac{2}{\|A^\top A\|} (F(x^{m-1}) - F(x^m)) \geq \|x^m - x^{m-1}\|^2, \quad (23)$$

i.e.,

$$\begin{aligned} &\frac{2}{\|A^\top A\|} [(m-1)F(x^{m-1}) - mF(x^m) + F(x^m)] \\ &\geq (m-1) \|x^m - x^{m-1}\|^2. \end{aligned} \quad (24)$$

By (24), we can deduce

$$\begin{aligned} &\frac{2}{\eta \|A^\top A\|} [-kF(x^k) + \sum_{m=1}^k F(x^m)] \\ &\geq \frac{1}{\eta} \sum_{m=1}^k (m-1) \|x^m - x^{m-1}\|^2. \end{aligned} \quad (25)$$

Adding (21) and (25), we have

$$\begin{aligned} &\frac{2k}{\eta \|A^\top A\|} (F(x^*) - F(x^k)) \\ &\geq \|x^* - x^k\|^2 \\ &\quad + \frac{1}{\eta} \sum_{m=1}^k (m-1) \|x^m - x^{m-1}\|^2 - \|x^* - x^0\|^2 \\ &\geq -\|x^* - x^0\|^2. \end{aligned} \quad (26)$$

Combining this with the fact $F(x^*) - F(x^k) \leq 0$, we obtain

$$\frac{2k}{\eta \|A^\top A\|} (F(x^k) - F(x^*)) \leq \|x^* - x^0\|^2. \quad (27)$$

Thus, the desired result follows.

Remark 2.3: Theorem 2.1 indicates that we can obtain an ϵ -optimal solution, denoted by \bar{x} , and requires the number of iterations at most $\lceil c/\epsilon \rceil$ such that $F(\bar{x}) - F(x^*) \leq \epsilon$, where $c = \frac{\eta \|A^\top A\| \|x^0 - x^*\|^2}{2}$.

Theorem 2.2: Suppose that Ω^* is bounded. Then, the $\{x^k\}$ generated by Algorithm 2.1 converges globally to a solution of (1).

Proof: By (11), using $F(x) \geq 0$, we know that $\{F(x^k)\}$ be convergent. Combining this with (23), one has

$$\lim_{k \rightarrow \infty} \|x^k - x^{k-1}\| = 0. \quad (28)$$

Applying (19) and the fact $F(x^*) - F(x^k) \leq 0$, we have

$$\|x^* - x^k\| \leq \|x^* - x^{k-1}\|. \quad (29)$$

By (29), then the nonnegative sequence $\{\|x^k - x^*\|\}$ is decreasing, so it converges. Since the solution set of (1) is bounded. Thus, $\{x^k\}$ is bounded, and let $\{x^{k_i}\}$ be a subsequence of $\{x^k\}$ and converges toward \bar{x} , combining this with (28), one has

$$\begin{aligned} \lim_{i \rightarrow \infty} \|x^{k_i-1} - \bar{x}\| &\leq \lim_{i \rightarrow \infty} \|x^{k_i} - x^{k_i-1}\| \\ &\quad + \lim_{i \rightarrow \infty} \|x^{k_i} - \bar{x}\| \\ &= 0. \end{aligned} \quad (30)$$

From (8), one has $\sigma\partial\varphi(x^{k_i}) + \nabla f(x^{k_i-1}) + L_{k_i}(x^{k_i} - x^{k_i-1}) = 0$. Combining this with (30) and (28), one has

$$\begin{aligned} \|\sigma\partial\varphi(\bar{x}) + \nabla f(\bar{x})\| &= \lim_{i \rightarrow \infty} \|\sigma\partial\varphi(x^{k_i}) + \nabla f(x^{k_i-1})\| \\ &= \lim_{i \rightarrow \infty} L_{k_i} \|x^{k_i} - x^{k_i-1}\| \\ &= 0. \end{aligned} \quad (31)$$

Since the function $F(x)$ be convex, combining this with (31), we have \bar{x} is a solution of (1). As a result, the \bar{x} can be used as x^* to discussion of Theorem 2.1 above. Thus, we obtain that the sequence $\{\|x^k - \bar{x}\|\}$ also converges, combining $\lim_{i \rightarrow \infty} \|x^{k_i} - \bar{x}\| = 0$, we have $\lim_{k \rightarrow \infty} \|x^k - \bar{x}\| = 0$. i.e. $\{x^k\}$ converges globally toward \bar{x} .

Remark 2.4: By (28), we know that the termination criteria in Step2 of Algorithm 2.1 is reasonable.

III. NUMERICAL RESULTS

In this section, we present some numerical experiments about BPDP to show availability for Algorithm 2.1. All of codes are written by MATLAB 9.2.0.538062 and performed on a Windows 10 PC with an AMD FX-7500 Radeon R7,10 Computer Cores 4C+6G CPU, 2.10GHz CPU and 8GB of memory. In these experiments, let

$$\mu = 0.001, n = 2^{11}, m = \text{floor}(n/4), k = \text{floor}(m/8),$$

and sensing matrix A is generated by MATLAB scripts below:

$$[Q, R] = \text{qr}(A', 0); A = Q'.$$

The initial signal \bar{x} is generated by

$$p = \text{randperm}(n); x(p(1:k)) = \text{randn}(k, 1).$$

We set the stop criterion is

$$\frac{\|F_k - F_{k-1}\|}{\|F_{k-1}\|} < 10^{-10},$$

where $F_k = F(x_k)$. The relative error is calculated by

$$\text{RelErr} = \frac{\|\hat{x} - \bar{x}\|}{\|\bar{x}\|},$$

where the recovery signal be denoted by \hat{x} .

A. Test on additive Gaussian white Noise

In this subsection, apply Algorithm 2.1 to recover a simulated sparse signal which observation data is corrupted by additive Gaussian white noise. We set

$$n = 2^{11}, m = 2^9, k = 2^6.$$

The original signal, the measurement and the reconstructed signal (marked by red point) by Algorithm 2.1 are given in Fig.1. Obviously, from the first and the third plots in Fig.1, all elements in the original signal are circled by the red points, which indicates that the Algorithm 2.1 can recover the original signal quite well.

On the other hand, use a same technique in [8] to create another type of matrix A . Using the parameters above, the original signal, the measurement and the reconstructed signal (marked by red point) by the Algorithm 2.1 is given in Fig.2. It can be concluded that our algorithm is can also reconstruct the original signal in [8].

Fig. 1. Signal Recovery Result.

Fig. 2. Signal Recovery Result (Matrix A is Generated by [8]).

B. Compare with Different k -Sparse Signal ($n = 2^{11}, m = 2^9$)

In this subsection, we compare the CPU Time and the RelErr among Algorithm 2.1, Algorithm 3.1 in [2] (PPRSM) and Algorithm 3.1 in [10] (LAPM). All algorithms have run 5 times, respectively, and the average of the the CPU Time and the RelErr are obtained. Some parameters about algorithms above are listed as follows:

Algorithms 2.1: $\beta = 4, \eta = 3, \sigma = 0.01, \gamma = 0.5$.

PPRSM: $\gamma = 0.2, \sigma = 0.1$.

LAPM: $\beta = 0.25; \tau = 0.6$;

The numerical results are listed in Table I. From the table, we can drive that CPU time of Algorithm 2.1 are obviously less than other algorithms in different k -Sparse signal whether it is Free noise or Gaussian noise. In addition, we can not only know that the running speed is faster than other algorithms, but also that our algorithm is more accurate than other algorithms, which shows that Algorithm 2.1 is batter than PPRSM and LAPM.

IV. CONCLUSION

In this paper, we consider a new self-adaptive method to solve the basis pursuit denoising problem (BPDP), which has received considerable attention in signal processing and statistical inference. Global convergence result of this method is given in detail. Furthermore, the global sublinearly convergent rate of the method also is shown. Finally, some numerical

TABLE I. COMPARE WITH DIFFERENT K-SPARSE SIGNAL WITH FREE NOISE OR GAUSSIAN NOISE

k-Sparse signal	Methods	No noise		Gaussian noise	
		CPU Time	RelErr	CPU Time	RelErr
60	Algorithm 2.1	2.4215	4.6268	2.2801	4.6119
	PPRSM	3.8147	4.6324	3.9575	4.9572
	LAPM	5.9058	4.4218	6.8491	4.6555
80	Algorithm 2.1	3.8112	4.1989	3.4419	4.3016
	PPRSM	5.0971	4.4387	5.4456	4.9157
	LAPM	8.6797	4.4898	9.0344	4.3922
100	Algorithm 2.1	4.1165	4.8924	4.3346	4.5957
	PPRSM	6.7260	4.7547	7.3171	4.0318
	LAPM	11.7922	4.6787	12.6948	4.7655

results illustrate that this algorithm is valid for the given tests on sparse signal recovery.

According to its limitations, this work has several possible extensions. Firstly, the parameters of Algorithm 3.1 is adjusted dynamically to further enhance the efficiency of the corresponding method. Secondly, we may established error bound for (1) just as was done for GLCP in [14], [15], [16], [17], and may use the error bound estimation to establish quick convergence rate of the new Algorithm for solving (1). This is a topic for future research.

Abstract—The inability to control the limbs is the main reason that affects the daily activities of the disabled which causes social restrictions and isolation. More studies were performed to help disabilities for easy communication with the outside world and others. Various techniques are designed to help the disabled in carrying out daily activities easily. Among these technologies is the Smart Wheelchair. This research aims to develop a smart eye-controlled wheelchair whose movement depends on eye movement tracking. The proposed Wheelchair is simple in design and easy to use with low cost compared with previous Wheelchairs. The eye movement was detected through a camera fixed on the chair. The user's gaze direction is obtained from the captured image after some processing and analysis. The order is sent to the Arduino Uno board which controls the wheelchair movement. The Wheelchair performance was checked using different volunteers and its accuracy reached 94.4% with a very short response time compared with the other existing chairs.

Keywords—Dilip; numpy; gaze ratio; facial landmarks points; deep learning

I. INTRODUCTION

Wheelchairs have become essential for the elderly and the disabled nowadays. Electric wheelchairs are available on the market and are typically controlled using a joystick [1]. In some cases, many people can be injured unexpectedly during various events, including falls, accidents, violence, or even injuries while playing sports. These events may result in devastating neuromuscular disorders, resulting in significant disabilities as a result of injuries to the spinal cord, which may be caused by a lack of nerve supply, paralyzing every affected part of the human body. As a result, there is an emerging need to assist these people in improving their abilities to carry out their daily routine without the assistance of others. [2]. This was a strong motivation for issuing this research paper, different systems were used to control wheelchairs, such as the voice control system [3], brain control system [4], and eye control system [5]. In the voice control system, the Wheelchair is controlled by the sound so that the user gives voice commands such as forward, right, left, and stop, and the system will recognize the word then send the command to move the Wheelchair accordingly. The Wheelchair controlled by the brain signals depends on capturing the patient's so-called EEG signal to move the chair. The downsides of these systems include a reduced immunity to noise, which might cause the system to become distracted and respond incorrectly.

This research focuses on designing a wheelchair that doesn't depend on any physical movement of the user but tracks the motion of the eye with achieving better accuracy than others also, minimizing the delay response time of the detection. The proposed eye-tracking electric wheelchair differs from others with good validation parameters of the controller which uses simple equations depend on counting the white pixels in both eyes to identify the eye pupil position and direction in the user's face. The main idea of this work depends on capturing the user's image using a webcam. some image processing techniques were performed to determine the location of the face, the eye, and its direction, and then control the Wheelchair via the Arduino board [6]. The face detection technique is a computer technology used to detect the human face from a digital image based on facial landmark points. It is considered as a set of key points on human face images [7]. These points are described in the image by their actual coordinates (x, y). A pictorial image has been used to model the facial landmarks relations, as shown in Fig. 1.

This figure is an example of a facial landmark 68 points model (from 1 to 68). After face detection, the system can detect the eye gaze. Then, the process of detecting the position of the eye sclera is performed by calculating the value of the gaze ratio. The gaze ratio is the ratio of the white pixels between each side in both eyes. This ratio allows determining the area at which the person is looking [8,9,10].

The proposed smart wheelchair contributes to facilitating the lives of the disabled and making their lives easier and reducing their financial burden. Also, improving the accuracy and reducing the time between the user's eye and chair movements than other wheelchairs.

Fig. 1. Facial Landmark Points.

II. RELATED WORK

The technology that allows extensive use of eye-tracking principles includes sectors in the automotive industry, medical science, exhaustion simulation, automobile simulators, cognitive tests, computer vision, behavior recognition, etc. Over a while, the importance of eye recognition and monitoring in industrial applications grew. This importance of eye-tracking applications leads to more effective and durable designs required in many modern appliances. An extensive review of the literature relating to the eye-tracking system has been carried out in healthcare applications.

The authors in [11] uses machine learning to extract the iris by segmentation algorithm. All experiments were implemented using the MATLAB software, the algorithm accuracy reached to 86% which is not satisfactory, also the authors mentioned that the speed of detection increased but did not mention its value.

A wheelchair is designed in [12], which is based on eye movement. This chair consists of three main parts: imaging processing module, wheelchair-controlled module, SMS manager module, and appliance-controlled module. The imaging processing module consists of a camera installed with glasses. The captured image is transferred to the Raspberry Pi microcontroller will be processed using OpenCV to derive the direction of the two-dimensional eyeball. The eyeball movement will be transmitted wirelessly to a unit controlled by a wheelchair to control movement. But the Calibration time is not calculated. Their proposed chair is relatively high cost and lack of components. A microcontroller called Raspberry Pi were used which may cost up to 70\$, But our proposed system used the Arduino Uno, which doesn't exceed 10 \$ and it reaches the same result.

In [13], the researcher designed a wheelchair that moves by eye-tracking, first the camera capture the user image and detect the eye position by edge detection technique (Laplacian), Then detect the pupil direction by segmentation algorithm (Haar cascade algorithm) then, controlling the wheelchair DC motor with the help of a PID controller. The accuracy of detection was 90%. But Calibration time is not calculated, also, the Laplacian technique is unacceptably sensitive to noise. Haar cascade is an algorithm that depends on edge or line detection so it's suitable for face and eye detection but not suitable to detect eye movement.

The main idea in [14] is that the Wheelchair is controlled by the eyeball movement with the aid of a webcam, which further undergoes multiple image processing techniques. Continuous image is captured to detect the eye pupil's location; then, the Haar cascade algorithm is applied with the wheelchair image processing techniques. The DC motor is mounted on the wheels for quick wheelchair travel. The ultrasonic sensor is mounted on the Wheelchair to locate any obstacles in the direction of its movements and prevents the movement of the Wheelchair as per sensor order. The chair accuracy was 91% which needs improvement. Also, Haar cascade is multiple weak classifiers as mentioned before in this application and the wheelchair move in 4 direction, doesn't move in 360° as our proposed wheelchair move in 360° in the direction of the eyes.

In [15], a wheelchair-based eye-tracking system is presented, which is based on record a video to user's face using an infrared camera, the video is then fed into the proposed algorithm that of six stages: (1) eye area extraction, (2) iris boundary detection, (3) keyframe detection, (4) pupil localization, (5) deviation estimation, and (6) evaluation of strabismus. A database was created that included cover test data from both strabismus and normal subjects. The results of the experiments show that our proposed method can accurately evaluate strabismus deviation. The accuracy was over 91%, in the horizontal direction, and it was over 86% in the vertical direction. The only drawback is that measuring accuracy can improve.

The authors in [16] propose a system that enables a person to have a control wheelchair across the eye gaze. The system consists of a wheelchair, eye-tracking glasses, and a depth camera, Ambient Space Engineering, Portable Computer Sit Flexible Stand for Maximum comfort, and a safety off switch to turn off the system when needed. The author uses the CNN algorithm to capture the eye and calculate its direction. The accuracy of their study reached 92% and the calibration time reached 36 s. CNN algorithm is not preferred in face and eye detections as it is complex. Also, from the results that the calibration time is very long 36 s.

The proposed system is based on the deep Learning base method which has better accuracy in all face parts detection and an easy method to extract eyes Using the dlib and his Face Landmark points.

III. PROPOSED SYSTEM ARCHITECTURE

The proposed system is simple and has low-cost components, as shown in Fig. 2. It is based on taking the user's face image. Getting the eye's location and then determining the pupil's direction which has a different value. The obtained values are transmitted to the Arduino board connected to a wheelchair to control its moving directions. The designed Wheelchair consists of an integrated circuit called L293d and a motor of the type of DC that works from 3 to 6 V.

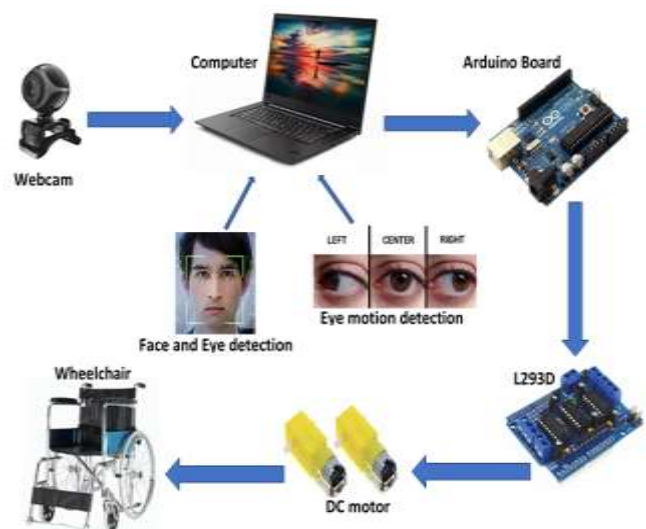

Fig. 2. Proposed System Architecture.

Face and eye detection are determined; then calculate the gaze ratio, which determines the eye direction is (left or right or center). The Arduino Uno is used with an L293D integrated circuit, which is a typical Motor driver or Motor Driver IC. L293D is a 16-pin IC that can control two DC motors simultaneously in any direction and then control in Wheelchair. 5 adult volunteers aged 15 to 50 years old are examined in this study.

This study presents a Technique depend on an algorithm is called "One Millisecond Face Alignment with an Ensemble of Regression Trees" developed by two Swedish Computer Vision researchers Kazemi and Sullivan in 2014[17,18], This detector is built in the dlib library and it detects facial landmarks very quickly and accurately and this algorithm is based on dividing the face into 68 points, Beside the pre-trained facial landmark detector inside the dlib library is used to estimate the location of 68 (x, y)-coordinates that map to facial structures on the face, This occurs by calling a frontal face detector from dlib library. This is a pre-trained detector based on Histogram of Oriented Gradients (HOG) features and a Linear SVM object detector [19]. And the dataset on which the dlib facial landmark was trained in the shape predictor 68 face landmarks" dataset. The facial landmarks with dlib technique don't need any preprocessing or filters but need a high-efficiency camera with strong lenses and high focus, The more efficient the camera, the higher accuracy of eye-tracking.

IV. METHOD

This work used a computational efficient technique to precisely predict the position of face landmarks. A cascade of regressors is used in our proposed strategy.

A. The Cascade of Regressors

To begin we introduce some notation. Let $x_i \in \mathbb{R}^2$ be the x, y-coordinates of the i^{th} facial landmark in an image I. Then the vector $S = (x_1^T, x_2^T, \dots, x_p^T)^T \in \mathbb{R}^{2p}$ denotes the coordinates of all the p facial landmarks in I. In this paper, the vector S is referred to as the shape. And $S^{\wedge}(t)$ is used to denote our current estimate of S. Each regressor, $r_t(\cdot, \cdot)$, in the cascade predicts an update vector from the image and $S^{\wedge}(t)$ that is added to the current shape estimate $S^{\wedge}(t)$ to improve the estimate:

$$S^{\wedge}(t+1) = S^{\wedge}(t) + r_t(I, S^{\wedge}(t)) \quad (1)$$

The regressor r_t makes its predictions based on features, such as pixel intensity values, computed from I and indexed relative to the current shape estimate $S^{\wedge}(t)$ [16]. We will explain how this indexing is performed in detail.

1) *Learning each regressor in the cascade:* Assume we have training data $(I_1, S_1), \dots, (I_n, S_n)$. To learn the first regression function r_0 in the cascade we create from our training data triplets of a face image, an initial shape estimate is obtained by,

$$(I_{\pi_i}, s_i^{\wedge 0}, \Delta s_i^{\wedge 0}) \text{ where } \pi_i \in \{1, \dots, n\} \quad (2)$$

$$s_i^{\wedge 0} \in \{S_1, \dots, S_n\} \setminus S_{\pi_i} \quad (3)$$

$$\text{And } \Delta s_i^{\wedge 0} = S_{\pi_i} - s_i^{\wedge 0} \quad (4)$$

For $i = 1, \dots, N$, $N = nR$ where R is the number of initializations used per image I, And by algorithm 1. The next regressor r_i in the cascade by setting (with $t = 0$) is obtained by:-

$$s_i^{\wedge(t+1)} = s_i^{\wedge(t)} + r_i(I_{\pi_i}, s_i^{\wedge(t)}) \quad (5)$$

$$\Delta s_i^{\wedge(t+1)} = S_{\pi_i} - s_i^{\wedge(t+1)} \quad (6)$$

This process is iterated until a cascade of T regressors r_0, r_1, \dots, r_{T-1} are learned which when combined give a sufficient level of accuracy.

2) Learning r_t in the cascade:

Have training data $\{(I_{\pi_i}, s_i^{\wedge(t)}, \Delta s_i^{\wedge(t)})\}_{i=1, N}$ and the learning rate

(shrinkage factor) $0 < v < 1$

Initialize

$$f_0(I, S^{\wedge(t)}) = \arg \min \sum_{i=1}^N \|\Delta s_i^{\wedge(t)} - \gamma\|^2$$

$\gamma \in \mathbb{R}^{2p}$

2. for $k = 1, \dots, K$:

(a) Set for $i = 1, \dots, N$

$$r_{ik} = \Delta s_i^{\wedge(t)} - f_{k-1}(I_{\pi_i}, s_i^{\wedge(t)})$$

(b) Fit a regression tree to the targets r_{ik} giving a weak regression function $g_k(I, S^{\wedge(t)})$.

(c) Update

$$f_k(I, S^{\wedge(t)}) = f_{k-1}(I, S^{\wedge(t)}) + v g_k(I, S^{\wedge(t)})$$

3. Output $r_t(I, S^{\wedge(t)}) = f_k(I, S^{\wedge(t)})$

B. Tree based Regressor

Now we'll go through the most important implementation details for training each regression tree.

Shape invariant split tests

We make a decision based on thresholding the difference between the intensities of two pixels at each split node in the regression tree. When defined in the coordinate system of the mean shape, the pixels used in the test are at positions u and v. Let k_u be the index of the facial landmark in the mean shape that is closest to u and define its offset from u as:

$$\delta x_u = u - x^{-k_u} \quad (7)$$

Then for a shape, S_i defined in image I_i , the mean shape image is given by

$$u^- = x_{i, k_u} + \frac{1}{s_i} R_i^t \delta x_u \quad (8)$$

Where s_i and R_i are the scale and rotation matrix of the similarity transform which transforms S_i to S^- , the mean shape. The scale and rotation are found to minimize.

$$\sum_{j=1}^p \|x_j' - (s_i R_i x_{i,j} + t_i)\|^2 \quad (9)$$

The sum of squares between the mean shape's facial landmark points, x_j^- 's, and those of the warped shape. V' is similarly defined. Each split is formally a decision involving three parameters $\theta = (\tau, u, v)$ and is applied to each training and test example as

$$h(I_{\pi i}, s_i^{\hat{t}}, \theta) = \begin{cases} 1 & I_{\pi i}(u') - I_{\pi i}(v') > \tau \\ 0 & \text{otherwise} \end{cases} \quad (10)$$

Where u' and v' are defined using the scale and rotation matrix which best warp $s_i^{\hat{t}}$ to S^- according to equation (7).

1) Choosing the node splits

The training of the regression tree

To train the regression tree we randomly generate a set of candidate splits, that is θ 's, at each node. We then greedily choose the θ^* , from these candidates, which minimizes the sum of square error.

This corresponds to minimizing Q , which is the set of indices of the training examples at a node.

$$E(Q, \theta) = \sum_{s \in \{l, r\}} \sum_{i \in Q_{\theta, s}} \|r_i - \mu_{\theta, s}\|^2 \quad (11)$$

where $Q_{\theta, l}$ is the indices of the examples that are sent to the left node due to the decision induced by θ , r_i is the vector of all the residuals in the gradient boosting algorithm, computed for an image I and

$$\mu_{\theta, s} = \frac{1}{\|Q_{\theta, s}\|} \sum_{i \in Q_{\theta, s}} r_i \text{ for } s \in \{l, r\} \quad (12)$$

The optimal split can be found very efficiently because if one rearranges equation (10) and omits the factors not dependent on θ then one can see that

$$\arg \min_{\theta} E(Q, \theta) = \arg \max_{\theta} \sum_{s \in \{l, r\}} \|Q_{\theta, s}\| \mu_{\theta, s}^T \mu_{\theta, s} \quad (13)$$

Here we only need to compute $\mu_{\theta, l}$ when evaluating different θ 's, as $\mu_{\theta, r}$ can be calculated from the average of the targets at the parent node μ and $\mu_{\theta, l}$ as follows:

$$\mu_{\theta, r} = \frac{\|Q\|\mu - \|Q_{\theta, l}\|\mu_{\theta, l}}{Q_{\theta, r}} \quad (14)$$

2) *Feature selection*: The thresholding of the difference in intensity values at a pair of pixels is used to make the decision at each node. Unfortunately, the drawback of using pixel differences is the number of potential splits (feature) candidates is quadratic in the number of pixels in the mean image. This makes it difficult to find good θ 's without searching over a very large number of them. However, this limiting factor can be eased, to some extent, by taking the structure of image data into account by the equation:

$$P(u, v) = \alpha e^{-\lambda \|u - v\|} \quad (15)$$

Over the distance between the pixels used in a split to encourage the selection of closer pixel pairs. We found using this simple prior reduces the prediction error on several face datasets.

V. EXPERIMENT

A. The Proposed System Flowchart

The proposed system is built based on Python programming language in Pycharm cross-platform. Building the system depends on OpenCV and Dlib libraries, it has been used dlib get frontal face detector in a frame or image. Dlib predictor is a tool that takes in an image containing some objects and outputs a set of point locations that define the pose of the objects. Here the shape predictor 68 face landmarks. The data model is used to create the predictor object.

The implementation of the system can be summarized in the following four points as in Fig. 3:

- The face and the eyes detection
- Calculating the gaze ratio to detect the eye direction
- The wheelchair design.
- The Connection between OpenCV and Arduino.

In this study, we can configure facial landmark points according to our specifications (detect the face and the eyes) as in Fig. 1. For instance, face landmarks that are enough can be from point 1 to point 27. Besides, left eye landmarks can be defined based on points 37-42, and then the right eye landmarks could be defined based on points 43-48.

B. Calculating the Gaze Ratio to Detect the Eye Direction

It is considered that the eye is divided into two parts white part (sclera) and the color part (pupil). The idea is to find out which of the two parts is more sclera visible as the sclera expresses the direction the eye is looking, as shown in Fig. 4.

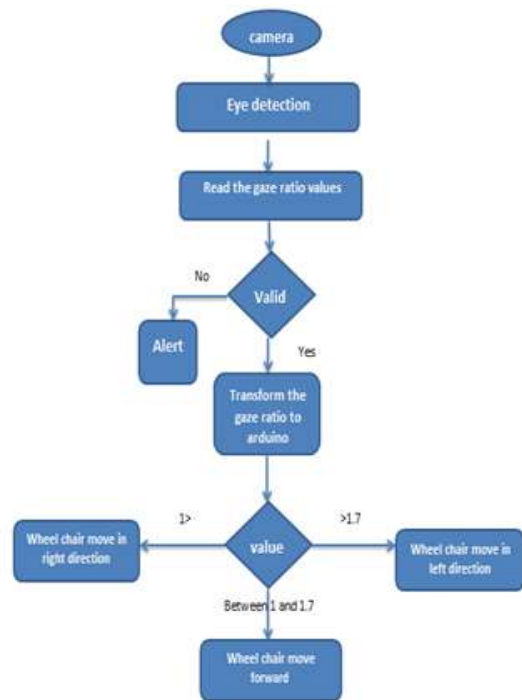

Fig. 3. The Proposed System Flowchart.

Fig. 4. Facial Detecting Eye Directions.

To detect the location of the sclera, convert the image into grayscale and calculate the number of white pixels on the left side and right side to both eyes. Then, calculate the gaze ratio to the right and left eye, which is the ratio between the left and white pixels and the right side of white pixels to each eye. Then, calculate the final gaze ratio to both eyes, which is the average value of the right and left gaze ratio. The values of the final gaze ratio could be computed using the following equation.

$$Gaze\ Ratio = \begin{cases} < 1, \text{Sclera in right direction} \\ > 1 \text{ and } < 1.7, \text{sclera in center} \\ > 1.7, \text{sclera in left direction} \end{cases} \quad (16)$$

These values are observed for all volunteers.

C. The Wheelchair Design

The smart Wheelchair consists of three main components, as shown in Fig. 5.

Arduino Uno board.

L293D integrated circuit.

Two DC motors.

Fig. 5. Wheelchair Back Architecture.

1) *Arduino Uno board*: -is used to revise the eye direction from OpenCV and it is connected to the L293D integrated circuit.

2) *L293D integrated circuit*: -Using this L293D motor driver IC is very simple. The IC operates on the Half H-Bridge principle, a setup that is used to operate motors in both clockwise and anti-clockwise directions is the 1, H bridge. As stated earlier, this IC can run the two motors in any direction at the same time. In this experiment, L293D revise the control order (eye direction) from Arduino and control DC motors' control command [20].

3) *Two DC motors*: - All types of DC motors have some function, either electromechanical or electronic, to change the motor periodically's current path. In the experiment, each wheel in the chair is connected to the dc motor, and each motor receives the control order from the L293D integrated circuit to move the wheels in all directions. As shown in Fig. 6, Wheelchair forward architecture consists of a place to sit and a battery.

Fig. 6. Wheelchair Forward Architecture.

VI. RESULTS AND ANALYSIS

The performance measure criteria in this study are: -

- 1) Calibration time.
- 2) Accuracy.

According to calibration time: During the testing time, it is very fast in the order of a millisecond. According to accuracy: Accuracy was calculated by counting the gaze detection for 3 persons (P1, P2, and P3). For each person, 30 gazes are tested, 10 for the right eye, 10 for the left eye, and 10 for the blinking eye, as shown in Table I.

Where:

$$Accuracy = \frac{\text{no of gaze detected}}{\text{total no od detection}} \quad (17)$$

TABLE I. THE CALCULATION OF THE SYSTEM PERFORMANCE

S.No	P1	P2	P3
Total Detections No	30	30	30
Total no. of max left Detection	8/10	8/10	10/10
Total no. of max Right Detection	10/10	10/10	10/10
Total no. of max blinking Detection	10/10	10/10	9/10
Total no. of max Detection	28/30	28/30	29/30
Accuracy	93.3%	93.3%	96.6%
Error	6.5%	6.5%	3.4%

The obtained average of accuracy is 94.4%. It is evident from the results that this study provided a noticeable improvement in eye tracking compared to previous studies. First, a Facial landmark with the Dlib technique one of the latest and more accurate techniques that are used in determining the face and eye was issued in 2014, besides it is clear from the results that the calibration time doesn't exceed a millisecond and accuracy is 94.4%, While the best results were previously monitored, the calibration time was 33.82 s and the accuracy was 90%. Table II presents all the proposed system components' costs.

TABLE II. THE COST OF THE MOST IMPORTANT TOOLS USED

Tool	Price
Arduino Board	10 \$
LD293D	2 \$
2 Dc Motor	1 \$
Wheelchair Model Design	5 \$
Total	18\$

VII. CONCLUSION

Eye-tracking is an interesting field of research, especially to help the completely disabled to communicate better with the community and practice all life activities without anyone's help. For the proposed eye-tracking system, a successful circuit was built between a wheelchair and a webcam which was used to capture the user's face. A face detection algorithm was used using the landmarks of the face and the eyes based on Facial Landmarks points which divide the face into 68 points. The gaze ratio was calculated by tracking the pupil area. We have found that when this ratio is less than 1, the pupil of the eye is in the right direction and when it is greater than 1. The pupil is in the left direction, otherwise, it is in the middle, then these values were passed to the Arduino board, then to an L293D circuit, and then to the wheelchair wheels. The experiment was prepared using Python programming language and OpenCV Library. The experiment achieved better results than other wheelchairs, as the accuracy of the gaze detection was about 94.4%, the time was one microsecond, and the cost didn't exceed 15\$.

Abstract—The Internet of Things (IoT) is a rising development and is an organization of all gadgets that can be gotten to through the web. As a central advancement of the IoT, wireless sensor networks (WSN) can be used to accumulate the vital environment parameters for express applications. In light of the resource limitation of sensor devices and the open idea of remote channel, security has become an enormous test in WSN. Validation as an essential security service can be used to guarantee the authenticity of data access in WSN. The proposed three factor system using one way hash function is depicted by low computational cost, and limit overhead, while achieving all other benefits. Keys are made from secret key for meeting for improving the security. We differentiated the arrangement's security and execution with some lightweight plans. As shown by the examination, the proposed plan can give more prominent security incorporates low overhead of correspondence. Encryption and unscrambling is done using numerical thoughts and by using the possibility of hash function. Mathematical thoughts are lightweight and update the security up by a staggering degree by diminishing the chances of cryptanalysis. When contrasted with different calculations, the proposed calculation gives better execution results.

Keywords—Internet of Things (IoT); authentication; one way hash function; lightweight environment; secret key

I. INTRODUCTION

As far off correspondence headway has made, brilliant world individuals can work by utilizing impending Internet of Thing (IoT) paradigm[1]. The fundamental contemplated the Internet of things, or IoT, is a strategy of interrelated getting ready contraptions, mechanical and automated machines, things, creatures or individuals that are given great identifiers (UIDs) and the capacity to move information over an association without expecting that human should human or human-to-PC facilitated exertion. Numerous splendid application can be made by using the data delivered by radio-frequency identification(RFID) and remote sensor organization. A comparable idea can be applied in various mechanical field[2] where canny application can be made using IoT devices. For example in healthcare[3] some distinguishing devices or sensors are embedded or attached to customer which assemble some basic information about customer, for instance, ECG, pulse, temperature and blood oxygen. these fundamental information is then shipped off affirmed clinical master with the help of a section encouraged

by the affiliation who runs the center, taking into account which the treatment is overseen without the actual presence of clinical master (This technique can be used to perceive COVID-19 patient among the people who are in separate so the spread of sickness can be avoided).

Using WSN biological data can be accumulated. WSN are regularly involved customers, passages(gateway server) and sensors centers. By and large sensor centers have limited energy, computational force and limit power moreover it has been seen that the energy usage of sensor center depends upon correspondence detachment [4][28], the energy usage for sending or tolerating a message of l -bits over or from a distance (d) are assessed by Eqs. 1 and 2, independently. Here the free space model is used if (d) isn't by and large a cutoff d_0 ; something different, multi-way model is used.

$$E_r(l, d) = \begin{cases} lE_{elec} + l\epsilon_{fs}d^2 & \text{for } d < d_0 \\ lE_{elec} + l\epsilon_{mp}d^4 & \text{for } d \geq d_0 \end{cases}$$

$$E_R(l) = lE_{elec}$$

where E_{elec} is the energy required by the electronic circuit, ϵ_{fs} and ϵ_{mp} are the energy required by the amplifier in free space and multi-path model, respectively. One of the plan for correspondence in WSN is showed up in Fig. 1

In Fig. 1, the customer can start the correspondence by sending login message to the gateway(the customer is currently enrolled with the portal the passage(server) moreover keeps up its correspondence with different sensors), as of now the server examinations the sales of customer and makes correspondence with remarkable sensor to make the correspondence possible among customer and sensor. Using this philosophy the power use of sensor center point can be decreased and the life of WSN can be extended. Considering limited security highlight of remote channel and confined resources of IoT devices, IoT faces veritable security and assurance challenges [5].

Fig. 1. Architecture for Communication.

Das in 2009 Das arranged a check scheme[6] for WSN, this arrangement was found having issue with inside attack, impersonation attack and server(gateway) center bypassing attack. In 2012 A.K Das [7] arranged powerful customer approval for progressive WSN using light weight calculation, for instance, hash work and symmetric cryptography, in any case it moreover had issues, for instance, inside attack, server primary key revelation attack[8]. In 2013, Xue et al. [9] proposed a lightweight client validation for WSN, and just hash activities are used to ensure the computational effectiveness. They asserted that their plan is secure against identity/secret key speculating assault and taken smart card assault. Be that as it may, their plan was discovered uncertain against stolen smart card assault, insider assault, following assault, and personality speculating assault [10].

As [8] reveals that most symmetric cryptography and hash based protocols are unreliable to user anonymity and smart card security breach assault, thus public key technique can be used like elliptic curve cryptography (ECC) which outfit same security as RSA with more diminutive key size. In 2011, Yeh et al. [11] considered affirmation convention for WSN reliant on ECC. This show had the issue customer namelessness (secrecy) and undetectability. Thereafter, Shi and Gong [12] presented an improved ECC based check convention for WSN. Regardless, these two shows can't give the features of customer namelessness (secrecy) and unrecognizability. In 2016, Jiang et al. [13] proposed an ECC based untraceable affirmation convention for WSN yet had some security defect as pointed by Li et al. [14].

In rest of this paper oversee proposed three-factor customer approval convention using one way hash function and contrasting encryption using one way hash function and disentangling calculation are similarly discussed and security discussion which are showed up in Sections II and III. Section IV oversees comparison of our show with other related show and discussion of security blemishes of Chang and Le's arrangement, Xiong- Li et al. scheme.

II. PROPOSED ANONYMITY AUTHENTICATION PROTOCOL FOR IIOT

In this part, we work with a three-factor validation protocol for modern web of things to accomplish client secrecy and oppose cell phone misfortune assault[15]. Here, we receive the fuzzy extractor [16] to handle biometrics data. More noteworthy degrees of safety are accomplished by biometric secret key, like fingerprints, retina examines. Notwithstanding, two biometric perusing are infrequently indistinguishable, despite the fact that they are probably going to be close. Notation used in full text is shown in Table I. Our plan contains four stages, for example initiation, registration, authentication and key agreement, and password change. We delineate these stages as follows.

TABLE I. NOTATIONS

Notation	Description
U_m, ID_m, PW_m	The Mobile Device(User), and the identification and secret Key
GN, X_{GN}	The gateway Server and its Server secret key
S_s, ID_s	The sensor hub and its identification
xx, XX	Private key and public key Gateway server
bm, Mm	Private key and public key of Mobile device(User)
X_{B-GN}	Shared secret key between Gateway Server and Sensor hub
PP	A point on the elliptic curve
$H1(\cdot), \oplus, \ominus$	The hash, XOR, and XNOR operation
A	An Attacker

A. Initiation Phase

To introduce the framework, Gateway Server picks a single direction hash work $H1(\cdot)$ which it imparts to every one of the clients. Additionally, it chooses an elliptic curve E dependent on a limited field F_p . From that point forward, Gateway server picks a subgroup GG of E with request huge prime n, and the generator is point PP. At that point Gateway worker produces a private key xx and figures the relating public key XX, where $xx \in Z^*n$ and $XX = xxPP$. Finally, GWN stores xx furtively and distributes the boundaries $\{E(F_p), GG, PP, XX\}$.

1) The Gateway Server(GN)

a) Gateway server chooses a secret key (X_{GN}) and one way hash function $H1(\cdot)$ which it shares with all the users through secured channel.

b) GN chooses an elliptic curve E dependent on a limited field F_p . From that point forward, GN picks a subgroup GG of $E(F_p)$ with request huge prime n, and the generator is point PP.

c) GN produces a private key xx and figures the comparing public key XX, where $xx \in Z^*n$ and $XX = xxPP$.

d) GWN stores xx covertly and distributes the boundaries $\{E(F_p), GG, PP, XX\}$.

e) Sensing Device(S_s) Registration Phase.

All the sensing hub(S_s) in IoT are registered offline by the GN as follows.

Step SD1. For each device S_s , the GN chooses a one way hash function $H1(\cdot)$ which it shares with all the sensor nodes in secured manner and a unique identity ID_s and calculates the corresponding shared secret key $X_{ID_s-GN} = (ID_s \oplus X_{GN})$.

Step SD2. The GN pre-loads $\{ ID_s, X_{IDS-GN}, H1(\cdot) \}$ in the memory of S_s

The Sensor Node(Ss)

The Server(GN)

Select IDs for Ss

compute $X_{IDS-GN} = X_{GN} \oplus IDs$

ID_s, X_{IDS-GN}

Store $IDs, X_{IDS-GN}, H1(\cdot)$

B. Registration Phase

To be associated with the framework as a legitimate client, the accompanying advances ought to be performed between client Um and GN, and afterward Um can get to the sensor information progressively by utilizing his/her cell phone.

Stage 1. A character ID_m , a secret word PW_m and an irregular number rm are picked by Um . Then, Um engraves the biometric data Bio_m on a cell phone with fuzzy extractor [16] and gets $Gen(Bio_m) = (\sigma_m, \tau_m)$. At that point Um ascertains the veiled secret key $RPW_m = PW_m \oplus rm$, (here \oplus stands for XOR operation) and submits $\{ID_m, RPW_m, \sigma_m\}$ to GN for enrollment.

Stage 2. While getting the enrollment demand, GN checks if ID_m in the data set. In the event that indeed, Um requested to present another character. Something else, GN figures $A_m = H1(ID_m \oplus X_{GN})$ and $B_m = A_m \oplus (RPW_m \oplus \sigma_m)$, and sends $\{B_m, XX\}$ to Um through a reliable manner.

C. Authentication Phase

When Um wants to access the sensor data of S_s , the following authentication steps should be performed among Um , GN and S_s , and a session key is shared among these three parties at the end of the authentication phase.

Step 1. Um inputs ID_m and PW_m on the mobile device, and imprints the biometric information Bio'_m on the mobile device with fuzzy extractor. Then the mobile device calculates.

$$\sigma_{m'} = Rep(Bio'_m, \tau_m),$$

$$RPW'_m = (PW_m \oplus rm)$$

$$A'_m = B_m \oplus (RPW'_m \oplus \sigma_{m'})$$

checks $A'_m \stackrel{?}{=} A_m$. Imbalance implies in any event one of three variables is invalid, and the login demand is rejected by the cell phone. Or disaster will be imminent, the cell phone plays out the following stage. The cell phone delivers an arbitrary numbers $bm \in Z_n^*$ and calculates.

$$MM1 = bm * PP,$$

$$MM2 = bm * XX$$

$$MM3 = ID_m \oplus MM2$$

$$MM4 = IDs \oplus MM2$$

$$MM5 = H1(A'_m)$$

(1)

Then the mobile device(User) submits the login request $\{MM1, MM3, MM4, MM5\}$ to GN.

Step 2. When receiving the request, GN first retrieves ID_m, IDs and then computes A'_m and then it calculates the hash value of A'_m that is $MM'5$.

$$MM'2 = xx * MM1$$

$$ID'_m = MM3 \oplus MM'2$$

$$ID's = MM4 \oplus MM'2$$

$$A''_m = (ID'_m \oplus X_{GN})$$

$$MM'5 = H1(A''_m)$$

GN server checks $MM'5 = MM5$ If yes then the GN Server get a assurance that the user is genuine then GN server calculates the shared secret key X'_{IDS-GN} between sensor node(Ss) (given by user) and itself then it calculates $MM6, MM7$ for performing authentication.

$$X'_{IDS-GN} = (ID's \oplus X_{GN})$$

$$MM6 = X'_{IDS-GN} \oplus ID'_m$$

$$MM7 = H1(X'_{IDS-GN}) \tag{2}$$

At last, GWN Server sends $\{MM6, MM7\}$ to sensor Node.

Step 3. After receiving the message from GN Server, Sensor node(Ss) first computes.

$$MM'7 = H1(X_{IDS-GN})$$

Sensor node checks $MM'7 = MM7$, if yes then sensor node(Ss) gets a assurance that the request came from correct server, then sensor node(Ss) calculates.

$$ID''_m = MM6 \oplus X_{IDS-GN}$$

$$MM8 = H1(X_{IDS-GN} \oplus ID''_m) \tag{3}$$

The Sensor node also gets the information about the user who wants to communicate, after that it sends responses $\{MM8\}$ to GN Server.

Step 4. After receiving the response from the sensor node(Ss) the GN Server retrieves computes.

$$MM'8 = H1(X'_{IDS-GN} \oplus ID'_m)$$

if $(MM'8 = MM8)$, GN Server gets an assurance that sensor node(Ss) is genuine and generates the session key to be given to both mobile device(user) and sensor node(Ss):

$$SKS = ID'_m \odot IDs \odot X_{GN} \odot A''_m \odot xx \tag{4}$$

$$MM9 = X'_{IDS-GN} \oplus SKS$$

$$MM10 = MM'2 \oplus SKS$$

$$MMM10 = H1(A''_m \oplus ID'_m)$$

Then GN Server sends $MM9$ to sensor node(Ss) and $(MM10, MMM10)$ to mobile device(user). Otherwise, server cuts off the communication.

Step 5. After receiving the message from GN Server, mobile device(User) computes MMM'10.

$$MMM'10 = H1(A'm \oplus IDm)$$

If $MMM'10 = MMM10$ then mobile device(user) gets a assurance that he is communicating with correct GN server then mobile device computes secret key(SK_m).

$$SK_m = MM10 \oplus MM2$$

$$MM11 = H1(MM10)$$

Then the mobile device(User) submits MM11 to GN Server.

Step 6. After receiving the message from GN Server, Sensor node(Ss) retrieves the secret key.

$$SK_s = MM9 \oplus X_{IDs-GN}$$

$$MM12 = H1(MM9)$$

Then the Sensor node submits MM12 to GWN Server.

Step 7. After receiving the message from mobile device(user) MM11 and Sensor node MM12, GN Server, computes the following.

$$MM'11 = H1(MM'2 \oplus SKS)$$

$$MM'12 = H1(X'_{IDs-GN} \oplus SKS)$$

If $M'11 = M11$ and $M'12 = M12$, GN Server gets a assurance that Mobile Device(User) and sensor node(Ss) are is genuine and received the correct secret key and hence key synchronization ends.

If mutual validation and key exchange phase completes successfully, both mobile device(user) and Sensor hub(Ss) will transfer information by using the meeting key which will be computed by the GN server and given to both mobile device(user) and the sensor hub(Ss) in secured way. First source authentication is achieved, for this a one way hash function is used. The message digest is created for date(A_m) which is available at both mobile device(user) and GN server, so this message digest will act as a authenticator. In the same way sensor node(Ss) and GN server mutual authenticate each other by creating a authenticator using hash function (HA-160) by using the common data X_{IDs-GN} . The details of hash function(HA-160) is given below. After all the devices get assurance about other devices the GN server generates a secret key and passes it to both sensor hub(Ss) and mobile device(user) in a secured way.

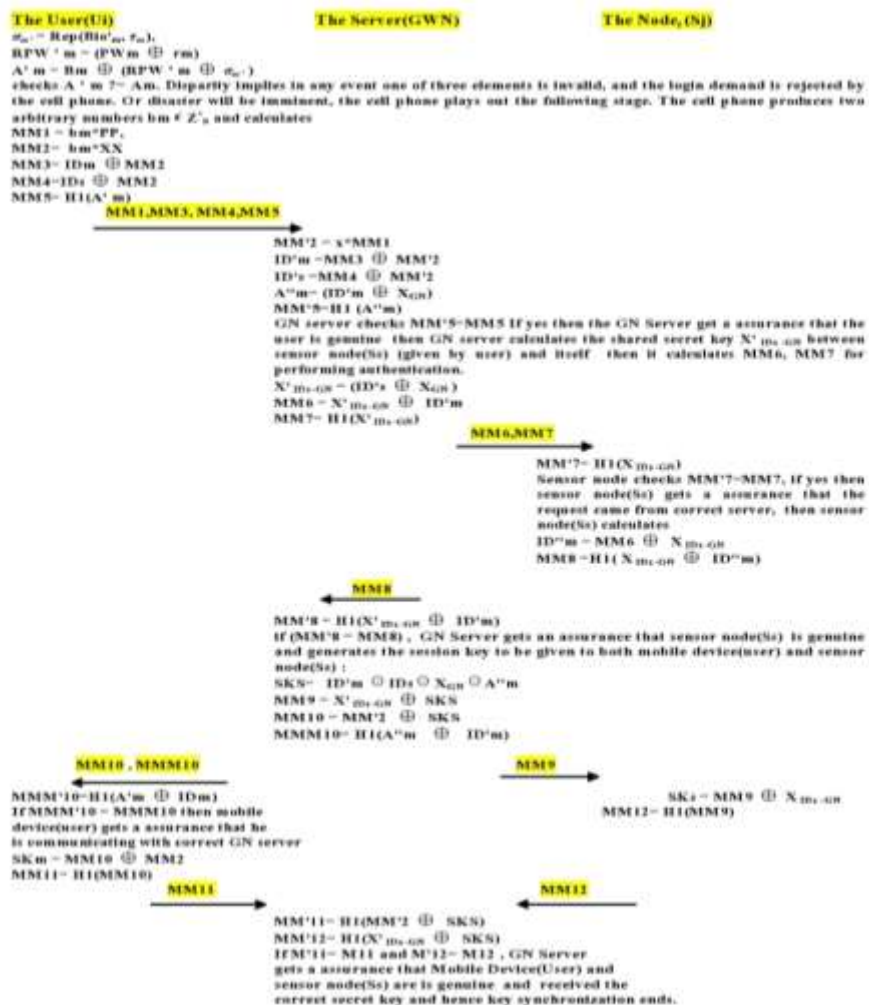

Fig. 2. Illustration of the Mutual Validation Stage and Key Synchronization Stage.

The Secret Key between User(Ui-Mobile) and Server(GN)

The Mobile device(User-Um)

private Key=bm

Public Key = MM1(MM1=bm*PP)

Secret key = bm*XX
= bm*xx*PP

The Server(GN)

private Key=xx

Public Key = XX(XX=xx*PP)

Secret Key =xx*MM1
= xx* bm * PP

The secret key for session synchronization is showed in Fig. 2. Hash algorithm and data encryption phase is described.

III. HASH ALGORITHM(HA-160)

The proposed calculation is named as HA-160[24][25][26]. This assessment HA-160 (Hash Algorithm) recognizes a message as responsibility with a most uncommon length of under 2^{128} pieces and makes a 160-piece message digest as yield. First the data message is isolated into squares of 1024 pieces. This 1024 pieces is taken as information, by then the information is diminished from 1024-digit squares to 512-cycle blocks. The Hash code creation work perceives two wellsprings of data which are 1024 pieces square of the message and the instate MD support (getting variable 160-bits). The cycle includes the going with advances.

A. Attach Padding Pieces

The message is padded so its length is reliable to 896 modulo 1024 (length = 896 mod 1024). Padding is continually done, whether or not the message is of needed length. Subsequently, the amount of padding pieces is in the extent of 1-1024. The padding contains alone 1 followed by the significant number of 0's for example 10... ..0.

B. Attach Length

A square of 128 pieces which contains the length of the message (going before cushioning) is joined to the message. This square is treated as an unsigned 128-digit number (most basic byte first).

C. Initialize MD Pad

A 160-piece cushion is utilized to hold impermanent and eventual outcome of the hash work. The assistance can be tended to as five 32-digit registers (SS0, SS1, SS2, SS3 and SS4) .These registers are instated to the going with 32-bit numbers (Hexadecimal qualities):

SS0 = 67 45 23 01

SS1 = efc dab 89

SS2 = 98 ba dc fe

SS3 = 10 32 54 76

SS4 = c3 d2 e1 f 0

These attributes are same as the secret vector evaluations of SHA-1 which are normalized by Federal Information Processing Standards Publications (FIPS PUBS). These qualities are dealt with in big endian plan, which is the standard byte of a word in the low-address byte position.

D. Processes Message in 1024-Bitblocks

The message digest age strategy contains five sub capacity. This part is named (HA-160) in Fig. 1 and its reasoning is showed up in Fig. 2. Fig. 1 depicts the general getting ready of message to make a information survey. The consequence of the underlying two phases (after add padding pieces and append size) yields a information that is a number various of 1024-piece long. The all-inclusive information is addressed as the gathering of 1024-piece blocks $XX_0, XX_1, XX_2, \dots, XX_{L-1}$, so the total size of the all-inclusive information is $L \times 1024$ pieces (L = the amount of 1024 bit hinders), that is the outcome of various of 32-bit blocks. Here K addresses the real length of the message in pieces, "IV" is the fundamental vector which is used to present the five 32-cycle registers (SS0, SS1, SS2, SS3 and SS4). VC_i, VC_{i+1}, VC_q and VC_{L-1} address instate MD(carry vector) which holds widely appealing and inevitable result of the Hash work, separately. Each round takes two data sources one 1024-cycle block (XX_q) of the message and a 160 piece pass on vector (VC_q). Close to the completion of the L^{th} stage produces 160 piece message digest. From the start the given message is disengaged into 1024-digit blocks, and each square is passed to Hash Code making capacity (HA) as a commitment close by the 160-piece vector(as shown in Fig. 3 and Fig. 4).

The Hash work (H_{HA-160}) rationale is:

Remouldingtask(R_m) converts the given 1024-bit block into adjusted 512-bit block.

Progression task(P_m) converts the given 160-piece initial vector into extended 512-bit vector.

32-digit XOR operation(XOR_{op}) performs XOR procedure on each 32-pieces of altered 512-bit block and extended 512-bit vector.

Fig. 3. Message Digest Creation using HA-160.

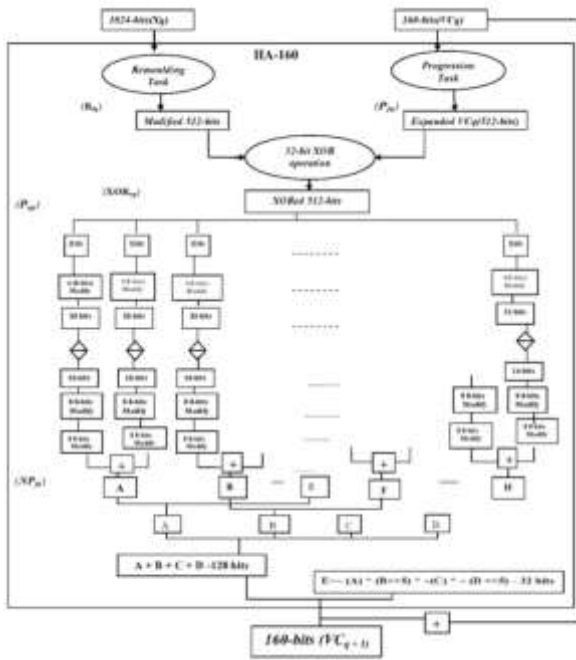

Fig. 4. The Rationale of Hash Work (Compression Work).

Partition and Modification operation (P_{op}) disconnects the 512-cycle block into 16 sub-square of 32-bits each and afterward each 32 digit block is isolated into four 8-bit block, after that it changes every eight bit block. This interaction is rehashed for every one of the 32 bit block.

New Point (on elliptic curve) estimation work (NP_{fn}) calculates new point on elliptic curve using 4 eight-cycle block (from each 32-bit block).

Where,

- XXq = the q th 1024-cycle square of the information.
- VCq = mooring variable arranged with the q th square of the information.
- Rfn = Remoulding task.
- $P=(xxx1,yyy1)$ and $Q=(xxx2,yyy2)$.
- Pfn = Progression task.
- $XORop=XOR(Exclusive-OR)$ development performed on each 32-cycle square of the adjusted 512-digit block (XXq) and relating 32-pieces of the comprehensive 512-bit block (VCq).
- Pop = 512-digit square can be withdrawn into 16 sub squares of 32-bits each and subsequently each 32 cycle block is confined into four 8-bit block, after that it changes each eight bit block.
- $NPfn$ = initial 32-cycle square further parceled into 2 sub parts of 16-piece each.

1stsub part = 16 bit, apportioned into two sub part (8-bits,8-bits) = $(xxx1, yyy1)$.

2nd sub part = 16 bit, divided into two sub part (8-bits, 8-bits) = $(xxx2, yyy2)$.

The characteristics ($xxx1, yyy1, xxx2,$ and $yyy2$ as showed in Fig. 5) are changed over into entire numbers followed by processing another point on elliptic curve. The above interaction is revamped for staying fifteen 32-cycle block and the outcome is 16 sub square every one of 16 pieces. Presently every one of this 8 sub square every one of 16 digit is changed, the initial 8-cycle of first square is XOR with a 8-bit sub square which are each of the zeros, the outcome is put away in initial 8-bit sub square. The subsequent 8-digit sub square of first square is added with initial 8-bit sub square and result is put away in second 8-cycle sub square and the interaction is rehashed for every one of the 8-piece sub square. The outcome is arranged 256 cycle block. Presently neighboring sub square every 16 pieces are added which brings about a sub square of 32 digit and we get eight 32 piece sub square. At that point this eight 32-digit sub square are converted to four 32-bit sub block by added first and fifth, second and sixth, third and seventh and fourth and eighth 32-digit sub square are added which brings about four 32-cycle sub square. By playing out some numerical procedure on over four processed 32 bit sub square and afterward XOR them brings about the fifth 32 cycle sub square. This five 32 piece sub square when concatenated adds up to 160 piece and when summed with introduced MD cradle shapes the hash code. This 160 piece hash code will be the contribution to next 1024 digit of message i.e it will go about as introduce MD cradle for next 1024 cycle of the info message. The last 160 piece code produced from last 1024 cycle of message will be the last message digest which will go about as confirmation code.

Fig. 5. Elliptic Curve Way to Represent Two Points.

1) *Remouldingtask* (R_{fn}): Each 1024-cycle square of data is isolated into 128 sub-blocks including 8-bits of each sub-block. One brief show of size 8 (Tempx8) is taken and instated with zeroes. The adjustment work includes two sub task as shown as follows.

Sub-work 1. Initially, the first 8-bits of 1024 block is XORed with Tempx8 variable i.e eight bit starting from least significant bit in Tempx8 is XORed with first 8-bits of 1024 block. the result is stored in first 8-bit of 1024 block (Modified Message) and Tempx8 is incremented by one. This extended Tempx8 is XOR with the going with 8-pieces of the message to make the going with 8-pieces of changed message as tended to in Fig. 6.

Fig. 6. Function of Sub-Work1.

Sub-work 2. The above result is again detached into sub square of 8 pieces and initial eight-cycle sub square and focus eight-bit sub square after bitwise complimenting(\sim) are XOR and the result is again bitwise complimented(\sim) and set aside in an alternate array(W2). The above cycle is reiterated for second 8-bit sub square and focus notwithstanding one 8-digit sub square and result is taken care of in second piece of disconnected array(W2). This is repeated for all extra 8-digit sub square. The result is 1024 cycle block is diminished to 512 digit block. The changed message as depicted under.

```
intMod_Inp(vector<int> mm, intnn)
{
    staticint W[130] ;//32 bits as a group
    int ii, jj=0,pp,qq,kk1=0,TT=0;
    pp=nn;
    nn*=128;
    for (ii=nn;ii<nn+128; ii++)
    {
        W[ii]=TT ^ mm[ii] ;
        TT++;
    }
    jj=((ii+nn)/2) ;
    qq=jj;
    for (i i=nn;ii<(qq+nn); ii++)
    {
        W2[kk1]=~(~(W[ii]) ^ ~(W[jj]));
        kk1++;
    }
    jj++;
}
return 0;
}
```

2) *ProgressionTask*(P_{fn}):The 160-piece Initial Vector (IV) is one of the commitments to the message digest creation work (HA-160). It will in general be stretched out to 512-bits by interfacing all hidden vector regards in indirect manner, which is called Concatenated Vector (VC). The association cycle is showed in Fig. 7.

Fig. 7. Formation of 160-Bit Block (IV) to 512-Bit Block (CV).

3) *32-bit XOR operation*(XOR_{op}):XOR movement is done on starting 32-piece sub-block of modified 512-cycle square and expanded 512-piece square. For this initial four 8-digit block are extended and summed with the goal that it becomes 32 piece square. At that point this 32-piece square is XOR with initial 32-bit of extended or instate MD cradle of 512-piece square. This interaction is reshaped for rest of the pieces of adjusted 512-bit and extended 512-digit block. The outcome is 512-cycle block as demonstrated underneath.

```
for (tt1 = 0; tt1 < 16; tt1++)
{
    WW3[t1] = (WW2[4 * t1] << 24) + (WW2[4 * tt1 + 1] << 16) + (WW2[4 * tt1 + 2] << 8) + (WW2[4 * tt1 + 3]);
    if(tt1==0)
        WW3[tt1]=((WW3[tt1]) ^ (EE));
    if(tt1==1)
        WW3[t1]=((WW3[t1]) ^ (DD));
    if(tt1==2)
        WW3[t1]=((WW3[t1]) ^ (CC));
    if(tt1==3)
        WW3[tt1]=((WW3[tt1]) ^ (BB));
    if(tt1==4)
        WW3[tt1]=((WW3[tt1]) ^ (AA));
    if(tt1==5)
        WW3[tt1]=((WW3[tt1]) ^ (EE));
    if(tt1==6)
        WW3[tt1]=((WW3[tt1]) ^ (DD));
    if(tt1==7)
        WW3[tt1]=((WW3[tt1]) ^ (CC));
    if(tt1==8)
        WW3[tt1]=((WW3[tt1]) ^ (BB));
    if(tt1==9)
        WW3[tt1]=((WW3[tt1]) ^ (AA));
    if(tt1==10)
        WW3[tt1]=((WW3[tt1]) ^ (EE));
    if(tt1==11)
        WW3[tt1]=((WW3[tt1]) ^ (DD));
    if(tt1==12)
        WW3[tt1]=((WW3[tt1]) ^ (CC));
    if(tt1==13)
        WW3[tt1]=((WW3[tt1]) ^ (BB));
    if(tt1==14)
        WW3[tt1]=((WW3[tt1]) ^ (AA));
}
```

```
WW3[tt1]=(WW3[tt1]) ^ (AA);  
if(tt1==15)  
WW3[tt1]=(WW3[tt1]) ^ (EE);  
}  
}
```

4) *Partition and Modification operation*(P_{op}): Each 32-digit square of the above outcome is additionally allocated 2 sub-squares of 16-bits each. By then every 16-bit block is segregated into two 8-cycle sub square, all of these eight pieces are changed that is First the four pieces are taken from the 8-digit regard starting from least basic position then it is XOR with a variable1(mm) whose value is zero, the result is kept in a variable2(mm1) also the assessment of variable1(mm) is invigorated for instance it is given the assessment of variable2(mm1). Ensuing to completing the above advance again from 8-digit value(input), four pieces starting from most critical position is taken care of in variable3(mm2) and variable3 is changed by playing out a XOR with variable1(mm) . The data is reproduced for example 8-cycle regard is recomputed by taking care of the assessment of variable3(mm2)(four bits starting from least basic situation) in four pieces starting from most huge position and next four pieces of early on eight bit(input) communicating from least critical position gets the pieces from variable2(km1) (four pieces starting from least huge position) so this way the 8-digit of data is changed . A comparative procedure is embraced for remaining three 8-bit regards made from 32 cycle that is

$BB1 = (WW3[t] \gg 8) \& 0xff; \rightarrow 2^{nd}$ 8- piece number made from 32 bit number

$AA2 = (WW3[t] \gg 16) \& 0xff \rightarrow 3^{rd}$ 8 cycle number made from 32 bit number

$BB2 = (WW3[t] \gg 24) \& 0xff \rightarrow 4^{th}$ 8 digit number made from 32 cycle number

$AA1 \rightarrow yy1$

int Mod_Int2(int yy1)

```
{  
inti,j,mm=0,mm1=0,mm2=0;  
mm1=yy1 & 0xf;  
mm2=(yy1 >> 4) & 0xf;  
mm1= mm1 ^ mm;  
mm= mm1;  
mm2= mm2 ^ mm;  
y1 = (mm2<< 4) + (mm1);  
return yy1;  
}
```

A same strategy is adopted for remaining seven 32-digit blocks.

5) *New Point(on elliptic curve) estimation task* (NP_m): Each 32-digit block is separated into two sub squares of same length. These sub squares go probably as two motivations behind an elliptic curve which are used in new point appraisal in elliptic curve as exhibited in Fig. 5. First by using two point slope(λ) of line is resolved the this slant value(M) is used in the calculation of new X and Y center point on elliptic curve. The resultant new point is 16 cycle regard i.e X center is 8 pieces and Y center point is 8 pieces so both taken together is 16 digit sub square. An amount of sixteen 16-cycle sub square is created after new point computation. As of now this new point are changed by performing XOR on new point. Each 8-digit sub square is XOR with its adjoining 8-cycle sub square beside beginning 8-bit sub square which is XOR with a 8 bit sub square, everything being zero. After above action connecting sub squares are incorporated an especially that it becomes 32 cycle sub square. Repeating this, achieves eight 32-digit sub square.

Incline of line in elliptic curve (for real) is determined as:

$$\text{slope}(\lambda) = \frac{(yyy2 - yyy1)}{(xxx2 - xxx1)}$$

where (xxx1,yyy1) and (xxx2,yyy2) are points on elliptic curve. New point on elliptic curve for reals are calculated using the following formula

$$xxx_3(\text{new point}) = (\text{slope}(\lambda))^2 - xxx_1 - xxx_2$$

and

$$yy_3(\text{new point}) = \text{slope}(\lambda) * (xxx_1 - xxx_2) - yyy_1$$

the above calculation is for the case when $xxx_1 \neq$ (not equal to) xxx_2 (this is assumed that xxx_1 is not equal to xxx_2). The logic of new point estimation is demonstrated below.

```
for ( tt = 0; tt < 16; tt++)  
{  
AA1 = WW3[tt] & 0xff;  
AA1=(Mod_Int2(AA1));  
BB1 = (WW3[tt] >> 8) & 0xff;  
BB1=(Mod_Int2(BB1));  
AA2 = (WW3[tt] >> 16) & 0xff;  
AA2=(Mod_Int2(AA2));  
BB2 = (WW3[tt] >> 24) & 0xff;  
BB2=(Mod_Int2(BB2));  
MM=(BB2-BB1)/(AA2-AA1);  
AA3[ii]=(MM*MM)-AA1-AA2;  
AA3[ii]=AA3[ii]^TT1 ;  
BB3[ii]=MM*(AA1-AA2)-BB1;  
BB3[ii]=BB3[ii] ^ AA3[ii];  
TT1=BB3[ii];  
}
```

```
ii++;  
}
```

The above process results in A3 and B3 array . Now each of this array element is altered using the strategy

```
for(ii=0;ii<16;ii=ii+2)  
{  
if(ii<2)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=2 && ii<4)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=4 && ii<6)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=6 && ii<8)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=8 && ii<10)  
{
```

```
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=10 && ii<12)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=12 && ii<14)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
if(ii>=14 && ii<16)  
{  
AA3[ii] = (AA3[ii] << 24) + (BB3[ii] << 16) + (AA3[ii+1] << 8) + (BB3[ii+1]);  
BB3[ii] = (BB3[ii] << 24) + (AA3[ii] << 16) + (BB3[ii+1] << 8) + (AA3[ii+1]);  
AA3[ii+1] = (AA3[ii+1] << 24) + (BB3[ii+1] << 16) + (AA3[ii] << 8) + (BB3[ii]);  
BB3[ii+1] = (BB3[ii+1] << 24) + (AA3[ii+1] << 16) + (BB3[ii] << 8) + (AA3[ii]);  
}  
}
```

that is AA3[i] is recreated from AA3[i], BB3[i], AA3[i+1] and BB3[i+1] i.e. here AA3[i] is left shifted by 24 bits, BB3[i] is left shifted by 16 bits, AA3[i+1] is left shifted by 8 bits and BB3[i+1] is left shifted by 0(zero) bits and then AA3[i], BB3[i], AA3[i+1] and BB3[i+1] are added to generate AA3[i]. Similarly BB3[i] is recreated from AA3[i], BB3[i], AA3[i+1] and BB3[i+1] i.e. here BB3[i] is left shifted by 24 bits, AA3[i] is left shifted by 16 bits, BB3[i+1] is left shifted by 8 bits and AA3[i+1] is left shifted by 0(zero) bits and then AA3[i], BB3[i], AA3[i+1] and BB3[i+1] are added to generate BB3[i]. For recalculating AA3[i+1] again AA3[i],

BB3[i], AA3[i+1] and BB3[i+1] are used i.e. here AA3[i+1] is left shifted by 24 bits, BB3[i+1] is left shifted by 16 bits, AA3[i] is left shifted by 8 bits and BB3[i] is left shifted by 0(zero) bits and then AA3[i], BB3[i], AA3[i+1] and BB3[i+1] are added to generate AA3[i+1]. Finally for recalculating BB3[i+1] again AA3[i], BB3[i], AA3[i+1] and BB3[i+1] are used i.e. here BB3[i+1] is left shifted by 24 bits, AA3[i+1] is left shifted by 16 bits, BB3[i] is left shifted by 8 bits and AA3[i] is left shifted by 0(zero) bits and then AA3[i], BB3[i], AA3[i+1] and BB3[i+1] are added to generate BB3[i+1]. The same process is repeated for all the value of 'ii'. Here 'ii' is incremented by 2 when the statements inside looping structure are rotated using ii

6) *Result:*The 160-piece hash code is acquired by adding four 32 bit sub square i.e. first and fifth, second and sixth, third and seventh and fourth and eight 32-bit sub square are added which brings about four 32-digit sub square. Presently this four 32-cycle block got in above interaction are numerically controlled which brings about last 32-digit sub square as demonstrated beneath. The message digest (160 pieces) is gotten by connecting the five 32-cycle block got in above interaction.

$EE = \sim(AA) \wedge (BB \gg 5) \wedge \sim(CC) \wedge \sim(DD \ll 5);$

160-bit Hash Code = AA || BB || CC || DD || EE

All hexadecimal numbers are copied into pass on vector (or instate MD cushion), which is the message blueprint of a given message(if the message size is 1024-piece square) in any case the above cycle is emphasized until the last 1024-digit square of the message.

IV. ENCRYPTION ALGORITHM

Step 1: In trigonometry operation, for encryption we use a trigonometric formula made up of Cos function i.e. $Cos(x * \pi / 180.0) = y$ then Sin function i.e. $Sin(y * \pi / 180.0) = z$, here we require the value of π for Cos and Sin function. At the time of encryption and decryption this value of pi will be needed. The actual value of $\pi = 3.141592$, but in this case the Sensor Node and mobile device (user) will take the value of π be current key generated from the secret key for session SK_m or SK_s . For example, let the value of key be 77.

Here is the method how the key for encryption or decryption is generated from secret key for session (SKi).

1) First the secret key is stored in a variable and then this variable is rotated ten times, for each rotation it checks whether the rotation is even or odd. If even, the variable is right shifted by one and the shifted value is stored in a new array (xx), also the variable gets the current value of array x and the array is incremented. If odd, the variable is left shifted by one and the shifted value is stored in a new array (xx), also the variable gets the current value of array x and array is incremented. This process is repeated for a array of size ten, so at the end of first step we get ten different values generated from secret key. The process is shown below:

```
y=sks
jj=1;
for(ii=0;ii<10;ii++)
{
if(ii%2==0)
{
xx[ii]=y<<jj;
y=xx[ii];
}
else
{
xx[ii]=y>>jj;
y=xx[ii];
}
}
```

2) Now the new array is analyzed that is from secret key ten different keys are generated in stage1, then this ten keys are XOR and the result of XOR operation is kept in a variable (t). After computing the value of t, the new array is modified that is array xx first position will now hold the value of array xx second position and array xx second position will now hold the value of array xx third position and the process continues till ninth position tenth array xx position will hold the value of variable t. After completion of above step one position of array xx (tenth position) is altered, the same process is repeated for all the position (ninth to one position) of array xx. So after stage2 the ten different key generated in step one will be holding all new values

```
jj=1.
for(jj=0;jj<10;jj++)
{
t=0;
for(ii=1;ii<10;ii++)
t=(t + xx[ii]) ;
for(ii=0;ii<10;ii++)
{
if(ii==9)
tt2[ii]=t;
else
tt2[i]=xx[ii+1];
}
jj=9;
for(ii=0;ii<10;ii++)
{
xx[ii]=tt2[jj];
jj--;
}
}
```

3) The ten key generated in stage2 are reduced to five that is first key is XOR with tenth key and the result is stored in a separate array(kk1) in first position after a left shift by zero, then second key XOR with ninth key and result is stored in array(kk1) second position after a left shift by one and the process continues till stage2 ten keys are reduced to five. The process is shown below:

```

    jj=10;
    for(ii=0;ii>jj;ii++)
    {
        kk1[ii]=(kk1[ii] + kk1[jj])<<ii;
        jj=jj-1;
    }

```

4) The ten keys of stage2 are reduced to five in stage3 then in stage4 this five keys are XOR and the result is stored in a variable (kkmm). the output of stage4 will be the input to stage5.

```

    kkmm=0
    for(ii=0;ii<5;ii++)
    kkmm=(kkmm^kk1[ii]) ;

```

5) Finally the result of stage4 is reduced to a number less than 10 by applying modular operation. This result as shown in Table II will be acting a key.

Shared secret key for session = 77

TABLE II. GENERATED KEY

KKi	Value
KK1	1155
KK2	2156
KK3	4235
KK4	8316
KK5	16555
KK6	32956
KK7	65835
KK8	131516
KK9	262955
KK10	525756

Final value of Key =3.000000

Step 2: Take the input message, for example “24, 32, 56, 65, 73”. Here every element of input message will be encrypted by calling the trigonohash technique. The input(xx) is taken from input string to be encrypted, first the input is converted into radians by multiplying xx with pi/180.0 and the generated value is given to Cos function. The output of Cos function will be the input to Sin function. The output of Sin function is again manipulated which forms the final cipher text to be transmitted to destination. So the process of

encryption can be described as four step process as illustrated below:

```

for(ii=0;ii<nx;ii++) // nx → Number of input data
{
    yy11[ii]=cos(sz[i]*key/180.0); // sz[i] → ith Data
    yy12[ii]=sin(yy11[ii]*key/180.0);
        ss1=int(yy12[ii]);
        frac1= yy12[ii]-ss1;
        ss2 = Mod_Int3(ss1);
        yy12[ii]=ss2;
        yy12[ii]=yy12[ii]+frac1;
        ab1[ii]= hash1(sz[i]);
    }
int Mod_Int3(int xx)
{
    int static r1;
    int AA1,BB1,AA2,BB2;
    AA1 =xx & 0xff;
        BB1 = (xx >> 8) & 0xff;
        AA2 = (xx >> 16) & 0xff;
        BB2 = (xx >> 24) & 0xff;
    r1 = (AA1 << 24) + (BB1 << 16) + (AA2 << 8) + (BB2);
return r1;
}

```

These values(xx in radian) will go into the Cos (xx) , and the output of Sin (yy) after manipulating it with Mod_Int3 function form the cipher text. As we have changed the value of $\pi = SK_1 = 1.137201$ (for example) the result will be automatically changed as seen in the cipher text.

The general methodology for calculating cipher text is a four step process.

1) The first input is given to Cos(input*key/180.0) as Cos function takes input in radian form, the input is multiplied with $\pi/180$ here π is assigned the value of generated key.

2) The output of Cos function will be the input to Sin function i.e. the out will be given to Sin(cos output*key/180.0), as Sin also takes radian value the same procedure is adopted as above for generating output.

3) The output of Sin function is manipulated using Mod_Int3 function which rearranges the bytes in the input i.e in Sin function output least significant byte is placed most significant bytes place i.e interchanged then (least significant - 1) byte is interchanged with (most significant -1) this is repeated for all the bytes /2 in the output. The output of

Mod_Int3 is the final cipher text which is transmitted to destination along with the hash value(HA-160) of input.

Now if $yy12[ii]$ and encryption algorithm are known to the attackers then also they will not be able to breach the information. Because the value of π is not general like $\pi = 3.141592$ rather than it is 1.137201 (SK₁ or generated key) Experimental results are shown in Table III.

TABLE III. DEMONSTRATION OF ENCRYPTION PROCESS

Input Message	Key (pi)	CipherText	Hash value of Input
24	3.000000	0.015350	05c8778d2274ca4940aca31e32a71ebfc99b597d
32		0.014351	82817f1da244ca39d0dca32eb2771eaf4654610d
56		0.009919	2814db78a2388a55c37d1a4ab26adecbebe7bd68
65		0.007806	4f15dbe822088a4553ad1a5a323adebb12e8bdd8
73		0.005780	e514db78a2388a55c37d1a4ab26adecba8e7bd68

V. DECRYPTION PROCESS

Take the input message, for example “0.000256, 0.000239, 0.000165, 0.000130, 0.000096”. Here every element of input message will be decrypted by calling the trigonohash technique. The input(xx) is taken from input string to be decrypted, first in the input, the effect of Mod_Int3 function of encryption module is nullified by arranging the bytes of input in original form by using Mod_Int3 function of decryption module. This output is given to *Sin* function and the output of *aSin* function will go as input to *aCos* function. The output of *aCos* function is given to hash function(HA-160). The calculated hash code is matched with the received hash code, if matched then the output of *aCos function* is accepted as the message transmitted by sender else rejected. So the process of decryption can be described as four step process as illustrated below:

```

for(ii=0;ii<nx;ii++) // nx → Number of input data
{
    ss1=int(yy11[ii]);
    frac1= yy11[ii]-ss1;
    ss2=Mod_Int3(ss1);
    yy11[ii]=ss2;
    yy11[i]=yy11[ii]+frac1;
    kk2[i]=(asin(yy11[ii])*(180.0/key));
    kk3[i]=(acos(kk2[ii])*(180.0/key));
    qq1=(int)round(kk3[ii]);
    ab2[i]=hash1(qq1);
}

int Mod_Int3(int xx)

```

```

{
    int static r1;
    int AA1, BB1, AA2, BB2;
    AA1 =xx & 0xff;
    BB1 = (xx >> 8) & 0xff;
    AA2 = (xx >> 16) & 0xff;
    BB2 = (xx >> 24) & 0xff;

    r1 = (AA1 << 24) + (BB1 << 16) + (AA2 << 8) + (BB2);
    return r1;
}

```

These values(xx) after rearrangement with Mod_Int3 function will go into the *aSin* (xx), and the output of *aCos* (yy) after calculating the message digest of output and comparing it with received message digest, if the comparison is positive will form the plane text or message to be accepted by receiver. As we have changed the value of $\pi = SK_1 = 1.137201$ (for example), the result will be automatically changed as seen in the plane text.

The general methodology for calculating *plain text* is a four step process:

1) The input to decryption algorithm is manipulated using Mod_Int3 function which rearranges the bytes in the input i.e input least significant byte is placed most significant bytes place that means interchanged then (least significant -1) byte is interchanged with (most significant -1) this is repeated for all the bytes /2 in the input. The output of Mod_Int3 is given as input to next stage.

2) The output of previous stage acts as the input to *Sin* function i.e. the out will be given to (*aSin*(*aTan* output)*key/180.0), as *aSin* also takes radian value the same procedure is adopted as above for generating output.

3) The output of *aSin*function will be the input to *aCos* function i.e. the output will be given to (*aCos*(*aSin* output)*key/180.0), as *aSin*function also takes radian value the same procedure is adopted as above for generating output as above for generating output. The output of *aCos* is given to Hash function(HA-160) for generating message digest, then the generated message digest is compared with received message digest(from sender), if matched then only the output of *aCos* is accepted as received message(plain text) otherwise it is rejected. Experimental results are shown in Table IV.

TABLE IV. DEMONSTRATION OF DECRYPTION PROCESS

Ciphertext	Key(pi)	Hash value check	Plain Text
0.015350	3.0000	Hash value check for each cipher text	24
0.014351	3.0000		32
0.009919	3.0000		56
0.007806	3.0000		65
0.005780	3.0000		73

VI. MYSTERY KEY FOR SESSION UPDATE PHASE AND USER PASSWORD UPDATE PHASE

Right when the data correspondence time among sender and beneficiary methodologies update period, GN Server makes information for update secret key for next session(DUMK) and encodes it and sends it to both User and Sensor Node.

$$EIDUMKSs = X IDs - GN \oplus DUMK$$

$$EIDUMKUm = MM2 \oplus DUMK$$

At that point server sends EIDUMKSs (encrypted data for update mystery key for next(new) meeting) to the Sensor Node and EIDUMKUm (encrypted data for update mystery key for next(new) meeting) to the User. Subsequent to getting this data, Sensor Node quits sending information and hangs tight for another mystery key meeting. Subsequent to getting the solicitation both User and Sensor Node suspends their activity and User sends { IDm , RPWm, σm } to GN Server and the cycle of enlistment and verification and meeting key synchronization start which brings about formation of new meeting key(i.e. second meeting so SKS₂) at both at mobile device(user) and Sensor Node(Ss) additionally at this junction, if client needs he too can change his password(PWm).

The aggregate of the above are the nuances of the lightweight arrangement. The arrangement consolidates three phases. In like manner approval stage, we present a grouping key (xx1, bm , X_{GN} and X_{IDs - GN}) and pre realized a solitary bearing hash function(H1). It can comprehend shared approval just as hinder various attacks. Variable gathering key is proper for different applications and prevents attacks satisfactorily.

VII. DISCUSSION OF SECURITY FEATURES

In this part, we show our protocol achieves some excellent functional properties and can resist well-known attacks. Besides, the comparative analysis of our protocol and other relevant protocols are also given in this part.

A. Proper Mutual Affirmation

The versatile device(user) and GN Server can validate each other in light of the fact that toward the beginning of verification, mobile device(user) himself checks if he is certified by contrasting a worth he makes i.e Am = A'm. The client registers A'm esteems from the information which he supplies at the hour of verification. The Am is pre figured worth done at the hour of enrollment from the data(Bm) given by GN server. So whenever figured value(A'm) is equivalent to preexisted value(Am) which implies that client is certifiable and when GN server registers MM5 = MM'5 , GN server gets a confirmation that the client is real Also the sensor hub get an affirmation about the GN server when it checks MM7=MM'7 . The GN server gets an affirmation about the sensor hub when it figures MM'8 and contrasts it and the got MM8 esteem from the sensor hub i.e MM'8=MM8 gives a confirmation to the GN server about the sensor hub. The portable device(user) get an affirmation about GN server when he figures MMM'10 and contrasts it and the got MMM10 esteem from the GN server. The GN server and mobile device(user) has a pre shared one way hash work H1(·), just real GN Server and portable device(user) realizes the arranged one way hash work H1(·)

and the GN worker and sensor hub has a pre shared one way hash work H1(·), just real GN Server and sensor node(Ss) realizes the arranged one way hash work H1(·).

B. Quickly Identification for Unapproved Login

Here the plan the Sensor Node information can be gotten to by versatile device(user) simply in the wake of passing shared confirmation and key synchronization stage and toward the beginning of the stage the client's login(identity ID) ,secret word and biometric needs to pass the check. Some unacceptable secret key checking instrument permits the cell phone to rapidly recognize and dismiss unapproved login brought about by wrong secret word, and the confirmation cycle can be found in the Step 1 of shared verification and key synchronization stage. Nonetheless, the protocol [17] had no such instrument to recognize wrong secret word.

C. Oppose Mobile Device Misfortune Attack

In the event that an aggressor A gets Um's cell phone ,A can recover the parameters { Bm, Gen(·),Rep(·), XX, τm } in the cell phone by utilizing power examination attack[18]. Here Bm = Am \oplus (RPWm $\oplus\sigma m$), RPWm = (PWm $\oplus\tau m$).

Am = Bm \oplus (RPWm $\oplus\sigma m$), and σm is an irregular number extricated from Um's biometric information . As Bm, RPWm and Am are figured from obscure arbitrary numbers RPWm, τm , σm and H1(one way hash work), the assaulter A will be unable to figure these boundaries precisely which may bring about finish of validation stage as the variable A'm at the hour of verification may not match so our protocol can dodge cell phone misfortune assault.

D. Customer Mystery and Intractability

Believe that a login demand message {MM3, MM4,MM5} is snooped by aggressor A, where MM3= IDm \oplus MM2, MM4=IDs \oplus MM2 and MM5= H1(A' m) where MM2= bm*XX is critical and this key is the result of private key of user(bm) utilizing elliptic curve idea and XX is the public key of GN server utilizing elliptic curve idea i.e. key is made by Diffie-Hellman key exchange idea, assailant A can't recover MM3,MM4 until it have the data about the private key of GN Server or private key of mobile device(user). MM5 is created from Am which is known to just mobile device(user) and GN server and from hash code the assaulter A can't recover Am. So by utilizing private key and public key (elliptic curve idea and Diffie-Hellman key exchange) , symmetric mystery key of GN server(X_{GN}) and one way hash work H1(·), the proposed convention accomplishes the component of client mystery. Here after GN Server gets the login data it can recover the Um recognizable proof (IDm) as it has the key additionally in this protocol first the client personality check is done carefully toward the beginning of validation and key synchronization phase(Am=A'm). Likewise the component of login request message relies upon bm(user private key), in this way aggressor A can't follow User(as no fundamental data is passed straightforwardly) from public channel. In any case, the scheme [17] can't accomplish the capacity of intractability.

E. Sensor Hub Mystery

In this plan, Sensor Node's personality isn't sent out in the open channel as plaintext. At the point when Um needs to get

to the Sensor Node(Ss) information, Sn character is scrambled when Um send the solicitation to GN server for correspondence with Sensor Node Ss which GN Sensor can recover by decoding it with comparing secret key. Any aggressor without the information on relating secret word can't get Sensor Node's personality IDs and the plan accomplishes the component of sensor hub namelessness.

F. Appropriate for Internet of Things Applications

In our plan, GN Server is a confided in outsider for mobile device(user) and Sensor Node(Ss) and the verification and key synchronization stage is finished with the assistance of GN Server . With this the over-burden of both User and Sensor Node is diminished additionally it saves energy utilization of both portable device(user) and Sensor Node(Sn) (as the energy utilization of sensor hub is straightforwardly extent to the correspondence distance) also expands the life cycle of sensor nodes. Alongside when the common validation and key synchronization stage finishes, a meeting key SKS at both mobile device(user(Um)) and Sensor Node(Ss) is given by GN server, which can guarantee the resulting secure correspondence among Um and Ss. Consequently the portray design for our plan is reasonable for most IoT application. However, in some past related work [13], the client discuss straightforwardly with sensor hubs, it would lessen the existence pattern of sensor organizations and isn't reasonable for IoT applications.

G. Restrict Impersonation Attack

From the depiction of verification and meeting key Agreement stage, assailant A necessities the data of IDm and Am = (IDm ⊕ X_{GN}) to mimic as a real client to make a substantial login demand. However, from the description above, the proposed protocol provides the feature of user anonymity, and any gathering with the exception of GN can't get client's personality IDm. Likewise, Am must be recovered by Um from Bm utilizing PWm, rm and σm or can be determined by GN server utilizing IDm and GNs(secret key of GN server) when he/she gets IDm. Therefore, aggressor A can't get Am without knowing required data, and our protocol can maintain a strategic distance from client impersonation assault. Additionally, to mirror as the GN worker, the private keys xx1 and GNs(secret key of server) is fundamental data for assailant A to produce substantial correspondence messages. Nonetheless, xx1(private key) and mystery key(X_{GN}) of GN server and known to GN server just, and the proposed convention can stay away from entryway impersonation assault.

H. Oppose Replay Assault

In this plan, the single direction hash work system is received to oppose replay assault. In various strides of confirmation and key synchronization period of the plan, the hash code is created by Um, GN Server and Sensor Node for processing correspondence messages. Since the hash code carefully follow avalanche effect little change in message will create gigantic change in hash code so it would be hard for an assaulter A to figure the shared message on which the hash code are produced, so it is hard to perform replay assault. Consequently, our plan is secure from replay assault.

I. Simple Secret Key Change

In our plan, as the update time frame for key finishes. The GN worker starts a solicitation for change of mystery key for meeting. For this the GN server sends encoded message to User and sensor hub, so the cycle of progress of secret phrase begins. In the wake of accepting the solicitation both mobile device(user) and Sensor Node(Ss) suspends their activity and User sends { IDm , RPWm, σm} to GN Server and the cycle of enlistment and confirmation and meeting key synchronization start which brings about production of new meeting both at User and Sensor Node. At this intersection the mobile device (user) can likewise change his password (PWm).

TABLE V. PARAMETERS VALUES

Parameters Values(in bits)
IDm - 80
IDs - 160
X _{GN} , X _{IDS-GN} , PWm(All Password) - 160
bm,xx1,XX,MM1 - 320
Hash value - 160
Note: Values taken as per Xiong-Li[21]

VIII. PERFORMANCE ANALYSIS

A. Process Computation Time

We look at the time of the common attestation stage, which is executed using[19][20] in the three conventions (DES algorithm, Xiong -li scheme(2017) and our convention). Analysis, were led on a PC with windows7 32bit, 2.00 GHz with 2 GB of internal memory utilizing C/C++ language. The yield says that our plan accomplishes the best time execution of 31000 μs(microseconds) as shown in Fig. 8, DES algorithm 31000 μs(microseconds) and Xiong-Li(2017) common attestation time is 31000 μs(microseconds) , which is shown in the Fig. 9 beneath.

Our proposed plot is having less overhead, and can restrict various attacks. Researching Xiong-Li(2017)[21] basic affirmation in this arrangement it allows the sensor device to go about as server as it makes the mysterious expression and accommodates customer and does an incredible arrangement getting ready which is illicit of lightweight count rules. Also ChangLi(P1) plan like shared confirmation isn't done suitably, faces stolen smart card attack, further more encounters tracking attack, not applicable to practical application, delayed and costly detection of wrong password input, lack of identity detection mechanism and unfriendly mystery key change In our arrangement, we simply use XOR and XNOR action, one way Hash work and elliptic curve cryptography methodology for shared approval and meeting key synchronization. Moreover, session key is created by server and synchronized with IoT node and user (mobile device). Fig. 9 shows that our scheme takes minimum time for authentication. It is a nice technique to minimize the overhead of IoT hub.

Fig. 8. Result of Execution of Our Algorithm.

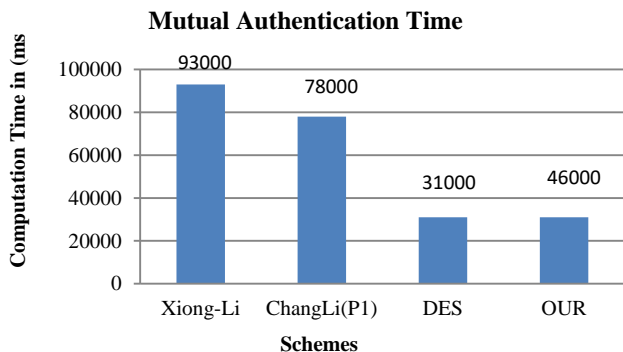

Fig. 9. Examination of Shared Confirmation Time among Xiong -Li(2017), Our Scheme and DES Algorithm.

B. Performance Analysis of Hash Algorithm(HA-160)

These three calculations HA-160, SHA1 and MD5 were tried for comparison dependent on the execution time necessities as shown in Fig. 10, Fig. 11 and Fig. 12. All the calculations have been actualized in C/C++ and run on windows 7 32-bit, CPU 2.00 GHz with 2 GB of internal memory. With the aftereffects of the analysis, it was discovered that SHA1 and MD5 requests more execution time than HA160 to create hash code.

The outcome in above Fig.11 shows time taken by three calculation (MD5, SHA1, and HA160(size of message taken by HA160 is double than SHA1)) for producing hash code for the message “ The quick brown fox jumped on the lazy dog “.

Fig. 10. Processing Time by HA-160 Algorithm“The Quick Brown Fox Jumped on the Lazy Dog”.

Fig. 11. Assessment of MD5, SHA1 and HA 160 Concerning Time Taken to Execute the Message “The Quick Brown Fox Jumped on the lazy Dog “ i.e. 34 Bytes.

Fig. 12. Demonstrating Avalanche Effect. The Input Message used and the Two Altered Message (Dog is Replaced by Cog and Eog in Input Message) for Comparison is Shown Below.

A. Message: “The quick brown fox jumped on the lazy dog “
 Compared with
 cog :“The quick brown fox jumped on the lazy cog “
 eog:“The quick brown fox jumped on the lazy eog “

Table VI shows the message digest conveyed by three calculation (HA160, SHA-1 and RIPEMD160) for the message "The quick brown fox jumped on the lazy dog". Table VII shows the adjustment in hash code when the message in Table VI is modified for example dog is dislodged with cog, HA-160 produces a hash code with change of paying little heed to hexadecimal attributes from e and f(starting from left showed up in solid), SHA-1 yield is a hash code with change of with or without hexadecimal attributes from 9 and 1(starting from left showed up in serious) and RIPEMD 160 produces a message digest with change of paying little mind to hexadecimal attributes from f (starting from left showed up in strong) and Table VIII shows the adjustment in hash code when the message in Table VI is adapted to occurrence dog is supplanted with eog, HA-160 produces a message digest with change of each hexadecimal quality , SHA-1 yield is a hash code with change of with or without hexadecimal attributes from f, 2, 4 and 3(starting from left showed up in unprecedented) and RIPEMD 160 produces a message digest with change of with or without hexadecimal qualities from 4 and 4(starting from left showed up in strong).So on an ordinary HA-160 shows better result when any character is changed. The result is better than SHA160 and RIPEMD160 as shown in Fig. 11.

TABLE VI. RESULT

Algo/Input: "The quick brown fox jumped on the lazy dog" HA160: a5abc142 e821f1a2 48d60829 f8544618 697ea332 SHA1: 42914f6d 22976baf d4bab416 fe23b03d 4fa74963 RIPEMD160 :39349b80 fc87ec4c 887ccd87 4943f253 ee051126

C. Communication Overhead

To investigate the correspondence overhead, we expect that the eight messages (i.e., Message1, Message2, Message3, Message4, Message5, Message6, Message7 and Message8) are communicated during the enrollment system and the confirmation method. All the more accurately, Message1 and Message2 are sent in the enlistment strategy and Message3, Message4, Message5, Message6, Message7 and Message8 are communicated in the verification technique. Message1 incorporates the sensor's character ID_m, RPW_m(encrypted password) and uniform random number generated from Biometric information(σ_m) and Message-2 includes B_m(a value generate from GWN server from A_m) and XX(public key of GWN Server) . In addition, Message3 includes MM1, MM3, MM4 and MM5 which are calculated as follows:

$$|MM1| = |bm * PP|$$

$$|MM3| = |MM2 \oplus ID_m|$$

$$|MM4| = |MM2 \oplus ID_s|$$

$$|MM5| = |H1(A' m)|$$

Moreover, the parameters MM6 and MM7 in Message 4 , are calculated as follows:

$$|MM6| = |X'_{ID_s - GN} \oplus ID'_m|$$

$$|MM7| = |H1(X'_{ID_s - GN})|$$

then, the parameter MM8 in Message 5 , is calculated as follows:

$$MM8 = H1(X_{ID_s - GN} \oplus ID'_m)$$

also, the parameter MM9, MM10 and MMM10 in Message 6 , is calculated as follows:

$$|MM9| = |X'_{ID_s - GN} \oplus SKS|$$

$$|MM10| = |MM'2 \oplus SKS|$$

$$|MMM10| = |H1(A''m \oplus ID'_m)|$$

Finally, the parameter MM11 in Message 7 and MM12 in Message 8 is calculated as follows:

$$|MM11| = |H1(MM10)|$$

$$|MM12| = |H1(MM9)|$$

Table V contains the setting of boundaries that we have accepted for assessing the correspondence overhead of the proposed component as shown in Table IX. Subsequently, the general transmission capacity overhead of the proposed component is determined as follows:

$$bw = \sum_{i=1}^8 \text{Message } i$$

Message 1 = |ID_m| + |RPW_m| + | σ_m (random number)| = 400 bits
 Message 2 = |B_m| + |XX| = 480 bits
 Message 3 = |MM1| + |MM3| + |MM4| + |MM5| = 1120 bits
 Message 4 = |MM6| + |MM7| = 320 bits
 Message 5 = |MM8| = 160 bits
 Message 6 = |MM9| + |MM10| + |MMM10| = 480 bits
 Message 7 = |MM11| = 160 bits
 Message 8 = |MM12| = 160 bits

TABLE IX. COMMUNICATION COST OF OUR PROPOSED MECHANISM

Scheme	Communication Cost
Our Scheme	3136 bits
Xiong-Li[21]	2688 bits
Chang-Le's[21]	2400 bits

D. Computational Expense

To figure the computational expense of the proposed system, we have thought about the accompanying documentations: Th indicates the expense of single direction hash work, T_m signifies the expense of Multiplication activity, T_s means the expense of encryption and unscrambling activity. In view of the three parts (i.e. brilliant sensor, client and verification worker) which are utilized in the proposed instrument, the computational expense of every segment is introduced as follows:

- 1) Smart Sensor: The brilliant sensor performs calculations just in the verification method.
- 2) User: The client performs calculations in the enlistment and verification stage.
- 3) GN Server: The GN server performs calculation activities in enlistment and validation stage. The proposed component's computational expense is delineated in Table X. Because of the way that the proposed verification system depends just on scalar duplication activity utilizing ECC, a symmetric encryption/decoding activity and hash activity.

We use the simulation result [23] where T_m(cost based only on scalar multiplication operation using ECC) = 1.226ms, T_s(cost based only on symmetric encryption/decryption operation) = 2.049 μ s and T_h(cost based only on hash operation) = 2.580 μ s.

TABLE X. COMPUTATIONAL COST OF OUR PROPOSED MECHANISM

Scheme	User(Mobile device)	GWN Server	Smart Sensor	Total Cost
Our Scheme	3*Th + 2*Tm	6*Th + 1*Tm	3*Th	2482.96 μ s
Xiong-Li[21]	7*Th+ 2*Tm + 2Ts	8*Th + 1*Tm + 4Ts	4*Th + 2Ts	3743.412 μ s
Chang-Le's[21]	6*Th + 2*Tm	8*Th	5*Th + 2*Tm	4953.000 μ s

Note: Considering the process computation time for mutual authentication, computation cost, communication cost and other indicators, our algorithm performs well in most of the cases. The most prominent advantage is its process computation time for mutual authentication and communication cost.

E. Encryption and Decryption Algorithm Analysis

The investigation of the proposed trigonohash calculation for encryption and unscrambling has been done and exhibited in Table III and Table IV. The Encryption and Decryption Algorithm was coded in C/C++ Language[19][20]. It was compiled with MinGW-GCC 4.8.1, on the Core 2 Duo Processor, 2.00 GHz under windows 7 OS(32 bit). The investigation boundaries are plain content size (in Bytes) and time taken in encryption and unscrambling (in μ seconds).

a) Comparative PerformanceAnalysis: The proposed Trigonohash algorithm(LW-algorithm) has been compared with other existed algorithms like RC4, Hill-Cipher[19][20], RSA, Present(Block Cipher with key 80 bits and plain content 64 bits or 8 bytes) [27] and ELSCA(LW-Stream Cipher) - (Varient-HassanNoura(2019(key consist of 4 location)) stream cipher)[22]. Likewise, the results are shown below. From the going with Fig. 13 and Table XI we can say that the run time unpredictability of trigonometric Algorithm is underneath than the other existed Algorithm plot.

TABLE XI. SAMPLE RESULT FROM DIFFERENT ALGORITHM.(RESULT IN MICROSECOND)

No of Bytes	RC4 (stream cipher)	Hill-Cipher (Symmetric encryption)	RSA (public key encryption)	Present(LW-Block Cipher(64 bits))	ELSCA(LWStreamCipher-2017)	Trigonohash(LW-algorithm)
12	31000	16000	31000	47000	15000	00000
20	46000	46000	31000	78000	46000	16000
28	62000	63000	47000	125000	47000	31000
36	93000	78000	78000	156000	93000	62000

Fig. 13. Execution Examination of Encryption Algorithm of different Protocol.

IX. CONCLUSION

In this paper, we propose a strong and weighty cryptographic arrangement for Industrial Internet of Thing using one way hash work, elliptic curve cryptography and trigonohash(trigonometry and hash work) idea and endeavored to improved security and execution of a cryptographic arrangement for lightweight contraption using key generation. It gives keen and feasible instruments for basic affirmation, meeting key synchronization and meeting key update. They are proper for IoT hub with limited handling resources and force. First thing, we present the nuances of shared affirmation using elliptic curve cryptography and one way hash work and a way to deal with hinder replay attack without timestamp. Besides, again elliptic curve cryptography and one way hash idea is progressed to simply recognize meeting key synchronization lastly by using mathematical thoughts data encryption and unscrambling are done to diminish the overhead of IoT center points. In addition, we have taken a gander at the security and execution of our arrangement with some lightweight approval and cryptographic plans. The arrangement is lightweight anyway can thwart attacks satisfactorily, which is useful for guaranteeing the security of the correspondence between IoT center points, users(mobile gadget) and server.

The proposed figuring for encryption isn't simply giving the quick data encryption anyway it gives an unrivaled security diverged from other count through a most grounded key as well. The assessment of π is changing each time which is created from the common key that makes the count adequate. The estimation moreover makes the cryptanalysis cycle complex. Since there are dark variables will be more and the amount of conditions will be less when stood out from other standard encryption computations. This calculation could be well valuable for online applications like secure web based talking, data transmission between resource constraint devices and health sector.

Abstract—Cloud computing has been adopted very rapidly by organizations with different businesses and sizes, the use of cloud services is rising at an unparalleled rate these days especially IaaS services as cloud providers offer more powerful resources with flexible offerings and models. This rapid adoption opens new surface attacks to the organizations that attackers abuse with their malware to take advantage of these powerful resources and the valuable data that exist on them. Therefore for organizations to well defend against malware attacks they need to have full visibility not only on their data centers but also on their resources hosted on the cloud and don't take their security for granted. This paper discusses and aims to provide the best approaches to achieve continuous monitoring of malware attacks on the cloud along with their phases (before, during, and after) and the limitations of today's available techniques suggesting needed developments. Logging and forensics techniques have always been the cornerstone of achieving continuous monitoring and detection of malware attacks on-premises, this paper defines the best methods to bring loggings and forensics to the cloud and integrate them with on-premises visibility, thus achieving the full monitoring over the whole security posture of the organization assets whether they are on-premises or on the cloud.

Keywords—Malware attacks; infrastructure as a service (IaaS); amazon web services (AWS); malware detection; cloud forensics; visibility

I. INTRODUCTION

The cloud is a technology that's not new anymore. Nowadays, using cloud services is increasing at an unprecedented pace [1], it has become more popular after the advent of the Fourth Industrial Revolution (IR 4.0) [2] In 2020, about 83% of business workloads operate in the cloud, and a whopping 94% of companies now use a cloud service in one form or shape [3]. There are three most utilized cloud services include Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS).

Infrastructure as a Service (IaaS) is one of the most critical and fastest-growing services in Cloud Computing. As shown in Fig. 1, according to BMC the growth rate from 2018 to 2022 of IaaS is projected to be 18% higher than that of other cloud services.

In this service model, cloud providers provide resources to users/machines such as virtual machines (VMs), raw (block) storage, firewalls, load balancers, and network devices. Resource management for IaaS gives the following advantages Quality of service, scalability, reduced overheads, optimum utility, increased throughput, specialized setting, reduced latency, a streamlined interface, and cost-effectiveness. Virtualization technology is used to offer Infrastructure which enables multiple consumers or tenants to share the same hardware. Virtual machines (VMs) play an important role in Cloud Computing because they allow powerful and systematic use of the hardware available [4].

All these outstanding features make it simple and convenient to access the IaaS service. However, many individuals use this technology in an effective way and few challenges to use it [5]. Infrastructure hosted on the IaaS cloud is becoming targets to many attacks like malware for the following reasons:

1) Cloud service providers steadily offer higher performance with high computation power for their customers. These VMs are big targets for crypto currency mining malware, which are becoming more sophisticated to take the resources of the server without getting noticed.

2) The increase of remote working and globally dispersed workforce and application accessibility especially after the COVID 19 give the attackers more chances to hide their malicious traffic to compromise the cloud-hosted VMs, and use them for their malicious campaigns (phishing campaigns, botnet command, and control, so on).

3) The increase in IoT applications that use cloud-hosted infrastructure to analyze the enormous amounts of data generated by these applications to create business value and insights. Most of these IoT appliances are built with no or weak information security measures thus attackers can easily get their way to the backend cloud-hosted VMs through these IoT devices and applications.

Fig. 1. The Growth Rate (from 2018 to 2022) of cloud Services.

Malware protection is becoming increasingly essential for cloud network security, as it presents a significant threat to network security. Since malware security is minimal, only PC-based protection is up to date [6]. According to Noëlle and others [7] present attacks in the IaaS cloud can be investigated using VMI-based mechanisms. [8] Gives a summary of the different malware detection methods used for intrusion detection. Various machine learning methods can be used to provide a Cloud Computing detection mechanism. In that way, an improved technique is needed to ensure effective intrusion detection for such techniques. The researchers have used a malware detection technique to detect malware in [9], which is SAIDS, a security monitoring system tailored for IaaS clouds, but it only handles one form of IDS. G. Murali and N. Moses [6] in this work propose a framework that deals with anomaly detection malware at the network level, stating that malware distribution in terms of networks varies. Many studies in [10] address cloud forensics in general terms without offering details.

Therefore, this research combines technologies and forensics to monitor and detect malware attacks that targeting VMs in the IaaS cloud. Begin to classify malware attacks in the infrastructure hosted on the IaaS cloud, shed the light on the importance of cloud services visibility to thoroughly track each malicious activity on the cloud-hosted infrastructure and quickly react to malware attack, then list the different approaches and techniques used to gain this visibility and how to perform analytics on this collected data to get insights helping improve the reactive and proactive defenses. Then testing the existing technologies and methodologies for monitoring cloud-hosted infrastructure and performing digital forensics on the cloud-hosted assets and how both can be used to speed up the detection of malware attacks then quickly deploy countermeasures to better stop them from reaching their goals.

This research which addressing the security of infrastructure in IaaS cloud is noble, because it focuses on an investigation that will render the safety of this service, which is conducted on the IaaS cloud. This cloud service has dominated not only small businesses but also global

enterprises including big multinationals. As such this topic is very informative since it will detect malware in its early stages. [11] All this provides organizations a feeling of reassurance that their assets are safe and secure.

II. BACKGROUND

A. Infrastructure as a Service (IaaS) Cloud

The cloud service model's bottom tier is IaaS [12]. It is the most fundamental and critical service, offering basic computing services such as servers, networking, and storage. These resources make use of virtualization technologies to execute services. IaaS also provides users with data security, backup, and maintenance [13, 14]. Consumers have full control over these tools, which are aggregated and controlled [15]. Some companies cannot afford to purchase a computer, so instead of buying the infrastructure, it can be leased or rented according to the needs of the users. This service enhances system availability while also lowering costs and offering a more flexible system.

Common examples of this service: Amazon Web Services (AWS), Google Compute Engine (GCE), Microsoft Azure, and Cisco Metapod.

Despite all of the technical developments in IT security over the last three decades, the Latest statistics also show an increase in malware activity, Deep Instinct conducted analysis and have published a study on the hundreds of millions of attempted cyber-attacks that occurred every day in 2020, Revealing that malware increased by 358 percent overall and Ransom ware increased by 435 percent compared to 2019.

B. Malware Attacks

Malware is a term that combines the word malicious and malware, thus malware is described as software that has a malicious and harmful effect on networks, software, operating systems, or other components [16].

Malware, according to [17], is a software program that is intended to help malicious attackers accomplish their goals. It was created to help attackers accomplish their objectives. Disturbing device processes, altering or hijacking core computing functions and network resources, tracking users' behavior, and stealing, encrypting, or deleting confidential data without the user's permission are just a few of these objectives.

One of the biggest challenges in the IaaS cloud world is malware attacks; malware has long been a major concern to home and business devices, as well as cloud virtual machines [18]. Virtualization, as one of the most important Cloud Computing techniques, blurs the lines between time and space. Virtualization would undoubtedly increase resource efficiency and reduce system management costs [19]. But unfortunately, virtualization creates new vulnerabilities, which are being exploited by malware.

According to Malwarebytes' 2021 Malware Study, attackers exploited the COVID-19 public health crisis in unthinkable ways previously, not only preying on uncertainty and fear during the early months of the global pandemic, but also enhancing malware, retooling assault tactics, and

extorting targets to the tune of \$100 million. Malware is multiplying at an unprecedented pace, every day AV-TEST registers more than 350,000 new malware in 2021, and there is an increase in the total of malware compare with the last five years as shown in Fig. 2.

Fig. 2. Total Malware in Last Five Years.

The malware must be discovered before it affects the most resources and networks. In order to protect infrastructure hosted in an IaaS cloud, malware detection must be successful.

C. Malware Detection Methods

In the IaaS cloud world, There are several unique and has different on-demand services available for consumers. These services provide easy and straightforward access to a range of web apps. The virtualized nature of IaaS environments may be a weakness when it comes to malware [20], As a result, malicious attacks and breaches may strike at any time, destroying important apps and files [5]. One of the most difficult challenges in the creation of resilient and stable cloud-based mechanisms is the accurate detection and identification of malware. This is attributed to that malware is often the starting point for phishing, massive Distributed Denial of Service (DDoS) attacks [21], and email spamming by the use of a botnet. For that detecting malware as soon as possible is very important. To resolve the many different attacks and threats that exist in IaaS clouds, continuous and automatic security monitoring of Infrastructure has become a primary requirement [22].

There has been a rapid rise in the number of research studies on malware detection in the IaaS cloud in recent years. A variety of techniques have been proposed to detect malware. These techniques can be divided into four categories: Signature-Based Techniques, Behavior-Based Techniques, cloud-based Techniques, and Machine Learning-Based Techniques.

The procedure for extracting features differs from one Technique to the next. It is difficult to prove that one detection approach is superior to another since each approach has its

own set of benefits and drawbacks [23]. Since malware comes in a variety of shapes, sizes, and behaviors, as well as various levels of danger, the same detection methods and mechanisms cannot be used in every situation. It is impossible to detect malware with only one approach to security. [24] As a consequence, having different detection techniques for various conditions is inevitable.

The following describes in detail the approaches to monitor and detect malware attacks:

1) *Signature-based techniques for malware detection:* A signature is often a short sequence of bytes that is exclusive to each known malware and enables new files to be correctly detected with a low error average [25]. They are commonly used in commercial antivirus software to detect known malware. Traditional signature-based techniques preserve a listing of signatures that are stored in the database, if a match is found, an alert is triggered, and the database is updated [26]. These signatures are formed by disassembling and analyzing the code, there are many disassemblers and debuggers tools are available to aid in the disassembly of portable executable (PE). In this way, code is analyzed then features are extracted. As a consequence, these features play a primary and important role in creating a malware family's signature [27].

Signature-Based techniques are very quick and effective to create a signature. The major feature of this method is the precision with which they detect malware. It is capable of detecting known malware instances quickly and with a smaller amount of malware. A downside of this technique is that of being unable to detect unknown malware. When new malware is released into the market, it must wait until it has infected many systems before its signature can be created and added to the databases. These techniques also have the drawback of being unable to identify encrypted or polymorphic malware [26] that indicates they are not resistant to malware obfuscating techniques.

2) *Behavior-based techniques for malware detection:* It's also known as Heuristic-Based Detection or anomaly Detection. A behavior-based detection technique uses monitoring tools to observe the programs' behavior and identified whether is it malware or benign? The main goal of this technique is to examine the behavior of malware, known and unknown [23]. It is divided into two phases [28, 29]:

a) *The training (learning) phase:* Involves monitoring the system's behavior in the absence of an attack or malware, also a learning task is carried out in order to teach the classifier to behave normally.

b) *The testing (monitoring) phase:* The normal stage is compared with the current behavior then detects suspicious behavior, identifying anomaly activities, looking up the protocols and ports used, and indicate any malicious activities in order to inform the responsible of deviations or major variations from the baseline [30].

The main feature of the behavior-based approach is the capability to detect both unknown malware. However, there are major drawbacks of this technique which are a high False-

Positive Rate (FPR) and a long monitoring duration [31]. Further, the ability to detect malware like zero-day attacks is directly impacted by the decrease of thousands of extracted features, evaluating similarities between them, and surveillance of malware activities [32].

3) *Cloud-based techniques for malware detection:* Cloud Computing has grown in popularity as a result of its numerous benefits, including easy access, on-demand storage, and lower costs. Because the cloud is so widely used, it's also been used to detect malware. Cloud-based malware detection improves the detection performance for devices and VMs with much larger malware databases and strong and many computational resources. This detection approach employs a variety of detection agents distributed across cloud servers and provides security as a service. The users can upload any type of file and get a record of whether or not the file is malware [23]. In [33] Sun et al created a cloud-based detection malware system, called Cloud Eyes, which has provided resource-constrained devices with effective and trusted security services. Cloud Eyes detected malicious buckets through cross-filtering on the

cloud server. In [34] the researchers implemented a malware detection infrastructure realized by an intrusion detection system (IDS) with cloud and mist computing to overcome the IDS sending problem in brilliant objects due to their constrained resources and heterogeneous sub networks.

IaaS cloud is the most flexible model. Users have more choices when it comes to performing IDS over this infrastructure. Intrusion Detection Systems (IDS) can be used in a variety of ways over the IaaS cloud layer [22], including:

4) *Network-based Intrusion Detection Systems (NIDS):* All network packets are collected and analyzed in the cloud environment using signature or behavior-based detection approaches to identify malicious events and activities like port scanning, DoS attacks, user to root attacks, etc [35-37]. It's used to keep track of network traffic between VMs and host machines, as well as between VMs [22].

There are several models for adapting NIDS to the cloud shown in Table I:

TABLE I. VARIATION BETWEEN CLOUD NIDS/NIPS MODELS

Cloud NIDS model	Ease of management	Cost of operation	Cost of implementation	Customization and Integration capabilities	Level of visibility
IDS on-premises and usage of VPC endpoints	Easy to be manageable as the on-premises IDS scope will just be extended to the cloud environment	High cost due to data transfer expenses as all data will be sent from the cloud environment to the on-premises IDS for inspection. plus, the cost of operating high-performance VPN tunnel	low cost as it doesn't involve purchasing new appliances or special cloud deployments or modifying network architectures	The IDS rules and policies will be consistent over both the on-premises environment and the cloud. The cloud will just look like an extension to the on-premises environment	The IDS will be able to monitor the traffic going in and out the cloud environment but there is no visibility on inter traffic within the cloud environment itself
IDS on VPC NAT instances or dual-homed systems	Easy to deploy model but hard to be manageable because the organization is responsible for the configuration and customization for each aspect of the IDS and keeping it in pace with new threats and attacks	High cost of operation One single point of failure that can lead to services unavailability when it's malfunctioned or misconfigured Needs high skilled engineers which can be expensive	The cost of implementing a VPC NAT instance will depend on the size of the VPC and its instances which can be Medium to high cost	Highly Customizable Security teams can add up new features at no cost Highly customizable dashboards and deferent detection mechanisms Due to the high customization, there won't be obstacles bringing the rules and policies from on-premises IDS, thus providing consistency along both environments	Has visibility on the cloud traffic that will go only through the cloud gateway Doesn't extend the capabilities of the on-premises IDS
Usage of 3rd party AMI as the NIDS	Custom route and traffic control is required Requires distinct network zone for the appliance for centralized monitoring Management of the appliance is the responsibility of the security team for the organization which adds extra tasks and extra appliances to be managed	Cost will depend the amount of data fed to the appliance As it's another appliance to be managed, there will be a cost of management will be added in terms of providing the adequate numbers to manage organizations' appliances	Cost will depend on the Vendor, the features purchased and the amount of data fed to the appliance which will range from Medium to High Cost Due to the high cost If the appliance technology differs from the IDS used on premises, then there will be additional costs for team training or hiring new skills	Customization is limited to the capabilities and features available of the purchased appliance If the technology of the cloud-based IDS differs from the on-premises IDS then there might be rules and policies inconsistency between both environments	Has visibility on the cloud traffic that will go only through the appliance which is to or from the VNet Due to the pay per the data ingested approach organizations usually don't integrate it with the test and pre-production environments on the cloud

5) *Host-based Intrusion Detection Systems (HIDS)*: At the host level, data is processed, tracked, and analyzed. It monitors and detects modifications in the host kernel, program behavior, and file system [38-40]. These IDS may be installed on a host, virtual machine (VM), or hypervisor (VMM) to detect intrusion events by analyzing device logs against user credentials and access control (AC) policies [41]. In this way, Customers then notify managers if they notice any abnormal activity [22].

The cloud user is in charge of monitoring HIDS deployed on a VM, while the cloud provider is in charge of HIDS deployment on the cloud [42].

6) *Distributed Intrusion Detection Systems (IDS)*: Multiple intrusion detection systems (IDSs) (such as NIDS and HIDS) are deployed over a wide network to track and analyze traffic patterns for intrusion detection, and they can function independently or collaboratively [43,44].

7) *VMM/Hypervisor-based Intrusion Detection Systems (HypIDS)*: Hypervisors that host VMs can easily access performance data; these data offer insight into the activities taking place inside a virtual machine without requiring direct knowledge of the virtual machine's operating system, software, or private data [45].

This type of IDS is installed at the hypervisor layer and monitors and analyzes information transmitted in communications between VMs (i.e., VM-VM), between the VM and the hypervisor, and between the cloud environment and the outside world [46, 47].

8) *Machine Learning-Based Techniques Malware Detection*: Since Machine learning (ML) can be generalized to never-before-seen malware families and polymorphic strains, machine learning is a common approach to signatureless malware detection [48]. There are a lot of Well-known ML algorithms that particularly useful in behavior-based detection and other detection methods like Artificial Neural Network (ANN), Decision Tree(DT), XGBoost, naive Bayes (NB), Associative Classifier (AC), C4.5 decision tree variant (J48), random forest tree (RF), k-nearest neighbor (KNN), support vector machine (SVM), logistic model trees (LMT), Shared nearest neighbor (SNN), multilayer perceptron (MLP), Bayesian network (BN), simple logistic regression (SLR), RIPPER, Deep Learning (DL), and sequential minimal optimization (SMO) [49-54].

D. Cloud Forensics

Cloud Digital Forensic techniques are typically used to gathering and preserving evidence, reconstructing incidents, deciding how, where, and where an incident happening, and producing threat information. Threat information includes Indicators of compromise that can be used to help an organization defend itself.

III. METHODOLOGY

The methodology has been divided into two practical parts:

The First: when the malware attack happened, make cloud analysis for malware detection.

The Second: is Forensics Analysis in the IaaS Cloud after the malware attack happens.

A. Cloud Analysis to Malware Detection

In this practical part, flow many steps as shown in Fig. 3:

1) *Choosing test environment*: The tests were performed on Amazon Web services (AWS) hosted infrastructure. choosing the Amazon Web services (AWS) for this research because it the market leader for public cloud services offering and has a wide service catalog making it a suitable choice for most organizations, Named as a Leader in Gartner's Infrastructure as a Service (IaaS) Magic Quadrant for the 7th Consecutive Year. (AWS) innovated many tools and techniques for data collection, monitoring, analysis for their customers which most of the other cloud service providers follow.

2) *Data set*: Fortunately, there are community initiatives that define and classify each cloud attack technique publicly witnessed; such as the NIST Cybersecurity Framework [55] and MITRE ATT&CK cloud framework.

Fig. 3. Flow Chart for Cloud Analysis to Malware Detection.

To define the data to be collected by using the MITRE ATT&CK framework, the combined techniques used to compromise cloud-hosted infrastructure which can be leveraged by the attackers to gain initial access and control over the environment- along with the malware techniques used in enterprise infrastructure. With that combination, the organizations implement continuous monitoring for their infrastructures whether it's on-premises infrastructure or cloud-hosted one. For the scope of research, Continuous monitoring on IaaS can be accomplished by gathering and processing the following [56]:

- API calls Monitoring (In AWS it can be achieved through CloudTrail's logs).
- Host logs and logs of deployed Host Intrusion detection System (HIDS).
- VPC flows.
- Logs of the cloud resources (in AWS it's the CloudWatch Logs) [57].
- Image and instance integrity validation.
- Automation through tools like AWS Lambda and AWS Config.

3) *Testing and analysis*: Performed the malicious activities performed by the malware without using real malware in this environment.

Use many tools like:

- Amazon CloudWatch: Collect and track metrics, collect and monitor log files, set alarms, and automatically react to changes.
- AWS CloudTrail: A web service that logs your account's AWS API calls and provides you log files.
- AWS Config: provides a comprehensive view of the AWS resource configuration in your AWS account. This involves how the services are connected to one another and how they were previously configured, allowing you to track how the settings and relationships change over time.
- SIEM software: Providing data analysis, event correlation, aggregation, reporting, and log management.
- SIFT is open-source: Includes most tools required for digital forensics analysis and incident response examinations.

Implementation of many testing labs:

a) *Create a billing alarm for AWS account*: According to the MITRE ATT&CK framework for cloud attacks, one of the most used attack vectors for Cloud attacks and malware attacks targeting cloud-hosted environments is cloud account takeover. There are many ways to detect cloud account takeover, one of the best ways is detecting changes in the usual billing as most cloud malware attacks aim to abuse the environment's resources or deploy new resources. Most public

cloud providers provide features to enable their customers to create billing and send them emails when these alarms are triggered

To create a billing alarm for the AWS account that can be used later in detecting any suspicious abuse of IaaS resources, first enable receive billing alerts for the account and then use AWS CloudWatch, to create a metric that will trigger an alarm whenever the billing exceeds a specific threshold.

Also, use the AWS Simple Notification Service (SNS) for sending an email once the alarm is triggered.

Results

When malware misuses the resources of the cloud or publishes expensive new resources, AWS calculates the charges and the estimates charges as per your approach and now have a threshold of 5\$ that whenever the charges are exceeded the alarm will be triggered as shown in Fig. 4 and receive an email as a notification.

b) *Perform continuous monitoring in the AWS environment*: AWS offers a service called AWS Config, this service allows monitoring AWS resource configurations and track resource inventory and changes, which can be used to detect any malicious configuration changes the attacker tries to make to gain control or persistence over the compromised account's resources. This monitoring feeds then can be consumed using AWS CloudWatch and SNS Notifications can be created based on them.

Malware attacks target and modify the data stored and any misconfigured cloud storage leading to leaked data. By using AWS Config to make many rules like sure storage versioning is enabled for AWS storage (S3). By enabling the s3-bucket-versioning-enabled rule, another action performed by attackers is to try to hide their malicious API calls by disabling API calls monitoring, configured a rule to detect if cloudTrail enabled or not and another rule to detect whether the volumes used are encrypted or not. Also to prevent the misuse of the root account, enable another rule to detect whether multi-factor authentication (MFA) is enabled for the root account or not.

In Fig. 5 the Dashboard of AWS Config detected the security issues in resources, which whether indicate a misconfiguration or malicious change.

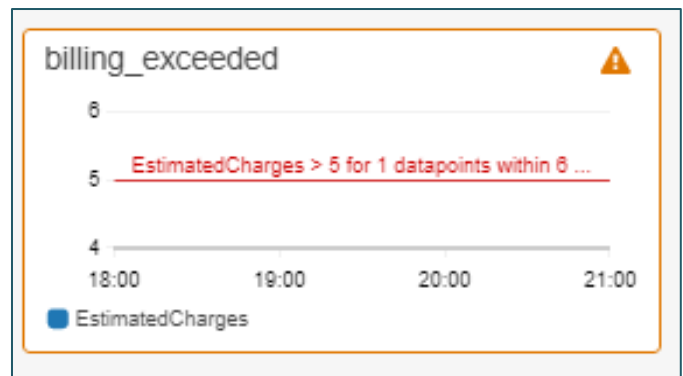

Fig. 4. Alarm for Exceeding Bill for AWS Account.

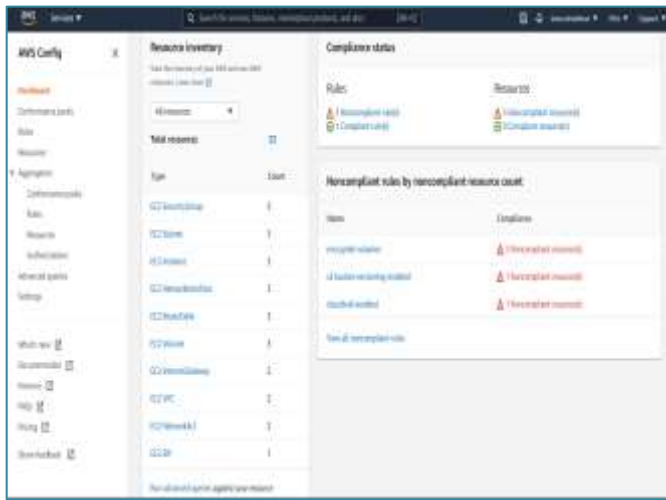

Fig. 5. AWS Config Dashboard.

Using the AWS Config resource inventory to view existing or deleted resources recorded. For a specific resource, view the resource details, configuration timeline, or compliance timeline. The resource configuration timeline allows you to view all the configuration items captured over time for a specific resource. The resource compliance timeline allows you to view compliance status changes. For example, used AWS Config to track the timeline of changes for an s3 bucket resource.

Results

- ✓ By using AWS Config detected Malware attacks that modify the data stored, and target any misconfigured cloud storage.
- ✓ By using rules in AWS Config can see if malware attacks try to hide their malicious API calls by disabling API calls monitoring.

Limitations

- ✗ Not all monitoring options are available for each region, cloud providers may offer their services to a specific region but monitoring these services may not be available for this region or came late.
- ✗ The AWS config service takes a few minutes to rebuild asset inventory, thus not providing real-time monitoring.

c) *Monitoring cloud API Calls:* In AWS CloudTrail is used to monitor account activity and API calls, this is a very important feature as cloud providers offer their services via APIs. CloudTrail feeds can be integrated with CloudWatch to create metrics generating alarms for any suspicious account's behavior or any account misuse.

Create a trail; I enable ongoing delivery of events as log files to an Amazon S3 bucket. Then get the logs and API Calls from CloudTrail Event history.

Fig. 6 detects console logins (recording the account used and the source IP that the user has when he logged in) which reveals any attempts to login from suspected places or countries.

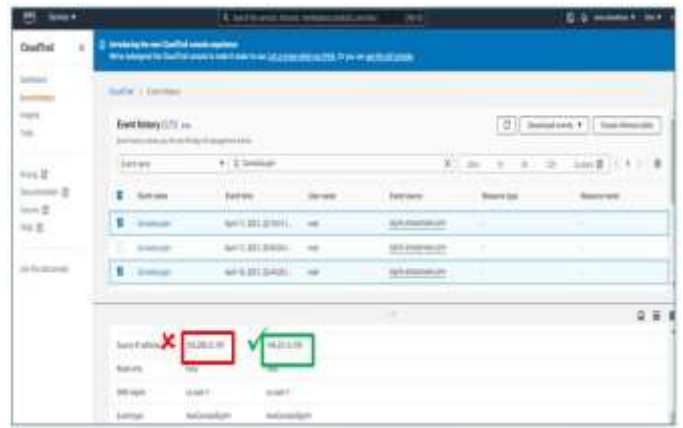

Fig. 6. Detecting Console Logins in AWS CloudTrail.

Also can find that AWS generated logs are formatted in JSON.

CloudTrail has a lot of great, very detailed log data. also, By setting up a CloudTrail trail I deliver CloudTrail events to Amazon S3 then review this in the console or view/download from S3.

Results

- ✓ Detect console logins from suspected places or countries.
- ✓ Because most of the time, organizations transfer cloud logs to their own data center for long term storage and correlation with other on-premises tools, it's very important to generate the logs in a text-like format such as JSON, thus enabling serialization of complex, high-quality log data and decouple the interpretation of logs from specific solution or vendor. From a test, notice AWS uses this concept in their generated logs and flows.
- ✓ Leverage the storage API (s3 API) to import cloud trails to a search and indexing platform or security management systems like (SIEM solution) for building more unified and robust use cases monitoring the security posture over the entire environment.

Limitations

- ✗ By default, there are no trails configured to log any of AW'S activities. Must enable what wants to monitor.
- ✗ CloudTrail Logs directly in the console is not as efficient as pulling the logs into some tool for parsing and normalization with better searching and filtering features.

d) *Generating VPC network flows (VPC Flows):* Producing flow logs of communications that occur in the VPC (north-west communications and east-west communications) is very crucial to detect activities related to malware attacks such as communications with malicious IPs and command and control servers, attempts of pivoting and lateral spreading, and suspicious communications behaviors and data exfiltration.

CloudWatch, created a flow log group to watch for flows within VPC [58] while one instance is performing lateral scanning, to detect the scan.

By generating these flows and sending those to CloudWatch then create metrics watching for specific suspicious behaviors or policy violation communications. For example, made a metric to watch for Telnet communications that can due to policy violation or scanning attempt and received an alarm as shown in Fig. 7.

Fig. 7. Alarm for unauthorized Telnet Communication.

Also, receive this notification by email.

Results

- ✓ Seeing all flow logs of communications that occur in the VPC.
- ✓ By sending flow logs to CloudWatch then create metrics watching for specific suspicious behaviors or policy violation communications.
- ✓ Instead of sending flow logs to CloudWatch, can send them to s3 bucket storage to be aggregated with other log sources and offloaded to on-premises with Storage API calls and leveraging them using SIEM Solution.

Limitations

- * Flow logs may take up to 5 minutes to appear, thus not providing real-time visibility.
- * Reviewing VPC Flow Logs directly in the console is not efficient while using CloudWatch Metrics to make use of these flows, leveraging the high potential of captured flows is achieved through sending them to some security event management tool like SIEM Solution for more flexible correlation and enrichment.

e) *Transferring logs to SIEM:* Must bringing cloud logs into a single point where they can be aggregated with on-premises security events and other security and intelligence feeds, thus enabling the threat management team to have a single pane of glass from which they can monitor the whole security posture of their organization.

To achieve this purpose, install IBM Qradar Community edition (SIEM Solution) locally and configure it to receive the AWS CloudTrail logs which configured earlier to monitor different services of the AWS account and its resources [56].

1) The first thing to notice that there are many protocol options to bring the CloudTrails Logs to SIEM solution.

2) Fig. 8 contains the different types of event formats that can be stored in s3 bucket (the important ones are AWS CloudTrail and AWS VPC Flow logs).

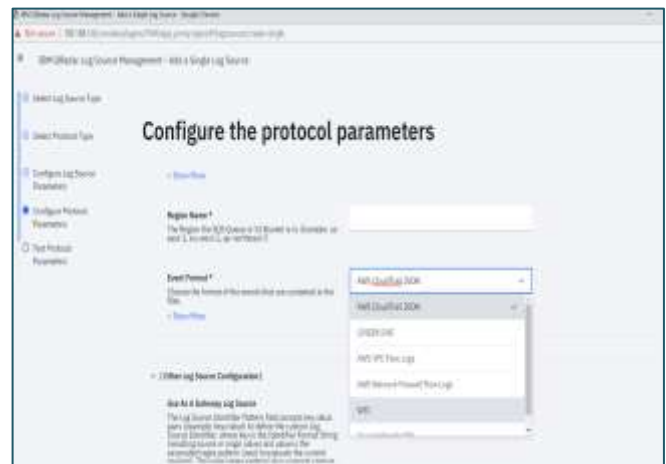

Fig. 8. Setting Options to Select Event Formats that Stored in S3 Bucket.

3) Specify the S3 bucket name and the directory where AWS CloudTrails resides.

4) The maximum frequency to poll the logs from the AWS s3 bucket is 1 minute, providing an adequate timeframe to detect attacks but still not real-time visibility.

Results

The different ways to transfer Flow logs from the cloud to threat management like SIEM is shown in Table II.

- ✓ For most IaaS use cases, the best way to transfer monitoring logs to on-premises threat management tools like SIEM is through the usage of Storage APIs, yet there are other methods suitable for the less common of today's use cases.
- ✓ Also, a statistic in Fig. 9 determines the number of logs that are generated per second from resources on the cloud, it helps us to determine the amount of visibility that gets from the logs, for example, NGFW and HDIS have many activities, so they give me the greatest amount of visibility and helps us see all the events in real-time and discover malware quickly.

B. Forensics Analysis in The IaaS Cloud

Using cloud forensics to assist companies in enhancing their incident response and threat detection capabilities [59] organizations must have sufficient forensics investigation expertise to apply to their cloud infrastructure to ascertain the root cause of an attack, detect signs of vulnerability, and better protect against IaaS malware attacks, as well as quickly locate malware and its objectives before they have an impact on the companies' operations.

In the event of a hacked virtual machine, several cloud users automatically terminate and destroy the virtual machine (VM), erasing all proof in the process.

TABLE II. THE BEST WAYS TO TRANSFER FLOW LOGS FROM THE CLOUD TO THREAT MANAGEMENT

	SysLog or SysLog Server	Storage API	Data Stream
Data transfer Speed	It's not considered a real-time data communication. Data is ready to be sent as soon It's generated or collected by the aggregation server. Because in most cases it's not compressed, it will take few minutes to arrive at the premises,	Faster than sending Syslog messages, but still will take time for the data to be written in the storage bucket. Fast but not real-time data communication.	Data processed as soon it's generated. Because it makes use of data analytics features the data transferred is small and fast. it provides real-time visibility. Example AWS Kinesis streams
Cost	High cost around 9 cents per Gigabyte	-Low cost around .007 cent per Gigabyte. -There will be additional cost for the storage bucket	Expensive service
Size of logs transferred	If there are big number of resources and no compression used, the size of logs will be big leading to more costs	High quality compressed data generated small size data transfers	Rich and Small size of data streams
Data enrichment and preprocessing	No analysis or processing is made before sending	Better quality data and fully inflated data to flows and logs	performs data analytics, correlation and enrichment with other feeds, sending only good quality actionable insights
Scalability	Not scalable as the volume of data increases	Scalable as it uses API communication methods	Scalable
Log Data protection	By default, data is sent in plain text unless sent over VPN connection or syslog collector used	the connection is encrypted	Communication is encrypted
Need for additional tools or management	For optimum experience VPN tunnel and syslog collector are used	configure additional storage to store the logs	Purchasing the data analytics stream service

Fig. 9. Logs Generated from Cloud Resources Per Second.

It can be difficult to plan for forensics in the cloud. Until recently, there have been few tools to assist analysts in inspecting applications and collecting data [60]. When it comes to gathering and analyzing evidence, must look for the following:

- Network packet captures (PCAPs) for network forensics.
- Memory for instance.

- A disk for instance.
- Event data and logs.

Recently, more vendors and community members have been concentrating their efforts on resolving forensics issues in the cloud. How do we best gather evidence? How do we store it properly? What tools work in the cloud well?

1) Evidence Capture

- Capture a disk is getting easier in a running instance. You take a snapshot of EBS (Elastic Block Store) in Amazon EC2 (Amazon Elastic Compute Cloud) [61], after that, attach it to a forensic workstation (covered in a moment). The Azure, You can grab IaaS OS and Data drives directly from the portal.
- Capturing memory in a shared environment would necessitate some form of per-instance basis capture. To put it another way, instances' running memory would have to be acquired using separate tools (local or remote).

2) Test environment preparation

3) Provisioning the Forensic machine and installing the required forensics investigation tools. Fortunately, a package that provides access to most of the forensics tools from one executable package is called SIFT. Prepare forensics investigation machine as follows:

a) create an instance that will be used to perform the investigation. In a test, named it cloudresearch-forensics-instance.

b) SSH into the cloudresearch-forensics-instance to download the SIFT tools as shown in Fig. 10 [in research time the latest SIFT version was 1.10.0-rc5].

Fig. 10. Download the SIFT Tools.

c) For ease of access move the executable file to the account binaries directory

```
mv ./sift-cli-linux /usr/local/bin/sift
chmod +x /usr/local/bin/sift
sudo sift install
```

- 1) Create a snapshot from the instance to perform forensics analysis on it.
- 2) Create a volume from it with the snapshot in the same available zone as cloudresearch-forensics-instance.
- 3) The Evidence Volume will be available to be attached to cloudresearch-forensics-instance to perform investigation.
- 4) Then attaché the evidence cloudresearch-forensics-instance by follow:

From volume actions we selected Attach Volume and choose to attach it to cloudresearch-forensics-instance as shown in Fig. 11 [62].

We confirmed the successful attachment from the console as shown in Fig. 12.

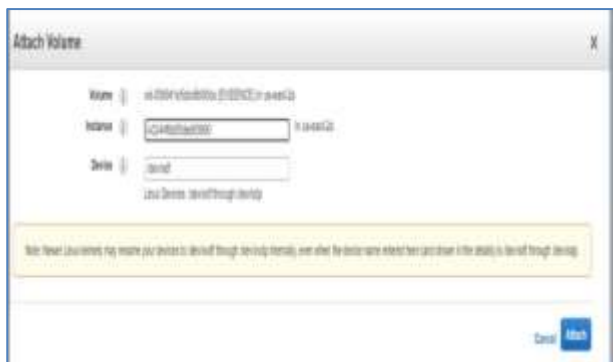

Fig. 11. Attaching the Evidence to the SIFT Workstation.

Fig. 12. Successful Attachment.

We verified that using lsblk command from cloudresearch-forensics-instance

```
$ sudo lsblk
```

NAME	MAJ:MIN	RM	SIZE	RO	TYPE
Xvda	202:0	0	8G	0	disk
└─Xvda1	202:1	0	8G	0	part /
Xvdf	202:80	0	8G	0	disk
└─Xvdf1	202:81	0	8G	0	part

The *xvdf* disk is attached volume with a single partition not mounted yet.

We determined the format of partition using *file* command

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo file -s /dev/xvdf1
/dev/xvdf1: SGI XFS filesystem data (blksz 4096, inosz 512, v2 dirs)
```

As we are analyzing a Linux machine, we can see that the format is XFS.

Mount the evidence Linux file system.

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo mount -o ro /dev/xvdf1 /mnt/evidence /
```

Verify a successful mount of the evidence volume using *ls* command.

```
$sudo ls -als /mnt/evidence/
total 20

5) *Forensic analysis on linux EC2 instance:* Fig. 13 contains perform common disk image forensic investigation domain exercises on the snapshot of EC2 instance's volume and define any limitations and special configurations needed to facilitate the investigation [63].

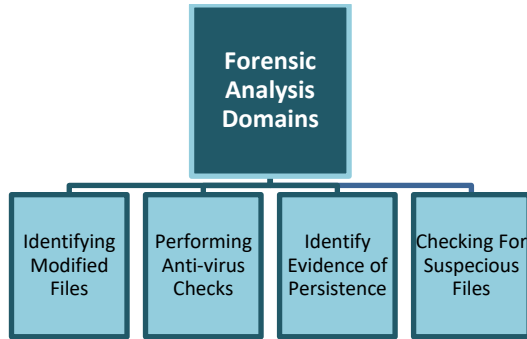

Fig. 13. Forensic Analysis Domains Test.

d) Identifying modified and added files in the invested file system:

1) Create a new instance from the same type of instance to perform forensics analysis on. This new instance will be used as a reference to a known good state. Achieve that by taking a snapshot of the newly created instance, mounting it to the cloudresearch-forensics-instance in read-only then creating hashes of all files on the reference volume to help identify the differences between the Evidence and the Baseline.

```
Ubuntu@cloudresearch-forensics-instance:~
$ lsblk
NAME        MAJ:MIN RM  SIZE RO  TYPE MOUNTPOINT
Loop0       7:0      0  55.5M 1  loop /snap/core18/1988
Loop1       7:1      0  33.3M 1  loop /snap/amazon-ssm-
Loop2       7:2      0  55.5M 1  loop /snap/core18/1997
Loop3       7:3      0  70.4M 1  loop /snap/lxd/19647
Loop4       7:4      0  32.3M 1  loop /snap/snapd/11588
Loop5       7:5      0  31.1M 1  loop /snap/snapd/11036
Loop6       7:6      0  69.9M 1  loop /snap/lxd/19188
Xvda        202:0    0    8G    0    disk
├─ Xvda1    202:1    0    8G    0    part /
├─ xvdf    202:80   0    8G    0    disk
├─ xvdf1   202:81   0    8G    0    part /mnt/evidence
├─ xvdg    202:96   0    8G    0    disk
└─ xvdg1   202:97   0    8G    0    part /mnt/baseline
```

2) creating a hash database of all Baseline Volume files as follows:

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo find /mnt/baseline/ -type f -exec /usr/bin/md5sum {} \; >
baseline_files.md5
```

3) Then making a hash of all files on the volume under investigation. And compare them with the reference file hashes, storing them in changed_files.txt

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo find /mnt/evidence/ -type f -exec /usr/bin/md5sum {} \; >
investigate_files.md5
```

```
Ubuntu@cloudresearch-forensics-instance:~
$ ls -al *.md5
-rw-rw-r-- 1 ubuntu ubuntu 4304670 May 6 15:18
baseline_files.md5
-rw-rw-r-- 1 ubuntu ubuntu 3865228 May 6 15:15
investigate_files.md5
```

4) After making a hash index of the both files using *hfind* command, the 2 hash tables to find the difference. then make the output in a text file.

```
Ubuntu@cloudresearch-forensics-instance:~
$ awk '{print $1}' investigate_files.md5 | hfind baseline_files.md5 |
grep "Hash Not Found" | awk '{print $1}' > difference.md5
```

```
Ubuntu@cloudresearch-forensics-instance:~
$ hfind -f difference.md5 investigate_files.md5 > different_files.txt
```

Fig. 14 shows a sample of Files that has been changed.

```
Ubuntu@cloudresearch-forensics-instance:~
$ head different_files.txt
f0e6470e204f1e32475f0c354946f4 /mnt/evidence/etc/openssh/ssh-agent-scriptable2net-functions
78a51e70481011111111111111111111 /mnt/evidence/etc/openssh/1/repalace

00754700024570211111111111111111 /mnt/evidence/etc/yum/repos/anaconda
```

Fig. 14. Sample of Output.

5) *Finding keys on the compromised system:* Private keys are usually found in hidden directories and the SSH by analysts. Looking for private keys in SSH and AWS hidden directories (.ssh/ and .aws/). In an EC2 case, unprotected private keys are a bad security practice that could be violating the company's security policy. If any private SSH keys or AWS keys are present, they must be supposed to be compromised.

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo ls /mnt/evidence/home/ec2-user/.ssh/authorized_keys
```

Sample of the command searching for the pattern AKIA[A-Z0-9] shown in Fig. 15.

Fig. 15. Sample of Output from Command AKIA [A-Z0-9] Pattern.

Another common practice is to look at the list of public keys used to SSH into the instance (home/*/.ssh/authorized keys), which can be used in conjunction with syslog messages to figure out who has accessed the system as shown in Fig. 16.

Fig. 16. List of Public Keys those are used to SSH to the Instance.

e) Performing Anti-Virus checks

1) Find any security software installed: Most cloud providers provide a mechanism for central management of VMs' systems deployed on the IaaS. These systems are used to patch, configure and audit the VMs to a baseline. Then information available through these systems may support the forensics investigation. For AWS this system is called AWS System Manager. If the AWS system Manager is present its default location will be /usr/bin/amazon-ssm-agent and its log path will be /var/log/amazon/ssm/amazon-ssm-agent.log. Another tool that can be offered by the Cloud provider to the deployed VMs is vulnerability scanner. AWS offers AWS Inspector. If this tool was deployed on the compromised machine indicates that there may be vulnerability data available via the console which can help focus the investigation.

2) Scan the image with antivirus: To validate if malware files can be detected by using AntiVirus Scan tools, download EICAR file to an investigated instance before taking a snapshot of its volume. EICAR is ANTI MALWARE Test file. The scanning of a snapshot volume has no different than

scanning conventional forensics images and able to detect the EICAR file. For this purpose, use ClamAV that comes with the SIFT package. Then scan the mounted evidence with ClamAV.

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo clamscan -i -r --log=/cases/clam.log /mnt/evidence/
```

The previous command results are shown in Fig. 17.

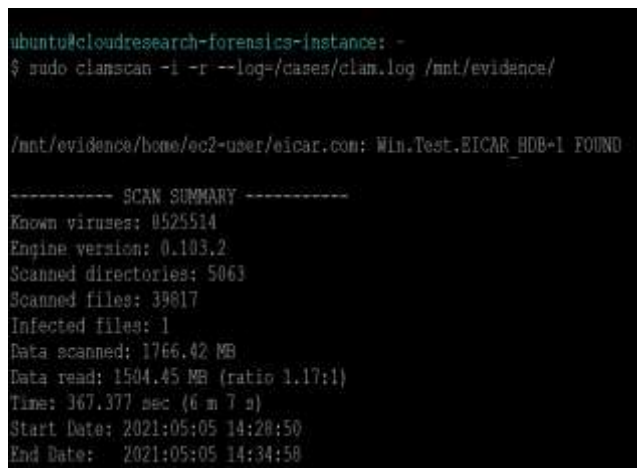

Fig. 17. Result of Scan the Image with Antivirus.

f) Identify Evidence of Persistence

The malware must use a persistence mechanism to survive a reboot. The two most popular methods are start-up scripts and cron jobs.

1) View the cron task by viewing crontab file and listing cron files as shown in Fig. 18:

Fig. 18. Snapshot of Corntab File and Corn Files.

Also check the corn jobs for all users.

```
Ubuntu@cloudresearch-forensics-instance:~
$ sudo ls /mnt/evidence/etc/cron.*
```

2) Looking for unusual start-up scripts: While entering a specific run stage, some malwares can use the start-up scripts that Linux runs at boot time. These scripts can be found in

/etc/init.d on some Linux distributions, but they will be in /etc/rc*.d on Amazon Linux as shown in Fig. 19:

```

ubuntu@cloudresearch-forensics-instance: ~
$ sudo ls -al /mnt/evidence/etc/rc*.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc0.d -> rc.d/rc0.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc1.d -> rc.d/rc1.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc2.d -> rc.d/rc2.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc3.d -> rc.d/rc3.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc4.d -> rc.d/rc4.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc5.d -> rc.d/rc5.d
lrwxrwxrwx 1 root root 10 Mar 26 17:35 /mnt/evidence/etc/rc6.d -> rc.d/rc6.d

/mnt/evidence/etc/rc.d:
total 16
drwxr-xr-x 10 root root 127 Mar 26 17:36 .
drwxr-xr-x 81 root root 5192 Apr 17 04:05 ..
drwxr-xr-x 2 root root 85 Mar 26 17:36 init.d
-rw-r--r-- 1 root root 471 Feb 3 2020 rc.local
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc0.d
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc1.d
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc2.d
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc3.d
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc4.d
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc5.d
drwxr-xr-x 2 root root 45 Mar 26 17:36 rc6.d
ubuntu@cloudresearch-forensics-instance: ~
$ sudo ls -al /mnt/evidence/etc/init.d
lrwxrwxrwx 1 root root 11 Mar 26 17:35 /mnt/evidence/etc/init.d -> rc.d/init.d
ubuntu@cloudresearch-forensics-instance: ~

```

Fig. 19. Snapshot of Start-up Scripts on Amazon Linux.

g) *Checking for Suspicious Files:* Perform all techniques related to looking and searching for suspicious files as perform them in the conventional forensic analysis. As follows:

- Look for the contents of the /tmp directory and unusual SUID files. To search for unusual SUID files, make a base line using baseline volume and compared it with the volume under investigation. Purposefully add a malicious _file that has suid permission enabled to the home directory of the ec2-user account on the compromised machine and successfully to detect it as shown in Fig. 20:

```

ubuntu@cloudresearch-forensics-instance: ~
$ sudo find /mnt/evidence/ -perm -4000 -print > suid_evidence
ubuntu@cloudresearch-forensics-instance: ~
$ sudo find /mnt/baseline/ -perm -4000 -print > suid_baseline
ubuntu@cloudresearch-forensics-instance: ~
$ cut suid_baseline -d"/" -f4 -> suid_baseline_relative
ubuntu@cloudresearch-forensics-instance: ~
$ cut suid_evidence -d"/" -f4 -> suid_evidence_relative
ubuntu@cloudresearch-forensics-instance: ~
$ diff suid_baseline_relative suid_evidence_relative
2d1
< usr/bin/mount
fd2
< usr/bin/mount
9a8,9
> usr/bin/mount
> usr/bin/mount
17a18
> home/ec2-user/malicious_file
ubuntu@cloudresearch-forensics-instance: ~

```

Fig. 20. Detect Malicious _file in Home Directory of the ec2-user Account.

- Use the same method to look for large files above a certain size limit and compare them to the base volume.
- Use the *strings* command to get a fast indication of the file's existence and to spot possible signs of compromise. The strings command's output can include IP addresses, file names, and configuration information that expose the malware's intent.

```

Ubuntu@cloudresearch-forensics-instance:~
$ string /mnt/evidence/home/ec2-user/eicar.com

X50!P% @AP[4\PZX45(P^)7CC)7]$EICAR-STANDARD-
ANTIVIRUS-TEST-FILE!$H+H*

```

- Use 3rd party tools like **VirusTotal** to investigate the suspected files detected by this exercise and validate if the samples have been seen in the wild as shown in Fig. 21.

For this purpose, calculate the SHA256 hash of detected malware (EICAR) and then look for it on VirusTotal.

```

Ubuntu@cloudresearch-forensics-instance:~
$ sudo sha256sum /mnt/evidence/home/ec2-user/eicar.com

275a021bbfb6489e54d471899f7db9d1663fc695ec2fe2a2c4538aabf6
51fd0f /mnt/evidence/home/ec2-user/eicar.com

```

C. Discussion and Area of Improvements

A common mistake is to let snapshots be shared publicly (across different AWS accounts), without great care is taken, this can lead to leakage of sensitive data and keys.

According to Amazon, the only way to capture the memory of an Amazon Linux EC2 instance is via an SSH session, passing the SSH keys that have the root privilege to a remote memory imaging tool.

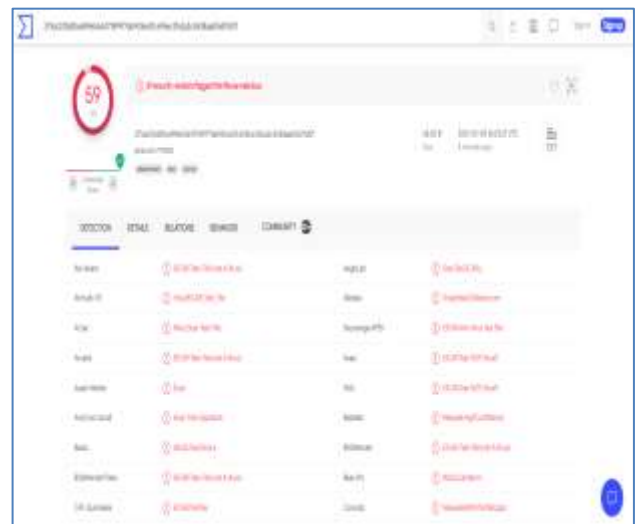

Fig. 21. Virustotal Result for the Malware we Detected on Machine.

As a best practice incident handler should provide a new forensics analysis machine for each case. Provisioning the forensics analysis machine on AWS takes some time, unlike the conventional on-prem machines. But one way to speed this up is to make an AMI (Amazon Machine Image) of the SIFT.

The volumes created from snapshots must be in the same availability zone of the forensics analysis workstation.

There is a quiet difference between conventional on-premises evidence gathering and evidence gathering from IaaS virtual machines and due to the need for rapid containment of the compromised cloud virtual machine, these evidence gathering processes must be integrated with infrastructure automated deployments tools for automating the evidence gathering.

Memory analysis for IaaS virtual machines is very challenging as most leading solutions for image analysis require a profile that is specific to the kernel of the system that was imaged, so they have profiles for operating systems used on-premises but don't have any profiles for the Cloud provided Linux images. Custom profiles can only be made for these tools if only the analyst has the source code for the kernel headers of these cloud-provided Linux images.

Amazon Linux differs from traditional on-prem Linux especially in the path for some services and files such as the path for the startup scripts and the path of all cron jobs, thus creating an inconsistency between different cloud providers Linux distributions and the forensic analyst have to learn the customizations before beginning his investigation.

The audit logs generated by the Amazon Linux process which is by default enabled will take some practice to read and learn how to read them.

For instances running web servers, the logs of the web service exist in unusual places on the volume, thus the best way to analyze these logs is to pull them into a log server or SIEM solution.

Using cloud web load balancers such as Amazon's Elastic Load Balancer may hide the address of the attacker if no special customization to the load balancer configuration.

EC2 instances are set to UTC by default, thus if anyone trying to make a timeline for malware attacks that spread from the cloud-hosted infrastructure to the on-premises infrastructure, to make a TimeZone correction before correlating cloud instances logs with on-premises logs.

Cloud instances use a default setting for Syslog that sometimes is inconsistent with the common or Syslog settings used on-premises. For example, Amazon Linux images in the marketplace use a default setting for Syslog that does not include the year in the date stamp. Ideally, a cloud administrator uses a configuration template for configuring new instances on the cloud which properly configures the Syslog timestamp to include the year, but this may not be the case with each organization or cloud administrator.

The challenge for forensics in the cloud is usually "Will it meet the chain of custody requirements?" and "Will it hold up in court?" You need to enable write-once storage that is

owned solely by the forensics and IR teams and carefully document your IAM policy for the IR/Forensics role. In addition, ALL activity around evidence acquisition and evidence storage location should be logged extensively.

Despite standardized, well-defined, and matured tools of Incident Response and evidence acquisition for suspected on-premises assets, there are no standardized processes for Digital forensics automation on the cloud and very few tools have been built to do this for the cloud today. Almost nothing is available commercially and each cloud service provider tries to provide its own solution for this purpose for example Microsoft has centered most of its security capabilities around Security Center and Sentinel within Azure.

IV. CONCLUSION

Recently, the number, severity, sophistication of malware attacks, and cost of malware infect on the world economy have been increasing exponentially. Malware should be detected before damaging the important assets in the company. In this research, we applied cybersecurity and security in-depth principles to the cloud IaaS environment. These principles embrace that defense controls will fail at some point and an attack will succeed so organizations must have response mechanisms to put off these attacks as soon as possible, to be able to detect and monitor the attack while and post its occurrence is very crucial. Log monitoring and digital artifacts gathering are the cornerstone enablers for monitoring and detection of active malware attacks. In this research, we defined a practical baseline of the security telemetry that needs to be configured on cloud IaaS environments to maintain continuous visibility and monitoring. We achieved the baseline of the practical part through using of MITRE ATT&CK framework for Cloud which classifies cloud attacks and cloud attack vectors that have been abused so far. After that, we validated the applicability and limitation of deploying this baseline using the AWS environment. Collecting logs without performing investigation and analysis of these logs will provide no help regarding the attack detection. This can be achieved by using security event management tools such as SIEM solutions that perform data correlation, enrichment, integration with other security events, and long-term storage. In the second part of the research, review the different ways to transfer logging data from IaaS environment to the SIEM solution located on-premises. The third part of this research investigated the applicability of performing Digital Forensic Investigations on the compromised IaaS VMs. In future work, we suggest that cloud providers should provide the maintenance tools for performing volatile memory analysis for their VMs. Also, develop a new automated tool for incident response and forensics investigation on the IaaS.

Reputation Measurement based on a Hybrid Sentiment Analysis Approach for Saudi Telecom Companies

Bayan Abdullah¹, Nouf Alosaimi², Sultan Almotiri³
College of Computer and Information Systems
Umm Al-Qura Univeristy
Makkah, Saudi Arabia

Abstract—Thousands of active people on social media daily share their thoughts and opinions about different subjects and different issues. Many social media platforms used to express the feeling or opinion and at top of it is Twitter. On Twitter, many opinions are expressed in many fields such as movies, events, products, and services; this data considered a valuable resource for companies and decision-makers to help in making decisions. This study was based on using a hybrid approach to extract the opinions from an Arabic tweet to measuring service providers' reputation. In this study, the Saudi telecom companies used as a case study. This research concentrates on determining peoples' opinions more accurately by utilizing the Retweet and Favorite. The number resulting from positive and negative tweets after applying the polarity equation was used to estimate reputation scores. The result indicated that the STC company represents a high reputation compared to other companies. The proposed approach shows promising results to expand existing knowledge of sentiment analysis in the domain of measure reputation.

Keywords—Reputation; sentiment analysis; Arabic language; social media

I. INTRODUCTION

Data analysis and mining are some of the most important areas studied in computer science [1]. Due to the importance of data in various fields and the amount of data that is generated during the day, many companies have paid great attention to data. The amount of data is increasing day by day due to a large number of social media platforms [2]. A large amount of content on social media is processed periodically. This data can provide information about users' loyalty, complaints, potential customers, or measure the reputation. To deliver several services and better understanding the customers companies rely on different social media platforms such as Facebook and Twitter [3].

Twitter is one of the popular platforms where people express their thoughts and opinions in 140 characters. The number of active users in this micro-blog is more than 328 million users, who vary between presidents, academics, organizations, and bodies [4]. Statistics indicate that the number of Twitter users in Saudi Arabia has reached 41%, which is a large percentage compared to other countries [5]. In addition, the Arabic language is considered one of the rich languages that have broad audiences, so the focus was on it and Saudi society.

With the millions of opinions that are disclosed on social media about some topic, it is out of the question that these opinions will be biased [6]. People tend to refer to people's comments and opinions about products before they buy them, the movies they will watch or the countries they are thinking of traveling to. The opinions expressed by online users are a kind of electronic word of mouth (eWOM) [7]. The opinions are greatly influencing the decisions a customer will make and its behavior [8]. Where these opinions are considered as more trustworthy and credible way because it's independent of marketers' selling efforts [9].

The spread of sentiment on the Internet has created a new field of text analysis. It attracted many studies in many fields such as education [10], stock market [11] and others. User-generated comments are contributing to the establishment of digitalized WOM forms, which in turn contributes to creating an online reputation. Reputation is a factor that influences the desirability of a product or service, so it needs investment and good management [12][13]. Reputation affects companies' capabilities as well as increases their chances of sustainability in the market [14][15].

The objective of this study is to measure reputation based on a hybrid sentiment analysis approach that combines textual and non-textual features. The analysis improved by including the number of retweets and favorite tweets. In the end, the reputation was calculated accurately for the service providers through the Beta reputation equation.

The rest of the paper is structured as: Section 2 investigates the related works of customer feedback analysis in different sectors. Then, Section 3 describes the methodology proposed which added a new step into the SA approach: the polarity equation, and reputation calculation by equation. Section 4 examines the supervised ML algorithm to determine which algorithm was the best and examines the reputation equation with two different experiments. Then describes the results after utilized the proposed methodology. Section 5 concludes the final notes of the work with recommended guidelines for future developments and research.

II. RELATED WORKS

Feedback from customers is important and it may be a complaint, recommendation, evaluation, etc. Different data mining techniques are used on the feedback to provide valuable

information. Analysis of customer feedback has been recently an active area. It covered several areas of the field of airline services, the smartphone industry, hotels, banking services, and many others.

The sources of feedback varied, some researchers resorted to using traditional methods such as the survey. The study of [16] was concerned about the customer satisfaction with the South Korean airline service with the two different customer groups the low-cost carrier and the full-service carrier. To investigate customer satisfaction, they related it to six different factors positive emotion, negative emotion, social words, comparison, risky values, and monetary values. They are analyzing more than 133000 of the customer feedback after they experience the airline service. The positive emotion and the social words were considered the most impactable factor on customer satisfaction while the monetary value has always a negative impact. The limitation of this study was they didn't pay attention to the demographic factor of the customer also they concern only with the English feedback.

Also, the work of [17] was based on the predictive analysis they investigated the customer intention to return visit the services provided by the airline services. By using the customer feedback comment and satisfaction rating for the previous use of the services they applied a machine learning approach. They used seven classifiers to analyze the sentiment in the comment. Their work was different from the previous work in that they lookup for the actual intention of the customer to return the visit. Also, they analyzed a huge data set what is contain with 309331 customer comment. All the long comment indicates higher accuracy. Their results indicated that customer feedback is very important to determine the actual intention for returned visits and also, it helps to understand the customer behavior over time.

Traditional methods are not recommended due to the sample that may participate in this survey. Also, the survey may be mandatory, which means the respondents may answering only for completion. Therefore, researchers have resorted to some alternative methods, which are based on social media or websites. These methods are more effective as they involve different samples and sectors.

Their work [18] was based on a sentiment analysis which they referred to as opinion mining. They come up with a new idea to analyzing customer feedback from Amazon. So, they designed a framework that received any kind of data from the user and preprocessing it, and then process the data. The result shows the amount of the sales product and the market share as a figure. Also, shows the count of the positive and negative reviews for each feature of the sold phones. Which is give the company a better picture of its product and helps it to succeed in the market.

Their work [19] was focused on the complaints of the customer they analyzed the data set from the Customer Relationship Management system (CRM). Which is a system that deals with the complaints of the customer for the Metropolitan Transportation Authority (MTA). The MTA provides several services that including a subway and buses and a railroad. From the correlation matrix they come up with the agency and subject matter attributes that are positively

correlated and there is no negative correlation. Also, they performed more analysis on details of the complaints to improve the quality of the services. For the classification, they applied different modeling: naive Bayes, KNN, random tree, and ID3. For each model, the input is the complement details that give the agency name as an output. Their work was helpful to determine the factor that led to the customer complaint and also helped the company to improve the quality of the provided services.

The comments that posted in different social media platform could be considered as customer feedback. Mini and Poulouse study [20] to discover the customer intention about the eco-tourism. They took a property in Kerala in India as a case study. They collected the data from Facebook and performed a sentiment analysis on it. They were able to determine the satisfaction and dissatisfaction of the customers which will help improve the quality and improvement process. In their study the focus only on collecting the comment from Facebook that was written in English. Also, the multiple emotion in the collected comments was not easy to extract it.

The study of [21] was based on user-generated content (UGC) to investigate the airport service quality. Their study was in London Heathrow airport services. Sentiment analysis was performing on the collected tweets. They were able to evaluate the quality of the services and determined they good services and the services that need to be improved. UGC is considered a better resource more than the traditional way. The limitation of this study they ignore the demographic characteristics and it's applied to one airport.

UGC on social media plays a significant role in measuring reputation. As the work is done by [22] they measure reputation for four companies Apple, Twitter, Google, and Microsoft by analyzing the tweet. Their proposed approach a distinct work on dealing with the misspelling in the tweet and can apply to all languages also, it does not need a text preprocessing stage. They sentimentally classify each tweet to one of the companies and determine the emotion in this tweet. By relying on using N-gram approaches their results to show better accuracy more than the Bayesian algorithm and a neural network.

The same data set was also analyzed in the study of [23]. Their study was focus on the user reputation by applying some factor to calculate to determine which user have a higher reputation than the others. Their proposed framework was first assigned a score for each tweet the positive tweet was indicated by 1 and the negative was indicated by -1. Then they extracted the ID of the tweet to retrieve the Twitter creator they extracted five factors for each creator: number of followers, number of following, Twitter lists, numbers of retweeted by the followers, and number of tweets posted by that user. Via these five factors, they calculated the reputation of the user. Then they calculate the accumulated weight by multiplying the sentiment score with the user reputation. The tweet from the higher reputation user will have a higher accumulated weight. The proposed method would be helpful to minimize the effort and the size of data by extracting the tweet that only relevant to the higher reputation users.

Online reputation may be useful in determining and measuring profits, according to a study of [24]. They emerged Booking review and Financial Analysis Made Easy (FAME) and used Latent semantic analysis on the textual content. They were able to determine which attributes are associated with financial profitability. From the positive review, they were able to determine that the hotel location and the room quality was indicated the highest impact attribute on the financial profitability. The study was conducted only on the UK hotels and they extract the review from the Booking platform only.

In the tourism sector, there have been several studies and research, such as the work that was done by [25]. They measured Marbella's reputation as a tourist destination. Their study focused on the factors that attract tourists and determine the geographical distribution of the countries from which they came. They analyzed visitor reviews according to sociodemographic characteristics of the city over three years. Their study was focusing only on TripAdvisor reviews.

Also, the study of [26] that took a different sector focused on the political sector. They examine the reputation of the members of the National Assembly (MNAs) of Pakistan on Facebook and Twitter. They were able to determine the credibility of the members and which platforms have a more supportive audience. The comment was chosen based on the systematic random sampling technique. The supportive audience was on Facebook more than Twitter.

Many kinds of research have been dedicated to the field of analyzing customer feedback. Regrettably, few studies consider the Arabic language.

The study of [27] was aimed at determining the polarity of the text only. Therefore, it dealt with several topics in politics, sport and education. They collected data from Twitter and Facebook and then applied three classifiers, SVM, Naïve Bayes, and K-NN using Rapid miner. The size of the data set was small, so no promising results were shown.

The study of [28] was also on the same area they concerned about the telecom Saudi company STC, Mobile, and Zain. Their study focused on the assignment of the polarity scores of the tweets by SWN. The determination of polarity in SWN was based on a lexicon as the results showed that most of the tweets tended to be natural. Defining polarity helped them better understand their customers and their needs. They were also able to identify areas of clients who had complained about some problems.

Previous studies have indicated determining the polarity of sentiment in the telecom industry, both of which were based on a lexicon-based approach. All previous studies focused on text analysis only, they did not include the number of retweets and favorites. The following Table I gives an overview of the previous studies, their purpose, source of data, and the approach used in their methodology.

III. PROPOSED METHODOLOGY

The methodology that followed in this study contains five different phases. Fig. 1 shows an overview of the proposed methodology. Later, in this section, every phase will explain in detail.

The polarity of the collected tweets was determined to positive, negative, or natural. For this study, only positive and negative tweets were included. Most of the sentiment analysis that was performed was focus on polarity only. For more precise a hybrid approach that combines textual and non-textual features was applied. The hybrid approach was based on the polarity equation [29]. The integer number from the polarity equation for both the positive and negative classes was the input for the reputation equation [30].

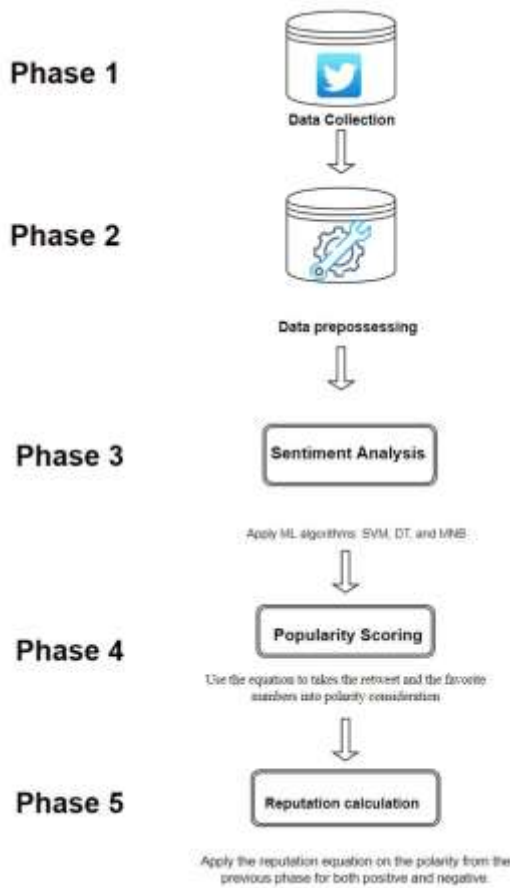

Fig. 1. Overview of the Proposed Methodology with the Five Phases.

A. Phase One: Data Collation

The data for this study was extracted through Twitter API. The analysis focused on the telecom service providers sector in Saudi Arabia. The providers were the data obtained from STC, Mobily, and Zine. The data was collected from the official account of the three providers: @stc_ksa, @Mobily, @ZainKSA. Each of these accounts is active accounts with thousands of tweets exchanged daily.

For each account, 5000 tweets were collected and the total amount of the data was approximately 15,000. Due to time constraints, data were collected within February only. The collected tweet was in the Arabic language mostly, while the tweets that contain some English words or letter were removed later as showed in Section III-B.

For each tweet, the time for its creation, tweet ID, text, the number of their retweet and favorite, user location, screen name, followers, and friends were extracted. For this study, only text, the number of their retweet, and favorite were used. Fig. 2 shows the statistical descriptive for the numerical values in the dataset.

B. Phase Two: Data Preprocessing

To prepared data that has been gathered for the sentiment analysis, it has to be cleaned and preprocessing. Preprocessing data means removing all the noise, unwanted parts, and missing values even the duplicate data. Performing all these procedures leads to get quality data and reliable results. The steps that followed on preprocessing data are:

1) Removed unwanted parts:

- Any English words, letter, or numbers.
- The retweet status, user mentions, URLs.
- Punctuation's, and the Tashkeel.

2) Normalized Arabic words: Arabic letter could be represented in many forms such (ا, إ, آ) all of it refer to (ا) letter. So, the three forms were replaced with (ا). Also, (ة) was replaced with (ه) and (ي) with (ي) .

3) Normalizing repeated letters if it was more than two letters.

4) Removed Arabic stop words: Same as any other language the Arabic language contains multilabel stop words. Stop words in Arabic are meaningless same articles (a, an, the) in English. The stop word such (لم عن الذي) removed based on two different corpora.

5) Removed line breaks and extra white spaces.

6) Removed Duplicates tweets.

(c) Zain Statistical Descriptive.

Fig. 2. Statistical Descriptive for Numerical Values for the Three Companies.

The collected tweets are considered unlabeled data. To use some of the ML algorithms an online tool was used to label data. The Mazajak tool¹ created by Ibrahim Abu Farha and Dr. Walid Magdy [31] classified the text polarity to Positive, Negative, or Neutral. However, there may be chances where some word polarity is not detected correctly. For example, the appearance of words that contains a prayer to Allah gives a positive labeled result. The tweet (ياربي متي ت عدل ون نكلم؟) labeled as positive, which indicated a negative opinion. Fig. 3 shows the class distribution for the three companies.

After selected Positive and Negative tweets the amount of data became 2,770 for STC, 1,552 for Mobily, and 2,553 for Zain. Therefore, the total amount of the three companies was 6,875.

C. Phase Three: Sentiment Analysis

This sentiment analysis stage refers to the primary stage. Where the analysis is performing on text-only. The binary sentiment analysis works only with Positive and Negative tweets, Tweets that rated Neutral were excluded from this analysis.

Fig. 3. Class Distribution for the Three Companies.

To prepare the target variable for classification the text must convert into a numerical record. Bag-of-Words representation works fine with a short text, is based on collect unique words in the dataset as features. Therefore, for the tweets in the proposed case Count Vectorizer was used for features extraction.

The dataset was split into training and testing sets. The training part was used to build the classification algorithms model, and the testing part to evaluate the model. Three Machine Learning (ML) algorithms were applied to the dataset Support Vector Machines (SVM), Decision Tree (DT), and Multinomial Naive Bayes (MNB).

D. Phase Four: Popularity Scoring

The popularity scoring equation takes the numbers of retweet and the favorite into polarity consideration. The popularity scoring equation can be considered as an advanced sentiment analysis stage. Since the primary stage dealt with text, the advanced stage deal with a retweet and the favorite.

A retweet means reposting someone’s tweet or message in your timeline [32]. Where the popular tweets are reposted many times. Any person following you was able to see the retweeted tweet. Favorite the tweet means to keep that tweet on your account under the favorite tab. To favorite the tweet only, the user must press the heart-shaped icon. Both retweet and favorite are considered as a sign of agreement and admiration on the content.

The Popularity Scoring Equation that applied adopted from a study of [29]. It consists of two equations dependent on each other. Where the outputs of the first equation are inputs to the second equation.

The first popularity scoring equation 1 takes the sum of the classified tweet Ct (e.g. Positive classified tweet) plus the number of its retweet #RT number plus the number of its favorite #F av.

$$\text{PopularityScoring} = Ct + \#RT + \#Fav \quad (1)$$

The output from equation 1 which is the popularity scoring of the classified tweet (e.g. Positive classified tweet) multiplied by 100 and divided by the total number of the popularity scoring for all the classified tweet 2.

$$\text{DevelopedPopularityscoring} = \frac{\pi 100 * \text{PopularityScoring}}{2 \sum |P \text{opularityScoring}} \quad (2)$$

E. Phase Five: Reputation Calculation

Most reputation measurement systems rely on the opinion generated by customers, where this opinion reflects the general community’s opinion [33]. From various principles of reputation measurement systems, this study is based on Bayesian systems. The Bayesian systems using the binary classes as input [34], and the reputation scores calculated based on statistical updating of beta probability density functions (PDF). To measure the reputation of service providers, the equation presented in a study was adopted [30]. The input in the sentiment analysis system is the positive and negative classes.

¹<http://mazajak.inf.ed.ac.uk:8000/>

In the proposed approach, the output from equation 2 used as input in the reputation equation. After the polarity calculated of both the positive and negative class, with the numbers of retweeting and favorite. The polarity number (e.g. positive class) took as a positive representation in the reputation equation. The equation 3 represent reputation equation:

$$R = \frac{\alpha}{\alpha + \beta} \quad (3)$$

The α represent $\alpha = r + 1$ and $\beta = s + 1$, where r is the output of popularity scoring number for positive classes and s the output of popularity scoring number for negative ones.

To clarify the equation let consider this example: if α equals 9 and β equals 3. After applying the equation 3, the reputation score can be calculated as: $R = 9/(9 + 3) = 3/4 = 0.75$.

IV. RESULTS AND EVALUATION

This section indicates the results of the calculated reputation through a proposed methodology. By applying a hybrid sentiment analysis approach on 15,000 collected tweets.

A. Evaluation Metric

The proposed sentiment analysis that was applied was based on two stages: the primary stage and the advanced stage. On the primary stage SVM, DT, and MNB classification algorithms are used to capture the sentiment. For the training model 80% of the data was used and for testing 20% was used. Moreover, to measure the performance of classification four measurements are used in this study, which are the accuracy, precision, recall, and F-score.

Accuracy: is the degree of closeness of the classified outcomes to the true value. Measurement of the accuracy is significantly important because it reflects the percentage to realize the correct pattern and polarity. Where T P indicate True Positive, TN for True Negative, F P for False Positive, and FN for False Negative.

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (4)$$

Precision: The ability of the model to anticipate the positive classes. It's calculated by divided true positives over a total number of true positives and false positives.

$$Precision = \frac{TP}{TP + FP} \quad (5)$$

Recall: The values that the model was able to determine correctly. It's calculated by divided true positives over a total number of true positives and false negatives.

$$Recall = \frac{TP}{TP + FN} \quad (6)$$

F-Score or the F-Measure: conveys the harmonic mean between the precision and the recall. It represents the integration of both precision and recalls into a single score.

$$F - Score = \frac{Precision * Recall}{Precision + Recall} \quad (7)$$

After the primary sentiment analysis stage performed the results of the evaluation model summarize Precision, Recall, F-score, and Accuracy in Tables II, III, and IV.

From the Tables II, III, and IV, the SVM gives a higher accuracy among the three classifiers. The accuracy of the three companies for STC, Mobily, and Zain equal 92%, 95%, and 89% respectively as Fig. 4 showed. DT mostly gives low results compared to the other classifiers because some classes are imbalanced.

TABLE II. THREE CLASSIFIER RESULT FOR STC COMPANY

STC			
Support Vector Machines classifier			
Data label	Precision	Recall	F-Score
Positive	0.95	0.91	0.93
Negative	0.88	0.93	0.90
Accuracy

0.86			

Fig. 4. Accuracy Comparison of SVM for the Three Companies.

B. Evaluation of Reputation

As mentioned before the analysis only included the positive and negative labels. After eliminating the natural labeled, duplicated, and blanked the dataset was reduced to 6,875. Two tests were applied to capture the impact of the Popularity Scoring equation on mustering reputation.

The first test was applied without the Popularity Scoring equation, so the number of retweets and favorites did not include. Only the total number of the classified tweet (e.g. Positive classified tweet) which represents α in the reputation equation. For example, the positive classified tweet for STC is 1636, where the negative is 1134. By applying the reputation equation 3 the reputation scores equal to 0.59.

The second test by applying the Popularity Scoring equation where the number of retweets and favorites counted. The result after applying the reputation equation was higher. The reputation score for STC was 0.97.

However, taking into consideration the number of retweets and favorites for each tweet showed an improvement in

calculating reputation. Table V and Fig. 5, 6 shows the difference in reputation score between the two testing.

TABLE V. COMPARISON OF THE REPUTATION SCORES OF THE THREE COMPANIES

Without Popularity Scoring	With Popularity Scoring
STC	
0.59	0.97
Mobily	
0.82	0.74
Zain	
0.31	0.19

Fig. 5. Comparison of the Reputation Scores of the Three Companies.

(a) STC Reputation Score.

(b) Mobily Reputation Score.

(c) Zain Reputation Score.

Fig. 6. Reputation Scores before and after Applying Popularity Scoring Equation.

From the result, the STC reputation score was higher after applying the Popularity Scoring equation. While Mobily and Zain indicate the lowest reputation score after applying the Popularity Scoring equation. The reputation scores of Mobily and Zain decreased, and this is not due to defective or erroneous results, but after applying a Popularity Scoring equation gave more accurate results that included the re-tweet calculation and favorites.

V. CONCLUSION AND FUTURE WORK

In this study, a new opinion review presented based on a hybrid approach focused on the undertaking of sentence-level sentiment analysis to calculate reputation scores from Arabic tweets. The divergence of opinions between the customers of Telecom service providers in Twitter causes a need for a new approach to determine the reputation score of service providers involving developing a new way to compute the polarity of Arabic sentiment.

A new step was added to the traditional sentiment analysis process to enhance its accuracy. First, the significance value of counting the retweets and favorites numbers in the polarity score explains, which represents a non-verbal opinion. Second, developing a reputation approach based on the polarity score of sentiment. The first step could assist the classifier to understand and make a better accuracy about the sentiment analysis in Arabic text.

Different measures to evaluate the performance and efficacy of the classification were used in this study: the accuracy, precision, recall, and F-score. The result indicates that the SVM is the best-performed classifier, while the lowest-performing classifier is the Decision Tree. Also, the degree of reputation indicates that the STC company represents the highest reputation among its customers compared to other companies.

For future work, the approach will expand to consider multilevel word polarity instead of binary level. Also, there is a need to study the demographic characteristics of customers. In the data label, there may be a possibility where some word polarity is not noticed correctly. Currently, those instances are not handled so, it's better to use a lexicon-based approach besides labeling data by the Maza-jak tool. Moreover, the spam tweets should distinguish and eliminate to deliver more reliable reputation scores.
