Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

Editorial Board

CONTENTS

Paper 1: A New Approach of e-Commerce Web Design for Accessibility based on Game Accessibility in Chinese Market
Authors: Hemn Barzan Abdalla, Lu Zhen, Zhang Yuantu
PAGE 1 – 8

Paper 2: Research on the Relationship between Exploratory Behavior and Consumer Values using Eye Tracking Gaze Data
Authors: Mei Nonaka, Kohei Otake, Takashi Namatame
PAGE 9 – 16

Paper 3: Lip Detection and Tracking with Geometric Constraints under Uneven Illumination and Shadows
Authors: Waqqas ur Rehman Butt, Luca Lombardi
PAGE 17 – 24

Paper 4: Data Hiding Method with Principal Component Analysis and Image Coordinate Conversion
Authors: Kohei Arai
PAGE 25 – 30

Paper 5: DCRL: Approach for Pattern Recognition in Price Time Series using Directional Change and Reinforcement Learning
Authors: Nora Alkhamees, Monira Aloud
PAGE 31 – 41

Paper 6: Constrained Quantum Optimization for Resource Distribution Management
Authors: Sara El Gaily, Sándor Imre
PAGE 42 – 51

Paper 7: Prototype Design and Experimental Evaluation e-Healthcare System based on Molecular Analysis Devices
Authors: Maxim Zakharov, Alexander Paramonov, Ammar Muthanna, Ruslan Kirichek
PAGE 52 – 59

Paper 8: MNN and LSTM-based Real-time State of Charge Estimation of Lithium-ion Batteries using a Vehicle Driving Simulator
Authors: Si Jin Kim, Jong Hyun Lee, Dong Hun Wang, In Soo Lee
PAGE 60 – 67

Paper 9: Learning Optimum Number of Bases for Indian Languages in Non-negative Matrix Factorization based Multilingual Speech Separation
Authors: Nandini C Nag, Milind S Shah
PAGE 68 – 77

Paper 10: Determining Local Hematology Reference Ranges: A Data-driven Approach
Authors: K.A.Hasara Semini, H.A.Caldera
PAGE 78 – 86

Paper 11: A WSM-based Comparative Study of Vision Tracking Methodologies
Authors: Sara Bouraya, Abdessamad Belangour
PAGE 87 – 98

Paper 12: Mobile Malware Classification for iOS Inspired by Phylogenetics
Authors: Muhammad Afif Husainiamer, Madihah Mohd Saudi, Azuan Ahmad, Amirul Syauqi Mohamad Syafiq
PAGE 99 – 105

Paper 13: ANNMDD: Strength of Artificial Neural Network Types for Medical Diagnosis Domain
Authors: Ahmed Hamza Osman
PAGE 106 – 119

Paper 14: Optical Character Recognition Engines Performance Comparison in Information Extraction
Authors: Tosan Wiar Ramdhani, Indra Budi, Betty Purwandari
PAGE 120 – 127

Paper 15: Higher Order Statistics and Phase Synchronization as Features in a Motor Imagery Paradigm
Authors: Oana-Diana Hrisca-Eva, Madalina-Giorgiana Murariu, Anca Mihela Lazar
PAGE 128 – 133

Paper 16: Enhanced Framework for Big Data Requirement Elicitation
Authors: Aya Hesham, Osama E. Emam, Marwa Salah
PAGE 134 – 143

Paper 17: Analyzing Predictive Algorithms in Data Mining for Cardiovascular Disease using WEKA Tool
Authors: Aman, Rajender Singh Chhillar
PAGE 144 – 150

Paper 18: Enhanced Clustering-based MOOC Recommendations using LinkedIn Profiles (MR-LI)
Authors: Fatimah Alruwaili, Dimah Alahmadi
PAGE 151 – 160

Paper 19: Constructing IoT Botnets Attack Pattern for Host-based and Network-based Platform
Authors: Wan Nur Fatihah Wan Mohd Zaki, Raihana Syahirah Abdullah, Warusia Yassin, Faizal M.A, Muhammad Safwan Rosli
PAGE 161 – 168

Paper 20: A Classification of Essential Factors for the Development and Implementation of Cyber Security Strategy in Public Sector Organizations
Authors: Waqas Aman, Jihan Al Shukaili
PAGE 169 – 176

Paper 21: Automatic Speech Recognition Features Extraction Techniques: A Multi-criteria Comparison
Authors: Maria Labied, Abdessamad Belangour
PAGE 177 – 182

Paper 22: An Approach for Requirements Engineering Analysis using Conceptual Mapping in Healthcare Domain
Authors: Aya Radwan, A. Abdo, Sayed Abdel Gaber
PAGE 183 – 190

Paper 23: Improved Rough-fuzzy C-means Clustering and Optimum Fuzzy Interference System for MRI Brain Image Segmentation
Authors: D. Maruthi Kumar, D. Satyanarayana, M. N. Giri Prasad
PAGE 191 – 205

Paper 24: Empirical Validation of WebQMDW Model for Quality-based External Web Data Source Incorporation in a Data Warehouse

Authors: Priyanka Bhutani, Anju Saha, Anjana Gosain

PAGE 206 – 215

Paper 25: Correlating Discriminative Quality Factors (CDQF) for Optimal Resource Scheduling in Cloud Networks

Authors: B.Ravindra Babu, A.Govardhan

PAGE 216 – 222

Paper 26: Development of Novel Algorithm for Data Hiding on Mobile Application

Authors: Roopesh Kumar, Ajay Kumar Yadav

PAGE 223 – 230

Paper 27: Fuzzy and Genetic Algorithm-based Decision-making Approach for Collaborative Team Formation: A Study on User Acceptance using UTAUT

Authors: Azleena Mohd Kassim, Norhanizah Minin, Yu-N Cheah, Fazilah Othman

PAGE 231 – 240

Paper 28: Secured SECS/GEM: A Security Mechanism for M2M Communication in Industry 4.0 Ecosystem

Authors: Ashish Jaisan, Selvakumar Manickam, Shams A. Laghari, Shafiq Ul Rehman, Shankar Karuppayah

PAGE 241 – 250

Paper 29: Evaluating and Comparing the Usability of Privacy in WhatsApp, Twitter, and Snapchat

Authors: Abdulmohsen S. Albesher, Thamer Alhussain

PAGE 251 – 259

Paper 30: Genetic Algorithm and Ensemble Learning Aided Text Classification using Support Vector Machines

Authors: Anshumaan Chauhan, Ayushi Agarwal, Razia Sulthana

PAGE 260 – 267

Paper 31: Object Detection Approaches in Images: A Weighted Scoring Model based Comparative Study

Authors: Hafsa Ouchra, Abdessamad Belangour

PAGE 268 – 275

Paper 32: On the Training of Deep Neural Networks for Automatic Arabic-Text Diacritization

Authors: Asma Abdel Karim, Gheith Abandah

PAGE 276 – 286

Paper 33: Unsupervised Clustering of Comments Written in Albanian Language

Authors: Mërgim H. HOTI, Jaumin AJDARI

PAGE 287 – 292

Paper 34: Mitigating Traffic Congestion at Road Junction using Fuzzy Logic

Authors: Amir Hamzah Pohan, Liza A. Latiff, Rudzidatul Akmam Dziyauddin, Nur Haliza Abdul Wahab

PAGE 293 – 299

Paper 35: Adaptive Demand Response Management System using Polymorphic Bayesian Inference Supported Multilayer Analytics

Authors: Sarin CR, Geetha Mani

PAGE 300 – 305

Paper 36: Determine the Main Target Audience Characteristics in M-learning Applications in Saudi Arabian University Communities

Authors: Alaa Badwelan, Adel A. Bahaddad

PAGE 306 – 320

Paper 37: Online Discussion Support System with Facilitation Function

Authors: Chihiro Sasaki, Tatsuya Oyama, Chika Oshima, Shin Kajihara, Koichi Nakayama

PAGE 321 – 331

Paper 38: Hybrid Spelling Correction and Query Expansion for Relevance Document Searching

Authors: Dewi Soyusiawaty, Denny Hilmawan Rahmatullah Wolley

PAGE 332 – 339

Paper 39: Usability Perceptions of the Madrasati Platform by Teachers in Saudi Arabian Schools

Authors: Wesam Shishah

PAGE 340 – 351

Paper 40: IDD-HPO: A Proposed Model for Improving Diabetic Detection using Hyperparameter Optimization and Cloud Mapping Storage

Authors: Eman H. Zaky, Mona M. Soliman, A. K. Elkholy, Neveen I. Ghali

PAGE 352 – 362

Paper 41: Emotional Cascade Model and Deep Learning

Authors: Carlos Pelta

PAGE 363 – 367

Paper 42: Diabetes Classification using an Expert Neuro-fuzzy Feature Extraction Model

Authors: P. Bharath Kumar Chowdary, R. Udaya Kumar

PAGE 368 – 374

Paper 43: A Multiagent and Machine Learning based Hybrid NIDS for Known and Unknown Cyber-attacks

Authors: Said OUIAZZANE, Malika ADDOU, Fatimazahra BARRAMOU

PAGE 375 – 382

Paper 44: Software Quality Analysis for Halodoc Application using ISO 25010:2011

Authors: Aditia Arga Pratama, Achmad Benny Mutiara

PAGE 383 – 392

Paper 45: The Novel CPW 2.4 GHz Antenna with Parallel Hybrid Electromagnetic Solar for IoT Energy Harvesting and Wireless Sensors

Authors: Irfan Mujahidin, Akio Kitagawa

PAGE 393 – 400

Paper 46: Smart Air Pollution Monitoring System with Smog Prediction Model using Machine Learning

Authors: Salman Ahmad Siddiqui, Neda Fatima, Anwar Ahmad

PAGE 401 – 409

Paper 47: Novel Secure Validation Scheme to Assess Device Legitimacy in Internet of Things

Authors: Ayasha, M Savitha Devi

PAGE 410 – 419

Paper 48: An Efficient IoT-based Smart Water Meter System of Smart City Environment
Authors: Raad AL-Madhrahi, Nayef.A.M. Alduais, Jiwa Abdullah, Hairulnizam B. Mahdin, Abdul-Malik H. Y. Saad, Abdullah B. Nasser, Husam Saleh Alduais
PAGE 420 – 428

Paper 49: White-Grey-Black Hat Hackers Role in World and Russian Domestic and Foreign Cyber Strategies
Authors: Mikhail A. Shlyakhtunov
PAGE 429 – 435

Paper 50: Mobile Computational Vision System in the Identification of White Quinoa Quality
Authors: Percimil Lecca-Pino, Daniel Tafur-Vera, Michael Cabanillas-Carbonell, José Luis Herrera Salazar, Esteban Medina-Rafaile
PAGE 436 – 442

Paper 51: Radiofrequency Temperature Control System for Fish Capture
Authors: Walter Vásquez-Cubas, Marvin Zarate-Cuzco, Michael Cabanillas-Carbonell, José Luis Herrera Salazar, Oswaldo Casazola-Cruz
PAGE 443 – 448

Paper 52: Ontology based Semantic Query Expansion for Searching Queries in Programming Domain
Authors: Manal Anwer Khedr, Fatma A. El-Licy, Akram Salah
PAGE 449 – 455

Paper 53: A Cryptographic Technique for Communication among IoT Devices using Tiger192 and Whirlpool
Authors: Bismark Tei Asare, Kester Quist-Aphetsi, Laurent Nana
PAGE 456 – 462

Paper 54: User-centred Design and Evaluation of Web and Mobile based Travelling Applications
Authors: Nor Azman Ismail, Siti Fatimah Nizam, Simon Yuen, Layla Hasan, Su Elya Mohamed, Wong Yee Leng, Khalid Krayz Allah
PAGE 463 – 470

Paper 55: Experimental Study of Hybrid Genetic Algorithms for the Maximum Scatter Travelling Salesman Problem
Authors: Zakir Hussain Ahmed, Asaad Shakir Hameed, Modhi Lafta Mutar, Mohammed F. Alrifaie, Mundher Mohammed Taresh
PAGE 471 – 482

Paper 56: Knowledge Extraction and Data Visualization: A Proposed Framework for Secure Decision Making using Data Mining
Authors: Hazzaa N. Alshareef, Ahmed Majrashi, Maha Helal, Muhammad Tahir
PAGE 483 – 489

Paper 57: Automated Labeling of Hyperspectral Images for Oil Spills Classification
Authors: Madonna Said, Monica Hany, Monica Magdy, Omar Saleh, Maha Sayed, Yomna M.I. Hassan, Ayman Nabil
PAGE 490 – 496

Paper 58: Logistic Regression Modeling to Predict Sarcopenia Frailty among Aging Adults
Authors: Sukhminder Kaur, Azween Abdullah, Noran Naqiah Hairi, Siva Kumar Sivanesan
PAGE 497 – 504

Paper 59: Adaptive Continuous Authentication System for Smartphones using Hyper Negative Selection and Random Forest Algorithms

Authors: Maryam M. Alharbi, Rashiq Rafiq Marie

PAGE 505 – 514

Paper 60: Lightweight Chain for Detection of Rumors and Fake News in Social Media

Authors: Yazed Alsaawy, Ahmad Alkhodre, Nour M. Bahbouh, Adnan Abi Sen, Adnan Nadeem

PAGE 515 – 525

Paper 61: Auditor's Perception on Technology Transformation: Blockchain and CAATs on Audit Quality in Indonesia

Authors: Meiryani, Monika Sujanto, ASL Lindawati, Arif Zulkarnain, Suryadiputra Liawatimena

A New Approach of e-Commerce Web Design for Accessibility based on Game Accessibility in Chinese Market

Hemn Barzan Abdalla, Lu Zhen, Zhang Yuantu
Department of Computer Science, College of Science and Technology
Wenzhou-Kean University, China

***Abstract*—China is the largest e-commerce market globally, with a share of more than 40% of the total value of e-commerce transactions in the world, down from just 1% a decade ago. The Chinese are the most used electronic payment, ordering services, and watching videos on smart devices worldwide. The study of e-commerce is one of the branches of business administration established electronically through the use of Internet networks, which aim to carry out buying and selling operations. With the popularity of e-commerce, people from more and more backgrounds are using e-commerce websites and apps, but among these users, some people are unable to use these apps/websites or have barriers to use them. Accessibility design enables anyone (regardless of ability, for example, Color-blind) to successfully navigate, understand and use some applications. The accessibility design is widely used in video games, which can give guidance to the e-commerce accessibility design. This study will analyze five well-known e-commerce websites worldwide and the consumption habits of people with barriers to use from the perspective of accessible design to suggest two new concepts of accessible design methods based on game accessibility and web accessibility to make these e-commerce websites/apps more suitable with the user habits of the particular group.**

***Keywords*—e-Commerce; accessibility design; color-blind; game accessibility**

I. Background

A. The Importance of Accessibility Design to e-Commerce Websites

Designing a professional online store for our business in an innovative way that provides a good user experience for our customers will undoubtedly build a different and strong image in front of consumers and increase their confidence in your services and products. China e-commerce has made remarkable achievements, increasing impact and penetration on the economic, social, cultural, and other fields, and has become a new driving force for economic growth. e-Commerce has also become an indispensable part of the daily life of the Chinese people. As a virtual place for businesses and consumers to communicate, e-commerce websites provide consumers with an excellent online consumption experience, including visual and auditory stimuli. With these advantages, those e-commerce websites encourage consumers to spend actively and give consumers a good experience. [1]. However, the vast majority of e-commerce sites are not explicitly designed for people with disabilities. The users of an e-commerce website should be all consumers, and it should provide more help to these disabled users. Because of their physical reasons, people with disabilities are subject to many restrictions when using e-commerce websites, so they cannot get a complete experience, undermining people with disabilities in using e-commerce websites.

B. Difficulties in using e-Commerce Websites for People with Disabilities

According to the 12th five-year Development Program data for the cause of disabled people in China, the total number of disabled people in China is about 85 million, which means in every 16 Chinese people, there's one has a disability. [2]. There is no doubt that it is challenging for people with disabilities to use e-commerce sites without accessibility design, even if they have some assistive devices, such as voice recognition and auxiliary input. To fundamentally solve the problem that it is difficult for people with disabilities to use, it is necessary to carry out the barrier-free design of e-commerce websites. However, the vast majority of websites are not specially designed for the disabled so far. The mainstream dynamic design and color layout of e-commerce sites are not effective enough for visually impaired people, making it difficult to obtain product information and purchase products.

C. Game Accessibility Solutions

As an entertainment tool that gives users powerful sensory impact, the accessibility design in video games is targeted and integrated. The integrated accessibility settings can be used in other fields, especially vision and hearing settings. Take "The Last of Us: Part II" for example; Naughty Dog studio designed more than 60 accessibility settings in one particular block called "Accessibility" shown in Fig. 1. The rules for classification and some methods such as "Magnification and visual aids" can inspire the accessibility design in e-commerce.

D. Objectives and Motivations

From the previous A and B part, the Chinese e-market has a large number of users with disabilities. Many of them have problems using e-commerce website, how to increase the user experience for this group of users is the question need to be solved in this paper. As a solution to the problem, better e-commerce using the system can increase the user experience directly; this system should consider different types of disabilities and put other solutions in an integrated environment. Designing an integrated setting or system for e-commerce accessibility is the purpose of this research; various tools and ideas are used to achieve this. Since the online website nowadays requires more on images, UI, and interaction quality, which are the core fields of video game design or game accessibility, it is possible to transport the experience of game accessibility to e-commerce accessibility. In total, this research aims at the e-market of users with a disability, trying to design an integrated system for e-commerce accessibility based on the experience from game accessibility; this system is the ideal solution to solve the using problems from users with disabilities.

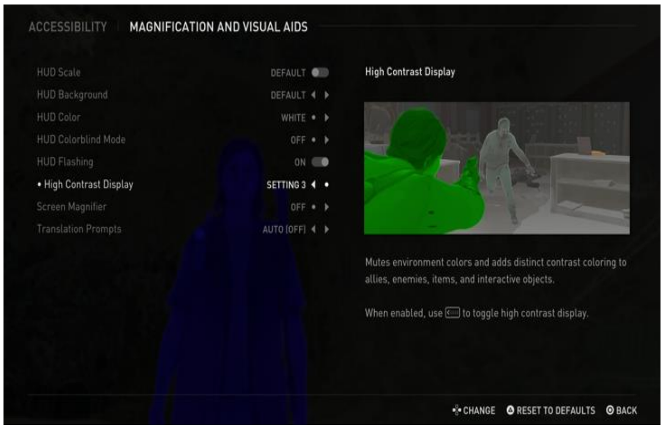

Fig. 1. Accessibility Setting in "The Last of US: Part II" (The Last of US: Part II Accessibility Introduction Page).

II. Related Work

Since the same research material could not be found, the researcher will analyze similar studies, namely on game accessibility, to inspire the design. Game accessibility is an approach commonly used in modern console games. In [3, 4], the methods and challenges of designing accessible games are analyzed from the perspective of the game itself and the user, which also gives the inspiration for the choice of the scope of this research. The scope, or user profile is essential for the whole design method in this research, not only in video games, this research also collect user profile from table games, in [5] the user profile and the way of typical methodologies, limitations are reported; respectively, an efficient accessibility game design will be one of this article's guidance, "The Last of US: Part II" is a uniformed and detailed example in-game field, in [6], the author demonstrates the importance between accessibility and game by providing Active Game Accessibility (AGA) development framework and game accessibility guideline. Although the content of game accessibility above cannot be copied in this paper, the framework they used will be a guide for building an integrated accessibility environment.

To be able to demonstrate the scientific validity of the proposed solution, this paper uses Chinese disabled data [2, 7] and consumer data of different shopping stages produced through the Taobao dataset [8] to be able to analyze the feasibility of the solution mentioned in this paper, this paper introduces two models based on the basic understanding of web accessibility [9, 10, 11], PEQUAL, a comprehensive website based on multiple analysis methods evaluation models, and Web Content Accessibility Guidelines (WCAG) 2.0 is a benchmark to guide web accessibility analysis and design. To visualize the website analysis by WCAG 2.0, tools for website review can be used. Also, an experiment about conversion rate and time of e-commerce websites and some literature reviews about the environment of the e-commerce website for people with disabilities are used for data comparison and discussion [12, 13]. In the models and data above, the detailed data of the users with a disability is not able to be calculated or predicted; this paper will treat the materials above as benchmarks, WCAG 2.0 will be the benchmark of detail UI design while PEQUAL and data from Alibaba open-sourced dataset will be the benchmark while testing.

Apart from WCAG 2.0, there is more technical, biological, or psychological research result that gives guidance to the design and analysis part of this article: The accessibility analysis in Australia e-Commerce website based on WCAG 2.0 [1] and the standard Munsell Color System, which can be the application for helping people with color blindness [14, 15]. The use of the standard Munsell Color System can be more accurate if "Gamut Mask" is also engaged in a website color analysis [16]. Pointing and Clicking difficulties can cause problems shopping online; the behaviors from and assessment for people with clicking challenges [17] can affect the design methods. Using an AI-based voice assistant can also be a solution except for the result above. A study about interaction quality or voice assistant system (VAS) [18, 19] can guide the voice recognition technology in the proposed solution. Both Munsell Color System and voice assistant system are widely used in the field of design and voice recognition, but can't find application in the field of e-commerce websites; this paper will use both of them to build two core functions about colorblind support and voice support in the whole system.

Due to the scope of target users, web accessibility design can be scattered, frameworks for improving accessibility design service [20] and the example for web design from e-government website [21] can give the inspiration to the final united and classified design methods. The external insights above in the both applications proved the feasibility of the solution provided by this paper, also gives the guidance for system testing, but this paper does not share the same group of users, the objective of users are different while using, so while testing and designing, this paper will consider both the successful application and user characteristics.

III. Scope and Purpose

A. Scope

The proposed solution and the analysis are mainly aimed at the classified groups in Table I [7]. At the same time, considering the existence of a particular group of sellers, changes in the design of online shopping systems could change the experience of the seller group; this change will not be considered in the designing part.

B. Purpose

By analyzing Web Content Accessibility Guidelines (WCAG) 2.0, some global e-commerce platforms, and some specific users of these platforms (see "III scope" for details of specific user groups), this article will suggest several solutions to build a more user-friendly online shopping environment for these particular groups. The solutions include 1) a new system design scheme based on user itinerary analysis of different websites; 2) a new interaction design scheme based on the roles of specific user groups.

TABLE I. DIFFERENT TYPES OF DISCUSSION AND THEIR CORRESPONDING SPECIFIC MANIFESTATIONS

The type of disability	the specific manifestation
Visual impairment.	Color blindness; maximum visual acuity in both eyes is less than 0.1; visual field is incomplete.
Hearing impairment.	The structure and function of the auditory system are severely impaired, the average hearing loss of the better ears is between 81 and 90(dB HL), and the comprehension and communication are severely limited.
Dyskinesia.	Cannot use the mouse to make fine movements; using the keyboard input is more complicated.
Comprehension barrier.	Unable to understand long sentences, dyslexia, low comprehension

IV. METHODOLOGY

A. *Analysis*

To make the proposed design method more convincible, the analysis of the using process and user profiles are needed. By analyzing the user journey, comparing the actions and time between different users, the needs from the particular group will appear. Based on WCAG 2.0, the unreasonable design of some certain e-commerce websites can also be found. In total, the analysis will provide the basic logic and reference for design.

1) Analysis of mainstream e-commerce websites: The duration of each step, including the interaction of every stakeholder in the whole user journey, is showed in Fig. 2. Almost every platform from the research, Taobao, JD, Amazon, and eBay, has shared the same process. Those platforms will use different sales strategies or recommendation strategies in different status, but the process itself won't be influenced.

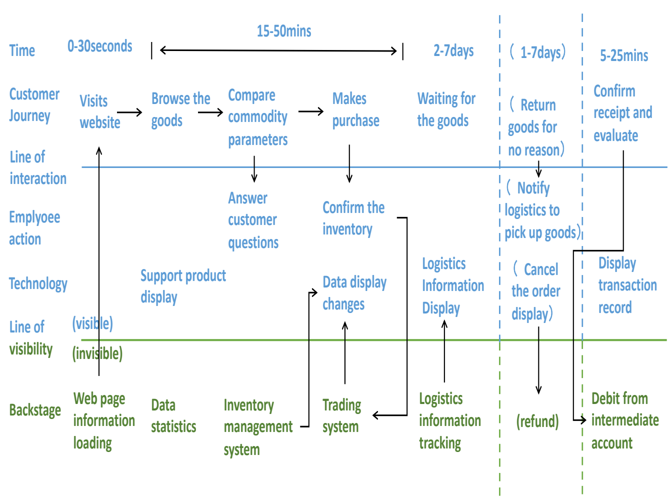

Fig. 2. The Service System of Mainstream e-Commerce Websites in the Market.

Meanwhile, Pinduoduo's service system, as an APP-only platform, is somewhat different from them. When paying for this link, customers can spend less waiting for another customer who purchases goods simultaneously. The general flow of the service system is shown in Fig. 3.

Based on the user journey above, user interface change may change the conversion rate for each status and average spending time on different pages. However, a recommendation system and other sales strategies could also affect the conversion rate. Testing and contrasting the average spending time in different shopping statuses could be more accurate and precise.

2) User analysis

a) User Reaction Time Based on Simulation: The reaction time data should not be affected by subject choices; simply calculating data from user behavior datasets from different e-commerce platforms can hardly ignore the error. A simulation experiment was designed to fix this problem.

This experiment chooses 15 different users who do not have problems using those e-commerce websites by giving them other shopping purposes (for example, user A is supposed to buy powdered milk) to decrease the influence of recommendation and memory. At the same time, this experiment gives users the use of barriers to simulate the target users. The change of CSS filter scale in the source code of an e-commerce website can affect the sight from different kinds of color-blind; the slightly shaking from the mouse to simulate the shaking from hands can be realized by C++ [5]. The experiment result is shown below; all the experiment was based on Taobao China website.

Based on the result in 4.1.1, the test was divided into four parts to simulate: (1) view the homepage and choose classification the user needs, to decrease the influence of personal preference, the classification was randomly chosen in one routine of the test; (2) choose the specific item in the classification page; (3) read the introduction page of items; (4) make payment.

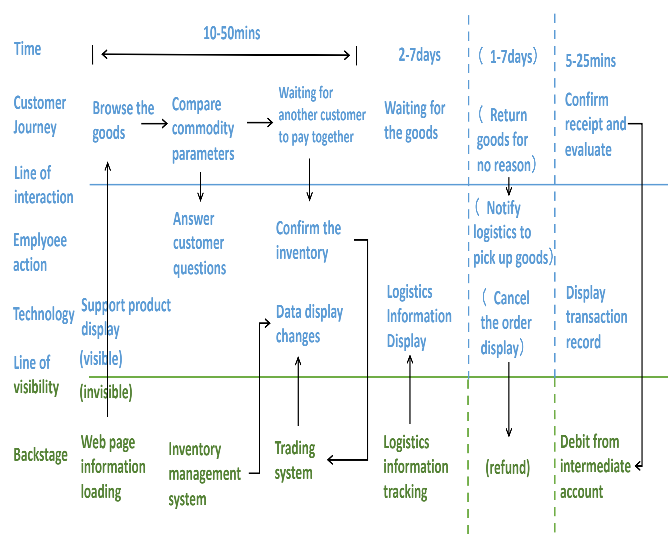

Fig. 3. Pinduoduo's Service System.

TABLE II. SIMULATION RESULT FOR 3 EXPERIMENTAL GROUP

	View homepage /s	determine the specific item/s	read the specification of an item/s	Payment time/s
All color Blind	50.54	16.93	293.93	28.67
presbyopia	56.71	18.94	310.43	33.00
Movement Disorders	42.33	24.57	269.96	36.65
Normal (control Group)	38.10	14.36	261.97	20.05

To ensure the data is accurate and precise, the variation (CV) coefficient was calculated for all the average data in Table II. All the CVs are under 15%, and the first 2 steps have higher CVs while CV in steps 3 and 4 are lower; the errors may come from different familiarities to the Taobao website.

To put four processes into side-to-side comparison, the time of reading the specification takes most of the whole process, which means the information from the item is more important to users. The assistant reading and understanding in this part will be more critical. Viewing the homepage and finding classification takes more time to compare with finding specific items; this result could lead to the question about the main navigation bar; too many sorts may distract the user's attention, or the color and font influence users' judgment.

Fig. 4 is the visualization of Table II. Using the chart to determine the gap of all kinds of simulations, the move disorders group spends more time determining the specific item and making payment. These two parts typically need more interaction, like clicking and typing. Meanwhile, viewing and reading parts are harder for group presbyopia, meaning that the text in those two-part is hard for people to read. Overall, the other 3 groups' average time is higher than standard data; a solution used in the whole process is needed.

b) Portrait the User According to the User's Behavior: The reaction data present the user behavior objectively while the user interview reflects the subjective feelings from the users, which could also be necessary. At present, 10 users were intensely interviewed, including their shopping habits, online shopping routine, and problems they've met were asked. Among these users, some hardly use the online platform for shopping and users who frequently use these apps as well as the linked industry apps; in this section, the target users will be further broken down, and the results of the interviews of these target users are shown in Table III.

The result of user analysis will affect the focus direction of the final solution; for example, the colorblind user takes more time viewing, and using process about "viewing" in these websites may need more colorblind-aimed assistance. In the opposite way, if the solution provided from this paper can decrease the particular using time, the solution can be treated as an ideal solution to the research question this paper proposed.

3) Web design analysis: With the increase in Internet users, the importance of owning a website has increased to manage the business and promote products in all its forms. Every company or business community, whether small or large, has a website that talks about it and its services and products. There must be many features for the design and content of the website to represent a tool to attract the most extensive audience base and attract many new visitors and retain existing visitors. The analysis above is based on users; this section will focus more on web design analysis. Based on WCAG, the color used for a website have strict rules, if the rules are not followed, users can take more time to recognize the message, take the main navigation and search bar from Taobao as an example (Fig. 5), by using a color review tool, the result of color using is showed on Fig. 6, Fig. 7 and Fig. 8.

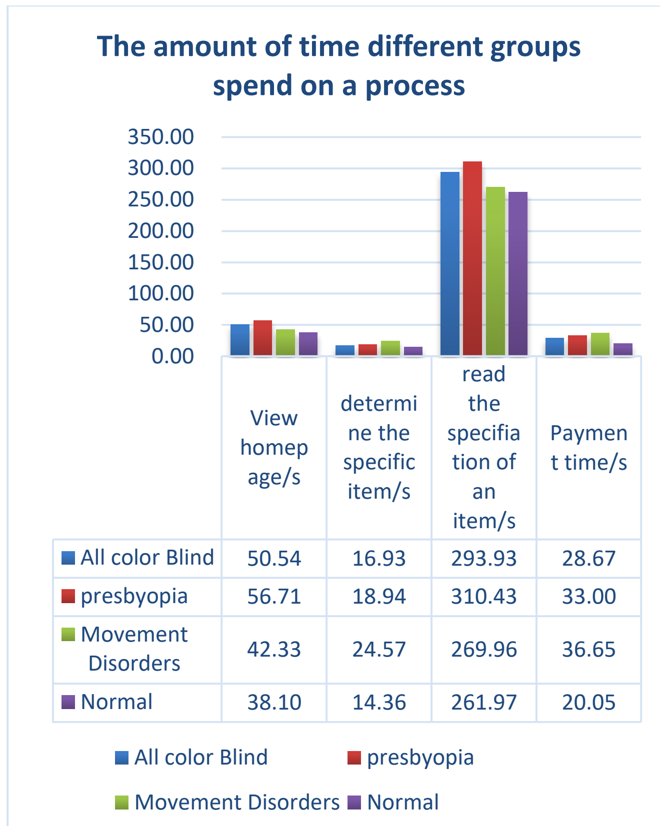

Fig. 4. The Amount of time different Groups Spend on a Process.

TABLE III. INVESTIGATION RESULT

User Type Specification	**User Characteristics**	**User Feedback through e-Commerce website now**
Visual impairment including color blindness, incomplete of visual field	familiar with e-Commerce website but have visual obstacle when using them	Too much information on the main page, hard to recognized different icons belongs to different sub-system
Elder without online shopping experience	familiar with offline shopping, not willing to learn how to shopping online	Too complicated to learn, too much information to understand
Elder with online shopping experience	familiar with all the digital platform for e-commerce, with high user viscosity, but easy be treated	Not familiar with all the discounting policy, cannot be focus sometimes, easy to get tired

Fig. 5. Main Navigation and Search Bar of Taobao (Taobao Homepage).

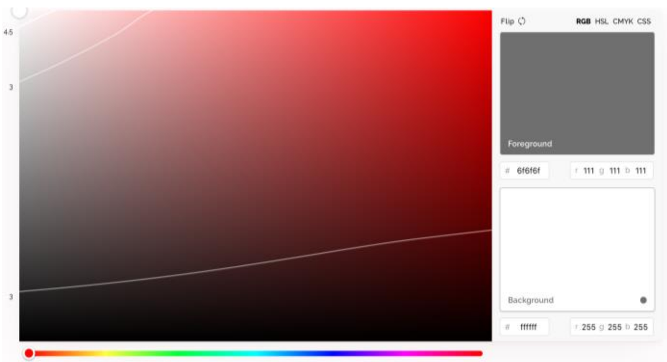

Fig. 6. Color Review of Main Navigation Bar While Not Clicking (ColorReview).

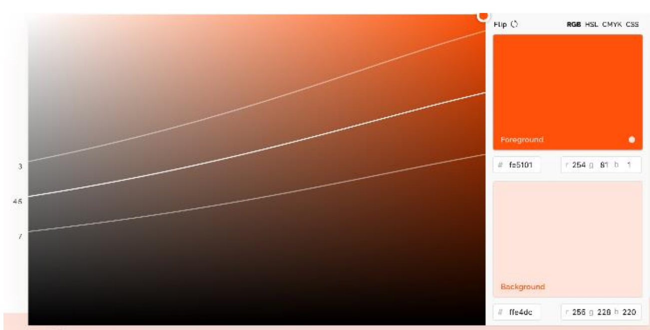

Fig. 7. Color Review of Main Navigation Bar While Clicking (ColorReview).

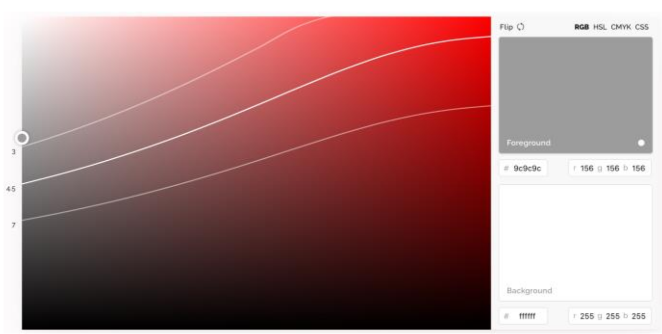

Fig. 8. Color Review of Main Searching Bar (ColorReview).

Three lines on the color review, "3", "4.5", "7", means three standards for AA and AAA in WCAG 2.0, the index of the circle in the graph the higher, the better. In the result of the color review, only the background-text color contrast ratio of the main navigation bar while not clicking fulfilled the WCAG 2.0 AA standard.

Meanwhile, in the main navigation bar, products are classified in 15 blocks, which can be complex for users to organize and remember.

The analysis of the web page, compare with WCAG 2.0 and other benchmarks, can provide the guideline about UI design for the final solution; since the benchmarks, this paper choose are widely used in other fields, including other websites, the result of web design analysis should be convincible and helpful to build a better UI for e-commerce accessibility.

4) Accessibility design: All design methods will be based on analysis and combined with the user profile in the scope. Design methods are divided into two parts according to the problems that need to be solved.

1) problems that need to be solved as soon as the user enters the page; and 2) problems that may need to be solved as the user uses the site.

The solution before using: 1) Visual aids, adjustable font and icon size for the main interface, enhanced contrast for image display, weaker background, highlighting text and product subjects; these adjustments are specified in WCAG 2.0 [10], i.e., text cannot be adjusted, the font needs to be 14-18 px; repeated scrolling of text needs to be in width 320 and height of 256 CSS pixels in the window. Contrast ratios of at least 4.5:1 for large text and up to at least 7:1 for other text. To prevent light epilepsy, interactive animations should preferably not be displayed on the home page, nor should any web content contain any flashing more than 3 times/second.

2) Motion/cognitive aids increase the feedback area, and to address the needs of Parkinson's patients, the delay of the web interaction will be longer, with the highest delay of 3s [10]. The user can control the length of the delay, and the size of the interaction module will be more significant.

The solution while using: 1) Colorblind, color-blind mode, anything related to the discriminability of the web page can be adjusted by the color-blind/color-blind mode, based on the Munsell Color System [4], which is shown in Fig. 9. All colors are represented by hue, luminance, and chroma. The hue is divided into red (R), red-yellow (YR), yellow (Y), yellow-green (GY), green (G), green-blue (BG), blue (B), blue-violet (PB), violet (P), and purple-red (RP); luminance is expressed from white to black from N0-N10; chroma is used to indicate the purity of the hue, and the upper limit of standard colors is about 10. The color-blindness mode mentioned in this paper will be designed for all types of color-blindness using quantitative experiments, which will first determine the lightness as N5 and the chroma as 5, then let users sort the hues, the system interface will have different color matching according to the sorting results (because there is red-green and blue-green color-blindness, the color-blindness mode will be designed for all types of color-blindness). After determining the hues, the adjustment of lightness and chroma will be made according to similar methods to ensure that the needs of all similar users are met.

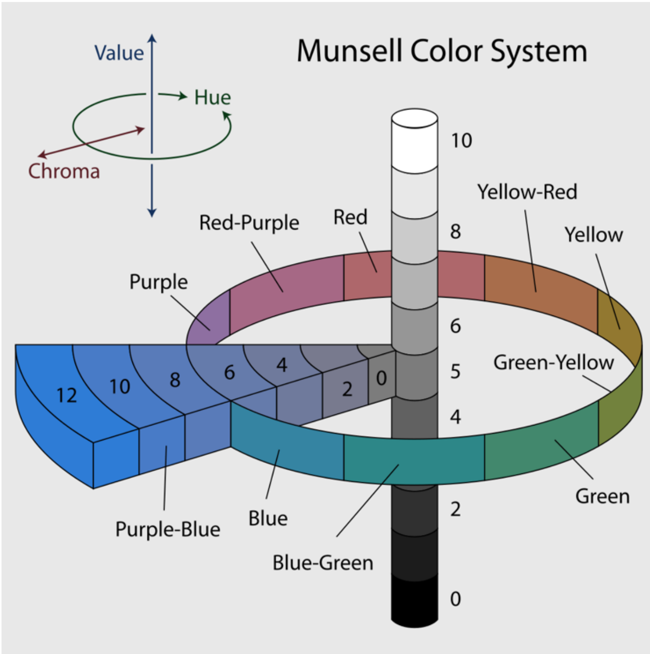

Fig. 9. Munsell Color System [10].

2) Cognitive assistance, this point also applies to users other than visually impaired users; when opening the assistance mode, you need to remove all irrelevant icons, reduce the length of advertising images by 50%, increase the font size to 18px and bold, in the mobile terminal, vibration and touch need to be corresponding adjusted, for example, increase the vibration feedback at each stage of shopping, such as adding a shopping cart, For instance, adding vibration feedback at each step of the shopping process, such as adding a shopping cart for a short vibration, and two long vibrations for payment. Long press on an interactive video can appear auxiliary subtitles, long-press on an extended language can play a voice to assist reading. This mode can also be open as a full voice assistant; users can use voice instead of clicking in the whole process.

The design part suggests separate parts of the e-commerce web accessibility design based on the needs from the analysis part. Also, based on the analysis part, these design methods will be used in the different user journeys to ensure the system's logic and make the system integrated and easy to use; the final solution will be concluded in Section V.

V. Proposed Solution

This section will specifically describe how the above design is implemented in the actual website, taking Taobao as an example; first, for the main page and all the pages that require reading, the contrast rate should at least be 4.5:1, font size need to be larger than 16px, the critical text need to be bold; all the thrilling video cannot be played, the descriptive text should be more precise, especially in the specific item description; The classification in the main navigation bar is suggested to be decreased. Those are a minimum requirement, based on the essential condition, the analysis result, and inspiration from game accessibility; two more things are needed for the system:

1) Calibration of the whole system, at the beginning of the entire process of using, a calibration for accessibility is needed; this article suggests putting the complete calibration in the login page for the influence to normal users won't be strong. Based on the design and analysis above, the calibration process needs to contain:

- Color Sensitivity test, the process will be similar to the method based on Munsell color system in 4.2.
- Font adjustment, adjust the font size, bold or not by giving the user an article.
- Web layout adjustment using block model and click adjustment, by giving a simulated website based on the e-commerce website which is made by different blocks, users can adjust the size of blocks, the system will change the size of pictures in the real website, after finalizing the block, users are required to click some of the buttons, by testing the accuracy of clicking, the system can get the force range and necessary delay.
- Whether to start voice input, if the voice input is open, the voice assistant can be opened, and users can use voice for payment and clicking.

2) Adjustment while using, similar to the settings in the game, users' requirements will change through the using process. The adjustment needs to contain the following functions:

Font: Options: 16px to 20 px, bold or not, all RGB adjust the size of font, color of subtitle and test	**Color:** Options: Blue-green color blindness; Red-green color blindness; Total color blindness adjust the color based on setup template, or do the test again	**Voice:** Options: open or close open or close voice assistant, including voice input and audio cues
Click: Options: small, middle, large; 1-3 seconds to change the button, including the size and delay, the initial delay is 0; size is small	**Hints:** Option: open or close open the hints will highlight all the important information, decrease the unnecessary pictures	**Process Assistant:** Options: open or close; based on the cognitive assistance in 4.2, the information for the products will be concentrated, the voice assistant will work for the whole process.

The adjustment can be a floating window on one side of the website; users can click to open the settings, choosing one of the functions to adjust.

VI. Discussion

Because all the proposed solutions are based on the analysis and authoritative data and models, it is considered as convincible, especially for the part of simulation experiment is useful, if it combines the calculating result based on Alibaba user behavior dataset and Learning optimal tree models under beam search [8], for example, the conversion rate from "adding to cart" to "buy" is 72.9%, these data about the percentage of conversion can also be influenced by time, shopping time and conversion rate are supposed to have some relationship, there's also an experiment support this idea. However, the rate of convincible is still in the theoretical part, in some of the application [20], it is found that users with disabilities are used to ask help while they have using difficulties [13], that makes the promotion and testing of the whole system harder. Also, since the design method may not be suitable for all of the websites (different companies have different design principles), it is better to make the design method of the system like a guideline as WCAG 2.0, which may be more friendly to all the companies.

VII. Challenges and Limitations

While taking care of particular groups, this paper also considers the impact of changing the system on e-commerce companies and tries to make some accessibility design with the most negligible effect on the system itself. The solution above does not need a lot of budget or some significant changes to the original system, so it is available to use.

The difficulty of this study is to find the proper users for testing. Second, because the accessibility design is scattered and fragmented, more requirements will be needed by increasing the user number, so it is necessary to develop more functions based on the coming conditions. The final test of the system is hard to simulate, especially for calibration; the alpha-beta test needs to take a lot of time due to this situation.

Another challenge this system faced is the possible conflict between accessibility and promotion; if the access mode is used, the promotion activities by the e-commerce company will be unavoidable decreased, except for recommender system, moderated promotion or advertisement can improve the profit as well as the user experience, thus, a better way of promotion or a better UI including advertisement is needed, to make the system easy to use and assure the profit of the company at the same time would increase the confidence level of this system.

The provided system can now only work for the buyers, but not the businessmen who also have this kind of situation; if a system for business people is also developed, other stakeholders with the same problems may also struggle because of disabilities, that is because the proposed system is only in the application layer, accessibility design can be used in multiple platforms, multiple occupations, and multiple devices; so, the whole solution can be raised to the system layer.

VIII. Conclusion

To solve the problems for users with disabilities while using e-commerce website, this paper based on the game accessibility design and other related application, analysis the user behavior and user journey and designed an integrated and flexible system for the whole process of online shopping, including UI design and special support (colorblind testing and voice assistant). The proposed system design is convincible by comparing with data and benchmarks, it still needs improvement in many ways like promotion, in the future, the application layer accessibility design may be placed by system layer accessibility, this proposed system is hoped to make some contribution to the narrow sense of accessibility design in the field of e-commerce.

***Abstract*—In recent years, the popularity of e-commerce has witnessed a significant uptick. Physical apparel stores need to implement measures that focus on the behavioral experience of shopping at physical stores, a trait that e-commerce lacks. The purpose of this paper is to clarify the relationship between customer values and product search behavior and proposed product placement and customer service methods based on their values. We used questionnaire data on the values of customer purchasing to perform factor analysis and cluster analysis. Moreover, we extracted the product search behavior using eye-tracking gaze data from an apparel physical store. The results showed that product search behavior differed based on three types: trend cluster, self-esteem cluster, and conservative cluster. Finally, we proposed product placement in a store considering the features of these clusters.**

***Keywords*—Consumer values; eye tracking; factor analysis; cluster analysis**

I. Introduction

In recent years, the popularity of e-commerce has witnessed a significant uptick. According to a market study on e-commerce [1], the e-commerce rate for clothing and apparel was 12.96%. This rate was higher than the average electronic commerce conversion rate of 6.76% for all industries. As for the change in the use of physical apparel stores over the past three years [2], 32.2% of the respondents indicated that the number of items that have "decreased a lot" or "decreased a little". From this result, we found that the opportunity to use physical apparel stores decreased. Furthermore, in the same survey, the top three answers for “characteristics of physical stores actually visited” were “trying it in direct contact,” “buying it on the spot and take it home,” and “shopping with family and friends.” Therefore, it is necessary to develop marketing strategies that take advantage of the strength of physical apparel stores. Physical apparel stores need to implement measures that focus on the behavioral experience of shopping at physical stores, a trait that e-commerce lacks. One of the major differences between physical stores and e-commerce is the ability to experience the store environment and to receive customer service [3]. Improving the services and merchandising offered by physical stores can help improve the store image, and in addition, such improvement increases customer satisfaction [4,5]. In order to improve these services and merchandising, it is necessary to clarify the customer service required by customers. Therefore, we focused on the relationship between customer values and customer purchasing behavior. Since the use of eye tracking is effective in visualizing purchasing behavior [6], we conducted an experiment using eye tracking devices in this study. In the first part of the paper, we discussed related research on the relationship between values and purchasing behavior, and related research on the eye tracking case used in the analysis, and finally, we proposed product placement and customer service methods.

II. Literature Review

To improve sales in youth clothing purchases, Matsumoto et al. [7] stressed the importance of improving the environment inside the store and customer service skills of its employees. Hence, the two key takeaways from this study are store environment and customer service. In their study on the hotel industry, Ando et al. [8] indicated that customer service requirements differ depending on the values of customers. Therefore, capturing customer value should serve as a guideline for customer service and product placement in physical stores so as to fully use the advantages of behavioral experience of a physical store. In the area of eye tracking research, the role of gaze information on purchasing has been studied [9]. By using eye tracking, it is possible to visualize what information is important in purchasing. Zuschke, N. et al. [10] about research on eye tracking suggested that in-store marketing activities would encourage product selection. Bialkova S. et al. [11] conducted an experiment in a laboratory and a supermarket and suggested that placement is an important determinant in a storefront environment. Thus, the information obtained from the experiment in physical stores can be useful. There are many studies that use eye tracking for fashion, for example, understanding the purchasing patterns of mobile consumers [12], understanding the information about online shopping [13], and evaluating the design of products [14]. However, in the research on shopping using eye tracking, there are few examples of viewpoint observation experiments in physical stores of fashion brands. Therefore, in this study, we conducted viewpoint observation experiments in physical store and analyzed them using the eye-tracking data obtained.

III. Purpose of this Study

The purpose of this study is to classify the relationship between customer value and product search behavior. Specifically, we used questionnaire data on the values of customer purchasing to perform cluster analysis. Next, we extracted the product search behavior using eye-tracking gaze data from an apparel physical store. Based on these results, we compared and analyzed clusters and propose customer service and product placement methods based on customer values.

IV. Data

A. Questionnaire Data of Customer Value

We used questionnaire data about the life index conducted in 2015. The target items included 23 items about fashion and values for purchasing. Questions about fashion include those about the quality and value of clothes, the way people choose clothes, and how they appear in those clothes. Questions about purchasing include questions about how people shop, how they choose, and how they think about products. The rating was based on a five-level scale (1: Not applicable at all, 5: Exactly applicable). This study included a total of 4946 people: 4930 women in their 20s and 30s, who were the subjects of questionnaire data analysis and 16 other who cooperated in the viewpoint observation experiment.

B. Viewpoint Observation Data at Apparel Stores

We conducted a consumer behavior experiment using a gaze-measuring device at a roadside apparel store on October 15 and 17, 2019 in Tokyo, Japan. Considering that the main target of the target brand in the store was for women in their 20s and 30s and fashion clothing involvement was significantly affected by a consumer's gender and age [15], we conducted this experiment with 10 women in the 20s under the same conditions. The store deals chiefly in bags, clothes, accessories, wristwatches, and shoes. Women's products could be found at the 1F and 2F floors. Fig. 1 and Fig. 2 show the layout of the store. Table I and Table II list the product shelves on each floor. We used "Tobii Pro Glasses 2" [16] to record eye tracking during the experiment. This device can move freely while wearing and records what the subjects are looking at. Moreover, when we analyzed the recording data, we used "Tobii Pro Lab" [17] to process the recording data. In order to unify the experimental conditions, the subjects wearing the eye tracking device looked around all floors in the store for 20 min. Before the experiment, we asked the subjects to answer a questionnaire about their preferences and characteristics. As the after-questionnaire once the experiment was over, we asked impressive items and items that they wanted. The study by Saijo et al. [18] was used as reference to create the experimental procedure and questionnaires.

TABLE I. The Product Shelves List at 1F

The Product Shelves	Kinds of Products
Shelf 1	Collaboration Products
Shelf 2	New Arrivals, Handbags, Tote Bags, Backpacks
Shelf 3	Handbags, Tote Bags
Shelf 4	Pass Cases, Wallets, Handbags, Shoulder Bags
Shelf 5	Shoulder Bags, Boots, Handbags, Backpack, Body Bags
Shelf 6	Shoulder Bags, Backpacks, Tote Bags, Sneakers, for Men
Chair	Handbags, Sneakers
Table	T-shirts, Handbags, Wallets
Glass Shelf 1	Wallets, Pass Cases, iPhone Cases, Key Cases, Pouches, Key Rings
Glass Shelf 2	Wristwatch
Rack 1	Small Shoulder Bags
Rack 2	Large Shoulder Bags

TABLE II. The Product Shelves List at 2F

The Product Shelves	Kinds of Products
Shelf 1	Sneakers, Boots
Shelf 2	Small Handbags, Sneakers
Shelf 3	Sandals, Boots, Handbag
Shelf 4	Small Handbags, Tote Bags, iPhone Cases
Shelf 5	Small Handbags, Shoulder Bags, Wallets
Shelf 6	Medium Handbags, Shoulder Bags, Sneakers, Backpacks
Shelf 7	Handbag, Shoulder Bags, Mini Wallets, Boots
Shelf 8	Boots, Pumps
Glasses	Sunglasses
Table	Handbags, Backpacks, Body Bags, Sneakers
Clothes	T-shirts, Jackets
Glass Case 1	Pass Cases, Key Cases, Wallets, iPhone Cases, Pouches, Key Rings, Handbags
Glass Case 2	Wallets, Key Cases
Glass Case 3	Wristwatches
Glass Case 4	Accessories
Glass Case 5	Wristwatches
Rack 1	Small Shoulder Bags
Rack 2	Large Shoulder Bags
Shoes 1	Sneakers
Shoes 2	Sandals, Pumps

V. Analysis of the Relationship between Customer Values and Product Search Behavior

This section describes the analysis results and the considerations regarding the values. The analysis flow is shown in Fig. 3. First, we conducted a factor analysis using questionnaire data to derive the basic values of fashion and purchasing. We categorize consumer values by referring to the flow of analysis in the study by Ando et al. [8]. In addition, we referred to the papers by Kimura et al. [19] and Matsuoka et al. [20] that used factor analysis and cluster analysis in the analysis of values. To classify customers into groups based on their values, we conducted a cluster analysis based on the results of the factor analysis [21]. Next, we conducted three kinds of analyses to extract, compare, and analyze consumer search behavior for each cluster. Finally, we propose customer service and product placement methods based on customer values.

A. *Derivation and Typification of Basic Values Related to Fashion and Purchasing*

Factor analysis is a multivariate analysis method used for finding common factors hidden in multivariate data. We executed the minimum residue method and promax rotation for 23 items of questionnaire data on living indicators. From the results of the screen plot, we identified six factors. Since we deleted five items for which the factor loading was not sufficient, we ended up with 18 items, and the explanation rate for variance was 44%. Table III lists the resulting factor loadings. We named each factor based on the characteristics of the questionnaire items.

The show-off factor was named after the response to wanting to attract attention in fashion. The quality importance factor was named after the response that emphasized quality. The innovator factor was named based on the importance placed on the new products. The faddism factor was named based on responses about how people around them saw them. The commitment factor was named after thinking about and buying things. The intuition factor was named based on the responses to impulse buying. Next, to classify customers based on their values, we conducted a hierarchical cluster analysis. Hierarchical cluster analysis is a statistical analysis method that collects similar items from a large group and divides them into groups. Based on the results of the factor analysis of the basic values of fashion and purchasing, we calculated the factor score using the regression method. To examine the tendency of respondents to the factor scores of six factors, we performed a cluster analysis using the Ward method and classified questionnaire respondents into three clusters based on the results of the dendrogram. We used the Euclidean distance as the distance between the data. The results are presented in Table IV and Fig. 4.

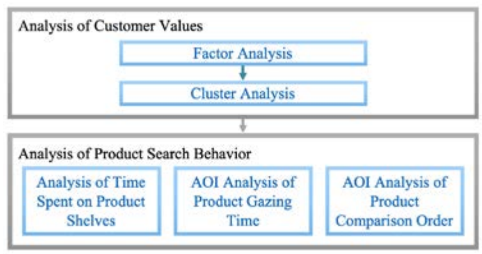

Fig. 3. The Analysis Flow in this Paper.

TABLE III. Questionnaire Items on Values Selected by Factor Loadings

Questionnaire Items	**Factor Loadings**					
	Show-off	**Quality-oriented**	**Innovator**	**Faddism**	**Commitment**	**Intuitive**
I want to attract attention in fashion.	0.982	-0.034	0.055	-0.111	-0.083	-0.111
I want to choose clothes that I can use for as long as possible.	-0.084	0.714	-0.084	0.062	-0.017	0.018
I want to choose good quality clothes. I want to handle them carefully.	0.304	0.679	0.023	-0.091	-0.056	-0.002
I want to use good things carefully for as long as possible.	-0.132	0.607	0.032	-0.007	0.148	0.046
I actually buy new products. I'm a person who tries various things.	-0.008	-0.023	0.715	-0.091	0.028	0.126
I check the information of new products diligently.	0.075	-0.024	0.688	0	0.074	-0.071
I'm curious about how I feel from the surroundings.	0	0.009	-0.168	0.686	0.043	-0.056
I often want what people around me have.	-0.041	-0.014	0.253	0.509	-0.136	0.109
I only want to put what I like around me.	-0.085	0.109	-0.018	0.036	0.548	0.088
I think that individuality appears in what kind of shopping you do.	0.031	-0.012	-0.045	0.112	0.53	0.091
Shopping often doesn't compromise until I find what I really want.	-0.059	0.076	0.144	-0.045	0.529	-0.263
I often buy what I like intuitively on impulse.	-0.117	0.043	0.034	-0.067	0.045	0.802
I'm in trouble because what I want comes out one after another.	0.062	0.009	0.099	0.264	0.017	0.295
I want to have something different from the people around me as much as possible.	0.255	-0.096	0.019	-0.147	0.433	0.167
I like to have branded things.	0.405	0.063	0.236	-0.018	-0.056	0.02
I want to improve my fashion sense.	0.45	0.144	-0.064	0.283	0.046	-0.037
I want to be seen from the surroundings.	0.458	-0.119	-0.077	0.263	0.159	-0.059
I often shop by referring to the best-selling rankings.	-0.048	-0.016	0.286	0.429	-0.003	-0.093

TABLE IV. THE AVERAGE VALUE OF FACTOR SCORE ON THREE CLUSTERS

Cluster Name	Factor Score					
	Show-off	Quality-oriented	Innovator	Faddism	Commitment	Intuitive
Trend	1.02	0.36	0.11	-0.38	-0.46	-0.20
Self-respect	-1.02	0.05	-0.03	0.18	0.34	0.50
Conservative	0.18	-0.43	-0.09	0.18	0.07	-0.40

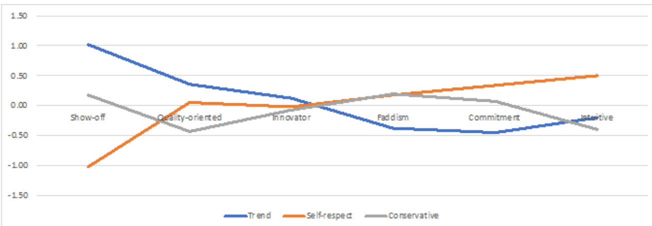

Fig. 4. Visualization of the Average Value of Factor Score on Three Clusters.

The trend cluster included 1583 people, the self-respecting cluster had 1842 people, and the conservative cluster had 1521 people. Among the 10 subjects who participated in the experiment under the same conditions, two were in the trend cluster, five were in the self-respect cluster, and three were in the conservative cluster. Furthermore, we categorized consumers into three clusters based on their values. The values of the show-off factors, quality-oriented factors, and innovator factors were high. As a result, they tend to grab new products and information and are more sensitive to fashion trends. For self-respect clusters, the values of the faddism, commitment, and intuition factors are high. It is a cluster that values one's core and sensibility while being sensitive to one's own way of seeing and the trends around oneself. Conservative clusters have only a high Faddism factor and less noticeable results for other factors. It is a cluster that likes basics and does not adventure.

B. Analysis of Time Spent on Product Shelves

To classify the differences between the clusters, we aggregated the time spent on product shelves. The results for 1F are shown in Fig. 5, and the results for 2F are shown in Fig. 6. The detailed results for each cluster are discussed in Section VA.

C. Product Evaluation on Product Shelves using AOI Analysis

Next, we conducted an area of interest (AOI) analysis to see whether there were differences in the products they were looking at on the shelves among the value clusters. The AOI analysis is a function of the eye-tracking device software Tobii Pro Lab [17], which enables us to measure the number of gazes and gazing time of the area of interest by specifying the area of interest from the recorded data [22]. Total visit duration on an information sign was found as the strongest predictor of product choice by Bridget K. Behe et al. [23]. In this study, we extracted total visit duration of the item area for three product shelves on the first and second floors. We set two conditions as selection criteria for the three shelves: the products could not be seen from multiple directions, and there were no clusters with zero time spent on the shelves. We chose Shelf 2, Shelf 3, and Shelf 4 on the first floor, and Shelf 1, Shelf 4, and Shelf 5 on the second floor. Here, we present the results of Shelf 4 on the first floor (Fig. 7 and Table V) and Shelf 4 on the second floor (Fig. 8 and Table VI), in particular, where differences among clusters are characteristically found.

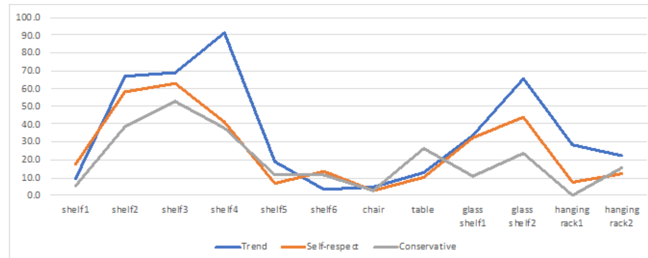

Fig. 5. Graph of Time Spent on the Product Shelves at 1F.

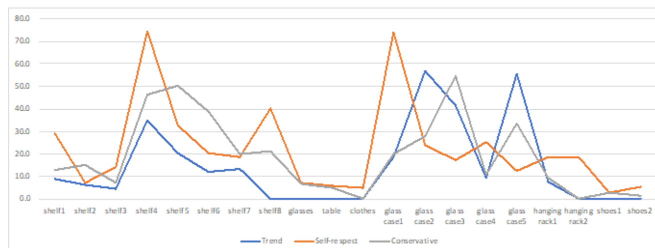

Fig. 6. Graph of Time Spent on the Product Shelves at 2F.

Fig. 7. Picture of Shelf 4 on the First Floor.

Fig. 8. Picture of Shelf 4 on the Second Floor.

TABLE V. AOI ANALYSIS RESULT OF SHELF 4 ON THE FIRST FLOOR

Cluster	**1_1**	**1_2**	**1_3**	**1_4**	**2_1**	**2_2**	**2_3**	**2_4**	**3_1**	**3_2**
Trend	0.00	0.26	0.55	0.42	2.06	1.02	1.32	2.41	0.70	1.38
Self-respect	0.00	0.26	0.31	0.12	0.26	0.83	0.19	0.28	1.05	1.36
Conservative	0.00	0.33	0.04	0.26	0.63	0.46	0.10	0.08	1.20	1.51
Cluster	**3_3**	**3_4**	**4_1**	**4_2**	**4_3**	**4_4**	**5_1**	**5_2**	**5_3**	**5_4**
Trend	1.94	3.41	1.45	2.04	3.91	4.05	1.19	2.18	2.80	5.20
Self-respect	1.18	1.57	1.04	0.77	0.98	0.64	1.52	0.31	0.36	0.17
Conservative	0.44	0.29	0.24	0.05	0.47	0.07	0.17	0.82	0.26	0.45

TABLE VI. AOI ANALYSIS RESULT OF SHELF 4 ON THE SECOND FLOOR

Cluster	**1_left**	**1_right**	**2_center**	**2_left**	**2_right**
Trend	0.00	1.90	0.75	0.57	1.23
Self-respect	0.15	1.85	1.41	0.82	2.91
Conservative	0.10	1.58	0.93	0.61	1.13
Cluster	**3_left**	**3_right**	**4_center**	**4_left**	**4_right**
Trend	2.81	3.56	0.44	0.60	0.64
Self-respect	2.04	4.67	1.82	0.70	0.29
Conservative	2.67	3.99	1.31	0.24	0.84

TABLE VII. THE TENDENCY OF THE ORDER OF GAZE AMONG THE CLUSTERS

Subject No.	**Cluster Affiliation**	**Action**	**Comparison Tendency**
1	Trend	The first time, she looked at all the products, and then compared them with the black products; the second time, she focused on the camera bag on the fourth shelf.	Compare shapes → Compare colors
2	Trend	She focused on the red and beige products.	Compare shapes
3	Self-respect	The first time, she compared shapes (black, red, and white); the second time, she compared the chain bag and then the camera bag.	Compare shapes → Compare colors
4	Self-respect	She compared vertically and compared colors by shape	Compare colors
5	Self-respect	She compared the same color to each other	Compare shapes
6	Self-respect	She barely looked at the beige product in the first row; she focused on the camera bags in the second and fourth rows	Compare colors
7	Self-respect	After she compared the camera bags in the second and fourth rows, she touched the products in 4_4 and compared the chain bag	Compare colors
8	Conservative	After looking at them, she touched 2_3 and 3_2	Don't look at anything but the product she was interested in
9	Conservative	She looked mainly at the camera bags on the second and fourth rows, then looked at the chain shoulder a little	Compare colors
10	Conservative	After looking at the whole, she compared the black products, and then touched 3_4 for the second time, comparing the color of the camera bag	Compare shapes → Compare colors

The AOI analysis includes a function to visualize the order in which the viewpoints were moved in each area for a single product shelf. We compared the tendency of the order of gaze among the clusters. In this study, we analyzed Shelf 5 on the second floor, where shoulder bags were lined up in the same shape as the products. The results are listed in Table VII. The results showed that there were four patterns of product comparison methods: those who compared shapes with colors, those who compared shapes, those who compared colors, and those who gazed at only the most visible product for a long time. However, there were no differences among clusters.

VI. DISCUSSION OF ANALYSIS RESULTS AND PROPOSALS FOR PRODUCT PLACEMENT AND CUSTOMER SERVICE METHODS BASED ON EXPERIMENTS

This section discusses the results of the analysis described in section IV. Specifically, this study clarifies the relationship between consumers' sense of value and searching behavior. In addition, based on the results of the analysis and consideration, we propose a shelf arrangement in the store.

A. Discussion of the Relationship between Consumer Values and Product Search Behavior

Based on the results of Section IVB, we found that the product shelves that are easily gazed at tend to be gazed at in all clusters. Shelves 2, 3, and 4 on the first floor and Shelf 4 on the second floor are the product showcases where people spend the most time. Therefore, the shelves with multiple types of bags facing the front left-hand wall from the entrance are in the golden zone, where they are easily gazed at and searched. In contrast, we found that the time spent in the product shelves of collaboration products, men’s products, clothes, and collection products that emphasize the attractiveness of the brand are short. From the results in Section IVC, the overall tendency of the results is that flashy products are more likely to attract attention in all clusters. Therefore, when placing products, combining eye-catching products with products that attract attention can effectively increase the chances of customers discovering the products. In addition, the height of the product shelves that are most likely to be gazed at correspond to the products on the second to third shelves from the top. This result was similar to the study of Piotr Chynał et al. [24]. This shows that the location of the product shelf and its position on the shelf are also important for optimal product placement. Table VIII shows the summary of product search behavior.

In the trend cluster, the results of Section IVB show that the time spent in the product shelves with small bags, small items, and wrist watches was longer. The results of Shelf 4 on the first floor show that it has the largest bias in terms of the time spent on the products, indicating that it is the cluster that tends to compare the products it likes. As for bags, there is a tendency to prefer small handbags and shoulder bags to large ones. This may reflect the recent trend for smaller bags rather than larger bags. In the self-respect cluster, the time spent on shelves with flashy bags and small items was long. Based on the results of Shelf 1 and Shelf 4 on the second floor, the self-respect cluster was the only cluster that often looked at shoes. In addition, the results of Shelf 4 on the second floor showed that they tended to look at products with patterns and flashy colors more often than other clusters. This may have been influenced by the concept of the fashion brand in this experiment as a self-respect cluster. As for the conservative cluster, the shelf-gazing time was shorter than that of the other clusters, indicating that they tended to look at the shelves from a bird’s-eye view. The conservative cluster tended to pay more attention to the eye-catching products. The conservative cluster tended to look at products from a bird’s-eye view and did not pay attention to any product for a long time, resulting in the least bias. Therefore, the conservative cluster reflected the tendency to prefer basic products and not to try new or flashy products.

B. Suggestion for Product Placement and Customer Service Methods based on Experiments

The display of trendy and recommended products on the product shelves of the first floor is necessary to present the brand concept. However, no one in any of the clusters gazed at the display for a long time to search for products. Therefore, it is effective to place the product shelves near the entrance to present the concept, and to arrange the products around the shelves so that they can be easily compared. Table IX shows the summary of suggestion based on experiments.

TABLE VIII. SUMMARY OF PRODUCT SEARCH BEHAVIOR

Cluster Name	Characteristics of product shelves with long staying time	Characteristics of products that are likely to attract attention
Trend	There're small bags, small items, and wrist watches.	Size: small
Self-respect	There're flashy bags and small items.	Colors: flashy, bright, patterned cloth Category: shoes
Conservative	No bias compared to other clusters.	They don't gaze at any product for a long time.

TABLE IX. SUMMARY OF SUGGESTION BASED ON THE EXPERIMENTS

Cluster Name	Product Placement Method	Customer Service Method
Trend	Placing products of multiple colors and shapes in the same place for easy comparison	Present products in a way that makes them easy to compare
Self-respect	Placement of recommended products in combination with eye-catching products	To introduce trends and popular products.
Conservative	To place together products that are easy to coordinate, flashy products that catch the eye, and products that are recommended	To combine products and present them as coordinated

Since the trend cluster tends to compare products they like, it is effective to place products of multiple colors side by side so that they can be easily compared and place trend products on the second to third height from the top where they can be easily seen. In terms of customer service, since customers often tend to compare products, it is considered effective to talk to them and recommend products to them when they have narrowed down their search. In addition, it is good to compare and recommend products with the same tendency as the products customers like. Self-esteem clusters tend to pay attention to products with flashy colors and patterns that are likely to catch their eyes, and thus, it is effective to present trends and recommendations in an easy-to-understand manner. Therefore, it would be beneficial to place recommended products in combination with eye-catching products and place products on the shelves in a conspicuous manner. In terms of customer service, it is important to inform customers of the current trend and popular products. The conservative cluster often looks at products from a bird's-eye view more than any other cluster, and thus, it would be beneficial to arrange products in such a way as to increase opportunities to encounter products, for example, by not placing similar shapes and colors of products together, so that customers can see a full range of products. Products that are easy to match as coordinates or flashy products that easily catch the eye and recommended products should be placed together. In terms of customer service, it is also important to recommend combinations of products and to encourage customers to compare products when they stop by so that they can find their favorite color or shape.

VII. Conclusion and Future Work

We aimed to clarify the relationship between customer values and product search behavior and proposed product placement and customer service methods based on their values. The results showed that product search behavior differed based on three types: trend cluster, self-esteem cluster, and conservative cluster. Trend clusters tended to observe and compare products more closely and had greater variability in product gazing time. Self-esteem clusters tended to look at products with patterns and flashy colors more often than other clusters. The conservative cluster tended to look at products from a bird's-eye view and did not pay attention to any product for a long time, resulting in the least bias. In addition, we proposed product placement in a store considering the features of these clusters.

In future work, we need to understand what kind of values the customers who use the store tend to have. Therefore, we think that it is necessary to speculate using purchase data, analyze the difference in the initial movement of product search for each sense of value, and analyze the reaction to customer service in future work.

Acknowledgment

We thank the target store for this study, employees of this store and participants of this experiment for providing experimental opportunity. This work was supported by JSPS KAKENHI Grant Number 19K01945, 21H04600 and 21K13385.

***Abstract*—In the modern era, recent advancement in computer vision has led to emergent attention in lip reading. Indeed, lip-reading is used to understand speech without hearing it, and the process is mentioned as a lip-reading system. To construct an automatic lip-reading system, locating the lip and defining the lip region is essential, especially under different lighting conditions, significantly impacting the robustness of the lip-reading system. Unluckily, in previous studies, lip localization under illumination and shadow consideration has not been well solved. In this paper, we extant a local region-based approach towards the lip-reading system. It consists of four significant parts, firstly detecting/localizing the human face, mouth and lip region of interest in the first video frame. Secondly, apply pre-processing to overwhelmed the inference triggered by illumination effects, shadow and teeth appearance, thirdly create contour line using sixteen key points with geometric constraint and stored the coordinates of these constraints. Finally, track the coordinates of sixteen points in the following frames. The proposed method adapts to the lip movement and is robust in contrast to the appearance of teeth, shadows, and low contrast environment. Extensive experiments show encouraging results and the proposed method's effectiveness compared to the existing methods.**

***Keywords*—Lip detection; lip tracking; illumination equalization; shadow filtering; 16 points lip model**

I. Introduction

The continuous progress of technology brings to an irreversible change of paradigms of interaction between humans and machines. Traditional ways of human-computer interaction using keyboards, mice, and display monitors are being replaced by more natural modes, e.g. speech, touch, and gesture. New PCs, tablets and smartphones are moving increasingly toward a direction that will bring in a short time to have interaction paradigms so advanced that they will be completely transparent to users. In recent years, to automate the process of voice communication with which they interact between themselves persons. Lip movement and reading are used to recognize speech from a speaker without hearing. It is a procedure that especially gets to grips by people having hearing problems. In 1976, audio-visual illusion became recognize as the McGurk effect [1], which shows that visual cues information combined into the listener's mind automatically and unintentionally. The listener perceived the syllable, which is dependent on the visual information and strength of audio from the speaker.

In the past, there are two main techniques, edge and region-based, proposed for lip segmentation and extraction by using spatial information (edge and colour) to track lip movement. Hue and edge information are used to attain mouth localization and segmentation [2]. Initially, visual features extraction is obtained in greyscale images [3, 4]. The vertical center of the lip region is used to initiate by compelling the sum of each row in the mouth region and finding the minimum value of the row. The corners of the lips are found by setting the threshold, and horizontal edges are representing by four parabolas of both lips (lower and upper lips edges). They use the linear filter to find the edges. Another method is applied to the greyscale image [4], which is very close to the above method, but this approach tracks the unnecessary features in the mouth region such as nostril and pupils. The statistical colour model was used to locate the face by normalizing the skin colour [5]. Outliers are used to find the position of features points in all frames of the image sequence, and sometimes these positions are not the best. The performance of these techniques failed to produce an accurate result in cases when a speaker has beard and teeth presence. The beards have high edges in both directions (vertical and horizontal) mentioned in [6]. Therefore, the edge-finding method is not helpful for persons having bears. The HSI (hue, saturation and intensity) colour space extracts mouth pixels and sorts out the illumination from colours[7]. Hue values redefine the lip pixels. Different colour spaces [8, 9] and approaches have been used for visual feature extraction, e.g. optic flow analysis [10]. However, these methods failed with data sets of more than one few words and were computational intensive [11].

The active contour model (ACM) detects the lip boundary's edge [12]. Unluckily, this model often converges to the wrong result when the lip edges are indistinct, or the lip is very similar to the skin region. The region-based approaches mostly use the regional statistic characteristics to comprehend lip tracking. Distinctive examples include deformable template (DT) [13, 14], region-based ACM [15], active shape model (ASM) [16,17], and active appearance model (AAM) [18]. A regional cost function is used by DT to divider a lip image into the lip and non-lip regions via a parametric template, which represents the lip shape properly. Therefore, globally statistical characteristics have been used in mostly region-based approaches.

Consequently, their performance may decrease due to the appearance of teeth, tongue or black hole. The localized active contour model (LACM) [19] have better results. However, LACM depends on the proper correlative parameters.

Moreover, the colour information is not considered [19], which is very important to improve extraction performance, particularly when the images have shadows [20, 15].

This paper presented an approach to lip detection and tracking with two main phases: (i) lip contour extraction for the first frame and followed by (ii) lip tracking in the following lip frames. In the first phase, we created the dataset from a different speaker, i.e. Male/ female, different age groups by uttering English alphabets and numeric numbers in different light conditions, defining the mouth ROI, and applying pre-processing methods. Then, we utilized a 16-point lip model [21] with geometric constraints to achieve lip contour extraction. We repeat the same procedure for the lip ROI image and compute the lip tracking in the second phase. The proposed approach is adaptive to lip movement and robust against the appearance of the illumination effects, teeth and shadow. Experimental results have shown promising results.

II. METHODOLOGY

Previously, videos dataset created by using compression, controlled light environment, constant background for processing [22] led to noisy pixels in frame images, slow performance and caused false feature detection. We created the video datasets in different lighting conditions, gender (male/female) and different age groups. Some male persons had a moustache as well. A small application was developed for recording the video files by using Visual C++ and OpenCV [23]. These videos were recorded in the Computer Vision Lab of the University of Pavia at different times, using a Logitech HDR webcam with the highest possible resolution supported by the camera. Each speaker had to record the video by uttering different alphabet letters and numbers.

A. Face and Mouth Detection

Face and Mouth detection have a vital role in lip localization. Firstly, it is necessary to detect the speaker's face in all video frames and crop the speaker face for the mouth area. Numerous approaches have been already developed and categorized as: i) colour based [24], ii) template-based [25], and iii) feature-based [26,27]. Face detection methods based on local features and machine learning-based binary classification methods[28] have been widely used in various face recognition studies because of their real-time capability, high accuracy, and availability in the OpenCV, but the mouth area detection was not detected accurately. Only face detection results were accurate. To overcome this problem, we used the face image and split it into two parts horizontally. The upper part has the eyes, forehead and a small part of the nose. The lower part has the mouth on which we applied the mouth cascade classifier, obtaining precise results as shown in Fig. 1.

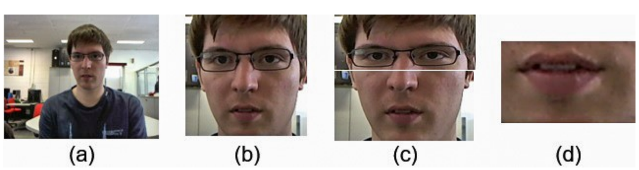

Fig. 1. Face and Mouth ROI Detection a)Frame Detection b) Face Detection c) Face Image Splitting d) Mouth Detection.

III. PRE-PROCESSING

A. Illumination Equalization

Mouth ROIs are extracted from videos acquired, where sometimes lightning is very strong and irregular. This irregularity is the cause of various disorders that can lead to malfunctions of the lip-reading application and make it challenging to identify the crucial points and construct the 16 points lip model. Different methods have been proposed for image enhancement [30], Histogram equalization, and lighting [20]. The method [29] works exclusively on the luminance value of the individual pixel. Although, It has few flaws, such as the effects of irregular lighting are attenuated only along with the single direction vertical and fixed scaling size of image 71 x 44 and mask size 3x3. We decided to improve the model [30], making it more robust with respect to light, multiple directions horizontal and vertical, working no more than on the single pixels and on local regions within the image. The extended algorithm can adapt to the multiple directions of the lighting, as shown in Fig. 2 [20].

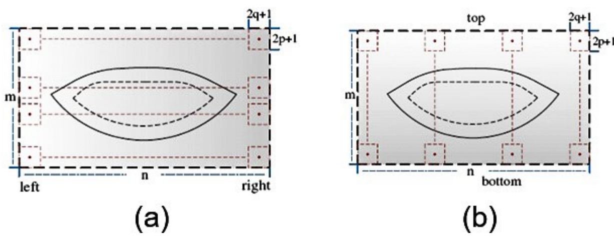

Fig. 2. a) Horizontal Direction b) Vertical Direction [20].

The colour lip image size m × n provided to the function's input is initially converted in HSV colour space, let L (i,j) is the L' (i,j) represents the luminance of each pixel respectively before and after the operation of equalization. To simplify the process, assume that the non-uniform illumination is instead linear along the direction of its application. As mentioned earlier, the innovation brought to a method implemented in this elaborate consists of manipulating the individual pixel's luminance value but work on a local region of size (2p + 1) × (2q + 1). Each pixel of the original image assumes the value obtained from calculating the average of the luminance values of all the pixels included in the mask that flows throughout the image along the two main directions identified. The luminance value of the pixels (Horizontal and Vertical directions) was calculated using the application formulated in formulas 1, 2.

$$\boldsymbol{L'}(i,j) = \begin{cases} L(i,j) + \frac{(n-2j+1)*(r(p)-l(p))}{2(n-1)}, & i \in [1,p] \\ L(i,j) + \frac{(n-2j+1)*(r(m-p)-l(m-p))}{2(n-1)}, & i \in [p, m-p] \\ L(i,j) + \frac{(n-2j+1)*(r(i)-l(i))}{2(n-1)}, & i \in [m-p, m] \end{cases} \quad (1)$$

$$\boldsymbol{L'(i,j)} = \begin{cases} L(i,j) + \frac{(m-2i+1)*(b(q)-t(q))}{2(m-1)}, & i \in [1,q] \\ L(i,j) + \frac{(m-2i+1)*(b(j)-t(j))}{2(m-1))}, & i \in [q, n-q] \\ L(i,j) + \frac{(m-2i+1)*(b(n-q)-t(n-q))}{2(m-1)}, & i \in [n-q, n] \end{cases} \quad (2)$$

Where l_i and r_i denote the average intensity of respectively left and right edges of the local region of size (2p + 1) × (2q + 1), to the i_{th} row of the mask. Similarly, t_j and b_j denote the average intensity of the upper and lower edges of the local region at the j_{th} column of the mask, as shown in Fig. 7.

B. *Teeth Filtering*

During the experiment, it was observed that illumination equalization is not enough to improve the system. Still, some other factors are to be considered, e.g. the teeth, black hole, and tongue region that can be visible in processed images. In the past, the researchers reported that without considering these factors cannot have a robust result for lip tracking [31]. The proposed teeth filtering method removes the teeth appearing in the mouth (ROI) in all frames. The presence of teeth in the image frame is observed when the mouth status is open. It was possible to construct a filter dependently on thresholds, which correctly identifies the range of colour that characterizes the range of the tooth region in the Mouth (ROI). The implemented function inputs the illumination equalized image and then convert it into two different colour spaces *CIELAB* and *CIELUV*. *RGB* colour space has characteristics that are not suitable for defining the thresholds based on which it filters the region of teeth. The teeth region is characterized by the lowest components a∗ and u∗ present in the image. The two threshold values have been set for the two chromatic components of interest. L_{au} has demonstrated that to achieve a satisfactory result, the teeth thresholds t_a and t_u should be set according to the formulas (3) [41].

$$t_a = \min\left(\mu_a - \sigma_a, 9\right] \text{ Otherwise if } \left(\mu_a - \sigma_a\right) < 9$$

$$t_u = \min\left(t_u - t_u, 29\right] \text{ Otherwise if } \left(\mu_u - \sigma_u\right) < 29 \qquad (3)$$

Where μ_a, σ_a, μ_u and σ_u are, respectively, the mean and standard deviation of the chromatic components to a∗ and u∗. According to this approach, all the pixels that relate to the teeth may identify pixels that correspond to the teeth i.e. $a^* < t_a$ or $u^* < t_u$ or L^* 35% or L^* 95% in the chromatic components reference as white, normalized to restrict their range of the standard deviation in 2 around the mean value. Each pixel characterizing the teeth is masked by resetting the colour value of all the chromatic components of the specific colour space identified. It cannot influence the future operations of search from the position of the mouth. If there are no teeth, a presence mask will not apply, and if teeth appear, the mask will remove the teeth pixels by changing the teeth pixels value to 0.

C. *Shadow Filtering*

A mean filter is used to reduce noise caused by shadows in the images described [32]. Again, these disturbances are because of different lighting conditions, e.g. sourcing light angles and shades beneath the lower lips. The rate of recognition of a lip-reading system is based on the accuracy of the lip position. Unfortunately, up to now, there are no algorithms not effectively solved the problem of locating the lips in uneven lighting conditions. Illumination equalized images used to reduce the interference brought by shadow. For the implementation of the shadow detection method, we used these steps: i) Convert the illumination equalized image into grayscale, ii) Considering the image as a matrix in which the rows are characterized by the index "i" and columns from the index j. iii) Calculate the accumulation of the grey level value for each column of the image and obtain a column index corresponding to the mean value of the accumulation curve as the boundary of shadow. It is used to divide the grayscale image into two sub-images, left Isl and right Isr, to enhance the contrast between lips and the surrounding skin region (4).

$$I_e = \frac{255(I - I_{min})}{(I_{max} - I_{min})} \qquad (4)$$

$$\delta_i = dist(I^{(i+1)}), \quad (I^{(i)}) \qquad (5)$$

Where, I_{min} is the minimum grey-level value in the image, and I_{max} is the maximum value. Euclidean distance δ_i is determined by calculating the distance between (I^i) and (I^{i+1}). If δ_{i+1} is greater or equal to δi then the process will stop, and (Ii) will be marked as the final image. The convolution process ends when the Euclidean distance decreases by less than two units between two subsequent iterations. We determined if each sub-image and the whole image and output image Isl are extracted by subtracting the initial and final images in the proposed function. The shadow detection ends by making a new image by merging two images, left Isl and right Isr. The middle line obtained between Isl and Isr by curve, having information about boundaries of lips and skin region and the minimum value of the row position, is considered the corner points of the lips. Finally, a convoluted image is extracted, as shown in Fig. 3.

Fig. 3. Smoothing the Contrast (a) Greyscale Image (b) Left Image (I_{sl}) Convoluted, (c) Right Image (I_{sr}) Convoluted (d) Output Image.

IV. Lip Detection

In this step, we have to mark the exact position of the lips. An elliptic shape function [36] was applied to detect the lip boundary. This method gives good results when the mouth status is closed, but when the variation in lips, some marginal parts of this elliptic region may be far away from the lip boundary. Lip corner dots are successfully implemented by using intensity variation and colour cues in [19, 33], as shown in Fig. 4(a). We proposed the extraction method for geometric positions by labelling the left corner, right corner, upper corner and lower corner as points L_a, L_b, V_a and V_b as shown in Fig. 4(b).

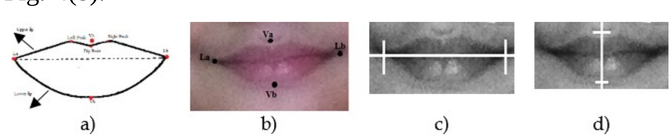

Fig. 4. a) Standard Lip Model b), Geometric Points of Interests, c) Crucial Points Horizontal d) Crucial Points Vertical.

A. *Crucial Points (L_a, L_b, V_a, V_b)*

To identify the horizontal crucial points; we extracted the left point L_a and right point L_b. Points are located on the median axis of the image and stored in a vector. The values of curve G have peaks of high frequency due to noise. This noise must be clear to ensure the precise extraction process of crucial points. A low-pass filter applied of Butterworth through mask size 3 3 pixels that run through everything the curve G to reduce the noise. The vector filtered result, called Gf proceed with the search of the crucial points. Accumulate the grey-level value for each column of the image and obtain correspondence column index to the mean value of the accumulation curve as the boundary of shadow. The boundary shadow value, median axis and sub-images Isl and Isr already have from the shadow filtering phase. This whole curve G consists of both sub-images divided by boundary shadows. The curve representing the vector G should be monotonically decreasing to quickly identify the crucial point left as that point occurs the maximum value of the gradient, considered absolute value. This value corresponds to the boundary between the mouth region and skin. The positions of mouth corners correspond to the steep slopes of the curve, as shown in Fig. 4(c,d). The method for searching for the left crucial point consists of several steps. Firstly, obtain the first minimum' m’ by scanning Gf from left to right. To work in the best possible conditions, make the monotonic curve and save this new curve in a vector support Gm using formula (6).

$$G_m^{(i)} = \begin{cases} G_f^{(i)} & (G_f^{(i)} \geq G_f^{(i+1)}) \\ G_f^{(i+1)} & (G_f^{(i)} < G_f^{(i+1)}) \end{cases} \tag{6}$$

Once curve is extracted, carry out all the values of the vector Gm in the correct range of processing for grayscale images, therefore ensuring the pixels fall in the range between 0 and 255 by using the following formula (7).

$$G_m^{(i)} = \frac{255(G_m - G_m^{(min)})}{G_m^{(max)} - G_m^{(min)}} \tag{7}$$

Gm is used to search the left crucial point, but unfortunately, there is no maximum rate, although the curve is monotonic. To overcome this problem, calculate the average pixels values of the vector Gm as shown in equations (8) and (9) are utilized to adjust the image's contrast on the horizontal median axis.

$$C^{avg} = \frac{\sum_{i=1}^{k} C'}{K} \tag{8}$$

$$I_{out} = \begin{cases} 255 & 1.5C^{avg} < I_{in} < 1 \\ \\ \frac{500}{C^{avg}}, & 0 < I_{in} < 1.5\, C^{avg} \end{cases} \tag{9}$$

Where I_{out} and I_{in} are the output and input grey level values, the I_{out} is obtained by adjusting the curve and a binary image; those pixels values are 0 or 255. The local minimum point is identified in the position for the first time, where the pixel changes from 255 to 0. Curve C was obtained after the adjustment of contrast and crucial points (L_a , (L_b). The vertical points made a start from the results as described in horizontal crucial points. Based on the position of the horizontal crucial points, calculate the mouth’s centre point, and its column index is marked as vertical midline of the mouth, in which two crucial points, vertical Va and Vb are situated. The pixels values that lie on the vertical axis are divided into two groups and stored on a vector to be processed. We built two more vectors, respectively called B1 and B2, containing only the pixels with a value equal to the maximum, corresponding to the value “1”, and the pixels with a value equal to the minimum conform to the value “0”. In addition, two binary vectors B_1' and B_2' are obtained by applying logical operation that provides outbound B1 and B2 as described in equation (10).

$$B_1' = B_1\, XOR\, (B_1 \ll 1) \quad B_2' = B_2\, XOR\, (B_2 \ll 1) \tag{10}$$

The operator $\ll$ indicates the logical operation of shift one position to the left. At this stage, crucial points Va and Vb are identified. These points where the first occurrence of the value of $'1'$ inside of the vector $B1'$ while Vb fits in the position in which, the last occurrence of the value $'1'$ inside of the $B2'$.

B. Draw Ellipse

The next step is to find an ellipse that encloses the mouth region. In some cases, the ellipse position is incorrect because the bottom point V_a is not proper. To overwhelm this problem, draw two half-ellipses, one for the upper lip and one for the lower lip. This trick shows more precise and realistic results. This method identifies the coordinates xI, yI of the horizontal crucial points Lax, Lbx and Lay, Lby and vertical crucial points Vax, Vbx and Vay and Vby by using geometrical formulas for drawing an ellipse. The centre of the mouth is calculated with equations (11).

$$x_c = \frac{1}{2}\,(La_x + Lb_x) \quad y_c = \frac{1}{2}\,(La_y + Lb_y) \tag{11}$$

The inclination of the half-ellipses for the horizontal plane is calculated with equation (12).

$$\theta = \arctan\left(\frac{La_x + Lb_x}{La_y + Lb_y}\right) \tag{12}$$

The semi-major axis a common to both the half- ellipses, calculated as in formula (13). The semi-ellipse of the upper lip and the lower lip's semi-ellipse is shownin equation (14).

$$a = \frac{1}{2}\left((Lb_x - La_x)^2 + (Lb_y - La_y)^2\right)^{1/2} \tag{13}$$

$$b_{up} = \frac{1}{2}\left((Va_x - x_c)^2 + (Va_y - y_c)^2\right)^{1/2}$$

$$b_{low} = \frac{1}{2}\left((Vb_x - x_c)^2 + (Vb_y - y_c)^2\right)^{1/2} \tag{14}$$

xc,yc be the centre of mouth coordinates and origin of the combined semi-ellipse, calculated as formula (15). Where ‘a’ is the semi-major axes, bup and blow are the upper and lower semi-minor axes. θ is the inclined angle, defined at the counter-clockwise direction.

$$\frac{x_{up}^2}{a^2} + \frac{y_{up}^2}{b_{up}^2} = 1 \qquad \frac{x_{low}^2}{a^2} + \frac{y_{low}^2}{b_{low}^2} = 1 \tag{15}$$

C. Lip Modeling

The Lip model was used to determine the accurate boundary line and geometric points around the lips. We have already extracted four points left, right, top and bottom in the previous section. Previously, lip modelling was performed without pre-processing, which may cause incorrect tracking results, i.e. four key points model with two parabolas for the lip contour used in [34] and six key points with cubic curves connected to describe the lip shape used in [35]. First, sixteen point geometrical deformable models are used in [21]. It is challenging for the modelling of the lips in non-ideal conditions. A model-based approach was proposed for lip contour extraction from colour images to overcome this problem. A region-based cost function is employed to formulate the entire lip contour extraction as a region partition problem instead of the conventional edge detection problem. The proposed algorithm is more robust with low colour contrast, and the final extraction result is less sensitive to the initial model parameters than the edge-based. Curve C0 is used as a curve of evolution for the initial model development of the model. The proposed algorithm is the extension of the 16 points lip model as described in [21]. These geometric constraints showed the lip boundary, and we will store the location of these points and then track the lip movement. The 16 lip boundary points labelled P0 to P15 in anti-clockwise and parameter set by equation (16).

$$\lambda_p = \{x_{pi}, y_{pi}\} \quad where\ i = 0, \ldots .15 \tag{16}$$

These points are divided into three groups as the lower lip (P_0,P_7,P_{15}), upper right lip (P_7- P_{11}) and upper left lip (P_{11}- P_{15}). A normalization process was used to translate the lip corner points P_7 and P_{15} to lie on the horizontal x-axis and point P_{11} on the vertical y-axis. The centre origin of lips is set to be the midpoint between the two lip corners, P7 and P15. After normalization of the mouth ROI, the next step is constructing the 16 points lip-model lips. Lip modelling is split into two parts model i) initialization and ii) thresholding.

- Lip Model Initialization

Elliptical regions extract the lip contours [36] but give the approximate surrounded area of lips, not precise lip. Therefore, a minimum-bounding ellipse as the initial evolving curve is used to find the extract of the lip contours. Model initialization is the starting point of the construction of the lip model. Using the ellipse's geometric parameters is already identified, and the ellipse showed the accuracy of locating the mouth region in the video frames. Therefore, some adjustment operations are required to simplifying the process of initialization of the model. We used three functions, probability map, cost function formulation and draw graph to obtain more accurate model construction.

The teeth pixels with a∗ < ta or u∗ < tu for colour component ‘a’ and ‘u’, also white pixels of L∗ ≤35 marked and discarded in lip initialization process and assign probability values on marked pixels. Teeth pixels are always inside the mouth and assigned high values of probability. It helps the model to separate the upper and lower lip. The surrounding teeth are considered lip pixels with low luminance values and equal probability values 0.5 are assigned. A low pass filter and cost function are applied to smooth the probability map to optimise the process and determine the optimum partition when the cost function in equation (17) is maximized [21].

$$max \left\{ C(\lambda_p) = \prod_{(x,y)\epsilon\, R_l(\lambda_p)} prob_l(x,y) \ * \ \prod_{(x,y)\epsilon\, R_{nl}(\lambda_p)} prob_{nl}(x,y) \right\} \tag{17}$$

Where λp is the 16 point model parameters, probl (x, y) and probnl (x, y) are the probabilities of lip pixels and non-lip pixels at location (x, y), Rl and Rnl are the enclosed and outside the region by the point model. The lip model fitness evaluated by extension of the cost function. Draw Graph proposed to draw the graph extraction points starting from the parameters of the lips. Draw the rectangle around the mouth, tolerance value calculated based on the image's height, and enlarge a variable value the rectangle within which to seek the edges of lips. The rectangle is determined by the ellipse, which allows the search of the representative point of the intersection with the green ellipse. Calculate the center point of La, Lb and Va, Vb crucial points and mark the points as shown in Fig. 5. The model initialization worked with two single-channel images ’H’ of HSV obtained from the original RGB and Ellipse image. The final mouth ROI image is obtained by subtracting the ellipse H image from the original input H image.

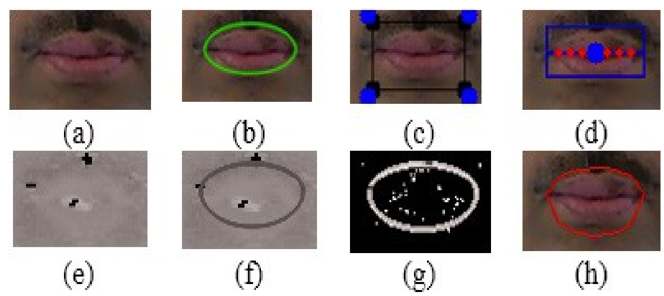

Fig. 5. a) Original Image, b) Ellipse Image, c) Draw Rectangular d) Graph Points, e) ’H’ Channel Image (b), f) ’H’ Channel Image of Ellipse *’RGB’* Image , g) Subtracted Image, h) Final Result.

- Lip Model Thresholding

In this section, we refine the position of the lips points and store the coordinates (x, y) of all points. These coordinates are stored in a file and later will be used in the lip-tracking phase. The channel ‘H’ is used to search the points of the model, and this process is implemented similarly to model initialization. The segmentation was carried out as follows: the red colour of channel H was exploited to find better positions for each point. We looked for neighbour pixels of each point; if there was a significant variation of the red colour (lips to the skin), upgrade the position of the point. The tolerance value for the lower and upper lips have already been calculated. The points P15, P7 have already been found and used in the same position. The position of the remaining 14 points will be upgraded by using means of this procedure. We divided the image into four parts. The lower lip boundary with white points and the upper lip boundary with yellow points are clearly visible. We added the two horizontal corner points P15,P7. Finally, the resulting image has 16 points, as shown in Fig. 6(e,f).

D. Lip Tracking

We have been extracted the 16 points with their positions and coordinates of the first frame. And then tracking algorithm is applied to track the movements of the lips with these points in the subsequent frames. They assumed that frames are extracted from the same video sequence and have almost the same geometric characteristics. It was decided to simplify the extraction phase of the contour of the lips in the remaining frames to considerably overcome the computational algorithm's burden. Pre-processing is carried on all frames. The bulk of the computational algorithm has segmented the image to identify the mouth. Once this process is completed for the first frame, the differences between two consecutive frames are minimal and are limited exclusively, e.g. the lips assume during speech. In this way, it is limited processing on the second frame to a portion of the image significantly smaller, as shown in Fig. 6(e), (f). The construction of the 16 points lip model on the second frame in the sequence is applied exclusively in the image identified. We have coordinates of lips points in the first and second frames. Table I is showing the (x, y) coordinates of two frames. The first frame is the initial frame when the mouth status closes, and the second frame when the speaker said alphabet B, the mouth status is changed and has different coordinates. The upper part of the lips is moved because slight variation is obtained in P5, P4, P6, P15 points, and considerable variation in P9, P13, P14 points.

V. RESULTS AND DISCUSSION

All the frames were processed in two sizes 150x150 and 360x360. The results showed that it was possible to extract the contour of the lips precisely in many of the data sets, but some experiments did not go well, where the software did not work correctly (about 5% of cases). The lip tracking procedure is applied to sequences of frames, starting with the first frame to complete the entire sequence. The average processing time for performing lip tracking is about 0.556 seconds to extract the contour of the lips from the first image of the sequence and approximately 0.09 seconds for subsequent frames. Such times include the operations of reading and writing the images used to test the algorithm. It is estimated that the video stream can achieve a frame rate of about 12-15 fps (frames per second) to allow a real-time execution. Face detection in videos was our first step to build the speech recognition system. Secondly, the mouth was detected in the face image, and mouth ROIs were defined for further processing. The accuracy of the classifiers is described in Section II(A), as shown in Table I. To increase the accuracy rate for mouth detection, we improved the mouth cascade and compared it with previous classifier results, as listed in Table II. The proposed method for mouth detection showed more precise results as compared to the earlier methods.

Furthermore, an effective method to reduce the effects of uneven illumination is proposed as more robust to light, multiple directions (horizontal and vertical), and working on both the single pixels and on local regions within the image. Fig. 7 is showing the effectiveness of the proposed illumination equalization method. There are some darker parts on the left or right side, and the same in vertical directions where darker parts are on the top or bottom. The darker part was significantly reduced by applying the proposed method, as shown in Fig. 7(d).

In the previous lip-reading system, teeth masking was not considered, as it was found based on local regions and exploited information on colour inside the mouth. The proposed teeth detection method successfully removes the teeth area in the mouth ROI in all frames and pixels belonging to teeth removed, as shown in Fig. 8(a).

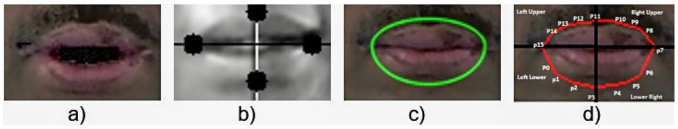

Fig. 8. Proposed Method Results a) Teeth Filtering b)Crucial Points c) Semi Ellipse d) 16 Points Lip Model.

In the past, shadow filtering methods have been proposed for indoor environments and have not been studied for lip localization. Therefore, we proposed a technique for shadow removal as described in the shadow filtering section. After applying the pre-processing steps, a filtered image was obtained where uneven equalization, teeth filtering, and shadows were significantly reduced. In the next step, mark the exact position of lips, which leads to lip detection and tracking. An elliptic shape function is used for lip detection [12]. In this method, lip detection is correctly performed when the mouth is closed; on the other side, some parts of the lip region are discarded during lip movement. Lip corner dots are successfully implemented by using intensity variation and colour cues in [37, 38]. These dots do not fit the exact geometric position of lip structure. Therefore, We proposed a method for extracting the horizontal and vertical positions of median axes of the mouth by labelling the left, right, upper and lower corners as points La, Lb and Va ,Vb. The results of crucial points as shown in Fig. 8(b). Crucial points are needed to draw the ellipse. The upper lip has three corners: left, right, and dip points due to Cupidon’s bow. Fig. 8(c) is showing the result of the proposed combined semi ellipses methods. Different lips models were applied, e.g. four key point models and six key point models [34,35]. We used the 16 points, lip model. The elliptical regions extract the lip contours [12], but they do not give precise lip contours. Therefore, the combined ellipse is used as the initial evolving curve to find lip contours in the proposed method. Some adjustment operations are applied to simplifying initialization by using probability map, cost function formulation and draw a graph to obtain more accurate model construction. A Thresholding function was used to refine the initial evolving curve image better to get a precise position. The lip image is divided into four parts: Left lower P0-P3, Lower right P4-P6, Right upper P8-P10 and Left upper P11-P14 and stores the coordinates of each point, as shown in Fig. 8(d).

Table III described the computation time obtained by the proposed method for the first frame as 0.556 seconds, which is smaller than the methods' results described in [21, 35, 15]. The average computation time of lip tracking for one frame is 0.099 seconds, which is less than the methods' values [21, 35, 15]. The method [21] needs to compute the probability map at every frame. The method [35] requires a bit more pre and post-processing techniques and adjustment processes to fit the lip boundary. However, the average computation time of tracking one lip frame is higher than [38].

The average extraction performance and lip boundary extraction degraded due to low contrast, uneven lighting conditions and irregular shapes in the lip image. The proposed pre-processing methods are applied to the complex appearance of shadows, uneven illumination and teeth. These factors are considered, and the extraction performance of lip boundary extended up to 96%, as shown in Table IV.

VI. CONCLUSION

An approach to detect and track lip boundaries is presented that highlights the lips and avoids other factors, e.g. false lip pixels and recovers from failures. The proposed algorithm comprised the lip-tracking module from the lip boundary lines, a feature vector of 16 points lip model. Three pre-processing steps, illumination equalization, teeth detection, and shadow removal, aim to investigate edge information and global statistical characteristics. The lip tracking method used 16 points lip model on the lips, stores the coordinates of these points and tracks these coordinates during the utterance by the speaker. Moreover, the proposed method is easy to implement and computationally efficient, capable of locating face and mouth and lips feature points that give a high accuracy rate for lip localization, modelling and tracking accuracy.

Experiments have shown that outliers detecting and better predicting ROIs can reduce the number of frames with locating or tracking failures. This research work brings together new methods, representations, and insights, which are quite generic and may have broader applications in computer vision, image processing, and speech recognition.

Data Hiding Method with Principal Component Analysis and Image Coordinate Conversion

Kohei Arai
Faculty of Science and Engineering
Saga University, Saga City, Japan

***Abstract*—Data hiding method with Principal Component Analysis (PCA) and image coordinate conversion as a preprocessing of wavelet Multi Resolution Analysis (MRA) is proposed. The method introduced in this paper, based on the characteristics of the original multispectral image, allows recovering the secret data. Through experiments, it is found that the proposed method is superior to the conventional data hiding method without any preprocessing. The method introduced in this paper allows only I who knows the characteristics of the original multispectral image to recover the secret data, i.e., when the information of the original image needs to be protected. Moreover, in the introduced method, the information of the secret data is protected by the existence of the eigenvector and the oblique coordinate transformation, that is, the secret data is restored if at least the information of the true original image is not known. The principal component transformation coefficient differs for each original image and is composed of the eigenvectors of the original image.**

I. Introduction

There are social problems such as illegal copying of digital contents such as DVDs and billing for music broadcasting / broadcasting. To solve this, it is necessary to keep content IDs and digital signatures highly confidential. Therefore, a global standard method such as copy prohibition and one-time copy permission is about to be developed. Digital contents of corporate electronic records, customer information, intellectual property, electronic medical records, etc. based on ISO 15489 (record preservation management guidelines) For copyright protection of digital contents (detection of digital signatures and tampering) that must be protected as personal information, and also by inserting a time tag in multimedia such as video, still image, music, etc. and using it to edit In order to efficiently perform charging, or to extract billing information classified by broadcast format, and only those who have obtained permission using a digital signature can share the content. Data Hiding techniques for such Kill manner are used [1].

Data hiding, which is also called information hiding, is a technique for hiding some information in the content. Here, the name of data hiding is used. Data hiding is a watermark (Digital Watermark) technique or steganography (Steganography) [2 - 4]. A technology that makes embedded information important and its existence unknown is called steganography. If the content itself in which confidential information is embedded is important, a digital watermark is used. The original content is called the original content, the data to be hidden such as a signature is called secret data, and the content in which the secret data is embedded is called distribution content. Watermark information embedding technology (watermark technology) has already been studied [5 - 8].

As a method of embedding the secret data in the content, a method of embedding the secret data in the real space of the content [9] and a method of embedding the secret data in the frequency space have been proposed [10],[11]. The latter has a higher ability to conceal the secret data information than the former because the secret data can be embedded in a specific frequency band that is relatively unaffected by the content quality. Therefore, for example, when the content is an image, it is necessary to manipulate the edge part of the original image to embed the secret data [9]. In the latter case, the frequency band of the original content in which the secret data should be embedded must be determined [7], [10].

A data hiding method has also been proposed when the original content is a color image [11], [12]. The secret data embedded in the original content is information such as copyright, and it has high resistance to image processing and removal attacks, and high confidentiality. The method of selecting the coefficient after the original content such as an image is transformed into the orthogonal frequency space and embedding the secret data in the frequency space is often used because it satisfies these requirements. Among them, a method has already been proposed to obtain distribution contents (images) by dividing the image into frequency components by wavelet multiresolution analysis (MRA) [13],[14], replacing any of the divided frequency component images with secret data, and reconstructing (combining).

The conventional method does not necessarily have sufficient confidentiality (it is possible to find it because any of the frequency component images contains confidential data), and the invisible (difficulty of visibility) of the confidential data is insufficient. When the original content is an image, data hiding using a color image has a higher ability to conceal secret data than other methods from the viewpoint of the amount of information in the original image. Therefore, a method of embedding secret data in a certain component (red, blue, or green component) of the original content (image) is generally used [4]. Since the embedding method is used, in this case, the information on the red and the blue components of the original image are not used. Because a certain color component is used in the embedding process.

Data hiding based on wavelet multi-resolution analysis is a method of investigating wavelet frequency components and embedding secret data in components that have a relatively small effect on image quality, but it is widely used. Since confidential data can be located by using this method, a problem remains in confidentiality. To overcome this problem, a method of applying principal component conversion to the original content (image) as a preprocessing of data hiding has also been proposed [15],[16],[17]. Since only I who owns the original content (image) can know the unique value of the original content (image), only I can restore it.

However, this method is not sufficiently confidential because it can estimate the approximate value of the eigenvalue by allowing a certain amount of error using the distribution contents (images) in which secret data is embedded. Pre-processing for cross coordinate transformation has also been proposed [18]. The cross angle of the cross coordinate can be set arbitrarily, and the principal component conversion can be performed based on this angle, which improves confidentiality [19]. A method has also been proposed that improves the visibility and confidentiality of confidential data in distribution images by converting the method [20].

Fundamentals of wavelet analysis and its application to data hiding are described in the books [21],[22],[23]. Method for data hiding based on Legall 5/2 (Cohen-Daubechies-Feauveau (CDF) 5/3) wavelet with data compression and random scanning of secret imagery data is proposed [24]. Improvement of secret image invisibility in circulation image with Dyadic wavelet-based data hiding with run-length coding is also proposed [25]. Meanwhile, noble method for data hiding using Steganography Discrete Wavelet Transformation (DWT) and Cryptography Triple Data Encryption Standard (DES) is proposed and well reported [26].

This paper outlines data hiding methods based on the wavelet multi-resolution analysis and evaluates the effect using images that are frequently used as standard images for data compression.

II. Data Hiding based on Multi-Resolution Analysis

A. Wavelet Multi-Resolution Analysis

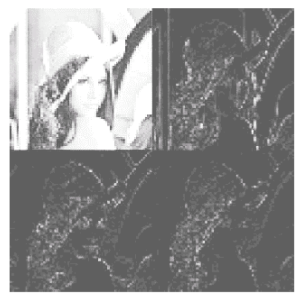
The biorthogonal wavelet decomposition (discrete wavelet transform based on biorthogonal basis function) applies $y = Cn\ x$ by applying the square matrix Cn to the original data (one-dimensional scalar data: $x = (x_1, x_2, .., x_n)$). It can be defined as x, where Cn is a transformation matrix based on a biorthogonal basis function with $CnCn^t = I$. After conversion, y consists of low-frequency component L and high-frequency component H. That is, x is transformed as y = (H1, L1), where the subscripts of H and L are the number of transformations, that is, the number of stages (level by applying Cn to this L1, it is transformed into H2 and L2, and by repeating this n stages, it is transformed into Hn and Ln. This is called decomposition.

The inverse transformation is $Cn^{-1}. = Cn^t$ applying to y. By repeating this inverse transform n times, x is restored. This is called reconstruction. This wavelet transform / inverse transform (decomposition / reconstruction) is repeated Then, the decomposition into wavelet frequency components and the reconstruction of the original data using the decomposed components are called multi-resolution analysis. When this is applied to two-dimensional data, for example, an image, y = (HH1, HL1, LH1, LL1).

Here, HH1 means the high-frequency component in both the vertical and horizontal dimensions, and similarly LL1 means the low-frequency component in both the vertical and horizontal dimensions. This is called the two-dimensional wavelet transform. Each frequency component can be decomposed, and the original image data can be safely restored (reconstruction) by repeating the inverse transformation as in the case of one-dimensional data.

Fig. 1 shows the images obtained by applying the two-dimensional wavelet transform to the [Lenna] in the standard image database (SIDBA), which is often used to evaluate the data compression method, in one and two stages. At this time, Daubechies is used as the biorthogonal basis function. This original image is shown in Fig. 2.

When the DWT is applied to n time series data in one stage, it can be decomposed into n / 2 high frequency components and n / 2 low frequency components. By further subjecting the n / 2 low frequency components to a one-stage DWT, the n / 4 low frequency components and the n / 4 high frequency components can be decomposed.



(a) Level 1

(b) Level 2

Fig. 1. Examples of Images of which 1st and 2nd levels of DWT Applied to Lena of Original Image.

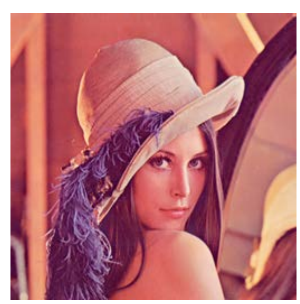


Fig. 2. Original Image of Lenna.

B. Wavelet Multi-Resolution Analysis Based Data Hiding

The secret data embedded in the original content (image) is information such as copyright and signature (including the image), and data hiding requires resistance to image processing and removal attacks, and high confidentiality. The method of selecting the coefficient after transformation to the orthogonal frequency space and embedding the watermark in the frequency space is often used because it satisfies these requirements. Among them, the wavelet multiresolution analysis introduced here (for each frequency component of the image This method is often used to obtain distribution data (images) by dividing them into images, replacing any of the divided frequency component images with secret data or secret data (images, signatures), and reconstructing (synthesizing).

C. Proposed Data Hiding Method

In order for improvement of confidentiality and visibility by eigenvalue expansion, the following data hiding method is proposed. Data hiding based on MRA is insufficient in confidentiality and visibility, and in order to overcome this problem, a method of performing principal component conversion as a preprocessing of data hiding based on MRA has been proposed. Only I who owns the original image can know the eigenvalue and eigenvector of the image, so only I can restore the original image. Therefore, I can claim the copyright of the original content. However, this method is not sufficiently confidential because the approximate value of the eigenvalue can be estimated by allowing a certain amount of error using the distribution image with embedded secret data.

In order to overcome this problem, there is also proposed a pre-processing to perform the oblique coordinate transformation after the principal component transformation, in which the oblique angle of the oblique coordinate can be set arbitrarily, and the principal component transformation can be performed based on this angle. The confidentiality of the content is highly protected under the condition that only the transmitting and receiving parties of the original content can know this angle information. Moreover, the Least Significant Bit (LSB) of the original content is encrypted by encrypting the angle information by a common key method. By inserting it in (the least significant bit in the quantization), the confidentiality can be set even higher. Here, I introduce data hiding based on multi-resolution analysis with principal component transformation and oblique coordinate transformation.

The process flow of this method is shown in Fig. 3. First, the energy of the original image is concentrated by principal component transformation, and the Cartesian coordinates of the transformed principal component image are transformed to oblique coordinates to further increase the energy concentration. Then, the MRA is applied to this, and the distribution image is obtained by reconstructing after embedding secret data in any of the levels and frequency components after decomposition. Since the principal component transformation parameters consisting of the eigenvalues and eigenvectors of the image are known, the original image and the secret data can be restored, but it is difficult for a third party who cannot know them to change the component to insert the secret data. This makes it possible to enhance the ability of data hiding based on multi-resolution analysis to protect information in secret data.

Cartesian coordinates and oblique coordinate representations in a two-dimensional plane are

$$W = X + Y\cos(\theta) \quad (1)$$

$$Z = Y\sin(\theta) \quad (2)$$

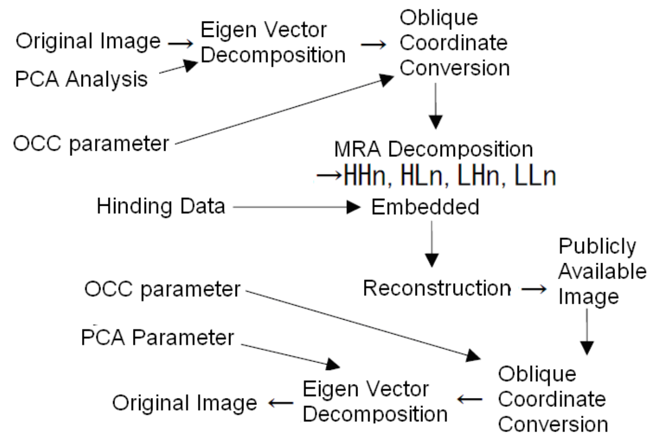

Fig. 3. Process Flow of the Data Hiding based on MRA using Eigen Vector Decomposition (or Principal Component Analysis (PCA)) and Coordination Conversion from Cartesian to Oblique Coordination Systems.

where *W*, *Z* is each axis in the oblique coordinates, *XY* is each coordinate in the Cartesian coordinates, and θ is the angle of the coordinate axes in the oblique coordinate transformation. An example of this is shown in Fig. 4.

In the figure, the red and green two-dimensional pixel distributions (scatter diagram) of the original image are transformed into two-dimensional coordinates composed of the first principal component axis PC1 and the second principal component axis PC2 orthogonal to it. Also, the Cartesian coordinates consisting of PC1 and PC2 are converted to the diagonal coordinates of the diagonal angle θ consisting of PC1 'and PC2'.

At this time, if the diagonal angle is changed without changing the quantization step, pixel definition is performed. The extreme example is when the domain is below the quantization step. In this case, only the quantization noise is transmitted, and no information is transmitted. The domain can be expanded (e.g. the pixel value is doubled when changing the oblique angle in the range of 90 degrees ± 45 degrees) and reduced when restoring the original image and the secret data. A reversible process, and this enlargement / reduction rate is known by only for content owners. Therefore, the only content owners can fully restore the original image.

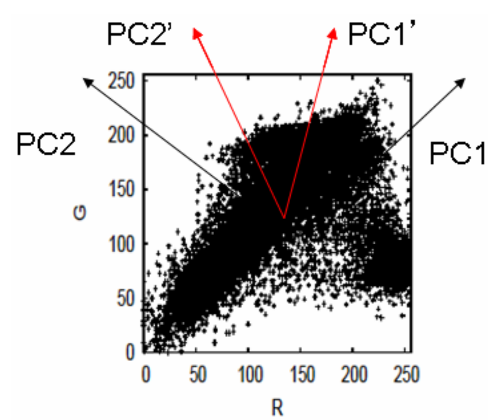

Fig. 4. PCA and Oblique-Coordinate Conversion (OCC) as a Preprocessing of the MRA based Data Hiding.

Next, the method of decrypting the secret data is explained. The first principal component image is used for the distribution image by using the coefficient when the principal component conversion is applied to the multidimensional original image before the secret data is hidden. Is implemented and wavelet decomposition is performed on the first principal component image. Decoding the secret data by the proposed method transforms the principal component transform into the multidimensional original image before hiding the secret data information. Decoding is possible only when the coefficients used are known, that is, the coefficients of principal component transformation differ depending on the multidimensional original image before hiding the secret data.

III. Experiments

An example of the experiment is shown as follows. I also used the Mandrill (Fig. 5), which was also selected from the standard image database for data compression evaluation (SIDBA), as the original image, and the time series data shown in Fig. 6 as the secret data. (Graph) was used.

The red, green, and blue primary color images of this color primary image are shown in Fig. 7. Here, the blue component is set to 0, and for the sake of convenience, it is used as two-dimensional multispectral image data. Fig. 8 shows the scatter diagram of the mean vector and transform coefficient matrix for performing the principal component transformation from the red and green two-dimensional scatter of the original color image, that is, the eigenvalue and the eigenvector, respectively.

λ =(133.772, 129.297)

V=|0.835 0.550|

|− 0.550 0.835|

Only I who owns the original image knows these accurate eigenvalues and eigenvectors (principal component conversion parameters), and even if the eigenvalue expansion is performed based on the circulation image, the restored image when the correct eigenvalues / eigenvectors are used. However, if the confidential data is image data with high redundancy, it is possible to recover the confidential data within the allowable error range and it is not enough. In order to enhance the confidentiality, I decided to add the oblique coordinate transformation as a pre-processing.

Convert the Cartesian coordinate axes after principal component conversion to any diagonal coordinate axes using the above Eqs. (1) and (2), where the diagonal angle of the diagonal coordinate axes is the diagonal coordinate transformation parameter θ. θ = 90 degrees is the orthogonal coordinate axis itself after the principal component conversion, and for example, if oblique coordinate conversion is performed with θ = 110 degrees and 70 degrees, Fig. 8 becomes Fig. 9. This diagonal angle can be arbitrarily set up to the range of the quantization step as described above, but the scaling ratio of the pixel value domain is changed depending on this angle. Therefore, it is necessary to adjust the quantized bit accordingly, and it is necessary to increase the processing resource, so I set it here to about ± 20 degrees. Restoration is extremely difficult because there is no information such as the diagonal angle and eigenvalue vector.

It is shown that the protection performance of the secret data is improved by the parameter θ. Therefore, I try to estimate the secret data from the first principal component image in Fig. 10 by using the wavelet transformation. The information of the wavelet basis and the component (for example, the HH1 component) in which the secret data is embedded is known by some method, i.e., the information such as the eigenvectors held by the parties and the parameter θ are known. The third party is unknown.

Fig. 9. Oblique Coordinate Converted Scatter Diagrams with 110 and 70 Degrees.

Fig. 10. Widely Available Image of which Hiding Image (Time Series of Data Graph) is hidden in the Original Image (Mandrill).

Fig. 11 shows the RMS deviations when secret data is embedded by changing the oblique coordinate transformation parameter θ and a third-party attempts to estimate secret data from the distribution data for each distribution data.

The RMS deviation when a third-party attempts to estimate the secret data from the distribution data depends on θ, that is, θ increases the confidentiality of the secret data. Therefore, it can be seen that the confidential data can be protected by protecting the information of the original image.

Next, I examine the degree of restoration of the secret data. I restored the secret data from the distribution image and evaluated the degree of restoration (mean squared error (RMS error) between the secret data and the restored secret data. The results are shown in Fig. 12. From this figure, it can be seen that the mean squared error between the original secret data and the secret data reconstructed from the distribution image increases. In other words, increasing the diagonal angle improves the confidentiality.

It is important for hiding. The degree of restoration of secret data was evaluated when noise due to image processing, removal attacks, etc. was included in the distribution image. The noise included was 5 steps with a mean of 0 and a standard deviation sigma of 5-20. After superimposing the normal random number changed in step 1, the secret data was reconstructed and the mean square error from the original secret data was evaluated. The results are shown in Fig. 13.

The mean square error increases steadily by the amount of superimposed noise, and the mean square error increases by about 10% by changing the oblique coordinate angle from 90 degrees (orthogonal coordinates) to 110 degrees. Therefore, there is no resistance to noise, and it is found that the restored secret data deteriorates by the amount of superimposed noise, and the effect of oblique coordinate transformation is about 10%. Although it is possible, the quantization error due to requantization after coordinate transformation increases, so it was judged that the limit is about 70 to 110 degrees.

IV. Conclusion

Data hiding method with Principal Component Analysis (PCA) and image coordinate conversion as a preprocessing of wavelet Multi Resolution Analysis (MRA) is proposed. The method introduced in this paper allows only I who knows the characteristics of the original multispectral image to recover the secret data, i.e., when the information of the original image needs to be protected. In this paper, the Daubechies basis function is adopted as the wavelet, but the secret data can be restored by using the biorthogonal wavelet, and the secret data can be protected by hiding what is adopted as the biorthogonal wavelet.

Through experiments, it is found that the proposed method is superior to the conventional data hiding method without any preprocessing. The method introduced in this paper allows only the owner of the original image who knows the characteristics of the original multispectral image to recover the secret data, i.e. when the information of the original image needs to be protected. Moreover, in the introduced method, the information of the secret data is protected by the existence of the eigenvector and the oblique coordinate transformation, that is, the secret data is restored if at least the information of the true original image is not known. The principal component transformation coefficient differs for each original image and is composed of the eigenvectors of the original image.

I have introduced a method that improves the confidentiality by applying principal component transformation and oblique coordinate transformation as preprocessing for data hiding based on wavelet multiresolution analysis. I investigated the confidentiality when a third-party attempts to extract secret data from only the data for distribution.

The proposed data hiding method can be applicable for all the images in the world. There is no limitation in terms of applicability at all.

V. Future Research Works

In the future, I will compare the proposed method with conventional data hiding methods such as steganography method. Influences on the restoration process due to tampering on the secret image hidden imagery data has to be investigated.

Acknowledgment

I would like to thank Dr. Kaname Seto of former student of Saga University and Dr. Leland M. Jameson of Naval Research Laboratory for their contribution of this study. I, also, would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

DCRL: Approach for Pattern Recognition in Price Time Series using Directional Change and Reinforcement Learning

Nora Alkhamees[1], Monira Aloud[2]
Management Information Systems Department
College of Business Administration, King Saud University, Riyadh, Saudi Arabia

***Abstract*—Developing an intelligent pattern recognition model for electronic markets has been a vital research direction in the field. Ongoing research continues for intelligent learning algorithms capable of recognizing and classifying price patterns and hence providing investors and market analysts with better insights into price time-series. In this paper, an adaptive intelligent Directional Change (DC) pattern recognition model with Reinforcement Learning (RL) is proposed, so called DCRL model. Compared with traditional analytical approaches that uses fixed time interval and specified features of the market, the DCRL is an alternative intelligent approach that samples price time-series using an event-based time interval and RL. In this model, the environment's behavior is incorporated into the RL process to automate the identification of directional price changes. The DCRL learns the price time-series representation by adaptively selecting different price features depending on the current state. DCRL is evaluated using Saudi stock market data with different price trends. A series of analyses demonstrate the effective analytical performance in detecting price changes and the extensive applicability of the DCRL model.**

Keywords—Machine learning; reinforcement learning; directional-change event; pattern recognition; stock market

I. INTRODUCTION

Pattern recognition in financial markets has been widely studied in the fields of finance, economics, computer science, engineering, modern physics, and mathematics [30,31,37,38,48,51]. Furthermore, artificial intelligence and Machine Learning (ML) have been widely used for financial market forecasting, pattern recognition, and event detection to provide decision support in various financial market segments [19,28,32,40,42].

In the financial literature, most developed ML algorithms and methods are based on physical time, for which prices are sampled at fixed time intervals (such as daily, hourly, etc.) [26,27]. To avoid the discontinuous nature of the price time-series, the Directional Change (DC) event approach provides an alternative method for sampling time-series data [6,27]. A price point is sampled when a significant price change in the price trend is observed. Therefore, the DC event approach represents a time-series as downtrend or uptrend events based on the magnitude of price changes. Several studies have been developed based on the DC event approach for pattern recognition [26], profiling price time-series [10,46], regime change detection [47], event detection [2], time-series analysis [7,33], forecasting models [15,16], and designing trading strategies [3,4,8-14, 29,50].

Reinforcement Learning (RL) is a learning method used for sequential decision-making problems [44]. RL is one of the three basic ML methods, along with supervised and unsupervised learning. In RL, the learning agent interacts and adapts from environmental interactions by exploitation or exploration. RL achieves performance improvements through continuous evaluations of and interactions with the environment [45]. RL has the advantages of self-learning and adapting to the environment towards decision making but lacks, to a certain extent, the environment's awareness capability. Despite the effectiveness of the RL approach, event detection and pattern recognition remain challenging in real-world time-series analysis for three reasons. First, using a physical time interval makes the price time-series discontinuous, given that prices are transacted at irregular times. Second, RL can be designed with a complex structure and a large number of parameters, which can interrupt the analysis. Lastly, the learning process of the dynamic continuous market environment's state representation and the associated learning strategy affect the RL model's interruption and converge.

In this work, an intelligent intrinsic time-driven model for automatic event detection in a price time-series - the Directional Change Reinforcement Learning (DCRL) - is developed. The DCRL is presented in two sequential phases: the RL phase and the DC event analysis phase. In particular, in the RL phase, the RL algorithm learns the environmental states and features to find the most applicable dynamic threshold for the DC event analysis. The aim is to find the best dynamic threshold definition method using the RL agent, which is subsequently used for DC event detection. We used the dynamic threshold introduced in [2], which replaces the DC given fixed threshold. For the DC event analysis phase, the generated threshold from the former phase is used to detect DC events in the price time-series. The proposed model is evaluated using the Saudi stock market (Tadawul). Stocks with different price trends and series patterns are selected to evaluate the model's performance. The experimental results demonstrate that the model is adaptable to various market conditions and might be used for designing algorithmic trading.

We are interested in developing an intelligent event detection (i.e. significant price movement) algorithm from a price time-series. This algorithm will allow investors or even artificial software agents to detect price movements in the market to capture investment opportunities. Hence, our motivation is that the DCRL can provide decision support methods for analysts and investors and can facilitate the automation of event detection for sampling price time-series. Therefore, a novel method for financial event detection and time-series sampling has been proposed.

The remainder of this paper is organized as follows. Section II reviews several related works in the financial literature. Section III introduces the proposed DCRL model. Section IV describes the datasets, presents the empirical evidence of learning and identification of events, and evaluates the effectiveness and robustness of the DCRL. The last section concludes the paper and presents some future directions.

II. Related Work

In the financial literature, several studies including but not limited to the following have been using the RL method for financial signal representation [32], designing trading strategies and algorithmic trading [17, 20, 32, 41], portfolio management [5], optimizing trade execution [39], trading systems [49], Foreign Exchange (FX) asset allocations [22], cryptocurrency market trading [18], and changes in market regimes [5].

Supervised learning methods have been used to forecast stock prices and the direction of price trend movements [21]. Several studies used deep ML methods to forecast a stock price using historical numerical and textual data [1,23]. The authors in [23] used deep learning for event-driven stock predictions. The events are extracted from news text and formulated as dense vectors that are trained using a neural tensor network. The deep convolutional neural network is used to model the events' impact on price time-series movements. The results showed that the proposed model could obtain an approximate 6% improvement in S&P 500 index forecasting. Nonetheless, the proposed method is challenging if attempting to achieve adaptable learning and simultaneously lacks the quick response to new dynamic market conditions given the high cost of retraining [32]. Thus, when designing event detection algorithms and algorithmic trading, the inherent characteristics and evolution of market fundamentals should be considered.

The RL method might be an alternative solution for event detection and algorithmic trading, given that it is more applicable for continuous decision making in financial market trading [32]. Bertsimas and Lo in [17] examined the application of RL for trading large blocks of equity over a specific period to minimize the expected cost of executing trades. Their results demonstrated that the RL trading strategy saved between 25% and 40% in execution costs relative to the naïve strategy. Experimental results in [20,41,43] also show that the adaptive event detection mechanism and algorithmic trading with RL methods achieve more stable returns. The experimental results by [18] confirmed the effectiveness of deep RL methods on a dataset of one of the largest cryptocurrency markets in the world, achieving average daily returns of over 24%.

Studies on algorithmic trading using the RL method can be categorized into two main groups: policy-based methods and value-based function methods. Work in [31] has designed an on-policy (policy-based) and an off-policy (Q-learning) discrete state and action RL agents for an individual retirement portfolio. Their study found that using the trading algorithm design results in the on-policy algorithm maintaining better evaluation and adaptation to the environment than Q-learning. Their study also found that the on-policy method's drawback is that it continuously remains to explore in the environment even when the best solution is learned. The works in [22,36] has demonstrated that the benefit of the policy-based model is that it has better results than the value-based function model.

The authors in [32] studied the representation of the stock market environmental state and developed a trading strategy using historical stock price and trading volume data. They developed a time-driven, feature-aware model jointly with a deep reinforcement learning model (TFJ-DRL) that had two parts - deep learning perception and RL decision making - to improve financial signal representation learning and, hence, decision making in algorithmic trading. The results showed that the TFJ-DRL model outperformed the state-of-the-art methods in the literature. A similar study by [24] introduced a decision support algorithm to filter trading signals based on RL and neural networks. The study aims to detect seasonality events of the basic strategy to improve the reward to risk ratios.

Maringer and Ramtohul in [34,35] introduced a regime-switching to the Recurrent RL (RRL), where regime-switching captures the different price trend movements over a time series. The results highlighted that the regime-switching RRL outperforms the traditional RRL when the price time series exhibits noticeably different regime characteristics. The RRL model in [36] is a policy-based model that offers the action of the previous time's trading with the current environmental state to direct RL, hence, create a trading action. This model's main obstacle is the direct input of all of the environmental features to the RL model without awareness and representation of the current environment's status. The study by [25] combined features based on Japanese candlesticks, a technical analysis technique, with RRL to produce a high-frequency algorithmic trading system for the E-mini S&P 500 index futures market. The results demonstrated a significant increase in both return and Sharpe ratio compared to relevant benchmarks, suggesting the capability of RRL to detect events in a high-frequency equity index futures trading environment.

Overall, the RL method has been recognized as being effective and efficient in forecasting asset prices in financial markets and, hence, make trading decisions. Previous studies used RL based on physical time, which is characterized by a fixed time interval, whereas the price time series is irregularly spaced in time. Therefore, to develop an adaptive RL algorithm for event detection, the DC event approach is used to represent and study the price time series. In this work, we use the RL to enhance the dynamic threshold definition method presented in [2]. We want to improve the dynamic threshold definition method so that we can set the dynamic threshold without the need for an additional source of data (such as news).

III. Methodology

In this section, we introduce the DCRL model which aims to identify financial events from stock market price time series and, hence, represent periodic patterns of the price time series. First, the DC event approach which constructs a price time series of continuous DC events is described. Then, the process of defining the DC dynamic threshold is explained. Finally, the DCRL model is introduced as a dynamic adaptive process to select the optimal equation for the DC dynamic threshold. In other words, a DCRL model is developed to identify DC events in a price time series using the different dynamic threshold equations (actions). Therefore, the goal is to improve the reward function under different states.

A. DC Event Approach

Using the DC event approach, price time series data are sampled at irregular time intervals using a given size threshold (λ), which is defined by the observer (fixed value) and is typically expressed as a percentage [6]. Thus, the DC event approach transforms the discrete nature of the price time series into continuous DC events independent of the notion of fixed physical timescales. Under the DC event approach, the price time series is summarized into alternating uptrend and downtrend DC events.

A DC event is identified as a confirmed price change that is larger than, or equal to, a predefined threshold (λ) [6]. A DC event can be either a downturn or an upturn DC event. The time interval between an upturn DC event and the next downturn DC event is called an upward run, whereas a downward run is the time interval between a downturn DC event and the next upturn DC event. During an upward run, the last high price (p_h) is continuously updated to the maximum value between the current asset price p(t) and the last high price (p_h). In a downward run, the last low price (p_l) is continuously updated to the minimum value between the current market price p(t) and the last low price (p_l) At the beginning of a data sequence, the last low price (p_l) and last high price (p_h) are set to the initial asset price p(t_0) at time t_0. An upturn DC event is detected during a downward run and, in particular, when the current asset price p(t) exceeds the last low price (p_l) by a given threshold (λ); refer to Formula (1). In contrast, a downturn DC event is detected during an upward run when the current asset price p(t) is lower than the last high price (p_h) by a given threshold (λ); refer to Formula (2).

$$p_t \geq p_l \times (1 - \lambda) \quad (1)$$

$$p_t \leq p_h \times (1 - \lambda) \quad (2)$$

The DC event approach captures the short-term dynamics of the price time series by detecting significant events and a clear picture of the time series behavior on the basis of the observer's needs. Most importantly, this approach reduces the complexity of the financial market price time series, given the defined dataset of periodic price points to study and evaluate. The selected threshold value controls the magnitude of the DC price events in a time series. Therefore, choosing a substantial threshold results in fewer detected DC price events, whereas a small threshold maps a series of insignificant patterns. The authors in [6] described the core mechanism of the DC event approach to study the financial price time series. In this work, a price time series is formulated using the DC event approach. Given a size threshold (λ), the mission is to detect events at the DC confirmation point regardless of whether or not the direction of the price trend changes at a certain point.

B. DC Dynamic Threshold

In this section, we describe the dynamic threshold definition method which replaces the DC fixed given threshold value [2]. The dynamic threshold definition method is suitable for markets that operate during specific opening and closing times (such as stock markets). The dynamic threshold is a flexible value and brings with it the advantage of allowing the identification of price changes (i.e., DC events) of different magnitudes in continuously changing environments.

In [2], significant price fluctuations were considered as an event occurrence indicator. Thus, the dynamic threshold definition method depends on the previous day's price behavior (short-term price history). The daily dynamic threshold value can be set in three possible ways, choosing the most appropriate one was not straightforward. They depend on an alternative source of data (news outlets) to facilitate the definition of the dynamic threshold. A suitable dynamic threshold definition method can be selected depending on the investigated asset news and market conditions. In this work, the best method for defining the dynamic threshold value without an alternative source of data is determined using RL. Hence, an agent is developed to select the most effective dynamic threshold definition method (i.e., the one that detects DC events at the right time).

Basically, the dynamic threshold can be set using one of the three equations (Eq. (3), Eq. (4), and Eq. (5)) as follow:

DT_Overnight=Up/Downward_ROC+Overnight_ROC (3)

DT_PreviousDay=Up/Downward_ROC+
PreviousDay_ROC (4)

DT=Up/Downward_ROC+PreviousDay_ROC+
Overnight_ROC (5)

DC dynamic threshold depends on the price Rate Of Change (ROC) between the DC p_h/p_l (refer to Section III.A) and the high/low prices (depending on the examined trend) for the current day. In addition, it finds the price ROC for the previous day (between the previous day's opening and closing prices), and the price ROC that occurred overnight (between the previous day's closing price and the current day's opening price). The dynamic threshold is defined by the sum of the aforementioned metrics, as shown in Eq. (5). However, in some circumstances in which something has happened the previous day or overnight, the shortened version of the dynamic threshold definition method (Eq. 3 or Eq. 4) is used to ensure a reduced threshold value that certainly increases the chance of identifying a DC event (either an upturn or downturn event). Also, to be mentioned is that if a defined threshold value by Eq. (5) was found to be less than 0.01, then we use the previous day's defined threshold instead. This approach is taken because we are almost certain that nothing has happened (experiencing a stable situation as no significant price changes occurred on the previous day or overnight), and an exceptionally low threshold value may detect a spurious or insignificant event.

C. DCRL

In this section, we introduce the DCRL model, which can identify financial events from a time series. The DCRL is based on the RL approach, which directs the dynamic thresholds definition method, and the DC approach, which is responsible for detecting the occurring DC events on the basis of the given threshold value from the RL phase.

RL is a learning approach through which an intelligence algorithm represented by an agent is designed to learn from interactions with the environment. Therefore, RL mimics human learning and, hence, appears well suited to processing the price time series. The goal is to train the RL agent based on a sequence of interactions to learn an optimal policy from the interaction to maximize the total cumulative reward obtained. In this section, the RL approach's key elements are introduced, and the approach is tailored to the goals of this study.

RL can be generally categorized into two types: the policy-based and value-based function methods [32]. Policy-based RL explicitly and directly builds a representation of a policy from the environment and, hence, creates continuous decisions from the policy. The established policy is stored in memory during the learning phase. The DCRL policy-based method is as follows: if the price ROC from the previous day or overnight is greater than a five-day price change moving average, then the first two equations (Eq. 3 or Eq. 4) from section III.B are used; otherwise, Eq. (5) is used.

The RL approach consists of the environment, agent, state, action, and reward. Considering discrete times $t = 0, 1, 2, 3,\ldots$, at each time t, a RL agent receives some representations of a state in the environment, denoted by $s_t \in S$, where S is the set of all possible states. Based on the current state s_t and the previously obtained information, the agent takes action $a_t \in A(s_t)$, where $A(s_t)$ is the set of actions available in state s_t. The space of actions in DCRL consists of the three equations for defining the DC dynamic threshold, as described in Section 3.2. The RL agent chooses an action on the basis of its policy π_t, which is a mapping from each state to the probabilities of deciding on each possible action. Therefore, π_t (s) denotes the chosen action when $S_t = s$ based on π_t. At the next time point $t+1$, the agent receives a numerical *reward* from the environment, denoted by $r_t \in R$, *because of its action* a_t *and* moves to a new state s_{t+1}. Based on the earned reward, the RL agent learns to adapt its actions on the basis of the market condition to maximize its future rewards.

The DCRL agent interaction with its environment is depicted in Fig. 1. As an input, we have the price time series, and as an output, we get the optimal chosen action a_t (the best dynamic threshold definition method) and the assigned reward r_t. The agent interaction with the environment is shown in the stage between input and output. Table I provides the set of all possible states in the environment and the set of actions presented for each state s_t, along with the associated rewards for each pair of state and action. In Table I, the DCRL approach takes the appropriate state-action policy π_t (s_t, a_t), which indicates the expected reward r_t for each possible action a_t. For this purpose, the DCRL agent starts with random initial values of π_t (s_t, a_t) for $s_t \in S$ *and* $a_t \in A(s_t)$. The DCRL agent then proceeds with the aforementioned interaction learning steps: (1) observes the current state s_t of the price time series, (2) executes action a_t, and (3) receives reward r_t and observes the next state s_{t+1}.

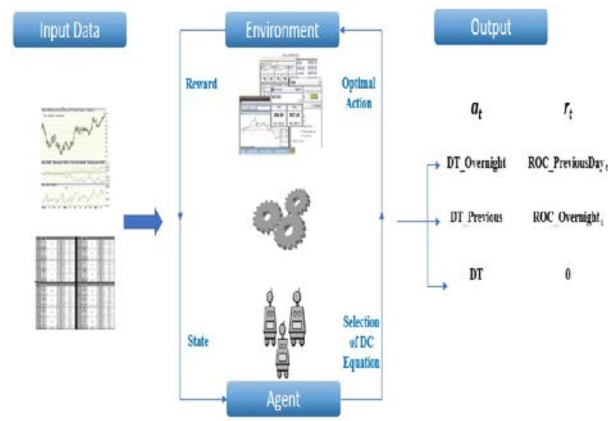

Fig. 1. DCRL Model Interaction with its Environment.

In each iteration, the DCRL agent observes the current state of the environment using the following state variables: a five-day price change moving average, the previous day opening and closing prices, and the previous day closing price and current opening price. This specification has established a learning architecture whereby the previous action at time $t-1$ is considered. In this study, we choose the previous day ROC (Ext_Previous$_t$), overnight ROC (Ext_Overnight$_t$), and Neutral (Neutral$_t$) state to represents the set of possible states S. Following the observation of the current state s_t, the RL agent chooses action a_t from three possibilities. (1) Equation 3 (DT_Overnight) is used to define the DC dynamic threshold considering that an overnight event has occurred. (2) Equation 4 (DT_PreviousDay) is used to define the DC dynamic threshold considering that an event has occurred during the previous day. These two possible actions are associated with the two states Ext_Previous$_t$ and Ext_Overnight$_t$. Note that an action that offers a lower threshold value is selected because it will increase the chance of detecting an event. For the Neutral$_t$ state, only one possible action exists, which is (3) using Equation 5 assuming that no extreme price changes have occurred. Hence, the following set of possible actions is obtained: a_t = { DT_Overnight, DT_PreviousDay, *DT}*.

The agent receives a reward on the basis of the selected action. The reward is the maximum of either ROC_PreviousDay or ROC_Overnight when actions DT_Overnight or DT_PreviousDay are chosen. Alternatively, no reward is assigned (reward = 0) when action DT is taken because it is always taken whenever action DT_Overnight or

DT_PreviousDay cannot be taken. More specifically, if action DT_Overnight was executed, then the assigned reward is ROC_PreviousDay; because the action was based on the lowest threshold value and was DT_Overnight (it led to the lowest threshold value), then the reward is ROC_PreviousDay because it is of greater value than ROC_Overnight. The same applies for action DT_PreviousDay: if action DT_PreviousDay was executed, then the reward assigned is ROC_Overnight.

TABLE I. SET OF ALL POSSIBLE STATES IN THE ENVIRONMENT AND SET OF ACTIONS PRESENTED FOR EACH STATE S_T ALONG WITH ASSOCIATED REWARDS FOR EACH PAIR OF STATE AND ACTION

S_t	S_{t+1}	a_t	*P*	*R*
$Ext\_Overnight_t$	$Ext\_Overnight_{t+1}$	DT_Overnight	0.33	$ROC\_PreviousDay_t$
	$Ext\_Previous_{t+1}$	DT_Overnight	0.33	$ROC\_PreviousDay_t$
	N_{t+1}	DT_Overnight	0.33	$ROC\_PreviousDay_t$
$Ext\_Overnight_t$	$Ext\_Previous_{t+1}$	DT_PreviousDay	0.33	$ROC\_Overnight_t$
	$Ext\_Overnight_{t+1}$	DT_PreviousDay	0.33	$ROC\_Overnight_t$
	N_{t+1}	DT_PreviousDay	0.33	$ROC\_Overnight_t$
$Ext\_Previous_t$	$Ext\_Previous_{t+1}$	DT_PreviousDay	0.33	$ROC\_Overnight_t$
	$Ext\_Overnight_{t+1}$	DT_PreviousDay	0.33	$ROC\_Overnight_t$
	N_{t+1}	DT_PreviousDay	0.33	$ROC\_Overnight_t$
$Ext\_Previous_t$	$Ext\_Overnight_{t+1}$	DT_Overnight	0.33	$ROC\_PreviousDay_t$
	$Ext\_Previous_{t+1}$	DT_Overnight	0.33	$ROC\_PreviousDay_t$
	N_{t+1}	DT_Overnight	0.33	$ROC\_PreviousDay_t$
$Netural_t$	N_{t+1}	DT	0.33	0
	$Ext\_Overnight_{t+1}$	DT	0.33	0
	$Ext\_Previous_{t+1}$	DT	0.33	0

IV. DATA AND EMPIRICAL RESULTS

To verify the effectiveness and robustness of the proposed DCRL model, a series of experiments were conducted using four price datasets for stock exchange indices. The DCRL utilizes a policy-based model that learns the policy from historical prices and defines a variety of continuous actions according to the learned policy. A descriptive analysis of the identified events is presented in Section IVB, it shows a discussion of the identified events along with a statistical description of the associated DC dynamic threshold values. The last section presents the evaluation results of the effectiveness and accuracy of the proposed DCRL model.

A. Data

Our empirical study relies on data from the Saudi stock market (Tadawul[1]) for the period from March 2015 to March 2020, the total number of investigated days is approximately 1285 days. We used four stock indices for the following two financial sectors: Al Rajhi, Alinma, and SABB banks (Sector: Financials Industry, Group: Banks), and STC (Sector: Telecommunication & Information Technology). These selected stock indices are well known in the Saudi financial market. The price time series for these four stock exchange indices are sourced from Yahoo finance[2]. Each row data includes the date along with opening, low, high, and closing prices. The choice of these four stock indices is based on the strength of their economic and financial factors. The distribution of each dataset composes of a variety of price trends and a series of patterns, which will contribute to the effectiveness of evaluating the DCRL model under different situations. Fig. 2 shows the price time series for the four stock indices during the five investigated years (2015- 2020).

Table II presents the basic annualized average summary descriptive statistical analysis of the datasets for the four stock exchange indexes during the period from March 17, 2015, to March 13, 2020. The mean (μ), standard deviations (σ), Skewness, Kurtosis, minimum, and maximum price values are reported for each stock index.

B. Results

In Table III, we report the statistical analysis results of the identified DC events using the DCRL model. Table III provides the average annualized of the following quantities: number of identified DC events, number of times (days) the previous day's defined threshold was also used for the current day, number of times an event was identified as the ROC taking place overnight was significant, and the number of times an event was detected as the ROC taking place the previous day was significant. When *DT_Overnight* and *DT_PreviousDay* are used more often to define the DC dynamic threshold, this use could mean that the price changes occurring overnight (between the previous day's and the current day's opening prices) or occurring on the previous day (between previous day opening and closing prices) are considerably high. Therefore, the identified DC events using the dynamic threshold definition method can capture the sensitivity of the market changes and, hence, the identification of potential events.

TABLE II. DESCRIPTIVE STATISTICS OF FOUR STOCK INDICES: ALRAJHI, ALINMA, SABB, AND STC. THE PERIOD SPANS FROM MARCH 17, 2015, TO MARCH 13, 2020, AND THE TOTAL NUMBER OF INVESTIGATED DAYS IS APPROXIMATELY 1285 DAYS

Index	μ	σ	Skewness	Kurtosis	Min.	Max.
Alrajhi	48.25	3.64	0.38	-0.37	40.20	56.39
Alinma	18.99	2.12	-0.17	-0.22	13.92	22.64
SABB	28.87	3.34	-0.059	-0.53	21.06	34.78
STC	77.95	5.38	0.16	-0.09	65.53	90.07

[2] https://finance.yahoo.com/

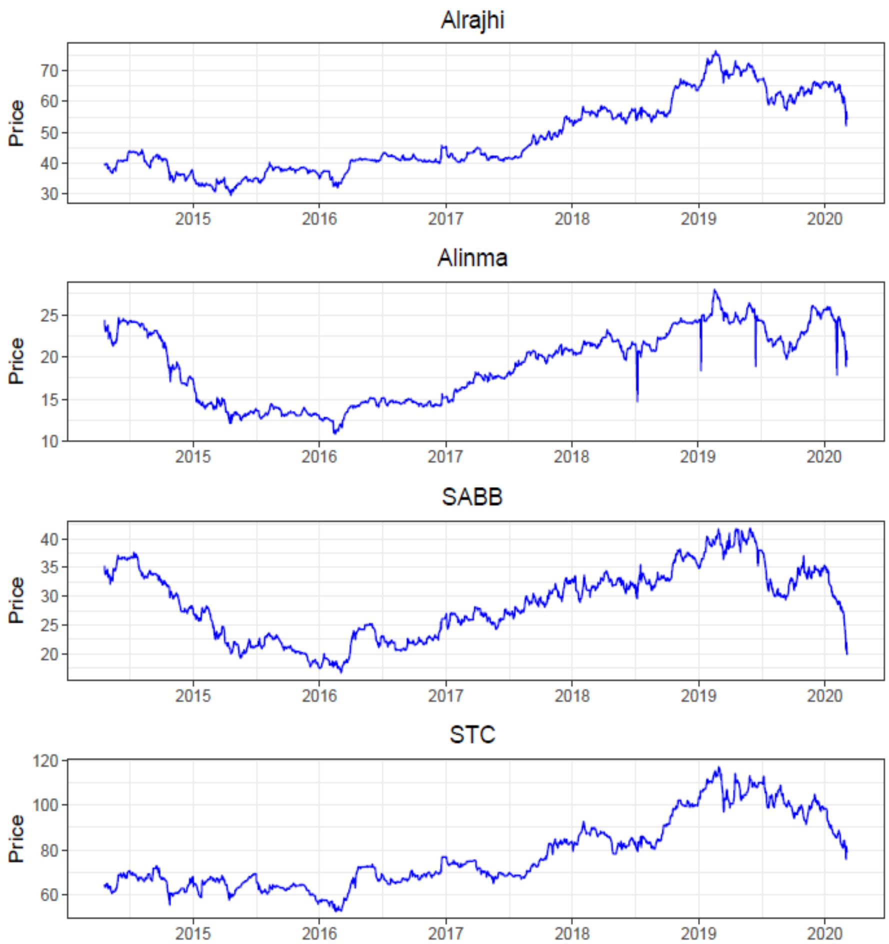

Fig. 2. Price Time Series for the Four Stock Indices: Alrajhi, Alinma, SABB, and STC over the Period from 17/3/ 2015-13/7/202 (x-axis Represents Price and y-axis Represents Year).

For all of the investigated stocks during the 5 examined years, more than half of the detected DC events from the dynamic threshold values were found using both equations DT_Overnight and DT_PreviousDay. Specifically, these equations have detected more than 60% of the DC events in Alinma and STC, and 70% of the DC events in Alrajhi and SABB, refer to Table III for a summary of the annualized average statistical analysis results. In addition, SABB had the fewest number of days on which the previous day defined threshold was also used for the current day to identify DC events (if any), on average, only 14% of the investigated days the previous day threshold was also used for the current day. In other words, on average each year in 221 days out of the 259 days, a new dynamic threshold was set each day to detect DC events, if any. Therefore, SABB may have been exhibiting a number of price variations; refer to SABB price time series in Fig. 2.

Also, the high number of identified DC events (an average of 54 DC event each year) confirms this phenomenon. In contrast, Alrajhi, Alinma and STC had a higher number of days for which the previous day threshold was again used for the current day (at least 25% of days); refer to Fig. 2 for Alrajhi, STC and Alinma price time series, which also maintains a number of price stability trends.

In order to have a deeper and closer look, in Fig. 3, we illustrate in more details the identified DC events using DCRL over the period from March 2019 to March 2020 for Alrajhi, Alinma, SABB, and STC price time series. The X-axis represents the date, and the Y-axis represents the daily closing price. In the chart, the square-shape event represents a downturn DC event, and the x-shape event represents an upturn DC event. Forty-nine DC events were identified from Alrajhi and STC. In addition, Alinma had 45 identified DC events, and 57 DC events were detected in SABB (refer to Fig. 3).

TABLE III. STATISTICAL ANALYSIS RESULTS OF AVERAGE ANNUALIZED IDENTIFIED DC EVENTS USING DCRL MODEL

Index	N_{DC}	$N_{\lambda(t-1)}$	$N_{\lambda(t)}$	**N(DT_Overnight)**	**N(DT_Previous Day)**
Alrajhi	51.4	66.4	192.2	17.4	18
Alinma	49.6	77.8	180.4	16.2	16
SABB	53.8	36	220.6	20.4	16.4
STC	49.8	63.8	192.6	19.8	14.4

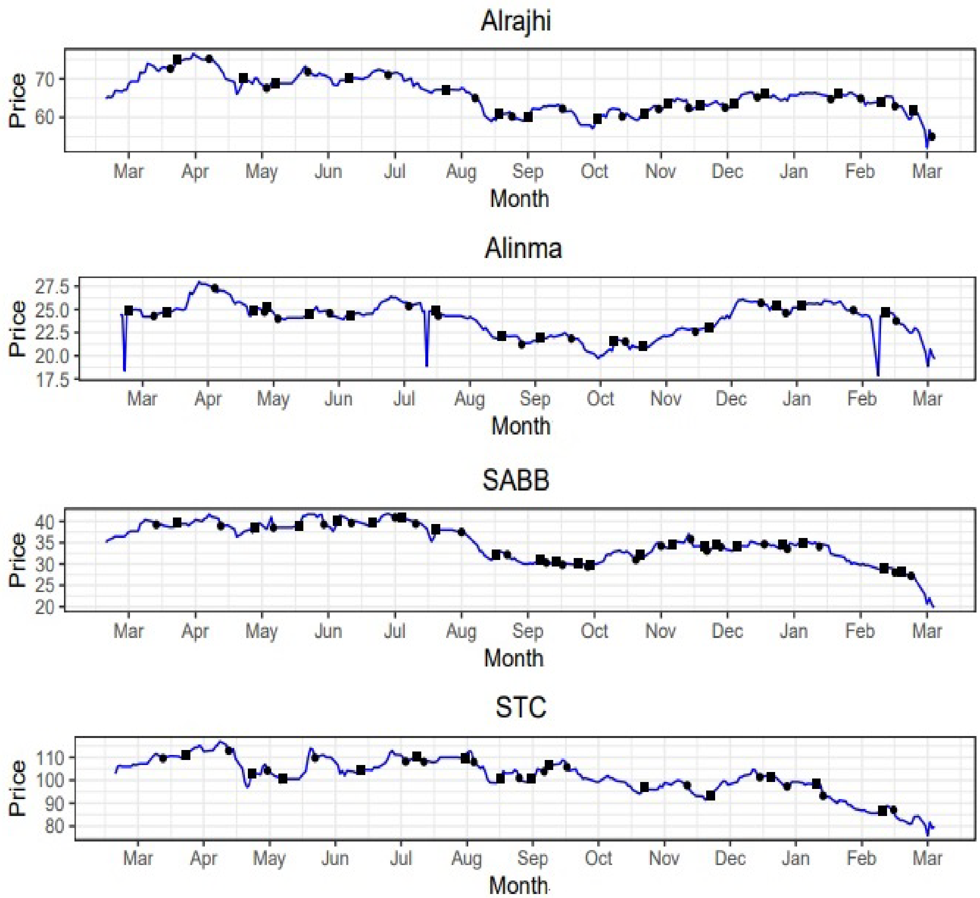

Fig. 3. Price Time Series for Four Stock Indices: Alrajhi, Alinma, SABB, and STC over the Period from March 17, 2019, to March 13, 2020. Identified DC Events (upward and downward) using the DCRL Model are shown for the Final Year in the Sampled Period.

Physical time (e.g., daily prices) fails to recognize the pattern flow of price movement, giving that the variety of price changes depends only on that considered time. Moreover, using daily or intraday prices to detect price patterns maps a range of patterns with different sizes, resulting in discontinuous pattern flow of price movements. On the other hand, the DC events reduces the complexity of a price time series giving that it detects periodic patterns in contrast to those detected by physical time.

Table IV reports an analysis of the defined DC dynamic threshold values and presents the mean value of the dynamic DC threshold values during the investigated period, the minimum and maximum DC dynamic threshold values, and, finally, the standard deviation values. Table IV clearly demonstrates that Alinma had a high standard deviation ($\sigma = 0.032$) relative to other stocks. This finding indicates that the defined threshold values are spread out with relatively high variations and are far from the mean. Additionally, Alinma has the highest maximum threshold (0.208), whereas all other stocks' maximum values were between 0.08 and 0.1 (Alinma's maximum value is at least two times higher than that of all of the other stocks); refer to Fig. 3 for the Alinma price time series to observe the significant price jumps encountered. For illustration, on March 18, 2019, the closing price was 24.4, which slipped to 18.3 on the next day. Subsequently, on March 20, 2019, the price bounced back to 24.4. During the investigated period, this significant jump occurred at least three times (in March and July 2019, and in February 2020). For the rest of the stocks, the standard deviation was between 0.012 and 0.016, indicating a smaller value. Thus, in these cases, the data points are close to the mean.

TABLE IV. DESCRIPTIVE STATISTICS OF THE DC DYNAMIC THRESHOLD VALUES DEFINED BY DCRL MODEL. FOUR DESCRIPTIVE VALUES ARE PRESENTED FOR DC DYNAMIC THRESHOLD: MEAN (μ), MINIMUM, MAXIMUM, AND STANDARD DEVIATION (Σ)

Index	μ	Min	Max	σ
Alrajhi	0.022	0.046	0.0893	0.012
Alinma	0.027	0.029	0.208	0.032
SABB	0.027	0.0102	0.109	0.017
STC	0.023	0.0109	0.085	0.013

C. Evaluation

To verify the effectiveness and robustness of the proposed DCRL model, we evaluate the results using the (i) length of the price-curve coastline, and (ii) accumulated reward value from the DCRL model. The length of the price-curve coastline offers an indicator of the usefulness of sampling the price time series, whereas the accumulated reward value evaluates the efficiency of the learning process in the DCRL model.

1) Price-curve coastline: The authors in [26] uncovered the scaling laws used to estimate the length of the price-curve coastline on the basis of the intrinsic time, which turns out to be long. A price-curve coastline can capture the price variations and, hence, the potential profit [26]. In this section, we measure the length of the price-curve coastline using two different models: DCRL (intrinsic time) and physical time (fixed time intervals). The goal is to evaluate their performance by summarizing the price movements and, thus, improves the understanding of the dynamic behavior of the price time series in a simplified manner.

The length of a price-curve coastline is defined by the sum of all price changes during a defined period *T*. Under intrinsic time, the length of the price-curve coastline during period *T* is the average of the price changes between the identified DC events [6]. The length of the price-curve coastline under the DCRL model *c(λ)* is defined by:

$$c(\lambda) = \frac{1}{N_{DC}} \sum_{i=1}^{N_{DC}} |p_i - p_{i+1}| \quad (6)$$

where N_{DC} is the number of identified events determined by the DC dynamic threshold (λ), p_i is the price of the *i*-th DC turning point, and p_{i+1} is the consequential DC turning point.

Under fixed physical time intervals, the length of the price-curve coastline during period *T* is the average of the price changes between the fixed points at which the time distance between all fixed points are equivalents [6]. The length of the price-curve coastline under physical time *c(t)* is defined by:

$$c(\mathrm{t}) = \frac{1}{n} \sum_{i=1}^{n} |p_i - p_{i+1}| \quad (7)$$

where p_i is the price at point *i* (refer to the table to observe the length of PTI for all investigates stocks), and *n* refers to the total number of fixed points, which equals the number of identified DC events (to ensure fairness in comparison).

It is essential to being aware with how well the established DCRL and the physical time price-curves fit the real price time series to evaluate their performance and effectiveness of sampling price changes in a time series. For instance, Fig. 4 shows the price time series for the STC index over the March 17, 2019, to March 13, 2020 (the blue solid line) and a zoom-in in the lower chart from November 24, 2019, to January 5th, 2020. The chart compares the price changes defined under the DCRL model (the red dashed line) and the physical fixed time interval model (the green dashed line) using the same number of points (49 DC events in DCRL and 49 points in the physical time scale). The DCRL model can identify price movements (DC events) as they occurred, while the physical time scale model fails to do so. Hence, it is clear that the DCRL can better sample the price changes than the physical time scale.

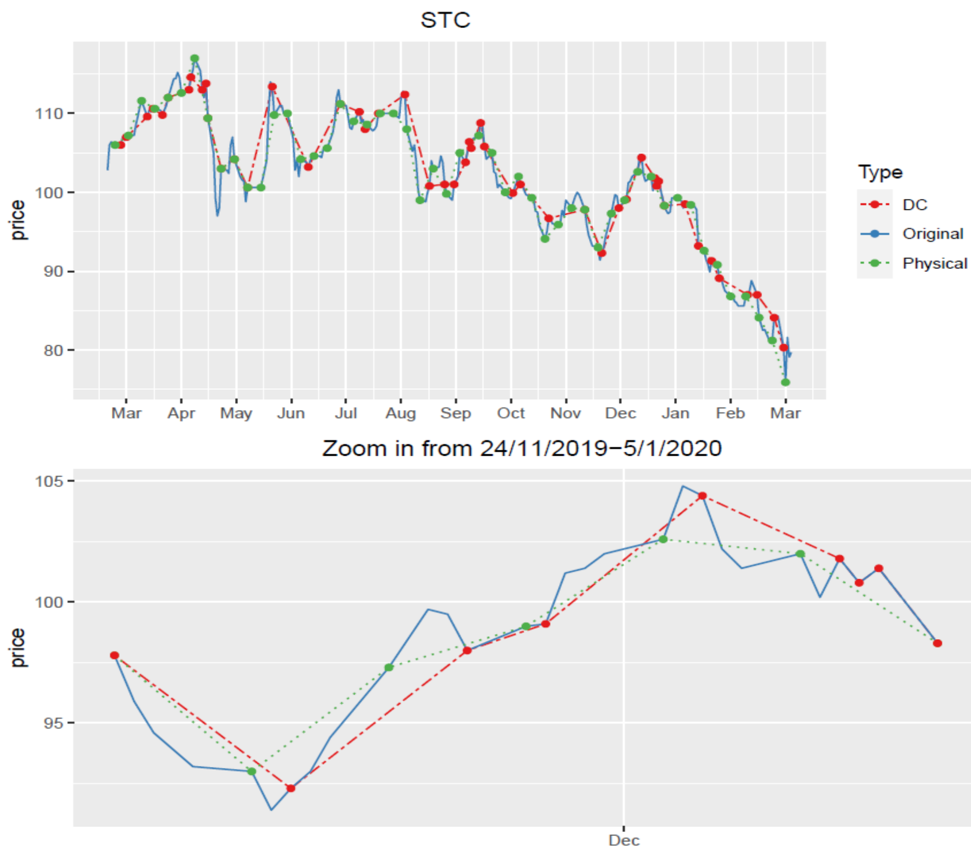

Fig. 4. The Price Curve Lines for STC Index using DC and Physical Time Compared to the Original Price Curve.

Table V compares the price-curve coastline of the events identified by the DCRL model using dynamic thresholds (intrinsic time intervals) against physical time changes (fixed time intervals) over the period March 17, 2019, to March 13, 2020. Table V clearly shows that the DCRL price-curve coastline c(λ) is longer for all investigated stock indices relative to the physical time price-curve coastline c(*t*). The coastline of Alinma under the DCRL model (i.e., DC intrinsic time) is more than three times longer than the physical time coastline (0.70 is the length of the DCRL coastline, and 0.22 is the length of the physical coastline). This difference can be the result of the time series evolution being unstable with significant price transitions occurring more frequently (refer to Fig. 2 for Alinma price time series). In contrast, SABB price-curve coastline using the DCRL model is slightly longer than its physical coastline but was closest to the physical coastline when compared with other investigated stock indices (0.89 was the length of the DCRL coastline, and 0.49 was for the physical time coastline). This finding can be the result of the often-recurring price transition but with insignificant price transitions (refer to Fig. 2 for SABB price time series). The DCRL price-curve coastline for the other stock indices (Alrajhi and STC) is at least two times longer than the physical coastline.

To summarize, the DCRL model-identified events using the intrinsic time outperforms the identified price transitions using the physical time for all investigated stock indices.

The natural fluctuation in the price time series suggests the need for diversification of the analytical scope of identifying financial events in the price time series. The DCRL mitigates the discontinuous price flow of prices in a time series and captures the periodic price changes.

2) Random-Based DC model: In this section, we further investigate the role and accuracy of the developed DCRL model in improving the decision-making process for the most appropriate dynamic threshold definition method. Therefore, we developed a random-based DC model that randomly selects a dynamic threshold definition method (randomly decide on one of the three dynamic DC equations: DT_Overnight, DT_Previous, or DT. The developed random-based DC model replaces the role of RL in selecting the DC dynamic threshold definition method. In contrast, DCRL finds the most appropriate dynamic threshold definition method using the DCRL policy (π).

Table VI provides a comparison for the accumulated reward value gained by the DCRL model and the random-based DC model over the period of March 17, 2019, to March 13, 2020. Evidently, the DCRL model outperformed the random-based DC model for all investigated stock indices, leading to the conclusion that the learning process of price movements (that is, upward and downward DC events) matters in the estimation of financial events in stock markets. The DCRL had proven to be effective in maximizing the accumulated value of the reward and, hence, the profitability during a sequence of learning steps for identifying events in different stock indices.

TABLE V. PRICE-CURVE COASTLINE LENGTH DEFINED BY: (I) THE DCRL MODEL C(Λ) AGAINST (II) PHYSICAL TIME CHANGES C(T) FROM 17/3/ 2019-13/3/2020. THE NUMBER OF DC EVENTS IS DENOTED BY NDC, AND PTI REPRESENTS THE PHYSICAL TIME FIXED INTERVAL

Index	N_{DC}	*c(λ)*	**PTI**	*c(t)*
Alrajhi	49	1.47	5.3 days	0.69
Alinma	45	0.70	5.8 days	0.22
SABB	57	0.89	4.5 days	0.49
STC	49	3.06	5.3 days	1.35

TABLE VI. ACCUMULATED REWARD VALUE GAINED BY THE DCRL AND RANDOM-BASED DC MODELS

Index	**DCLR**	**Random**
Alrajhi	2.21	1.82
Alinma	3.90	3.25
SABB	3.44	2.78
STC	2.64	2.09

V. CONCLUSION

In this paper, the DC event and RL approaches were used for automated pattern recognition from price time series. We proposed an intelligent intrinsic time-driven DCRL joint model, which can (1) adaptively set the DC dynamic threshold and conduct an event-based time series analysis using the RL approach, hence, improving the effectiveness, adaptability, and interpretability of the identified financial events; (2) jointly construct a price time series using the DC event approach, thus acquiring periodic continuous price events and improving the accuracy of the price time series representation. The DCRL is suitable for markets that operate during specific opening and closing times and can identify financial events without the need for an additional data source.

The effectiveness of the DCRL model is validated on the Saudi stock market with different price trends and patterns. The experimental results demonstrate that the DCRL model outperforms other physical time-based analyses and the random-based DC model with higher rewards and a more reliable representation of the price curves.

This work can be further extended and improved in future research directions. One direction can be conducting experiments on large-scale data, such as high frequency time series data, to confirm the effectiveness of and further enhance the DCRL model. Another promising research direction is to further apply the DCRL model to emerging markets, such as the cryptocurrency market. In addition, algorithmic trading can be developed using the DCRL model to trade one asset at a time and then can be improved and expanded to manage the portfolios of several assets. Finally, some financial features could be introduced to enhance the DCRL model; for example, trade volume could provide significant information for selecting the dynamic threshold.

ACKNOWLEDGMENT

We would like to thank the anonymous reviewers for their useful comments and suggestions. The authors thank the

Deanship of Scientific Research and RSSU at King Saud University for their technical support.

Constrained Quantum Optimization for Resource Distribution Management

Sara El Gaily[1], Sándor Imre[2]
Department of Networked Systems and Services
Budapest University of Technology and Economics, Budapest, Hungary

***Abstract*—The cloud computing field suffers from the heavy processing caused by the exponentially increasing data traffic. Therefore, optimizing the network performance and achieving a better quality of service (QoS) became a central goal. In cloud computing, the problem of energy consumption of resource distribution management system (RDMS) is presented as an optimization problem. Most of the existing classical optimization approaches, such as heuristic and metaheuristic have high computational complexity. In this work, we proposed a quantum optimization strategy that executes the tasks exponentially faster and with high accuracy named constrained quantum optimization algorithm (CQOA). We exploit the CQOA in RDMS as a toy example for pointing out the efficiency of the proposed quantum strategy in reducing energy consumption and computational complexity. Following that, we investigate the CQOA's implementation, setup, and computational complexity. Finally, we create a simulation environment to evaluate the efficiency of the suggested implemented constrained quantum strategy.**

Keywords—Quantum computing; constrained quantum optimization algorithm; quantum extreme values searching algorithm; resource distribution management; cloud computing

I. Introduction

Parameter optimization and the choice of the best solution candidate play a crucial factor in gaining optimal performance in many application types in a wide range of disciplines. It is useful to mention that most of the computational problems arising from the practical optimization world are frequently mapped to searching the minimum or maximum of a goal function (or a constraint goal function).

The cloud computing industry is suffering from intensive processing due to rapidly rising data traffic. As a result, improving the network speed and attaining a higher quality of service (QoS) became a top priority. In the last decades, several well-known quantum strategies have been proposed in quantum computing [1,2] such as quantum phase estimation (QPE) which is exponentially faster than the classical ones, it computes the eigenvalue of a unitary operator, it has many useful applications, here we list some examples, such as, quantum counting algorithm for computing the number of occurrences of a query (searched item) in a certain database, Shor's algorithm for integer factorization [3], or the HHL algorithm [4] for solving a linear system of equations. Another interesting well-known searching algorithm, the so-called Grover's algorithm (quantum solution for searching an item in an unsorted database) which enables a dramatic reduction in computational complexity. The optimal classical solution takes $O(N)$ iterations to carry out the search while Grover's strategy requires only $O(\sqrt{N})$ step [5-6].

In this work, we exploited the constrained quantum optimization algorithm (CQOA) [17]-[20] for optimizing the energy consumption of a proposed resource distribution management system (RDMS). It is important to mention that one of the motivations behind exploiting the CQOA in RDMS is that most of the constrained classical searching strategies suffer from high computational complexity for one of the following reasons,

- Most of the databases are Unsorted (unordered).
- The database may contain many local extremes (minimum or maximum) gratifying the constraint.
- The database structure is not always continuous.

The outline of this paper is as follows: Section II presents the literature review. Section III is devoted to introducing the CQOA and its computational complexity as well as showing a comparison between the CQOA and its original quantum algorithm version, the so-called quantum extreme value searching algorithm (QEVSA). Section IV deals with describing the resource distribution management model and the problem statement. Section V is concerned with implementing and configuring the proposed constrained quantum optimization approach in the desired resource distribution management. Section VI is devoted to discussing the computational complexity of the applied CQOA. Section VII presents the simulation results, and Section VIII concludes the paper.

II. Related Work

It is not easy to build a new efficient quantum algorithm that outperforms a classical one. For this sake, there are few discovered quantum algorithms. Concerning the constrained extreme value searching, the most leading quantum heuristic candidate is introduced in [7], the so-called quantum approximate optimization algorithm (QAOA) which approximates hard optimization problems by converting the classical objective function into a Hamiltonian problem. Later, the QAOA was exploited for solving a constrained optimization problem, this alternative solution investigates the ground state of the Hamiltonian cost function instead of minimizing the original cost function [8]. Another extended version of the QAOA, the so-called quantum alternating operator ansatz is designed for finding the approximate solutions to optimization problems with hard constraints [9].

The only drawback is that the calculation of the derivatives of the goal function can be computationally expensive. On the other hand, several well-known classical approaches for handling the constrained optimization search have been proposed in the literature, the most applied ones namely deterministic optimization algorithms and metaheuristic ones, these strategies are often failing to find the global optimum result when the goal function is non-monotonic, non-continuous, or the database is unsorted and very large [10]-[16].

It is worth showing the motivation behind applying the CQOA in RDMS. As it is known, new technologies continue to merge in cloud computing to meet the challenges imposed by the exponentially increasing data traffic [21]-[55]. Recent works [56-58], of the cloud radio access network, have shown significant performance gains by centralizing the management of radio and processing resources in the cost of computational complexity.

Due to the significance of the issues that the cloud environment addresses, many optimization methods have been proposed lately. The majority of them strive for a high quality of service.

The authors in [21] employed a hybrid prediction model that merges both statistical and machine learning approaches to generate higher-quality prediction outcomes for cloud computing. The proposed approach was able to predict with high accuracy the necessary workload. However, these techniques suffer from high computational complexity due to complex and highly nonlinear data. The model has been exploited to predict both seasonality and random workload patterns.

The authors in [22] proposed a hybrid technique with a shuffled leapfrog algorithm and ubiquitous binary search (SLFA-UBS) to resolve these issues with an optimal assignment and better resource distribution. The method performed better in terms of optimum dynamic resource provisioning with QoS and cheap cost.

Several metaheuristic approaches have been applied to improve the quality of service of cloud computing. For example, the authors in [26] suggested a multi-objective hybrid Ant Colony Optimization (ACO) with Bacterial Foraging (ACOBF) behavior to maximize resource utilization and also minimize the Makespan. While, the authors in [36] proposed another multi-objective hybrid method that combines the two well-known strategies, particle swarm optimization (PSO), and grey wolf optimization (GWO). The experimental outcomes proved that the newly developed method reduces the total execution time and cost compared to PSO, heterogeneous earliest time first (HEFT), ant colony optimization (ACO), and round-robin (RR) algorithms.

The author in [59] considered a cloud radio access network and aimed to minimize the energy consumption of the overall system while satisfying constraint demands. Moreover, the work in [60] executed sequentially two heuristic approaches for minimizing the power consumption of task processing. In addition, the author in [61] used the Matroid algorithm to optimally solve the constrained resource allocation problem. Another classical technique that is often used is the so-called knapsack optimization strategy which is widely investigated in the processing resource assignment in a cloud radio access network system [62-64]. However, the proposed optimization algorithms for task allocation require high computational complexity.

III. Constrained Quantum Optimization Algorithm

Before introducing the CQOA, let's present first the QEVSA. In [65]-[66] the author built a new quantum algorithm named quantum existence testing (QET) which is a special case of quantum counting algorithm that determines the number of occurrences M of a certain item in a database consisting of N entries [67]. While the QET tests whether a given entry exists or not in a certain database, in other words, it checks the value of M, if it equals zero or not. Next, the author developed a new quantum method called the quantum extreme value searching algorithm (QEVSA) by combining the well-known classical binary searching algorithm [68] and the QET. More details are presented in [65]-[66]. The QEVSA finds the extreme (minimum or maximum) of an unconstrained goal function or unsorted database.

The computational complexity (CC) of the QEVSA depends on,

- The CC of the binary searching algorithm embedded in the QEVSA which equals $O(log_2(T))$, where T is the maximum number of steps needed to run the logarithmic search.
- And, the CC of the QET which equals $O\left(log_2{}^3\left(\sqrt{N}\right)\right)$, where $N = 2^a$ is the entry size of the database, where a is the total number of the required qubits with respect to the size N of the database.

The overall number of bits n_E used in the physical implementation of the QET is strongly influenced by the quantum uncertainty and the classical accuracy of the application. In case the quantum uncertainty demand is neglected i.e. it corresponds to the idealistic phase estimation with no error, this implies that the value of n_E can be written as.

$$n_E = \underbrace{\frac{a}{2} - 1}_{c_E} \tag{1}$$

where c_E is the optimum number of qubits required for classical accuracy in order to represent the phase, in this case, the CC of the QET is $O\left(log_2{}^3\left(\sqrt{N}\right)\right)$. On the other hand, if the upper bound of the error probability is denoted by $\breve{P_\varepsilon}$ of the quantum uncertainty _originated from the QPE_ is taken into consideration by the application, then the value of n_E is expressed as.

$$n_E = \underbrace{\frac{a}{2} - 1}_{c_E} + \underbrace{\left\lceil log_2(2\pi) + log_2\left(\frac{1}{8\breve{P_\varepsilon}}\right)\right\rceil}_{p_E} \tag{2}$$

where p_E is the optimum number of qubits needed to handle the quantum uncertainty problem originating from the error probability of converting the phase to a probability amplitude. In this respect, the CC of the QET is $O\left(log_2{}^3\left(2^{\frac{p_E}{2}}\sqrt{N}\right)\right)$. We assume that the CC of the QEVSA is only influenced by the classical certainty parameter. For this sake, the CC can be written as $O\left(log_2(T)log_2{}^3(\sqrt{N})\right)$.

In compliance with what has been discussed, we see that the QET plays a fundamental role in the search efficiency of the QEVSA.

In [17]-[18], we developed a new extended version of the QEVSA, the so called CQOA, where we extended the functionalities of the QET(*ref*) to a new quantum function that answers whether there exists an item in a certain region of the database at all, and satisfies the engineering constraint *C* and index relation *R* (The value of *R* may refer to minimization or maximization of the constraint goal function) is needed. This new extended version is named the constrained quantum relation testing $CQRT(ref, R, C)$ where the parameter *ref* refers to the updated value which divides the database into two vertical parts, the index *R* refers to the used relation, and the constraint *C* can be equality or inequality constraint.

Also, we proved that implementing the constraint *C* and the relation *R* in the QET does not change the evaluation of QPE. For this sake, the estimated optimum number of qubits required for the classical accuracy denoted by c_R which corresponds to the CQRT function equals the c_E belonging to QET function, one obtains $n_R = n_E$. To this end, the computational complexity of the QEVSA equals the computational complexity of CQOA which equals $O\left(log_2(T)log_2{}^3(\sqrt{N})\right)$.

Note that the notation of *ref* value in the algorithm has been changed to $F_{med\,S}$. The CQOA is expressed as follows,

1) We start with S = 0 : $F_{min\,1} = F_{min\,0}$, $F_{max\,1} = F_{max\,0}$, and $\Delta F = F_{max\,0} - F_{min\,0}$

2) $S = S + 1$

3) $F_{med\,S} = F_{min\,S} + \left[\frac{F_{max\,S} - F_{min\,S}}{2}\right]$

4) $flag = CQET\left(F_{med\,S}, R, C\right)$:

- if $flag = Yes,$ then $F_{max\,S+1} = F_{med\,S}$
- Else $F_{max\,S+1} = F_{max\,S}$, $F_{min\,S+1} = F_{med\,S}$

5) If $S < log_2\,(T)$, then go to 2, else stop and $y_{opt} = F_{med\,S}$

It is important to mention that the QEVSA performs only the search in the continuous database structure because the QET cannot adjust the classical logarithmic search algorithm (binary searching algorithm) so that it is suitable for non-continuous databases.

The CQRT allows adapting the binary searching algorithm so that it is suitable for continuous database structures to non-continuous ones. To this end, the CQOA handles the search in a continuous or non-continuous database structure. The main similarities and differences between the QEVSA and CQOA are summarized in Table I.

TABLE I. THE MAIN SIMILARITIES AND DIFFERENCES BETWEEN THE QEVSA AND CQOA

	QEVSA	**CQOA**
Type of the goal function	Unconstraint goal function	Constraint goal function
Database type (Continuous/Non-Continuous)	Continuous	Continuous/Non-Continuous
The classical logarithmic search algorithm is combined with	QET	CQRT
Computational complexity	$O\left(log_2(T)log_2{}^3(\sqrt{N})\right)$	$O\left(log_2(T)log_2{}^3(\sqrt{N})\right)$
Database Structure (ordered/unordered)	Unordered database	Unordered database

IV. MODEL

This paper is an extension of the previous work published in [69-73], the of the current paper is reducing the energy consumption of processing resources by taking into consideration the delay constraint of the tasks. To model the general RDMS, we divided its functionalities into three main blocks. Fig. 1 represents the architecture of the proposed RDMS.

A. Multiple Task Generators

We consider multiple task generators, where each generator releases a task type to be served by computing units. We assume that the number of generators/task-types is denoted by *G*. Each generated task is composed of several subtasks selected from a set of subtask types, where the total number of different subtask types is V.

Each generator always produces identical tasks i.e. the same number of the total subtasks and the same number of subtask types. Moreover, each generator releases tasks according to an arrival time distribution (exponential intensity distribution, uniform intensity distribution, etc.). Note that, the memory needed to allocate the subtask type v is denoted by Δ_v. Furthermore, each task type has to be served within a specific delay constraint denoted by τ_g i.e. the subtasks belonging to task type g have the same *time constraint* τ_g i.e. all the subtasks of the task type g have to be served within this time constraint τ_g.

1) Computing units: The incoming tasks are served by computing units. The total number of computing units is denoted by *K*. Each computing unit has a maximum capacity c_k. Assuming that N_{vk} refers to the number of subtask type v under process on the k^{th} computing unit.

2) Decision maker: It controls the deployment of the incoming subtasks among computing units. The CQOA introduced in Section II will be implemented as a computational infrastructure core of the decision-maker.

B. Problem Statement

The decision-maker deploys the subtasks of the incoming task to different computing units. Assuming that the subtasks of the incoming tasks are processed sequentially. Fig. 2

illustrates the processing mechanism of subtasks in the k^{th} computing unit, where subtasks arrive in a FIFO manner, i.e. when a task arrives in the decision-maker, it decides instantly whether the task (consisting of subtasks) can be accepted and deployed to any of the computing units or not (rejected). The delay needed to process the actual load in the k^{th} computing unit (considering the task under the decision, too) denoted by τ_k^{act}, it has to be always less or equal than the delay constraint of the incoming task type i.e. $\tau_k^{act} \leq \tau_g$. The green hatched subtask is the subtask belonging to the new incoming task deployed into the k^{th} computing unit (see Fig. 2). This decision method guarantees that the delay constraint of tasks that are running on the k^{th} computing unit does not influence the fulfillment of delay constraint of the new incoming task and vice versa.

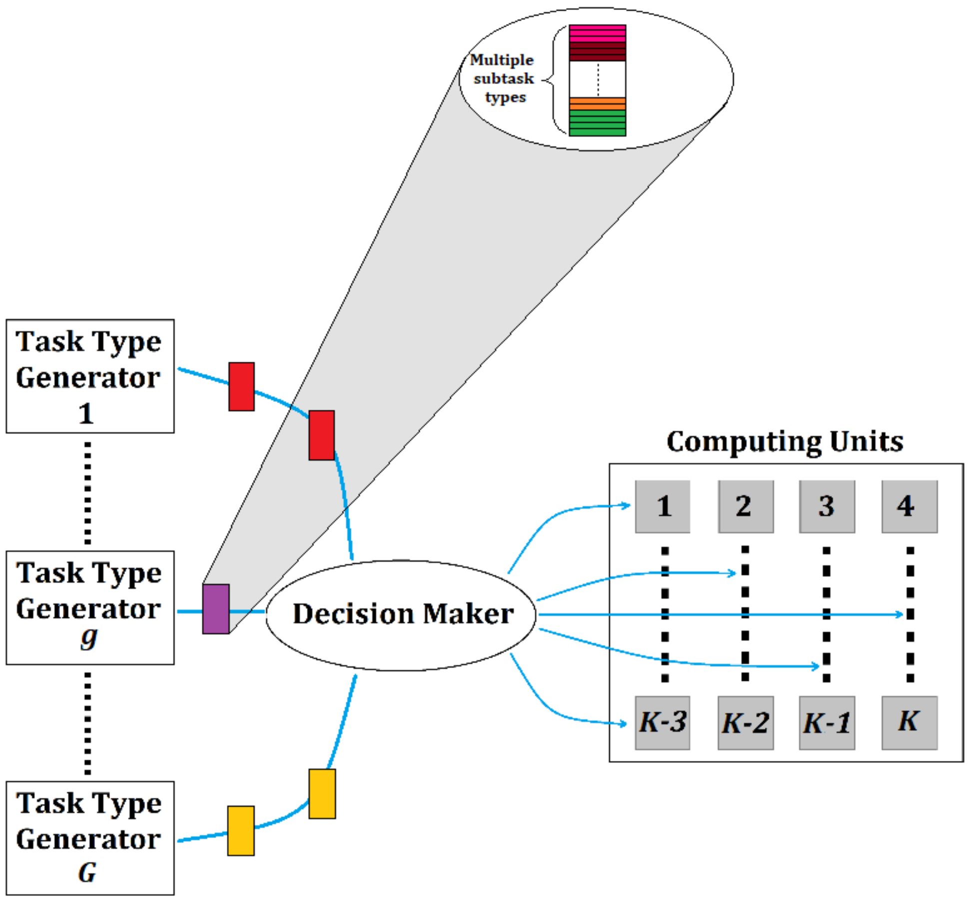

Fig. 1. Resource Distribution Management System.

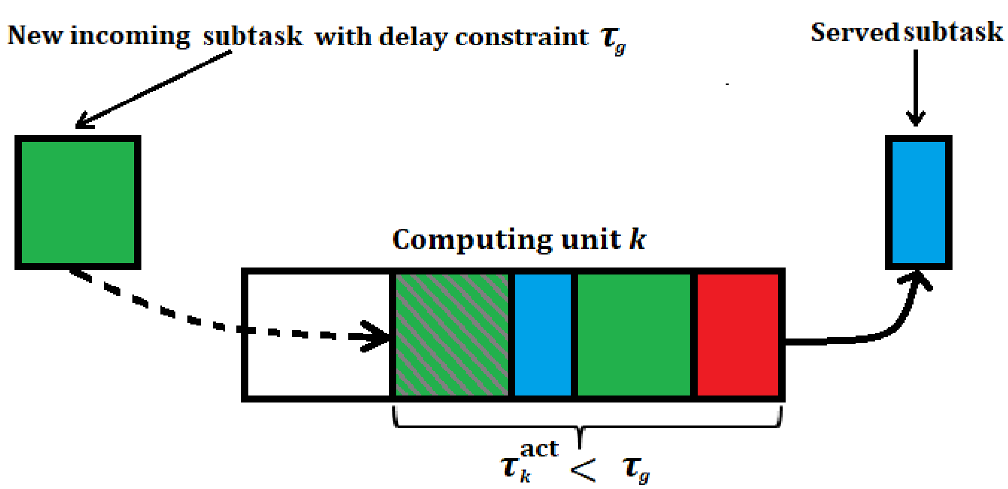

Fig. 2. Scheme Illustrating the Sequential Processing Operation of different Subtasks in the k^{th} Computing Unit.

Now, let's investigate the calculation of the total energy consumed by the RDMS. We consider that the initial power needed to turn on the computing unit k is denoted by P_k^{init}.

A subtask is composed of a specified number of identical memory pieces called *memory units*. The processing rate of the k^{th} computing unit is denoted by β_k and computed as follows,

$$\beta_k = \frac{number\ of\ memory\ units}{second} \quad (3)$$

On the other hand, the time needed to process a subtask type v on the computing unit k is Δ_v/β_k. Furthermore, the processing delay of the actual load on the k^{th} computing unit can be calculated as,

$$\tau_k^{act} = \frac{\sum_{v=1}^{V} N_{kv}\Delta_v}{\beta_k} \quad (4)$$

Assuming that $\tau_k^{act} \leq \tau_g$ and the processing of the subtasks is performed sequentially as illustrated in Fig. 2, the energy required to process the subtasks on computing unit k is given by formula (5), where ε_k is the energy consumption of one memory unit on computing unit k.

$$\begin{aligned} E_k^{act} &= \varepsilon_k \sum_{v=1}^{V} N_{kv}\Delta_v + P_k^{init}\tau_k^{act} \\ &= \left(\varepsilon_k + \frac{P_k^{init}}{\beta_k}\right)\sum_{v=1}^{V} N_{kv}\Delta_v, \end{aligned} \quad (5)$$

- $\varepsilon_k \sum_{v=1}^{V} N_{kv}\Delta_v$: The energy needed to serve the subtasks under process on the computing unit k without considering the energy required to turn on the computing unit k.
- $P_k^{init}\tau_k^{act}$: The energy needed to turn on the computing unit k in a period that is equal to τ_k^{act} (the energy of tasks is not considered).

It is straightforward to verify that the overall energy consumption of the system can be written as,

$$\begin{aligned} E^{act} &= \sum_{k=1}^{K} E_k^{act} \\ &= \sum_{k=1}^{K}\left(\varepsilon_k + \left.\frac{P_k^{init}}{\beta_k}\right|_{k\in H^{on}}\right)\sum_{v=1}^{V} N_{kv}\Delta_v. \end{aligned} \quad (6)$$

where the term $\frac{P_k^{init}}{\beta_k}$ is considered if and only if the k^{th} computing unit is switched on (The set H^{ON} of the switched-ON computing units). Our goal is to minimize the overall energy consumption E^{act}, one obtains.

$$E_{min}^{act} = \min_{\forall S_i \in S} E^{act}(S_i)\ and\ \forall k \in S_i : \tau_k^{act} \leq \tau_g \quad (7)$$

with S denotes the sets of different possible distributions of the subtasks of the incoming task among all computing units and S_i refers to the i^{th} distribution/deployment scenario of S, i.e. the i^{th} specific set of computing units $S_i = \{k\}$.

V. Implementation and Configuration of the CQOA

To select the best and the optimum deployment scenario, we apply the CQOA as a minimum constrained searching algorithm (MCSA). To this end, the function F is substituted by E^{act}, while the constraint C corresponds to the delay constraint of the incoming task type i.e. τ_g, and the implemented relation R is a "minimization".

The maximum number of steps needed to run the logarithm search T in (8) depends on two parameters: the variation of the energy consumption of the system denoted by $\Delta E = E_{max}^{act} - E_{min}^{act}$ and the step size α which is the smallest distance between the energies of two different scenarios among all the possible scenarios in the database. Fig. 3 shows these parameters.

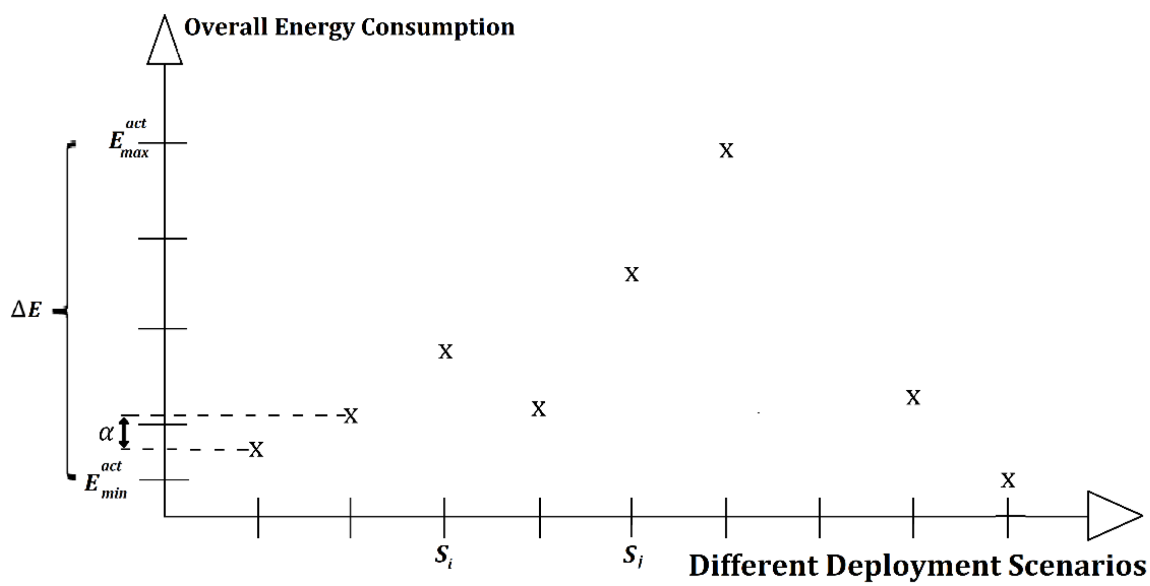

Fig. 3. The Horizontal Axis Presents all the Possible Deployment Scenarios, While the Vertical Axis Presents the Borders of the Total Energy Consumption Function (different Results), each Possible Scenario Corresponds to a Total Energy Consumption. Computing the Value of α Requires Selecting the Minimum Distance between Total Energy Consumption Functions of Two Deployment Scenarios S_i and S_j.

Since the searching region is obviously $\Delta E = E_{max}^{act} - E_{min}^{act}$, the stochastic parameter T can be expressed as follows.

$$T = \frac{E_{max}^{act} - E_{min}^{act}}{\alpha} \quad (8)$$

where E_{min}^{act} can be replaced by the energy consumption of the system without the new incoming task. We denote this energy value by $\breve{E}^{act}$ and one can observe that it does not depend on the deployment of the incoming task, this implies that.

$$T = \frac{E_{max}^{act} - \breve{E}^{act}}{\alpha} \quad (9)$$

An appropriate worst-case estimation for E_{max}^{act} can be considered as.

$$E_{max}^{act} = \breve{E}^{act} + \tau_g \sum_{k \in H^{OFF}} P_k^{init} + E_{max}^{inc}. \quad (10)$$

where,

- E_{max}^{inc} denotes the energy consumption if the subtasks of the incoming task are deployed onto that computing units having the largest ε_k , i.e., the least energy-efficient unit.

$\tau_g \sum_{k \in H^{OFF}} P_k^{init}$ is the total energy consumed by the set H^{OFF} of the switched-OFF computing units because the switched-ON computing units are already considered in $\breve{E}^{act}$.

On the other hand, the value of α can be written as,

$$\alpha = min_{\forall\, i \neq j} \left| E^{act}(S_i) - E^{act}(S_j) \right| \quad (11)$$

where $E^{act}(S_i)$ is the sum of the energy consumption of the system without the new task $\breve{E}^{act}$ and the energy consumption of the incoming task with assuming that it was distributed according to Z_i,

$$E^{act}(S_i) = \breve{E}^{act} + E^{inc}(Z_i). \quad (12)$$

where Z_i refers to the i^{th} set of those computing units which receive one or more subtasks of the new incoming task. It is straightforward to verify if one substitute (12) into (11), one obtains:

$$\alpha = min_{\forall\, i \neq j} \left| E^{inc}(Z_i) - E^{inc}(Z_j) \right| \quad (13)$$

Let M_{kvi} be the number of subtasks of the incoming task from subtask type v deployed onto computing unit k in case of the i^{th} deployment scenario. The formula of $E^{inc}(Z_i)$ can be expressed now by means of (14) as:

$$E^{inc}(Z_i) = \sum_{k \in Z_i} \left(\varepsilon_k + \left. \frac{P_k^{init}}{\beta_k} \right|_{k \in H^{on}} \right) \sum_{v=1}^{V} M_{kvi} \Delta_v \quad (14)$$

where this term $\frac{P_k^{init}}{\beta_k}$ is considered if and only if the k^{th} computing unit is switched-ON. To set up properly the stochastic parameter α, it is enough to investigate the non-zero solutions of $\left(E^{inc}(Z_i) - E^{inc}(Z_j) \right)^2 = 0$, the solutions are located on a hyper-plane, this result is already discussed in [73].

VI. Computational Complexity Analysis

As previously presented, in order to minimize the constrained overall energy consumption, we have exploited the CMSA as a computational infrastructure for the RDMS. Furthermore, we have proven that the computational complexity of the implemented CQOA is $O\left(log_2(T) log_2{}^3\left(\sqrt{N}\right)\right)$, it depends on the computational complexity of the CQRT function $log_2{}^3\left(\sqrt{N}\right)$ and the logarithmic search of the quantum algorithm $log_2(T)$, where N refers to the total number of possible deployment scenarios.

The computational complexity analysis is divided into two main parts,

- The value of T roughly depends on the value of the stochastic parameter α. As already investigated in [73], computing repeatedly the value of α poses a real challenge. To this end, we proposed an alternative solution that consists of setting up the T value in advance before starting the assignment operation, in this case, the computational complexity of determining the parameter α of the logarithm search will be $O(1)$. More details on the computational complexity of T are presented in [73].
- The size of the search space N. This section will be devoted to estimating the value of N which refers to the set of all possible assignment scenarios for each incoming task.

Let us assume that the new task under decision has arrived from generator g. This task contains M_{gv} identical subtasks from type v and we need to select M_{gv} pieces of computing units from the overall K where repetition is allowed, i.e. a certain computing unit can be chosen more than once. One can verify that the number of such possible different sets can be written as:

$$\binom{K + M_{gv} - 1}{M_{gv}} \quad (15)$$

Considering all the subtask types, one gets.

$$N = \prod_{v=1}^{V} \binom{K + M_{gv} - 1}{M_{gv}} \quad (16)$$

Now, we are ready to investigate the computational complexity of the lower and upper bounds of the size of search space N. It is easy to show that

$$\begin{aligned} \binom{K + M_{gv} - 1}{M_{gv}} &= \frac{\left(K + M_{gv} - 1\right)!}{(K-1)!\ M_{gv}!} \\ &= \frac{\left(K - 1 + M_{gv}\right)!}{(K-1)!\ M_{gv}!} \end{aligned} \quad (17)$$

Assuming that $K \gg M_{gv}$, it is interesting to note that by using formula (17), one can verify that it can be expressed in the following manner:

$$K \frac{(K+1)\cdot(K+2)\cdot\ldots\cdot(K-1+M_{gv})}{1\cdot 2\cdot\ldots\cdot M_{gv}} = \frac{K}{M_{gv}} \prod_{i=1}^{M_{gv}-1} \left(\frac{K}{i} + 1 \right) \quad (18)$$

Now we are in a position to give the upper bound for (16). Using (18), one can confirm that

$$\binom{K+M_{gv}-1}{M_{gv}} \leq \frac{K^{M_{gv}}}{min_v\, M_{gv}} \tag{19}$$

Using (19) and (16), the upper bound of the size of the search space N can be expressed as:

$$N = \prod_{v=1}^{V} \binom{K+M_{gv}-1}{M_{gv}} \leq \left(\frac{K^{M_{gv}}}{min_v\, M_{gv}}\right)^V \tag{20}$$

Next, we are interested in a close lower bound for (16). It is easy to verify that

$$N \geq \left(\frac{K^{M_{gv}}}{max_v\, M_{gv}!}\right)^V = \left(\frac{1}{max_v\, M_{gv}!}\right)^V K^{M_g} \tag{21}$$

where, $M_g = \sum_{v=1}^{W} M_{gv}$.

The lower bound expressed in (21) shows that the computational complexity of finding the optimal solution within the database is polynomial in terms of the numbers of computing unit K but exponential in terms of M_{gv}, i.e. if the number of subtask type V becomes large, the computational complexity rises dramatically. For this sake, performing a constrained classical computation method to find the optimum result will be time-consuming and hard to solve. So, our proposed quantum strategy is the best candidate to handle such a task assignment optimization problem.

VII. Simulation

To demonstrate the efficiency of the proposed CQOA, a simulation environment has been constructed, in which a constrained randomized method was considered as a reference for comparison with the proposed constrained optimization method. In the best case, the computational complexity of the constrained randomized method is $O(const)$, and in the worst case, it is $O(N)$.

This simulation aims to compare the performance of both methods in terms of computational complexity and the overall energy consumption with respect to the delay constraint.

The simulation of the RDMS hosts three computing units, the characteristics of computing units are presented in Table. II, we considered three computing units where they have an identical processing rate of 40. From a practical point of view, the RDMS contains significantly more computing units, however, to observe the trends and effects it is worthwhile investigating a small-scale model.

Also, we considered two task type generators such that tasks are generated exponentially, where one of the task types has a high-intensity distribution (the mean value of intensity distribution is smaller) compared to the other one. Furthermore, we considered two subtask type, their memory requirements are respectively $\Delta_1 = 2$ and $\Delta_2 = 4$. Table III presents the number of subtask types, total memory required, and the delay constraint of each task type. While Table IV shows the total number of tasks released for each intensity distribution. It is important to mention that the timeslot of task generation is 20 seconds.

TABLE II. THE CHARACTERISTICS OF THE COMPUTING UNITS OF RESOURCE DISTRIBUTION MANAGEMENT MODEL

	Computing Unit 1	**Computing Unit 2**	**Computing Unit 3**
c_k	40	80	120
P_k^{init}	20	25	30
ε_k	1	2	3

TABLE III. THE CHARACTERISTICS OF THE GENERATED TASK TYPES

	Number of Subtask type 1	**Number of Subtask type 2**	**memory**	**Delay constraint**
Task type 1	1	3	14	1.4
Task type 2	3	1	10	1.2

TABLE IV. THE NUMBER OF TASKS RELEASED FOR EACH INTENSITY DISTRIBUTION

	Mean = 0.4	**Mean = 0.3**	**Mean = 0.2**	**Mean = 0.1**
Number of tasks	39	57	91	203

It is interesting to note that the decision-maker checks first the capacity constraint i.e. if there is free space in the system for allocating the new task. Then, it checks the delay constraint. Also, it is very important to mention that we did not deal with the case where the system is overloaded, i.e. we did not investigate the queueing behavior of the system.

For each two task types that have different intensity distributions, we repeat the simulation 10 times, then we calculate the average overall energy consumed for each algorithm.

Fig. 4 compares the total energy consumed by the randomized and optimized methods for different exponential intensity distributions. It can be seen that for every experiment, the constrained optimized strategy consumes less energy than the constrained randomized one. Additionally, one can notice that when the intensity distribution of arrival tasks increases i.e. when the mean value of exponential distribution becomes smaller, the optimized strategy keeps consuming lower than the randomized one.

Fig. 5 shows the percentages of the overall energy consumption reduction of the three aforementioned experiments. For example, in the first experiment where the two task type generators have respectively 0.4 and 0.3 as means (the mean value of exponential distribution), the energy consumption of the optimized method is less than the randomized one by approximately 43.85 %.

As it is shown, in the worst case the constrained randomized algorithm uses N steps, but it cannot find the optimum deployment scenarios which correspond to the minimum total energy consumption of the RDMS. While the computational complexity of the constrained optimized strategy is $O\left(log_2(T)log_2{}^3\left(\sqrt{N}\right)\right)$.

	Mean = 0.4 & Mean = 0.3	Mean = 0.3 & Mean = 0.2	Mean = 0.2 & Mean = 0.1
Constrained Optimized method	676.05	1103.35	1925
Constrained Randomized method	1204.025	1925	3636.468

Fig. 4. Energy Consumption of the Optimized (Blue Bars) and the Randomized (Red Bars) Strategies according to different Intensity Distributions.

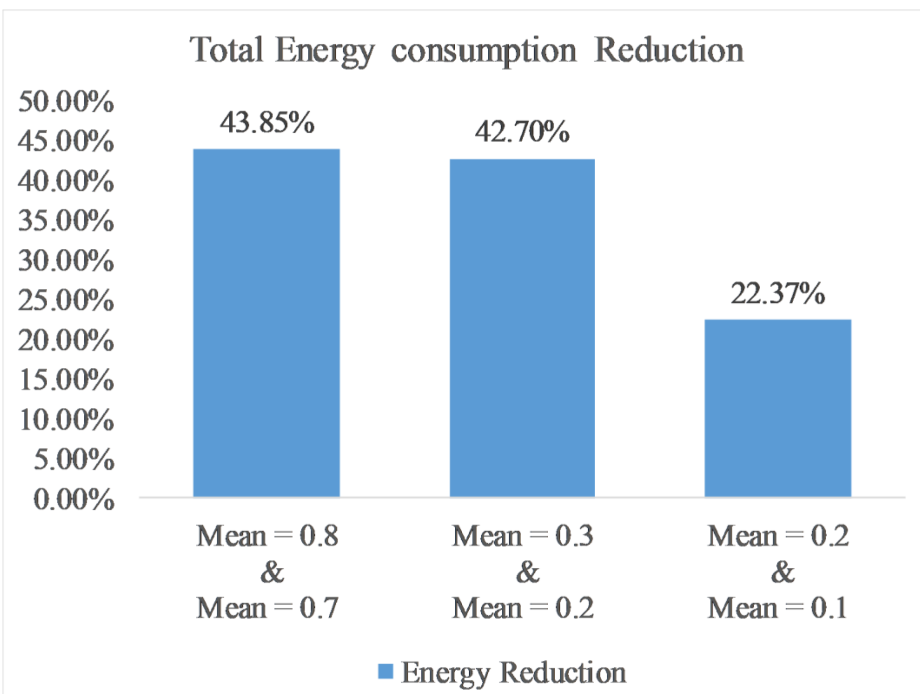

Fig. 5. Energy Consumption Reduction.

To sum up, we see that whatever the distribution intensity is, the constrained optimized approach offers a significant reduction in terms of energy consumption and computational complexity.

VIII. Conclusion

The CQOA finds the extreme optimum value for a constraint goal function or unsorted database with respect to certain constraints. It reduces significantly the costs connected to the application such as computational complexity and time, as well as, provides high accuracy and speed. We exploited the CQOA to minimize the constraint goal function (The total energy consumption) of the RDMS. We derived a simplified form of the constraint goal function, and we investigated the implementation and the configuration of the proposed constrained quantum strategy. Next, we proved that the computational complexity of finding the optimal solution within the database is polynomial in terms of the numbers of the computing units but exponential in terms of the number of subtasks. Fortunately, the proposed CQOA can handle such kind of optimization problem exponentially faster. In the end, we demonstrated by a simulation environment the effectiveness of the CQOA in terms of energy consumption and computational complexity by making a comparison between the constrained randomized strategy and the constrained quantum one. In future work, we will exploit the CQOA in resource distribution management by considering queueing aspect.

***Abstract*—Recently, wireless body area networks (WBANs) and mobile Internet of Things (IoT) have been greatly increased and integrated into a different type of systems such as electronic/mobile-healthcare (e/m-healthcare) systems. In addition, analyzing the composition of drugs or performing the medical rapid tests in the conditions field are the main tasks of the m-healthcare system, in which the traditional laboratory methods of analysis are not suitable. Therefore, in this study, we proposed a novel structure with a distributed e-health system to perform such analysis, where portable infrared micro spectrometers are utilized and then boundary calculations are applied. More specifically, this system is proposed to use a portable infrared micro spectrometer with a specially designed application connected to a public communication network, which can process the results of analysis using boundary calculations. Moreover, it provides remote processing and long-term storage of analysis data using artificial neural networks and cloud technologies. Finally, simulation results show that preprocessing (error checking), data buffering and Edge Computing can significantly reduce the network latency and volume of transferred data.**

I. Introduction

The quality of medical services in the modern world depends very much on several important factors. Firstly, it is the time before medical care is provided, and the shorter the time, the better for the patient. The second factor is the level of automation and informatization of the process of providing medical care, because it eliminates the human factor and improves the quality of medical services. The third factor is to reduce dependence on existing infrastructure and to provide medical care at any time and in any place. This factor significantly depends on the level of technology and telecommunications development [1].

When they talk about the integration of modern technology and medicine, the most commonly considered area of knowledge is e-Health (also written e-health). This is a field of knowledge that studies the tasks of digitalization of medical service delivery, development of new high-precision medical equipment, integration of medical systems with telecommunication technologies, implementation and application of robots and artificial intelligence (AI) in medicine [2, 3]. Today most countries in one way or another implement e-health system in everyday medical practice [4, 5, 6], the level of trust of patients and doctors in such systems is steadily increasing [7].

The concept of mobile e-health (m-health) has emerged due to the fact that tablets or smartphones have become the most common means of communication in today's world. It includes medical practice and public health carried out using mobile devices [8, 9]. Mobile e-health is developing very rapidly because it relies on the use of devices and technologies familiar to the average user, such as smartphones, tablets, smart watches, and the Internet. Importantly, m-health technologies allow patients to remain mobile and monitor their health status in their daily lives without significant limitations. On the other hand, m-health uses cloud platforms and Edge Computing [10, 11, 12] to accumulate data, process and store them, and perform deep analysis using AI.

m-Health technologies provide many different services. These include access to public health care sites for appointments or consultations, mobile applications for monitoring medication schedules or adherence to physical activity and daily routines [13], and various applications related to the collection and analysis of data from wearable sensors [14].

Some of the services that m-health provides are various methods for analyzing the composition of food and medicines [15, 16], noninvasive blood tests [17, 18, 19], and other medical tests that are based on the use of infrared spectroscopy [20, 21, 22].

Until recently, there were no devices whose technical characteristics would allow the use of infrared spectroscopy methods under "field" conditions. Such studies were previously carried out using bulky, expensive and complex equipment exclusively by highly qualified specialists. Fortunately, thanks to rapidly developing technology and an increasing level of production [23], a number of portable wearable spectrometers are now available that allow such analyses to be performed.

The reported study was funded by RFBR, project number 19-37-90140.

These spectrometers implement the "Lab-On-A-Chip" (LoC) (or sometimes even "System-On-A-Chip" (SoC)) concept, which involves using a microchip to perform a complete biochemical analysis procedure, allowing one or more processes on one microchip using a minimum number of samples for the study [24].

An important point that determines the possibility of massive use is the cost of such devices. Of course, a device with a very high cost will not be as much in demand and widespread as one with a small cost. Today there are already examples of devices for spectrometric analysis with low cost and small size [25, 26].

The main contributions of this study are summarized as follows:

- Developed a prototype of the e-healthcare system based on molecular analysis devices for recognizing medicines in case of absence or damage to the labeling on the package.
- Implemented the interception and analysis of network traffic generated during the operation of the system was carried out and its characteristics.
- Proposed an algorithm to minimize network latency and volume of transferred data when using e-healthcare system based on molecular analysis devices.

The rest of the paper is organized as follows. Section 2 the related work. Our proposed a prototype system is presented in Section 3. Then, the Network traffic interception and characterization in Section 4. The proposed algorithm and simulation results in Sections 5 and 6. Finally, Section 7 concludes the paper.

II. Related Work

Here are a few examples of m-health devices or systems that use handheld spectrometers to analyze the composition of various substances.

For example, the authors of one paper describe the development of a smartphone-based system for accurate and reliable assessment of sulfate and chloride levels in the water. The developed system is based on the detection of the transmitted modulated signal (for spectrophotometric study) and the intensity of the scattered signal (for turbid metric study) of the liquid sample. The specially developed application allows to carry out the analysis autonomously and to display the results in a user-friendly format. The system proposed by the authors to study the composition of liquids can become a scalable platform, which after some modernization can be used to monitor other parameters of water or other liquids [27].

Another article presents a miniature and cost-effective spectrophotometer used for real-time biomarker detection. The prototype consists of a highly sensitive spectrometer embedded in a low-cost housing made using 3D printing technologies and a specially designed printed circuit board that provides processing and wireless data transmission. The results show that the portable system developed by the authors can identify the tubulin protein, which is a well-known biomarker used in diagnosing various types of cancer. The developed prototype has a small size and low power consumption [28].

One of the articles describes the using of a portable low-cost spectrophotometer for detecting nitrites in a liquid that simulate the urine of patients. This can be used in medical practice to determine the presence of a bacterial infection in the urinary tract. When developing the spectrophotometer, the authors used an ultraviolet LED of peak emission at 370 nm as a light source. A silicon pin photodiode was used as a detector of the reflected spectrum. A microcontroller was used as a platform for controlling the sensors. This spectrophotometer provides a real-time display of the result. To test the operation of the spectrophotometer, the results of its operation were compared with the results of the study using a dipstick test. In the future, the authors plan to conduct additional studies on real urine samples [29].

In another article, the authors describe a peripheral system based on the Raspberry Pi platform for processing data from the intensive care unit (ICU). The authors propose to process incoming data from medical equipment on the periphery of the network to unload the hospital's cloud platform. Medical data was modeled on the basis of the PhysioNet MIMIC III database and transferred to the edge platform for processing and detecting emergency cases. Then the data was transferred to the cloud level [30].

In another study, the authors developed a machine learning application to estimate the reflected electromagnetic spectrum in infrared spectroscopy. The use of artificial neural networks improved the recognition results compared to the previously used methods [31].

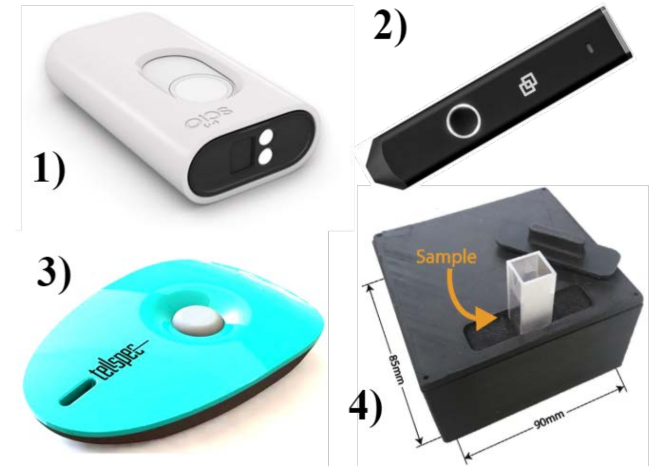
In another article, the authors review existing healthcare solutions and, as a result of their analysis, propose a new architecture for developing a dedicated e-health platform. It is assumed that such a platform will implement the Platform as a Service (PaaS) service delivery model and allow for faster development and implementation of specific medical services [10].

III. Developing a Prototype System

In this article, several handheld devices designed for infrared myrospectroscopy analysis were studied to develop a prototype m-health system. These devices are on free sale and already have a certain number of users. They are positioned by the developers as general purpose NIR spectrometers. The appearance of these spectrometers is shown in Fig. 1.

These devices are SCiO manufactured by Consumer Physics, LinkSquare manufactured by Stratio, Inc., Tellspec spectrometer manufactured by Tellspec, Inc. and a personal spectrometer developed on the basis of the open source project [26].

The devices interact with a smartphone, tablet or laptop during their operation in order to access the Internet in order to transfer data or to display the results in a user-friendly form. Let's look at the scanning process, which is about the same for these devices.



1) SCiO device, 2) LinkSquare device, 3) Tellspec device and 4) open source project

Fig. 1. Spectrometers considered in the Study.

During scanning, the infrared beam of the micro spectrometer falls on the object under study and is reflected. The energy absorption of the beam occurs at wavelengths whose energy corresponds to the excitation energies of the vibrations in the irradiated molecules. The reflected infrared beam with an altered spectrum hits the sensor of the micro spectrometer. Based on the reflected infrared spectrum, which is the wavelength dependence of the radiation intensity, the composition of the scanned substance is evaluated. Next, the data from the micro spectrometer is transmitted to a smartphone or tablet, where it is accumulated and preprocessed. After the preliminary analysis, the data from the user's smartphone is sent to a cloud server for further in-depth processing based on a database of reference spectra. The results of the analysis are transferred to the smartphone and displayed in the application in a user-friendly form.

In order to implement the m-health prototype system, an applet was developed for drug analysis using the LinkSquare NIR micro spectrometer and an AI-enabled cloud platform. The technical characteristics of the LinkSquare spectrometer are presented in Table I. The appearance of the LinkSquare spectrometer is shown in Fig. 2. The developed applet is a software module for the main application.

TABLE I. TECHNICAL CHARACTERISTICS OF THE LINKSQUARE NIR SPECTROMETER

Name	*Value*
Size (L x W x H)	114.0 x 23.9 x 23.9 mm
Weight	57g
Charging Time	< 1.5 hrs
Battery Life (Active)	~ 1000 scans
Battery Life (Idle)	24 hrs
Connectivity	Wi-Fi (802.11 b/g/n)
Wavelength	700nm - 1000nm
Data Points	600 points per scan

Fig. 2. LinkSquare NIR Spectrometer.

The developed applet should be able to recognize medicines sold in pharmacies without a prescription and issued in the form of tablets. The applet can be used by both ordinary users and medical professionals to recognize medicines in case of missing or damaged markings on the packaging, as well as to recognize counterfeit medicines.

To collect the data needed to train the neural network and create the applet, a specialized LS Collector application was installed on the laptop to collect spectrograms. The data collection in the LS Collector program is shown in Fig. 3. After that, spectrograms for different medicines were collected. The collected data was uploaded to the cloud platform to train the neural network and create an applet. Next the neural network was trained based on the collected spectrograms. The number of training iterations was 10 000.

Next, the developed applet was installed through the platform Google Play on a smart phone running the Android operating system, after which it was tested. The main technical characteristics of the LinkSquare application and the developed applet are presented in Table II.

The test consisted of scanning and recognizing a random sample of the drug. For this purpose, medicines were used in the form of tablets without packaging. The results were repeated many times and statistically processed. The probability of successful recognition was 93 percent.

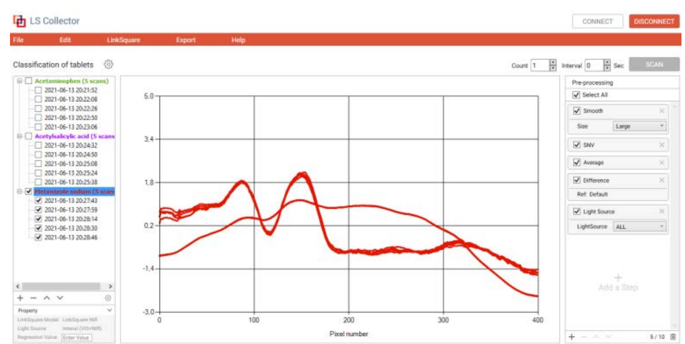


Fig. 3. Spectra samples Collection of various drugs for further processing

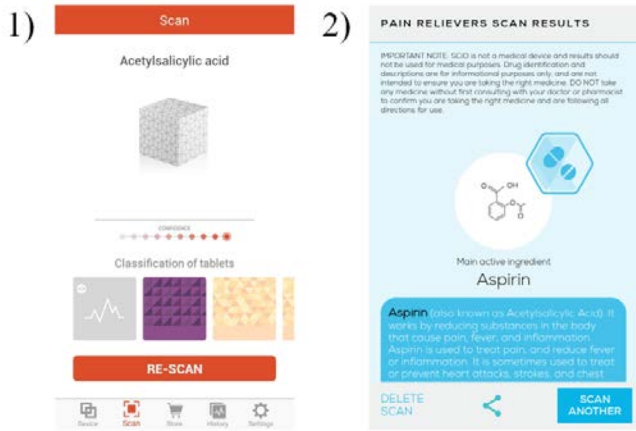
TABLE II. THE MAIN TECHNICAL CHARACTERISTICS OF THE LINKSQUARE APPLICATION AND THE DEVELOPED APPLET

Name	*Value*
Supported Platform	iOS 10.0 or above Android 5.0 or above
The size of the main LinkSquare application	94 Mb
The size of the developed applet	9 Mb
The number of iterations in the machine learning process	10 000
Probability of successful recognition	0,93

The Fig. 4 shows the result of the analysis and the appearance of the developed applet, as well as a comparison with a similar applet for the SCiO spectrometer.



(1) Developed Applet for LinkSquare, (2) Similar Applet for the SCiO Spectrometer.

Fig. 4. The appearance of the GUI of the created applet and the SCiO applet

Testing of the applet to verify its performance was carried out based on the developed m-health prototype system, the structure of which is presented in Fig. 5. The prototype simulates a scenario of micro spectrometer application in everyday life to analyze the composition of medicines.

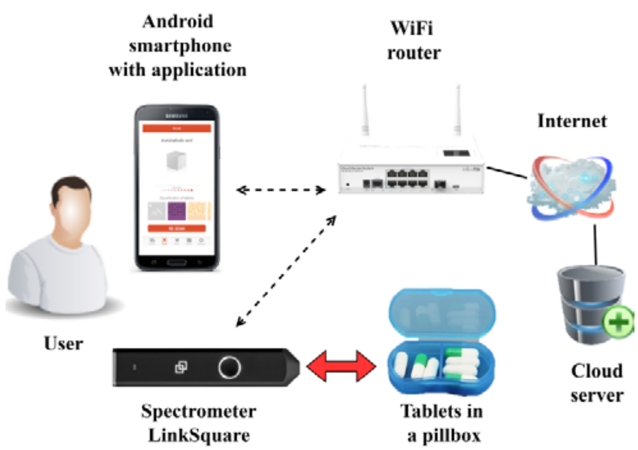


Fig. 5. Network Prototype.

IV. Network Traffic Interception and Characterization

The developed prototype was used to capture and analyze the IP network traffic generated by the m-health system. The traffic characteristics are presented in Table III.

The presented results were calculated with a confidence probability of 90%.

This is to assess traffic characteristics in detail and use them to further model the molecular analysis service delivery process using the m-health system. Such traffic and messaging algorithms may differ from those typical of the Internet [32], and a better understanding of the characteristics of m-health systems will solve existing problems and accelerate the development and diffusion of m-health in the future [33, 34].

TABLE III. Characteristics of the Network Traffic Generated during the Provision of the m-Health Service

Network traffic characteristics	***Sent by the spectrometer***	***Sent by the server***
The size of the sample (packets), n	5436	5510
The size of the sample (packets) per scan, n	34,3±0,57	29,05±1,05
Average packet length, bytes	1257,40±8,41	58,60±0,41
Packet receiving rate, packets/s	1,21±0,02	1,23±0,02
Packet receiving intensity, Kbit/s	11,87±0,22	0,56±0,22

To capture network traffic, the PCAP Remote mobile app was installed on the smartphone, which was used to capture and store network traffic. The traffic was then transferred to a laptop with WireShark traffic analyzer software for further study and evaluation of its characteristics.

In [12, 32], the following sequence of steps was described for an Internet-based real-time NIR spectrometer molecular analysis procedure, which is shown in Fig. 6.

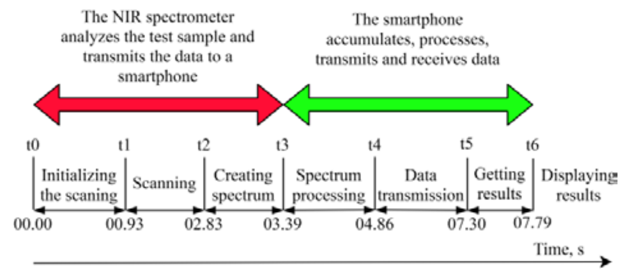

Fig. 6. The Sequence of Operations when using the m-Health System.

Obviously, in order to improve the quality of the m-health service, it is necessary to reduce the latency of the service. However, since we cannot influence the scanning speed of the spectrometer itself, we will further consider the delay associated with the accumulation, processing, transmission and reception of data by the smart phone.

V. Proposed Algorithm

After a detailed study of the operating principles and traffic analysis of m-health systems that use portable infrared micro spectrometers to analyze the composition of food and medicines, the following improved algorithm for the service was proposed. The algorithm is shown in Fig. 7.

A distinctive feature of this algorithm is the preprocessing of the data received from the spectrometer in order to compare it with a predetermined template. The template is selected depending on the applet used. The preprocessing allows you to discard data resulting from false positives and scanning errors. Thus, erroneous data is not transmitted over the Internet to a remote server for processing, which on the one hand reduces the amount of traffic transmitted, and on the other hand, discarding erroneous data allows the system to free up more quickly for the next scan.

Another distinctive feature is the presence of a buffer that accumulates data until its volume approaches the value of the maximum transmission unit (MTU), which reduces the number of transmitted packets and slightly increases the data transmission delay.

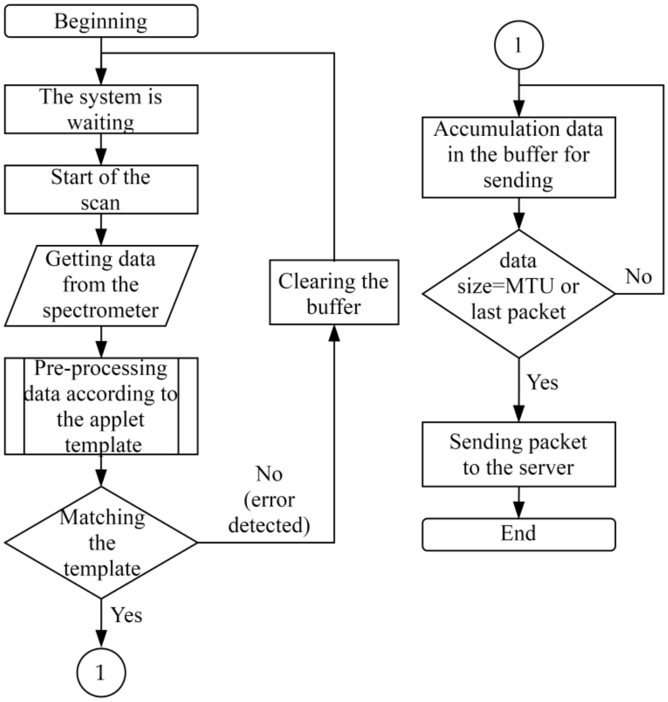

Fig. 7. Proposed Algorithm.

We should also consider the possibility of processing data not on a remote cloud server, but using Edge Computing technologies to reduce network latency and provide a higher level of m-health services [35, 36].

VI. Simulation Model

To verify the effectiveness of the above algorithm, a simulation models were developed in AnyLogic software. These models allows the simulation of both the basic scenario of service provision, as well as allows the simulation to take into account the features of the above-proposed algorithm and numerically assess the difference in the distribution of accumulation, processing and data transmission times in the process of providing m-health service using the NIR spectrometer and the volume of data transmitted for different scenarios. These are the basic scenario, the scenario with preprocessing (error checking), the scenario with buffering, and the scenario using Edge Computing.

The graph in Fig. 8 shows the distribution of the delay time associated with the accumulation, processing, transmission and reception of data in the basic scenario. It does not use any improvements, such as preprocessing (error checking) or Edge Computing. The simulation results are quite exactly the same as the results of the created network prototype.

The resulting distribution can be described with sufficient accuracy by an exponential distribution with a probability density

$$f_1(t) = \lambda e^{-\lambda t} \tag{1}$$

where λ is the intensity of service (served attempts).

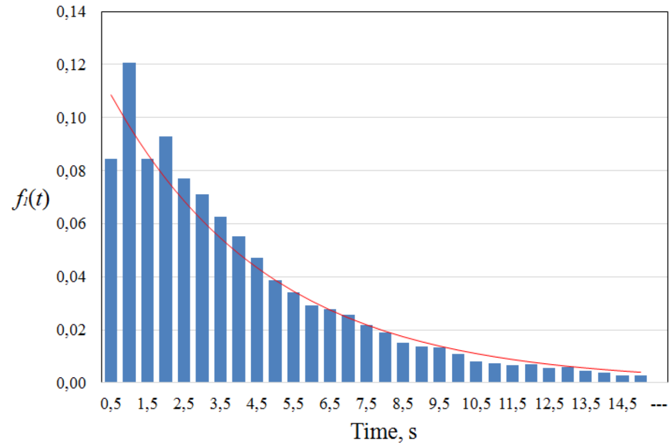

Fig. 8. Distribution of the Delay Time Associated with the Accumulation, Processing, Transmission and Reception of Data in the basic Scenario.

The graph in Fig. 9 shows the distribution of the delay time associated with the accumulation, processing, transmission and reception of data in a scenario with preprocessing (error checking). In this scenario, the delay reduction is achieved through preprocessing, which ensures that false scans are discarded even on the smart phone and the e-healthcare system is quickly released for subsequent work.

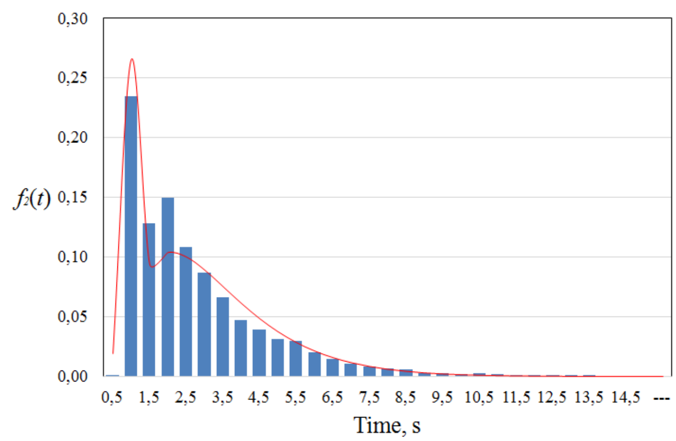

Fig. 9. Distribution of the Delay Time Associated with the Accumulation, Processing, Transmission and Reception of Data in the Scenario with Preprocessing (Error Checking).

This distribution is difficult to describe with a single function. We described it as a mixed distribution based on the assumption that this process can be represented as an aggregation of two independent processes. In this case, the probability density can be expressed as the weighted sum of the probability densities of two distributions.

$$f_2(t) = \eta_1 g_1(t) + \eta_2 g_2(t) \tag{2}$$

where η_1 and η_2 are weight coefficients, g_1 and g_2 are probability density functions (pdf).

$$g_1(t) = \eta_1 \delta(t) \tag{3}$$

where $\delta(t)$ – Dirac delta function.

$$g_2(t) = \begin{cases} \dfrac{t^{k-1}}{\theta^k \Gamma(k)} e^{-\frac{t}{\theta}}, & t \geq 0 \\ 0 & t < 0 \end{cases} \quad (4)$$

$g_2(t)$ – presents the Gamma distribution.

The graph in Fig. 10 shows the distribution of the delay time associated with the accumulation, processing, transmission and reception of data in a scenario with preprocessing (error checking), buffering and Edge Computing. In this scenario, the delay reduction is achieved through preprocessing, which ensures that false scans are discarded and the e-healthcare system is quickly released for subsequent work, as well as by processing data not on a remote cloud server, but using Edge Computing.

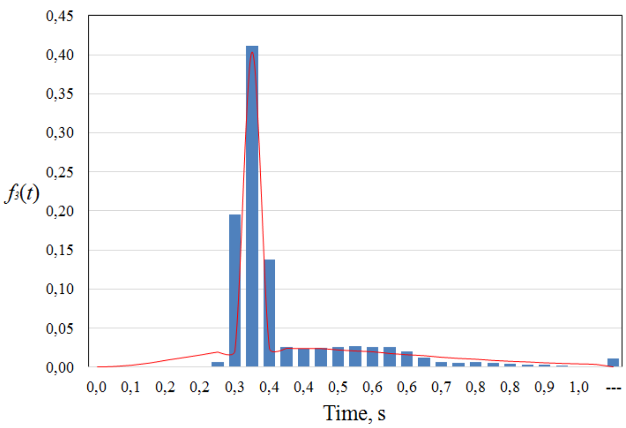

Fig. 10. Distribution of the Delay Time Associated with the Accumulation, Processing, Transmission and Reception of Data in the Scenario with Preprocessing (Error Checking) and Buffering and Edge Computing.

We described this distribution in a similar way using a mixed distribution with the difference that two Gamma distributions were chosen as terms.

$$f_3(t) = \eta_1 g_1(t) + \eta_2 g_2(t) \quad (5)$$

where η_1 and η_2 are weight coefficients, g_1 and g_2 are pdf functions.

$$g_2(t) = \begin{cases} \dfrac{t^{k-1}}{\theta^k \Gamma(k)} e^{-\frac{t}{\theta}}, & t \geq 0 \\ 0 & t < 0 \end{cases} \quad (6)$$

where $g_2(t)$ – presents the Gamma distribution.

Generalized results of modeling the distribution of time of service provision are presented in the Table IV.

The presented results were calculated with a confidence probability of 90%.

From the simulation results presented in Table IV, the use of preprocessing (error checking), buffering of data received from the spectrometer, and the use of Edge Computing for local data processing can significantly reduce the delay time associated with the accumulation, processing, transmission and reception of data.

TABLE IV. AVERAGE DELAY TIME

№	*Scenario type*	*Average service delivery time, s*
1	Basic scenario	4,354±3,923
2	Preprocessing (error checking)	2,543±1,860
3	Preprocessing (error checking) and buffering and Edge Computing	0,374±0,128

The graph in Fig. 11 shows the dependence of the amount of data transmitted in megabytes on the number of scans. As can be seen from the graph, the use of preprocessing (error checking) allows you to reduce the amount of data transmitted by discarding the spectra obtained as a result of erroneous or accidental (unintentional) scanning when using the e-healthcare system. Buffering reduces the number of transmitted IP packets, and therefore the amount of service information (headers), which reduces the total number of transmitted data.

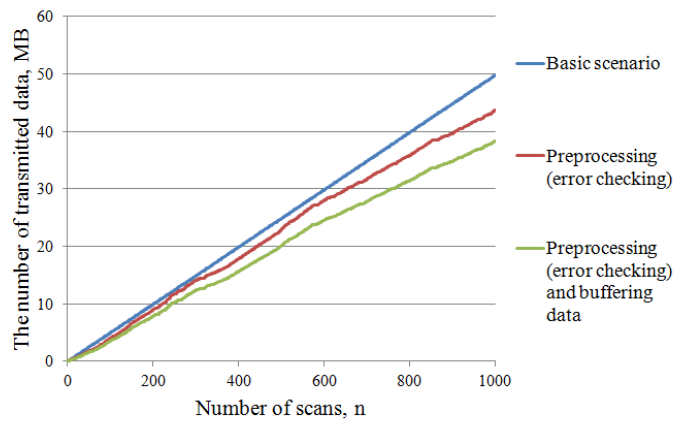

Fig. 11. Dependence of the Volume of Transmitted Data on the Number of Scans.

The resulting dependences can be described quite accurately by straight lines.

$$v(n) = a_i n \quad (7)$$

where a_i – is the corresponding slope ratio.

VII. CONCLUSION

In this paper, analyzes the use of infrared microspectrometers used for e-health and m-health systems and highlights the main promising areas of their use. In particular, m-health applet was developed using a cloud platform and AI, where this applet is designed to be installed on a smart phone or tablet under the Android operating system as part of the main application. Moreover, it is capable of analyzing the composition of medicines in the form of tablets, which can be useful in cases where there is no packaging for the specified drug or the label is damaged, as well as to recognize counterfeit medicines. Further, an efficient m-health prototype system was developed to test the created application, which includes a portable NIR spectrometer, a smartphone, a WiFi router for Internet access and a remote cloud platform for data processing. Afterward, based on the prototype developed, the network traffic generated in the analysis process was intercepted and analyzed to further evaluate its characteristics and develop models for m-health service delivery. At the same time, a group of models was developed to test Quality of Service (QoS) solutions for providing molecular analysis service using NIR spectrometers and the Internet and based on the intercepted traffic. Finally, AnyLogic simulation environment is utilized to perform the simulation, where four different sceneries are implemented, namely basic scenario, the scenario with preprocessing (error checking), the scenario with buffering, and the scenario using Edge Computing. Additionally, the average service time and the amount of data transferred were compared for each scenario. Simulation results show that preprocessing (error checking), data buffering, and Edge Computing can significantly reduce the network latency and volume of transferred data.

MNN and LSTM-based Real-time State of Charge Estimation of Lithium-ion Batteries using a Vehicle Driving Simulator

Si Jin Kim, Jong Hyun Lee, Dong Hun Wang, In Soo Lee*
School of Electronic and Electrical Engineering
Kyungpook National University, Daegu 41566, Korea

***Abstract*—Lithium-ion batteries (a type of secondary battery) are now used as a power source in many applications due to their high energy density, low self-discharge rates, and ability to store long-term energy. However, overcharging is inevitable due to frequent charging and discharging of these batteries. This may result in property damage caused by system shutdown, accident, or explosion. Therefore, reliable and efficient use requires accurate prediction of the battery state of charge (SOC). In this paper, a method of estimating SOC using vehicle simulator operation is proposed. After manufacturing the simulator for the battery discharge experiment, voltage, current, and discharge-time data were collected. The collected data was used as input parameters for multilayer neural network (MNN) and recurrent neural network–based long short-term memory (LSTM) to predict SOC of batteries and compare errors. In addition, discharge experiments and SOC estimates were performed in real time using the developed MNN and LSTM surrogate models.**

Keywords—Lithium-ion battery; state of charge; multilayer neural network; long short-term memory; vehicle driving simulator; real time

I. Introduction

With the recent occurrence of energy depletion and environmental pollution, research on eco-friendly and efficient energy sources is underway [1]. Recent developments in lithium-ion (Li-ion) batteries have yielded large energy density batteries with very low power losses (due to self-discharge) and longer life spans, making them the primary source of power for various electronic devices [2]. Secondary batteries, such as Li-ion batteries, also provide economic and environmental advantages over primary batteries used once and discarded. However, due to the nature of secondary battery operations (frequent charging and discharging), overcharging is a likely occurrence, in which case the electronic device may be shut down or risk an explosion [3]. Accurate identification and management of battery conditions are essential to solving these problems and ensuring efficient optimal usage and stability. A battery management system (BMS) helps manage energy efficiently and reliably when using secondary batteries. Related research has been recently undertaken as Li-ion battery applications continue to increase [4]. One of the parameters used in a BMS is the state of charge (SOC), an indicator of the remaining capacity of a battery, with 100% representing full capacity and 0% representing no capacity. It can also represent the state of health and the output performance of the battery [5]. Therefore, accurate prediction of SOC can help device users achieve better efficiency and reliability.

Methods for estimating SOC include open-circuit voltage (OCV), current calculation, and artificial neural network models. OCV is a method of estimating SOC by measuring voltages in open circuits where no current flows. However, it is difficult to achieve a real-time SOC estimation with this method due to the long stabilization time needed to attain equilibrium for accurate measurement [6]. The current accumulation method is easy to implement by randomly setting the initial SOC and then charging and discharging the battery to calculate the amount of change in the current. However, if the initial SOC setting deviates considerably from the expected value, the SOC error accumulates, making it difficult to estimate SOC accurately [7]. In this paper, The SOC was estimated using artificial neural networks. Artificial neural networks are implemented based on human brain structures and are used in various fields, such as pattern recognition, identification, and classification, and can efficiently learn the relationships between input and output parameters [8]. A battery SOC estimation using artificial neural networks does not require consideration of the battery's internal electrical and chemical properties. This method is advantageous for estimating nonlinear models and can operate on low-specification processors [9][10]. The artificial neural networks used in this paper are a multilayer neural network (MNN) and a recurrent neural network (RNN)-based long short-term memory (LSTM). An RNN is a neural network in which the previous learning information (history) influences the current learning [11]. It is structured in a chain format and is advantageous for predicting time-series data. However, as the amount of data increases, a gradient loss problem occurs; hence, an LSTM was employed to eliminate this challenge [12].

In this paper, a vehicle driving simulator has been built to estimate the SOC of Li-ion batteries based on the actual vehicle's output. After completing the production of the vehicle driving simulator, a Highway Fuel Economy Test (HWFET), a vehicle fuel efficiency test mode used by the U.S. Environmental Protection Agency, was applied to the motor driver in the simulator. Voltage, current, and discharge time data for the battery were collected according to the output of the simulator. The values were verified in real time and used as input parameters in the MNN and the LSTM for estimating the SOC.

*Corresponding Author

The composition of this paper is as follows. Section 2 describes the internal configuration and fabrication process of the vehicle driving simulator used in the battery discharge experiment. Section 3 introduces the proposed SOC estimation algorithm; MNN, one of the types of artificial neural networks used in this paper; and RNN-based LSTMs, and describes learning methods for SOC estimation. Section 4 describes the experimental process of the proposed algorithm, the number of input parameters, and the results of SOC estimation according to the MNN and the RNN used. Finally, Section 5 describes the conclusions of this study and plans for future studies.

II. Vehicle Driving Simulator

In this paper, a vehicle driving simulator has been created to determine the SOC change of the battery due to the actual vehicle output. The composition of the simulator is shown in Fig. 1.

The simulator is a two-wheel-drive vehicle consisting of a remote control (RC) car frame, four tires, two DC motors (rated voltage 12V and 6000 RPM), one motor driver (MDD3A), one Arduino pro-mini module, and one D.C. converter. The motor driver and Arduino pro-mini modules are devices designed to control the revolutions per minute (RPM) of the motor to be implemented according to the HWFET. It was applied as the driving cycle of the discharge experiment simulation, with the D.C. converter continuously adjusting the input voltage to the motor rated voltage of 12V. The HWFET, defined by the U.S. Environmental Protection Agency, is a test cycle to measure the fuel efficiency on a highway, as shown in Fig. 2.

Hyundai Motor's Avante Sports A.D. 16 model and 255/40/18 (cross-section width, flat ratio, wheel size) tire specifications were set as models to simulate precisely the actual vehicle speed. The motor's output in the simulator was controlled by the proposed motor driver for the HWFET after calculating the speed of the actual vehicle using the third gear ratio, tire specifications, and the motor RPM of the simulator. Fig. 3 shows a photograph of the built vehicle driving simulator. The simulator was fixed using steel frames and MC nylon board to prevent the simulator from moving or losing its balance due to motor vibration during the discharge experiment simulation.

III. SOC Estimation Algorithm using the Proposed Neural Networks

A. Battery SOC Estimation Method

This paper proposes a method to estimate the SOC of a battery using a vehicle driving simulator, MNN, and LSTM. Fig. 4 illustrates the proposed battery SOC estimation algorithm. First, four fully charged batteries are connected in series and used as input voltage for the simulator. Next, the discharge experiment was conducted using a vehicle driving simulator. After the discharge experiment was completed, the measured voltage, current, and discharge-time data were sent to a PC using voltage and current sensors and the Arduino modules. After processing the transmitted data with different numbers of input parameters, Four MNN and LSTM models were developed respectively to estimate the SOC of each battery.

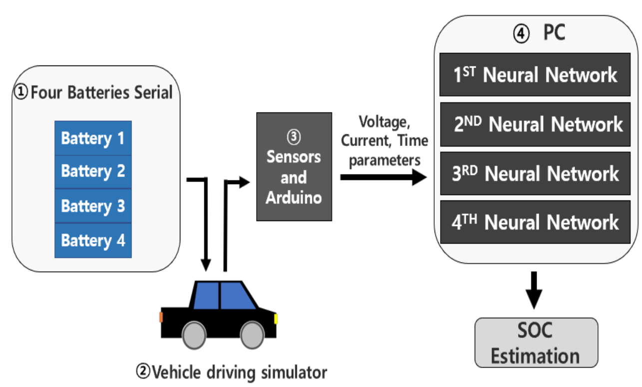

Fig. 4. SOC Estimation Diagram of Batteries using Artificial Neural Networks and a Vehicle Driving Simulator.

B. Multilayer Neural Network

A MNN compensates for the shortcomings of perceptrons, which can only be learned limitedly because they consist only of linear functions, by adding one or more hidden layers between the input and output layers in the tomographic perceptrons. The MNN is shown in Fig. 5.

Single-layer perceptrons use the feedforward method to update weights. In MNN, feedforward and backpropagation are used, unlike a single-layer perceptron. Feedforward updates weights in the direction of the output layer at the input layer, but backpropagation is a method of reducing the error by updating weights in the direction of the input layer at the output layer. Backpropagation is divided into four stages; calculate output values using existing weights as a first step. Then, in two steps, a partial value of the error of each weight is subtracted from the existing weight. The next three steps are stage 2 for all weights. Finally, steps 1 through 3 are repeated for the given number of lessons. Fig. 6 illustrates the concept of a backpropagation [13]. Due to these MNN learning methods, they can be expressed more complexly than single-layer perceptrons and are also advantageous for classification and numerical prediction.

The process of updating the weights of the backpropagation is shown in (1) through (5). First, the input and output values used to calculate net radio waves can be obtained from the following expressions.

$$net_j = \sum_i w_{ij} X_i \tag{1}$$

$$(X_j = f(net_j + \theta_j) \tag{2}$$

where net_j is the input value of the node j, w_{ij} is the weight of the i-th node entering the j-th node, $f(net_j + \theta_j)$ is the activation function, X_i, X_j is the output value of the previous node entering the *i* and *j* nodes, and θ is the input bias value. When updating weights with errors, the required values can be obtained in the following expressions:

$$\delta_i = \lambda(l_i - X_i) f'(X_i) \tag{3}$$

$$\delta_j = \lambda \sum_i \delta_i w_{ji} f'(X_j) \tag{4}$$

where *l* is the label value and *X* is the output value. Weights can be updated using the above obtained δ.

$$w_{ji}(t+1) = w_{ji}(t) + \eta \delta_j y_i \tag{5}$$

where *t* is the time index and η is the learning rate.

C. Long Short-Term Memoryn

The LSTM is an RNN-based neural network developed to improve the gradient loss problem as the distance between the learning data increases. Fig. 7 shows the structure of an LSTM, consisting of three gates and one cell state.

Equations (6)–(11) describe the process of the LSTM operation. First, the forget gate uses sigmoid functions to keep or discard previous and current learning data while the input gate stores the values to be updated in the cell state using the sigmoid and other activation functions. It then updates the cell state by adding the resulting values of the forget gate and input gate. Finally, the output gate determines the final output value by multiplying the current and previous data with the value from the sigmoid function, the value obtained by the cell state, and the value obtained using the activation function [14].

$$f_t = \sigma(w_f \cdot [h_{t-1}, x_t]) + b_f \tag{6}$$

$$i_t = \sigma(i \cdot [h_{t-1}, x_t]) + b_i \tag{7}$$

$$\tilde{C}_t = tanh(w_C \cdot [h_{t-1}, x_t]) + b_C \tag{8}$$

$$C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \tag{9}$$

$$O_t = \sigma(w_O \cdot [h_{t-1}, x_t]) + b_O \tag{10}$$

$$h_t = O_t \cdot \tanh(C_t) \tag{11}$$

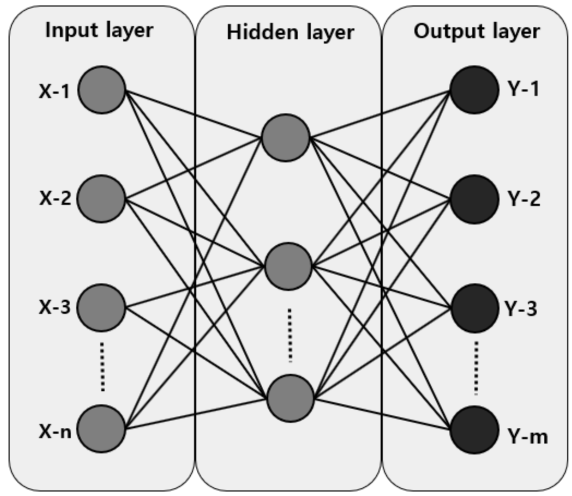

Fig. 5. Structure of the Multilayer Neural Network.

where h_{t-1} is the previous data, x_t is the current data, w and b are the weights and biases, f_t is the value of the previous and current data, i_t and $\tilde{C}_t$ are the values of the sigmoid and the activation functions, C_t is the updated value of the cell state, O_t is the value of the output gate, and h_t is the final output value.

IV. Experimental Process and Result

A. Experimental Process

In this research, a battery discharge experiment was conducted using a vehicle driving simulator. The equipment used in the discharge experiment included four Li-ion batteries (rated capacity 1300 mAh), a power supply, a battery chamber (to ensure fire safety due to the strong reactivity of lithium ions [15]), a vehicle driving simulator, voltage and current sensors, and an Arduino module. Fig. 8 shows the equipment used for the discharge experiment and the experimental environment.

The battery charging and discharging experiments were conducted by connecting the four batteries in series. As expected in series connections, the same amount of current flows through each circuit. However, frequent charging and discharging may result in charge imbalances depending on the electrical and chemical characteristics of the battery and the battery operating environment [16]. Therefore, this experiment used a cell balancing module to equalize the voltage of the four batteries during charging and discharging. The sequence of experiments for estimating each battery's SOC is as follows: First, by defining a SOC of 100% (full capacity), the four batteries were fully charged at constant voltages of 4.2 volts via a power supply. Next, the batteries were kept for a stabilization period of about an hour to overcome charge imbalances. The discharge experiment was then conducted using the four batteries as input voltages for the vehicle driving simulator. Fig. 9 shows a voltage graph of changes during one cycle discharge experiment for each battery. The x-axis is the number of samples, and the y-axis is the voltage of each battery. The number of samples per cycle is between 2000 and 2200. One cycle of the discharge experiment is defined as from the beginning of the discharge experiment to the point when some of the four batteries are discharged and the vehicle driving simulator is shut down. The above steps were then repeated to obtain the voltage, current, and discharge-time data for 10 cycles. The discharge-time data used in this experiment is time data that accumulates from the beginning to the end of the discharge experiment.

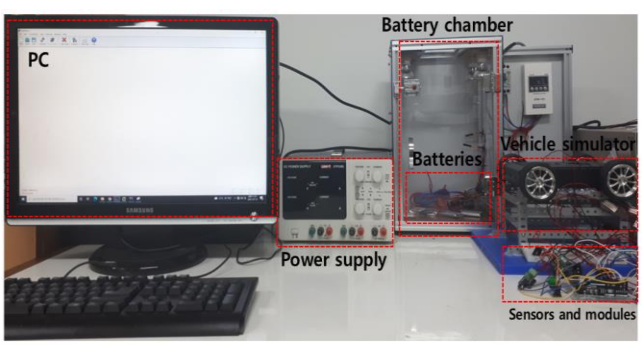

Fig. 8. Experimental Environment and Equipment.

(d)Discharge Graph of Battery 4.

Fig. 9. Cycle Discharge Experiment Voltage Graph for (a) Battery 1, (b) Battery 2, (c) Battery 3, and (d) Battery 4.

These data were later transferred to a PC and then used as input parameters for the MNN and LSTM to estimate the SOC of each battery (Python, TensorFlow, and Keras package were used for learning). To obtain the SOC to be used as the training label for the MNN and LSTM, four fully discharged batteries were charged individually and then any initial SOC was specified. The current data acquired by the discharge experiment are then computed using the current calculation method. The current calculation method is presented as

$$\mathrm{SOC(t)} = \mathrm{SOC(0)} - \int_0^t \frac{I(t)}{C_n} dt \qquad (12)$$

Where SOC(t) stands for SOC at time t, I(t) stands for current at time t, SOC(0) stands for initial SOC, and C stands for battery rated capacity.

Using MNN and LSTM, four models were developed that use different input parameters. The learning structure of MNN and LSTM used in this document is shown in Fig. 10 and 11.

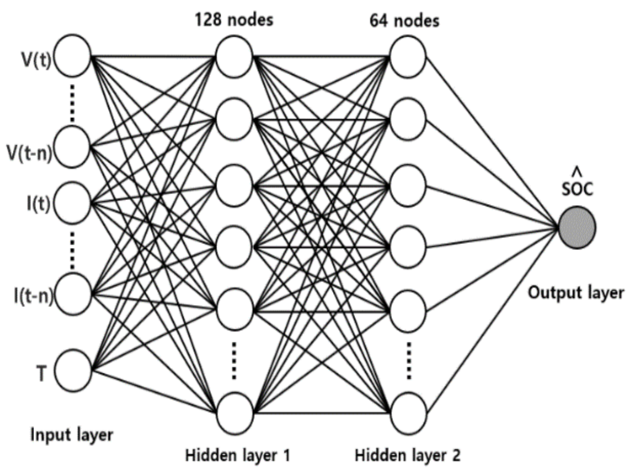

Fig. 10. Structure of the used MNN Models.

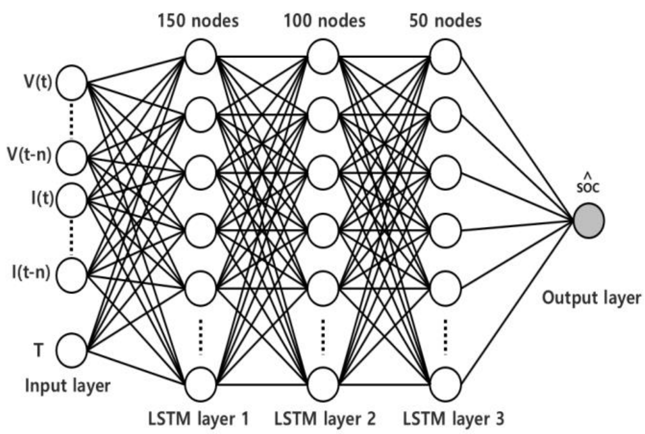

Fig. 11. Structure of the used LSTM Models.

One discharge time data was added to each of the four MNN models and four LSTM models constructed using 2, 3, 4, and 5 values for voltage (V) and current (I) data. In Fig. 10 and 11, the input parameter (T) represents the time from the beginning to the end of the discharge experiment, and voltage and current data are sampled once every two seconds of the discharge experiment. The four MNN models all have the same hidden layer structure, consisting of two layers. The first node count was 128, the second node count was 64, and the sigmoid was used as an activation function. There was one node in the output layer and the model was trained using 15000 epochs. The four LSTM models all have the same hidden layer structure, consisting of three LSTM layers. The first node count was 150, the second node count was 100, the third node count was 50, and the sigmoid was used as an activation function. There was one node in the output layer and the model was trained using 5000 epochs.

B. *Experimental Result*

In this paper, The SOC was estimated by adding different numbers of voltage and current data and one discharge-time parameter to MNN and LSTM. The SOC errors of each estimated battery using MNN are presented in Table I and Fig. 12. The models were named according to the number of input parameters employed: 5-input (two voltages, two currents, one discharge time), 7-input (three voltages, three currents, one discharge time), 9-input (four voltages, four currents, one discharge time), and 11-input (five voltages, five currents, and one discharge time). Each battery's error function was estimated using the mean absolute error (MAE) and is given as

$$\mathrm{MAE} = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}| \tag{13}$$

where n is the number of data to be calculated, y is the estimated value of SOC, and $\hat{y}$ is the predicted value using the current loading method and MNN or LSTM.

The SOC error estimated by the 5-input model showed that all four batteries had errors between 1% and 2%. The SOC error of the 9-input and 11-input models resulted in less than 1% errors on some batteries. The SOC error of the 11-input model is relatively smaller than that of the other models. The least estimated error (0.83%) among the four models was Battery 3 on the 9-input model. Consequently, the SOC estimation performance of 9 and 11 input models is considered to be superior to that of other models. The SOC error of each estimated battery using LSTM is presented in Table II and Fig. 13.

TABLE I. SOC ESTIMATION ERROR USING MNN MODELS

	Battery1	**Battery2**	**Battery3**	**Battery4**
5-input	1.68%	1.71%	1.41%	1.54%
7-input	1.31%	1.52%	1.02%	1.15%
9-input	1.35%	1.31%	0.83%	1.01%
11-input	0.95%	1.07%	0.89%	1.1%

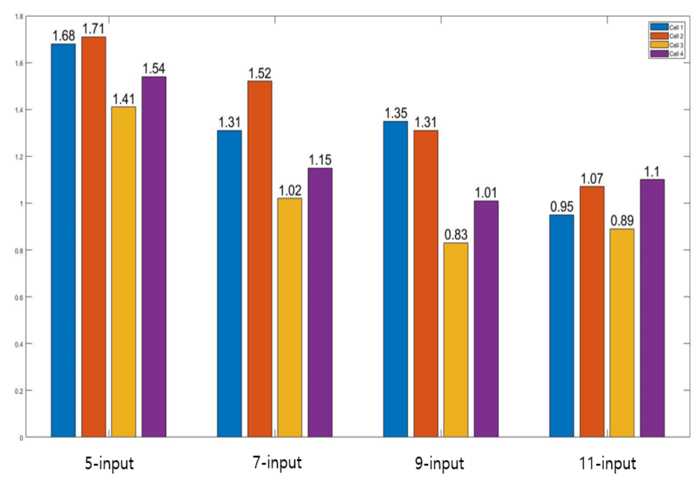

Fig. 12. SOC Estimation Error Graph using MNN Models.

TABLE II. SOC ESTIMATION ERROR USING LSTM MODELS

	Battery1	**Battery2**	**Battery3**	**Battery4**
5-input	1.6%	1.83%	1.82%	1.69%
7-input	0.82%	0.89%	0.8%	0.85%
9-input	0.65%	1.18%	0.76%	0.88%
11-input	0.61%	1.02%	0.73%	0.78%

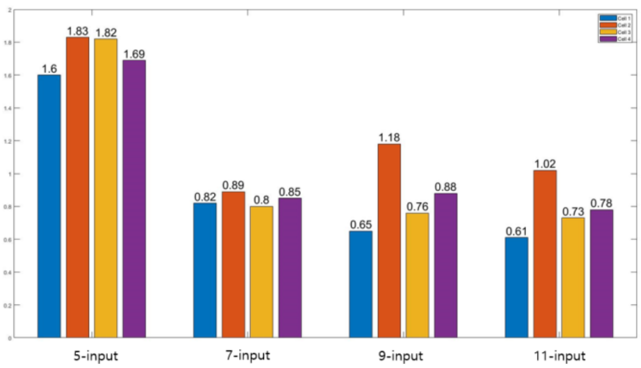

Fig. 13. SOC Estimation Error Graph using LSTM Models.

The SOC error estimated by the all models showed that all had errors below 2%. The SOC error of the 7~11-input models resulted in less than 1% errors on some batteries. The SOC error of the 11-input model is relatively smaller than that of the other models. The least error (0.61%) was Battery 1 on the 11-input model. Consequently, it is judged that the SOC estimation performance of 11 input models is superior to that of other models. Figs. 14 through 17 graph the SOC estimation results of the MNN models and LSTM models (Estimated Result of Battery 1). “Estimation” label and “Calculation” label in Fig. 14, 15, 16 and 17 show estimated values using artificial neural networks and SOC label values obtained using current integration, respectively.

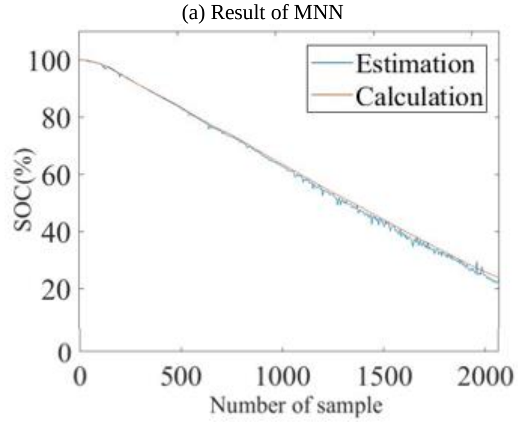
(a) Result of MNN



(b) Result of LSTM

Fig. 17. SOC Estimation Result of 11-Input Model for (a) MNN and (b) LSTM.

Using the LSTM in Table II, the estimated error of MNN in Table I was compared, and the estimated error of MNN in 5-input model was relatively small compared to LSTM. However, in other models with 7 to 11 inputs, LSTM's estimation performance can be determined to be superior to MNNs because the estimation error of LSTM was small.

According to Chemali et al. [17], the results obtained using LSTM showed an error of 0.573% at a fixed temperature of 10℃. The model with the smallest error in this paper was the LSTM 11-input model, with a SOC error of 0.61% for Battery 1, which was larger than that of Chemali et al. However, in the work by Chemali et al., the error in an environment with ambient temperature of 25℃ was 0.774%, indicating that the error in this work was smaller.

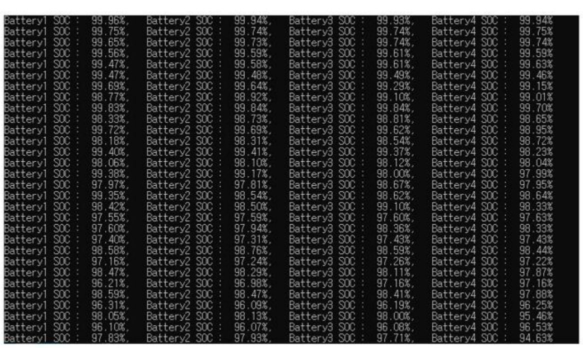


Fig. 18. SOC Estimation Display a LSTM Model.

Discharge experiments using the LSTM models in this work for SOC prediction in battery SOC estimation were made in real time. Fig. 18 shows a screen that uses the LSTM model to make real-time estimates. Real-time estimates were made using 7 inputs and 9 inputs, with the estimation errors shown in Table III.

TABLE III. REAL-TIME ESTIMATION ERROR WITH LSTM MODEL

	Battery 1	**Battery 2**	**Battery 3**	**Battery 4**
7-input	1.79%	2.63%	1.9%	2.25%
9-input	1.79%	1.23%	2.07%	1.88%

The estimation results show that the error in real-time estimation is relatively higher than that shown in Table III. It is judged that the error increased due to the influence of noise generated during real-time estimation. However, it was confirmed that real-time SOC evaluation using the learning model is possible.

V. CONCLUSION

In this study, we built a vehicle driving simulator to monitor changes in battery SOC when driving an actual vehicle and then applied the HWFET (cycle mode) to conduct discharge experiments. The SOC was estimated based on the obtained voltage, current, and discharge-time data using the vehicle driving simulator. We used that data as input parameters for the MNN and LSTM. We used four MNN and four LSTM models and compared the estimation errors of each model by adding two, three, four, or five voltages and currents and one discharge-time parameter. The SOC error of the four MNN models was less than 2%. Among the MNN models, the 9-input and 11-input models have errors of less than 1% in some batteries. The SOC estimation results of the LSTM model showed an estimation error of less than 2% for all four models and an overall error of less than 1% for the 7-input model and 11-input model. Estimation results from both MNN and LSTM show that the estimation error of the 11-input model is small compared to other models. Moreover, the SOC error results of LSTM were relatively small compared to MNN except for the 5-input model. Therefore, it was determined that the SOC estimation performance of LSTM was superior to that of MNN. Discharge experiments were conducted in real time using the 7-input LSTM model and 9-input LSTM model that were established for SOC estimation and SOC was estimated.

The discharge experiment was conducted using Li-ion batteries as input voltages for the vehicle driving simulators by checking and acquiring voltage and current data variations, which were expected to be applicable when driving an actual vehicle.

Further studies will consider conducting a discharge experiment by applying another driving cycle test, the Federal Test Procedure 75 (FTP-75) for city driving test used by the U.S. Environmental Protection Agency, to the vehicle driving simulators. The data obtained through the discharge experiments would be used as input parameters for MNN and LSTM to compare the SOC estimation and errors.

***Abstract*—Non-negative matrix factorization-based audio source separation separating a target source has shown significant performance improvement when the spectral bases attained after factorization exhibits latent structures in the mixed audio signal comprising multiple speaker sources. If all the sources are known, the spectral bases may be inferred on priority by using a training process on the database of isolated sources. The number of bases inferred for a source should not include bases matching spectral patterns of the interfering sources in the audio mixture; otherwise, the estimated target source after separation will be incorporated with undesirable spectral patterns. It is difficult to distinguish and separate similar audio sources in an overlapped speech, leading to a complex speech processing task. Therefore, this research attempts to learn an optimum number of bases for Indian languages leading to successful separation of target source in multi-lingual multiple speaker speech mixtures using non-negative matrix factorization. The languages used for utterances are Hindi, Marathi, Gujarati, and Bengali. The speaker combinations used are female-female, male-male, and female-male. The optimum number of bases which was determined by evaluating improvement in the separation performance was found to be 40 for all the languages considered.**

Keywords—Indian languages; optimum number of bases; non-negative matrix factorization; speech separation

I. Introduction

Separating audio source signals from a monaural recording is a complex problem. This problem is aggravated if the audio sources in the recording are overlapped with each other and are similar. A successful solution to these problems is compositional models, where the magnitude spectra of an audio signal can be decomposed into a linear combination of “spectral bases”. Therefore, the bases for all the sources comprising the mixture combine linearly to constitute the magnitude spectra of the mixed audio signals. This leads to the fact that optimum estimation of the contribution made by the bases of a particular source to the mixed signal will help separate the said source.

Lee & Seung demonstrated non-negative matrix factorization (NMF) as a method that learns to represent a face as a linear combination of its “basis images”. According to them, the basis images are local features corresponding to the parts of faces [1], [2]. The data matrix, in this case, is a non-negative image database which is NMF decomposed into two non-negative matrices, the part of the faces and their weights such that the original data matrix is approximated by their product.

The different domain using NMF expresses the columns of M (the data matrix) in terms of positively weighted sums of the columns of B (the parts or the basis vectors). Table I shows some examples of relations between the data matrix and the basis vectors or bases for some domains.

Apart from the above examples, this model became phenomenally successful as an audio source separation algorithm. It usually decomposes the spectrogram of an audio mixed-signal (M) into several “spectral bases” (B) and “temporal weights or activations” (A).

When the original data is corrupted, i.e., an audio signal is interfered with by simultaneous speakers and noise, NMF methods fail to learn an effective subspace or basis function matrix from the original data space or data matrix. In such cases, the basis functions matrix is populated with trained bases obtained by NMF decomposition of individual audio sources participating in the mixture. This basis functions matrix is then passed as a factor for data matrix (audio mixed signal) factorization, and only the activations matrix is updated. The estimated sources are obtained by multiplying the basis vectors with their corresponding activations. This procedure is called supervised source separation, as shown in Fig. 1, which provides improved separation performance. The limitation of such an approach is that it should know the sources prior to factorization.

TABLE I. Data Matrix and its Parts

Domain/ Application	M (data matrix)	B (parts or bases)
Computer Vision [1] [2]	Pictures of faces	Pictures of facial features
Document Clustering [3]	Documents	Base topics
Bioinformatics [4]	Spectra of chemical mixtures	Spectra of component molecules

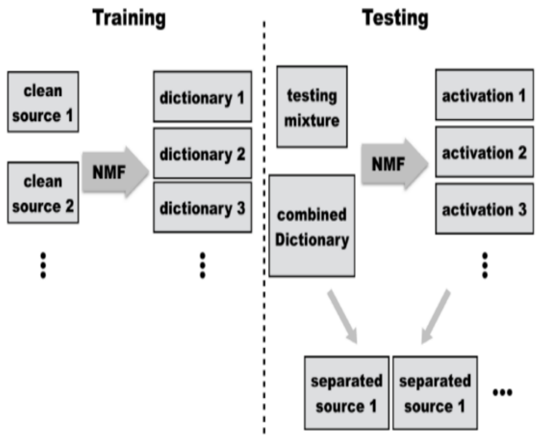

Fig. 1. Supervised Source Separation using NMF.

The separation problem is well studied for separating multiple speakers speaking the same language from a monoaural recording, but many multilingual overlapped speech recordings are not explored. A multilingual speech signal scenario is very usual in India, where 22 official languages are spoken. Any speech processing application addressing such speech mixtures as speech forensics or home assistant devices may find it challenging to recognize the desired speech leading to underperformance. Adding a speech separation module as a pre-processor to these applications in an Indian speech mixture scenario will help in improving the performance of segregating the desired speech. This leads to our motivation to further enhance the speech separation performance by identifying the bases obtained from individual sources, as discussed above in Fig. 1, which may better represent the mixed speech signal or the data matrix. The number of bases inferred for a speech source should not include bases matching spectral patterns of the interfering sources in the mixture; otherwise, the estimated target source after separation will be incorporated with undesirable spectral patterns.

Therefore, the objective is to learn the number of optimum bases representing individual Indian language speech sources to enhance the separation of one signal or all the participating signals from a multilingual, multiple-speaker speech signal comprising different Indian languages using NMF. The languages used are Hindi, Marathi, Gujarati, and Bengali. The evaluation metrics for separation performance were carried out by the "Blind Source Separation evaluation (BSS EVAL)" toolkit [5].

The organization of the paper is as follows: Related works are explained in Section 2, Methodology is elaborated in Section 3, Section 4 demonstrates the implementation, and Section 5 provides the results and discussion. The conclusion is given in Section 6.

II. Related Work

M.N Schmidt and R.K Olsson [6] proposed sparse NMF based source separation, which learns an over-complete set of non-negative basis vectors for each source. An over-complete set is a set where the number of bases is more than the spectral representation dimensions. According to the authors, better separation is achieved in separating individual audio sources from a mixture if each source is represented on an over-complete basis vector. The authors concluded that the dictionaries capture fundamental properties of speech; that is, the basis functions resemble phonemes. Convolutional NMF considers "spectro-temporal patterns" as bases instead of simple amplitude spectra in the paper [7]. This NMF variant extract cross-column patterns as single bases, therefore, capturing the temporal dependencies within bases.

Most of the previously discussed NMF-variants ignore individual signal phases and use the phase of the mixture signal while reconstructing the separated respective signals. This drawback of earlier NMF-variants introduced audible artifacts. Kameoka et al. in 2009 [8] presented an NMF-variant which allowed complex values and was given the name "complex non-negative matrix factorization". The authors proposed a mixing model called complex NMF established in the complex-spectrum domain. This paper aims to represent any observed complex spectrum where fewer active magnitude spectrum bases are paired with an arbitrary phase spectrum. King and Atlas in [9] named Complex NMF as "complex matrix factorization" (CMF). In this case, "each time-frequency point is multiplied with a phase term that allows each spectral base to assume the phase to fit the mixed-signal best", maintaining the non-negativity constraints of bases and activations.

Discriminative training of the NMF basis functions was introduced in [10], which generalized the model with separate analysis and reconstruction basis functions. Another research [11] selects active-set Newton algorithm (ASNA) for overcomplete NMF (over-complete set of basis functions), which outperforms other conventional source separation techniques. Simplex volume minimization [12] successfully estimates the source model, which learns an identifiable spectral basis. Working with dense basis matrix factors is allowed by these identifiability conditions. In addition, the basis matrix may have a full-column rank without any constraint imposed.

A pair of dictionaries was used for analysis and reconstruction in the paper [13]. It increases separation performance at low latencies, which is accomplished by utilizing shorter synthesis frames. According to the authors, if computational power is sufficiently available, this methodology may be applied to real-time applications. "Low-latency output allows a human listener to directly use the results of such a separation scheme without a perceptible delay". A binary subspace learning for the bases was proposed by [14]. Orthogonal NMF (ONMF) [15] adds orthogonality constraints to NMF in addition to the non-negativity constraint on one or both factors: the columns of B (bases) and the rows of A (activations) are required to be orthogonal. Newer variants of NMF [16] are being developed for hyperspectral and multispectral image fusion, which are yet to have been experimented with for audio source separation. Technologies other than NMF deliver competitive results in speech separation or enhancement, for example, deep learning neural networks (DNN) [17], but they are successful only with large training data. NMF is still suitable for a smaller dataset.

The number of bases retained during training differs for all the supervised speech separation discussed in existing research studies. Moreover, most of the research is based on a single language, primarily English or native languages. Therefore, studies on speech mixtures comprising different languages need attention. It is also crucial to identify the optimum number of bases or parts representing the latent structure of the data (mixed-signal) for successful separation of its comprising different language speech signals.

III. METHODOLOGY

The reason behind the successful separation of audio sources from a mixed signal using supervised NMF is the selection of an optimum set of basis vectors. Therefore, this section explains the methodology and the evaluation measures quantifying the separation performance. The performance is compared based on the metrics generated by BSS EVAL.

A. Non-negative Matrix Factorization

Positive Matrix Factorization was introduced by Paatero and Tapper in 1994, which was later coined as non-negative matrix factorization (NMF) [1]. Lee & Seung in 2001 [2] popularized NMF as a non-negative constrained algorithm capable of learning parts of faces from a facial image database favorably called image bases. The linear combination of these weighted parts constitutes each face. NMF decomposes the data (in this paper speech spectrogram) into basically two “non-negative components”. The components are the “basis functions matrix,” representing the spectrum of bases, and the “coefficient matrix,” representing the activation coefficients of the bases in the data as in Fig. 2.

Recognizing NMF’s capability, it was extended to several applications like “audio source separation,” as explained in the Introduction. It separates the audio signal considered as target source from other interfering speakers or noise or music considered as maskers. It is possible to separate all the participating signals present in the audio mixture signal in some cases. The data representation of the mixed audio signal (M) is accomplished using spectrograms. The magnitude of the mixed audio signal (M) spectrogram is decomposed into basically two “non-negative components”. The components are “basis functions matrix” (B) and “weight or activation or coefficient matrix” (A).

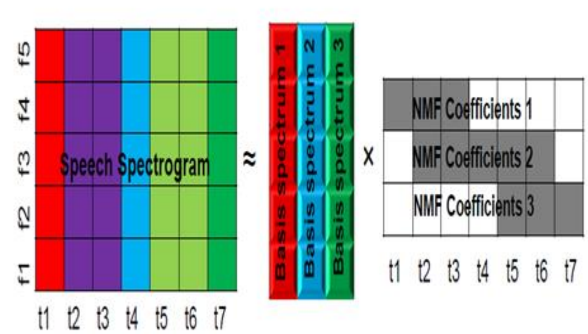

Fig. 2. A Speech Spectrogram is Factorized into bases and its Weights using NMF [25].

The interpretable factorization may be expressed as $M \approx BA$. BA is the matrix multiplication of B and A, where $M \in \mathbb{R}_{\geq 0}^{P \times Q}$ is subjected to the constraints of non-negativity $B \in \mathbb{R}_{\geq 0}^{P \times L}$ and $A \in \mathbb{R}_{\geq 0}^{L \times Q}$.

$P \in \mathbb{R}_{>0}$ is the number of the frequencies representing the spectrum of the mixed-signal M. $Q \in \mathbb{R}_{>0}$ is the time axis representing the mixed-signal M spectrogram. $L \in \mathbb{R}_{>0}$ is the number of the column basis vectors in B and activations row-wise in A. Cost functions along with multiplicative updates converge the non-negative factorization to a substantial approximation. For simplicity, M and BA are represented by X and Y for the following cost function expressions. X_{pq} and Y_{pq} are the elements (*p*=row, *q*=column) of the matrices X and Y, respectively.

The “Euclidean distance” (EUC) between X and Y [2] is given by:

$$\| X - Y \|^2 = \sum_{pq} \left(X_{pq} - Y_{pq}\right)^2 \tag{1}$$

The “Kullback-Leibler divergence” (KL) [2] is the cost function which leads to relative entropy when $\sum_{pq} X_{pq} = \sum_{pq} Y_{pq} = 1$.

$$div(X \,\|\, Y) = \sum_{pq}\left(X_{pq} \log \frac{X_{pq}}{Y_{pq}} - X_{pq} + Y_{pq} \right) \tag{2}$$

Another cost function given below is “Itakura-Saito (IS) divergence” [18]

$$div(X \,\|\, Y) = \sum_{pq}\left(\frac{X_{pq}}{Y_{pq}} - \log \frac{X_{pq}}{Y_{pq}} - 1\right) \tag{3}$$

Both the cost functions are non-increasing, which leads to minimization or convergence. The elements of B and A are initialized either randomly or using some pre-defined methodology with non-negative values. Convergence is achieved by executing the following multiplicative update theorems iteratively:

The EUC ‖ M – BA ‖ is updated by the following rules [2]:

$$A \leftarrow A \circ \frac{B^T}{B^T} \frac{M}{BA} \qquad B \leftarrow B \circ \frac{MA^T}{BAA^T} \tag{4}$$

The divergence *div*(M ‖ BA) for KL uses the following [2] to update rules:

$$A \leftarrow A \circ \frac{B^T \frac{M}{BA}}{B^T.1} \qquad B \leftarrow B \circ \frac{\frac{M}{BA} A^T}{1.A^T} \tag{5}$$

For IS divergence, the multiple updates established by [18] is given by:

$$A \leftarrow A \circ \frac{B^T \frac{M}{(BA)^2}}{B^T.\frac{1}{BA}} \qquad B \leftarrow B \circ \frac{\frac{M}{(BA)^2} A^T}{\frac{1}{BA}.A^T} \tag{6}$$

B. Performance Measures

BSS Eval toolkit presents signal level metrics which evaluates the amount of speech enhancement or improvement and interference reduction. According to [5] the separated or estimated source $\hat{s}$ is expressed as a sum of the target source s_{target} and three types of error as follows:

$$\hat{s} = s_{target} + e_{interf} + e_{noise} + e_{artif} \tag{7}$$

"where s_{target} is part of the estimated source, which is the true source signal modified by a permissible distortion. The term e_{interf} is the error caused by interference from the unwanted sources. The sensor noise represented as the part of the estimated source is e_{noise}. The artifact error term, e_{artif}, is the part of the estimated source perceived as coming from other sounds, like forbidden disturbances and/or 'burbling' artifacts".

The ratios "source to distortion ratio" (SDR), "source to interference ratio" (SIR), and "source to artifact ratio" (SAR) over the audio signals are computed, which determines the relative value of each of these estimated target source and error terms given as follows:

$$\text{SDR:} = 10\log_{10}\frac{\|s_{target}\|^2}{\|e_{interf} + e_{noise} + e_{artif}\|^2} \quad (8)$$

$$\text{SIR:} = 10\log_{10}\frac{\|s_{target}\|^2}{\|e_{interf}\|^2} \quad (9)$$

$$\text{SAR:} = 10\log_{10}\frac{\|s_{target} + e_{interf} + e_{noise}\|^2}{\| e_{artif}\|^2} \quad (10)$$

The mixtures considered in the experiments conducted and mentioned in this paper are assumed to be noiseless. Therefore, only the SDR, SIR, and SAR performance measures are used throughout the experimentation. "SIR measures the quantum of the interfering sources present in the separated or estimated signal. The SAR measures the unwanted energy present in the signal that is not part of either the target or interfering audio signals. Combination of SIR and SAR into one measurement results in SDR".

IV. Implementation

Supervised NMF obtains basis vectors from individual speech sources participating in a mixed speech signal during the training phase. During the testing phase, these speech basis vectors from the training phase are used as the basis vectors matrix, which is one of the factors for the mixed speech signal factorization. The other factor is the activations matrix, which is updated, keeping the basis vectors matrix constant. The multiplication of basis vectors with the respective updated activations provides the separated signals. The experimental setup and evaluation methods engaged in this research are given below:

A. Experimental Setup

Synthetic mixtures of speech signals comprising different Indian languages are selected for the investigation, mainly taken from Hindi, Marathi, Gujarati, and Bengali speech audio databases. Bengali male (SLR37) [19], Marathi female (SLR64) [20], Gujarati male and female (SLR78) [20] multi-speaker speech databases are taken from openSLR (Open Speech and Language Resources) developed by Google. Hindi female, Bengali male, and Marathi male multi-speaker speech databases are taken from TTS voice data from IIIT Hyderabad [21]. Bengali female and male multi-speaker speech databases are also taken from the SHRUTI speech corpus developed by the Indian Institute of Technology; Kharagpur (IITKGP) distributed by the Society for Natural Language Technology Research [22].

The mixed speech signal was created by digitally combining male or female speech utterances of one language with male or female speech utterances of another language. For each language, the training data chosen was 60 utterances ranging from 3.00 to 5.00 seconds. The testing data selected was 5 utterances of similar duration different from training data. The testing data was augmented by combining one language utterance to all 5 utterances of another language, making it 25 utterances. One of the speech signals separated from the mixed speech signal is the target speech signal, and the other speech signal is called the interfering or the masker speech signal. The target speech signal to the masker speech signal is mixed with a target-to-masker ratio (TMRs) of 0 dB.

All the speech audio sources (WAV files) categorized for the training and testing phase were sampled at 16KHz. For the time-frequency (TF) representation, the short-term Fourier transform (STFT) was computed using 1024 points. A 32ms long with a 16ms overlap Hamming window was utilized for the same. The number of basis vectors experimented with for both the sources (all language combinations in this paper) was 40, 75, 100, and 150. The algorithm was executed at 500, 1000, and 1500 test iterations for each number of basis vectors chosen.

The different language speech combinations engaged are Marathi with Bengali, Marathi with Hindi, Hindi with Gujarati, Gujarati with Marathi, and Bengali with Hindi. The NMF cost function used was KL divergence for all the experiments. PYTHON programming language was used for the NMF algorithm with multiplicative updates. Parselmouth, PRAAT in PYTHON [23] was used for the spectrograms.

B. Evaluation

The source separation results were evaluated using the signal level metrics BSS_EVAL tool (SDR-source to distortion ratio, SIR-source to interference ratio, and SAR-source to artifact ratio), which quantifies the speech enhancement or interference mitigation.

V. Results and Discussion

This section analyses the separation performance results to learn the optimum number of basis vectors required for individual speech spoken in different Indian languages in a supervised audio source separation using NMF, which will subsequently help in successful speech separation from a mixed speech signal.

As mentioned in Implementation, the mixed speech signal comprises two speakers of the same or different genders (female-female, male-male, and female-male) speaking different Indian languages simultaneously. The language combinations are Hindi-Gujarati, Hindi-Bengali, Bengali-Marathi, Hindi-Marathi, Marathi-Gujarati. The speaker combinations are female-female, male-male, female-male.

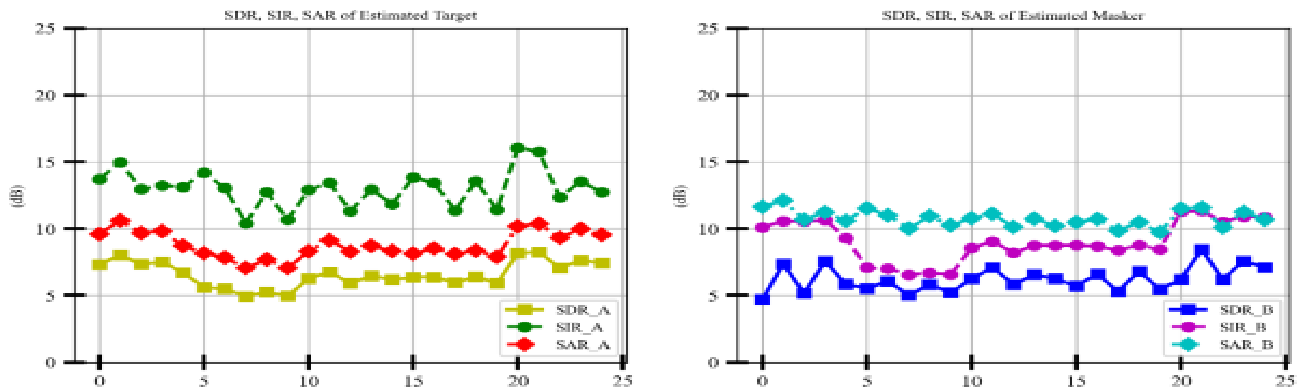

Fig. 3. Speech Separation Performance of Estimated Target (Hindi Female Speech) and Masker (Gujarati Male Speech) from 25 Testing Mixed Signals.

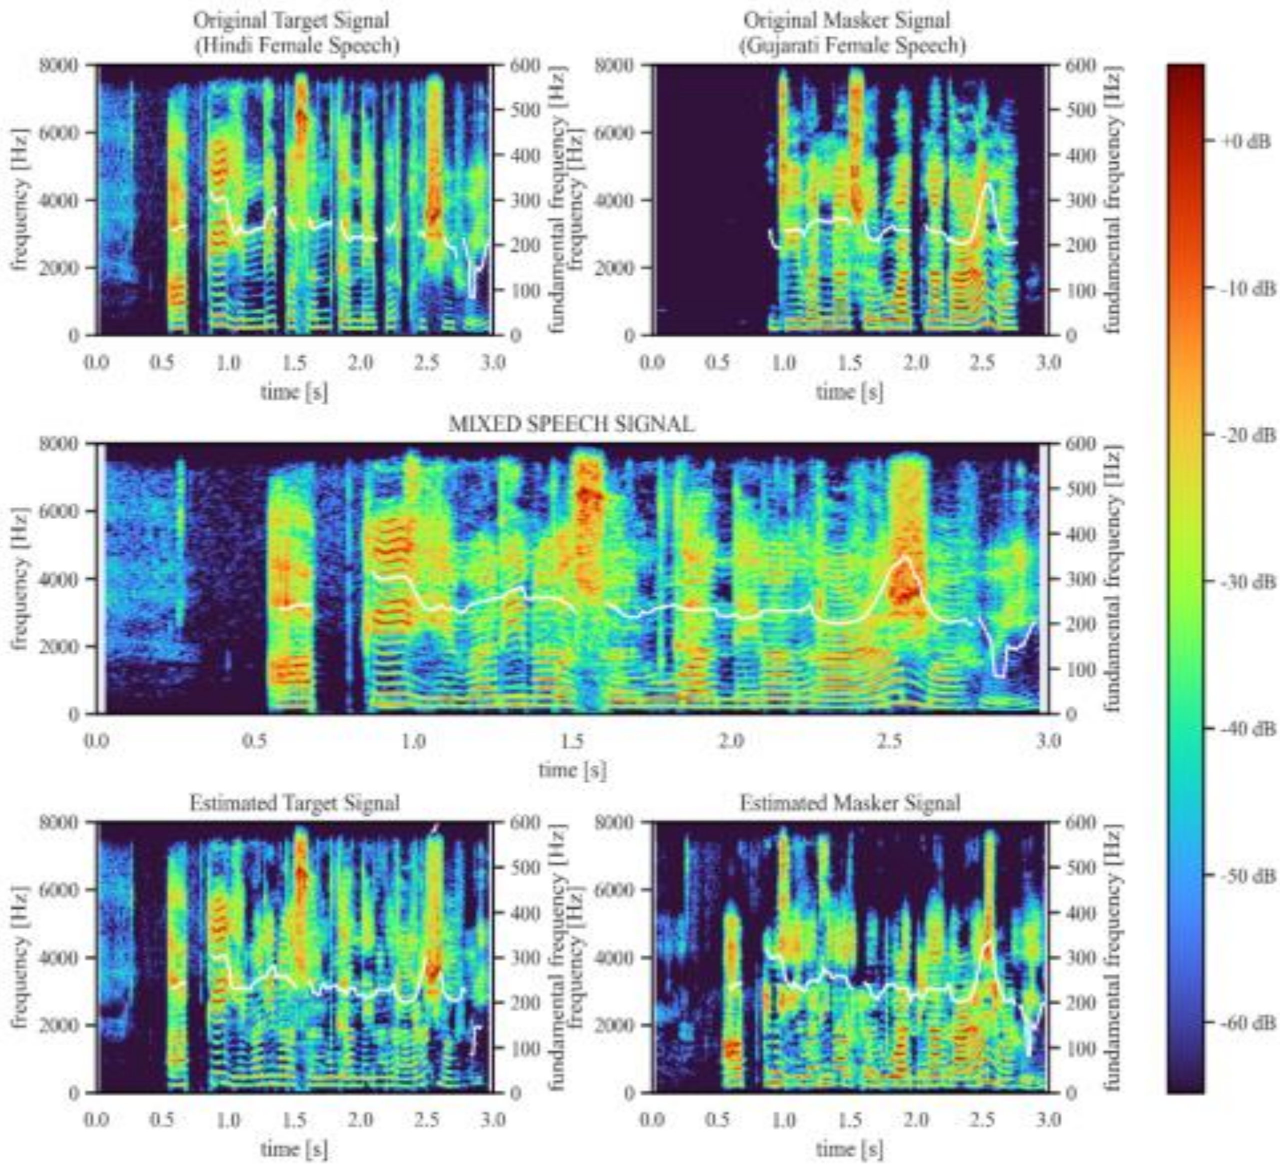

Fig. 4. Spectrograms of Original Target and Masker, Mixed Speech Signal and Estimated Target and Masker for Female-Female Combination.

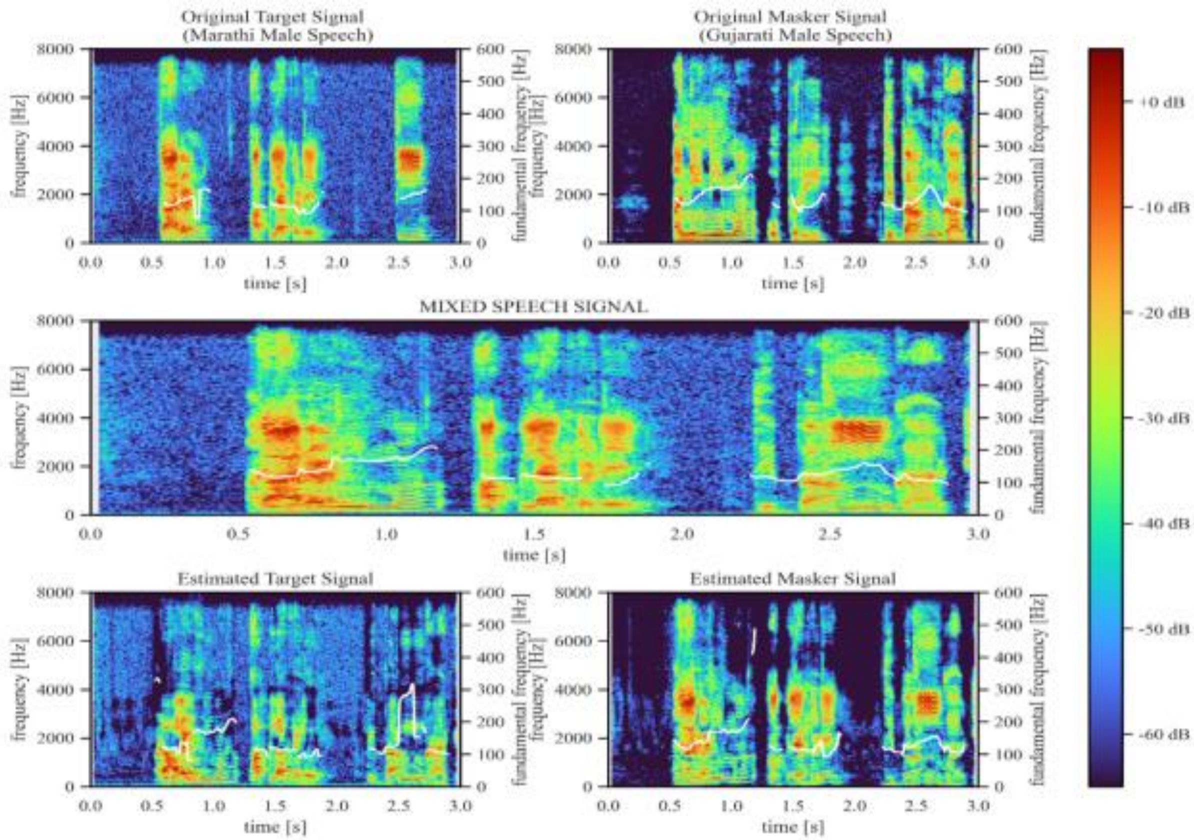

Fig. 5. Spectrograms of Original Target and Masker, Mixed Speech Signal and Estimated Target and Masker for Male-Male Combination Speaking Marathi and Gujarati, Respectively.

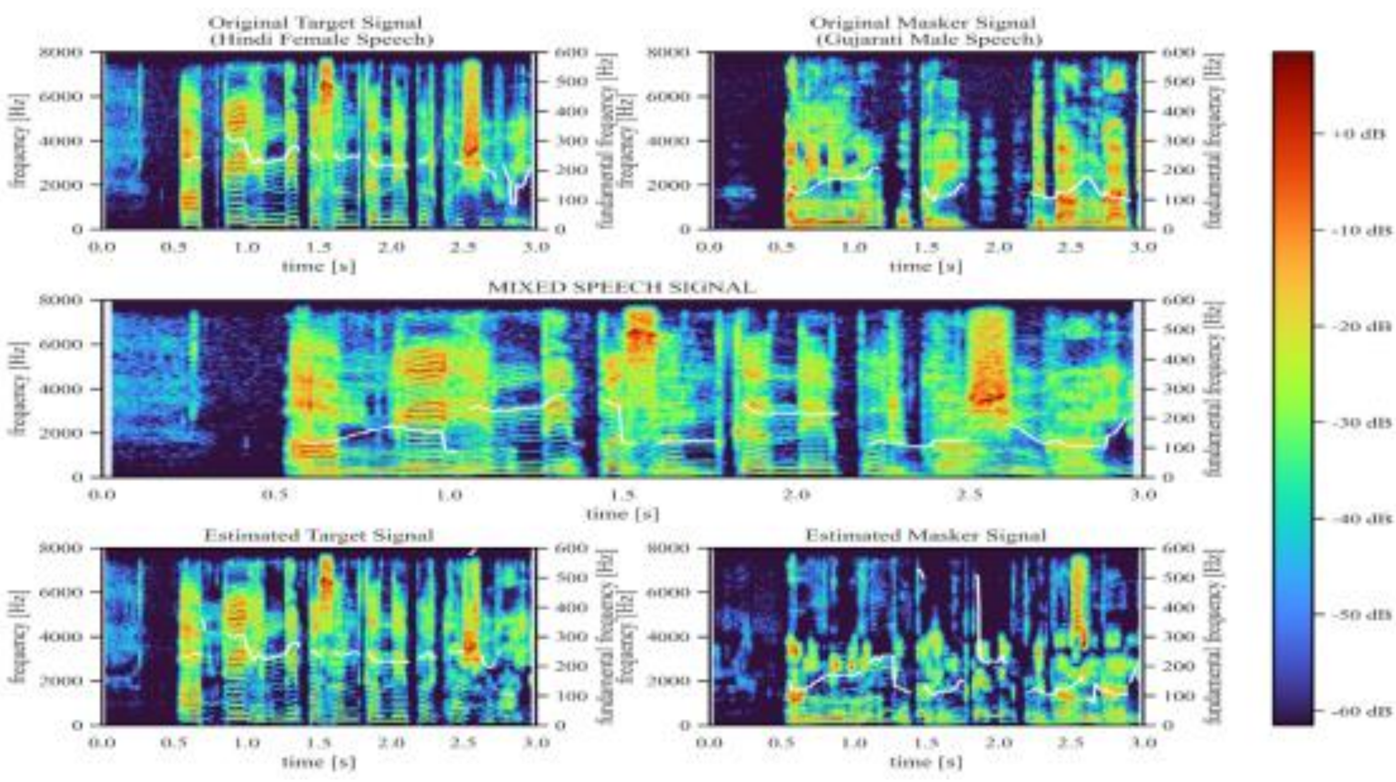

Fig. 6. Spectrograms of Original Target and Masker, Mixed Speech Signal and Estimated Target and Masker for Female-Male Combination Speaking Hindi and Gujarati, respectively.

For each of the combination BSS EVAL parameters, SDR, SIR, and SAR are used to quantify separation quality. As interpreted from the Implementation section, we have 25 mixed utterances in the testing phase; the evaluation parameters were computed for all the separated utterances. The same is displayed in Fig. 3 for one such combination. As evident from the figure, the deviation for the parameter values from the mean value is significantly less, within the range of 2 to 3 dB; therefore, the mean value is considered for this and other language-gender combinations.

Spectrograms are used to display the speech parameters. Fig. 4, Fig. 5, and Fig. 6 show the spectrograms of original target and masker, mixed speech signal, and estimated target and masker for female-female, male-male, and female-male, respectively, which displays speech separation. The pitch is highlighted in the spectrograms to show the interference, which is not a very significant presence in the separated target speech due to the masker speech and vice-versa.

NMF on the mixed speech signal for each pair of language-gender combinations was experimented with for basis vectors 40, 75, 100, and 150 to assess the optimum number of bases. Each set of basis vectors are obtained in the training phase with an updated iteration fixed at 1500. Each set of basis vectors was experimented with three different update iterations in the testing phase, namely 500, 1000, and 1500. For the remaining section, the number of iterations mentioned will be indicative of the testing phase.

The language combinations for female-female speech separation selected are Hindi-Bengali, Hindi-Gujarati, and Hindi-Marathi. The BSS EVAL parameters for one of the combinations (Hindi-Bengali) target speech and masker speech are tabulated in Table II.

TABLE II. BSS EVAL PARAMETERS OF HINDI FEMALE (TARGET) AND BENGALI FEMALE (MASKER) SEPARATED FROM A MIXED SIGNAL

Iteration	**Bases**	**Target**			**Masker**		
500		SDR	SIR	SAR	SDR	SIR	SAR
	40	3.11	4.67	5.60	2.03	3.36	7.64
	75	2.88	4.55	5.42	2.12	2.50	9.51
	100	2.75	2.65	6.65	1.82	1.69	9.21
	150	3.07	3.14	7.49	1.94	1.88	10.49
1000							
	40	2.44	3.04	5.34	1.82	2.00	7.36
	75	2.78	3.92	5.67	2.01	2.22	9.09
	100	2.78	2.77	6.33	1.85	1.90	8.84
	150	2.79	2.65	6.77	1.89	1.66	9.69
1500

	100	2.73	2.34	7.16	2.65	1.38	8.13
	150	3.40	3.14	8.01	3.12	2.81	8.76

The language combinations for male-male speech separation selected are Marathi-Gujarati, Bengali-Gujarati, and Bengali-Marathi. Table III tabulates the BSS EVAL parameters for one of the combinations (Marathi-Gujarati) target speech and masker speech. The language combinations for female-male speech separation selected are Hindi-Bengali, Hindi-Gujarati, Bengali-Marathi, Bengali-Gujarati, and Hindi-Marathi. One of the combinations (Hindi-Gujarati) target speech and masker speech BSS EVAL parameters are tabulated in Table IV.

Comparing the spectrograms of Fig. 4, 5, and 6 reveals that the estimated target and the masker have interferences from the other speaker's utterance, but they are insignificant. Careful observations show the quantum of interference is more in female-female and male-male than female-male combination. It is well understood as NMF is based on spectral bases. More are the similarity in spectral bases of the source speakers; less is the separation performance as it is difficult to distinguish similar frequencies. Therefore, the separation in the female-male combination is better as their speech fundamental frequencies are at different levels (i.e., male: 80-180 Hz and female: 160-250 Hz).

Now let us consider BSS EVAL parameter SDR for an estimated target separated from a different language female-male combination mixed speech signal. The results are shown as 3D bar plots in Fig. 7, 8, and 9, which show the comparison between the SDR of an estimated target separated from a Hindi-Bengali, Hindi-Gujarati, and Bengali-Marathi mixed signal for update iteration 500, 1000, and 1500, respectively. The SIR and SAR values are discussed from the tables mentioned above.

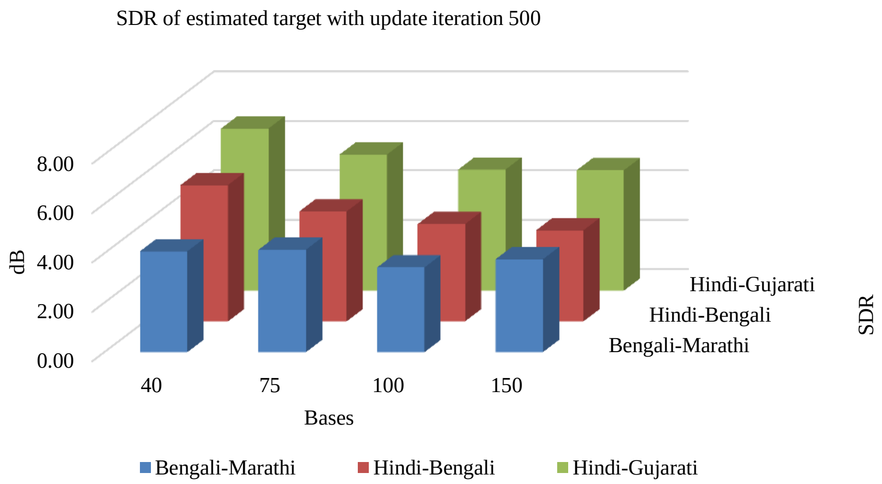

Fig. 7. Comparison of SDR of Estimated Target for Hindi Female (Target)-Bengali Male (Masker), Hindi Female (Target)-Gujarati Male (Masker) and Bengali Female (Target)-Marathi Male (Masker) Separated from a Mixed Signal with Update Iteration 500.

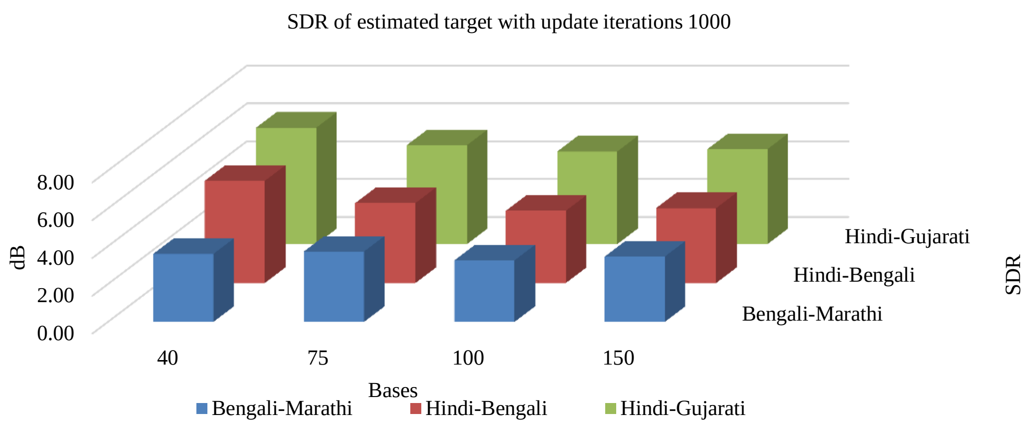

Fig. 8. Comparison of SDR of Estimated Target for Hindi Female (Target)-Bengali Male (Masker), Hindi Female (Target)-Gujarati Male (Masker) and Bengali Female (Target)-Marathi Male (Masker) Separated from a Mixed Signal with Update Iteration 1000.

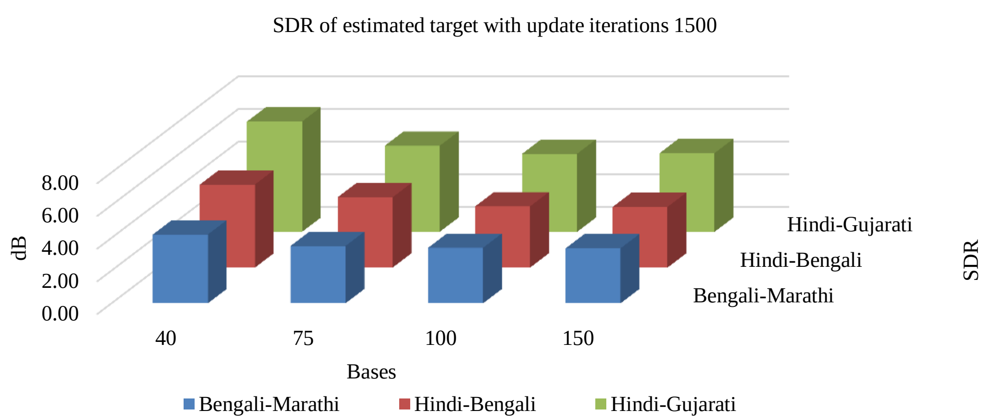

Fig. 9. Comparison of SDR of Estimated Target for Hindi Female (Target)-Bengali Male (Masker), Hindi Female (Target)-Gujarati Male (Masker) and Bengali Female (Target)-Marathi Male (Masker) Separated from a Mixed Signal with Update Iteration 1500.

From the above-mentioned plots, it is observed that the language combination Hindi-Gujarati (female-male) showcases the best result with SDR (estimated or separated target speech) almost nearing 7 dB for update iteration of 500 and 1500 in case of 40 basis vectors. It is also evident from Table IV. Another observation is for most combinations; the SDR is highest for 40 bases though the actual value between the language combination differs by 0.7 dB to 1.5 dB. Though the Bengali-Marathi (male-male) combination shows the lowest results, it shows the highest value of 4.15 dB and 3.72 dB in the case of 75 basis vectors for update iteration 500 and 1000, respectively.

Table III shows the language combination Marathi-Gujarati (male-male) exhibits higher SDR results with 40 basis vectors for 500 iterations followed by 150 bases for 1500 iterations applicable for both the target and the masker speech sources. Table II shows Hindi-Bengali (female-female) language combination for mixed speech signals. It is noticed that SDR values of both the target and the masker speech sources are higher for 500 and 1500 iterations with 40 basis vectors. The SIR result reflects the same as SDR. However, SAR results show higher results with 150 basis vectors for all the iterations, with the only exception in the female-male case where it displays higher results with 40 basis vectors for 1500 iteration. For all the combinations, the effects of update iterations 500 and 1500 are better than 1000. It is noticed that almost all the results suggest 40 basis vectors to be the optimum number after comparing the performance with respect to bases.

As mentioned above, the supervised separation performance of NMF, which is known for its reduced dimensionality depends on the bases representing the latent structures in the mixed speech signal; the objective of this study was to learn the optimum number of bases representing Indian language speech sources in a mixed signal.

TABLE IV. BSS EVAL PARAMETERS OF HINDI FEMALE (TARGET) AND GUJARATI MALE (MASKER) SEPARATED FROM A MIXED SIGNAL

Iteration	**Bases**	**Target**			**Masker**		
500		SDR	SIR	SAR	SDR	SIR	SAR
	40	6.56	13.02	8.77	6.21	9.04	10.77
	75	5.51	11.40	8.05	5.56	6.87	11.34
	100	4.90	9.97	7.80	5.09	5.80	11.74
	150	4.87	9.72	8.28	5.01	5.45	12.07
1000							
	40	6.16	12.95	8.07	6.00	8.56	10.36
	75	5.23	11.89	7.09	5.42	6.72	10.72
	100	4.90	10.78	7.19	5.16	6.04	11.14
	150	5.02	9.08	8.16	5.07	5.91	11.73
1500							
	40	6.75	12.91	9.08	6.31	9.35	10.94
	75	5.26	10.82	7.40	5.35	6.85	10.70
	100	4.78	10.49	7.06	5.08	5.80	11.23
	150	4.81	9.00	7.76	4.93	5.65	11.42

There is no fixed directive to identify the number of bases; the same was learned by utilizing a different number of basis vectors. Each set was used for a different number of iterations in the testing phase. The separation performance is at its best when the bases resemble phonemes or speech sounds of the language. From the literature study, it is known that the languages Hindi, Bengali, Marathi, and Gujarati are Indo-Aryan languages, and their phoneme ranges from 37 (Bengali) to 52 (Marathi) [24]. It is, therefore, understandable that the optimum number of spectral bases required for the individual speech source signal of different Indian languages emerging is 40, after comparing all the speech separation results delivered by NMF.

VI. CONCLUSION

Supervised speech separation of a desired or target speech source from a multi-lingual two-speaker speech mixture is considered, which is very relevant to an Indian scenario as India is a country with a vast population speaking different languages. For successful separation proper set of bases needs to be inferred from the participating speech sources in the mixed signal, i.e., bases matching spectral patterns of the interfering sources in the mixture should not be included as the estimated target source after separation may be incorporated with undesirable spectral patterns. Therefore, this research attempts to learn an optimum number of bases for Indian languages using non-negative matrix factorization. Hindi, Marathi, Gujarati, and Bengali Indo-Aryan languages are used for utterances. The speaker combinations used are female-female, male-male, and female-male.

The optimum number of bases determined by evaluating the separation performance for the individual speech source signal of different languages is observed as 40. This number is nearly like the phoneme sets of the languages engaged, which signifies that separation performance is better when the bases resemble phonemes or the speech language sounds. Though the number of bases is similar for all the languages, the separation performance parameter SDR shows different values for different language combinations. This difference in SDR values needs more insight into language correlation.

A pre-processor separating different language speech sources may be added to several speech processing applications, for example, audio or speech forensics, home assistant devices operating in Indian scenarios, thereby enhancing the applications' performance. The research can be continued for other Dravidian Indian languages, NMF variants and DNN may be utilized depending on the availability of the training dataset.

Determining Local Hematology Reference Ranges: A Data-driven Approach

K.A.Hasara Semini, H.A.Caldera
University of Colombo School of Computing
University of Colombo, Colombo
Sri Lanka

***Abstract*—Hematology is the study of blood, blood-forming organs, and blood diseases. Hematological tests such as Full Blood Count (FBC) can be used to diagnose a wide range of infections and diseases by comparing their results with the standard hematology reference (SHR) ranges. These ranges were established many years ago by considering the Caucasian population and all countries have used them until recent times to measure the healthiness of the people. But these reference ranges can be varied according to various reasons such as dietary habits, geographical location, climate, environmental factors, etc., and the use of them by all countries may not be correct. Many researchers have started research in finding Local Hematology Reference (LHR) ranges. Most of them used statistical analyses which have their limitations. Machine learning is a solution to overcome those limitations. Finding an approach to determine the LHR range based on machine learning techniques is the goal of this research. The dataset was generated using FBC test reports in Sri Lanka. The LHR range of WBC count of healthy adults in Sri Lanka is only addressed in this research. A difference between the SHR range of WBC and the LHR range of WBC is observed.**

Keywords—Hematology science; standard hematology reference range; domestic hematology reference ranges; local hematology reference range; machine learning; white blood cell count

I. Introduction

Medical Science helps to maintain and restore health. It is a combination of diagnosis, prognosis, treatment, and prevention of disease. Medical science can be divided into several sub-sections such as Cardiology, Anesthesiology, Dentistry, Hematology, and Physiology. Hematology consists of four major components as plasma, red blood cells, white blood cells, and platelets. Each of these four components consists of other sub-components. For example, white blood cells contain lymphocytes, monocytes, eosinophils, basophils, and neutrophils. Each of these components has a reference range that is considered to measure the healthiness of a person in Health-related fields.

When considering these hematology reference ranges, they are important to monitoring pathophysiological changes after getting infected with a disease. It can be used to detect diseases such as Dengue fever, HIV, cancer, etc., and track the effects of the given drugs or vaccines for clinical observations. The set of values for hematology reference ranges that are accepted worldwide is called “Standard hematology reference ranges” which were determined many years ago by doing some researches for the Caucasian populations. A Caucasian population is a group of people who are originated from Europe and are also commonly known as “white” or “white-skinned” people.

Gradually, people realize that the Standard hematology reference range can vary due to many reasons such as age, gender, genetics, attitudes, lifestyle, ethnic origin, dietary habits, geographical location, climate, environmental factors, etc.[1]–[3]. Hence the Clinical and Laboratory Standards Institute (CLSI) has recommended that a domestic hematology reference range should be established for each region [2], [4]. As a result, hematology reference ranges per country are the focus of this paper.

When considering Sri Lanka, the population is not a Caucasian population due to their significant variation on factors for which the standard hematology reference ranges were determined.. For example, suppose the minimum hemoglobin reference value of Sri Lankan healthy adults and the minimum value of the standard hemoglobin reference range are ‘x’ and ‘y’ respectively and ‘x’ has become less than ‘y’ due to the nutrition factors of Sri Lankan population. The doctors give medicines for hemoglobin deficiency to people whose hemoglobin values in between ‘x’ and ‘y’ until the local reference ranges are established. But these people may be healthy and do not need to take any medicine as far as the local conditions are concerned. These kinds of situations can happen to any other hematology attribute too. Taking medicine without any illness may cause dangerous side effects too. Therefore, a local hematology reference range is a mandatory thing for every country which is not under the Caucasian population category. As the local hematology reference ranges for Sri Lanka have not yet been determined, the research conducted in the paper is an attempt to fill this gap. Hence, the dataset used in this research was taken by considering the Sri Lankan population.

The paper is organized as follows. We first focus on related works in Section II investigating the impact of standard reference ranges on different populations and different methods in establishing the domestic reference ranges. Section III describes the proposed method in meeting the requirement. Results and Evaluations are described in Section IV. Finally, Section V presents the conclusion of this study.

II. Background Study

Eastern India, China, Morocco, Ethiopia, Sudan, Malawi, Nigeria, and many other African countries have successfully done many kinds of research and established the domestic hematology reference ranges for their countries which contain different values rather than the standard hematology reference range values [1], [2], [5]–[7].

Eastern India researchers had found lower hemoglobin (HB) and platelet (PLT) values when compared to the standard hematology reference ranges. The difference was statistically significant only for the platelet count [2]. The lower hematology reference range values for White Blood cells (WBC), Hemoglobin (HB), Hematocrit (HCT), Mean Corpuscular Volume (MCV), and platelet (PLT) counts which were compared to the standard hematology reference ranges had been found by researchers in Malawi. The research was driven by categorizing the dataset both gender-wise and age-wise. These researchers also compared the received male hematology reference ranges with domestic hematology values of other African countries and found that the male Malawians have lower HB and HCT values than others [5]. A lower reference range for WBC than the standard WBC reference range was found by the Sudanese research team who researched to find a local WBC reference range. The dataset which was used to take this result belonged to a particular city in Sudan. The research team identified that the received result was different by studying two other researches which were also conducted to find domestic WBC reference value considering another two cities in Sudan [1]. A Nigerian research team had analyzed blood and urine samples of males, pregnant females, and non-pregnant females to establish local reference ranges for their country. The different local reference ranges for males and females as well as pregnant females and non-pregnant females were received as the result of the research. They compared their result with reference ranges in the USA. Glucose levels, Urea levels, enzyme levels in the Nigerian population were higher than the USA reference ranges [8]. A local hematology reference range was established by considering both male and female healthy adults in Togo. The blood samples for the research have been taken from 1349 donors who were discovered as healthy. The received ranges have differed from other African countries [9]. In another research, hematology reference ranges were established based on the population of old people in rural southwest Uganda. The received ranges were compared with age groups which are categorized as adults, old people (age between 50 and 65), and very old people (65+). The ranges were changed between age groups [10]. Another research team has established Hematology Reference ranges among Healthy Adults in Bamenda, North West Region of Cameroon. The statistical analysis was used to determine the ranges [11].

Most of these researches were driven by considering age, gender, the country-wise or different area in the same country and were found different reference ranges if the considered dataset did not belong to the Gaussian country. Hence the researchers have focused to establish a local reference range to their countries. The blood samples were taken from the donors who were selected carefully by considering various conditions such as BMI value, medical history, and so on to generate a dataset. The number of data records that were used to establish the local hematology reference range in those countries was less than 1000. It may not enough to decide a local reference range for the whole country. Most of them used statistical analysis such as the Mann-Whitney U test, Chi-square test, t-test, and so on to establish those local hematology reference ranges. Hence, the dataset is statistically analyzed and described by using statistical theories. Most statistical theories define limitations to take a good result. In general, if the dataset contains huge data records then it will help to make a better output. But, because of the data limitation consideration, a huge dataset may not even give efficient results in statistical analysis. Every statistical theory may not apply to a certain dataset. And statistical analysis cannot be efficiently used to make predictions or find hidden patterns.

In general, most data-driven studies were handled by using data mining and machine learning concepts to avoid the above-mentioned problems. Many kinds of research in the medical sector have already used data mining and machine learning concepts to get efficient outcomes[12]–[14].

III. Methodology

Sri Lanka is a South Asian country. It is a tropical island with hot and humid weather all over the year. The population used in this research is Sri Lankan adults with age over 21 years and the data set used for the study is extracted from the Full Blood Count (FBC) test reports from a sample of the population. The sample contains both healthy and unhealthy people. Ethical approval is mandatory for this research as the research works with human medical data.

When considering the hematology components, some of them (dependent components) have an interrelationship with other components (independent components). The normal values of dependent hematology components may change as the independent component changes. For example, White blood cells (WBC) have two categories as granulocytes and non-granulocytes. Each of these categories has five types of white blood cells in human blood as Lymphocytes, Monocytes, Eosinophils, Basophils, and Neutrophils. The task of each of these white blood cells is given below.

- Lymphocyte: Generate antibodies, fight with inflection and viral cells. Also, it has B-lymphocyte, T-lymphocyte, and natural killer cells.
- Monocyte: Attacks chronic infections if present.
- Basophil: Sensitive when occurring allegories.
- Eosinophil: Working with the immune system's responses.
- Neutrophil: Helps to remove fungi and bacteria from the body.

All of these white blood cell types help to be healthy and highly affect the hematology components. When you take the FBC report, it shows leukocyte value (total WBC value) as well as values for five types of WBC cells. In this research, only the leukocyte value was considered. The normal value for leukocytes is taken when all WBC cell types follow normal values.

Data mining techniques and Machine Learning concepts are used to define the new approach which will be introduced via this research to determine local hematology reference ranges.

The general steps involved in the new approach are given in Fig. 1. A local hematology reference range for WBC count is only checked using the approach and a similar procedure can be used to determine local reference ranges of other hematology components.

A. Data Preparation

Various types of tests are used in hematology science such as the Full Blood Count (FBC) test, C-reactive protein (CRP) test, liver function tests, thyroid function tests, etc. Only the FBC test reports are considered to extract the required hematology reading as it is the most common test and shows all the main components of hematology.

As the initial data set obtained contained various types of blood tests, for example, WBC, on multiple rows, it was processed and restored to reflect all the individual's data on a single row as shown in Fig. 2. The values of Lymphocyte, Monocyte, Basophil, Eosinophil, and Neutrophil are stored as count values instead of percentages. A bivariable "Health State" is generated by using the standard hematology reference ranges of other hematology tests without considering the total WBC (leukocyte) value as a local hematology reference range for WBC count has experimented in this research. The Health State takes two values; "H" to identify the healthy persons and "UH" to unhealthy.

The 604 records are taken from the initial dataset for this research.

- 477 people in the dataset whose Lymphocyte value, Monocyte value, Basophil value, Eosinophil value, and Neutrophil value lie between the standard hematology reference range.
- 110 people in the dataset whose health state is equal to "H" generated by considering the other hematology reference ranges without considering the total WBC hematology reference range.
- 90 people in the dataset are healthy by considering all components in standard hematology reference ranges including the total WBC hematology reference range. This group of people will be called "SH" in further works in this research.

Preprocessing is one of the major steps in the Data Mining process and the dataset is explored for this purpose. The following preprocessing tasks were exercised to prepare the dataset for the data mining task.

1) *Removed unique attributes from the dataset.*
2) *Removed unwanted fields from the dataset.*
3) *Converted all data types to nominal.*
4) *Grouped data as necessary.*
5) *Set class attribute as "health state".*
6) *Visualized data:* This helps to take a proper image of the selected dataset. The visualization of the data is very important to make pre-decisions about every attributes before the analysis.

B. Classification Model

Building a classification data model is the next step. Classification can be applied to both structured and unstructured datasets. The classification technique categorizes new data instances into classes by learning through an experienced/training dataset where the classes of each instance of it are already given. When applying a classification algorithm for the training dataset, it separates each data point into given classes. This is the model that is created using a classification algorithm. The accuracy of the classifier is assessed on a separate data set called testing data set by checking the correctly classified records. There are two types of classification algorithms that are mostly used for data analysis. In Binary Classification, the class attribute has only two categories, but it has more than two categories in Multi-Class Classification. Each classification assumes that one data point belongs to only one class and non-class attributes of each data point must be independent of each other and discrete.

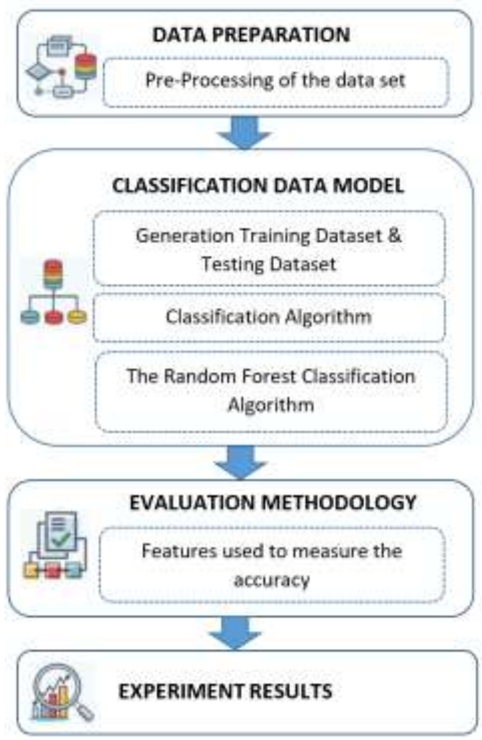

Fig. 1. Methodology Diagram.

Fig. 2. Dataset.

It is needed to find which classification algorithm is suited for analyzing the dataset and achieve the final goal. There are many classification algorithms available in literature but the tree-like algorithms are the most commonly used because of their ease of implementation and easier to understand compared to other classification algorithms [15]–[17]. Random Forest, Random Tree, REP Tree, LMT, J48, and Hoeffding Tree algorithms are such algorithms.

1) The Random Forest Tree (RFT) classification algorithm: Random Forest Tree (RFT) algorithm is a supervised learning algorithm categorizing under the decision trees. The word "Forest" is included in the name of the algorithm hence it makes a bunch of trees. It makes 500 trees in default. The bootstrapping techniques are used to make 500 samples from the dataset to make 500 trees. The algorithm uses ensemble methods to produce the final solution. The random forest algorithm uses horizontal filtering (make samples by considering the different variations of the dataset) as well as vertical filtering (make samples by considering ranks of the attributes) techniques. The main advantage of using a Random Forest algorithm is controlling the overfitting of the data set with predictions [18], [19].

2) Random Tree (RT) classification algorithm: Random Tree (RT) algorithm is also a supervised learning algorithm. The algorithm uses ensemble methods bagging technique to generate a random set of data from which to build a decision tree. The random tree uses k number of attributes at each node of the decision tree but no control over the overfitting of the data set [20].

3) REP Tree classification algorithm: The REP (Reduced Error Pruning) Tree is the simple and most comprehensible decision tree which is used to reduce error pruning strategy. It's a convenient decision tree learner that creates a decision or regression tree with feature selection using information gain based on class variable and prunes it with reduced error pruning. The tree traversal was performed using the REP algorithm from bottom to top, and then each internal node was checked and replaced with the most frequent class with the most concern about the tree accuracy, which must not be reduced. This technique will be repeated until no further pruning reduces the accuracy [20].

4) LMT classification algorithm: The basic structure of a Logistic Model Tree (LMT) is a regular decision tree structure with logistic regression functions at the leaves. A tree structure is made up of a set of non-terminal nodes and a set of terminal nodes. The LMT approach deals with both numeric and nominal attributes, and missing values, as well as binary and multiclass target variables. Induction trees and logistic regression are combined in LMT. Cost-complexity pruning is used in LMT. The speed of this method is much slower than the others [21].

5) J48 classification algorithm: Quinlan's C4.5 algorithm is used to create J48. It builds the tree by selecting the best attributes at each node using the gain ratio. Each feature of the dataset divides it into small partitions to rank the attributes based on criteria that each partition is more consistent with respect to the class outcome. The attribute with the highest rank is used to split the data set. The algorithm will ideally terminate when all the instance in each partition belongs to one class. J48 creates a decision node based on the class's predicted estimations. The J48 decision tree can handle specific characteristics, data with lost or incomplete attribute estimations, and variable attribute prices. Pruning can improve accuracy in this situation [17], [21].

6) Hoeffding Tree (HT) classification algorithm: The Hoeffding Tree (HT) algorithm is one of the most basic algorithms for both stream data and static data classification. In the case of stream data, it can learn from huge data streams incrementally and at any time, given that the distribution of producing examples does not change over time. It generates decision trees in the same way as the standard batch learning approach does. Mathematically, Hoeffding trees and decision trees are connected. The HT technique is based on the basic principle that minimum sample size can frequently be sufficient for determining the best splitting attribute [22].

C. Evaluation of the Methodology

A trained classifier performs the function of assigning new data items in a given 255 collection to a target category or class by using two approaches.

1) Holdout method: as shown in Fig. 3, in training a classifier, the data set is separated into the training data set and test data set. In general, the training dataset contains 2/3 of data from the dataset, and the rest of the data is categorized as the testing dataset[23], [24].

2) 10–folds Cross-Validation (10-folds CV): k-folds Cross-Validation (CV) is a commonly used training control technique in learning a classifier. It applies the resampling technique to evaluate classification algorithms. The dataset is split into k number of groups. It randomly selects 1 data group as the testing dataset and the remaining groups (k-1) as the training dataset. Then build the data model by using the training dataset and evaluates it by using the testing dataset. Here each group has a chance to select as the testing dataset at a time and select as the training dataset at k-1 times. In general, 10-fold CV is used [23], [24].

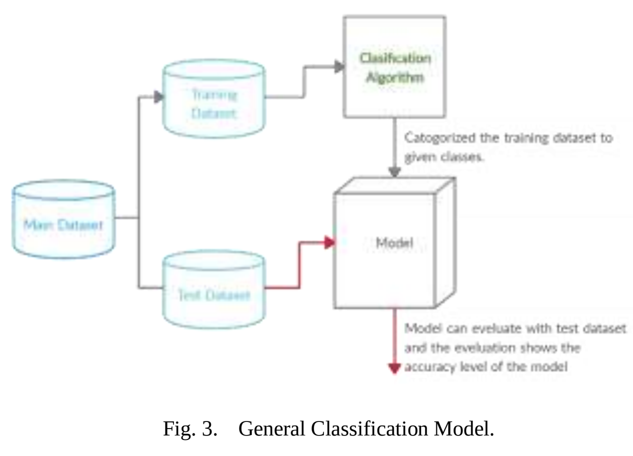

Fig. 3. General Classification Model.

There are several metrics to measure the accuracy of the classifier built.

1) Correctly classified instances and incorrectly classified Instances: This shows how many instances are correctly classified by the model and how many instances are incorrectly classified by the model. it gives numerical value as well as the percentage. Therefore, if it shows a higher value for the Incorrectly Classified Instances than Correctly Classified Instances then the built model is not good. And also, if it shows Correctly Classified Instances as 100% then it is also not a good outcome as the data over-fitting to the model may more validation error. The value between 80 to 100 for Correctly Classified Instances is usually accepted.

2) Confusion matrix: Confusion matrix also generates according to the Correctly Classified Instances and Incorrectly Classified Instances. The matrix size depends on the number of options in the output class. For example, if the output class has only two options then it generates a 2 by 2 matrix.

$option\_1$	$option\_2$	
a	b	$option\_1$
c	d	$option\_2$

In here,

a + d = value of Correctly Classified Instances

b + c = value of Incorrectly Classified Instances

3) Kappa statistic: This is also a good measurement to check the accuracy of the model. Simply it shows the accuracy of classifying into the correct class when considering any random data point. This value is generated by matching expected accuracy with observed accuracy. The following formula uses to calculate the kappa statistic.

$$\text{kappa statistic} = \frac{\text{observed accuracy} - \text{expected accuracy}}{1 - \text{expected accuracy}} \quad (1)$$

This statistic is used for the model evaluation as follows:

- Kappa statistic < 0 means there is no agreement with accuracy.
- 0 < kappa statistic < 0.20 means that the accuracy is slight.
- 0.21< kappa statistic < 0.40 means that the accuracy is fair.
- 0.41< kappa statistic < 0.60 means that the accuracy is moderate.
- 0.61< kappa statistic < 0.80 means that the accuracy is substantial.
- 0.81< kappa statistic <1 means that the accuracy is perfect.

4) TP rate: This means True Positive rate and it is also a numerical value. It gives how many positive instances are correctly classified into the classes. The following formula uses to calculate the TP rate.

$$\text{TP rate} = \frac{\text{True positive instances}}{\text{Total number of positive instances}} \quad (2)$$

5) FP rate: Opposite of the TP rate. This means a False Positive rate and it is also a numerical value. It gives how many negative instances are incorrectly classified into the classes. The following formula uses to calculate the FP rate.

$$\text{FP rate} = \frac{\text{False positive instances}}{\text{Total number of negative instances}} \quad (3)$$

6) Precision: This talks about how many selected items are relevant to the given class. It shows a proportion of instances that are truly inside the class. The value can take by using the following formula.

$$\text{Precision} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} \quad (4)$$

7) Recall: This talks about how many relevant items are selected in the given class. It shows the proportion of instances that are classified inside the class. The value is derived by using the following formula.

$$\text{Recall} = \frac{\text{True Positive}}{\text{True Positive} + \text{False negative}} \quad (5)$$

8) F-measure: This is a value that is taken by considering precision and recall. It shows the connection between the low false positives and the low false negatives. Therefore, it is better to get a value near 1 for this and if you take a value near 0 then the model is quite bad. The following formula determines F-measure.

$$\text{F} - \text{measure} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (6)$$

9) ROC Curve/AUC: The Receiver Operator Characteristic curves are commonly used to graphically show the relation between TP rate and FP rates for every possible cut-off test or a combination of tests. An important parameter associated with ROC curves is AUC that stands for Area Under Curve. The classifiers usually take an AUC value between 0.5 and 1.0 where 0.5(random guessing) is considered as worst and 1.0 is the best.

D. Generation of Training and Testing Dataset

Dividing the dataset into training and testing data can be done as shown in Fig. 4. The training dataset takes 2/3 of the total dataset and the testing dataset takes 1/3. All of these two datasets contain “SH” type people as well as people whose health state=“H” and health state = “UH”. Here the health state = “H” group contains both “SH” type people and the people who have become healthy without considering the total WBC’s standard hematology reference value. These notations were introduced and described under Data Preparation in Section III.

E. Experiment Results

Classification algorithms are applied to the dataset with training controls, holdout (using given training/testing dataset), and 10-fold cross-validation to find the best outcome. Table I shows the parameter measures needed to check the accuracy of the model for the training dataset.

The model built by the Random Forest algorithm using the training dataset and the model built by the Random Tree using the training dataset showed the highest number of correctly classified instances and the lowest number of incorrectly classified instances.

When considering the Kappa Statistic, the model built by the Random Forest algorithm's kappa statistic value is higher than the model built by the Random Tree algorithm's kappa statistic value. Therefore, the Random Forest Tree algorithm outperforms all the other algorithms.

The detailed experiment results of the RFT algorithm is given in Fig. 5. As depicted in Table I and Fig. 5, the model built by the Random Forest algorithm with the training dataset has the highest TP rate for both healthy and unhealthy classes. The weighted average of the TP rate and FP rate of this model are 0.915 and 0.279 respectively. The weighted average value for the precision and recall are 0.911 and 0.815, respectively.

F-measure value is an important value when considering the accuracy of the model. The F-measure value for healthy and unhealthy instances is 0.738 and 0.949, respectively. The weighted average is 0.911 which is close to 1.

As shown in Fig. 5, the Confusion Matrix of Random Forest summarizes that 48 healthy instances are classified as healthy, 24 healthy instances are classified as unhealthy, 318 unhealthy instances are classified as unhealthy and 24 unhealthy instances are classified as healthy.

The AUC curves drawn to the Random Forest models for both unhealthy and healthy instances are shown in Fig. 6 and Fig. 7, respectively. AUC values of it for both healthy instances and unhealthy instances give the same value of 0.971. Both curves have deviated much far from the diagonal line close to 1.0.

IV. RESULTS AND EVALUATION

The model built by using the Random Forest algorithm was used to evaluate the test dataset and the results of it are shown in Fig. 8. As similar to the results for the training dataset described in Fig. 5, the results for the test dataset have also shown the excellent performance of RFT with the low variance.

As depicted in Fig. 4, there are 38 healthy instances and 166 unhealthy instances. The confusion matrix shown in Fig. 8 shows that the deviation of TP and TN values from the actual is very much low.

An estimation of the local reference range of WBC is determined based on the values of WBC of the healthy instances predicted by the RFT algorithm. The manual inspection of those healthy instances shows that WBC values lie within the range of 4100mm^3 – 12800mm^3. When compared with the standard reference range of WBC shown in Fig. 9, it can be observed that the local reference range of WBC is not the same as the standard reference range.

Some local WBC reference ranges which were established in other countries are as follows.

- 4420mm^3 – 11100mm^3 in Estern India [2].
- 2900mm^3 – 9600mm^3 in Sudan[1].
- 1900mm^3 – 10100mm^3 in Togo [9].
- 2800mm^3- 7200mm^3 in Malawi [5].

The above ranges have differed from the standard WBC reference range as well as our result. The nutrition levels in African countries may cause to return very lower boundary value for WBC. Sri Lanka is in a better state when compared with the African countries regarding nutrition levels. Hence the received range for WBC is reasonable.

V. Conclusion

Medical Science is an immense area. Day by Day the area is updated. This research relates to Medical Science which spans across a vast area covering many disciplines and gets updated daily. The whole research was run based on certain disciplines such as Hematology, healthiness, unhealthiness, etc. The concept “healthy” is very complicated to define in medical science. It does not have a simple idea. It can be defined by using various subcategories. Hematology is such a subcategory. Medical officers may identify a person as healthy by looking at his blood reports. But it may not be correct as there will be a person with a good blood report but with disabilities on eye, ear, etc., inappropriate living styles like food habits, exercise habits, alcohol addictions, etc., diseases that cannot be detected from blood reports, or else everything is good but not healthy in mentally. Therefore, healthiness may not be determined always from the blood reports.

However, assuming that if a person is suffering from a disease, medical officers often check the blood reports to detect the disease, Hematology science is very helpful in such kinds of scenarios. This small area was addressed only through this research which assumes the healthiness depends only according to the blood reports.

The outcome of this research is to determine a local hematology reference range using data mining and machine learning techniques and the selected dataset was belongs to the adults in Sri Lanka. The research focused on finding a local reference range for total WBC value only. Hence a local reference range for the total WBC value was determined. The standard WBC (leukocyte) referential range is 4000mm^3 – 11000mm^3 and the local reference range which was empirically determined as the result of this research was 4100mm^3 – 12800mm^3. By repeating the same experiment for several different datasets and taking the average of the results, the accuracy of the local reference range can be further improved. And the proposed framework for WBC can be used to determine the local hematology reference ranges for other Hematology tests as well.

When considering the similar works discussed in Section II, most of the researchers who tried to establish local hematology reference ranges for their countries have used statistical approaches. The drawbacks of statistical approaches have been discussed in Section II. The proposed approach using data mining and machine learning concepts is the best solution to address all mentioned drawbacks. It does not depend on data distributions or the number of data records. Also, data mining and machine learning concepts perform well with the fair representation of the sample dataset.

There are several limitations in this research. The data used for the research belongs to people over 21 years old. The dataset has been taken from hospitals, laboratories in a particular area and hence does not cover the whole area of Sri Lanka. Further, the accuracy of the dataset plays a vital role in this nature of the research. In this regard, a carefully set up survey can be conducted to obtain blood samples from selected donors. Despite the set setup is not straightforward and involves high cost, the following suggestions are recommended in selecting the donors.

- Should cover different geographical areas, climate zones, cultural backgrounds, etc. in Sri Lanka.
- Use the medical history of the donors to categorize them as healthy or not.
- Incorporate the food habits, living styles, disabilities, BMI index, smoking habits, alcohol consumption, sexual diseases, etc. too to determine the healthiness of the donors.

A WSM-based Comparative Study of Vision Tracking Methodologies

Sara Bouraya, Abdessamad Belangour
Laboratory of Information Technology and Modeling
Hassan II University, Faculty of Sciences Ben M'sik
Casablanca, Morocco

***Abstract*—Vision tracking is a key component of a video sequence. It is the process of locating single or multiple moving objects over time using one or many cameras. The latter's function consists of detecting, categorizing, and tracking. The development of the trustworthy solution for video sequence analysis opens up new horizons for a variety of applications, including intelligent transportation systems, biomedical, agriculture, human-machine interaction, augmented reality, video surveillance, robots, and many crucial research areas. To make efficient models, there are challenges in video observation to deal with, such as problems with the environment, light variation, pose variation, motion blur, clutter, occlusion, and so on. In this paper, we present several techniques that addressed the issues of detecting and tracking multiple targets on video sequences. The proposed comparative study relied on different methodologies. This paper's purpose is to list various approaches, classify them, and compare them, using the Weighted Scoring Model (WSM) comparison method. This includes studying these algorithms, selecting relevant comparison criteria, assigning weights for each criterion, and lastly computing scores. The obtained results of this study will reveal the strong and weak points of each algorithm mentioned and discussed.**

Keywords—Multiple object tracking; object detection; WSM method; computer vision; video analysis

I. Introduction

Target/Object tracking is the challenge of determining the location, path, and attributes of objects of interest using sensor measurements [1]. A sensor could be any measuring equipment that collects information about targets in the environment, such as sonar, radar, infrared sensor, lidar, camera, ultrasound, microphone, or any other sensor. Object tracking is common goals include determining the number of targets, their states, and their identities, such as velocities, positions, and in certain situations their features. The radar monitoring of aircraft is a typical example of target/object tracking.

Based on measurements collected from radar, the object tracking issue, in this case, aims to determine the number of aircraft in a surveillance area, their types, such as commercial, military, or recreational, their speed, and their identities and positions. The object tracking problem contains a variety of sources of uncertainty, making it a difficult undertaking. Object motion, for example, is frequently subject to random disruptions; sensors could misdetect objects, and the number of objects/targets in a sensor's field of view could change at random. Sensor measurements are prone to random disturbances, and the number of measurements acquired by a sensor could vary and be unpredictable from one look to the next. Objects may be closer, and the measurements acquired may not be able to distinguish among them properly. Sensors could offer data even when there is no object in the area of view.

Humans could track objects visually with relative ease. However, it is not obvious, and it is difficult for a computer to track a moving object under illumination variation, with different shapes and format, object-to-scene and object-to-object occlusions, as well as background, clutters, and with several appearances in-camera projective space, object appearance, and object disappearance. Multiple object tracking is a set of tasks to reach tracking starting from object detection, object classification then objects tracking. Tracking objects is following their trajectory with video and their different positions within frames. Lastly, Multi-object tracking or multi-target tracking is gaining widespread interest across different research areas ranging from autonomous cars and vehicles, video surveillance, human-machine interaction, virtual environment, biomedical analysis, and so on. These objects may be pedestrians, cars, fish, vehicles, motorcycles. Although object tracking has a wide range of areas, it is still suffering from problems that we are going to discuss carefully in the next coming sections. Most of the researchers are trying to tackle these challenges carefully; however, some of them fail to solve some of the obvious problems. That is why we are offering you this comparative study that aims to identify, analyze, and compare the different object tracking methods.

As a result, this work provides a weighted scoring model (WSM)-based comparison evaluation of different methodologies. Our comparative study begins with the extraction of crucial criteria for comparison and a description of each criterion (Section 5). These criteria have been gathered from relevant work comparative research (Section 3) in addition to some other criteria that are missed. The WSM approach is then used to calculate final scores for each algorithm, which requires weight attribution (Section 5). The results are depicted as a chart and carefully discussed (Section 6).

II. Related Work

Many scientific studies have been conducted to develop multi-object tracking systems and applications based on a wide range of algorithms of the deep learning era and other eras. Many researchers and scientists have put up scientific efforts in this direction to apply several algorithms. The authors provide solutions in a variety of areas, including Smart City, Smart Vehicle, Industry, logistics, medical, surveillance, etc.

Several studies have compared multi-object tracking methods relied on different methods and directions. Each comparative study has its uniqueness and crucialness.

In [2], the authors picked up just three algorithms (Extended Kalman Filter [3], Gaussian mixture model GMM [4], and Mean Shift Algorithm [5]) and compared them. On the one hand, resulting in that GMM performs better when there is occlusion, contrary to Extended Kalman filter. On the other hand, the mean shift algorithm is best suited to single target tracking, at meanwhile, the results reveal that this approach is unable to detect many objects when even minor occlusion exists.

In [6], the authors are comparing multi-object tracking methods for sports events, choosing four algorithms; namely, Medianflow [7], boosting[8], multi-instance learning(MIL) [9], Kernalized correlation filter (KCF) [10], measuring as well as comparing their performances. Resulting from that the tracking of the object is efficient if the object's movement is constant when utilizing the MEDIANFLOW[7] algorithm. However, if the object's movement suddenly changes, it will be unable to follow the trajectory. For tracking many items in a sporting event, the KCF [11]algorithm, performed best, boosting had a greater tracking success rate than MIL, and it tracked roughly 5 times faster.

In [12], the authors are including an examination object detection method, object representation, and feature selection, and object tracking over many frames. By comparing seven different techniques (Kalman Filter[13], Particle Filte[14]r, Mean shift [7], CamShift[15], KLT tracker[16], template matching[17], Contour Tracking [18]) relied on number of object tracked, occlusion handling, optimal or not. Resulting from that Kalman Filter, KLT tracker, Particle Filter, Contour Tracking is handling occlusion and they are optimal strongly the last two ones could strongly track multiple objects.

In [19], the authors are presenting a paper that provides a brief overview of the numerous object detections, categorization, and tracking algorithms in the literature, as well as analysis and comparison of the many strategies utilized at various phases of tracking; reaching a comparison of the different techniques Point-Based Tracking, Kernel-Based Tracking, Silhouette Based Tracking. Concluding that single object tracking provides good accuracy for many types of movies with varying conditions, such as low resolution or weather changes.

In [20], the authors wrote a comparative examination of multiple vision tracker categories is conducted by the work to determine which one is the most successful in tracking construction resources. The benefits and limits of each kind of tracker are discussed, as well as the testing procedures for evaluating them. The methods are divided into the same categories used in the previous paper. The kernel-based ones are insensitive to illumination conditions and scale variation than point tracking-based methods as well as point tracking are effective under occlusion.

In [21], on the one hand, the authors examine various object tracking techniques in this research. The classification of these techniques is the same classification as in the previous papers kernel, silhouette, and point tracking-based. Their comparison is based on a wide range of criteria, concluding that point tracking methods are dealing better with occlusion; meanwhile, they are optimal. On the other hand, they present the advantage and the limitation of the different existing methods.

In [22] authors discuss Background subtraction, template matching, Frame difference, and shape-based approaches that are some of the most frequent approaches used in object tracking. In addition, they talk about topics like detection and tracking. At the end of this review on object detection and tracking methods, they summarize a table containing the advantages and disadvantages of usual object tracking methods. Concluding that the best method of object vision tracking vision is by combining different methods at the same time.

In [23], this comparison is evaluating 2D to 3D vision tracking method's performance, reaching a comparison also for the usual sub-categories kernel object tracking, point object tracking, silhouette object tracking. Concluding that the first findings of this comparison indicate that of the two types of trackers examined for construction-related applications, kernel-based approaches are more trustworthy.

In [24], the authors present a review of the existent approaches of moving object detection, their Challenges, and mentioning object tracking at the end. The object tracking methods that are mentioned in this article are Mean-shift, KLT, Condensation [25], TLD, Tracking Based on the Boundary of the Object. Mentioning that, TLD [26] is an award-winning, real-time method for tracking unknown objects in a video sequence.

III. Background

A. Vision Tracking

The difficulty of determining the trajectory of an object in the image plane as it moves across a scene is known as tracking. Various ways of tracking the object include kernel tracking, point tracking, and silhouette tracking.

Various ways of tracking the object include point tracking, kernel tracking, and silhouette tracking. The following categories could be used to categorize cribbed tracking methods.

Because of the enormous variety of applications and the high-performance of vision tracking in many fields, object tracking has sparked a lot of interest and attention in the field of computer vision. Two key stages must be completed in order to achieve vision tracking. The initial stage is to detect targets of interest, which could be done either automatically or manually depending on the approach used. The second stage, also known as target localization, involves following the discovered objects and predicting their changes in terms of position and form in subsequent image frames.

B. Target/Object Tracking Methods

As mentioned in Fig. 1 there are three main subclasses of object tracking [1]:

- Point tracking.
- Kernel tracking.
- Silhouette tracking.

Table I is summarizing an overview of object tracking methodologies their main goal, their advantages, their disadvantages, and some of their methods. Additionally, Table II illustrates the advantages and limitations of object tracking methodologies.

1) Silhouette based tracking approach: Because of their irregularity, many sorts of objects could not be successfully represented using simple geometric shapes due to their complexity. Silhouette-based approaches give a precise form description for different objects'/targets' shapes. Heads, hands, and shoulders are examples of composite shapes that are difficult to characterize with geometric geometry or shapes, that is what this category is made for; in other words, to shape non-geometric shapes. A suitable geometric shape for those objects/ targets will be given by this methodology. The main goal of this mechanism of tracking is to detect the target region in each frame using the assistance of a target model outputted from previous frames. It is possible to deal with a variety of object shapes, object split and merge and occlusions. The model is represented by object edges, a color hologram, or a contour. Shape matching and contour tracking are the two types of silhouette tracking that we use. These techniques are capable of handling a variety of problems such as it could be used to manage a wide range of objects of various shapes means dealing with a wide range of target's shape, and it also handles occlusion, silhouette tracker may split and merge objects as well. This silhouette-based tracking could be divided into two main categories, i.e. contour-based tracking approaches and shape matching tracking approaches.

a) Contour Tracking: Iteratively evolving an initial contour based on object placement in previous frames to a new place in the current frame is how this strategy works. Object portions in the current frame must overlap the object in the previous frame for the contour to evolve. When tracking is based on contour evolution, two ways could be used. State-space models, which are utilized for motion and contour shape modeling, are used in the first method. The other technique generates the contour directly by using direct minimization methods to reduce contour energy. Consider gradient descent, one of the most appealing aspects of this approach is its ability to handle a wide range of object shapes. The silhouette could be represented intuitively by a function defined on a grid, and it could also be expressed clearly by a set of control points to indicate its border.

b) Shape Matching: In the kernel technique, shape matching performs similarly to template-based tracking. Another method for Shape matching is to look for silhouettes that are similar in two consecutive frames. The process of silhouette matching is similar to that of point matching. Background subtraction is used to conduct Silhouette detection. Density functions, silhouette boundaries, and object edges make up the Models object. Hough transform techniques will be used to handle occlusion and dealing with a single object.

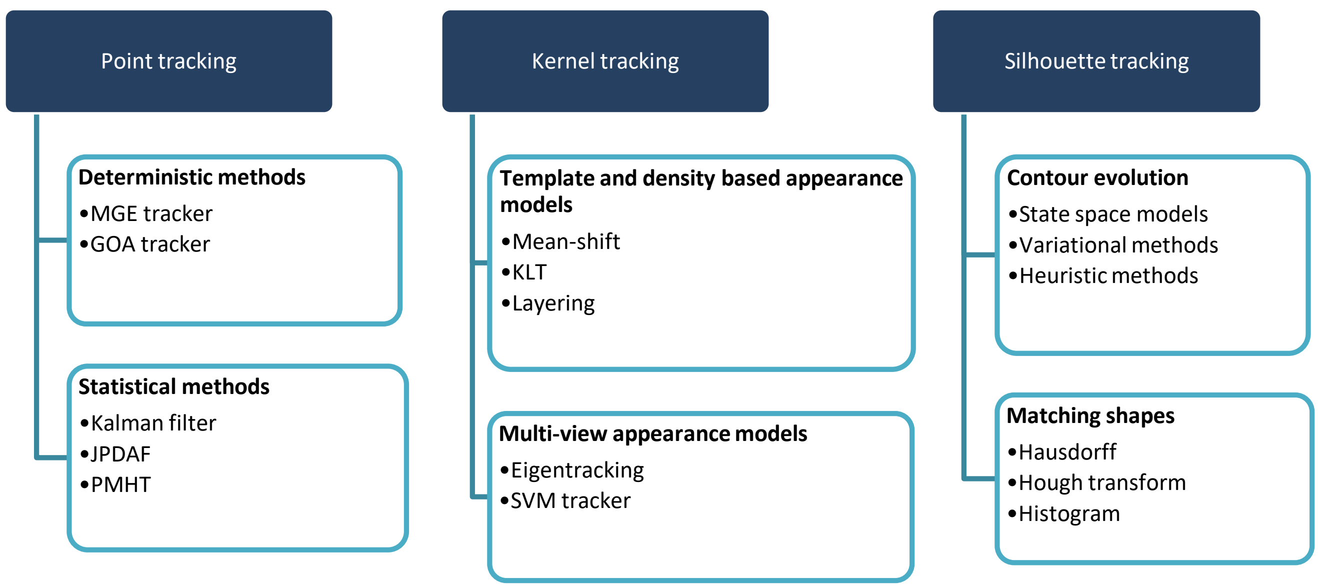

Fig. 1. Object Tracking Main Methodologies [1].

TABLE I. OBJECT TRACKING METHODS

	Kernel tracking		**Silhouette tracking**		**Point Tracking**	
Main goal	Estimating object motion		Tracking exact contour		tracking small objects	
Advantages	handling occlusion		Ability to represent a wide range of shapes, handle a large variety of object shapes		tracking small objects	
Disadvantages	handling multiple objects		handling occlusion and object merge and split		Handling occlusion at the meanwhile appearance and re-appearance	
Categories	Template based models	Multi-view models	Contour evolution	Matching Shapes	Deterministic	Statistical
Some of the methods	Mean-shift	SVM Tracker	Variational methods	Histogram	MGE Tracker	MHT filter

TABLE II. ADVANTAGES AND LIMITATIONS OF OBJECT TRACKING METHODS

Tracking Methods	**Advantages**	**Limitations**
Kalman Filter	. Capable of tracking pictures that are noisy. We could not rely on the average of past values if our sensors deliver incorrect data or if they do not produce any data at all for a certain time. Outliers are dealt with the use of Kalman filter. . Work for linear models and Gaussian distribution.	. Kalman filter is unusual for non-gaussian problems.
Particle Filter	. An efficient algorithm used in the world of non-gaussian and non-linearity. In addition to the capability of multi-modal filter that why it is widely used. . Particle filter methods are extremely adaptable, simple to develop, parallelizable, and suitable in a wide range of applications.	. Particle filters do not have a strict proof of convergence
Mean shift	. When there are a lot of colors, this is a good option.	. Could not be applied in the case of complex scenes.
KLT tracker	. Handle Occlusion	. Multiple object tracking this method Becomes complex.
Template matching	. It is a lot easier to set up and utilize.	. A slow method for recognizing new variations of a pattern. · It only works if the object is always visible in the video; else, false detects will occur. . When there are a lot of objects/targets, it is difficult to keep track of them all. . Complex templates are not recommended. . When items leave the frame or become occluded, problems could arise.
Contour Tracking	. Complex models for non-rigid and rigid objects could be highly handled. . Illumination levels do not have a high impact	. It is difficult to deal with entry objects.

2) Kernel-based trackers: Kernel-based tracker utilizes representations and appearance of the object/target of interest using ellipsoidal or rectangular shapes. It is possible to track a target or an object by tracking the motion of each kernel on the associated frame. The motion of a target or an object could be classified in different ways including rotation, translation, or transformation. The motion of an object could be categorized in different ways including affine transformations, rotation, and translation. Several algorithms could be utilized for this goal, which differs relying on the quantity of target tracking, object motion method, or object representation. For instance, in real-time applications, geometric shapes are frequently used to represent objects. One disadvantage of employing geometric shapes is that they may not completely encapsulate the target object, allowing background objects to be visible. The mean shift method, template matching, and CAMShift tracking are some available approaches that could be used for kernel tracking, relied on Kernel tracking methodology.

a) Simple Template Matching: Template matching is a computer vision program that finds related objects in photos. For mapping similar patterns between images, template matching is an important part of the image analysis process. Image processing is a computer-assisted technique for analyzing and manipulating images. It is mostly used to enhance the quality of an image, as well as to detect and highlight specific areas of the image. Image processing techniques are primarily used to improve the quality of an image and perform feature extraction and classification for a variety of purposes. In the automation process, template matching is used to recognize objects and improve the quality of the searching process. It is used to locate the target item from an image in astronomy, meteorology, medical imaging, remote sensing, and many other related domains. It is an image processing approach in which a specific object is chosen as a target, to be recognized and mapped to the original image. For images matching, a variety of techniques are utilized, with Edge-based matching and Greyscale-based matching being the most popular. Greyscale-based is an extension of correlation-based that works regardless of the orientation of the image. The greyscale-based technique recognizes both the template location and orientation, allowing us to recognize images from a variety of angles. Edge-based matching is similar to greyscale matching, except that instead of computing the entire image, only the edges of the image are recognized and matched with surrounding pixels.

*b) Mean Shift Method:*This tracking method utilizes density-based appearance models to describe a target. A histogram is used to represent the appearance model (color, texture) within this algorithm. This method employs an iterative tracking approach, which entails identifying similar pattern distributions within a sequence of frames.

c) Support Vector Machine (SVM): SVM is a general classification approach that uses a set of positive and negative sample values to define it. Positive samples containing tracked visual objects are used in SVM.

The negative samples are made up of everything else that isn't being tracked. It could handle a single picture as well as partial occlusion of an object, although physical initialization and training are required. SVM finds the best separating hyperplane between two classes. In SVM as a tracker, the positive examples for SVM-based trackers are photos of the object to be tracked, while the negative examples are those objects that are not to be tracked. Negative examples are typically made up of background regions that could be mistaken for the object.

d) Layering based tracking: Multiple objects could be tracked using this kernel-based tracking approach. Each layer has an elliptical form, motion (such as translation and rotation), and layer appearance (based on intensity). Layering is accomplished, first by accounting for background motion such that the object's motion may be calculated using 2D parametric motion from the rewarded image.

3) Point-based trackers: It is a common computer vision task with a wide range of applications. During tracking, moving objects are carefully represented as feature points in an image structure. Point tracking is a difficult problem, especially when occlusions occur. Point Tracking could handle the following situations, suitable for tracking extremely small objects. Objects identified in successive frames are represented by points, which are linked together based on the prior object state, which could include object position and motion. This method necessitates the use of an external system to detect the objects in each frame.

These are the main point-based trackers' methods:

a) Kalman Filter: This is one of the most used techniques of point-based trackers [27]. In a real-world scenario where we are tracking a moving object from our car or vehicle, we could not rely on the average of prior values if our sensors transmit incorrect data or if they do not send any data at all. Outliers are dealt with with the use of the Kalman filter. It only evaluates one sensor data at a time and compares it to prior values, giving the previously estimated measurement more weight if it has a low error and giving the newly taken value from the sensor more weight if it has a low error. Because it only analyzes a proportion of newly taken value at each time step, it avoids the problem of outliers. Well, the Kalman filter is used to anticipate most measurements where we acquire data from hardware, such as sensors, and we do not know how reliable the data is. The Kalman filter algorithm could be broken down into the following steps:

1) Initialize state and covariance matrices: When we receive the first sensor measurements, we initialize the state (position and velocity) of the moving target, such as a bicycle.

2) Forecast step: Based on certain prior data and the model, we produce a state prediction.

3) Step of updating: The predicted and measured locations are merged to produce an updated location. Depending on the uncertainty of each number, the Kalman filter will give greater weight to the projected or observed location.

4) The process is repeated as the automobile receives new sensor readings. They have relied on the algorithm of Optimal Recursive Data Processing.

b) Particle Filter: The versatility of particle filter technology is due to its efficiency in nonlinear and non-Gaussian systems. Furthermore, the particle filter's multi-modal (we want to track, simultaneously, zero, one, or more than one object) processing capabilities is one of the reasons for its widespread use. Particle filtering has been used in a variety of fields around the world. It is based on the Markov Chain Monte Carlo improvement strategy, by generating Markov chains with good convergence; the approach generates samples from the target distribution. Particle filter methods are extremely adaptable, simple to develop, parallelizable, and suitable in a wide range of applications. The particle filter method can handle different problems such as occlusions.

c) Multiple Hypothesis Tracking (MHT): Several frames have been detected in the MHT algorithm for better tracking results. The MHT algorithm is an iterative process. Each Iteration starts with a set of track hypotheses that already exist. Each theory is made up of a group of disconnected tracks. A prediction of the object's position in the next frame is made for each hypothesis. Then, the predictions are compared, using a distance metric. The MHT could track several objects, deal with occlusions, and calculate optimal solutions. The algorithm can create new tracks for objects entering the field of view FOV and terminate tracks for objects exiting the field of view FOV.

C. Research Areas

Due to the existence of several objects in our lives, for instance, humans being (pedestrians [28], sport players [6], shoppers), vehicles (cars [29], motorcycles, buses), animals (fishes [30], birds [31], cats), other (cells [32], insects), and so on; many scientific studies have explored implementing multiple object tracking using different algorithms. These initiatives are divided into research areas or domains; see Fig. 2, such as:

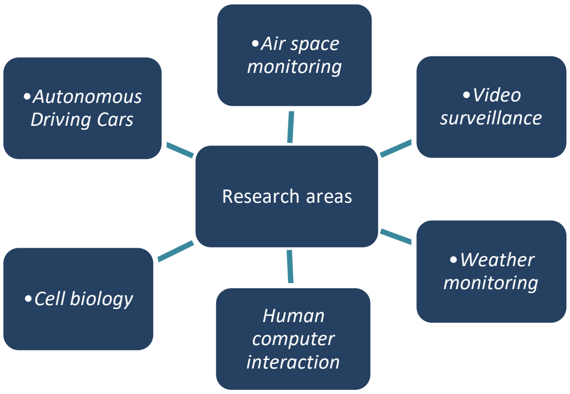

Fig. 2. Some Research Areas of Object Tracking.

- *Air space monitoring*: The tracking of aircraft using radar is a serious and crucial issue [33], for instance, air traffic control. Radar tracking is employed also in military surveillance systems to identify aircraft: identity, type, location, speed, and the item's potential intents to establish, for instance, if the object is a threat. Radar is capable of a wide range of observations, from high range measurements to simple-resolution imaging. Radar [34] utilizes radio waves to determine the object's distance, direction, and radial speed.

- *Video surveillance: Surveillance* [29] using digital video is becoming increasingly popular. Airports, banks, casinos, highways, stadiums, crowd gathering areas, buildings, streets, railway stations, department stores, and all government organizations now use video surveillance to reinforce their security. Video surveillance is employed in almost every aspect of society to deter criminal activity and improve public safety and security [35]. A large typical building in a major city has a vast network of cameras installed on main floors, entrances, huge gathering areas, hallways, offices, and labs.

- *Weather monitoring*: Weather bureaus employ a variety of approaches to give weather forecasts [36]. Tracking weather balloons, which offer data on high-altitude wind velocity, humidity, pressure, and temperature, is a widely used method. Each day, weather bureaus released 50 to 70 balloons at various times throughout the day. The frequency of releases rises during extreme weather because more data is required for good weather forecasting. Each weather balloon must be tracked to obtain weather-related parameters at various heights of the atmosphere.

- *Cell biology*: Pathologists and medical researchers commonly examine death and birth rates, as well as the mobility of biological cells [37], in research studies of humans, plants, insects, and animals. In immunology, the immune of organism response is linked and correlated with lymphocytes' life cycle. The division/death and birth rates of every generation of cells are the parameters of interest. The velocity or morphology of sperm cells is an interesting metric of infertility study.

- *Autonomous Driving Cars*: The self-driving [38] systems are also known as autonomous cars or driverless vehicles; a car is a vehicle that could sense its surroundings and move in designated lanes without the need for human intervention. In other words, object detection and tracking are required for autonomous vehicles to reliably recognize and localize dynamic targets in the environment surrounding vehicles that contain the tracking system. The principles of developing self-driving automobiles are completely based on perceiving their surroundings and automating tasks.

- *Human-computer interaction*: Gestures [35] have long been thought of as an inter-action approach that may help us communicate with our computers in more creative, natural, and intuitive ways [39]. Many modern apps rely on human-computer interaction are developed. Because of the interest of psychology and cognitive science, for example, understanding user behavior such as body motions, particularly facial expression recognition is one of the main uses of computer vision that are gaining a lot of interest due to its different uses.

- *Augmented reality*: Nowadays, this research area is gaining a crucial and wide range of interest. Augmented reality [40] is the fact of making users in a virtual environment using different virtual objects. By generating perceptual information to enhance real-world objects in a variety of ways, including aural, visual, somatosensory, haptic, and olfactory. Object tracking is implemented in augmented reality to reach sometimes the interaction between objects or targets.

- *Robotic*: Nowadays, this research area is gaining a lot of interest due to its importance in many cases. Robots may replace human tasks by doing these tasks efficiently or sometimes better than humans. Vision tracking is relying on detection or tracking reached by robots [41].

IV. Weighted Scoring Model

The Weighted Scoring Model is a mechanism for comparing objects and picking up between them, based on a set of criteria. The WSM Method is used to compare the algorithms. The application of this strategy could be done in the following steps (Fig. 3):

- Step 1: Determine which criteria will be used to perform each method.

- Step 2: Granting weights to groups of criteria based on the crucialness of each one.

- Step 3: Create a table with nominal values for each criterion of each distribution.

- Step 4: Create a table with weighted values for each criterion. The weight is expressed as a percentage. The overall weight is 100 percent.

- Step 5: A calculation of the product score of weights and nominal values is elaborated for each method.

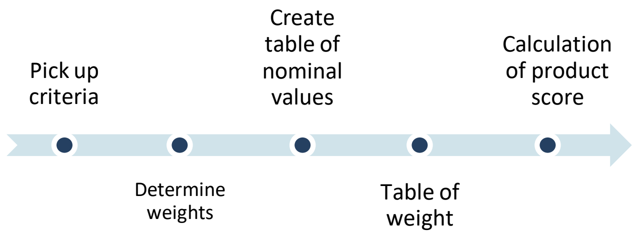

Fig. 3. WSM Process.

V. Comparison of Multiple Object Tracking Methods

A. Comparison Criteria

The comparative criteria were chosen based on several video analysis investigations especially object tracking. Some criteria have been derived from the works cited below. Those are essentially the challenges are mentioned in Fig. 4 that all multi-object tracking methods and algorithms have in common to tackle them or to deal with them:

- *Occlusion*: Occlusion when the target is fully or sometimes partially or occluded. Complex interactions between objects result in both temporally and spatially occlusions, making object tracking a challenging problem [42]. In other words, in complicated scenes and crowded settings, it is common for an object's direction to be obscured, either by a background component such as a stationary scene or by other targets.
- *Illumination variation*: The Illumination in the target area has been changed due to different issues such as obstacles that make birth of shadow, camera position and resolution, and the main source of illumination. Changes in illumination and posture are all essential elements that influence recognition rates, with the effect of light circumstances being particularly crucial. The direction of the light source may cause the image to be excessively bright or too dark, causing the algorithms to have difficulty in accurately obtaining crucial features [43].
- *Clutter*: The background in the vicinity of the target has the same color or texture as the target. A more complex scene results in more detection failures, which include undetected targets (false negatives) or spurious targets (false positives). As a result of the inadequate detection, data association accuracy is not reliable. Most algorithms are aiming at separating the background from targets [44].
- *Enter field of view*: Objects are moving in different directions with different motions. That makes the birth of more objects that enter the field of view and others leaving the field of view, and we are talking about object appearance and object disappearance, two different phenomena within a video for non-rigid objects.
- *Speed*: The motion or speed of the targets/ objects on the ground truth is large. The states of the targets, or their positions, change with time. At first glance, we are unsure about their precise location. However, Things become more complicated when the object's direction changes. Each object has its speed and direction. The model should be able to deal with these fast changes [45].
- *Scale variation*: The bounding boxes shape of the object in different frames is ranging widely. The algorithm or model should be able to track the target from numerous perspectives and scales. One of the reasons for the disparity in performance is the large-scale variation amongst object instances, particularly the difficulty of recognizing very small objects [46].
- *Optimal*: This criterion is defining if the algorithm needs training or not, it needs resources or not.
- *Outlier*: some values are outside the range of what is expected, unlike the other data. We call these values outliers.

B. Comparison Study

Table of nominal values is carried out. For each criterion, the value that corresponds to each method is assigned. These values are extracted from related work.

C. Application of Weighted Scoring Model

The score of each challenge based on its existence is determined using the WSM method, as shown in Table III. The weight percentages are assigned based on the importance of the criterion. This collection of criteria is given priority due to their necessary requirement: number of objects tracked– Enter Field of view – Outlier. A weight of 12% is ascribed to each of their criteria. The following category of crucialness is given to the criteria Scale Variation – Illumination variation – Occlusion. A weight of 10% is ascribed to each of their criteria. And optimal, a weight of 20% is ascribed due to its importance and 14% associated to speed.

By applying the weight scoring model in Table IV, we are going to associate to each value a number relying on its crucialness n/a →0, all the criteria are ranging from 1 to 5, after getting these values we multiple each value by its weight as illustrated in Table III of weights. The result is mentioned in the table.

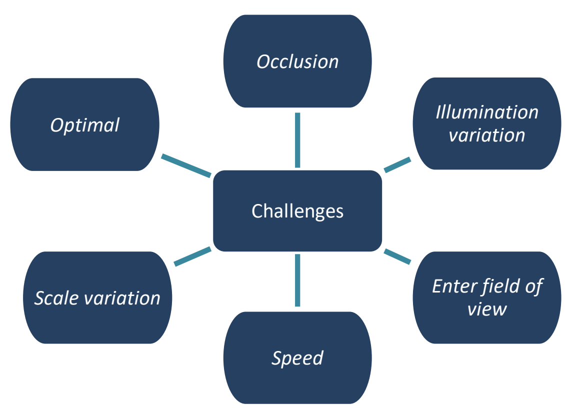

Fig. 4. Some Crucial Challenges of Object Tracking.

TABLE III. ASSOCIATED WEIGHTS TO EACH CRITERION

Criterion	**Abbreviation**	**Proposed weights**
Number of objects tracked	NO	12%
Illumination variation	IV	10%
Occlusion	OCC	10%
Enter Field of view	FOV	12%
Scale Variation	SV	10%
Speed	SP	14%
Optimal	OP	20%
Outlier	OUT	12%

TABLE IV. COMPARISON FOR DIFFERENT OBJECT TRACKING METHODS. (PT: POINT TRACKING, KT: KERNEL TRACKING, ST: SILHOUETTE TRACKING)

	TT	NO	OCC	IV	SP	SV	OP	FOV	OUT
Kalman Filter	PT	1	1	2	3	3	3	2	2
U Kalman Filter	PT	5	2	2	3	4	4	2	4
Particle Filter	PT	5	2	2	3	4	4	3	4
MGE tracker (D)	PT	5	2	1		4	1	2	4
GOA tracker	PT	5	2	2	n/a	3	2	1	n/a
JPDAF	PT	5	2	n/a	n/a	3	1	1	n/a
Multiple Hypothesis Tracking MHT	PT	5	2	n/a	n/a	4	1	3	4
Probabilistic Multiple Hypothesis Tracking PMHT	PT	5	2	3	3	3	1	3	n/a
Mean shift	KT	1	2	3	2	1	1	n/a	2
KLT tracker	KT	1	3	3	2	1	1		1
Simple Template matching	KT	1	1	1	2	1	2	1	1
SVM	KT	1	3	3	2	1	1	1	2
Layer/Layering based Tracking	KT	5	1	3	2	1	2	1	1
Eigentracking	KT	1	1	3	2	1	1	1	n/a
Shape Matching	ST	1	1	2	2	4	1	0	3
Contour Tracking	ST	5	1	3	2	4	1	1	3

D. Comparison

1) SilhouettComparison of tracking methodologies based on the three categories kernel, silhouette, and point: The spider Fig. 8 illustrates a comparison of silhouette, point, and kernel tracking category methodologies relied on the Number of objects tracked, Occlusion, illumination variation, speed, Scale variation, Enter field of view, Optimal, outliers.

2) Comparison of the three categories: According to Fig. 8 results, Multiple Hypothesis Tracking is the most favored algorithm within the three categories. Most of the advantages dealing with tracking multiple objects, handling occlusion, and give optimal solutions. Without ignoring that can handle object appearance and disappearance. There is a big lack of handling fast motion that should object-tracking methodologies take into consideration. Regarding our Comparison of Silhouette tracking, methodologies see Fig. 6, they are a bit similar to each other and that describes that they belong to the same category.

Fig. 5 shows that SVM within Kernel tracking methodologies is dealing better with occlusion and outliers. Regarding point tracking, in Fig. 7 multiple MHT and PMHT are gaining the best results due to their speed and their way to handle outliers, occlusion.

3) Comparison based on Table V: The Table V illustrates see that contour tracking, particle filter, MGE tracker, GOA tracker, JPDAF, MHT, and PMHT are gaining the best results to the other methods.

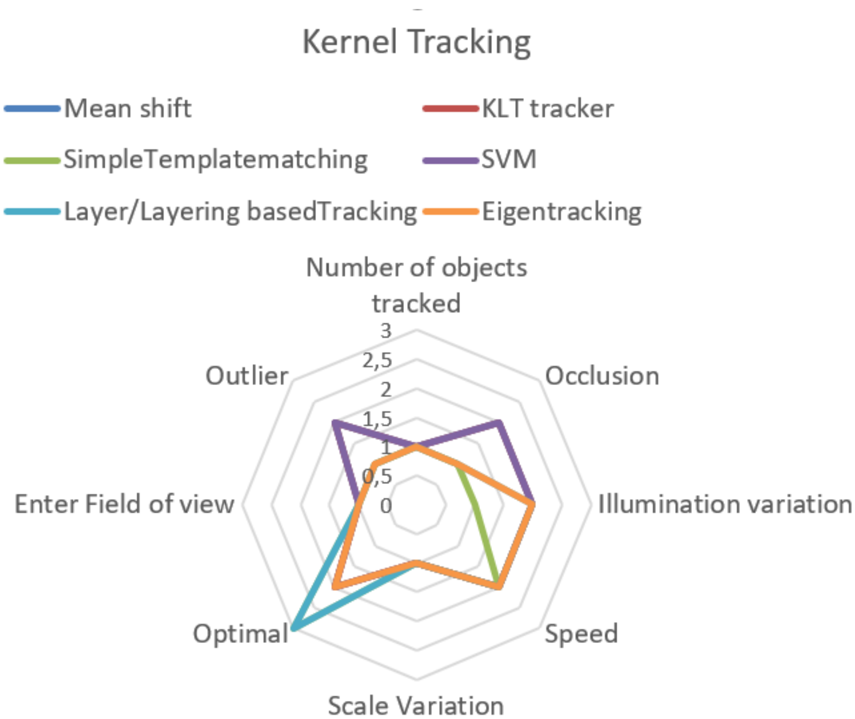

Fig. 5. Graph of Multicriteria Comparison of Kernel Tracking Methodologies.

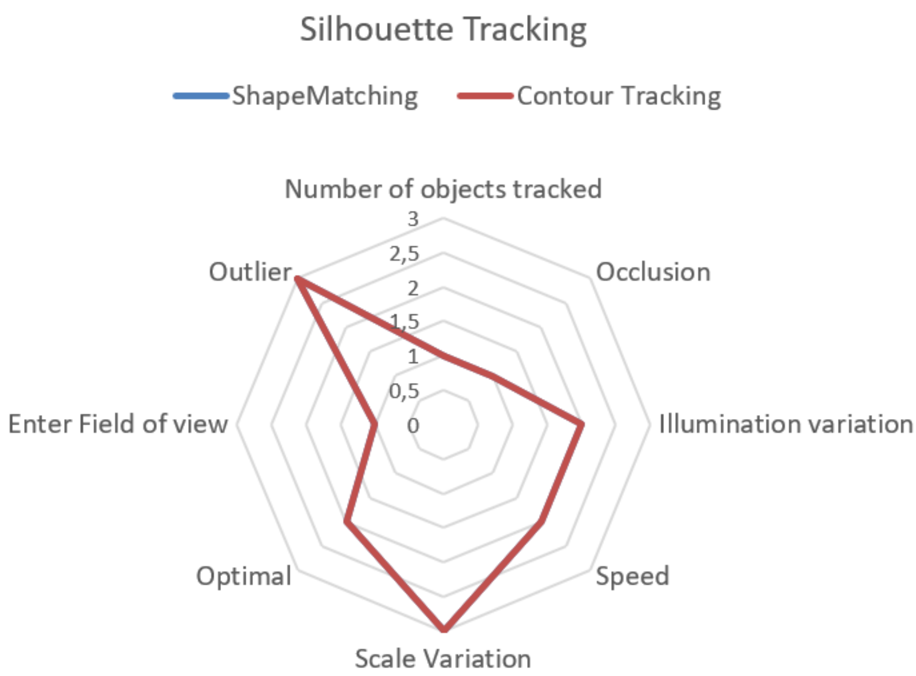

Fig. 6. Graph of Multicriteria Comparison of Silhouette Tracking Methodologies.

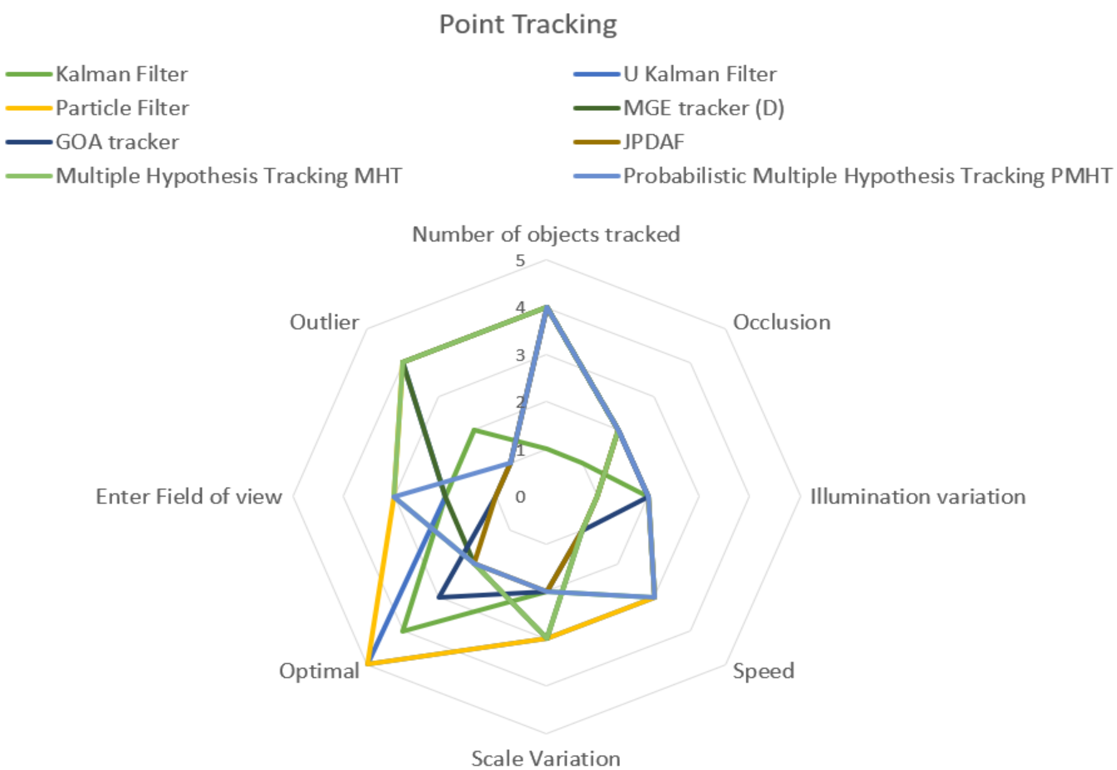

Fig. 7. Graph of Multicriteria Comparison of Point Tracking Methodologies.

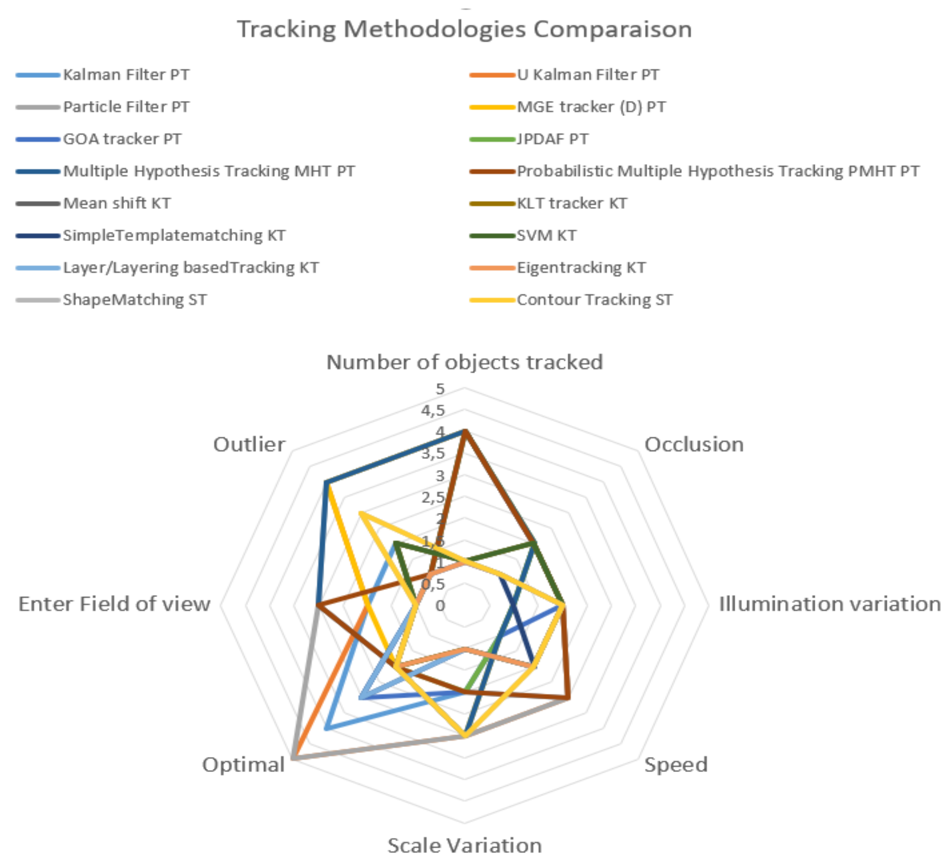

Fig. 8. Multicriteria Spider Graph.

TABLE V. COMPARING THREE OBJECT TRACKING CATEGORIES' METHODOLOGIES

Method	Score
Kalman Filter PT	2%
U Kalman Filter PT	10%
Particle Filter PT	10%
MGE tracker(D)	10%
GOA Tracker PT	10%
JPDAF	10%
MHT PT	10%
PMHT PT	10%
Mean shift KT	2%
KLT Tracker KT	2%
Simple Template Matching KT	2%
SVM KT	2%
Layer/ Layering based Tracking KT	10%
Eigen tracking KT	2%
Shape Matching ST	2%
Contour Matching ST	10%

VI. DISCUSSION

According to the previous results, some algorithms are dealing better with multiple objects such as Particle Filter, MGE tracker, GOA tracker, JPDAF, multiple hypothesis tracking, and so on. Point and Silhouette methodologies deal better with scale variation. However, they do not handle fully occlusion. Regarding kernel tracking methodologies they handle occlusion but they do not go forward with handling multiple objects.

On the one hand, relying on the comparative study-based WSM method Point Tracking is better to deal with small objects and tracking multiple objects, however, is not good to deal with occlusion and object appearance and disappearance.

On the other hand, Kernel tracking methodologies are handling better occlusion at the meanwhile estimate the object motion but they don't deal with multiple objects also this method is not a good choice to handle multiple objects.

Regarding Silhouette Tracking methodologies are dealing better with tracking object based on silhouette. This method is accurate to track objects or targets because of its ability to track different shapes. But these techniques are not good to handle occlusion at the same time these methods are not better to handle multiple objects.

Multiple object tracking is still facing a wide range of challenges. We could not find one category or method that deals with all of these challenges. Each algorithm or method is mastering to handle a challenge. Hope to find a hybrid method that deal with all these issues.

VII. CONCLUSION

A comparison of object tracking methods is has been presented in this research. This project has begun with the identification of a group of relevant works that are implementing these methods and the proposal of object tracking methods that fits the needs of various areas. Then a list of research areas that are concerned by these works has been discussed. There is also a set of criteria that this comparison has been based on. Using the Weight Score Model, the scores for each algorithm evaluated have been obtained. Various scores or results not only have been assisting us in determining an overall ranking amongst these platforms, but they have also revealed their internal strengths and shortcomings concerning each criterion.

This research has identified a collection of failures that object tracking algorithms face. The main problems that platforms face are the number of targets and it is optimal. Researcher must provide an algorithm that considers optimal aspects to provide an accurate model or algorithm of object tracking to the wide range of the research areas, such as surveillance, robotic, and other fields. The researchers must create a model or algorithm that could tackle and operate the different challenges, dealing with the different problems carefully due to the crucialness of this such as the biomedical one. Finally, researchers must embrace the resources used, which is a set of tools for increasing product quality and lowering development costs while also ensuring optimal delivery for users.

Future work will focus on the measurement of the accuracy of each method under each challenge. Our main goal is to implement, test, compare and analyze the results of point tracking methods, kernel tracking methods, silhouette tracking methods that we are going to implement to track multiple objects/ targets. Our main aim is that we are going to decorticate models or algorithms relying on their architecture, iteration, practical use, and their uniqueness. At the end, a summary table of the comparison is developed.

Nilai, Malaysia

***Abstract*—Cyber-attacks such as ransomware, data breaches, and phishing triggered by malware, especially for iOS (iPhone operating system) platforms, are increasing. Yet not much works on malware detection for the iOS platform have been done compared to the Android platform. Hence, this paper presents an iOS malware classification inspired by phylogenetics. It consists of mobile behaviour, exploits, and surveillance features. The new iOS classification helps to identify, detect, and predict any new malware variants. The experiment was conducted by using hybrid analysis, with twelve (12) malwares datasets from the Contagio Mobile website. As a result, twenty-nine (29) new classifications have been developed. One hundred (100) anonymous mobile applications (50 from the Apple Store and 50 from iOS Ninja) have been used for evaluation. Based on the evaluation conducted, 13% of the mobile applications matched with the developed classifications. In the future, this work can be used as guidance for other researchers with the same interest.**

Keywords*—*iOS; mobile malware; reverse engineering; exploitation; phylogenetic

I. Introduction

Currently, smartphones based on Android and iOS are commonly and widely used across the world. Yet, they also possess security concerns, especially security exploitation by malware such as ransomware and cryptojacking [1]. Unfortunately, the rapid increase of smartphone users contributed to mobile malware growth in the iOS environment. Malware is referred to as software that can infect devices, software, or networks with malicious attention without the owner's consent. It can harm the victim with malicious activities such as stealing confidential information, identity theft, and spying on the victim. There are different kinds of malware such as viruses, Trojan, spyware, worms, and ransomware. It will cause a lot of chaos when the malware has successfully penetrated the smartphone system.

Whenever new vulnerabilities are released, Apple will update or patch to fix the weaknesses. By keeping the patch up to date, Apple makes sure the devices are secure enough to use. The malware attacks are carried out by attacking the kernel, giving the attacker private APIs (Application Programming Interfaces) and permission, and eventually gaining confidential information about the user. Unfortunately, there is a growing number of malwares attacking iOS devices. For example, it uses private APIs to implement malicious intent and view and steal its data. Fig. 1 shows statistics on the detection of malware for iOS by Welivesecurity [2].

Compared with Android, iOS is considered more secure. For example, in the iOS platform, the hardware, software, and even their booting process are monitored and secured by Apple procedures [3]. This scenario has an impact where many attackers tend to focus on Android malware rather than on iOS. In addition, based on the Mc Afee Labs Threat report on June 2018 shows a drastic increase in malware growth, and there were almost 2.9 million samples recorded [4]. Furthermore, high-risk vulnerabilities were detected in 38 percent of iOS mobile apps in 2019 compared to 43 percent of Android mobile apps [5]. Indeed, 40 percent of iOS malware attacks in 2017 targeted banking services [6]. As in Q1 2020, new mobile malware cases have surged by 71 percent, and new iOS malware grew by over 50 percent [7]. Hence, this paper presents a new mobile malware classification for iOS inspired by phylogenetics to overcome the above challenges. Phylogenetics is a term borrowed from biology and has been mapped into the cybersecurity field. It can be used to detect and predict malicious activity. This approach consists of malware behaviour, vulnerability exploitation, and surveillance features [8].

The proposed malware classification developed in this paper can detect any malware attacks against possible social media and online banking exploitation. This new iOS classification aids in the detection, identification, and prediction of new malware variants.

This paper is organized as follows. Section II discusses the related works, while Section III presents the methods used, and Section IV explains the findings. Finally, Section V discusses the conclusions reached by this paper.

II. Related Work

A. iOS Malware Attacks

iOS malware attacks have been increased rapidly from years to years, and many researchers try to invade the issues and solve them to reduce the impact. Attackers evolve with the latest technology to ensure their intention to exploit user data can be conducted smoothly without interruption. Work by [9] found Trident worm and exploited three types of vulnerabilities once the link is clicked. Once it has been executed, the attackers will have the privilege to read, write, and any software in the infected device. Next, work by [10] found iKee Worm, which gathered logs on many jailbroken devices by scanning the OpenSSH port and used the root account and default password, and once infected, it will scan the surrounding IP address to spread the worm. They also found the YiSpecter worm, where the malware used ISP (Internet Service Provider) traffic, Window SNS (Self/Non-self) worm and offline applications installation, and other routes for transmission. It installed malware applications intending to collect private user information. Then, a previous study by [11] used Xcode Ghost worm where malware was sitting in the background of legitimate apps, then it did the data mining and injected malware in the apps when compiled. It possesses a new capability to prompt a fake alert dialogue to phish user credentials, hijack opening specifics URLs, and read and write data in the user clipboard. Work by [12] found AceDeciever that infects any Apple device connected to infected PC (personal computer) were capable of obtaining Apple ID (identification) and password. Finally, work by [13] found Keyraider worm, where it intercepted iTunes traffic and stole user login credentials, GUID (Globally Unique Identifier) devices Apple requests push service certificates and private keys, and iTunes receipts for purchase. It then sends this data to a remote server. Based on these previous studies, it can be concluded that there is a growing number of malwares attacking iOS users, and a solution to overcome these challenges is urgently needed. So, this paper proposes a new mobile malware classification as one of the mitigation solutions for the above challenges.

B. Phylogenetics

The phylogenetics aims to discover the origin of malware genes evolving [8]. It deals with evolutionary history and uses a tree diagram for different organisms and taxonomic groups. Malware phylogenetics emphasizes the similarities and relationships between a set of malwares. For example, a few types of phylogenetics tree models are the minimum spanning tree (MST), the persistent phylogeny tree, and the dendrogram [14]. Works by [15] used process mining which detects temporal logic properties designed to detect Android malware families and track the phylogenetic tree. [16] also used process mining where the program calls trace from a mobile application to classify associations and repeat execution patterns. Work by [17] used fuzzy clustering algorithm, where a malware program's syscalls can be modelled to produce a malware fingerprint with a number of associations and recurrent execution patterns. The author in [18] used discrete time Markov chain (DTMC) due to the paired KLD (Kullback-Leibler Divergence) and JSD (Jensen-Shannon Divergence) track calculation, it is computationally intensive. Bayesian network algorithm used by [19], learn a Directed Acyclic Graph (DAG) from observational data using statistical inference of conditional dependence and an informative antecedent to partial variable ordering. Work by [20] used extension of graphical lasso to discover a precision sparse matrix based on the kernel's combined matrix. An example of the phylogenetics diagram is depicted in Fig. 2. In this paper, there are three features mapped into phylogenetics to develop the classification. The identified features are malware behaviour, iOS version, and surveillance features.

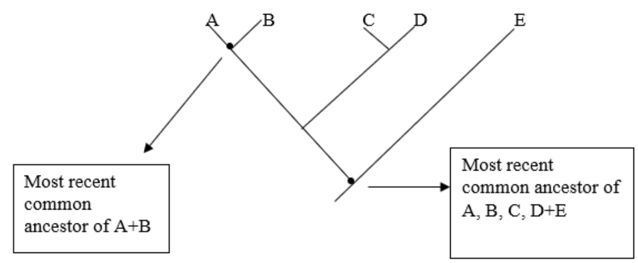

Fig. 2. Phylogenetic Diagram.

C. Features Mapped to Phylogenetic

Malware behaviour can be classified into five parts: infection, activation, payload, operating algorithm, and mitigation [8]. In dynamic analysis, these five components are significant to classify malware based on their behaviour. The malware behaviour used EDOWA (Efficient Detection of Worm Attack) worm classification as the underlying concept [21]. Apple keeps satisfying their customer by serving them with the best version of iOS. The version must be updated to make sure the user is secured enough from any current security issues. The update also has some new features that can help user’s life easier [22]. Surveillance features used in this research come from 5 basic functions in the smartphone, consisting of call, SMS (Short Message Service), photos, audio, and GPS (Global Positioning System). All these features are dangerous whenever been exploited. The attacker can profit by exploiting either one of its features [23].

As one of the mitigating options for the stated challenges above, this research presents a new mobile malware classification based on phylogenetics. Three features are mapped into phylogenetics, which are malware behaviour, iOS version, and surveillance features.

III. Methodology

The overall process involved in this experiment is summarized in Fig. 3.

The analysis took place once the malware had been executed. The findings were mapped during the research regarding malware behaviour, vulnerability exploitation, and mobile phone surveillance features to allow malware classification. Malware behavior is referred to as infection, payload, operating algorithm, activation, and propagation. Vulnerability exploitation refers to the iOS platform version, either iOS 10.x, 11.x, or 12.x, and the type of exploitation used. At the same time, mobile phone surveillance features are the features that attackers could use to exploit a mobile phone in the form of SMS,call log, camera, audio, and GPS. The mathematical formula for the proposed mobile malware classification is as follows:

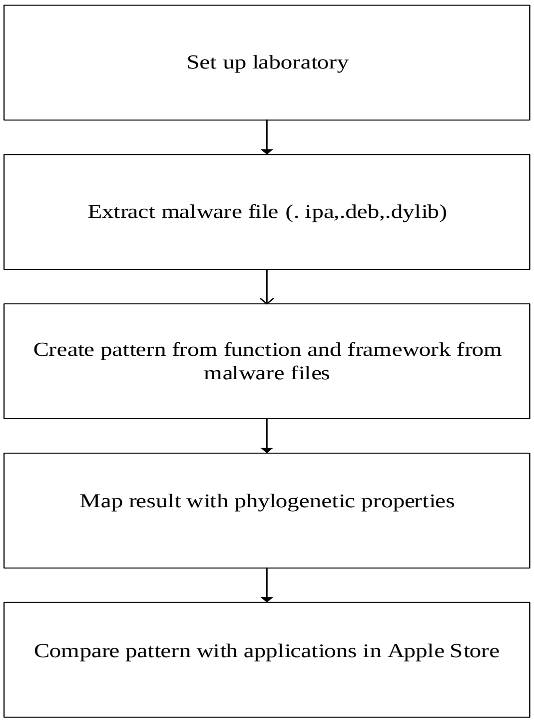

Fig. 3. Experimental Process.

Let α_1 be a malware architecture I, and $\alpha = \bigcap_{i=1}^{p} \alpha_i$, β_j be a mode attack j, and $\beta = \bigcup_{i=1}^{m} \beta_i$, γ_k be a connected asset in network k and $\gamma = \bigcap_{i=1}^{p} \gamma_i$.

Let M be the malware detection and T be a target asset. S is the detection model which can be defined in terms of the following function:

$$(M, T) = S \quad (1)$$

$$\text{where } M(\alpha, \beta, \delta) = \alpha + \beta + \delta \quad (2)$$

$$f(M_i, T_j) = S_{ij} \quad (3)$$

Where M represents the malware classification, T represents the target asset, and S is the detection model.

$$M(\alpha, \beta, \delta) = \alpha + \beta + \delta$$

$$\alpha = \alpha 1 \cap \alpha 2 \cap \alpha 3 \cap \alpha 4 \cap \alpha 5$$

$$\beta = \beta 1 \cup \beta 2 \cup \beta 3 \cup \beta 4 \cup \beta 5$$

$$\delta = \delta 1 \cup \delta 2 \cup \delta 3 \cup \delta 4 \cup \delta 5$$

$$\begin{array}{cccc} M_i & \alpha & \beta & \gamma \\ \vdots & & \ddots & \vdots \\ M_n & & \cdots & \delta_n \end{array}$$

where:

$\alpha 1 - \alpha 5$: payload, infection, operating algorithm, activation, and propagation

$\beta 1 - \beta 5$: iOS 10.x, iOS 11.x, iOS 12.x, iOS 13.x, iOS 1x.x

$\delta 1 - \delta 5$: SMS, call log, GPS, audio, and camera.

IV. Results

After the exploitation has been discovered, all the exploitation script's functions will be traced to their main frameworks to see what framework they are attacking during the malicious act. Then, the exploit is mapped into phylogenetics. The mapping result showed either the malware might lead to possible social media or online banking exploitation. If SMS or call is being exploited, it can be concluded as online banking exploitation. If any of those five features are being exploited, it is social media exploitation. Table I shows malware analysis results based on the mapping with the phylogenetics.

TABLE I. Malwares Mapped To Phylogenetic

Classification	**Description**	**Social Media Exploitation**	**Online Banking Exploitation**
E1: Unflod Malware			
α_1 - α_5 (Malware Behaviour)	**Payload:** Phishing. Stole the device's apple id, password and sent them in plaintext to the server. **Infection:** Host. From Chinese Cydia repositories **Operating Algorithm:** Stealth. **Activation:** Self-activation. Initiated their execution by exploring vulnerabilities in services that are available. **Propagation:** Passive monitoring. The malware infected those jailbroken devices that have download piracy Chinese repositories.	Possible exploitation	Possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1 (iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	GPS, SMS, call, audio, and photo		

E2: Spad Malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Destructive. Change the actual owner id for the ads into their id to obtain the revenue. **Infection:** Host. Result of some action taken by a user. The criminal hooks the legitimate functions and adds their tweaks. **Operating Algorithm:** Stealth. **Activation:** Human trigger. The malware will be functioning whenever the ads operate. **Propagation:** Passive monitoring. The malware only can infect jailbroken devices.	No possible exploitation	No possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	No surveillance features are involved as the attacker only exploits affect ads section		
E3+E4+E5+E6: Inception Malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Phishing. Collect device information and recording audio and send it to the c2(Command and Control) server. **Infection**: Host, Result of some action taken by a user. The malware will inject into the host whenever the user clicks a malicious link or download any doc files. **Operating Algorithm:** Stealth. **Activation:** Human activation. The malware will be executed when the file has been opened. **Propagation:** Passive monitoring. The malware only can infect those jailbroken devices that click the link or open the trojanized file.	Possible Exploitation	Possible Exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	GPS, SMS, Call Log, Audio, and Photos		
E7+E8: Xcodeghost Malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Destructive. Modifies Xcode, infects and steals some device information, and then sends it to the c2 server. **Infection:** Host. Infected the apps that Xcodeghost produced. **Operating Algorithm:** Stealth. **Activation:** Human trigger. The malware will be functioning whenever the apps been open. **Propagation:** Passive monitoring. The malware only can infect the user of the apps that have been created using Xcodeghost	No possible Exploitation	No possible Exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	No surveillance features are involved.		
E9+E10+E11+E12: Wirelurker Malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Phishing. Exfiltration of user data and exfiltration of application usage and device serial number information. **Infection:** Host. Infected through USB (Universal Serial Bus) when the device connects with the infected Mac. **Operating algorithm**: Stealth. **Activation:** Self-activation. It will start the malicious act once the malware has been injected into the device. **Propagation:** Passive monitoring. The malware only can infect users that connect their device with the infected Mac.	Possible exploitation	Possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	GPS, SMS, Photos, Audio, and Call All the surveillance features can be exploited by the attacker if they can brute force the victim's Apple ID as they already get the Apple ID.		
E13: Zerghelper malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Installing backdoor. Installed via a backdoor, requests the user to give Apple ID, shared Apple ID to other users, abuses the Apple ID by running different operations in the background, and abuses enterprise and personal certificates.	Possible exploitation	Possible exploitation

	Infection: Host. Spread via host file (mobile app). It camouflaged itself in a genuine mobile app. **Operating algorithm:** Stealth. **Activation:** Scheduled process. It is based on the location of the user and activates its payload only in China. **Propagation:** Passive monitoring. The malware camouflaged itself by claiming to resolve stability issues. It then guides the installation for two configurations. Only users in China will see the payload.		
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	SMS		
E14: Oneclickfraud malware			
α_1- α_5 (Malware Behaviour)	**Payload**: Destructive. Installing another app through OTA. **Infection:** Host. Distributed through an adult site. **Operating algorithm:** Stealth. **Activation:** Human trigger. The malware will be functioning whenever the play button been clicked. **Propagation**: Passive monitoring. The malware only can infect the visitor of the adult site	No possible exploitation	No possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below		
δ_1 - δ_5 (Surveillance Features)	No surveillance features involved		
E15: Xsser Malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Phishing. Act as spyware and harvesting information from user device thus send it to c2 server. **Infection:** Host. Installed via a rogue repository on Cydia, the most popular third-party application store for jailbroken iPhones. **Operating algorithm**: Terminate and resident. When triggered, xRAT will clean out its installation directory before issuing a package manager command to uninstall itself. Additionally, the developers behind xRAT created an alert system, flagging the malware operator if any of the following antivirus applications are present on a compromised device. **Activation:** Self-activation. It will start the malicious act once the malware has been injected into the device. **Propagation:** Passive monitoring. The malware only can infect users that use the repositories.	Possible exploitation	Possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	GPS, SMS, and Photo		
E16+E17: Muda malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Display advertisements over other apps or in the notification bar and ask users to download iOS apps it promoted. **Infection:** Host. Spreads via third-party Cydia sources in China and only affects jailbroken iOS devices. **Operating algorithm**: Stealth. **Activation:** Human trigger. The malware will be functioning whenever the apps are open. **Propagation:** Passive monitoring. The malware only can infect jailbroken devices that using third-party Cydia repositories.	No possible exploitation	No possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	No surveillance features are involved.		
E18+E19+E20: Tinyv malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Destructive. It connects with its C2 server to get remote commands and install specified IPA file or DEB file(s) in the background, uninstalling specified IPA app or DEB package(s) in the background and changing the /etc/hosts file. **Infection:** Hosts. Repackaged into some pirated iOS apps for jailbroken devices.	No possible exploitation	No possible exploitation

	Operating algorithm: Stealth. **Activation:** Human trigger. The malware will be executed whenever the apps are being used. **Propagation:** Passive monitoring. The malware only can infect the user that installed the pirated iOS apps.		
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below		
δ_1 - δ_5 (Surveillance Features)	No surveillance features involved		
E21+E22+E23+E24+E25+E26+E27: Yispecter Malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Destructive. Abusing enterprise certificates, installing malicious apps, uninstall apps, and self-monitoring and updating, collecting, and uploading device information, changing safari configurations, hijacking other apps execution, and pretending to be system apps. **Infection:** Host. Through hijacking of traffic from nationwide ISPs, an SNS worm on Windows, and an offline app installation and community promotion. **Operating algorithm:** Stealth. **Activation:** Self-activation. It will start the malicious act once the malware has infected the device. **Propagation:** Passive monitoring. The malware only can infect users that use the repositories.	No possible exploitation	No possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	No surveillance features are involved.		
E28+E29: Keyraider malware			
α_1- α_5 (Malware Behaviour)	**Payload:** Destructive. It is stealing Apple account data, certificates, and private keys. **Infection:** Host. Distributed through third-party Cydia repositories in China. **Operating algorithm:** Stealth. **Activation:** Human trigger. The malware will be functioning whenever the apps are open. **Propagation:** Passive monitoring. The malware only can infect jailbroken devices that using third-party Cydia repositories.	Possible exploitation	Possible exploitation
β_1 - β_5 (iOS Chain)	iOS version: Chain 1(iOS 10.x and below)		
δ_1 - δ_5 (Surveillance Features)	GPS, SMS, Call Log, Audio, and Photos		

Table I shows 13 of the 29 malware classifications mapped to phylogenetics, which can be used against possible exploitation for social media and online banking. The identified classification are E1 (Unflod malware), E3+E4+E5+E6 (Inception malware), E9+E10+E11+E12 (Wirelurker malware), E13 (Zerghelper malware), E15 (Xsser malware and E28+E29 (Keyraider malware).

In summary, the malwares have been reported based on the classification proposed. The analysis fits with the elements required for the classification based on this classification. Furthermore, every malware examined contains components that can be used for further exploitation.

Next, for the evaluation process, 50 anonymous apps from Apple Store and another 50 from the third-party store were selected. This is to test the practicality of the proposed classification in detecting any possible exploitation in the tested apps. As a result, 13% of the tested apps were identified with possible security exploitation. Two apps were from Apple Store, and 11 apps were from iOS Ninja. This 13% represents the possible exploitation either against social media or online banking.

V. Conclusion

Based on these experimental results, the proposed malware classification developed in this paper can be used to detect any malware attacks against possible exploitation for social media and online banking. These new iOS classification helps to identify, detect, and predict any new malware variants. Another important consideration for future improvement would be to revise the frameworks and functions involved in the iOS architecture from time to time and integrate with artificial intelligence-based alarms. Malicious apps will use the combinations of frameworks and functions in the iOS architecture to exploit the targeted feature successfully. Furthermore, as a newer iOS version will be introduced, a new framework and functions may also be offered. Hence, there is a need to add more malware classifications based on the mobile malware classification formulation developed in this paper.

Acknowledgment

The authors would like to express their gratitude to the Universiti Sains Islam Malaysia (USIM) for the support and facilities provided. This research paper project is under the grant: [P1-17-16120-UNI-CVD-FST].

ANNMDD: Strength of Artificial Neural Network Types for Medical Diagnosis Domain

Ahmed Hamza Osman
Department of Information System, Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Kingdom of Saudi Arabia

***Abstract*—The abundance of medical evidence in health institutions necessitates the creation of effective data collection methods for extracting valuable information. For several years, scholars focused on the use of computational techniques and data processing techniques in order to enhance the study of broad historical datasets. There is a deficiency to investigate the collected data of health disease in the data sources such as COVID-19, Chronic Kidney, Epileptic Seizure, Parkinson, Hard diseases, Hepatitis, Breast Cancer and Diabetes, where millions of people are killed in the world by these diseases. This research aims to investigate the neural network algorithms for different types of medical diseases in order to select the best type of neural network suitable for each disease. The data mining process has been applied to investigate the mentioned medical disease datasets. The related works and literature review of machine learning in the medical domain were studied in the initial stage of this research. Then, the experiments behind the initial stage have been designed with six neural network algorithm styles which are Multiple, Radial Based Function Network (RBFN), Dynamic, Quick and Prune algorithms. The extracted results for each algorithm have been analyzed and compared with each other to select the perfect neural network algorithm for each disease. T-test statistical significance test has been applied as one of the investigation strategies for the NN optimal selection. Our findings highlighted the strong side of the Multiple NN algorithm in terms of training and testing phases in the medical domain.**

Keywords—Medical data; neural network algorithm; multiple; radial based function network; dynamic; quick; prune; accuracy

I. Introduction

Currently the number of records in health databases is so huge thanks to technology which has made it possible to securely and effectively store and retrieve this large volume of data. The process of creating meaningful patterns or evidence from medical data sites is medical diagnosis [1]. The extract from these medical datasets helps the physician to diagnose disease in the early stages. The problem is largely solved by having adequate tools for dealing with such large data. A huge amount of research in this area has been carried out and it is still a very interesting area. There are numerous classification algorithms available, and it is worthwhile to do a more in-depth examination of these algorithms and their success on medical datasets such as [1-7]. We perform studies in this paper on a number of medical datasets using a variety of familiar prediction algorithms. The objective is to evaluate if preprocessing techniques prior to classification can improve classification performance. Materials containing the missing values, contours and noise are well known, and few papers analyze the effect of pre-processing to the best knowledge of the author [3].

For future documentation and for preparing future procedures, most healthcare organizations and research institutes digitally store patient records. Because of the difficulty and size of information, the noise and lacking of values, mining is a tedious task and it is very difficult to analyze in this heterogeneous medical dataset [8]. Most healthcare organizations and medical research institutions store their patients' data digitally for future references and future treatment planning [8]. Healthcare is a field which is closely linked to the daily life of all owing to the high uncertainty [9]. Machine learning (ML) is a powerful and flexible tool for analyzing and predicting biological outcomes and clinical data[10]. Early diagnoses benefit from the detection of useful trends in the medical dataset[11].

Machine Learning (ML) and Artificial intelligence (AI) and master learning are key terms for a range of algorithms, allowing computers to detect and determine data patterns. Despite a quiet time, AI's abilities are an omnipresent part of mainstream culture in a number of activities, from automated digital assistants to self-driving vehicles. Given some positive advances in cardiovascular oncology, however, a major AI revolution has not yet occurred. Cardiovascular routine patient care accumulates large quantities of electronic health record (EHR) data. Integrating a large amount of diverse data in a busy clinical environment is a challenge, leading to marked underuse of data that could influence clinical decisions. Artificial intelligence (AI) applies in general to computational algorithms, such that machines can gain secret information without being programmed directly[12]. Machine learning techniques are attracting substantial interest from medical researchers and clinicians [13]. Data mining is the discovery process of patterns and trends from the enormous amount of data and examines the various existing data mining techniques [14]. Several studies helped to find the most appropriate neural network algorithms for the classification of medical data and also showed the value of pre-processing in improving classification performance. Therefore, this study has investigated the effectiveness and efficiency of the neural network algorithms (NN) in healthcare in order to select the significant NN method that helps the medical doctor to make a diagnosis decision for a specific disease. Most healthcare organizations and medical research institutions store their patients' data digitally for future references and future treatment planning [8]. In addition to being used by clinicians, decision support systems are also helpful in making medical decisions; they're built on two main types, and the better ones assist with precise, consistent and prompt responses [15].

As machine training (ML) is commonly accepted as a technique to choose from in the common diseases pattern classification and predictive modelling, due to its specific advantages in critical features detecting in some diseases, the problems of this study can be summarized as:

1) Need for a clear method to identify the disease into disease stages, pattern or status. The number of patients who are infected is growing in specific disease.

2) The urgent need for an intelligent system that helps in the process of diagnosing diseases for themselves.

The goal of this research is to see the most useful disease features in predicting status and general patterns which can help us select models and select hyper parameters. The goal of this study is to identify the efficiency and effectiveness of some machine learning algorithms such as Neural Network algorithms in the healthcare domain. Our main objective is to investigate the neural network algorithms to adapt to a function that can predict the discreet new input class [16]. In particular, this study investigates and reviews the current healthcare systems in order to detect the shortcomings that need to be improved. The significant role in this study is to find and predict an early disease stage that can save patients' lives using neural network classification methods in order to help medical doctors to take suitable diagnosis decisions. Diagnosis at an early stage, when it isn't too large and hasn't spread, makes successful treatment more likely.

This study comprises six sections. The introduction to this study is explained in Section 1. The Section 2 discusses related works. The upgraded methodology and its fundamental method are discussed in Section 3. Section 4 will discuss data classification using neural networks. Section 5 will illustrate the experiments and results of the investigation. Finally, Section 6 will summarize the study's findings.

II. Related Work

For future documentation and for preparing future procedures, most healthcare organisations and research institutes digitally store patient records. Due to the complexity and volume of data and the noise and lack of values and noise, this mining is a tedious task, making it very difficult to analyse this heterogeneous medical dataset [8]. Most healthcare organisations and medical research institutions store their patients' data digitally for future reference and future treatment planning [8]. Healthcare is a field which is closely linked to the daily life of all owing to the high uncertainty [9]. Machine learning (ML) is a powerful and flexible tool for analysing and predicting biological outcomes and clinical data [10]. Early diagnoses benefit from the detection of useful trends in the medical dataset [11]. It's almost old news by now: big data is going to transform medicine. However, it is essential to remember that the data is useless by itself. Data must be analysed, interpreted and acted upon to be useful. Thus, it is algorithms that will prove transformative, not datasets. Obermeyer. and Emanuel (2016) therefore believed that attention needs to be shifted to new statistical tools in the field of machine learning, which are critical for everyone in the 21st century who practises medicine [17]. Shameer, et al. discussed existing approaches that use machine learning and bioinformatics for behavioural analysis as well as well as clinical, genetic and climatic methodologies in their talks [18]. Artificial intelligence (AI) applies in general to computational algorithms, such that machines can gain secret information without being programmed directly [12]. The computational study of machine learning is drawing significant attention from academics and clinicians alike [13]. The best of these schemes assist doctors in making decisions while others play a crucial part in making them [15]. Machine learning is the discovery procedure of patterns and trends from the enormous amount of data This study examined the various existing data mining techniques [14]. This study helps to find the most appropriate neural network algorithms for the classification of medicinal data and also will show the value of pre-processing in enhancing prediction results.

Much of the computer-based rule sets that deal with healthcare situations are "expert systems". Computer simulations operate in the same manner as ideal medical students: they apply theories to new cases. In the other words, machine learning methods go through training programs. The algorithms start with the patient stage, working their way through large quantities of variables in the process of compiling information before they come to a conclusion that can be applied to a variety of different patients.

Standard regression models, such as the result, the covariates, and statistical functions, may be seen to be in one way an extension of this phase Nonlinear, and immersive forms will work with a large number of predictors. When statistics are not feasible, the integration and interpretation of nuanced biomedical and healthcare data using artificial intelligence (CITL), supervised machine learning, deep learning, and cognitive approaches may be employed. H. Shameer, et al. (2018) was one of the research groups that explored the fundamentals and the uses of master learning algorithms; and they investigated the possible shortcomings and obstacles that machine learning could present in cardiovascular care[12]. Computer-based artificial intelligence and artificial-learning algorithms, respectively, are not all that novel in the medical field. In medical practice, risks are typically found in databases and are used to stratify patients or to provide anticoagulation guidance on which drugs to use [19]. This process entails analysing medical datasets in order to uncover intriguing trends in decision-making [14]. Machine learning algorithms have the potential to significantly increase the quality of healthcare in a variety of ways. Prognosis modelling algorithms assist health authorities in allocating money efficiently and physicians in selecting the right care choices for patients [19]. The multilayer perceptron of neural networks (MLPNN), logistic regression (LR) and validation is applied to test the predictive models [20].

Evaluation of machine learning algorithms depends on their accuracy, specificity and error rate [8]. Some used well-known regression equations, such as the simple linear and logistic, widely seen in clinical and modern statistical models such as Bayesian analysis, such as the data [18]. Analytic forecasting techniques include decision trees (J48) and

Bayesian analyses. The three mass classification methods used machine learning approaches to build three statistical models for the diagnosis of breast cancer. A standardised General Linear Model (GLM), a standard Support Vector Machine (SVM) with radial basis function, and single-layer neural networks were included. Predictive models were trained on the sample prior to the validation dataset. They used the validation datasets to compute the precision, sensitivity, and specificity of the three models – a decision aid for detecting breast cancer based on three kinds of decision tree factors. Simple decision tree (SDT) and Boosted simple decision tree (BDT). Many analyses were performed on several major classifiers including C4.5 (J48), Naïve Bayes, SMO, and Random Forests and compared with the results of these [11]. The Decision Tree C4.5 is unpruned. C4.5 is an increase in the previous ID3 algorithm of Quinlan. J48 creates decision trees using the idea of information entropy from the collection of labelled training data. J48 explores the uniform data benefit that results in choosing a data splitting attribute. The highest information gain attribute is used to make the decision. Then the little subsets use the algorithm. If all occurrences in a subset have the same class, the dividing strategy stops. A leaf node for this class is then made in the decision tree. The algorithm of Naive Bayes depends on conditions. It is using Bayes Theorem, an equation which calculates a probability by inspecting the recurrence of historical data values and values mixes. Given the probability of another opportunity that already occurred, Bayes' theorem finds the possibility of an occasion [21]. The document 'Prediction of diabetes use of the Bayesian Networks,' suggested by Mukesh Kumari et al. [22]. This article proposed to predict people, whether diabetic, not diabetic or pre-diabetic, by classifying the Bayesian Network. The dataset used is collected from a hospital that collects information from people with and without diabetes. Weka is the tool used for the study and exam. On the dataset of persons collected from the hospital, classification algorithm is applied and the results have been obtained. The author analysed the attributes' values to determine whether a certain individual is diabetic, non-diabetic or pre-diabetic in a dataset. The fact that a man is diabetic, non-diabetic or pre-dentinal had led to the determination of attributes such as qfast Gtt, casual Gott and diastolic blood pressure values above a given amount. The author concluded that 99.51 was best accurate in the classification with the Bayesian system. The paper 'Improved J48 Classification Algorithm for Diabetes Prediction' was proposed by Gaganjot Kaur et al. [23]. This work manages successful data mining to predict diabetes in patients' medical records. Today, diabetes in all populations and all ages is an extremely regular infection increasing the risk of developing renal disease, nervous damage, damage to the venous tract and visual impairment is a result of coronary disease. This paper uses the Pima Indians Diabetes Data Set which collects data from and without diabetes patients. Using the modified J48 classifier, the data mining method accuracy rate is determined. The WEKA data mining tool was used for manufacturing the J48 graders as a MATLAB API. The results of the test showed that the calculation J-48 is considerably different. Precision up to 99.87 percent have been demonstrated in the proposed calculation. V. Karthikeyan et al. [24]. Suggested the paper titled 'Data Mining Algorithm in Diabetes Disease Prediction Comparative Mining Classification (CDMCA)'. The data mining is an iterative development that is defined by discovery, by normal or manual techniques. Two types of supervised and uncontrolled classifications are classed in this paper, which uses the CDMCA data mining concept. This is the classification of the supervised diabetes-based data mining algorithms. It contains at least the plasma glucose diseases. This research describes C4.5, SVM, KNN, PNN, BLR, MLR, CRT, CS-CRT, PLS-DA as well as PLSLDA algorithmic discussion. The paper compares computer time performance, accuracy and data evaluated by means of a 10-fold Cross Validation error rate, and focuses on True Positive, True Negative, False Positive and False Negative and Accuracy. This shows that CS-CRT is the best algorithm. For this experiment, different data mining techniques are applied with the Pima Indian Diabetes Dataset. Pre-processing techniques convert raw data into useful and understandable formats to enable more precise results during algorithm execution. The features are extracted using permutation techniques from the pre-processed data and the classification techniques are performed in different combinations of features. The results achieved are evaluated for every combination [11].

Automatic risk prediction algorithms to guide clinical treatment; using unsupervised training techniques to more accurately phenotype complex conditions; and implementing algorithms to enhance the education of providers of healthcare intelligently [12]. Efficient classification of the medical dataset is then and now a big problem in data mining. Diagnosis, disease prediction and outcome accuracy can be enhanced if the relationships and trends are effectively extracted from these complex medical datasets [8]. The most serious scourge affecting the industrialised nations is CVD disease. Not only does CVD affect a large proportion of the population without warning but it also causes chronic suffering and disability in an even greater number [25]. The objective of this research was to collect the breast cancer data set for medical decision-making using clustering and data mining techniques [14]. Francis, F. and J. Saleema (2017) sought optimal features by combining the permutation input data attributes to improve the accuracy of the classifier [11]. These algorithms' performance assessments are based on precision, sensitivity, specificity and error rate. Heart statistics are the medical information used in this study[8]. BNs have been effective in developing powerful algorithms which can manage very large datasets and create predictive models of high quality from medical data and genomic [18]. A directed acyclic graph is a graph in which each node represents a variable and each arc represents a connection. Each arc is interpreted by BNs as a direct impact on a child node (variable) by a parent node (variable) [18]. The SVM, MLPANN, and LR models had accuracy, area under the curve (AUC), sensitivity, and specificity of 90.4 percent, 86.5 percent, 98.2 percent, and 49.6 percent, 85.9 percent, 76.9 percent, 97.3 percent, and 26.1 percent, and 84.7 percent, 77.4 percent, 97.5 percent, and 17.4 percent, respectively. Meanwhile, the independent predictors were discharge time creatinine, recipient age, donor age, donor blood type, etiology of ESRD, and post-transplant recipient hypertension [20]. The trained algorithms were capable of classifying cell nuclei with a high degree of accuracy (0.94 – 0.96), sensitivity (0.97 –

0.99), and specificity (0.97 – 0.99). (0.85 – 0.94). The SVM method produced the highest accuracy (0.96) and area under the curve (0.97) values. When algorithms were organised in a voting ensemble, prediction performance improved somewhat (accuracy=0.97, sensitivity=0.99, specificity=0.95) [13]. The results indicated that SDT and BDT obtained overall accuracies of 97.07 percent with 429 accurate classifications and 98.83 percent with 437 right classifications, respectively, during the training phase. BDT outperformed SDT on all performance indicators. The receiver operating characteristic (ROC) and Matthews correlation coefficient (MCC) values for BDT in the training phase were 0.99971 and 0.9746, respectively, which were superior to those of the SDT classifier. During the validation phase, DTF attained a classification accuracy of 97.51 percent, outperforming SDT (95.75 percent) and BDT (97.07 percent) classifiers. For DTF, the ROC and MCC values were 0.99382 and 0.9462, respectively [15]. That is the promise of medical machine learning: the wisdom contained in decisions made by almost all clinicians and the results of billions of patients should inform each patient's care. That is, every diagnosis, management decision and therapy should be customised based on all known patient information [26]. With machine learning located at the peak of inflated expectations, they considered soften as subsequent crash into a "trough of disillusionment" by encouraging a greater appreciation of the capabilities and limitations of the technology before they counter an idealised and unrealisable standard of perfection with computerised systems (or humans) [19]. Firstly, machine learning can improve the prognosis dramatically. Second, much of the work of radiologists and anatomical pathologists would be replaced by machine learning. These doctors mainly focus on the interpretation of digitised images. Firstly, machine learning can improve the prognosis dramatically. Second, much of the work of radiologists and anatomical pathologists would be replaced by machine learning. These doctors mainly focus on the interpretation of digitised images [17]. This would reduce the burden on doctors, increase and speed up access to care, reduce resources and cut costs for patients [10].

In the 18th century [27] Sir Galton introduced the first linear regression. Linear regression is a statistical method for modelling the connection between a variable dependent and one or more explicative variables. It assumes that weighted amounts of input variables can be predicted. Normally this is the very first model you would analyse when the outcome variable remains constant before moving into more complex models. Reed et al. [28] said that the association between highly accessible electronic health records (EHR) and ED visits, hospitalisations and office visits for diabetes mellitus patients has been researched. They used a linear regression model with patient-level effects and found that the use of EHR was associated with a small decline in ED and hospitalisation, but not with office visit rate among patients with diabetes. Yaffe et al. [29] have taken an account of the non-independence of the proportions as time series in the annual controls from the Kaiser Permanente Northern California hypertension registry, configuring a log linear proportion regression on time to make auto-correlated errors possible. They found that the application of a large-scale hypertension program was associated with a major increase in hypertension control in comparison with national and state control rates among adults with hypertension. In patients treated with target agents, Yuasa et al. [30] investigated the correlations between original tumour size and the tamper reduction rate. They used linear regression analyses both univariable and multivariate to determine that only the initial tumour size was associated with the rate of tumour reduction. This could be beneficial for doctors who treat patients' metastatic renal cell carcinoma.

In certain ways the logistic regression is similar to the linear regression. Regression of logistics assumes that the result can be explained by a weighted amount undergoing a specific mathematical transformation named log it. This transformation allows for the mapping of all weighted sums into a value between 0 and 1, which can be interpreted as a chance of a binary result. Therefore, logistic regression is widely used in the result variable with two outcomes, for example, whether or not you have a disease. From Vries et al. [31] the relation between mortality and iatrogenic diseases occurring outside the operating room has been investigated. The investigators carried out a multidisciplinary safety examination list with the medication, surgical side and medication checked by six hospitals. The relationship between checklist and mortality was evaluated by logistic regression. The research demonstrated a link between the full checklist and a decrease in surgical complication and mortality and high-grade hospitals. The relationship between maternal risk factors and congenital urinary tract anomalies was examined by Shmorhavorian et al. [32]. The study was carried out in case-control. In cases in which children were diagnosed with urinary anomalies while controls did not display urinary tract anomalies, they received Washington state birth-hospital discharge records from 1987-2007. The analysis identified increased risk of renal anomalies for gestational diabetes, pre-existing diabetes, and maternal renal disease. The results of these incidents have been studied by Peterson et al. The most common medical conditions were described and the form of assistance given on board. Through means of logistic regression, they established syncopes, respiratory symptoms and gastrointestinal symptoms in most medical emergencies in flight. In 1996, Somogyi and Sniegoski [33] first launched Boolean networks. Boolean networks were easily deployed as genetic networks with their convenient representation. But because Boolean networks do not specifically demonstrate the uncertainty the data may have, the vague characteristic of a bio-system cannot be modelled. Also note that no arrows are used when a Boolean network is created; thus, no path or cause of the model is clear.

In mathematics, differential equations have a long history of modelling a biological system [34, 35]. Chen et al. have modelled a simplified dynamic gene control system (with transcription feedback). Differential equations are more likely to model biological processes than boolean networks, but the computing costs of using differential equations are high and many of the parameters are often not available to use differential equation models. Since most of the genetic trajectory dynamics seem to be non-linear, a linear model appears to be working only on the limited genetic trajectories.

The BN model has been used extensively to learn data predictive models. BNs can model causality on the basis of the knowledge, data or both of the researcher. It is also utilised in a large number of medical fields as it can easily infer[36, 37]. One practical limitation of BNs is the fact that inferences in BNs are virtually impossible with a large number (> 50) of modelled variables [37], a frequently used limitation of many reasoning methodologies. A causal BN (or short causal network) is a BN, in which the parent variable and each arrow are interpreted as direct causal influence and the variable explicitly connected to which the variable is called the child variable [38]. Fig. 1 displays the structures of the five variables describing genes of a hypothetical causal BN system. The structure of the causal network in figure. For example, 1 indicates that Gene1 may regulate the level of expression (a cause of influence) of Gene3 which in turn may regulate the level of expression of Gene5. A variable is independent from its non-descendant since its parents occur (i.e., direct causes). It gives rise to conditional independence relationships defined in a causal BN.

III. Suggested Model

This section discusses the methodology that was used for the medical data classification and diagnosis. It was necessary to develop a sound methodology prior to the implementation of this research in order to improve classification of medical data. Research design of this study is a combination of several stages, each stage contains a number of steps. First access to the datasets of people infected with disease form data repertory such as UCI. Then, we define the second phase for six sub-stages of Knowledge data mining discovery (KDD) process, including data selection, data preprocessing and cleaning, data transformation, data mining, evaluation, and interpretation. In the third phase we design the experiments of this study using neural network algorithms. The fourth stage discusses the results and discussion phase. The fifth stage research is results analysis.

Operational guidance framework provides a structured manner and is used to help the researcher to achieve their goals. It is important that the operational framework is organization of a systematic process in this study. The framework has been divided into two phases: operational framework of the main action named planning phase, and the implementation phase. In this study, each of these stages is made up of different stages, starting with a review of the literature in the planning stage and the end of the written report. Fig. 1 below shows the operational framework.

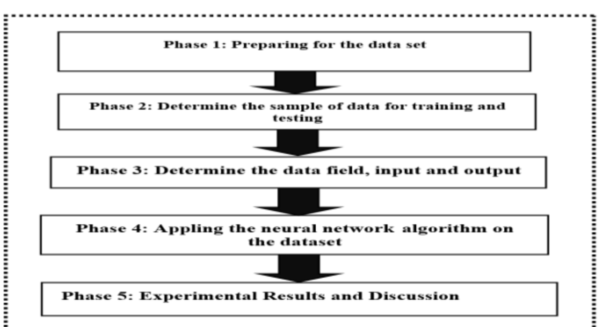

Fig. 1. Suggested Framework.

IV. Medicine Domain Classification using Neural Network

Artificial neural network (ANN) is a paradigm in the treatment of information based on biological nervous system data, such as the brain. The modern framework of the information management system is the core aspect of this model. It consists of many highly interconnected processing elements (neurons) which work together to solve specific issues. ANNs learn from examples, like people. For a specific application an ANN is configured by means of a learning process, like model recognition or data classification, Biology Systems Learning [39]. The goal is to create models of biological neural systems so that biological systems can understand how they work. Neuroscientists strive to link biological processing observed (data), neural theory (theory of statistical learning and theory of information) and biologically plausible neural methods for processing and learning (biological neuron network models) [40].

Neural networks are distinct from those of traditional computers in problem solving. Conventional computers use an algorithmic approach. In order to solve a problem, the machine follows a series of instructions. The computer can't solve the problem unless the specific steps the computer must take are known. This restricts conventional computers' problem solving capability to problems which we understand and are already able to resolve. But if computers could do things we do not know exactly how to do they would be much more useful [41].

ANNs are currently a hot area of medical research, and in the next few years they are expected to be widely used in biomedical systems. The research is currently primarily focused on modelling the human body parts and the recognition of diseases from various scans (for example, cardiograms, CAT scans, ultrasound scans).

Neural networks are suitable for identifying diseases using scans since a complex algorithm on how to recognise the disease does not need to be given. Neural networks learn by example to escape the need to classify the disease. A number of examples are needed which are representative of all the disease variations. The number of examples does not matter as much as the amount. The examples must be carefully selected for reliable and efficient performance of the system [42].

We provide some descriptions of the neural network types:

1) Quick: This approach chooses a topology using rules of thumb and features of the data the default number of hidden layers has changed in previous versions of clementine. The new process normally yields thinner layers that are quicker and more adaptable. if you get bad results at the default size, consider increasing the size of the "hidden" layer on the expert page. Fig. 2 shows the quick neural network structure.

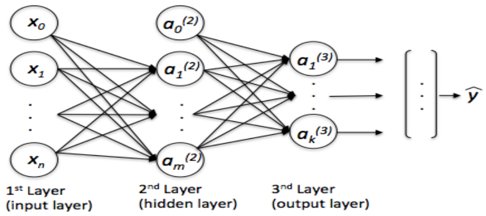

Fig. 2. Quick Neural Network.

2) Dynamic: It provides an initial topology, but adjusts it when training is underway. Fig. 3 shows the dynamic neural network structure.

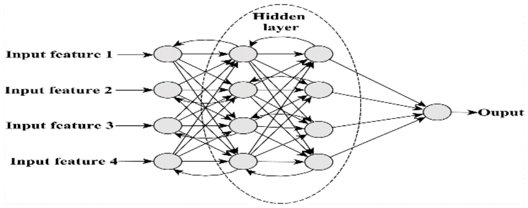

Fig. 3. Dynamic Neural Network.

3) Multiple: Several topologies are made (the exact number depends on the training data): pseudo-parallelization. The model with the lowest root mean square-squared error is declared the winner. Fig. 4 shows the multiple neural network structure.

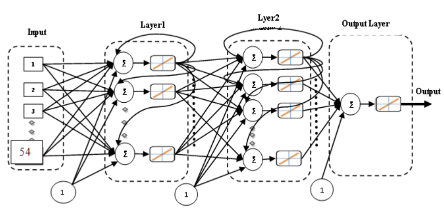

Fig. 4. Multiple Neural Network.

4) Radial based Function Network (RBFN): Similar to k-means clustering, the radial basis algorithm partitions the data on values for the target area. Fig. 5 shows the rbfn neural network structure.

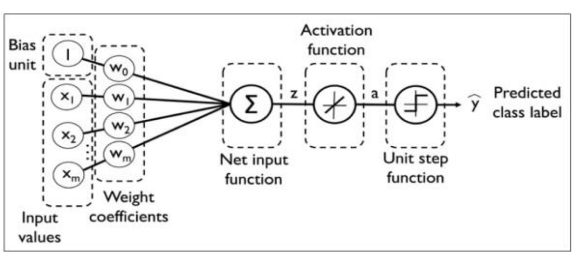

Fig. 5. RBF Neural Network.

5) Prune: Pruning is a compression technique that entails extracting weights from a learned model. Pruning is the process of removing unneeded branches or stems from a plant in agriculture. Pruning is the process of deleting superfluous neurons or weights in machine learning. Fig. 6 shows the prune neural network structure.

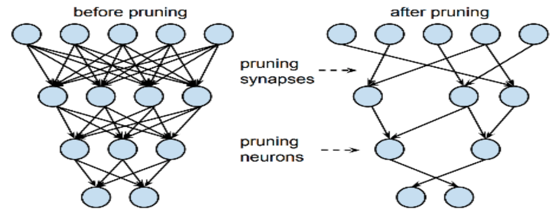

Fig. 6. Prune Neural Network.

The NN layout is motivated by the need to execute precise addition on a multidimensional array of information [43]. It can be thought of as a type of practical link network [37]. It employs a system design similar to that of classical regularization [44], in which the premise capacities correspond to the Green's components of the Gram's administrator associated with the stabilizer. The NN organization is obtained on the off-chance that the stabilizer exhibits outspread symmetry. From the estimation hypothesis's perspective, the regularization organization has three appealing properties [44, 45]: it can approximate any multivariate consistent capacity on a smaller space to a subjective degree of precision, given an adequate number of units; it has the best estimation property because the obscure coefficients are straight; and the arrangement is ideal by limiting a practical containment.

As illustrated in Fig. 7, the general function is a three-layer (J1-J2-J3) feed forward neural network. Each node in the hidden layer is activated by an activation function such as (RBF), denoted by (r). The hidden layer performs a nonlinear transformation on the input, whereas the output layer is a linear integrator that maps the nonlinearity to a new space. In general, the activation function is applied to all nodes; that is, NN nodes have the nonlinearity $(\vec{x})=\phi(\vec{x}-\vec{c}i)$, $i=1,\ldots,J2$, where ci is the prototype or centre of the ith node and $\phi(\vec{x})$ is an NN. The output layer neurons' biases can be approximated with an additional neuron in the hidden layer with an activation function of $\phi 0(r)=1$. Fig. 7 demonstrates the general architecture of the NN.

The $J1$, $J2$, and $J3$ neurons are used in the input, hidden, and output layers, respectively. $\phi 0(\vec{x})=1$ denotes the output layer's function, whereas $\phi i(\vec{x})$ denotes the hidden nodes' nonlinearity.

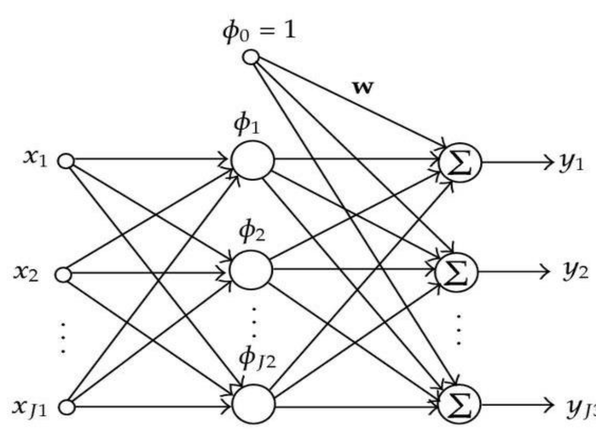

Fig. 7. Architecture of the Neural Network.

V. Experimental Results and Discussion

The purpose of this experiment was to filter and detect patient status as a positive or negative diagnostic of disease. Each sample from the dataset was classified into five groups. Each category had a predetermined sample size (disease cases). Four sets were deemed learning stages, while the remaining one was used as a cross-validation testing dataset. The purpose of this research was to demonstrate the robustness of neural network type prediction and classification when applied to medical information.

As previously stated, the dataset was prepared and tested using the 5-fold cross-validation approach. The examination connected the datasets using the outputs of a neural network classifier in order to assess the strength of NN Types for medical domain diagnosis. The cross-validation approach resulted in the following judgment accuracy outcomes:

$$Accuracy = \frac{(TN+TP)}{(TN+FP)+(TP+FN)} \times 100 \quad (1)$$

True Negative (TN): The number of wrongly identified positive and negative executable; True Positive (TP): The proportion of benign and positive executable that have been appropriately diagnosed; False Negative (FN): The number of positive executable that have been incorrectly classified as negative; False Positive (FP): The number of benign executable that have been incorrectly identified as negative.

In this study, the IBM SPSS modeler software has been used as the machine leaning tool to design our experimental models. The IBM Modeler is the high-performance data mining tool for enterprise. Via an in-depth understanding of data, Modeler enables organizations to strengthen consumer and citizen partnerships. Businesses use Modeler insight to retain successful clients, find cross-selling opportunities, recruit new customers, track fraud, mitigate risk, and enhance government service delivery. The visual interface of Modeler encourages users to apply their domain knowledge, which results in more efficient predictive models and a shorter time to solution. Modeler includes a variety of simulation methods, including algorithms for prediction, sorting, segmentation, and association detection. Modeler Solution Publisher facilitates the enterprise-wide distribution of models to decision makers or to a database after they are developed. The experiments of the investigation study are divided into several steps:

- Step 1: Data collection and preparation from the (UCI dataset).
- Step 2: Divide the dataset into training and testing parts.
- Step 3: Apply different Neural Networks Algorithms (Quick, Dynamic, Multiple, and Radial Basis Function Network (RBFN), Prune, and Executive Prune).
- Step 4: Results analysis.

A. Data Collection and Preparation

- Data collection: In this step, the medical datasets has been collected from University of California Irvine (UCI) Machine Learning data Repository as a source of the datasets. The UCI repository currently maintains 559 datasets as a service to the machine learning community. You may view all datasets through the searchable interface and the following website:
- Data Preparation: We performed pre-processing steps during this procedure, which includes data cleansing, outlier values elimination, and missing values handling (?). The pre-processing has been handled with the following choice based on the dataset description.

1) Delete the corresponding row from the dataset (if the number of missing values in less).

2) Determine the average value for each function and then substitute it for the missing value (numeric values).

3) Counting the number of zeros and ones in each feature and then substitute the highest count values (0 or 1) in the missing value in each feature individually.

- Dataset Descriptions: this section discussed the medical datasets that have been used which are Breast cancer, Chronic Kidney, Diabetes, Parkinson, COVID-19, Epileptic Seizure, HCV, and Heart Disease.
- Breast Cancer Dataset

The breast cancer databases were obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. The description of the dataset is illustrated in Table I.

TABLE I. Breast Cancer Dataset Description

Features Description	No of Samples	No of Features	Machine Learning Task
Integer	699	10	Classification

- HCV (Hepatitis C Virus) Dataset

The data collection includes laboratory results for blood donors and Hepatitis C patients, as well as demographic information such as the age of the patient. The description of the dataset is illustrated in Table II.

TABLE II. HCV Dataset Description

Features Description	No of Samples	No of Features	Machine Learning Task
Real & Integer	615	14	Classification & Clustering

- Parkinson Dataset

The dataset contains a variety of biomedical speech measurements taken from 42 people with early-stage Parkinson's disease who were enrolled in a six-month trial with a digital symptom progression tracking system. Automatic recordings were made in the patients' homes. The description of the dataset is illustrated in Table III.

TABLE III. PARKINSON DATASET DESCRIPTION

Features Description	No of Samples	No of Features	Machine Learning Task
Real & Integer	5875	26	Classification, Clustering, Regression

- Heart Disease

Heart disease database includes 76 attributes; all reported studies make use of a subset of 14. To date, only the Cleveland database has been used by machine learning researchers. The "goal" area indicates if the patient has heart disease. It is an integer number from 0 (no presence) to 4. The description of the dataset is illustrated in Table IV.

TABLE IV. HEART DISEASE DATASET DESCRIPTION

Features Description	No of Samples	No of Features	Machine Learning Task
Real, Integer, Categorical	303	75	Classification

- Diabetes

Diabetes medical records were gathered from two sources: an automated electronic recorder and paper records. The automated system had an internal clock that was used to timestamp events, while paper documents contained only "logical time" slots (breakfast, lunch, dinner, bedtime). Breakfast (08:00), lunch (12:00), dinner (18:00), and bedtime were both set times in paper documents (22:00). Thus, while paper documents contain fictitious standard tracking dates, electronic records contain more accurate time stamps. The description of the dataset is illustrated in Table V.

TABLE V. DIABETES DATASET DESCRIPTION

Features Description	No of Samples	No of Features	Machine Learning Task
Integer, Categorical	100000	55	Classification & Clustering

- Epileptic Seizure

The original dataset from the guide is divided into five directories, each of which contains 100 files, each of which represents a single subject/person. Each file contains a 23.6-second recording of brain activity. 4,097 data points are sampled from the corresponding time sequence. Each data point represents the value of the EEG recording at a certain time point. Thus, we have a total of 500 people, each with 4,097 data points over a period of 23.5 seconds. The description of the dataset is illustrated in Table VI.

TABLE VI. EPILEPTIC SEIZURE DATASET DESCRIPTION

Features Description	No of Samples	No of Features	Machine Learning Task
Real, Integer	11500	179	Classification & Clustering

- Chronic Kidney

The dataset can be used to classify chronic kidney disease and was obtained from a hospital over a period of almost two months. The description of the dataset is illustrated in Table VII.

TABLE VII. CHRONIC KIDNEY DATASET DESCRIPTION

Features Description	No of Samples	No of Features	Machine Learning Task
Integer, Categorical	100000	55	Classification & Clustering

- COVID-19

The X-ray data is saved in the png, jpg, and jpeg formats. Johns Hopkins University uses the two databases from the *Kaggle X-ray* competition as part of their medical database. The comparisons were made between cases with a virus causing bacterial pneumonia, healthy people, and cases caused by COVID19 [46]. One of the photographs in the dataset is of people who have had pneumonia. The COVID X-ray image database was created by Cohen JP using open access images from many different sources. This archive contains a lot of photographs that have been shared with the creators. This archive contains 125 photographs of an X-ray diagnosis of COVID. There are 43 women and 82 men who have demonstrated that they have a certain propensity for creative thinking within the study. Datasets without complete metadata do not include all users. The average age of COVID patients is 55, but the ages of the members range from 26 to 89 years. a database of chestray8 has been developed by Wang et al. [47] in order to compensate for unbalanced images from this series of unbalanced data, we've produced an even distribution of 500 no-finding and 500-frontal chest X-rays that looks random.

B. *Divide the Dataset into Training and Testing Parts*

After the data mining pre-processing steps, we then divide the dataset into two groups. The first group is training data and the data distribution. The investigation models were built based on training and testing dataset. The training dataset was divided into 90, 80, 70, 60, and 50 whereas the testing dataset was divided into 10, 20, 30, 40, and 50 respectively. The training results of the neural network algorithms were examined based on learning groups for each neural network algorithm (Quick, Dynamic, Multiple, and Radial Basis Function Network (RBFN), Prune, and Executive Prune). The accuracy measurement was calculated to examine all the collected medical datasets, including Breast cancer, Chronic Kidney, Diabetes, Parkinson, COVID-19, Epileptic Seizure, HCV, and Heart diseases. Then the average results were computed to select the optimal neural network algorithm for each dataset.

C. *Appling Neural Network Algorithms*

Our investigated study used the neural network algorithms for data prediction to diagnosis different types of diseases. The model was built by selecting the original data after dividing the datasets into training and testing parts. The IBM SPSS Modeler contains six types of neural network algorithms which are: Quick, Dynamic, Multiple, and Radial Basis Function Network (RBFN), Prune, and Executive Prune. The advantage of using the SPSS modeler is that the system applies integration and data visualization in order to show the predicted results explicitly. A sample of investigation model is demonstrated in Fig. 8.

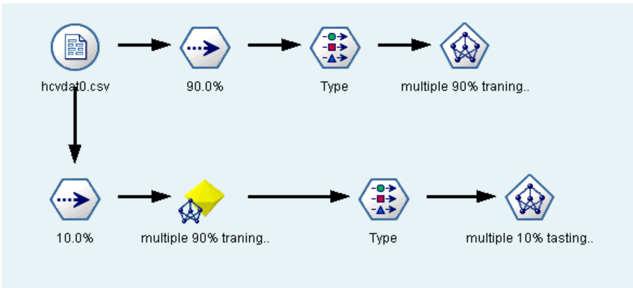

Fig. 8. Sample of Investigation Model using Neural Network Algorithms.

The experimental design process and running procedure has been examined based on the training and testing models.

D. Results Analysis

In the experiments, the medical datasets were used in order to determine the patient (injured or not injured) or predict the diagnosis percentage for some diseases. The dataset had each instance reported as either an injured or not injured case or labelled with target field (Class feature). The neural network algorithm was applied by training and testing the dataset using our investigation models. The main objectives of the learning model in this study is to investigate the diagnosis level by collecting the patients' samples with similar patterns together, thus the variation will be reduced and the diagnosis interpretation will be accurate.

The obtained results of the investigation models have been extracted and analyzed individually for training and testing results. The average results for each algorithm based on the specific disease have been calculated and figured out in different shapes. We noted that the multiple neural network algorithm is better than the other five neural network algorithms in many medical datasets for prediction diagnosis measure. Each fold in the training and testing model is examined with the individual dataset. Fig. 9 to 13 demonstrate the training results of each dataset using different types of neural network algorithms, while Fig. 14 to 18 shown the testing results for accumulated 5 folds cross validation.

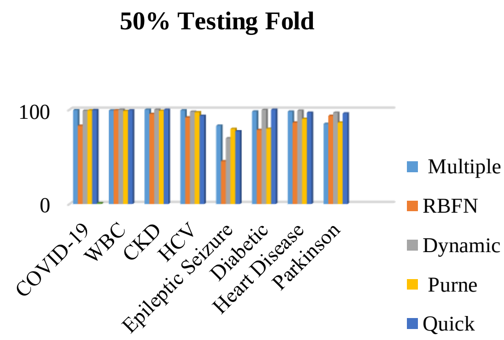

Fig. 18. Testing Model with 50%.

The accuracy of the results of the training and testing model using the five parts folds has been calculated for each dataset using the five main types of the neural network algorithms. Table VIII and Table IX demonstrate the training and testing results for each fold.

The findings of our prediction model trials indicated that neural network algorithms improved performance, and the t-test technique was utilized to quantify the improvement. Low t-test scores (usually less than 0.05) indicate that the two variables have been adjusted significantly. This criterion was emphasized in the assessment measures in light of the diagnosis accuracy values obtained in Table X between the multiple neural network method and the other five neural network algorithms. This demonstrates that Multiple NN outperformed RBFN, and Prune in terms of diagnostic performance. The results of the t-test statistical significance test are shown in Table X.

As shown in Table X, the significant T-test strategy has been applied between the investigated neural network algorithms in this study. We noted that the multiple neural network algorithm achieved significant results less than 0.05 when compared with RBF and Prune algorithms with P-value equal to 0.21 and 0.20 respectively. On the other hand, the Multiple neural network obtained better classification accuracy results as shown in Tables V and IV when compared with Quick and Dynamic algorithms without significant different results under the T-test investigation.

VI. CONCLUSION AND FUTURE WORK

Machine-learning modelling is analysed to support the provision of the best possible care to all patients with medically relevant data used by millions of healthcare clinicians in decision making for trillions of patients. The speeding up of vast volumes of healthcare data would radically change the structure of the healthcare system. We firmly agree that the relationship between patient and doctor will be the fundamental cornerstone of treatment for many patients and that new developments into machine learning will contribute to this relationship. We expect a few early models, along with the development of regulatory frameworks and economic incentives for value-based services, to be published in the next several years to make us meticulously optimistic about machine education in the field.

This study attempted to analyse medical disease diagnostics in order to modify the prediction method for different types of neural networks. We highlighted the quality of illness prediction models by utilising Quick, Multiple, Dynamic, and RBFN neural network algorithms, as well as prune neural network algorithm. In this study, the experiments conducted were based on different types of medical datasets such as Breast cancer, Chronic Kidney, Diabetes, Parkinson, COVID-19, Epileptic Seizure, HCV, and Heart disease. Our investigation found that the diagnosis results can be predicted and achieved by the neural network algorithms with different types of medical datasets. Additionally, our extensive investigations revealed that the multiple neural network algorithm had the greatest results in terms of diagnostic accuracy for a variety of ailments. In addition, P-value scores have been computed and indicate that the multiple neural network algorithm has significantly better performance compared with other neural Network algorithms. In future work, our research has try to improve all the objectives that were addressed in this study. However, the quality of prediction methods in medical disease has been investigated using neural network algorithms. At some point, this study will plan to apply another types of the neural network algorithms on different medical datasets to achieve high prediction and diagnosis models.

ACKNOWLEDGMENT

This project was funded by the Deanship of Scientific Research (DSR), King Abdulaziz University, Jeddah, under grant No. (D-172-830-1440). The authors, therefore, gratefully acknowledge DSR technical and financial support.

Universitas Indonesia
Depok, Indonesia

***Abstract*—Named Entity Recognition (NER) is often used to acquire important information from text documents as a part of the Information Extraction (IE) process. However, the text documents quality affects the accuracy of the data obtained, especially for text documents acquired involving the Optical Character Recognition (OCR) process, which never reached 100% accuracy. This research tried to examine which OCR engine with the highest performance for IE using NER by comparing three OCR engines (Foxit, PDF2GO, Tesseract) over 8,562 government human resources documents within six document categories, two document structures, and four measurements. Several essential entities such as name, employee ID, document number, document publishing date, employee rank, and family member's name were trying to be extracted automatically from the documents. NER processes were done using Python programming language, and the preprocessing tasks were done separately for Foxit, PDF2GO, and Tesseract. In summary, each OCR engine has its drawbacks and benefit, such as Tesseract has better NER extraction and conversion time with better accuracy but lack in the number of entities acquired.**

Keywords—Named entity recognition; information extraction; optical character recognition; government human resources documents

I. Introduction

Information extraction from scanned documents has been an issue in many countries and domains. Pathel and Bhatt in 2020 [1] used an end-to-end sequential approach for abstractive information extraction on scanned Malaysian invoices. Nguyen et al. in 2020 [2] used a rapid and convenient text-mining method to automatically extract pathology features from complex text-based scanned photocopies of Australian typewritten clinical pathology reports drawn from multiple different sources. Bures et al. in 2020 [3] proposed a system design to extract information from several countries structured scanned invoice documents by an ordinary office scanner device. Rastogi et al. in 2020 [4] used knowledge graph and Formal Concept Analysis (FCA) template detection to extract information from 1,400 scanned trade finance documents. Those issues also have been a problem in Indonesian Government.

In Indonesia, every human resources division in the government has the same problem of extracting information from scanned human resources documents. The information extraction process usually was done manually by entry operators, which is time-consuming and error-prone.

The government's human resources division records a vast number of employee documents each year. For instance, Bogor local government, one of the ninety-eight city governments in West Java, Indonesia, recorded more than 200,000 human resources documents during the 2009 to 2020 period. Those numbers are increasing each year, like in 2018, there are 10,880 recorded documents, while in 2019, the number increased to 28,784 recorded documents. With only two data operators to handle such data, this is really time-consuming, not to mention the human error factor while inserting essential pieces of information from each document into the human resources management system.

This manually extracted information is essential since it has been used for many human resources management system modules like a decision support system for talent management, executive statistics dashboard, salary budget prediction, employee formation, and many others.

Each document was acquired using scanners in PDF format. The recording process was taken manually by operators inserting important information of each document into the human resources database through the human resources management system web-based interface. With the help of IE tasks like NER, this process can be simplified using automated NER to make the data management more effective and efficient.

OCR converts the scanned images of handwritten, typewritten, or printed documents into machine-readable format [5]. IE process is used to extract structured content in entities, relations, facts, terms, and other types of information [6]. In general, NER is a subtask of IE that aims to find and categorize specific entities in text documents [7]. The documents source may vary from the web, generated PDF, and scanned documents in PDF format. In scanned documents case which involves OCR engine, to get good accuracy, precision, and recall of the entities acquired is a challenge for this research.

Three different OCR engines with different environments were selected for the experiment. Foxit as the desktop-based OCR engine, PDF2GO as the web-based OCR engine, and Tesseract as an open-source programable OCR engine. Among those OCR engines, we would like to examine which engine has the highest measurements score to extract essential information from government human resources documents using four measurements.

The measurement results will determine which engine is the suitable solution to handle IE tasks involving NER and OCR process in two document structures. The results will also help any organization to manage scanned documents more effectively and efficiently. As for Indonesian government, an effective and efficient document management would really help any government division to work more efficient with less or even none human resources involved with the help of automated IE from this study.

The following sections of this paper are the related works in Section 2, the materials and methods in Section 3, experiments results and discussion in Section 4. Lastly, the conclusion is in Section 5.

II. Related Work

IE using scanned documents is often noisy and often suffering from blur effects, faded text, watermarks, scanning artifacts, and wrinkles. Those noises often caused the downstream OCR and other errors [4]. Those noises are the cause of low accuracy in IE using scanned documents.

In some cases, preprocessing tasks, such as image contrast improvement, noise reduction, binarization, and image deskewing, are required to get a visual improvement of the scanned documents [3]. High accuracy and low latency for processing large numbers of documents are required to have the best result of OCR [1]. IE in a medical domain has proven that keyword trigger-based automation with OCR correction and negation handling is rapid and convenient and provides consistent and reliable data abstractions from scanned clinical records [2]. Those cases showed that preprocessing has an important role to get a better result in IE using scanned documents.

Taghva et al. in 2006 [8] and Pereda in 2011 [9] proved that the IE task is significantly influenced by OCR errors, while Vijayarani and Sakila in 2015 [10] tried to compare 8 OCR tools using image and PDF documents. NER previous research on PDF documents like legal documents had been done to extract information for specific entities. Solihin and Budi, in 2018 [11], researched the extraction of data from general criminal court decision documents using the rule-based method. Meanwhile, Leitner et al. in 2019 [12] used machine learning methods like CRF (Conditional Random Fields) and deep learning methods like BiLSTM (Bidirectional Long Short-Term Memory) to extract information using NER on legal documents. Nuranti and Yulianti in 2020 [13] also tried the same method in Indonesian legal documents. Those research [11,12,13] used generated PDF legal documents as their data source, while our study used scanned PDF documents which may have lower accuracy influenced by OCR errors.

Tesseract library is often used in several research of IE involving OCR. Patel and friends produced 70% accuracy using 20 sample images in 2012 [14]. Kumar and friends produced 97% accuracy for small scanned bill documents and 83% accuracy for small scanned bill documents using Tesseract OCR on 25 scanned bills in 2020 [15]. Akinbade and friends produced 81.9% character accuracy and 69.7% word accuracy on 11 sample images in 2020 [16]. Haraj and Raissouni produced an average of 95.77% charcater accuracy using tesseract and opencv library over 4 sample images in 2015 [17]. Those research [14,15,16,17] only used relatively small samples (less than 50 documents), while our study used more documents (8,562 documents in 6 Categories and two document structures). Previous research [14,15,16,17], which also employed the Tesseract library, only used string matching to measure the OCR. On the other hand, our study used four measurements, i.e., conversion time, NER time, string match accuracy as precision, and the number of entities acquired as recall.

III. Material and Methods

The proposed method we use in this study is an adaptation of the general framework for text analysis in mining text data literature as shown in Fig. 1 [18]. The framework start with text corpus as an input source, followed by preprocessing phase. Then followed by the text representation process and it ends with the knowledge discovery process as shown in Fig. 1.

Fig. 2 shows the four main phases of the proposed method. The phase began with data collection, followed by the preprocessing step by converting PDF to text. Then, the NER process used rule-based entity recognition written in Python, followed by the end's evaluation process.

The reason we use the prosed method as an adaptation from the general framework for text analysis is because it has suitable phases that also can be implement for IE using NER in this study. Nevertheless the original framework has different examples in each phase since the example is used for text data analytics in social media.

The data collection refers to the text corpus phase, the preprocessing phase is similar, the NER phase refers to the representation phase, and evaluation refers to the knowledge discovery phase.

A. Data Collection

Eight thousand five hundred sixty-two government human resources documents within 6 document categories were collected as data samples. Those documents were downloaded from the human resources server of Bogor local government using PHP script for each document category selected. Table I demonstrates the number of entities and the number of records of each class.

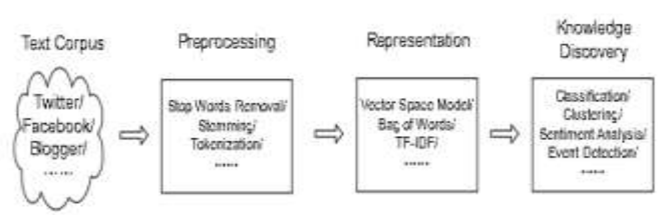

Fig. 1. The General Framework for Text Analysis in Mining Text Data [17].

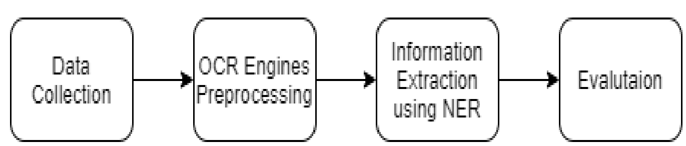

Fig. 2. The Main Phases of the Proposed Method.

TABLE I. DOCUMENTS AND ENTITIES OF EACH DOCUMENT CATEGORY

Category	Average Size	Samples	Entity	Structure
Retirement	505 Kb	110	6	Tabular
Recruitment	448 Kb	453	6	Non table
CV	39 Kb	5,964	7	Tabular
ID conversion	419 Kb	1,168	5	Tabular
Employee position	501 Kb	265	5	Non-table
Family allowance	332 Kb	602	6	Tabular

The category selection was based on the head of National Civil Service Agency regulation number 18 in 2011 about manuscript layout management of the national human resources document [19]. From those categories, four categories (curriculum vitae, ID conversion, family allowance, retirement) have a tabular data structure, and the other two categories (recruitment, employee position) do not have a table data structure.

Each document category has a similar average size and similar number type of entities except for Curriculum Vitae, which has only 39 Kb average size per document. Retirement documents are the fewest, with 110 documents, and Curriculum Vitae is the most significant sample with 5,964 documents.Each document type has at least two same entities: name and employee ID. They are employed as primary keys in the rule-based NER written in Python language to compare the actual values of each entity within the human resources database with the entities acquired from the OCR process results.

The entity selection for each document category were based on the existing information stored in the human resources database. Therefore we can validate and measure the accuracy of each entity acquired by comparing it with the actual value from the human resource database. We used word level accuracy as a measurement for each entity acquired. Therefore we only compare some part of each document as entities with the actual value from the human resources database instead of using the whole text from each document.

Each category has different important entities to extract. Each entity in every type has its own character, as shown in Table II.

TABLE II. RETIREMENT DOCUMENT CHARACTER

Entity	Format
Name	Free text
New ID number	18 digits number
Old ID number	Nine digits number
Document number	Nine digits number + year
Working period	Two digits year and month
Retirement date	dd-mm-YYYY

Fig. 4. Recruitment Document Sample.

There are four document types with tabular structure data: retirement, curriculum vitae, ID conversion, and family allowance. There are only two document types with non-table document structures, which are recruitment and employee position.

The following Fig. 3 is an example of an ID conversion document as the tabular structure document, and Fig. 4 is an example of a recruitment document as the non-table structure document.

B. OCR Engines Preprocessing

The next phase after collecting the scanned PDF documents is to convert them into text format. Three OCR engines from three different environments were used in this phase. An offline desktop-based application called Foxit, an online-based application called PDF2GO, and an open-source OCR library called Tesseract were used to convert all documents. Patel et al. in 2012 [14] produce 70% accuracy, Kumar et al. in 2020 [15] produce 97% accuracy and, Akinbade [16] produce 81.9% accuracy using the Tesseract library on scanned documents.

Each engine has its benefits and drawbacks. For Foxit, it has better reading for tabular data and preserves spaces from the original document. However, it has no batch conversion feature. Hence, it must be done manually, one by one. Another drawback for tabular data is the required RTF conversion to get a better result before converting to a TXT file.

On PDF2GO, it has a 500 document conversion per batch feature and supports the Indonesian language feature on the OCR process. However, it does not preserve spacing from the original document, and it takes more time to upload and download the document since it is an online application.

It has unlimited batch conversion on Tesseract since we can customize the process, supporting the Indonesian language OCR process. However, it does not preserve spacing from the original document. The Foxit OCR engine has better OCR quality for tabular data. Still, since it has no batch conversion feature and needs an RTF conversion first before converted to text files, it makes it not efficient in terms of processing time. PDF2GO has 500 documents per batch conversion, and Tesseract has an unlimited document batch. Still, even though it takes 5 to 10 seconds to convert a document for Tesseract, it takes a longer time in PDF2G0 since we have to upload and download the paper first, which consumes more time. In terms of conversion time, Tesseract is the best option. In terms of the OCR feature, Foxit can preserve the space and better handle tabular data. Even though Tesseract included this feature in their library, the page segmentation mode will help extract information from tabular data.

C. Information Extraction using NER

The IE process using NER was written using Python programming language since it has features for NLP tasks. The rule-based method was used since OCR results from the documents are not 100% accurate, unlike the generated PDF documents.

The employee ID number is the primary key used to connect to each entity's other actual value. If we get the wrong OCR result for the employee ID number, it will get the wrong or even empty weight from the human resource database. Each document category from each OCR engine has a different extraction time, as shown in Table III. The table shows that each document category has the various best time for each OCR engine. Foxit has better time records on the retirement category with 0.017 seconds per document and the family allowance category with 0.077 seconds per document. Tesseract has better time records on recruitment category with 0.088 seconds per document, employee position category with 0.0104 seconds per document, and Curriculum Vitae with 0.040 seconds per document. PDF2GO only has a better time record on the ID conversion category with 0.011 seconds per document. On average, Tesseract has the best extraction time with 0.044 seconds per document, followed by PDF2GO with 0.046 seconds per document and Foxit with 0.050 seconds per document.

TABLE III. NER TIME FOR EACH DOCUMENT CATEGORY

Category	**Foxit**	**PDF2GO**	**Tesseract**
Retirement	0.017	0.019	0.023
Recruitment	0.096	0.089	0.088
Curriculum Vitae	0.074	0.071	0.040
ID conversion	0.022	0.011	0.012
Employee position	0.016	0.010	0.010
Family allowance	0.077	0.078	0.092
Average	0.050	0.046	0.044

D. Evaluation

In terms of quality measurement, the string match function from the Python library was used by comparing the entity string acquired with the actual data from the human resources database. This function is based on the G*estalt* pattern matching, which measures accuracy by this equation:

$$D_{\boldsymbol{\gamma}\mathbf{0}} = \frac{2K_m}{|S_1| + |S_2|} \tag{1}$$

The D$\boldsymbol{\gamma}$0 value ranged from 0 to 1, where one value means 100% the same and 0 value means vice versa. The S1 and S2 refer to the character number from the first and second strings, respectively. Km refers to the number of the same character between two strings being compared [20]. We used percentages ranged from 0 to 100 to represent the D$\boldsymbol{\gamma}$0 in our experiment.

The quantity measurement used a simple counter parameter on the rule-based NER Python code each time an entity was acquired. The actual quantity for each entity was obtained using the SQL count function from the human resources database.

IV. RESULTS AND DISCUSSION

A. Results

After the NER process, precision and recall measurement divided for each document category to see which OCR engine text result has better precision, recall, and F1-Score percentages shown in Table IV.

TABLE IV. PRECISSION, RECALL AND F1 MEASUREMENT

Document Type	Structure	Foxit (%)			PDF2GO (%)			Tesseract (%)		
		Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score
Retirement	Tabular	93.99	85.06	89.30	93.62	86.58	89.62	88.19	52.42	65.76
Recruitment	Non Table	83.66	73.66	78.34	86.85	92.20	89.45	86.86	90.91	88.83
Curriculum Vitae	Tabular	86.28	86.64	86.46	80.13	97.91	88.13	84.14	80.98	82.53
ID Conversion	Tabular	68.85	84.33	75.81	74.45	77.84	76.11	74.99	54.40	63.06
Employee position	Non Table	87.59	100	93.38	86.46	99.62	92.57	92.8	99.62	96.09
Family allowance	Tabular	95.22	75.87	84.45	92.16	72.84	81.37	91.17	71.42	80.10
Average		85.93	84.26	84.62	85.61	**87.83**	**86.27**	**86.36**	74.96	79.39

Based on Table IV, we can see that in terms of precision by string matching, Tesseract has the highest accuracy with 86.36%. However, in terms of recall, PDF2GO has more identified entities with 87.83%. PDF2GO has the highest F1-Score with 86.27%.

Even though it seems PDF2GO has the highest F1-Score on average, but in terms of document structures, the highest F1-Score are different. Foxit has the highest F1-Score average for tabular data structure with 84.01%, followed by PDF2GO with 83.89% and Tesseract with 72.85%. Tesseract has the highest F1-Score average for non-table data structure with 92.46%, followed by PDF2GO with 91.01% and Foxit with 85.86%.

The results show that the tabular data structure F1-Score average for Tesseract is very low (72.85%). Consequently, it caused the total average of 6 document types also low at 79.39%, even though for non-table data structure Tesseract has the highest F1-Score with 92.46%. Even though Foxit has the highest F1-Score average for tabular data structure with 84.01%, it also has the lowest F1-Score average for non-table data structure with only 85.86%.

In general, PDF2GO has the highest F1-Score average with 86.27%. In terms of tabular document structure, Foxit has the highest F1-Score average with 84.01%. Tesseract has the highest F1-Score average with 92.46% for non-table document structure.

Even though Tesseract has the best precision, however, it has the worst recall. Therefore it also has the worst F1-Score since the precision gap between each OCR engine is slightly different, and the recall gap for Tesseract is far.

In the IE phase, we recorded the processing time of OCR engines for each document category. We can compare which OCR has the best OCR processing time, as shown in Fig. 5.

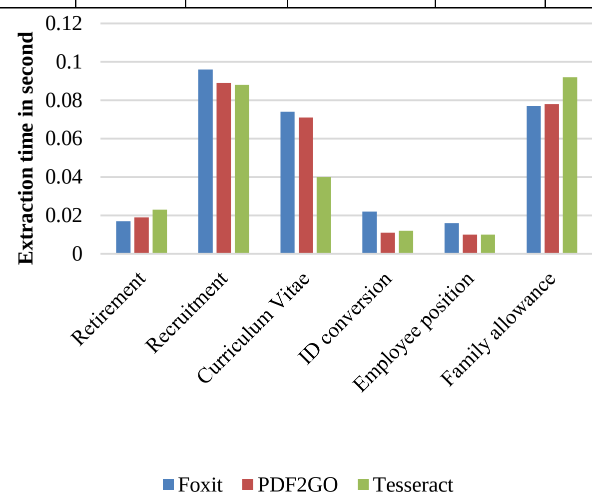

Fig. 5. Extraction Time per Document for each Category.

Tesseract is dominant in three document categories with 0.004 seconds per Curriculum Vitae document, 0.008 seconds per recruitment document, and 0.01 seconds per employee position document. On the other hand, Foxit is dominant in two document categories with 0.017 seconds per retirement document and 0.077 seconds per family allowance document. PDF2GO is only prevalent in one document category with 0.011 seconds per ID conversion document.

On average, Tesseract is the fastest OCR engine with 0.044 seconds per document, followed by PDF2GO with 0.046 seconds per document and Foxit with 0.050 seconds per document. Even though the NER times are slightly different, the impact is enormous since the volume of the document to extract is also enormous. We can say that in terms of NER information extraction time, Tesseract has the best time record, not to mention the benefit of having unlimited batch conversion. In contrast, in Foxit, you have to do the conversion one by one, and in PDF2GO, the batch conversion is limited to 500 documents in the preprocessing phase.

In the precision measurement phase, we recorded the precision of each OCR engine for each document category. Each acquired entity was compared automatically with the actual value from the human resources database records using the *Gestalt* string matching function described previously. From those records, we can compare which OCR has the best string match accuracy, as shown in Fig. 6.

Tesseract has the highest precisions in three document categories with 86.86% in the recruitment category, 92.8% in the employee position category, and 74.99% in the ID conversion category. Foxit has better precision in three document categories with 86.28% in the Curriculum Vitae category, 95.22% in the family allowance category, and 93.99% in the retirement category.Tesseract is more dominant in three documents. Besides, it has the best precision average with 86.36%, followed by Foxit with 85.93% and PDF2GO with 85.61%.

We recorded the number of entities acquired for each OCR engine in each document category in the recall measurement phase. The number of entities acquired for each entity compared to the number of entities in the human resources database using the employee ID number as the primary key. We can compare which OCR has the most entities acquired for the recall measurement from those entity numbers, as shown in Fig. 7.

We can see that PDF2GO has more entities acquired in three document categories, with 86.58% recall in the retirement category, 92.2 % recall in the recruitment category, and 97.91% in the Curriculum Vitae category. Foxit has more entities acquired in three document categories with 84.33% recall in the ID conversion category, 100% accuracy in the employee position category, and 75.87% recall in the family allowance category.

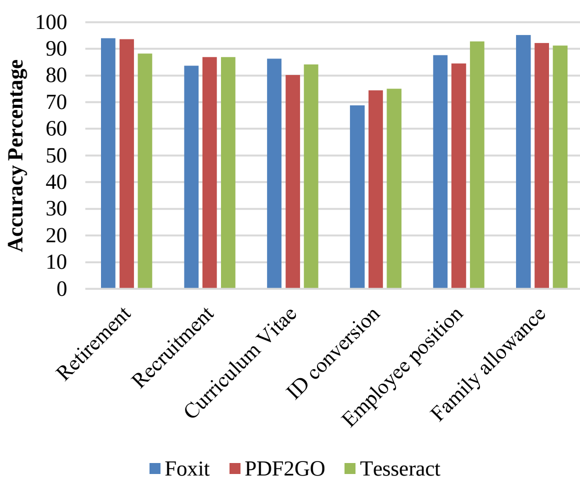

Fig. 6. The Precision Percentage for each Document Category.

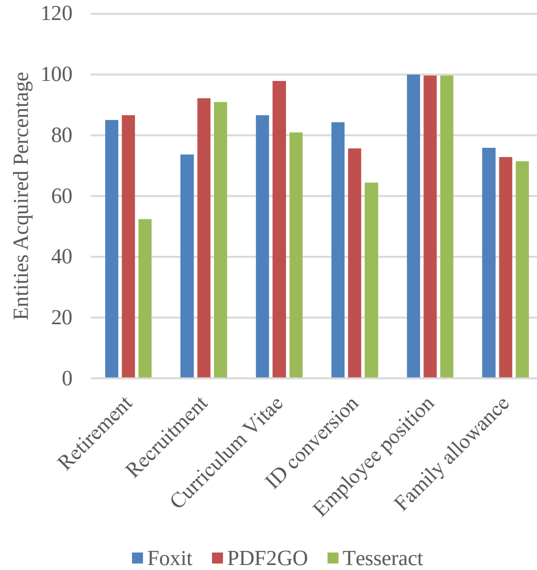

Fig. 7. Recall Percentage for each Category.

Tesseract has the lowest number of entities acquired with only 74.96% recall. PDF2GO and Foxit each have three dominant categories in the number of entities gained. On average, PDF2GO has the highest entities acquired with 87.83%, followed by Foxit with 84.26% and Tesseract with 74.96% entities acquired.

B. *Discussion*

We found a trade-off selection of the OCR engine from the measurements we conducted since Tesseract is good on preprocessing, information extraction time, and accuracy but lacks entity acquirement. On the other hand, PDF2GO and Foxit are dominant for entity acquirement. It lacks accuracy, extraction time, and preprocessing phase since Foxit has no batch conversion feature, and PDF2GO limits the batch conversion of 500 documents per batch.

It shows that Tesseract seems to be the best option for NER in scanned documents regardless of the number of entities acquired. The dominant measurement for Tesseract in preprocessing time, NER time, and precision proved that this OCR engine is reliable to get time efficiency and string match accuracy even though it has a low percentage of recall. The gap between Tesseract and PDF2GO on entities acquired is 13%.

The number of entities acquired is significant since having fast preprocessing and NER time would be meaningless if we have low numbers of information extracted. Writing a better algorithm in rule-based NER, having an automated text normalization, or using deep learning methods for NER might increase the number of entities acquired.

PDF2GO has the best F1-Score with 86.27%, regardless it has a slower NER time with 0.046 seconds per document and slower preprocessing time with 500 documents limit per batch and additional download and upload time to the PDF2GO web.

Even though PDF2GO has the best F1-Score, we found that Foxit has better precision in tabular document structure (retirement, CV, ID conversion, family allowance), as shown in Table IV. For tabular document structure, Foxit has an 84.01% average F1-Score followed by PDF2GO with 83.89% and Tesseract with 72.85%. For non-table document structure (retirement and employee position), Tesseract has the best F1-Score with 92.46%, followed by PDF2GO with 91.01% and Foxit with 85.86%.

Even though the F1, precision, and recall, and OCR engines are less than the previous research [10], we processed many more documents, categories, and documents structure. It consists of 8,562 documents within six categories and two document structures to prove that the OCR comparison using more documents in two different structures may have different results. The previous research [10] only employed string matching as a measurement to compare OCR engine results. In contrast, our study performed at least five measurements, which are preprocessing time, NER time, precision, recall, and F1-Score. Those measurements are more comprehensive than just string matching for an end-to-end information extraction system to manage many documents.

Similar research employed the Tesseract library [16] with only 11 images as input yielding 69.7% precision. On the other hand, our study produced 83.07% precision with 8,562 documents as the same library input. It may not be a fair comparison since the previous research using English text documents while our documents are in the Indonesian language. Tesseract support both English and Indonesian language, therefore even using more variety of document categories and different languages, Tesseract can have a better accuracy result.

Previous research that also performed rule-based NER [11] has 89% F1-Score while our study has 86.27% F1-Score. The preceding experiment employed generated PDF documents with no OCR involves, while ours used scanned documents, and it has the worst text result after the OCR process. In this case, there is a 2.73% gap between scanned documents and generated PDF using the same rule-based NER method. The experiments' results are a potential reference for an end-to-end information extraction system using a vast number of scanned documents involving an OCR engine.

C. Limitations

There are several limitaions on this study such as:

- We had only use tabular and non-tabular document structures in six categories.
- Six document categories were selected from ten available categories based on the head of National Civil Service Agency regulation number 18 in 2011.
- The number of entities for each document category were selected based on esential informations that stored in the human resources database of Bogor local government.
- We only measure the precision through the NER results, therefore we do not use the whole text of the scanned documents since only essential entities such as names, dates, organizations are being extracted and compared to the ground truth from the database.
- We only compared three OCR engines which are Foxit as an offline engine, PDF2GO as an online engine and Tesseract as an opensource engine.

V. Conclusion

This research analyses which OCR engine is the most suitable for IE using rule-based NER written in Python over 8,562 scanned PDF government human resources documents within six document categories. Those categories are retirement, recruitment, Curriculum Vitae, ID conversion, employee position, and family allowance documents with tabular and non-tabular structures. Involving more document structures such as watermark and handwriting scanned documents may have a better data representation for future research.

Three OCR engines from three different environments were compared during the experiment. Foxit as an offline desktop OCR engine, PDF2GO as an online OCR engine, and Tesseract as a free and open-source multiplatform OCR engine library. Tesseract is the most suitable solution in terms of preprocessing since it provides an unlimited document conversion batch. Tesseract is also the fastest OCR engine in NER extraction time; nevertheless, numbers of entities acquired Foxit and PDF2GO are more dominant on three documents each. In terms of string match entity accuracy as precision, the Tesseract OCR engine is dominant on three document categories.

On average, PDF2GO has the highest F1-score (86.27%). In terms of tabular document structure, Foxit has the highest F1-Score (84.01%). Tesseract has the highest F1-Score (92.46%) for non-table document structure. Those scores show that Tesseract is more suitable for non-table documents and Foxit is more appropriate for tabular documents.

***Abstract*—The paper proposes an approach based on higher order statistics and phase synchronization for detection and classification of relevant features in electroencephalographic (EEG) signals recorded during the subjects are performing motor tasks. The method was tested on two different datasets and the performance was evaluated using k nearest neighbor classifier. The results (classification rates higher than 90%) have shown that the method can be used for discriminating right and left motor imagery tasks as an offline analysis for EEG in a brain computer interface system.**

Keywords—Brain computer interface; motor imagery; higher order statistics; phase synchronization; EEG

I. Introduction

The brain computer interface (BCI) system has aroused a real interest, as it has become an important tool in translating the measured brain activity into control commands.

The BCI was developed for biomedical applications, which led to the development of assistive devices for restoring movement and communication force for patients with disabilities. The use of electroencephalography (EEG) in the state-of-the-art of brain-computer interface technology has expanded to enhance quality of life, with medical and non-medical applications [1]. Various BCI innovations, such as the BCI wheelchair [2], spellings, BCI exoskeleton [3], BCI prosthesis, BCI robot [4] and others are the result of this huge interest in BCI [5].

The electroencephalogram is a source of information often used in BCI because it records the electrical activity of the brain with the help of the attached electrodes on the scalp. The BCI system amplifies the collected signals, notifies these changes and transforms them into control signals for communication or control of external equipment. BCI allows patients with paralysis or motor disorders to have an alternative method of communication and control.

Compared with other existing neuroimaging modalities, electroencephalogram has higher time resolution, portability, availability, and, so it is more commonly used.

EEG based BCI systems are centered on several paradigms [6-7]: Steady State Visual Evoked Potential (SSVEP), P300, Slow Cortical Potential (SCP) and Motor Imagery (MI). Motor imagery implies imagination of hand/arm/finger/foot movement. More precisely, motor imagery is the translation of the motor intention into control signals for a BCI device. After imagination, event-related synchronization (ERS) and desynchronization (ERD) are produced over the sensorimotor cortex region [8]. Brain activity recorded via EEG is classified into five different rhythms: Delta (0-4 Hz), Theta (4-7 Hz), Mu (8-12 Hz), Beta (12-30 Hz), Gamma (30-70 Hz). Mu and Beta rhythms are associated with actions like preparation and movement of limbs.

Methods like autoregressive model [9], independent component analysis [10], wavelet transform [11] have been applied in order to extract relevant features contained in the EEG signal while a motor imagery task was performed.

The aim of the paper is to propose a combination of features which includes higher-order statistics (HOS) based on bispectrum and bicoherence and phase synchronization based on phase locking value and phase lag index. The features can be used for discriminating motor tasks in a motor imagery paradigm.

In Section II the handled datasets are described and Section III presents the methods, features extraction and classification. Section IV belongs to results and Section V to conclusions.

II. Datasets Description

Dataset I contains EEG signals acquired in our laboratory. The brain activity was recorded using a gMobilab+ module [12] and BCI 2000 platform [13]. Dataset II was downloaded from the internet [14]. Table I presents the information regarding the manipulated datasets.

TABLE I. DATABASES SUMMARY

Database information	**Dataset I**	**Dataset II**
Number of subjects	57	9
Channels	C3, C4, CP3, CP4, P3, P4, Cz	
Number of Trials	60	90
Sampling frequency	256 Hz	100 Hz
Paradigm description	On a monitor screen right and left arrows were displayed. The subjects had to perform the motor task indicated by the arrow (left hand and right hand motor imagery).	

III. Methods

Higher order spectra are expressed in terminologies of higher order statistics such as moments and cumulants of a random process, in this case EEG signals [15-16].

Bispectrum is commonly applied in the biomedical area mainly for EEG signal processing. Bispectrum is d in the bi-frequency domain [15]:

$$B(f_1, f_2) = E[X(f_1)X(f_1)X^*(f_1 + f_2)] \quad (1)$$

where $X(f)$ is the Fourier transform of a windowed portion of a single realization of the EEG signal $x(nT)$, n is an integer index, T is the sampling period and $E[.]$ represents the expectation operation.

Bicoherence is given by the following relationship [15-16]:

$$B_{norm}(f_1, f_2) = \frac{E[X(f_1)X(f_1)X^*(f_1+f_2)]}{\sqrt{P(f_1)P(f_2)P(f_1+f_2)}} \quad (2)$$

where $P(f)$ is the power spectrum of $x(nT)$.

When the oscillatory phases from two brain regions are correlated the phase synchronization appears. The phase synchronization from the motor imagery period is different from the phase synchronization in the relaxation period so it can be exploited by BCI applications [17].

Large scale synchronization appears between brain signals acquired from electrodes located in the primary motor area and from electrodes located in the additional motor area.

Phase locking value (PLV) [17] and phase lag index (PLI) [18] are calculated in order to detect changes in the large scale synchronization and in order to measure the synchronization between two signals $x(t)$ and $y(t)$.

PLV represents the lastingness of the phase difference between instantaneous phases $\varphi_x(t)$ and $\varphi_y(t)$:

$$PLV = \left|\langle e^{j\Delta\varphi(t)}\rangle\right| \quad (3)$$

$$\Delta\varphi(t) = \varphi_y(t) - \varphi_x(t)$$

The phase lag index is defined by:

$$PLI = |\langle sign[\Delta\theta(t_k)]\rangle| \quad (4)$$

$sign$ is the signum function and $<.>$ denotes the time average.

A. Data Processing for Higher Order Statistics

Two sets of data were formed: one related to right hand movement imagery and the other corresponding to left hand movement imagery.

First, the EEG signals aquired from channels C3, C4, CP3, CP4, P3, P4 when the subject imagined the right hand movement were segmented in 30 (Dataset I) and 45 (Dataset II). The bispectrum and bicoherence were estimated using functions from HOSA toolbox [19]. Two different frequency ranges were extracted for analysis in the bi-frequency plane (f1 – f2): Mu – Mu, Beta – Beta. The module of the bispectrum was calculated for these frequency ranges. In the next step only the elements above the main diagonal (those below the main diagonal being equal to those above) were extracted for the two frequency ranges.

A direct method is applied to estimate the bicoherence.

Four quantity measures for each frequency range were settled: the sum of the bispectrum modules, the sum of the squares bispectrum modules, the sum of the bicoherence modules, the sum of the squares bicoherence modules.

The steps described above were followed for the EEG signals corresponding to left hand motor imagery.

B. Data Processing for Phase Synchronization

Four sets of data were created: the right hand movement imagery, the rest after right hand movement imagery, the left hand movement imagery and rest after left hand movement imagery. In order to compute PLV and PLI, the instanteneous phase of the EEG signals must be determined. The instanteneous phase of the EEG signals is computed using Hilbert transform. The Hilbert transforms were calculated for the EEG channels mentioned.

One electrode from the auxiliary motor imagery area, Cz, three electrodes from the right hemisphere, C4, CP4, P4 and three electrodes from the left hemisphere, C3, CP3, P3 were utilized in order to establish the combinations. The completed pairs of electrodes were: Cz-C4, Cz-CP4, Cz-P4, Cz-C3, Cz-CP3, Cz-P3. The differences between PLVs of the rest period and motor imagery period were formed for the above pairs of electrodes.

The steps mentioned above were repeated for PLI.

C. Feature Vectors

Nine feature vectors were created by bringing together two, three or four of the already mentioned measures. So, the first feature vector is formed by bicoherence and PLV, the second by bicoherence and PLI, the third by bicoherence, PLV and PLI, the fourth by bispectrum and PLV, the fifth by bispectrum and PLI, the sixth by bispectrum, PLV and PLI, the seventh by bicoherence, bispectrum and PLV, the eighth by bicoherence, bispectrum and PLI and the ninth by bicoherence, bispectrum, PLV and PLI. These nine feature vectors were named according to their way of grouping: *Bicoherence_PLV* was attributed for the feature vector combining bicoherence and PLV, *Bicoherence_PLI* for the feature vector merging bicoherence and PLI, and so on.

The discrimination between right and left motor imagery was evaluated with k nearest neighbor (kNN) [20]. The performance of classifier was assessed through classification rate, sensitivity and specificity. The classification rate, the specificity and the sensitivity are characterized using the following terms: true positive (TP), true negative (TN), false negative (FN) and false positive (FP) [21]:

$$Classification\ rate = \frac{TN+TP}{TN+TP+FN+FP} \quad (5)$$

$$Sensitivity = \frac{TP}{TP+FN} \quad (6)$$

$$Specificity = \frac{TN}{TN+FP} \quad (7)$$

IV. RESULTS

In Fig. 1 is displayed the bispectrum of an EEG signal corresponding to right hand motor imagery for channel C3 (Dataset I) and Fig. 2 illustrates the bispectrum of an EEG signal corresponding to left hand motor imagery for channel C4 (Dataset I). The bicoherence of an EEG signal corresponding to right hand motor imagery for channel C3, respectively the bicoherence of an EEG signal corresponding to left hand motor imagery for channel C4 are shown in Fig. 3 and Fig. 4.

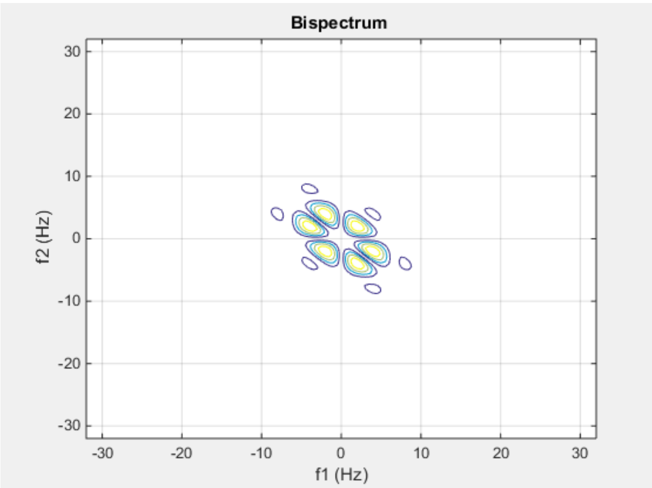

Fig. 1. The Bispectrum of an EEG Signal Corresponding to Right Hand Movement Imagery for Channel C3 - Datatset I.

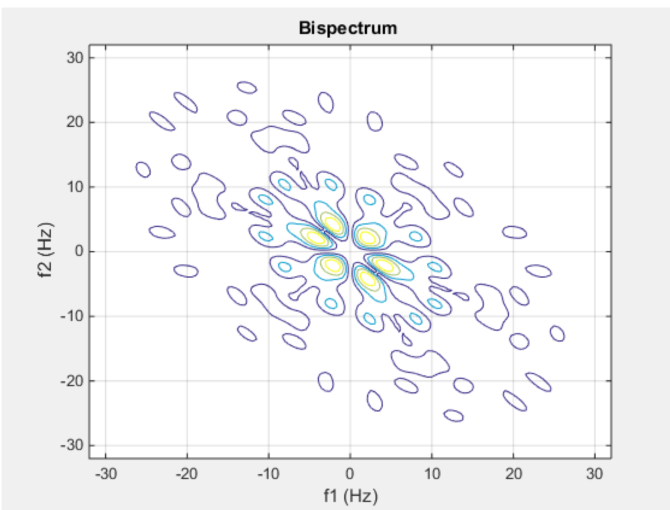

Fig. 2. The Bispectrum of an EEG Signal Corresponding to Left Hand Movement Imagery for Channel C4 - Datatset I.

From the above figures we can see that the bispectrum and the bicoherence yielded to different graphs for EEG signal corresponding to right versus left hand motor imagery and this suggests that can be used as feature vectors for classification.

Fig. 5 shows the box plots for the classification rate, the sensitivity and the specificity using as feature vectors Bicoherence_PLV, Bicoherence_PLI and Bicoherence_PLV_PLI for Dataset I. The highest value (90%) of the median for classification rates was obtained for Bicoherence_PLV_PLI and all the subjects attained classification rates in the range 84% to 94%.

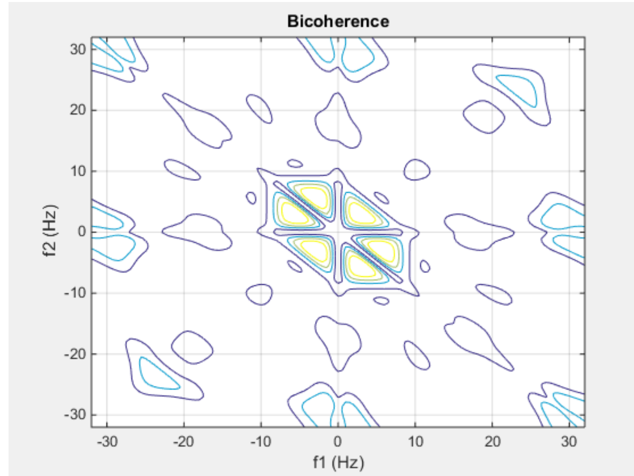

Fig. 3. The Bicoherence of an EEG signal Corresponding to Right Hand Movement Imagery for Channel C3 - Datatset I.

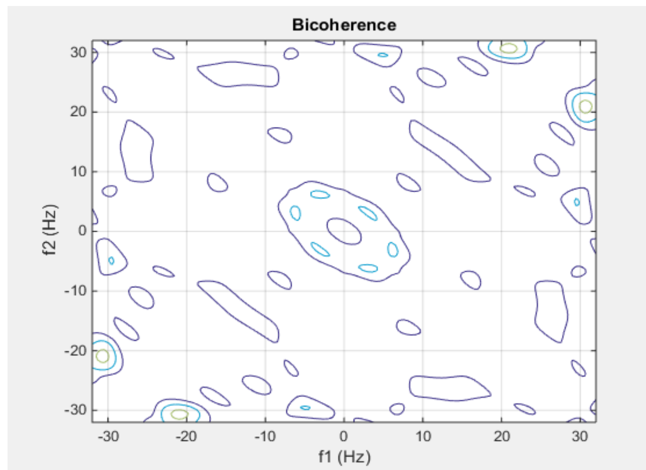

Fig. 4. The Bicoherence of an EEG Signal Corresponding to Left Hand Movement Imagery for Channel C4 - Datatset I.

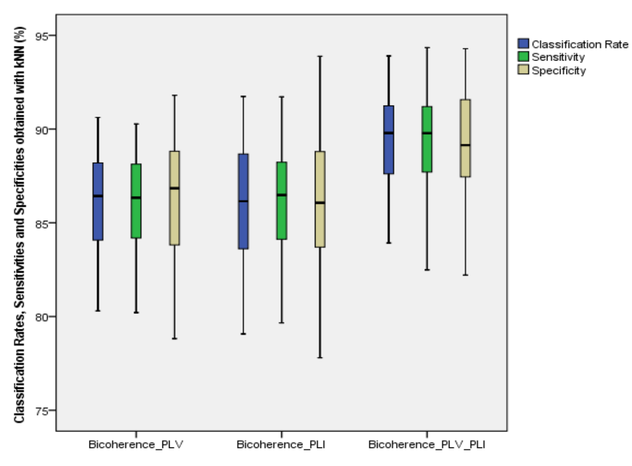

Fig. 5. The Box Plots for Classification Rate, Sensitivity and Specificity using Feature Vector Bicoherence_PLV, Bicoherence_PLI and Bicoherence_PLV_PLI – Dataset I.

The box plots for the classification rate, the sensitivity and the specificity using as feature vectors Bispectrum_PLV, Bispectrum_PLI and Bispectrum_PLV_PLI - Dataset I are displayed in Fig. 6. The medians for the classification rates, the sensitivities and the specificities obtained were above 88% for Bispectrum_PLV_PLI. The outliner marked in blue color represents the highest classification rate attained (the value isn't relevant since belongs to a single subject).

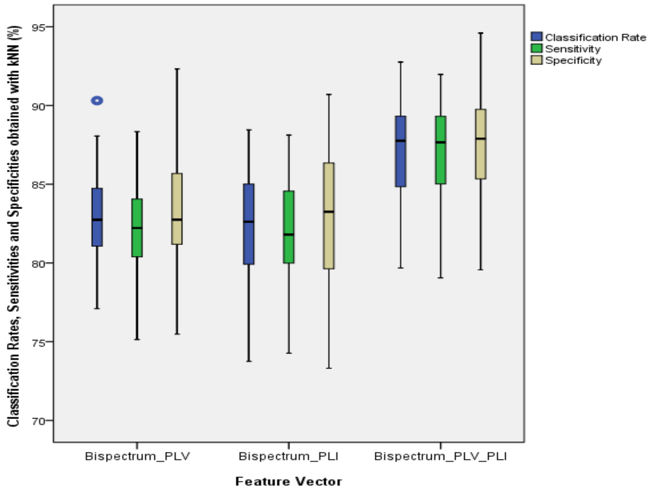

Fig. 6. The Box Plots for Classification Rate, Sensitivity and Specificity using Feature Vector Bispectrum_PLV, Bispectrum_PLI and Bispectrum_PLV_PLI - Dataset I.

In Fig. 7 are presented the box plots for the classification rate, the sensitivity and the specificity using as feature vectors Bicoherence_Bispectrum_PLV, Bicoherence_Bispectrum_PLI and Bicoherence_Bispectrum_PLV_PLI – Dataset I. The highest classification rates, sensitivities and specificities were realized for Bicoherence_Bispectrum_PLV_PLI.

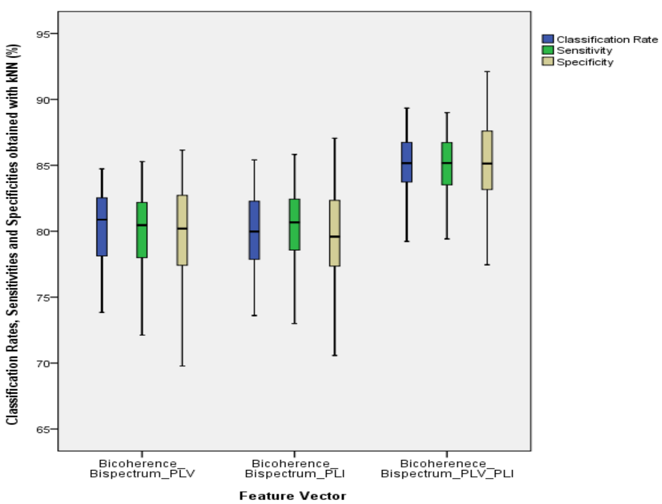

Fig. 7. The Box Plots for Classification Rate, Sensitivity and Specificity using Feature Vector Bicoherence_Bispectrum_PLV, Bicoherence_Bispectrum_PLI and Bicoherence_Bispectrum_PLV_PLI – Dataset I.

Fig. 8 shows the box plots obtained for the classification rate, the sensitivity and the specificity using as feature vector Bicoherence_PLV, Bicoherence_PLI and Bicoherence_PLV_PLI - Dataset II. The highest classification rates were for Bicoherence_PLV_PLI. The outliners marked with "*" for all the figures are for Subject 9.

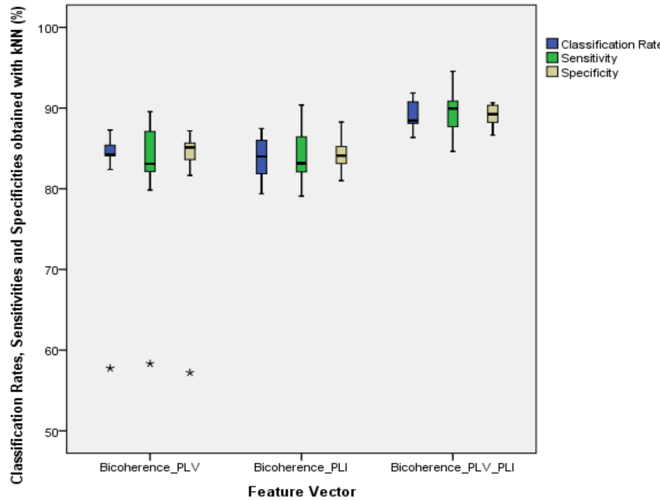

Fig. 8. The Box Plots for Classification Rate, Sensitivity and Specificity using Feature Vector Bicoherence_PLV, Bicoherence_PLI and Bicoherence_PLV_PLI - Dataset II.

Fig. 9 displays the box plots achieved for the classification rate, the sensitivity and the specificity using feature vector Bispectrum_PLV, Bispectrum_PLI and Bispectrum_PLV_PLI - Dataset II. Overall, the best classification rates (85%), sensitivities and specificities were obtained for Bispectrum_PLV_PLI .

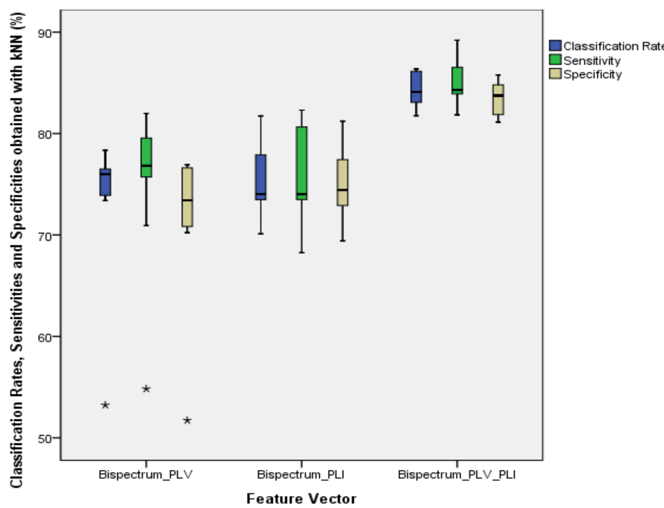

Fig. 9. The Box Plots for Classification Rate, Sensitivity and Specificity using Feature Vector Bispectrum_PLV, Bispectrum_PLI and Bispectrum_PLV_PLI - Dataset II.

The box plots for the classification rate, the sensitivity and the specificity using as feature vector Bicoherence_Bispectrum_PLV, Bicoherence_Bispectrum_PLI and Bicoherence_Bispectrum_PLV_PLI – Dataset II are presented in Fig. 10. Comparing to the other feature vectors, the smallest classification rates, sensitivities and specificities were obtained for the feature vectors from Fig. 10.

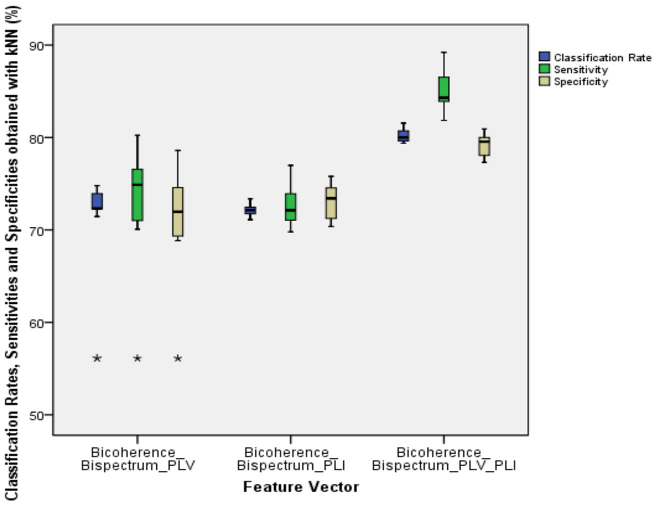

Fig. 10. The Box Plots for Classification Rate, Sensitivity and Specificity using Feature Vector Bicoherence_Bispectrum_PLV, Bicoherence_Bispectrum_PLI and Bicoherence_Bispectrum_PLV_PLI – Dataset II.

In Table II are summarized the maximum and the median of the classification rates for Dataset I and Dataset II attained with the mentioned feature vectors. The best classification rates were attained for feature vector *Bicoherence_PLV_PLI* for both datasets.

In [22] where a framework for achieving subject transfer strategy is proposed, the classification rates obtained for subject 9 were in the range 57.93% to 70.93% with linear discriminant analysis. The results are consistent with the results obtained with our feature vectors.

In [23] where was investigated a method based on multiple frequency spatial synthesized features with support vector machine classifier, the classification accuracies were smaller than the results reported in this paper.

TABLE II. THE MAXIMUM AND THE MEDIAN CLASSIFICATION RATES FOR THE FEATURE VECTOR USED – DATASET I AND DATASET II

Feature Vector	Dataset I		Dataset II	
	Classification rate			
	Max	Median	Max	Median
Bicoherence_PLV	90.62%	86.43%	87.28%	84.08%
Bicoherence_PLI	91.74%	86.15%	87.45%	84.00%
Bicoherence_PLV_PLI	93.90%	89.79%	91.86%	88.44%
Bispectrum_PLV	90.31%	82.74%	78.35%	76.00%
Bispectrum_PLI	88.45%	82.79%	81.73%	74.04%
Bispectrum_PLV_PLI	92.76%	88.15%	86.37%	84.11%
Bicoherence_Bispectrum_PLV	84.73%	80.88%	74.79%	72.31%
Bicoherence_Bispectrum_PLI	85.41%	79.98%	76.39%	72.28%
Bicoherence_Bispectrum_PLV_PLI	89.34%	85.71%	83.08%	79.70%

In [24], [25] were manipulated only PLV and PLI without being in combinations with other methods, but more channels were taken into account. The results achieved in these two cited works are approximately the same with the results stated in this paper with feature vector *Bicoherence_PLV_PLI*. The maximum classification rates of 86% are attained using PLI and SVM classifier.

V. CONCLUSION

An offline analysis was performed on two datasets that contained 57 subjects and 9 subjects. Using combinations of bispectrum, bicoherence, phase locking value and phase lag index, nine features vectors were formed.

By means of Bicoherence_PLV_PLI as feature vector and kNN as classifier, the highest classification rates, sensitivities and specificities achieved for Dataset I were 93.90%, 94.35% and 94.29% respectively and for Dataset II were 91.86%, 94.56% and 90.67%, respectively.

The best classification rate attained with Bicoherence_PLV_PLI for both datasets highlights that, regardless of the database and of the conditions in which the electroencephalographic signals were recorded, the grouping of the three measures that compose this feature vector discriminates the best the two classes. The explanation might be linked to the fact that there are taken into account both the information of nonlinear interaction described by bicoherence and of the large scale synchronization described by PLV and PLI, and together they discriminate better than alone the two tasks.

The subjects from Dataset II were trained and the subjects from Dataset I were untrained. Even if the subjects from Dataset II were trained, the results obtained were worse than those for Dataset I. This fact suggests that the method used for creating feature vector *Bicoherence_PLV_PLI* is adequate to be used for discrimination of motor imagery tasks in a BCI, no matter the degree of subjects' training.

The future work implies testing the method on other available datasets that provide EEG signals recorded from the subjects while performing motor imagery tasks.

***Abstract*—Requirement engineering is one of the software development life cycle phases; it has been recognized as an important phase for collecting and analyzing a system's goals. However, despite its importance, requirement engineering has several limitations such as incomplete requirements, vague requirements, lack of prioritization, and less user involvement, all of which affect requirement quality. With the emergence of big data technology, the complexity of big data, which is defined by large data volume, high velocity, and large data variety, has gradually increased, affecting the quality of big data software requirements. This study proposes a framework with four sequential phases to improve requirement engineering quality through big data software development. By integrating the proposed framework's phases in which user requirements are collected in a complete vision using traditional requirement elicitation techniques with agile methodology and mind mapping, the collected requirements are displayed via a graphical representation using mind maps to achieve high requirement accuracy with connectivity and modifiability, enabling the accurate prioritization of requirements implemented using agile SCRUM methodology. The proposed framework improves requirement quality in big data software development, which is represented by accuracy, completeness, connectivity, and modifiability to understand the value of the collected requirements and effectively affect the quality of the implementation phase.**

***Keywords*—Requirement engineering; big data requirement; agile methodology; mind mapping**

I. Introduction

Software requirement engineering represents business needs and goals, including functional and nonfunctional dependency competencies that must be represented and achieved. Several issues in the requirement engineering life cycle have contributed to a high failure rate for software engineering projects, such as the lack of comprehensive requirements, including unclear, incomplete, and inaccurate requirements; requirement conflict, leading to insufficient estimation of social and technological requirements; the lack of customer involvement, leading to customer dissatisfaction; and concurrent changes in requirements [1]. Nowadays, the development of big data software applications is prevalent. According to big data technology market analysis [2], "The big data market size is projected to grow from USD 138.9 billion in 2020 to USD 229.4 billion by 2025, at a compound annual growth rate of 10.6% during the forecast period." With the increasing growth of data, defining the term "big data" has become more challenging when considering big data characteristics such as volume, which refers to the quantity of data generated; velocity, which refers to the speed at which data are generated; and variety, which refers to different types of data generated (e.g., text, documents, video, audio, and images). Consequently, requirement challenges have increased because representing a huge volume of data and determining the exact time that data will be received and how long they will take to arrive are essential factors to consider. Additionally, it is critical to determine the type of data received because each data type has its customization, so considering these characteristics in the requirement election phase became more challenging [3]. Big data characteristics pose severe challenges to achieving software requirement quality standards for security, performance, scalability, privacy, and other quality requirements. Additionally, how to systematically handle quality requirements involving big data characteristics to better understand the requirements of big data software projects is a challenge [4]. A well-planned framework for the requirement elicitation process can mitigate the negative effect of big data software requirement limitations. Mind mapping provides the best practice in requirement election representation on the basis of its graphical concept, i.e., mapping the main ideas together to obtain the best value, producing an accurate and clear requirement representation while considering big data characteristics and quality attributes, which greatly aids in obtaining well-prioritized requirements. Nowadays, agile SCRUM methodology has gained popularity because of its properties, such as flexibility, which can handle the technical issues mentioned above, as it handles changes in requirements, customer involvement, and satisfaction, besides documenting the requirements in the product backlog [5]. Although agile is the commonly used methodology in big data projects because of its resilience in accepting new and changes in requirements during the implementation process, big data project needs more optimized methodologies to deal with the massive changes of requirements especially in big data project considering its characteristics. So, by the integration with mind mapping, it'll help develop a prioritized product backlog, as agile SCRUM is the initial requirements specification document [6].

In summary, focusing on the entire process of requirement elicitation for big data software projects, not only on better requirements but also on the quality of the elicited requirements, is an excellent way to set the stage for accurate software development.

This paper proposes a framework for requirement elicitation that comprised four phases: a collection phase, mind mapping phase, prioritization phase, and agile phase, all the phases were explained in Section IV. The integration of these phases provides a complete and accurate path for requirement gathering that will help a system analyst team elicit, analyze, and manage requirements for a big data software project. The framework serves the requirement elicitation and analysis phase in the big data projects development life cycle, and it promotes the achievement of high-quality big data requirements during this stage. It's necessary to place a strong emphasis on achieving quality factors that are highly supportive of the big data characteristics of completeness, correctness, connectedness, and modifiability in order to meet the needs for large volume, velocity, and variety of data.

The following parts are organized into five sections. The background of this research is presented in Section II. In, Section III, the literature review is presented. In Section IV, the methodology is provided. The framework implementation is discussed in Section V. Conclusions are presented in Section VI.

II. Background

This research is an integration of different parts, including requirement elicitation, big data, agile methodology, and mind mapping, and each part will be introduced in the following sections.

A. Requirements Elicitation

First, requirement elicitation is considered to be one of the most critical activities in the software development industry [7]. It defines a project scope by gathering requirements, which are considered stakeholders' needs, and merging this information to produce a meaningful and understandable method for developing a system that will meet these needs.

Several empirical studies have discussed requirement engineering challenges in the software development life cycle [8]. These challenges have been traced and collected under two main aspects, which are customer and system aspects, as shown in Fig. 1. The two aspects are interdependent, as challenges from the customer aspect, such as a lack of understanding of users' needs, customer collaboration, and a common language, lead to challenges in the system aspects, such as requirement changes and updates and a lack of accurate documentation, requirement quality, and requirement prioritization.

The first step in eliciting requirements from a customer is to understand what the customer wants because interactions with customers typically occur in a natural language, which makes it difficult to obtain complete and clear requirements, and the second step is to engage with the customer to gain a better understanding of the elicited requirement; however, because of the lack of customer collaboration, understanding customer needs and requirement clarification is hampered [9]. Changing requirements during the development process causes loss of system requirement objectives, increases cost and time, and necessitates a continuous update to the stored requirement documentation. Additionally, storing requirements in the form of user stories in a system backlog is not an appropriate solution to fully understand the system requirement and track updates on it according to the agile development life cycle [10]. Prioritizing requirements according to specifics factors such as business value, risk, importance, cost, dependency, and constraints becomes more challenging in a complex system [8]. The above challenges significantly affect requirement quality, especially when dealing with complex projects such as big data projects, as we have discussed in this study. Hence, the main objective of this study is to improve requirement quality, thereby improving the functionality and services provided to end-users.

B. Requirement Engineering and Big Data Projects

With the ubiquity of emerging technologies such as big data and the Internet of Things, the processes of software engineering, such as requirement gathering, design, implementation, and testing, must be evolved and improved to apply these new technologies [11].

Specifying the requirement engineering processes must be improved in the context of big data projects, as the process complexity has increased because of the existence of several dynamic components, such as distributed networks, databases, business intelligence layers, middleware, and computation node, making requirement election in this complex distributed environment extremely difficult [12]. Additionally, data scientists and software engineers face difficulty when measuring and determining the maximum value of big data.

The main big data characteristics include volume, velocity, and variety. Volume is the size of data, which are generated from different data sources. Velocity is the data speed. Variety is the data type, including structured, semi-structured, and unstructured data, such as text, image, audio, and video. Recent research has claimed that the above-mentioned big data characteristics are the most effective factors that affect the quality of big data projects because it is extremely difficult to provide system requirements with high quality standards, such as performance, security, accuracy, availability, and reliability [13].

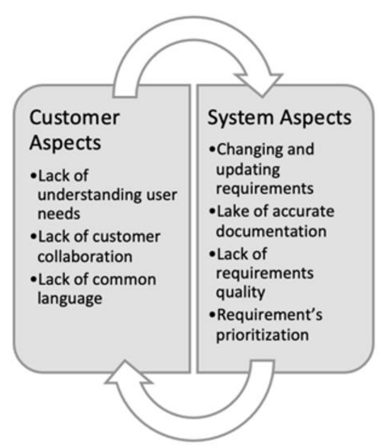

Fig. 1. Requirement Engineering Challenges.

C. Agile and Big Data Projects

A Project Management Institute Report stated that more than 70% of companies have adopted an agile approach, concluding that agile projects are 28% more effective than traditional ones [14]. The requirement elicitation for big data software applications using agile methodology is not easy and straightforward. A detailed requirement is required in the software development life cycle, but agile focuses on less documentation, neglecting quality requirements, difficulties with communication in distributed teams, and quick processing, which can lead to skipping necessary user requirements [5]. Customer satisfaction is the only evidence that requirements are complete and comprehensive, and agile methodology provides many ways to keep the customer involved. However, more customer involvement without any knowledge regarding nonfunctional requirements and experience in the project field lowers the likelihood of project success [15]. Requirement prioritization is a critical issue that can increase cost and time estimation [16].

Different agile methodologies include SCRUM, Kanban, Extreme Programming, Agile Unified Process, and Adaptive Software Development. This research focuses on SCRUM because of its advantages [14].

SCRUM follows agile development process principles as its highest priority is to gain customer satisfaction through all development stages [17]. SCRUM uses short iterations called sprints, which occurs every 2 or 4 weeks. New requirements are developed until the project is completed in each sprint, as shown in Fig. 2. The figure shows the workflow of SCRUM methodology, starting with the product backlog, which includes the prioritized requirement list that has been estimated and added according to the business value of a product owner; then, the team adds a few requirements to the sprint backlog and decides how to implement them. Afterward, the development team starts to implement those requirements through sprints, which occur every 2–4 weeks. They also meet in a daily SCRUM meeting to assess the progress of the project. At the end of a sprint, the developed requirements could be delivered to stakeholders. In the next sprint, the same process, starting again from selecting some requirements from the product backlog to delivering the requirements to stakeholders.

In SCRUM methodology, changes in requirements or technologies are always welcomed at any stage of the development process; however, concurrent changes in requirements negatively affect the entire cycle of software development [14] [17], as well as requirement prioritization, which may increase cost and time estimation [18]. In this case, integrating mind mapping and SCRUM methodology is the most effective, as it helps in obtaining understandable and detailed prioritized requirements, which will significantly and positively affect the software development cycle, as demonstrated in the following section.

D. Mind Mapping

Mind mapping is a technique representing a system's main ideas hierarchically, which helps a team organize, visualize, and generate new ideas, considering the entire aspects of the system [19].

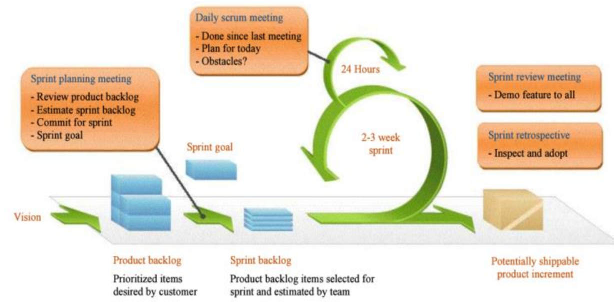

Fig. 2. SCRUM Methodology [35].

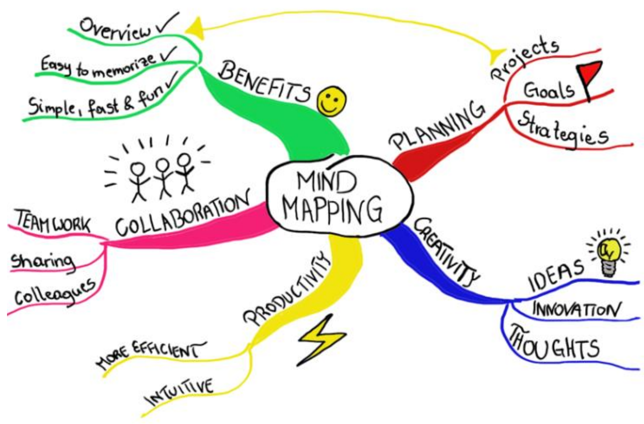

Fig. 3. Mind Mapping Diagram [20].

Mind mapping is performed by placing the most relevant concept in the center of a diagram and connecting it to other concepts, as shown in Fig. 3. This figure is an example of how to represent information in mind maps using multiple layers, and these layers are divided according to the project's requirements.

Mind mapping aids capturing requirements in multiple layers. When collecting data, this results in high quality and accurate requirements by involving stakeholders in the requirement engineering process. This aids in gaining a better and deeper understanding of the overall system's requirements [19]. Mind mapping is a well-known graphical representation concept that can be used on paper or any other tools to most appropriately and accurately represent a system's goal, obtaining complete requirements with their objective value and assisting in obtaining highly prioritized requirements to be implemented [18]. Mind mapping, with its advantages, helps in enhancing a system's requirement quality, which significantly and positively affects the development process and its success. Additionally, integrating mind mapping with SCRUM methodology significantly improves the overall quality of the product backlog.

III. Related Work

Several studies have been conducted on big data requirement elicitation, as it is a new topic that has attracted researchers' attention in recent years. However, little success has been accomplished in this area, which includes the phases of the requirement engineering process, requirement types, application domains, requirement engineering research challenges, and solutions suggested by requirement engineering research in the context of big data applications [10]. The authors in [21] proposed an artifact model that can capture the main requirement elicitation components and their relationship with the development of big data software applications. In [22], a model was proposed that can engage software engineers and data scientists to discover software requirement processes with their business values for big data software using a use case diagram.

The main objective of this study is to obtain high quality requirements. The authors in [4] presented an approach that specifies quality requirements in the context of big data systems by considering requirement engineering challenges in big data projects. The main idea is to intersect big data characteristics with quality attributes and then identify the system's quality requirements on the basis of that intersection. This proves that big data quality characteristics are mapped to quality requirement specifications. There have been some research papers published on the use of an agile methodology in big data system development to mitigate the challenges of big data system developments. The authors in [23] studied the possibility of applying an agile methodology to big data projects. They gathered information by interviewing experts in big data projects from various organizations. Data are analyzed to determine which agile manifesto concepts can be used to manage big data projects. They have recommended using an agile approach to big data management. In [24], the authors proposed an architecture-centric agile big data analytics development methodology. This architecture enables stakeholders to collaborate effectively to evaluate the importance of the proposition for the system in development and to concentrate on more critical tasks such as value validation. In [25], the authors claimed that in big data analytics using agile methodology, there are three phases. The planning phase is the phase in which the system's stakeholders, goals, and requirements are identified and documented by the product owner in a user story that is prioritized on the basis of independent features. The development phase is the phase in which data are collected according to users' needs, which are then analyzed, and requirements are developed to discover the system's goals and objectives. The closure phase occurs when all requirements are implemented and tested. In [26], the authors studied and analyzed agile methodologies to determine the best practice of business intelligence in big data. They introduced an agile framework that addresses big data's effect on business intelligence using two layers. The first layer comprises five steps (discovery, design, development, deployment, and value delivery) to achieve business goals. The second layer consists of six steps (scope, data acquisition/discovery, analysis, visualization, validation, and deployment) for data analysis and deployment. The two layers are combined to ensure the framework's implementation and management. In [14], a method was proposed for enhancing the quality of the requirement gathering process by combining I*organizational models with standard agile SCRUM methodology; however, because of the complexities of big data projects, it will necessitate additional research.

There are several techniques for requirement elicitation, and the mind mapping technique is the most appropriate for completely and effectively representing the collected requirements and it is effective in large-scale and big data systems [15]. The authors in [27] concluded that the requirement engineering processes (elicitation, analysis, specification, validation, and requirement management) are considered in the development of mind maps and revealed that only functional requirements are considered during the development of mind mapping maps in requirement engineering, with no evidence to consider nonfunctional requirements. In [19], the authors proved the contribution of the mind map development to the software agile methodology results in a high-quality derived product backlog, so mind mapping was recommended for setting up a proper product backlog with agile development methodology such as SCRUM.

According to the above studies, to enhance the quality of big data system's requirements, the best practice for achieving high quality requirements is to integrate requirement gathering election techniques with mind mapping and SCRUM methodology.

IV. Methodology

In the following section, the proposed framework has been introduced in detail with its integrated sequentially phases. The framework is divided into four main sequential phases, as shown in Fig. 4.

This figure depicts the proposed framework flow, starting with the requirement collection phase, which helps in gathering requirements from stakeholders to gain complete and understandable requirements reflecting the project's scope, aim, and objectives, as described in Section A. The output of this phase is a valuable input to the next phase, which is the mind mapping phase, where all collected requirements will be graphically represented in mind maps, and based on mind mapping and its representation, it will be an added value to obtain the best practice in mapping the collected requirements under the appropriate quality attribute and big data characteristics, as described in detail in section B. In this phase, all requirements will be identified, which will help in identifying functional and nonfunctional requirements for the desired big data project. The output of this phase will be input into the prioritization phase. In this phase, requirements are prioritized on the basis of the business needs and other aspects that will be introduced in section C. Finally, prioritized requirements will be added to the SCRUM product backlog, as shown in Section D.

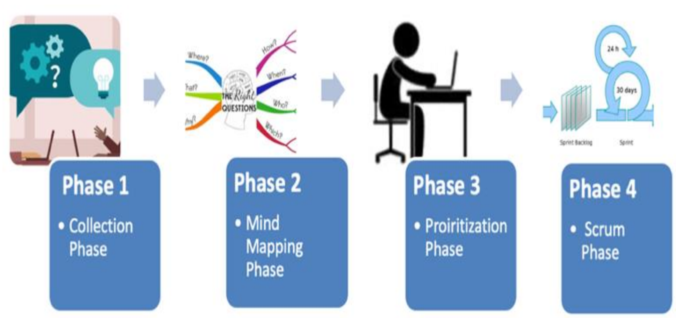

Fig. 4. Proposed Framework Phases.

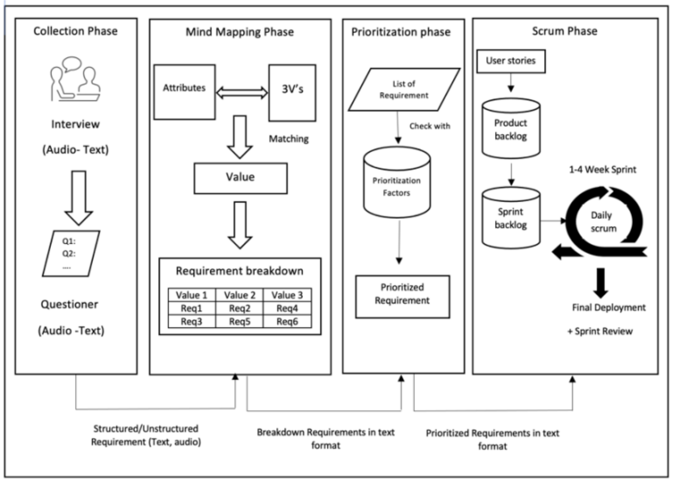

Fig. 5. Framework Methodology.

In the following sections, detailed steps at each phase in the proposed framework are described, as shown in Fig. 5. The steps at each phase are briefly described, and it is demonstrated how beneficial the output of each phase is to the quality of the next phase.

A. Collection Phase

In the collection phase, all system requirements are collected and specified. Requirement gathering is divided into two steps, each using one of two main requirement elicitation techniques, which are the interview and questioner techniques. The interview technique is extremely effective and useful for gaining full and precise information regarding system requirements, and through the feedback, errors in requirements can be easily found and explained. The interview with stakeholders is based on questions and answers and open discussions, so during the interview, organizational goals, needs, and objectives are identified. Additionally, system users' needs and constraints are identified. Thus, well-defined and organized requirements are identified during the interview, and the interview is recorded and typed in a natural language format to be accessible after the interview. Results from the interview are verified, analyzed, and broken down into clear and understandable points and questions. The requirements are converted into a questionnaire form, then it will be shared with the stakeholders in the second requirement collection step, which is the questioner technique. Presenting all requirements in the form of a questionnaire will gain a better understanding and confirmation of the identified requirements. The outputs of the collection phase are fed into the mind mapping phase, which helps in visualizing complete requirements with high quality.

B. Mind Mapping Phase

In the mind mapping phase, the most precise requirements are categorized and represented to achieve high quality requirements for big data systems. With the benefits of mind mapping graphical representation and considering big data characteristics, the mind mapping representation is considered the best practice for achieving quality requirements for big data systems. Hence, the objective of mind mapping is to represent the collected requirements under a permutation of big data characteristics, such as volume, velocity, and variety, and quality attributes, such as performance, security, accuracy, availability, and reliability, to achieve the requirement value, as shown in Fig. 6.

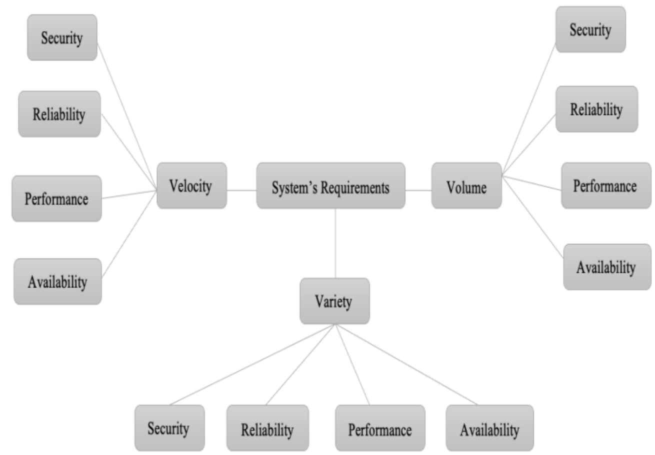

Fig. 6. Mind Mapping Phase Representation.

The figure depicts the division level of mind mapping branches. The first branch level will represent big data characteristics. The second branch level will represent quality attributes. The third branch level will represent all collected requirements from the collection phase. Through two steps, all collected requirements are broken down. In the first step, each big data characteristic will be matched with quality attributes on the basis of the output of requirements of the collection phase. Thus, big data characteristics can be matched with one or more quality attributes according to the big data quality requirement description and goals. In the second step, the collected requirements are matched under each permutation, as discussed in the first step, and shown in the example below.

> "System users initiate 10,000 transactions per minute for normal system operations, and these transactions are processed in an average latency of two seconds."

Here, in the above example, the requirement will be added to velocity and performance branches, and the related requirements will be added to these branches as well.

In this phase, all requirements are presented and described without any missing, duplicate, or incomplete information. However, even when new requirements or changes in requirements are added, they will be easily added to the appropriate branch. This will also help in deciding when and how the new requirement will be implemented. Mind mapping has a good visualization effect for the collected information, as it provides users with an in-depth insight to avoid any missing details, and all functional and nonfunctional requirements will be defined.

C. Prioritization Phase

In the prioritization phase, after the requirements are defined and mapped in the mind mapping diagram, the requirements are prioritized using MoSCoW technique. Based on the MoSCoW technique advantages which are handling a large number of requirements and it is the ease of use and scalable [28]. MoSCoW technique helps in identifying which requirement is mandatory and which is out of scope. By its feature, all the gathered requirements from the mind mapping phase will be assigned under four priority categorize; M is a must-have category in which all the mandatory requirements are assigned so any missing in these requirements will cause a system failure, S is a should-have category in which all the high priority requirements are assigned that can't be postponed, C is a could-have category in which all second priority requirements are assigned, and W is a wont-have category in which assigned requirements will not be implemented in the current development phase and will be implemented in the future.

All the requirements are categorized based on the required evaluation criteria such as business value, which represents the importance of the requirement and how it will affect the organization's needs; profits, which will affect system efficiency if not considered as a priority or necessitate further changes after implementation, thereby affecting the estimation time and cost; importance, that is, implementing the important requirements first always leads to customer satisfaction; cost, that is, selecting requirements according to its importance based on the budget, as budget is one of the system constraints; and dependency, that is, some requirements depend on others, so it is critical to avoid the disorganization of the dependencies, and constraints, which is if developers should research new technologies this will affect the project cost and time [29]. This categorization will highly affect in the next phase in which it will help product owner to select the most effective features to be implemented.

D. SCRUM Phase

In the SCRUM phase, prioritized requirements are added to the product backlog, which is used for documenting the entire system's requirements as user stories. The advantage of the prioritization phase is that it helps the product backlog obtain well-identified and prioritized requirements, which helps in making a good decision on which requirements will be added first to the product backlog to efficiently implement the collected requirements using SCRUM methodology.

V. Implementation

An evaluation study has been conducted on the proposed framework through a set of big data software companies in different application domains to assess the quality of the requirements that followed the proposed framework phases. Conducting a set of surveys for the project's key roles of system analysts team lead, developer team lead, and quality team leads assessing the output's credibility and effectiveness by analyzing survey results. In this section, the evaluation study has been conducted in three steps, i.e., planning, action, and output.

A. Planning

The planning step aims to identify how to conduct the evaluation study using sequential steps to obtain an effective result for the proposed framework. The sequential steps begin by identifying the business limitations that will be improved within the proposed framework, followed by preparing the survey questions to which participants will respond according to their technical viewpoint, and finally, identifying the appropriate participant to assist in conducting the evaluation study.

1) Identify business limitations: In the first sequential step, the main objective of the framework is to mitigate these limitations and obtain the system's requirements with high quality. Thus, requirement elicitation limitations have been investigated and observed through the literature review, and the quality factors that have to be addressed are selected and categorized into two parts. The first part includes accuracy and completeness in which the proposed framework aims to achieve requirements with fewer missing details, and conflict requirements, and considering big data characteristics, namely, variety, volume, and velocity, in the requirement specifications because specifying all the related requirements will improve the development cycle and testing cycle as well. The second part includes connectivity and modifiability in which the proposed framework aims to accept any new requirement or any change in the requirement smoothly continuously, and all requirements are connected to generate more understandable and linked requirements, which prioritize the requirements in an effective way that will aid in the development cycle.

The requirement elicitation limitations have been classified under each quality factor part, as shown in the next section.

2) Prepare survey questions: Survey questions mainly evaluate the requirements that passed all phases of the proposed framework using four quality factors: requirement accuracy, requirement completeness, requirement connectivity, and requirement modifiability. These factors are related to the common limitation in the requirement elicitation process. The requirement accuracy goal is to obtain requirements that demonstrate the extent to which data accurately characterize the real project and accurately represent all of its elements and aspects. The requirement completeness goal is to obtain complete requirements that contain all essential information, including constraints and conditions, that will help implement the requirements that meet the project's needs. The requirement connectivity goal is to obtain requirements that are linked together, and each word, definition, characteristic, and element is specified and linked as an entire set. The requirement modifiability goal is to obtain a requirement hierarchy that enables the creation of any new requirement or change in the requirement to be applied completely and consistently while also avoiding any duplication or redundancy in requirements.

The survey questions are divided into two main sections. The first section includes seven questions to evaluate the current company's framework used by the company. Thus, participants will respond to the survey questions, which indicate how far these limitations are a problem in the followed framework. The second section includes nine questions to evaluate the proposed framework. Hence, participants will respond to the survey questions, which show how far these limitations are still a problem. The survey questions contain multiple-choice responses and one open-ended question. The multiple-choice responses range from 0 to 5, where 0 means strongly disagree and 5 means strongly agree. The open-ended question is general feedback on the proposed framework. A briefly described document has been prepared about the proposed framework, which participants use as a manual guide whenever they need more details while answering the survey questions.

3) Identify participants: Identifying participants from big data software projects with their different roles, including system analyst leads, developer leads, and quality leads, as they are the key persons of any project, and their participation in the research based on their technical expertise will have a significant impact on assessing the proposed framework. In this regard, we contacted approximately 20 big data software companies. A request will be sent to all participants to respond to the designed survey's questions according to their technical experience. Responses will be analyzed and converted into a statistical representation showing how far the limitations are a problem before and after applying the proposed framework.

B. Action

The survey questions and descriptive documents were distributed among the three main roles at the 20 selected companies. Direct communications have been established with the three roles to provide them with additional clarifications regarding the proposed framework and to assist them in implementing all its phases.

C. Output

Fifteen companies agreed to participate in the study, but some of them did not accept announcing their affiliation because of company constraints. Two other companies declined to participate because of company constraints, and the other three companies did not respond. The responses have been analyzed on the basis of two sections, which are responses on the current company's framework, and responses after applying the proposed framework.

1) Participant responses based on the current framework: The participants' responses have been analyzed and represented, as shown below in Table I. The first row lists the seven questions. Q1: How far was the conflict in requirements a problem in your project? Q2: How far was the missing requirement a problem in your project? Q3: How far was the data variety of big data requirements identified using your current project? Q4: How far did the requirement specifications identify data with huge volume and velocity (speed of the received data)? Q5: How complete and consistent was the change in requirements? Q6: How far are the collected requirements linked together and understandable? Q7: How effective was prioritizing the requirements in the implementation phase?

Then, the first column includes the response scores ranging from 0 to 5, where 0 means strongly disagree and 5 means strongly agree. The second column contains the participants in which SATL denotes the system analyst team lead, DTL denotes the developer team lead, and QTL denotes the quality team lead.

The responses are represented as the total number of responses from each participant in each role for each question.

As shown in Table I, the responses identified the extent of the limitations in the software companies, as conflict and missing requirements are still considered an issue in the current working framework. Most of the participants' responses were between 3 and 5, indicating that they strongly agreed on the missing requirements and the requirement conflict. The requirements with their big data characteristics (volume, velocity, and variety) are unspecified, and this is based on the participants' responses, with the average response ranging from 1 to 3. The efficiency of changing any requirement constantly is still a research gap based on the participant's responses, which are ranged from 1 to 3.

Fig. 7 shows the average responses from all companies' participants' roles based on the company's' current framework.

TABLE I. RESPONSES BASED ON THE CURRENT FRAMEWORK

Score	Role	Q1	Q2	Q3	Q4	Q5	Q6	Q7
0	SATL							
	DTL					1		
	QTL			1		2	1	1
1	SATL			4	8	3	1	1
	DTL			4	2	5	1	4
	QTL			6	3	8	2	4
2	SATL	5	3	6	2	4	4	3
	DTL	1	2	7	8	5	5	4
	QTL		2	6	7	3	8	4
3	SATL	1	2	5	3	7	4	4
	DTL	4	2	4	4	3	6	7
	QTL	5	3	2	4	2	3	6
4	SATL	7	5		1		5	3
	DTL	7	4		1	1	3	
	QTL	4	5		1		1	
5	SATL	2	5		1	1	1	4
	DTL	3	7					
	QTL	6	5					

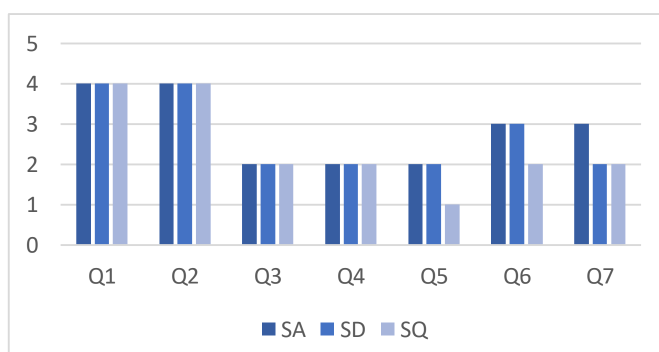

Fig. 7. Average Participant Responses for the Current Framework.

2) Participant responses after using the proposed framework: The participants' responses have been analyzed and illustrated, as shown below in Table II. The first row lists the eight questions. Q1: How far was the conflict in requirements still a problem in your project? Q2: How far was the missing requirement still a problem in your project? Q3: How far was the data variety of big data requirements identified within the proposed framework? Q4: How far did the requirements specifications identify the data with huge volume and velocity (speed of the received data) within the proposed framework? Q5: How complete and consistent was the change made in requirement using the proposed framework? Q6: How far were the collected requirements linked together and understandable using the proposed framework? Q7: How far prioritizing the requirements are applied effectively in the implementation phase within the proposed framework? Q8: How far did the elicited requirements specify the required technologies and tools that should be used, and the absolute constraints to the project using the proposed framework? Q9: Open questions on the participant comments and feedback. Then, the first column contains the response scores, which is ranged from 0 to 5, where 0 means strongly disagree and 5 means strongly agree. The second column contains all participants, where SATL denotes the system analyst team lead, DTL denotes the developer team lead, and QTL denotes the quality team lead. The responses are represented as the total number of responses from each participant in each role for each question.

TABLE II. RESPONSES BASED ON THE PROPOSED FRAMEWORK

Score	Role	Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8
0	SATL	6	3	1	1				
	DTL	4	9						
	QTL	5	3						
1	SATL	4	7	1	1				
	DTL	7	5	1					
	QTL	6	7						
2	SATL	1	2	1		2			
	DTL	3	1						
	QTL	3	4						1
3	SATL	2	1	1	2	1	2	1	2
	DTL								1
	QTL	1	1		1				
4	SATL	1	1	3	4	9	2	5	6
	DTL	1		8	7	6	7	5	8
	QTL			7	6	8	8	9	7
5	SATL	1	1	8	7	3	11	9	7
	DTL			6	8	9	8	10	6
	QTL			8	8	7	7	6	7

As illustrated in Table II, the responses demonstrated the effectiveness of the sequential phases of the proposed framework on mitigating the software requirement limitation, so conflict and missing details in requirements are identified in the second phase of the proposed framework on the basis of the participants' responses, which ranged from 0 to 3 that strongly disagree with limitation existence and the participants' feedback as well. Using mind mapping, all requirements related to big data characteristics are identified in an understandable and connectable way, allowing for changes in requirements and effective prioritization of requirements.

Fig. 8 represents the average responses from all companies' participants' roles based on the proposed framework.

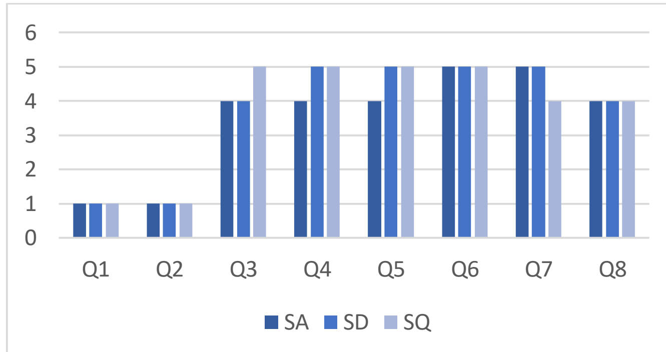

Fig. 8. Average Participant Responses for the Proposed Framework.

The survey questions are formulated to measure the four quality factors, which are divided into two parts:

3) Part 1: Completeness and accuracy are represented by Q1, Q2, Q3, and Q4: Survey question responses for the first four questions indicate that the completeness and accuracy of requirements become more realistic and consider the entire main aspects and elements of the project, which primarily applies to the big data project. When comparing the participants' responses before and after applying the proposed framework, requirement completeness and accuracy were improved by more than 50% of the current situation, as shown in Fig. 9.

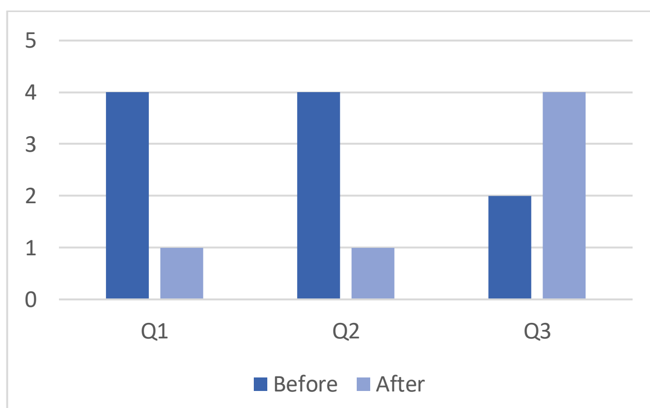

Fig. 9. Comparative Analysis between, before and after applying the Proposed Framework.

4) Part 2: Connectivity and modifiability are represented by Q4, Q5, Q6, Q7: Survey question responses for the three questions indicate that the connectivity and modifiability of the requirements help in mapping and linking the requirements together in an understandable and clear scenario; additionally, by identifying big data characteristics, the required technologies and tools that will be used and the absolute constraints applying to the project are specified. When comparing the participants' responses before and after using the proposed framework, the requirement connectivity and modifiability were improved by more than 30% of the current situation, as shown in Fig. 10.

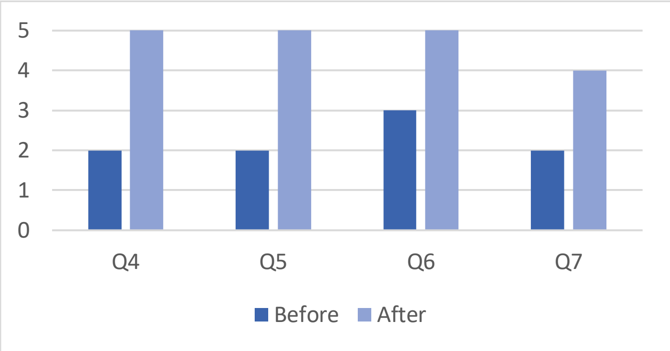

Fig. 10. Comparative Analysis between, before and after using the Proposed Framework.

VI. Conclusion and Future Work

Requirement engineering is the most crucial stage in the software development life cycle, and more attention should be given to its limitations, such as incomplete, unclear, and conflict in requirements. The complexity of collecting accurate requirements and achieving high quality of the collected requirements becomes more challenging when considering big data characteristics. Representing the huge volume, velocity, and variety of the data in the big data project requirements is the main reason to increase the complexity. An integrated framework with four different phases is proposed; each phase works independently to get the best results for the next phase to improve the requirement engineering process in big data software development. Collection phase is using traditional requirement elicitation techniques to clearly identify all the system requirements from the stakeholder. Mind mapping phase map all the collected requirements under big data characteristics and the quality attributes. The prioritization phase helps to identify requirements under four categories; server, high priority, less priority, and not required to classify which bulk of requirements should be developed first and which should be postponed. SCRUM phase to efficiently implement the big data project requirements. A survey was conducted with industry experts to validate the proposed framework on the basis of their technical background, in which the survey question is assessing the output performance before and after applying the proposed framework. The survey results prove the usefulness of the proposed framework in obtaining high-quality, complete, and detailed requirements for big data projects.

In the future, the proposed framework will be extended and verified to handle different phases in the software engineering process like the design, and the testing phase. Each phase will require different big data characteristics and different big data quality factors need to be achieved.

Analyzing Predictive Algorithms in Data Mining for Cardiovascular Disease using WEKA Tool

Aman, Rajender Singh Chhillar
Department of Computer Science and Applications
Maharshi Dayanand University
Rohtak, India

***Abstract*—Cardiovascular Disease (CVD) is the foremost cause of death worldwide that generates a high percentage of Electronic Health Records (EHRs). Analyzing these complex patterns from EHRs is a tedious process. To address this problem, Medical Institutions requires effective Predictive Algorithms for the Prognosis and Diagnosis of the Patients. Under this work, the current state-of-the-art studied to identify leading Predictive Algorithms. Further, these algorithms namely Support Vector Machine (SVM), Naïve Bayes (NB), Decision Tree (DT), Random Forest (RF), Artificial Neural Network (ANN), Logistic Regression (LR), AdaBoost and k-Nearest Neighbors (k-NN) analyzed against the two datasets on open-source WEKA software. This work used two similar structured datasets i.e., Statlog Dataset and Cleveland Dataset. For Pre-Processing of Datasets, The missing values were replaced with the Mean value and later 10 Fold Cross-Validation was utilized for the evaluation. The result of the performance analysis showed that SVM outperforms other algorithms against both datasets. SVM showed an accuracy of 84.156% against the Cleveland dataset and 84.074% against the Statlog dataset. LR showed a ROC Area of 0.9 against both datasets. The findings of the work will help Health Institutions to understand the importance and usage of Predictive Algorithms for the automatic prediction of CVD based on the symptoms.**

Keywords—Logistic regression (LR); support vector machine (SVM); Statlog; Cleveland; WEKA

I. Introduction

The heart is a vital organ that circulates rich oxygenated blood through coronary arteries. When these arteries block, such a situation is term as CVD. Major risk factors mostly relate to the patient's lifestyle (e.g., eating behaviour, obesity, smoking, alcohol, and physical inactivity). Global Burden of Disease (2019) reported that nearly a quarter of all deaths in India is because of CVD [1]. It is estimated that every year average of 17 million people dies from CVD, reported by World Health Organization (2019) [2]. There is another report in which the Lancet Medical Journal (2019) reported that women in India are more vulnerable than men [3]. Analyzing complex and similar EHRs is not a cost and effort effective solution.

Predictive algorithms in Data Mining have been used for finding patterns and generalize this for prediction in the last few decades. In our previous work [4], we have discussed: (1) The state-of-the-art for the usage of Data Mining in the Health Sector, (2) Top ten causes of Deaths from chronic Disease. One of the foremost applications of Data Mining in the Health Sector is to build an effective Clinical Disease Prediction System (CDPS) by the algorithm(s). Poorly designed CDPS can be devastating and may result in unwanted outcomes. But properly designed and analyzed CDPS will help hospitals to reduce their expenses. Traditional decision making in healthcare facilities is heavily reliant on the instincts and skills of doctors, rather than the amount of data concealed in EHRs. The consequences of this will be unintentional biases, mistakes, and superfluous medical costs that will impact patient care.

Before analyzing the algorithms, we had several questions like what algorithms to choose for CVD prediction, and on what basis. So, we put them as Research Questions (RQ) and later analyzed them on WEKA Tool. RQ for unbiased and effective analysis of algorithms are as follow:

- RQ1: What are the leading algorithms for the prediction of CVD after extensive study of related work?
- RQ2: Out of these, which Algorithm(s) outperforms other algorithms in terms of performance analysis?

This work divides into multiple Sections. Section II discusses related work by various researchers related to the prediction of CVD using data mining algorithms. Section III outlines the Methodology for performance analysis of the algorithms. This section briefly discusses the datasets, performance metrics, Software, and leading predictive algorithms. Section IV discusses the result of the analysis.

II. Related Work

To answer the RQ1, we have collected several research papers related to CVD from various sources such as IEEE Xplore, Google Scholar, Scopus, and Springer. Then these papers were filtered out based on the Year of Publication (2019—2021). This will help to find the recent usage of algorithms in the prediction of CVD. After extensive study, we have compiled the list of popular algorithms in Table I that answer the first research question. Further, these algorithms will use for performance analysis.

Muniasamy *et al.* [5] stressed on usage and applications of Machine Learning (ML) techniques for CVD prediction. They have used six algorithms viz. SVM, DT, k-NN, RF, and Linear Discriminant Analysis (LDA), Multilayer perceptron (MLP/ANN). They have used four heart datasets (i.e., Cleveland, Switzerland, Hungary, Long Beach VA) available on the UCI (University of California, Irvine) repository. They used 10-fold cross-validation for splitting training and testing data on WEKA software. Later their performance was evaluated using Metrics. Their work concluded that four algorithms i.e., LDA, RF, DT, and MLP suitable for the prediction of CVD.

Deshmukh et al. [6] suggested a Heart Disorder Prognosis System, in which they used two datasets from the UCI ML repository (i.e., Hungary, Cleveland dataset). They applied k-NN, ANN, DT, and SVM on described datasets using Python Programming language. Their result concluded that DT/ID3 outperform other algorithms on both datasets with the accuracy of 84.08% and 100%, respectively.

Garg et al. [7] performed a comparative analysis of five Data Mining Algorithms namely k-NN, NB, RF, SVM on four datasets collected from the UCI repository (i.e., Cleveland, Switzerland, Hungary, Long Beach VA). The analysis was performed using Python Programming language and concluded SVM outperforms others in terms of accuracy.

Katarya & Meena [8] used the python programming language to study the advantages and disadvantages of eight algorithms viz. LR, NB, SVM, k-NN, DT, RF, ANN/MLP, Deep Neural Network (DNN) for prediction of CVD.

Karun [9] performed a comparative analysis to find the best suitable model for the Prediction of CVD. They used the heart disease dataset from the UCI repository and concluded that RF outperforms other algorithms i.e., SVC/SVM, and k-NN.

Li et al. [10] proposed a feature selection algorithm i.e., “Fast Conditional Mutual Information (FCMIM)”. In their work, the Cleveland heart disease dataset was used, collected from the UCI repository. During pre-processing of data, data normalized by min-max scalar and then visualized using heat-map to understand the correlation. In the next phase, feature selection techniques viz. LASSO, MRMR, Relief, and FCMIM were applied to extract relevant features out of the dataset. To check the performance of each feature selection, data was passed to various classifiers (i.e., DT, ANN, LR, k-NN, SVM, and NB). Research work concluded that FCMIM when used with an SVM classifier gives better accuracy and reduces execution time than other cases.

Singh & Kumar [11] calculated the accuracy of various heart prediction algorithms such as SVM, k-NN, and Linear Regression classifiers. This work utilized the heart disease dataset from the UCI repository and then split it into 73% as a training dataset, 37% as a testing dataset. During the pre-processing phase, data balancing and feature selection were carried out on Jupyter (Python). Research work concluded that k-NN perform better than other classifiers in terms of accuracy (87%).

Choudhary & Narayan Singh [12] suggested using AdaBoost over DT because DT may lead to the over-fitting problem. They used the Cleveland dataset and experimented with the python programming language. Results concluded that AdaBoost gives almost the same accuracy (89%) at test sizes 40% and 10% of the model.

Sangle et al. [13] analyzed the theoretical aspect of different work in the field of ML and Deep Learning (DL) for the prediction of Cardiovascular Disease. They have studied the pros/cons of techniques like DT, k-NN, SVM, NB, ANN, and Ensemble Learning. Finally, the authors suggested using ensemble learning/hybrid models to boost the CVD model's prediction accuracy. Shah et al. [14] discussed and experimented with various predictive algorithms like NB, k-NN, DT, and RF where k-NN outperform other algorithms at k=7 in terms of accuracy. They have used the Cleveland dataset and analyzed it with Python Programming language.

Peng et al. [15] presented and discussed the importance/usage of ANN in the prediction of Cardiovascular disease. They have discussed previous work by various researchers related to neural networks for the prediction of CVD.

Hamdaoui et al. [16] proposed a clinical predictive system for Cardiovascular disease. They have used various algorithms like NB, k-NN, SVM, RF, and DT and then applied them to the Cleveland dataset. They used two separate validation techniques i.e., 10-Fold cross-validation, and 70-30 Split validation. In both, the scenario NB outperforms other algorithms. In Split validation, NB gets higher accuracy (84.28%) than Cross-Validation (82.17%).

Kumar et al. [17] calculated various performance metrics like Accuracy, AUC ROC score, and execution time of various classifiers such as RF, DT, LR, SVM, and k-NN. It utilizes a heart disease dataset from the UCI repository and was carried out on Jupyter (Python). Research work concluded that RF performs better in terms of accuracy (85%), ROC AUC score (0.8675), and execution time (1.09 sec).

Santhana Krishnan & Geetha [18] concluded that DT (accuracy=91%) perform better than NB (accuracy=87%) in terms of handling heart medical dataset. The experiment was carried out using Python Programming language by utilizing the heart disease dataset from the UCI repository.

Mohan et al. [19] presented a hybrid CVD prediction model based on RF with a Linear model. Feature selection was carried out using DT entropy and then the result passed to various classifiers like NB, Linear Model, LR, Deep Learning, DT, RF, Gradient Boost Trees, SVM, VOTE, and proposed model HRFLM. An experiment was carried out on R Studio and the result concluded that HRFLM produced better accuracy (88.47%) than other classifiers.

TABLE I. LIST OF ALGORITHMS WITH THEIR REFERENCE COUNT USED IN RELATED WORK

Algorithm	References	Count
SVM	[5], [6], [17], [19], [7]–[11], [13], [14], [16]	11
NB	[7], [8], [10], [11], [13], [14], [16], [18], [20]	9
DT	[5], [6], [18], [19], [8], [10]–[14], [16], [17]	12
k-NN	[5]–[10], [13], [14], [16], [17]	10
LR	[8], [10], [17], [19]	4
ANN	[5], [6], [8], [10], [13]–[15], [19], [20]	9
RF	[5], [7]–[9], [16], [17], [19]	7
Boosting	[12], [19]	2
LDA (others)	[5]	1

Repaka et al. [20] developed Smart heart Disease Prediction (SHDP) that collect heart-related data of the users and predict risk. AES (Advanced Encryption Standard) was used while storing the data, which helps in increasing data security. The research concluded that NB performs better than SMO (Sequential Minimal Optimization), Bayes Net, and MLP regarding accuracy and execution time.

III. Methodology

To answer the RQ2, This work purposed a methodology for finding which algorithm outperforms other algorithms in terms of performance. The complete and step-by-step workflow has shown in Fig. 1. This Section divides into four sections: (1) Datasets used and their pre-processing, (2) Algorithms selected from the first research question, (3) Software used for analysis, (4) Performance metrics.

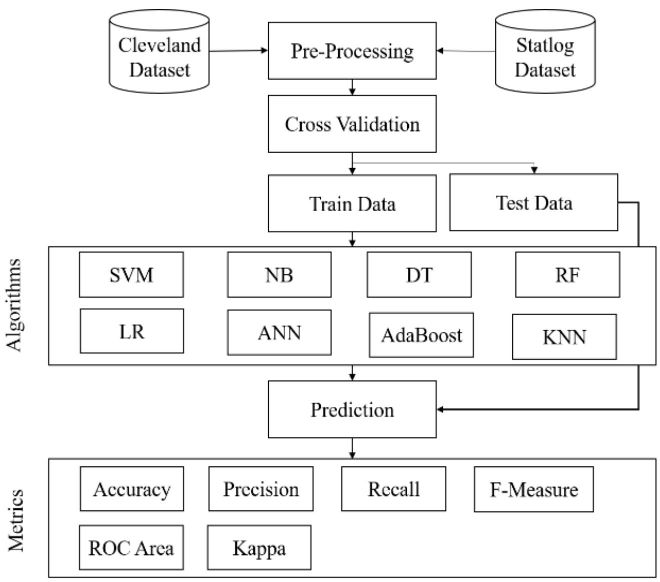

Fig. 1. Methodology for CVD Prediction.

A. Datasets

We have used two similar structured datasets related to CVD (i.e., Cleveland Dataset, Statlog Dataset). Both of these were collected from UCI ML Repository [21][22] and their properties in mentioned in Table II. Cleveland dataset contains 76 attributes, but only 14 attributes are usable for CVD prediction. In this dataset Age, Tresbps, Chol, Thalach, Oldpeak, and Ca are of numeric type and others are of Nominal type. Statlog dataset has 13 feature attributes. Unlike Cleveland dataset, it does not have any missing values. The goal of these datasets is to predict whether the patient is may suffer from CVD in the future or not based on feature attributes. If the outcome of the target variable comes Yes then it means the presence of Cardiac disease else not.

TABLE II. Properties of Datasets

Properties	**Cleveland Dataset**	**Statlog Dataset**
Number of Attributes	14	14
Number of Instances	303	270
Missing Values	Yes	No

B. Selected Algorithms

The selection of algorithm(s) largely depends on the Dataset and type of problem (e.g., classification, clustering etc.). Table I shows the list of popular algorithms after the extensive study (RQ1). In this sub-section, algorithms that had $Research\ Count \geq 2$ in Table I is discussed.

1) Support vector machine: SVM identifies the hyperplane with the greatest distance between two classes (see Fig. 2) [23]. The supporting vectors are the vectors (cases) forming the hyperplane. Researchers/Scholars must optimize the distance between hyperplanes. SVM employs a non-linear kernel function to map information at a place where a linear hyperplane cannot isolate the data. The kernel trick is the kernel function, which converts the data into a higher dimensionality, allowing for linear separation. In this work, we have used SMO (Sequential Minimal Optimization) function in the WEKA tool.

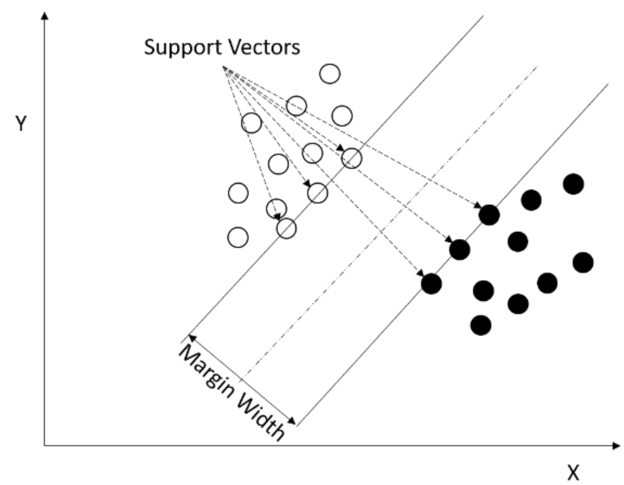

Fig. 2. Linear Support Vector Machine's Architecture.

2) Naïve Bayes: The foundation of the NB classifier is grounded on the theorem of Bayes (see Equation (1)) with the assumptions of independence among predictors [24]. An iterative parameter estimate that is especially useful for the very largest datasets is simple to construct, without a complicated iteration model. NB classifier does not struggle to be very simple and often works extremely well, as it often beats more complex classification methods. Here, we have used the NaiveBayes filter in the WEKA tool.

$$P(K|L) = \frac{P(L|K) \times P(K)}{P(L)} \quad (1)$$

Where $P(K|L)$ is the possibility of occurrence of K if L has already happened; $P(L|K)$ is the possibility of occurrence of L if K has already happened; $P(K)$, $P(L)$ is the independent possibility of event K and L respectively.

3) Decision tree: DT builds a prediction model in the shape of a tree structure [25]. DT provides a simple graphical solution to the problem which makes it most easily understandable among all classifiers. DT divides a dataset into successively smaller subgroups while building a new decision tree. The end output is a tree with decision/prediction and leaf nodes. The decision node has two or more branches (for example obesity? exercise?). A classified node (e.g., Unfit, Fit) is a decision as shown in Fig. 3. If Age < 40 and the person is Obese then it means the Patient is Unfit. If Age > 40 and not doing Exercise then the patient is unfit. DT is capable of handling both numerical and nominal/categorical attribute types. We have used the J48 (Implementation of DT based on JAVA) function in WEKA Tool.

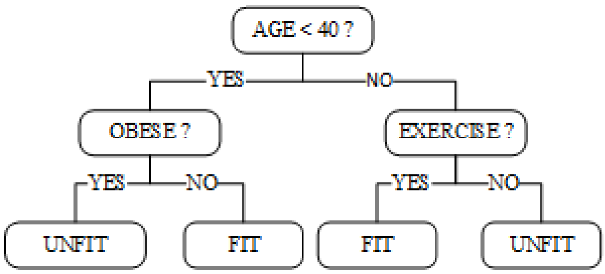

Fig. 3. Decision Tree for Obesity.

4) Random forest: RF (i.e., Random Forest) is a classifier that advances from DTs as shown in Fig. 4 and it consists of many decision trees [26]. Each decision tree provides training data as input and then their result aggregates and most voted will result as a prediction. Overfitting is a common concern in DT; RF aids in preventing this problem. Here, we have used the RandomForest function in WEKA Tool.

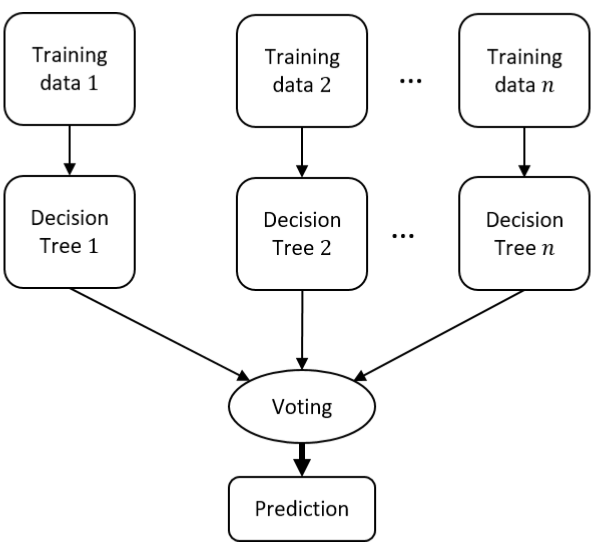

Fig. 4. Random Forest Tree Architecture.

5) Artificial neural network: ANN is composed of three layers: input, output, and hidden layer(s) as shown in Fig. 5 [27]. The input layer nodes communicate with the hidden layer nodes, as do the output layer nodes from each hidden layer node. The network data are taken from the layer of input. The hidden layer receives raw data from the input layer and processes it. The value obtained is transferred to the output layer, which also processes and returns data from the hidden layer. Incapable of justifying its choices is ANN's most critical shortcoming. Here, we have used the MutilayerPerceptron function in WEKA Tool.

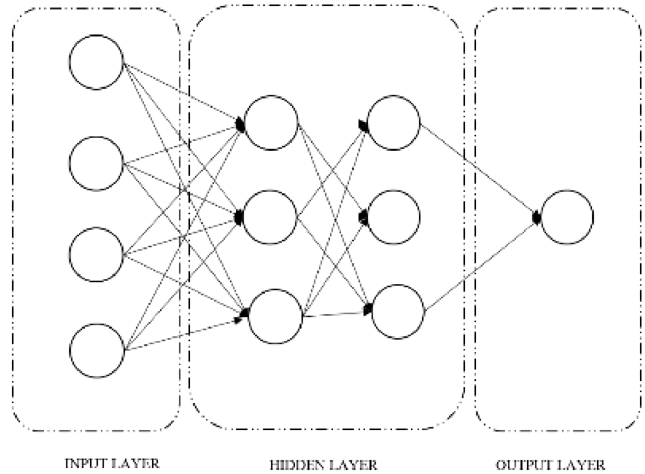

Fig. 5. Simple ANN Architecture.

6) Logistic regression: LR uses sigmoid function instead of linear function as shown in Fig. 6 [28]. In Fig. 6, y represents linear regression and probability p represents LR. The vertical axis is the likelihood of a particular number, and the horizontal axis represents the value of x. A sigmoid function is used by the logistic function to limit the y value from a wide-scale to inside the range (0, 1). Here, we have used the SimpleLogistics function in WEKA Tool.

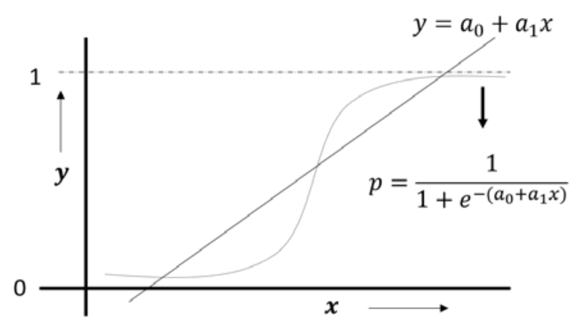

Fig. 6. Graphical Comparison of LR and Linear Regression.

7) Adaptive boosting: Adaptive Boosting (AdaBoost) is an ensemble learning technique that is used to enhance the accuracy of weak binary classifiers i.e., DT. Unlike RF, here weak classifiers add sequentially. For Dataset having number N feature variables, N decision stumps will create. Initially, all decision stumps assigned equal-weighted data. The selection of the base model (first stump) will be based on the lesser value of Entropy. After that, each observation updates with normalized new weight based on performance and total error. Finally, based on a random number and normalized weight a new decision stump will select, and so on. In WEKA Tool, Implementation of Adaptive Boosting is known by AdaBoostM1.

8) k-Nearest Neighbors: k-NN is a classifier that classifies data points based on their closest neighbours. Implementation of k-NN consists of simple steps. Initially, data points transform into vectors. In the next step, the distance between vector points is found by using a mathematical equation such as Euclidian Equation, and Manhattan distance shown in Equation (2). Then the probability of these points calculates being like test data. Finally, the classification of these vector points having the highest probability. Here we have used the IBk (Instance-Based Learner) (Implementation of k-NN) function in WEKA Tool.

$$d(p,q) = \sum_{i=1}^{t} |p_i - q_i| \qquad (2)$$

where $d(p,q)$ is the distance between vector p and q; t denotes the number of data points in the vector.

C. Software used

WEKA (Waikato Environment for Knowledge Analysis) is a free and open-source software application designed to address a range of data mining issues [29]. The framework allows the implementation of several algorithms for data analysis and provides an API to call inbuilt algorithms from a particular application by JAVA Programming Language. It provides a variety of tools for classification, regression, clustering, removes irrelevant features, builds associate rules, and visualization of the dataset. We have used WEKA v3.8.5 on Intel® Core™ i3 @ 1.70GHz with 8GB RAM on x64 bit Windows 10 Operating System.

D. Performance Metrics used

1) Confusion matrix: Confusion Matrix represented by $N \times N$ table shown in Fig. 7 that describes how well a classifier performs for which the true values are known. It consists of 4 entities. True positive (TP) are the cases where the classifier predicted that patients have the illness and, they have the illness. True negatives (TN) are those where classifier predicted patient does not have the illness and, they have no illness. False-positive (FP) is also referred to as Type I Error. In this, the classifier predicted that patients have the illness but, they do not have. False-negative (FN) is also referred to as Type II Error. In this case, the Classifier anticipated that the patient would not have the disease, but they do.

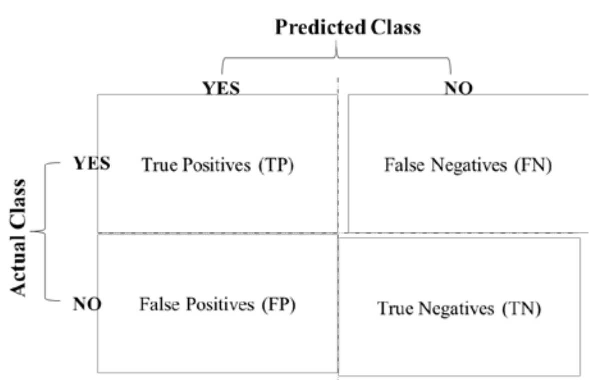

Fig. 7. Representation of Confusion Matrix.

The confusion matrix will then be used to determine Accuracy, Precision, Recall (Sensitivity), and F-Measure. Accuracy means how often is the model correct? Mathematically, it is shown in Equation (3). Precision is defined as the ratio of True Positives to Total Positives and the recall is how many true positives were found by the model. Mathematically, Precision and Recall are shown in Equation (4), Equation (5), respectively.

F-Measure is defined as the Harmonic Mean of Precision and Recall as stated in Equation (6). Instead of balancing the trade-off between Precision and Recall, the researchers can look for a good score of F-Measure. The Receiver Operator Characteristic (ROC) curve is a probability curve that compares the True Positive Rate (TPR) to the False Positive Rate (FPR) at different threshold levels. The greater the ROC Area, the better is the model's ability to differentiate between positive and negative groups.

$$Accuracy = \frac{(TP+TN)}{(TP+FP+FN+TN)} \qquad (3)$$

$$Precision = \frac{(TP)}{(TP+FP)} \qquad (4)$$

$$Recall = \frac{(TP)}{(TP+FN)} \qquad (5)$$

$$F\ Measure = 2 \times \frac{precision \times recall}{precision + recall} \qquad (6)$$

2) Cohen's kappa: These metrics use to measure how closely the instances are classified by the classifier when matched with labelled data as ground truth. It is mathematically shown in Equation (7). The greater the value of Cohen's kappa, the greater will be the level of agreement and the higher will be the percentage of reliable data. A value below 0.60 usually considers a weak classifier.

$$Cohen's\ kappa = \frac{P_a - Pe}{100 - P_e} \qquad (7)$$

where P_o is actual percentage agreement, P_e is expected percentage agreement based only on chance.

IV. Experimental Results

This paper examined two research questions for effective and unbiased analyzing the algorithms. To answer RQ1, we have inspected the extensive state-of-the-art related to Predictive algorithms and CVD. Table I clearly showed that *SVM, NB, DT, RF, LR, ANN, AdaBoost and k-NN* are the most common and popular choices for CVD prediction. To answer RQ2, we stated methodology for opting which algorithm outperforms on two similar structured datasets (i.e., Cleveland Dataset and Statlog Dataset). Unlike the Statlog dataset, Cleveland Dataset poses missing values. To remove these missing values, we have applied ReplaceMissingValues Filter in WEKA that replaced these values with modes/means. Later balancing of Datasets has performed by ClassBalancer filter so that each class has the same total weight.

Following data pre-processing, each dataset was divided into Training and Testing data (for validation) using 10-fold cross-validation. Algorithms from RQ1 were applied to these datasets. To measure the effectiveness of these algorithms, each one was put to the test using performance measures, the results of which were displayed in Table III and Table IV.

Against Cleveland Dataset, the result of the performance analysis showed that both SVM and ANN perform better than other selected algorithms with the accuracy of ~84.15% and ~84.09% respectively (Table III). DT scored 73.62%, Naïve Bayes scored ~81.67%, RF scored ~81.37%, Logistic Regression scored ~81.37%, AdaBoost scored ~82.99%, and k-NN scored ~75.74% in terms of accuracy. The accuracy of the ANN classifier is very close to SVM but the ROC Area value of ANN (0.907) is more than SVM (0.842) (see Table III). So, both ANN and SVM are suitable choices for the prediction of CVD against the Cleveland Dataset.

Analysis Result against Statlog Dataset showed there were three algorithms whose performance was worthy to talk about (Table IV). SVM scored the highest accuracy of ~84.07%. Next in order, NB and LR showed the same accuracy of ~83.70%. DT scored ~76.66%, RF scored ~76.29%, ANN scored ~78.14%, AdaBoost scored 80% and k-NN scored ~75.18% in terms of accuracy. If we compare the ROC area then both NB and LR are better than SVM (see Table IV).

The results discussed were about individual datasets. If we compared the accuracy of algorithms against the Cleveland dataset and Statlog dataset then SVM performed better than other algorithms (see Fig. 8). Against Cleveland Dataset, it showed an accuracy of ~84.15% and Against Statlog Dataset, it showed an accuracy of ~84.07%. Next in order, NB showed an accuracy of ~81.67% against the Cleveland Dataset and an accuracy of ~83.70% against the Statlog Dataset.

TABLE III. PERFORMANCE METRICS OF THE ALGORITHMS AGAINST CLEVELAND DATASET

Algorithms	Accuracy (in %)	Precision	Recall	F1	ROC Area	Kappa
SVM	**84.1568**	0.843	0.842	0.841	**0.842**	0.6831
NB	81.6733	0.817	0.817	0.817	0.899	0.6335
DT	73.6232	0.736	0.736	0.736	0.741	0.4725
RF	81.3702	0.814	0.814	0.814	0.900	0.6274
LR	81.3702	0.814	0.814	0.814	0.900	0.6274

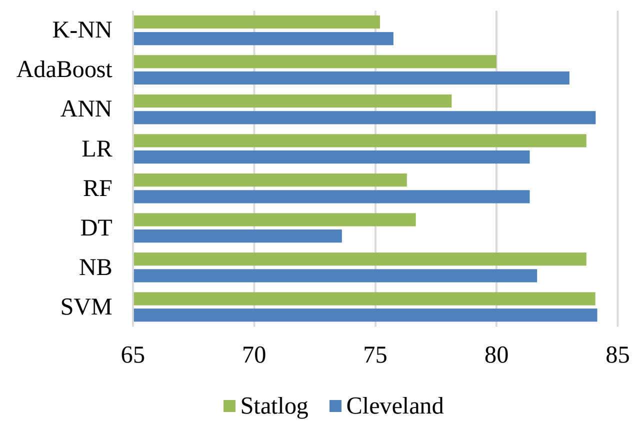

Fig. 8. Comparison of Accuracy (in %) against Cleveland and Statlog Dataset.

Algorithms having a ROC Area value near 1 generally consider a good classifier against the dataset. LR scored a ROC Area of 0.9 against both datasets (see Fig. 9). Next in order, ANN showed 0.907 against Cleveland Dataset and 0.839 against the Statlog Dataset.

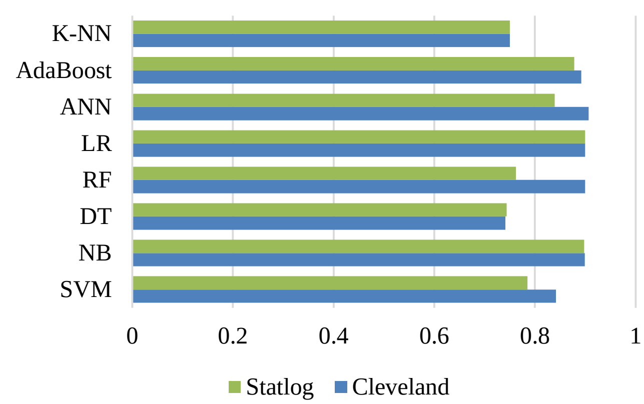

Fig. 9. Comparison of ROC Area against Cleveland and Statlog Dataset

V. CONCLUSION AND FUTURE WORK

Predictive Algorithms founds to be very effective in the automatic prediction of CVD. In this work, we analyzed popular predictive algorithms namely SVM, NB, DT, RF, LR, ANN, AdaBoost and k-NN. They were chosen based on the state-of-the-art related to the CVD and Predictive Algorithms. The experiment was conducted using two similar structured datasets (i.e., Cleveland and Statlog Dataset) on open-source WEKA software. The outcome of the experiment concluded that (1) SVM showed maximum accuracy against the datasets, (2) LR showed a ROC Area of 0.9 against both the datasets. These results imply that (1) SVM shows better accuracy against most of the datasets by finding optimal hyperplane using kernel tricks, (2) LR shows better ROC Area against the binary classification datasets.

These findings will help the researchers and Health institutions (1) To understand the current trends related to CVD prediction using the algorithm(s), (2) To build successful and effective CDPS (i.e., Clinical Disease Prediction System) for CVD. Unfortunately, we were unable to study and analyze hybrid models/algorithms but it can extend in future by considering this work as a blueprint/base. Future work should give priority to (1) Real-time and Complexed CVD data, (2) Ensemble Learning and Hybrid Models for analysis, (3) Checking the effects on the value of Performance Metrics against different validation and features selection techniques.

Enhanced Clustering-based MOOC Recommendations using LinkedIn Profiles (MR-LI)

Fatimah Alruwaili, Dimah Alahmadi
Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah
Saudi Arabia

***Abstract*—With the rapid development of massive open online courses (MOOCs), the interest of learners in MOOCs has increased significantly. MOOC platforms offer thousands of varied courses with many options. These options make it difficult for learners to choose courses that suit their needs and compatible with their interests. So, they become exposed to many courses on all topics. Therefore, there is an urgent need for personalized recommendation systems that assist learners in filtering courses according to their interests. Therefore, in this research, we target learners on the professional platform, LinkedIn, to be the basis for user modeling; the number of extracted profiles equals 5,039. Then, skill-based clustering algorithms were applied to LinkedIn users. Subsequently, we applied the similarity measurement between the vector features of the resulting clusters and the extracted course vectors. In the experiment result, four clusters were provided with the top-N course recommendations. Ultimately, the proposed approach was evaluated, and the F1-score of the approach was .81.**

Keywords—MOOCs; recommendation systems; content-based; clustering; term frequency-inverse document frequency (TF-IDF); LinkedIn

I. Introduction

Currently, the world has significantly developed regarding the services provided to learners over the internet. These services have expanded to include courses, academic qualifications, and science lessons and have become known as e-learning. After the emergence of e-learning, many students worldwide have participated in online courses in virtual classes [1]. Recently, E-learning has gained colossal attention since the emergence of Massive Open Online Courses (MOOCs), which attract numerous learners to engage[2]. MOOCs are an online platform that provides services for learners of different ages and academic levels worldwide in different geographic locations. It serves the community's largest possible segment and has more than 100 million students [3]. Some MOOCs are offered as free educational courses for learners in various fields in many languages. It is also characterized by its flexibility to accept students and facilitate their access to available educational content. MOOCs offer different styles to deliver courses where they can access course content in text or video lectures. They can take advantage of extending course content by using discussion boards or blogs [4][5]. MOOC evolutions are considered the most popular platforms that have evolved to include all countries globally, with many providers such as Coursera, Udacity, Udemy, and Edx [6].

However, due to the large number of provided courses, the learners may face difficulties obtaining the desired content. In terms of choosing the right course, the number of users who make a wrong decision exceeded 90% [7]; thus, a meaningful recommendations engine has become critical for MOOC users. Based on these facts, the importance of personalized recommendations for users in education or other fields should be mentioned. The recommendations provided to learners have great significance and may be one of the most critical factors motivating them to expand their learning experience with various courses offered to them. MOOC recommendations have importance for both sides, learners, and MOOC providers, as learners face difficulty reaching the appropriate content. At the same time, MOOC providers also face problems represented in suggesting the proper course. There are different recommendation techniques; some recommendations can be achieved using collaborative filtering methods, which provide the learner with recommendations similar to the courses that their peers joined in the platform. Other systems have relied on user modeling by analyzing their search history in the platform or analyzing their profile in the MOOC platform [8]. Recent studies have confirmed that the most effective methods in the recommendations are the ones that rely on the analysis of social networks because it is closer to match the taste of users. Recommendation systems used social network data to give the user more customized recommendations based on each user's personal information [9]. This research has relied on the utilization of social network content to customize recommendations. Specifically, LinkedIn was chosen to be the primary source for this research's dataset for many reasons. First, it is one of the best professional social networks where users express their education, academic experience, skills, and educational interests. The proposed approach in this paper analyzes users' profiles on LinkedIn and then provides course recommendations for the most appropriate course of these profiles.

The paper will be organized as follows: Section 2 will discuss the related works to MOOC recommendation systems, especially content-based systems. Then, Section 3 will discuss our proposed approach to courses recommendation based on LinkedIn data, starting with data collection, description, cleaning, the clustering process for LinkedIn profiles, and the recommendation process. Then, the evaluation process of the proposed approach will be discussed in Section 4. After that, we will discuss the results in Section 5. Finally, in Section 6, we will conclude the work and present the future directions for this research.

II. Literature Review

Due to the knowledge and information rapid explosion worldwide, there is an urgent need to improve the efficiency of the learning process. Therefore, MOOC platforms became more popularized to fulfill this need equipped with recommendation systems.

Recent studies have also confirmed the effectiveness of integrating information derived from social networks with recommendation systems in terms of accuracy. The additional information about the user increases the understanding of the user's behavior and preferences. Thus, the user can be better understood and modeled, reflecting positively on the accuracy of the recommendation [8][10]. Data mining has helped researchers develop recommendation systems (RSs) to provide users with suggestions related to specific items or content to achieve personalization [11]. Many studies were initiated to assist in recommend courses for learners. For example, Dumitru Radoiu [7] addressed the user attributes, user behaviors, and item attributes in MOOC platforms such as 'user profile' (user attribute), 'user history' (user behavior), and 'course description' (item attribute) to provide learners with suitable course recommendations to improve their completion rate.

Other ways to use recommendation systems in e-learning, as in the study by Kardan et al. [2], which analyzed social networks to lead learners to match relevant information in MOOC platforms. Additionally, in terms of the efforts to solve the cold start problem, a study by Kumar Abhinav et al. [12] presented a framework of hybrid recommendation systems. Many predictive models have been used to contribute to providing efficient course recommendations for learners. At the same time, other studies such as Xiao Li et al. [13] have applied the user preferences and behavior inside the demographics data to develop accurate recommendations to serve their needs. The definitive study by Alzahrani & Maccawy [14] proposed a hybrid model for MOOC search based on personalization known as the MOOC Recommender Search Engine (MRSE) to access relevant courses easily. In a new study in 2021, Khalid et al. [15] proposed an algorithm based on ratings. The system implements a new algorithm characterized by flexibility and scalability; what is more, it is more accurate than previous algorithms. Its results were also compared with the Collaborative Filtering and Clustering algorithms, and they showed great superiority in the accuracy and classification metrics.

Furthermore, in content-based recommendations algorithms, the item's content is used to provide recommendations; it includes the information to describes the items [11]. Many studies have adopted this technique in building MOOC course recommendation models for learners. For example, a study by Piao & Breslin [16] presented a system that gives learners personalized recommendations by taking advantage of their LinkedIn pages' data. This system ranks the courses obtained from Coursera (using google custom search engine GCSE) according to its similarity with the user's profiles. Jing & Tang [17] developed a new algorithm called Hybrid Content-Aware Course Recommendation (HCACR); they employ collaborative filtering to develop a course recommendation algorithm that combines user interests and demographics as well as analyzes pre-course requirements. They tested the proposed algorithm on the "XuetangX" platform [18], a Chinese courses platform; their algorithm proved its effectiveness, as it achieved a high click rate on the recommended courses. Another study by Huang & Lu [19] presents a content-based MOOC model for intelligent education, contributing to user profiling development. They have used user interest analysis on the MOOC page to create a user profile and provide recommendations that match the user's activity log. In another study by Zhang et al. [20], the authors developed a recommendation model based on content analysis for learners and educational courses (named MOOCRC), which relies on deep belief networks (DBNs). This graphical model combines probability and statistics with machine learning and neural networks in MOOC environments. Their proposed model achieved higher accuracy and coverage rate than the traditional recommendation systems. Using a context-aware factorization machine algorithm, Chanaa & El Faddouli [21] designed a new recommendation approach for a MOOC platform in order to provide further recommendations that aligned with each learner using predictions about user behavior; this was studied by analyzing user interactions in the MOOC platforms, including rating, feedback, and likes.

In specific applications, many researchers used LinkedIn in recommending MOOC courses. LinkedIn offers the opportunity to obtain the user's profile in order to analyze the user's educational taste. Users' profiles contain reliable information about learners' scientific backgrounds and research fields, which is considered the largest professional social network on the internet [22]. Besides the valuable information existing in user profiles, such as the educational degree and work experience [23]. In a similar study of Dai et al. [24], the data was collected and analyzed from the professional profiles on LinkedIn. The authors used the natural language processing techniques (NLP) to study the users' behavior on Online Social Networks (OSN) to provide recommendations that improve their decision-making process. Also, Dai et al. [25] used the available personal data on LinkedIn pages to provide customized recommendations to learners based on their preferences. However, these preferences were built by focusing on the job market to make the recommendations more relevant to the job market's needs. Another study for Pourheidari et al. [9] used data taken from two well-known social networking sites, LinkedIn and Twitter, to provide users with recommendations that essentially correspond to their information written on LinkedIn and Twitter. This study proved to be highly effective in recommendation systems. The last research was by Kumalasari and Susanto [26], who collected data from professional profiles on IT professionals from LinkedIn to be used as a reference for the skills presented later as a recommendation for students (job seekers).

A. Research Gap

The learners had difficulty in obtaining the appropriate training courses. There have been many studies to solve this problem, and one of the most effective ways is to provide personalized recommendations for learners. Therefore, this research will present a personalized recommendations approach for learners based on their skills. According to the literature, the studies that used the content-based recommendation had a good performance. Other studies that used social networks in personalization also achieved recommendations closer to the learner's needs. Therefore, in this research, these two features will be combined to personalize courses for learners better.

The content-based recommendation will be used as well as the applying of clustering algorithms besides utilizing the TF-IDF technique. Recommendations will also be personalized based on social networks. Therefore, in this research, the professional social network "LinkedIn" will be relied upon, as it is the most formal social network; besides focusing on the user's skills present on LinkedIn. In addition, the studies that highlight users' skills in LinkedIn are limited, so the skills here will be used as a guide to the course's recommendation process since it was closest to describing the user's interest. So, the contribution of this research will be to apply clustering algorithms to LinkedIn users to provide personalized course recommendations to learners based on their profiles, especially their skills present on LinkedIn.

III. MOOC Recommendation based on LinkedIn Profiles KR-LI Approach

A. Proposed Approach

This section presents our approach "MOOCs Recommendation based on LinkedIn MR-LI" to recommend MOOC courses to learners based on their LinkedIn profiles. This approach aims to identify the learner's interests through the mentioned skills in him/her profile that explicitly expresses the scientific field in which he/she is interested. Fig. 1 illustrates the general framework for the proposed approach.

First, the approach extracts data from the LinkedIn and Coursera websites. The crawling process is performed on LinkedIn profiles to scrape the entire information from each profile, and then store the scrapped data into a user's dataset. As well as for Coursera, then it is stored in a separate dataset for the courses. Second, the approach begins with the cleaning and preprocessing of datasets. Third: LinkedIn users are clustered into clusters based on the similarities between the users. At this step, the skills field on LinkedIn is taken as a feature for clustering on its basis. Fourth: begins with the feature extraction for datasets (LinkedIn and Coursera) and the calculation of weights for feature vector construction using term frequency-inverse document frequency TF-IDF. Fifth, the similarity between the learners and the courses is measured using Cosine Similarity. Finally, the approach provides recommendations for learners' clusters with ten courses that are most similar to these clusters. The following section will discuss these steps in detail.

B. Dataset Collection

1) LinkedIn dataset: In order to validate MR-LI, we used LinkedIn as the primary resource for our learners' dataset. This is because LinkedIn is one of the most popular social network sites in which people express their interests and educational backgrounds more formally and professionally, as it is specific to employment and education development, so it is the best environment to obtain accurate data for the recommendation process [9].

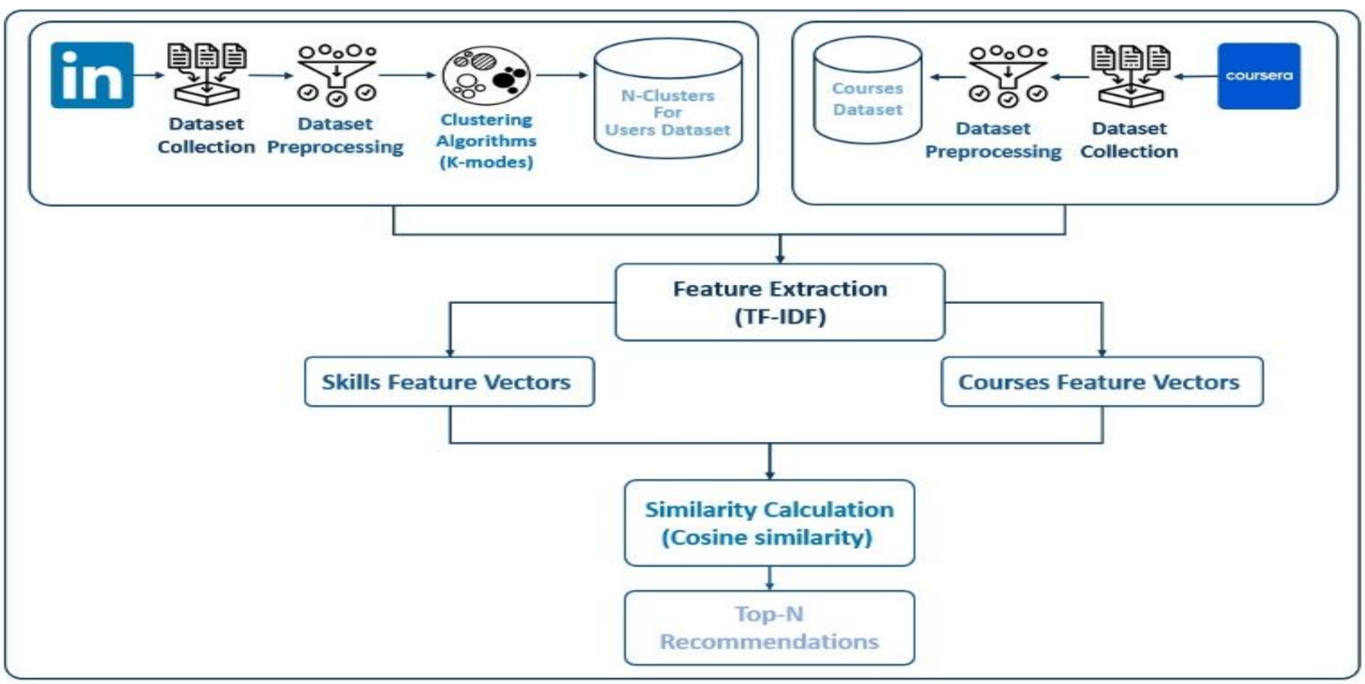

Fig. 1. The Framework for the Proposed Approach MR-LI.

We used Python as the programming language to deal with the LinkedIn API. The BeautifulSoup and Selenium libraries were used to access users' profiles [24] and then store the data in JSON and CSV format. Using LinkedIn API, we can access public data for users such as name, current job, past jobs, degrees, brief description, skills, interests, languages, etc. Fig. 2 provides an example of a public profile on LinkedIn. There are two profile types on LinkedIn (public & private), and we can access the public profile only. In order to extract our dataset, we identified the subscribers in common companies and universities in Saudi Arabia to reach the actual active users in Saudi Arabia. After the data scrapping process, the number of users reached more than 20,000. Table I shows the most important information on users' LinkedIn profiles.

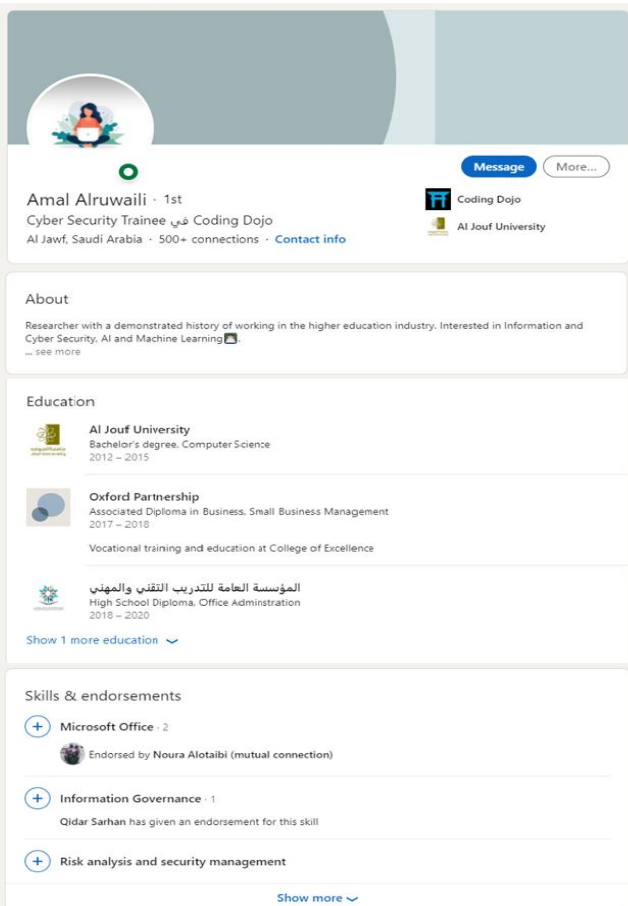

Fig. 2. Example of Full Profile on LinkedIn.

TABLE I. THE MOST IMPORTANT INFORMATION ON USERS' LINKEDIN PROFILE

Field Name	Description
About	Brief introduction about the user.
Activity	Posts the user publishes and the posts he/she interacts with.
Experience	Practical user experiences.
Education	Educational qualifications obtained by the user.
Licenses & Certification	Professional licenses and certificates are obtained by the user.
Skills	Skills the user possesses.

2) Coursera dataset: Conversely, to obtain data for the courses that will be recommended to learners, we have chosen the Coursera website [27], one of the largest global platforms that offer courses in various technology fields and others. Coursera provides details about the courses on each course page, as in Fig. 3. Therefore, it is considered an excellent platform in terms of the details available about the offered courses. The API with BeautifulSoup and Selenium libraries on Python also have been used to scrape 12173 courses in JSON and CSV format. Table II shows the most important information on the course page on the Coursera website, such as the course title, description in "about this course", instructors, etc.

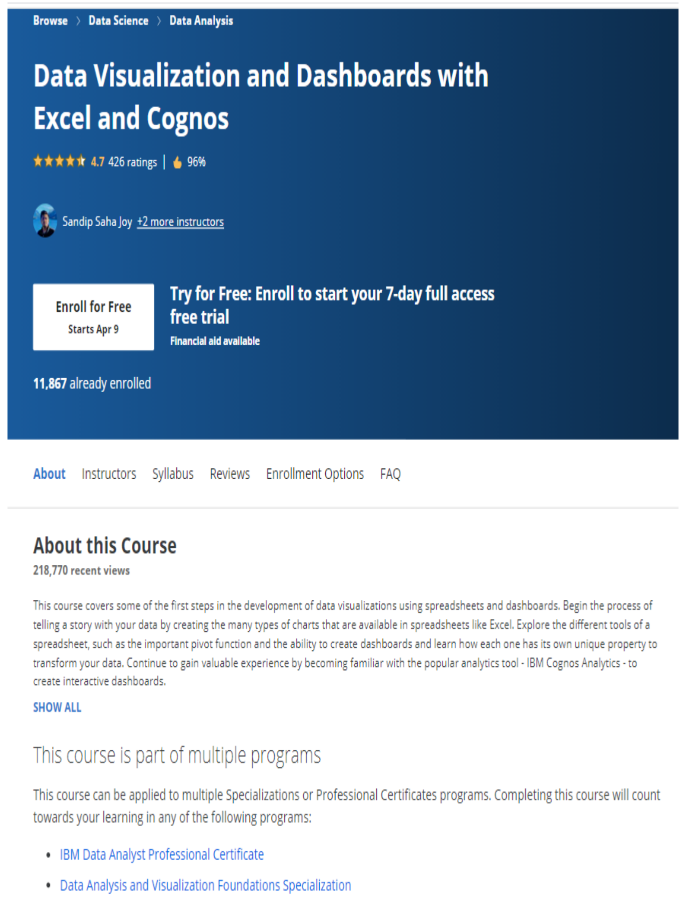

Fig. 3. Example of Course on Coursera.

TABLE II. THE MOST IMPORTANT INFORMATION ON THE COURSE PAGE

Field Name	Description
Course Title	Title of the course.
About	General description of the course and its contents.
Instructors	Details about the instructors presenting the course.
Syllabus	Details about the course content.
Review	Learners' rating and feedback about the course.
Enrolment Options	Options for attendance and payment methods.

C. Dataset Cleaning and Preprocessing

1) LinkedIn dataset: The initial total of data extracted was over 20,000 files. In order to obtain satisfactory results, files that do not contain primary data for the recommendation process include: profileurl, firstname, lastname, schooldegree, schooldegreespec, schooldegree2, schooldegreespec2, allskills, skill1, skill2, skill3, skill4, skill5, and skill6 are excluded. Also, the number of profiles written in Arabic was scarce due to the reliance of the majority of users on writing their profiles in English. Because the small dataset number did not yield satisfactory results, we had to exclude the Arabic profiles. Therefore, emphasis was placed on the English profiles only; the profiles written in other languages were excluded.

In addition, we performed some preprocessing on the data: first, transforming the text to lowercase. Second, removing the punctuations, stop words, and URLs. Third, excluding meaningless rows with long descriptions from skills or not writing them in text. Fourth, excluding profiles that contain less than six skills. Finally, separating the skills using "|". The data size after cleaning amounted to 5,039 files.

LinkedIn gives its users complete freedom to express themselves, their skills, academic qualifications, and experiences [24]. Therefore, there is no specific way to write the skills. For example, we find that a person may express 'Leadership' in 'Team Leadership', 'Team Management', or 'TeamLeadership'. In this way, the writing style can affect the distribution of users in clusters. Therefore, we normalized the skills as shown in Table III. After that, we performed the lemmatization process on the dataset to avoid data duplication. By the end of this process, we found that the common skills were "Microsoft Office", "Project Management", "Teamwork", and "Leadership".

TABLE III. THE NORMALIZATION FOR LINKEDIN DATASET

Skill	Keywords
'Programming'	'Program', 'programming'
'Project Management'	'Project', 'Project management', 'PMP', 'End-to-End Project Management'
'Teamwork'	'Team', 'Team work', 'Team Work', 'team work'
'Leadership'	'Team Leadership', 'Team Management'
'Time Management'	'Time', 'Time Management', 'time management', and 'TimeManagement'.
'Accounting'	'Accounts', 'Accountant', and 'Accounting'.
'Microsoft Office'	'Office', 'Microsoft', and 'microsoft'.
'Presentation Skills'	'presentation', 'presentation skills'.
'Strategic Planning'	'Strategy', 'Strategic',
'Data Analysis'	'Data', 'Data Analytics',
'Financial Analysis'	'finance', 'Finance', 'Financial'
'Web Development'	'Web', 'webdenepment', 'webdeveloper'.
'Business Development'	'Business', 'Business developer', 'Business Skills'.
'Quality Assurance'	'Test', 'Tester', 'Quality', 'Assurance of quality'.
'Object-Oriented Programming (OOP)'	'OOP', 'Object-Oriented Programming'

2) Coursera dataset: The scraped data contains the following information: CourseId, Description, CourseTitle, DurationInSeconds, ReleaseDate, AssessmentStatus, IsCourseRetired. However, the primary data for each course is the CourseId, CourseTitle, and Description columns, so courses that do not contain this information have been excluded. Also, the "IsCourseRetired" column represents the course's state in real-time is available or not. So, the courses with value = "No" in this column were excluded from the recommendation process to avoid making recommendations to learners with unavailable courses. The data have been cleaned of stop words, symbols, punctuation marks, and all characters except numbers and letters. Also, terms like "ll" used in "Description" texts, such as 'we'll' and 'you'll', were also removed along with '-' (hyphens) from the CourseId. The data size after the cleaning equaled 3,471 courses.

D. Clustering LinkedIn Profiles

The purpose of this section is to categorize users based on their skills. Nevertheless, due to the freedom granted to users by LinkedIn, they can express their skills in various names without using pre-defined labeling. So, LinkedIn profile fields do not follow a specific standard, such as the UNESCO used to classify the users' skills [28]. In this sense, the classification algorithms become very difficult. So, the solution here is clustering algorithms, as it clusters the users according to how similar they are to each other. Considering the size of the obtained dataset, we decide to apply the K-modes clustering method due to its efficiency and effectiveness in the used size of the dataset. Before using the K-modes algorithm, we must determine the number of clusters "k" since it is a sensitive parameter for this clustering process [24]. We applied the Elbow method to guide the choice of the "k" parameter [29].

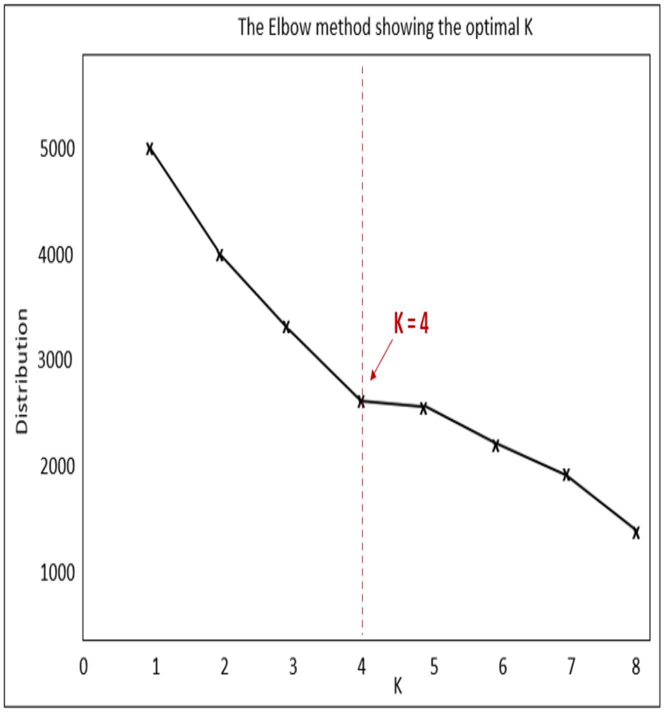

Fig. 4. The Result of the Elbow Method.

As shown in Fig. 4, the elbow method computes the squared distance's total for each cluster. We assign different k-values from 0 to 49; by analyzing the generated graph, it is clear that the k equals the breakpoint, which is the elbow point. In this case, according to the graph, the optimal k will be 4.

The K-Mode algorithm was applied to 5039 profiles. Table IV shows the number of profiles in each one of the four clusters.

We notice that more than 75% of the profiles are located in the first cluster. Therefore, a lemmatization process was performed on the dataset to reduce the similarity between profiles. Table V represents the distribution of the profiles on the four clusters after the lemmatization process.

We created word clouds corresponding to each cluster to clarify the distribution of the profiles in the four clusters. In the beginning, we notice the repetition of some skills in all clusters, such as "Microsoft Office", "Teamwork", and "Time management", but at different rates from one clause to another. Table VI shows the commonly used skills in each cluster.

For the first cluster, as shown in Fig. 5, it is clear that the most common skills among users are combined, and this explains why it is the largest cluster among the four clusters, as it contains "business," "planning," "problem-solving," and "communication" as the most common skills in this cluster. As for the second cluster in Fig. 6, it is clear that the most common skills are "human resources", "development", "recruit", "team management", and "social media", it can be described as it combines social, employment, and communication skills in general. As for the third cluster in Fig. 7., it is widely noted that it combines skills that indicate interest in the field of cybersecurity such as "defense", "protection", "threat", "awareness" and "iam", which are terms widely used in the field of cybersecurity. Finally, the fourth cluster in Fig. 8 gathered skills that generally referred to project management and software engineering. Fig. 9 shows the skills that are most frequently used among the users of the four clusters.

TABLE IV. THE NUMBER OF PROFILES IN EACH CLUSTER

Cluster ID	Number of profiles
Cluster 1	3,859
Cluster 2	392
Cluster 3	367
Cluster 4	448

TABLE V. THE NUMBER OF PROFILES IN EACH CLUSTER AFTER THE LEMMATIZATION

Cluster ID	Number of profiles
Cluster 1	3,175
Cluster 2	463
Cluster 3	952
Cluster 4	448

Fig. 8. Wordcloud of Cluster 4.

E. Recommendation Process

This phase consists of two steps in which we aim to identify the recommended courses for the four user clusters.

1) TF-IDF: In order to extract the important features in the datasets, the term frequency-inverse document frequency (TF-IDF) was used, which proved to be effective in detecting important words for the dataset [30]. In the vector space model, TF-IDF is the commonly used weighting method in describing the documents [31].

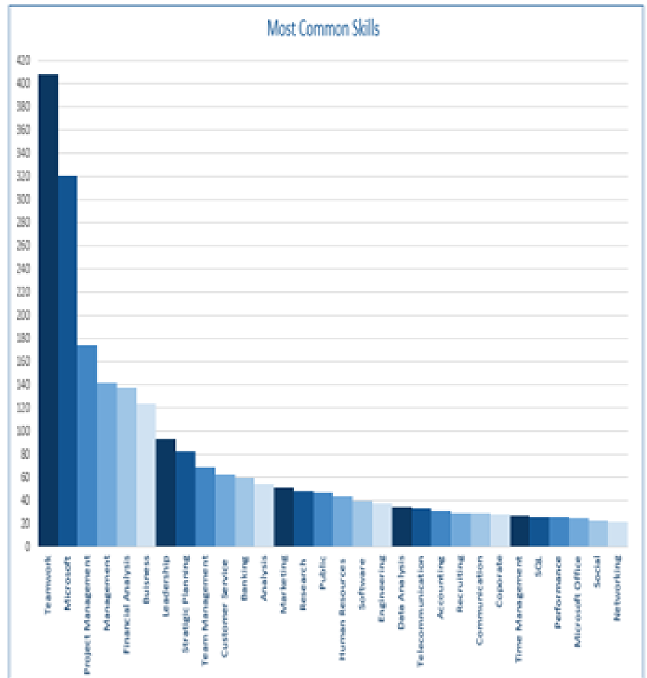

Fig. 9. The Most Commonly used Skills in the Four Clusters.

TF-IDF indicates the importance of the term for the whole document. It is related to the number of times the word appears in a document compared with its frequency in the document. Thus, Tf in TF-IDF weight measures the frequency of the terms in a document, while IDF measures the term importance in the document. The following equation illustrates the TF-IDF method.

$$tfidf_{i,j} = tf_{i,j} \times \log(\frac{N}{df_i}) \quad (1)$$

$tf_{i,j}$ = number of occurrences of i in j.

df_i = number of documents containing i.

N = total number of documents.

Therefore, the importance of a word increases with the value of TF-IDF for that word. Thus, the higher the TF-IDF value for a specific skill in Cluster, the higher the value of this skill will be, and likewise for the courses data set, vice versa.

2) Similarity measure: In order to begin the recommendation process, the similarity between each of the four clusters should be measured with the courses in the course dataset. In this step, one of the most popular metrics used to measure similarity is the cosine similarity [32]. The formula is:

$$similarity = \cos(\theta) = \frac{A.B}{||A||||B||} = \frac{\sum_{i=1}^{n} A_i B_i}{\sqrt{\sum_{i=1}^{n} A_i^2 \; \sum_{i=1}^{n} B_i^2}} \quad (2)$$

The similarity of each cluster is measured using the ten most similar courses in the course dataset. After that, these ten courses are presented as user recommendations in this cluster; this proceeds for all four clusters.

Subsequently, ten-course recommendations are presented for each cluster based on the results of cosine similarity, which are the top 10 similar courses for each cluster. Table VII represents the recommendations resulting from the four clusters.

TABLE VII. THE RESULTED RECOMMENDATIONS FOR EACH CLUSTER

Cluster ID	**Recommendations**
Cluster 1	Building Excel Online Automation with Office Scripts Building Websites with HTML, CSS, and JavaScript: Getting Started Build Your First Dashboard with GoodData How Novices Learn to Program: What I've Learned Teaching in a Coding Bootcamp Gin: A Website Application Framework for Go Organizational Design: Going from Features to Experiences: Front 2019 Exploring Product Sales Unlocking Unstructured: Leveraging Data Discovery Creating and Using Track Mattes in After Effects AWS Infrastructure with Python: Getting Started
Cluster 2	PMP® Exam Prep â€“ Project Human Resource Management Introduction to Presentation Design PMPÂ® Exam Prep â€“ Project Communications Management Computing, Communication, and Business Integration for CASP (CAS-002) Managing Delivery of Your App via DevOps Leveling up Planning and Designing Microsoft Azure Networking Solutions Website Performance LinkedIn Fundamentals Creating Animated Web and Social Media Banners in Photoshop and Flash
Cluster 3	Building Your Cyber Security Vocabulary Cyber Security Awareness: Malware Explained Cyber Security While Traveling Layer 2 Security for CCNA Security (210-260) IINS The Issues of Identity and Access Management (IAM) Incident Detection and Investigation with QRadar CompTIA Security+ (2008 Objectives) Cyber Security Awareness: Social Engineering SSCPÂ®: Monitoring and Analysis & Risk, Response, and Recovery (2012 Objectives) Preparing for the Google Cloud Professional Cloud Architect Exam
Cluster 4	Driving Engineering Culture Change at Microsoft: An Experimental Journey Scalable, Flexible, Modular, Preventative Architecture Agile Estimation Managing Work with Team Foundation Server 2012 Testing AngularJS from Scratch Easily Estimate Projects Using Statistics and Excel Secure Software Development CISSPÂ® - Software Development Security Windows 2000 Server Group Policy Java: JSON Databinding with Jackson

IV. EVALUATING MR-LI APPROACH

At first, we used experts to carry out the recommendation process manually. We asked the experts to separately provide ten-course recommendations for each cluster by matching the skills in each cluster to the most appropriate courses based on the course description. Then, we provide them with the four clusters and skills in each cluster, with the weight of each skill besides the courses. The experts generated ten ordered recommendations for the four clusters. Next, to evaluate the performance of the proposed approach, we compared the results generated from the approach against the results from the experts. By comparing the results, we find that only two cases result from comparing the recommendations. The first is that the approach's recommendation matches the human recommendation, and we refer to this case as true (true is quantified by 1). The second case is the opposite: the experts give a recommendation that does not match the recommendation resulting from the approach; we refer to this case as false (false is quantified by 0).

In order to achieve this, we created two empty lists, "T" and "F", one for the values of the ones, the other for zeros, and to do this between results, the comparison is based on the equality of the match results in both ways; thus, if a recommendation from cluster1 for the approach as an example exists in cluster1, then the recommendation is correct. The value of '1' will be added to the "T" list, in the other case, it is a false recommendation, and '0 'will be added to the "F" list, and at the end, the accuracy is the number of correct recommendations divided on the total number of recommendations. The following equation illustrates this process.

$$Accuracy = \frac{(T)}{(T)+(F)} \quad (3)$$

As a result, the accuracy of the proposed approach was 0.675. In addition to accuracy, other measures are used to evaluate the statistical result, namely precision and recall. Precision calculates the percentage of the related documents with the selected documents illustrated in Equation 4. In contrast, the recall measures the percentage of the related documents compared to all related documents found in the selected documents and is shown in Equation 5. Therefore, after applying accuracy and recall, we can apply F-Measure as shown in Equation 6. Table VIII shows the results.

$$P = \frac{TP_i}{TP_i + FP_i} \quad (4)$$

$$R = \frac{TP_i}{TP_i + FN_i} \quad (5)$$

$$F = \frac{2 \times P \times R}{P + R} \quad (6)$$

As a result, the F1 score was .81, which means we have an excellent working approach for our recommendations if we consider that we are treating strings matching (Skills / Courses). And for the precision, we are trying to find how much trues exist in the positives, but we have the false positives = 0, so the precision was 1, to make it clear, FP = 0, because the human way never recommend a course which is false for a certain skill, then the false = 0 and that's why precision = 1. Finally, the recall was 0.68.

TABLE VIII. THE PERFORMANCE RESULTS

	Precision	Recall	F1 Score
Cluster 1	1	0.50	0.67
Cluster 2	1	0.70	0.82
Cluster 3	1	0.80	0.89
Cluster 4	1	0.70	0.82
MR-LI	1	0.68	**0.81**

V. CONCLUSION

Social networks are extremely valuable in obtaining information that assists in modeling the user in a manner similar to reality. Therefore, LinkedIn, one of the largest professional social networks, provided customized course recommendations to users. These recommendations help users quickly reach the courses that suit their interests without requiring much search effort. This paper presents MR-LI as a course recommendation approach that relies on clustering algorithms to group the users according to their LinkedIn skills, resulting in four dataset clusters. Subsequently, feature vectors are extracted using TF-IDF for the user datasets and course datasets. The similarity was measured between each cluster's feature vectors and the courses using cosine similarity. The resulting ten recommendations were presented for each cluster based on the highest similarity. Finally, the proposed approach was evaluated by comparing the results with the human recommendations using experts. As a result, the F1 score of the proposed approach was .81. In the end, we faced some limitations in this research, including the lack of research that contributes to users modeling based on LinkedIn profiles in general, contributing to providing customized recommendations based on LinkedIn profiles in particular.

VI. FUTURE WORK

For future work, we will consider implementing this approach with some enhancements, including:

- Implementing the proposed algorithm in Arabic.
- Modeling users utilizing other LinkedIn sections, such as education and experience, and then comparing them.
- Evaluating the proposed algorithm after including it in one of the MOOC platforms.

***Abstract*—Internet of things (IoT) is the things or devices with software, intelligent sensors interconnected via the internet to send and receive data with another device. This capacity makes things, i.e., smartphones, smart homes, intelligent toys, baby monitors, IP cameras, and many more to act as intelligent devices like artificial intelligence (AI) and be utilized in the everyday life-world widely. IoT has enormous expansion potential, and many challenges have been acknowledged but are still open today. The botnet is a collection of bots from IoT devices used to launch extensive network attacks. In addition, rapid growth in technology has led to an incomplete understanding of IoT. The increasing number of IoT devices has led to the spread of malware targeting IoT devices make IoT Botnet behaviors challenging to identify and determine. To detect these IoT Botnets, a preliminary experiment on flow analysis is necessary. This paper is to identify IoT Botnet attack patterns from the IoT Botnet behavior that get from IoT Botnet activities. Therefore, this research is to identify IoT Botnet attack patterns in a host-based and network-based environment. First, this paper contributes to discovering, recognizing, categorizing, and detecting IoT Botnet activities. Next, organizing information to have a better understanding of the IoT botnet's problem and potential solutions. Then, construct the IoT Botnet attack pattern by analyzing the characteristics of the IoT Botnet behavior. This IoT Botnet attack pattern divides into two environments which are host-based and network-based. As a result, this paper aims to inform people about the attack pattern when the IoT device has been infected and become part of the botnet.**

***Keywords*—IoT; botnet; IoT botnet; host-based; network-based**

I. INTRODUCTION

Internet of things (IoT) is the things or devices with software, intelligent sensors interconnected via the internet to send and receive data with another device. This capacity makes things, i.e., smartphones, smart homes, intelligent toys, baby monitors, IP cameras, and many more, act as intelligent devices and widely be utilized in the everyday lifeworld. For instance, a smartphone can be streaming any melody that can be searched from the worldwide song, even though it's not in the storage of that smartphone. Besides smartphones, the intelligent home recently received much attention from the public, such as in [1]–[3] as it has been put into action as IoT devices. Moreover, Botnet is the short form of robot and network as claimed by [4],[5]. In addition, Botnets can compromise any machine system and become bots, automatons, drones, or zombies, from an assortment of computers infected with a malicious program [6]–[8].

This paper is to identify IoT Botnet attack patterns. The paper's goal is to identify IoT Botnet attack patterns in a host-based and network-based environment. Subsequently, the paper title Discovering IoT Botnet Detection Method: A Review [9] proposed placing IoT Botnet attack improved generic taxonomy. To detect these IoT Botnets, a preliminary experiment on flow analysis is necessary. The primary purpose of this experiment is to identify IoT Botnet attack patterns in a host-based and network-based environment. Then, the integration of the integrated analysis approach with static and dynamic analysis approaches has been performed. The integrated analysis will be used in profiling IoT Botnet attacks and characteristics. Then, the findings of both studies resulted in attack pattern identification and integrated analysis are contributed to IoT Botnets' attack patterns.

The flow of this experiment starts with discovering, recognizing, categorizing, and detecting IoT Botnet activities; Second, organizing information to have a better understanding of the IoT botnet's problem and potential solutions. The third step is data collection. The dataset used is IoT-23 since it provides real-world network information and a massive dataset of real-world and categorized IoT Botnet; fourth, analyzing the characteristics of the IoT Botnet behavior. Fifth, construct IoT Botnet attack pattern divides into two platforms which are host-based and network-based. As a result, this paper proposed a general IoT Botnet attack pattern for host-based and network-based platforms.

The expected output is the proposed general IoT Botnet attack pattern for host-based and network-based platforms using a dataset from IoT-23 [10]. From this dataset, the IoT Botnet attack pattern is constructed in two environments which are host-based and network-based. Therefore, even though this paper will face many constraints, but the expected output can be achieved. Crucially, the proposed is for developing the improved IoT botnets detection technique. Furthermore, this IoT Botnet attack pattern is constructed because nowadays, IoT has been used widely, as shown in Fig. 1. The Internet of Things is the decisive technology, as stated by Deloitte Global analysis [11].

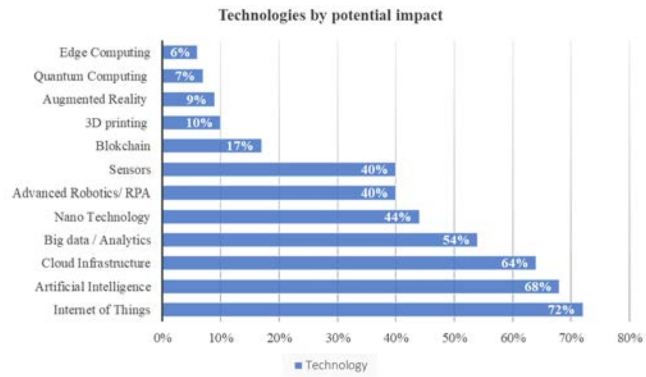

Fig. 1. Static Technology by Potential Impact in Industry 4.0 from Deloitte Global Analysis [11].

This paper has four sections, the Section I is the introduction of this paper consist of background, problem statement, objectives, and improvement of IoT Botnet. Next is Section II, which discusses the related work from previous research based on IoT devices infected by malware. Then, in Section III, discuss the methodology and implementation of this paper consist of the analysis process, data preparation, IoT Botnet experimental approach, IoT Botnet behavior for host-based and network-based platform, and present the proposed general IoT Botnet attack pattern for host-based and network-based platform. Lastly, section IV discusses the conclusion of this paper, limitations, and further work of this research.

II. Related Work

The Internet of Things is the things that are being connected with the internet. When something is connected with the internet, that implies it can send data, get data, or in both conditions. This capacity to send and receive data makes things brilliant such as a smartphone for instance. A smartphone can tune any melody that can be searched from the worldwide song, even though it's not in the storage of that smartphone. Yet, your telephone can send data by requesting the tune and afterward get data and streaming that tune on the telephone.

The next example is IoT of the home, which is a smart home; there are numerous studies and articles on the smart home. One of all these is the Implementation of IoT in a smart home [1]–[3] in this paper makes two systems, the first system is energy efficiency systems and the second is security systems. It links all devices to a device known as an intelligent central controller. For each device, this device is linked to a switch module. Then, connect to the router to access the Internet to communicate with the user, if necessary, if a license is needed. Smart Homes are just a network of devices that are used in daily life and other sensors which help to make life easy [1]. Devices communicate with each other but in reality, all devices communicate information to the smart central controller which then due to triggers and other programmed modifications the setting of other devices.

According to Table I, IoT devices include [12] IP cameras, motion sensors, smart bulbs, smart switches, and smart plugs. Next, [13] using this IoT device Danmini, Ennio, Ecobee, Philips B120N/10, Provision PT-737E, Provision PT-838, Simple Home XCS7-1002-WHT, Simple Home XCS7-1003-WHT, and Samsung SNH 1011N. Next, type of IoT device is used in toys, such as Hello Barbie, Furby Connect, Toy-Fi Teddy, and I-Que Intelligent Robot [14], [15] state that surveillance cameras are used in the experiment while [16] used Central hub, Lightbulb, Power switch, Motion sensor, Security cam for the testbed. In this journal [14], using toys that can be connected to the internet. The toys can be attacked by malware, it is because the toys using the open port to update information on the internet. These toys don't have login and passwords just need an internet connection to use. These toys also can be dangerous because they can take personal information by asking, listen and talk to the children with the basic information. This toy can talk with each other as a two-way connection. It contains sensors such as speakers, a microphone, and a camera. So, it can be easy for the hacker to attack when the device is not actively protected.

Furthermore, the Philips B120N/10 baby monitor from [13] has been reported for eavesdropping and espionage against other devices with a microphone or camera. This device can collect the data and samples from the user devices to harm the user in multiple ways. From this paper [12], [13], [15], [16], the device that recently been attack is Ip Camera and Security Camera. There are many reasons for Ip Camera can be easily attacked by malware. The first reason is the IoT devices have no security update because the developers take low priority in security. Next, the processing power and memory are expensive for implementing conventional cryptography. Furthermore, [12] state that IoT devices have weak login because the manufacture provides it for the users and using the default login. Some IoT devices leave open ports to support remotely. Lastly, Users often connect the device without going through the firewall. Therefore, this paper proposes to identify IoT Botnet attack improved generic taxonomy. Crucially, the proposed is developing the improved IoT Botnet detection technique.

III. Methodology and Implementation

Based on Fig. 2, the experiment's flow begins with the use of recording methods that are used in data collection processes. Before the malware samples are executed, both tools will begin capturing network traffic. Following malware execution, the data analysis process will begin by examining data from both tool-based results. The Wireshark tool will generate a large number of packets capture call as PCAP files, while the Process Monitor tool from the testing environment will generate a massive data log to reduce the studying workload for raw data and processed data, each of the data will be studies using a filter provided by the tools.

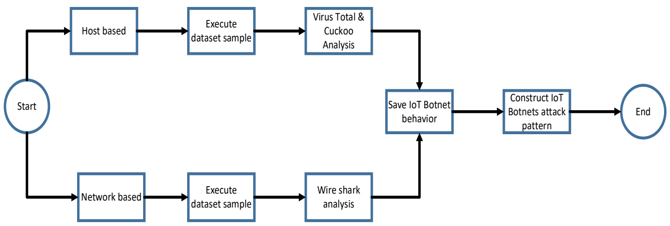

Fig. 2. Flowchart of the Analysis Process.

Fig. 2 depicts the overall analysis process, which begins with the analysis of each IoT Botnet infected folder. There were two levels of analysis approach which are host-based and network-based. The approach analyses network packet captured and on every single host log to control whether the payloads are spam or malicious. But if it corresponded follows unusual conventions or to a remote check for vulnerabilities not follow to standard IoT Botnet options. The integrated analyzer, as shown in Fig. 2, works by taking two perspectives into account: the host-based level and the network-based level. The host logs were examined at the host level using the file system monitoring, registry monitoring, and log monitoring characteristics. As an alternative, the characteristics of the full-payload from a network packet have been investigated at the network level as refer to MIT Lincoln Lab [6].

To detect these IoT Botnets, a preliminary experiment on flow analysis is necessary. The primary purpose of this experiment is to identify IoT Botnet attack patterns in a host-based and network-based environment. Then, the integration of the integrated analysis approach with static and dynamic analysis approaches has been performed. Static analysis function as examines the application or internet structure as compared to functional testing. Besides, the dynamic analysis is performed when the application programmed is running refer to MIT Lincoln Lab [6]. The integrated analysis will be used in profiling IoT Botnet attacks and characteristics. Then, the findings of both studies resulted in attack pattern identification and integrated analysis are contributed to IoT Botnets' attack patterns.

The methodology of overall analysis process is illustrated in Fig. 3 started by preparing dataset. Stratosphere Laboratory [10] is a dataset used in this study and labeled dataset of malicious IoT network traffic. Next step is overview of IoT Botnet experimental approach. This research analyzes the IoT Botnet attack pattern based on host and network environment. Then, the general approach used in the experiment, hardware, and software used, and datasets used for both analyses is discussed. In addition, the third step is IoT Botnet analysis flow. Technically, the analysis is divided into two parts: attacking pattern analysis and integrated approach analysis. The next following segment discusses the analysis of IoT Botnet attack pattern host-based and network-based platform that have been evaluating and generalized in detail. Lastly, proposed general IoT Botnets relationship model for host-based and network-based platform. Therefore, the goal of this research is to identify IoT Botnet attacks pattern and improved generic taxonomy.

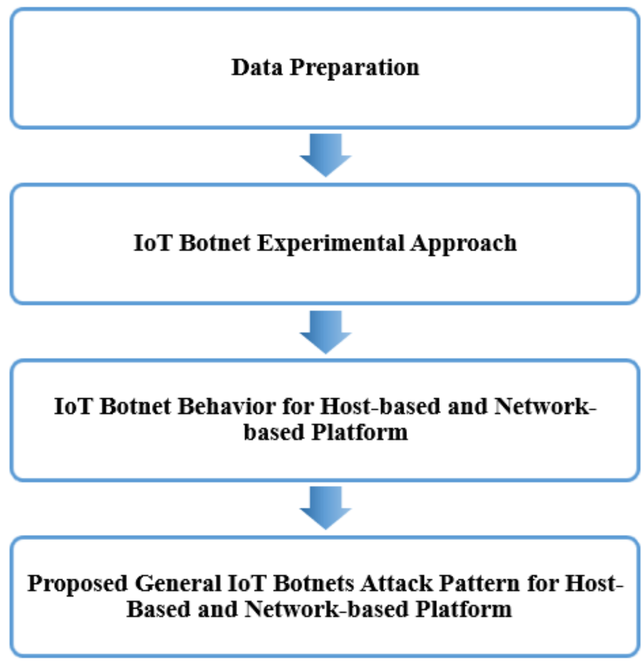

Fig. 3. Methodology.

A. Data Preparation

The data consists of real IoT malware infections as well as benign IoT traffic. Stratosphere Laboratory [10] is a dataset used in this study and labeled dataset of malicious IoT network traffic. This study makes use of seven data points from this dataset. In each situation, an exact or real malware was executed in a Raspberry Pi, which was used to make various actions and various protocols. Table II summarizes the characteristics of each scenario, and the malware used to infect the device. The details of a table can be seen in Table II. The dataset used is IoT-23 since it provides real-world network information and a massive dataset of real-world and categorized IoT Botnet. This dataset uses the updated IoT device, the duration of the experiment is 8 to 24 hours, and the dataset use the real IoT Botnet malware.

The dataset IoT Botnet network traffic is shown in Table II. The actual IoT network traffic is collected on two levels: host and network. The host-based level was selected based on the monitoring attack performed on its host as well as the actions that occurred within a suspicious activity for that host. Meanwhile, one important reason to choose network-level capture is that monitor network traffic for specific network devices to detect suspicious activity that studies network and protocol. To detect bots accurately, host-level and network-level analyses had to be developed. These two types of analyses balance individually in detecting malevolent activity in the IoT Botnet network. As a result, the network packets captured in this study originate in both a host and a network environment.

TABLE II. IoT BOTNETS DATASETS SUMMARY

Name of Dataset	Duration (hrs)	#packets	#zeekFlows	Pcap size	IoT Botnet type
CTU-IoT-Malware-34	24	233000	23146	121MB	Mirai
CTU-IoT-Malware-44	2	1309000	238	1.7GB	Mirai
CTU-IoT-Malware-49	8	18000000	5410562	1.3GB	Mirai
CTU-IoT-Malware-48	24	13000000	3394	1.2GB	Mirai
CTU-IoT-Malware-9	24	6437000	6378294	472MB	Linux. Hajime
CTU-IoT-Malware-42	8	24000	4427	2.8MB	Mirai
CTU-IoT-Malware-35	24	46000000	10447796	3.6G	Mirai

Clarification of the experimental method and each dataset is used in the study. Based on Table II, the network traffic capture is from these three types of IoT devices to get real network which are the Amazon Echo that uses as a home intelligent private assistant for the owner's home, a Somfy which is a smart door lock that automated, and Philips HUE which is the smart lamp. It is significant to note that the three Internet of Things devices is actual devices of hardware, not simulations. The use of real devices of IoT tolerates for the capture analysis of real network attacks from simulated traffic. The malicious scenarios, like any other genuine IoT device, operate in a controlled network environment with unrestricted internet access. By running a specific piece of malware on a Raspberry Pi, the malicious scenarios were created. Mirai and Hajime traffic are included in this dataset. Malware captures are carried out over extended periods.

B. *IoT Botnet Experimental Approach*

This research analyzes the IoT Botnet attack pattern based on host and network environment. Existing IoT Botnet detection techniques were classified and profiled based on their technique, criterion, platform analyses, and previous framework. In this section, Fig. 4 shows the illustration of the IoT Botnet testbed in detail to collect the sample malware. This IoT Botnet testbed has three steps to setup the testbed.

The first section of the IoT Botnet testbed is the network configuration used in this experiment refers to the network simulation and formally has been modified using Linux and Windows 7 to suit the testbed experiment of this research. The experimental testbed lab is used to monitor the activities of the IoT Botnet. This testbed was carried out in a controlled setting. The network design depicted in Fig. 4 illustrates the network testbed proposal used in this research, which is comparable to [8], [17], [18]. This research replicates their design of experiment due to the success achieved. As a result, the testbed design consists of 1 router, 2 switches, 4 personal peers or computers with new installations of Windows and Linux, 1 server to complete the packet capture method and one NTP server. Several software specifications are essential to help make the project succeed.

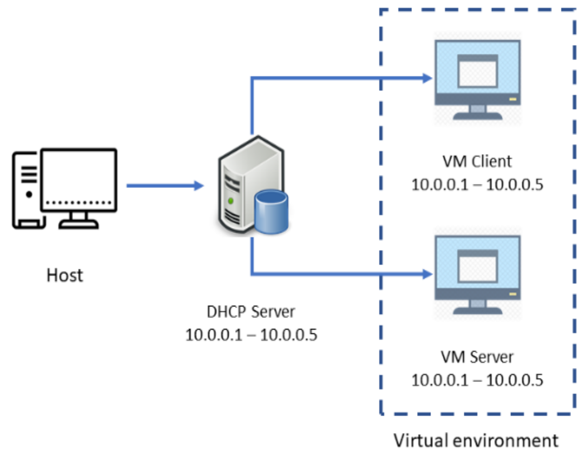

Fig. 4. IoT Botnet Testbed.

There are four softwares that are used in this experiment. The first software is Cuckoo Sandbox, an open-source security program for suspicious file security. Moreover, it uses custom components that track malicious process activity when operating in an isolated environment. The second software is Virus Total, an online system that provides antivirus engines and website scanners to analyze files and URLs to detect viruses, worms, trojans, and other types of malicious content. This can also be used to spot false positives. Last software is Wireshark, a packet analyzer for networks. An analyzer of network packets provides as much information as possible about the captured packet data. Thus, the overview of the IoT Botnet Experimental Approach for this research to identify IoT Botnet attacks pattern and improved generic taxonomy.

C. *IoT Botnet Behavior for Host-based and Network-based Platform*

This section discusses the IoT Botnet behavior for host-based and network-based platform. In a host-based approach, [17], [19] monitoring behaviors are carried out in a single host, and events for suspicious activity occur within that host. The data is simulated from Virus Total for the file system. The network-based analyzed the full payload packet data framework using Wireshark. This tool is the effective network analyzer for the network based. This section identifies C&C servers and infected hosts in the network. Data is collected at each peer and throughout the traffic. Each peer produces a security log, a system log, and an application log. The service generates network traffic using tcpdump. Wireshark and tcpdump are used to verify traffic between specific hosts at the network level. There are seven datasets which are CTU-IoT-

Malware-34, CTU-IoT-Malware-44, CTU-IoT-Malware-49, CTU-IoT-Malware-48, CTU-IoT-Malware-9, CTU-IoT-Malware-42, and CTU-IoT-Malware-35. The Host-based data can be simulated from Virus Total while the network-based is simulated from the Wireshark. Therefore, this section discusses IoT Botnet behavior for host-based and network-based platform.

1) Host-based: In a host-based approach, [17], [19] monitoring behaviors are carried out in a single host, and events for suspicious activity occur within that host. The overall system behavior continuously records each host monitor. All host been observed by the log monitoring. All abnormal behaviors and characteristics will be identified in every single activity that occurred in the host. The Host-based data can be simulated from Virus Total. From the seven dataset CTU-IoT-Malware-44 are the best datasets that illustrate the attack pattern for host-based platform as shown in Table III.

TABLE III. IoT Botnet Behavior for Host-based Dataset

IoT Botnet data	Filed open	File written	File copied	File dropper
CTU-IoT-Malware-44 (Mirai)	locale.alias	.dat.nosync100c.Y3KZqJ	.dat.nosync100c.Y3KZqJ	/System/Library/CoreServices/pbs
	en_US.UTF-8	mdsDirectory.db_	mdsObject.db_	
	en_US.utf8	.dat.nosync0fa1.JacR1I	.dat.nosync0fa1.JacR1I	
	en_US	mdsObject.db_	mdsDirectory.db_	
	en.UTF-8	com.apple.smb.server.plist-lock	A66DD831-8DB9-49C7-85C6-87F3F660A041.perfd.events.XXXXXX.stats	
	en.utf8	supportedCountriesTraffic-5.plist	networkDefaults.plist	
	en	default-shields-index-extralarge-70.shieldindex	ResourceManifest.pbd	
	.CFUserTextEncoding	ResourceManifest.pbd	default-16637.styl	
	com.apple.nsservicescache.plist	hybrid-1426.styl	default-search-3806@2x.styl	
	AppleInternal	default-genericshields-extralarge-6.genericshieldstyles	globe-default-1522.styl	
	com.apple.NSServicesRestrictions.plist	default-shields-index-large-88@2x.shieldindex	hybrid-1425@2x.styl	

The Experiment data was tabulated as Table III and classified into four columns that are FileOpen, FileWritten, FileCopied, and FileDropper. The data from Table III simulated from Virus Total for the file system. FileOpen is a function that opens a file named and flagged with the given name and flag. The IoT Botnet samples are injected into the FileOpen, which initiates the creation of an IRC channel for infected clients to join. When opening a FileOpen encrypted document in Adobe Acrobat or Adobe Reader, the FileOpen plugin is only available. It contains no spyware or malware, leaves nothing running on the machine, and makes no changes to the Windows registry or system files. The FileWritten function is designed to write data information into a CSV folder automatically. The character “rn” will be shown at the end line, after writing into the file. The message is either a string expression or a number that contains the text that is written to the file. The following function, FileCopied, copies the first file which is the original file from a local or shared folder to a different file. FileCopy.exe is an executable file included in the IObit Advanced SystemCare Ultimate 8 programmed. The software is typically 498.97 KB in size. Finally, FileDropper is a type of Mirai (Trojan) that some type of malware designed to install such as backdoor and virus; on a target device system.

Based on the result of this research, the IoT Botnet attack sample showed similarity and unique behavior during the experiment. In the lifecycle of IoT Botnet, typical IoT Botnet showed the process that will be downloaded by using one of the methods which are file dropper, mail attachment, or drive-by download before execution of the malware. Since the IoT Botnet samples are already downloaded from infected devices after the experiment was launched, IoT Botnet's initial lifecycle behavior for this experiment may be negligible. The bots can contact the infected machines by IP address. The data product form and rundown of known bots to reach the bots’ answer. The bot will remove the record and refresh if one of the bots' forms is lower. Thus, the rundown of each bot for the infected devices will develop and updates itself immediately into single known bot. As IoT botnets keep on developing, being utilized dispatch DDoS assaults. Since IoT gadgets are Linux and Unix-based frameworks, they frequently are focuses on executable and linkable arrangement format ELF binaries, a typical record design found in inserted frameworks' firmware. The malware conveyance strategy regularly targets SSH or Telnet network conventions by misusing default, hardcoded accreditations. Once undermined, the malware payload is conveyed to the gadget for enlistment into the botnet. Thus, the existing IoT Botnet detections based on host-based techniques were classified in terms of are FileOpen, FileWritten, FileCopied, and FileDropper.

2) Network-based: The network-based analyzed the full payload packet data framework using Wireshark. This tool is the effective network analyzer for the network based. This section identifies C&C servers and infected hosts in the network. This section of the analysis focuses on defining the unique communications to form IoT Botnet malware, IP address, Port number and protocol over a suspicious port. The detecting any indication of malevolent activity attack that attempts the network, and identifying which IoT botnets are on the infected network host. From the seven dataset CTU-IoT-Malware-34 are the best datasets that illustrate the attack pattern for network-based platform as shown in Table IV.

TABLE IV. IoT BOTNET BEHAVIOR FOR NETWORK-BASED DATASET

Dataset	IoT botnet	IP Address	Port Number	Protocol
CTU-IoT-Malware-34	Mirai	185.244.25.235	6667	IRC
	script bots	192.168.1.195	48986	IRC
	amplified attacks

	bot-master shadoh	123.59.209.185	80	TCP
	STD Dos	74.91.117.248	5376	UDP

The network-based pattern is extracted from full payload network traffic that captured the whole activity of IoT Botnets. The pattern is studied in the protocol used, suspicious port, suspicious IP address, and attack that have been launched. The IoT Botnets attack pattern at the network level is summarized in Table IV. The summary then has been discussed in this section. The dynamic analysis, for the first phase the controlled environment has been implemented known as IoT Botnet testbed environment. The static analysis had been done in reviewing the real codes of infected files to reveal and study their true characteristics. In the dynamic approach, the capabilities are highly concerned with the detection of malicious activities during or after program files execution. The IoT Botnets' activities are captured through the event host logs and whole network traffic.

Subsequently, the dynamic analysis is performed on the event host log and network traffic datasets. The IoT Botnet test bed setup applied by controlled environment where the datasets were collected. Process monitors and process explorer capture the event host log to gather information on the localhost. Meanwhile, the tcpdump service has captured the overall network traffic. Through this dataset, the IoT Botnets' attack and characteristics are fully observed to ensure the interaction on the botnet's server and the effect on each of the infected files to a real environment. After that, the integration of analysis results on static and dynamic analysis will be correlated together to construct the basic and general attack model of IoT Botnets. This research analyzes the IoT Botnet attack pattern for host-based and network-based platform. Thus, the existing IoT Botnet detections methods were classified and profiled in terms of analyzing IP address, port number, and Protocol.

D. Proposed General IoT Botnets Attack Pattern for Host-based and Network-based Platform

This section proposed general IoT Botnets attack pattern for host-based and network-based platform. This proposed based on these seven datasets which are CTU-IoT-Malware-34, CTU-IoT-Malware-44, CTU-IoT-Malware-49, CTU-IoT-Malware-48, CTU-IoT-Malware-9, CTU-IoT-Malware-42, and CTU-IoT-Malware-35. The proposed general IoT Botnets attack pattern for host-based platform consists of FileOpen, FileWritten, FileCopied, and FileDropper, it considered as risky event process that happens to allow the attacker in operating systems, replace the original files. Next, the proposed general IoT Botnets relationship model for network-based platform consist of IoT Botnet malware, IP address, port number, and protocol. Therefore, this section discusses the proposed general IoT Botnets attack pattern for host-based and network-based platform.

1) Proposed general IoT botnets attack pattern for host-based platform: The generic IoT Botnets attack pattern and integrated approach as described in the earlier section are utilized to construct the IoT Botnets attack pattern. For the finest of information, there is no published study has been found that performs the IoT Botnets attack pattern model based on the file system for the host-based. As a result, this study implemented the IoT Botnets attack pattern model following the proposed IoT botnets attack pattern for the host-based based on a file system. The following section describes the details Fig. 5.

Fig. 5. Proposed General IoT Botnets Attack Pattern for Host-Based Platform.

The static analysis began with isolating the experimental setup in a controlled environment. The ability to detect malicious activities by static analysis before the execution of programmed files and then implement the data in Virus Total. The operation processes involved in all IoT Botnets infected files have been created as its main process start. The information of IoT Botnets infected files has been discovered in four main components. The proposed model consists of FileOpen, FileWritten, FileCopied, and FileDropper for the host-based as shown in Fig. 5, are considered as risky event process that happens to allow the attacker in operating systems, replace the original files. Here, malicious activity attempts to exploit the victim host to create an.exe file and remove essential files in the system directory. Otherwise, the frequent changes in the registry had been noticed as a high possibility of malicious activity has arisen. The specifics are as follows: The IoT Botnet samples enter the FileOpen, which creates an IRC channel for infected clients to join. The FileWritten function is designed to write data information into a CSV folder automatically. The character "rn" will be shown at the end line, after writing into the file. The following function, FileCopied, copies the first file which is the original file from a local or shared folder to a different file. Finally, FileDropper is a type of Mirai for Trojan that some type of malware designed to install such as backdoor and virus; on a target device system.

2) Proposed general IoT botnets attack pattern for network-based platform: The network-level pattern is extracted from full payload network traffic that captured the whole activity of IoT Botnets. The pattern is studied in a protocol used, suspicious port, suspicious IP address, and attack that have been launched. Generally, on a network level, the scanning activity is mainly concerned with a protocol. Both suspicious port and suspicious IP addresses can be found in exploit and C&C connection attack steps. The generalized attributes designed for exploit activity are concern with protocol and, destination port. The C&C connection considers the detection of IoT botnets and the C&C website as the attribute. Moreover, the generalized attributes for impact or effect steps allowed the attacker to launch an attack on a remote address attack. As a summarization of the generalized IoT Botnets attack patterns, the findings are relatively depicted in Fig. 6 based on the discussion in analysis of generalized IoT Botnets from a network-level perspective.

Fig. 6. Proposed General IoT Botnets Attack Pattern for Network-Based Platform.

The generic IoT Botnets attack pattern and integrated approach as described in the previous section are utilized to construct the IoT botnets attack pattern. For the finest of information, there is no published study has been found that performs the IoT botnets attack model. As a result, this study implemented the IoT Botnets attack pattern model following the proposed IoT botnets attack pattern for the network-based based on IoT Botnet malware, IP address, port number, and protocol. This research analyzes the IoT Botnet attack pattern for host-based and network-based platform. The existing IoT Botnet detections methods were classified and profiled in terms of analyzing IP address, port number, and Protocol.

Based on the proposed pattern, show the general IoT Botnet attack pattern analysis. From the finding have been referred to develop new IoT Botnet attack pattern. This IoT Botnet attack pattern has been designed for host-based and network-based. The host-based attack pattern provides explanation for the IoT Botnet attacks aims and strategies in protecting from the attack. Practically, the attack pattern provided by researchers to identified the bot server and botmasters. While the network-based pattern is used to identify the method of network attack by the Botmaster. Overall, this paper was effective in recognizing the characteristics and behavior of IoT Botnet for host-based and network-based. The result was improved outcomes to researchers to create a new IoT Botnet attack pattern.

IV. Conclusion and Further Work

In conclusion, the researchers have studied the host logs data and network traffic data to determine the attack pattern from host-based and network-based perspectives. The attack pattern serves as a guide for administrators in determining who the true attacker is behind the scenes. The analysis's output is proposed as the general IoT Botnets attack pattern on the host and the general IoT Botnets attack pattern on the network. Furthermore, this paper also presents the integrated approach to studies and classify the whole IoT Botnets activities and events to recognize the attack pattern and characteristics of IoT Botnet. This study combines static and dynamic analysis approaches to gain a better understanding of how IoT Botnets behaved in a real-world IoT network environment. The attack pattern and integrated analysis result are inherited to construct the basic and general IoT Botnets attack, pattern model.

This paper contributes to discovering, recognizing, categorizing, and detecting IoT Botnet activities. Next, organizing information have a better understanding of the IoT botnet's problem and potential solutions. Then, construct the IoT Botnet attack pattern by analyzing the characteristics of the IoT Botnet behavior. This IoT Botnet attack pattern divides into two environments which are host-based and network-based. As a result, this paper aims construct the attack pattern when the IoT device has been infected and become part of the botnet. The limitation of this research is the dataset from IoT-23 is bigger, and need more space to run the dataset. Therefore, the result for this paper has been accomplished and the aim objective has been complete. This is ongoing research in finding an effective technique to make the detection on IoT Botnets attack pattern. The further work for this research is developing the IoT Botnet attack pattern in graph degree theory. The graph degree theory will visualize the attack pattern of the IoT Botnet.

A Classification of Essential Factors for the Development and Implementation of Cyber Security Strategy in Public Sector Organizations

Waqas Aman*, Jihan Al Shukaili
Department of Information Systems, College of Economics and Political Science
Sultan Qaboos University, Muscat, Sultanate of Oman

***Abstract*—To ensure the achievement of quality security to safeguard business objectives, implementing, and maintaining an effective Cyber Security Strategy (CSS) is crucial. Inevitably, we need to recognize and evaluate the essential factors, such as technological, cultural, regulatory, economic, and others, that may hinder the efficacy of a CSS development and implementation. From the literature review, it is evident that such factors are either abstractly stated, or only assessed from singular viewpoint and are scattered across the literature. Moreover, there is a lack of holistic studies that could assist us in comprehending the critical factors affecting a CSS. In this paper, we present a systematic classification of distinct, structured, and comprehensive list of key factors covering multiple aspects of an organization's CSS, including organizational, cultural, economic, legal and political, and security, to provide a more complete view of understanding the essentials and analyzing the aptitude of a planned or given CSS. The proposed classification is further evaluated to examine the critical factors verified by conducting semi-structured interviews from security experts in different public sector organizations. Furthermore, we present a comparison of our work with the recent attempts that reflects that a significant accumulation of essential factors have been holistically identified in this study.**

***Keywords*—Cyber security strategy; critical factors; risk treatment; culture; threats**

I. INTRODUCTION

This Cyber security is a vital concern for both the public and private sectors. However, the public sector is unique as it comparatively has a vast IT infrastructure covering a broader and general user base [1]. Public sector organizations have experienced targeted attacks continuously and increasingly [2]. Around 70% of breaches target public or government organizations [3].

Security is becoming harder to manage in today's dynamic information systems and necessitates an efficient strategy to deal with the adverse incidents and to protect the organization from the potential risks [4]. A Cyber Security Strategy (CSS) is a long–term high-level plan designed to achieve security goals to ensure that the business meets its set objectives, mission, and vision effectively [5]. It provides a collection of frameworks, procedures, and corresponding objectives that aim to achieve certain quality in securing the organization infrastructure and operations.

As stressed in [6] and [7], CSS is very important to the public sector because:

- Cyber-attacks in this domain is more permanent and their consequences can last for a long period.
- The public sector is composed of the most sensitive and critical infrastructure.
- There is a need to develop justifications for and foresee low risk investments of public funds in cyber security solutions and services.
- It will assist in implementing a uniform plan across the organization to protect public resources, and therefore assist in building and retaining a high-level public trust.

The reliance of technology for almost every single process in an organization has led to push CSS and its success factors to the top of the business agenda. A CSS can only be designed and implemented efficaciously, if we recognize and assess the corresponding influencing factors [8]. During our study, we found that there have been numerous efforts made in highlighting these factors however, their focus is either a particular aspect of business like regulatory needs and technical concerns, or abstractly identified in a particular operational infrastructure, e.g., healthcare. We couldn't find any appropriate study that provides a holistic and comprehensive classification or list of essential factors, which we can refer to for (re)consideration, while we plan to design and implement an effective CSS.

In this study, we present a classification of distinct and well-structured list of more than twenty essential factors that will help a public sector's organization to evaluate key business and operational aspects when designing or implementing their CSS. For every long-term planning, such as a CSS, it is vital to consider the major business contexts. This includes the human factors, regulatory and political contexts, economic capabilities, the potential threat landscape and its methodological management, etc. [9]. To ensure that our classification encompasses all major and mission-critical business themes, we developed our classification to include six principal classes as: Organizational, Cultural, Legal and Political, Economic, Technical, and Risk. Similar business themes are also stressed to be evaluated in [9-11]. This classification ensures that all the identified factors are aligned with and cover the vital concerns related to the key contexts of

*Corresponding Author

an organization. To further refine the factors and to highlight the critical ones, we have conducted open-ended semi-structure interviews. The interviews, comprising of seventy questions, were held with experts in the field to comprehend what they believe to be crucial factors for a successful CSS. Moreover, a comparative analysis is performed with the existing related work that shows that our classification provides a more comprehensive and complete list of factors, and provides an organization a broader view of the dynamics related to the development and implementation of an effective CSS.

The rest of the article is structured as follows: In Section 2, we summarize the area, factors and methodology used in the related work. The methodology used and results are detailed in Section 3. This section also highlights the reflection made on the critical factors identified. A comparison of the proposed classification with related work is provided in Section 4. Finally, the study limitations and conclusion are presented in Section 5.

II. Related Work

Several studies highlighted some of the factors that can influence the design and implementation of CSS. In this section, we have reviewed the most related literature. These works also form the basis of the proposed classification and are also used in the comparison.

Jalaai et al. [2] has explored the organizational perspective of cyber security in the Healthcare sector. The study followed a systematic literature review and focused on the most important aspects needed to tackle a successful strategy adopted for healthcare. The study highlighted and focused on organizational factors that also touched the technical readiness of the healthcare institutes. The factors identified in this study were software development security, disaster recovery planning and business continuity.

The human factor in the current cyber security landscape is studied by Benson et al. [12]. Using a systematic literature review, the authors outlined the most critical factors in human element domain are: Awareness, Individual Attitudes, Norms and Cultural context.

Fritzvold, in [13], has focused on the Cyber security in the organization with focus on the sectors of power distributions, railway and healthcare. The study followed a case study approach to explore the factors that directly or indirectly influence the cyber security posture in the mentioned domains. The key factors outlined in this work are: competence, compliance, awareness, leadership engagement and system technology management.

Awan et al., in [14], have studied the security strategies to overcome security measures, the authors pointed out the effective factors that influence the success of implementing such strategies to overcome such measures. Following a systematic literature review, the factors stressed are: Level of governance in critical information infrastructure (CII), level of protection, sharing of Cyber-security information and insufficient market preparation.

In [15], the authors studied the human factors in the information security culture and stated that the human factor has always been the weakest link when it comes to security enforcement. To strengthen this aspect, some procedures need to be taken into consideration. Following a systematic literature review, the authors included that the essential human factors that form the basis for a successful security program enforcement are: information security (IS) policy, deterrence, incentives, attitude, involvement, training and awareness and management support. The authors concluded that only employing technology-oriented security controls are not sufficient, and that people at all levels of the organization play an important role in bringing a positive value to the information security culture and therefore, should be assessed and addressed in any security program.

Khansa et al. [16], have followed two rounds of a qualitative survey to study the impact of organizational control in cyber environment. The study emphasized on exploring the relationship between employees' cyberloafing and formal organization control. Cyberloafing is defined as the surfing of employees over the internet for personal reasons during work hours [17, 18]. Such a behavior negatively affects the productivity and may lead to unwanted and severe security issues. The study suggested that that factors such as, attitude, subjective norms perceived, behavioral controls and lack of punishment. These factors play a vital role in designing organization controls that are crucial to be considered for any given CSS.

Ebenezer [19] studied how staff accessing, using and sharing published information online is conducted within the National Health Service (NHS) in England along with the potential impacts they may have on the trust of these services. The author makes use of semi-structured interviews and document analysis methods and shows risk factors that can adversely affect the security of these services are information manipulation, identity theft, insider, productivity loss and cyber-attacks.

Cooke [20] conducted a systematic literature review to identify the factors related to the success of strategies implemented in the public sector. The study concluded factors such as, IT skills, adequate funding, engagement to CSS, cybercrime law and public enlightenment programs are inevitable to be considered for a successful strategy.

Choejey et al. [21] explored the critical success factors for cybersecurity in government organizations in Bhutan. The authors conducted a questionnaire-based survey for data collection. The study concluded several critical factors needed for the successful implementation of cyber security. They are: awareness and training, security policy, budget, security audit, security responsibility, organization structure, change management, and communication and collaboration.

Peursum [22] studied the building blocks necessary for a security strategy from an organization perspective. The author adopted an expert interviews methodology to confirm data collected from the literature. The key factors highlighted are, systems, skills, staff, strategy, style shared value and structure.

While developing and implementing the cyber security strategy the alignment with business objectives should be taken into consideration. Developing a CSS is certainly not a single perspective task. It should be aligned with the organization's objectives and vision. It should also build the trust that needed to realize the objectives and protecting the organization from the cyber-threats [23]. The key factors and the focus area of the reviewed literature are summarized in Table I.

III. Methodology and Results

To achieve our objective of a well-defined and structured classification of the essential factors for an effective CSS, we have utilized two-step approach; first, to develop the classification, and second, to recognize the most critical factors.

A. *Factors Classification*

Firstly, a literature review method has been employed to devise a structured classification of the essential factors. This was necessary to collect the necessary factors, summarized in the Table I that are scattered across the literature, some of them were synonymous. For instance, awareness, public enlightenment programs, and training and awareness have the same meaning and objective, which need to be transformed to a common terminology. Similarly, as productivity loss, cyber-attacks, and insider threats represent instances of threats and attacks, they are accumulated in accordingly. Moreover, there was a need to re-label a few of them to widely recognized terminology in the context of CSS, e.g., "structure" needs to be resolved to organizational structure, which is less confusing and a more commonly known phrase. Therefore, to have a refined classification and to avoid the mentioned concerns in a systematic manner, we exercised the following steps in a process manner as shown in Fig. 1.

Factors are classified in accordance with essential business themes to ensure that all mission-critical contexts are appropriately addressed and are underlined as: Organizational, Cultural, Legal/Political, Economic, Technical, and Risk. By exercising the above listed steps, a set of 31 factors were finalized and mapped to the respective classes as illustrated in Fig. 2.

TABLE I. List of Identified Factors

Factor (Revised Label): [Study]	**Factor (Revised Label): [Study]**
1. Information Security Policy: [15, 21] **2.** Deterrence:[15, 24] **3.** Attitude (Attitude and Behavior): [15, 16, 25] **4.** Involvement: [15, 16, 26] **5.** Training & Awareness (Awareness): [12, 13, 15, 16, 21] **6.** Management Support: [15, 16] **7.** Identity Theft (Threats and Attacks): [19] **8.** Insider (Threat Actor): [19] **9.** Productivity Loss (Threat and Attacks): [19] **10.** Cyber-attacks (Threats and Attacks): [19] **11.** Information Manipulation (Threat and Attacks) [19] **12.** Behavioral Controls (Deterrence): [16] **13.** Lack of Punishment (Detterence): [16] **14.** IT Skills (Skills & Expertise): [20] **15.** Adequate Funding (Funding): [20, 21] **16.** Motivation (Involvement): [20] **17.** Cybercrime Law: [20, 26] **18.** Public Enlightenment Prog. (Awareness): [20, 26] **19.** Security Audit: [21] **20.** Security Responsibility (Due Diligence): [21] **21.** Change Mangement: [21] **22.** Structure (Organization Structure): [21, 22] **23.** Software Development Security (Application Security): [2] **24.** Disaster Recovery Planning: [2] **25.** Business Continuity: [2, 21]	**26.** Individual attitude and norms (Attitude and Behavior): [12, 25] **27.** Cultural based strategy (Strategy): [12] **28.** Compliance: [13, 27] **29.** Awareness (Awareness): [20, 26, 28] **30.** Leadership engagement (Management Support): [13] **31.** System Technology Management (Systems): [13, 22] **32.** Interest level of government on CII(Critical Information Infrastructure) (Govt. Interest): [14] **33.** level of protection: [14, 26] **34.** Insufficient market preparation (Competence): [14] **35.** Systems (Systems): [22] **36.** Skills (Skills and Experience):[22] **37.** Strategy (Strategy): [22] **38.** Style (Strategy): [22] **39.** Shared value: [22] **40.** Personality traits (Attitude and Behavior): [25, 29] **41.** Impulsiveness (Attitude and Behavior): [25] **42.** Computer skills (Skills and Experience): [30] **43.** Experience with CS practices (Skills and Experience): [30] **44.** Risk Posture: [29] **45.** Flexibility (Attitude and Behavior): [29] **46.** Ethical Attributes (Attitude and Behavior):[29] **47.** Connectedness (Collaboration): [29]

B. *Identifying Critical Factors*

Critical factors may vary from the type of organization to country or region they are operating in, as they might be influenced by their respective regulations, culture, threat spectrum, and other circumstances. In this study, we have explored critical factors in the context of public sector organizations working in Oman. We conducted open-ended and semi-structured interviews from a target group of ten participants to further refine and confirm these critical factors. Participants were selected based on the criteria such that they have at least a five years' experience in the security domain and have been involved in key business processes related to CSS at the organizational level in the public sector. A summary of the participants' profiles is highlighted in Table II.

Seventy questions were asked in each interview with at least two distinct questions to assess the importance (criticality) of each factor listed in the classification. The questions were validated using face validation and pilot testing with two experts, as suggested in [31] that assisted us to eliminate and modify the redundant and out-of-context questions. The interview sessions were recorded and transcribed into text, and analyzed using the Interactive Analysis Model [32]. A Likert-scale was then used to evaluate the overall feedback concerning the importance of a given factor. The importance scale used was: Very Important= 5, Important=4, Moderately Important=3, Less important =2, Unimportant= 1). Factors having an average value of 4 and above are characterized as critical. The factors criticality level of each factors with respect to each participant (P) response is depicted in Table III to VIII.

1) Organizational factors: As can be seen in Table III, Organizational Size, Shared Values, and Risk Postures were considered as no critical. The majority of the participants concurs that the organizational size does not affect the CSS development and execution as long as there is a clear structure, guideline, and resources available. Risk posture was dominated because the majority of participants acknowledged that they adapt from the existing standard risk management methodologies and practices as per their needs instead of defining and utilizing their own as it takes considerable time and effort to conclude it. Moreover, since shared values are motivated by the competitiveness in the market, it is less perceived in the public sector [33] and was therefore not acknowledged by the P2, which lowered its overall score in the class.

2) Cultural factors: From all the interviews conducted, as evident in Table IV, it was concluded that the majority of the participant, based on their experiences, believed that the employees' positive attitude, knowledge, and collaboration are critical to complete tasks in a teamwork. Employee compliance with the organizations policy and rules is also accounted as critical. The popular perception about deterrence was that although related penalties and actions exist, it is not usually experienced in practice. Pressure was believed to be rarely existed, as government authorities do not frequently introduce changes.

3) Legal and political factors: The interviews were conducted before April 2021 when there were no taxes and interest rates introduced in Oman. They were not applicable and therefore were unimportant, as reflected in Table V. Even with their introduction an application, it is still a nominal concern for government driven organizations. On the other hand, laws and regulations and government interest were marked as critical as commonly commented as actively overseen in the participants' organization as key factors.

4) Economic factors: As primarily based on government funding, all participants concur that it is critical. As for the cost and budget, the majority believes that although cost is an important factor to invest in the efficacy of the CSS, it has not been a key problem for the public sector. These verdicts are also reflected in Table VI.

5) Technical factors: As reflected in Table VII, all participants strongly believed that the technical aspects of the CSS are of utmost importance. This perception is true mainly because a substantial part of the operations and processes are supported by IT-based systems in which the listed factors are inevitable. However, a few participants pointed out that change management is unless important. They remarked that the changes introduced are either infrequent or are easily manageable. This notion is also supported the perception about the pressure factor in the Cultural class.

6) Risk factors: The common consensus about the risk factors was that all of them are high importance as they all are necessary to be monitored, analyzed, and managed earnestly not just in the context of an effective CSS but, also with regards the sensitivity of the public information that they are dealing with. They also indicated to have a clear risk treatment plan and protocols that their organization follow. P2 stated that they don't have such plan and mechanism in place and that their organization tends to decide one when there is a need and that too for only severe and organizational wide risks. Table VIII highlights the scores associated with the risk factors.

Based on the interviews and the scaled defined, the list of critical factors are identified, as illustrated in Fig. 3.

TABLE II. PARTICIPANT PROFILE SUMMARY

Interviewee Code	Age	Qualification	Designation	Overall experience	Experience in security setting
P1	35	Bachelor	Security Analyst	5	5
P2	38	Master	Head of Data center	8	8

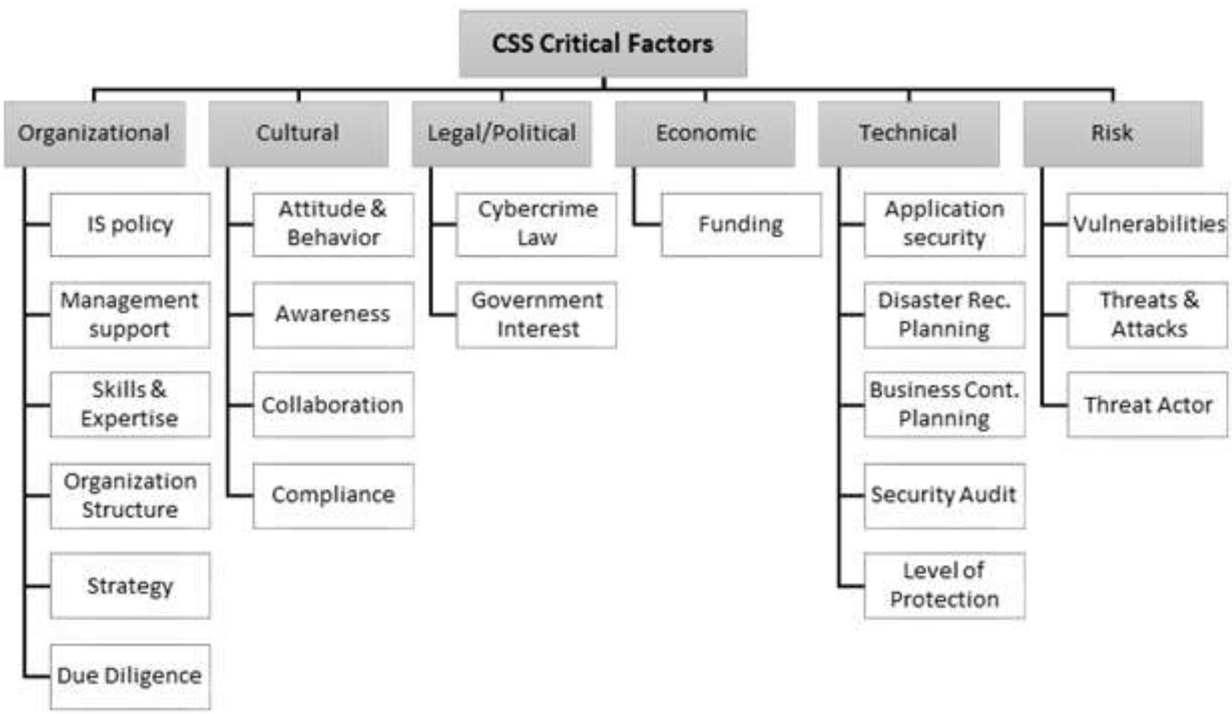

Fig. 3. List of Critical CSS Factors.

IV. COMPARISON

In this section, we provide a comparison of our classification with the studies summarized in Table I. However, we have selected only the 10 most relevant ones that cover the majority of the factors that are also common in the other attempts listed there. The comparison is provided in Table IX to XI. The tick mark indicates that a particular factor is stressed as an essential CSS factor whereas, the cross sign highlights that the given factor is not addressed essential. Overall, it can be concluded that our work provides a more complete list of factors rather than emphasizing a particular set of factors. Moreover, it can be observed that most of these works have mainly focused on the organizational and cultural aspects, whereas other key contexts of the business have been overlooked.

V. Conclusion

To develop and implement an effective CSS, we need to recognize and evaluate the necessary factors that might influence its efficacy. In this article, we have accumulated a comprehensive list of such essential factors in accordance with the critical areas of an organization that are vital to be recognized and evaluated for any long-term planning, such as developing a CSS. The comparison depicts that the proposed classification covers and provides a broader view of the essential CSS Factors as compared to the current attempts that emphasize on a specific domain or context of a business. Such a holistic classification of essential factors can provide a fundamental ground for organizations planning to develop and implement a CSS to understand and evaluate the influencing aspects of it and to plan accordingly. Furthermore, we have also listed the critical factors in the public sector in Oman. However, we believe that this study is limited in scope and that the corresponding critical factors assessed may vary considerably in regions or spaces with different legal, political, economic, and cultural backgrounds. More data need to be collected and analyzed to conclude whether this list of critical factors will shrink or grow, and it will be interesting to see how different types or organizations in a broader geospatial context comprehend the criticality of the different factors. In future, we plan to further refine the classification proposed and conduct a wider data collection approach to evaluate the critical factors.

Automatic Speech Recognition Features Extraction Techniques: A Multi-criteria Comparison

Maria Labied, Abdessamad Belangour
Laboratory of Information Technology and Modeling LTIM
Hassan II University, Ben M'sik Faculty of Sciences
Casablanca, Morocco

***Abstract*—Features extraction is an important step in Automatic Speech Recognition, which consists of determining the audio signal components that are useful for identifying linguistic content while removing background noise and irrelevant information. The main objective of features extraction is to identify the discriminative and robust features in the acoustic data. The derived feature vector should possess the characteristics of low dimensionality, long-time stability, non-sensitivity to noise, and no correlation with other features, which makes the application of a robust feature extraction technique a significant challenge for Automatic Speech Recognition. Many comparative studies have been carried out to compare different speech recognition feature extraction techniques, but none of them have evaluated the criteria to be considered when applying a feature extraction technique. The objective of this work is to answer some of the questions that may arise when considering which feature extraction techniques to apply, through a multi-criteria comparison of different features extraction techniques using the Weighted Scoring Method.**

Keywords*—*Automatic speech recognition; feature extraction; comparative study; MFCC; PCA; LPC; DWT; WSM

I. Introduction

Features extraction is a fundamental step in the Automatic Speech Recognition (ASR) process, in which relevant data are extracted from a speech. After pre-processing a speech signal (noise reduction, endpoint identification, pre-emphasis, framing, and normalization), the feature extraction stage retains a set of predefined features from the processed speech, using extraction techniques such as Mel-Frequency Cepstral Coefficients (MFCCs), Discrete Wavelet Transforms (DWTs), Linear Predictive Coding (LPC) and other techniques that will be explored in greater depth in this paper focusing on the advantages and disadvantages of each one.

The content of this paper is structured as follows. In Section 2 we review related work that has been done to compare existing features extraction techniques. In Section 3 we describe the different features extraction techniques. Then, in Section 4, we present the main advantages and disadvantages of each extraction method. In Section 5 we provide a multi-criteria comparison of the different methods based on the Weighted Scoring Method (WSM). Finally, we end with a conclusion.

II. Related Work

Several works have been conducted to compare ASR features extraction techniques [1][2][3][4][5][6]. Most of this research has been focused on the advantages and disadvantages of each extraction method. Nevertheless, it is relevant to illustrate the importance of each one depending on the criteria that represent the key elements when deciding on which method to use for feature extraction in a speech recognition system.

In the research [3] most commonly used feature extraction techniques have been discussed, like LPC, MFCC, Zero Crossings With Peak Amplitudes (ZCPA), DTW, and Relative Spectral Processing (RASTA). In this work, the limitations of each the advantage of each technique have been addressed. Also, it was mentioned that most research used only a single feature extraction technique and that is important to think about using hybrid techniques that combine between two or more than one feature extraction technique. In the same scope, another research [4] has been established a comparison of various feature extraction techniques (MFCC, LPC, DWT, PLP…) considering the specific advantages and the shortcomings of each.

An analysis of different feature extraction techniques has been investigated in the work [5], for isolated words speech in a clean and noisy environment for feature extraction techniques like PLP, RASTA PLP, LPCC, and MFCC. This analysis has been based on a comparison of the obtained accuracy, using each technique in both noisy and clean environments. Another work [6] has studied the performance of commonly used feature extraction techniques (MFCC, LPC, and PLP) for speech recognition. Through illustrating their benefits and drawbacks. This paper highlights the importance of hybrid feature extraction techniques to benefit from the advantage of multiple techniques at the same time.

III. Speech Features Extraction Techniques

The features extraction methods are used to remove irrelevant information from a speech signal. Depending on the type of feature to be extracted, feature extraction methods can be classified into two main categories: Spectral feature analysis methods, which use the spectral representation of the speech signal. And temporal feature analysis methods, which use the original form of a signal.

The well-known feature extraction method in the field of ASR is the Mel-frequency cepstral coefficient (MFCC). In addition to this technique, there are other extraction methods for ASR, such as the Discrete wavelet transform (DWT), Wavelet packet transforms (WPT), Relative Spectral-Perceptual Linear Prediction (RASTA-PLP), Linear predictive coding (LPC), and others. We present in-depth each of these methods in the following sections.

A. Spectral Feature Analysis Methods

1) Mel-Frequency Cepstral Coefficients (MFCC): Several researchers chose MFCC as their feature extraction method. Since the mid-1980s, MFCCs are the most widely used feature extraction method in the field of ASR. Most of the works concerning Moroccan Darija Speech recognition have used the MFCC as a feature extraction method [7], [8]. The main purpose of this feature extraction method is to mimic the human ear. The MFCC is calculated by first splitting the speech signal into alternating frames with a length of 25 or 30 milliseconds and a 10-millisecond overlap between consecutive frames. The discrete Fourier transform (DFT) is computed on each windowed frame after each frame is multiplied with a Hamming window function.

MFCC is well-known and commonly used in the field of speech recognition, but they do have some drawbacks. The key disadvantage of MFCC is its poor robustness to noise signals, as noise signals change all MFCCs if at least one frequency band is skewed. Various normalization techniques are used for enhancing the robustness of MFCC to noise-corrupted speech signals, in both training and testing conditions. These include features statistics normalization techniques such as mean and variance normalization (MVN), histogram equalization (HEQ), and cepstral mean normalization (CMN). Another important issue with MFCCs is that these are derived only from the power spectrum of a speech signal, ignoring the spectrum phase. However, the provided information by this phase is also useful for speech perception. This problem is tackled by performing speech enhancement before starting features extraction.

2) Principal Component Analysis (PCA): Determining a linear combination that can be used to represent the original speech signal is the main role of PCA in the feature extraction stage. PCA is mainly used for dimensionality reduction and features de-correlation. It is the most used method to increase the robustness of the speech recognition systems in a noisy environment. The research presented in [9], states that the PCA analysis is required when the speech signal is corrupted by noises. Another research confirms that the usage of PCA had given further reduction in the error rates [10]. In the research [11] the combination of PCA with MFCC had increased the recognition rates obtained with noisy speech signals from 63.9% to 75.0%. However, less accuracy is obtained using PCA for spontaneous and continuous speech recognition [12].

3) Linear Predictive Coding (LPC): The LPC is the most important method for extracting features [13] and the most used in several works [14][15]. Unlike MFCC, this method imitates the basic structure of a vocal tract when a sound is produced. LPC analysis is carried out by generating frames for the input speech signal, then performing windowing on each frame to reduce the discontinuities at the beginning or the end of a frame. Finally, the inter-frame autocorrelation is calculated. LPC method recognition quality is affected by noises, several works proposed new approaches to enhance the performance of this method in a noisy environment [16]. Multiple works have used LPC in combination with DWT [17], by using DWT to decompose the input speech signal and LPC to model each sub-band. The results obtained confirm that this method outperforms by 10% the MFCC method.

4) Linear Predictive Cepstral Coefficient (LPCC): The LPCC is considered as an extension of the LPC method [8]. After performing the LPC analysis, cepstral analysis is carried out to obtain the corresponding cepstral coefficient. Many researchers studied the performance of both LPCC and MFCC. The results obtained in [18] show that MFCC and LPCC share the same results. Another research [19] compared the two methods confirm that LPCC was 5.5% faster and 10% more efficient than MFCC.

5) Perceptual Linear Prediction (PLP): The PLP method is mainly used to remove unwanted information from a speech signal and improves the speech recognition rate. The PLP analysis consists of two important stages. First by approaching the auditory system spectrum by the model of all poles, then calculating the auditory spectrum [20]. The results of PLP analysis and LPC are identical, with the exception that the order of the PLP analysis model is half of the LPC model. This model allows for storage saving of automatic speech recognition storage and also provides good ASR performance.

B. Temporal Feature Analysis Methods

1) Discrete Wavelet Transforms (DWT): In addition to the frequency information, the temporal information in speech signals is also important for speech recognition applications [21][22]. Due to the non-stationary nature of speech signals, DWT obtains temporal information by re-scaling, shifting, and analyzing the mother wavelet. In this manner, the input speech signal is analyzed at various frequencies and resolutions. Since a speech signal is analyzed at decreasing frequency resolution for increasing frequencies, the DWT provides an appropriate model for the human auditory system and it was used in various researches at the feature extraction stage [23][24]. In comparison to MFCC, the DWT offers better frequency resolution at lower frequencies. As previously mentioned, MFCC is not robust for noise-corrupted speech signals. Because of their ability to provide localized time and frequency information, DWT was effectively used for de-noising tasks.

Several researchers considered combining the DWT and the MFCC to gain the benefits of both methods. This combination is known as Mel-Frequency Discrete Wavelet Coefficients (MFDWC) and is produced by applying the DWT to the Mel-Scaled log filter bank energies of a speech frame. In the works [25][26] the MFDWC method was used and for both clean and noisy environments, the results showed that MFDWC achieved higher accuracy as compared to MFCC and wavelet transforms alone.

2) Wavelet Packet Transforms (WPT): The wavelet packet transform is an extension of the standard wavelet decomposition that provides extra signal processing options. When compared to the wavelet transform, it better represents high-frequency information. The main difference between wavelet transforms and wavelet packet transform is that the latter split details as well as approximations.

WPTs are similar to DWTs, except that both the approximation and detail coefficients are more decomposed. The research [1] compared WPT's performance to that of DWT for the task of ASR, the results showed that WPT-based methods performed better as than WPT's.

3) Relative Spectra–Perceptual Linear Prediction (RASTA-PLP): The RASTA–PLP analysis involves combining the RASTA technique with the PLP method to improve the robustness of the PLP features. This method is based on the fact that the temporal properties of a speech signal environment differ from those of the speech signal. Thus, by using band-pass filtering on each frequency sub-band of a speech signal, the effects of channel mismatch between the training and testing environments are reduced and the short-term noises are smoothed [27]. The work done in [28] confirms the robustness of RASTA–PLP for noisy environments. Another work [29] have compared the RASTA–PLP with LPC and MFCC feature extractions techniques, the obtained results shown That the RASTA–PLP performs better than MFCC and LPC for noisy speech signal with an accuracy of 73% while 60% accuracy had been obtained using MFCC and 53% of accuracy obtained using LPC. Furthermore, RASTA-PLP performs much better when it is combined with the WPT method.

IV. Comparison of Feature Extraction Techniques

There are several criteria to consider when chosen a feature extraction technique, such as the accuracy of recognition in a noisy speech environment, computations costs, storage space, temporal information of speech signals, and others.

When it comes to noisy environments RASTA–PLP outperforms MFCC, PLP, and LPC features extractions methods. The MFCC is suitable for a clean speech and performs better for an isolated speech environment, while it is low robust to noise and not suitable for a continuous speech environment since the MFCC frame may contain information of more than one phoneme. For more robustness either MFCC, LPC or PLP may be combined with other feature techniques such as DWT or WPT for enhancing systems robustness when it is needed to use such feature extraction techniques in a noisy environment [30]. The temporal information of a speech signal is as significant as its frequency information. The DWT and WPT outperform the well-known MFCC for such issues. Thanks to these two methods a better accuracy is achieved for phonemes recognition. Also, available memory space is an important criterion for choosing the feature extraction method that will achieve good accuracy with a limited feature vector size. DWT may be a good option when only small storage is available. While MFCC requires more storage space. For this reason most of the time, MFCC is used in combination with other features extraction techniques to reduce the dimensionality of extracted features and to obtain good accuracy, vector quantization (VQ), PCA, or LDA [31][32].

The profits and constraints of the above discussed features extraction techniques are illustrated in Table I.

TABLE I. Features Extraction Techniques Comparison

Feature extraction	Pros	Cons
MFCC	- High recognition accuracy [27] - Good discrimination and low coefficients correlation [27]	- Inaccurate recognition in noisy speech [27] -high dimensional features vectors [31]
PCA	- Robustness to noises [9] - Reduce the feature vector's size while retaining important information [15]	- Expensive in terms of computing for high-dimensional data [27]
LPC	- Computation speed - Robust for extracting features from speech signals with a low bit rate [33]	- Highly correlated feature coefficients [27] - Unable to distinguish words with similar phonemes
LPCC	- Decorrelate feature coefficients by the cepstral analysis - Robust than LPC [27]	- Unable to analyze local events accurately
PLP	- Low-dimensional feature vector [27] - Reduce the gap between voiced and unvoiced speech	- Altered Spectral balance [27]
DWT	- Denoising speech signal [34] - Compressing speech signal without significant loss of its quality [27]	- Inflexible [27]
RASTA–PLP	- Robustness - Excludes variations between cepstral components and speech signal [27]	- Low performance for noiseless speech [21]

V. Multi-criteria Comparison

After describing the advantages and disadvantages of each feature extraction method in this section we present a multi-criteria comparison of these methods. In this comparison, we used the Weighted Scoring Method (WSM), which is known as the simple additive weighting method, which involves adding up the criteria values for each alternative and applying the individual criteria weights [35]. To apply this method, we went through the steps below:

- Criteria selection.
- Assigning weights to criteria based on their importance.
- Creating a matrix containing weights for each criterion.
- Calculation of weights scores.

A. Comparison Criteria

The choice of comparison criteria was based on the common characteristic shared between previously cited feature extraction methods. In the following we present the most important criteria to be considered when choosing a speech feature extraction technique:

- C1=Robustness to noises: This criterion involves if we can use a feature extraction technique when a speech signal is corrupted by noises.
- C2=Memory storage: This criterion concerns the size of storage space required for the spectral analysis of a speech while maintaining important information from a speech.
- C3=Dimensionality reduction: This criterion indicates the ability of a feature extraction technique to reduce the dimensionality of extracted features while obtaining a good accuracy.
- C4=Computational Complexity: This criterion covers the computational costs of a feature extraction method in terms of time and speed.
- C5=Computational Speed: This criterion covers the computational costs of a feature extraction method in terms of time and speed.
- C6=Temporal information within speech: This criterion highlights the implication of temporary information of a speech by the feature extraction method.
- C7=Suitability for continuous speech: This criterion considers the performance of a feature extraction method in the context of a continuous speech.
- C8=Suitability for spontaneous speech: This criterion considers the performance of a feature extraction method in the context of a spontaneous or a real-time speech.
- C9=Suitability for isolated words speech: This criterion points out the performance of feature extraction when dealing with isolated words speech.
- C10=Reinforcing recognition rate: This criterion indicates whether the application of a feature extraction method improves the speech recognition rate.

B. Application of WSM

The application of the WSM method consists of determining the multi-criteria matrix where the columns represent the feature extraction methods and the rows represent the criteria with their corresponding weights. The score attributed to each criterion has been induced from the comparison detailed in the previous sections.

The scoring is based on five levels where each one is defined as follows:

- Score "1": A poor nor lower performance is obtained using a method.
- Score "2": Inflexibility and lack of efficiency using a method.
- Score "3": A good option, but there are some limitations to use a method.
- Score "4": Significant results are obtained, more flexibility for foreign contexts is needed.
- Score "5": Approved efficiency, all requirements are met by using a method.

In Table II, the resulting WSM Matrix is presented according to the score assigned to each criterion.

TABLE II. WSM Matrix

	MFCC	**PCA**	**LPC**	**LPCC**	**PLP**	**DWT**	**RASTA–PLP**
C1	1	5	1	1	4	5	5
C2	2	4	3	3	5	4	5
C3	2	5	4	4	5	5	4
C4	5	2	3	4	4	2	4
C5	3	4	5	5	4	4	5
C6	3	4	1	1	3	5	3
C7	2	3	2	3	4	4	4
C8	2	2	2	3	3	3	4
C9	5	4	4	4	4	2	3
C10	4	5	3	4	4	5	5

VI. Discussion

According to the multi-criteria comparison of different feature extraction techniques, each feature extraction technique performs better for a particular criterion, as shown in the WSM results in Matrix presented in Table III, we can see that MFCC is less complex and effective for extracting features from an isolated words speech, but it lacks robustness to noises, which make it non preferred for other speech types (spontaneous, continuous).

TABLE III. WSM RESULTS

	Weights	MFCC	PCA	LPC	LPCC	PLP	DWT	RASTA–PLP
C1	10	10	50	10	10	40	50	50
C2	10	20	40	30	30	50	40	50
C3	10	20	50	40	40	50	50	40
C4	10	50	20	30	40	40	20	40
C5	15	45	60	75	75	60	60	75
C6	5	15	20	5	5	15	25	15
C7	10	20	30	20	30	40	40	40
C8	5	10	10	10	15	15	15	20
C9	15	75	60	60	60	60	30	45
C10	10	40	50	30	40	40	50	50
Scores	100	305	390	310	345	410	380	425

Other extraction methods like PCA, DWT, and RASTA-PLP are effective in reducing noise, which is an important factor in building a robust ASR system. Temporal information within a speech is less considered by most feature extraction methods. Also, memory storage optimization is an important issue to be filled by a feature extraction method.

From these results, we can deduce that none of the presented methods meet the flexibility and robustness requirements of ASR. The multi-criteria spider graph shown in Fig. 1 illustrates that there is no complete extraction method that respond to each criterion. However, we emphasize the importance of combining multiple feature extraction techniques to benefit from the effectiveness of each.

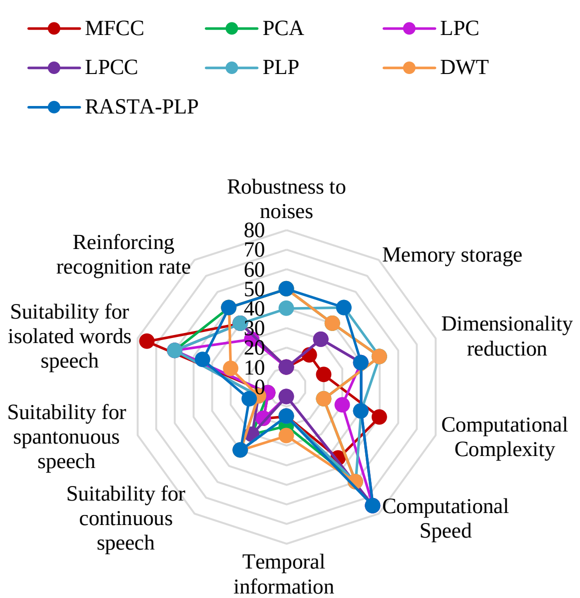

Fig. 1. Multi-criteria Spider Chart.

VII. CONCLUSION

In this work, we presented a multi-criteria comparison of commonly used feature extraction techniques in ASR. The choice of feature extraction techniques is a crucial step in the speech recognition process since the wisely we choose the extraction technique, the more accurate results we get.

This comparison revealed that each extraction method has reliability and performance issues. Also, the results showed the importance of applying hybrid feature extraction techniques since each of the presented extraction techniques complements the work of another.

The main objective of this multi-criteria comparison is to help researchers to select the feature extraction method according to the criteria that matter most for speech recognition.

An Approach for Requirements Engineering Analysis using Conceptual Mapping in Healthcare Domain

Aya Radwan, A. Abdo, Sayed Abdel Gaber
Faculty of Computers and Artificial Intelligence, Helwan University, Cairo, Egypt

***Abstract*—Healthcare systems aim to achieve the best possible support for patient care and to provide good medical care. Good analysis of requirements is essential to avoid any crises. Elicitation of healthcare systems requirements is an emerging and critical phase. It is a challenging task to deal with constraints from the stakeholders and restrictions of the legal issues. In this research, an approach "Conceptual Mapping for non-functional Health care Requirements; CMHR" is proposed to perform an analysis and to evaluate the relationship between the clinical non-functional requirements of medical devices (ventilators as an example in this research) according to the following five attributes: prioritization of requirements, suitability, feasibility, achievability, and risky. Requirements are automatically clustered using the K-means++ algorithm to find out the optimal number of clusters. Requirements are then clustered to visualize the concept map. Clustering is applied on different combinations of the attributes to sort the requirements and to visualize them. Label names are assigned to the classes of requirements to assign each requirement to the appropriate class. Consequently, a prediction of a new requirement can be figured automatically. The approach achieved less rework, fast delivery of the project with good quality, and achieved a higher level of user satisfaction.**

Keywords—Conceptual mapping; healthcare systems; clustering; requirement engineering analysis

I. Introduction

Healthcare systems aim to achieve the best possible support for patient care and to provide good medical care. software engineering is an emerging field for healthcare systems. Clinical requirements are more complex comparing to other types of requirements as they should be in specific terms. Software requirement engineers should concentrate when eliciting requirements to avoid making mistakes that could be disastrous in healthcare [1]. Software Requirement analysis; also known as software requirement engineering, aims to ensure that systems meet the needs of stakeholders while also determining user expectations. Requirement analysis consists of activities that are important to the software development process [2]. This process is composed of the following activities [2]: elicitation, modeling and analysis, assurance, management, and Evolution. First, the elicitation phase is called software requirements elicitation, which is a challenging task to understand and analyze software requirements specifications. Its objective is discovering stakeholders' needs, and understand the context [2]. It's important to perform this step carefully, to minimize the changes that may occur in order to save software development time [3]. Second, requirements analysis and negotiation; requirements are identified, and system modeling is performed. Third, requirement specification while the requirement should be documented in a format of Software Requirements. Fourth, validate the requirements to ensure that requirements meet the needs of the stakeholders. Finally, Requirements management is the last activity to manage all requirements-related activities [4] [5]. Further, the requirements are written in natural text format, requirements should be thoroughly analyzed to generate the software requirements specifications needed to validate and verify the final product. Software requirements are divided into Functional and non-Functional requirements [6]. Functional requirements are about the software service and its functional behavior, while non-functional requirements focus on the performance and the quality of requirements that are unrelated to software functionality [7].

The healthcare system is an emerging field. Projects should be well analyzed to avoid any crises. The consequences of poor requirement analysis lead to project failure, consuming effort and time, and repeating tasks and processes. In this research, an approach is presented to analyze non-functional requirements through the use of unsupervised learning to arrange the related requirements into clusters. This approach visualizes and sorts the nonfunctional requirements through conceptual mapping. Furthermore, the approach can predict the class of the new requirements.

The rest of this paper is organized as follows: Section 2 explains the background of some related concepts, Section 3 illustrates the literature review, Section 4 discusses the proposed methodology, and finally Section 5 explains the experimental results.

II. Background

Machine learning consists of three different types, which are supervised learning, unsupervised learning, and reinforcement learning [8]. In this research, the k-means clustering method is used to group similar data into one group. The related data is combined to make it easier to find relationships between data.

The requirement engineering consists of a series of activities, [4] that begin with requirement elicitation and inception to meet the needs and desires of the stakeholders. Then requirements analysis and negotiation; requirements are identified, and system modeling is performed, which necessitates that the product is completely modeled and designed prior to the construction. Then requirement specification; requirement should be documented in a format of SRS. While the validation of the requirements to ensure that they meet the needs of the stakeholders is the next activity. Finally, Requirements management is the last activity to manage all requirements-related activities. [5].

Conceptual mapping is a diagram that visualizes the semantic relations between concepts [9]. Conceptual maps help to give a consistent evaluation. This process mainly composed of the following steps; first, make brainstorming then generate the statement of needs, after that sorting and rating these statements, then represent the statements on the map that's could be called as conceptual mapping analysis. Finally, they make interpretation for the map and utilize it [10][11]. Conceptual mapping creates a structure of clustered concepts and provides a visual or graphical representation of data.

III. Literature Review

Al-Dahmash et al. in [12], proposed SEMHTA, a methodology for healthcare to build system and application with reliable and protected software. It stands for software engineering methodology for healthcare applications development, this methodology relies on what developers do when building a different system. There was no consideration for the elicitation phase. Gausepohl et al. in [13], proposed a methodology in a healthcare system that focused on storytelling in the elicitation phase for medical device requirements. Results contributed similar quantity and breadth of information in significantly less time. Participants contributed more distinct context-of-use information with an emphasis on the social context using ontology technics. However, this methodology presents the elicitation of medical device requirements rather than a clinical requirement. Kaiya et. al. [14] did similar work to enhance requirement elicitation using ontology technical web mining and lightweight natural language processing, but this wasn't applied with healthcare systems. Widya et al. in [15], proposed a methodology for eliciting requirements in the eHealth domain. Developers developed a scenario that reflects the treatment protocol and it works with telemedicine treatment. Martin et al. in [16], proposed a user center designed approach in the clinical systems to keep users in the cycle of development. They performed semi-structured open-ended interviews to investigate the clinical need for the device as well as the supposed effects for patients and clinical users. Regarding approaches in requirements engineering in the non-clinical systems: Laporti et al. in [17], proposed the Athena approach that applied requirements elicitation by grouping storytelling from users to be merged in one story. Stories then transformed to scenarios then to use-cases. Andreas et al. in [18] explore and define a requirement engineering methodology for machine learning systems. This methodology incorporates additional types of standards, such as special legal requirements, and explains the ability and freedom from prejudice, in order to enhance the requirement engineering process. They improve the machine learning models by taking too many decisions. Kamal Rudin et al. [19] [20] have created a simple method for gathering consistent requirements from the client stakeholders. A library pattern that supports various application domains is developed to store the essential requirements following the essential use-case. The library pattern, on the other hand, is not concerned with the use of healthcare requirements. Hamzeh Eyal Salman in [21], designed an approach to cluster functional requirements automatically based on semantic measure Using Agglomerative Hierarchical Clustering (AHC) by grouping similar functional requirements into clusters. Results achieved high performance according to a well-known measure and didn't apply yet for the clinical system. Zeng Zhen in [22], applied the TA-ART algorithm ta generate an automatic concept map for text, by making text analysis and set records into clusters. Nadiah Daud in [23] created a methodology to enhance requirements elicitation. This methodology is composed of three phases; 1) the analysis: they collect requirements to analyze it or read the literature and gather requirements to analyze gaps and requirements. 2) they go to the design and development. 3) they make an evaluation and test the results. Rebecca Orsi in [10] presented a study using concept maps analysis by running more than multiple cluster analyses to describe a quantitative validity analysis. She used the R statistical software methods and packages to represent four clustering methods.

IV. Proposed Approach

This research presents a novel approach; "Conceptual mapping for health care non-functional requirements, (CMHR)". This approach is applied to requirement engineering to enhance the analysis process of the requirements. CMHR is composed of three phases as illustrated in Fig. 1. The first phase is Requirements Gathering. In this phase, the non-functional requirements are extracted from the software requirements specifications. The domain experts rank requirements by the identified attributes (suitability, priority, stability, risky, achievable) from 1 to 5. The second phase is Data Preprocessing. In this phase, the data pass through preprocessing phase to prepare the data for the next step and to ensure that the data is cleaned. The third phase is Machine Learning and visualization. In this phase, the approach starts to perform clustering using the k-means++ algorithm to perform the conceptual mapping analysis. In this phase, The Elbow method is used to calculate the number of clusters, then clustering the related requirements to each other based on similarity according to the identified attributes. Then, a visualization is performed through a matplotlib plot, and the data is exported to CSV file. Now labeling of the clusters and requirements can be performed. The benefit of labeling the data is to make a classification for the requirements and split it into the training and testing set. Finally, predict the new requirements classification. The details of these phases are decelerating in the following diagram.

Phase 1: Requirements Gathering. This phase consists of two main steps. Step1: Extract non-functional requirements from SRS. The structured requirements are extracted and the non-functional requirements are being selected to analyze it. In this research, 104 non-functional requirements are collected from SCRIBD1 website about ventilators as a medical device. Table I illustrates a sample of these requirements.

[1] https://www.scribd.com/document/467320184/10053865Q00-PB560-Ventilator-Power-Pack-Essential-Requirements-Matrix-pdf

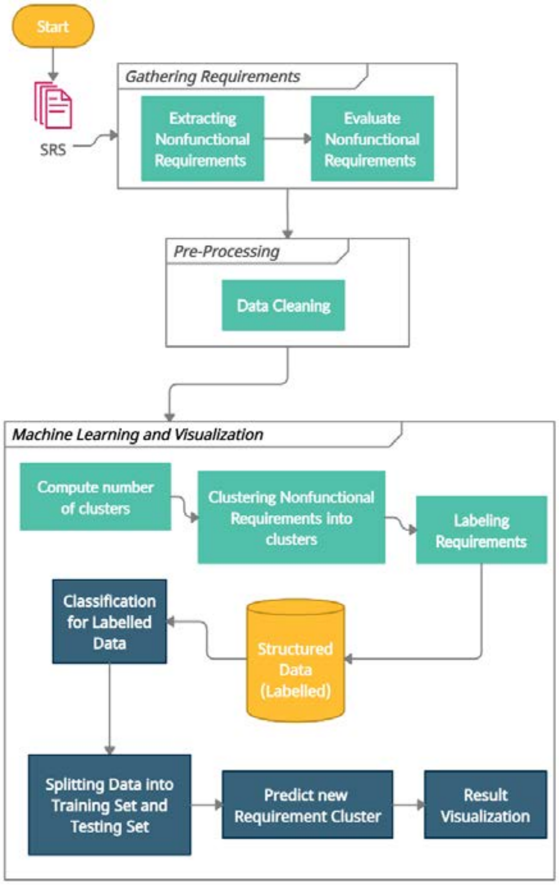

Fig. 1. Conceptual Mapping for Health Care non-Functional Requirements: CMHR.

TABLE I. A SAMPLE OF NON-FUNCTIONAL REQUIREMENTS FOR VENTILATORS DATASET

12.1 For devices which incorporate software or which are medical software in themselves, the software must be validated according to the state of the art taking into account the principles of development lifecycle, risk management, validation and verification.
12.2. Devices where the safety of the patients depends on an internal power supply must be equipped with a means of determining the state of the power supply.
12.3. Devices where the safety of the patients depends on an external power supply must include an alarm system to signal any power failure.
12.4. Devices intended to monitor one or more clinical parameters of a patient must be equipped with appropriate alarm systems to alert the user of situations which could lead to death or severe deterioration of the patient's state of health.
12.5. Devices must be designed and manufactured in such a way as to minimize the risks of creating electromagnetic fields which could impair the operation of other devices or equipment in the usual environment.
12.6. Devices must be designed and manufactured in such a way as to avoid, as far as possible, the risk of accidental electric shocks during normal use and in single fault condition, provided the devices are installed correctly.
12.7.1. Devices must be designed and manufactured in such a way as to protect the patient and user against mechanical risks connected with, for example, resistance, stability and moving parts.
12.7.2. Devices must be designed and manufactured in such a way as to reduce to the lowest possible level the risks arising from vibration generated by the devices, taking account of technical progress and of the means available for limiting vibrations, particularly at source, unless the vibrations are part of the specified performance.

Step 2: Requirements Evaluation. In this step, a group of qualified scientists evaluates the non-functional requirements from the SRS document with attributes. The selected attributes are suitability, priority, stability, risky, achievable. Then the following questions are asked about every single requirement to a domain expert.

- Suitability: How much this requirement is complete, correct, and appropriate?
- Priority: How much this requirement is important?
- Stability: Does the requirement has reached a certain level of stability?
- Risk: What's at stake if the requirement isn't implemented?
- Achievable: How far this requirement could be achieved?

The mean of the answers of the survey is taken and be considered during analysis.

Phase 2: Pre-processing. Data cleaning is the process; which implemented at this phase. The kernel-based random method is used. This method finds the relations between concepts or data to perform data cleaning and normalization [24]. Data cleaning detects errors, expels mistakes and irregularities from information in arrange to progress the quality of information [25]. So, this step, try to fill the missing data by setting the most relevant value by calculating the mean value using machine learning.

Phase 3: Machine Learning and Visualization. This phase consists of four main steps. Step1: Compute the number of clusters using the ELBOW method to determine the optimal number of clusters for the data. It uses the k-means++ algorithm and applies a range of values for the k from 1 to 10 on the dataset to calculate the WCSS. WCSS stands for the Within-Cluster-Sum-of-Squares. It's the sum of squares of the distance of each data in all clusters to their centroid point using the following formula:

$$WCSS = \sum_{C_k}^{C_n} \left(\sum_{d_i \, in \, C_i}^{d_m} distance(d_i, C_k)^2 \right)$$

Where,

C is the cluster centroids. And d is the data point in each Cluster. (1)

Step 2: Clustering similar Non-Functional Requirement: The k-means++ algorithm used to present multidimensional scaling by measuring similarity, which can be defined as the distance between various datasets; calculating the sum of the distance between point and centroid point. After calculating the distance, the group of related clusters is combined then the requirements could be visualized among the selected attributes throw the multidimensional scaling of the conceptual map and can be exported through CSV file. Requirements could be dynamically sorted based on any two selected attributes. Also, the map could fit for three attributes is developed.

Step 3: Labeling Requirements: Data labeling is the method of identifying the raw data. Data here is ready to be labeled after performing clustering; each requirement can be assigned with a label name. Assume there are four clusters, so a label will be assigned to each cluster based on the data in that cluster.

Step 4: Classification of labeled data: Data now in the shape of multi-label classes. Since the requirements are labeled in the last step, so the data is ready to be classified. The Naïve Bayes technique is applied in this research to make a classification for the labeled data. Naïve Bayes split the data into a training set and testing set in aim to learn the machine.

Step 5: Predicting the new requirement cluster: This is the final step. The developed approach can predict the classification of new requirements or for an edit of an existed requirement.

V. Experimental Study and Evaluation

The CMHR approach is applied to non-functional requirements of a ventilator device. First, 104 requirements were extracted from the SRS. Then the domain experts evaluated each requirement based on the defined attributes as it was explained in the previous section. The mean average of the evaluation was calculated and assigned to each requirement. Then the file is converted into CSV file. A sample of the data is presented in Table II.

The second step performs the preprocessing phase by using the sklearn library in python to complete the missing data. The data is ready now to perform the machine learning phase. This phase starts with computing the number of clusters using the ELBOW method to determine the optimal number of clusters, as shown in Fig. 2.

Fig. 2 depicts the result of the Elbow method. The clustering is applied based on prioritization and suitability. And figure showed the result of the optimal clusters is five.

Fig. 3 depicts the result of the Elbow method. Prioritization and achievability are used to cluster the requirements. The figure showed that the optimal clusters is four.

The next step is to cluster similar non-functional requirements using the k-means++ algorithm. The multidimensional scaling of the requirements is presented in Fig. 4 and Fig. 5.

In Fig. 4, Requirements are sorted and visualized based on prioritization and suitability attributes. Requirements are clustered into the five clusters as the Elbow method showed.

In Fig. 5, Requirements are sorted and visualized based on prioritization and achievability attributes. Requirements are clustered into four clusters as the Elbow method showed.

CMHR approach is implemented dynamically. It offers clustering the requirements based on three attributes and makes a 3-Dimensions representation. For example, Assum the clustering is made based on three attributes prioritization, suitability, and achievability.

Fig. 6 presents the result of the Elbow method. The clustering is applied based on prioritization, achievability and suitability. The figure showed that the optimal clusters is five.

Going through the next step to cluster similar non-functional requirements, the multidimensional scaling of the requirements is presented using the k-means++ algorithm in Fig. 7.

TABLE II. Ranking of Non-functional Requirements for Ventilators (Sample of the CSV File)

Requirements	**Suitable**	**Priority**	**Achievable**	**Feasible**	**Risky**
For devices which incorporate software or which are medical software in themselves, the software must be validated according to the state of the art taking into account the principles of development lifecycle, risk management, validation and verification.	4.1	3.7	4.5	4.96	4.9
Devices where the safety of the patients depends on an internal power supply must be equipped with a means of determining the state of the power supply.	4.05	3.7	4.35	4.9	4.87
Devices where the safety of the patients depends on an external power supply must include an alarm system to signal any power failure.	4.78	4.56	4.3	4.74	4.3
Devices intended to monitor one or more clinical parameters of a patient must be equipped with appropriate alarm systems to alert the user of situations which could lead to death or severe deterioration of the patient's state of health.	3.82	3.48	3.88	4.36	3.66
Devices must be designed and manufactured in such a way as to minimize the risks of creating electromagnetic fields which could impair the operation of other devices or equipment in the usual environment.	3.88	3.89	4.9	3.8	3.8
Devices must be designed and manufactured in such a way as to avoid, as far as possible, the risk of accidental electric shocks during normal use and in single fault condition, provided the devices are installed correctly.	4.52	1.72	4.87	3.1	4.67
Devices must be designed and manufactured in such a way as to protect the patient and user against mechanical risks connected with, for example, resistance, stability and moving parts.	4.85	4.35	2.61	2.6	1.4
Devices must be designed and manufactured in such a way as to reduce to the lowest possible level the risks arising from vibration generated by the devices, taking account of technical progress and of the means available for limiting vibrations, particularly at source, unless the vibrations are part of the specified performance.	2.1	4.3	4.1	3.8	1.5

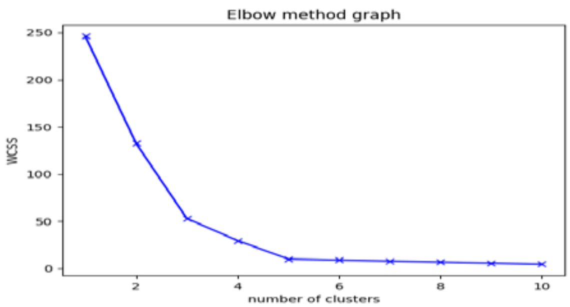

Fig. 2. Elbow Method Graph for Prioritization and Suitability Attributes.

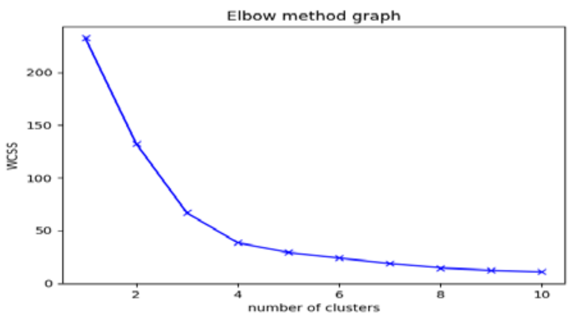

Fig. 3. Elbow Method Graph Prioritization and Achievability Attributes.

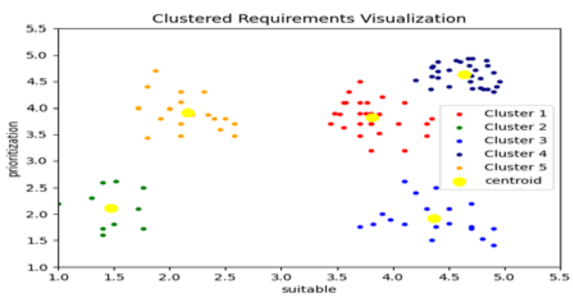

Fig. 4. 2D Visualization for Five Clustered Requirements.

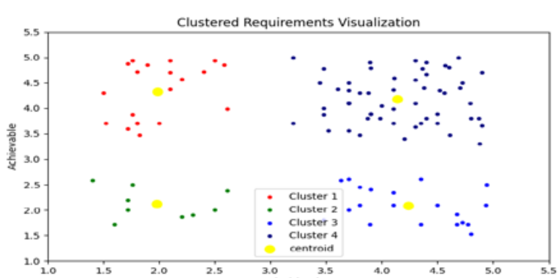

Fig. 5. 2D Visualization for Four Clustered Requirements.

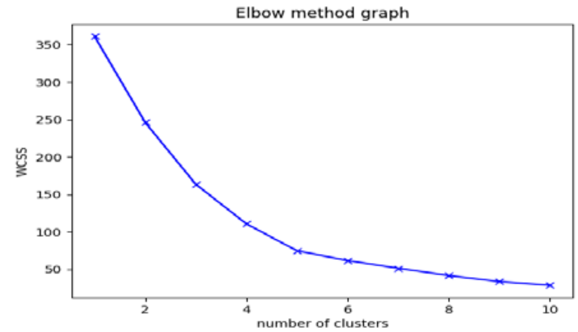

Fig. 6. Elbow Method Graph for Assigned Three Attributes Prioritization, Achievability and Suitability.

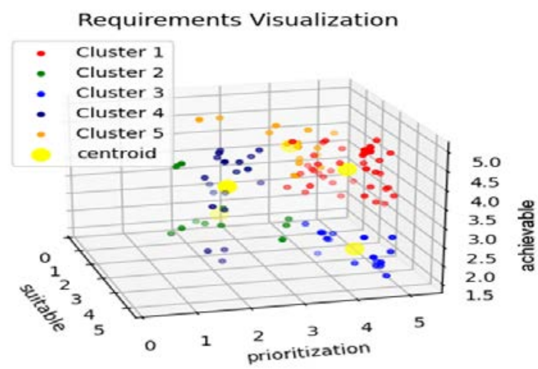

Fig. 7. 3D Visualization for Clustered Requirements.

In Fig. 7, K-means++ algorithm runs based on the evaluation of three attributes, which are suitability, prioritization, and achievability, Requirements are clustered into five clusters as the Elbow method showed. The Requirements sorted and visualized through 3-Dimensions matplotlib.

Silhouette method is applied to evaluate the clustering. This technique used to determine the performance and how much the clustering technique that has been used is correct. [26] Silhouette scope determines the measures between every object in the cluster and the other objects from other clusters. [26] Silhouette coefficient range from -1 to 1, where 1 implies that clusters are well separated and the objects are related to each other at the same cluster, while 0 implies that clusters are not separated well and distance between clusters are too close. -1 implies that objects and clusters are wrongly appointed. [27] Silhouette score coefficient is calculated for requirements to determine the optimal number of clusters. It tested from 2 clusters to 6 clusters and the result is presented here in Fig. 8 to 12.

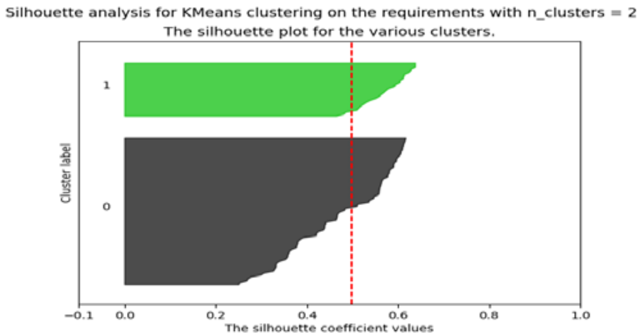

Fig. 8. The Silhouette Coefficient Value for Two Clusters.

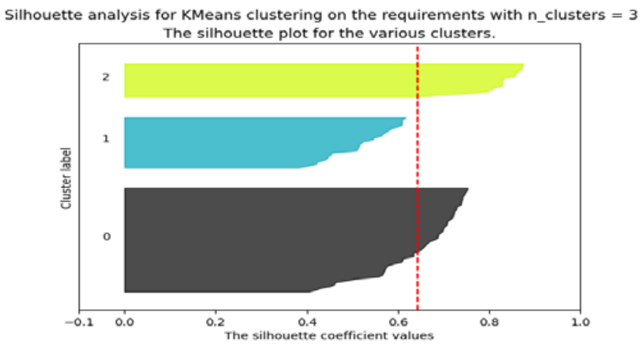

Fig. 9. The Silhouette Coefficient Value for Three Clusters.

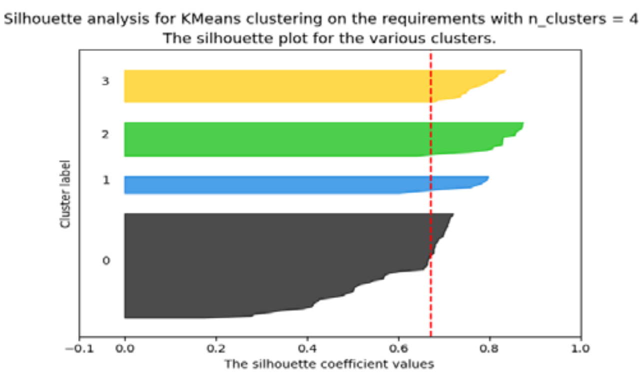

Fig. 10. The Silhouette Coefficient Value for Four Clusters.

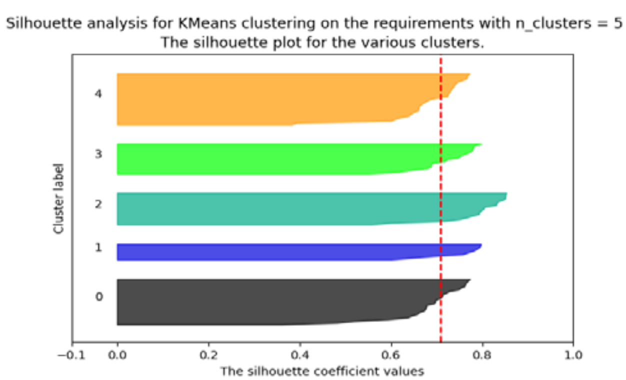

Fig. 11. The Silhouette Coefficient Value for Five Clusters.

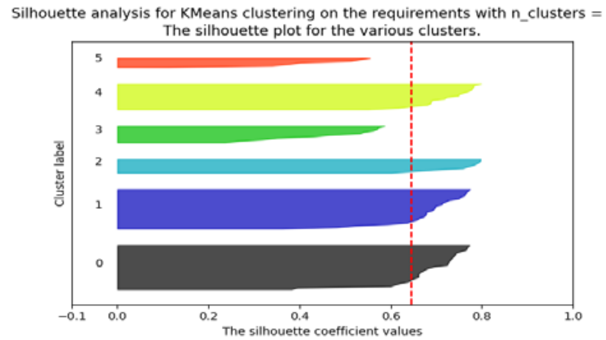

Fig. 12. The Silhouette Coefficient Value for Six Clusters.

Fig. 8 to 12 shows the silhouette analysis for Kmeans clustering. The cross column on the x axis shows the silhouette score as it's explained in Table III. The thickness of the silhouette plot represents the related requirements for each cluster. Fig. 11 shows the silhouette score is 0.71.

In Table III, shows silhouette score for the different number of clusters.

Fig. 4 showed that there are five clusters. Labeling of these clusters showed in Table IV.

Since the requirements were labeled then the data can be classified. Data were split into a training and testing set; with 80% for training and 20% for testing. The data splitting is to confirm the predicting of the class of any new element. The number of tested requirements is 21. The Confusion matrix is a visual evaluation technique used in machine learning. It presents the actual class result associated with the prediction class result [28]. The result of the confusion matrix is presented in Table V and the accuracy score was 1 for the tested cases.

TABLE III. AVERAGE SILHOUETTE SCORE FOR NUMBER OF CLUSTERS

Number of clusters	Silhouette score
2	0.49
3	0.64
4	0.67
5	0.71
6	0.64

TABLE IV. LABELING THE CLUSTERS

Cluster Number	Label Name
1	High Priority High Suitability
2	Very Low Priority Very Low Suitability
3	High Suitability Very Low Priority
4	Very High Priority Very High Suitability
5	High Priority Low Suitability

TABLE V. CONFUSION MATRIX FOR THE TESTING SET

Class 1	Class 2	Class 3	Class 4	Class 5
8	0	0	0	0
0	3	0	0	0
0	0	6	0	0
0	0	0	2	0
0	0	0	0	2

In Table V, 21 requirements had been tested with the classification technique Naïve Bayas. Results are shown in the table that eight requirements belong to class 1. Three requirements belong to class 2. Six requirements belong to class 3. Two requirements belong to class 4. Two requirements belong to class 5.

The classification report is used to assess the accuracy of a classification algorithm's predictions. The classification report presents the precision, recall, f1-score.

Precision = (TP/(TP+FP))

Recall = (TP/(TP+FN)).

The classification report shows that the precision is one for the five classes. The recall is one for the five classes. The F1-Score is one for the five classes.

VI. CONCLUSION AND FUTURE WORK

In this research; a novel approach "Conceptual mapping for health care non-functional requirements; CMHR" is applied to enhance requirement engineering analysis of healthcare systems. The approach focuses on ranking requirements using a set of attributes and calculates the mean value of each requirement for every attribute. CMHR is applied using the K-means++ algorithm to gather the related requirements into one group according to its semantic similarity. Semantic similarity is captured using conceptual mapping of the requirements. The CMHR approach can be extended to any different number of clusters. Clusters can be defined based on two or three attributes to sort the data based on the attributes and visualize it. Assigning labels to the clusters is essential to identify every cluster and requirement, in order to make a classification. CMHR offers an automatic classification for a new requirement. CMHR is applied to medical device requirements and generated five clusters of the requirements depending on prioritization and suitability with a silhouette score 0.71. Also, generated four clusters depending on prioritization and achievability. It generated five clusters based on three attributes. CMHR can work dynamically between any two or three attributes. In future work, CMHR will be applied on more than project to consume the time will be saved to finish the project. More attributes will be found to enhance CMHR approach and to find relations between requirements. Swarm intelligence can be applied to get more enhancement for the proposed approach.

***Abstract*—The categorization of brain tissues plays a vital role in various neuro-anatomical identification and implementations. In manual detection, misidentification of location and sound of unwanted tissues may occur due to visual fatigue by humans. Also, it consumes more time and may exhibit enormous partially inner or outer the manipulator. At present, automatic identification of brain tissues in MRI is vital for investigation and healing applications. This work proposed MRI image tissue segmentation using Improved Rough Fuzzy C Means (IRFCM) algorithm and classification using multiple fuzzy systems. Proposed research work comprises four modules: pre-processing, segmentation, categorization, and extracting features. Initially, the elimination of boisterous occur in the given image is done through pre-processing. After the pre-processing, segmentation is carried out for the pre-processed brain image to segment the tissue based on clustering concept using Improved Rough Fuzzy C Means algorithm. Later, the features of Gray-Level Co-Occurrence Matrix (GLCM) are extracted from segmentation, and the features extracted from segmented images are applied to Optimum Fuzzy Interference System (OFIS). Then the entire system parameters are optimized using Enhanced Grasshopper Optimization Algorithm (EGOA). Finally, the novel OFIS classifier helps to classify the brain-based tissue images as Gray Matter (GM), White Matter (WM), Cerebrospinal Fluid (CSF), and Tumor Tissues (TT). The results using MRI data sets are analyzed and compared with other existing techniques through performance metrics to show the superiority of the proposed methodology.**

Keywords*—Cerebrospinal fluid; fuzzy interference system; enhanced grasshopper optimization algorithm; improved rough fuzzy c-means clustering

I. Introduction

In abnormal and normal brain tissues studies, Automatic classification of brain tissue from MRI is very important [1]. The troop of unidentified cells that are grown in the brain or around the brain is said to be a brain tumor, and it is the maximum cause of increasing impermanence among adults as well as children across the world. Few brain tumors are benign (non-cancerous), and some are malignant (cancerous) [2]. The main aim of identifying images in the brain-based tumor is to separate the sufferer-specific clinical information and their distinctive characteristics. The collected information was inserted in multidimensional image data; after detection and locality of disease, it instructs and monitors the interventions, and it undergoes disease treatment, clinical observation, and analyzes the stage of disease [3]. In any part of the body, if there are uncontrolled tissues grown is said to be a tumor. It is classified into two stages: primary and secondary. If it is starting stage, then it is said to be primary and if the tumor spreads around and grown in their own way is known to be secondary. Moreover, CSF (Cerebrospinal Fluid) is mainly affected by the tumor [4-5]. The automatic identification and separation of brain tumors is a difficult task and faces many issues in identification. In an automatic computerized system, the separation is a challenging task in brain tumors, and it involves the nature of the disease, intensity, and identification of the shape of MRI images.

The most used object in image segmentation which was shown that mutually exclusive regions which consist of pixels and other regions included homogenous, has implemented with predefined criteria [6]. Brain tumor segmentation has involved different methods of separating different tumor tissue, which consists of GM, WM, and CSF [7]. Its goal in segmentation has shown that changing the depiction in the image is more meaningful and easier to find out. It was used to order the local object and its boundary images. Finally, the result says that the seat of regions mostly covers the entire image [8]. There are many challenging issues in the image segment, which has been developed by a modified approach, and it is mostly implemented in all types of applications and figures. Moreover, the choice has the proper method to find out the image in difficult problems [9]. The major issue in the brain tumor segment indicates that the tumor varies its shape, size, and location-based on image intensities [10]. The manual segment of a brain tumor was derived by the human experts, and it has to be long time, which makes clearer that a computer-aided system for a brain tumor has observed an advisable method.

Clustering is mostly used in MRI image segments. The clustering process is defined by a grouping of pattern arrangements. Cluster analysis says various unsupervised learning techniques that are applied to resolve the changes in cluster problems. There are many various unsupervised instruction techniques such as s k was indicated by Fuzzy C means algorithm etc. and it indicates the K as simplest [11]. To group the objects, K-means clustering is implemented, and it confides on the ascribe characteristic into k no of groups. In k-means clustering, trooping is implemented on Euclidean distance among the cluster center and information [12]. In real-time problem solving such as target identification, image separation, mineralogy, uranology, and images in medical Fuzzy C-Means clustering is used, and it acts as a clear training method. The clustering methods are very important since the images in medical are limited pixel quantity, poor distinction, boisterous, and the variation is non-uniform [13-14]. In the brain image of MRI, the edges of several tissues are unclear. So, clustering methods are commonly applied for the identification and detection of brain tumors.

Research work helps to identify the tissue type of MRI brain images. For the purpose of tissue classification, at first, speckle noise removal is applied in the pre-processing stage. Next to pre-processing, segmentation-based clustering is carried out by means of the Improved RFCM method based on pixel similarity. Then GLCM has extracted the particular characteristics of the improved method. After the feature extraction stage, the OFIS classifier is performed to classify the brain tissue images where its parameters are optimally selected using Enhanced GOA. The remaining sections of the proposed work are discussed below, and the related work of several researchers is described in Section 2. Problem definition and contribution of the research work are given in Section 3, and Section 4 highlights the overall background of the study. Section 5 elaborates the proposed methodology. In Section 6, the result is summarized, and the conclusion of the presented work is provided in Section 7.

II. Literature Survey

In current days, recognition of tumors and their classification system is the most developing research area. Hence, Hao Dong et al. [15] has developed an automatic detection of brain tumor and segmentation approach. Here, this developed approach is utilizing the deep convolution framework based on the U-Net methodology. Moreover, the proposed method segmentation process is compared with various physically defined ground accuracies. The comparison demonstrates segmentation process is robust and effective. In addition, to validate the effectiveness, the entire tumor areas, and higher tumor areas outcomes are compared with core tumor areas. Here, the developed method provides the brain tumor segmentation of particularly affected persons without physical intrusion. Also, this approach is significant permits the objective injury analysis for medical responsibilities like that patient observing diagnosis, arrangement of treatment, and diagnosis. Besides, this method is evaluation is mainly based on the multimodal image segmentation dataset. These datasets include higher and lower grades of brain tumor cases as 220 and 54, respectively. To verify the efficiency of the segmentation procedure, cross-validation is taken.

Recognition of tumors in the brain is the most significant performance in these modern days. Hence, the automatic detection system is developed by Soltaninejad et al. [16]. Moreover, this detection scheme detects the brain tumor in the abnormal tissue related to the segmentation process. This approach mainly bases on the Fluid- Attenuated Inversion Recovery (FLAIR) with MRI image segmentation. Here, the experimental outcomes are having high segmentation performance and higher recognition ratio. Moreover, the performances are validated based on the ERT classifier system. Consequently, the detection sensitivity, error rate, and overlap measure of the proposed technique have attained 6%, 89.48%, and 0.88% separately. In addition, multimodal tumor segmentation performance outcomes are summarized below, 88.09% detection sensitivity, 6% of error rate, and 0.88% dice overlap amount. Here, the developed detection sachems take the original brain tumor images. To classify the images superpixel approach is utilized. Moreover, the original brain tumor image features consist of four types of classification. That is, curvatures, intensity bases feature classification, Gabor textons, and fractal examination.

Cabria et al. [17] has developed a Potential Field Segmentation (PFS) algorithm based original MRI brain tumor segmentation process. Also, the author presents and investigates the outcomes of the created PFS and other approaches to attain the bonded segmentation. Here, the proposed PFS method is mainly based on the Potential Field Clustering (PFC) and other recently proposed clustering approaches concept is incorporated with PFS. Moreover, the term “mass” is represented as a potential field to create the intensity of the MRI pixel vision. Particularly, each and every pixel of MRI is estimated, and a smaller area of the brain tumor pixel was related to the adaptive potential threshold. Moreover, the segmentation condition is “small potential”. It is automatically verifying the brain tumor pixels for a long time. Therefore, there is no “mass” and larger potential surroundings are much larger than the segmentation criteria. Then, the attained performances results are compared with different approaches consist of MRI bases benchmark dataset with multimodal tumor segmentation.

Mohammad et al. [18] have proposed a Deep Neural Networks (DNNs) bases automatic brain detection method is utilized. In this method, take the MR images to perform the low and high-grade networks. Consequently, the brain tumor is affecting is appeared in anywhere of the brain region. Also, the brain tumor is classified based on the size, shape, and divergence; these are the issues in the machine learning methodologies. In addition, the low flexibility and lower ability are the surveyed problems of ML techniques. To overcome these types of issues Convolution Neural framework (CNF) is developed through the Deep Neural Networks. Moreover, the newly proposed CNF structure is totally different from the conventional methods. The process of CNF is initially done with the local features and global contextual features. Implementations are done in the 40 fold speed up with a fully connected layer of the CNF. Finally, the outcomes of the CNF have validated bases on the comparison of the additional source of the dataset for succeeding CNF.

Rajinikanth et al. [19] have developed an innovative algorithm depend on the meta-heuristic optimization method. To evaluate the MRI brain tumor classification, the proposed method is utilized. Moreover, the proposed method improves the mines tumor core, as well as edema sector of the Teaching Learning Based Optimization (TLBO), based brain MRI integrating. Additionally, entropy examination and level set examination-based segmentation procedures are taken to execute the entire process efficiently. Here, the proposed approaches are implemented in flair, T1C, and T2 modalities. Also, the experimental performances are estimated using CEREBRIX and BRAINIX datasets. Furthermore, the optimization algorithm is validated based on the MICCAI separation of brain tumors by multimodal image separation challenge at the 2012 dataset. Attained outcomes are compared with Jaccard index values in terms of accuracy, precision, specificity, and sensitivity. Therefore, the developed segmentation process is medically important.

The accurate identification of tumors in the brain is a difficult and challenging task. To address this issue, Soltaninejad et al. [20] presented a 3D supermodel-based training method for the identification of tumors in multimodal MRI. Collected information and characteristics from multimodal MRI includes systemic MRI, and it results in accurate identification of brain images. Super voxels were created for applying the information, and a variety of characteristics is calculated by Gabor filters for every super voxel. The calculated characteristics are applied to the RF (random forest) classifier to categorize the tumor. The result shows that it gives better results in the separation of tumors. For increasing accuracy, the multimodal MRI is added, and it shows improvement in accuracy, and it provides better delineation among all tumor grades. The detection of brain tumor using multimodal MRI, it is the fastest method; it gives high accuracy and classifies the brain tissue as healthy or brain edema.

Nabizadeh et al. [21] had presented an automated identification of brain tumors in MRI for evaluation of the changeability and difficulty of the position, size, form, and appearance. Some techniques were used in multi-spectral anatomical MRI because of the similarities in intensity between the tissues normally found and injured brains. However, in multi-spectral MRI, there are some limitations in cost and time, and it faces some difficulties; to conquer this, a single-spectral anatomical MRI was developed to detect the tumor tissues. Also, he presented a fully automatic system it detects the tumor area and describes the portion which is damaged. As a result, the experiment shows that it successfully segments the tissues with less difficulty in computation and high accuracy. The benefit of a single contrast mechanism is separating the tissue segments, and it can able to identify the tumor tissues. Furthermore, it also includes an overview that evaluates the benefits of statistical characteristics over Gabor wavelet characterization by applying various classifiers.

III. Problem Definition

Brain tissue categorization in MRI is a vital stage in identifying the disease, diagnosis, planning for surgery, and process of treatment. In present days, MRI classification is a challenging task despite several existing artifacts such as boisterous, complexity in images, and incomplete volume effect. In automatic brain classification, some of the methods are complex, and few are not sufficiently accurate for a certain application. The proposed works contributions are described below:

- The main principle of proposed work is to analyze which type of tissue is occurred in the brain is analyzed from MRI images collected from the database.
- For segmentation, clustering is carried out to segment the brain tissue using Improved RFCM. Here the improved technique manages overlapping clusters.
- Five GLCM features, namely interaction, distinction, energy, disarray, and quantity variance alone, are extracted for the optimum solution.
- To obtain the optimal solution, EGOA is utilized in FIS, which helps to classify brain tissue MRI by optimizing the system structure.

IV. Background of the Study

Several processing methods were proposed by the existing researchers for the separation and categorization of tissues in the brain for MRI. In early researches, numerous techniques were developed and discussed for identifying the brain tissues in MRI; fully automated detection, extraction of features, segmentation, and categorization is essential. A series of steps involved in image processing is utilized on MRI images to do brain tissue segmentation, and categorization of images that were inspired from proposed algorithms, and its background knowledge is analyzed in this section.

A. Fuzzy C-Means Clustering Algorithm

Generally, C-Means are the commonly used and most known clustering models because it is a smallest square model. Fuzzy C-Means is very widespread due to its handling capability of overlying clusters when compared with C-Means clustering algorithm. Based on fuzzy integration, FCM instructs each pixel (data points) to clusters. Let $Y = \{y_1, y_2, \dots, y_l, \dots, y_O\}$ be the set of O objects and $W = \{w_j, \dots, w_j, \dots, w_d\}$ be the set of d centroids; where $Y = \{y_1, y_2, \dots, y_l, \dots, y_O\}$ be the set of d centroids; where $y_l \in S^n$, $w_j \in S^n$and $w_j \in Y$. It separates Yinto $d$clusters by iteratively reducing the function of objectives:

$$K = \sum_{i=1}^{d} \sum_{y_l \in C(Y)} \left(\eta_{jl}\right)^x \|y_l - w_i\|^2 \quad (1)$$

Where $1 \leq n < \infty$ is the operator in fuzzifier, w_i represents the j^{th} centre of force correlated to cluster Y_j, $\eta_{jl} \in [0,1]$ is the patterns fuzzy integration y_l to cluster Y_j, and distance criteria is represented as $\|\bullet\|$. The resulting partition is controlled by fuzziness parameter n, where $n = 2$ is used. The pixel near to a centre of cluster achieve membership value as high then the function of objective is reduced and those distant from it are designate the membership value as low. The value of membership depends on the proportional distance of the object to centre of cluster as inverse. Algorithm is outlined as follows:

- Allot initial centre of force w_j, $j \in 1$ to $d$for clusters.
- Find d value of membership for O pixel by following:

$$\eta_{jl} = \frac{1}{\sum_{i=1}^{d} \left(\frac{\|y_l - w_j\|}{\|y_l - w_i\|}\right)^{\frac{2}{n-1}}} \quad (2)$$

And update cluster centers as,

$$w_j = \frac{\sum_{l=1}^{O} \eta_{jl} \times y_l}{\sum_{l=1}^{O} \eta_{jl}} \quad (3)$$

Subjected to

$$\sum_{j=1}^{d} \eta_{jl} = 1 \nabla land 0 < \sum_{l=1}^{O} \eta_{jl} < 1 \quad (4)$$

In a cluster, each dataset is assigned, and it carries the membership value is high. If the membership value is low, then the belongingness is also low. Iterate steps two again until the center of gravity stabilizes that are the previous iteration is identical to the present iteration, and there is no additional work. The point which is to be noted is the dependency of FCM on proportional interval among the centre of clusters and the data points, which makes it delicate to boisterous.

B. Rough Set Theory

Rough set theory is based on idea of space of approximation and it is designated by two attributes. Lower estimation, $S_U(Y)$, Upper estimation of the Rough set, $S_L(Y)$ is describe as, Here, subset is denoted as $Y \subseteq Uni$,and Uni is represented as universe, S is the Uni connection of equivalent then we have:

$$S_U(Y) = Uni\{Z \in Uni/S | Z \subseteq Y\} \quad (5)$$

$$S_L(Y) = Uni\{Z \in Uni/S | Z \cup Y\} \neq \varphi \quad (6)$$

Where φ represents empty set.

The lower approximation $S_L(Y)$ is the union of all the elementary sets which are subsets of $Y$and the upper approximation $S_U(Y)$ is the union of all the elementary sets which have a non-empty intersection with Y. The interval $B(Y) = [S_L(Y), S_U(Y)]$ is the delineation of a normal set Yin the space of approximation $< Uni, S >$ or simply it is called Y rough set. The bottom set of approximation describes that all elements were surely refer to Y, whereas in approximation is upper, and then it is a collection of those elements that definitely belong to Y. An object y_l can be lower most part of any approximation. If $y_l \in S_L(Y)$ of cluster Y then simultaneously $y_l \in S(Y)$. If y_l is not a part of any lower approximation, then it belongs to two or more upper approximations.

C. Grasshopper Optimization Algorithm

Optimization refers to attain the best result in a solution space in regard to some predetermined norms. Among several optimization algorithms, GOA is considered to be the efficient technique to find out the best solution. Generally, Grasshopper is a catastrophic insect in agriculture, and it has two stages, nymph and adulthood. Normally, the nymph Grasshopper has no wings, and it eats all vegetation in its path. After a period of time, the wings were grown slowly, and it flies in the air and moves to a large distance in a certain time. Moreover, the grasshoppers' nature is individual; and grasshoppers were joining as a big hive of all beings. The measurements of the hive may be of small size, and it is incubus for farmers. The behavior of hive is found in both phases of grasshoppers, and it is a unique aspect of grasshoppers. The key distinctive of the hive is a slow movement in their phase of larval, and it is the fewer steps for grasshoppers. Distant range and sudden motion is the necessary characteristic of the troop in adulthood. The other characteristic of grasshopper troops is searching of foods by dividing their process of search into two, namely exploration and exploitation. Here each Grasshopper illustrates an answer in the community. Fig. 1 shows the general framework of the grasshopper optimization algorithm:

To replicate the swarming behavior of grasshopper, mathematical model is done and is represented as follows:

$$Y_j = R_j + H_j + A_j \quad (7)$$

Where,Y_j represents the $j - th$ grasshopper position, R_j is the interaction on social, H_j is the $j - th$ grasshopper gravity force, and A_j shows the advection of wind.

1) Social interaction: The element fully replicates the movement of grasshoppers, yet the component which is mainly originated from the grasshoppers and it is discussed below:

$$R_j = \sum_{\substack{i=1 \\ i \neq j}}^{M} t(e_{ji})\, \hat{e}_{ji} \quad (8)$$

Where, distance between $j - th$ grasshopper and $e_{ji}$is $i - th$ grasshopper and it is defined as,

$$e_{ji} = |y_i - y_j| \quad (9)$$

Here, t is a function to define the social forces strength, as shown in equation (9) and e_{ji} is a unit vector from the $j - th$ grasshopper to the $i - th$ grasshopper which can be defined as,

$$\hat{e}_{ji} = \frac{y_i - y_j}{e_{ji}} \quad (10)$$

The function, t defines the social force, is calculated as follows:

$$t(s) = g f^{\frac{-v}{m}} - f^{-s} \quad (11)$$

where g indicates the intensity of attraction and l is the attractive length scale. The grasshopper's impact on social interface is shown as function t. The parameters were adjusted for social force g and m which is not suitable for applying strong forces among grasshoppers with large distances among them.

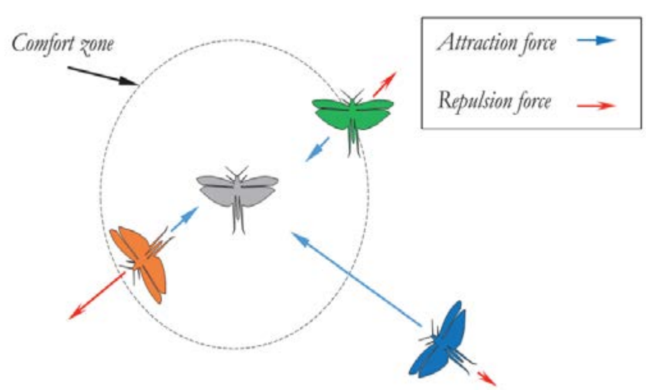

Fig. 1. Generalized Framework of Grasshopper Optimization Algorithm.

For providing random behavior, the equation can be describe as

$$Y_j = s_1 R_j + s_2 H_j + s_3 A_j \tag{12}$$

Where s_1, s_2 and s_3 are random numbers in [0, 1].

2) Gravitational force: The enhanced grasshopper force of gravity is represented below:

$$H_j = -h\hat{f}_h \tag{13}$$

Where h is the constant value in gravitational and $\hat{f}_h$ shows a union vector towards the center of gravity.

3) Wind advection: The grasshopper advection can be calculated as follows:

$$A_j = v\hat{f}_w \tag{14}$$

where, v is constant drift and $\hat{f}_w$ is a unity vector in the direction of wind. Movements of grasshoppers are coordinate with the direction of wind because it has no wings. The values of $T, H\&B$ are substituted in equation (7) and is expanded as follows:

$$Y_j = \sum_{\substack{i=1 \\ i\neq j}}^{M} t\left(\left|y_i - y_j\right|\right)\frac{y_i - y_j}{e_{ji}} - h\hat{f}_h + v\hat{f}_w \tag{15}$$

where, M represent the number of grasshopper.

V. Proposed Brain Tumor Tissue Detection Methodologies

The primary objective is to outline and build up a technique for classifying MRI brain images using various stages. The redundant data will be reduced by the rough sets and also reduced data to achieve information dimension and also reduction in accuracy and sensitivity. And also, problems in the definition of fuzzy similarity relations. These limitations need to overcome. Therefore, to achieve a better outcome, the Improved Rough FCM is used. The block illustration of the proposed methodology is demonstrated in Fig. 2. Subsequently, a novel brain tissue classification method using MRI images is presented by utilizing Improved Rough Fuzzy C Means algorithm and optimal fuzzy interference system (OFIS) to classify the brain tumor as background (BG), gray matter (GM), White matter (WM), Cerebrospinal Fluid (CSF), and tumor tissues (TT). To accomplish this, the proposed framework is comprised of five modules, namely,

- Pre-processing by speckle noise removal
- Segmentation using Improved RFCM.
- GLCM based feature extraction.
- Brain tissue Classification by OFIS.
- Optimization by means of EGOA.

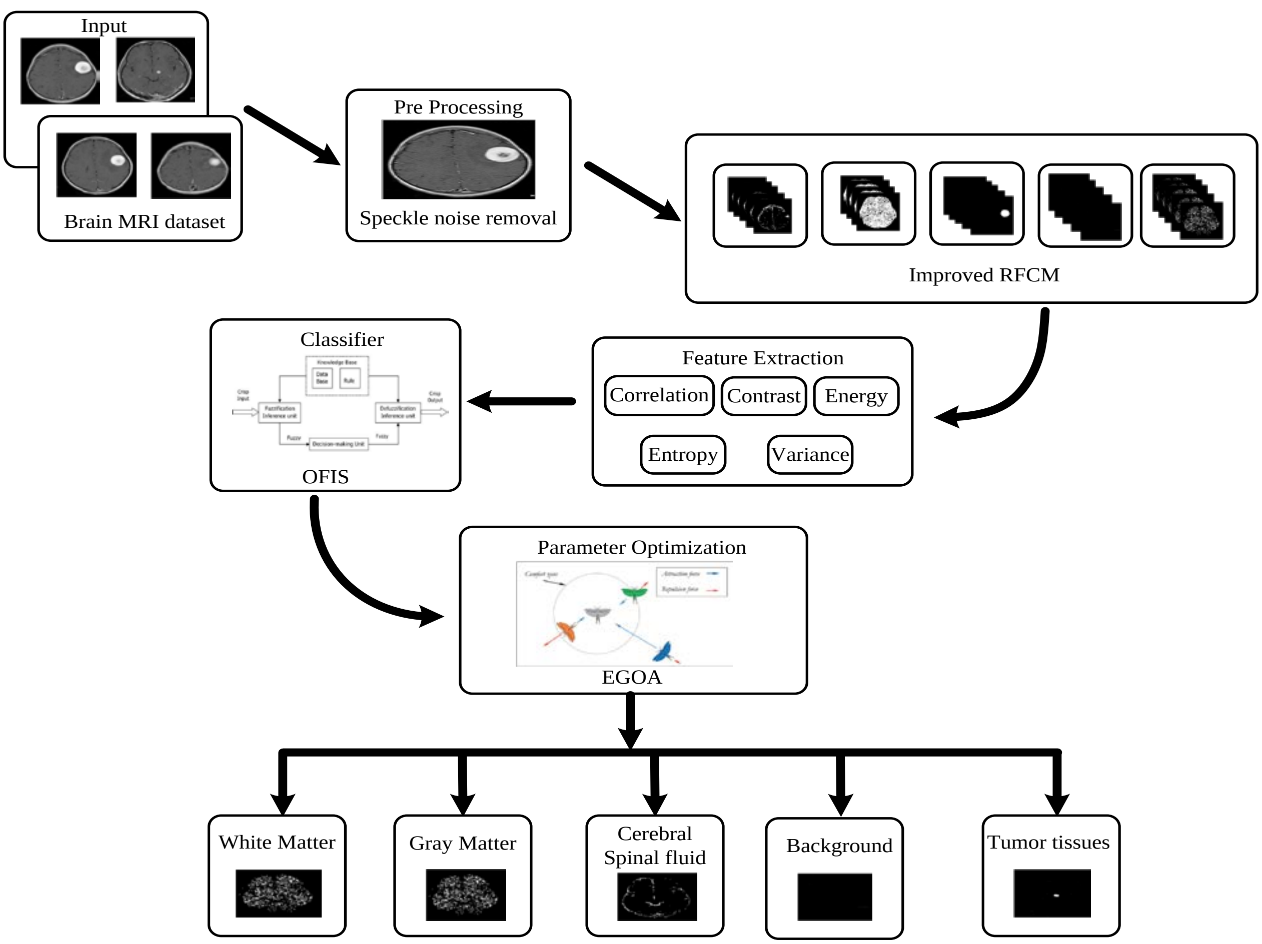

Fig. 2. Block Diagram of the Proposed Methodology.

Initially, the brain MRIs are given to the pre-processing stage, where speckle noise removal is applied to remove the noisy content of the input image. Further segmentation is carried out to segment the tissue based on clustering using Improved RFCM. Then the features are extracted using GLCM. The OFIS classifier is generated for those extracted features, and its parameter gets optimized through EGOA, where the brain tissues are classified as WM, GM, CSF, BW, and TT. The proposed methodology is briefly clarified in the below sections.

A. Pre-Processing

Pre-processing is carried out to eliminate contaminants or noisy data from the picture. Moreover, one of the primary challenges in the processing of medical images is to reduce noise. Different techniques for noise reduction were addressed in prior works. Speckle noise is usually observed in medical pictures. This noise can affect the segmentation quality of the image. The mathematical model of the speckle noise can be represented as:

$$h(o,n) = \xi(o,m) + g(o,n) * v(o,n) \quad (16)$$

Where, $h(o,n)$ defines the input image observed from MRI, $v(o,n)$ represents the multiplicative and the speckle noise additive element is denoted as $\xi(o,n)$, the sample image both axis is represented as $v(o,n)$. The additive noise element is neglected for the noise elimination, which is expressed in equation (17).

$$h(o,n) = g(o,n) * v(o,n) \quad (17)$$

The above equation defines to be the noise eliminated image. After reducing the noise, the image is segmented based on pixel similarity using Improved RFCM algorithm.

B. Tissue Segmentation using Improved Rough Fuzzy C-Means Clustering Algorithm

After pre-processing, the brain MRI images are formed as a cluster concept for the function of tissue segmentation. Novel improved fuzzy C-Means method is used to segment the brain tissue types based on pixel similarity. Consequently, the hybrid rough fuzzy C-Means algorithm is compared with the other methods for validating the effectiveness of the developed model in segmenting brain MRI images.

1) Improved rough fuzzy c-means clustering: A Rough Fuzzy based clustering procedure is a combination of rough sets along with fuzzy sets methods. The rough sets approximation of upper and lower in addition to the concept of the membership of the Fuzzy set is integrated into the C-means clustering. The RFCM partitions a set of objects as o into clusters d by minimizing the objective function.

$$K(Uni,W) = \begin{cases} \psi_{low} \times \beta + \psi_{high} \times \alpha, if S_L(Y_j) \neq \varphi, C(Y_j) \neq \varphi \\ \alpha, if S_L(Y_j) \neq \varphi \\ \beta, if S_L(Y_j) \neq \varphi \end{cases} \quad (18)$$

where

$$\beta \Rightarrow \sum_{j=1}^{d} \sum_{y_l \in S_L(Y)} \left\| y_l - w_j \right\|^2 \quad (19)$$

$$\alpha \Rightarrow \sum_{j=1}^{d} \sum_{y_l \in C(Y)} \left\| y_l - w_j \right\|^2 \quad (20)$$

Where W_j denotes the j^{th}cluster Y_j centroid, the ψ_{low} and ψ_{high} parameter corresponds to the qualified position of lower bound and border area, that leads to $\psi_{low} + \psi_{high} = 1$. Consider that η_{jl} has the identical membership function by means of that placed in fuzzy C-Means. From the computation of β using equation (19) that weights of objects in below approximation are fuzzified in RFCM. To some extent, the centroids updating using equation (19) may lessen the significance of objects in lower approximation and cause the subsequent centroids to float away from right areas [22]. To avoid this problem, a new centroids equation is proposed. The centroids updating for IRFCM is given in equation (21).

$$K(Uni,W) = \begin{cases} \psi_{low} \times \beta + \psi_{high} \times \alpha, if S_L^C(Y_j) \neq \varphi, C_1(Y_j) \neq \varphi \\ \alpha, if S_L^C(Y_j) \neq \varphi, C_1(Y_j) = \varphi \\ \beta, if S_L^C(Y_j) = \varphi, C_1(Y_j) \neq \varphi \end{cases} \quad (21)$$

$$\beta = \frac{1}{|S_L^C(Y_j)|} \sum_{x_j \in S_L^C(Y_j)} x_j \quad (22)$$

$$\alpha = \frac{1}{n_j} \sum_{x_j \in C_1(Y_j)} (\mu_{ij})^m x_j \quad (23)$$

$$n_j = \sum_{x_j \in C_1(Y_j)} (\mu_{ij})^m \quad (24)$$

Using this function, we can improve the clustering accuracy.

C. GLCM based Feature Extraction

After clustering, the feature extraction process is done to the segmented image. The functional extraction phase aims to reduce the original data set by identifying the essential characteristics. By selecting ideal characteristics, classification outcomes are strongly affected. The GLCM based extraction approach is used in this proposed study. Moreover, Haralick's GLCM calculated texture features are a typical approach for representing picture texture as they are easy to implement and result in a collection of interpretable texture descriptors. GLCM is a pixel pitch and direction statistical approach which analyses the picture texture through the spatial connection of the pixels. Let consider, GLCM $(p_{prob}, q, \varphi, r, s)$ regulates the pixel with intensity 'r' ensues in compared with another pixel 's' at distance 'q' and direction 'φ'. Also, the GLCM feature extraction can control up to 14 features. At this period, several of the most significant texture characteristics were determined such as correlation, energy, contrast, and entropy.

1) Correlation (F1): Correlation is defined as the duration of the link between pixels and their nearby pixels. Also, the correlation is estimated by the equation (25) as,

$$Corr = \sum_{r=0}^{P-1} \sum_{s=0}^{P-1} \frac{[r*s]*log(M(r,s)) - [\mu_b * \mu_c]}{\sigma_b * \sigma_c} \quad (25)$$

Where, μ_b, $\mu_c$and σ_b^2, is the mean and σ_c^2 is the variance of r, s, are given as,

$$\mu_b = \sum_{r=0}^{P-1} r \sum_{s=0}^{P-1} M(r,s); \mu_c = \sum_{r=0}^{P-1} s \sum_{s=0}^{P-1} M(r,s) \quad (26)$$

$$\sigma_b^2 = \sum_{r=0}^{P-1} (I_b(r) - \mu_b(r))^2;$$

$$\sigma_c^2 = \sum_{s=0}^{P-1} (I_c(s) - \mu_c(s))^2 \quad (27)$$

2) Contrast (F2): Because of the local similarity of a picture, contrast is stated as the change in luminance. Furthermore, it is estimated using the following equation (28).

$$Cont = \sum_{p=0}^{P-1} p^2 \{\sum_{r=1}^{P} \sum_{s=1}^{P} M(r,s)\}, |r - s| = p \quad (28)$$

where, $M(r,s)$ is represented as Co-occurrence Matrix.

3) Energy(F3): The energy also influences the uniformity of the images. Energy is defined as the total of the GLCM Angular Second Moment entry squares. The second angular moment is large if the picture is extremely homogeneous otherwise if pixels are very similar. The energy is calculated by the equation (28) as follows:

$$Ene = \sum_{r=0}^{P-1} \sum_{s=0}^{P-1} M(r,s)^2 \quad (29)$$

4) Entropy(F4): Entropy is defined as showing the quantity of image data to enable compression by evaluating image data loss. Consequently, the entropy can be articulated as equation (30) as follows:

$$Ent = -\sum_{r=0}^{P-1} \sum_{s=0}^{P-1} M(r,s) * log_2(M(r,s)) \quad (30)$$

5) Sum of Squares (F5): Variance or Sum of squares is an arithmetical system, and it is used in regression study to found the dissemination of data location.

$$V = \sum_{r=0}^{P-1} \sum_{s=0}^{P-1} (r - \mu)^2 \quad M(r,s) \quad (31)$$

This feature places relatively high weights on components which differ from the typical standard value which is referred as $M(r,s)$.

D. Optimal Fuzzy Inference System(OFIS) for Classification

To achieve the optimal classification, the correlation, energy, contrast, sum of square variances and entropy of extracted features are provided to the FIS method. There are three main operations performed in the fuzzy inference scheme: initial Fuzzification, evaluation of rule, and the process of Defuzzification. Fuzzy inference is the technique to map with a fuzzy logic from a given input to an output. Then the mapping offers a framework for making judgments or discerning trends. In the fuzzy inference scheme function, different types of process are proceed such as Logical Operations, Membership Functions (MF) and the rule of If-Then. For performing fuzzification process, collected all the extracted features values of segmented images and estimated all feature minimum (m_n) and maximum (m_x) values. The performance of fuzzification operated by the subsequent equations (32) and (33):

$$m_n L^{(Corr)} = m_{in} + \left(\frac{m_x - m_n}{3}\right) \quad (32)$$

$$m_x L^{(Corr)} = m_n L^{(Corr)} + \left(\frac{m_x - m_n}{3}\right) \quad (33)$$

Where $m_x L^{(Corr)}$ and $m_n L^{(Corr)}$ are the maximum and minimum limit standards of the feature $Corr$. The similar derivation are utilized for the features such as$(Cont)$, (Ene), (Ent) and (V) are required to compute the minimum and maximum limit values. The schematic diagram of the fuzzy inference system (FIS) is shown in Fig. 3.

In the fuzzification stage, the input crisp values of five features namely correlation $(Corr)$, contrast $(Cont)$, energy (Ene), entropy (Ent) and variances (V) are given to the OFIS classifiers which are transformed into fuzzy variables. Also, the membership function (MF) is evaluated for all fuzzy variable in this system. For each feature, fuzzy variables are classified in the range [0, 1] and are classified as Low (L), Lowest (LL), medium (M), high (H) and Highest (HH). Moreover, the fuzzy variables of the output are WM, GM, CSF, BG and TT. Triangular MF and Trapezoidal MF are used in this model to get optimal outcomes. These triangular MF and Trapezoidal MF are used for a boundary as well as intermediate variables. Fig. 4 and 5 shows the MF of fuzzy variables for the input variables and MF of the output variable.

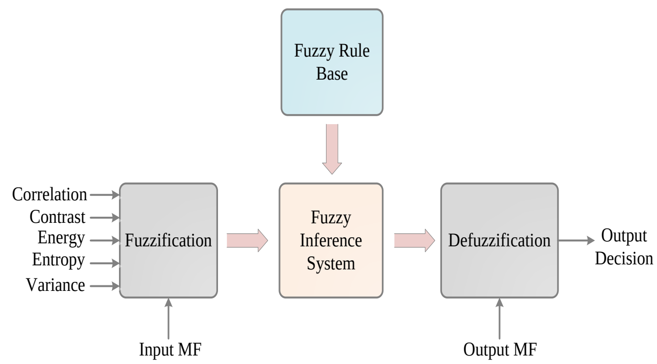

Fig. 3. Fuzzy Inference System Structure.

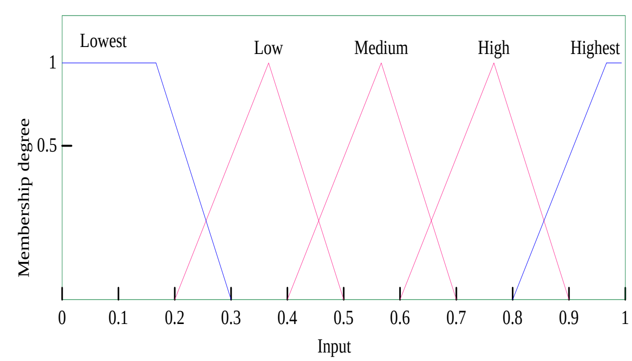

Fig. 4. Membership Function of Input Features.

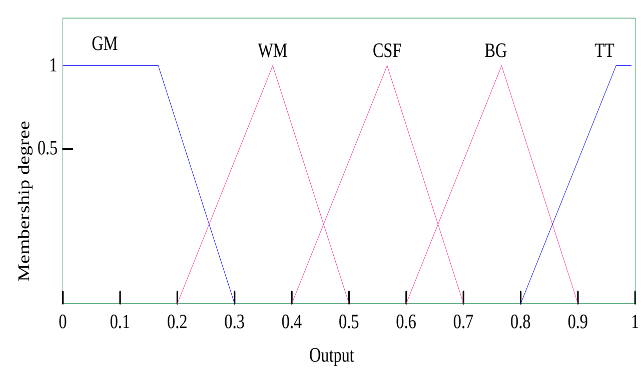

Fig. 5. Output Features of Membership Function.

In the Defuzzification (Z) stage, there are five processes provided to convert the fuzzy set of images into crisp rates for defuzzification. The techniques used for defuzzification are provided as follows as Last of Maxima Method (LOM), Bisector of Area Method (BOA), Mean of Maxima Method (MOM), Center of gravity (COG), and First of Maxima Method (FOM). Then, the sample function of fuzzy rules is demonstrated in Table I.

TABLE I. SAMPLE FUNCTION OF FUZZY RULE

Rule No.	F1	F2	F3	F4	F5	output
1	M	H	L	HH	LL	CSF
2	LL	M	H	L	HH	GM
3	L	H	L	HH	M	WM
4	H	LL	M	L	HH	WM
5	H	LL	M	LL	H	TT
6	HH	L	LL	HH	M	GM
7	M	H	H	M	L	TT
8	L	M	H	HH	HH	CSF
….	….	….	….	….	….	….
n	LL	H	HH	H	M	WM

As shown in Table I, F1, F2, F3, F4, and F5 represent the features for the given image. The rule basis of the FIS system should be updated for each time with the input and output parameters of the MFs altered. Therefore, optimum incorporation of these factors is highly important. The subsequent parameters of the FIS system must be optimized in this approach:

The input variable in triangular MFs must be optimized. For instance, if the triangular shape is assumed as three peak rates like p, q and s, which is illustrated in Fig. 6. The demonstration shows that the variables s and q are fixed when altered the value of p. In this developed FIS function, the triangular shapes are considered to all input variables and those parameters should be optimized for further processing.

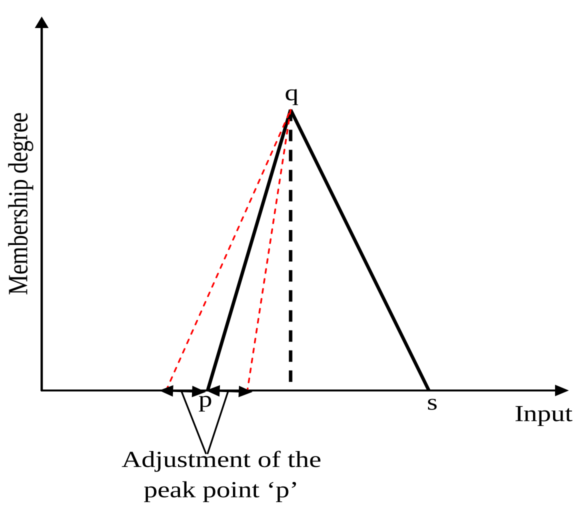

Fig. 6. Triangular MF Peak Points Position.

The optimal fuzzy rules are optimally chosen by the mid fuzzy rules. Consequently, optimal defuzzification process estimated along with the defuzzification methods (Z) and these parameters.

Thus, the FIS parameter has been chosen as the first solution. The selection of the best available solution provides maximum network accuracy. Therefore, an optimization technique is developed for FIS design difficulties that should be given, so that identify an ideal FIS and reduce preliminary modification time. A novel EGOA method is provided in this technique for the optimization of the FIS system parameters.

1) Parameter optimization by Enhanced Grasshopper Optimization Algorithm (EGOA): The parameter used in the FIS method is significantly optimized by the developed EGOA method for enhancing the performance of brain tissue, which is described in this section. The developed EGOA algorithm linked FIS system scheme step by step process is explained as follows:

a) Initialization: Initially, the parameters of FIS system is initialized arbitrarily and the EGOA parameters are also initialized. Furthermore, the population size N along with the candidate outcomes and agent's location is also initialized. The configuration of solution is represented in Fig. 7.

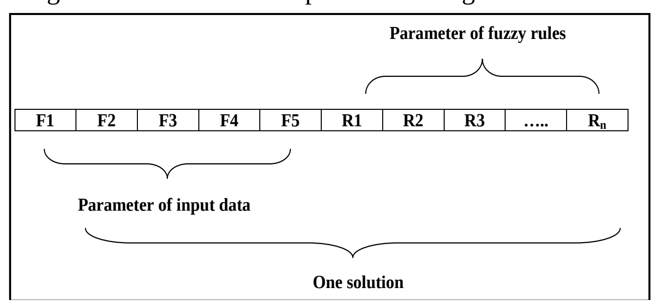

Fig. 7. Generalized Structure of the Solution.

Consider, d dimensional space for the initialized candidate solutions and agents location using equation (34).

$$Y = \{FIS_1, FIS_2, FIS_3 \ldots., FIS_d\} \tag{34}$$

Where, d^{th} dimension of optimal FIS solution or the agent location is denoted as FIS_d. Then, constraints of the input parameter are given as follows:

$$\{p_n \le x_n \le s_n; \quad n = 1,2,3,4 \tag{35}$$

b) Fitness calculation: After finishing the primary solution of generation process, the fitness value is evaluated. In this work, the utmost accuracy is considered as a fitness function. Also, the fitness rate of this proposed system is estimated by given equation (36).

$$Fitness = m_{ax}(Accuracy) \tag{36}$$

$$Accuracy = \frac{Total.TN + Total.TP}{Total.TN + Total.FN + Total.TP + Total.FP} \times 100 \tag{37}$$

c) Updation of using GOA parameters: Subsequently, the outcomes are updated using GOA parameters after the estimation of fitness value. The Updation function is given in equation (38).

$$Y_j = T_j + H_j + B_j \tag{38}$$

d) Crossover operator: To enhance the GOA, the cross over operator is added to GOA. The crossover operator is the function that is used to choose the genes from the chromosomes of parent and generate fresh offspring constraints. The operation in crossover is articulated by the various parameters such as permutation encoding, binary encoding, tree encoding and value encoding. The Fig. 8 shows cross over process.

e) Mutation operator: After the operation of cross over function, the better solution is updated via mutation. Also, the mutation operator is in compared to crossover that can seek for new regions. The Fig. 9 shows mutation operator. The exploitation fitness is considered as crossover operator and the exploration fitness function is worked by the mutation operator.

f) Termination criteria: Up to the ideal solution, the optimal FIS system, procedures are continued. Once the optimal FIS system has been achieved, the algorithm has closed the process of segmentation. This improved FIS system is utilized as a system for tissue categorization, which enhances the system's overall accuracy. The proposed EGOA method pseudo-code is demonstrated in Algorithm 1.

Algorithm 1: Pseudo code of proposed EGOA
Input : Parameter of FIS and parameter of GOA,
mutation rate 0.2, Crossover rate 0.1.
Output: optimized FIS.
Start:
Initialization: population size($\boldsymbol{M}$),$\boldsymbol{c_{max}}$, $\boldsymbol{c_{min}}$and maximum number of iteration ($\boldsymbol{s_{max}}()$)
Generate a random population ($\boldsymbol{Y}$)
Set the current iteration $\boldsymbol{s = 1}$
While ($\boldsymbol{s < s_{max}}()$) do
Evaluate the fitness of each solution by equation (37)
Renew the value of solution by equation (38)
Apply crossover operator
Apply mutation operator
$s = s + 1$
End while
End
Output: Optimized FIS

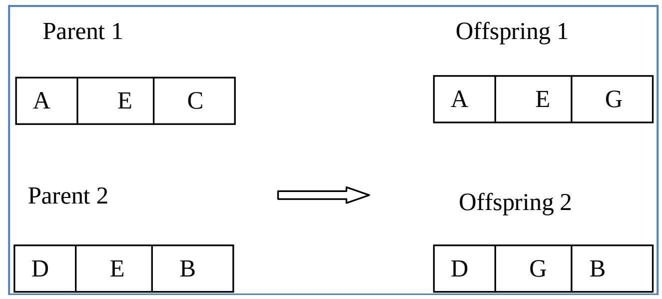

Fig. 9. Mutation Operator.

VI. Results and Discussion

In this section, the consequences and discussion around brain tissue segmentation and classification by using Improved RFCM and OFIS. The proposed configuration has been tested on the data sets of brain MRI named as BRATS 2017. Consequently, the performance of the proposed system is evaluated by the comparison of developed model outcomes with the conventional like Default FIS and KNN.

Accuracy is the proportion of true results among the total number of cases examined. Precision is a valid choice of evaluation metric when we want to be very sure of our prediction. True Positive, True Negative, False Positive, False Negative, sensitivity, and selectivity are the metrics used to know whether correctly predicted or incorrectly predicted the tumor. With these the decision can be taken that the tumor is detected properly or not.

A. Evaluation Metrics

The performance of the developed system is analyzed via the estimation of different evaluation metrics like, Specificity, Sensitivity, PPV, Accuracy, FNR, NPV, and FPR, which are detailed in the subsequent descriptions:

1) Sensitivity: The value of sensitivity is defined as the ratio of total true positives to the summation of total false negative and false positive value.

$$Sensitivity = \frac{Total.TP \rightleftarrows value}{Total.FN + Total.\rightleftarrows\rightleftarrows TP} \tag{39}$$

2) Specificity: The parameter of specificity is defined as the ratio of total true negatives to the summation of total true negative and false positive value.

$$Specificity = \frac{Total.TN}{Total.FP + Total.TN} \tag{40}$$

3) Accuracy: The accuracy metrics are estimated by the parameters value of specificity and sensitivity, which is expressed by equation(41).

$$Accuracy = \frac{Total.TN+Total.TP}{Total.TN+Total.FN+Total.TP+Total.FP} \quad (41)$$

4) Positive Predictive Value (PPV): The rate of PPV is estimated for the positive proportion of experimental and numerical results, which is articulated in equation(42).

$$PPV = \frac{Total.TP}{Total.TP+Total.FP} \quad (42)$$

5) Negative Predictive Value (NPV): The rate of NPV is estimated for the negative proportion of experimental and numerical results, which is articulated in equation(42).

$$NPV = \frac{Total.TN}{Total.TN+Total.FN} \quad (43)$$

6) False Positive Rate (FPR): The rate of FPR is estimated as the ratio of amount of overall incorrect positive forecast to the summation of overall true negative and false positive values. Also, it is estimated from the specificity as referred as 1-specificity value.

$$FPR = \frac{Total.FP}{Total.FP+Total.TN} \quad (44)$$

7) False Negative Rate (FNR): The rate of FNR is estimated as the ratio of amount of overall incorrect negative forecast to the summation of overall true positive and false negative values.

$$FNR = \frac{Total\ FN}{Total\ FN+Total\ TP} \quad (45)$$

B. *Experimental Setup*

The main innovation of this proposed methodology is tissue classification in MRI brain images by multiple phases. Moreover, the performance of the proposed multiple stage execution is validated with the use of various evaluation metrics estimation. In this article, the functions have been characterized the performance measure based on considered tissue types. The foremost aim of the proposed work is to recognize the type of brain tissue in input MRI's. Also, the comparative analysis is provided between the proposed OFIS technique with prevailing methodologies such Default FIS and KNN techniques. The sample collected image is specified in Fig. 10.

Initially, pre-processing is applied to the taken input images to remove the noisy content. Segmentation is carried out for the pre-processed images using the Improved RFCM algorithm. Consequently, the GLCM method is used for the extraction of foremost features from the pre-processed images. Finally, a novel OFIS classifier is executed to classify brain tissue images. The obtained segmented results for the given input images with proposed Improved RFCM technique is shown in Table II.

The proposed segmentation algorithm performance is validated in terms of segmentation, specificity as well as accuracy which are shown in Table III. In this article, IRFCM algorithm is utilized for the purpose of segmentation. IRFCM is a combination of roughest and fuzzy C-Means which is overcome the challenges present in the individual FCM method and rough set theory. While examining Table III, it shows that the proposed approach attains the utmost accuracy of 0.972. However, using rough FCM method has attained only 0.970 and 0.969 is achieved for the use of Rough K-Means algorithm. Similarly, sensitivity and specificity also proposed approach attain the better results.

Average of Tissues		0.927	0.987	0.969	0.927	0.988	0.970	0.936	0.989	0.972

Fig. 11 illustrates the average measure obtained by the proposed IRFCM and existing RFCM and RK-means techniques for FPR and FNR measures. In the proposed method, the MR image is initially segmented by Improved RFCM. Then successfully, the tissue parts of brain MR images are classified by choosing the parameters optimally. The proposed system is mainly developed for the association of brain images tissue identification.

Fig. 12 describes the segmentation outcome of different measures like sensitivity, specificity, accuracy, PPV and NPV for proposed and existing technique. Thus, the developed IRFCM method achieves the efficient result than existing techniques.

An input sample image is tested by the proposed approach in GUI representation is shown.

The Graphical User Interface (GUI) based sample output and taken input test image is demonstrated in Fig. 13. Since, the test image of input is uploaded, then it provides the classification and segmentation consequences in the display. Thus, this GUI linked proposed approach can shows the corresponding outputs even varying the input test image of different MRI brain pictures.

Fig. 14 and 15 is a GUI example for the different images given. The results of this are evaluated by changing the input image. The resultant values obtained by the evaluation metrics such as Specificity, Sensitivity, PPV, Accuracy, FPR NPV, and FNR for existing Default FIS, KNN and the proposed OFIS technique under a sample test images. By analyzing the performance metrics, the sensitivity of proposed methodology is 0.95, accuracy is 0.975, PPV is 0.95 which is more superior than other existing techniques. Similarly, NPV, FPR and FNR give better performance for proposed technique than existing techniques.

TABLE IV. COMPARISON BETWEEN PROPOSED AND EXISTING METHODS FOR DIFFERENT METRICS

Evaluation metrics	KNN	FIS	*Proposed OFIS*
PPV	0.77	0.81	0.95
NPV	0.925	0.926	0.98
FPR	0.075	0.058	0.01
FNR	0.225	0.225	0.05

The obtained experimental results of the MRI images for the proposed OFIS and different existing technique for metrics PPV, FPR, NPV, and FNR are shown in Table IV. Thus, the comparative analysis from the graph shows that the proposed technique function is significantly enhanced, which is finest for identifying the portion of tissues in brain MRI images.

VII. CONCLUSION

Brain tissue classifications are the foremost challenging feature in the diagnosis of diseases via medical images. In this work, an efficient approach is proposed to identify the type of brain tissue of MR images. To this classification, primarily, the input of MRI brain image is pre-processed by speckle noise removal method to eliminate the noisy contents contemporaneous in the input image. The pre-processed image is then segmented using an Improved RFCM algorithm based on the clustering mechanism. Next to this, significant texture features are alone extracted by the use of the GLCM feature extraction technique. Afterward, the features were extracted from the previous function are fed into the stage of classification. In that place, OFIS is applied to classify images as WM, GM, CSF, BG, and TT. In OFIS, its parameter is optimally chosen via EGOA for optimally classifying brain tissue. The whole work is executed in the working of MATLAB® platform. The performance of the developed model is analyzed by the evaluation metrics to differentiate the developed and conventional approaches. The complete analysis shows that it is clear that the proposed technique accomplishes an efficient outcome over existing techniques. In future work, the extra information can be added to improve the system as more sensitive; the data for the analysis will consider from the location or textures. In addition to this, future work can be focused on the pathological investigations of classification with the basic goals of monitoring as well as locating the lesions in tissues of the brain.

Empirical Validation of WebQMDW Model for Quality-based External Web Data Source Incorporation in a Data Warehouse

Priyanka Bhutani, Anju Saha, Anjana Gosain
USIC&T, GGSIP University, Dwarka, New Delhi, India

***Abstract*—In recent years, World Wide Web has emerged as the most promising external data source for organizations' Data Warehouses for valuable insights required in comprehensive decision making to gain a competitive edge. However, when the Data Warehouse uses external data sources from the Web without quality evaluation, it can adversely impact its quality. Quality models have been proposed in the research literature to evaluate and select Web Data sources for their integration in a Data Warehouse. However, these models are only conceptually proposed and not empirically validated. Therefore, in this paper, the authors present the empirical validation conducted on a set of 57 subjects to thoroughly validate the set of 22 quality factors and the initial structure of the multi-level, multi-dimensional WebQMDW quality model. The validated and restructured WebQMDW model thus obtained can significantly enhance the decision-making in the DW by selecting high-quality Web Data Sources.**

***Keywords*—Data warehouse; external data sources; web data sources; quality evaluation model; quality model validation**

I. Introduction

The importance of incorporating external data in the Data Warehouse to gain valuable insights into the market, competitors, products, or customers for comprehensive and unbiased decision making, has been long recognized in the research literature [1], [2]. The use of World Wide Web (WWW or Web) [3] as an external data source for the Data Warehouse (DW) [4] has grown considerably over the past few years [5]–[16]. The WWW helps provide a wide-angle lens for the decision-making in organizations in a very low-cost and highly accessible manner [4] (see Fig. 1). It is a known fact that the quality of the DW data sources hugely impacts the quality of the DW itself [1], [2]. This fact makes the quality-aware evaluation and selection of high quality, credible, and compatible Web Data Sources (WDSs) a very crucial task in the incorporation of Web data in the DW [4], [17]–[27]. There are, however, many challenges in this task like the availability of a massive amount of information, the heterogeneous structure and format of the Web Data [4], the dynamic nature [17], and poor reliability [18] of a significant chunk of Web Sources.

For the aforementioned task of quality-aware evaluation of Web Data Sources for a Data Warehouse, various quality models, frameworks, or a set of factors have been proposed in the research literature (see, for example, [19], [22]–[24],[4], [21], [20], [25], [26]). However, these quality models are only conceptual in nature. To the best of the authors' knowledge, none of these quality evaluation models for evaluating WDSs as external data sources for a DW have been empirically validated to corroborate their applicability in this problem area. In order to fill this research gap, in this paper, we present the empirical validation of the state-of-the-art multi-level, multi-dimensional WebQMDW (Web quality model for evaluating web sources for the DW) quality model [27] to enhance the decision making in a Data Warehouse. WebQMDW model [27] is the first of its kind model which segregates the quality factors in such a way to introduce automated quality evaluation as screening (at the first level) and separation of expert evaluation of different expert areas into different dimensions (at the second level). The present work complements and extends the authors' previous work [27] of the quality-based evaluation of the websites of academic institutions for incorporation as WDSs in a University DW. The said work proposed and used the novel $WSEM_{QT}$ (Web source evaluation with multi-criteria decision-making methods and web quality testing tools) process in conjunction with the underlying novel WebQMDW quality model. We believe that the empirical validation of the WebQMDW model will be an important milestone in the quality evaluation of WDSs for a DW, aiding the DW professionals in providing advanced data analytics for decision-making in the organization.

Hence, the objective of this paper is the empirical evaluation of the WebQMDW model in order to

- Validate the set of quality factors of the WebQMDW model; and eliminate or add new factors, if indicated by the validation results.
- Validate that the quality factors have been suitably placed in the level/dimension of the WebQMDW model; or if they should be placed in a different level/dimension according to the validation results.

The rest of the paper's overall arrangement is as follows: Section II discusses the frame of reference of the current work, including the related work, WebQMDW quality model, and motivation. Section III presents the empirical validation process of the WebQMDW model, including the analysis of results and restructuring of the model. Section IV discusses the various threats to the validity of the survey and how we dealt with them, followed by conclusion and future work in Section V.

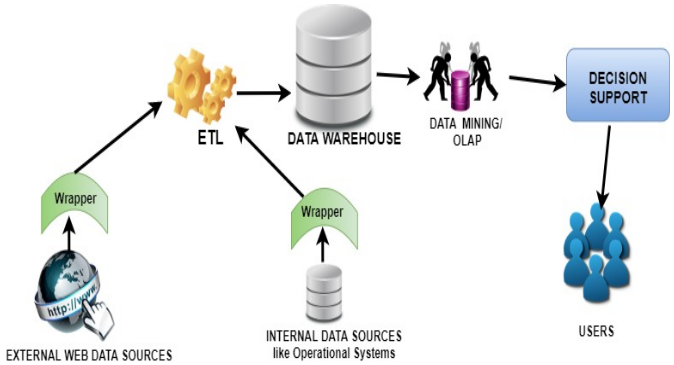

Fig. 1. Web Data as External Data Source for a Data Warehouse.

II. Frame of Reference

A. Related Work and the WebQMDW Quality Model

Quality is a critical and hence, widely researched concept in the context of both software products and data. From the point of view of Data/Information Quality (DQ/IQ), there are established standards (like ISO/IEC 25010/25012 [28], [29]) as well as "de facto" standards (like the Wang and Strong model [30]) in the relevant literature. Due to the peculiar characteristics of Web portals as opposed to a traditional software product, a plethora of research works have specifically addressed the Website/Web portal quality [31]–[33]. The quality evaluation of WDSs for a DW, however, encompasses the data quality as well as the source Website quality because due attention needs to be given to the quality requirements specific to the destination of the WDS incorporation, i.e., the Data Warehouse and the underlying business domain as well [27]. Few of the important works in the area of defining quality factors/models for using the WDSs as EDS for the DW are summarized in Table I. Huang et al. [4] have suggested integrating Web Data in a DW by considering both Quality and Coverage aspects. Quality aspect evaluation is proposed by using quality factors of Speed of loading, Accuracy, Currency, Presentation, Format, Content, and Source as put forward by Rieh [33]. Coverage aspect evaluation is proposed by determining two factors of Scope and Variety. Lóscio et al. [20] have used the three quality parameters of Data Completeness, Schema Completeness, and Correctness for determining the relevance of a WDS for a particular application domain. For a quality-aware Web Warehouse, Marotta et al. have proposed managing Data and Service Quality in their work [21]. In this work, the organization of Data quality is in six dimensions: Reliability, Consistency, Uniqueness, Freshness, Completeness, and Accuracy [21]; Whereas the organization of Service-Related quality is in six dimensions of Stability, Usability, Business Value, Security, Interoperability, and Service Level. The WebQM quality model proposed by Zhu and Buchman [19] has three classes of Web Source Stability, Web Application Specific Quality, and Web Information Quality, used to group the twelve quality factors in this model. These quality factors are Timeliness, Presentation, Relevance, Metadata, Objectivity, Completeness, Correctness, Origin, Refresh Rate, Durability, Accessibility, and Availability [19]. For WDS quality, Mihaila et al. have used the four quality factors: Granularity, Frequency of Updates, Recency, and Completeness. [25]. Naumann et al. used the three quality factors of Availability, Extent, and Understandability in their work [26].

In a previous work, authors have proposed the WebQMDW quality model [27] with 22 quality factors classified in 2 levels (Fig. 2). At Level-1(Automated quality testing level), those quality factors based on which the overall quality of the Website/Webpage can be assessed by using the available website quality testing automated tools are placed. This level has seven quality factors: Performance, Accessibility, Domain Reliability, SEO (Search Engine Optimization), Security, Best Practices, and Web Search Engine Ranking. At Level-2(Expert evaluation level), fifteen quality factors according to which the experts need to evaluate the WDSs are allocated. This level is further divided into three dimensions based on the expert area required for judging them. Dimension 1, with Web Data Related Quality Factors, has five quality factors: Interoperability, Media Format, Cost of Access, Amount of Data, and Timeliness. A Web Data expert evaluates them. Dimension 2, with Data Warehouse Context-related Quality Factors, has five quality factors: Metadata interpretability, Time Period Correspondence, Concise Representation, Consistent Representation, and Completeness. A DW expert evaluates them. Dimension 3, with Business Domain related Quality Factors, has five quality factors: Business Value Addition, Accuracy, Objectivity, Believability, and Uniqueness. A Business Domain Expert evaluates them. In the current work, we choose to focus on this model as the selection and structuring of quality factors is in such a way that it solves the two main issues of the quality evaluation process of Web data sources [27]. The first issue of an enormous load of evaluation on experts is tackled due to the screening of the vast number of web sources to a select few through automated Website quality testing tools at the 1st level of the model. The second issue in previous quality models was the bottleneck of finding experts with expertise in all the related domains of quality evaluation. This issue is also resolved at the 2nd level of the model as different experts need to evaluate the quality factors separated into different dimensions according to the required expertise, namely Web, Data Warehouse, and underlying business domain. The initial structure of the WebQMDW model is shown in Fig. 2. The details of these 22 quality factors in the context of the Web Source Quality evaluation and the detailed account of the model's application to a practical case study of a University DW can be found in [27].

TABLE I. SUMMARY OF SOME WORKS DEFINING QUALITY MODELS FOR QUALITY-BASED EVALUATION OF WDSS FOR DW

Author(s)	Domain	Structure of quality model/ framework	Whether empirically validated? (Yes/No)
Huang et al. [4]	Quality of WDS for DW	2 dimensions; Total 9 QFs	No
Lóscio et al. [20]	Web Data Source quality	Total 3 QFs	No
Marotta et al. [21]	Quality-aware Web Warehouse	2 categories; Total 12 QFs	No
Zhu and Buchman [19]	Quality of WDS for DW	3 categories; Total 12 QFs	No
Mihaila et al. [25]	WWW Source selection	Total 4 QFs	No
Naumann et al. [26]	Quality driven Web Source selection	3 dimensions; Total 3 QFs	No
Bhutani et.al [27]	Quality of WDS for DW	2 levels, 3 dimensions; Total 22 QFs	No

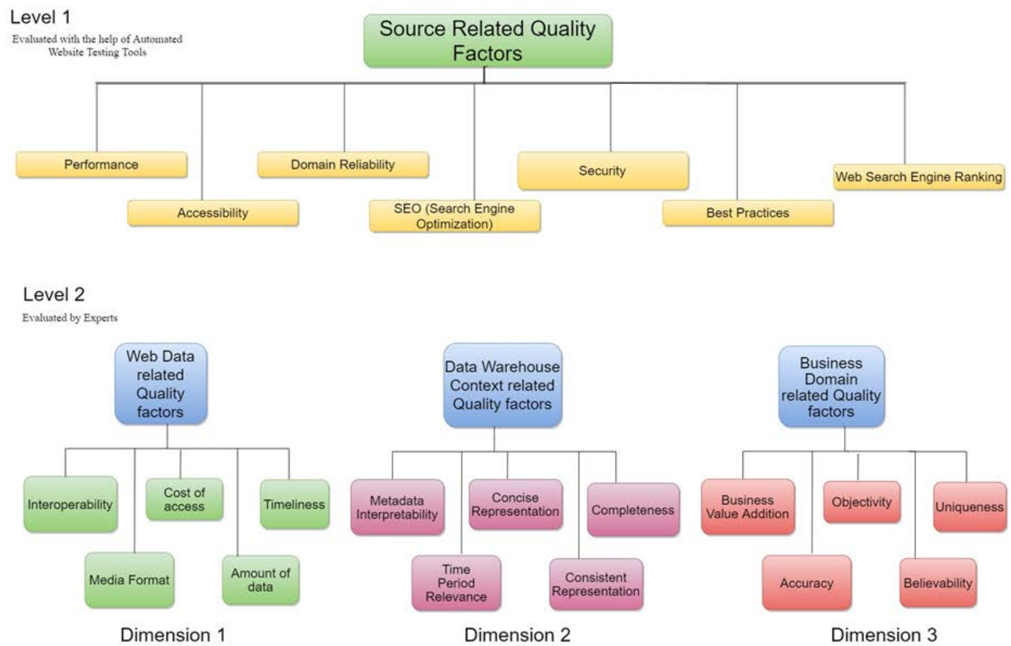

Fig. 2. WebQMDW- a Quality Evaluation Model for Web Data Sources as EDS of a DW [36].

B. Motivation

For any area, after proposing the quality model, the next step is its validation from the perspective of the users of the respective domain. The validation is important due to two reasons. Firstly, it is essential to consider users' choices of quality factors due to their profile, experience, and knowledge in the respective field [34]. Secondly, the robust statistical analysis from the empirical validation attaches confidence to the adequacy of the proposed quality model [35].

In the area of generic quality evaluation of Websites, there are several empirical validations works in the research literature (Table II). The work of Caro et al. [32] validates a quality model for evaluation of the quality of Websites. The research work [36] of Moraga et al. validates a quality model for website quality specifically from the point of view of "University-educated users." A quality model for evaluating health websites' data quality is validated through experts in the work of Liete et al. [35]. Some authors [32], [36] have performed the validation using the survey method. Few authors have used the Delphi method [37] for the validation of the quality models [35].

However, no such validation works of quality models specific to the context of evaluation of WDSs as EDS to a DW (see Table I) could be found in the research literature, to the best of the authors' knowledge and belief. Hence, the current work provides the validation of the WebQMDW model (described in the previous section), which is specific for the said context [27]. It is performed by using the survey method according to the guidelines of the work of Pfleeger and Kitchenham[38]–[43], as described in the subsequent sections (see Sections III and IV).

TABLE II. SUMMARY OF SOME RELATED WORKS DEFINING/ VALIDATING QUALITY MODELS FOR EVALUATION OF WEBSITES

Author(s)	Domain	Structure of quality model/ framework	Whether Validated? (Yes/No)
Caro et al. [32]	Web Portal Quality	4 categories; Total 33 QFs	Yes
Moraga et al. [36]	Web Portal Quality	4 categories; Total 42 QFs	Yes
Liete et al. [35]	Health UnitWebsites' Quality	3 categories; Total 23 QFs	Yes

III. Validation Process of the WebQMDW Model

As described in the previous section, the WebQMDW model has been obtained by bearing in mind the definitions of the quality factors and the defined categories (i.e., levels/dimensions) identified for structuring the factors. This section elaborates the validation process of both the set of quality factors and the initial hierarchical structure of the WebQMDW model.

A. Research Methodology

Several empirical validation methods [44] are described in the research literature, like case studies, controlled experiments, ethnographies, and surveys. The survey method [38]–[44] has a defining characteristic of studying the applicability of the phenomenon on the target population by polling the survey questionnaire on the representative subset of the target population. Bearing in mind that we need to study the applicability of the WebQMDW model in the opinion of the Web and Data Warehouse users (the target population), this was the best applicable method for our work. So, in this paper, we use the survey method as the validation method to thoroughly validate the set of quality factors and the structure of the WebQMDW model while following the guidelines and principles of research proposed by Kitchenham and Pfleeger [38]–[43]. These guidelines describe the various activities for collecting information for describing, comparing, or explaining knowledge, behavior, and attitudes, by using the survey instrument [43].

B. Setting of Objectives

Measurable and specific objectives are set in this step. We set the main objective of our survey as: ‘‘To acquire the viewpoint of Web and Data Warehouse users regarding the importance as well as the placement (in the levels/dimensions) of each of the quality factors in the WebQMDW model.”

C. Selection of Subjects

Keeping the objective mentioned earlier in mind, the target subjects required were both Web and Data Warehouse users. For the purpose of empirical analysis, many researchers have pointed out the advantages of taking students as subjects [45], [46] as the students’ knowledge tends to be homogenous and a high number of students as subjects are conveniently available simultaneously. According to us, the students who have the knowledge and practical hands-on experience of Data Warehouse and the World Wide Web were well suited to be this survey’s subjects. Additionally, if the students have the knowledge of Data and Software Quality, they will be able to assess the importance of each quality factor better. Hence, it was decided to use “Convenience sampling” and administer the survey to a set of students, the 74 students of the Data Warehousing & Mining Course of the final-year class of Information Technology program at USIC&T, GGSIP University, New Delhi, India. These students not only had knowledge of the Web and Data Warehouse but had also studied an entire course on Software Engineering as part of their curriculum previously. The survey was conducted as a part of the mandatory practical laboratory session of the Data Warehousing & Mining course. Therefore, there was enough motivation in the students to be a part of the survey.

D. Selection of the Design of the Survey

The descriptive design of the survey is considered most appropriate, where the objective requires a description of the phenomenon of interest. The objective of this survey requires a description of the opinion of the respondents regarding the importance and placement of quality factors in the WebQMDW model. Hence, the descriptive design [38] was considered appropriate and selected by us rather than the experimental design.

E. Preparation of the Survey Instrument

The guidelines of designing the survey instrument, i.e., the questionnaire [39], suggest that the survey questions should be chosen, keeping in mind the objective of the survey. Hence, in accordance with the objective mentioned earlier, we constructed the questionnaire with 22 Likert-style closed questions divided into sections I and II, asking the importance of the 22 quality factors of WebQMDW model Level I and Level II, respectively (Fig. 3, Fig. 4). Only the naming of quality factors in the questions could have led to ambiguity in the respondents' minds about the meaning of the quality factors. So, we formulated the questions in conventional simple English language by adapting the definition of each factor from the research literature [27], [32]. The answers to the closed questions were supposed to be marked in the 5-point Likert scale ranging from the lowest score ‘1’ signifying ‘Not Important’ and highest score ‘5’ signifying ‘Very Important.’ Section III consisted of 2 open questions regarding the structural placement of quality factors in the levels/dimensions of the WebQMDW model (Fig. 5). The first open question focused on any suggested switching of the category (i.e., Level/Dimension) of the factors in the WebQMDW model. The second open question focused on any other quality aspect or factor to be added to the WebQMDW model.

Section- I (corresponding to importance of WebQMDW Level 1 quality factors)

Level 1

Q.1 The importance value of the Performance i.e the Speed of loading of the Web Source, should be:

Q.2 The importance value of the Web Source having proper navigation mechanisms to be accessed speedily and with ease, should be:

Q.3 The importance value of the Web Source domain being considered trustworthy and delivering appropriate data, should be:

Q.4 The importance value of the Web Source having a strong SEO (Search Engine Optimization) for the relevant data to be discovered easily, should be:

Q.5 The importance value of the Web Source having security provisions (like SSL certificate) for preventing manipulation and unauthorized access to data, should be:

Q.6 The importance value of the various Best Practices that are followed by the Web Source (e.g practice of deferring download of unnecessary resources), should be:

Q.7 The importance value of the Web Source having high popularity and being considered worthy of great reputation for its content and services, should be:

Fig. 3. Survey Questionnaire -Section I (Reproduction of Questions from the Google form Questionnaire).

Section- II (corresponding to importance of WebQMDW Level 2 quality factors)

Level 2, Dimension 1
Q.8 The importance value of the Web Source data having the ability to be accessible over different platforms (operating systems or hardware architecture), should be:
Q.9 The importance value of the media format (text/HTML/pdf/audio/video etc) of the data from the Web Source fitting within the processing ability of the organization, should be:
Q.10 The importance value of the degree to which the data from the Web source is worthy of the cost associated (if it requires access fees), should be:
Q.11 The importance value of the amount or quantity of data provided by the Web Source being significant, should be:
Q.12 The importance value of the Web Source providing the data within the time constraint specified by the need of organization, should be:

Level 2, Dimension 2:
Q.13 The importance value of the description or metadata of the data from the Web Source being easy to interpret in accordance with the Data Warehouse schema, should be:
Q.14 The importance value of the data from the Web Source corresponding to the required time period according to the usage of Web data in Data Warehouse, should be:
Q.15 The importance value of the data from the Web Source being concise and free of superfluous elements that are not required for the right purpose in the Data Warehouse, should be:
Q.16 The importance value of the data from the Web Source being consistently represented in same or compatible formats throughout the Web pages of the Web Source, should be:
Q.17 The importance value of the data of the Web Source providing a complete coverage in terms of the depth, breadth and scope of the task at hand of the Data Warehouse, should be:

Level 2, Dimension 3:
Q.18 The importance value of the degree to which the data from Web Source is beneficial and adds value to the business of the organization, should be:
Q.19 The importance value of the data from the Web Source being correct and guaranteed to be error-free especially in the context of the application domain, should be:
Q.20 The importance value of the data from the Web Source being impartial and free from bias, should be:
Q.21 The importance value of the extent to which the data from the Web Source is believable, should be:

Fig. 4. Survey Questionnaire -Section II (Reproduction of Questions from the Google form Questionnaire).

Section- III (corresponding to open questions for structure of WebQMDW model)

Q.23 Do you suggest the switching of the category (i.e level or dimension in the WebQMDW quality model) of any quality factor?
Q.24 Do you suggest the addition of any new quality factor, not covered in the WebQMDW quality model?

Fig. 5. Survey Questionnaire – Section III (Reproduction of Questions from the Google form Questionnaire).

F. Validation of the Survey Instrument

We pre-tested the questionnaire to validate the survey instrument. Ten respondents (5 of them pursuing Ph.D. in the field of Data Warehousing and the rest 5 pursuing Ph.D. in the field of Web Engineering) answered the questionnaire before its actual administration. Following their feedback about the understanding of the questions, three questions (with questions no. 6, 9, and 10) were modified with examples and simpler language to improve the questionnaire.

G. Administration of Survey

The survey was administered to the subjects in an online session of a Data Warehousing & Mining laboratory class. The questionnaire was delivered in the form of a Google form whose link was shared with the subjects. Before the beginning of the session, the purpose and importance of the study were briefly explained to the respondents. The time limit of one hour for submitting the responses to the survey was also communicated to them.

H. Analysis of the Data

The survey was supposed to be administered to an expected sample of 74 subjects. In the actual scenario, the survey session was attended by 59 subjects because the remaining subjects were absent during the session. The recorded response rate was, hence, 79.7%. However, during the session, two subjects could not complete the survey due to network issues. So, the rest of the 57 responses were considered.

First, we analyzed the internal consistency of our data from closed questions with the help of Cronbach's alpha value (Equation 1) [47]. We determined Cronbach's alpha for data of section I and section II of the questionnaire, corresponding to importance value responses for quality factors from Level 1 and Level 2 of the WebQMDW model, respectively (see Table III). As a thumb rule, the value of Cronbach's alpha above 0.7 is considered acceptable. For our data, the values obtained were 0.889 for Section I and 0.920 for Section II. Hence, the survey can be said to have good internal consistency and reliable results for further analysis.

TABLE III. RESULTS OF CRONBACH'S ALPHA VALUE ANALYSIS

Questionnaire Data	Cronbach's Alpha Value
Section I (corresponding to Level 1 of WebQMDW model)	0.889
Section II (corresponding to Level 2 of WebQMDW model)	0.920

Cronbach's alpha [47] i.e., $\alpha = \frac{N \cdot \bar{c}}{\bar{v} + (N-1) \cdot \bar{c}}$ (1)

Where N= the number of items

$\bar{c}$= average inter-item covariance

$\bar{v}$= average variance

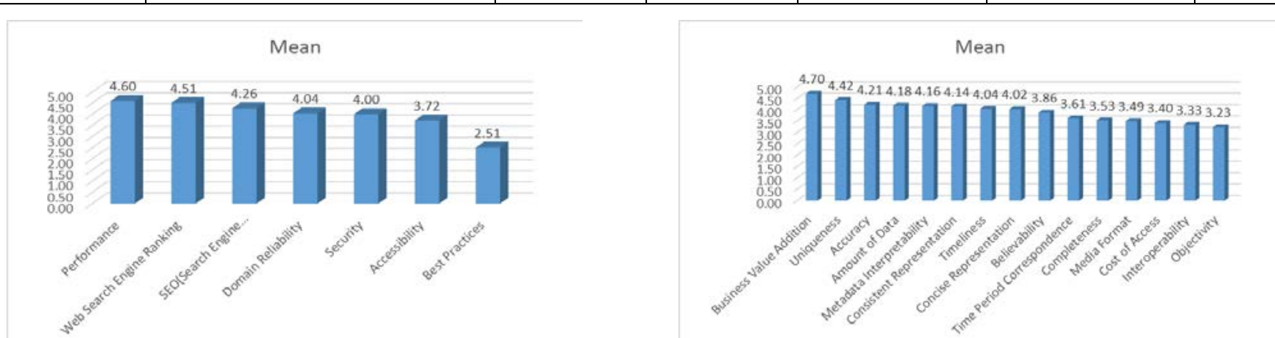
Tables IV and V shows the descriptive statistics of the responses for the importance values for the 22 quality factors. In this work, we have calculated the mean (i.e., average value) and the percentage coefficient of variation (%CV) of the importance values, to be used as the indicators for including or excluding the quality factors. It was decided to eliminate the factors whose mean value was below the value 3.0 (mid-point of the scale) as conceptually, in the view of the participants, they did not seem significant enough to be considered a quality factor for the evaluation of Web sources. We also decided to eliminate those quality factors for whom the percent variation coefficient was above 33% because conceptually, there was inconsistency in the participants' viewpoint about the importance of this quality factor. Thus, considering the ranked values of mean importance of factors in Fig. 6, most of the 22 factors of the WebQMDW model had a mean importance value above 3. These values signified that the respondents considered most of the factors to be having moderate or high importance. Among the highly important factors were Performance, Web Search Engine Ranking, Business Value Addition, and Uniqueness. However, the quality factor Best Practices was eliminated as its mean value fell below the decided indicator of 3.0. None of the factors had a percent variation coefficient of above 33%, so no factor was eliminated for this particular constraint (Fig. 7). The open question (number 23), which focused on any suggested switching of the category (i.e., level or dimension) of any quality factor, was not answered by any of the respondents. The last open question (number 24), which focused on the addition of any new quality factor, was answered by four participants who suggested including Reputation as one of the factors. On close review of meanings of the factors from the review of literature, it was seen that in the context of Web Sources, in particular, this factor of Reputation [30] was synonymous to the factor Web Search Engine Ranking that was already included in the WebQMDW model [27]. The factor name Reputation was also used in the pioneering work of Wang and Strong, considered a de-facto Data Quality standard [30]. So, instead of adding another factor, we decided to consider renaming the factor Web Search Engine Ranking to the more general name of Reputation.

TABLE IV. DESCRIPTIVE STATISTICAL ANALYSIS OF EACH QUALITY FACTOR OF LEVEL 1

Quality Factor	Min. Value	Max. Value	Mean Value	Standard Deviation	%CV
Performance	3	5	4.60	0.53	14.50%
Accessibility	2	5	3.72	0.80	21.41%
Domain Reliability	3	5	4.04	0.57	14.02%
SEO (Search Engine Optimization)	2	5	4.60	0.77	18.02%
Security	3	5	4.00	0.46	11.57%
Best Practices	1	4	2.51	0.71	28.31%
Web Search Engine Ranking	2	5	4.51	0.68	15.18%

TABLE V. DESCRIPTIVE STATISTICAL ANALYSIS OF EACH QUALITY FACTOR OF LEVEL 2

Dimension	Quality Factor	Min. Value	Max. Value	Mean Value	Standard Deviation	%CV
Dimension 1	Interoperability	3	4	3.33	0.48	14.27
	Media Format	3	4	3.49	0.50	14.45
	Cost of Access	2	5	3.40	0.80	23.47
	Amount of Data	2	5	4.18	0.87	20.80
	Timeliness	3	5	4.04	0.42	10.44
Dimension 2	Metadata Interpretability	3	5	4.16	0.53	12.69
	Time Period Correspondence	2	5	3.61	0.70	19.39
	Concise Representation	3	5	4.02	0.52	12.87
	Consistent Representation	2	5	4.14	0.81	19.60
	Completeness	3	5	3.53	0.54	15.26
Dimension 3	Business Value Addition	2	5	4.70	0.60	12.69
	Accuracy	3	5	4.21	0.80	18.90
	Objectivity	1	4	3.23	0.68	21.12
	Believability	2	5	3.86	0.91	23.70
	Uniqueness	2	5	4.42	0.71	15.96



(a) (b)

Fig. 6. Ranked Quality Factors of WebQMDW Model According to Mean of Importance Values (a) Level-1 (b) Level-2.

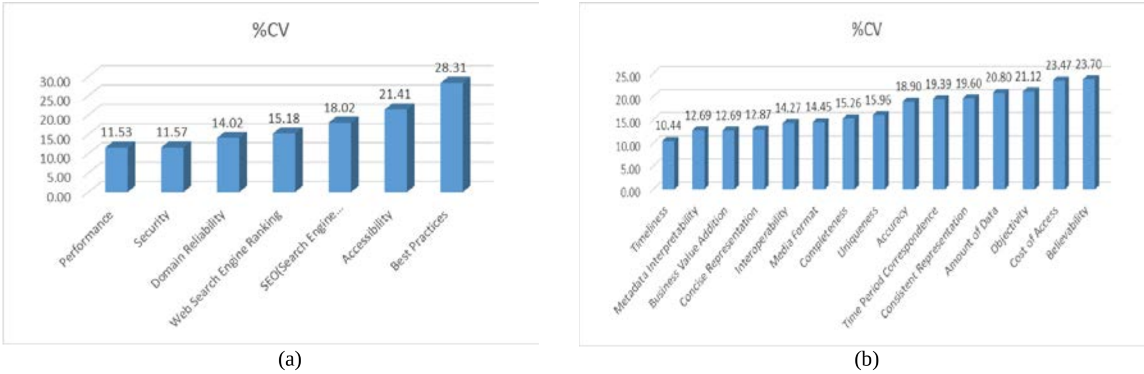


Fig. 7. Ranked Quality Factors of WebQMDW Model According to Percent Coefficient of Variation (%CV) of Importance Values (a) Level-1 (b) Level-2.

I. Restructuring of the Quality Factors of the WebQMDW Model

The initial structure of the WebQMDW model is shown in Fig. 1. After completing the above-stated validation process, the WebQMDW model now consists of a set of 21 factors, instead of 22, as one of the factors Best Practices was eliminated in the validation. As stated above, the factor Web Search Engine Ranking was renamed as Reputation. Since none of the participants suggested switching of the categories (i.e., level/dimension) of the factors, no other restructuring was done. The final structure of the WebQMDW model (with the above-stated changes) is as shown in Fig. 8.

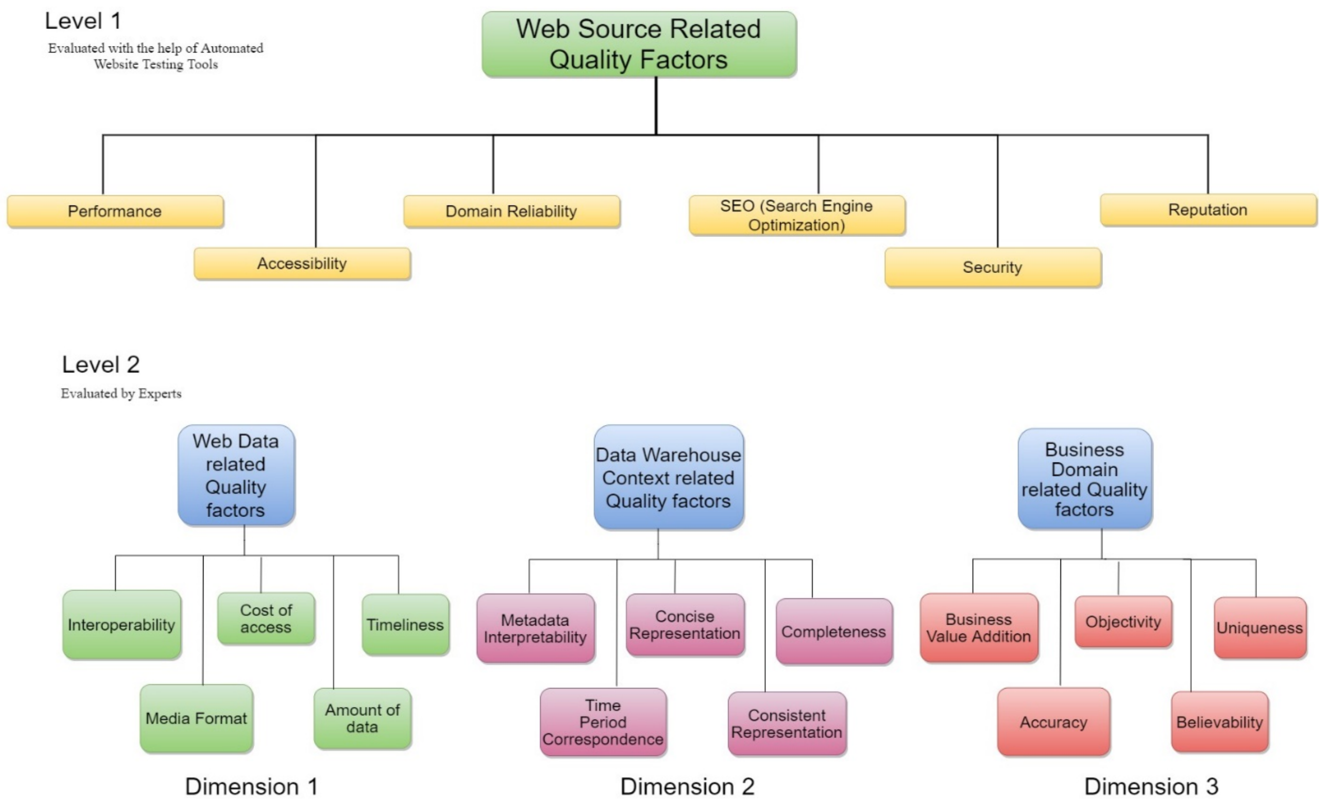

Fig. 8. Restructured WebQMDW Model- after the Validation Process.

IV. Threats to Validity

This section discusses the threats to the following kinds of validity and also how they were minimized:

A. Construct Validity

The survey uses the 5-point Likert scale to gather the opinion of the participants about the importance of the factors, with the lowest numerical value ‘1’ signifying ‘Not Important’ and the highest value ‘5’ signifying ‘Very Important.’ The Likert scale is used in many previous similar studies [32], [35] to gather the opinion of participants. This scale is an efficient tool for observation and hence, can be considered as a valid construct.

B. Internal Validity

To ensure internal validity is to make sure that the results are not being derived from casual relationships. For this aspect, we considered the following issues carefully:

- The students enrolled in the same class of Data Warehousing & Mining were taken as subjects. The subjects had adequate knowledge of Data and Software Quality as they had also studied an entire course on Software Engineering as part of their curriculum. Hence, it can be said that all the subjects had the same profile and level of experience both in Data Warehousing and Data Quality. Thus, the variability among subjects was reduced.
- Since the subjects had not taken part in any survey on the same lines as the present one, so the persistence effect was nullified.
- Since the survey was provided to be filled only once, so no learning could have taken place. Thus, the threat of the learning effect was not present.
- The survey was administered in a one-hour session. This time was much less than even one practical laboratory session time of the students. Hence, the fatigue effect was not that relevant in this case.
- The survey was conducted as part and parcel of the ongoing practical laboratory sessions of the subjects’ Data Warehousing & Mining course. The subjects were also motivated by telling them the importance of their contribution to the current research in the Data Warehousing field. Also, since subjects had already studied Web Warehousing as one of the advanced topics in the course, they showed sufficient interest in participating. Hence, we had achieved sufficient subject motivation for the survey.
- Since the survey was conducted in an online session with the subjects participating from their homes, their influence on each other was, if at all, very minimal. Further, to avoid plagiarism, it was ensured that the subjects kept their videos on during the entire one-hour session and were informed not to communicate with each other.

C. External Validity

External validity is the degree of generalizability of the research results to the population of interest and beyond in actual practice. External validity was ensured by mitigating the following two issues:

- Material and task used: A survey questionnaire structured as a Google form was the material used. This survey was independent as no previous task was needed to be done in order to fill it.
- Subjects: The students were used as subjects of this survey due to two major reasons. Firstly, the students clearly represented the population understudy for the survey as they had experience as Data Warehouse users as well as Web Portal users, along with the knowledge of Data Quality. Secondly, many researchers have argued in favor of using students as subjects [45], [46] without impacting the external validity much. However, we do not rule out the possibility of conducting a replicated study with experts from the industry in the near future.

D. Conclusion Validity

Conclusion validity is the statistical validity of the conclusion of the research. For this concern, the size of the sample (57 subjects) could be the only issue. However, most of the quality factors identified from the research literature have been previously used and mostly validated, in the sub-areas of the current problem domain, like Web Portal quality and Data Warehouse quality. Hence, the concern is subjugated. We will still consider conducting a replication study with a larger number of subjects from the industry.

V. Conclusion and Future Work

Over the last few decades, Web Data Sources have established their position as good, viable, and highly accessible External Data Sources for a Data Warehouse. However, the assessment of the quality of the Web Data Source is critical before their incorporation in the DW. Some quality models have been conceptually proposed in the research literature. However, to the best of the authors’ knowledge, none of the previously known models for the Web Data Source evaluation for a Data Warehouse have been empirically validated. Hence, this paper presents the validation process of the multi-level, multi-dimensional WebQMDW model for quality evaluation of Web data sources for a Data Warehouse. The objective was to provide an empirically validated quality model which will guide the DW professionals to provide enhanced decision making in the Data Warehouse by quality-based incorporation of external Web data sources. The thorough empirical validation is carried out through a survey based on the Pfleeger and Kitchenham work guidelines, which are considered a de-facto standard. A questionnaire with three sections was used as the instrument for the survey. Sections I and II correspond to the importance values of the quality factors from level 1(automated quality evaluation) and level 2(expert evaluation) of the WebQMDW model. Section III focuses on the structuring of the model into levels and dimensions. The statistical analysis of the results obtained from the validation survey revealed that 21 factors of the WebQMDW model are considered to be having either high or moderate importance for Web Source quality evaluation. The restructured and validated WebQMDW was obtained as suggested by the results of the empirical validation and supported by the research literature, which can be considered a significant contribution in this area. We plan to conduct a further study with a larger number of subjects, especially from the industry, in the near future. Such a study could be beneficial to refine the model further. We also plan to work on the measures for each quality factor and the refining of the granularity of the model.

***Abstract*—The Correlating Discriminative Quality Factors (CDQF) for Optimal Resource Scheduling in cloud networks has been addressed in this manuscript. It is since the resources under the cloud platform are loosely coupled according to the SLA between the cloud platform and the resource partakers. This enables the possibility of multiple resources from diversified partakers, those intended to accomplish similar services. The resource scheduling intends to select one resource among available resources to accomplish the scheduled task(s). The contemporary contributions related to resource scheduling are specific to traditional QoS factors, including cost, deadline constraints, and power consumption. However, the quality of service is often influenced by the contextual factors of the IAAS. Hence, this manuscript portrayed a novel resource scheduling strategy that orders the resources under the degree of optimality proposed in this manuscript. Unlike traditional resource scheduling methods, this manuscript portrayed a set of context-related factors that are further used to define the heuristic measure called "Degree of Optimality." The experimental study on the simulated environment elevates the proposal performance advantage as opposed to other existing methods.**

Keywords*—*Resource management (RM); resource scheduling (RS); resource provisioning (RP); QoS; infrastructure-as-a-service (IAAS)

I. INTRODUCTION

With the increased number of digital resources deployment on the networked cloud systems, the corresponding resource optimization scheduling mechanisms with higher levels of quality factors have a significant impact on the consumers' community and the providers' community of Cloud platforms. Nowadays, almost all organizations are leveraging Cloud computing capabilities to minimize their ownership cost and improve the productivity of their employees. Optimal resource scheduling quality factors are vital to improving end-user satisfaction, so this study focused on correlated discriminative quality factors for optimal resource scheduling in cloud networks.

Resource management (RM) is signified as a protection activity containing diverse workloads and resources from the submission to the workload's execution. The RM in the cloud contains 2 phases: a) resource scheduling (RS) and b) resource provisioning (RP). The RP is determined to detect sufficient resources for the specified workload based on QoS pre-requisites described by the cloud's consumers. At the same time, RS is mapping and performing cloud consumers' workloads based on RP's chosen resources.

Based on QoS pre-requisites, resource scheduling for sufficient workloads could be a challenging task. For effective resource scheduling, it is required to deliberate the requirements of QoS [1]. Hence, there is a requirement for uncovering RS's research tasks to perform the workloads deprived of impacting other QoS pre-requisites.

RS is an evolving research domain in the cloud because of the huge resource cost and execution time. Diverse RS factors and criteria are directed towards divergent classifications of RSAs (Resource Scheduling Algorithms). The effective RS lessens the cost of execution, energy consumption, performance time, and deliberating other QoS essentials such as availability, reliability, scalability, and security.

This paper is structured as follows. Section 2 discusses the various existing solutions that are closer to optimal cloud resource scheduling and its quality factors, while Section 3 presents correlating discriminative quality Factors for Optimal Resource Scheduling. Section 4 presents the experimental setup and empirical setup. The conclusion of Section 5 includes the future scope of the work.

II. RELATED WORK

The researchers have contributed "Multi-objective optimization scheduling" based on considerations such as economic costs, system execution, confines, and consumption of energy. By deliberating computational resources, the scheduling model is suggested, which segregates the budget costs and resources for lessening the task length, hence reducing the completion time of the task and enhancing the resource utilization of the system [2]. The work [3] presents fast completion time replication algorithms for "task-based replication." Initially, the algorithm adapts fuzzy clustering for preliminary resource pre-processing and later implements task duplication and acyclic graph scheduling. By deliberating the execution times of task, utilization rate, and resource costs are considered in the cloud environment utilizing multi-output, multi-input feedback "control dynamic resource scheduling algorithm" for assuring application under time confines for the optimal implementation execution [4]. For indefinite parameters in a hybrid environment, two "dynamic resource allocation" algorithms utilizing the Pareto optimization model have been suggested based on deadline and cost restraints [5].

Nevertheless, two of the algorithms' time intricacies are maximum, and both are higher than or equivalent to O (n2). The "adaptive workflow scheduling heuristic" model, which considers the confines of time and cost, has been proposed, even though the method schedules only data workflow analysis in the hybrid environment of the cloud [6]. The work [7] presents that the “Multi-objective scheduling” model is proposed based on cost & time optimization objectives with storage & bandwidth confines.

The model concentrated on enhancing the usage of “private cloud resources” for attaining the balance between costs and performance. The work [8], [9], [10] presents the scheduling issue in the way the same to concentrate on current research. For addressing the optimization and IaaS provider benefits, here, an “adaptive hybrid cloud particle swarm optimization scheduling algorithm” has been proposed. Nevertheless, this model only deliberated the cloud provider’s benefits without any cost from the users’ perception. The work [9] presents further; the researchers have suggested that the concentration needs to enhance the overall system’s performance despite whether exploring private or public resources of the cloud.

Lastly, the task outsourcing towards the public cloud method is suggested for lessening the outsourcing cost while simultaneously increasing the rate of using the internal cloud data center [10]. Consequently, the research assumed mathematical programming for optimized scheduling. Nevertheless, this method cannot solve scheduling issues containing a huge amount of data, and its “optimization objectives” are costly. The work [11] presents the cloud RM program’s proposal based on identical objectives of increasing the utilization of resources and lessening the costs. Nonetheless, the method is mostly utilized for migrating on and off the virtual machine and is not implemented for the real instance of optimizing the task scheduling.

Researchers in [12] analyzed different job types along with the availability of resources and developed a scheduling strategy that performs at a resource broker. However, the model was deported due to its computational cost and scheduling overhead. The contemporary contribution [13] portrayed a resource scheduling strategy for IAAS, using multiple Quality factors to schedule the resources. However, the contribution estimating optimality of resources has been limited to quality factors such as make-span, price, and availability. The quality factors linked to the context of the target IAAS are not in the scope of this contemporary model, and load is the other crucial factor, which is not in the scope of this contemporary scheduling strategy. Jiang et al. [15] investigated the scheduling of concurrent workflows in high-performance computing resources (HPC clouds). They describe a scheduling strategy that tries to reduce the total cost of computation, communication, and the earliest possible start time. In the last decade, a dynamic algorithm [16] for load balancing had been proposed. The static algorithm requires extensive knowledge of the forthcoming quantity of requests (tasks) and the availability of cloud-based virtual machines (cloud resources). When the number of clients grows, a long auction deadline interval will have a detrimental effect on the cloud service provider's earnings. Proposed a Cloud Resource Broker (CRB) by Somasundaram et al. [17] that has been assisted by an adaptive load balancing (ALB) and elastic resource provisioning and de-provisioning and (ERPD) mechanism. Yang et al. [18] proposed the bat algorithm (BA) as a unique heuristic optimization method in 2010, and a number of enhanced variants have been developed to deal with cloud computing resource scheduling. In [19], used stochastic integer programming to solve problems involving resource provision optimization. In a cloud computing context, the technique reduces the total cost of resource provisioning. The optimal solution is derived using a two-stage approach for formulating and solving stochastic integer programming. [20] In this research, the BAT method is utilized to address the multi-objective workflow scheduling problem in the Cloud, with the goal of optimizing execution time and reliability. Comparative simulations using the Basic Randomized Evolutionary Approach (BREA) were conducted, and it was observed that the BAT algorithm outperforms the other algorithm. In [21], an Opposition Learning-based Grey World Optimizer Algorithm is presented as a hybrid strategy for reducing the duration and expense of Cloud jobs. The evolutionary algorithm for cloud-based e-learning workload scheduling was introduced to optimize the scheduling of e-learning workloads subject to a predetermined set of conditions [22]. The two-tier VM architecture includes a front and background VM that dynamically share the VM's processing speed [23]. The issues of load balancing include scalability, availability, and load migration. To solve these obstacles, the hotspot mitigation algorithm [24] was created. [25] offered a detailed comparison of resource scheduling methods and resource allocation policies. This survey focused on resource scheduling and left other aspects of distributed computing out. It is based on the Imperfect Information StackelBerg Game (IISG) with a hidden markov model [26]. (HMM). Due to the cloud's heterogeneous and dynamic character, it's vital to deploy models that benefit both parties. It includes execution time, communication delay, reaction time, migration time, etc. Scheduling reduces completion time [27] and maximizes resource usage [28, 29]. Cloud scheduling is difficult due to the uncertainty of arriving jobs [30]. A Profit Maximization Algorithm (PMA) can address the profit maximization problem by dynamically arranging all arriving workloads in private or public clouds [31].

With these common constraints observed in these contemporary models, this manuscript aimed to derive a novel resource scheduling strategy intended to estimate the degree of optimality of the corresponding resource through contextual quality factors defined.

III. Correlating Discriminative Quality Factors (CDQF) for Optimal Resource Scheduling

This manuscript’s contribution portrayed a novel method that schedules the resources in IAAS of cloud computing under a heuristic measure called the degree of resource optimality (dro) that has been estimated by using diversified quality of service factors related to the context of the service called IAAS. The adopted qualities of service factors related to the resources of the IAAS are (i) Degree of Response Time (ii) Degree of Service Denial, (iii) Degree of Realization, (iv) Degree of Load Adoption, and (v) Degree of Cost Feasibility.

The information about the task(s) initiated at the SAAS includes the roundtrip time that indicates the arrival and expiration time of the corresponding task, the required service, and the resource’s acceptable budget. Based on the corresponding task(s) information header, the resource broker performs the resource scheduling under the proposed scheduling strategy.

A. QoS Factors of the Resources

The proposed method of resource scheduling in IAAS of cloud computing estimates the optimum scope of pairing the task(s) initiated at SAAS and the available resources at IAAS under the diversified quality of service factors. Unlike the traditional scheduling strategies, the proposal derived quality of service factors in the context of Infrastructure-As-A-Service (IAAS), which are used further to estimate the optimality of a resource to be scheduled.

Primarily, the above-stated approach has evaluated the projected quality metrics of resource transmission for overall resources available. Later, these resources are ordered as per quality metrics, and these are deliberated to be the prominent pre-requisite for optimal utilization of the resource. Moreover, this model has been utilized to evaluate every optimal metric of resource utilization, which has been exhibited regarding the available resources and has been discussed in the below sections.

By receiving the task's headers, the scheduler has scheduled the corresponding tasks towards optimum resources, which attain the task. Moreover, this article's intent is optimal resource scheduling for attaining high optimality towards completing tasks and utilizing resources. Here, the resources set, which were available towards schedule were $R = \{r_1, r_2, r_3, ...r_x\}$.

Resource scheduling towards tasks has been required as the utilization of resources and completion of the task. Moreover, the resource selection by the degree of resource optimality is scheduled for the respective task proposed in the manuscript. Here, aspects for optimal utilization of resources have been explored as follows:

- Often, the resource reflects the divergent scope and diversified QoS factors.
- The primary concern of metrics associated with the quality of resource utilization is divergent from one another.

Thus, it is evident that resource, which has scored better under QoS is not optimal, often under manifold objective quality parameters. Further, in terms of this limitation, this contribution's projection deliberates manifold objective quality parameters for scheduling resources for a respective task.

The depicted diversified quality factors of the resources recommended towards resource scheduling in IAAS are,

1) Degree of response time (drt)*:* This metric term the maximum time required for the corresponding resource to respond to the resource broker, which is the aggregate of mean value and mean deviation observed from the past anomalies of the response time of the corresponding resource observed by the resource broker. This metric was critical during resource allocation (s) to the deadline constrained task(s) (Eq. 1).

$$art(r) = \frac{1}{n}\sum_{i=1}^{n} rt(t_i, r)$$

$$mdrt(r) = \frac{1}{n}\left(\sum_{i=1}^{n}\sqrt{\left(art(r) - rt(t_i, r)\right)^2}\right) \tag{1}$$

$$drt(r) = art(r) + mdrt(r)$$

2) Degree of service denial (dsd)*:* The Degree of service denial is another crucial factor of quality of service that indicates the scope of unresponsiveness of the scheduled resource, which is the aggregate of mean and mean deviation of unresponsive schedules against the total number of schedules of the corresponding resource (Eq. 2):

$$rsr(r_i) = \frac{\sum_{j=1}^{ruc(r_i)}\begin{Bmatrix} 1 \exists reschedule\ is\ true \\ 0 \end{Bmatrix}}{ruc(r_i)} \tag{2}$$

From the above-stated equation, the notation $rsr(r_i)$ signifies the resource r_i rescheduling rate representing the schedules ratio perceived in averse to the number of times the r_i has been scheduled. Furthermore, the representation $ruc(r_i)$ indicates the actual amount of times r_i has been scheduled.

3) Degree of realization (dr)*:* The other quality factor of resource scheduling adopted is Degree of Realization, which is the absolute difference between the mean count of successful task realizations and the corresponding mean deviations.

$$\boldsymbol{ar(r) = \frac{1}{n}\left(\sum_{i=1}^{n} 1\exists task\ t_i\ realized\right)}$$ // average of realization.

$$mdr(r) = \frac{1}{n}\left(\sum_{i=1}^{n}\left(ar - \begin{Bmatrix} 1\exists if\ task\ t_i\ realized \\ 0 \end{Bmatrix}\right)\right)$$ // mean distance of the realization.

$dr = r - mdr$ // degree of realization.

4) Degree of load adoption (dla)*:* The expected load on the resource during the stipulated schedule expected by the task(s) is another quality factor of the resources labeled as Degree of Load Adoption. The estimation of load adaption carried as follows:

Find the time interval of the resource in use, which is the average time of the corresponding resource against the total number of times that resource is scheduled.

Find the number of time intervals of the resource, which is the ratio of the total time that resource in service and the time interval.

Then find the mean load and mean deviation of the load observed in all of these time intervals. The aggregate of these mean load and mean deviation of the load can denote the Degree of Load Adoption.

$$tin(r) = \frac{1}{n}\sum_{i=1}^{n} et(t_i, r)$$ // time interval

$$al(r) = \frac{1}{n}\sum_{i=1}^{n} l(tin_i, r)$$ // mean load

$$mdl(r) = \frac{1}{n}\left(\sum_{i=1}^{n}\sqrt{\left(al(r) - l(tin_i, r)\right)^2}\right)$$ // mean load deviation

$$dla = al(r) + mdl(r)$$ //degree of load adoption

5) Degree of cost viability (dcv) *:* The resource cost is crucial; resource scheduling is carried under the Service Level Agreement. The client who initiated the task accepts the pay per resource, which is certainly lesser than the upper limit concluded in SLA. Hence, the resource with minimal cost would be most viable. However, it is not at the loss of other quality factors. In this context, rather than opting for a resource with minimal cost, the proposed scheduling strategy adopts a resource that is qualified under other quality factors and has a cost of pay per use as lesser than the agreed budget level. The selected resource's coast viability can derive as the difference between the max level of the agreed cost and the estimated cost of the resource against pay for one use (Eq. 3):

$$ac = \frac{\sum_{i=1}^{n}\left(ecr(r_i) - mac(t)\right)}{n}$$

$$mdc = \frac{\sum_{i=1}^{n}\left(\sqrt{\left(ac - \left(ecr(r_i) - mac(t)\right)\right)^2}\right)}{n} \quad (3)$$

$$dcv = ac - mdc$$

B. The Heuristic Measure (Degree of Resource Optimality (dro) *)*

Let Degree of Response Time (drt), Degree of Service Denial (dsd), Degree of Realization (dr), Degree of Load Adoption (dla), and Degree of Cost Viability (dcv) as a set of QoS metrics denoted for each resource r_i as $M_{(r_i)} = \{drt, dsd, dr, dla, dcv\}$.

To explore the proposed model, let $dcv(r_i), dla(r_i)$ be QoS factors that have been utilized for identifying every resource scope. These key metrics have been utilized for sequencing the resources, as described in the following algorithm.

The initial process normalizes the feasibility of cost and degree of load adoption (dla) as follows and as shown in Fig. 1:

step 1. $foreach\{r_i \exists r_i \in R \wedge i = 1, 2, 3, ..., |R|\}$ // Begin.

step 2. $ndcv(r_i) = dcv(r_i)^{-1}$ //degree of cost viability in normal form $ndcv$, which lies among 0 & 1.

step 3. $ndcv_{abs} \leftarrow abs(ndcv(r_i))$ //The set $ndcv_{abs}$ comprises absolute values of the corresponding degree of cost viability in normal form perceived for every resource.

step 4. End // of step 1.

step 5. $foreach\{r_i \exists r_i \in R \wedge i = 1, 2, 3, ..., |R|\}$ // Begin.

step 6. $ndla(r_i) = dla(r_i)^{-1}$ // the degree of load adoption in a normal form $ndla$ which is in the range of 0 to 1.

step 7. $diff_{abs} \leftarrow abs(ndla(r_i))$ //The set $diff_{abs}$ comprises absolute values of entries in $diff$.

step 8. End // of step 5.

step 9. $foreach\{r_i \exists r_i \in R \wedge i = 1, 2, 3, ..., |R|\}$ // Begin.

step 10. $km(r_i) = 1 - \left(ndcv(r_i) \times ndla(r_i)\right) \exists \left(ndcv(r_i) < 1 \| ndla(r_i) < 1\right)$ //the outcomes have been subtracted from one that is to attain maximum value since the product of 2 decimal fractions provides another decimal fraction, which is lower than fractions of decimal incorporated in multiplication.

step 11. End // of step 9.

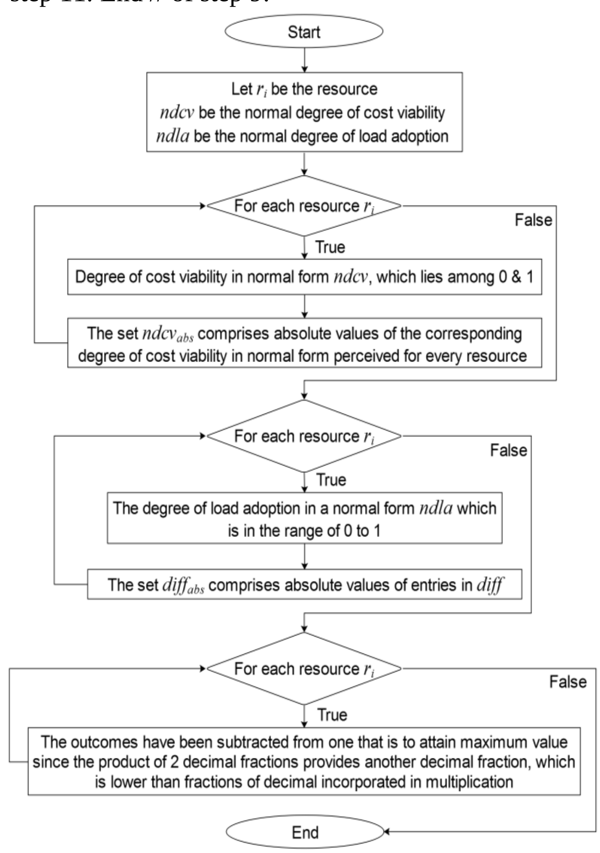

Fig. 1. Flowchart Representation of the Heuristic Measure.

Later, the resources available have been rated about every metric so that every resource would have a unique rating for a metric. Moreover, resources would be rated in an increasing sequence of resulting metric values. When maximum values are optimal, then such a resource possessing minimum value over the resulting metric would be rated as one. Besides, resources possessing maximum value for the respective metric would be rated in the form of $\{n \exists n \le x\}$. The representation x depicts the number of resources. When minimum values are said to be optimal, then resources would be rated in a decreasing sequence of resultant metric values so that the resource possessing maximum value for the resulting metric has been rated as one. In contrast, the resource possessing minimum value for the resulting metric has been rated to be $\{n \exists n \le x\}$.

With the process completion, every resource reflects manifold ratings about specific quality parameters. Moreover, these ratings would be utilized as input for assessing the Degree of Resource Optimality $dro(r_i)$ as follows (Eq. 4):

For each resource $\{r_i \exists i = 1, 2, ..., x\}$ // Begin.

$$\mu(r_i) = \frac{km(r_i) + drt(r_i) + dsd(r_i) + dr(r_i)}{4} \tag{4}$$

//The above-stated equation portrays average ratings attained for divergent resource r_i metrics.

$$dro(r_i) = \left[\frac{\left\{ \sqrt{(\mu(r_i) - km(r_i))^2} + \sqrt{(\mu(r_i) - drt(r_i))^2} + \sqrt{(\mu(r_i) - dsd(r_i))^2} + \sqrt{(\mu(r_i) - dr(r_i))^2} \right\}}{4} \right]^{-1} \tag{5}$$

Eq 5 Degree of Resource Optimality $dro(r_i)$ is the inverse of root mean square distance of ratings allocated to a resource r_i as the lowest distance is said to be optimum.

With the completion of evaluating the degree of resource optimality for specified resources, then resources would be organized in decreasing sequence of their rating attained for prominent metrics.

Further, choose a set of resources possessing an optimal rating about key metrics under the given threshold.

The chosen resources have been organized in decreasing the sequence of their Degree of Resource Optimality $dro(r_i)$ that assists in projecting the optimal resource in the primary place of its sequenced list. Here, a similar order would be considered the preferred order to select resources regarding the task schedule.

IV. Experimental Setup and Empirical Analysis

The empirical study compares of projected CDQF model and other existing "job scheduling with efficient resource monitoring (JS-ERM) approach [12]" & "multi-objective scheduling method based on ant colony optimization (MOSACO) [13]" that is simulated utilizing Cloudsim [14]. Here it allows for simulating high dimensional CC network synthesizing input jobs so that there could be no priority sequence applicable to corresponding jobs. The confines are executed for performing simulation from 1 processor towards another, and pre-emption is not enabled. They are scheduling the resources utilizing the QoS factors considered by proposed & other existing methods to analyze the performance. Moreover, we noticed the metrics of performance discussed in the next segment at distinct intervals of time.

The proposed CDQF has been assessed by comparing it with another JS-ERM [12] and MOSACO [13] contemporary approaches. Here, performance would be measured under several QoS metrics such as completion rate of the task, resource utilization rate, and rescheduling rate.

The rate of resource utilization perceived for CDQF would be high and maximum when compared with other contemporary MOSACO and JS-ERM approaches. Here, the rescheduling rate perceived for the CDQF model would be linear and minimal compared to other approaches. The rate of resource scheduling has been perceived as low in CDQF, which delivers an optimal job completion rate. Here, process complexity would be minimal for CDQF, which is minimum because of the scalable method modified for the degree of resource optimization assessment.

Here, Table I and Fig. 2 depict the rescheduling rate noticed at diverse intervals of time. The perceived rate of rescheduling is averse to the load of the task. This figure signifies that the projected model of this contribution CDQF has been prominently the best for lessening the rescheduling rate compared to other approaches. Further, Table II and Fig. 3 portrays that the rate of job completion perceived for the proposed model CDQF would be recommendable and prominent compared to MOSACO and JS-ERM contemporary approaches. Table III and Fig. 4 portray that CDQF added an advantage over the other two existing models for resource utilization rate that is considered a significant objective of resource scheduling techniques.

TABLE I. Resource Rescheduling Rate Statistics

JS-ERM	0.05	0.052	0.07	0.09	0.12	0.135	0.14

CDQF	0.88	0.9	0.91	0.91	0.93	0.93	0.94

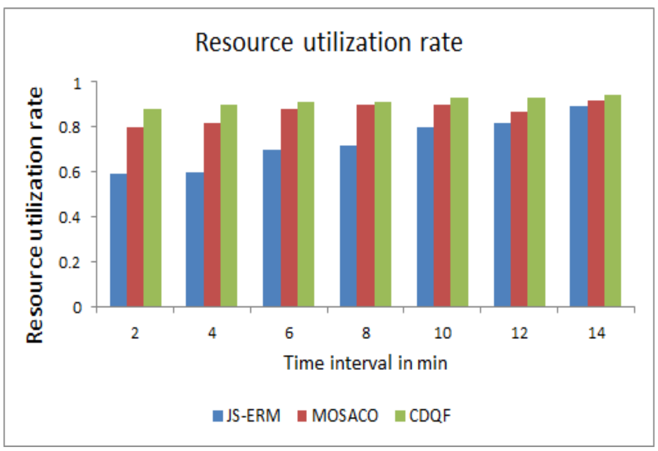

Fig. 4. Resource Utilization Rate Observed.

V. CONCLUSION

In this manuscript, a quality-aware scheduling algorithm optimizes the completion of tasks and resources scheduling cloud computing. Moreover, this article projected a novel scale known as Degree of Resource Optimality that signifies resources fitness under diversified QoS proposed metrics. The outcomes attained from this contribution's projected model have been compared to the other two existing methods, JS-ERM & MOSACO. The performance analysis is exhibiting that the projected method has been surpassed compared with the other two existing methods for divergent quality metrics. Here, empirical analysis of the proposed method of this contribution might impact further research for development. The load balancing and scheduling technique for attaining optimum VM scheduling (virtual machines) as resources in CC.

***Abstract*—We can easily observe that in the current era of communication, Computers, mobile phones, and the Internet are widely used mediums. In such an environment, information security is an important issue. The most common techniques used for information security are Cryptography and Steganography. Many research works have been done on image Steganography. These images have different kinds of formats like BMP, GIF, and PNG. Several compression methods are available which applied to the images having the format BMP, GIF, and PNG is comparatively less effective than the JPEG image. JPEG compression steganography method is complex to implement even then some algorithms have been developed for it. They provide single-level or two-level information securities. This paper presents a method in which is the combination of Cryptography and Steganography is used over android mobile phones. Here we are performing encryption two times on data to be hidden and then that encrypted data hidden both in text and image. We are using the Advanced Encryption Standard (AES) algorithm to hide text within a text, Discrete Cosine transform (DCT) for image steganography, and Data Encryption Standard (DES) for encryption of text. This paper gives the idea of three-level information security over the android environment.**

Keywords—Steganography encryption; discrete cosine transform; DES; F5Algorithm

I. Introduction

Information security is a popular research area. It attracted researchers towards the security concept of data by using different kinds of techniques. The commonly used are Steganography, watermarking, and cryptography. When we look at all these techniques, we found that Steganography gives more security comparatively other methods. As well as digital communication technology has changed security features also required some variations. Information security attracted many researchers and has become the widely scoped area of research in wireless and mobile communication. The field of Steganography is very vast, but researchers have been motivated toward mobile steganography because of the intensive use of mobile phones as well as the exchange of information among the users. In the same context, "Short Messaging System (SMS) was introduced with GSM mobile phones and became too much popular among users" [2]. After some time, the multimedia message was introduced and gained more popularity due to its advanced features. Later, smartphones have come to light with many advanced features for communication. It is a small handy portable device that the user can carry with him anywhere. Thus, users can use these devices in various ways like photo capturing, sharing of information in images, audios videos and calling, etc. To stop unauthorized access and attacks, we must have to use systems with some data security techniques. We have described few data security techniques earlier in which one of the trendiest techniques is steganography.

II. Steganography

We start with the security of information that so many techniques are present. Fig. 1 depicts the different disciplines of information hiding. Steganography alludes to the study of "imperceptible" correspondence. In contrast to cryptography, where the objective is to make safe correspondences from a user, steganographic strategies endeavor to hide the very nearness of the message itself from an onlooker [4]. Steganography is the craftsmanship and study of imparting so that the nearness of a message can't be distinguished [5].

Steganography is the science that includes imparting mystery information in a suitable sight and sound bearer, e.g., Image, sound, and video. It goes under the presumption that if the element is noticeable, the purpose of assault is obvious, therefore the objective here is consistently to disguise the very presence of the installed information [9]. The word steganography is of Greek cause and signifies disguised composition from the Greek words steganos (στεγανός) signifying secured or ensured, and graphei (γράφη) signifying composing. The principal recorded utilization of the term was in 1499 by Johannes Trithemius in his Steganographia, a treatise on cryptography and steganography masked as a book on enchantment. By and large, messages will give off an impression of being something different: pictures, articles, shopping records, or some other spread content, and, traditionally, the concealed message might be in undetectable ink between the obvious lines of a private letter [14]. Steganography implies concealing the presence of data in such a way along these lines that nobody can recognize. Three procedures of data security are fundamentally the same Cryptography, watermarking, and steganography. Pictures are used as the bearer to perform steganography. A mystery message is implanted in the transporter picture so that nobody can recognize that mystery message. Ancient steganography worries about the ways of inserting the mystery message in a spread picture. The implanting needs key without which an outsider cannot identify or evacuated the original message. The cover picture with the implanted message is called Stego Image.

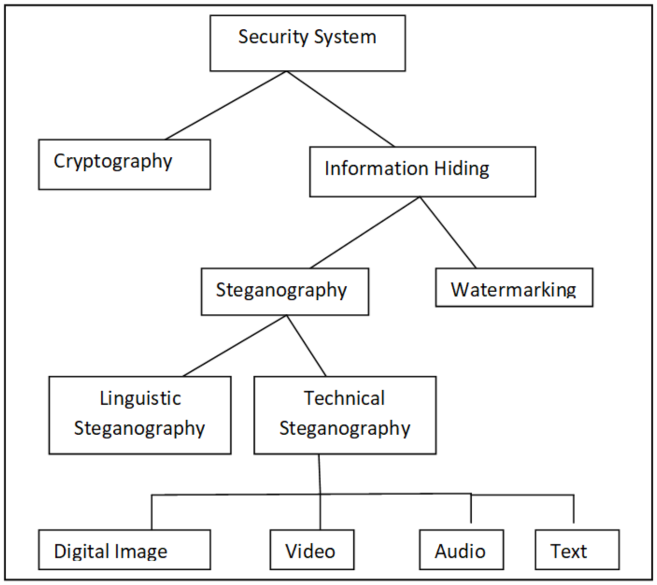

Fig. 1. Types of Security System.

A. *Working of Steganography*

A steganography algorithm shows a combination of a mystery message-which needs to cover up, picture – which contains the implanted message. The general working of steganography is to get the message to stow away, get the picture wherein information to cover up, Apply the suitable algorithm which produces the stego picture. This Stego picture sends to the beneficiary, receiver interprets the stego picture and gets the first message.

With the help of Fig. 2 general idea of steganography can be understood.

The message is the information that the correspondent needs to keep secret. It may be a plain content, figure text, another picture, or something that can be implanted in a bitstream, for example, a patent mark, an incognito correspondence, or a sequential digit. Key is a particular word, which guarantees that the beneficiary who realizes the relating disentangling key will have the option to remove the message from a Stego picture. The spread picture is likewise called a transporter. The generated picture with the secretly inserted message is known as the stego message. Recouping data from a Stego image requires the stego picture itself and a relating deciphering input if the input is used throughout the encoding procedure.

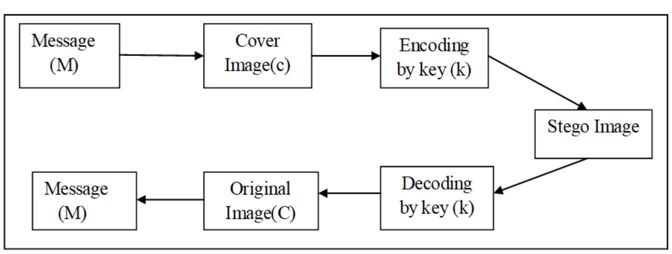

Fig. 2. Representation of Steganography.

III. Cryptography

Cryptography is the preparation and examination of disguising information. It consolidates the request for number juggling, programming building, and electrical structuring. Cryptography is encryption, which is the route toward changing over standard information into muddle information. Deciphering is the opposite system of getting authentic information from confounded information.

A. *Working of Cryptography*

A cryptographic estimation works in blend in with a keyword, number, or articulation—to encode the plain text. The proportional plain text scrambles to different text with different keys. The security of encoded data depends on two things: the nature of the cryptographic estimation and the secret key. A cryptographic algorithm, in addition to every potential key and all the conventions that make it work, involves a cryptosystem. With the help of Fig. 3, the general idea can be comprehended.

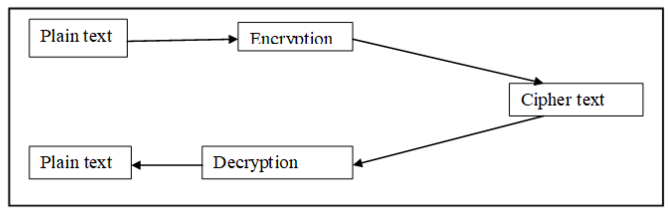

Fig. 3. Cryptography Concept.

IV. Literature Review

Most of the work has been done in the field of steganography. Mainly steganography has been done on bit map pictures, gif pictures, and grayscale pictures.

The most widely recognized and easiest steganographic technique is the least significant bit inclusion strategy is presented earlier. The least Significant Bit Substitution strategies are called due to how the message information m is inserted inside a spread picture c. In software engineering, the word Least Significant Bit (LSB) alludes toward the littlest (right-most) piece of a parallel succession. The organization of binary is with the end goal that every number may just be either a 0 or a 1, frequently idea of as on separately. Beginning from the right, the worth (if on) signifies a 1. The incentive to one side (if on) means a 2, etc. wherever the qualities are twofold every time [1]. Afterward new encoding strategy utilizes a matrix. The best appropriate procedure for jpeg steganography is considered F5 algorithm [2]. The first recorded use of steganography found from 440 BC back when Herodotus informed to Greece about the forthcoming attack by writing a message on the wooden and covered it by wax. Another example of ancient steganography is Histiaeus who shaved the head of his slave and tattooed the message on it after hair grown message was hidden [3]. In this author has provided the review of steganography techniques and steganalysis technique [4]. According to this paper, a secure stego system is proposed using the stego text distribution close to the cover text distribution. Here observer no need to know about the secret key. The embedding function depends on the cover text distribution [5]. This paper presented and discussed the possibility for using steganography in MMS and also suggested SMILE Steganography. Here presented algorithms and evaluation are on theoretical basis only [6].

As well as mobile phones became popular, so MMS techniques were used for communication. So, there was also some research in such area which shows the calculation for hiding information in MMS utilizing Portable Network Graphic picture also shows the novel strategy for steganography utilizing both content and pictures [7]. Steganography technique used in a game known as the Sudoku puzzle. It shows that how we can hide data in the Sudoku puzzle for secure information transfer [8]. In this paper different analysis of existing steganography has been done. Here are also given some differences between steganography and watermarking. Some questions may also arise such that is this technique is useful or not? [9]. Here we find how we can use steganography in MMS for Smartphones. Two-level of security has provided using image and text both [10]. Here author suggested Elliptic Curve Cryptography method for MMS security purpose [11]. This paper gives a comparative study of different mobile environments and their development technology. Also, introduce security issues for android OS [12]. In this paper authors provided steganography for JPEG image over the mobile phone. Here algorithm is implemented through the combination of text, image, and encryption [13]. This paper gives idea of hiding the text message inside one small image using LSB and then hided that image in larger image using DWT algorithm. It is implemented on gray images not on color images [14]. In this paper author implemented steganography method on android environment using LSB method and also used TEA algorithm for cryptography also for reducing the size of message LZW compression method is used [15]. Multi-Level steganography with dissemination in painting and YASS Algorithm on the external level and One-Time stuffing of the mystery note with key picture and YASS on internal level used for steganography [16]. In another paper author described about a model called Ste-Chy as an evidence of idea of the blend of the strategies. This methodology helps the client as far as the trading of secret information by online offer in Android base media. In support of the classified confirmation reason, the secret message is concealed along with the objective picture. At an adequate level image is created by this work using nature of original and stego pictures [17]. In [18] authors were used emoticons or lingoes to hide the information. He has proposed his idea for embedding data in emoticons or using lingoes in SMS than the recipient can extract the hidden information. In [19] we find the information regarding different steganographic techniques and gives performance metrics for mobile image steganography. In [20], creators have built up an android application through which we can shroud information behind the picture, and we can share an apk document through WhatsApp. This application is created by utilizing steganography and the LZMA firmness strategy. In this research authors have given idea of video watermarking using steganography. For steganography they have used DCT method. Here water mark is embedded inside the quantized coefficients [21]. It gives improvement in multiphase encryption by encrypt the data with different encryption algorithms. Here proposed algorithm itself append the information along with secret text on the other hand in multiphase sender provide the specific order to receiver for decrypting the message [22]. In this work creators suggested Image steganography using k means clustering and AES encryption together. Messages are hided in object area which form as cluster with that encryption has also used for improvement [23]. Benefit of this application is it gives twofold security by utilizing hiding and firmness strategy. For jpeg image, a steganography technique is proposed. A part of data may be lost after the quantization of frequency values in the JPEG compression procedure, in the proposed method, the embedded message is added to the image after the discretization stage. The method utilizes two adjacent pixels in the steganography process [24]. The authors suggested cryptography and Steganography method for smart phones. Here they have used RSA algorithm for encryption and LSB insertion method for information hiding [25]. Message is sliced in parts and hided in multiple images. LSB technique is used for each image and image contain some header information so that at the receiver side any specific order is not required [26]. This paper gives idea of different techniques for jpeg steganography. It summarizes various algorithms and techniques used in the past and in present. This paper also analysis's these algorithms based on the basic parameters of image steganography: Unidentifiable, robustness and hiding capacity [27]. Here author proposes a JPEG steganography algorithm to provide strength to the Stego image using DCT coefficient and maintain an even coefficient distribution based on the JPEG characteristic [28]. In this paper author has suggested LSB embedding method using BMP and PNG images. He has hided secret message in pixel values and modified values have shown in new generated images [29]. "This paper introduced the concept of steganography using bit selection of cover image. Basically, here also LSB Technique is used for hiding the secret message. Message can be in any format text or image. Here gray scale image has been taken as example to perform this operation. Secret message image must be smaller then cover image [30].This paper suggested the modification in F5 algorithm of data hiding. It is based on idea of modified matrix embedding (MME). In proposed method all nonzero AC coefficients collected in single array and divides array into small coefficient blocks, then find the coefficient with least distortion to embed message [31].

The rise of mobile phones has led to new demands of android operating systems and applications to run on it. Nowadays image steganography is a very wide area for research work. The field steganography is very vast but, in that field, and the present requirement mobile steganography work motivates the researchers to introduce some new and innovative ideas. Steganography poses a lot of interesting research problems and there are so many techniques to implement it and require some further improvement. There is still not too much work that has been done on JPEG steganography over cell phones.

V. Motivation

There is too much research that has been done on image security over the different kinds of image formats BMP, GIF, and PNG. Several compression methods are available that applied to the image having the formats BMP, GIF, and PNG is comparatively less effective than the JPEG image. Even the

JPEG compression steganography method becomes difficult though some algorithms show JPEG Steganography. But they provide a single-level or two-level security. Most of the techniques are computer system based but not for mobile phones. Now day's everyone has a mobile phone became so handy. Chatting is one popular application of mobile through which one can share different kinds of data such as pictures, audio, and videos among users. When we consider information security over mobile phones, steganography is the best security procedure because most of the correspondence with the assistance of sharing pictures. Although steganography has been done in all types of image format still this technique is an interesting research area for mobile application. The motivation for this work is that steganography is the way to provide secure communication. Its main goal is to hide information so that no one can detect it and provide information securely to the sender. Hackers or attackers cannot identify the hidden message in any way. In this carrier, the image keeps a secret message and looks like an original image so that intruder cannot pay attention to it. Most security agencies are using this technology for secure communication. In the present scenario, the mobile phone has become a popular device for communication due to which information flows freely, so information security becomes a primary concern. Hence this motivated mobile application development.

VI. Proposed Method

Earlier work is carried out using text steganography and image steganography and for this purpose PNG (Portable Network Graphic) image was used [7].

In this work, we are using JPEG images for steganography. We will encrypt an original text message two times later split it into two halves to hide the first half in the image and the second half in the cover message.

Steps for procedure:

Input: An Image (Cover Image), Text message (Plain Text), Text message to hide

Output: Stego Image with hidden Text, One text file

1) Write Text to hide.

2) Take original image known as cover image.

3) Write Short text message which is known as plain text.

4) Encrypt the text which to be hidden using DES algorithm.

5) Re-encrypt the received encrypted data using the DES algorithm again to produce ciphertext.

6) Split the cipher text in two halves.

7) Hide the first half cipher text in Cover image using matrix encoding algorithm.

8) Hide the second half cipher text in cover message using markove chain method.

9) Generate stego image and one text file.

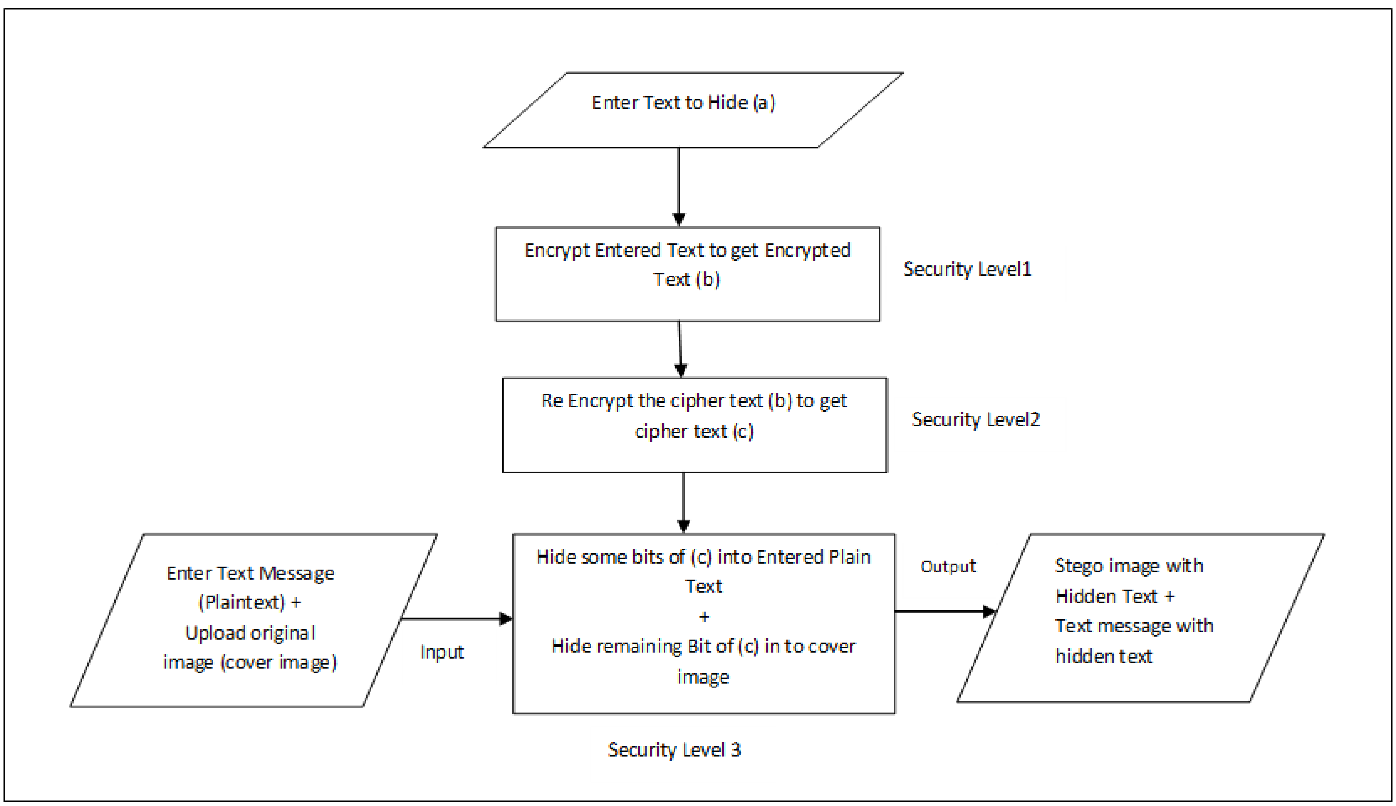

Fig. 4. Workflow Diagram.

For receiver side follow the procedure in reverse order but there we provide Stego image, Cover message and generated text file as input to extract original message Fig. 4 shows the basic idea of workflow.

Algorithm

S1: Select the image on which we have to perform operation called original image.

S2: Enter the message which must be hidden.

S3: Enter Cover Message which is used for text steganography.

S4: Apply DES Algorithm on message enter in step2 to get encrypted text.

S5: Again, apply DES algorithm on received encrypted text from previous step to get final cipher text

S6: Divide the final cipher text in two halves

S7: Take one half of cipher text and Image loaded in Step1 and Apply F5 algorithm to hide the text in image

S8: Take the other half of cipher text and Cover message (S2) apply Markov chain method to hide cipher text in cover message

VII. Implementation

To encrypt the text which has to hide, "DES Algorithm" has been used in this paper. We encrypted the text first by DES algorithm through which we received Encrypted Text and Further that encrypted text is encrypted again through the same DES Algorithm to get final ciphertext. After receiving this ciphertext, we have split the ciphertext in two half one portion to hide in the image and the other portion to hide in text. We have used the F5 algorithm to hide the text inside the image. It is most commonly used an algorithm based on matrix encoding.

We do quantization of coefficient and then we embed the message using bit position and performing XOR operation. We can understand it through an example.

We want to embed Two bits p1, p2 in three-bit places q1, q2, q3 changing one place at most.

There may be four condition arises. If we find p1 is equal to XOR operation between q1 and q3, and p2 is equal to XOR operation between q2 and q3 then we don't change in bits.

If we find p1 is not equal to the XOR operation between q1 and q3, and p2 is equal to the XOR operation between q2 and q3 then we change bit q1.If we find p1 is equal of XOR operation between q1 and q3, and p2 is not equal of XOR operation between q2 and q3 then we change in bits q2 bit.

If we find p1 is not equal of XOR operation between q1 and q3, and p2 is not equal of XOR operation between q2 and q3 then we change in bit q3. In all these conditions we do not change more than one bit.

Text hiding within text:

Hide text in text with the help of cover messages using a Markov Chain method. This generates an encryption vector based on the relationship between the cumulative character score of the cover message and each character of an input string. Decrypt messages by reversing the encryption on the encryption vector and retrieving the original message based on the cumulative character score and the relationship between the cover message and the input string.

Generating an Encryption Vector:

Take the sum of all the ascii character codes of each character in the cover message:

Example: hello,

h = 104, e = 101, l = 108, l = 108, o = 111

Sum hello = 104 + 101 + 108 + 108 + 111 = 532, this forms the cumulative character score S. Append the difference of S and the ascii character value of the input string to an Array List to form the encryption vector

S = 532

Input = "dog", d = 100, o = 111, g = 103

Evector = {532 – 100, 532 – 111, 532 - 103} = {432, 421, 429}

To hide the text encryption vector Evector, use AES – 256 Encryption Algorithm to encrypt the Array List for message. For retrieving the information at receiver side, the received Message and its Evector are first decrypted by initializing a Java Cipher object in decryption mode using the secret key yielding a decryption vector Dvector. Then it follows reverse process to get original message. Here Fig. 5 represent the GUI of developed app.

Fig. 6 Show the encoding view though which user can enter original and cover message.

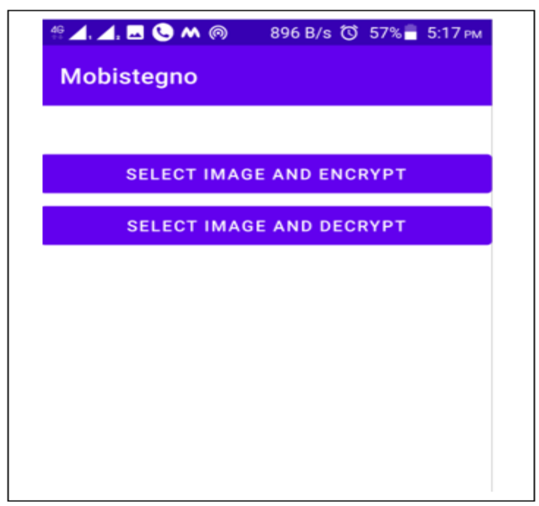

Fig. 5. App Start View.

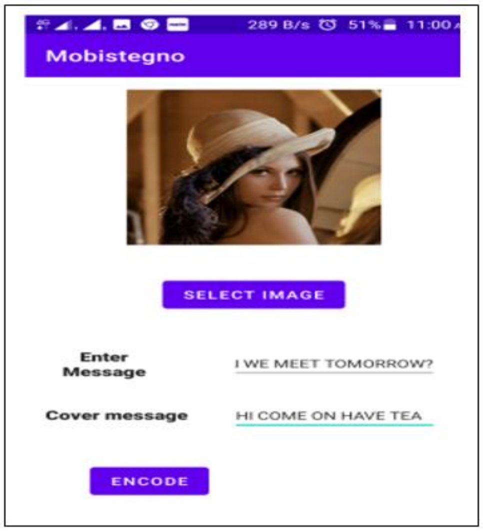

Fig. 6. Encoding View.

Fig. 7 depict the decode view of app in which user can enter the cover message to get back original message.

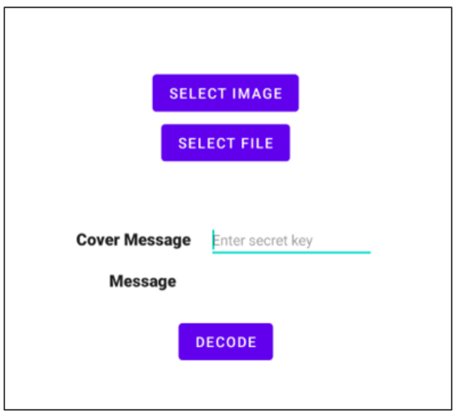

Fig. 7. Decode View.

Here the Fig. 8 represent the result view where user get original message.

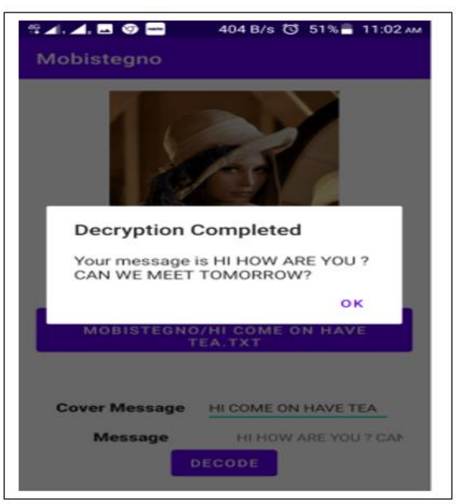

Fig. 8. Result View.

VIII. Result and Discussion

When we embed the data in the image it increases in the Mean Square Error (MSE). This automatically reduces the Peak Signal to Noise Ratio (PSNR) and vice versa. The PSNR is to be measured in decibels (dB). Usually, PSNR of more than 35db is considered good quality, so our results have good values. The lesser the MSE value higher will be the PSNR values. Equation 1 shows the formula for calculating PSNR.

$$PSNR = 10.log_{10}\left(\frac{MAX_I^2}{MSE}\right)$$

$$= 20.log_{10}\left(\frac{MAX_I}{\sqrt{MSE}}\right) \quad (1)$$

$$= 20.log_{10}(MAX_I) - 10.log_{10}(MSE)$$

Formula for calculating mean square error is given by equation 2.

$$MSE = \frac{1}{mn}\sum_{i=0}^{m-1}\sum_{j=0}^{n-1}[I(i,j) - K(i,j)]^2 \quad (2)$$

It shows the changes between the original image and the stego image. Here m and n show height and width of the image.

We have used different images to embed the data inside. Here one message is conveyed, and text is hidden inside the image. Also, some part of the text is hidden in cover message. Here we have used three-level security for data hiding on the android environment. Table I shows the comparisons of features. Table II shows the PSNR values for different images hiding the different data. Original images contain the secret data which produces stego images. The PSNR value gives the peak signal-to-noise ratio.

Cover message for image 1: hi come on have tea.

Message to hide: hi how are you? Can we meet tomorrow?

Cover message for image2: good morning dear friend

Message to hide: dear ajay thanks for making life fun and being my friend you are most amazing person I know.

Cover message for image 3: we need urgent meeting

Message to hide: This is very important message. There is chance of terrorist attack we need army

We have implemented this on Android SDK and tested on Lenovo k6 Note also run-on Android emulator. We have calculated the PSNR and MSE values on NetBeans IDE.

TABLE I. Comparison of Algorithms

Features	**F5Algorithm**	**Previous Algorithm**	**Proposed Algorithm**
Color	Yes	Yes	Yes
Format	JPG	PNG, GIF	JPG
Security	Yes	Yes	Yes
Micro	No	Yes	Yes
Android Device	Need Modification	No	Yes

TABLE II. COMPARISON OF ALGORITHMS

Original Image	Image after Steganography	MSE Value	PSNR Value
Original Image1,JPG	Stego Image1.JPG	0.15%	46.27
Original image2.JPG	Stego Image2.JPG	0.69%	39.69
Original Image3.JPG	Stego Image3.JPG	0.39	42.18

IX. CONCLUSION

As we know that technologies have been improving in the field of communication, its result is that many microdevices have also arrived in the market. The most commonly and widely used device is the android smartphone. In such environments, the concern of security may arise that how can we keep protected our data and information. For this purpose, many researchers have used either cryptography or Steganography techniques. Some of them also tried a combination of both. When we see the previous work we found that very little work has been done over JPEG image format in the android environment and whatever the work has done they have to provide only one level or two-level security. Here we have given a method for enhancing the security by using cryptography and Steganography at three-level security over the android environment. Here hiding information in two different parts that are image and text makes it more robust to attack. We have encrypted the message two times with the DES Encryption algorithm and then divide that encrypted message into two halves so that one part is hidden in the image using the F5 algorithm and another part is hidden in the cover message using the Markov chain method for text Steganography. In this manner, two times encryption and further hiding in text and image make this system the best application to ensure data security. Till now F5 algorithm implementation is not available for android application so it is very secure application for image steganography over mobile phone. It is extensively using DES algorithm with f5, so it takes some time in processing. In comparison of other this method has advantage of security at three level which has not implemented till now on android phone using F5 algorithm for JPEG images. The limitation of this application is that it is tested on the upper than android 6 version not supported on the lower version and gives the best result for short messages, not for long payload.

***Abstract*—Forming an optimal collaborative team is achieved using members characteristics to improve team efficiency. A team's performance may have a negative effect when a team is formed randomly. Moreover, it is quite impossible to achieve an optimal team manually as the formation can expand into countless possibilities. Hence, this paper presents a decision-making framework for collaborative team formation by incorporating Fuzzy Logic and Genetic Algorithm (Fuzzy-GA). The framework has been initiated by combining effective team formation factors such as skills, trust, leadership, and individual performance. Unified Theory of Acceptance and Use of Technology (UTAUT) is utilised to survey the readiness and technology acceptance of the organisations' employees in adopting the proposed decision-making approach to form a collaborative team. The UTAUT survey had proven that behavioural intention (BI) had a positive impact on the performance expectancy (PE), effort expectancy (EE), social influence (SI) and facilitating conditions (FC). However, behavioural intention (BI) had a negative impact on the voluntariness of use (VU); thus the transformation of collaborative team formation must be further explored to increase the team's voluntarism towards this automated collaborative team formation.**

Keywords*—Collaborative team formation; genetic algorithm; fuzzy logic; unified theory of acceptance and use of technology (UTAUT)

I. Introduction

It is important to have an effective team in an organisation, particularly where there is an issue with the operating costs. Hence, an organisation needs to enforce the team development model for developing an effective team [1,2]. A team must work together to accomplish organisational activities, share common goals and interact socially [3].

A collaborative team comprises people with a variety of skills to execute a task collaboratively, where they are able to share the resources, information, and cost to deliver optimal outcomes [4]. Positive outcomes can be reached when the team members incorporate their knowledge, work well together, and welcome feedback. It has been shown that team performance exceeded the efficiency of two self-employed people [2,5]. This indicated the importance of communication and collaboration between team members. Bahrami et al. [6] also stated that accuracy in a collaborative team is higher because the team's precision is higher than that of the individuals.

An organisation consists of employees with diverse expertise, knowledge, and experience. An efficient team can enhance the team's innovativeness. Thus, for a collaborative task to be implemented efficiently, selecting team members of a collaborative team is a crucial process. [7] stated that the problem in the collaborative team formation using the decision-making approach in selecting the team members is that they are not always strategic and do not give the best output as cost and time play a big role. Hence, numerous research was executed to ascertain the effective decision support approach to form a collaborative team in an organisation. However, not much of the research focused on studying the acceptance towards the collaborative team formation technology.

This research is supported by the Short-Term Grant, Universiti Sains Malaysia (304/PKOMP/6315392).

Thus, this paper aims to study the acceptance of the proposed fuzzy and genetic algorithm-based (Fuzzy-FA) decision-making approach of collaborative team formation. To achieve this aim, the objectives of this paper are 1) to outline the combinations of factors for the decision-making system to form a collaborative team, 2) to propose a framework of a decision-making system by using Fuzzy Logic (FL) and Genetic Algorithm (GA) and 3) to evaluate the acceptance by using the Unified Theory of Acceptance and Use of Technology (UTAUT) survey.

In the next section of this paper, the related works relevant to collaborative work are presented. Subsequently, Section III highlights the framework of the collaborative team formation by finalising the team formation factors and combining the FL approach and GA (Fuzzy-GA). Section IV explains further the details of the proposed Fuzzy-GA. Section V focuses on the user acceptance survey development of the proposed Fuzzy-GA. Section VI presents the results from the UTAUT survey, which was used to evaluate the users' acceptance of the proposed framework. Section VII provides a conclusion to the paper.

II. Related Work

Leadership and trust were identified as factors for a team to have a high performance, where leadership was identified to have a direct influence on team performance, whereas trust could facilitate the leadership impacts [8]. Trust was reported to be an important factor to be considered in team formation

[9,10]. These findings showed that trust is an essential factor in establishing a collaborative team and sustaining the whole team. Zhang and Zhang [11] reported that team trust was a good predictor; thus, establishing trustworthy relationships in teams would lead to improved performance.

Skill was another crucial factor in team formation [12,13] where this factor indicated the workability of the people in the team [13]. Without the proper selection of team members with the right skills, the project to be executed might face failure and, at the same time, waste the organisational resources [12]. Fathian et al. [12] recommended three key factors: skills, collaboration network, and reliability for their proposed team formation optimisation model. These three factors were proven to support and enhance collaborative work in the context of team formation.

Knowledge was recognised as one of the key factors that could positively influence team effectiveness [14]. The knowledge factor would always greatly influence individual performance by measuring working experiences and capability [15]. Furthermore, [14] claimed that factors like leadership, management support, team diversity, reward, and goal clarity would directly affect team efficacy. A reasonable human resource allocation framework was presented with the assignment of human resources for multiple teams formation [16]. However, the optimisation approach utilised was not mentioned, and the limitation was that it did not include important human-related factors such as individual performance.

The genetic algorithm (GA) approach has been widely used in some works related to team or group formation. The Bayesian Network-based Team Formation (BN-TF) was utilised to develop a team in the setting of a business process by applying the problem as a Most Probable Explanation (MPE) [17]. GA was applied with some modifications where the Forward-Backward Greedy GA was developed as the outcome. Two factors were used: handover relation and individual expertise, but the tool to define the degree of these factors were not available.

To assist managers in multiple projects team formation, GA was utilised as a decision-making tool by using the group cohesion factor [18]. The GA showed near-optimal results, which was achieved in a short processing time. Nonetheless, when multiple combinations of employee skills were used, this approach was reported as unsuitable for forming teams dynamically. The decision support system was developed by utilising the fuzzy descriptors to assist the requirement specifications based on the team members' skills [19]. Then, the fuzzy criteria were optimised using GA, and the outcome proved that the decision support system was computationally efficient. Although it was reported to be practical, however, they did not put priority on choosing employees that have high rating values. Moreover, [19] only focused on one factor in team formation: the skills factor.

Silva and Krohling [20] proposed an algorithm based on sociometry to form a team with the human resource as the main factor, by using the fuzzy numbers approach to maximise cohesion. The algorithm allowed the expression of personal preferences provided to the sociometric test. The study reported a promising result where project managers were found to have the potential in using the algorithm as a decision-making tool; however, they overlooked the skills factor. Another limitation was that the part-time employees from the employee database were not considered to be assigned to a group formation. Based on some previous research [8,9,10], the decision-making approach is an important criterion in forming a collaborative team, and many decision-making approaches were discovered.

One of the well-known theories for user acceptance is known as the Technology Acceptance Model (TAM) [21] and further extended by the researchers [22]. Davis et al. [22] suggested two important variables toward the usage of computers: perceived usefulness and perceived use. These two variables are seen as the main variables to affect the results of the user acceptance indirectly or directly [23]. The Unified Theory of Acceptance and Use of Technology (UTAUT) model is another well-known theory used in the study for acceptance and adoption of technology [24]. In comparison to TAM, UTAUT is considered to have a clearer objective to assess the acceptance of technology from the users' point of view [25]. Venkatesh et al. [26] reported that UTAUT performed better than other models in terms of 70% variance in behavioural intention.

UTAUT illustrates a set of factors that influence the user behaviour of acceptance and the behavioural intention towards an information system: Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI) and Facilitating Conditions (FC) [14]. Besides that, the UTAUT model recognises four moderators, which influences the relationships between these constructs: Age, Gender, Voluntariness of Use, and Experience. UTAUT was utilised to analyse the proposal for introducing an e-mobile payment service targeted at Brazilian mobile phone users [27], whereas another study employed UTAUT to validate the acceptance of online games [28]. UTAUT was used to evaluate an electronic health record system by looking into factors impacting users' intention to use the system [29]. Howard et al. [30] extended the UTAUT model to further understand the perceptions towards working with building information modelling (BIM). Howard et al. [30] utilised the moderators of experience and voluntariness and, from the results, implied that there was a need to relook at the policies to improve the acceptance towards the BIM.

III. PROPOSED COLLABORATIVE TEAM FORMATION

A. Factors in the Collaborative Team Formation

The identification process and critical evaluations are important for improving the team development process. For the team formation problem, there are a lot of different factors that can be taken into account, where the factors may or may not directly influence the efficacy of the team formed [8]. Table I shows the factors that were identified in some related works. Trust, skills and leadership are important factors in forming a collaborative team to improve team efficiency in organisations. Hence, these three main factors are adopted and incorporated together in this work.

TABLE I. FACTORS IDENTIFIED FOR TEAM FORMATION

Factors	Type of Team and Reference
Leadership and Trust	Exhibitor team [8]
Trust	Virtual team [9]
Trust	Global virtual team [10]
Skill, reliability, and collaboration network	Cross-funtional team [11]
Skill, leadership, reward, management support, team diversity and goal clarity	Technical project team [14]
Human resource allocation	General team formation [16]

The factors, collaboration network and reliability by [11], together with management support, reward, team diversity and goal clarity by [14] were not included in this proposed work as those factors are related to the group as a whole, whereas the focus on this work at this stage is to leverage on the strength of each individual's factor as a contribution to the group formation. Human resources were assigned to form multiple teams but did not focus on individual performance, which was the limitation of the work by [16]. Thus, individual performance is included in this proposed work as it was considered an important factor related to individuals that contributed to a group's efficiency [16].

As a result, together with the three important factors: skills, trust, and leadership, individual performance is included as the fourth factor for the proposed team formation framework. This research presented in this paper consolidates all these four important factors while designing an effective decision-making approach to form a collaborative team.

B. *The Decision-making Approach*

A systematic and accurate decision-making approach to form an effective collaborative team is important to improve team effectiveness. The combination of FL and GA enhances collaborative work in team formation and is based on previous research [19]. FL was shown by [19] as a powerful tool in classifying the imprecise input from skill factor with the manipulation of the FL number (where the process of fuzzification generates the fuzzy set values - between 0.0 and 1.0 in a fuzzy set, denoting different levels or degrees). Meanwhile, GA has been used as an optimisation method for determining the best fitness result in fuzzy criteria.

1) Fuzzy Logic (FL): Extended from a classical set theory, FL handles problems with ambiguous and imprecise data [31]. There are 3 FL concepts 1) Fuzzy set, which allows the FL to set some boundaries, 2) Fuzzy set describes variables with values generated by linguistic variables, and 3) Constraints on the value linguistic variable values by fuzzy set assignment based on distributions of possibility [32]. Before the implementation takes place in the real world, the fuzzy approach supports ambiguity and can be assessed repetitively [33].

2) Genetic Algorithm (GA): GA is one popular approach to solving optimisation problems [34]. Motivated by the natural selection process, GA is seen to be very efficient in solving real-world problems. For example, mixed-integer programming is one of the problems that can be solved using GA [35]. The fitness level is calculated based on the required criteria of the problems' desired requirements. The phases in GA include 1) the initialisation of the population, 2) evaluation of the fitness value, 3) selection, where better results are reported to be achieved with a good selection strategy [36], 4) crossover - a process of recombining parents to have a chance of producing better individuals [37], 5) mutation - an operator that helps to bring some genetic diversity to the chromosome produced [34], 6) repetition of the new population until the best fitness value has been met or the termination criteria achieved.

C. *Fuzzy-GA Approach for the Collaborative Team Formation*

The proposed collaborative team formation has the FL and GA components, which was also used in the model presented by [19]. However, this proposed work is different and extended in terms of 1) determination of the pool of employees, 2) suitable employees are chosen with high rating values, 3) incorporating more factors related to team efficiency, in the team formation.

In this study, the four factors (skills, trust, leadership, and individual performance) were accessed from the employee database, and the fuzzy value properties were derived for each factor. Fig. 1 shows the framework of the proposed decision-making approach, using the FL and GA (Fuzzy-GA). In the project requirements, the inputs may seem to be imprecise; thus, using FL can attain a more robust solution.

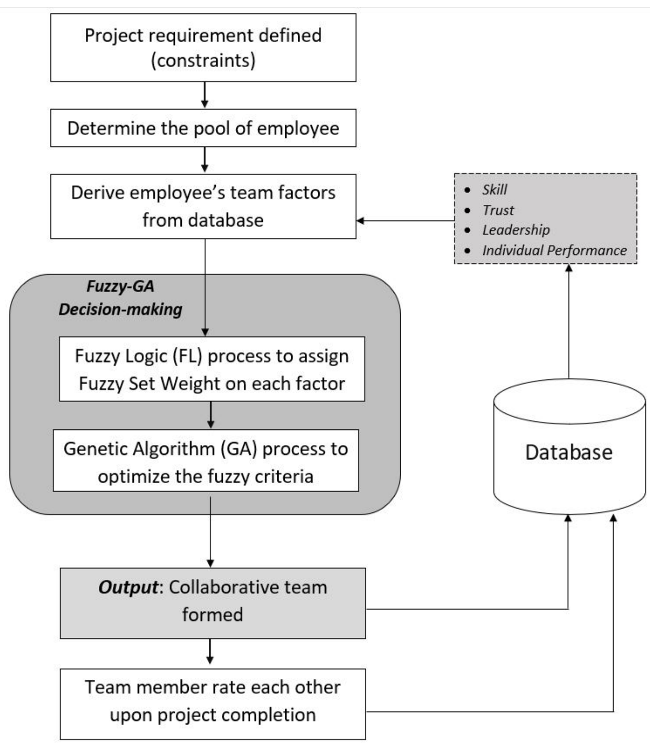

Fig. 1. The Framework of the Fuzzy-GA Decision-making Approach.

First, FL would generate the fuzzy criteria for the factors extracted. Then, the GA would formulate the fuzzy criteria into a fitness value calculation and optimise the solution to form the team. Upon the team formation and completion, the team members would be allowed to rate their other team members based on the skills, trust, leadership and individual performance factors.

D. Fuzzy Evaluation Weight

The selection of team members depended on certain project requirements. Project requirements usually contain ambiguous terms like high, low, medium, easy, or maximum. In this case, FL could help to interpret the ambiguous terms. The method to assign the weight of the fuzzy evaluation is shown in Fig. 2, where the FL approach focused on checking and defining membership set and fuzzy set. This definition is based on trust, skill, leadership, and individual performance factors.

A fuzzy number is derived from a fuzzy membership function A: R → [0, 1], where A has at least a real number in the set of numbers, R; and the elements in R are mapped to the value between 0 and 1 [38]. Thus, to assign the fuzzy number, it needs to be represented by membership sets. The author in [39] utilised the same distribution of fuzzy sets (low, medium and high) for the membership functions, whereas [40] used three fuzzy sets (small, medium, large) in their work. Biswas and Ghosh [41] explained that the fuzzification process can be done by allocating the triangular form of membership functions and that this triangular form is the simplest approach. [41] applied the three linguistic fuzzy sets- which were low, medium and high, as the input parameters and they were equally spaced to make use of the entire input spaces.

In this study, the membership set was categorised as high, medium and low for each factor, as previous researchers [39, 40, 41] had recommended this range to simplify the solution. Table II presents the fuzzy sets for each membership set, for each type of factor, respectively. Each factor had its rating, whether based on category or a range of values**,** to be categorised into the different membership sets, as shown in Table II. Based on the membership set, the fuzzy set weight was assigned, where value 1.0 was assigned for "high", value 0.5 was assigned for "medium", and value 0.1 was assigned for "low".

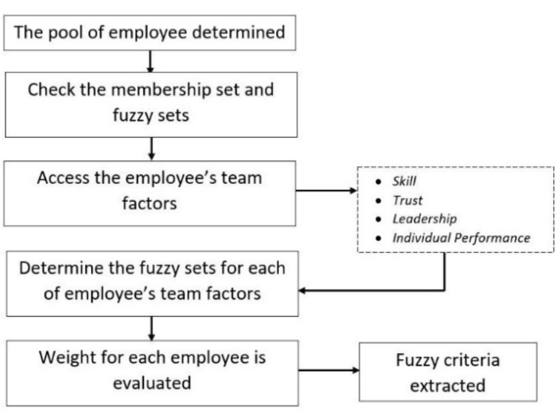

Fig. 2. The Assignment of Fuzzy Evaluation Weight.

TABLE II. FUZZY SETS AND MEMBERSHIP SETS

Factors	**Rating (category/value range)**	**Membership Sets**	**Fuzzy Sets Weight**
Skills	Expert	High	1.0
	Intermediate	Medium	0.5
	Beginner	Low	0.1
Trust	8 – 10	High	1.0
	4 – 7	Medium	0.5
	0 – 3	Low	0.1
Leadership	8 – 10	High	1.0
	4 – 7	Medium	0.5
	0 – 3	Low	0.1
Individual Performance	8 – 10	High	1.0
	4 – 7	Medium	0.5
	0 – 3	Low	0.1

The detailed steps are shown in the pseudocode, as shown in Fig. 3. The project requirements were filtered, and the suitable employee with their rating from the database was determined for each of the four-team factors, f_1 to f_4 (skills, trust, leadership, and individual performance). The steps in FL can be seen from lines 6 to 12. The process continues with the GA approach, which is explained further in the next section.

```
Start
1  Enter Project Requirement, a, b, c
     a = description of project
     b = department involved
     c = number employees
2  Get employee details from database
3  Determine the pool of employees
4    Filter employees that meet at least one condition of constraint a or b
5  Get employee's rating for team factors, f_1^4
6     Fuzzy Logic (FL) starts:
7       Define fuzzy variables
8       Determine fuzzy variables team factors, f_1^4
9       Establish membership set for these variables
10      Generate weight based on fuzzy set
11    Fuzzy criteria extracted
12    FL ends
13    Genetic Algorithm (GA) starts:
14      Generate the initial random population, C_x^y
15      While iteration <= maximum_iteration
16        For each C_x to C_y
17        Identify gene with value "1", G_i to G_n
18           For each gene, G_i to G_n
19              Calculate the gene's fuzzy weight, G_i = Σ f_1^4
20           End for
21        Calculate the fitness for C_x, Fitness_x = Σ_i^n G
22        End for
23        Selection of C_x and C_p2
24        Perform Crossover on C_x and C_p2 if probability 0.95 is accepted
25        New offspring created and chromosomes number updated, C_y++
26        Selection of C_m1
27        Perform mutation if probability 0.5 is accepted
28        Evaluate the pool of C from best to worst until y number of C
29        Generate new population newC_x^y
30        Update C_x^y = newC_x^y
31        Iteration +1
32    End while
33    Return best chromosome, C as the Team Formed
34    GA ends
35 Return Team Formed as the output
End
```

Fig. 3. The Fuzzy-GA Pseudocode for the Team Formation.

E. Optimisation of Fuzzy Criteria using GA

After the FL has generated weights for the four factors based on a fuzzy set using the employee's rating database, the GA would then generate the population of parents as chromosomes. The steps in GA are shown in the pseudocode in Fig. 3 from lines 13 to 34.

For the initial population, *y* number of parent chromosomes, *C* were randomly generated. For this study, *y* = 100, which means there were 100 parent chromosomes, *C* in each generation (iteration). The solution representation of each *y* chromosome, *C* consists of genes of individuals, *G*, where the number of the individuals were based on the number of employees available in the database.

For example, if there are 10 employees, then the size of each chromosome is 10 genes (individuals). Based on the requirements set during the constraint requirement, the number of people formed into a group, *c*, was pre-determined. Thus, during the initial population, the number of genes to be assigned to a group was based on the set constraint. In the solution representation, the genes in the chromosome assigned with value "1" indicate that they were assigned to the group, whereas values "0" indicate that they do not belong. Thus, *n* number of genes, *G*, was assigned with value "1", indicating that there was *n* number of people to be formed into a team.

For example, in the constraint requirement, if the number of people in a group was set to 5, then 5 genes in the chromosome would be randomly assigned with value "1" while others were assigned with value "0". Fig. 4 shows the example of the chromosome representation for the requirements of 5 people to be formed in a group, with 10 people available for the group formation (individuals labelled as A to J). In this example, in the current solution, individual (gene) C, E, G, I and J were assigned with value "1" denoting that they were selected to be in the current group formation.

A	B	C	D	E	F	G	H	I	J
0	0	1	0	1	0	1	0	1	1

Fig. 4. Example of Chromosome Structure for the Solution Representation.

The fitness value of the current chromosome solution (parent) would be calculated based on the genes assigned to value "1" in the current solution. The fitness calculation for the *i*-th individual gene assigned to value "1", G_i, is shown in Equation (1). The fuzzy weight values generated based on fuzzy set for each factor, f_1 to f_4 (skill, trust, leadership and individual performance) for the *i*-th individual, are added as the total weight for the G_i. Assume that there was *n* number of people set to be in the group formation in the constraint requirement. Therefore, there would be *n* number of people to be assigned with the value "1". The overall fitness value for the current solution, *x*, ($Fitness_x$) would be calculated, where the gene values from $individual_i$ to $individual_n$ were summed together, as shown in Equation (2).

$$G_i = \sum f_1^4 \quad (1)$$

$$Fitness_x = \sum_i^n G \quad (2)$$

Then, GA would proceed with the crossover and mutation process to produce new offspring from the pool of parents. A high crossover rate is usually used as it was reported to have good results on the optimisation process. Following the suggestions by [42] and [43], a crossover rate of 0.95 was applied. For the mutation rate, the suggested value of 0.5 by [44] was adopted as this was reported to have a better solution quality. Thus, crossover and mutation were implemented, and then fitness was calculated again for the newly formed offsprings and parents. The new generation was produced with a selection of 100 chromosomes with the best fitness values, replacing the 100 parent chromosomes in the previous generation. This process was repeated until the highest fitness score was converged or reached the stopping criterion. Finally, a group was formed with the best fitness value and produced as an output of the collaborative team formation.

IV. User Acceptance Survey on the Proposed Collaborative Team Formation

This section presents the development of the case study, the Unified Theory of Acceptance and Use of Technology (UTAUT) framework, and the data collection details. The case study was created to produce an artefact to be evaluated by the respondents. To evaluate the user acceptance, a survey was carried out, and the UTAUT model was used. Thus, the details of the framework and the hypothesis created are presented in this section.

A. Development of the Case Study

To study the user acceptance of this framework, a case study was constructed based on the team formation with the requirements of five employees to complete a project. The case study for this proposed framework was on the collaborative team formation in IT Department that required experts with a specification in UNIX server programming. The rules were defined for extraction using the standard format for project requirements. While this example was drawn from the IT department of an organisation, a similar practice can extend to all kinds of organisations with different project member requirements. This case study was built to be used as an artefact in the survey of user acceptance using the UTAUT questionnaire.

In this case study, the project required people who have skills in UNIX programming. The employee's database had already been assigned with values in the four factors of the Fuzzy-GA collaborative team formation. The four factors were derived for the FL process. From the rating values of the employees for each factor, FL generated the final weight using the membership set and fuzzy set. The case study followed the Fuzzy-GA collaborative team formation steps as presented in Section III. The example of this case study was developed as a prototype and produced as an artefact to be evaluated using the UTAUT survey for user acceptance.

B. Development of Unified Theory of Acceptance Framework

UTAUT is an acceptance model that justifies the information system's usage and intention by the user [24]. The proposed framework in this research was validated based on UTUAT model using a questionnaire survey method. Fig. 5 shows the framework of the user acceptance model proposed in this study. Six variables were involved, with the primary variable being the dependent variable, the Behavioural Intention (BI). BI variable denotes a person's intention to use technology, and in this case - the intention to use the Fuzzy-GA collaborative team formation system. The UTAUT framework proposed in this study predicted that BI could be influenced by four independent variables: Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI) and Facilitating Conditions (FC).

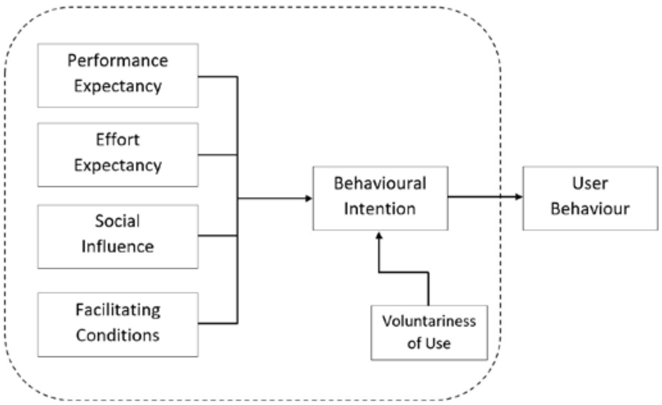

Fig. 5. User Acceptance Model Framework based on UTAUT.

In this study, one variable acted as the moderator from the UTAUT model, which was the Voluntariness of Use (VU). VU explores the extent to which an individual or an organisation believes that the acceptance or the use of new technologies happens voluntarily [45].

Hence, in this study, the VU evaluated the employee's readiness towards the collaboration team formation based on the Fuzzy-GA approach, whereby the more voluntarily a person wanted to use the proposed system, the higher the person's intention was to use the system. When automated team formation is to be implemented in an organisation, it may be a part of the requirements that the employees need to use the system. However, if they are not required to use the system, the question lies if they may still intend to use the proposed system. Therefore, the VU moderator was included in this study to find out the employees' level of voluntarism to use this proposed system. Based on the model proposed, the following hypotheses were established for this study:

- Hypothesis 1 (*H1*): PE has a positive effect on individual BI to use the Fuzzy-GS collaborative team formation system.
- Hypothesis 2 (*H2*): EE has a positive effect on individual BI to use the Fuzzy-GS collaborative team formation system.
- Hypothesis 3 (*H3*): SI will exert a positive influence on individual BI to use the Fuzzy-GS collaborative team formation system.
- Hypothesis 4 (*H4*): FC has a positive correlation with individual BI to use the Fuzzy-GS collaborative team formation system.
- Hypothesis 5 (*H5*): VU is positively related to the individual BI to use the Fuzzy-GS collaborative team formation system.

The development of hypotheses H1, H2, and H3 was supported by [46], where the constructs of PE, EE and SI were used to investigate the acceptance (BI) of the respondents to their virtual team framework in a learning environment. In [47], it was reported that the attitude towards the intention to use could be influenced by SI and FC, where FC was seen to be instrumental in empowering the individuals to have positive acceptance of the technology. Hence, this supports the hypothesis H4 tested in this study. In [45], the work had predicted the negative impact of VU on BI. However, in this study, the VU was investigated to find the positive impact on BI. The focus was to verify whether the respondents were inclined to voluntarily accept the technology.

C. Data Collection

Based on the UTAUT model framework in Fig. 5, a Likert-scale questionnaire was used to collect data on the acceptance of IT department employees towards the proposed Fuzzy-GA approach for collaborative team formation in an organisation.

The questionnaire and the artefact for the collaborative team formation framework were distributed to the respondents, who are employees of an organisation in Penang, Malaysia. The data was used to analyse the technology acceptance by the organisation's employees. The constructions of the questions are shown in Table III.

TABLE III. THE CONSTRUCTION OF QUESTIONS

Construct	**Item**	**Questionnaire item**	**Cited from**
Performance Expectancy	PE1	I would find the Fuzzy-GA collaborative team formation system as useful in my job.	[30]
	PE2	Using Fuzzy-GA collaborative team formation system will enable me to accomplish my job more quickly.	[41]
	PE3	Using Fuzzy-GA collaborative team formation system will increase my productivity.	
	PE4	Using Fuzzy-GA collaborative team formation system will improve my performance in my job	
Effort expectancy	EE1	It will be easy for me to become skilful at using the Fuzzy-GA collaborative team formation system.	[30]
	EE2	Learning how to use Fuzzy-GA collaborative team formation system will be easy for me.	[41]
	EE3	I understand clearly on how to use the Fuzzy-GA collaborative team formation system.	
	EE4	I do not have any difficulties in explaining why using Fuzzy-GA collaborative team formation system may be beneficial.	
Social influence	SI1	People who influence my behavior think that I should use Fuzzy-GA collaborative team formation system.	[41]
	SI2	People who are important to me think that I should use Fuzzy-GA collaborative team formation system.	

	SI3	The organisation has supported to use Fuzzy-GA collaborative team formation system.	[30]
Facilitating conditions	FC1	I have the necessary resources to use Fuzzy-GA collaborative team formation system.	[41]
	FC2	I have the necessary knowledge to use Fuzzy-GA collaborative team formation system.	[30]
	FC3	A specific person or specific group is available for assistance if there are difficulties concerning the use of Fuzzy-GA collaborative team formation system.	[41]
Behavioural intention	BI1	I intend to use Fuzzy-GA collaborative team formation system in the future.	[41]
	BI2	I predict that I will use Fuzzy-GA collaborative team formation system in the future.	
	BI3	I plan to use Fuzzy-GA collaborative team formation system in the future.	
Voluntariness of use	VU1	Although it might be helpful, using Fuzzy-GA collaborative team formation system is certainly not compulsory for my job.	[41]
	VU2	My use of Fuzzy-GA collaborative team formation system data is voluntary.	

V. Result and Discussion

During data collection, the artefacts were presented to the respondents, and the questionnaires were answered. In this section, the results from this data collection are presented. The survey was conducted to study the user's acceptance of the proposed Fuzzy-GA collaborative team formation system. With the help of the UTAUT framework, the results projected the respondents' intention to use the proposed system as a decision support system for collaborative team formation.

A. Data and Descriptive Analysis

As mentioned in Section VI-C, the five-point Likert scale was used, representing Strongly Disagree to Strongly Agree. 70 questionnaires were administered, and a total number of 50 were returned, with a response rate of 71%. The statistical tool, SPSS 24, was applied to capture and analyse the data from the questionnaire. Table IV shows the descriptive statistics for the UTAUT constructs from the response to each question. The mean values for PE, EE, SI, FC and VU were between 3 and 4, implying that most responses from the respondents were somewhat Neutral and Agree.

B. Pearson's Correlation

Pearson's Correlation was employed to define the strength of the relationship between two variables. Table V presents the range and categories of Pearson's Correlation coefficient strength described by [37], which was used as a benchmark of the relationship strength.

To investigate the acceptance of the proposed collaborative team formation approach, the impact of the UTAUT constructs of the independent variables, PE, EE, SI and FC towards the dependent variable, BI and the employee's readiness for the VU towards BI were evaluated. Table VI shows the result based on Pearson's Correlation analysis.

TABLE IV. Descriptive Statistics

Code	***Minimum***	***Maximum***	***Mean***	***Std. Deviation***
Performance Expectancy (PE)				
PE1	2	5	4.13	.730
PE2	2	5	3.77	.858
PE3	2	5	3.80	.961
PE4	2	5	3.93	.785
Effort Expectancy (EE)				
EE1	3	5	4.00	.788
EE2	2	5	4.10	.923
EE3	2	5	3.87	1.137
EE4	2	5	3.67	.994
Social Influence (SI)				
SI1	2	5	3.47	.819
SI2	2	5	3.57	.858
SI3	2	5	3.90	.803
Facilitating Conditions (FC)				
FC1	2	5	3.80	.805
FC2	2	5	3.93	.785
FC3	2	5	3.50	1.009
Behavioural Intention (BI)				
BI1	2	5	3.83	.950
BI2	2	5	3.83	.986
BI3	2	5	3.87	.973
Voluntariness of Use (VU)				
VU1	1	5	3.67	1.155
VU2	2	5	3.67	.758

TABLE V. The Range and Categories of Pearson's Correlation Coefficient Strength [37]

Range Value	**Category of the Relationship Strength**
0.50 -1.0	Strong
0.30-0.49	Moderate
0.10-0.29	Weak

TABLE VI. Pearson's Correlation Results for All Variables

	M_PE	***M_EE***	***M_SI***	***M_FC***	***M_BI***	***M_VU***
M_PE	1	.739**	.780**	.752**	**.785****	.023
M_EE	.739**	1	.852**	.879**	**.790****	.114

M_FC	.752**	.879**	.835**	1	**.784****	.172
M_BI	.785**	.790**	.858**	.784**	1	.214
M_VU	.023	.114	.204	.172	**.214**	1
**. Correlation is significant at the 0.01 level (2-tailed).						

C. Hypothesis Evaluation

In this section, the five proposed hypotheses are evaluated. The correlation values to validate these hypotheses can be referred to in Table VI.

Table V is used as the reference to determine the strength of the relationship between two variables in each hypothesis.

- Hypothesis 1: The Pearson's correlation value for mean PE (M_PE) to mean BI (M_BI) was 0.785. Thus, PE had a strong positive effect on individual BI. Hence, hypothesis *H1* was supported.
- Hypothesis 2: The Pearson's correlation value for mean EE (M_EE) to mean BI (M_BI) was 0.790. Thus, EE had a strong positive effect on individual BI. Hence, hypothesis *H2* was supported.
- Hypothesis 3: The Pearson's correlation value for mean SI (M_SI) to mean BI (M_BI) was 0.858. Thus, SI has a strong positive influence on individual BI. Hence, hypothesis *H3* was supported.
- Hypothesis 4: The Pearson's correlation value for mean FC (M_FC) to mean BI (M_BI) was 0.784. Thus, FC had a strong positive correlation with individual BI. Hence, hypothesis *H4* was supported.
- Hypothesis 5: The Pearson's correlation value for mean VU (M_VU) to mean BI (M_BI) was 0.214. Thus, VU had a weak positive correlation BI. Hence, hypothesis *H5* was not supported.

D. Discussion

As mentioned previously, the Pearson's Correlation results for all the variables tested are shown in Table VI. The relationship of the first independent variable, Performance Expectancy (PE) to the Behavioural Intention (BI) can be interpreted from the mean PE to mean BI correlation value, where the value was 0.785. For the next independent variable, Effort Expectancy (EE), the correlation value of mean EE (M_EE) to mean BI (M_BI) was 0.790.

Next, the relationship of the independent variable Social Influence (SI) with BI can be referred to where the mean SI (M_SI) to mean BI (M_BI) had the correlation value of 0.858. For the last independent variable, Facilitating Conditions (FC), the correlation value of mean FC (M_FC) to mean BI (M_BI) was 0.784.

Referring to the benchmark value shown in Table V and the Pearson's correlation values of the independent variables PE, EE, SI and FC to the dependent variable BI, the values were within the range of 0.5 – 1.0. This shows that there were strong relationships and positive effects between those independent variables with the BI. Therefore, the survey showed that the employees (respondents) were positive towards accepting the proposed Fuzzy-GA-based decision-making approach for collaborative team formation, where their intention to use the system was high.

Currently, limited research applied UTAUT to investigate the acceptance towards collaborative team systems. Thus, this study was motivated to investigate the level of acceptance towards a collaborative team system using the UTAUT construct, as previous researchers [25,26] reported the advantage of UTAUT compared to other models such as TAM. Because of the limitations, comparisons were made with other studies that used UTAUT for acceptance towards technology in general.

The work by [46] explored acceptance towards virtual teams but focused more on the learning environment using the UTAUT. The author in [46] investigated variables PE, EE, SI and FC towards the BI. In their findings, PE, SI and FC had a positive impact on BI, which coincides with the result achieved for the same variables in this study.

However, in [46], EE did not have a positive impact on BI. On the contrary, this study found EE to have a favourable result to BI, where it had the second-highest correlation to BI. This may be due to the respondents finding that the artefact of the system seemed to be understandable and simple to be used if implemented. Thus, not much effort is required to adapt to the new system.

In [47], the researcher carried out an extensive review on the acceptance level of teachers and students on computer- and technology-based education systems. From the systems reviewed for the year 2017 to 2020 in [47], there were 16 works reviewed that used all four variables (PE, EE, SI and FC) in their studies. In that 16 works, each of the variables that had a direct or positive impact on BI were reported as such 1) PE - 15 direct impacts, 2) EE - 12 direct impacts, 3) SI - 11 direct impacts, 4) FC - 10 direct impacts, where one study had shown a very significant impact of FC compared to other variables. In this paper, the most significant variable was found to be SI.

In this study, from the strong relationship of PE to BI, it can be deliberated that the respondents had a positive expectancy that using the proposed system, if implemented in the organisation, can somehow help their tasks be completed more efficiently and increase their productivity.

The relationship of EE to BI was also strong; thus, the respondents would have no problem making an effort to use the system. The correlation value of the relationship of FC to BI was slightly lower compared to the other independent variables but was still in the range of a strong relationship. Hence, this implies that the respondent believed that there would be enough facilitating resources and help when using the proposed system.

The independent variable SI had the strongest positive correlation with BI as it had the highest correlation value. This shows that employees can be influenced by their social peers and networks towards accepting the proposed collaborative team formation. This demonstrates the importance of social influence among the employees when adopting new technology within their working environment.

Although the independent variables all showed positive effects towards intention to use the proposed system that was not the case with the moderator variable, Voluntariness of use (VU). For the moderator VU, the value of Pearson's Correlation for mean VU (M_VU) to mean BI (M_BI) was only 0.214. This is in the range of 0.00 – 0.29, as shown in Table V, which indicates a weak relationship.

The value shows that the VU was negatively related to BI. This coincides with the result achieved by [45] that had predicted there would be a negative impact of VU towards BI. Even in the study by [48] that reported VU had a positive impact on BI and other independent variables, the VU was negatively correlated to the user behaviour.

From the findings in this study for moderator VU, the negative correlation may have occurred because the employees were not ready to voluntarily transform the manual collaborative team formation into an automated collaborative team formation. They might have the intention to use it if it was made compulsory by the organisation and also had a positive attitude in their intention to use the system, but they were not inclined towards using it voluntarily.

VI. Conclusion

This research studied the user's acceptance of the proposed framework for organisational collaborative team formation by incorporating the Fuzzy-GA approach and integrating four factors that influence team formation: leadership, trust, skills and individual performance. FL was utilised to assign a detailed weight for the four team formation factors as fuzzy attributes. Then, GA was applied to optimise the fuzzy attributes. The acceptance of users to the Fuzzy-GA collaborative team formation was evaluated by using the UTAUT survey, and the results were presented.

The results from the analysis showed that the organisation's employees accept the proposed Fuzzy-GA based approach on collaboration team formation based on the positive Behavioural Intention (BI) on the Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI) and Facilitating Conditions (FC). This shows that the employees tend to accept the use of the system if it were to be imposed on them. Thus, this proposed framework is believed to be capable of forming a high visionary workforce while improving team performance at all levels. Looking at the positive outcome from the variables PE, EE, SI and FC, in the results of the user acceptance study, this proposed study is seen to have the potential to be implemented in organisations.

However, the employees were not ready to voluntarily transform towards an effective collaborative team formation, shown from the low coefficient strength of Pearson's Correlation analysis on Voluntariness of use (VU). From this finding, although they might intend to use it if it was made compulsory or found it helpful in project completion, they might not be ready to adapt to the system voluntarily. This may be because this type of system was still new to them, and they were not familiar with it. Hence, this paper can serve as a reference for potential top management in organisations that intend to adopt a similar automated collaborative team formation to strategise a better approach to increase their employees' voluntary involvement in such a system.

In future work, the rating component of the Fuzzy-GA collaborative team formation can be further expanded. The team members rating from the successfully formed team and implemented project can be reused. Thus, a new project requirement can be added, for example, experience in successful team formation for future team formation consideration. Besides that, the future work for the Fuzzy-GA collaborative team formation will focus on the improvement and further evaluation of the Fuzzy-GA efficiency especially on the optimisation of the group formation. The Fuzzy-GA will be considered for further enhancement by tuning the GA component of the framework. For example, the Fuzzy-GA approach can be hybridised with other metaheuristic algorithms such as simulated annealing or ant colony optimisation.

***Abstract*—The manufacturing industry has been revolutionized by Industry 4.0, vastly improving the manufacturing process, increasing production quality and capacity. Machine-to-Machine (M2M) communication protocols were developed to strengthen and bind this ecosystem by allowing machines to communicate with each other. The SECS/GEM protocol is at the heart of the manufacturing industry, thriving as a communication protocol and control system for years. It is a manufacturing equipment protocol used for equipment-host data communications. However, it is not without drawbacks, despite being a widely adopted communication protocol used by leading industries. SECS/GEM does not offer any type of security features as it was designed to work in a closed network. Such shortcomings in the protocol will allow attackers to steal secrets such as manufacturing processes by looking at recipes, perform reconnaissance prior to sabotage attempts, and can have severe implications on the entire industry. This paper proposes a mechanism to secure SECS/GEM data messages with AES-GCM encryption and evaluate the performance with the standard SECS/GEM protocol. The results from our evaluations showed that the proposed mechanism achieves data confidentiality and authenticity with a negligible overhead of 0.8 milliseconds and 0.37 milliseconds when sending and receiving a message, respectively, compared to the standard protocol.**

***Keywords*—SECS/GEM; HSMS; cybersecurity; industry-4.0; machine-to-machine communication; AES-GCM**

I. Introduction

Industry 4.0 is bringing forth significant changes to the manufacturing industry. Industry 4.0 aims to take the manufacturing industry to the next level of technological advancement for an interconnected manufacturing ecosystem where machines communicate through the network to exchange messages, instructions, and data. With sophisticated machinery and automation, more integrated machine-to-machine communication, real-time monitoring and data collection, machine learning, and enhanced inter-connectivity, Industry 4.0 is changing the existing manufacturing process for the better and improving overall production [1]. As machines are interconnected, they generate activity analysis, predictive diagnostic data, performance statistics, and other monitoring and control information. Thus, real-time decisions can be made quickly with advantages such as time and cost-saving. In many circumstances, human interaction will be removed from the factory environment. With predefined and maintained settings and parameters, the factory equipment can make crucial decisions by itself, ensuring maximum cost-effectiveness for the industry.

Industry 4.0 deals with large volumes of data. Therefore, data security is a major concern when trying to achieve the true potential of Industry 4.0. It is essential to implement end-to-end encryption to fix vulnerabilities against various attacks [2]. With Industry 4.0's increased data density and the convergence of information and operational technologies, new issues emerge, particularly in the field of cybersecurity [3]. Cybers-attacks are the most critical problem that all countries are concerned about. It is a method of safeguarding digitally stored corporate data and valuable information about a system or subject from misuse, unauthorized access, and theft. Cyberattacks have become more common as network connections have grown, owing to a growing tendency to exploit data for various reasons, including financial gain and strategic reasons [4]. It is especially true in the case of cyberattacks against the manufacturing industry.

Although the manufacturing industry has been gradually updating and improving its IT security over the years, it can be seen in the Verizon Data Breach Investigation Report 2019, detailing 352 cyberattack incidents, out of which 87 were against the manufacturing industry. Recent attacks and security breaches against the manufacturing industry are alarming, making it a highly targeted and vulnerable entity for attackers [5]. A survey by the Engineering Employers' Federation (EEF) shows that 60% of manufacturers were victims of cyberattacks at some point in time, and one-third of the affected manufacturers have suffered financial losses and market loss. A 2021 study by Cybersecurity Ventures predicts that corporations worldwide will suffer losses up to $10.5 trillion yearly by 2025 resulting from cyber-attacks, estimated in 2015 to be $3 trillion [6]. The cyberattack on Taiwan Semiconductor Manufacturing Company (TSMC) was in Taiwan's history, the worst data security infringement to befall them. It completely exposed data security vulnerabilities at TSMC's production foundries. These cyber-attack incidents are happening as the manufacturing industry embraces the shift to Industry 4.0, with more and more machines becoming connected for communications and automation [7].

The SECS/GEM protocol is at the heart of the semiconductor industry in companies such as Intel, Samsung, TSMC, IBM, Qualcomm, and many more [8]. It has been profoundly used as a Machine-to-Machine (M2M) communication protocol and control system for decades. The SECS/GEM protocol is a specially designed semiconductor

*Corresponding Author

manufacturing equipment protocol used for equipment-host data communications.

A study by A. Laghari et al. [8] reveals that although SECS/GEM has been widely adopted and is critical to the semiconductor manufacturing industry, it is not without drawbacks. It does not offer any type of security features. It uses binary encoded messages to communicate between machines, making it open for anyone on the network to read the data; thus, data confidentiality is lost. Attackers on the network can modify data inside the messages as there are no authenticity checks. SECS/GEM protocol standards were designed in an era where machines were not required to be connected to the network [9]. The machines were initially expected to be working behind an air-gapped network and therefore did not require security features like network and data security. Thus, the focus was only needed on physical security. With Industry 4.0, the machines are required to be connected to the network for accessing data, analysis, and much more. These requirements open up air-gapped networks, and hence, the attack surface is enlarged in the process. Thus, cybersecurity in the manufacturing ecosystem is of the most importance. Data confidentiality, authenticity, and availability in machinery connected to the industrial network are all considered in the context of cybersecurity [10]. SECS/GEM is susceptible to these issues since it does not provide any kind of security features.

As SECS/GEM is a widespread M2M communication protocol used all around the world, we cannot simply introduce a new protocol. This paper proposes a security mechanism for the SECS/GEM protocol to attain data confidentiality and authenticity in SECS/GEM communications. We propose to encrypt the data payload of SECS/GEM messages to protect the data from attackers. In addition, we propose to use a hash-based tag to verify message data authenticity to ensure data has not been modified or corrupted by attackers.

To our knowledge, no prior research has been done on the security aspects of the SECS/GEM protocol. Hence, this is a novel field of study and has no known related works for comparison.

The rest of the paper is structured as follows. In Section II, the SECS/GEM protocol standards are described briefly. Section III discusses the security issues found in SECS/GEM protocol standards. In Section IV, we present the proposed mechanism in detail. Section V presents the implementation and testbed details. In Section VI, we present our evaluation and results for the proposed mechanism. Section VII concludes this work and discusses future work.

II. SECS / GEM PROTOCOL STANDARDS

SEMI (formerly Semiconductor Equipment and Materials International) has released five major protocols over the years. With the first release in the year 1978 and the latest revision being released in 2020. Though the SECS/GEM communication protocols were published two decades ago, they are regularly maintained and published. This section is an overview of the major SECS/GEM protocol releases. Table I gives a brief description of SECS/GEM standards.

TABLE I. SECS / GEM PROTOCOL STANDARDS

Year	SEMI Standard	Description
1978	**E4** SECS-I	**SEMI Equipment Communications Standard-I** protocol allows various equipment and a host to communicate over an RS-232 connection.
1982	**E5** SECS-II	**SEMI Equipment Communications Standard-II** facilitates data exchange between equipment and host as a specific stream and function message in a predefined format.
1992	**E30** GEM	**Generic Equipment Model** aids in specifying usage of any particular SECS-II message as well as the monitoring of equipment behavior when communicating with the host
1994	**E37.1** HSMS-SS	**High-Speed SECS Message Service – Single Session** is a TCP/IP-based communication protocol that manages a single machine-to-machine communication link between equipment and a host.
1994	**E37.2** HSMS-GS	**High-Speed SECS Message Service – Global Session** is an extension to E37.1 with handling multiple sessions and maintaining the state of the equipment as an additional feature.

A. SEMI Equipment Communications Standard-I

The SEMI Equipment Communications Standard-I (SECS-I), also referred to as SEMI E4 standard, is the oldest SECS/GEM standard. The exchange of communication messages between manufacturing equipment and a host computer is described in this standard. The equipment and host are not required to be familiar with one another to exchange messages [11] [12]. The SECS-I standard uses the RS-232-c standard for communication. Over RS-232, the SECS-I has a sluggish data transfer rate and does not offer support local area networks based on TCP/IP. The messages and data are exchanged asynchronously. The connection is bidirectional but limited to work in half-duplex mode. The rate of communication is generally between 9,600 baud and 19,200 baud. The protocol uses 256-byte blocks for multiblock data transfers. However, longer distances are not suitable for RS-232 transmission, and it has a low noise immunity. SECS-I is only used in old legacy production machinery and is not used in any newer machinery.

B. SEMI Equipment Communications Standard-II

The SEMI Equipment Communications Standard-II (SECS-II), also referred to as SEMI E5 standard, is a communication protocol that defines a generic messaging layer to send or receive any given data structure supported by the standard. Additionally, it specifies a collection of standard messages, each with its purpose, structure, and identity. It decodes the message type, message structure, data types, and message contents sent between the manufacturing equipment and the host. The message types are specified for various categories that cover a wide range of functions, generic as well as for specific purposes. The messages are divided into streams based on the particular category the message falls into (e.g., equipment status is dealt by Stream-1, whereas recipe management specifications are handled by Stream-7, etc.), with functions being individual messages within each stream [13].

The streams and functions are represented by numbers of size 1 byte. Since only one byte is used, the numbers start from 0 and can go up to 255. The combination of stream and function numbers can be represented as SnFm, wherein n represents stream number and m represents function number designated for data exchange. The request messages are represented by odd-numbered function codes, whereas response messages are represented with even-numbered function numbers. For example, a request message of Stream 1 and Function 13 (S1F13) is an "Establish Communication Request" message for a host/equipment. Upon receiving an S1F13 message, the equipment/host would send a stream-1 and function-14 (S1F14) message as a reply. A request message and its corresponding response message are called a transaction (i.e., S1F13/S1F14). A unique ID is assigned to each transaction. The sender specifies the SystemBytes, a field in the message header of size 4 bytes. The SystemBytes is used to link a request message with the respective response message.

The SECS-II standard provides data types for encoding data in a compact, bandwidth-efficient format. Integers, both unsigned and signed, can be stored in 1-byte, 2-byte, 4-byte, and 8-byte sized fields. Floating-point values can be stored in fields of size 4 and 8 bytes. On/off, values are represented using the 01-byte Boolean data type. Strings are described using the ASCII data type, while file data such as images and statistical plots are stored using the binary datatype. The List data item type can contain nested lists as well as a sequence of other primitive data items. The total number of items in a list is obtained from the length bits of the List data item. The maximum size for a data element within a SECS-II message is 16,777,215 bytes (approximately 16.5MB) long, according to the E5 standard. A message could contain only one single data element (for example, binary data or encoded text), or a large, sophisticated data structure (for example, lists stored within another list), or even no data at all.

C. Generic Equipment Model

The Generic Equipment Model (GEM), also referred to as SEMI E30 standard, defines a set of minimum requirements for describing factory equipment using a generic model, as well as optional features, use cases, and scenarios. A subset of SECS-II messages is used in the GEM model [14]. The GEM interface includes basic requirements as well as additional equipment capabilities. The GEM standard defines the generic model for equipment so that whatever the scale or sophistication of the production equipment, a generic interface (GEM) can be implemented for it. Some basic equipment, for example, does not require recipe management because it does not have any recipes for processing. For complex equipment, having many recipes to pick from, the requirement is that it must push/pull recipes to and from the host machine. GEM is also scalable in terms of data size. Simple devices with limited capabilities, for example, may publish a dozen different collection events. On the other hand, complex factory equipment may generate large amounts of events and data and publish many collection events in a short period. Yet, both can use the same GEM interface.

D. High-Speed SECS Message Service

High-Speed SECS Message Service (HSMS), also referred to as SEMI E37 standard, is a SEMI standard that defines the transport protocol for SECS/GEM message communications [15] [16]. HSMS is based on TCP/IP. It is, in fact, a derivation of TCP/IP with minor modifications and employs nearly the same techniques for creating connections as specified in RFC 793 [17]. One such change is that RFC 793 specifies to allow the communicating parties to connect to each other simultaneously. The HSMS protocol, on the other hand, restricts the connection-establishment procedure and defines two separate modes to establish connections, the passive and active modes. Devices running active mode can only initiate a request to establish a connection. The devices in passive mode can only accept connection establishment requests from other devices in active mode. HSMS carries SECS-II messages in binary encoding format to monitor status, control processes, report on events, and perform numerous other machinery operations after a communication link between equipment and host has been established. Between the communicating entities, the established connection is maintained for as long as required. Messages are exchanged between equipment and host until either device disconnects for some reason, such as hardware/software upgrades, machine additions or removals, or maintenance. The messages are sent as a data stream with a fixed header structure. The header fields are described in Table II. The first 4 bytes determine the encoded SECS-II message's total length, including the size of the header (10 bytes). The smallest HSMS message is 10 bytes (i.e., just the header size), while the largest conceivable size of the message is 4 GB. The structure of a HSMS message is depicted in Fig. 1.

TABLE II. HSMS HEADER FIELDS

Header Field	***Size***	***Description***
Session ID	2 bytes	It is used to associate reference between control messages and subsequent data messages
Stream	1 byte	Represents the Stream number of the message
Function	1 byte	Represents the Function number of the message
PType	1 byte	It is an enumerated type to define encoding used. HSMS defines PType with value zero to mean SECS-II message encoding. Non-zero PType values are reserved for subsidiary standards' future use.
SType	1 byte	It is an enumerated type to identify if the message is a control message (non-zero) or a data message (zero)
System Bytes	4 bytes	It is used to associate primary messages with the respective secondary message (reply)

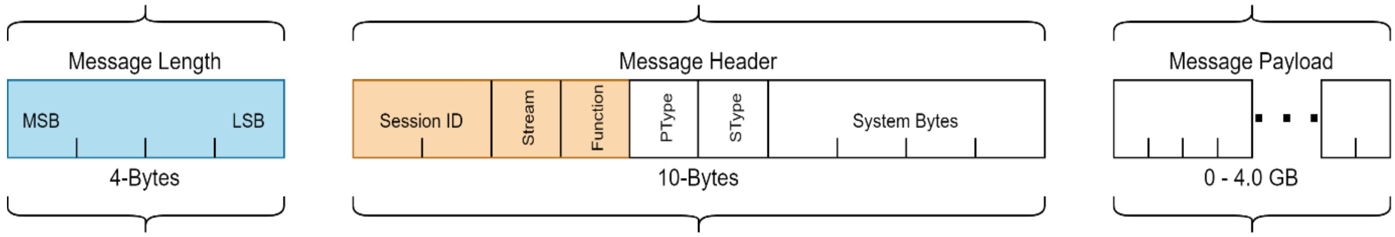

Fig. 1. Standard HSMS Message Structure.

The SECS/GEM interface allows factory hosts to monitor equipment actions and provides total equipment control. Everything happening on the machinery can be monitored, and enhanced logic can be put on the equipment to make better decisions. Various applications can be implemented using SECS/GEM to monitor and analyze statistical data, troubleshoot, predict possible maintenance requirements, control processes for feedback/feedforward, check usage, track materials, validate recipes, etc. These systems also eliminate the requirement for an operator-to-equipment interaction, resulting in fewer operators needed in the production environment. Factories can reduce material scrap and waste by using effective recipe management. For example, storing golden recipes in a centralized location via the SECS/GEM interface makes sure that the right recipes and materials are used.

III. Security Issues

The SECS/GEM protocols in its original standard do not specify any encryption for its message data and all messages between equipment and host are unencrypted binary encoded data. This shortcoming introduces opportunities for attackers to exploit and disrupt the health of the production environment. Attackers can launch attacks, disrupt communications, steal intellectual property belonging to the company, and more.

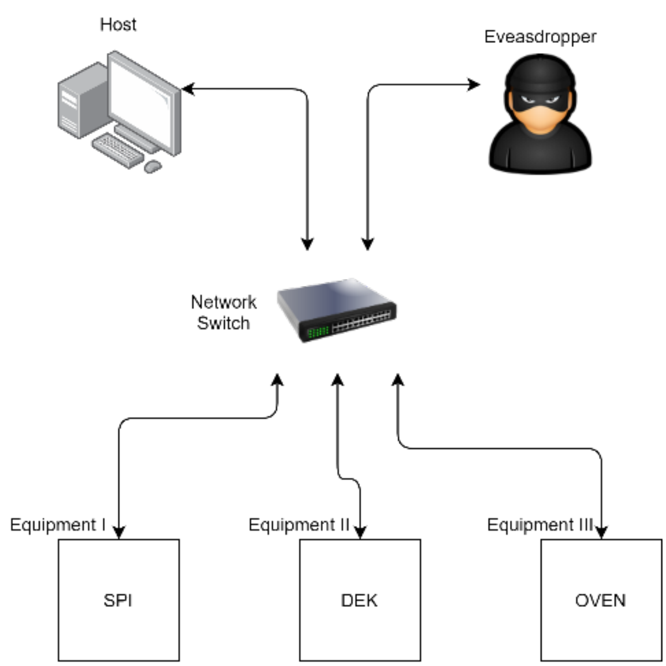

Fig. 2. Attacker on the network Eavesdropping Communications.

In this paper, we focus on data confidentiality and authenticity issues in SECS/GEM protocols. Due to data being transferred in binary encoded format, attackers can eavesdrop on equipment-host communication and lead to loss of data confidentiality. Fig. 2 shows how an attacker may position themselves on the network to eavesdrop on communication messages passively. Attackers can learn machine parameters and settings, product design information from communication messages. Intellectual property such as product designs, parameters, and settings for the manufacturing process can be stolen by attackers for monetary gain. Such an attack can be a life-or-death situation for companies as the industry is always competitive, and loss of IP can cost a company their leadership in the industry.

A study by A. Corallo et al. [10] shows that if a product's design information is no longer confidential, it could negatively affect the company's competitive advantage. The loss of unique knowledge about the items and their manufacturing methods may work in competitors' favor. Data confidentiality of machine settings and parameters or machinery status, if lost, could lead to a decline of the company's reputation. This information provides insight into the production ecosystem's health. Therefore, if sensitive information such as machine malfunctions are revealed, the company's reliability would be questioned and could lead to investors leaving and losing customers. The loss of confidentiality of product properties, like quality indicators, would negatively affect the company's leadership and change in favor of its competitors. In fact, in the event of a product fault, competitors may exploit the situation by using ad hoc styled marketing strategies to win a larger market share.

Attackers can also launch tailored attacks such as Man-In-The-Middle (MITM) attacks to disrupt production and cause financial losses as part of sabotage operations. Such attacks can range from disrupting communications, injecting false data, causing machine failures, etc. It is easy for attackers to launch such attacks as current SECS/GEM protocol implementations do not provide data confidentiality or perform authenticity checks on the data.

To further discuss the seriousness of this issue, consider the scenario where an attacker launches a passive eavesdropping attack on the network and listens to communications. Over time the attacker can gather enough data about the machine settings and parameters to launch MITM attacks. For example, attackers may learn parameters that can make machines run differently, cause malfunctions or create defective products that fail quality checks. Such knowledge will let attackers launch attacks that will look normal to the system and intentional disruptions of the manufacturing systems. Attacks of this kind can cause failure rates to be high and make it look like the machines malfunction or fail even when they are not. This type of attack is proven to be possible.

The infamous STUXNET virus is a real-life example of the previously described scenario which targeted the Iranian nuclear program and caused equipment to malfunction [18], [19]. The STUXNET virus had the pattern described in the example scenario. It recorded data from the Supervisory control and data acquisition (SCADA) systems controlling the equipment during its incubation period. It then starts actively attacking the facility by sending malicious parameters to make the equipment fail. It replayed the previously recorded data during the attacks to trick the operators from knowing the actual status of the equipment [20]. It appeared to the operators as just equipment malfunction. In this case, a slight change in the rotation speed of certain parts of the equipment caused them to malfunction and explode. STUXNET is considered to be an attack on a nation. If a nation is at risk from such attacks, it only makes it more apparent that a manufacturing company is even more susceptible to such attacks.

An attack such as STUXNET on the manufacturing industry may be a targeted attack against a company's sustainability. An attacker will launch attacks to disrupt operations until the company is forced to stop operations due to substantial financial losses. If the attacker cannot see the data being transmitted through the communication messages, it can help protect against the attacker’s reconnaissance attempts and stall following attacks. Unsolicited messages from attackers with possibly malicious instructions can be blocked if the data is checked for authenticity.

Hence, data confidentiality and authenticity have a significant impact on the industry's ecosystem. The SECS/GEM protocol is at the heart of the semiconductor industry, and therefore these issues are of serious nature. With the leap of the manufacturing industry into Industry 4.0, machines will need to communicate with other machines through the production network. With the ongoing Corona Virus Disease 2019 (COVID-19) global pandemic, during the time of this research, the need for remote access and communication with production machines has become more necessary due to work-from-home scenarios [21]. Managers and operators overlooking factory equipment require remote access to check equipment status all the time. However, allowing machines to connect to the network and operations personnel further increases the attack surface for cybercriminals to gain access to the production environment. Therefore SECS/GEM protocol's method of communication with binary encoded data becomes a major security issue and must be addressed to thwart attack attempts from cybercriminals.

All major industries are attempting to bring their factories up to the Industry 4.0 standards to reap the benefits. Machine-to-Machine communication is essential to automate the processes in every industry. For example, machines can communicate with other machines when they need more components, a change of recipe, or when an error occurs, the previous machine on the production line needs to stop sending more batches to process. Such coordination between factory equipment can help a lot with automation and with the overall efficiency of the manufacturing process as Industry 4.0 compatible factories would need lesser human interaction.

IV. Proposed Mechanism

This section describes, in detail, the proposed mechanism for preserving data confidentiality and authenticity in SECS/GEM during transmission in production networks. Data confidentiality is a critical part of the production network since data may go through several hops. This can be ensured using a secure encryption mechanism. This is necessary due to the wide range of devices, services, and networks that communicate/operate with a lot of data and thus present sufficient opportunity for data confidentiality violations as well as modifications due to the ease with which data may be accessed in SECS/GEM communication [22]. A data transfer mechanism for secure and efficient SECS/GEM communication is proposed in response to this requirement. The proposed mechanism is designed for the HSMS protocol in the SECS/GEM protocol stack. HSMS was chosen as it is the latest SECS/GEM protocol and is supplied with the latest machines.

We propose to use the Advanced Encryption Standard Galois/Counter Mode (AES-GCM) encryption scheme to achieve data confidentiality in SECS/GEM communication. Galois/Counter Mode (GCM) is one of several modes available for symmetric-key cryptographic block ciphers. It is adopted widely for its performance and throughput rates. With inexpensive hardware resources, throughput rates as high as 10 Gbps can be achieved [23]. It is an authenticated encryption algorithm that provides both data confidentiality and authenticity. GCM is defined for block ciphers that operate on a block size of 128 bits, and hence AES-GCM is used.

A. *Proposed Mechanism Design*

The proposed mechanism is designed to encrypt the data payload of the HSMS packet and verify its authenticity at the receiver end. The proposed mechanism's packet structure is depicted in Fig. 3. The message has 4 bytes of message length denoting the size of the HSMS message, including the header and payload length. The header of the message consists of 10 bytes. The header fields are described in Table II.

The header and the length bytes follow the same structure as in the standard HSMS message. The message payload, however, has a different structure from a standard HSMS message data payload. The data message payload of the proposed mechanism has a structure, as depicted in Fig. 3. It has fixed sizes for certain data at the beginning and end of the payload structure. The first 16 bytes of the message payload is the nonce. Next comes the ciphertext data message of variable length up to maximum payload size in bytes minus sum of nonce size and tag size. The last 16 bytes of the message payload is the message tag.

The nonce is a pseudorandom value of length 16 bytes. It is generated by the encryption mechanism as an input for internal use. The nonce is similar to an initialization vector (IV) used in various encryption schemes. The same nonce is required to decipher the ciphertext back into plaintext.

The tag is a hash of length 16 bytes generated by the encryption mechanism. It is used to verify the message's authenticity. The tag is computed during the deciphering process and checked with the sender's tag to verify message authenticity.

B. Proposed Mechanism Flow

Fig. 4 illustrates the flow of the proposed mechanism. Three inputs are required for the encryption mechanism to work, the pre-shared key, a nonce, and the plaintext data. The pre-shared key is a 256-bit symmetric encryption key (32 bytes). The nonce is a pseudorandom value of size 128 bits (16 bytes). It is used as an IV for the encryption scheme and the hashing function used to generate the message verification tag. The plaintext data is the HSMS message's original payload. The encryption scheme is AES-GCM 256, as the key is 256 bits in length, and a longer key implies increased security against exhaustive brute force attacks [24].

The algorithm used to encrypt the payload and generate the tag is shown in Fig. 5. The plaintext data is passed into the encryption mechanism along with the pre-shared key. A pseudorandom nonce is generated on the fly and is used as an initialization vector for the encryption mechanism's internal counter. The same nonce is required at the receiver end to decipher the ciphertext and is written to the data payload as it is safe to share nonce along with the message. The nonce is written to the first 16 bytes of the message payload. The encryption scheme then encrypts the data as 128-bit blocks using the provided key and part of the nonce as an IV for its internal counter. The ciphertext data is then appended to the message payload after the nonce. Upon completing the encryption process, a tag is generated by the encryption mechanism and written to the last 16 bytes of the message payload. This tag is essentially a hash generated by the encryption mechanism. The tag is used to verify the message authenticity on the receiver's end.

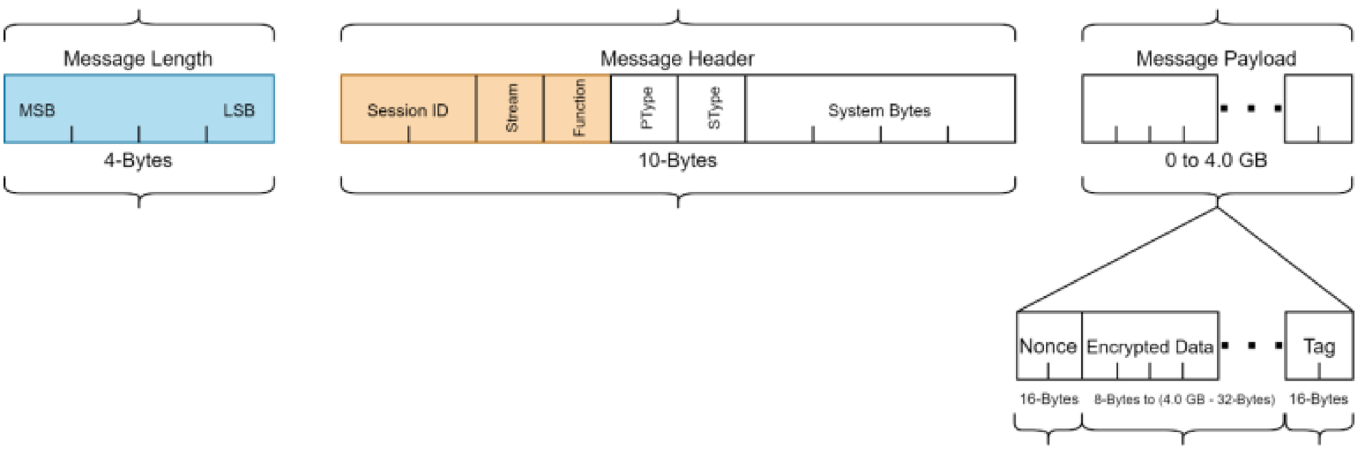

Fig. 3. Proposed HSMS Message Structure with Encrypted Data.

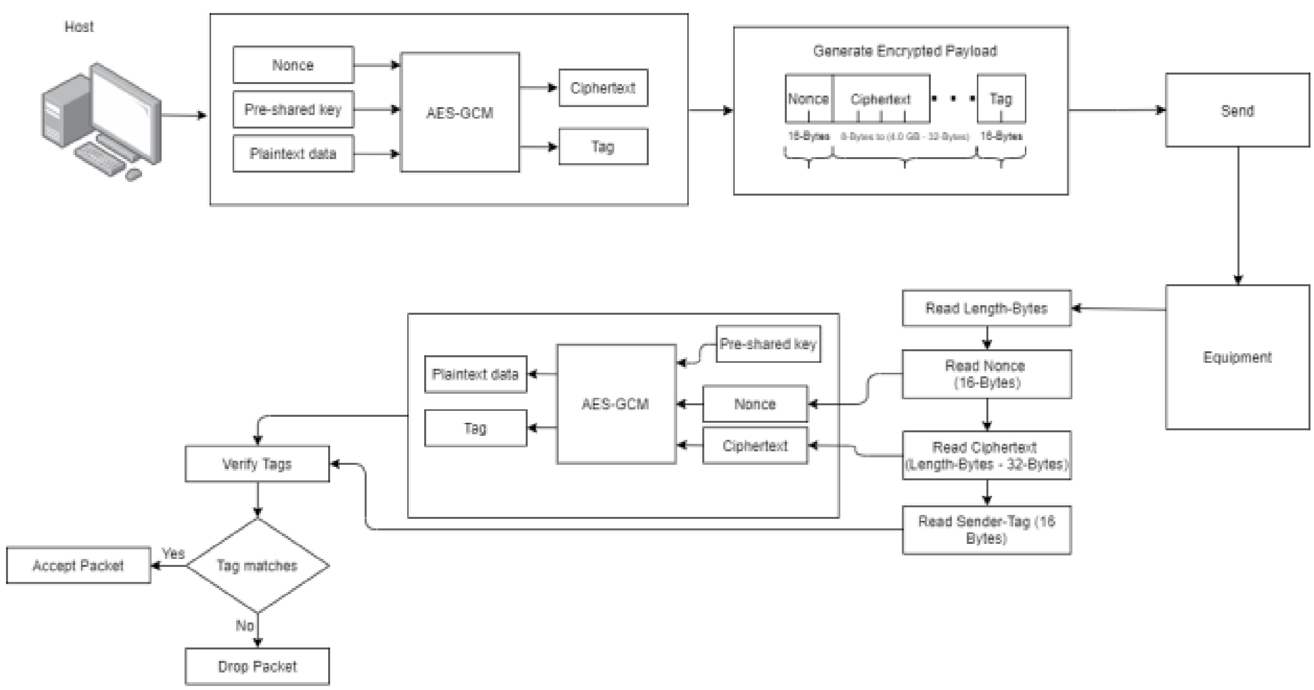

Fig. 4. Proposed Mechanism.

The algorithm used to decrypt the payload and verify its authenticity is shown in Fig. 6. On the receiver end, the data payload of the HSMS message is read as in the packet structure for the proposed mechanism. The first 16 bytes of the message payload are read as the nonce. Since the last 16 bytes of the encrypted payload is the tag generated by AES GCM, 16 bytes are subtracted from the length of the remaining payload, and the data is read for that length. Equation (1) can be used to calculate the size of the ciphertext data within the payload:

$$C_{len} = P_{len} - N_{len} + T_{len} \tag{1}$$

C_{len} is the ciphertext length computed by calculating the difference between P_{len}, the payload length, and the sum of N_{len} and T_{len}, where N_{len} is the size of nonce and T_{len} is the size of the tag. The nonce, ciphertext, and the pre-shared key are passed in as inputs to the decryption mechanism. The decryption mechanism takes 128-bit blocks of cyphertext and decrypts them. After decryption, a tag is generated by the decryption mechanism. This tag would be the same as the tag obtained from the encryption mechanism. If the tags match, the message is accepted; otherwise, the payload's authenticity fails, and the message is rejected.

	Algorithm: Send HSMS message with encrypted data
1	Start
2	***If*** the message length is 10, ***then*** Go to step 7
3	*nonce* = generate random value.
4	*ciphertext* = encrypt the payload with *preshared-key*, *nonce* and get ciphertext output
5	*tag* = Get message authentication tag from AES-GCM output
6	Replace message payload with *nonce* + *ciphertext* + *tag*
7	Send message
9	End

Fig. 5. Algorithm to Encrypt Payload and Generate Tag.

	Algorithm: Receive HSMS message with encrypted data
1	Start
2	***If*** the message length is 10, ***then*** Go to step 9
3	*nonce* = read first 16 bytes of payload
4	*ciphertext* = read payload size – 32 bytes of data
5	*plaintext* = decrypt *ciphertext* with *preshared-key*, *nonce* and get plaintext output
6	*tag* = Get message authentication tag from AES-GCM output
7	*sender-tag* = read last 16 bytes of payload

8	***If*** *sender-tag* is the same as *tag*, ***then***
	Replace message payload with *plaintext*
	Else
	Drop the message and go to step 10

9	Accept and process the message
10	End

Fig. 6. Algorithm to Decrypt the Payload and Verify the Authenticity.

The proposed secure version of the HSMS protocol runs on a different port from the standard HSMS protocol. For example, if the standard version runs on port 5000, the proposed version can run on port 5001. The secure version is thus distinguishable from standard communication protocol. A different port is required because the standard protocol would not be expecting an encrypted payload and may run into errors when trying to parse the payload. The proposed mechanism acts as an overlay protocol. It handles data confidentiality and authenticity on both ends and then forwards the message to the next layer, where the message is processed.

V. Implementation and Testbed Setup

A. Implementation

We used secsgem from [25], a python implementation of SECS/GEM protocols, as the base for our implementation. The implementation is free and available online on GitHub. For implementing AES-GCM encryption over secsgem, we used the Python Pycryptodome library from [26]. Pycryptodome is a library of implementation for cryptographic algorithms.

B. Experimental Testbed Setup

Our testbed consists of two machines running SECS/GEM simulator with Machine-I acting as the host and Machine-II as the equipment. Both machines have the configuration as stated in Table III.

TABLE III. Experimental Testbed Machine Configuration

	Specification
Processor	Intel Core i3-9100F @ 4.2Ghz
Memory (RAM)	2 GB
Operating System	Ubuntu 18.04 LTS
Network	100Mbps ethernet

Machine-I (host) was set up to be the active device initiating connections to machine-II. Machine-II (equipment) was set up to be a passive device listening for connections from Machine-I.

VI. Performance Evaluation and Results

For the evaluation of the proposed mechanism, the host machine was configured to connect to the equipment machine and send over 1000 SECS/GEM messages at regular intervals. The SECS/GEM implementation was configured to compute the time taken for processing while sending and receiving messages and store it in a log file. The experiments were conducted for both the standard HSMS protocol and the proposed mechanism. The processing times were then obtained from the log files for each experiment. The processing time obtained from the log files was labeled as described in Table IV.

TABLE IV. Processing Time: Label Description

Label	***Description***
Host-S	the processing time taken by the host to process the initial message to be sent (to equipment).
Equip-R	the processing time taken by the equipment to process the message received (from the host).
Equip-S	the processing time taken for the equipment to process the reply to be sent (to the host).
Host-R	the processing time taken by the host to process the reply received (from equipment).

C. Processing Time

The evaluation of the performance of the standard HSMS protocol and the proposed mechanism experiments and obtained the following results.

The standard HSMS protocol experiment's results are plotted in Fig. 7. It can observed that the host takes the longest time to send a message (Host-S), followed by the reply being sent from the Equipment (Equip-S). This variation is due to the differences in the size of the data payload. Host-S is the initial message, and Equip-S is the reply, essentially two different messages. The time taken for the host to process the response from the equipment (Host-R) takes the least amount of time, whereas processing time for the equipment to receive data (Equip-R) is slightly higher. This shows that the pattern in Host-S and Equip-S is the same in Equip-R and Host-R due to varying payload sizes of the initial message and reply message.

The processing times taken for the proposed mechanism are plotted in Fig. 8. The graph shows that the processing time for the host to send data (Host-S) was the longest. Following Host-S, the second-longest was the time processing time taken for the equipment to send a reply (Equip-S). The time taken for the equipment to process the message from the host (Equip-R) and the time taken for the host to process the reply from the equipment (Host-R) were similar. However, the processing time Equip-S was below the processing time Host-R for the most part. The pattern in the standard HSMS experiments is also seen in this experiment, meaning very well that the different sizes in the initial messages and the replies influence the processing time.

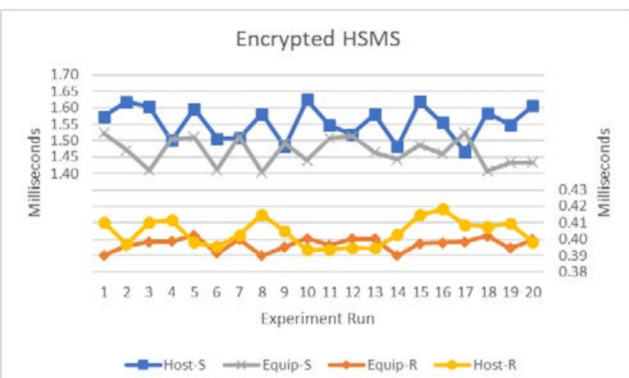

Fig. 7. HSMS with Data Encryption.

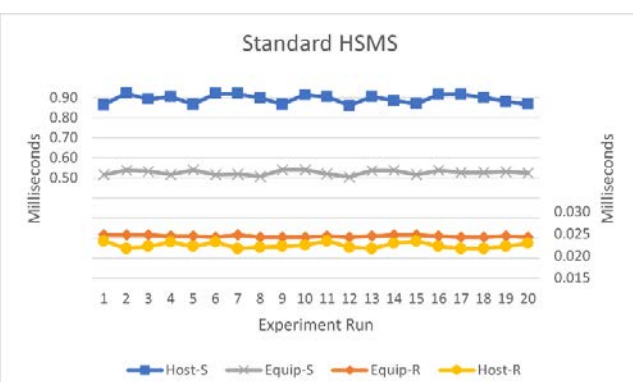

Fig. 8. Standard HSMS Experiment.

We computed the minimum, maximum, mean, and standard deviation in processing time for both the standard protocol and the proposed mechanism from the data we obtained in our experiments. Table V shows the mentioned metrics for the processing times of the standard protocol. It is seen that the mean processing time for Host-S and Equip-S is between half millisecond and one millisecond and Equip-R, and Host-R is below 1 microsecond.

TABLE V. PROCESSING TIME (MILLISECONDS): STANDARD HSMS

	Host-S	*Equip-R*	*Equip-S*	*Host-R*
Min	0.8607	0.0243	0.5054	0.0217
Max	0.9217	0.0248	0.5400	0.0234
Mean	0.8941	0.0245	0.5260	0.0224
SD	0.0218	0.0002	0.0112	0.0006

Table VI shows the metrics calculated for the processing time taken by the proposed mechanism. The results show that the mean processing time for Host-S and Equip-S is between 1.6 milliseconds and 1.4 milliseconds, and approximately 0.4 milliseconds for Equip-R and Host-R.

TABLE VI. PROCESSING TIME (MILLISECONDS): PROPOSED MECHANISM

	Host-S	*Equip-R*	*Equip-S*	*Host-R*
Min	1.464	0.390	1.404	0.394
Max	1.625	0.402	1.525	0.418
Mean	1.555	0.397	1.468	0.404
SD	0.051	0.004	0.043	0.008

Table VII shows the difference in processing times between the standard HSMS protocol and the proposed mechanism. The differences show that Host-S and Equip-S are between a half millisecond to one millisecond. Equip-R and Host-R are below a half millisecond. Analysis shows that encrypted SECS/GEM messages have a slight overhead. The time required for processing each message (sending and receiving) is increased by an average of 0.8 milliseconds due to encryption and decryption of data bytes in the HSMS message. The Encrypted HSMS message also has 32-Bytes of overhead. The nonce and tag are attached to the data bytes for the receiver to decrypt the ciphertext data. Thus, the maximum payload size is slightly reduced by 32 bytes as the proposed mechanism uses 32 bytes for the nonce and tag.

TABLE VII. PROCESSING TIME (MILLISECONDS): DIFFERENCE

	Host-S	*Equip-R*	*Equip-S*	*Host-R*
Min	0.603	0.365	0.899	0.372
Max	0.703	0.378	0.985	0.395
Mean	0.661	0.372	0.942	0.382

However, no encryption is performed for control messages such as "Link-Test Messages" as these messages do not contain any data bytes. The proposed mechanism checks for the length of data bytes and only performs encryption and decryption if the size of data bytes is greater than zero.

D. Control Overhead

Table VIII shows the control overhead for the proposed mechanism for messages with various payload sizes. For control messages without data, there is no added overhead. For a message of size 1 KB, we see an overhead of a 3% increase in payload size over the standard protocol. This is as a result of the nonce and tag being added to the payload. However, with bigger messages such as 1 MB and 10MB, we see the overhead is reduced drastically to a point where it is negligible as the size of the nonce and tag have fixed size for all messages.

TABLE VIII. CONTROL OVERHEAD

	Message Size (bytes)	*Control data (bytes)*	*Total*	*Control Overhead*
Control msg (header-only)	10	-	10	0.00%
Data msg (1KB)	1024	32	1056	3.03%
Data msg (1MB)	1048576	32	1048608	0.0031%
Data msg (10MB)	10485760	32	10485792	0.0003%

The processing time overhead observed is also negligible, considering that data confidentiality and authenticity are achieved in SECS/GEM communication. Furthermore, AES-GCM is a block cipher algorithm widely adopted for its performance. The experiments were conducted were on a general-purpose computer where the encryption was software-based. In a real industry scenario, this would be done on a dedicated yet inexpensive hardware-based encryption module, leading to even better performance of up to 10Gbps speeds of encryption.

E. Security Analysis of Brute-Force Attack

The proposed mechanism encrypts the plaintext data into ciphertext, making it meaningless to anyone monitoring the ciphertext data. Thus, passive attacks such as eavesdropping and reconnaissance are rendered useless as attackers will not be able to get the plaintext data. For an attacker to obtain plaintext data, the secret key is required for decryption. Without the key, the attackers can only try to make an exhaustive brute force attack to guess the key. The proposed mechanism uses a 256-bit pseudorandom key, and thus it would require the attacker to try at least half of the keys on average to find the correct one. Therefore, on average, the attacker will need to try 2^{255} different keys.

The latest processor with special instructions for AES operations uses about 0.16 cycles to process 1 byte of plaintext [27]. Table IX shows the time taken in years to crack the encryption with an exhaustive brute force attack. Equation (2) was used to compute the time required (in years) to break AES-GCM for various computers [28]. The results are shown in Table IX. T is the time complexity to break AES-GCM. $K_{possibilities}$ is the average number of keys the attacker has to try before finding the correct key. For the proposed mechanism, it is 2^{255} possibilities, as discussed previously. C_{sec} is the number of cycles or operations the CPU can perform in a second. C_{byte} is the number of cycles required to process one byte of plaintext, while B_{size} is the size of one block of plaintext in bytes. B_{size}, in this case, is 128 bits (16 bytes) as AES-GCM operates on 128-bit blocks. Y_{sec} is the total number of seconds in a year (60 × 60 × 24 × 365.25 = 31,557,600 seconds).

$$\mathrm{T} = \frac{K_{possiblities}}{\left({C_{sec}}/{C_{byte} \times B_{size}}\right) \times Y_{sec}} \quad (2)$$

TABLE IX. YEARS REQUIRED TO BREAK AES-GCM WITH 256-BIT KEY

Computer	*Speed*	*Time required in years*
Intel Core i7-10870H	280 Gflop/s	1.6773622363071781004323484314 75e+58
Fugaku (Japanese supercomputer)	442 Pflop/s	1.0625824121402938192784107710701e+52
All computers in the world	200 Gflop/s × 2 billion	2.2932686824512200591848513711572e+55

For our security analysis of the proposed mechanism, we calculated the time complexity of cracking AES-256-GCM on the latest Intel Core i7 processor and Fugaku, the world's most powerful supercomputer at the time of this research [29] and all the computers in the world combined. The total number of computers in the world is around 2 billion [30]. The results presented in Table IX show the number of years required to successfully brute force the key is in multiples of trillions of trillions of years. Thus, an attacker cannot decipher the ciphertext with the technology available as of now. It remains safe to assume that the proposed mechanism would not be broken anytime soon.

Using AES-GCM, the proposed mechanism attains data confidentiality. It can prevent passive attacks such as eavesdropping and reconnaissance by attackers. The data is encrypted, and thus, attackers are unable to read the data. As the data authenticity is checked, the proposed mechanism protects against MITM attacks where attackers try injecting false data or modify the data. An attacker cannot modify the data as it is encrypted. Even if the attacker has altered parts of the encrypted data in the message payload, the authenticity of the data will fail as every message has a tag to verify message authenticity. Thus, the message's authenticity is verified.

VII. CONCLUSION AND FUTURE WORK

In this paper, we proposed a mechanism for SECS/GEM's HSMS Protocol to attain data confidentiality and check data authenticity in its data communication messages by encrypting the data payload using the AES-GCM encryption scheme. We also evaluated the performance of the proposed mechanism with the standard protocol. The results indicate that AES-GCM encryption of HSMS data messages has a slight overhead of 0.8 milliseconds and 0.37 milliseconds when sending and receiving a message, respectively, compared to the insecure standard HSMS protocol. However, this overhead is negligible considering that encrypting HSMS data messages makes the protocol secure from eavesdropping attackers seeing the data transferred in the messages while also checking the authenticity of messages. Thus, the proposed mechanism achieves data authenticity and confidentiality. This will be a step further towards Industry 4.0 for the HSMS protocol-enabled machines.

The proposed mechanism aimed to protect data confidentiality and check data authenticity. However, SECS/GEM protocol has other shortcomings that need to be addressed to secure it completely. The proposed mechanism only encrypts the data payload part of a message. The header is still visible to the network. Although it does not expose sensitive data such as parameters, settings, or confidential data, an entity on the network can still see the frequency of each type of message sent on the network. Furthermore, SECS/GEM is still vulnerable to attacks such as replay and Denial of Service (DoS) attacks. Future research to enhance SECS/GEM security may include investigations into the implications of these problems and potential remedies. Future studies may potentially look at problems such as authentication and privacy for SECS/GEM communications in Industry 4.0 ecosystem.

***Abstract*—With the increased use of social networking platforms, especially with the inclusion of sensitive personal information, it has become important for those platforms to have adequate levels of security and privacy. This research aimed to evaluate the usability of privacy in the WhatsApp, Twitter, and Snapchat applications. The evaluation was conducted based on the structured analysis of privacy (STRAP) framework. Seven expert evaluators performed heuristic evaluations and applied the 11 STRAP heuristics to the privacy policy statements and settings provided in the WhatsApp, Twitter, and Snapchat applications. This study provides useful information for designers and developers of social media applications as well as users of the apps. In particular, the results indicate that Snapchat had the highest severity rating, followed by Twitter and WhatsApp. Moreover, the most notable severity rating for all the apps was regarding the ability to revoke consent, where all of the apps had a very high number of usability problems.**

***Keywords*—HCI; usability; heuristics evaluation; STRAP; privacy; usable privacy; social media**

I. Introduction

Individuals are becoming more reliant on social media platforms as essential mediums for communication. The global average penetration rate for social media increased from 40% in 2018 to 49% in 2020 [1]. In other words, more than three billion people use social media. Most social media users prefer to connect to their accounts using an application (app) on their smartphones [1], [2]. Social media platforms provide individuals with ways to interface and offer information and snapshots of their lives.

As the commitment of users to social networking platforms expands, the volume of private and personal data that is shared online increases in a like manner. While these platforms offer privacy settings so that users can secure their online privacy, several reports (as cited in [3]) have shown that the average social media user does not change his or her security settings. A lack of public knowledge has resulted in the intermittent use of these settings by many users. Albesher and Alhussain [4] discussed the reasons for not adjusting privacy settings, which included a lack of awareness of the possible risks, the time it takes to read and understand each setting, and the diversity of the settings.

This paper contributes to the knowledge of understanding the term “usable privacy” and how it can improve the usability of privacy settings and policies in social media. As a result, users would deal with these settings and policies effectively and efficiently. Comparing the privacy settings and policies of three different examples of the most popular social media grants practical ideas for improving the design of usable privacy settings and policies. This comparison becomes more useful when a trustable framework is applied. This paper evaluates the usability of privacy settings and policies in the WhatsApp, Twitter, and Snapchat apps within the structured analysis of privacy (STRAP) framework [5]. It further contributes to the existing knowledge on online privacy by testing the STRAP framework in the usability of privacy context. The study provides useful information for designers and developers of social media applications as well as users of the apps to enhance the usability of privacy. All the investigated apps could involve similar privacy issues, and it is a user’s responsibility to carefully adjust the privacy settings to protect his or her information. Although WhatsApp looks simple in terms of usage, it could present several privacy issues because it allows communication with unknown people. Users are responsible for deciding who can see their personal information, such as their profile photos and “about” sections. Conversely, while Twitter and Snapchat appear to be public networks, they allow users to keep their private information hidden from the public. A consequence of that policy is that users can control several aspects of privacy when selecting options for their privacy settings in those apps.

The paper is structured as follows. Section II introduces usability and privacy, followed by more details about the usability of privacy in social media. Next, Section III describes and justifies the research methodology used in this study, and the data collection methods used is presented. Section IV presents and discusses the main results, and Section V presents the conclusion.

II. Literature Review

A. Usability

Usability is a well-known concept in design. Recently, usability has become a popular term when designing privacy policies and settings. Generally, the usability of a system refers to the measure of certain metrics, such as the ease of use and efficiency of that system. Similarly, the usability of a private setting or policy means measuring the ease of reading, locating, and adjusting that setting [6]. A potentially appropriate definition of usability for all fields of study could be “an evaluation of the level of quality of a user’s experience (UX)” because UX has a broader meaning [6]. In fact, Don Norman indicated that UX covers different parts of the interaction between users and systems. This interaction includes industrial design graphics, interfaces, physical interactions, and manuals [7].

B. Privacy

Privacy has different definitions and they are varied depending on the entity that is protected. Nonetheless, privacy has general definitions that could be broad enough to cover many privacy issues. One example is the definition by Oxford English Dictionary (as cited in [8]) which defined privacy as the "state or condition of being free from being observed or disturbed by other people". Another example was brought by Warren & Brandeis [9] which is "the right to be left alone". On the other hand, there are specific definitions for specific entities such as information privacy. According to Miltgen and Smith [10], information privacy concerns the security of personal or private data and, as a rule, identifies individual information stored on PC frameworks. For the most part, Miltgen and Smith [10] insisted that information privacy is viewed as a significant part of data and information sharing. This position is based on, for example, the view that, given the headway made in the digital age, personal and private data vulnerabilities have expanded. Similarly, Choi, Park, and Jung [11] stated that information privacy is already applicable in many forms that aim to secure personal user data. These researchers further indicated that information privacy might be applied through various means, including encryption, data and information masking, or authentication—each to guarantee that data are accessible to only those with approved access. These defensive measures are designed to forestall information mining and the unapproved utilization of individuals' data.

More particular, there are some specific definitions for privacy that can be very useful for the case of protecting personal information in social media. For instance, Bünnig and Cap [12] defined privacy as "protecting personal information from being misused by malicious entities and allowing certain authorized entities to access that personal information by making it visible to them" (as cited in [13]). Additionally, Alan Westin [9] described privacy as the right to let people decide when, how, and to what extent their information is exposed to others (as cited in [14]).

C. Privacy Settings

When people register for social media, they are presented with certain privacy policies and settings; in this context, privacy settings refer to the restriction of the disclosure of shared content to only authorized people [3]. Users could be considered the authors of the settings, but then different usability problems could occur [15]. Indeed, more usable privacy settings lead to experiences that better meet users' preferences and needs [16]. Akcora and Ferrari [17] posited that users will make poor decisions about their private information when they must deal with many options in privacy settings.

Kane [18] observed that social networking platforms offer people simple approaches to interacting online, making new companions, and staying in contact with existing connections. Nonetheless, Kane [18] asserted that in meeting individuals on the internet with whom one has no prior acquaintance, a user encounters certain inherent risks. Kane [18] insisted that users, when talking and sharing ideas and information online, should remember that once a message, photograph, or video is shared, they no longer have any influence over where it goes. Trottier [19] asserted that the need for privacy settings emerged because of that feature. Privacy settings are control mechanisms accessible on social networking platforms and sites that permit clients to limit who can see their profiles and filter what data or information other users or guests can see. Put simply, privacy settings help guarantee that online users have control over the friends they choose to accept online and whether the information they share is made public or not.

D. Usability of Privacy

The usability of privacy is not a new concept although scholars used slightly different terms to refer to this concept. For example, Aldhafferi et al. [13] mentioned the term "privacy by design" and defined it as granting more authority to users to specify what type of information they want to share and with whom. Another term that has a similar meaning is "usable security," which refers to whether an app grants its users enough information to make informed decisions about who can access their data and with whom it is shared (as cited in [20]).

Over the last decades, use of the term "usable privacy" has increased rapidly because there has been a significant increase in the number of research papers studying this term [21]. In fact, there are well-known conferences such as the Symposium On Usable Privacy and Security (SOUPS) that are conducted to encourage researchers to publish in this area. Additionally, there are specific courses in highly ranked universities such as Carnegie Mellon University and the University of California-Berkeley that are named "usable privacy and security".

Some scholars have defined usable privacy as the ability of users to locate, understand, and successfully use privacy controls to protect their privacy [22]. Thus, developers should design interfaces that help users protect their privacy through alignment with this concept. By applying the fundamentals of user-centered design to privacy, organizations can enhance their users' trust and avoid legal issues [22].

There are several research papers and projects related to usable privacy. For instance, Raschke et al. [23] relied on usability engineering lifecycles that were created by Nielsen and Möller to evaluate privacy. They aimed to design a usable privacy dashboard that could manage the requirements of the General Data Protection Regulation (GDPR). Additionally, Sadeh et al. [24] aimed to achieve usable privacy policies by combining crowdsourcing, machine learning, and natural language. In this project, they relied on the principles of iterative, user-centered design. Moreover, Angulo et al. [25] proposed an approach for designing usable interfaces for privacy policies to assist users in making mindful decisions regarding the dispersal of their personal information. This approach relied on predefined levels of privacy settings. Furthermore, Jones et al. [26] designed a prototype for privacy policies for a British media service. This prototype created a new interactive design that helped users make informed decisions about their data usage. The results showed that users were more comfortable with the new design, which had positive effects on their trust in the media service.

E. *Usability of Privacy Settings in Social Media*

Privacy settings are a central issue for users of social media. Fiesler et al. [27] indicated that the principal choice users must be aware of when they are creating accounts on Twitter is whether they will post secure tweets or open tweets. The secured tweet highlight implies that nobody other than a user's permitted followers will see the user's messages. It also means that other users will not be able to retweet the user's messages or post them to their streams. If a user picks a secured account, the user can also generally change it later to an open account in the privacy settings. However, it should be noted that Twitter fails to offer the same degree of granular control as other social media platforms. Regardless, it has some better-than-average choices for controlling what different clients can see and what level of access they need to interact with another user. These settings are more for controlling tweets that are sensitive, both the tweets a user creates and the tweets a user views. Accordingly, Twitter permits clients to not only block delicate media but also mark something they are going to post as sensitive. For instance, the privacy setting "Safety" is the place where users can choose to reject tweets that are offensive or unwanted, as well as mute or block accounts. Likewise, there are privacy settings that allow users to select, for instance, a setting to "receive anybody" or the option to allow read receipts.

Dev, Das, and Camp [28] indicated that WhatsApp settled on a security decision dependent on usability because it had 1 billion clients and closing down conversations could be irritating for many clients. This means that the entire framework may be less secure. However, although most clients know that they can modify their WhatsApp privacy settings, the majority only use the privacy options "everybody" or "my contacts," conceivably on the grounds that they want to permit family and friends to see whatever they post online. While there are other options in the privacy settings for WhatsApp, most WhatsApp's clients use only the basic settings, indicating that the use of the privacy settings is not that common for users.

Furthermore, WhatsApp offers its users the ability to control who can access their online data. Regardless of whether users decide to limit access to their data, they are given the option to choose a specific setting, for example, to display their online data either to their entire contact list or to no one else under any circumstances. Dev, Das, and Camp [28] appeared to insist that a user can change who has permission to view the user's profile photograph, "about" message, and status in the privacy settings, with differing results for the various choices. For instance, if a user hides the "Last Seen" setting, it means that the user's contacts will not see when the user last logged into WhatsApp. Conversely, even if a user does not use this degree of protection, he or she should be aware that others might.

In contrast, Snapchat is tremendously well known for its privacy settings, as Mondal et al. [29] articulated. Snapchat's prevalence implies that if users are not cautious, they will undoubtedly receive snaps, invites, spam, or even calls from random individuals—unless they secure their privacy on Snapchat. There are a few settings for enabling or disabling Snapchat features that will successfully forestall all the issues mentioned above. Mondal et al. [29] mentioned that Snapchat offers a variety of privacy settings that users are expected to alter to fit their inclinations and comfort level. For the most part, these settings are overtly simple to locate and can be turned on or off whenever users wish, should their perspective on any one aspect later change. In addition to its settings, Snapchat provides general protection updates that users have access to, such as notices about how to use Snapchat without unintentionally sending a private Snapchat to the wrong individual or posting something to their story that they initially intended to send privately. The usability of the privacy settings in Snapchat is moderately high given the ease of use.

Aljohani et al. [30] also mentioned the privacy settings in Snapchat, which, like an instant messenger, permits users to send photographs and drawings regardless of content. Pictures posted in a straightforward manner to companions vanish from Snapchat's servers after the assigned 24-hour timeframe lapses. In contrast to other networking platforms, Snapchat clients must add companions to have the option to collaborate, which demonstrates the usability of its privacy settings. If somebody unknown to a user attempts to send a snap, the user will be informed that he or she needs to include the sender as a companion. As already noted, users can modify Snapchat's privacy settings for enhanced security. The settings to adjust include the option of who can send snaps and who can see an account. Users can also select either "everybody" or "my friends only" for who will have access to the snaps they post. However, several privacy risks are associated with the use of such social media networks, which is the topic of the next section.

F. *Privacy Risks in Social Media*

Townsend and Wallace [31] reported that online users frequently post statuses about being out of town, visiting new locations, leaving their apartments with no one at home, and much more such information. Moreover, online users post photographs of themselves and share their complete names and birthdays, where they went to school, and where they work, all while seemingly unaware of the possibility that somebody could use that information to attempt to hurt them, find them, or impersonate them. A New York Times analytical report uncovered that an American organization named Devumi gathered millions of dollars in a shady worldwide commercial online fraud scheme. The company sold Twitter followers and retweets to individuals who hoped to become influencers on social media and increase their online popularity [32]. Devumi's customers were provided with millions of followers with profiles that could have been profiles of anyone but were certainly not profiles of actual people. This illustrates one of social media's privacy risks.

While there is proof that social networking platforms have been significant to individuals, Bergström [33] indicated that individuals are hesitant regarding issues concerning the personal data that are gathered and shared and the security of their information. For example, a 2014 review found that 91% of Americans concurred or unequivocally agreed that they had lost authority over how their private and personal data are gathered and used by a wide range of actors. In addition, a significant number of social media clients reported that they worried about businesses and organizations gaining access to the information they share on networking platforms. Based on these concerns, most online users supported the recommendation that governments be more involved in regulating promoters.

Baruh, Secinti, and Cemalcilar [34] noted that other surveys have revealed that social media platform users are not confident concerning their privacy settings in services such as Twitter, Snapchat, and WhatsApp. This is because most users are convinced that social media organizations are not capable of securing the information they share online. Even worse, Bergström [33] stated that users' concerns regarding privacy settings are founded on the fact that most users struggle to comprehend the nature and extent of the information gathered about them. Only a few social media users believe they have significant control over the data collected about them, which is certainly not always the case.

III. Methodology

A review of the available research methods for an evaluation study of the usability of privacy guided our decision to adopt the STRAP framework. Heuristic evaluation is a technique that is dependent on specific principles or rules ordinarily referred to as heuristics. Essentially, when performing a heuristic evaluation, a specialist evaluator uses guidelines for checking a compliance list to not only assess usability but also assign severity ratings to the heuristics [35]. Accordingly, in this type of evaluation, the heuristics incorporate a mixed combination of components, the greater part of which are derived from Nielsen's heuristics. This means that the principles and rules observed in heuristic evaluations can be derived either from explicit guidelines, practices, or hypotheses. In this way, proper heuristics offer designers the most effective corrective measures.

There are several advantages to this method that demonstrate why it is the most frequently chosen technique for usability analyses. More specifically, heuristic evaluations are not only fast but also intuitive, which allows them to provide feedback outcomes more quickly. In addition, they are moderately economical because time is conserved and assets are managed effectively [35]. Heuristic evaluations can also be joined with other ease-of-use testing strategies to more closely inspect potential ease-of-use issues. Using such a methodology prior to evaluator testing can reveal the quantity and seriousness of the design and development mistakes found by experts.

STRAP heuristics is a framework that is centered on user design and acts as a privacy awareness design tool. The objective of the STRAP framework is to address a portion of the investigations performed on privacy analysis systems. Accordingly, the STRAP framework joins components of heuristic evaluation and goal-focused analysis with an end goal of accomplishing viability while minimizing expenses [5]. A basic property of the STRAP framework is that it is not necessary for analysts to learn new skills or abilities. It is basically meant to support analysts by distinguishing privacy issues and the usability of systems. In turn, it is an add-on technique and is not used for addressing other components of design procedures. Table I shows the details of the STRAP heuristics.

TABLE I. STRAP Heuristics and Descriptions for Each

Heuristic		Description
1-Notice/Awareness	a. Available, accessible, and clear	Information about app activities is always available to users in a way that is simple to access and understand.
	b. Correct, complete, and consistent	Disclosure is complete, correct, and consistent in order for users to make informed decisions.
	c. Presented in context	Relevant information is presented for each transaction to minimize memory load and ensure users are aware of the consequence of their actions.
	d. Not overburdening	Disclosure takes into consideration human limitations in memory, ability, and interest. It provides succinct and relevant information.
2-Choice/Consent	a. Meaningful options	Whenever possible, users are given real options rather than opt-in/opt-out choices to avoid coercion and maximize benefits.
	b. Appropriate defaults	Privacy default settings reflect most users' concerns and expectations with regard to protecting their privacy.
	c. Explicit consent	The app avoids assuming consent whenever possible.
3-Integrity/Security	a. Awareness of security mechanisms	Users are provided with enough information to judge the security of the app and their information.
	b. Transparency of transactions	The app provides transparency in transactions and data use to build user confidence and trust.
4-Enforcement/ Redress	a. Access to own records	Users have access to all information the app has collected about them, regardless of source.
	b. Ability to revoke consent	Consent is retractable.

A. Justification for using the STRAP Framework

For investigating the usability of privacy in terms of HCI issues, relevant privacy frameworks are reviewed and can be broadly divided into two classifications:

1) Guidelines: The Fair Information Practices are a prime example of guidelines; they were early design guidelines designed to support data protection regulations and provide a system-centered viewpoint.

2) Process frameworks: Examples of process frameworks include the STRAP framework [35] and the question options criteria (QOC) process. These offer direction in terms of the evaluation and design of privacy-sensitive IT applications and have a user-centric emphasis.

The structured analysis of privacy (STRAP) framework puts forward 11 dedicated sets of privacy heuristics that are intended to be employed by designers to assess interactive systems. Based on usability heuristics and fair information procedures, the STRAP framework represents a structured method of evaluating nonfunctional user requirements (NFRs). There are two primary motivations as to why the STRAP heuristics are useful for this study. First, the approach is based on the notion that designers do not have a strong track record of paying sufficient attention to addressing social issues, such as privacy, when designing information systems. As such, they benefit from the utilization of a simple, lightweight application that can highlight social problems such as privacy. Second, heuristic evaluation approaches are affordable and valuable.

Additionally, the effectiveness and efficiency of the STRAP heuristics have been tested and evaluated by several researchers, such as Jamal and Cole [36] and Jensen [37], who have found that the tool represents a useful means of identifying security, privacy, and correlated usability problems. The explanation for picking the STRAP usability heuristics as opposed to others is that the STRAP heuristics indicate the weakness identified in privacy issues [5]. Jensen and Potts [35] stated that nonfunctional requirements are those related to the quality of a system. In that regard, the STRAP framework combines heuristics from other relevant frameworks, such as “GBRAM,” which makes it more effective as it builds on goal-oriented analytical approaches [38]. Gritzalis et al. [39] asserted that the STRAP framework proves to be more than effective when evaluating the privacy of systems. Regarding social media apps, the STRAP framework can be used to evaluate privacy based on whether they provide effective protection from privacy vulnerabilities. For instance, Gritzalis et al. [39] mentioned that the STRAP framework is effective because it combines elements of heuristic evaluation and elements of goal-oriented analysis, which not only minimizes expenses but also achieves better effectiveness. Moreover, for evaluating social media app privacy, the STRAP framework is justifiable because there is no need for analysts or evaluators to learn different or new skills. In these ways, the STRAP framework supports analysts in identifying privacy issues in social media apps.

B. Data Collection and Analysis

In this study, a STRAP heuristic evaluation was used to evaluate the usability of privacy for the WhatsApp, Twitter, and Snapchat apps. The reason for selecting three apps was to be able to make a reasonable comparison. In fact, the selection of these apps was based on their usage ranking and simplicity. For example, unlike Facebook, which has an unclear main purpose, Twitter is known for microblogging news, WhatsApp for instant messaging, and Snapchat for sharing personal stories.

Table II provides the specific versions of each app that were investigated. There were minor differences between the tested apps on Android and iOS. However, the authors ensured that these minor differences had no effect on the evaluation. In fact, some evaluators used Android, while the others used iOS.

TABLE II. THE INVESTIGATED VERSION OF EACH APP

App	Android	iOS
WhatsApp	2.20.157	2.20.51
Twitter	8.45.0-release.00	8.19
Snapchat	10.82.50	10.82.5.78

The authors of this study asked for the participation of eight faculty members in the departments of information technology and information systems in different universities near their area who had experience in this type of evaluation. The selection was based on the authors’ knowledge of who had the ability to perform this type of evaluation. One faculty member refused to perform the evaluation, claiming that there was no reward, while the others agreed. As stated by Nielson [5], heuristic analysis can be highly effective for general HCI problems by a small number of evaluators. In fact, Nielsen and Molich [40] recommended 3 to 5 evaluators to find most of the usability problems. However, we asked three more evaluators to ensure that we cover a larger number of usability problems.

Each evaluator performed the evaluation separately to avoid influencing each other. The evaluation process began with the expert evaluators applying the 11 STRAP heuristics (stated in Table I) to evaluate the privacy policy statements and settings provided by WhatsApp, Twitter, and Snapchat. All of the evaluators were given the same procedures to perform during the evaluation. For each privacy heuristic that was violated, the evaluator assigned one of the following severity ratings:

0 = I don’t agree that this is a usability problem at all

1 = Cosmetic problem only

2 = Minor usability problem

3 = Major usability problem

4 = Usability catastrophe

Seven expert evaluation lists were produced and then merged into one list by calculating the severity ratings for all of the survey statements for WhatsApp, Twitter, and Snapchat. For example, the number of evaluators for every severity rating for each heuristic for WhatsApp was counted, and then this number was multiplied by the severity rating to obtain the total (3); the totals are shown in Table III.

TABLE III. RESULTS OF THE STRAP HEURISTIC EVALUATIONS OF THE THREE APPS

Heuristic		WhatsApp	Twitter	Snapchat
1-Notice/Awareness	a. Available, accessible, and clear.	3	8	14
	b. Correct, complete, and consistent.	8	9	13
	c. Presented in context.	9	11	17
	d. Not overburdening.	8	6	10
2-Choice/Consent	a. Meaningful options.	12	14	18
	b. Appropriate defaults.	7	15	19
	c. Explicit consent.	17	10	14
3-Integrity/Security	a. Awareness of security mechanisms.	8	12	16
	b. Transparency of transactions.	11	11	16
4-Enforcement/ Redress	a. Access to own records.	19	9	10
	b. Ability to revoke consent.	17	17	20
Total		116	122	167

IV. RESULTS AND DISCUSSION

The severity ratings of the usability problems regarding privacy issues in each app are presented in Table III. This table includes both the ratings for each heuristic individually and the ratings for all heuristics added together. The description of each heuristic was previously provided in Table I. Table III reveals that, overall, Snapchat had the highest severity rating (167), which was much higher than the ratings for WhatsApp (116) and Twitter (122). It shows the total severity rating for each app based on the five scales of the severity rating. As shown in Table III, the severity rating for Snapchat exceeded the score for minor usability problems.

Snapchat consistently had the highest rating for each separate heuristic except for meaningful options and access to the user's own records, where WhatsApp had the highest ratings. In the rest of the heuristics, Twitter had higher usability problem ratings than WhatsApp, except in three heuristics. In the heuristic "not overburdening," WhatsApp had a higher rating (8) than Twitter (6). In the heuristics of "transparency of transactions" and "ability to revoke consent," the apps had the same ratings (11 and 17, respectively). In fact, when the five scales of the severity rating are applied to one heuristic individually, the maximum score is as follows:

Catastrophic = 28

Major = 21

Minor = 14

Cosmetic = 7

None = 0

By looking at the severity rating for each heuristic separately, WhatsApp had the lowest rating (3) with regard to the availability, accessibility, and clarity of privacy notices. Twitter's rating (8) was notably higher than WhatsApp's rating, while Snapchat's rating (14) was the highest. This result is not surprising given that Snapchat suffers from various issues that belong to this heuristic. Snapchat confuses users by mixing certain information together and making several settings difficult to understand. For example, Snapchat has a section called "additional services" that contains several privacy settings, and under that section, there is another section called "privacy," as shown in Fig. 1. Additionally, Snapchat takes users away from the settings screen when they do not interact with the app for a few moments, which makes it difficult for users to return to where they left off.

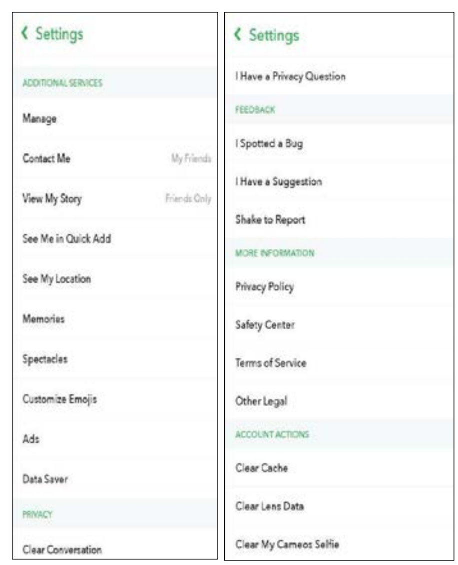

Fig. 1. Privacy Settings in Snapchat.

In contrast, WhatsApp has all its privacy settings in one location (i.e., under "privacy"). Furthermore, this section is displayed with a lock sign, which gives users a hint about the types of settings in that section. Moreover, this section is contained under "account," which is designated with a key symbol, as shown in Fig. 2. Additionally, the privacy policies are listed under "help," which is denoted by a question mark sign. Using icons reduces the mental load for users and allows for smooth navigation [41], [42]. Thus, the privacy settings and policies look organized and clear in WhatsApp. In Twitter, the privacy settings also look organized; however, it is not clear how to find the privacy policies. It is important to mention that the interface of the privacy settings may look slightly different in the two operating systems that were investigated (Android and iOS). However, the analysis is still valid for both. Regarding the second heuristic (Table III, 2a), which measures the completeness, correctness, and consistency of a disclosure, the severity rating was similar for WhatsApp (8) and Twitter (9) but was notably higher for Snapchat (13).

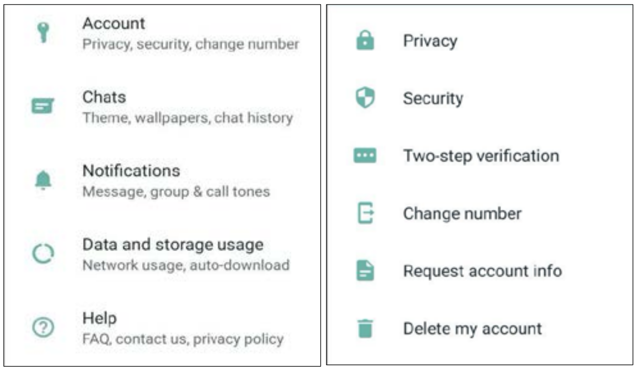

Fig. 2. Privacy Settings in WhatsApp.

The fourth heuristic (Table III, 4a), measuring whether a disclosure is overburdening, resulted in a slightly lower severity rating for Twitter (6) than for WhatsApp (8) or Snapchat (10). It is not surprising to see that Twitter's rating is the lowest here. One reason is that Twitter divides its privacy policies into sections, each of which is color coded, as shown in Fig. 3. The colors make it easy for humans to link information to the right section. In fact, some scholars have indicated that "color in user interface can control the user's attention, help to recognize interface elements, express the meaning of indicators in complex professional systems, as well as be used for visual grouping of similar objects" [43].

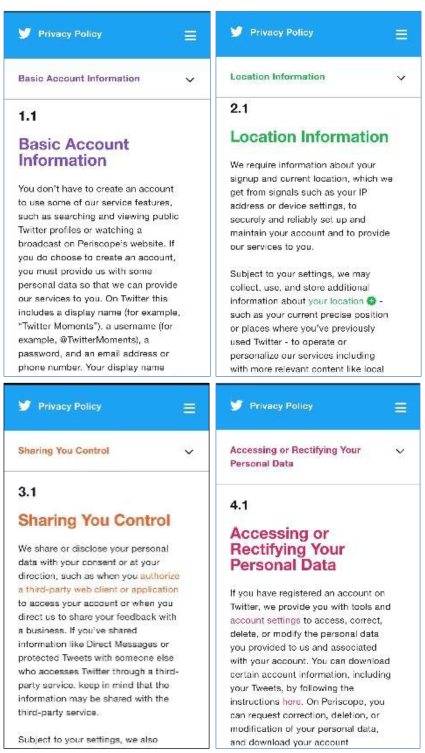

Fig. 3. Privacy policies on Twitter.

The third heuristic, which measures the presentation of relevant information that belongs to each transaction, revealed that the highest severity rating was given to Snapchat (17). Twitter's rating (11) for this heuristic was closer to that of WhatsApp (9). Generally, Twitter provides a short explanation for each setting and a link to "learn more," as shown in Fig. 4. Conversely, while neither Snapchat nor WhatsApp provides a link to additional explanations for each setting, WhatsApp performs slightly better because it does not have jargon that could result in some users being unaware of the consequences of certain actions. For instance, Snapchat has the setting "clear top locations," which is used for "Map Actionmoji." However, there is inadequate information provided about this jargon and the consequences of the setting.

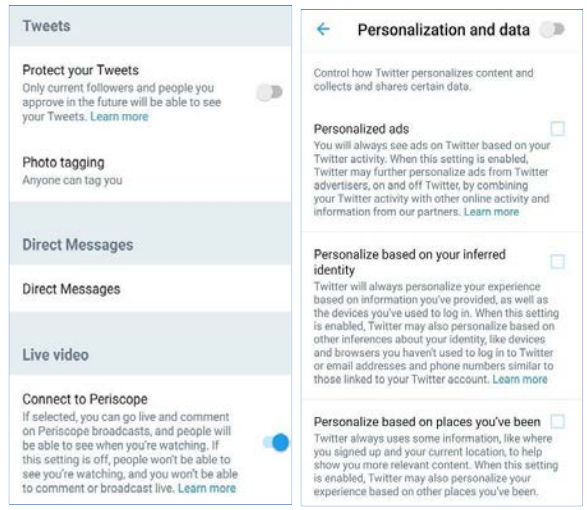

Fig. 4. Privacy Settings on Twitter.

Generally, the heuristics evaluating "choice and consent" revealed more usability problems than the heuristics evaluating "notice and awareness." In the second group of heuristics, evaluating whether apps provide meaningful options, all the apps had high severity ratings. Specifically, the rating was 12 for WhatsApp, 14 for Twitter, and 18 for Snapchat. In other words, users are given the choice to opt in or opt out rather than more specific options for most privacy issues. The next heuristic in this group, which evaluated whether the apps had appropriate defaults, resulted in a significant difference between WhatsApp and the other apps. WhatsApp's rating (7) was less than half the ratings for Twitter (15) and Snapchat (19). WhatsApp still does not allow banner ads as Twitter and Snapchat do, which is one reason for the lower rating for WhatsApp. Additionally, Twitter and Snapchat normally allow interaction with unknown people more than WhatsApp does.

Moreover, because Twitter and Snapchat sell ad space, they prefer that users select the default settings, which maximize their benefits. Snapchat has the highest score here because it is basically about sharing a personal story and, thus, it is about sharing very sensitive information. In marked contrast, WhatsApp's rating for avoiding an assumption of consent whenever possible was the highest (17) compared to Twitter (10) and Snapchat (14). An example that could explain why WhatsApp had the highest rating here is the fact that users have no choice about whether to share their private information with

Facebook. Overall, usability problems were high for all the apps under this heuristic. One reason for the usability problems is that the apps share users' private information with third parties whether the users agree or not.

The evaluation of the awareness of security mechanisms and transparency of transactions shows that Snapchat had the most usability problems overall. One reason for this evaluation is that Twitter and WhatsApp explain why they collect data in several cases, unlike Snapchat. WhatsApp and Twitter also provide specific explanations of the data they collect, while Snapchat provides general explanations to encompass all the data it collects. However, all the apps need to provide more convincing details about how users' data are being used and how users are protected. In Twitter, several settings cannot be controlled solely through a user's Twitter account. Users are therefore asked to opt out of other organizations' services to attain certain privacy goals. This is commonly seen with settings related to ads. For example, users are encouraged to opt out of Google Analytics by installing Google's opt-out browser add-on and to opt out of interest-based Google ads using Google's Ads Settings.

In the last group of heuristics, evaluating users' ability to access their own records, WhatsApp had the worst severity rating (19). In fact, WhatsApp does not provide a clear way for users to access their own records. Conversely, Twitter and Snapchat clearly show that feature in their privacy settings. Because not all records are accessible, usability issues still existed for this heuristic. The results related to the last heuristic, measuring the ability to revoke consent, are the most notable because all the apps had a dramatically higher number of usability problems. In other words, there is no option to revoke the user agreement in any of these apps. In Twitter, consent is revocable for several settings but only with certain conditions. In other words, changes may not occur immediately or may not be applied in certain cases. For example, when users change the setting for their tweets from public to protected, there is no guarantee that no past tweets will be shown in search engine results.

V. Recommendation

Based on the analytical results of the current study, we can say that the way privacy settings and privacy policies are presented needs to be reconsidered. The tested apps present their privacy settings and privacy policies differently, which makes using them difficult. For example, WhatsApp places its privacy policies under "Help", Twitter under "About Twitter", and Snapchat under "More Information". The current presentation or mapping works against one of the core principles of usability (i.e., consistency). Thus, it is recommended that these apps make privacy a main section that includes both their privacy settings and their privacy policies.

Another recommendation is about the need to attach interactive visual signs to the text that describes the privacy settings and policies. Furthermore, assigning different colors for different settings and policies helps users recognize the differences between them and increases their learnability toward the usage of the settings and policies.

VI. Conclusion

This paper presented a heuristic evaluation of the usability of privacy in WhatsApp, Twitter, and Snapchat based on the STRAP framework. It highlighted useful information for designers and developers of social media applications as well as users of the apps to enhance the usability of privacy. The results of the study pointed out several privacy issues in each of the investigated apps. It further indicated that Snapchat had many more usability problems than WhatsApp and Twitter, which had relatively close scores regarding usability problems. In terms of evaluating each heuristic individually, the most notable severity rating for all the apps was on the ability to revoke consent, where all the apps had a very high number of usability problems. Overall, careful consideration needs to be given to the issues discussed in this paper to enhance the usability of privacy in these social media apps. Finally, it is suggested that future research should consider how to increase users' awareness to protect their information on social media networks.

Acknowledgment

Genetic Algorithm and Ensemble Learning Aided Text Classification using Support Vector Machines

Anshumaan Chauhan, Ayushi Agarwal, Razia Sulthana
Department of Computer Science and Engineering
Birla Institute of Technology and Science Pilani
Dubai, UAE

***Abstract*—Text classification is one of the areas where machine learning algorithms are used. The size of the dataset and the methods used for converting the textual words into vectors play a major role in classifying them. This paper proposes a heuristic based approach to classify the documents using Genetic Algorithm aided Support Vector Machines (SVM) and Ensemble Learning approach. The real valued representation of the textual data into vectors is done on applying Term Frequency – Inverse Document Frequency (TF-IDF) and Bi-Normal Separation (BNS). However, in this paper, the common data misclassification issue in SVM is overcome by introducing two algorithms that adds weightage to accurate classification. The first algorithm applied BNS and TF-IDF along with ensemble learning and constructs a voting classifier for classifying the textual documents. The results produced justify that TF-IDF produces good results with voting classifier than BNS for classification. Henceforth TF-IDF is applied in the subsequent approach for vector generation. Secondly, genetic algorithm is applied along with OneVsRest strategy in SVM to overcome the drawback of multiclass multilabel classification. The results show that Genetic algorithm improves the accuracy of classification even with a very small labelled dataset, as genetic algorithm applies the process of Mutation and Cross over across many generations to understand the pattern of right classification.**

***Keywords*—Genetic algorithm; ensemble learning; support vector machines; text classification**

I. Introduction

Text classification is a primary domain focused by companies that handle big data and big data related applications. To search the relevant and related documents, these companies evolve new methods to classify and organize their data. Extensive collection of research articles, newspapers, journals and other related textual content are available online to be classified in various categories. It still remains a cumbersome process to sort them with prevailing algorithms as they are time consuming and are inefficient. However, machine learning algorithms have a forte in these kinds of applications. There exist many supervised algorithms such as Naïve Bayes (Probabilistic Generative classifier), Decision Trees (DT), Random Forest (RF), SVM which are used for text classification. Though in earlier days SVM were not used for text classification, in earlier 2000s, it contended with neural networks producing the most desirable results [1]. SVM is compared with Logistic Regression [2], Naïve Bayes and K-Nearest Neighbor (KNN) [3][4] where it returned a satisfactory recall, F1-score and accuracy. SVM outperforms Gaussian kernel and Naïve Bayes by producing a root mean squared error of 15.7% and 22.62% respectively [5]. Another article [6] compares SVM with NB and proves that the former provides better results than latter.

Text classification is a sub-area of Natural Language Processing, where a classifier is used to study a text and then assign a category to that document. It is also known as text categorization or document categorization. There is a lot of data out there which is not eligible for use until it is classified into a proper category and gets structured and organized. Data is properly categorized after doing text classification can be used in many places such as Sentimental analysis, Movie Reviews and many more.

The main contributions in this work are:

1) BNS and TF-IDF along with Ensemble Learning is applied to reduce the misclassification and increase the accuracy of the SVM model. This model is tested on a Spam text classification dataset from Kaggle which is a binary dataset. The results give the inference that TF-IDF will always work better than BNS scaling and the proposed model where TF-IDF along with the Voting Classifier is used shows the best performance.

2) Genetic Algorithm along with OneVsRest classifier is applied to increase the performance of labelled dataset when the provided dataset has limited labelled tuples and more un-labelled tuples. This enhances the performance of classifying multilabel multi-instance classification. It is tested on the Reuters dataset.

The organization of the rest of the paper is given here: Section 2 contains Literature survey of the research regarding the subject. Section 3 comprises the methodology of the proposed approaches. Section 4 contains the evaluated results. Section 5 concludes the paper.

II. Literature Survey

Text classification is the process of categorizing documents. This task is imperative in companies that demand classifying data to ease managing them. SVM is a contemporary approach that is applied to classify the textual content. Although, SVM outperforms a number of algorithms, it becomes challenging to draw the decision boundary as SVM requires identifying the support vectors and then classifying the data. Articles [7][8][9] applies feature scaling using TF-

IDF and neglects to scale the words appropriately. The article [7] came up with a new method of converting words into vectors known as BNS. BNS scaling is a weighting term proposed by HP labs and is applied in most of the research articles. In it BNS score for each of the feature words is calculated and then TF-BNS is used instead of IDF for a better scaling. The difference value between the inverse normal cumulative function of TPR (true positive rate) and FPR (false positive rate) is used as a BNS score. When tested, performance metrics of BNS were better than all other algorithms such as TF, IDF and TF*IDF. It's also a proven fact that, TF and IDF when applied individually delivered better accuracy than TF*IDF.

The article [8] applies the weighting algorithm TF-RF (Term frequency relevance frequency) which proved to be better than TF-IDF as it improves the effect of identifying the discriminating terms. Approaches like Word2vec (a google product) or latent semantic indexing is combined with TF-IDF to bring an extra feature that helps to train SVM further for text classification [10]. However, it becomes arduous for SVM to classify the data, if there are not enough features or the dataset is not big enough for training [11][12].

Hybrid models and hierarchical models were developed to overcome the problem of misclassification of data points that lie near the decision boundary. SVM is combined with decision trees in [13][14], with random forest in [15] and both the models were too complex and took increased training time. The former applied SVM in each node of the Decision tree to separate some group of/individual classes from the rest. Accuracy score of DT+SVM was better than Naïve Bayes, standard SVM and standard DT. The latter extended this idea and applied RF. This model reduced the misclassifications near the decision boundary and performed exceptionally well for only large datasets. However, when this method was tested on an average sized dataset, it did not have a good accuracy score. SVM in hierarchies were applied in [16][17] and produced trivial results than those produced by decision trees and random forest.

A hybrid model of SVM with KNN (K-Nearest Neighbor) is proposed in [18]. The concept of incremental learning is applied to speed up the process of training. Results showed that the F1-score of the hybrid model was better than standard SVM as well as standard KNN.

It's well known that SVM is a supervised ML algorithm which can show remarkable performance when executed with appropriate kernels. An experiment using 4 different kernels-Linear, Polynomial, Gaussian and Sigmoid is done in [19]. Results showed that the Gaussian (Radial Basis Function) kernel produced good results for text classification. For multiclass classification, either OneVsOne and OneVsRest classifiers are preferably applied. The author in [19] substantiates that OneVsRest is much more robust when it comes to classification of categories that have a very small number of documents for training. OneVsRest was compared with OneVsOne for multiclass classification in [20] and the author compared four different algorithms for multiclass classification and accuracy was measured. OneVsRest showed 98% accuracy and proved better than other algorithms.

III. METHODOLOGY

In the proposed model, SVM, BNS, AdaBoost and Voting Classifier are applied for text classification. A brief description of all the algorithms used is given here.

A. Support Vector Machine

SVM, a supervised ML algorithm is applied both in Regression and classification. SVM creates a hyperplane/decision boundary for a 2D/nD data, such that classes are separated as widely as possible. It identifies the support vectors to create a margin that is as wide as possible (Fig. 1).

Compared to other classification algorithms SVM is much faster, accurate and handles well the problem of overfitting. SVM being a binary classifier limits it for certain applications. Yet SVM can be combined with many other algorithms such as OneVsOne and OneVsRest which enables it for multiclass classification. In the proposed algorithm, OneVsRest algorithm is applied over Reuters dataset.

B. Bi-Normal Separation

BNS is applied for term weighting and overcomes the problem faced by IDF (Inverse Document Frequency), i.e., inappropriate scaling of some terms. Formula used by them for assigning a score to a word is given here.

$$|f(TPR)-f(FPR)| \quad (1)$$

f is the inverse normal cumulative distribution function.

Let p = total documents categorized as positive class in training dataset, n = total documents categorized as negative class in training dataset, tp = True positives: number of documents of positive class label which comprises the ‘word’, fp = False positives: number of documents of negative class label which comprises the ‘word’.

$$fn=p-tp, \quad tn=n-fp \quad (2)$$

tpr = Probability that word is present in a document, given the document belongs to the positive class label.

$$tpr=tpp \quad (3)$$

fpr = Probability that word is present in a document, given the document belongs to the negative class label

$$fpr=fpn \quad (4)$$

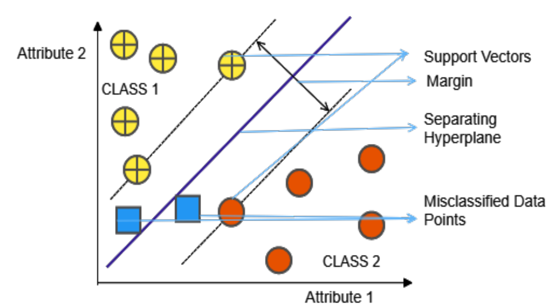

Fig. 1. Support Vector Machines.

C. AdaBoost

Ensemble Learning is a type of learning which combines many weak classifiers to form a strong classifier. Weak classifiers have low accuracy and strong classifiers have high accuracy. Ensemble Learning is of 3 different ways, i.e., Bagging, Boosting and Stacking. In the proposed method Boosting is applied. Boosting is an Ensemble Learning approach which helps us to create more accurate classifiers with minimal error. Boosting algorithms are less prone to overfitting problems. AdaBoost is a boosting algorithm which aims to fit the training set in a better and more accurate way after each iteration/pass (to other classifiers). It constantly increases the weights of misclassified points, and this modified dataset with modified weights is passed onto the next weak classifier. This is a sequential kind of process, where the output of one classifier becomes the input of another (Fig. 2). This process will terminate when the maximum number of classifiers are reached, or the dataset fits completely.

D. Voting Classifier

Voting Classifier works similar to real life elections. A person who gets the majority of votes wins and in a similar way the outcome which is predicted by majority of classifiers is given as final output. It strives to increase accuracy. Since predictions of many classifiers are being considered, voting classifiers help in decreasing the error rate thereby minimizing the chance of misclassification. In (Fig. 3), a simple working of Voting Classifier is explained.

E. Classification using Ensemble Learning on applying TF-IDF and BNS

One of the prevalent challenges of SVM mentioned by many research papers is that SVM does misclassification when the test data tuple lies within the area of hyperplane. To overcome this drawback, a Voting classifier along with the AdaBoost algorithm is used so that the misclassifications would be reduced.

1) Dataset: The spam text classification dataset was chosen to test the proposed method 1. The dataset is split into 2 halves. 80% of the dataset is used for training purposes and 20% of the dataset is used for testing purposes. The Table I shows the train test split ratio of the number of tuples.

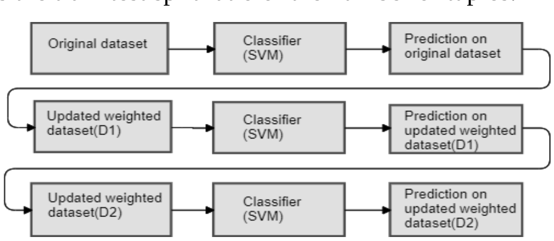

Fig. 2. Adaboost with SVM.

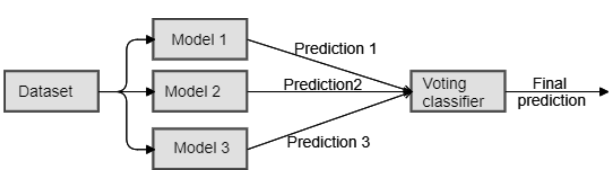

Fig. 3. Voting Classifier.

TABLE I. TRAINING-TEST DATASET SPLIT

Dataset splits	*Number of tuples*
X_{train}	4457
Y_{train}	4457
X_{test}	1115
Y_{test}	1115

2) Proposed ensemble algorithm: As already mentioned about the key features of BNS, BNS scaling for feature scaling/term weighting (word to vector) is applied to improve the accuracy of SVM. Following steps are done in the proposed algorithm:

Step 1: Firstly, preprocessing (Fig. 4) is applied on the whole initial dataset D.

Step 2: Now the preprocessed dataset D is split into 2 datasets: D_{train} and D_{test}. Following which, the featured words are converted into vectors using both TF-IDF and BNS, in order to compare the difference in accuracy.

Step 3: AdaBoost classifier that uses SVM with kernel as RBF function (Gaussian function) is applied. The classifier takes a number of iterations to fit the dataset.

Step 4: Succeeding, a Random Forest is created. Though random forest takes a longer time to train and predict as compared to a single decision tree classifier, it also has the advantage that it gives better accuracy.

Step 5: In the final ensemble model: AdaBoost, Random Forest, SVM and Decision Tree are combined together. This ensemble model is used as Voting classifier. The generated ensemble model is trained and the results of the prediction are obtained.

Step 6: Standard SVM with RBF kernel is applied on both the datasets (dataset converted using BNS and dataset converted using TF-IDF) and the results of the prediction are obtained.

Step 7: The accuracy score of both the classifiers 'Voting Classifier' and 'SVM with RBF kernel' is compared.

In the (Fig. 5) above, you can get a better diagrammatic representation of framework-1.

In this Section, ensemble learning along with TF-IDF as well as BNS is applied and the results of TF-IDF were better than BNS. Henceforth in the next section TF-IDF is applied to classify multi class dataset using SVM.

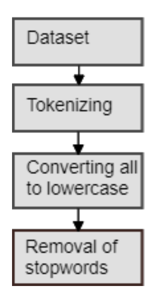

Fig. 4. Steps Involved in Pre-processing.

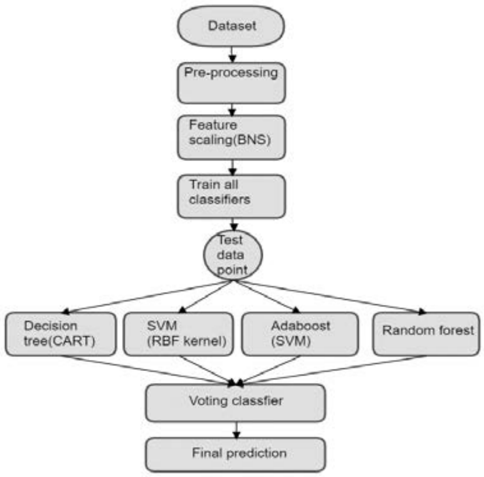

Fig. 5. Framework-1.

F. Genetic Algorithm over SVM

Genetic Algorithm (GA) has been used in many Artificial Intelligence (AI) applications for generating dataset. They were used in many applications such as training of Recurrent Neural Networks, GBML (Genetic Based Machine Learning Algorithm) and DNA Analysis, etc.

This concept is applied in the framework to create a sample labelled dataset which can be used to train the Machine Learning algorithm in a much better manner. There are many instances when due to unavailability of proper labelled dataset, the accuracy is not to satisfiability level. By unavailability, it means reduced number of tuples for training a particular class label or reduced features and comparatively smaller number of tuples. The framework aims to solve the hypothesis where the tuples are more, with few labelled and rest un-labelled.

1) Dataset: To create a temporary label for some random un-labelled tuples, which can further help us to achieve greater stability, the following steps are applied over the Reuters dataset. It has a total of 7769 documents for training purposes and 3019 documents for testing purposes. Out of these 7769, 2590 documents are taken as labelled and out of the remaining 5179 documents, 740 documents are taken as unlabeled ones. For these unlabeled ones we will run the genetic algorithm and try to create a label which will be as close to the real label as possible. Reuters dataset has a total of 90 classes in it. The dataset split is shown in Fig. 6 and Fig. 7.

On applying K- Nearest Neighbors and Decision Trees over 3019 documents the accuracy obtained was 8.07 and 9.13 respectively. This poor accuracy value motivated us to apply genetic algorithm over SVM for further classifying the tuples. Our framework improves the accuracy of classification.

2) Proposed genetic algorithm for classification: Objective: To label the unlabeled tuples and to arrive in generating an SVM model that classifies the tuples with maximal accuracy. It is implemented over Reuters Dataset.

Step 1: Split the initial dataset D into two parts: $D_{labeled}$ and $D_{unlabeled}$. As Reuters is a labelled dataset, tuples (text document) are randomly picked from the Reuters dataset, remove their labels and store in $D_{unlabeled}$.

Step2: To convert the labels of the dataset $D_{labeled}$ to numeric values, MultiLabelBinarizer is used (As the objective is to perform Multi class classification).

Step 3: Text documents of datasets $D_{labeled}$ and $D_{unlabeled}$, are preprocessed, i.e., operations in the (Fig. 4) are done on the datasets before the words are converted to a suitable numeric/binary type.

Step 4: Feature scaling (converting words into vectors) is applied on datasets $D_{labeled}$ and $D_{unlabeled}$ by applying TF-IDF. Further the dataset, $D_{labeled}$ is split into training $D_{labeled}$ dataset and test $D_{labeled}$ dataset. Preprocessing the data involves the same steps that were shown in Framework-1.

Step 5.a: Let the number of tuples in the unlabeled dataset be T. For each of these tuples the labels are predicted using a random prediction approach.

Step 5.b.: Train an SVM classifier, x on the tuples labelled in step 5, and classify the labelled tuples.

Step 5.c: Calculate the accuracy and fitness score of the SVM classifier, x.

Step 6. Run the step 5 for N times. This is the completion of one generation. At the end of the generation, the fitness score of N SVM classifiers is obtained.

$$fitness\ score = \{SVM-1, SVM-2, \ldots, SVM-N\} \quad (5)$$

Fitness score is a measure of accuracy that the model shows on labelled dataset.

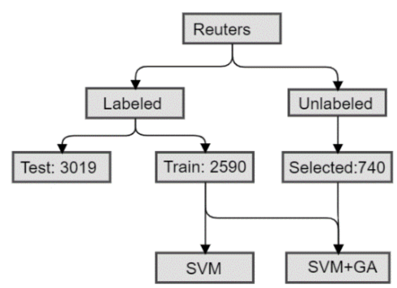

Fig. 6. Tree Representation of Smaller Dataset.

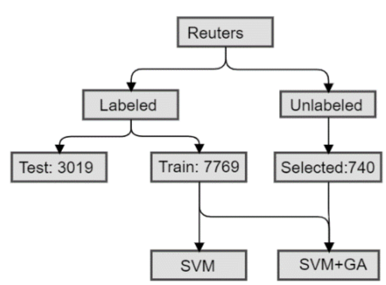

Fig. 7. Tree Representation of Bigger Dataset.

Step 7: After calculating the fitness score of each classifier, the mating pool is created. The purpose of mating pool is to identify the two SVM classifiers that has highest accuracy among N other SVM classifiers

$$fitness\ score = \{SVM - 1 > SVM - 2 > \cdots SVM - N\} \quad (6)$$

Here the models are arranged in decreasing order of their fitness scores.

Step 8: Now starts the Genetic algorithm operations

Step 8.a: Crossover: The crossover is done on the labels of the tuples generated by the top two classifiers chosen in Step 7. An initial probability, p, for cross over is chosen by the algorithm during runtime. The value of p decides crossover between the results of the two classifiers. If it is lower than the number expected, crossover is performed otherwise the parents are passed on as the off springs (new population) (Fig. 8).

Step 9: Mutation: Randomly change the values of the labels classified by the SVM and this represents the new set of labels for the unlabeled dataset. A mutating variable, p1 acts as a deciding factor to change the values of the tuples (Fig. 9).

Step 10: Step 5 to Step 9 is named as one generation in GA. Check if the number of generations, G is reached. The value of G is decided based on the accuracy of the final classifier generated. If not, then go back to step 5, otherwise move on go step 11.

Step 11: At the end of G generations, all the labelled tuples of the unlabeled dataset is moved to train $D_{labeled}$ dataset.

Step 12: An SVM is trained on the new train $D_{labeled}$ dataset and the performance is measured.

Step 13: Test this classifier on the test $D_{labeled}$ dataset and the performance is measured.

The generated SVM on applying TF-IDF and GA classifies the documents into 90 classes and produces better accuracy.

In the (Fig. 10), the diagrammatic representation of the algorithm used is shown.

IV. Implementation and Results

In this section the performance of frameworks is evaluated based on evaluation metrics:

A. Performance Metrics

In the following section, a brief explain about the performance metrics used is given.

Accuracy and F1-score will be used to compare the performance of the proposed and existing frameworks.

Accuracy can be defined as correctly classified points over total instances in the dataset.

Accuracy= True Positive + True Negative / True Positive + True Negative + False Positive + False Negative (7)

Precision is the ratio of correctly predicted positive instances over total predicted positive instances.

Precision=True Positive / True Positive + False Positive (8)

Recall is the ratio of correctly predicted positive instances over actual positive instances.

Recall= True Positive/True Positive + False Negative (9)

F1-score takes both false positives as well as false negatives into account. For a good F1-score, good precision as well as good recall is needed. Having a model with good F1-score will be better than the one with lower F1-score. F1-score is 2 times the inverse of harmonic mean of Precision and Recall.

F1-score= (2* Precision * Recall)/ (Precision + Recall) (10)

TABLE II. CONFUSION MATRIX FOR FRAMEWORK-1

		SVM(BNS)		***VC(BNS)***		***SVM(TF-IDF)***		***VC(TF-IDF)***	
		Predicted Class Label							
Actual Class Label		***0(Not Spam)***	***-1(Spam)***	***0(Not Spam)***	***-1(Spam)***	***0(Not Spam)***	***-1(Spam)***	***0(Not Spam)***	***-1(Spam)***
	0(Not spam)	0	0	0	0	130	2	131	2
	-1(Spam)	161	954	149	966	19	964	17	965

B. Confusion Matrix of all the 4 Models BNS vs TF-IDF

The evaluated model's confusion matrix is given in Table II. The spam text is classified into two classes: spam and not spam. The contemporary SVM with BNS and TF-IDF is compared with the proposed Voting Classifier with BNS and TF-IDF.

C. Tabulated Results of Framework-1

The results of the framework-1 are tabulated in Table III. It is found that accuracy score and F1-score of models when TF-IDF is used much better than the models when BNS is used.

Another notable feature is that Voting Classifiers perform better than SVMs. TF-IDF when used with Voting Classifier shows the best results. Therefore, TF-IDF gives better real valued representation of textual data when converted into vectors.

The following figures (Fig. 11 and Fig. 12) show the Accuracy scores and F1-scores of all the 4 models.

1) SVM (RBF kernel) with BNS
2) VC with BNS
3) SVM (RBF kernel) with TF-IDF
4) VC with TF-IDF

TABLE III. PERFORMANCE METRIC VALUES OF THE 4 MODELS

Models/Evaluation Metrics	***Accuracy***	***F1-score***
SVM(BNS)	85.6%	91.2%
VC(BNS)	86.3%	92.8%
SVM(TF-IDF)	98.11%	98.2%
VC(TF-IDF)	98.26%	98.9%

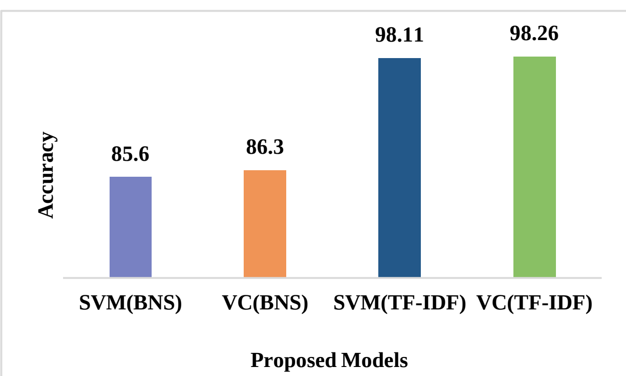

Fig. 11. Accuracy Measures of Framework-1.

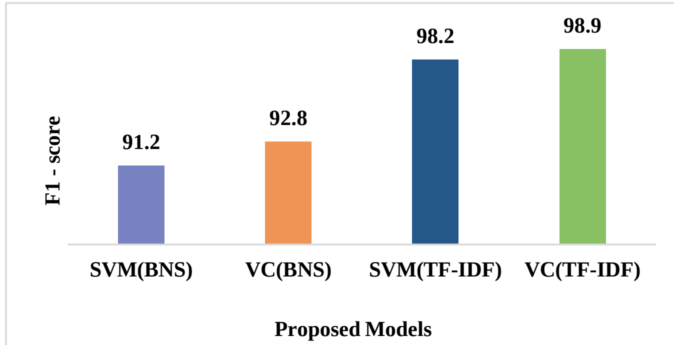

Fig. 12. F1-scores of Framework-1.

TABLE IV. PERFORMANCE METRIC VALUES OF SVM AND SVM+GA OVER SMALLER DATASET, 1- GENERATION AND 3- GENERATIONS

	1-generation		**3-generation**	
Models/Evaluation Metrics	***Accuracy***	***F1-score***	***Accuracy***	***F1-score***
SVM	6.12%	11.59%	6.12%	11.59%
SVM+GA	20.07%	27.98%	36.52%	42.82%

D. Tabulated Results of Framework-2

On applying genetic algorithms over SVM, the performance of the system shows greater increase with small labelled dataset. Accuracy and F1-scores of SVM applied over small labelled dataset (Table IV) are 6.12% and 11.59% whereas SVM+GA are 20.07% and 27.98%. As we can see that when GA is implemented for 1 generation and 3 generation, there is a huge difference between the results of SVM and proposed methods in terms of evaluation metrics. The GA is applied on a smaller dataset to show the increase in the performance.

Over the complete Reuters dataset SVM and SVM + GA is applied and the performance is measured and Tabulated in Table V. It's found that with GA, a substantial increase in accuracy is found, as because GA learns the pattern of allocating labels to the unlabeled data that are much closer to the original labels.

TABLE V. PERFORMANCE METRIC VALUES OF SVM AND SVM+GA OVER COMPLETE DATASET, 1- GENERATION AND 3- GENERATIONS

	1-generation		**3-generation**	
Models/Evaluation Metrics	***Accuracy***	***F1-score***	***Accuracy***	***F1-score***
SVM	86.53%	88.12%	86.53%	88.12%
SVM+GA	90.37%	91.45%	93.88%	96.72%

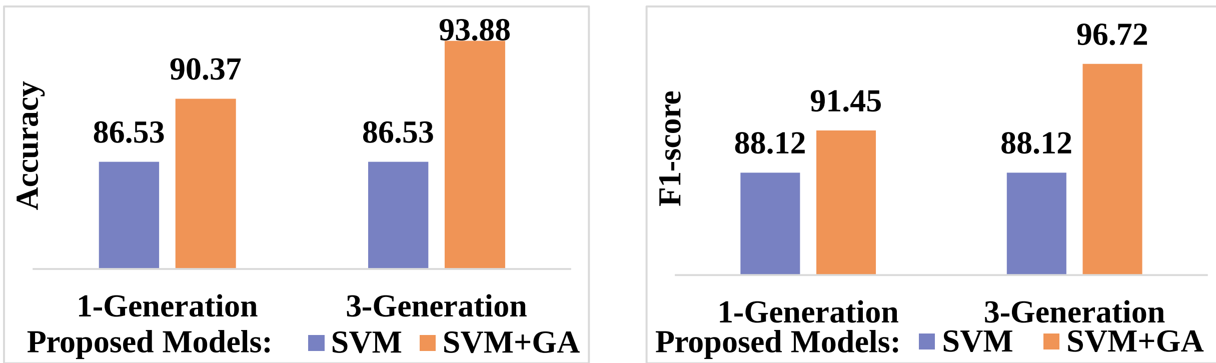

Fig. 14. Accuracy and F1 Score of Measures of Framework-2 with a Large Labelled Dataset.

Following figures (Fig. 13 and Fig. 14) show the graphical representation stating the accuracy and F1- score of SVM and SVM+GA with small and large labelled dataset.

V. Conclusion

This paper proposes two algorithms for binary and multi-class text classification. The two-vector representation of textual data: TF-IDF and BNS is explored and is identified that TF-IDF produces good results than BNS. The contributions are made in two-fold. The first proposed algorithm is the voting classifier that is created with four different classifiers. It is tested on Spam Text classification dataset from Kaggle. From results it is found that the use of TF-IDF improves the accuracy than BNS and the results ensured that Voting Classifier when used along with TF-IDF will give best accuracy (98.26%). The second algorithm classifies the dataset with limited number of labelled training samples. This algorithm applies Genetic Algorithm to generate labels for unlabeled datasets over which SVM is applied. Cross over and Mutation are the genetic operations that are applied in many generations. The results are measured in two folder: with smaller labelled dataset and with larger labelled dataset. With a small labelled dataset, an increase of accuracy from 6.12 % to 20.07% is found with one generation and 6.12 % to 36.52% with three generations on applying SVM and SVM+GA. With a large labelled dataset, an increase of accuracy from 86.53% to 90.37% is found with one generation and 86.53% to 93.88% with three generations on applying SVM and SVM+GA. This proposed algorithm is applied on the Reuters dataset. An increase in generation and on application of GA operations might slow down that process but has a positive side that helps in increasing the accuracy by a good margin. The future scope will be to incorporate genetic algorithm along with neural networks for the task of Text Classification. We also aim to research on using different pre-processing steps that will enhance the model's performance metrics score.

Hassan II University, Faculty of Sciences Ben M'sik
Casablanca, Morocco

***Abstract*—Computer vision is a branch of artificial intelligence that trains computers to acquire high-level understanding of images and videos. Some of the most well-known areas in Computer Vision are object detection, object tracking and motion estimation among others. Our focus in this paper concerns object detection subarea of computer vision which aims at recognizing instances of predefined sets of objects classes using bounding boxes or object segmentation. Object detection relies on various algorithms belonging to various families that differs in term of speed and quality of results. Hence, we propose in this paper to provide a comparative study of these algorithms based on a set of criteria. In this comparative study we will start by presenting each of these algorithms, selecting a set of criteria for comparison and applying a comparative methodology to get results. The methodology we chose to this purpose is called WSM (Weighted Scoring Model) which fits exactly our needs. Indeed, WSM method allows us to assign a weight to each of our criterion to calculate a final score of each of our compared algorithms. The obtained results reveal the weaknesses and the strengths of each one of them and opened breaches for their future enhancement.**

***Keywords*—Computer vision; object detection; images; WSM method; object detection algorithms**

I. Introduction

Object detection consists of several subtasks such as face recognition, pedestrian detection, skeleton detection, etc., and has use cases such as surveillance systems, autonomous cars, etc.[1][2]. There are two types of approaches to object detection in images: one based on two-stage detectors and the other based on one-stage detectors. One-step object detection algorithms work by immediately detecting objects on a sample of possible locations such as Fast R-CNN [3], R-CNN [4], Faster R-CNN [5], etc. Two-step object detection algorithms will first propose a set of regions of interest and then rank the relevant regions such as SSD [6], YOLO [7], CenterNet [8], etc. The architectures of these algorithms differ from each other in terms of accuracy, speed, and required hardware resources.

These approaches rely on deep learning models that are capable of end-to-end object detection, as they use a multi-layer structure of algorithms called neural networks that allow to perform many tasks, such as clustering, classification, or regression. A neural network is composed of input, hidden and output layers, all of which are composed of "nodes" as shown in Fig. 1.

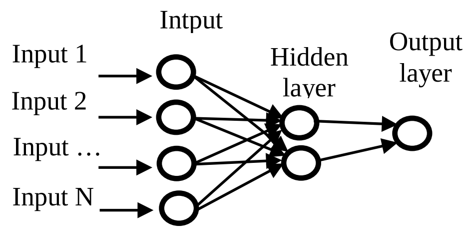

Fig. 1. A Simple Neural Network.

This paper, therefore, proposes to compare these algorithms based on the Weighted Scoring Model (WSM). Hence, we begin our comparative study by extracting the most relevant criteria for comparison and justify our choice for each criterion. Next, we present the WSM method before moving to assigning weights to each criterion and obtaining final scores for the compared object detection algorithms that are finally represented using a spider graph. The purpose of this spider graph is to show us the best detection model according to a set of scores for each criterion such as accuracy, speed, etc.

The document is organized as follows: Section II describes works related to our topic; Section III presents a background of object detection algorithms; Section IV presents our comparative study of object detection algorithms; Section V discusses the outcomes of this study and finally in Section 6 we draw a conclusion.

II. Related Work

Object detection is a challenging task that arises in many image processing applications such as human-computer interaction, civil and military surveillance, virtual reality, and human motion analysis or image compression. This challenge rises in unconstrained environments where the tracking system will have to adapt to important variability of objects, to variations of luminosity, to occlusions (partial or total) as well as to motion detection problems.

The introduction of deep learning algorithms, especially CNNs, to computer vision problems has progressed rapidly which has led to very robust, efficient, and flexible vision systems. Since the results of the "ImageNet 2012 challenge" event [9], Deep Learning and especially convolution networks have become the best method to solve this kind of problem.

Object detection is a very active field of research that seeks to classify and locate regions/areas of an image. This field is at the crossroads of two others: image classification and object localization [11]. Research in object detection has naturally integrated image classification models, which has led to the creation of models such as SSD [6] and R-CNN [4], etc.

Many scientific works are aimed at discovering approaches to object detection in images and algorithms and techniques that exist in each approach. Many researchers have made scientific efforts in this area to compare and show advantages and disadvantages of each algorithm and techniques that detect objects in images. Several research works tried to compare algorithms and models for object detection in images [7][6][12][13][14][15].

Sanchez et al. [16] have performed a review of state of the art related to the performance of pre-trained models for object detection in order to make a comparison of these algorithms in terms of reliability, accuracy, time processed, and problems detected. In this research [16], different pre-trained models using two datasets MS COCO[17] and PASCAL VOC[18] have been reviewed for object detection such as R-CNN, R-FCN, SSD, and YOLO, with different feature extractors such as VGG16, ResNet, Inception, MobileNet.

Srivastava et al. [19] were presented a comparative analysis of 3 major image processing algorithms: SSD, Faster R-CNN, and YOLO. In this analysis, they chose the COCO dataset to evaluate the performance and accuracy of the three algorithms and analyzed their strengths and weaknesses. They implemented these models and based on the results obtained, they determined the differences between the performance of each algorithm and the appropriate applications for each. The evaluation metrics are accuracy, precision, and F1 score.

In this work by Gupta et al.[20], the COCO dataset was used to extract sample images and then they used three architectures and three extractors to build different combinations of models in order to calculate the speed and accuracy (mAP) of each of these models.

All these comparative studies are based on the results of the implementation of each model used. For the comparison criteria, they focused on two criteria: accuracy (mAP) and speed. Most of these studies compared two-step detector-based approaches with one-step detector-based approaches.

The authors show that single-stage detectors are divided into two types [21][12]: Detectors with anchors and detectors without anchors, these two types each have advantages and disadvantages. The first major problem with anchored detectors is the involvement of several hyperparameters, which makes the algorithms very slow and computationally intensive [12]. This results in a low accuracy rate and makes the unanchored detectors outperform the anchored detectors. The best-known models in this approach are: YOLO [7], CenterNet [8], CornerNet [22], FCOS [12], etc. Then, they showed that the principle of two-stage detectors is that the first stage generates a set of regions of interest by the region proposal network (RPN) and the second stage for the classification of regions of interest. Among the algorithms that are based on this principle, we have R-CNN [21], Faster R-CNN [5], etc.

Our work is also based on the comparison of these approaches and algorithms based on the results of the implementations of previous works, and then according to a set of criteria, besides these two criteria: Average Accuracy (AP) and Speed (FPS), we have other criteria that we will discover in Section IV. What distinguishes our work from the others mentioned above is that this work uses the Weighted Scoring Model (WSM) which is one of the multi-criteria decision analysis methods. This method is adopted to make this comparison and get the work that is more favored for most of the criteria and discuss the result of this comparison.

III. Object Detection in Images

Object detection and recognition are computer vision techniques that allow the detection of object instances in images or videos [23].

Models and techniques for object detection in images generally use extracted features and learning models to recognize instances of classes of objects. These models are based on convolutional neural networks known as CNNs, which can vary in architecture, which play a key role in the construction of algorithms, but the basic principle remains the same [23].

A. Background

1) Convolution neural network (CNN): CNNs are one of the most popular classes of neural networks, especially for high-dimensional data (e.g., images and videos). CNNs work very similarly to standard neural networks. A key difference, however, is that each unit in a CNN layer is a two-dimensional (or high) filter convolved with the input to that layer. This is essential in cases where we wish to learn patterns from high-dimensional input media, such as images or videos. CNN filters incorporate spatial context by having a similar (but smaller) spatial shape as the input media, and use parameter sharing to significantly reduce the number of variables that can be learned [24].

CNNs can vary in architecture that play a key role in building algorithms, but the basic principle remains the same. Fig. 2 shows the Convolutional neural network architecture. It receives an input feature map, i.e., a three-dimensional matrix whose size of the first two dimensions corresponds to the length and width in pixels of the images.

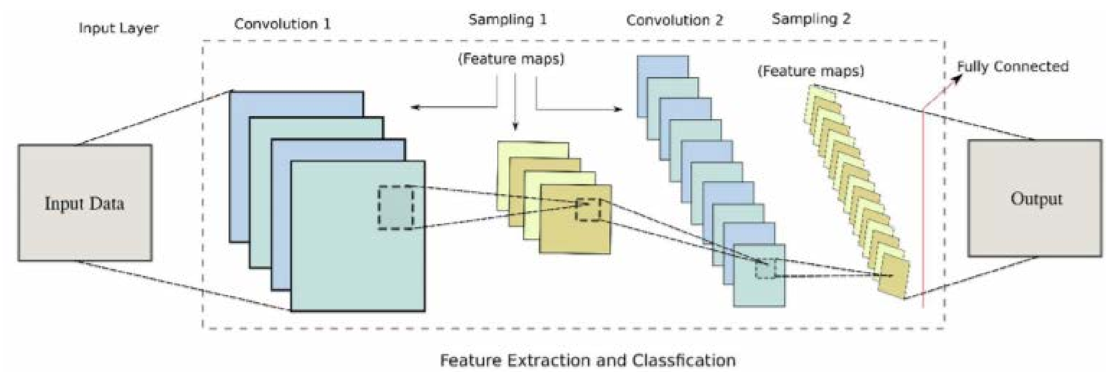

Fig. 2. CNN Architecture[10].

The size of the third dimension is three corresponding to the three channels of a color image: red, green, and blue. After this feature map, there are:

- Convolutional layer: The role of this layer is to extract fields from the input feature map and apply filters to them to compute new features, thus producing a convolved feature map.
- Max Pooling: The goal of this layer is to minimize the dimensions of the input while preserving as much information as possible because the processing of the convolutional layer is a very computationally expensive operation. And for this purpose, pooling is one of the techniques used to minimize the dimensions.
- Fully connected: After these previous layers, we have this layer whose role is to perform a classification based on the features extracted by the convolutions. And generally, this layer contains a SoftMax activation function, which provides a probability value between 0 and 1 for each of the classification labels that the model tries to predict.
- Output layer: this layer shows the result, i.e., the result of the classification algorithm used.

2) Region proposal network (RPN): Region Proposal Network (RPN) [5] is a fully convolutional network that simultaneously predicts object boundaries and objectivity scores at each position. It is trained end-to-end to generate high quality region proposals, used with the Fast R-CNN model that was proposed by[3] for object detection in images and reduces the number of candidate object locations by filtering out most background samples. This network is essential in the architecture of Faster R-CNN model which has been improved by researchers [5]. Fig. 4 shows the principle of Region Proposal Network.

3) Feature pyramid network (FPN): Feature Pyramid Network (FPN) [25] is a feature extractor and generates multiple layers of feature maps with better quality information than the regular feature pyramid for object detection. FPN consists of a bottom-up and top-down path. For the bottom-up path, it is the usual convolutional network for feature extraction. As we go up, the spatial resolution decreases, and with more high-level structures detected, the semantic value of each layer increases. For the downward path, it is to build higher resolution layers from a semantically rich layer. Some simultaneous works like RetinaNet [13] also use this type of network. Fig. 3 shows the Feature Pyramid Network architecture.

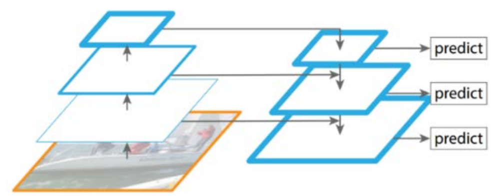

Fig. 3. Feature Pyramid Network (FPN).

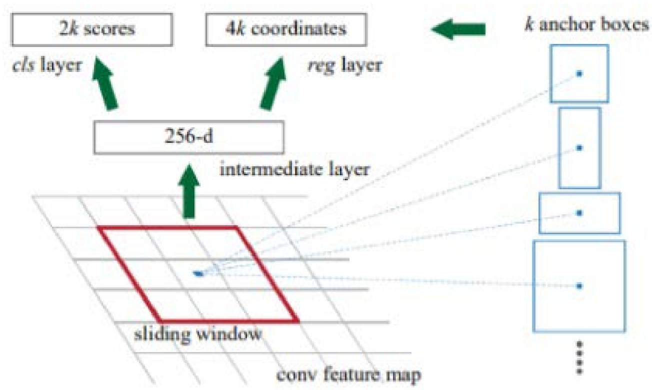

Fig. 4. Region Proposal Network (RPN).

B. *Principle of Staged Detectors and their Advantages and Disadvantages*

Object detection approaches in images are divided into two categories: approach based on two-stage detectors and approach based on one-stage detectors. Each approaches contains many models, in Section IV, we will detail and compare these models.

1) Two-stage detectors: The principle of two-stage detectors is that the first stage generates a set of regions of interest using Region Proposal Network (RPN), which reduces the number of candidate object locations by filtering most of the background samples. The second step is the classification of regions of interest among candidate object locations extracted in the first step [23].

The advantage is that the models and algorithms that exist in this approach such as: : R-CNN [21], R-FCN [15], Fast R-CNN [3], Mask R-CNN [26], etc., have a high accuracy but the disadvantage is that at the level of processing time of each image is very slow due to repetitive detection and classification [23]. In Table II, we will list advantages and disadvantages of one and two-stage detectors.

2) One-stage detectors: The main goal of one-step detectors is to unify detection and classification in one step which will result in a single pass through the neural network. Thus, it predicts all candidate object locations at once which increases the speed of object detection [23] but on the other hand, they suffer low accuracy. The most known models in this approach are: YOLO [7], RetinaNet [13], SSD [6], CenterNet [8], etc.

One-stage detectors are divided into two types: Anchor-based detectors [27] and others anchor not based detectors. For Anchor-based detectors, the detection is done by a frame around the detected objects [23]. This frame is called an anchor or bounding box as seen in this figure. Concerning, anchor-not-based detectors, the detection is made by a point in the center of the detected object. The first major problem with anchor detectors is the involvement of several hyperparameters, which makes the algorithms very slow and requires much computation power. This results in a low rate of accuracy and makes anchorless detectors outperform anchor detectors [23].

IV. Comparison of Object Detection Approaches in Images

Comparison of object detection models in images is based on the WSM method which allows to differentiate between compared objects according to a set of criteria [28].

A. Weighted Scoring Model

Weighted scoring model [29] is a project management technique that combines quantitative and qualitative measures to facilitate operational decision-making and allows multiple criteria to be considered. Specific scoring criteria can be selected based on well-defined objectives and product metrics.

This technique assigns a weight to each criterion based on its relative importance, with the most important criterion being assigned the highest weight. To realize the application of the WSM method, we have four steps to follow [28]:

- Step 1: Select a list of features and other initiatives being considered.
- Step 2: Select criteria, including costs and benefits, on which you will evaluate each of these initiatives.
- Step 3: Determine the respective weighting of each criterion that you will use to evaluate your competing initiatives.
- Step 4: Assign individual scores to each feature, for all your cost and benefit criteria, and then calculate these overall scores to determine the ranking of the list of features.

1) Comparison criteria: Each approach contains many different models as presented in the sections above, and each model has a set of criteria that help the user to make the decision to choose the best performing and most adaptable model for his project. The choice of criteria for comparing each model is extracted from previous work that has enriched the object detection domain. We have identified five criteria:

- Average Accuracy (AP): This criterion indicates the accuracy value of each object detection model. It depends on the quality of the input images, the number of training samples, the model parameters, and the required accuracy threshold. The values presented in Table IV of this criterion are scores from 1 to 5 according to the following intervals to which the accuracy value (AP) of each model belongs.
- Detection time (FPS): This criterion indicates the number of frames processed per second for each object detection model. It expresses the processing speed of the model. In Table IV, the values presented of this criterion are scores from 1 to 5 according to the following intervals to which the SPF value of each model belongs.
- Real-time: This criterion shows how well the model works for real-time object detection. This criterion is evaluated in three values: 1 which means poor, 4 which means fair, 5 which means good.
- Number of stages: this criterion shows the number of stages of each model and designs the category of detectors. We have two categories: One-stage detectors and two-stage detectors.
- Simple network structure: This criterion shows if the model is easy and simple to use for object detection. This criterion is evaluated as a Boolean value that shows the availability of this criterion for each model.

Table I shows the intervals to which the accuracy value (AP) and detection time (FPS) of each model belong and their scores.

Table IV shows the scores from 0 to 5 of each criterion corresponding to each model according to the evaluation of each criterion that we explained in section 5.1.1.

TABLE I. AP and FPS Scores for each Interval

Intervals	Scores
[0,10]	1
[10,20]	2
[20,30]	3
[30,40]	4
[40,50]	5

TABLE II. ADVANTAGES AND DISADVANTAGES OF OBJECTS DETECTION MODELS

Model / method	**Category**	**Advantages**	**Disadvantages**
Fast R-CNN	Two-stage detectors	High detection accuracy, Low misdetection rate	Non-real-time detection, speed of object detection per image is low
Faster R-CNN			
R-FCN			
Mask R-CNN			
CenterNet	One-stage detectors	Object detection can be in real-time, Simple network structure, speed of object detection per image is high.	Low detection accuracy, Poor results for small and dense objects, Easy to mislocate
CornerNet			
RetinaNet			
YOLO v2			
YOLO v3			
SSD			
FCOS			

TABLE III. VALUES OF THE CRITERIA CORRESPONDING TO EACH MODEL ACCORDING TO THE RESULT OF THEIR IMPLEMENTATION

Criteria	**Fast R-CNN [3] (VGG-16)**	**Faster R-CNN [14] (ResNet-101)**	**R-FCN [15] (ResNet-101)**	**Mask R-CNN [26] [30] (ResNet-101-FPN)**	**CenterNet [8] (DLA-34)**	**CornerNet [14] (Hourglass-104)**	**RetinaNet [13] (ResNet-101-FPN)**	**YOLO v2 [31]**	**YOLO v3 [32](DarkNet-53)**	**SSD [6]**	**FCOS [11] (ResNet-101-FPN)**
AP	35,9	34,9	31,5	35,7	41,6	42,1	40,8	44	33	46,5	41,5
FPS	0,5	5	12	5	28	4,1	5,4	40	20	22	8,1

TABLE IV. COMPARATIVE STUDY OF CRITERIA FOR EACH MODEL

Criteria	**Values of criteria corresponding to each model**										
	Fast R-CNN [3] (VGG-16)	**Faster R-CNN [14] (ResNet-101)**	**R-FCN [15] (ResNet-101)**	**Mask R-CNN [26] [30] (ResNet-101-FPN)**	**CenterNet [8] (DLA-34)**	**CornerNet [14] (Hourglass-104)**	**RetinaNet [13] (ResNet-101-FPN)**	**YOLO v2 [31]**	**YOLO v3 [32] (DarkNet-53)**	**SSD [6]**	**FCOS [11] (ResNet-101-FPN)**
AP	4	4	4	4	5	5	4	5	4	5	5
FPS	1	1	2	1	3	1	1	5	3	3	1
Real-time	1	1	4	1	5	1	1	5	5	5	1
Number of stages	2	2	2	2	1	1	1	1	1	1	1
Simple network structure	0	0	0	0	1	1	1	1	1	1	1

2) Comparative study: The values of the average accuracy (AP) and detection time (FPS) criteria as shown in Table III are extracted from the studies of many researchers that we have already cited in the previous sections. All these models are trained and tested on the same dataset called MS COCO.

MS COCO dataset has been described by Lin et al [17] as a set of data for large-scale object detection, segmentation, and subtitling. It contains a large, richly annotated dataset of images representing complex everyday scenes of common objects in their natural context: photos of 91 types of objects that would be easily recognizable by a 4-year-old child.

B. Application of Weighted Scoring Model

The Table V shows the WSM results for each object detection model in the image. The allocation of weighting percentages is done according to the importance of the criterion. Because of their mandatory nature, priority is given to these two criteria: Average precision (AP) and detection time (FPS), a weight of 0,3 is assigned to each of these criteria. The second category of importance is given to this criterion: Real-time, a weight of 0,2 is assigned to this criterion. The next two criteria are not of great importance: number of stages and simple network structure, each of these two criteria have a weight of 0,1. The weight of the total scores is equal to 1.

TABLE V. RESULTS OF WSM

Criteria	Weight	Requirement score										
		Fast R-CNN [3] (VGG-16)	Faster R-CNN [14] (ResNet-101)	R-FCN [15] (ResNet-101)	Mask R-CNN [26] [30](ResNet-101-FPN)	CenterNet [8] (DLA-34)	CornerNet [14] (Hourglass-104)	RetinaNet [13] (ResNet-101-FPN)	YOLO v2 [31]	YOLO v3 [32] (DarkNet-53)	SSD [6]	FCOS [11] (ResNet-101-FPN)
AP	0,3	1,2	1,2	1,2	1,2	1,5	1,5	1,2	1,5	1,2	1,5	1,5
FPS	0,3	0,3	0,3	0,6	0,3	0,9	0,3	0,3	1,5	0,9	0,9	0,3
Real-time	0,2	0,2	0,2	0,8	0,2	1	0,2	0,2	1	1	1	0,2

V. DISCUSSION

According to the previous results, the YOLO v2 model is the best performing model for object detection in images. It is a model that was proposed by J. Redmon and A. Farhadi in 2016 in [31].

In terms of speed, this model is one of the best object detection and recognition models, capable of recognizing objects and processing frames up to 40 FPS (in our case) and sometimes up to 150 FPS depending on the architecture used. However, in terms of AP accuracy, YOLO v2 was not the top model but has good accuracy (AP) of 44% when trained on the MS COCO dataset. However, Fast R-CNN, Faster R-CNN which was the state of the art at that time has an AP of 35.9% and 34.9% successively. YOLO v2 belongs to single-stage detectors. Generally, the architecture of this type of detector is simple and easy to use compared to the other models based on two-stage detectors such as Fast R-CNN, Faster R-CNN, R-FCN, and Mask R-CNN.

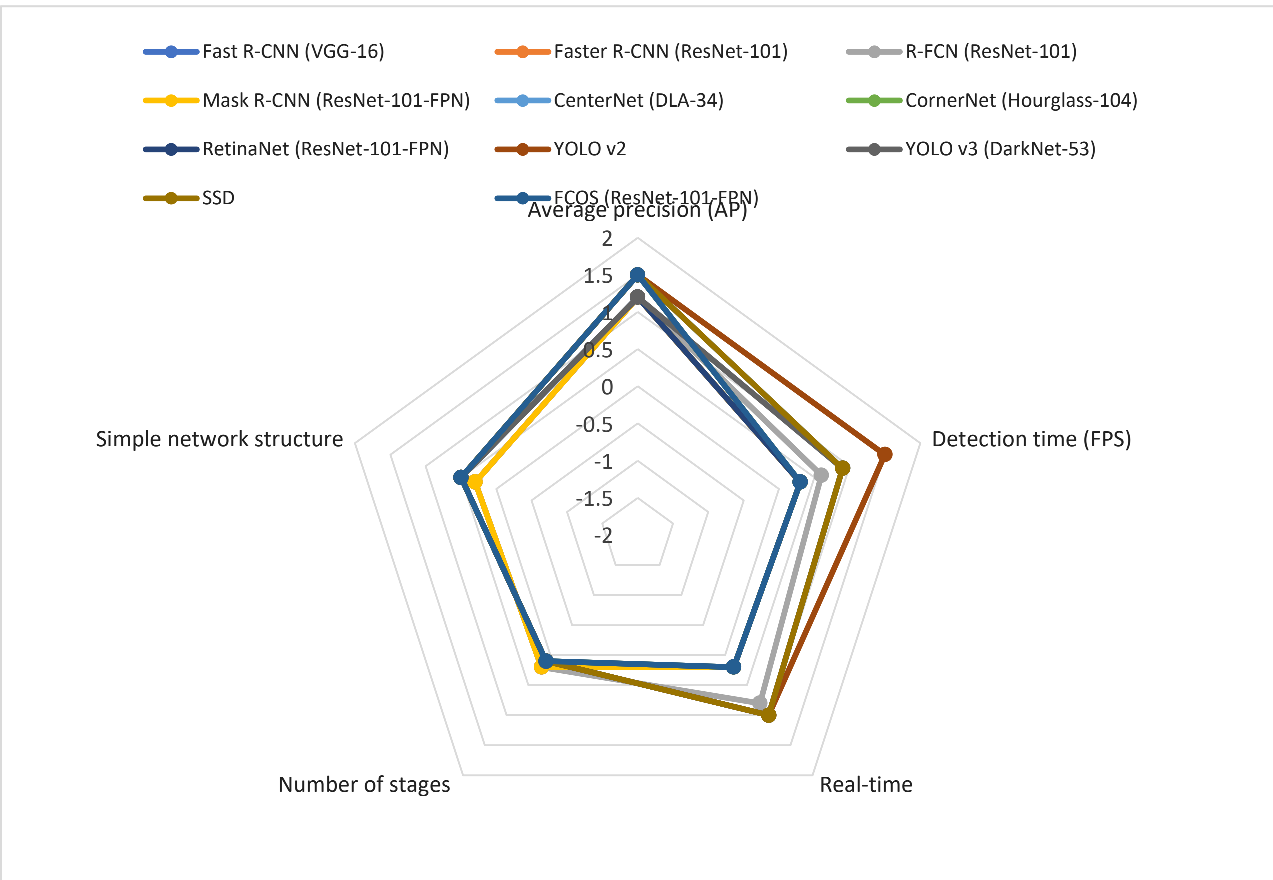

Fig. 5. Spider Chart Multi-Criteria Decision.

The other models CenterNet [8], CornerNet [22], RetinaNet [13], YOLO v3 [32], SSD [6], and FCOS [12] are quite efficient but not as efficient as YOLO v2 in terms of speed (FPS) and accuracy (AP) because these models have sometimes low accuracy and slow speed compared to YOLO v2 so they do not work well in real-time. This result is reflected in the multi-criteria radar graph presented in Fig. 5.

Many works do not consider the use of multi-criteria decision analysis (MCDA) methods which is a valuable tool that can be applied to many complex decisions.

It can solve complex problems that include qualitative and/or quantitative aspects in the decision-making process [33]. In the literature of this field, there is a great lack of this kind of comparison like this article which uses one of the multi-criteria analysis methods such as AHP, WSM, MAUT, and WPM, etc.

VI. Conclusion and Future Work

In this paper, a comparative study based on a weighted scoring model is presented. This study is a comparison of models for object detection in images. This work starts by identifying a set of relevant works that adopt the different models of object detection in images. Then, we described the main architectures of the models that are cited in these works. We have also seen the advantages and disadvantages of the models studied in this article. Thus, we defined the WSM method and then we identified a set of criteria of each model to realize this comparison.

According to the result of our comparison, the best performing model is YOLO v2 because it has high accuracy (AP) and the frame rate per second (FPS) is fast, this means that this model works well in real-time against other models sometimes are slow and they have low accuracy. Based on the Weighted Scoring Model method, the scores of each of the studied models are obtained.

These scores helped us to establish a general classification between these models, but they also showed their strengths and weaknesses concerning each studied criterion.

In future work, we will study the algorithms and models that are effective for the classification of satellite images, and we will try to make an implementation of the most efficient model for the detection and classification of images, especially satellite images. This work provides a contribution to computer scientists and data scientists to help them choose between the different existing models and algorithms, according to their needs and the criteria that matter most to them. The aim of this study is to help the user to make the decision to choose the most efficient model for his project.

On the Training of Deep Neural Networks for Automatic Arabic-Text Diacritization

Asma Abdel Karim, Gheith Abandah
Computer Engineering Department
The University of Jordan
Amman, Jordan

***Abstract*—Automatic Arabic diacritization is one of the most important and challenging problems in Arabic natural language processing (NLP). Recurrent neural networks (RNNs) have proved recently to achieve state-of-the-art results for sequence transcription problems in general, and Arabic diacritization in specific. In this work, we investigate the effect of varying the size of the training corpus on the accuracy of diacritization. We produce a cleaned corpus of approximately 550k sequences extracted from the full dataset of Tashkeela and use subsets of this corpus in our training experiments. Our base model is a deep bidirectional long short-term memory (BiLSTM) RNN that transcribes undiacritized sequences of Arabic letters with fully diacritized sequences. Our experiments show that error rates improve as the size of training corpus increases. Our best performing model achieves average diacritic and word error rates of 1.45% and 3.89%, respectively. When compared with state-of-the-art diacritization systems, we reduce the word error rate by 12% over the best published results.**

Keywords*—Arabic text; automatic diacritization; bidirectional neural network; long short-term memory; natural language processing; recurrent neural networks; sequence transcription

I. Introduction

The Arabic language is vastly spoken and written in many countries around the world. Arabic scripts mainly exist in two forms: Classical Arabic (CA) represented in holy scripts and old books, and Modern Standard Arabic (MSA) which is a contemporary form of CA used nowadays to write stories, books, newspapers, and formal speeches. Moreover, people use dialects that differ from one region to another, to communicate in their everyday lives [1].

Arabic sentences consist of sequences of words, written from right to left, composed of letters and diacritics. Diacritics are generally zero-width characters that appear in the form of marks added above or below the letters. They provide syntactic and semantic distinction that is essential to pronounce and understand Arabic texts [2]. However, diacritics are optional in most texts, especially MSA texts. This causes problems in understanding the text for non-native speakers and children since they may not be able to infer diacritics from the context. Moreover, it poses challenges on automatic Arabic language processing applications which require text to be diacritized such as automatic speech recognition (ASR), text to speech (TTS), and machine translation (MT) [1].

The Arabic language consists of 28 letters and eight basic diacritics. A total of 36 variants of the Arabic letters result from adding the six Hamza letters (ء، آ، أ، ؤ، إ، ئ), the Teh Marbuta (ة), and the Alef Maksura (ى) to the basic 28 letters. These variants have the Unicode hexadecimal codes 0621–063A and 0641–064A. The eight basic Arabic diacritics are: three short vowel diacritics (Fatha, Damma, Kasra), three nunation (Tanween) diacritics, double consonant diacritic (Shadda), and the no-vowel diacritic (Sukun). Arabic diacritics have the Unicode hexadecimal codes 064B–0652. The nunation diacritics are Fathatan, Dammatan, and Kasratan. They can only appear on the last letter of the word. Shadda diacritic is usually combined with either a short vowel or nunation diacritic. With these combined forms, we get a total of thirteen possible different diacritization of a letter in the Arabic language. Table I show the Arabic diacritics along with their transliterated names and list their shapes and sounds when written on the letter Beh (ب).

Diacritics can be classified into two categories: lexemic diacritics and inflectional diacritics. Lexemic diacritics distinguish between words in Arabic morphology that have the same orthography (spelling) but different pronunciations and meanings [3]. Example 1 in Table II shows how adding diacritics to the word كتب in two different ways results in two different pronunciations and meanings. The diacritized word كَتَبَ, pronounced "kataba", is a verb which means "he wrote". The diacritized word كُتُب, pronounced "kutub", is a plural noun which means books. Specifying which diacritization form to use for a word depends on the context.

TABLE I. Arabic Diacritics, their Transliterated Names, and Pronunciations

Diacritic	Transliterated Name	Shape	Sound
Short Vowels	*Fatha*	بَ	/ba/
	Damma	بُ	/bu/
	Kasra	بِ	/bi/
Nunation (Tanween)	*Fathatan*	بً	/ban/
	Dammatan	بٌ	/bun/
	Kasratan	بٍ	/bin/
Double Consonant Diacritic	*Shadda*	بّ	/bb/
No-vowel Diacritic	*Sukun*	بْ	/b/

Example 2 in Table II shows how diacritizing the word كتب using one of the two mentioned forms depends on the context it appears in. More specifically, it differs based on the third word in the sentence. In the first case, it is diacritized as the verb "kataba" since the third word is the noun lesson (الدرس) indicating that this is a verb-subject-object sentence. In the second case, it is diacritized as the noun "kutubu" since the third word is the adjective useful (مفيدة) indicating that this is a nominal sentence. In more complex sentences, diacritizing a word may expand to depend on words even further away in the sentence.

Inflectional diacritics distinguish different inflected forms of the same word. The diacritic of the last letter in the word depends on the position and role of the word in the sentence [3]. Example 1 in Table III shows how placing the noun كُتُب "kutub" in three different positions changes the last letter ب diacritic between Fatha, Damma, and Kasra. The last letter diacritic is often referred to as end case diacritic. Restoring this diacritic is considered a challenging task even when performed manually since it depends on the way the sentence is formed syntactically. Moreover, words (both nouns and verbs) may be inflected by appending suffixes that add features such as voice, number, person, tense, case, and other categorical information [1].

Example 2 in Table III shows how the diacritic of the last letter changes when the verb كَتَب is inflected in three different ways to represent masculine second narration using Fatha in the word كَتَبْتَ, feminine second narration using Kasra in the word كَتَبْتِ, and first narration using Damma in the word كَتَبْتُ. Inflected words make syntactical position of the word affect the diacritization not only of the last letter, but even the letters before. Example 3 in Table III shows the plural noun كُتُبه which is inflected by adding the possessive masculine pronoun ـه. The diacritization of the letter ب which is the letter before the pronoun ـه is the one affected by the position of the word in the sentence.

Consequently, recovering diacritics of undiacritized Arabic text is a challenging yet an important task. Many models have been proposed to automate the process of diacritizing Arabic texts. The performance of these models has been measured using two main metrics that represent the accuracy of the model in providing correct diacritics for the input undiacritized text. These metrics are the diacritics error rate (DER) and word error rate (WER). DER is computed by finding the percentage of wrong diacritics to the total number of characters in the input sequences. WER is computed by finding the percentage of words with at least one wrong diacritic to the total number of words in the input sequences.

TABLE II. EXAMPLES OF LEXEMIC DIACRITICS

Example Number	Forms	Meaning	Pronunciation
1	كَـتَـبَ	he wrote	/kataba/
	كُتُب	Books	/kutub/
2	كَتَبَ أحمد الدرس.	Ahmad wrote the lesson.	
	كُتُبُ أحمد مفيدة.	Ahmad's books are useful.	

TABLE III. EXAMPLES OF INFLECTIONAL DIACRITICS

Example Number	Forms	Meaning	Pronunciation
1	كُتُبُ أحمدَ مفيدة.	Ahmad's books are useful.	/kutubu/
	قرأتُ كُتُبَ أحمدَ جميعها.	I read all Ahmad's books.	/kutuba/
	أعجبت بكُتُبِ أحمدَ جميعها.	I liked Ahmad's books.	/kutubi/
2	كَتَبْتَ	You wrote (masculine)	/katabta/
	كَتَبْتِ	You wrote (feminine)	/katabti/
	كَتَبْتُ	I wrote	/katabtu/
3	كُتُبُهُ مفيدة.	His books are useful.	/kutubuhu/
	قرأ أحمد كُتُبَهُ.	Ahmad read his books.	/kutubahu/
	اعتنى أحمد بكُتُبِهِ.	Ahmad took care of his books.	/kutubihi/

Although the best previous solutions have shown steady improvement in accuracy over time, we think that the latest accuracies can be improved further using better models and training datasets. In most cases, the accuracy is restricted due to the lack of large, cleaned training dataset with acceptable diacritization to character rate. In this work, we extend the cleaning process performed in [4] to include the entire Tashkeela dataset. We concentrate on finding the effect of the training dataset size on the diacritization accuracy and on reducing the error rates through using larger datasets. Finding the effect of the dataset size on model accuracy and the best training size would hopefully help interested researchers to reach even better accuracies. The cleaning process was performed in steps such that eight corpora are extracted and cleaned with incremental sizes in terms of number of sequences. We perform experiments that use these corpora to explore and analyze the effect of increasing the training dataset size on the accuracy of our baseline model.

We build on our previous experience in designing a model that exploits the efficiency of bidirectional long short-term memory (BiLSTM) recurrent neural networks in automatic diacritization of Arabic texts. These networks are characterized with their ability to utilize long-term past and future contexts to predict diacritics. Our work produces a cleaned dataset of 543,364 sequences with diacritization to character rate of at least 80%. This dataset can be used to experiment training more sophisticated diacritization models. Moreover, our best-performing BiLSTM model achieves DER of 1.45% and WER of 3.89%.

The rest of this paper is organized as follows. The next section reviews systems proposed to automate the diacritization of Arabic text. Section III provides background information of sequence transcription and recurrent neural networks. Section IV illustrates our experimental setup. Section V presents and discusses the results of our experiments and compares our best results with the results of previous best performing models. Finally, we conclude our work in Section VI.

II. Literature Review

Diacritization is the process of adding diacritics to the letters of undiacritized texts. This operation is essential to many applications that involve translation and text-to-speech (TTS) conversion. Many models have been proposed over the years to automate the process of diacritizing Arabic text. These models involve rule-based models, statistical models, and hybrid models. Rule-based natural language processing (NLP) systems depend on using a set of well-defined language-dependent rules which are formed by exploiting solid linguistic knowledge. These systems are based on dictionaries and/or morphological and syntactic analyzers/generators [5][6]. Although rule-based approaches achieve acceptable results, their main drawback is the difficulty of maintaining and including all aspects of the language in a comprehensive set of rules. This is even more significant with a complex language morphologically and syntactically like the Arabic language [7].

Statistical approaches use large corpora of diacritized texts to predict the probability distribution of diacritics for a sequence of characters. The main advantage of these approaches is that they do not depend on a set of rules to solve the problem and hence do not require solid linguistic knowledge. Statistical methods that have been applied to Arabic text diacritization include hidden Markov models (HMM) [8][9], n-grams [10], finite state transducers (FST) [11], conditional random fields (CRF) [12], and neural networks. Recently, most proposed systems combined statistical approaches with linguistic knowledge such that the stochastic process is guided by language specific rules, introducing hybrid approaches [3, 13-19].

More recently, RNNs have been successfully used to solve restoring diacritics of Arabic texts as a sequence transcription problem. Our previous work in [20] proposed, trained, and tested a bidirectional LSTM network that transcribes raw undiacritized Arabic sequences with fully diacritized ones. Error correction techniques were used as a post processing step to the output of the network to overcome some transcription errors. We also experimented preprocessing the RNN input using a morphological and syntactical analyzer in [21]. Mubarak et al. [22] implemented a sequence-to-sequence model using an encoder-decoder LSTM RNN with content-based attention. They used a fixed length sliding window of character-based n-words in the training process and a voting algorithm of n-gram probabilistic estimation to select the most likely diacritic form of a word. They trained their model using 4.5 million tokens and tested it using the freely available WikiNews corpus of 18,300 words.

In [4], Fadel et al. tested and compared a few existing web-based automatic diacritization tools. They produced a cleaned subset of 55K sequences from the Tashkeela dataset which is split into training, testing, and validation sets. In [23], they implemented and tested several neural network models that belong to two main approaches, feed forward neural networks and recurrent neural networks. They explored several models using different types of input layers, using a CRF classifier instead of the softmax layer, and optimizing gradients normalization using block-normalized gradient (BNG).

Darwish et al. [24] proposed an approach to automatic diacritization that consists of two bidirectional LSTM RNNs. The first network is responsible for core-word (i.e., all letters other than the last letter of the word) diacritics and the second is responsible for case-ending (i.e., last letter) diacritics. They trained and tested their approach on two sets: one that represents MSA texts and the other represents CA texts. Their model included post correction using a unigram language model.

In our most recent work [25], we trained and tested RNN models using two datasets: Linguistic Data Consortium's Arabic Treebank part 3 (LDC-ATB3) [26], and the cleaned subset of Tashkeela [4]. We performed extensive experiments to explore and analyze the effect of tuning several network parameters, such as the number of network layers and using dropout, on the accuracy and execution time of the tested models. We also experimented models built using different network architectures, alternative approaches to handle problems in sequence lengths, and multiple encoding methods for the diacritized output sequences.

Madhfar and Qamar [27] implemented and experimented automatic diacritization using three character-level deep learning models. The first model is a network that consists of six layers: an embedding layer, followed by three bidirectional LSTM layers, a projection layer, and finally, a softmax layer. The second model consists of an encoder and decoder with location-based attention. The third model consists only of the encoder part of the second model. Its core architecture is implemented using a 1-D convolution bank, a multi-layer highway network, and a bidirectional GRU network. The model is named CBHG (1-D Convolution Bank + Highway network + Bidirectional GRU).

In this paper, we experiment training a deep BiLSTM model using several datasets with incremental sizes extracted from the Tashkeela dataset. Our goal is to test the accuracy of the trained model in each case, thus investigating the effect of the training set size on the accuracy of diacritization. Moreover, our work includes extracting a cleaned corpus of the full dataset of Taskeela which includes only sequences with diacritization to letter rates greater than 80%.

III. Sequence Transcription

Many machine learning tasks can be implemented as a sequence transcription problem, in which input sequences are translated into corresponding output sequences. These include speech recognition, machine translation, and text to speech [28]. Arabic text diacritization has been expressed successfully as a sequence transcription problem as well [20-27]. In our work, an input sequence X consists of characters $x_1, x_2, x_3, \dots, x_T$ that represent the undiacritized sequence. The output sequence Y is a sequence of diacritics $y_1, y_2, y_3, \dots, y_T$ such that y_i is the diacritic of the letter x_i.

Recurrent neural networks (RNNs) have proved to perform best on sequence transcription problems. This is because cells' hidden states are functions of all previous states with respect to time. This provides RNNs with their ability to maintain correlations between data points in the input sequence and the capability of pointing backward in time [28]. Basic recurrent neural networks are generalization of feedforward neural networks to sequences [29]. Given a sequence of inputs $(x_1, x_2, \ldots, x_T)$, a standard RNN computes a sequence of outputs $(y_1, y_2, \ldots, y_T)$. At each time step, a recurrent neuron receives the output vector from the previous time step $y_{i(t-1)}$, in addition to the input vector $x_{i(t)}$. Hence, $y_{i(t)}$ is a function of $x_{i(t)}$ and $y_{i(t-1)}$, which is a function of $x_{i(t-1)}$ and $y_{i(t-2)}$, which is a function of $x_{i(t-2)}$ and $y_{i(t-3)}$, and so on. Consequently, $y_{i(t)}$ is a function of all input vectors since $t = 1$ [30].

Sequence transcription problems solved using RNNs can be classified into four categories based on the lengths of input and output sequences [30]. One-to-one networks take an input sequences and produces an output sequence of the same length. Sequence-to-vector networks transcribe input sequences into one final output by ignoring all previous outputs. Vector-to-sequence networks take one input vector and produce an output sequence. The general sequence-to-sequence network has output sequence that is generally not of the same length as the input sequence. This type is often implemented using the encoder-decoder architecture [31]. In this work, we implement automatic Arabic diacritization as a one-to-one sequence transcription problem since for each input sequence of characters; the output sequence of diacritics is of the same length.

Long short-term memory (LSTM) RNNs were first proposed in [32] to deal with the basic RNNs' problem of decaying or slowly changing weights. This results in their disability to learn long dependencies in the input sequences. LSTM networks, on the other hand, which use purpose-built memory cells, can converge faster, and detect long-term dependencies in the sequences [28]. Each memory cell has two states, the short-term state (also used as the cell output) $h_{(t)}$ and a long-term state $c_{(t)}$. These states are updated using an input gate, a forget gate, an output gate, and a cell activation unit. The operation of these gates collectively enables the LSTM cell to capture long term patterns by recognizing important inputs, preserving them as long as they are needed, and extracting them whenever they are needed. Fig. 1 shows a basic RNN cell and an LSTM cell.

Conventional unidirectional RNNs can make use only of previous context. However, many sequence transcription problems, including diacritization, require exploiting future context as well. Bidirectional RNN layers achieve this by comprising two unidirectional layers that process the sequence in both time directions producing two hidden vectors. The output is a function of both vectors and, consequently, exploits past and future contexts [33]. Fig. 2 shows the general structure of the bidirectional neural network unfolded for three time-steps. RNNs are made even more powerful by stacking multiple layers on top of each other forming a deep RNN. Deep networks are necessary to solve complex transcription functions. In such architectures, the output sequence of one-layer acts as the input sequence for the next layer.

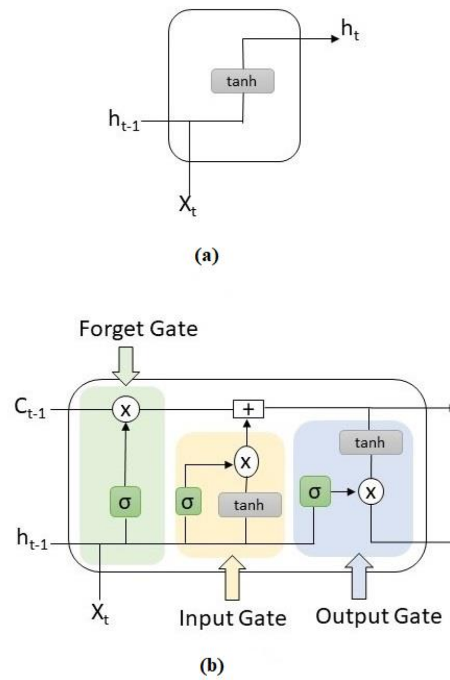

Fig. 1. (a) Basic RNN Cell, (b) LSTM Cell.

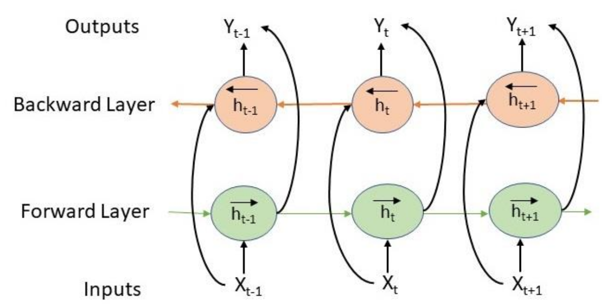

Fig. 2. General Structure of the Bidirectional Neural Network Shown unfolded for Three Time Step.

IV. Experimental Setup

In this section we provide the details of the experiments conducted in this work. We illustrate the methodology used, how datasets were extracted and preprocessed, the scheme used to encode sequences, and the structure of our baseline model. We performed all experiments on the Cyclone supercomputer of the High-Performance Computing Facility of The Cyprus Institute [34]. The processing and memory specifications of the used resources on the platform are listed in Table IV.

TABLE IV. Processing and Memory Specifications of the Experimental Platform

CPU	Intel Xeon Gold 6284 @ 2.5 GHz, 20 cores (40 threads), 27.5 MB cache
GPU	Nvidia Tesla V100-SXM2 @ 1.53 GHz, 5120 CUDA cores, 32 GB memory
Memory	192 GB DDR4-SDRAM

A. Methodology

We performed several experiments which involved training of our baseline model using corpora with different sizes. All experiments went through two phases: the first phase is training the model and the second phase is testing its diacritization accuracy. In the training phase, diacritics are removed from diacritized training sequences to generate undiacritized sequences. Generated undiacritized sequences represent the model input sequences whereas diacritic sequences are the model target sequences. Both undiacritized input sequences and diacritic target sequences are fed to the model after being encoded. Fig. 3 shows the steps performed in the training phase of the performed experiments.

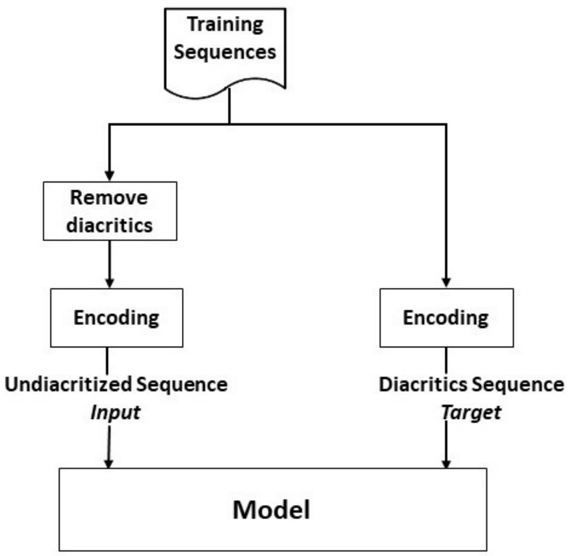

Fig. 3. Training Phase of Experiments.

In the testing phase, diacritics are removed from diacritized testing sequences. The trained model takes the generated undiacritized sequences as input to predict their diacritics. We perform minor corrections to the output sequences according to rules developed in our previous work in [20]. Corrected output sequences are stored in a text file named diacritized_output.txt. We test the accuracy of the model by comparing the model diacritized sequences, in the file diacritized_output.txt, with the correctly-diacritized target sequences, stored in a file named target_output.txt, in measures of DER and WER rates. Fig. 4 shows the steps performed in the testing phase of the performed experiments.

B. Training Datasets

The Tashkeela dataset [35] consists of 75 million diacritized words. In its main part, it is collected from 97 books filtered from 7079 books of Shamela library which is an Islamic electronic library. These books are example of CA text. Only 1.15% of the Tashkeela dataset consists of MSA texts which is drawn from modern books and crawled from the Internet. This makes Tashkeela mainly an example of CA. In [4], Fadel *et al.* extracted a subset of 55,000 sequences from the Tashkeela dataset with diacritization to character rate of at least 80%. The subset was cleaned by removing English letters and extra whitespaces, fixing some diacritization issues, and separating numbers from words, among other techniques. The subset was divided into 50,000 sequences for training, 2,500 sequences for validation, and 2,500 sequences for testing. This subset was used in our previous work in [25] to train and test the developed model.

In this work, we use the cleaning and filtering scripts developed by Fadel *et al.* [4] to extract the larger datasets used in our experiments. In addition, we wrap sequences such that they have maximum lengths of 400 characters. This step is performed to reduce the training time and memory usage and is based on experiments we conducted in our previous work [25]. One of the main goals of this work is to study the effect of incrementing the training data size on the diacritization accuracy. We use the 50k training sequences of Fadel et al. as a base dataset from which smaller training sets are derived and larger training sets are formed by adding more sequences to it. Three smaller subsets are derived by randomly selecting 6,250, 12,500, and 25,000 sequences from the basic dataset. Since the basic dataset is cleaned and filtered to meet the diacritization to character rate of 80%, except for wrapping to 400-character length, no further work was needed for these subsets.

In order to construct larger datasets, we randomly select sequences from the Tashkeela corpora to be added to enlarge our sets, starting with the 50K set. The sequences are selected to have at least 80% diacritics to characters rate. Then, they are processed using the cleaning scripts. To avoid duplication of sequences in our sets, the selected sequences are checked not to be already included in the set to be enlarged. Finally, we wrap sequences lengths to 400 characters. By repeating this process, we extracted datasets that consist of 100,000, 200,000, and 400,000 sequences. We also obtain the largest set used in our experiments which results from including all available sequences from Tashkeela that satisfy the above criterion, which is 543,364 sequences.

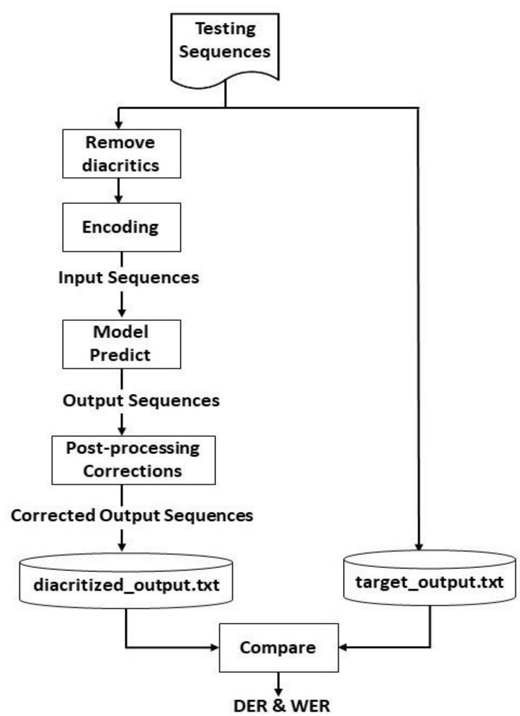

Fig. 4. Testing Phase of Experiments.

Except for the largest dataset, the sizes of the datasets are incremented by doubling the number of sequences from one set to the next. Moreover, the incremental process by which a new set is formed by adding sequences to the current set maintains the inclusion property, such that each dataset is a subset of the next. Table V shows size statistics of the used datasets in terms of word count, letters per word, words per sequence, and the number of sequences after the dataset is wrapped. All used subsets have close letters per word and words per sequence rates. For all experiments, we use the same validation set of 2,500 sequences, and testing set of 2,500 sequences to test the DER and WER of the trained model in each experiment.

TABLE V. SIZE STATISTICS OF THE EXTRACTED DATASETS

Dataset Size (# of sequences)	Word Count	Letters per Word	Words per Sequence	# of Sequences after Wrapping
6,250	259,847	3.98	41.5	7,675
12,500	522,502	3.97	41.7	15,334
25,000	1,059,573	3.97	42.4	30,847
50,000	2,103,071	3.97	42.1	61,453
100,000	4,180,191	3.97	41.8	122,817
200,000	8,410,559	3.97	42.1	245,994
400,000	16,854,689	3.97	42.1	492,288
543,364	22,729,365	3.97	41.8	667,990

C. Data Encoding

Sequences used in our experiments are either undiacritized consisting of letters only, or diacritized consisting of both letters and their diacritics. Undiacritized sequences are encoded using the Unicode representations of their letters. For diacritized sequences, we experimented using different encoding schemes in our previous work [25]. A one-to-one encoding scheme which represents each diacritic produced the best results in all performed experiments. Hence, we use this encoding scheme in this work. This scheme benefits from the fact that letters must not change between the input and the output sequences. Only diacritics must be added. Hence, it limits the classes at the output to the number of possible diacritics codes which is 16. Table VI shows the binary codes used for the eight Arabic diacritics. In Arabic, a letter may have two diacritics if one of them is *Shadda*. In this case, the diacritic code is formed by ORing the *Shadda* code (1000) with the other diacritic code. Fig. 5 shows an example of encoding the diacritized word صَيَّادٌ (hunter) which includes letters with no, one, and two diacritics.

D. Base Model

For building our models, we use Keras (Python deep learning library) with TensorFlow at the backend [36]. Our baseline model is an BiLSTM that consists of an embedding layer of 32 dimensions, four bidirectional LSTM layers each consisting of 256 cells, followed by a 16-cell fully-connected output layer. The Softmax function is used for activating the diacritic class with the highest probability at the output layer. Adam optimizer is used in training, and the sparse categorical cross entropy is used as the loss function. The batch size is set to 128 sequences for all experiments. In addition, the maximum number of epochs used in training is 100 with early stopping such that training stops if the validation accuracy does not improve for five consecutive epochs. Fig. 6 shows the structure of our baseline model.

TABLE VI. BINARY BIT CODES USED TO ENCODE DIACRITICS IN OUR EXPERIMENTS

Diacritic	Bit Code
No diacritic	0000
Fathatan (◌ً)	0001
Dammatan (◌ٌ)	0010
Kasratan (◌ٍ)	0011
Fatha (◌َ)	0100
Damma (◌ُ)	0101
Kasra (◌ِ)	0110
Sukun (◌ْ)	0111
Shadda (◌ّ)	1000

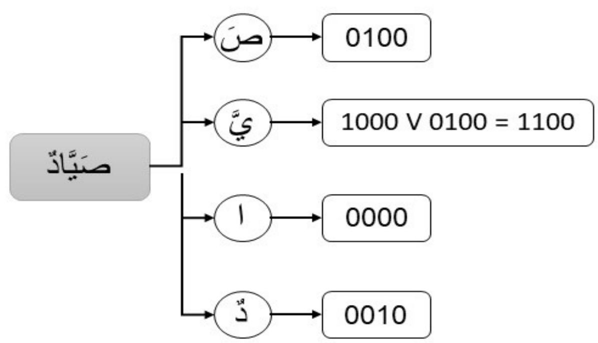

Fig. 5. Example Encoding the Diacritized Word صَيَّادٌ (Hunter).

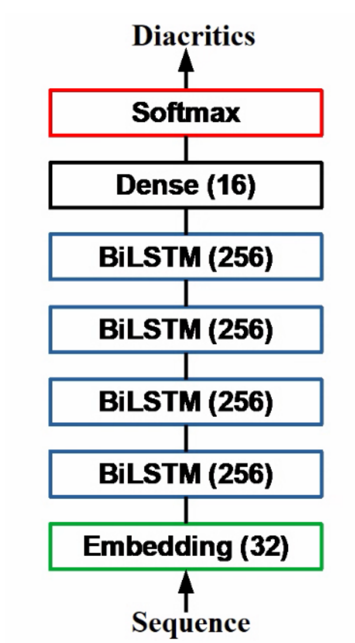

Fig. 6. The Structure of the base Model used in our Experiments.

V. Experiments and Results

The following subsections present the experiments performed and discuss their results. We also compare our best results with previous work.

A. Experiments

We experimented training our baseline model using the eight corpora we extracted from the Tashkeela dataset. We evaluated the trained model in each experiment in terms of time required to train the model and the model accuracy. We report the training time both in terms of the training total execution time and the average training time per epoch for each of the eight experiments. Table VII shows the total training time, average execution time per epoch, and number of executed epochs for each of the eight experiments. As expected, larger corpus size results in longer training time. However, the increase in the execution time is not directly proportional to the increase in number of sequences. This is dependent on the number of epochs which vary from one experiment to another based on when the early stop occurs. On the other hand, it can be observed that the increase in average time per epoch is proportional to the corpus size.

We report the performance of the models during training using the validation set in terms of validation loss and validation accuracy. Fig. 7 shows the validation accuracy and Fig. 8 shows the validation loss as functions of the training epochs for each experiment. In all reported results, we refer to each experiment by the number of sequences of its training dataset (i.e., 6,250, 12,500, 25,000, …). Training using larger number of sequences generally results in slower learning, higher values of accuracy and lower loss values. The best validation accuracy and validation loss achieved are 0.988 and 0.016, respectively, using the largest dataset of 543,364 sequences.

We tested the diacritization accuracy of the trained models using the eight extracted corpora. For all testing experiments, we use the test set of 2,500 sequences defined by Fadel *et al.* [4]. Fig. 9 shows diacritization error rates and word error rates for the eight models. The results show that both DER and WER improves as the number of sequences used in training increases. The best improvement, which is 22%, is observed when the training set increases from 6,250 sequences to 12,500. The improvement decreases gradually as we move towards larger datasets. No improvement is observed in the error rates when increasing the training set from 400,000 to 543,364 sequences. The best DER and WER achieved are 1.45% and 3.89%, respectively.

TABLE VII. Total Training Time, Average Execution Time Per Epoch, and Number of Executed Epochs for the Eight Experiments

Dataset Size (# of sequences)	Total Training Time (hours)	Epoch Average Training Time (hours)	# of Epochs
6,250	5.1	0.05	100
12,500	9.2	0.09	88
25,000	10.6	0.18	58
50,000	21.4	0.36	60
100,000	32.1	0.63	51
200,000	56.3	1.22	46
400,000	191.0	2.27	85
543,364	336.0	3.43	98

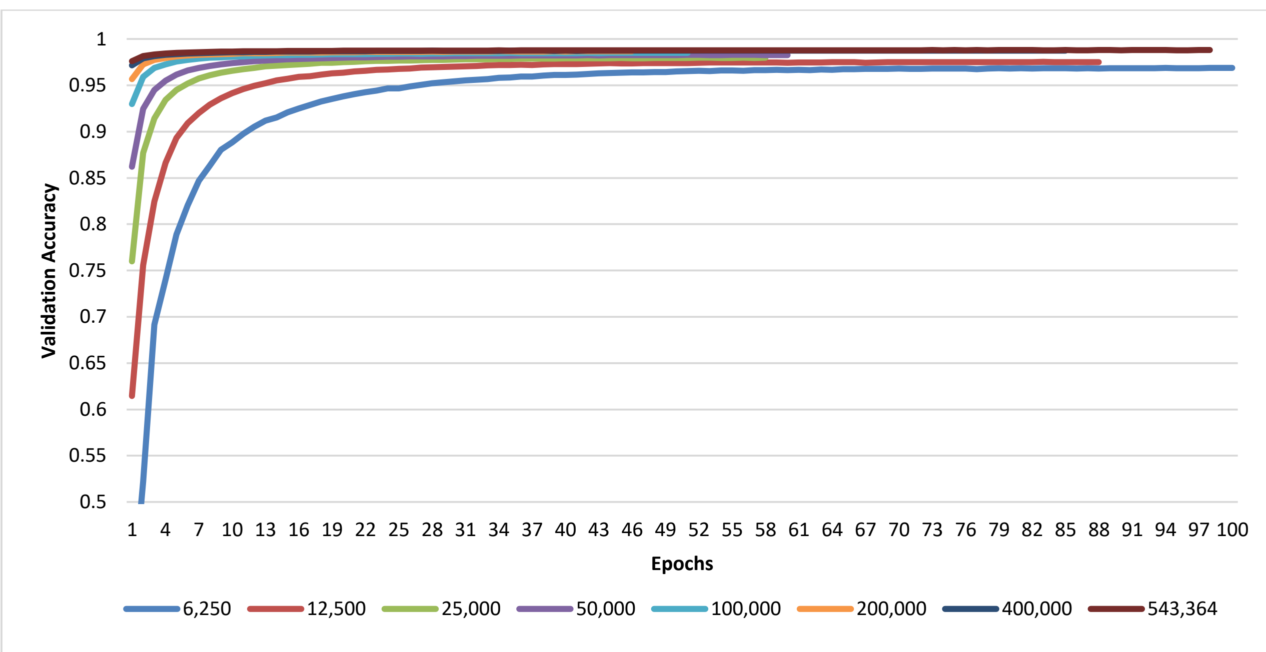

Fig. 7. Validation Accuracy Recorded during Training the Model using Datasets with different Number of Sequences.

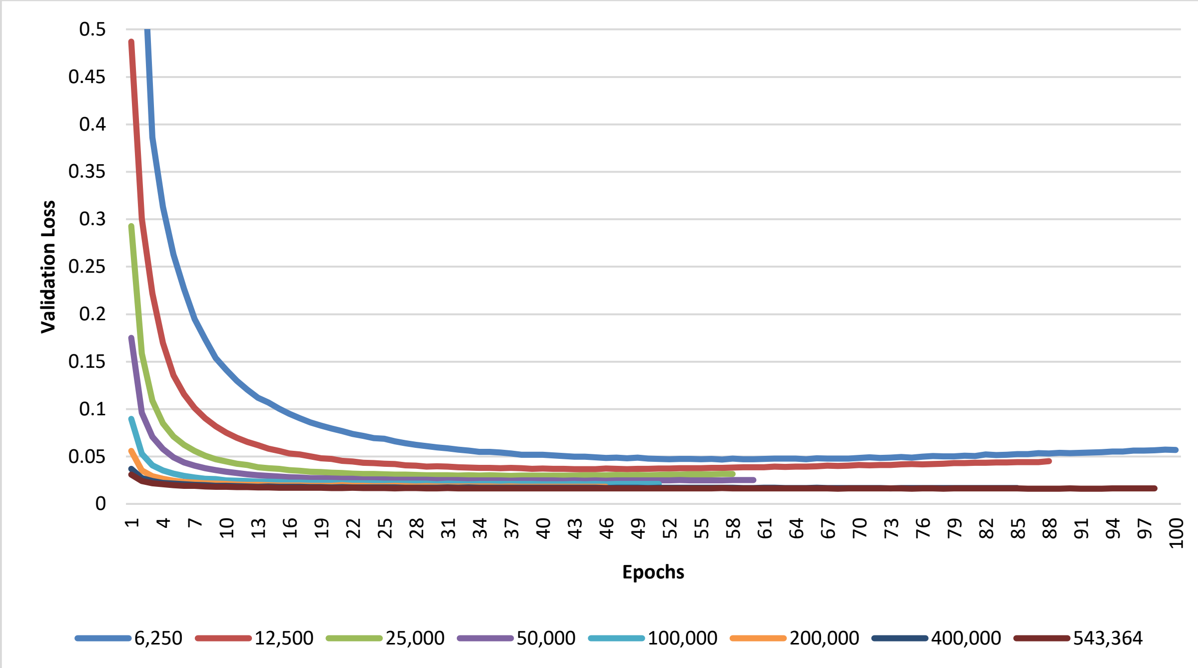

Fig. 8. Validation Loss Recorded during Training the Model using Datasets with different Number of Sequences.

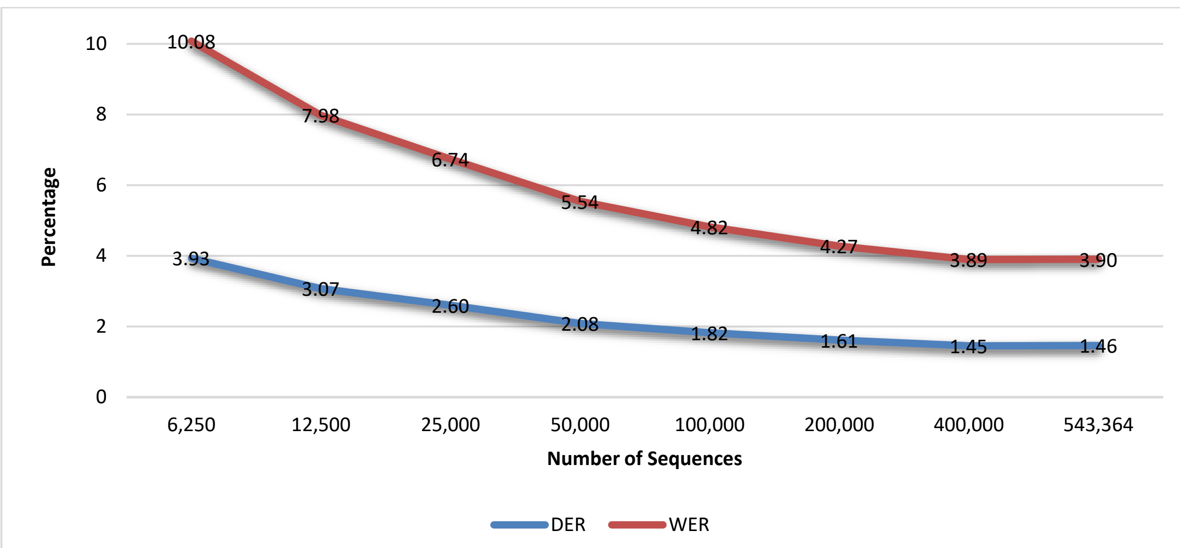

Fig. 9. DER and WER Values for Models Trained with different Number of Sequences.

We analyze errors of our system by enumerating the errors according to the number of errors per word and presence of end-case diacritization errors. The results of this analysis are shown in Fig. 10 and 11. Fig. 10 shows that for all dataset sizes, most of the miss-diacritized words have one diacritic error. Words with three or more diacritic errors are not frequent contributing to less than 6% of the errors in all experiments. Moreover, the ratio of multiple errors per one word decreases with larger datasets. Fig. 11 shows the end-case diacritization errors contribution in the DER and WER ratios. As explained earlier, end-case diacritization depends on the context and is subject to complex inflection rules. In our results, end-case diacritization errors contribute to about half of the word errors in all experiments. The best DER and WER values when ignoring end-case diacritization errors are 0.91 and 1.95, respectively.

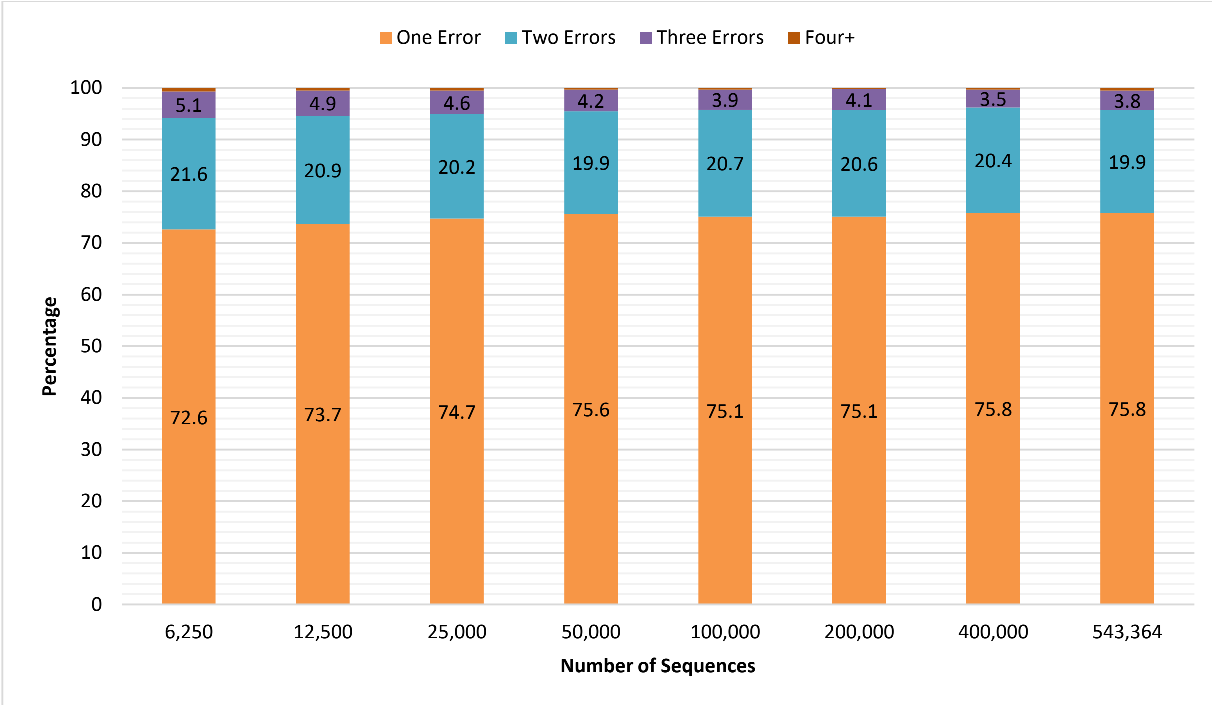

Fig. 10. Number of Errors per Word for each Experiment as a Percentage of the Total Number of Errors.

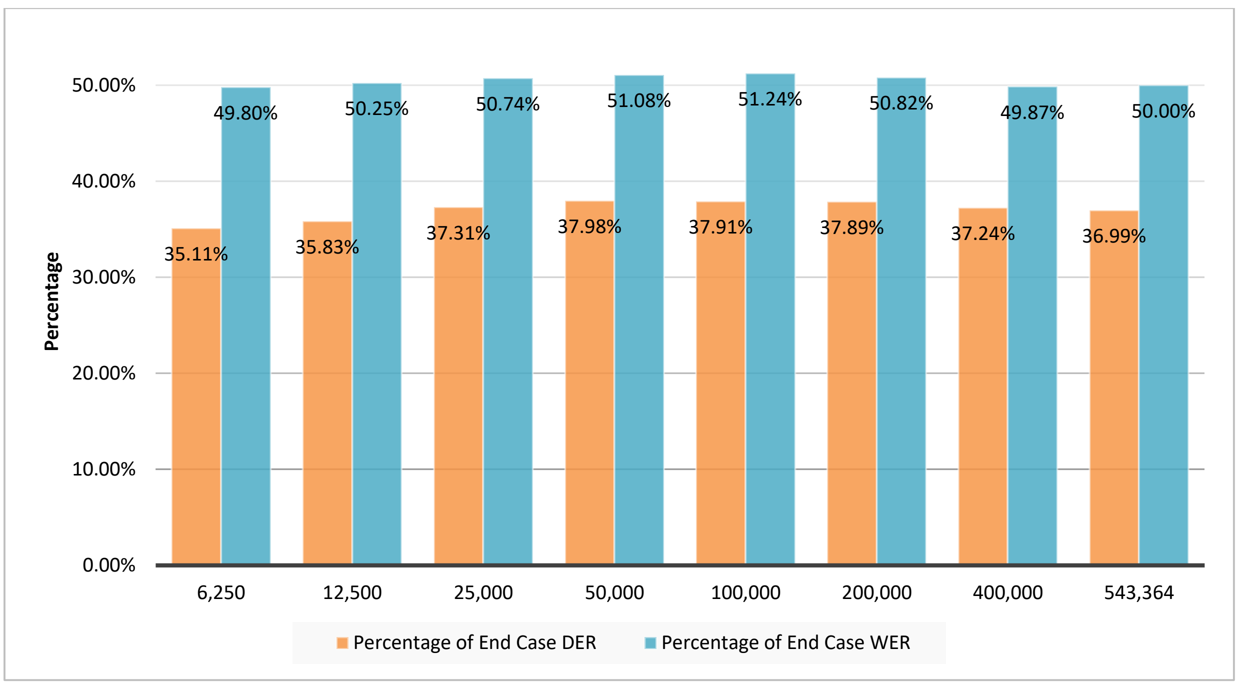

Fig. 11. Contribution of the End-case Diacritization Errors in the DER and WER Ratios.

B. *Comparison with Previous Work*

Our best results are reported here are for the model trained using 400,000 sequences. Table VIII summarizes the comparison of the best results in this work and best published systems. For each system, the table shows its publication year, the database used in evaluating it, and its DER and WER values both when including all diacritics errors (i.e., with case ending) and when ignoring last-letter diacritization errors (i.e., without case ending). The last column shows DER resulting from last letter diacritization errors only.

TABLE VIII. COMPARISON OF OUR BEST DER AND WER RESULTS WITH PREVIOUS WORK

System	***Dataset***	***All Diacritics***		***Ignore Last***		***DER Last***
		DER	***WER***	***DER***	***WER***	
Zitouni *et al.* (2006) [15]	ATB3	5.5	18	2.5	7.9	3.0
Habash&Rambow (2007) [3]	ATB3	4.8	14.9	2.2	5.5	2.6
Rashwan *et al.* (2011) [17]	ATB3	3.8	12.5	1.2	3.1	2.6
Said *et al.* (2013) [18]	ATB3	3.6	11.4	1.6	4.4	2.0
Fadel *et al*. (2019) [23]	Tashkeela	2.18	4.44	1.76	2.66	0.42
Abandah *et al.* (2020) [25]	ATB3	2.46	8.12	1.24	3.81	1.22
	Tashkeela	1.97	5.13	1.22	3.13	0.75
Madhfar and Qamar (2021) [26]	Tashkeela	1.13	4.43	0.84	2.47	0.29
This work	**Tashkeela**	**1.45**	**3.89**	**0.91**	**1.95**	**0.54**

Most previous work used either LDC's Arabic Treebank Part 3 (ATB3) [26], which represent an example of MSA, or Tashkeela, which represents an example of CA, or both. To the best of our knowledge, our previous work in [25] achieves the best published results for ATB3. The size of the ATB3 dataset is limited to 22,170 training sequences, which makes it unsuitable for the experiments we perform in this work. We do not include the results of Darwish et al. [14] since they use different training and testing datasets in both their MSA and CA experiments and hence comparison would not be fair. They used the training dataset of the RDI diacritizer in [18] and a test set of WikiNews for their MSA experiments. For their CA experiments, they used data from an undefined publisher.

The best DER and WER achieved in this work are 1.45% and 3.89%, respectively. This improves over our previous work which used a subset of the Tashkeela dataset and reported a DER of 1.97% and a WER of 5.13%. We compare our results with the best results of Fadel *et al.* [23] and Madhfar and Qamar [26] since both works use the Tashkeela dataset for training and testing. We outperform the model developed by Fadel *et al.* in DER and WER both with and without case ending. However, they achieve better last letter diacritization error rate.

Among the models they experimented, Madhfar and Qamar report the best DER and WER values for their CBHG model. In our comparison, the CBHG model of Madhfar and Qamar achieves the best DER in all cases. However, our best-performing model word error rates outperform those of the CBHG model indicating that our model results in less percentage of wrongly diacritized words. Noting that they perform their own cleaning and filtering process, but with different rules, to extract datasets used in training their models. It's worth mentioning that our best-performing model outperforms the baseline model of Madhfar and Qamar, which is a deep BiLSTM RNN. DER and WER values reported for their baseline model are 2.24% and 8.74%, respectively.

It can be observed that our base model achieves results that are comparative to more complex models such as the CBHG model proposed by Madhfar and Qamar. This shows that training using a large clean dataset with high diacritization to letter rate provides competitive diacritization accuracy. Training more-sophisticated models using such a dataset would certainly provide even better results. Although this work involves experimentations using a basic BiLSTM RNN, it generates cleaned corpora with incremental sizes that can be used to experiment with several other models. Moreover, it shows that state-of-the-art error rates could be achieved when training using large clean corpora.

VI. CONCLUSION

Automating diacritization of Arabic texts is a crucial operation for many Arabic NLP applications. In this paper, we have conducted several experiments to study the effect of changing the training data size on performance. Our work included generating several cleaned subsets of the Tashkeela corpora with incremental size in terms of number of sequences. Our largest subset, which consists of 543,364 sequences, can be used for training other models and comparing them, such as the model used by Madhfar and Qamar [26]. Our baseline model is a deep LSTM bidirectional RNN. We evaluated the performance of our baseline model during training using each of the generated corpora by monitoring the validation loss and accuracy using the validation set. We tested the diacritization accuracy of the model after being trained using each corpus by finding its DER and WER values when diacritizing the 2,500-sequence testing set.

Our experiments indicate that performance of the trained model improves as training set size increases. However, improvement in DER and WER values decreases as the number of sequences increases. Best achieved DER and WER values are 1.45% and 3.89%, respectively, using a training dataset size of 400,000 sequences (about 17 million words). Our WER value is the best when compared with other state-of-the-art results. In order to further improve the performance, we aim to experiment with other proposed models and to develop a loss function that considers unharmful differences between the output and target sequences when training is performed.

Unsupervised Clustering of Comments Written in Albanian Language

Mërgim H. HOTI, Jaumin AJDARI
Faculty of Computer Science, South East European University (SEEU)
Tetovo, Republic of North Macedonia

***Abstract*—Now-a-days, social media and communications in social media have become very important for services providers and those play a key role in service quality improvement as well as in decision making. The services consumers' discussions usually are written in their local languages and extracting important knowledge sometimes is very hard and problematic. In this field the natural language processing techniques are helpful, but different languages have their specifics and difficulties, and some languages are not prosperous enough in the techniques and methods on NLP, especially the local speaking of the language. In this scientific paper, we have tried to solve such a problem for the Albanian language spoken in Kosovo. Namely, for a dataset of the comments, written in Albanian language in Kosovo (local speaking), collected from the social media, by use of unsupervised clustering techniques, to make clustering regarding the topic of discussion in the comment. In this research, the different techniques of text feature extraction (vectorization and others) and clustering algorithms (K-means, Spectral, Agglomerative, etc.), are used with the idea to find and define more appropriate techniques for the Albanian language. In this paper are shown the results of the conducted experiments as well as discussions about what to use in case of the Albanian language and other languages similar or in group with Albanian (those which have a weak NLP).**

Keywords*—Unsupervised clustering; k-means; spectral; agglomerative; vectorization; Albanian language

I. Introduction

Data flow nowadays is produced in various industries and fields using technology and this is a challenge in itself which requires management in concrete form. Except for electronic sources such as websites and communication forms by using other mediums. So, social networks are one of the main factors that continue to allow all users to produce different information. At the same time, trends show that different companies tend to use these comments/ sentiment by creating a profile for each user in order to suggest their products according to users' activity. This process, as a whole, requires data management which we otherwise call big data. So, most of the social networks that exist and are used in the world have taken the role of big data producer [1] [2] [3].

This paper mainly examines the use of unsupervised clustering algorithms on social media comments written in Albanian language. Furthermore, this paper demonstrates the text analysis process in reviewing the public opinion of services of Vala Telecommunication Company towards a certain brand and presents hidden knowledge (e.g. services, quality and challenges during operation of their services) that can be used for decision making after the text analysis is performed. Through this paper, we will be focused on implementation of several unsupervised clustering algorithms which they have a wide range field implementation even in different field such as [4], [5], [6], where the main purpose is to identify and create clusters by classifying collected data and distinguishing them as content from extracting and presenting concrete results from processed data through different algorithms. According to Smita Agrawal et al. [2], clustering analysis try to identify the groups of objects such that it forms the groups of similar or related objects groups and in difference forms they are not related to the objects in other groups. Also, Alrence Santiago Halibas et al. [7], shows classification by using similarity by using techniques on English language, the same such in our case we used on Albanian language and as content have classification and clustering of extracted data from social network Twitter. Also, they have used preprocessing techniques preparing data in order to display the visualization of the dataset used.

This paper is organized as follows: Section II is a short literature review regarding the topic, then section III the research methodology used. Implementation of several unsupervised clustering algorithms is shown in Section IV. And, finally, the conclusions and findings in Section V.

II. Literature Review

In this section, we briefly introduce the related technologies involved in our algorithms, including preprocessing phases and visualization of gained results, which are widely used by unsupervised clustering. Our proposed implementation form of clustering of sentiment written on Albanian language is based on the improvement of these three algorithms, which will be described in detail in Section IV.

So, extracting semantic relations has been successfully applied and shown in this part. As found in, Alrence Santiago Halibas et al. [7], use K-Means algorithms where it determines the set of *k* clusters and assigns each example to a specific cluster. This is applied by using sentiment of business analytics on Twitter social network. It has been extracted from the dataset by using preprocessing procedures and visualizing the results of the dataset.

Another researcher, Juan Antonio Lossio-Ventura et al. [8], have used the same social network where they used health-related models and document clustering applications on a Twitter composed of two subsets: HPV and Lynch syndrome

Tweets. Also, it uses Calinski-Harabasz index and Silhouette Coefficient to evaluate the accuracy and performance of implemented algorithms.

Liqiao Zhang et al. [9], propose a methodology of analyzing social media by using consumers' opinions. It uses different social media such as (Facebook, Twitter, Sina Weibo, etc.). Also, it includes three different collective classification algorithms (Local classifier-based method, Logistic regression classifier, Naive Bayes classifier) in the experiment and in the last part of their research shows a visualization method of results, they have reached. According to their conclusions, in the experimental part, the Gibbs sampling method with logistic regression classifier as local classifier performs the best among all the CC (collective classifier) algorithms.

Kai Wang et al. [10], proposes an e-commerce product personalized recommendation system based on learning clustering representation. Also, it uses a methodology of users' for a period time such as income, and occupations, interest. To achieve results for their dataset's [six of them with different of content (shopping, entertainment, sport, film, music and business)], it's used several unsupervised algorithms including Gaussian Mixture Model [11], K-means clustering [12], Density-Based Spatial Clustering of Applications with Noise (DBSCAN) [13], K nearest neighbors (KNN) [14], hierarchical clustering (HC) [15], multi-assignment clustering (MAC). But as a part of their research it noted that the KNN method has its limitations in selecting an adjacent object set. So, they used the neighbor factor and time function and leveraged the dynamic selection model to select the adjacent object set. Also, they combine RNN as well as an attention mechanism to design the e-commerce product results and the performance of proposed algorithms, where it shows better results in six types of dataset.

Kristina P. Sinaga and Miin-Shen Yang [16], propose a new schema with a learning framework for the k-means clustering algorithm in that way where it automatically finds an optimal number of clusters without giving any initialization and parameter selection. Some of the points that have been experimented are feature characteristics, number c of clusters, number n of instances and number f of features in 8 different datasets.

Eric K. Tokuda et al. [17] focuses in applying of agglomerative clustering using unimodal and bimodal datasets where it presents the difference of dendrogram visualization and identifying the clusters in dendrogram, The implementation idea of the proposed approach presents the cluster size s and a number of clusters *k*, the dendrogram is first obtained and then analyzed in a bottom-up approach. Clusters are merged until *k* clusters having at least *s* elements are identified for the first time. Since the last cluster merge might generate a cluster having size much larger than *s*, it is checked if the last merge should be undone.

So, we can clearly see that the chosen algorithms in this paper treat mainly language processing cases, so in our case Albanian language is very specific. Also, these algorithms are shown very successfully in several cases and we are convinced that the results obtained represent the concrete situation in this regard.

III. Research Methodology

In this section, we introduce the state-of-the-art of unsupervised clustering algorithms and sentiment analysis taken from social networks, written on Albanian language. The main focus of the algorithms used is K-Means, Spectral and Agglomerative clustering algorithms.

In our paper we will show three algorithms which we have implemented by using sentiment on social networks written on Albanian language. Problems and challenges of text preparation as in any language, also in Albanian language it has its specifics taking into account the fact of writing not only in one standard or dialect. This further complicates the preparation process or preprocessing stages as it is a very important process in this part.

A. Pre-processing of Dataset

The data that we will use in the acquired dataset are taken from social networks, where to do this we used web scraper, which are taken only the comments/ content of various posts. As a case study we take comments made on the official fan page of VALA Telecommunication[1].

Dataset contains a considerable number of comments which include the various services that the company offers including the latest offers, prices, rewards and services that they offer in the framework of their operation. The dataset is UTF-8-"latin1" encoded, since the Albanian alphabet contains some non-ASCII symbols, like ë, ç, Ç, etc. The next step is to normalize the comments, i.e. to change the comments from upper case to lower case. This step can be skipped to evaluate the influence of the normalization. To split the comments into its words and punctuation marks two different tokenizers are used: The Word2Vect and TF-IDF, which treats a simple emoticon as a single word. The next step in the process is to remove Stopwords. We adopted a list of Albanian Stopwords Ardit Dina [18], where we add more keywords to do more valuable for the implementation on Albanian, also, we comparison with others language such as in Andrej Gajduk and Ljupco Kocarev [19], Henríquez C, Guzmán J [20]. We used Stopwords because we think that it can potentially help in improving performance, and the classification accuracy improved. Now the tokens are converted into *n*-grams. To get the best results, we created a list of words which we have used as stemming of repeated words such as "Interneti", "Internetin", "Internetit", and we have extracted just in one word "Internet", this it helped increasing accuracy of algorithms and optimizing it by easy identifying assigned terms.

B. Feature Extraction

In daily life, implementing machine learning techniques on a large dataset is normal and very important to present the accuracy and originality of results. Every day and more of using social networks and associated types of communication media it produces new amounts of data. This it expresses the

[1] Public company in Republic of Kosovo (https://www.facebook.com/valamobile)

need of managing and implementing new feature extraction by adopting adequate language, whether local language or more spoken language. In fact, techniques of using feature extraction represent a part of the dimensionality reduction process, in which an initial set of the raw data is divided and reduced to more manageable groups. So, this helps the process of managing and seeing if the data are correctly divided according to language perspectives, which it makes it easier. The most important valuable element of using feature extraction on large datasets is that they have a large number of variables. And, the number of variables requires a lot of computing resources to process them. So, feature extraction also helps to get the best feature from those big datasets by selecting and combining variables into features, thus, effectively reducing the amount of data. In our case, after we implement two feature extractions where we have achieved very good results by using of TF-IDF and Word2Vect, where, this it proves that these techniques are suitable and produce original data from core dataset.

To implement TF-IDF we have used two forms of representation data, this we have seen as a process of preprocessing phase:

- Dense vectorization, and;
- Spare vectorization.

As a process, first we present the Dense Vect then the Spare Vect. The explanation of Spare Vect. is that it creates (N x N) matrix, which represents $N_{\text{(horizontal line)}}$ (terms number achieved) **x** $N_{\text{(vertical line)}}$ (number of comments/ rows), then it can be extracted in Dense Vect.

Spare Vectorization form it represents results in this way:

00 0800 080010000 10 10 dite ... zoti çdo çmim është është kosovës…
0 0.0 0.0 0.0 0.0 0.0 ... 0.0 0.0 0.0 0.0 0.0
1 0.0 0.0 0.0 0.0 0.0 ... 0.0 0.0 0.0 0.0 0.0

The list is bigger but in this case we didn't present.

Dense Vectorization form it represents results in this way:

(0, 960)	*0.4576438590753533*
(0, 490)	*0.4758177241051434*
(1, 725)	*0.7071067811865475*
(1, 527)	*0.7071067811865475*
(2, 1096)	*0.32606112714163765*
(2, 877)	*0.30343163250680155*

First column (0, 1, 2 …) shows row/ comments number, second column shows the position of the terms inside of the dataset and the last column shows weight of terms which is identified according to row and column sorting.

Regarding the implementation technique of word2vect we have used two sub-techniques such as:

- Continuous Bag of Words (CBoW), and;
- Skip-grams.

CBoW and Skip-grams have extracted similarities between terms which are used in all datasets.

C. Similarities between Terms in Dataset

CBoW:

[('punso', 0.2354489415884018), ('bane', 0.2187425047159195), ('teknikes', 0.20852388441562653), ('korruptuar', 0.20763424038887024), ('perndryshe', 0.19758988916873932), ('met', 0.19453111290931702), ('besimin', 0.19172176718711853), ('virusi', 0.18643076717853546), ('çdo', 0.18365386128425598), ('master', 0.16957449913024902)]

Skip-Gram:

[('ni', 0.38147056102752686), ('tv', 0.3492451012134552), ('keni', 0.3451632261276245), ('për', 0.34493157267570496), ('sms', 0.34084585309028625), ('vales', 0.3397885262966156), ('150', 0.3364603519439697), ('kerka', 0.3312993347644806), ('euro', 0.3179359436035156), ('ofert', 0.3156954348087311)]

While, in this part we have presented the similarities between two same terms and we present the accuracy of these sub-techniques of Word2Vect.

Table I shows the comparison of these two sub-techniques where it has generated better results for Skip-Grams than CBoW, because of accuracy that Skip-Grams has managed to extract is 0.26 while CBoW 0.05.

TABLE I. SUB-TECHNIQUES OF WORD2VECT.

Sub-Techniques of Word2Vect	
CBoW	**Skip-Grams**

IV. EXPERIMENTAL RESULTS AND ANALYSIS

As we have stated, the focus of this study is to generate and compare the performance of applications using unsupervised clustering algorithms for the sentiment taken from social networks written on Albanian language, where we have specified three of them.

The experiment was developed using the following hardware specifications: Processor: Intel(R) Core(TM) i5, 2.50GHz, RAM 8 GB, System Type: 64-bit Operating System. To see gained results from the extraction data and preprocessing phase, we have used four different criteria of filtering and producing. This, we did to have better results and to see if the data will be presented properly and correctly. This helped the visualization for each implemented algorithm.

The criteria of filtering and production data are:

- With Stopwords & N-Grams;
- With Stopwords & without using N-Grams;
- Without using Stopwords & with N-Grams;
- Without using Stopwords & N-Grams;

In every case, we have achieved a different number of terms, this because when we used N-Grams it divides in more terms such as, "Mbushje", "Mbushja", "Mbushjen" and it make implementation much more complex as a whole.

Achieved results will be presented according to algorithms, which are implemented the techniques explained.

A. K-Means

K-means clustering is a classical clustering method based on data partitioning according to *Hao Yu et al.* [21]. The main idea is to gather the original data into *k* clusters, so that samples with similar attributes are in the same cluster. The main processing procedure is as follows: Firstly, *k* samples are randomly selected from the original data, each sample is taken as the center of *k* clusters, and then the distance between the remaining samples and the *k* center samples is separately calculated, each sample is divided into its nearest center. In total, we achieved three clusters such as Cluster 0, Cluster 1 and Cluster 2. Most of the sentiment is clustered in cluster 0 because it has similar terms between them, than in cluster 2 and the last one is shown in cluster 1. These results are shown in Fig. 1; we have presented a visualization and seen how they stand on this form.

In this way, we have analyzed and shown the mini-framework of K-Means, how it works by using sentiment on Albanian language. The results achieved are satisfactory because of putting centroids in three clusters and every comment which is related to its centroids. The visualization is shown in Fig. 2 where we can clearly see it in three different colors. With yellow representing cluster 1, green is for cluster 2 and the most classified comments from K-Means are clustered in cluster 0 which are in purple.

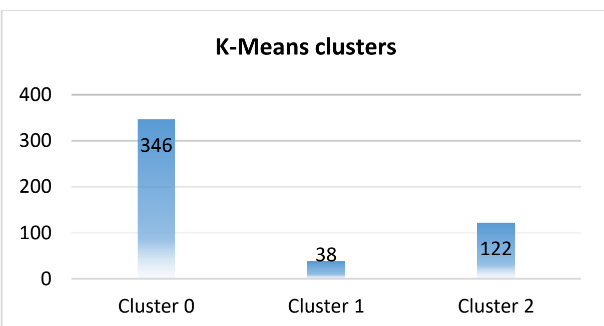

Fig. 1. K-Means Clusters.

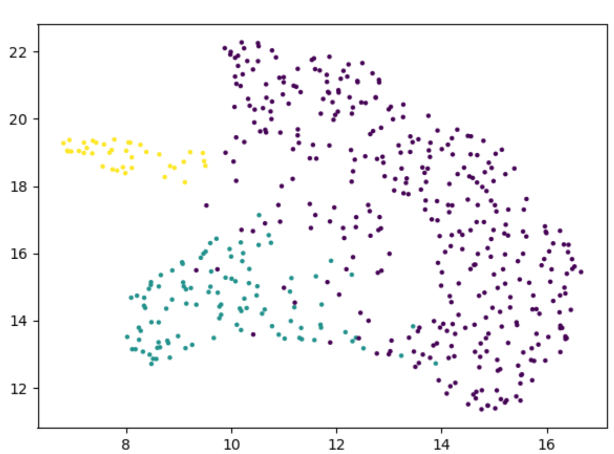

Fig. 2. K-Means Cluster Results.

Our proposed application form of the algorithm is optimized and it is faster than several proposed algorithms in other different researches and examples such as [16], [22] and [23] which are implemented in different cases and datasets. So, the execution time of our proposed form of implementation on Albanian language is 1.662015799999999 seconds. To see and prove, if our visualization is correct and our results correspond with the real statement of implementation we used the silhouette coefficient, to see what kind of results will produce. As we know, silhouette coefficients study and present the separation of distance between the resulting clusters. Also, it computes for each point a width depending on its membership in any cluster. This silhouette width is then an average over all observations according to [8].

This is based on:

$$SC_k = \frac{1}{n} \times \sum_{i}^{n} \frac{b_{i-}a_i}{\max(a_{i,}b_i)}$$

Where, n represents the total number of elements in a cluster, a_i is the average distance between an element i of the cluster and all other elements within the same cluster, b_i represents the average distance between the element i of the cluster and all other elements in the nearest cluster.

Also, we have used silhouette to predict what is the best form of visualization with our dataset. And the results are shown in Fig. 3.

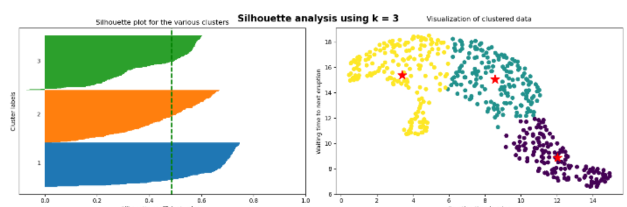

Fig. 3. Silhouette Prediction using Dataset.

While, accuracy is identified with two, three and four clusters presented in percentage in Table II:

TABLE II. SILHOUETTE SCORE WITH DIFFERENT NUMBER OF CLUSTERS

Silhouette clusters accuracy	
Number of clusters: 2	0.7108542990876117
Number of clusters: 3	0.6360185043007658
Number of clusters: 4	0.5455599807949814

B. Spectral Clustering

Spectral Clustering is one of the best known unsupervised algorithms, where, it has performed better than many traditional clustering algorithms in many cases, where we mentioned in related work.

Spectral uses the connectivity approach of clustering, wherein, the parts of nodes (i.e. terms it uses) immediately are next to each other, identified in graphs. The term or connectivity form is then mapped to a low-dimensional space that can be easily segregated to form clusters. Spectral algorithms use data from the eigenvalues of the matrices it created by it i.e. Affinity Matrix, Degree Matrix and Laplacian Matrix derived from the graph or the data we use for our experiment. In our case, we have used the best known techniques for spectral algorithms and the number of clusters' in total are three of them. The most common comments classification is cluster 0 where it has achieved 330 from the total of the dataset, then cluster 1 classified 131 comments and the last one cluster 2 classified 45 comments. These results are shown in Fig. 4, graph model of classification comments for each cluster's.

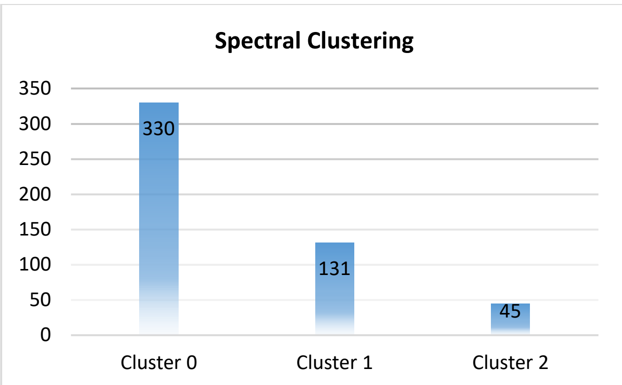

Fig. 4. Spectral Clusters.

Also, spectral clustering visualizes three different colors, which represent each cluster in Fig. 5. For cluster 0 it is purple, green cluster 1 and cluster 2 it's in yellow color. The accuracy of related comment classification with colors are separated very well because the possibility of error is very small, whereas, it seems only three comments which are not classified as it should be but they are missing. Also, we think that as many comments there are in the dataset, the accuracy will be higher. This is because the algorithm can train itself and identify key terms how to separate for each cluster.

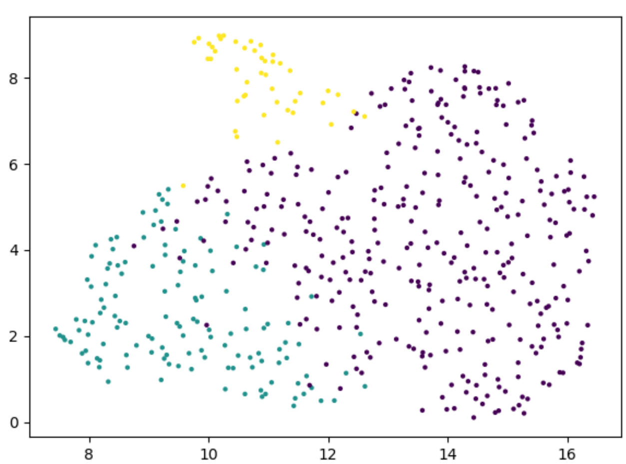

Fig. 5. Spectral Clusters.

C. Agglomerative Clustering

The agglomerative algorithm is part of family algorithms which execute hierarchical clustering. The form of implementation is by grouping objects in clusters based on their terms which are generated by passing preprocessing phases. The main element which increases the accuracy of AC is feature extraction, specifically spare and dense vectorization. The focus of the algorithm is by treating each object as a singleton cluster. In our case, each comment is identified according to the content which is placed in a group of clusters and as seen in Fig. 6, they take on a certain color as a separate cluster. Then, the algorithm continues to compare with other groups of clusters, which, according to the similarities they have managed to make another special group which takes on another special color until the classification of a group in the form of hierarchical clustering as it is presented in Fig. 6. This form of implementation helps algorithms to increase accuracy and present visualization in the best form. So, the results are generated and the algorithm was successful by dividing comments in precisely form for the cluster it should be. The process of clustering is known as hierarchical/ dendrogram model of clustering.

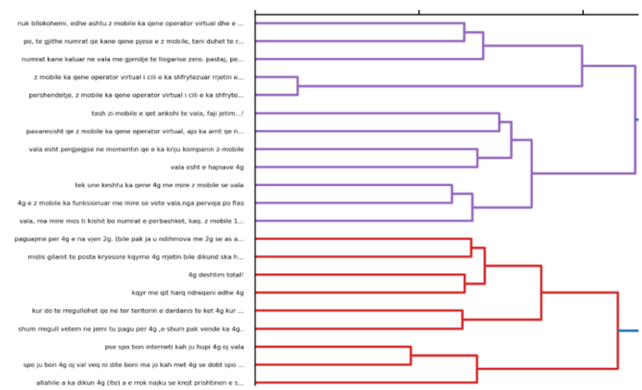

Fig. 6. Agglomerative Clusters.

The list of results it's bigger than it's presented but this is just to understand the idea and results achieved of implementation in our experiment.

V. Conclusion

In this paper, we have applied and tested which of the three selected algorithms is most suitable for the Albanian language. Results obtained are extracted by using the same dataset for three algorithms but the results are different between algorithms. The optimization of each of the algorithms has shown growth and efficiency, as we have presented in this paper the accuracy of the execution of K-Means algorithm dividing into two clusters is 0.71%, three clusters is 0.63% and four clusters is 0.54%. While other algorithms such as Spectral and Agglomerative have shown better results on identification and comparison through terms which create main centroids than groups of their clusters. The best example in our experiments is Agglomerative because the idea of implementation is hierarchical grouping data. So, this is the reason why we have taken only three clusters to see achieved results where this helps to take the average of identifying comments in better form. Finally, we consider that this work is just the first step to improve the accuracy of *k*-means, spectral and agglomerative clustering of dataset/ corpus written in Albanian language. The machine learning models, such as K-Means, Spectral and Agglomerative were used in several different languages but it's the first time on

Albanian according to the best of our knowledge. But, that the techniques and results obtained in this paper help to identify and facilitate the form of use in other content. So, we mention sentiment analysis of consumer in different businesses such as restaurants, hotel, public services, sports and patient impression about the services they receive which they express in several social networks which are written especially on Albanian language. Also, the limitations of this paper are mainly limited academic literature and professional real implementation of surrounding text analytics of social network data. Also the limitations of the work was the lack of research and the form of implementation of the algorithms mentioned for the Albanian language, has shortcomings and needs to be worked on even more in this regard. Future work in this field can also be focused on real-time analytics of social network data streams and improving accuracy and trying to give solutions on distinguishing the dialect of the Albanian language. Also, theoretical analysis and experiments on a benchmark dataset have presented the superiority of our proposed method.

***Abstract*—The timing of traffic lights at intersections is determined by the Local Authority. It is based on the peak hour statistics and the timing is maintained even during an off-peak hour. This one standard green time will be used every time in a day regardless of the number of vehicles and the road width. This approach will have a long green traffic light even though the number of vehicles is only a few and hence, will cause a long waiting time at the intersections. Therefore, the aim of this study is to vary the timing of traffic lights at junctions according to the number of vehicles. This paper will also consider road width variable which have not been considered so far. Fuzzy logic rules will be used to classify the number of vehicles and road width and time taken for vehicles to move at the intersections which was proposed in a previous work. The new timing will commensurate with the number of vehicles and road width. Field test data were gathered from Sala Benda and Semplak intersections which are amongst the busiest intersections in Bogor, Indonesia. Comparisons were made and show that the green light timing obtained is appropriate to the two factors considered. Also the waiting time for vehicles in each traffic cycle was also reduced. This study have formulated an optimal green lights timing in each intersection and will be used by local authorities to determine the timing of green traffic lights at the intersection and hence, can implement traffic control and an appropriate waiting time.**

Keywords—Traffic fuzzy classification; congestion; traffic lights control

I. Introduction

Monitoring and controlling city traffic are a big problem in many countries. Indonesia is one of the highest traffic conglomerates in the world with the capital Jakarta as the largest and densest urbanized area in Indonesia [1]. One of the causes of traffic congestion is the large population (4th place in the world) and an unbalanced distribution of the Indonesian population [2]. With the huge population and consequently increasing vehicle ownership on the highways and thus the need for traffic control on the highways, the Department of Traffic and Road Transport (DLLAJR), the Ministry of Transport as the main authority in Indonesia need to find new ways or steps to resolve this problem. The steps taken by the Ministry of Transport have included the development of new roads and bridges in the city center, the development of several highways in the city as internal, middle and outer lanes as well as public transport acquisitions such as Light Rail Transit (LRT), Public Transit (MRT) and various new mode buses namely Transjakarta, Transbogor. Given the rapid growth of population and large urban development as well as human activities and life spans, it is undeniable that almost every major city in Indonesia faces serious transport problems, including traffic congestion and delays, especially at intersections. Traffic congestion can cause many problems, and has the biggest impact that road users will face. Vehicles on the road will experience a deep decline in travel speed, requires longer travel time. The effect is that the cost of travel such as time, fuel consumption, wear and tear, carbon emissions and so on, must be borne by road users.

The road system of any country is basically a network of roads that cover all places and regions. The highways will be built to accommodate high traffic between major cities. From here, the highway will have several entrances and exits to connect business centers, residences, government administration offices and even schools or colleges. Therefore, the road system will have many intersections. The traffic light system is a means of traffic management at the intersection to provide a system of circular motion between the intersections of the intersection. With this movement system, it will reduce accidents and be organized as well as give you the right to cross at all intersections.

Local authorities in Indonesia refer closely the Manual Kapasiti Jalan Indonesia (MKJI) [3] or Indonesia Road Capacity Manual (IRCM) to determine the traffic lights timing at each junction which is a one standard time used throughout the day. The number of vehicles on the road varies to the time of day where a high number of vehicles can be seen in the morning for office workers commuting to work, the business traffic at mid-morning, lunch traffic and going home traffic. In between these times and also during the weekends, the traffic has a different profile throughout the day. This will result in long waiting time for junctions with fewer vehicles. Hence, it is hoped that with varying the green time according to the number of vehicles, the waiting time will be greatly reduced.

II. Literature Study

This literary study will provide an overview of the setting of green lights followed by the discussion of traffic light modelling focusing on the classification of traffic light timing at intersections. And lastly, a review traffic monitoring methods at junctions.

This article was partially funded by UTM Collaborative Research Grant No. 08G12.

A. Overview of Green Lights Settings

In Indonesia, the timing of the traffic light at the intersection is determined by reference to the Manual Kapasiti Jalan Indonesia (MKJI) [3] or Indonesia Road Capacity Manual (IRCM) solely using one standard time. The manual explained that the average number of vehicles is the basis for determining the daytime green light setting taken during peak hour traffic. This means that the green light is fixed and does not change although the number of vehicles at a given time is fewer or greater than the peak time scenario. This will affect other junctions in the same intersection as more time are allocated to the branch [4][5]. Also, it will cause a delay due to long waiting time in cases that there are few vehicles in the branch. Adjusting the green time according to the number of vehicles should be analyzed so that each junction of the intersection will be given an appropriate time to allow all vehicles to pass the junction. The author in [6] mentioned that the control at traffic lights is important but the author proposed using RFID. Data from traffic monitoring is in the form of vehicle densities, and current behavior of the junction must be captured in real-time.

B. Traffic Light Modelling

In an effort to mimic the behavior of traffic lights, mathematical models have been created and can be used to make theoretical models. The mathematical description of the general features of signal processing modeling has been studied for more than four decades [7]. Based on the traffic light model with image processing, it also uses an artificial intelligence model to determine signal lights. Fuzzy logic model [8] is a method of fuzzy inference system, in which the estimation of the behavior of the signal lights, and the accuracy of the model depends on the number of vehicles. The signal light controller is designed for crossing traffic based on a normal system using a single two-way intersection.

The system in Fig. 1 is an automatic signal transmission using an IR sensor and a Microcontroller. The top-down design approach is adopted [8]. This approach involves breaking down the system into smaller units to allow designers to gain more insight into the system. The system is broken down into several units which are Power Supply Unit, Control Unit and Sensor Unit. From the tests conducted on the circuit, it is observed that LEDs of the same color have the same time, and that each of the four poles of the traffic light controls, alternating and repeating until the circuit is disconnected from power.

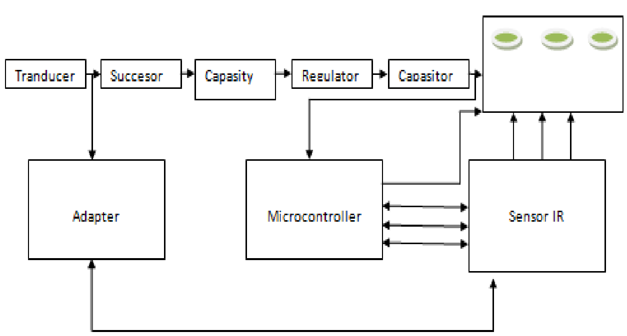

Fig. 1. Block Diagram of the Intersection Model System [23].

Sensors help in keeping the count of vehicles entering the road and the microcontroller then allocates an appropriate time delay as to give the right priority to each road. The microcontroller used is an optocoupler, used to provide coupling while ensuring electrical isolation between input and output. Another purpose of an optocoupler is to prevent rapid voltage or high voltage changes on one side of the circuit from transmission deviations or damage components on the other side of the circuit. This new design will reduce time delays, increase efficiency and reduce accidents by including modifications [8].

Other models for determining signal traffic using Fuzzy smart circuits are, the results of frequency simulation (number of cars completing cycles) per minute for predetermined (fixed) traffic control and fuzzy logic traffic control systems [9][10][11]. According to analysis, the fuzzy logic traffic control system consistently performs better because it has a higher frequency (number of cars completing cycles) at a certain point in time. However, it should be noted that there are variations in performance at certain time points where the number of cars completing cycles is relatively higher for fuzzy logic traffic control systems than for pre-time (fixed) traffic control systems [12]. The researchers interpreted this finding as a further indicator of performance improvement in fuzzy logic traffic control systems based on estimates at certain points during high traffic density, so that the number of cars completing the cycle was slightly higher than the density in low traffic [13][14].

TOPSIS Fuzzy Algorithm is a new method using problem solving to understand the human behavior on the decision making [1]. The TOPSIS Fuzzy Algorithm concept which must have the shortest geometry distance from the positive ideal solution and the longest geometry distance for the negative ideal solution. This fuzzy method determines the traffic lights by determining the length of the vehicle closest to the traffic light on. This study produces an optimal green light time but however only consider the number of vehicles in the branch only.

C. Traffic Monitoring

To determine the average traffic density, it is necessary to monitor the number of vehicles passing the highway [15] Monitoring is usually carried out by observers. The observers sometime will generate errors in the calculation process due to vehicle congestion, environmental influences or internal investigators themselves [17][18]. In addition, human calculations require separate costs which indicate the implementation becomes less efficient [8]. Therefore, this study will also design and calculate the number of vehicles on the branch, using cameras and C ++ programming with the OpenCV library (18). OpenCV is used as its own subprogram or library which can be combined to be multiple functions in the programming which relates to digital image.

The author in [19] proposes a case in which the traffic junction topology monitoring will control traffic light systems. The system uses a camera which is connected to the computer and is place at the center of the junction and it has multiple sensors based on RFID. ZigBee traffic monitoring will be depending on the parameter used in the traffic monitoring.

Measurements are made to determine the number of vehicles, movement and classification of the vehicle at a certain location.

Another work by [20] is developed to combine the dynamic smart algorithm to monitor and predict the parameter strategy for traffic light. This system used wireless technology and low power energy. This system is going to be one of the traffic light systems that are very effective in Taiwan [8].

In discussing the traffic light system, there is a huge gap where road width was not considered when determining the green time. Therefore, a clearer and accurate determination of green timing at traffic lights that considers the number of vehicles and road width would appropriately reduce the traffic congestion due to ineffective green light timing is the main focus of this paper. This work will also consider the time taken to cross the junction based on values proposed by [1][11] Fuzzy classification will be the focal of this work. By monitoring, examining and determining the number of vehicles that will pass the junctions and the road width, it can determine the green light time with respect to the NWHS proposed by [1][21].

III. Methodology

The overall methodology is shown in Fig. 2 which illustrates the two inputs required that is the road width and the number of vehicles in the branch. The output is the appropriate green time at the intersection. The method will use image processing at the intersection to determine the number of vehicles and use Google maps to determine the width of the road. Both inputs will be used for the classification in Fuzzy logic which will determine various levels of membership, then will be used to determine the level of green time membership. The original equation in IRCM will be modified to include the road width criteria and the proposed NWHS from [1].

A. Fuzzy Rule Recommendations and Green Classifications

Fuzzy logic is one way to map the input space to the output space [4] [10]. The fuzzy logic has been selected to map data input points to membership values or referring to membership levels with fuzzy sets. The first step in computing is to create a set of fuzzy variables [22]. There are two input variables that have been indicated by their degree of membership, namely the number of vehicles (few, moderate and many), width of the road (wide, medium and narrow) [16][23]. The green light output, on the other hand, is short, moderate and long membership. The fuzzy assembly for each variant is shown in Table I.

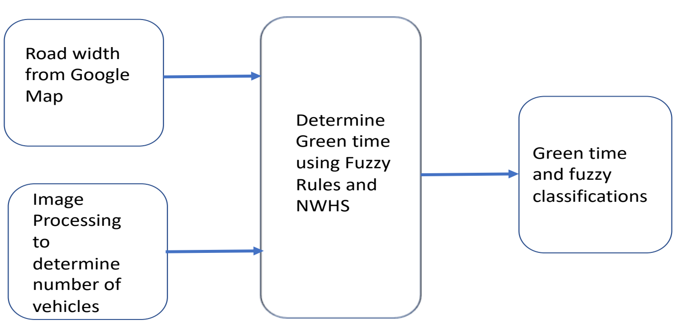

Fig. 2. Research Method of Traffic Controller (TC).

TABLE I. FUZZY LOGIC INPUT AND OUTPUT CRITERIA

Functions	Criterion	Fuzzy classification
Input	Number of vehicles	Few
		Moderate
		Many
	Road width	Wide
		Medium
		Narrow
Output	Green Time	Short
		Moderate
		Long

The inputs were further detailed as given in Table II. Determination of the number of vehicles from the camera, mapped to degree of membership is illustrated as a straight line using the data in the table. The number of vehicles were classified into three categories, namely, many, moderate and few vehicles; for example, many vehicles are in the range of 20 to 60 vehicles.

Road width (LJ) denotes the width of the road; however, further modification was used which is the LJ coefficient factor. This factor is based on the number of lanes that the width of the road can accommodate. Having several lanes in the branch will increase the number of vehicles to cross the junction at each click timing. For example, the number of vehicles to pass the junction is doubled if the LJ coefficient is 2. And the same calculation for other road width is given in Table II.

In this study, the value of NWHS as proposed by [3] where the average value of all possible types of vehicles on the road is used. The image processing capability will determine the number of vehicles only but not the type of vehicles that crosses the junction. From [1], car took 1.86 seconds to cross, the bus took 2.58 seconds while the truck took 2.77 seconds. Because vehicles on the road in Bogor are a combination of these three types of vehicles, they will certainly affect the short-term movement of vehicles. This is the reason why the NWHS value used in this work has been modified as the average time of all number of cars, buses and trucks take to cross the road and has a value of 2.73 seconds. This value was not considered in previous work.

TABLE II. FUZZY LOGIC INPUT CRITERIA

No	***Criterion***	***Number of vehicles***
1	Few vehicles	2 – 8 units
2	Moderate vehicles	7 – 25 units
3	Many vehicles	20 – 60 units
No	***Criterion***	***LJ coefficient factor***
1.	Narrow Road (1m - 3 m)	1
2.	Medium Road (2 m – 6 m)	2
3.	Wide (5 m - 10 m)	3
No	***Vehicle Movement Time***	***NWHS* [Galang et al 2018]**
1.	Car	1.86 s
2.	Bus	2.58 s
3.	Truck	3.77 s

The following Fuzzy rules were used to classify the green time output for all JK and JK input conditions that were previously categorized as above. The Fuzzy Rule Recommendations for the green light consists of nine rules and are as follows:

a) If the number of vehicles in the branch is many and the road width is wide then the green time is short.

b) If the number of vehicles in the branch is many and the road width is medium then the green time is moderate.

c) If the number of vehicles in the branch is many and the road width is narrow then the green time is long.

d) If the number of vehicles in the branch is moderate and the road width is wide then the green time is short.

e) If the number of vehicles in the branch is moderate and the road width is medium then the green time is moderate.

f) If the number of vehicles on the branch is moderate and the road width is narrow then the green time is long.

g) If the number of vehicles in the branch is few and the road width is wide then the green time is short.

h) If the number of vehicles in the branch is few and the road width is medium while the green time is moderate.

i) If the number of vehicles on the branch is few and the road width is narrow then the green time is long.

The graphical representation of the nine rules is illustrated in Fig. 3.

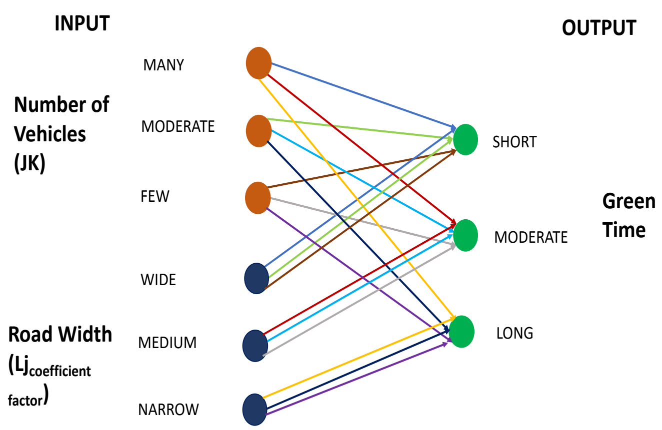

Fig. 3. Schematic Fuzzy Rules to Determine the Output Green Time.

B. Determination of Green Lights Time

From IRCM, the original equation did not consider the road width and since the number of lanes that can be determined based on the road width, therefore, the LJ coefficient factor is used and not the exact road width. Therefore, Equation (1) shows the green time formula used in this research and is expressed as in

$$€ = \frac{JK}{LJ_{coefficient\ factor}} * NWHS \quad (1)$$

where

€ = Green Time in seconds

JK = Total number of Vehicles

$LJ_{coefficient\ factor}$ = Road Width coefficient factor

NWHS = 2.73 s

Equation (1) is the equation used in Traffic Controller (TC) algorithm which uses two inputs that is the number of vehicles (JK) and LJ $_{coefficient\ factor}$. The intersections to be studied are the Sala Benda and Semplak intersections. From Table II and the nine fuzzy rules, the green time for each class of vehicles (many, moderate or few) and each class of road width (wide, medium or narrow) will be calculated using Equation (1). Only the highest number of vehicles in each category are used (many=60, moderate=25, few=8) while the LJ coefficient factor will be 1, 2 or 3 depends on the road width at Sala Benda and Semplak intersections. These values were calculated for each input category of vehicles and road width. The output will be the three categories and the range of green time are short, moderate and long as given in the following and also follow the nine fuzzy rules and shown schematically in Fig. 3.

Range of Short Green time : {7.3, 22, 54} secs

Range of Moderate Green time : {11, 34, 82}secs

Range of Long Green time : {22, 68, 164}secs

The classification of green time is shown in Fig. 4, where it depicts the LJ coefficient of 1 and 3 only.

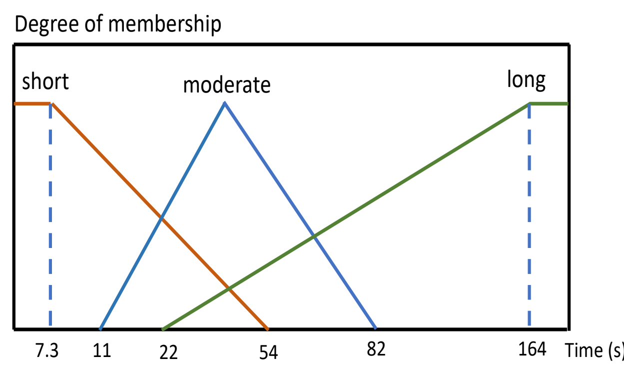

Fig. 4. Classification of Green Time.

IV. RESULTS

Data collected from Sala Benda intersection are tabulated in Table III while Table IV has data collected for Semplak intersection. The number of vehicles and the timing of the green lights are recorded and road width is obtained from Google Map. These are the data for MKJI system. The results of the calculation of the number of vehicles at the crossing of the Sala Benda and the video capture were captured between 10:00 and 10:30 and the vehicle calculation is about 80% accurate.

A. Inspection at the Sala Benda Intersection

The Sala Benda has three branches and road width obtained from Google Maps is 6.96 meters for branch 1, 6.73 meters for branch 2 while branch 3 is 7.03 meters. Based on Table I, all 3 branches have LJ coefficient factor of 3. Data was collected at 9 am to 10 am and also at 12 noon to 1 pm and as shown in Table III.

TABLE III. MKJI DATA AT SALA BENDA INTERSECTION

Nos	Details	Branch 1	Branch2	Branch 3
	Road Width (m) (LJ coeff factor)	6.96 (3)	6.73 (3)	7.03 (3)
1	No. of vehicles	43	47	37
	Green Time	55	62	37
2	No. of vehicles	41	46	25
	Green Time	55	62	37
3	No. of vehicles	44	45	23
	Green Time	55	62	37
4	No. of vehicles	5	12	11
	Green Time	55	62	37

B. Inspection at the Semplak Intersection

Semplak has four different branches and the width of the branch 1is 6.96 meters, branch 2 is 7.19 meters, branch 3 is 6.86 meters, and branch 4 is 7.11m obtained from Google Maps also. With these widths, the LJ coefficient factor is 3 for all branches. Refer Table IV.

TABLE IV. MKJI DATA AT SEMPLAK INTERSECTION

Nos.	Details	Branch 1	Branch 2	Branch 3	Branch 4
	Road width (m) (LJ coeff factor)	6.96 (3)	7.19 (3)	6.86 (3)	7.11 (3)
1	No of vehicles	23	37	34	54
	Green Time	33	67	37	66
2	No of vehicles	29	25	25	51
	Green Time	33	67	37	66
3	No of vehicles	22	41	37	50
	Green Time	33	67	37	66
4	No of vehicles	23	27	26	52
	Green Time	33	67	37	66

Notice that the green time for MKJI is also found at the intersection where the green time is constant in each branch despite the changing number of vehicles. This is the basic approach that is followed in MKJI.

C. Comparison between MKJI and TC

Using Equation (1), the green time of each simulation and for each branch were calculated as shown in Table V and Table VI. The difference in green time using the MKJI and TCs are also given. The waiting time for both MKJI and TC were also shown which the total waiting experience by all branches for every cycle.

As illustrated in Table V, at Sala Benda, the green time depends on the number of vehicles in the branch and shows a difference in timing ranging from -9 % to -91%. As discussed in the literature, MKJI gets the green time during peak hour in a day. This means that the green time will not change if the number of vehicles decreases or increases, in other words MKJI is fixed throughout the day. For TC, the green time will change according to the number of vehicles queueing in each branch. Also shown in the same table is the waiting time for vehicles in the next branch waiting for the traffic light at their branch to be green.

TABLE V. COMPARISON OF MKJI GREEN TIME WITH TC AT SALA BENDA

Nos.	Branch	Green time (s)		% of Diff. in green time	Waiting time(s)	
		MKJI	TC		MKJI	TC
1	1	55	39.13	-29	0	0
	2	62	42.77	-31	55	39.13
	3	37	33.67	-9	117	81.9
2	1	55	37.31	-32	0	0
	2	62	41.86	-32	55	37.31
	3	37	22.75	-38	117	79.17
3	1	55	40.04	-27	0	0
	2	62	40.95	-33	55	40.04
	3	37	20.93	-43	117	80.99
4	1	55	4.55	-91	0	0
	2	62	10.92	-82	55	4.55
	3	37	10.01	-72	117	15.47

TABLE VI. COMPARISON OF MKJI GREEN TIME WITH TC AT SEMPLAK

Nos.	Branch	Green time (s)		% of Diff. in green time	Waiting time(s)	
		MKJI	TC		MKJI	TC
1	1	33	20.93	-36.57	0	0
	2	67	33.67	-49.75	33	20.93
	3	37	30.94	-16.37	100	54.6
	4	66	50.94	-22.82	137	85.54
2	1	33	26.93	-18.39	0	0
	2	67	22.75	-66.04	37	26.93
	3	37	22.75	-38.51	100	49.68
	4	66	50.21	-23.92	137	72.43
3	1	33	18.97	-42.52	0	0
	2	67	39.92	-73.19	37	18.97
	3	37	37.76	2.05	100	58.89
	4	66	45.50	-59.85	137	96.65
4	1	33	20.93	-36.57	0	0
	2	67	24.57	-63.33	37	20.93
	3	37	23.66	-36.05	100	45.5
	4	66	47.32	-28.30	137	69.16

As illustrated, in Table VI, at Semplak intersections which has four branches, the green time depends on the number of vehicles in the branch and shows a percentage difference in timing ranging from +2 % to -73.16%. MKJI gets the green time during peak hour in a day and this means that the green time will not change if the number of vehicles decreases or increases. In other words, MKJI is fixed throughout the day.

Comparing the waiting time at Sala Benda, the waiting time correspond to the number of vehicles in each branch. In other words, smaller number of vehicles will have a small green time and hence less waiting time. For the first simulation, branch 3 has to wait for a total of 81.9 seconds to start crossing the intersection for TC while for MKJI, vehicle in branch 3 has to wait for a total of 117 seconds. Other simulations also show the same profile and have less waiting time for TC compared to MKJI.

V. Conclusion

This project shows that incorporating the number of vehicles and road width in TC implementation, using fuzzy logic, have shown that optimization of green time at traffic lights can reduce congestion. The difference in green time obtained from the simulation compared to the field test at the intersection of Sala Benda is very significant with a range of difference from - 9.00% to - 91.0% and at the intersection of Semplak from + 2.05% to -73.19%. This shows that with the TC method, the green time at Sala Benda and Semplak intersections can be adjusted based on the number of vehicles and the width of the road in the field.

The findings of this study can also provide three classifications of green time at intersections using TC methods as the basis for the fuzzy rules used. This Fuzzy rule was formulated using three categories of the number of vehicles namely many, medium and few vehicles with road width input categorized into 1 lane, 2 lanes and 3 lanes. From here, based on TC, green time are classified as short time ranges from {7.3, 22, 54} seconds each for a width of 1 lane, 2 lanes and three lanes respectively; moderate time ranges from {11, 34, 82} seconds while the long green time times ranges from {22, 68, 164} seconds. This is in contrast to the MKJI which gives a green time day value for the whole day, regardless of how many vehicles are lined up at the intersection.

The proposed TC compared to the work of other researchers is much better in terms of green time. Previous work uses the input of the number of vehicles only, whereas the intersection of four branches is more complex. TC uses the number of vehicles and the width of the road. Incorporating road width in traffic light system has not been done in previous work proposed to reduce congestion. This work shows a good performance in terms of optimizing the amount of green time as needed, if the traffic light setting uses TC rules then the result is green time according to the number of vehicles and short waiting time in the next branch depending on the arrival of the vehicles in each phase.

Based on the classification of green time given in Section III(B), at Sala Benda and Semplak intersections, all timings can be classified to have short green time which ranges from 7.3 to 54 seconds.

***Abstract*—The most significant limitation of stand-alone microgrid systems is the challenge of meeting unexpected additional demands. If demand exceeds the capacity of a stand-alone system, the system may be unable to satisfy demand. This issue is alleviated in grid-connected technology since the utility system will provide more power if it is demanded. As a result, load scheduling is an integral element of the demand response of a standalone system. There are two components to this problem. If the capacity of a battery-supported power system is restricted, for the period of time that the source is available, it will not be able to meet the entire demand. Appropriately the demand is dispersed across a period of time until the next charge becomes available. Some demands may be disregarded in order to accomplish peak load trimming or if the system is incapable of meeting demand without compromising other important technical and consumer objectives. This is a challenging assignment. This article aims to develop an Adaptive Demand Response Management System (ADRMS) capable of load scheduling and load shedding using an interwoven multidimensional Bayesian inference supported by multiple mathematical models. A two-stage hardware architecture is being developed, with the first hardware measuring demand and source capacity before sending the data to the second hardware via LPWAN for mathematical analysis. In the first phase, two approaches are used to forecast demand: Gaussian Naive Bayes Model (GNBM) and Bayesian Structural Time Series analysis. GNBM is rapid but fails to properly forecast the output when there is zero frequency error whereas BSTS can offer more precise results than GNBM but is slower. Hence two approaches are employed in tandem. The next stage is to assign demand source integration. This is accomplished using Bayesian Reinforcement Learning (BRL), which is based on a number of incentives, including anomaly, cost factors, usefulness, reliability, and size. All Bayesian models are subjected to much of the common Bayes rule, resulting in the formulation of a blended polymorphism model that reduces computing time and memory allocation, and improves processing reliability. The Isolation Forest (IF) method is used to identify and avoid vulnerable loads by determining demand anomalies. The last step employs a Dynamic Preemptive Priority Round Robin (DPPRR) algorithm for preemptive priority based load scheduling based on forecasted data to allocate the next loads to be added.**

Keywords*—Adaptive control; Bayesian; demand response; energy management system; load scheduling

I. Introduction

A. Background

Increased Solar Photovoltaic Generation System (SPVGS) installations have enabled many residential, commercial, and industrial facilities to operate as stand-alone microgrids [1][2]. In such systems, SPVGS will deliver energy to demand throughout the day, with a portion of it being stored in battery systems [3]. When solar energy is in short supply, especially at night, the stored energy from the Battery Energy Storage System (BESS) is used to satisfy demand [4]. Because of limited power capacity, demand response management is a key challenge in standalone solar-powered battery systems [5]. If demand rises in a grid-connected system, additional power can be pulled from the utility grid [6]. However, the capacity of the standalone system is constrained [7]. If the load exceeds supply limit, the system will have to drop certain loads in order to maintain the demand-supply balance [8]. The watt hour capacity of a BESS limits the amount of power it can supply [9]. Consequently, if several loads are connected and the total watt hour demand exceeds the watt hour capacity of the entire storage system, some of the loads must be bypassed. The BESS is charged from the additional supply from the SPVGS [10]. As a result, if the load is close enough to the SPVGS supply, the BESS will be drained because there will not be enough power to charge it. A portion of the load is evacuated in these circumstances to free up energy to charge the BESS [11]. It is a significant challenge to develop demand response models that satisfy all of the above characteristics while remaining efficient, cost-effective, and consumer-friendly [12]. Thereupon, numerous researches on load scheduling and intelligent demand management for stand-alone systems are now being undertaken.

B. Literature Review

Sharda et.al. investigate the overview, problems, and potential of Demand Management (DM) in standalone systems [13]. They also address real-world problems encountered while implementing DM with load scheduling for home energy management systems. Lu, Xinhui, et. al. investigated supply and demand side optimal load scheduling in a smart grid system, with an emphasis on economic, social, and environmental benefits for all market participants [14]. O'Shaughnessy et. al. looked into the end-user economics of

BESS and DM that boost the value of SPVGS by regulating and temporally altering their output [15]. The preceding papers offer an overview of the factors that go into load scheduling for stand-alone systems. The topologies of reconfigurable battery management systems are investigated by Viswanathan et. al., with an emphasis on load interface protocols and load scheduling optimization approaches [16]. Sanjari et. al. developed an optimum control approach for battery-integrated energy systems that uses analytical rather than numerical approximation methods to account for load demand unpredictability [17]. Md Masud et. al. developed a model for a hybrid gas turbine generator, SPVGS, and Battery Energy Storage System (BESS) for isolated microgrids [18]. Jonathan T. Lee et.al. experimented with non-intrusive load control in energy-constrained microgrids under unpredictable load conditions [19]. To address load management concerns, the aforementioned articles use a wide range of methods, and many of the solutions use time-based optimization methodologies. Traditional time series analysis techniques use historical data to forecast model parameters. Because the loads are only coupled for a short period of time, in most circumstances, the load gradients comprise zero values across the curve. Standard time series approaches for load forecasting are contentious due to the difficulty in distinguishing seasonality or stationarity in the zero gradient curve. This problem can be solved using a structural model, in which the parameters are expressed as the composite of individual parameter contributions, or probabilistic prediction procedures. Bruce G. Marcot et. al., provide a great deal of information on recent advances in Bayesian network modeling and integration of Bayesian rule engine for series analysis [20]. Steven L et. al. demonstrate how to integrate a structural time series model for the target series with a regression component that takes real-time search query data inputs into account [21]. The application of a spike-and-slab prior on the regression coefficients results in sparsity, which significantly reduces the size of the regression problem. As a result, in the event of uncertainty, Bayesian modeling will be an appropriate approach for load forecasting.

C. Objectives

The ideal goal of a Demand Response Management System (DRMS) is to ensure that the load receives consistent electricity. However, if the sources' capacity is limited, especially in a freestanding grid, a portion of the load is dropped or rescheduled over time to satisfy the demand via peak load cutting. An intelligent DRMS should be capable of load scheduling and load shedding in order to achieve maximum power efficiency, optimum economic gain, and user satisfaction. In order to perform load scheduling and shedding, the system should be able to distinguish between loads and determine which loads should be maintained or discarded. The DRMS should have the potential to ascertain when and for how long each load should be scheduled and shed. This is a difficult undertaking that might be accomplished utilizing a variety of mathematical methods. Because of the non-uniform zero gradients in the load curve, utilizing time spectrum analysis alone is less successful. As a consequence, a new hybrid mathematical model for analysis that combines the properties of time series analysis, spectrum analysis, and probabilistic regression is to be established.

D. Contributions

The objective of this project is to establish a multi-layer DRMS hardware that uses a two-stage hardware architecture for energy monitoring and decision making. An edge controller transforms a Wi-Fi module into an energy monitoring circuit that monitors demand and source capacity and delivers the data to a Centralized Data Processing Unit (CDPU). CDPU will save this information in a database and analyses it using a blend of mathematical models. To begin with, the Isolation Forest (IF) algorithm will be utilized to evaluate anomalies in load data. This data is used to construct a Bayesian prior. A two-stage time-series analysis is employed in the following step, using Gaussian Naive Bayes Model (GNBM) and Bayesian Structural Time Series (BSTS). One of the weaknesses of Naive-Bayes is frequency error, which causes the probability estimate to be zero if there are null-gradients in load data. BSTS can address this issue and is more accurate than GNBM, but it is also slower. Therefore, GNBM is frequently used for load forecasting, with BSTS employed in tandem if there is a zero frequency error or a significant RMSE. A Bayesian Reinforcement Learning (BRL) algorithm is utilized to identify the optimal load-source assignment combination based on the projected values. In a preemptive priority assessments approach, a Round Robin algorithm supplemented by a Dynamic Programming model is used to select the best sources from all available sources and schedule loads.

E. Organization

The paper is split into three sections. The first part is an introduction that examines the context of the problem, conducts a thorough literature review, and formulates the problem. The described problem is used to establish the goals of the project. The following session will go over the strategies used to solve this problem in detail. The results and discussion section examine the implementation of the project in depth, and are found in the last section. The result and discussion session is split into two parts: the first looks at the data, and the second looks at the implementation approach and consequences.

II. Adaptive Demand Response Management System (ADRMS)

As illustrated in Fig. 1, this project develops a two-stage hardware architecture for a multilayer Adaptive Demand Response Management System (ADRMS). A switching relay circuit couples the loads to the battery, allowing any load or source to be added or disengaged independently at any time. The system's operation is structured down into different phases, as follows.

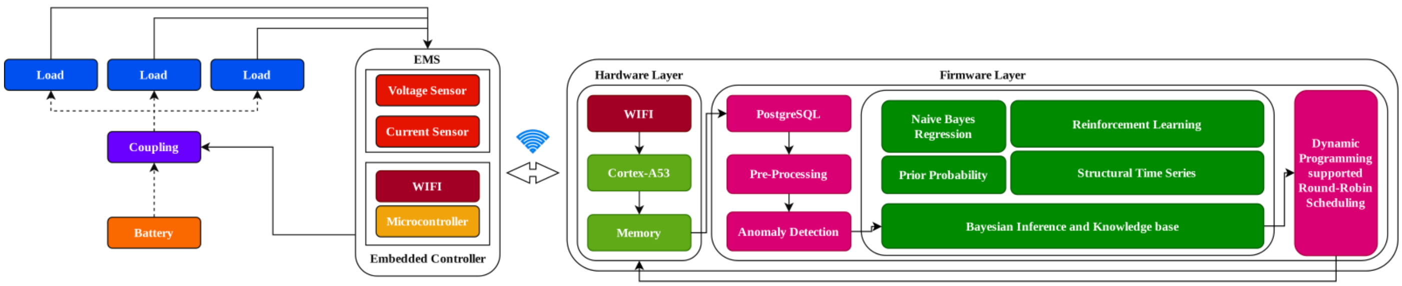

Fig. 1. Architecture of Adaptive Demand Response Management System.

Stage 1 Energy monitoring and communication: Energy monitoring module is composed of an Atmega328 microprocessor, a voltage measuring circuit based on a potential divider, an esp8266 module and an ACS712 current sensor. The energy monitoring circuit evaluates the power consumption of each load and the SOC of each battery using measured voltage and current. With the aid of a Wi-Fi module, this data is transferred to the CDPU. The CDPU is a Broadcom BCM2711 quad-core Cortex-A72 (ARM v8) 64-bit SoC with 2GB RAM and 1.5GHz single board computer. Hardware in a Loop model is used to finish the execution of operational parts.

Stage II Data storage: The data is initially saved in a PostgreSQL database using the Node-RED development tool as it reaches the CDPU. This approach is useful for analyzing real-time data.

Stage III Data Pre-processing: A large volume of data would be captured because the system will record data every millisecond. Analyzing all of this raw data would result in longer computational costs. For faster processing, the data is resampled from milliseconds to second levels. Then the data is preprocessed which involves a number of steps, including replacing missing data with local standard deviations, normalizing the data, and converting it to categorical variables.

Stage IV Anomaly with Isolation Forest (IF): Anomalies in the load curve indicate a fault or maybe a quantitative inaccuracy. Proper spotting anomalies in the load curve might help decision-making, for identifying faults and taking remedial action during forecasting. Because historical data aids in distinguishing anomaly from normal deviation, anomaly calculation is left out of the Bayesian engine. An unsupervised outlier time series analysis based on IF is used to discover anomalies. IF uses clusters of isolation trees for a given data collection, with data higher than the Euler-Mascheroni constant being deemed anomalies. When load consumption is represented as $P_L = \{P_1,.., P_n\}$, where P_{LF} and P_{RR} is the load to right and left element of tree, P_i consumption at i^{th} load, t_h is the threshold, the isolation tree is built again every time a new value is added using the equation 1 and 2. Isolation forest provides the added benefit of allowing points that cannot be isolated to be classified as normal or abnormal to be easily detected.

$$P_{LF} = P \epsilon P_n \vee P_i < t_h \tag{1}$$

$$P_{RR} = P \epsilon P_n \vee P_i \leqslant t_h \tag{2}$$

Stage V Bayesian inference and Knowledge base: The following step is to create a Bayes interference engine and knowledge base. In the comprehensive mathematical model, three distinct Bayesian oriented mathematical strategies are employed for three different applications: GNBM, BSTS, and BRL. Because the Bayes theorem governs all methods, each model undergoes numerous equivalent joint phases and processes during the operation. A polymorphism model produces a hybrid object engine that works as a centralized interference rather than adding different variables, memory assessments, and processes for each activity. Polymorphic objects are called when a common set of rules is followed, which reduces the computation cost. Independent mathematical procedures are employed in the final stages of computations. The Bayes theorem is represented as Equation 3. P(PL) is the probability of next load data and PH is the prior probability.

$$P(P_L \vee P_H) = \frac{P(P_H \vee P_L) P(P_L)}{P(P_H)} \tag{3}$$

Stage VI Gaussian Naive Bayes Model (GNBM): The load is then scheduled relying on available source capacity. As previously stated, scheduling the load based on its temporal behavior is essential for enhanced power quality, longer load longevity, higher economic sustainability, and user satisfaction. In the following phase, load is forecasted using GNBM and Bayesian Structural Time Series Analysis (BSTS). The load is forecasted in the first stage using GNBM. The probability of the load variation is predicted using equation 4.

$$P(P_L \vee P_H = \mathrm{X}) = \left(\frac{1}{\sqrt{2 * \Pi * \sigma^2}}\right) e^{\frac{-(P_L - \mu_x)^2}{(2 * \sigma^2)}} \tag{4}$$

Stage VII Bayesian Structural Time Series: BSTS is a time series interpreter that uses Bayesian criteria to choose output parameters. BSTS is based on Bayesian model averaging ensemble learning, which uses an average number of models to do stepwise regression forecasting, with the input weighting the posterior probability of each model. If Pt is the time series to be predicted, whereas αt denotes the inherent features of the load curve, Kt is a vector of coefficients for state variables, Ht is the variance with normal distribution error term with a mean of zero εt , equation 5 represents time series calculations.

$$P_t = \mathrm{K}_t^T \alpha_t + \epsilon_t \rightarrow \mathrm{for} \epsilon_t \in N(0, \mathrm{H}_t) \tag{5}$$

Now the value of α is updated with equation 6 where block diagonal transitions matrix T_t , the covariance matrix Q_t of the rectangle block R_t and each component contributes to the block with η_t.

$$\alpha_{t+1} = \mathrm{T}_t \alpha_t + \mathrm{R}_t \eta_t \rightarrow \mathrm{for} \eta_t \in N(0, \mathrm{Q}_t) \tag{6}$$

Stage VIII Bayesian Reinforcement Learning (BRL): Once the load is predicted and anomalies are handled, the following step is to allocate loads to different sources depending on the forecast value. The optimum loads for the ideal sources may be found using BRL with maximum exploitation of sources. Thompson of Sampling is a strategy to explore the progressive rewards based on the rule of Bayesian control and maximize them. The cumulative reward (R) of the load (P) is decided based on Gaussian Bayesian reward function (E) for every individual reward function μ for two consecutive stages is shown in equation 7. The system always tries to maximize the reward in a greedy manner. If the source capacity exceeds the loads, a dynamic program is integrated with BRL to locate the best resources.

$$R_t = \sum_{t=t_1}^{t_n} E\,(P_t^I - P_t) \rightarrow \max(\mu_t) \tag{7}$$

Stage IX Dynamic Preemptive Priority Round Robin (DPPRR): Following the identification of the most relevant combination using BRL, the next step is to include sources and assign loads to them. This issue is divided into two parts: the first is the source selection using dynamic programming, and the second is the source assignment using preemptive priority scheduling using Round Robin. To conserve energy, sources are only used when absolutely necessary. As a consequence, dynamic programming is utilized to choose the best sources from all available sources. Now depending on the load demand, sources are employed in a certain sequence in a time spectrum allocation using preemptive priority scheduling based Round Robin technique.

III. Results and Analysis

As shown in Table I, 49 sources were linked as a DC microgrid with a battery capacity of 20 KWH and an SPVGS of 1200 W in order to realize the idea. Table II shows the 27 distinct loads that were investigated with a maximum load capacity of 5.7 KW. In a laboratory setting, the entire technique is implemented as HIL. Due to the typical operational characteristics of the utilities grid, no automated switching is done, thus the decision making are determined using all developed models with the last step in manual switching mode.

The initial stage of execution is the assessment of source capacity and loads. At first, all batteries are charged to their maximum capacity. The next stage is to evaluate how much energy each load consumes. The load consumption is captured every millisecond and resampled to a scale of seconds by estimating the average usage each minute. The load dataset is divided into two sections: a historical segment and an instantaneous component. Instantaneous data is taken as test data, while historical data is used to train the model. When a new measurement appears, the previous instantaneous data becomes historical data. A day's worth of average load consumption data per minute is indicated in the Fig. 2. This data is used for training the model. As a result, at each point on the load curve, the data on the left is utilized for prior training and the data on the right is used for posterior learning.

Once the load statistics and source capacity have been identified, the following stage is to identify any anomalies. The system's anomalies are discovered for each load utilizing IF, and each load is graded based on the anomaly. In the last stage, this information is used as a reward during reinforcement learning as well as in priority-based queuing. Fig. 3 illustrates an anomaly over the whole training data set. Table III depicts an anomaly for a sample subset of data. Any count that is less than zero is deemed an anomaly in the table. It may be identified that even if the rate of change exceeds a particular level, it is not always deemed an anomaly because an anomaly is a function of time-dependent deviations. As such, an anomaly is defined as anything that deviates from the confidence interval, which may fluctuate over time owing to load variations.

TABLE I. Source Capacity, Type and Count

No	Type	Capacity	Number	Total
1	Li-Ion	100 WH	20	2000 WH
2	Li-Ion	250 WH	6	1500 WH
3	Li-Ion	500 WH	5	2500 WH
4	Lead Acid	1000 WH	10	10000 WH
5	Lead Acid	2000 WH	2	4000 WH
6	SPVGS	200 W	6	1200 W

TABLE II. Loads for Realization

No	Load (W)	Type	Number	Total
1	50	Fixed	5	250
2	100	Fixed	5	500
3	200	Fixed	5	1000
4	300	Variable	10	3000
5	500	Variable	2	1000

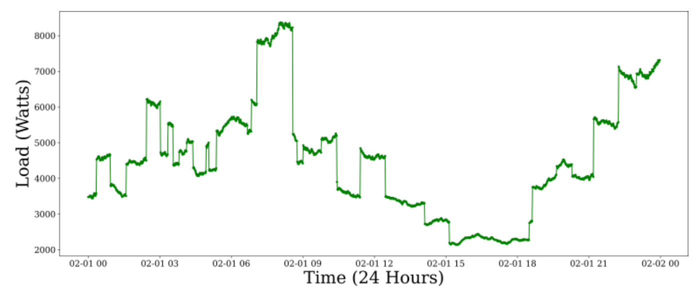

Fig. 2. Load Data for 24 Hours to be Utilized for Training.

TABLE III. Anomaly of Load Data for 12 Minutes

Time	Load (Watts)	Anomaly
1	18.94	No
2	18.95	No
3	18.83	No
4	18.89	No
5	18.88	No
6	18.94	No
7	21.09	No
8	21.03	Yes
9	20.89	Yes
10	20.95	Yes
11	20.76	Yes
12	20.80	Yes

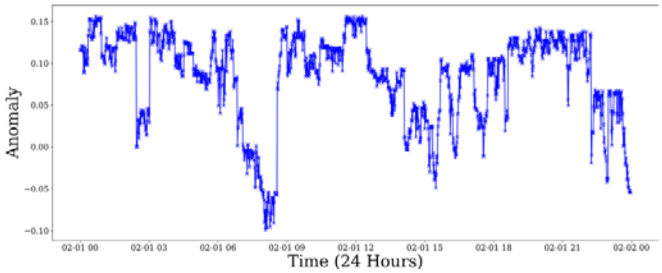

Fig. 3. Anomaly of Load Data for 24 Hours.

Furthermore, a time series analysis of the load has been presented. As previously indicated, in the short term, GNBM is used to forecast load. Two instances of GNBM based load forecasting are shown in Fig. 4 and 5. The first scenario illustrates a more accurate system, whereas the second case depicts a system with a greater RMSE. This is primarily due to the fact that GNBM is frequency dependent. In such circumstances, BSTS will be used.

BSTS is used to forecast the load with more precision, although it takes more computational cost. Fig. 6 demonstrates the load forecasting of the test data using BSTS, which is based on consecutive train-test splits. Now, each load is awarded five reward points based on anomaly, economic criteria, need, timing and magnitude, depending on the forecasted data. Based on these data, BRL is used to estimate the time allocation for each load. Table IV shows a sample of reward data for four different loads, along with the output selection time period in the last column.

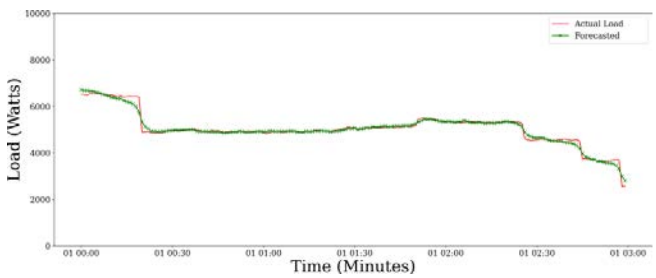

Fig. 4. GNBM based Load Forecasting.

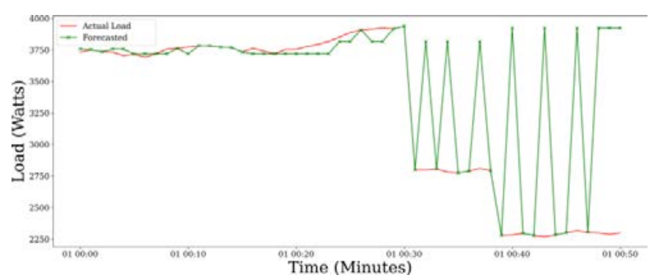

Fig. 5. GNBM based Load Forecasting – Gradient Error.

TABLE IV. REWARD BASED BAYESIAN REINFORCEMENT LEARNING

	R1	R2	R3	R4	R5	Time (Hours)
L1	2.7	6.7	0.8	2.8	1.3	3
L2	5.7	6.5	5	1.5	1.5	0
L3	7.4	2.5	2.6	4.2	1.8	2
L4	7.6	4.2	6.1	2.8	5.1	1

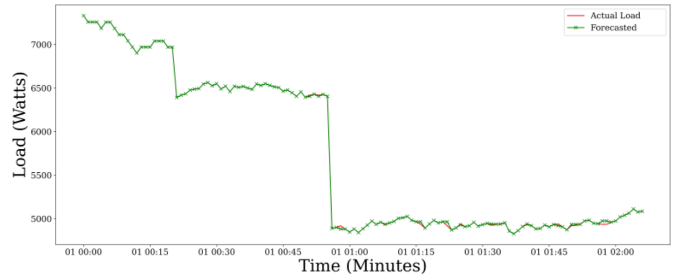

Fig. 6. BSTS based Load Forecasting.

The next step is to add sources and allocate loads to them. Dynamic programming is used to select the best sources from a large number of options. Using a Priority-based Round Robin method, sources are now employed in a certain order in a time spectrum allocation depending on load demand. The sole criterion employed to select sources is State of Capacity. Table V lists all accessible sources at instant and their capacities. Only 7 of the 10 sources with a total capacity of 477 Watts are used to satisfy a load of 331 Watts. The DPPRR based time spectrum allocation of loads is shown in Table VI.

TABLE V. SOURCE SELECTION BASED ON DYNAMIC PROGRAMMING

Source (Watts)	81	66	34	16	42	27	33	95	51	32
Total Capacity = 477 W , Load = 331 W Selected Source capacities = 66, 34,16,42,27,95,51 W										

TABLE VI. PREEMPTIVE PRIORITY ROUND ROBIN SCHEDULING

Load	Battery	Assigned Period (Hours)	Waiting time (Hours)	Execution Time (Hours)
Load 1	1	5	0	5
Load 2	1	3	5	8
Load 3	2	4	8	12
Load 4	2	7	12	19
Load 5	3	2	19	21

IV. CONCLUSION

This work developed an Adaptive Demand Response Management System (ADRMS) capable of load scheduling and load shedding using an interwoven multidimensional Bayesian inference backed by various mathematical models. The system was designed with a two-stage hardware architecture, with the first stage measuring demand and source capacity before sending the data to the second stage CDPU through LPWAN for mathematical analysis. Gaussian Naive Bayes Model (GNBM) and Bayesian Structural Time Series Analysis were employed to forecast demand. To ensure maximum precision, the two methods were used in conjunction. Bayesian Reinforcement Learning (BRL) was used to integrate demand sources based on a variety of incentives, including anomalies, cost considerations, usefulness, dependability, and size. A blended polymorphism model was developed, which decreased computation time and memory allocation while also improving operational efficiency. The Isolation Forest (IF) approach was used to identify and avoid vulnerable loads by recognizing demand anomalies. A Dynamic Programming integrated preemptive priority based Round Robin technique was used to allocate the next loads to be added.

Jeddah, Jeddah, Kingdom of Saudi Arabia

***Abstract*—In the fourth economic revolution, which is based on digital transformation, the e-learning process represents one of the most important processes needed to deal with the revolution through increased skills and knowledge. Thus, the automation services in the e-learning field represent one of the most important and supportive means of transferring and disseminating knowledge to reach a diverse and wide segment. This study focuses on defining the parameters and characteristics of the target audience, who are interested in the e-learning method, through smart device applications in higher education institutions in Saudi Arabia. The study used a quantitative method and data collected from 539 participants from several universities and institutes to determine their characteristics. The study segment represents one of the basic aspects of and full motivations for accepting new technology; 70% of Saudi smart device users form the youth segment, which is the university age group. This is the category that is expected to have the most use of e-learning in light of the coronavirus pandemic, which has cast a shadow over the six continents of the world. This approach could help the adoption of M-learning applications by the target audience according to a number of technical and design requirements, which are presented in this study.**

Keywords*—M-learning; mobile learning; UTAUT; KSA; MOE; application quality; qualitative study

I. Introduction

E-learning represents one of the main and most important channels in the process of digital transformation, which has begun to mature in many continents and countries where e-learning represents one of the channels that helps in spreading knowledge among the various segments of society. This online process has had a great impact on the completion of the educational life march in schools and universities during the spread of the coronavirus pandemic during 2020. Through this approach, many entities were able to adopt digital transformation as a means to reduce the gap between reality and expectations during this pandemic. Many economic, commercial, and health purposes have been able to adopt digital transformation as one of the methods for reducing the impact of this pandemic that has resulted from social distancing, which is considered one of the best means of reducing the spread of the virus in societies.

There are shortfalls to be addressed in the quality of education and its opportunities for Saudi communities that require a high level of privacy and the separation of genders in education [1],[2]. According to the MOE policy in Saudi Arabia, gender segregation in education reflects the country's religious and traditional values as well as the national policy in general [3]. It is important to consider strengthening mobile learning (M-learning) approaches by determining the requirements that produce acceptable M-learning application designs for students in Saudi universities. In the meantime, more than 75% of mobile subscribers in Saudi Arabia are already using smartphone devices for most of their daily life purposes [4]. Thus, there are several opportunities that would help the target audience to more readily accept learning applications in this community. Further, the community can expand their knowledge while still maintaining the government policy associated with religious values.

Thus, M-learning applications have several requirements in their design to be more compatible and acceptable for Saudi communities. These applications would be required to promote an education policy in Saudi Arabia that is based on the separation of genders at all levels of education; at a distance, males and females can digitally exchange and share their information easily without breaking the religious restrictions of the Saudi society. Many previous studies have focused on the factors influencing M-learning's acceptance in the Kingdom of Saudi Arabia (KSA); however, there is a shortage of information concerning the main practical requirements related to particular societal or traditional elements related to the KSA community background as well as the community characteristics that could help and use the M-learning approach through the digital transformation revolution. These characteristics help to assign the main personas interested in using M-learning applications intensively, which could help with the professional application function design and analyses of the M-learning application systems in order to assess whether they are suitable and well-developed for students in higher education institutions in KSA.

Also, the policy of gender segregation in education in the KSA limits women's opportunities to fully develop their capabilities and skills, especially due to the restrictions regarding women that are based on religious values in Saudi Arabia [5]. These restrictions not only affect the flexibility of learning through the same channels provided for men but also do not allow for women to learn similar courses that would encourage them to use their knowledge with the same gender in the future [5],[6]. Some examples include restrictions around driving a car, the lack of public transportation infrastructure, and the prevention of women from traveling without permission from a male relative, such as a husband, father, or brother [7]. Some of these issues have been resolved in the last two years, but their residual influence on the Saudi community means changes will take more time to be adopted. These examples of the disparity in access to mobility have given men more chances and flexibility while delaying the same for women in KSA. These reasons lead to limitations for women in opportunities to learn similarly to men in KSA. Furthermore, many of the academic disciplines that were established recently for female students, such as industrial environmental engineering, have been available to male students for more than two decades due to several traditional considerations. However, the majority of faculty members are male, which makes learning these sciences an obstacle for female students because of the same considerations of gender segregation in the various stages of education. This affects the learning process between male teachers and female students.

This research may help students accept the potential value of an M-learning environment as a way to increase the knowledge, skills, and information sharing for the target audience and, in fact, for all potential user communities. Therefore, the expected output of this research is to determine the target audience's characteristics through M-learning as an acceptable theoretical framework to enhance their learning opportunities. The main purpose for choosing the student segment is to search for new sources for exchanging knowledge outside the formal distance-learning platform of the universities. The universities' distance learning is sponsored by the KSA government and depends on the foundations of current education policies in Saudi Arabia. Therefore, M-learning applications could be helpful for students to increase their knowledge about the subjects related to universities' courses and many other learning aspects they are interested in.

The research question is, "From an end user's perspective, what are the requirements for the acceptance of mobile learning technology for smart devices at higher education institutions in Saudi Arabia?" The end users are students studying in universities or academic institutes. In addition, this research focuses on the technological and traditional requirements needed that are important to the target audience and that will increase the acceptance level. There are sub-questions that are helpful in conducting deeper research related to the main question, specifically: How do gender, experience, and willingness influence the acceptance and use of M-learning applications in KSA? The main question identifies the importance of requirements in Saudi society, which are helpful to design the requirements for this particular society. How can these requirements be explained to increase the level of acceptance of M-learning applications for students in Saudi universities? The sub-question focuses on the unique features related to societal characteristics such as those for gender, experience, and willingness, and their influence on the level of acceptance for using M-learning applications in university students in KSA.

The research structure is divided into several parts, which are the literature review, theoretical framework, research methodology, analysis of quantitative data, discussion of results, and the implications and recommendations.

A. M-learning Definition

From a student's perspective, the essence of M-learning is the potential to learn from any location at any time using personal mobile devices [6],[8], including the support of all mobile learning methods by means of mobile computing devices or other mobile learning environments [9]-[11]. This can facilitate the educational process through mobile devices or in places where only mobile devices are available [12]. Furthermore, M-learning is a subset of e-learning, which means learning at the right time and in the right place that enables access to educational materials and communication with colleagues or with teachers at other educational institutions [13],[14]. In short, M-learning can be summed up as providing learning opportunities through mobile and handheld devices using learning applications that are compatible with smart device operating systems (OS). In addition, M-learning it can be considered as learning within one's own context in time and space [15],[16]. It is the central affordance of mobile technologies to facilitate learning, which is the key factor in any definition of M-learning.

II. Literature Review

With the wide spread of the coronavirus pandemic, digital transformation has become one of the basic aspects of many ministries that seek to benefit from providing an appropriate environment in which to activate communication channels and spread knowledge. Therefore, in the field of M-learning, we look at the importance of learning via mobile phones and the importance of learning by mobile phone in higher education in general and in academic institutions, particularly King Abdul Aziz University in Saudi Arabia.

One of the main reasons for using smart devices in the online learning field is the improvement of technologies that have appeared over the past decade [17]. This progress and achievement has contributed to reducing costs of learning compared to using desktop computers, which has led a wide range of societies to replace desktop computers with tablets or smart devices, which has further led to a steady increase in mobile device users [18],[19]. Additionally, smart devices provide many beneficial features such as cloud storage, instant access to the Internet, and continuous communication, which will help to increase their penetration and the confidence of users in their use [20].

The number of Internet users through 3G and 4G has reached more than 70% of all internet users in general, as indicated by the Communications and Information Technology Commission (CITC) in KSA [19]. This use has increased dramatically with the repercussions of the coronavirus pandemic over the past year. Therefore, there is great opportunity to benefit from the digital transformation trend by supporting mobile learning applications that are compatible with the 2030 vision of Saudi societies that serve the aspirations of the government and the people simultaneously [2]. With the limitations in the specifications of mobile devices, many of the capabilities of smart devices remain untapped due to the relatively low level of technological awareness. Therefore, mobile devices can help easily target learners and spread the mobile learning approach more widely due to the limited options on the smart device screen, which helps to spread particular information smoothly and quickly [21],[22]. Furthermore, smart devices are widely used by residents of Saudi Arabia. Therefore, students can be involved in online learning activities, and female students can be included in learning activities without any societal restrictions.

A. M-learning's Importance for Higher Education

One of the significant advantages of e-learning is the availability of many useful functions and features related to online learning, such speed in interaction and sharing of information between learners. Smart devices do not require specialized skills to use and are lightweight, are easier to use than a keyboard and mouse, and take advantage of smart features such as Bluetooth and switching between the various levels of network coverage.

The study [23] indicated eight main activities that are beneficial in the M-learning field, especially in higher education. These are sending and receiving pictures, videos, or audio files; accessing the Internet; making voice and video calls; sending and receiving emails; organizing notes; reading books; sending and receiving SMS or MMS messages; and providing learning environments without time and place restrictions [23]. These eight categories can be the main requirements for increasing the level of acceptance in M-learning applications. Moreover, the study [24] suggested that the widespread use of mobile devices on campus helps to provide multiple learning approaches and greater availability and flexibility for students [24]. Thus, the importance of M-learning in higher education will be more attractive to potential students for several reasons. Smart devices are lighter and easier to hold [25]; smart devices are becoming more acceptable compared with desktops [26]; smart devices help to increase the benefits of M-learning in the future through designed features and are built with the goal of future technological development [27]; and smart devices make a collaborative learning environment because they have social applications that can be integrated and used to share information, such as learning and teaching materials, including formative means for assessments and feedback between students and their teachers [26],[28].

III. THEORETICAL FRAMEWORK

Many studies in the field of electronic systems acceptance and adoption give priority to the requirements of the target audience and could be beneficial in increasing the level of acceptance in the M-learning fields. Therefore, many studies have provided an evaluation of the Technology Acceptance Model (TAM) focus, E-learning Acceptance Model (ELAM), and UTAUT model. The previous models presented are fundamental models in user attention and attention behavior requirements fields. These theoretical frameworks are related to the actual use and user acceptance in various field of M-learning.

A. Unified Theory of Acceptance and use of Technology

This study focuses on identifying the requirements of M-learning applications by studying the differences between the characteristic demographic groups. This could help to reach the target segment smoothly and easily. Additionally, this study searches for new development aspects in M-learning, particularly in an in-depth manner through theoretical frameworks that focus on consumer behavior.

UTAUT was developed by [29] by combining the characteristics of many previous theoretical frameworks, for example TAM, ELAM, & DOI, which focus on product characteristics and the characteristics of the target segment (see Fig. 1). Furthermore, UTAUT focuses on studying the differences between the poles of the target segment by applying moderators to understand the characteristics of the target segment. The moderators that were applied in this study were gender - experience - voluntary, which represents a direct impact on the acceptance and approval of electronic systems [29]. A number of studies have also indicated they eliminated some moderators who did not show the common differences between both sides, whereas the study [25] indicated that the age vector has been dispensed of, as students at the university have a similar age group between 22 to 30 years. Therefore, this age group has great common characteristics, which means that their interests are common and similar to some extent.

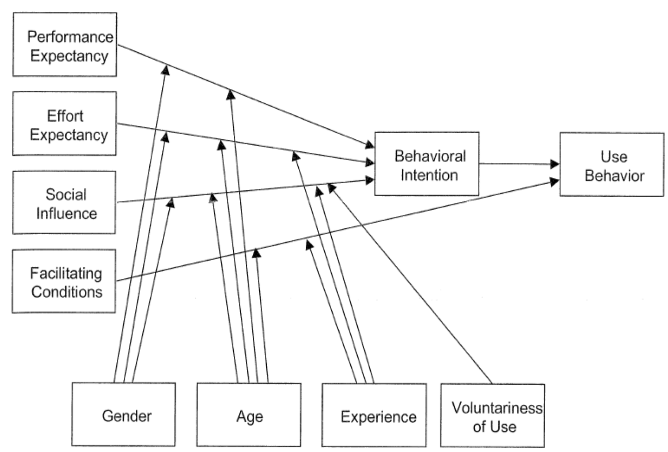

Fig. 1. The Unified Theory of Acceptance and use of Technology (UTAUT) Model.

As in study [20], it is important in bridging a gap in the analysis of gender and age as factors in M-learning technology acceptance. In particular, it was demonstrated that age differences moderate the impact of social influence and effort expectancy on M-learning using intention [20]. That is, for older mobile learners, a high effort expectancy and social influence may play a greater role in the acceptance of M-learning. Additionally, it was established that gender differences moderate the impact of self-management on learning and of social influence on M-learning acceptance. In particular, the study demonstrated that social influence is "…a stronger predictor of behavioural intention for men than for women" and "…self-management of learning influences behavioural intention more strongly for women than for men" [20]. The authors hypothesized that the lesser impact of social influence on women may possibly be explained by "…women being more unfamiliar with relatively advanced and complex M-learning technology, making them less likely to be influenced by their close friends in the early stages of M-learning development" [20]. Although this hypothesis seems plausible, one must take the cultural and national context of M-learning acceptance into account, as that study was conducted among Taiwanese students (330 respondents), who may differ from their Western peers.

The study [30] investigated the factors that influence students' intention to use M-learning. They tested and validated a model based on the UTAUT using a sample of students from the University of Technology Malaysia and analysed their quantitative data using the Statistical Package for the Social Sciences (SPSS). Briefly, [30] sought to derive a completely new model to explain or conceptualize M-learning. They began by arguing that M-learning has the potential to significantly enrich the education sector by putting educational content in the hands of all students without regard to their location. Their study concluded that M-learning is independent of the geographical location of both the learner and the instructor, and the former can learn continuously from any place. Thus, the authors set out to develop an integrated model that investigated the predictors of behavioral intention by university students to make use of M-learning. The main constructs used in this study were the self-management of learning and perceived usefulness. Both constructs have been deemed to be quite important determinants and predictors of behavior. Voluntariness of use has been added as a possible influencing factor on the behavioral intention to use M-learning [30].

The author in [25] also used UTAUT as a starting point from which to investigate the factors influencing M-learning acceptance among students. In particular, their study extended the UTAUT to include such variables as the quality of service, personal innovativeness, and the social influence of lecturers, which replaced the "facilitating conditions" factor of the initial UTAUT framework. To test the impact of these variables as well as the performance expectancy, effort expectancy, and lecturers' influence, [25] conducted a survey of 174 participants from Brunei University. They excluded the age and gender moderators of the UTAUT framework, as the majority of the sample selected was made up of males of roughly the same age. Students' prior experience with mobile technologies was selected as a key moderator in shaping their acceptance of M-learning. The study revealed that all factors and moderators had a significant impact on M-learning acceptance among Brunei University students. Effort expectancy was found to be the strongest predictor of students' intention to use M-learning [25]. However, the authors acknowledged that the validity of these findings was limited in several respects. The limitations were the non-inclusion of actual M-learning usage in the research process and the potential bias of the sampling method (non-inclusion of female and elderly participants) [25].

B. *Framework of M-learning Acceptance in Saudi Arabia*

Following the examples provided by the reviewed studies, the current research uses the UTAUT framework as a starting point for the M-learning acceptance analysis. This framework was positively assessed by various researchers and was determined to provide an integrated vision of technology acceptance by exploiting the cumulative insights of other widely used frameworks [22],[25]. In addition, the UTAUT framework includes various moderating variables, such as age and gender that are central to understanding how the various technology acceptance factors may translate into the intention to use a given technology.

Notwithstanding its benefits, however, the UTAUT framework would also benefit from being adjusted to the specific context of M-learning technologies. Various studies discussed in the literature review have used adaptations of the UTAUT model, which include additional factors as perceived playfulness, personal innovativeness, attainment value, quality of service, and self-management of learning and self-efficacy, among others [20],[25],[30],[31]-[33]. Proceeding from the critical analysis of these contributions offered in previous parts, the present study next advances an extended UTAUT framework that includes the following parameters. Each parameter is defined according to the objectives of this study.

- Performance Expectancy: Personal belief in whether a type of information technology can contribute to educational and professional performance and/or success.
- Effort Expectancy: Attitude towards the effort (knowledge, information, and time) required to master a particular information technology.
- Lecturers' Influence: The extent to which a person believes in the importance of others' attitudes towards his/her usage of a given technology.
- Personal Innovativeness: A measure of a person's creativity and willingness to try out any new kind of information technology.
- Application Quality: The quality is defined as value that promotes satisfaction, appropriate use, and ultimately positive effects on the individual or organization, and thus affects the application's capabilities and positive impact on user satisfaction. Fig. 2 outlines mobile application quality as a standalone factor in the model. It should be noted here that this term is made of three secondary factors that measure mobile application quality. As we wanted to measure individual responses to different aspects of quality, we chose the broad heading of mobile application quality and derived three measures from the systems quality literature discussed above.
- Behavioral Intention: One's behavioral disposition towards the use of an information technology as affected by the above factors.

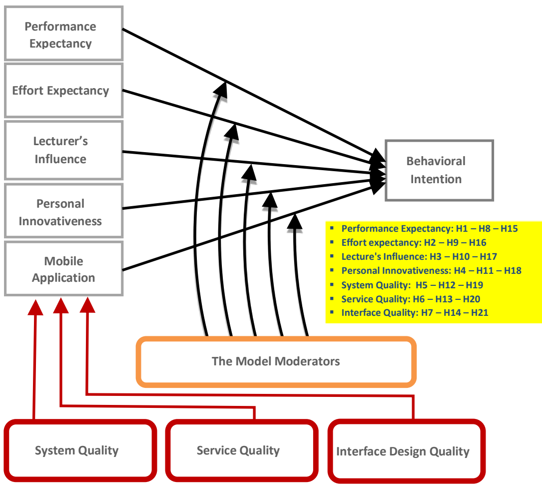

Fig. 2. The UTAUT (Modified) Model for Successful M-learning Application.

The proposed model utilizes three factors formulated in the initial UTAUT framework: effort expectancy, behavioral intention, and performance expectancy, as well as a modified "social influence" variable emphasizing the lecturers' influence in M-learning acceptance. Additionally, the framework extends the UTAUT to include personal innovativeness, which we consider to be important in understanding the M-learning context. In particular, personal innovativeness refers to an individual's willingness to acquire a creative experience with new information technology and also his or her ambition to develop personal creative capacities. The inclusion of personal innovativeness in the framework was motivated by the available evidence of its role in technology acceptance. In particular, the IDT framework suggests that innovative individuals are attracted to positive ideas and changes in technology and have higher levels of uncertainty tolerance [34]. Similarly, the [25] hypothesized that those students with high levels of personal innovativeness "would be more risk taking and have a more positive intention to use M-learning in their study" (p. 91). Also, mobile application quality concentrates on the quality assessment, which drives an increase in M-learning's acceptance level by students, as mentioned in detail in other previous parts of this research [7].

C. *The Theoretical Framework for this Study*

The proposed framework alters a set of UTAUT moderators by including gender, experience, and voluntary use. The age moderator was excluded because the proposed framework was tested on students from a similar age group from 19 and 25 years of age. The "voluntariness of use" moderator was divided into high and low levels of voluntariness, because the framework will be applied to regular M-learning courses at Saudi public universities but will be optional for online or on campus courses. The experience moderator was divided into two groups: a high level of experience (more than three years) and a low level of experience (three years or less). Similarly, the gender moderator was divided into two groups (female and male).

D. *Summary of the Research Model Measurements*

As presented in Section 2.7, the measurements used in this study are as follows:

Performance Expectancy (PE)

1. PE1: M-learning must be useful for the students' studies.
2. PE2: Using the M-learning applications should enable students to achieve learning tasks more quickly.
3. PE3: The use of M-learning in students' studies should increase their learning productivity.
4. PE4: M-learning applications should improve the users' collaboration with other classmates.
5. PE5: Using M-learning applications may gradually improve students' academic performance.
6. PE6: M-learning applications have clear educational goals.

Effort Expectancy (EE)

1. EE1: The M-learning application should be a flexible system that is easy to use.
2. EE2: Multimedia files should be provided to help users operate an M-learning system.
3. EE3: Clear and understandable instructions that let the user interact with M-learning application should be available.
4. EE4: The learning features of the M-learning applications should be easy to use.

Lecturer's Influence (LI)

1. LI1: I would use an M-learning application more if it were recommended by academic lecturers.
2. LI2: The M-learning application would be used if there were technical and academic support channels.

Personal Innovativeness (PInn)

1. PInn1: New M-learning applications and technology can be used without any reservations.
2. PInn2: It is important to provide the online educational resources for learning through smart devices.

Mobile Application Quality (MQ)

System Quality (MQSY)

1. MQSY1: Sufficient processing time is allowed to determine the actual courses or relevant material.
2. MQSY2: An advanced search mechanism in M-learning application is provided.
3. MQSY3: An adequate response time is allowed to download and launch the learning material on smartphone devices.
4. MQSY4: M-learning applications are able to support different languages.
5. MQSY5: Features that give M-learning applications the ability to support learners and tutors with different learning needs are offered.

6. MQSY6: The M-learning application has understandable language and is free from grammatical and syntactical errors.
7. MQSY7. The M-learning application is easy to find and install in any given device or system.

Service Quality (MQSE)

1. MQSE1: It is important that the content of the M-learning application systems is of high quality.
2. MQSE2: From a security perspective, the M-learning application systems are secure and keep confidential information in a safe place on the devices or in the application.
3. MQSE3: Providing a mechanism for updating information periodically is important.
4. MQSE4: Users can easily handle mobile devices and applications.

Interface Quality (MQIN)

1. MQIN1: The design of M-learning applications has to be in comfortable colors and fonts in the applications to be used.
2. MQIN2: A short menu and shortcut buttons should be included to allow users to easily access the application's main functions.
3. MQIN3: The functions required by individual users are provided.
4. MQIN4: M-learning applications should provide a drop-down menu for the most frequently used links.

Behavioral Intention (BI)

1. BI1: I use M-learning applications in my studies regularly.
2. BI2: I predict that I will use M-learning applications frequently.
3. BI3: I intend to increase my use of mobile services in the future.
4. BI4: I will enjoy using M-learning applications due to the appropriate features of this system.
5. BI5: I would recommend M-learning systems to others.

E. *Moderator Hypotheses*

The hypotheses related to the moderators measure the impact and the significant relationship of these moderators to the main constructs in the theoretical framework. A number of previous studies have indicated that individuals may have different characteristics because of their gender, experience, and level of voluntariness, which are the main moderators in UTAUT. The potential moderator of the age group was ignored because the sample is fairly homogenous in terms of age.

Some researchers have supported the concept that the expected effort will be a stronger determinant of women's individual intentions (e.g., [29], [35]). Also in study [20] and [36] noted the difference between women's behavioral intention in using M-learning and in using smart devices. Therefore, it is expected that students' acceptance of M-learning via smart devices depends on the ease of use as well as societal characteristics based on the differences in moderator variables, which are divided into three sections: gender, experience, and level of voluntariness. Thus, the five hypotheses will be applied separately with each moderator, as presented in Appendix B.

IV. Methodology

This study sample was of students from the universities who have an existing infrastructure of distance learning in Saudi universities. Before the COVID-19 pandemic, the main three universities that had a distance learning sector and relevant magnificent structure were King Abdul Aziz University (KAU), Saudi Electronic University (SEU), and King Faisal University (KFU). The students at these universities were helpful to the research team because of their previous experience [37]-[39]. The availability of distance learning facilities at these universities was helpful in determining the main requirements for M-learning applications that might be beneficial to increasing these applications' level of acceptance.

The questionnaire was distributed to undergraduate students based on email lists supplied by the Office of the Deans of Information Technology at these universities. Other potential participants were selected from social networks such as Twitter, Facebook, and LinkedIn using the "snowballing" technique. This technique is useful in Saudi Arabia because willingness to participate is likely to be increased by receiving the invitation from a known person. The following conditional questions were used to filter participants who qualified as the main targets of this study:

- Have you ever used E-learning systems before?
- Do you use smartphone devices?
- Are you a resident of Saudi Arabia?
- Are you a higher education student? If yes, please enter your age (…………) and your degree program (Diploma/Bachelor/Master/PhD).

Positive answers to all of these questions qualified the participant for the survey and vice versa.

A. *Data Analysis and Main Findings: Demographic Questions*

The demographic questions are categorized into three main groups. The first group determines the participants' basic characteristics (Q1 to Q3) and focuses on participants' genders, ages, and educational levels. The second group concentrates on the characteristics of learning through M-learning applications (Q4 to Q6) and focuses on their previous experience with smart devices, level of knowledge regarding E-learning, and frequency of learning via electronic channels. The last group of questions focuses on the characteristics of working on smart M-learning devices (Q7 to Q11). This last group includes a focus on the type of internet service provided, the type of operating system used, the type of smartphone used in general, and the type of learning process adopted in particular. Appendix 1 summarizes the result of the demographic survey.

The results showed many principal points required focus. With respect to the first group of questions, both the male and female participants (46.2% and 53.62%, respectively) generally exhibited interest in online learning through smartphone applications. This finding is attributed to the spread of these devices in the Arabic region, particularly in Saudi Arabia. The responses to the second question indicated that, among the university students expressing considerable interest in online learning, 54% were studying for undergraduate degree programs and 45.09% were studying under master's or doctorate degree programs. This question was also intended to determine whether the bachelor's, master's, and doctorate students were aged between 18 and 30.

The second group of demographic questions highlighted three ideas of interest related in this study. First, measuring previous knowledge of dealing with smartphone applications was facilitated by experience with electronic applications in general and M-learning in particular. The findings showed that 36.18% of the students used M-learning applications for more than five years and that 58.45% had experience of between one and four years. Among the participants, 75.51% stated they had a good level of experience with applications and learning through mobile applications, which helped determine the main acceptance requirements of the target segment. The responses to Q4 and Q5 indicated that the experience and knowledge of the target segment were fairly high (42.49% and 36.18%, respectively). The responses to Q6, which focused on the participants' willingness to use M-learning applications through smart devices and their levels of preparation for such endeavor, reflected equality among the participants (High - Low) in terms of willingness.

In the third group of demographic questions, the responses to Q7 showed that 62.71% of the participants used the Internet daily. These results reflected the variety of options available for internet access and indicated that a larger segment of the sample preferred postpaid and DSL services, given the appeal of these offerings to the youth in Saudi Arabia. As shown in the responses to Q9, 3G users accounted for over 59.74% of the sample, whereas the 4G users did not exceed 25.23%, showing that fewer areas in Saudi cities and in the countryside are ready to provide 4G services by ISPs. Among the participants, 13.54% or less accessed Wi-Fi services. The responses to Q10 showed that 69.2% of the respondents used smartphones to connect to the Internet, supporting the importance of developing and implementing innovations that are compatible with M-learning smartphone applications. As shown in the responses to Q11, the participants regarded smartphones, iPads and tablets, ultra-laptops, and palmtop PCs as the most important devices used in online learning, with percentages being 92.95%, 67.72%, 79.41%, and 42.12%, respectively.

B. *Testing the Moderator Hypotheses*

A number of previous studies have delved into theoretical acceptance models, such as the UTAUT dealing with electronic system acceptance and consumer behavior, which is generally one of the fundamental aspects of increasing levels of technological acceptance [29]. One of the main reasons for establishing moderators in the UTAUT model is the need to probe into the influence of moderators on the acceptance and use of electronic systems and the effects of traditional communities on such reception and adoption. According to study [25], different moderators influence the acceptance of technological systems. The use of moderators is an important approach to dealing with theoretical models that are grounded in the unique characteristics of specific communities.

In the relevant previous study, the basic analytical requirements, which centered on the reliability and stability of the theoretical framework were completed. The current study, the acceptance of M-learning through smartphones among Saudi higher education students, was illuminated on the basis of three moderators: gender, level of experience, and extent of willingness. The data was divided into two groups for each moderator. That is, gender was classified into male and female; level of experience was divided into high, which corresponds to more than three years, and low, which is equivalent to less than three years; and the extent of willingness was divided into high and low levels. The number of moderators by group is presented in Table I.

TABLE I. NUMBER OF RESEARCH MODERATORS BY GROUP

Moderator	**Group Level**	**Sample Distribution by Moderator Group**	
		N	**P**
Gender	**Male**	250	46.38%
	Female	289	53.62%
Experience	**High**	254	47.12%
	Low	285	52.88%
Voluntariness of Use	**High**	295	54.74%
	Low	244	45.27%

The purposes of these moderators were to identify the differences among the participants and determine the characteristics of acceptance of M-learning applications on the basis of the acceptance requirements identified in this study. Correlation coefficients, critical ratios, and p-values were used for each construct to pinpoint the differences in relationships between the constructs. The chi square ($\chi 2$) and degree of freedom (df) were likewise necessary in calculating the differences among the groups of moderators. Computing the path of differences among the moderator groups necessitated calculating all the 21 hypothesized paths (gender - experience - willingness) to determine any significant path in the model. Then, insignificant paths were removed, and effective paths were retained in the moderator groups. Subsequently, the $\chi 2$ and df of the constrained and unconstrained models were calculated to determine the level of change in the groups' model Δ $(df = 1)$ and to identify significant paths [40].

The grouping of the participants was determined according to the division of the theoretical model's moderators. The males accounted for 46.38% of the sample, and the females accounted for 53.62% (see Table II). The relationships between the constructs on the basis of gender were PE → BI - EE → BI - LI → BI - PInn → BI - MQSY → BI - MQSE → BI - MQIN → BI, all of which were significant, except for LI → BI - PInn → BI. This means that the gender moderator reflected high interest among Saudi university students in learning through M-learning applications. The constrained and unconstrained tests indicated a significant difference between the males and females and significant relationships between BI and PE, EE, MQSY, MQSE, and MQIN in both the male and female groups.

Experience was treated as a principal moderator because it is a key driver of the acceptance and use of M-learning applications. Among the participants, 47.12% and 52.88% had high and low experience with M-learning applications, respectively. The relationships reflected based on the experience moderator were similar to those demonstrated based on the gender moderator. LI → BI and PInn → BI had no significant relationship with respect to experience, but the other hypothesized relationships were significant among the respondents with high and low experience.

TABLE II. SUMMARY OF PATH COEFFICIENTS, T-VALUES AND P-VALUES FOR GENDER AND EXPERIENCE MODERATORS

Gender		Male, N= 250, 46.38%			Female, N= 289, 53.62%			Constrained model		Unconstrained model		Δ (df =1)	Testing result
		Estimate	t-value	P	Estimate	t-value	P	$\chi2$	df	$\chi2$	df		
H1	PE → BI	0.573	5.829	***	0.629	6.498	***	3455.3	57	3450.9	51	4.4	Supported
H2	EE → BI	0.626	4.998	***	0.701	6.209	***	3227.8	55	3221.2	50	6.6	Supported

Willingness to learn through M-learning applications is an equally important aspect of technological acceptance. The use of learning techniques to enrich and spread education is paramount, because the users have all the fundamental requirements that they need to learn through M-learning applications. This is expected to increase willingness and interesting opportunities to learn through educational applications. Out of the participants, 54.74% and 45.27% exhibited high and low willingness, respectively. The relationships PE → BI, EE → BI and LI → BI were nonsignificant with respect to both high and low willingness, but the other hypothesized relationships were significant (see Table II). The relationship PInn → BI was insignificant under the $\Delta\, \boldsymbol{df}$ computation; thus, this relationship was eliminated because of its insignificance. The relationship MQSY → BI - MQSE → BI - MQIN → BI was significant for those with both high and low willingness. As shown in Table II, most of the hypothesized paths for the gender, experience, and willingness moderators were important and significant with respect to the sample. MQSY, MQSE, and MQIN were also significant under both divisions of each of the three moderators.

V. Discussion

There are two main questions associated with the current research. Therefore, M-learning applications can be implemented in accordance with various supportive functions and user features in KSA society, and the main difference between the two sides of the target audience moderators can be determined.

How can M-learning applications be appropriately implemented in accordance with the technical support, awareness and knowledge, and tools and features connection functions in KSA?

This section clarifies and combines the main M-learning requirements that are important for the target audience of this study. The questions presented for some these requirements were mentioned in the open-ended questions in the survey. These requirements are presented in detail in Fig. 3, which focuses on the various difficulties encountered by users.

The requirements were categorized into three groups. The first is technical support, which pertains to the development of tools that support users and the manner in which appropriate solutions to problems are formulated. The second is awareness and knowledge, which centers on the presentation of information and features that users need to motivate their engagement with M-learning applications. The third concerns the tools and features connection, which revolves around the tools, capabilities, and features that hasten the evolution of the M-learning process and the full connection of applications with users. The first and second groups are critical in increasing M-learning acceptance and use, and the third attaches credibility to such applications and ensures their availability for use by the target segments. Although the third group is regarded only as moderately valuable, it is still important to provide a way to link consumers and M-learning applications. The viewpoints shared by the participants were consolidated to enable the management of the requirements related to each group. The consolidation resulted in eight elements, as listed in Table III.

As previously stated, the open-ended questions were intended to gain a broad picture of the developmental requirements for M-learning applications from the target audience. Identifying issues and proposing appropriate solutions based on students' perspectives may determine what application features are suitable for this population. The participants proposed several services for supporting and connecting content in M-learning applications for instructors, developers, and students (as presented in Fig. 3).

TABLE III. M-Learning Application Requirements from Both the Students' and Developers' Perspectives

No.	Requirements	Related Group
1.	Provide online support services for operating and activating M-learning applications through discussions with an experienced team.	Technical Support
2.	Provide basic information that a user needs to run an application (instructions).	Awareness & Knowledge
3.	Provide basic information that explains the advantages and features of M-learning applications.	
4.	Implement regulations and policies for education in general and M-learning in particular.	
5.	Clarify rights and responsibilities, including those related to safety and privacy, in dealing with M-learning applications.	
6.	Provide information and explanations that increase the acceptance of M-learning applications and the confidence in using them.	
7.	Provide data storage methods, whether these are in-device features or external repositories, such as servers or cloud platforms.	Tools & Features Connection
8.	Ensure the availability and reliability of an electronic presence across different channels of communication for the servicing of E-learning and M-learning needs.	

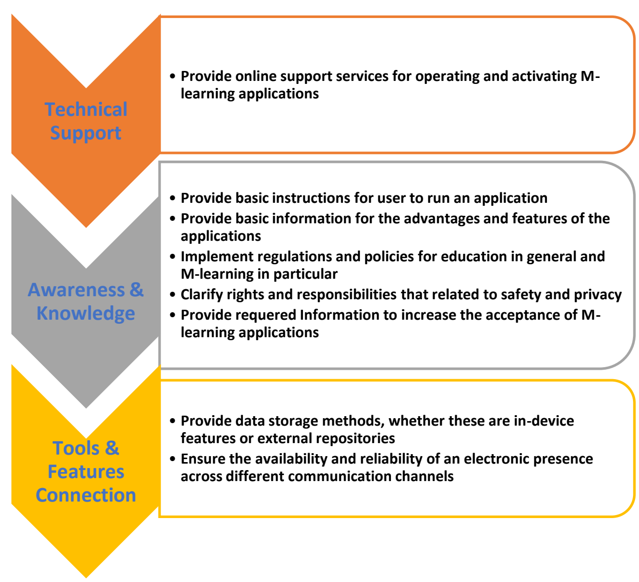

Fig. 3. M-Learning Application Requirements from both the Students' and Developers' Perspectives.

How do gender, experience, and willingness influence the acceptance and use of M-learning applications in KSA?

A. *Effects of Gender*

The gender moderator significantly affects the relationship between BI and the other constructs (PE, EE, MQSY, MQSE, MQIN) and plays a key role in moderating M-learning acceptance in relation to the aforementioned constructs. The results on the hypotheses related to gender are positive, confirming that females are more strongly affected by M-learning applications than are males, but the first test on the hypotheses generated empirical evidence that both genders have a strong relationship with the use of M-learning applications (see Table II). The respondents specified the effort that they expect to exert in dealing with various learning stages and expressed the belief that they can accomplish their online learning missions through M-learning applications.

This accomplishment can be included as a core expectation from users given that online learning through smart devices reduces the effort and time required to complete learning tasks and reflects academic performance as accurately as possible [36],[41]. Effort is a concern of the target users, and the statistical results indicated that expected effort is significantly associated with both genders. Both the male and female participants recognized the importance of expected effort in relation to many different aspects of online learning. Examples of these aspects are high flexibility in learning through M-learning applications, the availability of multimedia and assistive instructions, and the highlighting of features that help elevate learning on these applications [42]. As expected effort facilitates a thorough engagement with applications, providing online learning resources and other features and tools may increase such engagement, acceptance, and reuse in various disciplines and for various purposes [42],[43].

Generally, both genders moderated the relationship between LI and PInn and the relationship between LI and BI, and no difference existed between males and females as to this moderation [44]. The aforementioned relationships are therefore of a normal nature.

Quality requirements are viewed as an important component because MQ is significantly related to both genders in terms of the public relations ideas expressed in H5, H6, and H7. However, this level of importance is greater among women than men in the gender moderator tests, supporting the earlier consideration of providing equal educational opportunities for women in Saudi Arabia [36],[45]. Saudi family orientations and community traditions dictate that women stay at home rather than venture outside, unlike Western women, and Saudi females serve inside the houses more often than do Saudi males. Gender segregation in formal education also denies women many educational opportunities [3]. The results on gender pointed to the need for fairness in education for Saudi women—a goal that can be achieved through the provision of education via various electronic services, including M-learning [badwelan].

Females ascribed significant importance to using the M-learning applications compared with males, as evidenced by the difference between the constrained and unconstrained model tests (see Table II). That is, it is more important to determine women's requirements than those of men because, despite the value of establishing a framework commensurate with the desires of both genders, females are the main target group for the acceptance and use of M-learning applications [36],[45]. Nevertheless, these results should encourage interested private sector companies in Saudi Arabia to continue developing and designing features that fit the requirements of both men and women as the findings on gender as a moderator confirmed that both groups strongly wish to accept and use M-learning applications.

B. *Effects of Experience*

As stated in [29], the experiential impact of electronic applications is one of the most important moderators of BI. In the current research, the experience of dealing with smart device applications is an equally vital mediator of the relationships between PE, EE, LI, PInn, MQSY, MQSE, and MQIN as the core constructs and BI as the target construct (see Table II). The experience moderator measures the experience that builds upon high and frequent demand for the use of an information space through smart devices and internet connectivity [46]. The results indicated that actual and high access to the Internet through smart devices, laptops, or desktops markedly increases the usage of smart device applications [19]. High engagement with the Internet means users would be considerably proficient in identifying the features that would elevate their acceptance of M-learning applications [29],[47]. The findings also demonstrated that previous experience helps attract highly proficient internet users. PE, EE, MQSY, MQSE, and MQIN thus have a significant relationship with the behavioral intention to use easy and/or complex M-learning applications, which explains why more comprehensive encounters with such innovations increases their acceptance.

The results regarding H8, H9, H12, H13, and H14 support the principal function of internet usage in increased acceptance. Many examples in the literature on the smartphone context corroborated the proposition that dealing with smart device applications helps augment the chances that they will be adopted by university students. The results of the present research are therefore consistent with those of a number of previous studies, including [29],[34],[35].

C. *Effects of Willingness*

Willingness was another key moderator used to measure the acceptance and use of smart device applications. Voluntary usage, instead of compulsory adoption, facilitates the patronage of technology and many different electronic systems [28]. Willingness can be employed to measure user awareness of how to deal with M-learning applications, what their advantages are and how to obtain information that can persuade users of the benefits of their use [2]. The results on willingness showed that this moderator is significantly related to system, service, and interface quality, as proposed in H19, H20, and H21. Quality exerts a positive impact on increasing willingness and, hence, the BI and actual use by target users in the future [26],[48]. The availability of various quality features elevates willingness, as suggested in the positive results for the aforementioned hypotheses [49]. The difference between increases in users' engagement with educational applications may be attributed to the availability of these quality features. The statistical findings are consistent with those of previous studies (e.g., [2],[25],[28],[50]).

VI. Implications

Apart from the UTAUT framework-based identification of requirements, other research questions contributed to pinpointing many other needs related to increasing awareness and knowledge of the use of M-learning applications. There are some implications related to this study that are summarized in the following parts.

1) Technical support for learning applications: The study discovered a weakness in the technical support for M-learning applications, making this one of the main obstacles to their acceptance and adoption [36],[45],[51]. The most reliable way to deal with technical service problems is to effectively provide technical support. Even though technical support failures may be minor, these may rapidly reduce the appeal of electronic systems to target users [56]. Therefore, a highly qualified technical support team should be tasked with quickly detecting and responding to technical problems or user requests. Responses to target users' queries should be highly efficient, and support teams should be able to demonstrate how online learning tools are used.

"Technical support" should also be defined to determine what functions can be covered under this term [36], [51]. The author in [52] described technical support as the "information that helps users of computer solutions to be outstanding, whether in hardware or software." Technical support can thus mean a help desk, an information center, an online communication channel, a telephone call system, an email response system, and other similar facilities. The study [36] emphasized that technical support requirements are key points that may increase the acceptance of M-learning applications in smartphones.

2) Lack of awareness of e-government services: The study also identified a lack of awareness and information about online learning services, and this requirement ranks second to technical support as a fundamental and important component [53]. The availability of comprehensive information may increase awareness of M-learning applications and their usage [36]. The information needed by target users differs depending on the traditions and abilities of communities. The information required by Saudi university students to raise their awareness and knowledge of M-learning centers on five key aspects.

Firstly, this population requires basic information on operating online learning applications. Secondly, they need information that improves their understanding of the features and services available in M-learning applications. Thirdly, they require accurate policies and regulations for learning and E-learning. Fourthly, the rights and responsibilities of users and developers of M-learning applications should be clarified and concentrate on safety and privacy. Finally, they need clarifications that help them run M-learning applications more professionally and thereby increase their acceptance and confidence in dealing with these technologies [45],[51].

Providing the many types of information users need for understandability increases the possibility of use and the BI to engage with these online learning applications in the student communities of Saudi universities [53]. In addition, students can be persuaded to use M-learning applications through promotions and advertisements in social networking sites, which are frequently visited by university students, or through discount cards for subscriptions to the educational materials available on smartphone applications [2]. Previous studies have demonstrated that there are generally many ways to raise awareness of any new technology or service and support its use [2],[43],[54].

3) Availability and reliability of internet connection: The availability of high-speed internet services may inspire community acceptance and usage of M-learning. High-speed internet enables users to download basic information and resources via applications, making such connectivity a feature that most reliably motivates engagement with M-learning applications [55]. Naturally, slow internet speeds negatively affect the operation of electronic applications and reduce users' motivation to use M-learning technologies [47].

One of the key reasons for poor connectivity in Saudi Arabia is the implementation of filters and firewalls for secure internet access; this regulation is overseen by the Communications and Information Technology Commission, and it means that access to information resources is slower in Saudi Arabia than in countries that do not have such a filter system for internet resources [56].

High-speed connectivity increases the motivation of target users to try out the various features of M-learning applications and reduces the effort needed to engage with electronic systems or the time spent accessing informational resources [47]. Connecting to the Internet can also shorten certain tasks that usually take considerable effort and time through traditional learning methods (e.g., visiting universities or academic centers in person to obtain information versus acquiring the same information by navigating the resources included in online learning applications).

VII. Conclusion

This study focused on determining the target audience's main characteristics that could be helpful in activating a digital transformation through M-learning methods in smart phones. This approach defined the target segment in Saudi universities, a large segment, for using smart phones in Saudi Arabia, along with most internet users through smart phones. Therefore, automation services in M-learning represent one of the most important means supporting the transfer and dissemination of knowledge. This study focused on identifying the number of basic requirements related to different groups of moderators (Technical Support - Awareness & Knowledge - Tools & Features of Connection). One of the main benefits for studying the target audience characteristics is spreading the M-learning approach through smart devices in higher education institutions and universities in Saudi Arabia to support the Saudi 2030 vision through applying the digital transformation solution in various aspects of life. The quantitative method was used to determine these characteristics, which are expected to have the greatest effort throughout the coronavirus pandemic, as this approach is expected to help to with adoption of M-learning applications by the target audience according to the number of technical and design requirements contained in this study.

Appendix B: The Hypotheses of Moderators

A. The Hypotheses of Gender Moderator

H1. Increased performance expectancy will have a positive effect on the behavioural intention to use M-learning for female more than for male users of mobile devices.
H2. Reduced effort expectancy will have a positive effect on the behavioural intention to use M-learning for female more than for male mobile device users.
H3. The lecturer's influence has a positive or negative influence depending on whether they support and understand M-learning for female more than for male users of mobile devices.
H4. Increased personal innovativeness has a positive effect on the behavioural intention to use M-learning for female more than for male users of mobile devices.
H5. Increased 'mobile application system quality' has a positive influence on behavioural intention to use M-learning more positively for female than for male users of mobile devices.
H6. Increased 'mobile application service quality' has a positive influence on behavioural intention to use M-learning more positively for female than for male users of mobile devices.
H7. Increased 'mobile application interface quality' has a positive influence on behavioural intention to use M-learning more positively for female than for male users of mobile devices.

B. The Hypotheses of Experience Moderator

H8. Increased performance expectancy will have a positive effect on the behavioural intention to use M-learning for more experienced users of mobile devices than for less experienced users.
H9. Reduced effort expectancy will have a positive effect on the behavioural intention to use M-learning for more experienced users of mobile devices than for less experienced users.
H10. The lecturer's influence has a positive or negative influence depending on whether they support and understand M-learning for more experienced users of mobile devices than for less experienced users.
H11. Increased personal innovativeness has a positive effect on the behavioural intention to use M-learning more positively for more experienced users of mobile devices than for less experienced users.
H12. Increased 'mobile application system quality' has a positive influence on behavioural intention to use M-learning for more experienced users of mobile devices than for less experienced users.
H13. Increased 'mobile application service quality' has a positive influence on behavioural intention to use M-learning for more experienced users of mobile devices than for less experienced users.
H14. Increased 'mobile application interface quality' has a positive influence on behavioural intention to use M-learning for more experienced users of mobile devices than for less experienced users.

C. The Hypotheses of Voluntariness of Use Moderator

H15. Increased performance expectancy will have a positive effect on the behavioural intention to use M-learning more positively in voluntary users of mobile devices than it does in less voluntary users.
H16. Reduced effort expectancy will have a positive effect on the behavioural intention to use M-learning more positively in voluntary users of mobile devices than in less voluntary users.
H17. The lecturer's influence has a positive or negative influence depending on whether they support and understand M-learning more positively in voluntary users of mobile devices than in less voluntary users.
H18. Increased personal innovativeness has a positive effect on the behavioural intention to use M-learning more positively in voluntary users of mobile devices than in less voluntary users.
H19. Increased 'mobile application system quality' has a positive influence on behavioural intention to use M-learning more positively in voluntary users of mobile devices than in less voluntary users.
H20. Increased 'mobile application service quality' has a positive influence on behavioural intention to use M-learning more positively in voluntary users of mobile devices than in less voluntary users.
H21. Increased 'mobile application interface quality' has a positive influence on behavioural intention to use M-learning more positively in voluntary users of mobile devices than in less voluntary users.

Online Discussion Support System with Facilitation Function

***Abstract*—In this paper, we present a discussion board system (DBS) with a facilitator function that we developed for the purpose of facilitating discussions that require decision-making that incorporates diverse values and opinions. Its function is to constantly extract nouns from the utterances of discussion participants and display them on the DBS on each participant's personal computer. Items to be decided in the discussion are displayed together with a frame (called a "box"), and each participant puts the displayed keywords in the box according to their own opinions and intentions. No other participant can see what the individual is doing. The color of any keyword that all participants put in the same box changes to green. Furthermore, comments are automatically presented based on the time when each participant last spoke and the time when the keyword was moved. This is intended to encourage participants who appear to be less involved to join the discussion. Experiments with the DBS suggested that it might be possible to capture the will of participants who disagree but do not speak. However, it was also deemed necessary to post comments that encourage participants to express their intentions independently, and to have a mechanism that can link the motivated manifestation of intentions to appropriate actions.**

***Keywords*—Discussion board system; decision-making; facilitation function; diverse values and opinions**

I. Introduction

In recent years, the realization of "diversity management" has become an issue for Japanese companies. The diverse perspectives shared by employees of different genders, nationalities, and backgrounds are thought to enhance corporate competitiveness. However, discussions that touch upon diverse values are easily confused, and participants in the discussions can easily lose sight of their goals and the current situation. Participants may forget what they have and have not yet discussed, or may not be able to reach a conclusion in time due to conversation loops, derailments, and incorrect time allocation. Furthermore, in situations where the hierarchical relationships [1] among individuals is clear, such as meetings within a company, the "peer pressure" [2] [3] that must be synchronized with the remarks of superiors hinders participation. This is also a factor that causes participants to hesitate to express various perspectives. The existence of a facilitator [3] is thought to have a certain effect on reducing the peer pressure among participants and appropriately advancing discussions based on various viewpoints. Mori [3] organizes the roles of facilitators into four tasks. The first is "designing the process." The facilitator clearly sets the goals of the discussion [4] based on the objectives and deliverables and logically and psychologically designs the optimal process toward the goals. The second is "controlling the process." The facilitator controls the process of discussion and prevents emotional conflicts from interfering with the discussion. While maintaining neutrality, the facilitator encourages other participants to speak so that a small number of hardline opinions and peer pressure do not lead to a conclusion. The facilitator assumes a referee position for the participants and provides a psychological safety zone for them by approving and encouraging the expression of different opinions as a necessary act. The third is to "organize and inspire discussions." The facilitator inspires participation in the discussion by asking the participants questions, summarizing and paraphrasing the opinions they present, and organizing the story so that the overall understanding is deepened. The fourth is to "form an agreement." The facilitator elicits opinions from all participants as much as possible and gives a sense of conviction that the discussion was properly and adequately conducted. Identifying the right time, the facilitator encourages participants to reach conclusions and encourage consensus building.

Despite their benefits, competent facilitators are not always present in discussions and cannot play these roles. Therefore, based on the role of these facilitators, we aimed to develop an artificial intelligence (AI) facilitator capable of autonomously facilitating discussions. In this paper, as the first step toward the AI facilitator, we developed a discussion board system (DBS) that realizes some of the facilitator's functions [5][6]. We verify whether the support of the DBS system is effective in reducing peer pressure and providing a psychological safety zone for group discussions. This study does not cover discussions aimed at generating many ideas, such as brainstorming sessions. Similarly, it excludes guided discussions where it is best for a highly specialized person to take a leadership role and decide everything. What we envision is a discussion aimed at forming a collective consensus on a given set of issues and drawing conclusions after considering various opinions.

Related research will be described in the next section. Section III gives an overview of the DBS. Section IV describes the system design based on the facilitator function [3]. In Section V, we outline our experiment with the discussion using DBS ver. 1.0, which implements facilitator Functions 1 and 2. We analyze the differences between the conclusions that the participants perceive as "agreed" and the opinions left on each participant's DBS [5]. In Section VI, we outline our experiment with discussions using DBS ver. 2.0, which implements facilitator Functions 1–4. Analyses were conducted concerning whether the comments displayed by the DBS were useful for facilitating discussions. Furthermore, by considering the intentions of the participants in the discussion from the viewpoint of peer pressure, we consider the role required for AI facilitators in the future. The paper is summarized in Section VII.

II. Related Research

To date, many discussion support systems have shared their screens among all participants. The MERMAID provides a way for people remote from one another to share information in multimedia forms such as video images, voice, text, graphics, still images, and hand-drawn figures [7]. However, to maintain the consistency of the displayed contents among the participants, one must acquire the right to operate the shared screen. In recent years, it has become possible for multiple people to share a document, for example "Google docs," retrieve and quote discussions from previous meetings [8], evaluate participants' contributions to discussions and visualize these views to the participants [9], and indicate participants' degree of self-confidence using a six-point scale in order to generate clues regarding the possibilities for compromise [10]. In the system proposed in this paper, to secure a psychological safety zone, the space for displaying the participants' opinions is not disclosed to other participants during the discussion.

There are some existing systems for new idea-generation support. Gungen [11] was developed to perform the distributed KJ method. Combinator [12] supports a designer's new idea creation by combining familiar ideas. Nishimoto [13] developed a system that structurally visualizes keywords automatically extracted from the comments of each participant during a discussion based on a word's appearance rate and reproduction efficiency. Idea expander [14] and SWISS [15] are idea-generation support systems that present images searched for based on the participants' text chats [14] or utterances [15]. In contrast, this paper focuses on discussions aimed at forming group consensus on tasks and drawing conclusions.

In the systems for group decision-making meetings, INGA [16] is a system that automatically searches for and presents electronic data from meeting materials that are highly relevant to discussions based on keywords obtained from voice input. Ohira [17] aimed to evaluate participants' ability to discuss and improve motivation through a form of discussion called "gamification discussion." Shimizu [18] presented a system in which participants can vote on ideas during a discussion. Discussion Media [19] is a system in which each participant can arbitrarily input their stance regarding the presentation and any arguments with other participants using a button device. The system proposed in this paper also has a function for categorizing keywords into boxes, but these are not published to other participants during the discussion.

COLLAGREE [20] is an open web-based forum system that has facilitator support functions and was deployed during an internet-based town meeting in Nagoya, Japan as a city project led by its mayor. D-Agree [21] analyzes the words written on a bulletin board and automatically facilitates the discussion. The system proposed in this paper is intended for discussions among small face-to-face groups aimed at decision-making. The system also has a facilitation function that presents comments based on the time while each participant is silent and/or a history of moving words in a display created by the participant.

III. Discussion Board System

We developed DBS ver. 1.0 [5] (see Fig. 1) and ver. 2.0 (see Fig. 2) to promote good discussions. A "good discussion" in this study is defined as below:

- In the shortest time, draw conclusions related to all items that need to be considered.
- The consensus of more attendees is a better decision than one with a lower level of consensus.

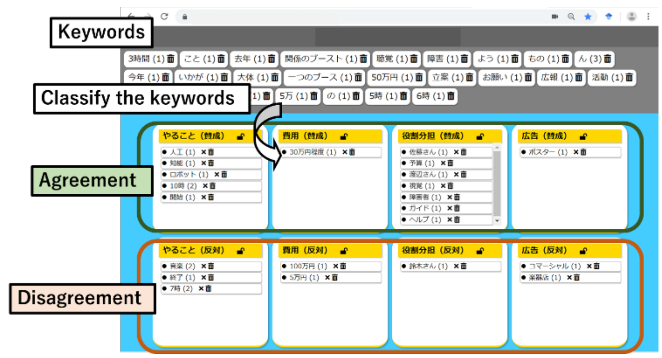

Fig. 1. DBS ver. 1.0.

Fig. 2. DBS ver. 2.0.

All attendees participate in the discussion. Even if they make no remarks, they will think of possible solutions to the problem and will ultimately be called upon to express their willingness / agreement with the decisions made.

A. Overview

The DBS displays the "boxes" of the categories to be decided in the discussion on each participant's screen. For example, in the case of the theme of "a gift," the terms "flowers," "fruits," "handkerchiefs," "accessories," etc. are displayed as category boxes on the DBS display.

The DBS uses speech recognition to extract nouns (hereinafter referred to as "keywords") from discussions and display them. Each participant can express their opinion concerning whether or not words are appropriate for the category by putting the keywords in the box using the “drag and drop” operation according to their opinion and intention, because each participant's screen is intentionally made invisible to other participants. For example, keywords such as apples and grapes are lined up on the display. If one participant puts “apples” in the “fruit” box, he is indicating the decision “if the gift is a fruit, apples are good.”

The DBS also presents boosting comments on the screen and encourages participants who have not spoken or manipulated the screen for a certain period of time to participate in the discussion with comments.

After the discussion is over, the number of keywords in the box is totaled. It is also possible to share the results among participants without revealing information about who moved which keyword to the box and when.

If all participants put the same keyword in one category box, the DBS will change the color of that word to green. Participants then know that other participants entered the same keyword in the category box.

The following sections detail the four functions of the facilitator, as realized by the DBS.

B. Function 1: Designing the Process

The DBS clarifies items to be discussed (goals), what has already been discussed, and what has not yet been discussed (current position). This feature helps participants reach the necessary and sufficient conclusions in time.

- Set a box on the terminal screen for each item to be decided (implemented in DBS ver. 1.0, 2.0).
- Show how many minutes are left to reach a conclusion (implemented in DBS ver. 2.0).
- Show the status of the box by commenting to all participants (implemented in DBS ver. 2.0).

Fig. 3 shows an algorithm for displaying comments (A) to (C). It is executed at regular intervals (every 8 minutes in Experiment 2) and displayed to all participants at the same time.

(A) It seems that “x (item name of the corresponding box)” is not filled yet.

(B) “x” seems to vary.

(C) It seems that “x” is just around the corner.

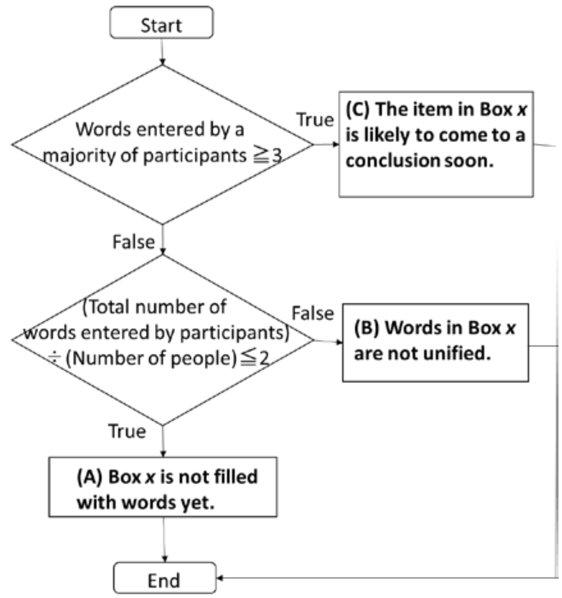

Fig. 3. An Algorithm for Displaying Comments A-C.

C. Function 2: Controlling the Process

The DBS provides a psychological safety zone to control the process of discussion and prevent emotional conflicts from interfering with it. Each participant moves the keywords to the box according to their own opinion and intention, without being seen by others. It is hoped that the true intentions of each participant will therefore be expressed. After the discussion of each item is concluded, participants press the “lock” button to indicate the discussion’s end. After the discussion is over, the system can aggregate the keywords in the boxes and share them among the participants. At that time, it is not clear who moved each keyword into the box. Therefore, the box area is a “semi-personal space” that can be shared by all participants while they easily express their personal opinions.

D. Function 3: Organize and Inspire Discussion

The DBS will display comments to encourage participants who have stopped speaking or moving keywords for a while to stimulate discussion. This function was implemented in DBS ver. 2.0. Fig. 4 shows an algorithm that is executed at regular intervals (every 8 minutes in Experiment 2) among the comments displayed to the relevant participants.

(D) (If there is only one participant who puts a keyword different from the others in the box) You put “keyword y” in “box x.” Would you like to give us your opinion on “y”?

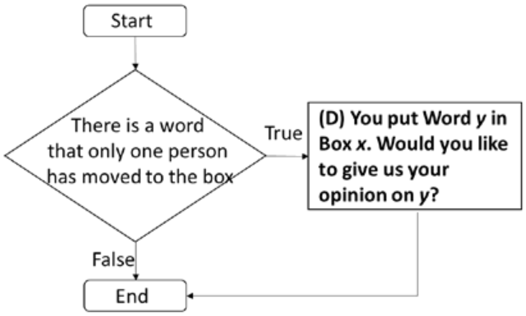

Fig. 4. An Algorithm for Displaying Comments D.

Fig. 5 shows an algorithm that is always running while the system is running and is presented to the relevant participants.

(E) You don't seem to have spoken for a while. Would you like to give us an opinion?

(F) You don't seem to have been operating for a while. Could you give me more ideas?

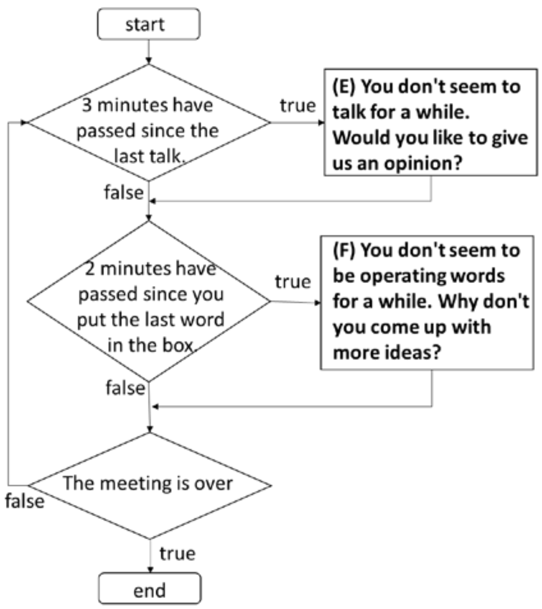

Fig. 5. An Algorithm for Displaying Comments E and F.

E. Function 4: Form an Agreement

When all participants enter the same keyword in the same box, the keyword changes to green (call this function a “deliverable display”) (implemented in DBS ver. 2.0). By turning green, participants know that all participants are likely to agree, and it is an opportunity to settle the discussion.

The “parking area” is a place to temporarily store keywords for which it is difficult to decide whether or not to put into a box (implemented in DBS ver. 2.0). The words in the parking area are disclosed to other participants. This function avoids the DBS treating words with the same intention as different words. For example, “Venice” and “Venetia” have exactly the same meaning, but they are recognized as different words in the DBS. However, if “Venice” is in the parking area, most of the participants will move “Venice,” not “Venetia,” into the box, when they agree with this word. This function is also useful for the deliverable display function.

F. Extracting and Displaying Keywords

Each participant’s voice is recognized by each personal computer, and the extracted keywords of all participants are displayed on all terminals at almost the same time [5][6]. As shown in Fig. 6, utterances are always recognized by the speech recognition capability of the “Web Speech API.” The recognized characters are parsed using the Japanese morphological analysis engine “kuromoji.js” or the named entity extraction API (selectable). “Keywords” are extracted from the word group after the parsing is completed. Suffixes and particles to be adnominal are grouped as the same keyword. Keywords are sent to the server and registered.

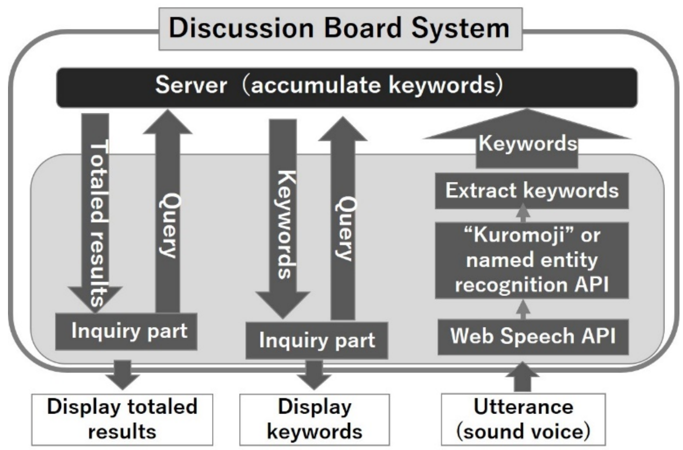

Fig. 6. System Flow.

At the same time that the voice recognition starts, the application inquires at regular intervals whether a new keyword is registered on the server. Keywords extracted from the utterances of all participants are targeted. If there is a new keyword, it will be acquired and displayed on the screen. The time of the inquiry server is recorded, and then only the keywords registered after the recorded time are acquired and the last inquiry time is updated. The inquiry interval can easily be changed by setting the DBS, and four types, of 0.5/1/2/3 seconds, are prepared, where the initial state is 1 second. In other words, the maximum set inquiry interval is delayed from the time the keyword is registered until the screen is displayed.

IV. Experiment 1

A. Purpose

DBS ver. 1.0 (Fig. 1) was used for the discussion, and the following two points were considered. (1) The effect of the box and (2) the usefulness of a semi-personal space. Regarding (2), we aimed to verify our findings based on the differences between individuals’ and overall decision-making, as estimated from the keywords left in the box.

B. Method

The participants in the experiment were four first-year male graduate students (participants A–D). Each participant was given a laptop computer with the DBS.

Of the four participants, two entered separate soundproofed rooms, while the other two sat in the opposite corners of a room approximately 50 square meters in area. Their discussion was held online using the Internet calling system Skype. No images were transmitted, only each participant's voice.

The agenda set for the four participants was "Think about how to entertain children and their parents at a fun kindergarten event."

The terms of the discussion were summarized on a piece of paper and passed to the participants: The performers were the four participants in this experiment / Days before the fun event / Performance time / Location / Room situation (fictitious photo with mini stage and speakers) / Kindergarten age / Gender / Number of children and parents / What to expect from the kindergarten / Background of the party (PR for becoming a kindergarten that you want to attend) / No budget.

The items to be decided during the discussion were specified by the experimenter. These were: 1. What to do, 2. Preparations, 3. Role sharing, and 4. Cost. Two types of boxes were provided for each item, "agree" and "disagree." For example, for the item "cost," if the participant agreed with "about 300,000 yen," he moved the keyword "300,000 yen" to the box marked "cost-agree." If not, it is moved to the box "cost-disagree." Keywords can also be moved to another box or deleted. A total of eight boxes were prepared. Prior to the experiment, the experimenter registered eight boxes in each computer's system. Participants were instructed to decide on these four items within a specific time.

It was requested that the movement of keywords to the box should be decided by the participants' own intentions and opinions, rather than taking direction from the group. We instructed all participants to decide these four items (agreement) within 40 minutes. The screen recording software "Filmora Scrn" was used to record the screens of each participant, in addition to their faces and utterances. However, due to a malfunction of the experimental equipment, it was not possible to capture the video for Participant C's screen.

C. Questionnaire Survey

After the experiment, the four participants answered Questionnaire 1 while seated at the same table. At the time of the experiment, the "item box" element was called a "category."

1) Questionnaire 1

Question 1-1: What was the conclusion of the discussion (concluded / not reached)? Please write the final conclusions of your perceived discussion by category (what to do / preparation / separation / costs). Do not consult with the other participants, and answer using your own words. If there are any categories for which you have not yet reached the end of the discussion, please write down the conclusions that you think are the most likely at this time. If there was not one conclusion, please describe all conclusions reached.

Question 1-2: What did you think and judge when moving keywords to the categories? Fill in as much detail as possible about the criteria for sorting and what you were thinking when moving the words.

Question 1-3: How did the discussion proceed?

- Was the discussion lively?
- Were participants' opinions easy to agree with?
- Do you feel that you reached the conclusion smoothly?

Next, the four participants responded to Questionnaire 2 while looking at the results of the totals for all eight items and their responses to Questionnaire 1.

2) Questionnaire 2

Please answer the following questions about Questionnaire 1, which you completed earlier, while looking at the display showing all of the results from all participants.

Question 2-1: What was the biggest difference between the final conclusion you reported in Questionnaire 1 and the actual results from all participants?

Question 2-2: Remember the flow of the discussion. Were there any times where your intentions and opinions were different from the opinion and story flow of the entire group? What did you think about that?

Question 2-3: Look at the tally results on the display. Are there any of your conclusions in Question 1 from Questionnaire 1 that you think should be corrected? If so, what are they?

D. Results

1) Participants' commenting behaviors: The following tends were observed from the analysis of utterances. The basic form of the discussion was that multiple opinions were presented in response to the questioning remarks (for example, "Is there anything other than the play?" "What are the preparations?"), and the most-supported remarks were expanded to the next discussion. When there were concerns or points to be noted regarding the remarks, the behavior was seen in which the topic was interrupted, rather than expressing dissenting opinions. Participants sometimes suddenly made remarks that were not linked to those immediately before. For example, immediately after "cleaning up time is about 5 minutes," They switched to the next discussion with "then, preparations." In the latter half of the discussion, participants began to speak with an emphasis on nouns.

2) Keywords left in the box: Table I shows the keywords that finally remained in the box and the aggregated results. There were almost no differences in the number of keywords between items other than "cost" and among the participants. However, all four participants put only five keywords in the same box, four of which were in "role division." In "what to do," two people put "magic" and another two put "magic tricks." These two keywords are considered synonymous, so it can be said that there was a total of six common keywords. Participants B and C left the "curtain" in the "preparation (agreement)," while A put it in the "preparation (opposite)." Analyzing the utterances, Participants A, B, and C recognized that they would use the kindergarten curtains. However, B and C put the keyword in “agree,” in the sense of “preparing the curtain,” while A put it in “opposite,” in the sense that “the curtain is at the kindergarten, so no preparation is necessary.”

TABLE I. KEYWORDS LEFT IN EACH BOX

category	participant	remaining keywords	totalization
what to do (agree)	A	Momotaro, Oni(devil), workshop, magic (in English), juggling, Talk (free conversation), lecture, background music	one using cards(3), magic (in English)(2), magic (in Japanese)(2), juggling(3),participation(2), workshop (2), simplification, Momotaro, Oni, lecture, background music, Talk, participation, communication
	B	one using cards, magic, simplification	
	C	one using cards, magic (in English), juggling, magic (in Japanese)	
	D	participation, workshop, one using cards, juggling, communication	
what to do (disagree)	A	arrangement of effects, projection mapping	Momotaro(2) arrangement of effects, projection mapping(2)
	B	Momotaro, projekution mapping	
	C	Momotaro	
	D	--	
preparation (agree)	A	banana, cards, costume for a behind-the-scenes supporter	handkerchief(2), banana(4), cards(3), curtains(2), costume for behind-the-scenes supporter(2), cloth of a dog, low-cost, beanbags, bowling pins
	B	handkerchief, low-cost, banana, cards, curtains, beanbags	
	C	handkerchief, banana, cloth of a dog, cards, curtains	
	D	banana, teacher, cards, beanbags,bowling pins, costume for a behind-the-scenes supporter	
preparation (disagree)	A	curtains, spotlight, building clocks, projector	spotlight(2), 10 pieces, wall, hole, curtains, building clocks, projector
	B	10 pieces, wall, hole	
	C	--	
	D	spotlight	
role sharing (agree)	A	assistant, a behind-the-scenes supporter, moderator, magician	assistant(4), a behind-the-scenes(4), moderator(4), magician(4), background music(2), Neta, juggling, teacher
	B	Neta (a joke material), assistant, a behind-the-scenes supporter, moderator, juggling, teacher, background music, magician	
	C	assistant, a behind-the-scenes supporter, moderator, magician	
	D	assistant, a behind-the-scenes supporter, moderator,background music, magician	
costs (agree)	A	--	4000 yen (3)
	B	4000 yen	
	C	4000 yen	
	D	4000 yen	
costs (disagree)	A	4580 yen	4580 yen (2) price of a dog
	B	4580 yen	
	C	price of a dog	
	D	--	

TABLE II. RESULTS OF QUESTION 1-1.

Category	Participant	Conclusion	Final conclusions recognized by individuals	Difference in number from words left in the box
What to do	A	yes	magic show	Seven words decreased
	B	yes	magic	Two words decreased
	C	yes	magic	Three words decreased
	D	yes	magic, juggling	Four words decreased
Preparation	A	yes	banana, cloth, cards, ling, beanbags	One word decreased, three words increased
	B	yes	handkerchief, cards, ball for juggling, cloth, banana	Three words decreased, two words increased
	C	yes	handkerchief, banana, cards, curtain	One word decreased
	D	yes	banana, beanbags, cards, cloth, costume for a behind-the-scenes supporter	Two words decreased, one word increased
Separation	A	yes	magician, moderator, assistant, a behind-the-scenes supporter	No change
	B	yes	magician, moderator, assistant, a behind-the-scenes supporter	Four words decreased
	C	yes	magician, moderator, assistant, a behind-the-scenes supporter	No change
	D	yes	magician, moderator, assistant, a behind-the-scenes supporter	One word decreased
Costs	A	yes	4000 yen or less	"4000 yen" remained
	B	yes	about 4000 yen	"4000 yen" remained
	C	yes	4000 yen	No change
	D	yes	4000 yen?	"4000 yen" remained

3) Relationships between utterances and keyword movement: There was one example in which the intention expressed in the participant's utterance and the intention expressed in the movement of his keyword were different. Fragment 1 shows the example.

Fragment 1 (English translation):
01B: What Participant C said a little while ago. I think it is one of the good ideas.
02D: Is it an idea what someone eats bananas?
Participant D put “banana” in the “preparation (agreement)” box.
03B: The banana disappeared because one of us ate the banana, didn’t it?
04C: Oh.
05D: So, it was a good hook.
06B: It was a good hook.
07C: It was a good hook.
Participant A put “banana” in the “preparation (agreement)” box.

They are talking about eating bananas as a comical means of realizing magic tricks where objects disappear. Member B did not put the “banana” in the box after all, even though he made a favorable and agreeing statement about magic and using bananas.

4) Questionnaire results: Table II shows the results of Question 1-1, compared to the keywords written there with the keywords in the “Agree” box (Table I), and it shows the number written in only one of them. All participants judged that all items were “concluded.” The final conclusions each participant wrote in the questionnaire were roughly the same for all four; however, especially for the items of “what to do” and “preparation,” there was a large difference between the keywords left by each participant in the DBS box and the questionnaire responses.

There were slight differences in the answers to the “cost” questionnaire, such as “4000 yen,” “4000 yen or less,” and “about 4000 yen,” and it is possible to read the difference in the recognition of the participants. Regarding Question 1-2, All participants but C sorted the keywords into boxes at their own discretion. The average values of the answers to the three questions (four levels of answers) in Questions 1–3 were 3.25, 3.25, and 3.5, respectively. Participants felt that the discussions were lively, the opinions tended to be the same, and the conclusions were reached smoothly. Question 2-1 showed that the results perceived by the participants themselves and the aggregated results including others were slightly different, in terms of preparation and the division of roles. In Question 2-2, Participant B wrote, “How to erase (object) with magic tricks, I answered BOX, and the others were cloth (answered)," while D said, "The item of division of roles, who played that role." There was a slight discrepancy among the participants in their perceptions of the debate about what to do. It turned out that there was a discrepancy in the details. In Question 2-3, all participants looked at the keywords left by other members in the box and indicated their willingness to add or modify keywords for all four items.

E. Discussion

The DBS has the ability to display boxes for items to decide on. As a result, participants may be motivated to fill an empty box. Therefore, the next discussion (topics about empty boxes) may suddenly begin, regardless of what was being talked about immediately before. This is considered to have contributed to the fact that all items could be decided within the specified time. Later in the discussion, participants tended to speak around nouns to make them more visible in the DBS. This had the effect of preventing ambiguity about each speaker's intent. However, noun-centered remarks also had the effect of eliminating complex content and nuances, as shown by the example of the subtle variations seen in the "cost" questionnaire response.

The conclusions that each participant recognized after the discussion ended were almost the same among the participants. In other words, it can be said that the consensus was formed by the discussion, and the participants correctly recognized this. However, there were differences in the keywords that remained in each participant's box. In addition, there was one case (the example of the "banana") in which participants did not move keywords despite returning a positive response.

Some situations were observed during the discussion. When someone expressed concern about an idea, even if it was just a confirmation act, the other participants might recognize that the idea was denied and stop considering it and move on to another topic. As the banana example shows, participants always had to react positively, so that they would not take each idea out of consideration. Participants did not disagree with the other participants, even though the keywords left in the box differed from the overall conclusion. Based on these results, during the discussion process, each participant was able to freely express their personal opinions and intentions on the individual display (semi-personal space) of the DBS without fear of denying the ideas of others.

Also, in this experiment, the "opposite" box was almost non-functional. This is because it was sufficient for participants not to move the keyword to the "agreement box" if there was any objection.

V. Experiment 2

A. Purpose

We conducted a second experiment using DBS ver. 2.0 to show changes in participants' behaviors by displaying comments during discussions, and to try to estimate participants' intentions based on their movement of keywords.

B. Method

Participants were three males in the second year of a master's program (Participants E–G) and one male in the fourth year of the undergraduate program (Participant H). They received an explanation of the experiment, signed a consent form, and then participated. Each participant was given a desktop personal computer displaying DBS ver. 2.0.

The experiment was conducted in the same room as the experiment outlined in Section 5. Participants E and H each entered a separate soundproof room, and F and G sat diagonally from one another across a large room. The four made voice-only calls using the Internet calling system Microsoft Teams.

The subject of the discussion was the same as in Experiment 1, but a fictitious reward was added to further motivate the participants. The content of the reward was "If the kindergarten teacher and parents voted the plan for the first place, the university will cover the cost of the gift up to 10,000 yen." Participants acknowledged that the setting was fictitious and started the discussion. The items to be decided in the discussion were the same as the experiments in Section V.

C. Questionnaire Survey

After the discussion, we asked each participant to answer a questionnaire about the comments displayed on the DBS during the discussion. These comments were displayed on a separate display from the DBS, for the purpose of encouraging participants to take specific actions. At the beginning of the questionnaire, a list of comments (Comments A– F), as shown in Section IV, was provided. Not all comments were displayed to all participants, because the timing and content of comments displayed varied from participant to participant. Therefore, some participants had not seen some of the comments in the survey on the DBS.

1) Question 1: Do you think there were any comments that changed the flow of the discussion? If there were, write the symbol of the comment (A) to (F) and what kind of change it made. It doesn't matter as long as you remember.

2) Question 2: Please rate each comment (A– F). Did the comments make it easier for you to speak? We asked them to circle the applicable numbers from "Comments did not trigger speaking (1)" to "Comments triggered speaking (5)." Also, if they had any impressions of the comments, they were asked to write them in detail. If they had a comment that was not displayed, they were asked not to reply.

D. Results

1) Keywords left in the DBS box: In the end, a total of 73 keywords remained in the boxes of the four participants. There was almost no difference in the number of keywords among the participants. All participants had the highest number of keywords in "preparation."

Six of the remaining keywords were converted to green during the discussion. (If all participants put the same keyword in the same item box, it turned green.) There was 1 for "what to do," 3 for "preparation," and 2 for "role division." The keyword "game" turned green once, but returned to colorless at the end because Participant E removed it from his box. Regarding the cost, both "10,000 yen" (3 people) and "free" (2 people) remained, so we can see that these were not decided.

2) Questionnaire results: In Question 1, Participants F, G, and H answered that "Comment (A) changed the flow of discussion." In Question 2, as well, comment (A) led the same three people as in Question 1 to be "triggered to speak." On the other hand, G replied to comment (B), "I couldn't think of how to make a statement."

Participant F had the impression that "I personally felt that it was organized," in response to the comment (C). Participant H replied that even if comments (D), (E), and (F) were displayed, they did not lead him to speak.

3) Behavior seen after displaying comments: Participant E let go of the mouse and spoke, but when Comment (F) was displayed, he put the keyword "cardboard" in the "what to do" box. This keyword was not directly related to what was being said at the time. At the same time, he deleted the keyword "drama" from the "what to do" box. Participant G also let go of the mouse and spoke, but when comment (F) was displayed, he seemed to touch the keywords in the parking area one by one with the cursor. However, he eventually started the next statement without moving any keywords. Participant H was laughing while listening to the other participants but not speaking, and he did not move the cursor at all. Once comment (F) appeared, he started moving the cursor and put the keyword "cardboard" in the "preparation" box.

4) Participants' opinions estimated from the movement of keywords: In this section, we extracted the utterances of each participant and the movement of keywords on the DBS to try to estimate the change in the participants' thoughts based on these actions. The subject was the keywords "game" and "VR" in the "what to do" box, and the changes in the intentions of Participants E and F for them.

The underlined part shows their utterance excerpts and indicates the display and movement of the keyword. Fragment 2 shows the reactions of other participants to Participant E's proposal "game" and "VR (virtual reality)."

Fragment 2 (English translation):

4'47"

08E: Young children seem to like games and VR.
"Game" is displayed in the text area. F puts the keyword "game" in the parking area.
09E: You see, the teacher's son was very excited about VR. What do you think?
<u>"VR" is displayed in the text area. G puts "VR" in "what to do."</u>
10F: Oh, that might be fine. It doesn't cost much to prepare.
E puts "game" in the "what to do" box.

Participant E only put "game" in the box, but it can be inferred from his utterance that the participants were speaking in a state where the concepts of VR and game were not so distinguished. It is probable that they tried to proceed as with the ambiguous idea of whether it was VR or a game. Participant F made a positive statement, "that might be fine," and moved only the keyword "game" into the parking area. The fact that he did not put the keyword in the box as a decision suggests that the proposal was still considered a candidate for him at that time.

Fragment 3 is an excerpt from the conversation after Participant E proposed attaching cardboard to a smartphone (VR goggles).

Fragment 3 (English translation):

7'19"

11F: I think the game might be better.

12E: Yeah.
13F: I think it's easy to imagine.
(10 seconds)
14E: There is no restriction that the event must be on stage. (5 seconds)
15G: There is only a designation to carry it out in the play room.
16E: How about bringing some candidates for the time being?
<u>H puts "game" in the "what to do" box.</u>
17E: 26 children.
18G: That's right
<u>G puts "game" in the "what to do" box. The word "game" in the "what to do" box turns green.</u>

Participant F momentarily hovered his cursor over "VR" in the parking area, but did not move it to the box or put the adjacent keyword "game" in the "what to do" box.

Participant F was concerned about the "VR" in the parking area, but put only the word "game" in the box, before immediately saying, "The game may be better." From this utterance, the following two points can be inferred. F thought that the "VR" plan and the "game" plan were different. At that time, the participants' conclusions tended toward "VR," but F thought that the conclusion of "games" was good.

Participants H and G also put the keyword "game" in the box, and the word "game" turned green. However, the thoughts of the other participants remained unclear, and the topic changed to a place for the show. Neither G nor H had given a concrete opinion on the idea of VR or the game. It is possible that F's remarks triggered them to just put the "game" in the box.

Fragment 4 is an excerpt of a conversation that begins with G's question about the content of the game.

Fragment 4 (English translation):

9'27"

19G: The rest of the tasks are what the game will be. What to do with the contents.
<u>E puts "VR" in the "what to do" box.</u>
14'50"
20G: How about fetching material from YouTube? Like a roller coaster.
<u>H puts "VR" in the "what to do" box.</u>

Immediately after G asked about the game, E put “VR” in the box. He may have wanted to push the VR plan in opposition to the game plan.

Fragment 5 is an excerpt of a conversation that begins with G's question about expensive preparations.

Fragment 5 (English translation):

24’22”

21G: I [can] borrow a 360-degree camera from my acquaintance's laboratory. Is there anything else (expensive)?
E removes “game” from “what to do.”
(Omission)
30’09”
22E: Like a VR aquarium…
23F: That's a good idea.
F puts “aquarium” in the parking area.
(Omission)
33’13”
24G: We may place an order outside.
25E: Order?
F puts “aquarium” in “preparation.”
26E: How about using Fablab?
F puts “VR” in “what to do.” The term “VR” in the “what to do” box turns green.

In response to G's remark, E deleted the “game” that had been converted to green.

In the first place, E considered games and VR to be separate ideas. It is also thought that he was convinced that the “game” plan and the “VR” plan, whose recognition was ambiguous among the participants, proceeded to VR following the remark about G’s “360-degree camera.”

After that, F put “VR” in “what to do” and the keyword “VR” was converted to green. F agreed with E’s “VR aquarium,” but did not remove “game” from the box at that time. It is thought that F recognized that the VR plan was being finalized and accepted it because G made a statement on the premise of the VR plan (the external order for a 360-degree camera).

E. Considerations

Regarding Function 1, “designing the process,” participants completed discussions on four items within the time limit, suggesting that the box is useful, as was the case of the experimental results in Section V.

Regarding Function 2, “controlling the process,” Participant F put a “game” in the box and then immediately said, “A game may be better.” It is thought that this encouraged the remarks of others.

By contrast, while Participants E and F tended not to hesitate to express their opinions to others, a conversation analysis suggested that G’s remarks determined the flow of discussion.

It cannot be denied that the reason why F could not push the “game” plan to the end was that the movements of G and E came as a result of sympathetic pressure. The movement history of keywords may be effective in guessing participants’ true intentions, and by using this, it is possible to promote discussions from multiple perspectives. In addition, the flow of the discussion may have changed if the concrete examination of the game content was advanced at the initial stage of the discussion. To broaden the effectiveness of the discussion, it was considered necessary to have a mechanism for prompting other non-independent participants to think and speak concretely about each proposal.

Regarding Function 3, “organize and inspire discussions,” participants answered in the questionnaire that comment (A) triggered them to review their utterances and keywords. When analyzing the behavior after the comment was displayed, there was a tendency to move the cursor and put the keyword in the box after comment (F), “It seems that you have not operated for a while,” is displayed (see Fig. 5). However, some participants tried to move the cursor to do something, but did not move the keyword. Based on this, it can be said that, although the comments aroused a motivation to take action, there was not always an appropriate action to match it. The DBS generates keywords based on utterances, so even if non-speaking participants have different opinions, there is no matching keyword.

Regarding Function 4, “form an agreement,” in Experiment 1, in Section V, the common keyword was biased toward the “role division” box. However, in Experiment 2, in this section, there was a common keyword that turned green in the three boxes other than “cost.” The deliverable display function that changes the color of the common keyword clearly indicates whether each item has been decided or left undecided, so it may have been effective for drawing conclusions. However, although E deleted the keyword “game,” which had converted to green, and G and H also put “game” in the box, there were few remarks suggesting a game plan. Based on this, we can say that, if there is no particular objection to the keyword, it may be put in the box according to the flow of discussion, or the keyword, once put in the box, may not necessarily be in favor, due to the flow of discussion. At the beginning of the experiment, participants were asked to “put keywords that match their intentions in the box,” but this instruction was not thorough enough, and it seems that the boxes were used, instead, as a record of the overall opinion. In order to realize Function 4, it may be necessary to strengthen the work of inputting the individual intentions of each participant into the DBS, instead of the overall opinion, and at the same time, to confirm the individuals’ conclusions.

VI. Discussion

We experimentally examined the functions required for a system that helps participants to form a consensus and draw conclusions after giving various opinions during an online discussion.

The deliverable display function that changes the color of the common keyword clearly indicates whether each item has been decided or left undecided, so it may have been effective for drawing conclusions. However, if we do not ensure that participants put only their personal conclusions in the box, the boxes can become just notes on the discussion.

We also discovered some concerns. It is possible that some participants will try to settle the discussion and invite other participants to move a keyword in order to turn it green. This action may promote peer pressure that is contrary to the purpose of the DBS. It can be said that the AI facilitator not only displays comments that encourage discussion, but also has a mechanism for protecting participants from peer pressure. To that end, there is a need for a mechanism that eliminates the above concerns, encourages silent participants to think independently, and links their aroused willingness to manifest their intentions to appropriate actions.

VII. Conclusion

This paper proposed a discussion board system (DBS) for a future AI facilitator. The following four facilitator functions have been realized: 1) Design the process, 2) Control the field, 3) Inspire discussions, and 4) Form consensus.

Experiments with the DBS suggested the following:

1) By displaying the items to be decided, the topic can be easily changed to the next agenda item, and a conclusion can be drawn within the allotted time.

2) If the discussion participants can express their opinions and intentions on a screen that cannot be seen by others, peer pressure can be avoided to some extent.

3) The comments displayed from the system prompts users' operations on the screen. The comments triggered them to review their utterances and keywords.

4) The deliverable display function that the keyword changes to green when all participants enter the same keyword in the same box provides an opportunity to settle the discussion.

In a future effort, we aim to create a system that encourages participants to express their intentions independently by solving problems and examining the content of the comments to be displayed, and to further reduce the influence of peer pressure in the discussion.

Hybrid Spelling Correction and Query Expansion for Relevance Document Searching

Dewi Soyusiawaty, Denny Hilmawan Rahmatullah Wolley
Informatics Engineering, Ahmad Dahlan University, Yogyakarta, Indonesia

***Abstract*—A digital library is a type of information retrieval (IR) system. The existing IR methodologies generally have problems on keyword searching. Some of search engine has not been able to provide search results with partial matching and typographical error. Therefore, it is required to be able to provide search results that are relevant to keywords provided by the user. We proposed a model to solve the problem by combining the spell correction and query expansion. Searching is starting with indexing the title of the document by preprocessing the title of all incoming document data and then weighting the Term Frequency – Inverse Document Frequency (TF-IDF) against all terms of the whole document. Levenshtein Distance algorithm is used in the search process to correct typo-indicated keywords. Before calculating the relevance between the keywords and the documents using Cosine Similarity, the keywords are expanded using Query Expansion to increase number of documents retrieved. Calculation results using Cosine Similarity are then added to Query Expansion weight calculation to get final ranking result. Results show improvements over IR system compared with system without spell check and query expansion. The results of the study in the form of web-based application conducted testing for 50 times with number of data of 2,045. The system was able to correct typo-indicated keywords and search documents with average recall value of 95.91%, average precision value of 63.82% and average Non Interpolated Average Precision (NIAP) value of 86.29%.**

Keywords—Cosine similarity; information retrieval; Levenshtein distance; TF-IDF; typographical error; query expansion

I. Introduction

Digital library is one of information service providers in the forms of digital documents that can be accessed online. It is very helpful for students in searching information to complete assignments as well as searching supporting documents for research they are conducting. The large number of digital documents at digilib makes the scope of information search even greater so that information and the needs of relevant information are increasing [1]. Based on observation, some digilib has not been able to provide search results with partial matching and typo-indicated keywords (typing error).

In searching information, the model used and the choice of keywords can influence the level of document relevance towards user's keywords. One of them is VSM (Vector Space Model) where this model represents documents into the forms of vector space. VSM enables to determine relevant documents with keywords depending on the similarity measurement [2]. One of popular VSM measurement models is Cosine Similarity that calculates the cosine angle between two vectors. In addition, Cosine Similarity can be implemented on document matching and partial matching [3]. With the ever increasing size of the web, relevant information extraction on the Internet with a query formed by a few keywords has become a big challenge. Query Expansion (QE) plays a crucial role in improving searches on the Internet [4]. Query expansion plays a major role in reformulating a user's initial query to a one more pertinent to the user's intended meaning. It is to retrieve the most relevant expansion words for expanding the initial query of the user in order to enhance the outcomes of web search results. The reformulated query is then used to obtain more appropriate outcomes from a large amount of information on the web [5].

Spelling errors are words that spell-checker could not find in its lexicon [6]. Typo on keywords is one of reasons why the search result is not relevant since keywords entered are not in the database, so the search engine cannot find relevant documents with the typo-indicated keywords. Several research on search engine concluded that the keyword spelling errors by users are relatively high [7]. The causes for errors are usually related to writing ignorance, positions of keyboard buttons, and finger's movement [8]. Therefore, it needs spelling correction. Levenshtein Distance, also called edit-distance, is used to find word candidates suggested based on number of minimum characters that need to be substituted, inserted, or deleted to change words from string A to be string B [9]. Levenshtein Distance provides good results in solving problems of matching string data to provide text suggestion, for instance in handwriting recognition, search words and misspelled words, so the input effectiveness increases, misspelling can be avoided and auto-complete accelerates human computer interaction [10] [11].

Based on problem explanation, the researchers conducted research to improve the relevance of document search by using Query Expansion, Levenshtein Distance algorithm and Cosine Similarity calculation.

II. Literature Review

A. Text Preprocessing

Text Preprocessing is a process to bring unstructured data form into structured one as needed for further processing in text mining. In this research, text preprocessing is for the titles of research documents and query from users [12]. It uses several general processes such as:

1) Case folding: a process of changing letters in a document into upper-case or lower-case. In this research, lower-case is used.

2) Tokenizing: a process of breaking down string into some smaller units called term. Token can be in the forms of a word / number, sentence or paragraph. In this research, term from the tokenizing result is in the form of a word [13].

3) Filtering: a process of removing symbols from string. In this research, all symbols except for alphanumeric are removed.

4) Stopword removal: a process of removing unessential words in the description by checking words of description parsing result whether they are in the unessential word list (stoplist) or not for instances are conjunction “adalah”, “dan”, “dari”, “yang”, “di” and “ke” [14].

5) Stemming: a process of removing affixes including prefixes, infixes, and or suffixes on the word group to process.

This research adds one more process to change acronym into its original form in order that term table for TF-IDF weighting becomes more structured.

B. Synonym Table Formation

Every word included in the wordlist table is then processed to find its synonym as Query Expansion reference. The search of synonym uses scraping technique towards webpage of kamuslengkap.com. The results of synonym are then stored in the wordlist table as shown in Fig. 1.

C. Query Expansion

Query Expansion reformulates user’s original query to improve the effectiveness of information retrieval [15]. The use of query expansion in this research aims at increasing recall value by taking documents that have similar meaning or synonym with terms from query. The process of query expansion is done to term that has not experienced stemming [16]. Table I used for searching synonym of keywords is wordlist table containing word group from documents and the synonyms that have been found through prior scraping. For instance, if we need to search with keywords “Pencarian dokumen” (document search), each term will be expanded based on the synonym of each term in the wordlist table.

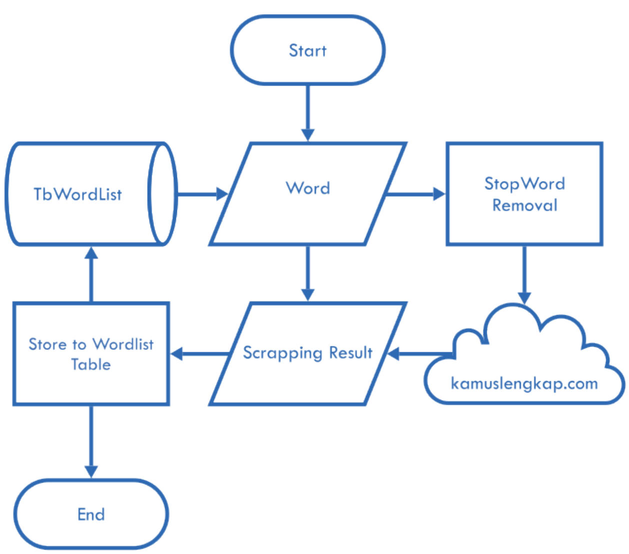

Fig. 1. Process of Synonym Table Formation.

TABLE I. SYNONYM OF KEYWORDS

Keyword	**Expansion**
Pencarian	*Penelusuran, Pelacakan*
Dokumen	*Arsip, Naskah*

Therefore, documents to search are not only those with terms “pencarian” and “dokumen” but also “penelusuran”, “pelacakan”, “arsip” and “naskah”.

D. Term Frequency- Inverse Document Frequency (TF-IDF)

TF-IDF is a process of weighting a term of a document towards the whole document. TF-IDF calculation is a technique that weighs relevance of term towards document by combining two concepts in weighting, namely the frequency of a term occurs in a document (term frequency) and inverse document frequency containing the term [17].

Term Frequency (TF) that frequently occurs in documents becomes more critical since it can indicate the topic of documents. There are some formulas used to calculate term frequency in documents, but in this research TF calculation uses binary TF that focuses on a term in documents. If it is found, it scores one (1) regardless of the occurrence frequency in documents. If it is not found, it scores zero (0). Inverse Document Frequency (IDF) is used to indicate discriminative power of term i. Generally, terms that occur in a variety of documents less indicates of a particular topic. Formula of inverse document frequency is defined as followings:

$$idf_i = log\left(\frac{n+1}{df_i+1}\right) + 1 \tag{1}$$

Where df_i is document frequency of term i or number of documents containing term i and n is the number of all documents.

Weight W_ij is the multiplication result of term frequency matrix and IDF value of each term that can be defined as followings:

$$W_{ij} = tf_{ij} \times idf_i \tag{2}$$

Where df_i is document frequency of term i or number of documents containing term i and n is the number of all documents.

TF-IDF weighting is done to terms previously collected in TermList table. Fig. 2 shows the flow [18][19].

E. Spell Checker

Spellcheck is a technique that identifies incorrect words or misspelled words then changes them into correct word combinations properly. There are two main methods used to develop spelling checker application, namely identification (error detection) and correction (error correction). Besides, spelling checker is divided into two types, namely non-word error spell checker and real-word spell checker. Non-word error spell checker manages misspelled words due to typing errors, while real-word error spell checker manages substitute words to replace errors in the sentence [20] [21].

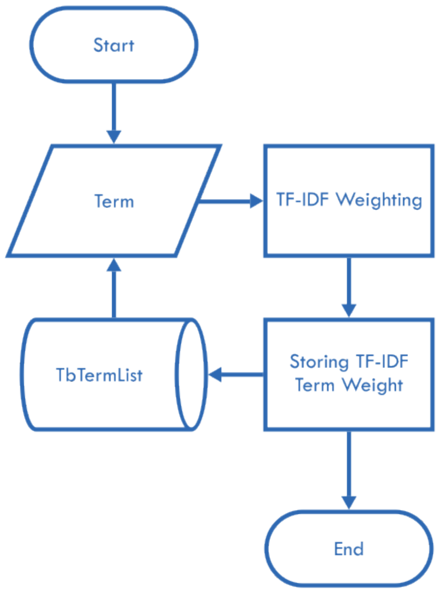

Fig. 2. Process of TF-IDF Weighting.

F. Levenshtein Distance

Levenshtein Distance is an algorithm that measures distance between two strings by calculating number of minimum operations needed to change one string to another. The operations are deletion, insertion, and substitution. Mathematically, Levenshtein Distance between two strings can be formulated as followings:

$$lev_{a,b}(i,j) = \begin{cases} max(i,j) \\ min\begin{cases} lev_{a,b}(i-1,j)+1 \\ lev_{a,b}(i,j-1)+1 \\ lev_{a,b}(i-1,j-1)+1_{a_i \neq b_j} \end{cases} \end{cases} \quad (3)$$

In this research, Levenshtein Distance algorithm is used to process user's query to find out whether query typed by users is indicated typo or not. The typo-indicated words are those that are not in the wordlist table [22]. This process calculates the distance of words in query with word groups in the wordlist table. The words chosen as the correction result from the typo-indicated query words are those with the closest distance based on Levenshtein Distance calculation.

G. Relevance Calculation with Cosine Similarity

In this stage, calculation of relevance using Cosine Similarity between query and document from TF-IDF weighting previously obtained is done. The results are in the forms of similarity value between a document and the query, the higher the similarity value of a document with the query, the more relevant the document to the query. Calculating similarity between documents and query is done by dividing dot product of document vector and query vector with multiplication of Euclidean value of document vector and Euclidean value of query vector. Euclidean value is calculated by finding out the square root of the sum of the squared term weight in documents. The calculation is as the followings (4).

$$sim(d_i,q) = \frac{\vec{v}(d_i)\cdot\vec{v}(q)}{|\vec{v}(d_i)||\vec{v}(q)|}, |\vec{v}| = \sqrt{\sum_{i=1}^{M} \vec{v}_i^2(d)} \quad (4)$$

H. Calculation of Term Weight of Expansion Result

This stage adds the calculation by using IDF value of each document term of search result since the term from expansion result of query has lower degree of importance compared to that from original query. Documents containing term from original query can have higher similarity compared to those with term from expansion result. This research used calculation based on the reference as shown in (5) [23] [24].

$$sim = Cosim + \sum_{i=1}^{n} \begin{cases} 1 & ,Term = QA \\ 1-\left(\frac{1}{log(dfi)}\right) & ,Term = QE \\ 0 & ,df(QE) \leq 10 \end{cases} \quad (5)$$

Calculation is done by adding the calculation result of Cosine Similarity (Cosim) with value determined in (5). If number of term in a document is n original query term (QA), value of one (1) is added as many as n. If there is term from expansion result (QE) and df of QE > 10, so it is added 1 – (1/(log(dfi)). If df of QE ≤ 10, so it is added 0. The example of the calculation is as followings [25]:

Query: Sistem pakar penyakit tulang

Table II consists of expansion result from the tokenization of the query.

Table III consists of the calculation result of Cosine Similarity with the document.

The next is searching terms from the title of each document that intersect with original and expansion keywords in Table IV.

The intersected term results are then calculated by using equation (5) can be seen at Table V.

TABLE II. EXPANSION RESULT

I. Recall, Precision and Non-Interpolated Average Precision (NIAP) Testing

Effectiveness of information retrieval system is the ability measurement of system to retrieve a variety of documents from database in accordance with the user's request. There are two critical things usually used in measuring ability of information retrieval system, namely ratio or comparison of recall and precision. Recall and precision calculation are calculation done to a group of documents from search result (set based measure) in overall, so it cannot describe the performance of information retrieval system in terms of relevant document ranking [2]. NIAP is used to check the search success of software developed [26].

Testing is done for 50 times for each of those with spelling correction and query expansion and those without them for testing the relevance level of document search results retrieved by system. Formula for recall, precision and NIAP are shown in (6), (7) and (8).

$$recall = \frac{\#(relevant\ items\ retrieved)}{\#(retrieved\ items)} \tag{6}$$

$$precision = \frac{\#(relevant\ items\ retrieved)}{\#(relevant\ items)} \tag{7}$$

$$NIAP = \frac{1}{\#relevant\ items} \times \left(\sum_{d_i \in relevant}^{n} \frac{i}{Rank\ (d_i)}\right) \tag{8}$$

III. METHOD

This research has two critical processes, namely storage and search processes.

The storage process stores data of documents consisted of id, title, year of publication, and author into document table. Then, the title of document is extracted. Term of the document title is taken for TF-IDF weighting and a group of words from documents title is taken for synonym table formation. Fig. 3 shows flow of storage process.

Document search processes consist of correction process of keywords from user's query by using Levenshtein Distance, query expansion based on synonym table formed, relevance calculation by using Cosine Similarity, and expansion term weighting process to add to relevance value of Cosine Similarity calculation result. Fig. 4 shows flow of document search process.

A. Data Collection

Dataset used in this research is in the forms of titles in excel file format containing research document titles. Data of the scraping results consist of 2,083 records with four attributes, namely ID, title, author, and year.

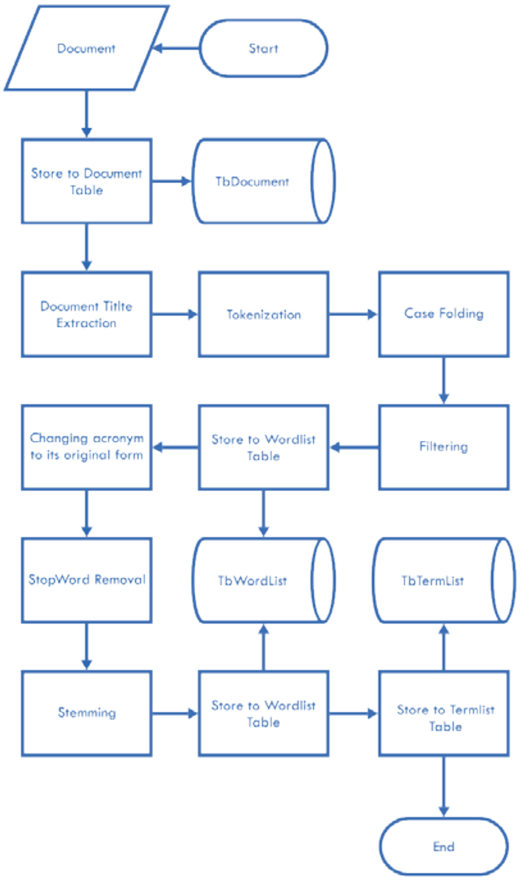

Fig. 3. Flow of Data Storage Process.

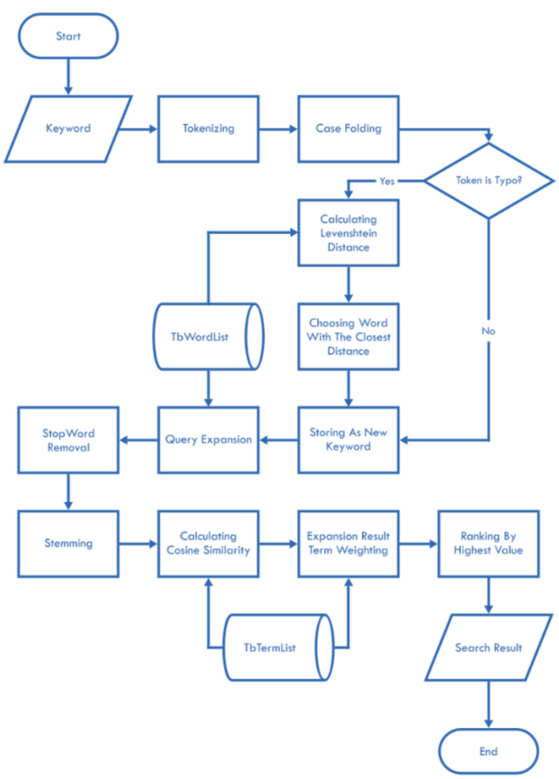

Fig. 4. Flow of Document Search Process.

IV. RESULT AND DISCUSSION

Testing is done for 50 times by using data of 2,045 document titles in database with different keywords in every testing both with the use of spelling correction and query expansion on query keywords or not.

A. *Testing without Spelling Correction and Query Expansion*

This testing only uses similarity calculation with Cosine Similarity without spelling correction and query expansion on keywords to compare recall and precision value with those with spelling correction and query expansion. In Table VII, it can be seen that several rows have errors in keyword writing which finally the Rt value = 0 and also follows the recall value, precision and NIAP = 0. Writing errors can be seen in the blocked rows, such as in the 3, 4, 5, 8, 11, 17 and so on. Various writing errors are such as missing letters, excessive letters and letter placement errors. This testing obtains average recall of 69.11%, precision of 69.28%, and NIAP of 60.72%.

B. Testing with Spelling Correction and Query Expansion

This testing uses similarity calculation with Cosine Similarity and spelling correction on keywords with Levenshtein Distance algorithm followed with query expansion. This testing obtains average recall of 95.91%, precision of 63.82% and NIAP of 86.29%. In Table VIII it can be seen an increase in recall value, this is due to the improvement of keywords in several tests that have writing errors. The RT value was previously 0 in Table VII changes depending on the data in the database. In the correction keyword column, the rows that are blocked are spell-checked words and produce the appropriate words so that they can be found in the database. For example: "levemstein" becomes "levenshtein", "roshio" becomes "rocchio", "steganogarfi" becomes "steganography" and so on.

TABLE VIII. SEARCHING RESULT WITH SPELLING CORRECTION AND QUERY EXPANSION

	AVERAGE		**95.91%**	**63.82%**	**86.29%**

Search results with keyword correction have higher average recall and precision value than those without keyword correction even though each trial has same keywords. The reason is that the use of Levenshtein Distance algorithm can correct some typo-indicated keywords correctly, so that system can find documents that have the keywords.

Fig. 5, Fig. 6, and Fig. 7 show comparison of recall, precision and NIAP value based on the number of term.

Fig. 5 shows that recall value of testing with spelling correction and query expansion is higher than that without them. The reason is that the use of spelling correction can display documents with typo-indicated keywords while the use of query expansion can find documents that have similar meaning with keywords from user's query.

Fig. 6 shows that precision value of testing with spelling correction and query expansion tends to be lower than that without them. The reason is that query expansions on keywords are too general; as a result, some documents that are less relevant are also displayed.

NIAP value in Fig. 7 shows the excellence of testing with spelling correction and query expansion compared to that without them. The reason is that the use of query expansion can display relevant documents that have similar meaning with keywords from the query and the ranking result is above the documents that are less relevant based on Cosine Similarity and term weighting of query expansion.

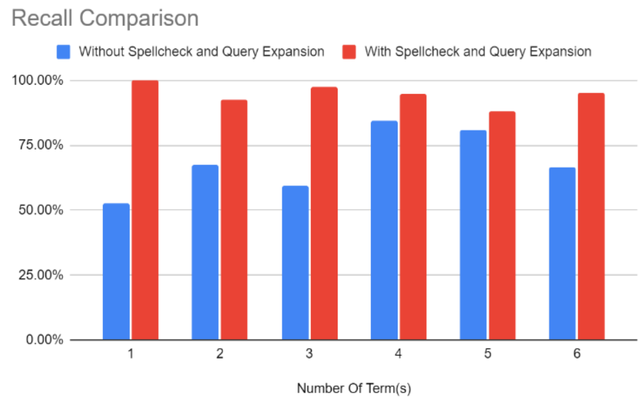

Fig. 5. Comparison of Recall Value on Number of Term.

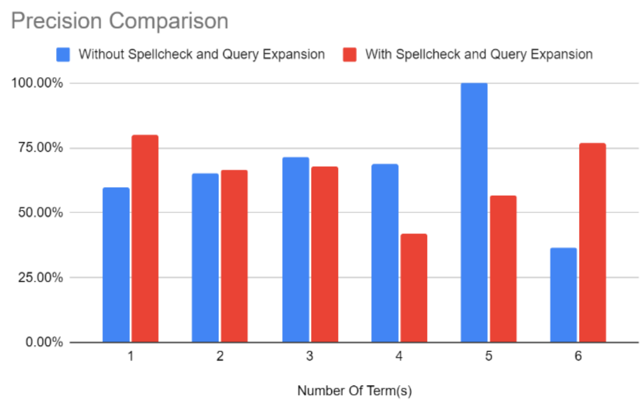

Fig. 6. Precision Comparison.

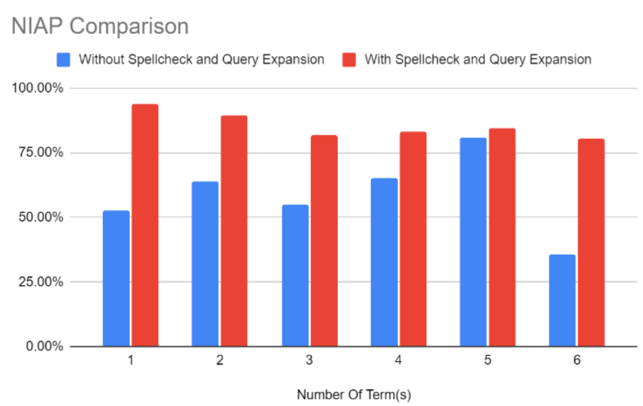

Fig. 7. NIAP Comparison.

V. Conclusion

Hybrid spelling correction and query expansion on keywords are able to improve relevance of document searching. The reason is that the use of spelling correction can display documents with typo-indicated keywords while the use of query expansion can find documents that have similar meaning with keywords from user's query. The proposed methods are able to improve relevance of document searching with average recall from 68.11% to 95.00%, but the precision decreases from 69.28% to 63.32%. However, the decrease does not influence the ranking of relevant documents retrieved by system because there is an increase of NIAP value from 60.72% to 86.29%, so the low precision is tolerable.

VI. Future Work

This research can be further developed by optimizing algorithm to correct typo-indicated keywords, so it can correct typo-indicated keywords based on the linkages of the keywords in query and not only based on their Levenshtein Distance. Besides, query expansion can be optimized in finding synonym of keywords, so term of expansion results are not too wide and to add feature to find expansion results of phrases, so it is not limited to only term from user's query. Therefore, the recall value can increase without lowering the precision value.

Usability Perceptions of the Madrasati Platform by Teachers in Saudi Arabian Schools

Wesam Shishah
College of Computing and Informatics
Saudi Electronic University, Riyadh, Saudi Arabia

***Abstract*—As a result of the COVID-19 pandemic, the Saudi Ministry of Education launched the Madrasati Platform for distant teaching and learning for schools. Therefore, recognizing the design and the usability challenges that are linked to this new platform is significant. This paper reports the results of a study that examines the usability level of the Madrasati Platform from the perspectives of the schoolteachers in Saudi Arabia. It also investigates the usability issues that teachers faced when using the platform. A total of 759 teachers responded to the Computer System Usability Questionnaire (CSUQ). Semi-structured interviews were also conducted with ten teachers. The findings of the study indicated that the usability of the Madrasati Platform for the schoolteachers is inadequate and needs to be improved further. Navigation issues were the most reported issues by the participants. Finally, the paper presents some recommendations for improving the usability and experience with the Madrasati Platform.**

Keywords—Usability; Madrasati Platform; e-learning; Saudi Arabia; schools

I. Introduction

As information and communication technology has rapidly spread over the world, the internet has become an increasingly vital means of connection between educational institutions and their students. Schools, colleges, and universities are increasingly using e-learning as a teaching and learning tool. E-learning has numerous clear advantages over traditional learning methods, not the least of which is its flexibility to be used at any time and in any location. Furthermore, it creates environments that allow students to be active participants in their learning, to acquire independence, to become self-reflective, and to collaborate with others, as well as provide a lot of options for creative teaching approaches [1].

As a result of these advancements in internet technology, learning management systems (LMS) have emerged. LMSs are robust software platforms for managing educational activities, with the goal of assisting instructors in conveying knowledge to students and speeding up the learning process. LMSs can be used by educational institutions to store, administer, and distribute educational content as needed [2]. In recent years, a variety of learning management systems (LMS) have emerged, each with its own set of features and benefits for users. Blackboard (BB), Desire2Learn (D2L), and Moodle are examples of learning management systems. By 2025, the global market for LMSs is expected to grow from 13.4 billion dollars in 2020 to 25.7 billion dollars [3].

There is an increasing recognition that high levels of usability are required for LMS development and application to be successful. Instructors save time with useable LMS because they can design and deliver courses more quickly and efficiently. Tutors and students can focus on course content rather than dealing with troublesome technologies, which improves the learning experience. Nonetheless, some studies suggest that the design of LMSs has received little attention, resulting in major usability issues [4]. As a result, institutions considering introducing any LMS must carefully examine its usability before deploying it.

As an emergency move to prevent the spread of the COVID-19 epidemic, schools and colleges around the world have closed face-to-face instruction and sent students home. Saudi Arabia, like many other countries across the world, employed remote learning via virtual classroom as a preventative step to protect teachers and students from COVID-19. In the face of COVID-19's rapid spread, schools were forced to choose between postponing lessons for an unknown period or introducing online classes right away [5]. Consequently, the Ministry of Education (MOE) established the Madrasati Platform, which is an LMS that facilitates teaching and learning in Saudi schools. It became obligatory for schools to use the Madrasati Platform to introduce courses. At the same time, teachers were learning how to use this platform. Traditionally, they had always used face-to-face instruction as a method of delivery. However, this transition to online learning has highlighted concerns about the quality of education [6].

Following the onset of COVID-19, this platform had just recently been adopted in Saudi Arabia's educational system so research on the platform's usability is limited. The author in [7] conducted the only study we found that evaluated the Madrasati Platform's usability. They evaluated the platform using different web diagnostic tools and measures and did not include any target groups of the Madrasati Platform such as schoolteachers and students. To the best of our knowledge, no studies have focused on evaluating the usability of the Madrasati Platform from the perspective of a target user of the platform as this study does; therefore, this study addresses the following research questions:

- Research Question 1 (RQ1): What is the usability level of the Madrasati Platform from the perspective of schoolteachers in Saudi Arabian?

- Research Question 2 (RQ2): What are the major usability issues that teachers faced when using the Madrasati Platform?

II. Literature Review

A. Covid-19 and Education in the Kingdom of Saudi Arabia

Saudi Arabian schools and universities have been forced to convert all their regular face-to-face classes to online classes as a result of the COVID-19 outbreak. Saudi Arabia's Ministry of Education made this decision on March 8, 2020. The Ministry responded to the closure decision by issuing a document called "The COVID-19 Pandemic Protocols" for universities to follow, in which online teaching became the primary form of instruction. Students were not permitted on campus, and no staff or faculty gatherings were permitted [8].

Since then, students and teachers have only been able to communicate via online platforms such as Blackboard and Zoom (an online video communications application). Thousands of teaching members were compelled to offer their lessons in front of a computer display, with students viewing from home using the internet. This significant transformation occurred in a short period of time. Due to the quick global development of COVID-19, the switch to online teaching was adopted in 61 more countries by March 13 [9].

Saudi Arabian universities have offered limited online education choices as part of an open education network since the early 2000s. Because the information and network technology infrastructure were not well developed, the number of online courses grew slowly over time. Furthermore, due to a lack of computer access for some students and inadequate computer skills among some faculty members, students and faculty members exhibited limited interest in online instruction [8]. Prior to the COVID-19 epidemic, the quantity of online courses compared to face-to-face courses was very low [10].

Shifting all current courses to online platforms in a matter of days was a significant issue. In addition, creating and delivering online courses involves precise lesson planning, specialized training, technology tools, and an IT team's help [8]. The unexpected breakout of COVID-19, on the other hand, revealed the lack of online teaching skills among faculty members as well as the unpreparedness for an entirely online approach among departments and schools. Students, on the other hand, showed fewer problems with online technologies and platforms, but they experienced issues with self-control, offline learning environments, and learning behavior [11], [12].

In Saudi Arabia, education is given a lot of attention and care by the government. Dr. Hamad bin Mohammed al-Sheikh, the Saudi Minister of Education, announced that Saudi Arabia began offering online education years ago, but the systems were recently updated in response to the coronavirus outbreak [13]. Since the start of this shift, the Ministry of Education (MoE) has introduced five virtual learning alternatives that could be accessed at any time and from any location. These are possibilities available to those who do not have access to the internet via television. Students can access their lectures via iEN TV channels, iEN's Youtube channel, iEN's educational portal, Future Gate, and the unified education database [14]. Moreover, the Ministry of Education has been broadcasting educational materials for all grades on television and through social media. Also, approximately 127 teachers and administrators have been nominated to teach regular classes in 112 enlightening courses on various television channels (broadcasting nationwide from a classroom in Riyadh) [15].

Furthermore, the Ministry of Education prepared to launch the new Madrasati Platform by the beginning of the 2020 academic year. The Madrasati Platform allows teachers to construct virtual classes and provide students with a wide range of content, including presentations, educational videos, textbooks, exercises, and courses at various levels: elementary, intermediate, and secondary [16]. The Ministry of Education has also created several educational policies to help students effectively utilize these electronic and educational opportunities. For example, morning hours are allocated to intermediate and secondary students, while afternoon hours are allocated to elementary students, so that parents would be able to follow up with the students to provide help with their distant learning in the evening [17]. Al Mayman points out that the MoE is working closely with other ministries to ensure that every student has the necessary tools and resources to successfully complete the school year via distant learning. The objective is to assist students who lack internet access, or who do not have any devices to access the platform by broadcasting lessons during school time [16].

AlSalih points out that the Ministry of Education is working in cooperation with experts in international organizations to conduct an extensive validating assessment study on distant learning in universities and schools, during and after the pandemic [18]. Therefore, online learning is not just a temporary solution for this period. The Saudi Minister of Education has declared that online learning could eventually become a strategic choice for Saudi Arabia and not just an alternative in response to the coronavirus crisis [19].

Many studies have evaluated the effect of COVID-19 on education in Saudi Arabia [8], [15], [20]. In a study conducted in Saudi Arabia's elementary schools, researchers investigated the teachers and the students' perspectives of e-learning. Overall, teachers and students in primary schools expressed positive attitudes toward e-learning [20]. Another study conducted in Jubail Industrial College reported that E-learning according to many teachers, saves time and energy when it comes to revising and modernizing teaching materials. A small percentage of teachers consider e-learning to be an additional liability because they are not confident in their capacity to handle the technical needs during the pandemic. The majority of teachers were enthusiastic about the idea of incorporating new technologies and approaches into the classroom. Teachers, on the other hand, pointed out that proper training and workshops are essential to improve the effectiveness and efficiency of e-learning activities [15].

B. Madrasati Platform

As abovementioned, the Madrasati Platform was established by the Ministry of Education (MoE) as a result of the decision by the Saudi government to close all public schools in the country. Originally, the schools were to use the Madrasati Platform for the first seven weeks of the first semester of the 2020 academic year. As the coronavirus situation continued, the MoE announced that schools are to continue using the platform until further notice. The Madrasati Platform is an e-learning environment consisting of many tools that support the teaching and learning process for all education levels from the 1st to the 12th grade. It also helps in following the lesson plans and achieving educational aims and objectives set by the curriculum. Furthermore, it aids students in acquiring skillsets, values and new knowledge, and at the same time being compatible with the digital needs and requirements of the present and future [21].

The Madrasati Platform features a package of educational tools to assist the teaching and learning process. The platform features a virtual classroom that enables teachers and students to meet via virtual conference or at any suitable time via recorded lessons. In addition, it includes the Microsoft Office (365), which includes email client, Teams, and a variety of networks for communication amongst learners, teachers, or parents. The platform also provides educational books, videos, and cartoons, containing 450,000 electronic lesson plans and 45,000 educational contents. Moreover, it contains tools related to lesson planning and design that allow teachers to design lessons with equality and diversity in mind. Teachers can also design assignments or online tests using this platform. The platform also has test-banks that contain in excess of 100,000 questions for evaluation and measurement of cognitive and educational achievements [21], [22].

By the end of the first semester in 2020, the Madrasati Platform facilitated more than 89,000 virtual lessons for private and public schools in Saudi Arabia, with about 489 million visitors. Moreover, teachers created more than 2.5 million electronic test forms using this platform during the first semester, while students submitted more than 15 million assignments and made more than 10 million enquiries to teachers [23].

Madrasati's features and performance are quite similar to those of commercial providers like Moodle, Blackboard, and Canvas. Madrasati Platform, on the other hand, is an internally built LMS that is designed by an organization rather than one that is purchased and deployed by a commercial company.

Khanfar (2020) investigated the most significant obstacles encountered by female teachers in Eastern Region public schools in Saudi Arabia during the coronavirus pandemic. She concluded that the most important challenges were the skills and the infrastructure required in using the Madrasati Platform based on 375 female teachers' opinions [5]. However, as discussed above, the Madrasati Platform incorporates a variety of Microsoft Teams features which enables safe virtual classrooms for learners to interact with their teachers when it comes to class homework and e-activities [21]. In another study, [22] concluded that most teachers believed that the platform would reduce the teachers' responsibilities in future, especially in theoretical materials, and hoped to continue teaching using this platform even after the coronavirus pandemic has ended. The teachers also reported that due to the difficulties during the registration process, some students and teachers were hesitant to use the platform when it was first introduced [22].

Moreover, the teachers also indicated that using the Madrasati Platform has many advantages such as ease of teaching, an integrated platform, online tests and assignments. The platform also saves time, effort, and data; builds learners self-reliance; reduces financial waste, and traffic congestion. Nonetheless, the Madrasati Platform also has several disadvantages and negative aspects, including less interaction, no direct communication between teacher and student, and a decrease in students' attention levels and lack of flexibility in tackling them. Also, there is the issue of evaluating outstanding students, which led them to decide not to attend the asynchronous virtual classroom (iEN channels or other recorded video) and only concentrating on synchronously virtual (live) classroom on Teams. Finally, there are some technical issues with the suspension of the platforms' system [22].

C. *Usability of e-Learning*

According to [24] and [25], current e-learning systems are more concerned with the course material than with the design of the content. The majority of e-learning research studies focus on the information quality rather than the design's usability [26], [27]. The main problem faced by e-learning designers is the creation of sophisticated technologies that allow learners to easily endure their learning activities regardless of time or location [28]. According to [29], the interface is the most important aspect in the user's first impression.

Human-Computer Interaction (HCI) is mostly accomplished using interfaces. This defines the e-learning tool's learning environment [28]. In the e-learning environment, interface design has an impact on the student and instructor's ability to collaborate effectively [30]. According to [31], usability is the most important component in HCI. The ability to use the system in a simple manner is referred to as usability [32]. Total usability, according to [33], is comprised of a few essential components, including learnability, efficiency, memorability, error frequency, and subjective satisfaction.

Perceived usability is an important component of the higher-level construct of us-ability [34]–[37]. The Computer System Usability Questionnaire CSUQ [38] and the System Usability Scale [39] are two of the most widely used standardized questionnaires for assessing perceived usability. They were created independently in the 1980s by IBM and DEC and released in the mid-1990s. According to recent studies, the SUS and CSUQ questionnaires are highly associated and appear to be assessing the same thing, probably perceived usability [40], [41].

Many studies on evaluating usability of e-learning websites have been undertaken in Saudi Arabia [42]–[45]. For example, Al-Omar (2017b) investigated and assessed the internal and exterior usability aspects of 12 university websites in Saudi Arabia that offer distant education courses and found that these websites are reliable but violate basic usability criteria. Also, [43] and [45] investigated the usability of JUSUR LMS using usability techniques based on satisfaction surveys. The findings revealed that the investigated students liked JUSUR LMS and found it simple to use. However, the system has some technical and functional issues that make it difficult to use. Moreover, [4] evaluated the design user interface to prove their hypothesis that Blackboard LMS is accessible and usable by teachers at King Saud University by questionnaires. The result was that the software is simple to access and use. Also, [46] recently published an empirical study in Saudi Arabia on Saudi students' preferences for Moodle and Blackboard systems. In their study, the authors compared three metrics: user interface, download and upload service, and materials organization. As a result, in terms of usability, students preferred the Moodle learning management system over Blackboard. Furthermore, a recent paper presented the findings of a study that investigated the usability of the Blackboard system from the perspective of academics at Umm Al-Qura University in Saudi Arabia, using two of the most used usability measures, SUS and CSUQ. The study's findings revealed that Blackboard's usability is insufficient and needs to be improved [40].

Furthermore, the content accessibility and usability of the Madrasti Platform were evaluated by [7]. In the examination, different web diagnostic tools and measurements based on Nielsen usability criteria were employed. The measures broke links compliance with WCAG guidelines. The evaluation was conducted on only 5 main pages in a student account which are the Sign in page, Home page, My courses page, My homework page and My schedule page. According to the findings, the Madrasti Platform is considered inaccessible by some disabled users. Also, the Madrasti's usability is considered as low [7].

III. METHODOLOGY

Both qualitative and quantitative data were collected in this study. As a result, both quantitative and qualitative approaches were used in the data analysis. This section will describe the methods used which are survey, semi-structured interview, and thematic analysis.

A. *The Questionnaire*

The study was conducted using the questionnaire as a data gathering tool. Questionnaires are one of the most used data collection techniques, across all fields of research, not just usability studies. The questionnaire was identified as the most appropriate for the study because large amounts of data could be collected in real time, it is familiar to several respondents, and it is easier to administer [47]. The questionnaire included 24 questions in three sections. The first section includes 4 questions that are related to age, gender, school level in teaching and region of the kingdom. The second section also includes 4 questions that related to teaching experience, whether an e-learning system has been utilized previously, device used and the internet browser. The third section of the questionnaire includes 16 questions (see Fig. 1) which are related to Computer System Usability Questionnaire (CSUQ). These questions produce four scores (one overall score and the other three are subscales). The following are the rules for determining these scores:

- Overall: average of the answers to questions 1-16 (all questions).
- The Usefulness of the System: average of the answers to questions 1–6.
- Information Quality: average of the answers to questions 7–12.
- Interface Quality: average of the answers to questions 13–15.

	The Computer System Usability Questionnaire Version 3	Strongly Agree						Strongly Disagree	
		1	2	3	4	5	6	7	NA
1	Overall, I am satisfied with how easy it is to use this system.	O	O	O	O	O	O	O	O
2	It is simple to use this system.	O	O	O	O	O	O	O	O
3	I am able to complete my work quickly using this system.	O	O	O	O	O	O	O	O
4	I feel comfortable using this system.	O	O	O	O	O	O	O	O
5	It was easy to learn to use this system	O	O	O	O	O	O	O	O
6	I believe I became productive quickly using this system.	O	O	O	O	O	O	O	O
7	The system gives error messages that clearly tell me how to fix problems.	O	O	O	O	O	O	O	O
8	Whenever I make a mistake using the system, I recover easily and quickly.	O	O	O	O	O	O	O	O
9	The information (such as online help, on-screen messages and other documentation) provided with this system is clear.	O	O	O	O	O	O	O	O
10	It is easy to find the information I needed.	O	O	O	O	O	O	O	O
11	The information provided with the system is effective in helping me complete my work.	O	O	O	O	O	O	O	O
12	The organization of information on the system screens is clear.	O	O	O	O	O	O	O	O
13	The interface* of this system is pleasant.	O	O	O	O	O	O	O	O
14	I like using the interface of this system.	O	O	O	O	O	O	O	O
15	This system has all the functions and capabilities I expect it to have.	O	O	O	O	O	O	O	O
16	Overall, I am satisfied with this system.	O	O	O	O	O	O	O	O

** The "interface" includes those items that you use to interact with the system. For example, some components of the interface are the keyboard, the mouse, the microphone, and the screens (including their graphics and language).*

Fig. 1. The CSUQ [36].

The resulting scores range from 1 to 7, or NA (not applicable), with lower scores indicating the higher agreement level of the user. The CSUQ scales had high reliability, with coefficient alphas exceeding .89 for all scales. [38], [40].

The respondents were given the questionnaire in their native language (Arabic). The Arabic version of the CSUQ was created using the translation approach as used by [48]. Google Forms was used to host the questionnaire online. The questionnaire was designed for teachers who were familiar with the Madrasati Platform in Saudi schools for all grade levels, as stated on the welcome page of the questionnaire. They were also informed that participation in the study was completely optional, and they could withdraw at any time. Also, to ensure clarity, three teachers piloted the questionnaire before it was distributed. After the questionnaire distribution, statistical analyses were conducted to analyze the data using the software - Statistical Package for the Social Sciences (SPSS).

B. *Semi-structured Interview*

Following the questionnaire, semi-structured interviews were conducted. They provided the flexibility we required for the interviews. They allowed us to focus on the most pressing usability issues about interface and design, as well as ask follow-up questions. As a result, we received detailed feedback on specific concerns. To recruit participants, we sent our request to find participants who had experience with the Madrasati Platform via social media tools such as WhatsApp and Twitter. Participants who were interested in being part of the study sent us their contact. We per-formed interviews until thematic saturation were reached [49], as the last few inter-views provided no new patterns or topics. A pilot study was conducted with one participant to ensure the clarity of the questions. As a result, the researcher decided to ask the participants to share their screen while using the Madrasati Platform which helped in providing more information about what the participants would like to express (see Fig. 2). All interviews were conducted online using Microsoft Teams. Each interview lasted between 40 minutes and one hour. To ensure consistency throughout all sessions, an interview guide was created. All participants gave their informed consent to be audio-recorded and participate in the study. The participants were given a brief explanation of the technique before the interviews began. The subjects discussed during the interviews were background information, teaching and technical experience, interface design issues, challenges, and suggestions for improvement. All the interviews were done in Arabic by the same inter-viewer, who wrote notes, audio-recorded and transcribed the conversation. The transcript was translated to English and reviewed by two linguistic experts (English and Arabic).

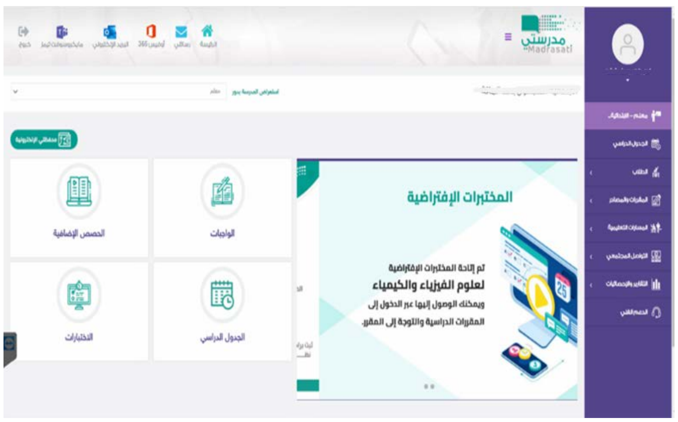

Fig. 2. A Screenshot of the Madrasti Platform from a Teacher Account.

C. Thematic Analysis

The researcher used Braun and Clarke's thematic analysis approach (see Table I) to analyze the qualitative data [50]. A method for detecting, analyzing, and reporting patterns (themes) within data is thematic analysis [50]. The thematic analysis was conducted using Nvivo, a qualitative data analysis software tool.

The researcher familiarized herself with the data by looking over it twice and collecting notes in the first step of the analysis. The noteworthy features in data were coded in a systematic manner across the full data set in the second stage, and data relevant to each code was gathered. The third stage was to group the codes into possible topics. According to [51], researchers should code 10–50 percent of the data first, and then have another coder confirm the coding reliability. The researcher used this suggestion to examine 25% of the data and create early coding groups and definitions. After then, the data was given to an independent coder to double-check. The independent coder had prior qualitative coding experience but had no prior knowledge of the subject. The researcher and the independent coder reviewed the themes in the fourth step to make sure they functioned with the coded extracts and the whole data set. After that changes were made to improve the coding scheme. The researcher continued to code the rest of the data after refining the technique. The topics were given names and descriptions in the fifth step. A scholarly report on the analysis was created as the final phase. The independent coder then double-checked all the segmentations and coding. Both the researcher and the independent coder collaborated to discuss and resolve issues, as well as to come up with the final category names.

TABLE I. THEMATIC ANALYSIS'S PHASES [50]

1.	Familiarization with the data
2.	Generating initial codes
3.	Searching for themes
4.	Reviewing themes
5.	Defining and naming themes
6.	Producing the report

IV. RESULTS

The results of the questionnaire and the interviews are presented in this section.

A. Participants

A total of 759 participants responded to the questionnaire and 20% of them were male while 80% were female. 12.6% were between the ages of 26 and 35; 35.1% were between the ages of 36 and 45; 32.4% were between the ages of 46 and 55; and 1.6% were beyond 55. In addition, most of the participants (71.3%) had teaching experience of more than 10 years. 42% were teaching the primary level, 26.6% were teaching the intermediate level, 24.6% were teaching the secondary level and 6.4% were teaching more than one level. Also, 37.7%, 34.8% and 7.9% of the participants were from Riyadh region, Makkah region and Madinah region, respectively. Moreover, 61.5% of participants reported that they never been utilized any e-learning systems previously. Furthermore, Google Chrome was the browser used with the Madrasati Platform by 64% of the participants. 20.7% used Microsoft Edge and 7.8% used Safari. Finally, 552 teachers (72.7%) used the Madrasati Platform via laptops, 10.3% via tablets or iPads, 11.9% via mobiles and only 5.1% via desktops. Table II provides an overview of the descriptive statistics of the participants.

For the interviews, it was conducted with ten teachers who agreed to participate with ages ranged from 34 to 45 years. 70% of the interviewees had a bachelor's degree, 20% had a master's degree and 10% had a diploma. Moreover, 40% of interviewees were teaching the secondary level, 30% were teaching the primary level, and 30% were teaching the intermediate level. Also, 80% of the interviewee had a teaching experience of more than 10 years.

B. CSUQ

Fig. 3 shows the average response to each item in the CSUQ questionnaire from all participating teachers. Numbers range from 1 to 7, with lower scores indicating a higher satisfaction level. The average of teachers replies to the statements range between 2.61 and 3.97. The overall score of the CSUQ, as well as the scores of the three subfactors: System Usefulness, Information Quality, and Interface Quality, are shown in Fig. 4. The CSUQ's overall score was 3.14 (SD = 1.97) and the three subfactors had average scores of 2.83, 3.41, and 3.25, respectively.

TABLE II. SUMMARY STATISTICS ON PARTICIPANT DEMOGRAPHICS

Demographic Attributes		Number of respondents	%
Gender	Male	152	20
	Female	607	80
Age	<25	2	.3
	26–35	96	12.6
	36–45	403	53.1
	46–55	246	32.4
	>55	12	1.6
Teaching Experience	<1	2	.3
	1 year> and <5 year	31	4.1
	6 years> and <10 year	185	24.4
	10 years >	541	71.3
School level	Primary	322	42.4
	Intermediate	202	26.6
	Secondary	187	24.6
	> level	48	6.4
Region:	Riyadh	286	37.7
	Makkah	264	34.8
	Eastern	46	6.1
	Madinah	60	7.9
	Al Baha	2	0.3

In order to determine the level of satisfaction, CSUQ scores were transformed to a 0–100-point scale from their previous scale of 1-7. This conversion is used in previous studies [40], [41] to convert CSUQ scores to SUS scores then the scores were matched against the Sauro–Lewis CGS (Table III). The process of this conversion is as follows:

- Taking the mean of the CSUQ items (16 separate items).
- minus 1, and.
- multiplying by 100/6.
- subtracted the result from 100.

For example: Using the best possible CSUQ mean of 1, the score converted to the SUS scale is: 100 – (1–1) (100/6) = 100–0 = 100.

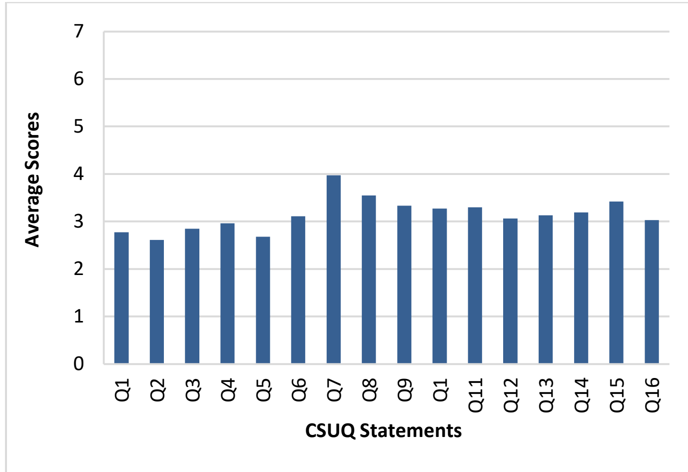

Fig. 3. Statement-by-Statement Comparison of CSUQ.

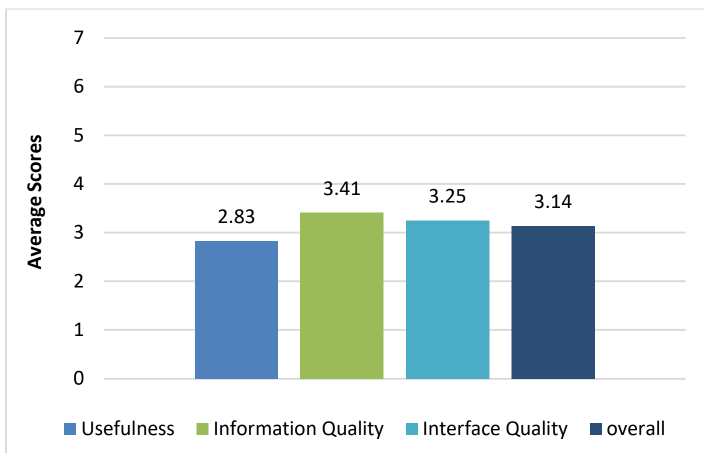

Fig. 4. Overall Score of CSUQ and the Three Scores of CSUQ Subfactors.

Table IV shows the converted scores for the CSUQ (overall and the three subfac-tors). The overall mean CSUQ was 64.36 (Grade: C-) which indicates that the Madrasati Platform has a low average of usability and teachers were not entirely satisfied with it. The converted scores for both Information Quality and Interface Quality are low (Grade: D) while the score of the Usefulness is within the average (Grade: C).

TABLE III. THE SAURO–LEWIS CURVED GRADING SCALE

SUS score range	Grade	Percentile range
84.1–100	A+	96–100
80.8–84.0	A	90–95
78.9–80.7	A –	85–89
77.2–78.8	B+	80–84
74.1–77.1	B	70–79
72.6–74.0	B –	65–69
71.1–72.5	C+	60–64
65.0–71.0	C	41–59
62.7–64.9	C –	35–40
51.7–62.6	D	15–34
0.0–51.6	F	0–14

TABLE IV. CONVERTED SCORES FOR THE CSUQ (OVERALL AND THE THREE SUBFACTORS)

factor	Mean	Score range	Grade
overall	3.14	64.36	C-
Usefulness	2.83	69.51	C
Information Quality	3.41	59.80	D
Interface Quality	3.25	62.52	D

C. Themes

Table V shows the number of usability issues reported by interviewees. In total, 135 issues were reported. Seven themes emerged from the thematic analysis of the interviews. Table VI describes how each theme in this study is defined. 28.15% of the issues were about navigation theme and 26.67% were about missing features. Furthermore, 20%, 11.11% and 8.15% of the issues were about broken features, compatibility issues and system messages' issues, respectively. The lowest percentage of the issues was about inability of the platform to prevent errors with 4.44% and accessibility with 1.48%.

Missing Features: All the ten interviewees proposed features that were missing but may help them use the Madrasati Platform more effectively. Features and example quotes include the following:

1) Assignment notification: "When students submit their assignments, they notify me with their submission via WhatsApp because there are no assignments notifications in the platform." User4.

2) Synchronize the Madrasati Platform with the Noor system: "After we finish, we need to insert all grades in "Noor" system. Why is there no link between the two systems? It is double works for us." User2.

3) Download all files: "It is better if the platform provides the option to download all assignments as one file or a compressed file." User9.

4) Message status Read/Unread: "When I go to the students' inquiries page, I don't remember which messages I read and which ones I didn't. There is no message status (read and unread) and this makes me check all messages each time." User1.

5) Share questions with other schools: "There is no questions bank for my course, and I wish that I could share questions with other teachers who are teaching the same course in other schools. This will save our time." User7.

6) Sort Assignments: "When I view students' assignments, I cannot sort them as what I need. It displays Assignments based on alphabetic of students' names. I would like to sort them based on the submission date." User8.

7) Submit project: "There is no option for students in the secondary level to submit their projects and we use Telegram for this." User6.

8) Search filter by date in attendance report page: "In attendance report, I cannot search by date or by the class, only search by status is available." User3.

9) Synchronize the Madrasati Platform with Microsoft Team: "Taking attendance for each class is exhausting and it is hard especially when I have two continuous classes. Why the platform is not linked with Teams and can take the attendance automatically." User9.

10)Charts and Graphs: "The report pages not comfortable to our eyes because all statistics are represented as numbers and texts. It is too much information here. Using charts and graph is preferable." User10.

11)Help and support documents: "The platform lacks help documents, if I faced any problem; I go to YouTube to see what people who have the same problem do." User5.

12)Save Session: "When I start to prepare the session and I go to add assignment and come back to my session again. I do not find it because there is no save session option, so I have to recreate it again." User7.

TABLE V. NUMBER OF THEMES EMERGED BY EACH USER

Themes	U1	U2	U3	U4	U5	U6	U7	U8	U9	U10	Total	%
Missing features	2	3	5	3	4	3	4	5	4	3	36	26.67

TABLE VI. THEMES' DEFINITIONS

Theme	Definition
1) Missing features	Users face difficulties due to the absence of certain functions
2) Broken features	Users face difficulties due to some current functions not working, provide inaccurate result or cause delay in work.
3) Navigation	Users have difficulty moving between pages or selecting appropriate links for information or function.
4) Accessibility.	Users with disabilities have difficulty contributing, perceiving, comprehending, navigating, and interacting with the platform.
5) Preventing errors	Users find the platform not helping them from prevents a problem from occurring in the first place.
6) Compatibility	Users face difficulties when using specific browser or specific device.
7) System Messages	User experienced unclear, wrong or useless error message. Also, user does not receive a message or feedback when it is required.

Broken Features: All the ten interviewees mentioned problems with the Madrasati Platform's present features. Some of the current features, such as motivational stars, grades, and academic records, are not working. Other features, such as system email, announcements, and a short time for automatically logging out, caused them to experience delays. Other issues were mentioned, such as lost assignment files and inaccurate teacher reports. Examples of quotes that mention those issues are as follows:

- "Teacher report is not accurate, and this is really annoying me because I add a lot of things, but the number in the report is not correct. I take pictures for what I did and send it to the leader of the school because she asks me about it, and she cannot see my efforts via the platform". User9.
- "The auto logout is short and if have two continuous classes, I have to login twice." User3.
- "If I add enrichments in enrichments' bank, it does not appear in the class, but it is counted in the report. And if I add it from my Timetable, it appears in my class but not counted in the report. So, I have to add it twice in the two places to make sure it will appear in both my report and my class." User10.

Navigation: The Madrasati Platform was difficult to navigate for all the ten interviewees. There were complaints about being unable to return to the previous page, duplications, and seeing assignments one by one. The concerns are described in the following quotes:

- "I can send assignment to students from two places. From my timetable and from my assignments. This is really confusing." User7.
- "Back button is missing from many pages, and each time I have to click the main menu to go to the page that I want." User10.
- "It is really hard viewing assignment one by one. I have six classes and each class has 40 students. I send assignments twice a week and downloading assignments one by one is time consuming." User9.
- "When I download the student's assignment, the file name is not meaningful and not related to students. So, when I need to find the specific student assignment, I have to navigate all of them." User3.

Accessibility: One teacher mentioned the content accessibility issues in the Madrasati Platform with her students who have a hearing impairment. The teacher mentioned the videos with no subtitles, sign language, or a summary. Examples of quotes that mention this issue are as follows:

- "In our school we have special classes for hearing impairment students. We summarize the content for them not like other students. But in the Madrasati Platform, the same content for all, even the videos there is no written summary next to them that can help those students." User2.
- "The cartoon films without subtitle or the use of sign language. Thus, students go to Ein channel which has all videos in sign language". User2.

Preventing errors: Four teachers shared examples of how the Madrasati Platform failed to prevent faults or mistakes from occurring. Drop down menus that are not synchronized, manual calculations, and duplicate sessions are all examples of issues. Examples of the quotes that mention this issue are as follows:

- "When I select the level in the first dropdown menu, I can select a course for another level from the next dropdown menu. In the second dropdown menu, I'm supposed to see only the courses related to the level that I have selected in the first dropdown menu." User1.
- "I have to calculate the number of minutes when I create the exams or session. It is better if the platform calculates it to avoid any mistakes or at least to give us another option like choose hours." User3.
- "I can create the same session twice and this caused a lot of delay in waiting to move students to one of them." User4.

Compatibility: Nine teachers mentioned cases related to this theme. The Madrasati Platform was difficult to use via Google Chrome compared to other browsers. Also, some problems were mentioned when using mobile phones or tablets. The issues are described in the following quotes:

- "We prefer to use Google Chrome, but we had a problem with it. It keeps saving the data and we cannot use different accounts even when delete the data. To solve this problem, we create many accounts in the same laptop, one for me, one for my husband and one for our son and one for our daughter." User4.
- "I usually use Google Chrome but with the Madrasati Platform, I found that Microsoft Edge is better. I faced many problems with Google Chrome, the system hangs a lot with it" User2.

- "I cannot use specific types of questions like matching question. It will not work effectively in mobile or tablets." User5.

System Message: Six teachers expressed issues with the system's messages and responses. Some error messages were unclear, there was no system reaction, and there was a lack of problem explanation in the message. The concerns are described in the following quotes:

- "The system shows me errors in creating assignment, but I don't know what the reason is or how I can solve it. I only try again and again." User1.
- "I have uploaded the file, but no message tells me its uploaded. Then, when I refresh the page, the file is there." User7.
- "I found that if I uploaded a large image, the message does not tell me you uploaded a big file and by guessing I know that this is the reason." User4.
- "Some error messages have ambiguous codes, and I don't understand it." User3.

V. Discussion

This section discusses the study's findings, as well as their relevance to other studies. The goals of this study were to determine the usability of a Madrasati Platform from the perspective of schoolteachers in Saudi Arabian, as well as to identify the most common usability concerns that teachers encountered when using the platform.

The first research question aims to investigate how teachers perceived the Madrasati Platform in terms of usability. A total of 759 teachers from different regions in Saudi Arabia responded to the CSUQ in our study. The CSUQ's mean total score was 64.63, which was lower than expected. Based on this finding, it seems that the usability of the Madrasati Platform on the teacher side is inadequate and needs to be improved. Comparing this result with the findings of the study with the Madrasati Platform in a different context, it is consistent with the research of [7] which reported that students' pages in the Madrasti Platform had several issues in terms of usability. Looking to the three subscales of the CSUQ, the results show that the acceptable mean score for the Usefulness while the scores are lower than expected for both Information Quality and Interface Quality. These findings are similar to the results of [40] when evaluating the usability of the Blackboard using CSUQ.

The second study question was to determine the most significant usability concerns that teachers had when using the Madrasati Platform. Teachers found the Madrasati Platform difficult to navigate. There were concerns about inability to access the previous pages and many duplications. Navigation is a critical issue and requires more considerations which have an impact on user satisfaction and continuity with e-learning systems [52]. Comparing this result with the findings of previous research in a different context, it is consistent with the research of [40] which found that the navigation is a significant issue on the Blackboard by the instructors. Teachers in our study also complain about functions that are not working. As previously stated, the system was developed throughout the epidemic, and the Ministry of Education made numerous updates and improvements during that time [53]. Working on the system for such a short period of time may not be sufficient to carefully test the functionalities that have been reported as broken. Furthermore, teachers mentioned other usability difficulties, such as the platform's inability to prevent them from making mistakes and issues with the platform's messages and responses. Unclear error messages, a lack of problem explanation in the message, and manual calculations that allow for human error are just a few examples. This result is in line with [54] which examined the usability of Khan Academy and found the major issues in "Error Prevention" when the system does not prevent users from making errors and users don't get properly informed in the state of error. Moreover, the Madrasati Plat-form's content accessibility concern for students with hearing impairment was identified. Subtitles, sign language, and videos brief summaries are not supported on the Madrasati Platform. This finding is consistent with prior research by [7], who found that the Madrasti platform is inaccessible to some disabled users. Based on the findings, the present study's recommendations for enhancement are as follows:

- It is necessary to conduct extensive testing of the platform's functions, and bro-ken features should be marked as inactive.
- It is advised to connect the Madrasati Platform to the Noor system to assess students immediately.
- Madrasati Platform developers are encouraged to follow the World Wide Web Consortium (W3C) guidelines to ensure that people with disabilities have the same access to information on the platform as everyone else.
- Access to the previous and next pages should be made easier for the user. Adding "Back" and "Next" buttons, for example, will be beneficial.
- The Madrasati Platform should offer appropriate help online and provide documentation that is easily accessible and searchable.
- It is suggested to reduce the amount of text in the page by using graphs and charts in the statistical and reports pages.
- It is recommended to include sign language in the content provided by a video and to employ cartoon films with subtitles. Also, next to each video, include a summary in writing.
- It is suggested to integrate the Teams program and Madrasati Platform. As a result, student attendance and absence records on the Platform will be immediately linked to the Teams program.
- Eliminate redundancy on the platform whenever possible to reduce cognitive overload and confusion.
- A database for scientific material, such as assignments and tests, should be available.

- Replace human calculations with system calculations and synchronize corresponding dropdown menus to prevent users from selecting the incorrect option.
- it is recommended that the platform should not use jargon in messages to pro-vide clear and understandable helping messages.
- The number of clicks required to access any page should be kept to a minimum. For example, send assignment button can be added in the create assignment page.
- It is advised to increase the duration time for the automatically logout.
- It is essential to enhance the search by adding common search features and filters.
- Allow users to download all files at once to save time downloading large numbers of files one at a time.
- Adding features such as assignment notification, sort assignment, share question with other schools, message status and submit project will be useful.
- Continuous user feedback will improve Madrasati Platform's usability and acceptability in schools.

The outcomes of this study contribute to the fields of e-learning system and usability evaluation in a variety of ways. The research provided here is the first to assess Madrasati Platform's perceived usability from the perspective of schoolteachers and make recommendations based on the findings. The findings have significant implications for e-learning system usability. It will aid the Saudi Ministry of Education in developing policies and programs that will ensure the success of e-learning in the kingdom.

VI. Limitations

It is important to mention that generalizability of the findings has limitations. First, the participants of the study were all recruited from a single target group: teachers. While this has not hampered our research because they are one of the primary target groups for the system being examined, it may limit the applicability of the findings to other groups who use it. Second, the data collecting methods in this study were a standardized usability questionnaire and semi-structured interviews. It would be interesting to know if data gathered from traditional usability research showed consistent results. Third, the study was conducted during the pandemic since the Madrasti Platform is still new to most teachers and they are unfamiliar with it. The results may change when teachers become more familiar with the platform.

VII. Conclusion

The Madrasati Platform is a new system for all school levels in Saudi Arabia that was developed by the Saudi Ministry of Education during the covid-19 pandemic. Usability is one of the most important characteristics of a system since it affects how users interact with it. Therefore, in this paper, we examined the usability level of the Madrasati Platform from the perspective of schoolteachers in Saudi Arabia, as well as the most common usability difficulties that teachers encountered when using the platform. Both questionnaires and semi-structured interviews were conducted to collect the data. According to the study's findings, the Madrasati Platform's usability in schools for teachers is insufficient and should be improved further. Teachers stated many usability issues faced by using the Madrasati platform such as navigation, broken features, inability of the platform to prevent user mistakes to occur, message error issues, compatibility issues and content accessibility issues for the disability users. Additionally, a list of recommendations for enhancement was presented based on those findings. For future work, evaluation of the Madrasati Platform's usability with other target groups, such as students, school leaders, and parents, is helpful. Also, examine into whether the demographics of users have an impact on the total CSUQ scores. Furthermore, combination of evaluation methods, such as focus group, heuristic evaluation, and eye tracking, would be useful. Moreover, examination of other usability factors, such as memorability, learnability and accessibility, would be valuable in the future.

Abstract*—Readmission to the hospital is an important and critical procedure for the quality of health care as it is very costly and helps in determining the quality level of the point of care provided by the hospital to the patient. This paper proposes a group model to predict readmission by choosing between Machine Learning and Deep Learning algorithms based on performance improvement. The algorithms used for Machine Learning are Logistic Regression, K-Nearest Neighbors, and Support Vector Machine, while the algorithms used for Deep Learning are a Convolutional Neural Network and Recurrent Neural Network. The reasons for the appearance of the efficiency of the model depend on the are preparation of correct parameters and the values that control the learning. This paper aims to enhance the performance of both machine learning and deep learning based readmission models using hyperparameter optimization in both Personal Computer environments and Mobile Cloud Computing systems. The proposed model is called improving detection diabetic using hyperparameter optimization , the proposed model aims to achieve the best rate of between prediction rate accuracy for hospital readmission at the same time minimizing resources such as time delay and energy consumption. Results achieved by proposed model for Logistic Regression, K-Nearest Neighbors, and Support Vector Machine are (accuracy=0.671, 0.883, 0.901, time delay=5, 7, 20, and energy consumed=25, 32, 48) respectively, for Recurrent Neural Network and Convolutional Neural Network are (accuracy=0.854, 0.963, time delay=25, 660 energy consumed=89, 895) respectively. However, this proposed model takes a lot of time and energy consumed especially in Convolutional Neural Network. So, the experiments were conducted again, but in the cloud environment, based on the existence of two types of storage to preserve the accuracy but decreasing time and energy, the proposed model in cloud environment achieve for Logistic Regression, K-Nearest Neighbors, and Support Vector Machine (accuracy=0.671, 0.883, 0.901, time delay=2, 3, 8, and energy consumed=8, 9, 11) respectively, for Recurrent Neural Network, Convolutional Neural Network (accuracy=0.854, 0.963, time delay=15, 220, and energy consumed=20, 301) respectively.

Keywords—Machine learning; deep learning; diabetes; hospital readmission; hyper parameter optimization; cloud computing; mobile cloud computing

I. Introduction

With the change of lifestyle and the massive expansion in many countries, diabetes, which is considered a chronic and non-communicable disease, has become one of the most deadly diseases. Despite this, many deaths can be prevented through data analysis [18]. Therefore, in most developing countries, diabetes is a primary health care concern, the healthcare sector collects and processes medical data for diabetic patients in huge quantities of diverse sizes and structures [19].

The meaning of readmission to a hospital is the time it takes for the patient to return to the hospital again. Hospital quality is measured and health care costs are reduced by measuring readmission hospitals are financially penalized for exceeding the permitted rate of 30-day readmissions [21]. Machine Learning (ML) algorithms can be used to create objective models which then can be used to measure risk. These models are more complex but may be able to create more accurate risk predictions that should lead to improved diabetic patient outcomes [20]. Deep Learning (DL) algorithms have recently attracted a lot of interest in educational circles and commercialism because of their effective impact in various fields of research, such as speech recognition, natural language processing, and brain computer interface [16].

When creating ML and DL algorithms, there are many possibilities to define the architecture of the learning model. Often, the optimal model architecture for a given model is not known, and thus a range of possibilities must to be able to explore. In the way of ML and DL, the machine is asking to perform this exploration and automatically determine the optimal model structure. The parameters that define the structure of the model are referred to as hyperparameters [13], hence the process of searching for the ideal structure of the model is referred to as hyperparameter optimization [27].

Despite all this, ML and DL face an important challenge, as the performance of the algorithm depends heavily on its choice of parameters. DL requires hyperparameter optimization more than ML because (1) DL has more hyperparameters to be optimized, (2) DL has a higher dependency on the configuration of hyperparameters.

The accuracy of using deep learning changes drastically from 32.2% to 92.6% due to the variable selection of hyperparameters as reported [17]. Therefore, an effective hyperparameter optimization method is necessary for ML and DL.

*Corresponding Author

Other models used different ML and DL algorithms with different preprocessing methods but could not predict readmission for diabetic patients with high accuracy, nor did it take into account the point of saving resources such as reducing the time and energy consumed in the prediction process.

The goal of the paper is to 1) develop an accurate and generalized machine learning and deep learning models that is applicable to predicting 30-day readmission for diabetic patients by using hyperparameter optimization to control learning of machine; 2) to demonstrate the efficiency of (IDD-HPO) in mobile cloud computing environment with saving resources to minimize the total cost; 3) compare (IDD-HPO) results with the results of state-of-the-art models.

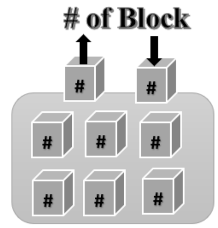
II. Background

Cloud Computing (CC) has recently emerged as a new framework to facilitate and implement online services [22], storing, analyzing, and displaying data requires significant modifications to the current cloud model, which in turn requires financial constraints and computational cost [23,24]. Many CC platforms provide these web services for ML and DL. The most popular of these are Amazon Web Services, Microsoft Azure, Google Cloud, and IBM Cloud [25]. Cloud storage is the online storage of data on the cloud. The data on the mobile is sent and stored in the cloud, the mobile device can access this data any time anywhere by sending data requests.

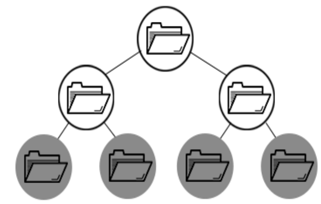
The two most common technologies of the system cloud storage are block-level storage and file-level storage. These two storage levels are described as follows [26]:

Block-level storage: Data is stored in blocks on a device with fixed sizes for each block (e.g., 512 Bytes). Data is stored according to the data format, type of ownership for each block, data stored as blocks in hard drives, which are installed in remote storage, a request is sent from the filing system to the storage this request is responsible for writing data to certain blocks and then retrieve it as shown in Fig. 1(a). Block storage is built to simplify larger workloads and improve Input/Output Operations per Second (IOPS), they are apt to be more expensive than file storage systems. However, this seriously depends on the chosen seller, conditions, features, cost of the storage operating system (OS), and some other variables.

File-level storage: Simply having an efficient, easily reached, and existing location to store files and data folders continues to be the most important requirement of any organization. For file-level storage, the only thing that is required is having a location to unload the data as shown in Fig. 1(b). File storage is stores data in a hierarchical architecture so the data and its metadata are stored in the form of files and folders. File storage systems are usually less costly than block storage. However, this seriously depends on the chosen seller, conditions, features, cost of the storage operating system (OS), and some other variables.



(a) Block-level Storage.



(b) File-level Storage.

Fig. 1. Types of System Cloud Storage.

This paper proposes a model with the objective of predicting diabetic readmission rate in hospitals, this model is named “Improving Detection Diabetic Using Hyperparameter Optimization” ((IDD-HPO)) by using ML algorithms (e.g., Logistic Regression (LR), K-Nearest Neighbors (KNN), and Support Vector Machine (SVM)) and DL algorithms (e.g., Convolutional Neural Network (CNN), Recurrent Neural Network (RNN)) for predicting hospital readmission among diabetics using hyperparameter optimization method in two scenarios, the first in personal computer (anaconda 3) and the second in the cloud environment.

This paper aims to: Improving the prediction of readmission to hospitals using hyperparameter optimization for both ML and DL algorithms. These prediction models are tested in two environments: personal computer and mobile cloud computing MCC system. The aim of these models is to achieve the best performance with high accuracy and decreasing total cost (e.g. time delay and energy consumed) based on mapping storage in the cloud. As a case study, the proposed model ((IDD-HPO)) was applied in a personal computer and cloud computing system.

The rest of this paper is organized as follows; the next section presents some related works. Then the proposed method will present in Section III. Subsection A in Section III presents the dataset description, subsection B presents the details of Machine Learning and Deep learning models tuning Using Hyperparameter Optimization, subsection C presents the details of the Cost Model for sending and receiving data to/from a server, and subsection D presents the details of the proposed Improving Detection of a Diabetic using Hyperparameter Optimization (IDD-HPO) model. Section IV presents the experiments for (IDD-HPO) on Personal computer system, subsection B presents the experiments for (IDD-HPO) on MCC system, subsection C presents the Comparative analysis Against State-of-the-Art Models with Results. Finally, conclusion and future works.

III. Related Work

In the field of health care, readmission to the hospital is considered a high priority because it represents whether the hospital is good or not, as it also aims to reduce costs. Little research has focused on readmission for diabetes, although diabetes on hospitalized patients has a large, growing, and costly burden.

In [2], this study was focused on the application of data mining techniques to predict the early hospital readmission by using ML algorithms, the most efficient algorithm was Random Forest with 0.898% of accuracy.

In this study [3], the prediction is done using Support Vector Machine (SVM), Random Forest (RF), Multilayer Perceptron (MLP), and Deep Neural Network if the discharged patient will be back in 30 days or not and the best presented accuracy value is 0.840%.

In [4], the model used in this study consists of 5 models tested and selected from 15 models. These blends are variables from logistic regression, decision trees, neural networks, and a naive Bayesian enhancer [5]. The performance of the model was on an unbalanced data set, and these models were selected after several tests and analysis of their accuracy, the accuracy value is 0.635%.

In [6], in the problem of readmission of diabetic patients to hospitals, the deep convolutional neural network (CNN) was used as an effective prediction method. This model is based on sample size scaling and data engineering processes. Using normalization is key to improving deep learning performance. This model achieves 92% better performance than other ML models.

In [7], Deep learning models (CNN, RNN) and machine learning algorithms (LR, KNN, SVM) were used to solve the problem of readmission of diabetic patients to hospital, this model is based on the use of data without normalization and the results were compared in the case of normalization and without normalization for (CNN, RNN, LR, KNN, SVM). The optimal performance in training and testing was in CNN in the case of using the data without normalization, where the accuracy ratio was achieved 0.924%.

In [8], the proposed Multilayer Perceptron model based on preprocessing process included comprehensive data cleaning, data reduction, and transformation aiming at better optimizing and selecting prominent features for 30-day unplanned readmission among diabetes patients. Random Forest algorithm is used for feature selection and SMOTE [9] algorithm for data balancing. a model consisting of two hidden layers with dropout [10] to achieve high overall accuracy and ROC. The proposed model with feature engineering is improving the performance of the others Machine learning algorithms, the accuracy value is 0.95%.

In [11], the researchers analyzed the readmission of diabetic patients using unsupervised methods and proposes an approach of generating embeddings for categorical features concatenated with normalized continuous features were fed into a neural network, the accuracy achieved is 0.952%.

In conclusion, most recent models relied on several methods for presenting data. These methods include: using Ensemble, normalization, non-normalization, Ensemble by age groups, and using data mining, all these methods do not achieve a high rate of accuracy. In this paper, the proposed model aims to use hyperparameter optimization methods to control the learning and evaluate the performance for the optimal values with the highest possible accuracy, but hyperparameters take a lot of time delay and energy consumed for the learning process. Hence the idea of using a hyperparameter in the cloud environment to reduce the time delay and energy consumed is proposed.

IV. The Proposed Method

This work proposes a model for improving the readmission rate. This model for improving detection of a diabetic using hyperparameter optimization ((IDD-HPO)) is implemented and compared in two environments: personal computers and cloud environment, then calculate accuracy, time delay, and energy consumed for each environment.

Fig. 2 summarizes the overall architecture of the proposed (IDD-HPO) model. In the following subsection, the model will be illustrate in more detail for each stage to build.

An intelligent model ((IDD-HPO)) based on hyperparameter optimization technique is proposed to enhance a choice between two classes (0, 1) where 0 is not readmitted and 1 is readmitted). Models used to apply ((IDD-HPO)) are CNN and RNN as DL algorithms and KNN, LR, and SVM as ML classifiers for the prediction of readmission.

In MCC, diabetes data set sent from mobile to cloud and retrieve from it to mobile based on the existing two levels of storage, file and block level.

The problem at the first applying ((IDD-HPO)) for data set in a personal computer system (anaconda3) and calculate the accuracy and total cost (time delay and energy consumed) for training and testing. Second applying ((IDD-HPO)) for data set in the cloud according to how to map mobile data item taking into account the limited resources of a mobile device by selecting the most suitable storage level for each data item to decreasing the time of training band testing for hyperparameter tuning and calculate accuracy and total cost (time delay and energy consumed).

In the rest of this section, the model is introduced then the (IDD-HPO) problem will be formulated.

A. *Dataset Description*

This proposed study is performed on a dataset represent 10 years (1999-2008) of clinical care at 130 hospitals across the United States and is provided by the Center for Clinical and Translational Research at Virginia Commonwealth University [1]. This data was used to predict the probability of readmission within the next 30 days for a patient with diabetes. The extracted information from the database for interviews must meet the following global criteria [14]:

1) All data taken during the meeting are from hospital cases.

2) Only diabetics are the ones to take data from at the meeting.

3) Range of stay patient in the hospital about 1-14 days.

4) Laboratory tests were carried out during the meeting.

5) Medicines were provided during the meeting.

101,766 encounters were identified to fulfill all of the above five inclusion criteria and were used in further analysis.

The data set was generated through three steps:

First, important features were extracted from the database. It was found that there were 55 features to be used in the study.

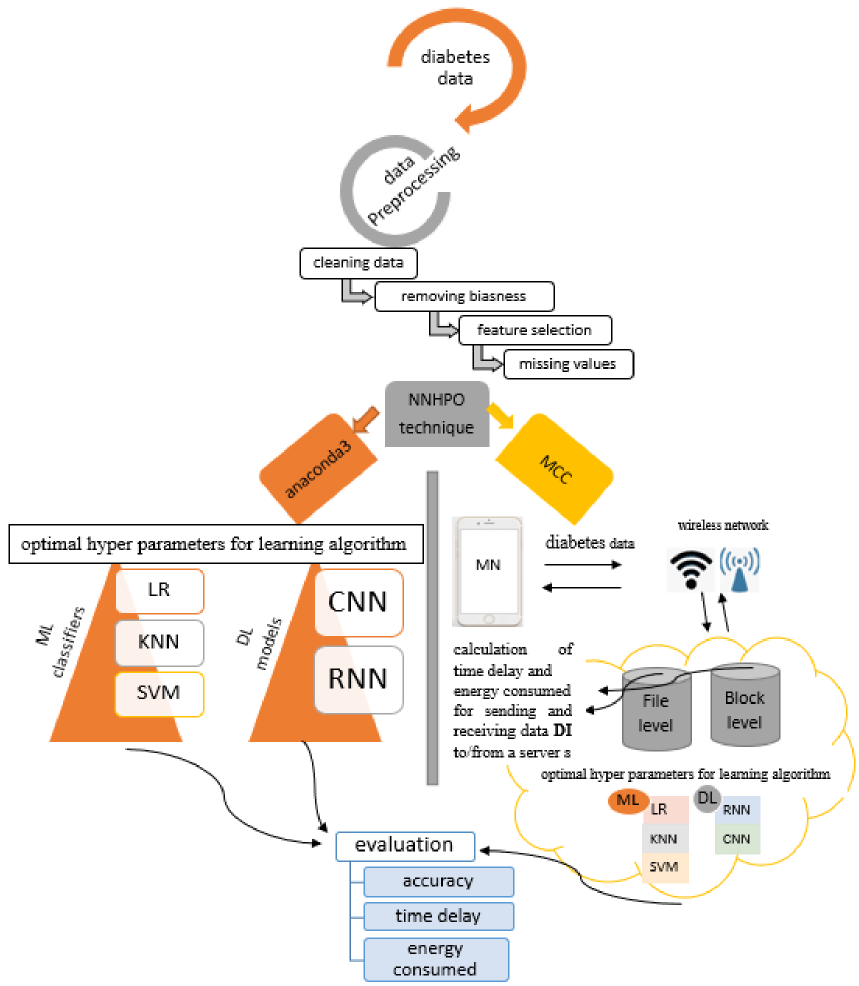


Fig. 2. The Proposed (IDD-HPO) Model in Personal Computer and MCC System.

Second, the data was preprocessed to extract useful information for research [11].

Third, the data set was upload to the cloud and store in two levels of storage file and block.

Data preprocessing will be implemented through the following steps:

- Cleaning Of Data: Firstly, delete records of patients who appear more than once to ensure that each patient has a unique identity. Then remove the features "patient_id,encounter_id" which tells about the Patient Number and Unique Identifier of a patient respectively.
- Removing Biasness: Also remove patient data dead or discharged to a hospice. Some rows are also repeat because the number of patients admitted within 30 days is very low.
- Feature Selection: There are a total of 55 features in this dataset, 23 of them medicine related features. After visualizing each other's dependency with the readmission feature found that the drugs the least role it plays in readmission, so 22 out of 23 medical features have been removed.
- Missing Values: Features that have a large percentage of missing values such as weight contain 97% so cannot be used in the analysis. So, the features with more than 30% missing values are removed. There is a feature, "medical specialty" that defines the specialty of attending physician which has some missing data so fill "Missing" in the missing place as this is the important feature for analysis. Then convert all the string categorical data into Integer categorical data to do analysis.
- Non-normalization technique: Data set will use without using any normalization. The advantage of the non-normalization technique is the facility to fix all features. It allows the classifier model to get the benefit of all features. Normalization is a packed down data between either -1 and 1 or 0 and 1. So data are need to use without any normalization to get correct output [7].

B. *Machine Learning and Deep Learning Models Tuning using Hyperparameter Optimization*

In ML and DL, the problem of selecting a set of optimal hyperparameters for a learning algorithm is hyperparameter optimization or tuning [10]. A hyperparameter is a parameter whose value is used to control the learning process and evaluates the problem to finding a set of optimal hyperparameters y* in the domain Y that return the best performance as evaluated on a validation set y:

$$y^* = \arg\min_{y \epsilon Y} f(y) \quad (1)$$

where the optimal solution is defined as the minimum of objective function *f*(*y*) that commonly corresponds to a loss function or an error rate.

The learning algorithm uses hyperparameters when it learns but it is not part of the resulting model. Parameters of the model have been trained which is effectively considered as a model at the end of the learning process, hyperparameters that were used during training are not part of this model. For example, the values of the hyperparameters that were used to train a model can not know from the model itself, the parameters of the model that were learned only know [12].

Tuning ML models is a kind of optimization problem. A set of hyperparameters exist and aim to find the correct combination of their values which can help us find the maximum (e.g. precision) of a function. For the proposed model, sets of ML and DL algorithms are used with different hyperparameters. The following is the list of used algorithms with their associated parameters.

- Logistic Regression (LR) tuning

Logistic regression does not contain any important hyperparameters to adjust. But sometimes, there are differences in performance with different solvers (*solver*).

- ➢ solver in [‘newton-cg’, ‘lbfgs’, ‘liblinear’, ‘sag’, ‘saga’].
- ➢ Regularization (*penalty*) can sometimes be helpful.
- ➢ penalty in [‘none’, ‘l1’, ‘l2’, ‘elasticnet’].
- ➢ The C parameter controls the penality strength, which can also be effective.
- ➢ C in [100, 10, 1.0, 0.1, 0.01].

- K-Nearest Neighbors (KNN) tuning.

The important hyperparameter for KNN is the number of neighbors (*n_neighbors*).

- ➢ Test values between at least 1 and 21.
- ➢ weights in [‘uniform’, ‘distance’]

- Support Vector Machine (SVM) tuning

There are a large number of hyperparameters in SVM algorithm to tune. For example, the parameter kernel will control how the input variables will be projected.

- ➢ kernels in [‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’]

Another parameter that can take on a range of values is the penalty (C).

- ➢ C in [100, 10, 1.0, 0.1, 0.001]

- CNN and RNN Tuning

Grid Search and Random Search are applied for DL using Kera Classifier, it is possible to apply in the same way when using scikit-learn ML models. Some of CNN and RNN parameters will be optimized such as: how many epochs to use in each layer, the number of batch size, and which activation function and optimizer to use as shown in Fig. 3.

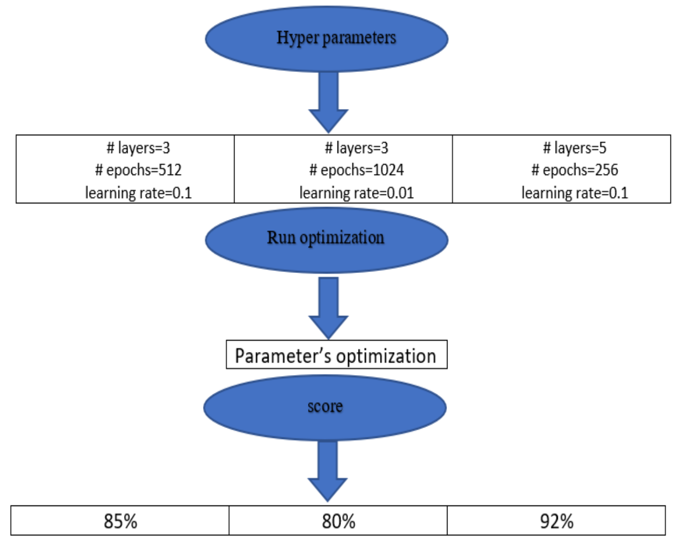

Fig. 3. CNN and RNN Hyperparameters.

C. *Cost Model for Sending and Receiving Data DI to/from a Server s*

In this subsection, the cost model is described for using the file and the block servers.

- Cost by using block cloud server

Block storage is built to simplify larger workloads, each data item needed to classify before storing it in the appropriate block. So, the cost for sending includes sending, classifying, and searching costs, and the cost for receiving includes retrieving and searching costs, they are apt to be more expensive than file storage systems. However, this cost depends on the chosen seller, conditions, features, cost of the storage operating system (OS), and some other variables.

- Cost for time delay in block cloud server

The cost of the time delay for sending DI to the block cloud server bcs is calculated as follows

$$CTD(S)_{bcs}(DI) = \sum_{d_i \epsilon DI} ctd_s(d_i, bcs) \quad (2)$$

The cost of the time delay for receiving DI to the block cloud server bcs is calculated as follows:

$$\mathrm{CTD(R)_{bcs}(DI)} = \sum_{\mathrm{d_i \epsilon DI}} \mathrm{ctd_r(d_i, bcs)} \quad (3)$$

By using Equations 2, and 3 the total cost for time delay by using bcs can be defined as follows:

$$\mathrm{TCTD_{bcs}(DI)} = \mathrm{CTD(S)_{bcs}(DI)} + \mathrm{CTD(R)_{bcs}(DI)} \quad (4)$$

- Cost for energy consumed in block cloud server

The cost of the energy consumed for sending DI to the block cloud server bcs is calculated as follows:

$$CEC(S)_{bcs}(DI) = \sum_{d_i \in DI} cec_s(d_i, bcs) \quad (5)$$

The cost of the energy consumed for receiving DI to the block cloud server bcs is calculated as follows:

$$CEC(R)_{bcs}(DI) = \sum_{d_i \in DI} cec_r(d_i, bcs) \quad (6)$$

By using Equations 5, and 6 the total cost for energy consumed by using bcs can be defined as follows:

$$TCEC_{bcs}(DI) = CEC(S)_{bcs}(DI) + CEC(R)_{bcs}(DI) \quad (7)$$

By using Equations 4, and 7 the total costs by using bcs is defined as follows.

$$TC_{bcs}(DI) = TCTD_{bcs}(DI) + TCEC_{bcs}(DI) \quad (8)$$

- Cost by using file cloud server.

File storage systems are usually less costly than block storage because the cost for sending includes sending without classification and searching costs and the cost for receiving includes retrieving and searching costs. However, this cost depends on the chosen seller, conditions, features, cost of the storage operating system (OS), and some other variables.

- Cost for time delay in file cloud server.

The cost of the time delay for sending DI to the file cloud server fcs is calculated as follows.

$$CTD(S)_{fcs}(DI) = \sum_{d_i \in DI} ctd_s(d_i, fcs) \quad (9)$$

The cost of the time delay for receiving DI to the file cloud server fcs is calculated as follows.

$$CTD(R)_{fcs}(DI) = \sum_{d_i \in DI} ctd_r(d_i, fcs) \quad (10)$$

By using Equations 9, and 10 the total cost for time delay by using fcs can be defined as follows.

$$TCTD_{fcs}(DI) = CTD(S)_{fcs}(DI) + CTD(R)_{fcs}(DI) \quad (11)$$

- Cost for energy consumed in file cloud server.

The cost of the energy consumed for sending DI to the file cloud server fcs is calculated as follows:

$$CEC(S)_{fcs}(DI) = \sum_{d_i \in DI} cec_s(d_i, fcs) \quad (12)$$

The cost of the energy consumed for receiving DI to the file cloud server fcs is calculated as follows:

$$CEC(R)_{fcs}(DI) = \sum_{d_i \in DI} cec_r(d_i, fcs) \quad (13)$$

By using Equations 12, and 13 the total cost for energy consumed by using fcs can be defined as follows:

$$TCEC_{fcs}(DI) = CEC(S)_{fcs}(DI) + CEC(R)_{fcs}(DI \quad (14)$$

By using Equations 11, and 14 the total costs by using fcs are defined as follows;

$$TC_{fcs}(DI) = TCTD_{fcs}(DI) + TCEC_{fcs}(DI) \quad (15)$$

D. (IDD-HPO) Proposed Model

The (IDD-HPO) model is used at the beginning with the ML classifiers (e.g., LR, KNN, and SVM), and DL algorithms (e.g., CNN, RNN), then the performance of (IDD-HPO) is measured by Accuracy, time delay, and energy consumed. Comparing it with the state of the art and proving the effectiveness of using (IDD-HPO) for diabetes data, (IDD-HPO) model is performed in a personal computer system (anaconda3) environment and both the time and energy consumed in the training and testing process are measured.

To reduce the time and energy consumption of (IDD-HPO) model in both ML and DL algorithms, the experiment environment is changed by using (MCC).

In a personal computer system (anaconda3) environment, the main goal of (IDD-HPO) model is using hyperparameters to control the learning process and evaluates the problem to finding a set of optimal hyperparameters that return the best performance as evaluated on a validation set.

In MCC, the main goals of (IDD-HPO) model are (1) minimizing the cost of time delay and energy consumed spent for sending and retrieving data. So, based on the previously described cost model in subsection C, the goal is finding the best cloud server (e.g. file cloud server (DI_{fcs}) or block cloud server (DI_{bcs})) to store data in the cloud. Such that no data item can be mapped to bcs and fcs at the same time. Then used a hyperparameter on the best cloud server controls the learning process and evaluates the problem to finding a set of optimal hyperparameters that return the best performance with the smallest time delay and energy consumed compared to time and energy on a personal computer.

To conduct training and testing in the cloud, depending on that the data is stored on the mobile, the data is sent from the mobile to the cloud and stored in the cloud depending on two types of storage, file, and block. The time and energy consumed in the process of storing data in each of the two types of storage (file and block) are calculated to determine the best type of storage according to the type of data used in the cloud. The time and energy consumed to conduct the training and testing process using (IDD-HPO) model are compared in both personal computer systems (anaconda3) and cloud computing environments. Here, MCC system model involves (1) mobile node, MN, (i.e., mobile device with a user) which has a set of data for diabetes $DI = \{d_i, 1 \leq i \leq n\}$, and each data item di represents different types of data (e.g., text, numbers, symbols, etc.). (2) a file cloud server, fcs, which stores all received data elements di from MN as files. (3) a block cloud server, bcs, which stores all received data elements d_i from MN as blocks. The energy consumed for sending and receiving a data item d_i to/from a server s are denoted as $cec_s(d_i; s)$ and $cec_r(d_i; s)$, respectively. Wheres can be a file server fcs or a block server bcs. Also, the time delay for sending and receiving a data item d_i to/from a server s are denoted as $ctd_s(d_i; s)$ and $ctd_r(d_i; s)$, respectively.

To improve the performance of the hospital readmission problem, the basic idea of (IDD-HPO) model is based on the following three issues: (a) using an (IDD-HPO) model for each model (ML, DL) in a personal computer and calculate the accuracy, time delay, and energy consumed. (b) estimating the total cost data sets DI on the file and block cloud servers by calculating their costs which were determined by using Equations (4,7,10,11). (c) comparing the calculated total costs and selecting the best appropriate mapping server based on the needs of a mobile user (e.g., minimum mapping costs).

The steps of these two cases are described as follows in Fig. 4 and 5.

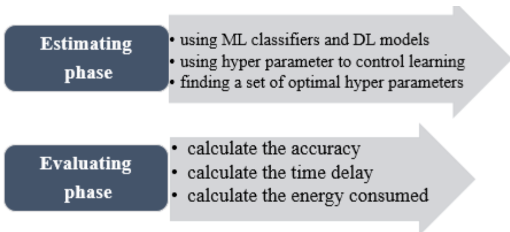

Fig. 4. Proposed (IDD-HPO) in Case 1 (a Personal Computer).

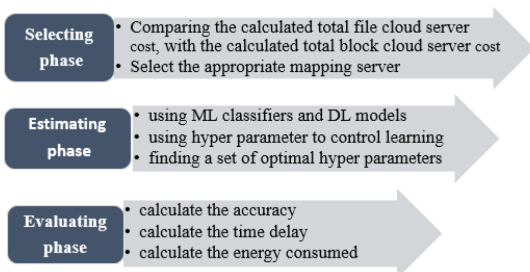

Fig. 5. Proposed (IDD-HPO) in Case 2 (MCC System).

V. Experimental Result

This section evaluates the performance of the proposed method for predicting hospital readmission using (IDD-HPO) model. through comparing it in two cases. The first one is when applying learning and testing for ML algorithms and DL algorithms in personal computers (anaconda3) with the state of the art, and calculate the time delay and energy consumed for (IDD-HPO) model. The second case is when applying learning and testing for ML algorithms and DL algorithms in the MCC system.

For the first experiment: (IDD-HPO) model with ML classifiers and DL algorithms, as the intelligent model, is built in Spyder Python 3.7 environment with processor intel(R) Core (TM), i5-2500 CPU @3.30 GHz.

For the second experiment: at the first the OMNet ++ [15] simulator was used to evaluate the best level of storage (e.g., fcs or bcs) for decreasing the total cost. Also, each experiment is repeated 5 times and the average was taken.

Then The (IDD-HPO) model is developed using Spyder python computing environment. Prediction models using (IDD-HPO) in the research were developed using the deep learning toolkit provided by the Anaconda software. The network configuration is initially determined based on the model that is built. The model is implemented on a GPU-enabled system with an Intel Core i7 processor with a capacity of 16 GB RAM.

CNN and RNN models are applied with one input layer, three hidden layers with uniform initialization, and one output layer. Softmax activation function was chosen for the output layer, while PRelu activation function was chosen for input layers. Added Dropout with rate=0.1 after hidden layers to limit overfitting and hence DL algorithms.

The selected optimization algorithms were [rmsprop, adam, sgd].

(IDD-HPO) model is used to find optimal hyperparameters (Table I). The classifiers with the optimal hyperparameters were tested on the holdout test set. This approach ensures that the training, validation, and evaluation data are completely separated.

A. *Experiments for (IDD-HPO) on Personal Computer System (Anaconda3)*

In this experiment, both ML classifiers against DL algorithms are used with (IDD-HPO) model. A hyperparameter is used to control the learning process and evaluates the problem to finding a set of optimal hyperparameters. For LR a hyperparameter (Regularization (*penalty*) is used to choose from the range [none, 11, 12, elasticnet], KNN a hyperparameter (Number of neighbors) is used to choose from the range [1-21], SVM a hyperparameter (kernels) is used to choose from the range [linear, poly, rbf, sigmoid], RNN hyperparameters (learning rate *lr* and Optimizer**)** are used to choose from the range [0.004, 0.008, 0.0012] and [rmsprop, adam, sgd] respectively, and CNN hyperparameters (epochs and batch_size) are used to choose from the range [50, 100, 150, 200] and [16, 32, 64] respectively. As shown in Table I.

TABLE I. (IDD-HPO) Model for ML and DL

Classifier	**hyperparameter**	**Range**	**optimal**
LR	Regularization (*penalty*)	[none, 11, 12, elasticnet]	none
KNN	Number of neighbors	[1–21]	3
SVM	kernels	[linear, poly, rbf, sigmoid]	linear
RNN	learning rate *lr*,	[0.005, 0.01, 0.015]	0.005
	the regularization coefficient λ	[0.004, 0.008, 0.0012]	0.004
CNN	Optimizer	[rmsprop, adam, sgd]	Adam
	epochs	[50, 100, 150, 200]	150
	batch_size	16, 32, 64	64

TABLE II. PERFORMANCE MATRIX FOR (IDD-HPO) IN A PERSONAL COMPUTER

Classifier	Accuracy for (IDD-HPO)	Time delay for (IDD-HPO)	Energy consumed for (IDD-HPO)
LR	0.671	5	25
KNN	0.883	7	32
SVM	0.901	20	48
RNN	0.854	25	89
CNN	0.963	660	895

Table II shows a comparison performance for ML and DL algorithms when used (IDD-HPO) model with test size 10. As shown in Table II the performance of DL algorithms is more accurate in predicting the use of ML. ML algorithms always need structured data, while DL networks rely on ANN (Artificial Neural Networks) layers. Therefore, the performance of DL was better as the data is not structured but it is multi-dimensional data. Also, time delay and energy consumed are calculated for training and testing both ML and DL algorithms.

Fig. 6, Fig. 7, and Fig. 8 show the accuracy, time delay, and energy consumed respectively for training and testing for Dl with (IDD-HPO) is very high compared to ML, where accuracy, time delay, and energy consumed to training and testing DL is (0.963%, 660 minutes, and 895 joules), respectively.

B. Experiments for (IDD-HPO) on MCC System

The experiment is applying in a cloud computing environment so, at the first calculate the time delay and energy consumed for (IDD-HPO) model if data is store at the file and block cloud server.

Table III, shows the accuracy, time delay, and energy consumed for ML algorithms and the DL algorithms when used (IDD-HPO) model in fcs and bcs with test size 10. Also, time delay and energy consumed are calculated for training and testing both ML and DL algorithms if data is store in the cloud as fcs and bcs.

Fig. 9, and Fig. 10 show the comparing of the time delay and energy consumed respectively of using (IDD-HPO) model which is calculated by Equations 4, 7, 11, and 14 when training and testing are played in personal computer and MCC system using fcs and bcs. As shown in Fig. 10, and Fig. 11 The time delay and energy consumed of using (IDD-HPO) are decreasing if the data set is stored in the cloud as fcs against stored data in the cloud as bcs, and use (IDD-HPO) in a personal computer.

Fig. 11 shows the comparing total cost for (IDD-HPO) in the personal computer against (IDD-HPO) in cloud environment based on fcs and bcs which can be calculated by Equations 8, 15 the total cost for (IDD-HPO) in fcs is less than the total cost for (IDD-HPO) in personal computer and total cost for (IDD-HPO) in bcs which satisfies the required conditions for the proposed method in case 2.

TABLE III. PERFORMANCE MATRIX FOR (IDD-HPO) BY USING FCS AND BCS

Classifier	Accuracy for (IDD-HPO)	Time delay for (IDD-HPO) (fcs)	Time delay for (IDD-HPO) (bcs)	Energy consumed for (IDD-HPO) (fcs)	Energy consumed for (IDD-HPO) (bcs)
LR	0.671	2	3	8	6
KNN	0.883	3	5	9	7
SVM	0.901	8	10	11	8

C. Comparative Analysis against State-of-the-Art Models with our Results

In this section, a comparison between the proposed model with the highest accuracy measures ((IDD-HPO)) and other state-of-the-art models illustrated before in the related work section is discussed. Table IV provides a complete analysis of such a comparison. It compares (IDD-HPO) model with other models reported in [7], [11], [2], [8], [3], [4], and [6]. Each one of these models used different ML and DL algorithms with different preprocessing methods (e.g. [7] used ML and DL algorithms, [11] used Categorical Embeddings and Neural Networks, [2] used Data Mining technique with Random Forest, [8] used Multilayer Perceptron, [3] used Multilayer Perceptron (MLP) and Deep Neural Network, [4] used ML with Ensemble Technique, and [6] used CNN with Normalization technique).

TABLE IV. COMPARATIVE ANALYSIS AGAINST STATE-OF-THE-ART MODELS WITH OUR RESULTS

Year	**LR**	**KNN**	**SVM**	**Simple Neural Network**	**RNN**	**CNN**	**Computing environment**	**Model basis**	**Ref.**
	Readmission Prediction Accuracy								
Proposed model	**0.671%**	**0.883%**	**0.901%**	-	**0.854%**	**0.963%**	A personal computer system (anaconda3)	(IDD-HPO) model	-
(2021)	0.642%	0.872%	0.886%	0.873%	0.837%	0.924%	A personal computer system (anaconda3)	ML, RNN, and CNN with non-normalization Technique	[7]
(2021)	---------					0.952%	Personal computer system	Categorical Embeddings and Neural Networks	[11]
(2021)	0.898%						Personal computer system	data mining techniques with random forest	[2]
(2019)	---------					0.95%	Personal computer system	Multilayer Perceptron	[8]
(2019)	0.840%						Personal computer system	Multilayer Perceptron (MLP) and Deep Neural Network	[3]
(2019)	0.635%	-	0.2946%	0.7999%	-	-	Personal computer system	ML with Ensemble Technique	[4]
(2018)	---------					0.92%	Personal computer system	CNN with Normalization Technique	[6]

The proposed model (IDD-HPO) model used hyperparameter optimization which achieves high accuracy for ML algorithms as follows: LR=0.671%, KNN=0.883%, SVM=0.901%), and for reported high accuracy for DL algorithms as follow: RNN=0.854%, and CNN=0.963%. It also comes with the advantage of hyperparameter which is used to control the learning process and evaluates the problem to finding a set of optimal hyperparameters and return the best performance with the smallest time delay and energy consumed.

VI. Results and Discussion

In the first experiment, DL and ML performed higher when ((IDD-HPO)) was used in a personal computer compared to state-of-the-art models. DL algorithms especially CNN reported an overall accuracy of 0.963% using (IDD-HPO) model. But according to performance metrics, time delay and energy consumed for (IDD-HPO) model in DL (CNN) was very high, 660 minutes for time delay and 895 joules for energy consumed.

In the second experiment, (IDD-HPO) model was used for ML and DL algorithms in the MCC system to improve performance matrices by decreasing time delay and energy consumed, at the first data sets must be stored in the cloud according to how to map mobile data item taking intoaccount the limited resources of a mobile device by selecting the most suitable storage level for each data item to decreasing the time of training band testing for hyperparameter tuning. The result was that time delay and energy consumed for (IDD-HPO) model in a cloud environment for DL (CNN) was 220 minutes and 201 joules respectively if data store in the cloud as fcs and 290 minutes and 252 joules, respectively if data store in the cloud as bcs.

Based on these results, (IDD-HPO) model can be used to improve the prediction of hospital readmission in two cases (personal computer and cloud environment) with an accuracy of 0.963% with the smallest time delay and energy consumed if the process of training and testing will be done in a cloud environment based on storing data as fcs.

VII. Conclusion and Future Work

In this paper, the proposed model ((IDD-HPO)) using hyperparameter optimization with ML and DL to improve prediction of hospital readmission over a clinical data set, after applying some preprocessing on the input data then ((IDD-HPO)) is using with ML classifiers (e.g., LR, KNN, and SVM) and DL algorithms (e.g., CNN, RNN) to improve the performance of models. The performance of model was tested and evaluated under two different environments.

The proposed (IDD-HPO) model is successful to improve the accuracy of prediction of hospital readmission in a personal computer compared to state-of-the-art models. Then improve time delay and energy consumed by decreasing them if (IDD-HPO) model performed in cloud based on storing data at fcs. That will have a strong effect on the health care costs and the hospital's efficiency and reputation.

As future work, the (IDD-HPO) will be improved to not only be limited to numbers and text data but also to apply to dynamic audio and video data with the use of hybrid storage in the cloud according to the importance of the data used.

Emotional Cascade Model and Deep Learning

Carlos Pelta
Dept. of Experimental Psychology
Cognitive Processes and Speech Therapy
UCM, Madrid, Spain

***Abstract*—Emotional Cascade Model proposes that the emotional and behavioral dysregulation of individuals with Borderline Personality Disorder can be understood through emotional cascades. Emotional cascades are vicious cycles of intense rumination and negative affect that may induce aversive emotional states that generate abnormal behaviors to reduce the effect of intense rumination. Borderline Personality Disorder is a psychiatric disorder whose main symptoms to diagnose it are mood instability and impulsivity. This disorder often involves risky behaviors such as non-suicidal self-injury or substance abuse. Recently, Selby and collaborators have proved that the Emotional Cascade Model has a high explanatory and diagnostic capacity using Temporal Bayesian Networks. Taking into consideration the meta-analytic study developed by Richman et al., in this article it has been designed a deep learning model, based on cascading artificial neural networks, following the correlations established for the Emotional Cascade Model. It has been confirmed with accuracy estimates reaching up to 99%, the predictive power of this model relative to the various types of rumination that influence some of the basic classes of symptoms of Borderline Personality Disorder.**

***Keywords*—Emotional cascade model; borderline personality disorder; rumination; deep learning; cascade-correlation algorithm**

I. Introduction

Borderline Personality Disorder (BPD) is a psychiatric disorder characterized by symptoms such as affect instability, impulsivity, self-harm and identity disturbances [1]. Such syndrome causes behaviors as suicidality [2], non-suicidal self- injury (NSSI) [3], chronic pain [4], substance abuse [5], binge-eating [6], and gender violence [7]. The pioneering and perhaps most complete theory of BPD has been that of Linehan [8]. It is a biological, psychological and social theory claiming that individuals with BPD develop extreme emotional vulnerability.

Selby, Anestis and Joiner [9] propose in their Emotional Cascade Model (ECM) that the cycle of affect and rumination (the emotional cascade) leads to dysregulated behavior that functions to distract attention from this negative internal experience. Rumination is typical in people with BPD and predicts dysregulated behavior [10]. It is a form of repetitive thinking in which individuals focus their attention on emotionally relevant stimuli [11,12]. Rumination usually magnifies negative affect. According to the ECM, the reciprocal relationship between negative affect and ruminative processes results in an "emotional cascade", which is initiated by an event that elicits an emotion. This event causes the individual to ruminate intensely, increasing the intensity of the emotion. As the intensity of the emotion increases it is more difficult to escape from the emotional experience paying full attention to the emotional stimulus. Then, it is generated a positive feedback loop between rumination and negative affect. There is a synergistic [13] effect between rumination and negative emotion predicting impulsive behaviors typical of BPD and forming emotional cascades [14]. Emotional cascades create a complex disorder that may be involved in the emergence of BPD. Emergence is the phenomenon by which a complex system arises from the interaction of its component network [15]. Broadly speaking, there is bidirectionality between emotional cascades and symptoms of BPD.

There are various types of rumination. The most common in BPD patients are pain rumination [16], depressive rumination [17,18] and anger rumination [19]. Anger rumination is repetitive thinking about anger experiences and has maladaptive outcomes such as physiological arousal or aggressive behavior. Stress and anxiety rumination can also appear [20,21]. Nolen-Hoeksema conceptualizes the depressive rumination as repetitively focusing on the fact that one is depressed and the possible causes and consequences of the depressive symptoms [22].

Richman et al. [23] have performed a meta-analysis to assess how the four main categories of BPD symptoms (affect-instability, relationship issues, self-harm/impulsivity, and identity disturbances) correlate with the five types of rumination mentioned above (pain rumination, depressive rumination, anger rumination, anxious and stress rumination). This meta-analysis of the correlations extracted between the data provided by 13 studies has supplied us with the basis for designing a cascading artificial neural network capable of simulating the ECM for BPD. Cascade-correlation (CasCor) [24] is an algorithm starting with a minimal network architecture, to which hidden nodes are added as required, forming feature detectors within the network. It is an algorithm especially suitable for modeling developmental cognitive cascades as Shultz does in [25] or processes such as representational redescription [26, 27]. The author of this article has also used it to model the psychological phenomenon of catastrophic worry [28] or the interaction between cytokines appearing together with lymphopenia in COVID-19 disease [29].

Deep learning uses multiple layers with non-linear processing units to extract and transform features. Each layer uses the output of the previous layer as input. Cascade-correlation algorithm is a pioneering algorithm in this type of machine learning, since it adds new layers as new neurons are added, in a constructive process that avoids the disadvantage of having to predeterminate the structure of an artificial neural network from the start [30] and adapts very adequately to the modeling of any cascade phenomena by means of “cascades” of layers.

In this article is demonstrated, using deep learning techniques, how it is possible to computationally model with an exceedingly small error the interaction between the network elements that intervene in the emotional cascades typical of patients with BPD. Thus, it has been reinforced the predictive value obtained by Selby and collaborators [31] about their model of emotional cascades of psychological disorders and it has been reaffirmed, using the technique of artificial neural networks, the value of their model as a source of explanation for these disorders. Using a different computational technique, it has been improved the accuracy in the validation of the model-reaching 99%.

II. Literature Review

Computational psychiatry [32] is a recent field that addresses a phenomenon as complex as mental illness using computational tools. We can distinguish between biophysical models (for instance, in [33] has been studied the role of dopamine in the central cortex of patients with schizophrenia), reinforcement learning models (for example, in [34] has been investigated the relation between reinforcement learning and the diagnosis of Alzheimer Disease), connectionist models (the first major paper on a neural network model of psychopathology [35] simulated the processing of the information on schizophrenia and in the 1990s came the first anthologies of articles [36,37]) and Bayesian network models.

Selby et al. [31] have proposed a Temporal Bayesian Network (TBN) model to examine the ECM in a sample of adolescents and young adults who actively self-injure and including those with BPD.

TBN is an extension of the Bayesian technique incorporating time dependence [38]. A TBN model consists of several connected clusters of nodes, one cluster corresponding to one-time step. The clusters of nodes at different time steps are interconnected in the same way within each cluster. The connections among the clusters of nodes correspond to the time dependence of the variables, updating one´s knowledge of other variables by calculating the posterior probability distribution over the remaining variables given the obtained evidence. Four core features of the ECM were modeled and used in model prediction evaluation: (a) rumination and negative emotion generate positive feedback on each other, (b) they generate positive feedback on themselves, (c) these positive feedbacks provoke dysregulated behavior, and (d) dysregulated behavior then reduces rumination and negative emotion. Time invariant variables for psychiatric diagnosis were specified. These variables were BPD, Major Depressive Disorder (MDD), and Posttraumatic Stress Disorder (PSD) and they were used in determining model predictive accuracy of BPD diagnosis, state rumination, negative emotion, and dysregulated behaviors. The predictive accuracy was then evaluated based on real-world data and using the *k*-fold cross-validation method [39] on interim models. Several interim models were initially built. For each of the models, a model structure was first generated using causally connected nodes corresponding to the momentary negative emotion, rumination, and dysregulated behavior, measured at five-time steps during each day, and including nodes corresponding to the diagnostic statuses of the participants. TBN analysis suggested that the ECM predicted BPD diagnosis (with accuracy estimates around 90%) and momentary prediction of rumination, negative emotion, and dysregulated behaviors with accuracy estimates above 80% and reaching up to 100%, depending on the level of momentary prediction selected.

III. Materials and Method

A. Database

The database used the correlations between BPD symptoms and types of rumination obtained by Richman et al. [23] selecting the results provided by 13 articles. Following to [23], when correlation values were not available, correlation values were calculated from reported univariate t-statistics, or p-values. Correlations were classified as small (0.1-0.3), medium (0.3-0.5), and large (0.5-1). To assess homogeneity of the correlation sizes across studies for each rumination domain, the Cochran Q-statistic was used. In all cases, significant at $p<.001$ and 95% CI. For N=28,165, Table I shows the types of rumination correlation with BPD symptoms that have been used as the parameters for adjusting the weights of the connections between the units of the neural network.

Besides, Table II shows the BPD symptoms correlation with rumination for the same sample. Also, these correlations have served for adjusting the weights of the artificial neural network.

TABLE I. Types of Rumination Correlation with BPD Symptoms

Types of rumination	***Overall BPD symptoms correlation***
Overall rumination	0.41
Pain rumination	0.68
Anger rumination	0.46
Depressive rumination	0.39
Stress rumination	0.35
Anxious rumination	0.28

TABLE II. BPD Symptoms Correlation with Rumination

BPD symptoms	***Overall rumination***
Overall symptoms	0.43
Affective instability	0.42
Unstable relationship	0.39
Identity disturbance	0.37
Self-harm/impulsivity	0.25

B. Design of the Artificial Neural Network

It has been used MemBrain (version V03.08.01.00) software, created by Jetter [40], for the design of the artificial neural network. Cascade-correlation algorithm seems adequate to simulate the ECM and, therefore, the positive feedback between types of rumination and the main BPD symptoms. BPD is an emerging phenomenon that allows explaining, through the spread of emotional cascades, why unregulated behaviors are succeeding each other. Subjects respond more and more negatively towards these behaviors and their cognitions are distorted in a process that Selby [41] calls “expectancy validation” and that adds more suffering to the subjects.

The cascade-correlation architecture is a multi-layer supervised connectionist learning system. The most interesting difference between it and other multilayer systems is that in a cascading artificial neural network the number of hidden units is not predetermined. Instead, these units are added as necessary and achieve a progressive reduction in error. The network starts with only specified inputs and outputs. Neurons are typically trained off-line, and a pool of new hidden neurons or candidates is created. The best of these candidates is situated in a separate layer and connected to the output neurons. If a candidate correlates positively with the error at a given neuron, it will develop a negative weight to compensate for that error, while if the correlation is negative, the weight will be positive. The weights on the connections to the new hidden neurons are frozen and the input-output and hidden-output connections are re-trained to readjust overall performance. This process is repeated until the total error at the output has converged or there has been a lack of significant improvement in error (stagnation) over a period of epochs (patience).

The learning algorithm has been cascade-correlation using backpropagation and target net error has been 0.01. The weights of the connections between the neurons have been initially randomized until adjusting to the values indicated in Table I and Table II. A symmetric logistic activation function has been used with values between -0.5 and 0.5 and an error threshold of 0.4. We have established as parameters, the learning rate (η), the maximum growth rate (μ) which limits the size of any change in weights performed after each presentation of the training set, the weight decay (γ) which ensures that the weights do not grow excessively, the patience percentage calculated from the change in error required over a period to continue training, the patience period or the period over which the change in error is measured through epochs (or lesson runs), and the activation function offset. When the maximum number of epochs has been reached or no progress has been made in the training of the candidate neurons, the best candidate is placed into the network and the output layer is retrained. The algorithm cycles through installing hidden nodes. In the following Table III, we indicate the values for output layer training parameters.

It has been designed the artificial neural network by introducing 11 units, of which the input neuron has been overall rumination (O-RUM), in a first layer, 5 neurons have been placed referring to the 5 types of rumination (P-RUM, A-RUM, D-RUM, S-RUM, AX-RUM, respectively) and the candidate neurons have been the units corresponding to the four main types of BPD symptoms (AI, UR, ID and SH), to end in the output O-BPD that corresponds to the overall BPD.

The maximum number of candidates has been 8 and the size of the set of candidates has been 4. For the training candidates, the correlation stable tolerance has been 5%.

The structure of the network can be seen in the Fig. 1 and the training parameters of the candidates can be seen in the Fig. 2.

TABLE III. OUTPUT LAYER TRAINING PARAMETERS

Parameter	***Output value***
η	0.4
μ	1.5
γ	0.0
Patience percentage	1%
Patience period	300
Activation function offset	0.1

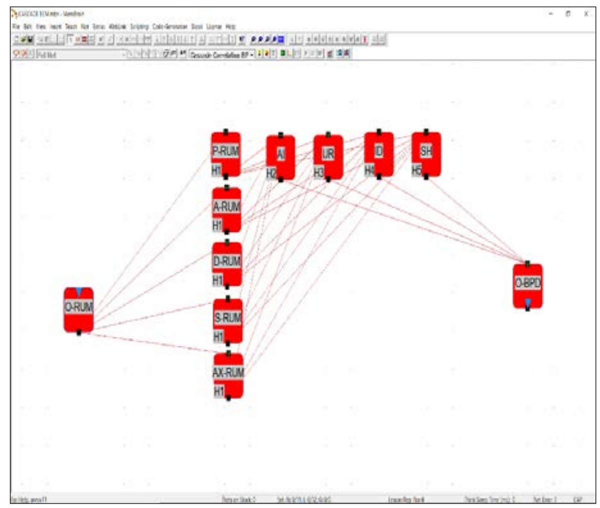

Fig. 1. Structure of the ANN (All the Neurons are Activated in Red and the Connections in Red Express Positive Weights).

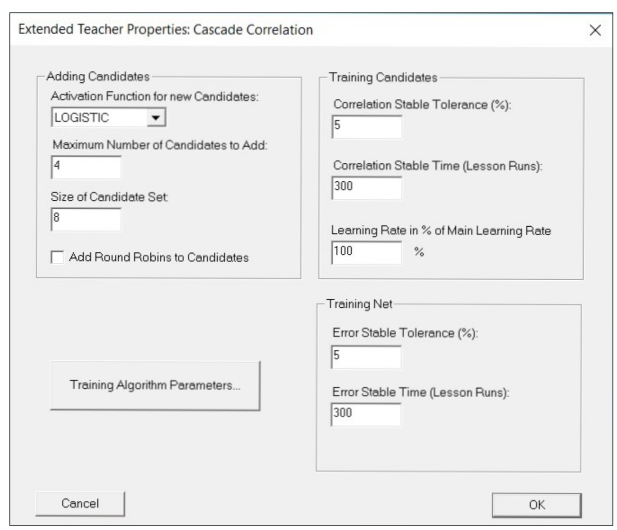

Fig. 2. Training Parameters of the Candidates in the Net.

IV. Result and Discussion

The learning rule has been applied to minimize the Mean Squared Error (MSE), which is calculated with the average difference between the observations and the expected values, obtaining the result with the iterations produced with the help of the learning algorithm. As Fig. 3 of the Net Error Graph shows, the Net Error has been 0.00991199644037891.

This result proves that the correlations established by the meta-analytic study [23] between types of rumination and overall rumination and the main classes of BPD symptoms and overall BPD allow designing a computational simulation using an artificial neural network in cascade that adjusts in a remarkably high degree to these correlations. By the way, it has been improved the precision in the validation of the ECM by means of a different computational technique. Selby and colleagues used a Temporal Bayesian Network and, in this article, has been employed a cascading neural network. Using this computational tool, it has been reached a validation of the ECM of almost 100%.

The fundamental merit of the ECM is to capture very well the inherently dynamic and cascading nature of the BPD as it is fed by rumination and the negative affect generated. In other perspectives, BPD is understood as a hardwired disorder activated by emotions. In the ECM, the BPD symptoms are increased by an intense rumination process that, in turn, generates negative emotional states. BPD unfolds over time periods far beyond the presence of the emotions that caused the symptoms, and the component processes themselves (called “hysteresis”), a nonlinearity that is typical for complex systems. The symptoms are maintained and affect the emotional state space influenced by rumination and negative emotions. Of course, not all rumination processes are identical, but BPD cascade is amplified by a persistent rumination process.

BPD psychopathological preconditions and effects are accurately simulated by the computational architecture of a cascading artificial neural network, as we have tried to demonstrate in this article.

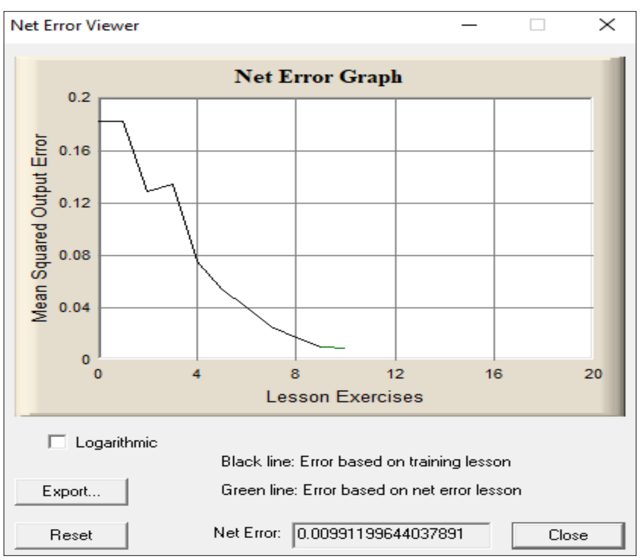

Fig. 3. Net Error.

Really, the cascade-correlation algorithm is suitable for modeling numerous psychopathological processes that present a cascade structure, that is, processes that take place in a staggered fashion and that start a cycle with positive feedback. For instance, disorders such as neurosis or catastrophic pain deserve to be computationally modeled using this kind of artificial neural network. Furthermore, psychological processes involving developmental cascades, that is, processes by which function at one level of behavior affect the organization of competency in later developing domains, admit to being modeled following this methodology and not simply the usual models of structural equations that do not capture the constructive and evolutionary nature of this class of systems.

V. Conclusion

This article has sought to design a suitable artificial neural network (ANN) for simulating the Emotional Cascade Model (ECM) by Selby and collaborators applied to the borderline personality disorder (BPD). According to ECM, the main BPD symptoms are triggered by an insidious rumination process that generates negative emotional states. These negative emotional states, in turn, intensify the rumination types and the borderline symptoms. The ANN type has been a cascade-correlation network with backpropagation. Cascade-correlation architecture is well suited for modeling cascading events. These events are self-amplifying cascades of strong negative emotions. Cascading networks with backpropagation grow in a similar manner to the process of emotional cycles typical of the ECM and have allowed us to validate the correlations between the main symptoms of BPD.

***Abstract*—Diabetes is one of the challenging diseases prevailing in recent times. Due to the incompleteness, uncertainty and imprecise details, classification of diabetes using machine learning algorithms is turning out to be even more challenging. The efficiency of the classification model is influenced by the data present in the dataset. This study enhances the classification of diabetes by using a Neuro-Fuzzy model with special attention to Feature Extraction. The main goal of the present study is to enhance the diabetes prediction technique that helps the medical practitioners to easily identify the disease and diagnose it appropriately to reduce several complications that diabetes may cause to the patient in the future. The proposed model initially applies fuzzification on diabetes data to produce membership values. Later the membership values are examined by the proposed model to check the contribution of the features in diabetes classification. The feature extraction algorithm passes the significant features to a neural network after the features are extracted. The proposed model is tested on standard PIMA diabetic dataset to evaluate the performance. The proposed model is able to outperform all the existing machine learning algorithms.**

***Keywords*—Diabetes; neuro-fuzzy model; feature extraction; artificial neural network**

I. Introduction

Diabetes is now one of the most affecting diseases on the human race. Diabetes occurs mainly due to the insufficient production of insulin in the body. As per the details of the World Health Organization (WHO), diabetes is rapidly increasing in developing and underdeveloped countries. It is expected that by 2030, the severity of the disease increases very drastically, becoming a dreadful disease that will lead to the death of many human beings [1], [2]. Diabetes comes in three variations; namely Type I, Type II and Gestational.

Type I diabetes occurs mostly in children and is very rare, Gestational diabetes occurs during pregnancy, but both of these are very rare. Type II diabetes is more common in humans [3]. Type II diabetes causes a serious effect on the health of an individual and at present, there is a lot of research going to predict diabetes at the early stages using various models [4], [5]. Type II diabetes models require appropriate algorithms to efficiently detect the disease and thus help physicians to diagnose the disease early [6]. Early diagnosis [7] of the disease helps to overcome the impact that diabetes causes on various organs in the human body like kidneys, heart, eyes, etc. The disease prediction models that handle the diabetes data often face issues like noisy, missing, irrelevant and inconsistent data [15], [16].

The performance of the model depends on the quality of the diabetes data presented to the model and hence the researcher must supplement accurate data to the classifier for effective disease prediction [17]. In the machine learning domain, classification is an important task as it derives knowledge to handle real-world applications [18], [19].

Classification constructs a model to predict the target class of the data accurately. Classification models like artificial neural networks (ANN) do not work efficiently to produce high accuracy due to their slow convergence rate, also suffer from the local minima problem and is a very high computational model. Although ANN is adaptive, it requires a high amount of time to produce the result because of its complex structure. ANN is not ideal to deal unclear, imprecise details [7].

To address the various issues of ANN, this paper aims to develop an ANN-based fuzzy model (ANNFM) that converts the numeric features into appropriate linguistic terms such as very low (VL), low (L), medium (M), high (H), and very high (VH). Each feature in the dataset is converted into a suitable membership value based on the five linguistic terms mentioned above. Thus all the features in the dataset are converted into linguistic features. Fuzzy logic enhances the ANN model to deal with the uncertainty problem by giving membership values to all the features. The proposed model performs classification by using fuzzy logic and the ANN model. The majority of classification models reduce the features at the pre-processing stage. This leads to loss of information and prediction capability will be affected if the features are reduced in the training process. Hence the proposed approach considers all the features initially and applies fuzzification on the features to determine the significant features for efficient decision making. The main motive of this research is to develop a model that integrates the linguistic terms of fuzzy logic and ANN and to use an efficient feature extraction algorithm to classify the data.

The rest of the paper is organized as follows: the second section covers the existing work in this domain. Section 3 presents the proposed approach for diabetes classification based on fuzzy linguistic terms and artificial neural networks with special attention to feature extraction. Section 4 presents the results of the proposed approach and the state-of-art

diabetes classification approaches. Section 5 concludes the paper with a direction towards possible future aspects.

II. Related Work

This section covers the related work in the domain of diabetes classification and management. This section also explains how the existing models predicted different alignments using neuro-fuzzy models.

This work [7] presents an adaptation of neuro-fuzzy inferences to perform the classification of electrocardiogram signals. This model integrated the benefits of fuzzy inference system with the neural network for better classification of electrocardiogram signals. This work [8] presents a machine learning paradigm to classify diabetic data. The work focused on applying classification techniques like linear discriminant analysis, Naive Bayes to classify the PIMA dataset. The authors did not focus on efficient preprocessing techniques. The performance of various classifiers using various evaluation metrics is reported in this paper. But due to inefficient handling of missing data the results are not higher on the PIMA dataset.

The authors in [9] performed the classification of diabetes using the Levenberg-Marquardt learning algorithm. The authors constructed a neural network to perform the classification of the PIMA diabetes dataset. The algorithm is dynamically applied to the neural network to calculate the sensitivity and specificity of the developed model. The authors did not handle the missing values of the dataset properly and hence the results of this model are not promising.

The work [10] presents a model to classify diabetic data. This model aims to integrate Ant Colony-based optimization model with fuzzy rules to diagnosis the diabetic data. The optimization proved effective in classifying the data and achieved better results. This work [11] presented an ensemble system to diagnose diabetes using J48 and Adaboost techniques. The main work this paper focused on is to use the rules to help undiagnosed individuals to reduce the risk of diabetes incidence. The main aim of this work is to classify different adult groups of Canada and help the physicians to carry out the research. The works [12], [14] are also a machine learning approach to predict diabetes on the PIMA dataset.

The authors [13] proposed a neural network-based model using radial basis function to classify the diabetes data. The model comprises hidden layers also to increase the performance of the classification. The model uses the Bat-based clustering approach to find the number of neurons required in the hidden layer. The works [19], [20] focused on diagnosing kidney disease in the patients who are affected with the diabetes using classification. The authors [21] worked on the adverse effects that diabetes disease cause with respect to cardiovascular and kidney diseases.

Few models based on deep learning [15], [16] also stressed the importance of analyzing the diabetes at the early stages. All the discussed models in this section focused on diabetes classification only. The machine learning algorithms also paid attention to classify diabetes data. The discussed models paid little attention to the data pre-processing and fuzzification aspects. Hence in the next section, an efficient model to perform data preprocessing efficiently and to apply the fuzzy linguistic parameters to enhance the artificial neural networks for classifying type-II diabetes on the PIMA dataset is presented.

III. Materials and Methods

This section provides the detailed description of the proposed work and the dataset used.

A. *Assigning Fuzzy Membership Values to the Features in the Dataset using Fuzzification and Performing Classification of Data*

The initial phase is to perform the fuzzification process on the data. Each entry in the dataset consists of many features. In the first phase, this work converts the feature into a linguistic term like VL, L, M, H and VH.

If dataset is having ‘P’ records with each ‘n’ features per record,

$$P_i = [\, f_{i1}, f_{i2}, ...f_{in}] \tag{1}$$

Where ‘i’ represents the ith record in the dataset and f_{ij} represents the jth feature of the record.

For each feature in the record membership values are assigned using the π-type function. The π-type assigns fuzzified values based on the five linguistic terms. Hence, the feature vector contains 5*n fuzzified features, if there are ‘n’ features per record.

$$f_{ij} = [\mu_{VL}(f_{ij}), \mu_{L}(f_{ij}), \mu_{M}(f_{ij}), \mu_{H}(f_{ij}), \mu_{VH}(f_{ij})] \tag{2}$$

The data is transformed into fuzzy membership values initially. Once each feature is assigned with five membership values, the size of the feature vector grows significantly which increases complexity. To overcome this problem, the present work uses principal component analysis to store all the significant features and discard the unnecessary features. Moreover, the data in the dataset has many missing values. This paper uses imputation techniques to fill the missing data and after the fuzzification process, all the significant features are restored. The procedure of the proposed methodology is shown in Fig. 1. There are two phases in the proposed approach. Fig. 1 shows the detailed step by step working principle of the paper.

The first phase performs two tasks, a) fuzzification of data and b) feature extraction. The second phase handles the neural network aspects of the model. After the feature extraction model, a suitable neural network is built to perform classification of data. The process of classification is shown in Fig. 2. The input to the ANN is membership values of the feature vector. The initial weights of the network are in the range (0, 1). The input layer has as many nodes equivalent to the number of features after feature reduction. The output layer has nodes equivalent to the number of the classes in the dataset.

B. *PIMA Dataset*

This dataset has records of 768 patients and for each record there are 8 features and a class label, specifying whether the patient is diabetic or non-diabetic. The description of various attributes of the dataset is mentioned in Table I.

The dataset has many missing values. The proposed model has used imputation techniques to fill the missing values in the dataset. For example, the Glucose column in the dataset has 374 and the skin thickness column has 227 missing values. Along with these two columns, there are some other missing values in the dataset also. This work applies the imputation technique to fill the missing values. Later the features in the dataset are assigned fuzzy membership values and after this, the significant features are extracted using principal component analysis. The feature vectors of all the records of the PIMA dataset are obtained at this point.

The missing values in the dataset are shown in Fig. 3. From the figure, it is observed that the skin thickness and insulin are having more missing values.

In this paper imputation techniques are used to fill the missing values of the dataset for efficient classification. After the imputation, the correlation of the attributes in the dataset is shown in Fig. 4.

From Fig. 4, it is observed that the attributes pregnancies and age are more correlated. BMI and skin thickness, Glucose levels and Insulin are also more correlated.

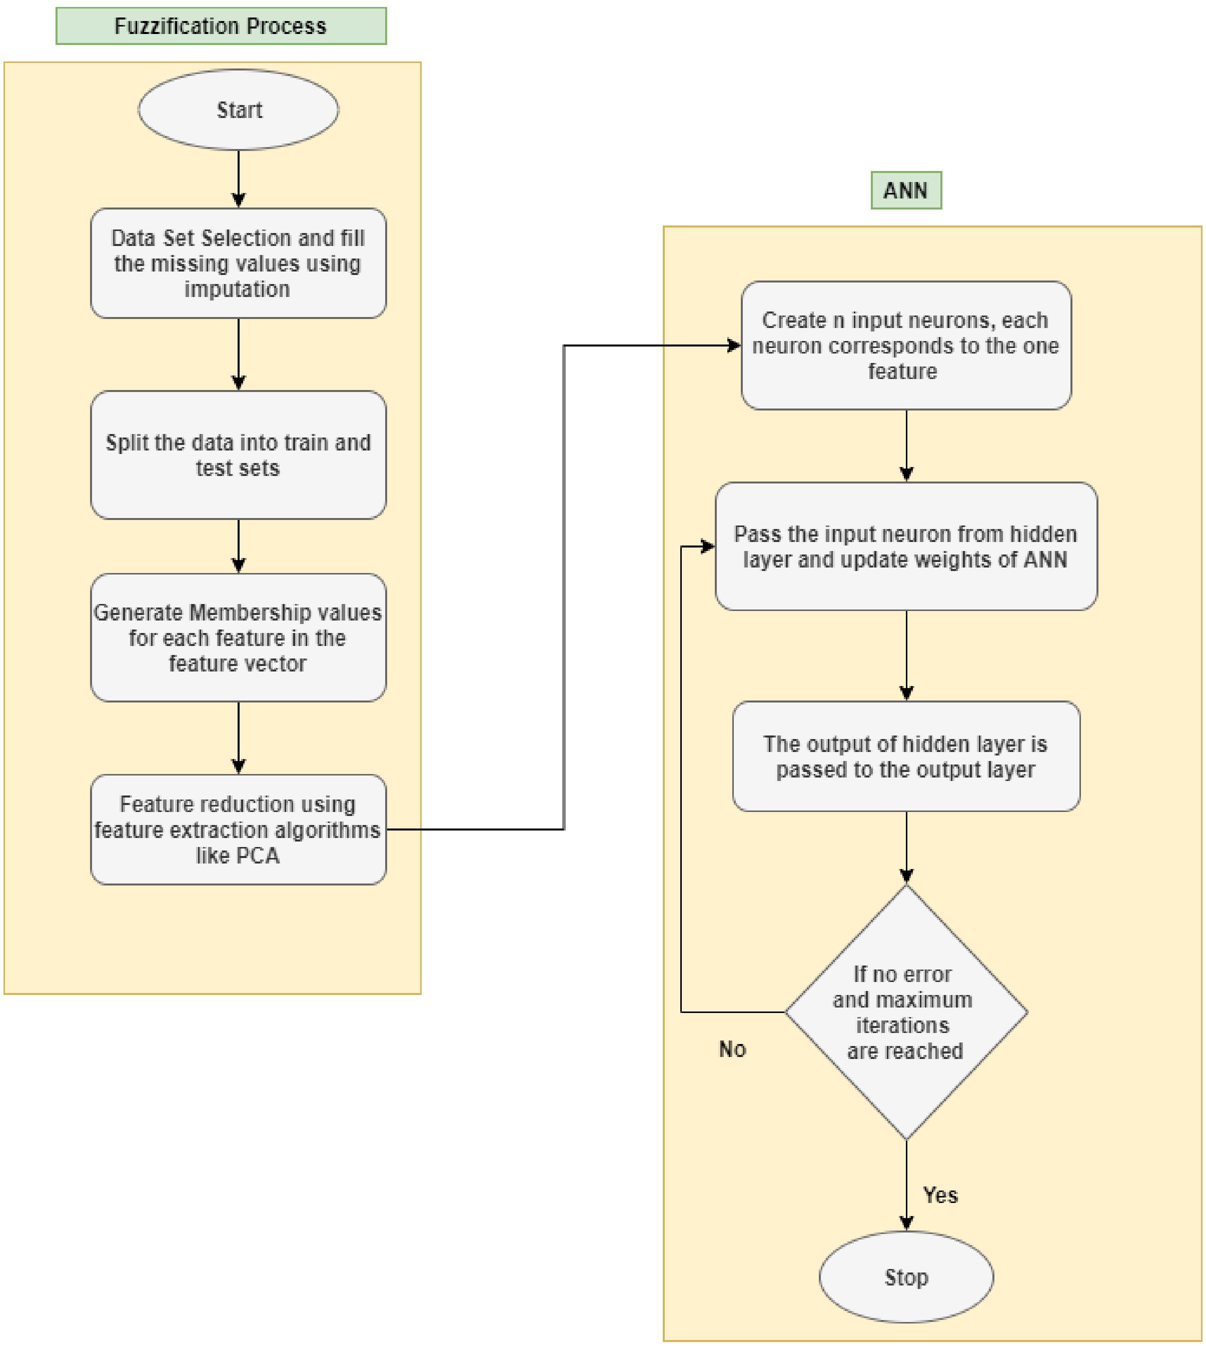

Fig. 1. Architecture of Proposed Model to Classify Diabetes.

TABLE I. PIMA DATASET DESCRIPTION

Attribute	Attribute Description
P	Count of number of times pregnant
G	The concentration of Plasma glucose concentration
BP	Blood pressure
ST	It gives the thickness of skin folds.
I	Two-hour serum insulin.
BMI	Body Mass Index
PF	Relatives history regarding diabetes
A	Persons age
O	Class of diabetes (Yes- 1, No -0)

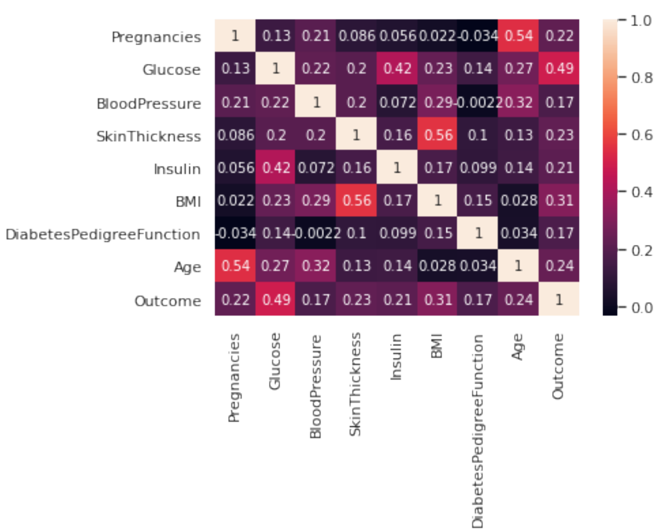

Fig. 4. Correlation of Attributes after Imputation.

Fig. 5 and 6 show the attribute values for a diabetes and non-diabetes patient. Fig. 5 shows the attributes of the PIMA dataset. The figure contains all the attribute values of the Diabetes patient.

Fig. 6 shows the attributes of a non-diabetic patient in the PIMA dataset. From both the figures it can be observed that there is a clear distinction in the ranges of the values of most of the attributes.

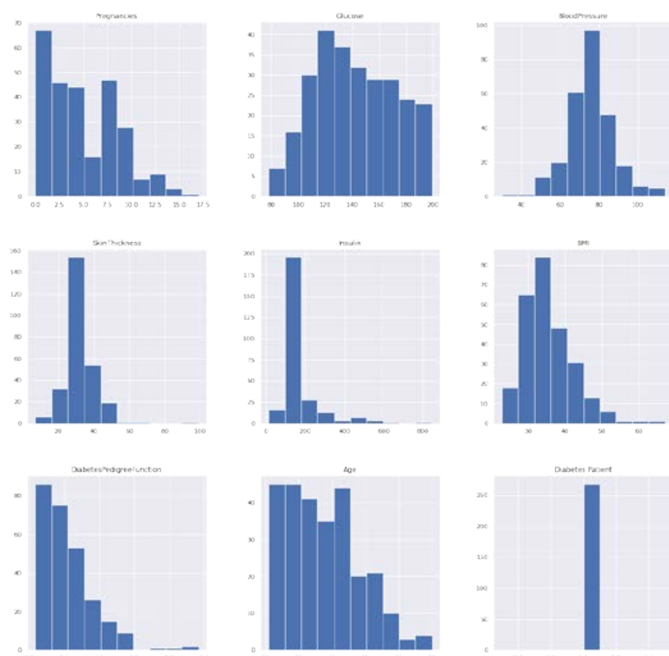

Fig. 5. Attributes for a Diabetic Patient in PIMA Dataset after Imputation.

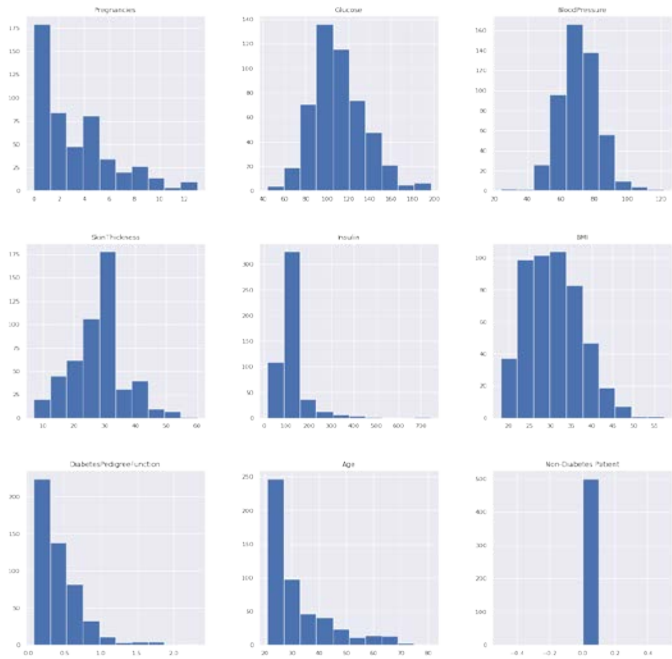

Fig. 6. Ranges of the Attributes for a non-Diabetic Patient in PIMA Dataset after Imputation.

To classify the dataset, the dataset is split into 70-30 ratio for training and testing purposes. The feature vector is the input to the neural network. The input layer assigns weights initially and passes this to the hidden layer and performs the classification task. The weights are updated until the network reaches a certain threshold. The next section provides the results of the proposed approach.

IV. Results and Discussion

In this section, the experimentation and results of the proposed approach on the PIMA dataset are given. Machine learning approaches like Decision trees, J48, SVM, Logistic regression are used for comparison.

The following are the evaluation parameters used in this paper to evaluate the performance of different models:

$$Accuracy = \frac{Number of correct predictions}{Total predictions} \quad (3)$$

$$precision = \frac{tr\_pos}{tr\_pos + fl\_pos} \quad (4)$$

$$recall = \frac{tr\_pos}{tr\_pos + fal\_neg} \quad (5)$$

$$F1 = 2 * \frac{pr * re}{pr + re} \quad (6)$$

Table II shows the results of various approaches on the PIMA dataset. From the results, it is observed that the proposed approach outperformed all the existing machine learning algorithms.

TABLE II. Comparison of different Algorithms with the Proposed Algorithm Enhanced Naïve Bayes Classifier on PID Dataset

Model	Accuracy	Precision	Recall	F1-score
Decision tree	73.16	0.73	0.73	0.70
SVM	71.85	0.71	0.72	0.68
J48	73.16	0.73	0.73	0.70
Logistic Regression	70.80	0.68	0.69	0.65
Naïve Bayes	76.92	0.77	0.77	0.77
ANN	82.00	0.81	0.81	0.80
ANN with fuzzy rules	82.33	0.85	0.83	0.81
Proposed Approach	**84.66**	**0.87**	**0.86**	**0.82**

Machine learning models like Decision tree and SVM achieved 73.16, 71.85 accuracy levels. J48 and Logistic regression model achieved 73.16 and 70.80 accuracy. Compared to these machine learning models Naïve Bayes achieved highest results. But the performance of neural networks on PIMA dataset is relatively high. The neural network model integrated with fuzzy rules also outperformed the other machine learning model results. But the highest accuracy level 84.66 is obtained when PIMA dataset is tested with the proposed model. The proposed model is able to outperform the existing models because of the following reasons:

1) The proposed model introduced fuzzy membership values for each feature in the input feature vector.

2) The significant features of the model are retained using principal component analysis.

3) The model is trained with artificial neural network and the weights are updated till there is minimal error.

The proposed work compared to other models has more advantages as the model is based on neuro fuzzy model. The model can be easily enhanced to predict the other diseases at early stages. The proposed model has outperformed all the machine learning algorithms. It is easy to draw the inferences using fuzzy models to predict the diseases and also the fuzzy model enables to easily classify the data compared to the other models.

V. Conclusion

Diabetes is considered a very serious disease in recent times since it causes many health complications. Hence, the researchers are trying to bridge the gap between technology and the medical field by developing various methods to ease the treatment procedures. In this regard, this work proposed a neural network model using fuzzy linguistic terms to classify diabetes data. The proposed model used linguistic terms to assign membership values to the features of the data and performed feature extraction using principal component analysis. After feature reduction, the features are passed to the input layer of the artificial neural network and the weights of the neural network in the input and hidden layers are updated until the error minimizes. The main goal of the proposed research is to predict the disease at early stages to deal with the other complications that may arise in the future. The proposed model aims to develop a robust approach for the early detection of diseases to mitigate the adversaries that the disease may cause to the patient and to help the practitioners in medical domain to diagnose the diabetic patients. Moreover, the proposed model is able to outperform all the existing machine learning approaches.

In future, the research can be easily extended to predict and diagnose other diseases. The proposed work can be modified with fuzzy inference rules to improve the performance. The present study can deal with the missing data of smaller datasets and in future it can be enhanced to handle large amounts of data.

A Multiagent and Machine Learning based Hybrid NIDS for Known and Unknown Cyber-attacks

Said OUIAZZANE, Malika ADDOU, Fatimazahra BARRAMOU
ASYR Team, Laboratory of Systems Engineering (LaGeS)
Hassania School of Public Works (EHTP)
Casablanca, Morocco

***Abstract*—The objective of this paper is to propose a hybrid Network Intrusion Detection System (NIDS) for the detection of cyber-attacks that may target modern computer networks. Indeed, in the era of technological evolution that the world is currently experiencing, hackers are constantly inventing new attack mechanisms that can bypass traditional security systems. Thus, NIDS are now an essential security brick to be deployed in corporate networks to detect known and zero-day attacks. In this research work, we propose a hybrid NIDS model based on the use of both a signature-based NIDS and an anomaly detection NIDS. The proposed system is based on agent technology, SNORT signature-based NIDS, machine learning techniques and the CICIDS2017 dataset is used for training and evaluation purposes. Thus, the CICIDS2017 dataset has undergone several pre-processing actions, namely, dataset cleaning, and dataset balancing as well as reducing the number of attributes (from 79 to 33 attributes). In addition, a set of machine learning algorithms are used, such as decision tree, random forest, Naive Bayes and multilayer perceptron, and are evaluated using some metrics, such as recall, precision, F-measure and accuracy. The detection methods used give very satisfactory results in terms of modeling benign network traffic and the accuracy reaches 99.9% for some algorithms.**

Keywords—Intrusion detection; zero-day attacks; machine learning; multi-agent systems; security

I. Introduction

The Global Internet Usage Statistics report confirms a growth of 1,114% and more than 2 quintillion bytes of data are generated every day. Along with this growth, cybercrime is becoming more sophisticated and continues to grow day by day [1, 2, 3]. As a result, the risks of being attacked and targeted by the hacker community remain more likely and could be costly for victims of cyber-attacks. Thus, the importance of Network Intrusion Detection Systems (NIDS) continues to grow and attract the interest of researchers [4] and NIDSs have become indispensable for securing network infrastructures against cyber-attacks [5]. However, the evolution of NIDSs is slowed down due to several challenges that are mainly related to the volume of network data, the emergence of increasingly sophisticated attacks [6] and unbalanced learning datasets [42]. In addition, real-time processing of network traffic is a very important feature of an effective NIDS to monitor all network events [8]. Not to mention that network traffic is continuously changing and therefore, the training datasets need to be updated regularly to effectively evaluate the detection models [5]. According to [22] and [42], the lack of more adequate datasets for anomaly detection-based intrusion detection has caused intrusion detection methods to suffer in analysis and deployment. The authors of [7] confirm that all these challenges remain a blocking obstacle against the evolution of the IDS domain in terms of performance, accuracy, and execution time during the learning and detection phases. Furthermore, the approaches proposed in the literature are not clear in terms of architecture and do not opt for hybrid architectures adopting, both, signature-based and anomaly detection-based NIDS. Most of the research works, carried out in this sense, remain theoretical and do not propose more efficient mechanisms capable of detecting known and unknown attacks.

In this research work, we will propose an effective intrusion detection approach to detect known and unknown cyber-attacks. Our approach consists of a Snort-based intrusion detection model to detect known intrusions and then machine learning techniques to detect any suspicious deviation from the baseline profile of benign network traffic. This baseline is designed by regularly training the system on normal network events using machine learning methods.

The selection of the research works carried out by the scientific community working on cybersecurity was done using a database of 17 journals (Q1 and Q2) and the used search terms are presented in Fig. 1 according to the methodology of [44].

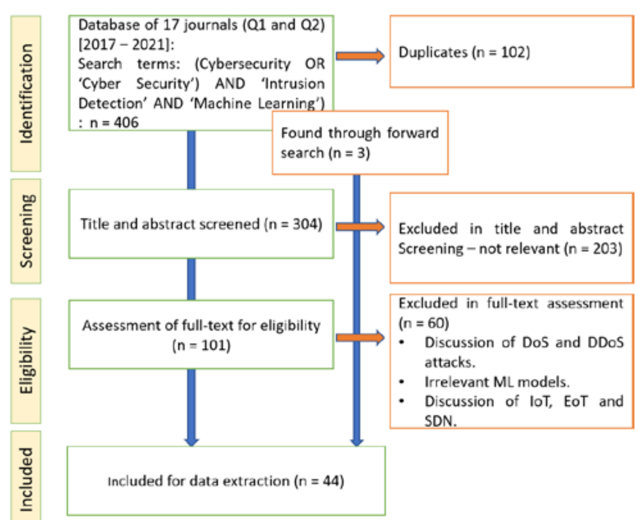

Fig. 1. Flow Diagram to Perform Papers Selection.

The remainder of this paper is structured as follows. Section II highlights some related works conducted by scientific community. Section III highlights gives some basics related to our theme of research. Section IV presents our proposed approach and finally Section V handles the conducted tests and experiments to validate the classification of benign network traffic.

II. Related Work and Discussion

A. Related Work

In this section, we will highlight some of the research works that have been carried out by researchers to ensure a quick advance of intrusion detection mechanisms based mainly on Machine Learning, Data Mining and Deep Learning techniques.

Since the beginning, researchers started to propose various approaches to effectively deal with the problem of Intrusion Detection. Notably, the Table I below summarizes some of the research works carried out by the scientific community to contribute in enhancing NIDS.

B. Discussion

It is true that several research works have been conducted by researchers to develop the field of intrusion detection systems. However, most of the aforementioned works have shortcomings in terms of architecture, datasets used as well as the machine learning methods used and each research work addresses a specific problem. For example, in the paper [25], the researcher limited himself to intrusion detection in wireless networks, in [39], the author proposed an IDS for SDN-based networks etc. In our research work, we will propose a universal NIDS, capable of being deployed in any type of computer networks. Our NIDS model will be based on a multi-layer architecture with the use of the multi-agent paradigm and will also be based on a hybrid detection mechanism combining a Signature-based NIDS (SNIDS) and an Anomaly-based NIDS (ADNIDS).

[4]	State-of-the-art study of various previous cybersecurity surveys focused on Deep Learning.	Details about IDS including input data, detection mechanisms, deployment modes as well as different evaluation strategies.
[39]	An approach for intrusion detection in Software Defined Network (SDN).	Decision Tree algorithm.
[40]	Hybrid IDS	Signature-based detection and Anomaly-based detection.

Our NIDS model will be based on mutli-agent technology in order to make the system modular and distributed. Thus, the proposed system will be extensible and capable of adding other components to perform large-scale detection missions in huge networks. Moreover, as we have already said, our system combines both detection mechanisms (SNIDS and ADNIDS) in order to detect all types of attacks (known and unknown). The used SNIDS is based on the famous open source NIDS SNORT and allows the detection of known intrusions. Moreover, ADNIDS intervenes when the packet is not recognized by the SNIDS and compares the packet's characteristics against the baseline patterns (benign traffic) modelled by supervised machine learning techniques applied to the cleaned and optimized CICIDS2017 dataset.

In order to improve the accuracy and precision of the used detection mechanism to model the benign network traffic, we opted for cleaning and reducing the dimension of the CICIDS2017 dataset. Thus, the used training dataset is devoid of any unnecessary information that could falsify the classification results.

III. Context of the Study

A. Cybersecurity

Cybersecurity is a discipline that has been evolving exponentially over the past decade [9]. It refers to the set of practices to protect the cyberspace environment against suspicious activities that may affect its security principles [10]. Among the security principles, we have the integrity of the data that aims to prevent the alteration of the information by unauthorized persons. The second principle is confidentiality, which confirms that the data should not be accessible by malicious people and finally the principle of high availability which ensures that the computer assets are available at any time to serve legitimate requests [11, 12].

B. Intrusion Detection Systems

The Intrusion Detection System (IDS) is one of the key components for ensuring the security of mobile clouds [13]. IDSs are classified according to the data source and the used detection method. Based on the nature of data sources, we can distinguish between two types of IDS: Host-based IDS and Network-based IDS. Furthermore, based on the used analysis method, we have two types of IDS: Signature-based IDS and Anomaly-based IDS [2].

NIDS analyses network traffic passing through computer environments [14, 3]. Its role is mainly to monitor the network events against suspicious activities that may violate or bypass security policies of security components such as firewalls, Web Application Firewalls and proxies. A NIDS usually consists of three main modules which are Monitoring, Analysis and detection, and Alarm modules. The Monitoring module observes network traffic, resource usage and patterns. The Analysis and Detection module is the key part of the system; it identifies cyber-attacks based on specific algorithms. Finally, the Alarm module is responsible for notifying the security administrators in case of possible intrusions [15]. Furthermore, conventional security mechanisms cannot detect unknown zero-day attacks [16] that have no signature or whose patterns are not yet known to security experts. Another issue that modern computer networks are facing is that network traffic is responding to Big Data issues (volume, variety and velocity). As a result, network traffic processing must make use of Big Data technologies to improve the quality of analysis and to reduce execution time during learning phases [17].

C. Snort: Open source Network Intrusion Detection

Snort is an open source IDS developed by Sourcefire in 1998 and has gained a very good reputation over the past decade due to its frequent use by researchers. Snort is structured in a TCP/IP stack architecture to capture and inspect network packets. This IDS is in its version 3.0 just released to overcome the single-thread limitation to support by default multithreading [18].

D. CICIDS2017 Dataset

A dataset for intrusion detection is developed by collecting network traffic events from heterogeneous sources. These events can describe system, user and configuration behaviors [19]. These datasets do not include network events that can represent zero-day attacks [20]. The CICIDS2017 dataset is one of the most modern datasets [21].

IV. Proposed Approach

A. Proposed Model

1) Architecture of the proposed model: Fig. 2 presents the proposed intrusion detection system model to ensure the detection of known and unknown attacks (0 Day) within any type of computer network. The proposed architecture is mainly based on three layers that collaborate together to perform cyber-attack detection missions.

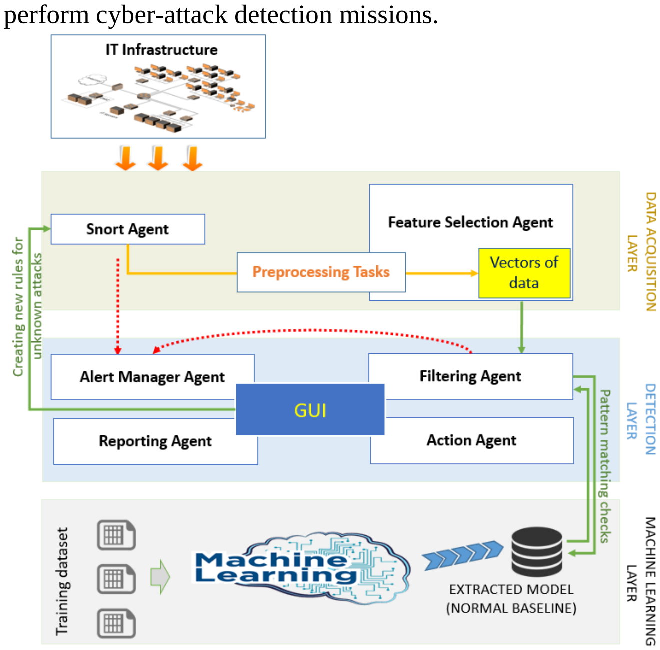

Fig. 2. The Proposed Network Intrusion Detection System.

2) Components of the proposed model

The system has three main layers:

- Data Acquisition Layer (DAL): This layer is responsible for data capture and pre-processing of network traffic. It also performs feature extraction to transform the captured network packets into data vectors to be used by machine learning methods. The DAL includes Snort Agent, a small component responsible for pre-processing tasks and an agent responsible for feature extraction.
- Detection Layer (DL): This component is responsible for detecting deviations from a network baseline. It is based on a machine learning model developed after training the system on a training dataset containing benign network traffic. The DL also sends alerts when an intrusion is detected and allows the security administrator to generate reports and take actions on the network and system infrastructure in case of a security incident.
- Machine Learning Layer: This part allows the NIDS system to perform training tasks on normal network behavior. Using supervised machine learning techniques on a dataset including benign network traffic, a model is developed that will check the fit to detect deviations from the designed baseline.

B. *Operating Principle*

Our system must be trained regularly on benign network traffic devoid of any type of cyber-attacks. Thus, datasets like CICIDS2017 are used to develop and design a baseline identifying the normal operation of a computer network. The training process of the proposed NIDS is mainly done in six steps:

- Data acquisition: The system collects data to train itself and to obtain the network baseline describing normal network behaviors. We used the CICIDS2017 dataset (Benign traffic) devoid of any kind of cyber-attacks.
- Pre-processing: In order for the data to be exploitable by machine learning based classification techniques, data preprocessing actions must be undertaken. Thus, missing value removal, scaling and partitioning techniques are all used to improve the quality of the training dataset.
- Classification: In this step, machine leaning based classification techniques are used to model the normal behavior of the network based on the benign dataset. Several machine learning algorithms are used to select the one with the highest accuracy, with very low false alarm rates and with an increased processing speed.
- Testing and validation: After using a set of machine learning techniques, it is now time to evaluate these algorithms based on specific metrics that address intrusion detection issues. From there, the most efficient machine learning technique is chosen to model the normal network traffic.
- Use of the model “Baseline”: After modeling the baseline of the network during normal operation based on the CICIDS2017 dataset, the generated model will be used to identify any deviation from normal behavior. Thus, unknown 0day attacks can be easily identified.

C. *Real Time Detection Flowchart*

Fig. 3 shows the detection principle of our NIDS model. Indeed, our system is supposed to train beforehand on benign network traffic that does not include any trace of cyber-attack, so the generated model will be considered as the network baseline to which the system will compare the real network packets.

Our system ensures the detection of intrusions in the networks according to the following steps:

- Step 1 – Sniffing and gathering: During this step, the NIDS listens to the network to collect all the packets that are passing through it. To do this, the proposed model relies on the Snort agent to capture the network traffic.
- Step 2 – Matching check: During this step, the Snort agent compares the patterns of the network packets it receives against a signature database describing all known cyber-attacks (Snort DB). Based on the result of the matching check, the Snort agent notifies the NIDS administrator if there is a known attack in the network.
- Step 3 – Data preprocessing: At this point, the captured packet is not recognized by Snort's knowledge base. Therefore, the network traffic must undergo pre-processing operations so that it can be consumed by machine learning algorithms. Thus, feature extraction techniques are applied to the captured network traffic in order to transform the data streams into data vectors that can be exploited by machine learning models.

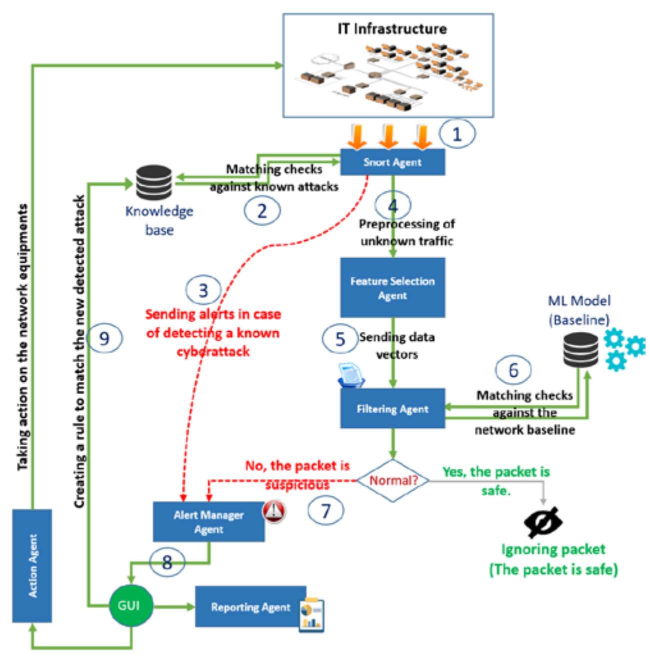

Fig. 3. The Flowchart of the Detection Mechanism.

- Step 4 – Filtering and matching check: After transforming the network flows into data vectors, the Filtering Agent checks the match between the data it receives and the "Network Baseline" model previously generated after training the system on benign network traffic. Depending on the result of the matching verification, two scenarios could arise: If the network packet is normal, no alert is generated and if the packet does not match the network baseline, the NIDS administrator must be informed in time to analyse the event.

- Step 5 – Enrichment of the Snort knowledge base: In case an event deviates from the network baseline, the NIDS system must notify the administrator. The administrator must then intervene to diagnose and analyse the suspicious event, and can also contact security vendors and publishers to identify the nature of the suspicious network event. The security administrator can create rules in the Snort to intercept similar events that may occur in the future. The detected suspicious network event can be Zero-day attacks for which the security vendors have not yet developed a patch or signature.

V. Experimentation and Tests

This section focuses on the experiments and tests performed to evaluate the performance of the different algorithms used for benign traffic modeling. For this purpose, the CICIDS2017 dataset is used and therefore it is necessary to analyze and clean it before using it by machine learning algorithms.

A. *Composition of the used Dataset*

We analyzed the CICIDS2017 dataset published by the Canadian Cybersecurity Institute using the Pandas framework in Python. The latter allowed us to analyze the content of the various CSV files constituting CICIDS2017 dedicated to research in the field of intrusion detection systems based on Machine Learning and Deep Learning.

The CICIDS2017 dataset consists of a set of eight files in a CSV format; these files include data about network traffic captured during five days from Monday to Friday. After analyzing the content of the set of CSV files using Pandas, we were able to identify the composition of the CICIDS2017 dataset and Table II summarizes the obtained results.

From the above statistics, it appears that the dataset is unbalanced due to the abundance of normal traffic compared to attack traffic, in addition to the existence of few records of certain types of attacks. This imbalance in the traffic classes automatically implies a biased machine learning model. Knowing that the class with a lot of traffic will be favored over the others with less records during the learning stage. As a result, the classes with few records make the machine learning model learn nothing about them and consequently have a biased detection model towards attacks with few records in the learning dataset.

TABLE II. Composition of the CICIDS2017 Dataset [41]

Day	Class of captured traffic	Number of records
Monday	Benign	529918
Tuesday	Benign	432074
	SSH-Patator	5897
	FTP-Patator	7938
Wednesday	Benign	440031
	DoS Hulk	231073
	DoS GoldenEye	10293
	DoS Slowloris	5796
	DoS Slowhttptest	5499
	Heartbleed	11
Thursday Morning	Benign	168186
	Web Attack Brute Force	1507
	Web Attack Sql Injection	21
	Web Attack XSS	652
Thursday – Afternoon	Benign	288566
	Infiltration	36
Friday – Morning	Benign	189067
	Bot	1966
Friday – Afternoon – PortScan	Benign	127537
	Port Scan	158930
Friday – Afternoon – DDoS	Benign	97718
	DDoS	128027

B. *Cleaning and Pre-processing of the Training Dataset*

As we already said, the CICIDS2017 dataset dedicated to researchers operating in the field of intrusion detection is composed of eight files. Hence, these files need to be merged into one more comprehensive, one including all the labelled network traffic. The concat() function in Pandas was used to concatenate the set of CSV files and then the to_csv() command could then be used to export the concatenated dataset in CSV format. Fig. 4 shows the workflow adopted to clean, balance and reduce the size of the CICIDS2017 dataset.

C. *Experimenting with Machine Learning Techniques to Model benign Traffic*

In this part, we will see some machine learning algorithms that we applied on the optimized training dataset CICIDS2017. This experimentation consists in trying a set of algorithms that we will compare between them in order to retain only those effective and efficient that allow us to better modeling a network baseline during its normal operation (benign traffic). Throughout this phase, the Knime tool is used to evaluate the performance of the machine learning algorithms applied on the optimized dataset.

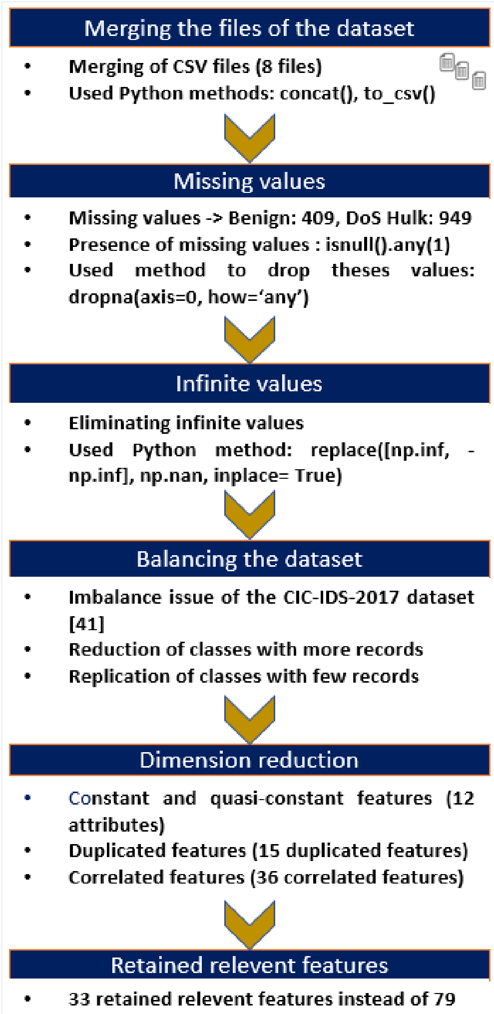

Fig. 4. The Performed Pre-processing and Feature Reduction Tasks to Optimize the CICIDS2017 Dataset.

1) Machine Learning algorithms used to model benign network traffic

a) Decision Tree: The Decision Tree (DT) algorithm was used and performed very well in terms of accuracy, false alarm rates, and execution time. According to the confusion matrix, it turns out that the Decision Tree algorithm provided better detection of all classes of network traffic. The accuracy reached 99.9% while classifying bengin network traffic. The Table III shows the confusion matrix and the Table IV summarizes the obtained results after applying DT algorithm on the optimized CICIDS2017 dataset.

The obtained results are conclusive and highlight the efficiency of the DT algorithm. We are interested in the accuracy of the algorithm with respect to the recognition of benign traffic, especially since our intrusion detection system relies on a baseline of the network during its normal operation. Thus, the Decision Tree was able to detect benign traffic with an accuracy of 99.99% and this, with a total number of false alarms equal to 229 (135 False Negatives (FN) and 94 False Positives (FP)).

TABLE III. CONFUSION MATRIX OF DECISION TREE TO CLASSIFY BENIGN TRAFFIC

Predicted	Actual		
		Positive	Negative
	Positive	74704	94
	Negative	135	174779

TABLE IV. PERFORMANCE STATISTICS OF DECISION TREE ALGORITHM TO CLASSIFY BENIGN TRAFFIC

Metrics	Rate (%)
Recall	99.8
Precision	99.9
F-Measure	99.8
Accuracy	99.9

b) Random Forest: The Random Forest is used to make the NIDS learn the normal behavior of the network. This algorithm performed very well in classifying the different classes of network traffic. As can be seen in Table VI, the detection accuracy reaches 99.8% for benign traffic using Random Forest classifier. RF is very effective in identifying benign traffic and thus designing the network baseline during its normal operation, knowing that the number of false alarms does not exceed 353 (FP: 75 and FN: 278) and with a number of TP equal to 74561 (see Table V).

c) Naïve Bayes: The Naive Bayes (NB) was also tested and unfortunately gave poor detection results for most classes of the dataset. For example, the correct detection of benign traffic is almost zero (accuracy reaches 100% for misclassified instances). Tables VII and VIII below show the statistics related to the use of NB algorithm. The classification of benign traffic is very low compared to other algorithms, as the accuracy does not exceed 70%.

TABLE V. CONFUSION MATRIX OF RANDOM FOREST TO CLASSIFY BENIGN TRAFFIC

Predicted	Actual		
		Positive	Negative
	Positive	74561	75
	Negative	278	174798

TABLE VI. EVaLUATION METRICS OF THE RANDOM FOREST ALGORITHM

Metrics	Rate (%)
Recall	99.6
Precision	99.9
F-Measure	99.8
Accuracy	99.8

TABLE VII. CONFUSION MATRIX OF NAIVE BAYES TO CLASSIFY BENIGN TRAFFIC

Predicted	Actual		
		Positive	Negative
	Positive	16	0
	Negative	74823	174873

TABLE VIII. EVALUATION METRICS OF THE NAIVE BAYES ALGORITHM TO CLASSIFY BENIGN TRAFFIC

Metrics	Rate (%)
Recall	0
Precision	100
F-Measure	0
Accuracy	70

d) MultiLayer Perceptron: Using the MultiLayer Perceptron (MLP) technique, the benign traffic was classified with an accuracy of 97%. Tables IX and X highlight the confusion matrix and the statistics obtained after using MLP-based technique.

TABLE IX. CONFUSION MATRIX OF MLP TO CLASSIFY BENIGN TRAFFIC

	Actual		
Predicted		Positive	Negative
	Positive	72227	4957
	Negative	2925	169603

TABLE X. EVALUATION METRICS OF MLP ALGORITHM TO CLASSIFIY BENIGN TRAFFIC

Metrics	Rate (%)
Recall	96.1
Precision	93.6
F-Measure	94.8
Accuracy	96.8

D. Summary of benign Traffic Classification Results

This section summarizes the obtained results after applying the classification algorithms on the optimized CICIDS2017 dataset. We emphasize that we are interested in modeling the network baseline in the absence of any suspicious activity. As a result, the different algorithms used at training time are evaluated based on the classification ability of benign traffic. Thus, Table XI summarizes the results obtained after applying the set of learning algorithms we saw in the previous section.

TABLE XI. SUMMARY OF THE OBTAINED RESULTS USING DIFFERENT MACHINE LEARNING ALGORITHMS

Algorithms	*Recall*	*Precision*	*Accuracy*
Decision Tree	***0.998***	***0.999***	***0.999***
Random Forest	***0.996***	***0.999***	***0.998***
Naïve Bayes	***0***	***1***	***0.7***
Multilayer Perceptron	***0.961***	***0.936***	***0.97***

From the summary table above, it appears that most of the techniques were able to model normal traffic. However, Naive Bayes did not perform well in classifying benign traffic. In addition, the Decision Tree and Random Forest are very efficient in terms of accuracy during training. However, the time complexity of the used algorithms is unfortunately not given in this work and will be the subject of our next article. For example, according to [43], the Decision Tree has a time complexity that is equal to O (mn2) where n is the number of instances and m represents the number of attributes. The temporal complexity metric allows for better evaluation of machine learning methods.

VI. CONCLUSION

It is true that many approaches based on machine learning techniques have been proposed to develop more effective and efficient NIDS. However, existing intrusion detection systems are still not able to detect unknown cyber-attacks more effectively. In this research work, we proposed a new approach based on a Multi-agent model, a Snort IDS and on machine learning techniques. The proposed NIDS is capable of handling network traffic that meets the big data issues in terms of volume and transition speed. First, we analysed the CICIDS2017 dataset with the aim of gaining more visibility on its composition, cleaned it up and removed unnecessary attributes. Then, we tried a set of classifiers on the optimized dataset in order to choose the most efficient algorithm in terms of detection and execution time. Thus, the Decision Tree and Random Forest algorithms give a detection accuracy of more than 99.8% for the detection of benign traffic. However, the work does not end here and the following tasks remain to be accomplished in a future work:

- Definition of how to create rules at Snort when a deviation from the baseline is detected,
- Using the benign traffic model to recognize normal packets in a production environment,
- Using a redundant and powerful module for processing and storing network traffic,
- Testing and validating the NIDS in a real environment.

Abstract*—The rapid spread of the Covid-19 disease and the ongoing social distancing have disrupted community activities. This consequently makes people use information and communication technology, especially in the fields of health, education, and business. The use of information and communication technology in the health sector plays an important role in preventing the spread of the Covid-19 disease. One of its uses is Telemedicine. One of the developing telemedicine in Indonesia is Halodoc. This study will test the quality of the Halodoc application to determine the quality of the Halodoc application using the model of the International Organization for Standardization (ISO), namely ISO 25010:2011. Software quality assurance can use this model as the basis for testing. Therefore the test will include 8 characteristics and 29 sub-characteristics. The assessment in this tests will use a weight where this weight is determined using Analytical Hierarchy Process (AHP) method. The testing method is carried out using Black-Box testing, stress testing, and distributing questionnaires to 100 respondents for Usability testing. Functional Suitability, Compatibility, Reliability, and Maintainability got a maximum score of 5. Performance Efficiency get a score of 4,886, Usability gets a score of 4, Security gets a score of 3,549, Portability gets a score of 3,718. The total results of the Halodoc application assessment get a score of 4,515 out of a maximum score of 5.

***Keywords*—Halodoc; ISO 25010:2011; software quality assurance; telemedicine**

I. Introduction

In 2020, the disease Covid-19 made the world difficult. The spread of this disease is so fast that the governments of each country are implementing isolation and social distancing. Indonesia is one of them. The Indonesian government has implemented social distancing to reduce the spread of the Covid-19 disease. The rapid spread of disease and social distancing rules that are still in effect disrupt community activities. Activities such as teaching and learning, working, doing business, and others cannot be carried out as usual. This effect makes people use information and communication technology, especially in the fields of health, education, and business [1]. The use of information and communication technology in the health sector plays an important role in preventing the spread of the Covid-19 disease. One of its uses is Telemedicine. Telemedicine is the service of remote health care services by all health care professionals using information and communication technologies. Another benefit of telemedicine is that it can prevent the spread of Covid-19 in Indonesia.[2]. One of the developing telemedicine in Indonesia is Halodoc.

Halodoc provides features that make it easier to consult with doctors, including about the Covid-19 disease that many people suffer from. This feature provides convenience because patients can consult a doctor anytime and anywhere, doctors available for consultation are available from general practitioners to specialists, patients can ask doctors about their disease and symptoms, and will be given treatment prescriptions according to the patient's illness. Perceived usefulness, perceived behavioral control, trust, self-health awareness, system quality, and attitude are factors that influence users in using Halodoc [3]. Therefore if the Halodoc application wants to make users satisfied using the application, it must pay attention to these factors. The quality of the system or software factor can be assessed by testing the quality of the software. The quality of the system or software can be assessed by testing the quality of the software so that users remain satisfied.

There are various methods or models of software quality testing. McCall model, Boehm model, or model of the International Organization for Standardization (ISO) like 9126-1 and 25010:2011 model, and many other models. The ISO 25010:2011 model includes all the quality factors of the previous model like the McCall model, Boehm model, and 9126-1 model [4]. Therefore, this model can be used as a basis for testing software quality.

This journal will use the ISO 25010:2011 model as the basis for testing the quality of the Halodoc application. Furthermore, the test will use eight characteristics of the model. The total assessment of the quality of the Halodoc application will be calculated using the weight determined in the research using the Analytical Hierarchy Process (AHP) method multiplied by the score from each characteristic. In addition, this journal will also use all sub-characteristics except Modularity and Modifiability of the Maintainability characteristic in the test. The supporting software that will be used in this research is “TestProject.io” which is used for Time Behavior testing, “UI/Application Exerciser Monkey” for Maturity testing, “Apache JMeter” for Availability testing, and “SPSS” for testing Validity and Reliability of the questionnaire.

This journal will organize as follows. First, this journal will provide a brief overview of related work. After that, this journal will explain the research methods that will be used. Next, it will present the research result and discuss it. Finally, this journal will give a conclusion about this journal.

II. Related Research Work

Previous research related to the topic of analyzing the quality of mobile applications already exists. First, there is a journal that uses the ISO 9126-1 model to measure electronic driving license application quality. The tool used for testing is a questionnaire, and the results from the journal are that the application meets the standard model 9126-1[5]. Nevertheless, this model is an old model. There is already a new model that develops from this model that is ISO 25010:2011 model [6].

Another research conducted a software quality analysis using the McCall model [7]. This model uses three characteristics, namely Product Revision, Product Transition, and Product Operation. This study aims to measure the quality of the financial system for cashiers. The results show that the performance of the system can still be improved. But the drawback of McCall's model is that the functionality of the application does not consider the functionality of the software [4].

Testing of quality analysis research uses the characteristics of the ISO 25010:2011 model. Those characteristics are Compatibility and Performance Efficiency. The test results from this study say that the Elektronika Analog application has a satisfactory quality. This research conducts the test using software cloud.bitbar.com. The test in this study has a weakness in which the Co-existence sub-characteristics are not tested [8].

Another research uses the ISO 25010:2011 model to ensure the quality of school information management applications. The test will use the characteristics like Functional Suitability, Usability, Performance Efficiency, Portability. Tests are carried out using tools such as gtmetrix for Performance Efficiency characteristics, System Usability Scale (SUS) for Usability characteristics, and Black-Box testing for Functional testing [9].

Other research uses the AHP method in calculating the final results of the test. The model used for testing is ISO 25010:2011. This research uses the characteristics like Functional Suitability, Reliability, Usability, and Performance Efficiency. The test method uses a questionnaire for all characteristics. The final result is calculated from the questionnaire data, which is then entered into the AHP. After that, the weights of the characteristics are compared to see which characteristics and sub-characteristics need improvement [10].

The difference between this journal and previous research is that it will use eight characteristics and all of their sub-characteristics except Modularity and Modifiability. Testing will also be carried out by determining the weight of each characteristic and sub-characteristic. The weight will be deterimined using AHP method. This weight is then multiplied by the value of each test performed.

III. Research Methods

A. Software Quality Assurance

A set of activities that define and assess the adequacy of the software process to provide evidence that establishes confidence that the software process is appropriate and produces a software product of the appropriate quality for the intended process [11]. Software Quality Assurance (SQA) software is a fundamental activity for many businesses that produce products that will be used by both internal and external users of the company. Software assurance has several purposes such as ensure that the team has carefully reviewed the requirements model for high quality, The design model must be assessed by the software team to ensure the high-quality model and meets the requirements, source code and associated work products must conform to local coding standards and exhibit characteristics that will facilitate software maintenance, SQA analyzes the allocation of resources for review and testing to assess whether or not resources are allocated in the most effective manner [12].

B. Characteristics and Sub-characteristics of ISO 25010 Quality Model

This ISO 25010 quality model consists of eight characteristics that are related to the dynamic and static properties of a computer system. The characteristics and sub-characteristics provide a consistent term for defining, measuring, and evaluating the quality of systems and software [13]. Fig. 1 shows ISO 25010:2011 diagram.

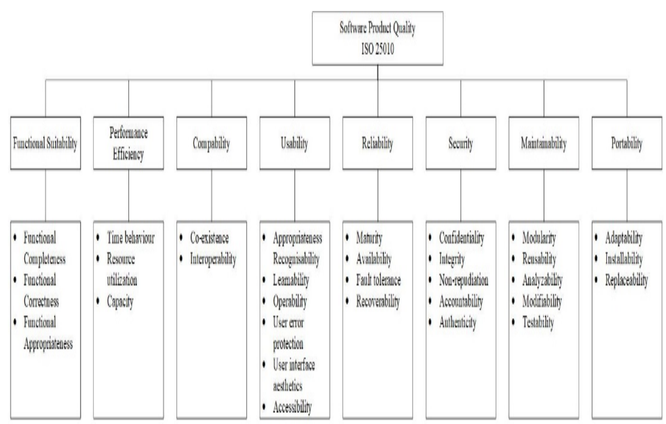

Fig. 1. ISO 25010:2011 Model.

Eight characteristics of ISO 25010 is Functional Suitability which represents the extent to which a product or system provides a function that satisfies stated needs when used under certain conditions. This characteristic has three sub-characteristics, namely: Functional Completeness, Functional Correctness, and Functional Appropriateness [14]. Performance Efficiency represents performance relative to the resources used under the stated conditions. This characteristic consists of sub-characteristics, namely: Time Behavior, Resource Utilization, Capacity [14]. Compatibility represents the extent of the system or product can exchange information or perform required functions with other system or product while sharing the same environment. This characteristic consists of sub-characteristics, namely: Co-existence and

Interoperability [14]. Usability represents if a system or product can be used by certain users to achieve certain goals with effectiveness, efficiency, and satisfaction in a particular context of use. This characteristic consists of sub-characteristics, namely: Appropriateness Recognizability, Learnability, Operability, User Error Protection, User Interface Aesthetics, and Accessibility [14]. Reliability represents how well a system, product or component performs a particular function under certain conditions for a certain period of time. This characteristic consists of sub-characteristics, namely: Maturity, Availability, Fault Tolerance, and Recoverability [14]. Security is the characteristic to know the extent a system or product protects information and data with a level data access following type and level of authorization. This characteristic consists of sub-characteristics, namely: Confidentiality, Integrity, Non-repudiation, Accountability, and Authenticity [14]. Maintainability is used to know the level of effectiveness and efficiency with which a product or system can be modified to improve it, improve it or adapt it to changing environments, and requirements. This characteristic consists of sub-characteristics, namely: Modularity, Reusability, Analyzability, Modifiability, and Testability. In this research, the sub-characteristic that will be used only 3, namely: Reusability, Analyzability, and Testability [14]. Portability will be used to determine the degree of effectiveness and efficiency with which a system or product can be transferred from one hardware, software, or other operational or usage environment to another. This characteristic consists of sub-characteristics, namely: Adaptability, Installability, and Replaceability [14].

C. Black-box Testing

Black-Box Testing is testing based on requirements specification and there is no need to check the code in Black-Box testing. This is purely done from a user point of view, only the tester knows the predictable set of inputs and outputs [15].

Black-Box testing plays an important role in software testing; it helps in validating the overall functionality of the system. Black-Box testing is done based on customer requirements-so incomplete or unpredictable requirements can be easily identified and can be addressed later [16]. The main advantages of Black-Box testing are required relatively few resources compared to White-Box testing, resource effectiveness can be done by testing automatically hence contributing to a shorter testing period, and ability to perform almost all test case groups, such as availability (response time) reliability, load durability and test groups related to the operation, revision and transition factors [17].

D. Stress Testing

Stress testing is used to test the reliability and stability of the system. This test can determine the system's resilience and fault handling under very heavy load conditions. Tests outside the normal operating point and evaluating how the system performs under these extreme conditions are included in Stress testing. Stress Testing is carried out to ensure that the system will not crash under crisis situations. The existence of large amounts of data with very high frequency and volume will result in the performance of the software being disrupted or not [18].

E. Questionnaire

A questionnaire is a data collection instrument used to collect large amounts of data. The trick is to provide several written questions in a structured manner to respondents related to their responses to the various variables studied [19]. Questionnaires can also be referred to as written interviews because the contents of the questionnaire are a series of written questions addressed to the respondent and filled out by the respondent himself. Things that need to be considered in compiling questions in the questionnaire use words that are easy to understand, questions that are not too general, avoid suggestive questions, avoid questions that embarrass the respondent, avoid questions that rely on the respondent's memory [20]. Usability testing will be conducted using the J.R. Lewis Usability questionnaire. This questionnaire uses a Likert scale. The data that will be obtained must pass validity and reliability test [21] (see Appendix).

The measuring instrument must perform a validity test and then test its reliability so that the measuring instrument is reliable with a reliability test. The validity test is used to determine whether the questions in the research instrument are valid or can collect information according to the questions given, while the reliability test is carried out to see the level of reliability of the research instrument. Especially research that is a case study, collects research data using research instruments [22].

F. Analytical Hierarchy Process

The Analytic Hierarchy Process (AHP) was introduced by Thomas L. Saaty to solve problems that have many factors and many criteria. AHP is a structured method related to the decision-making process on complex problems, which consists of many alternatives such as projects, actions, and scenarios. AHP is developed according to the hierarchical structure of several alternative combinations in decision-making. For example, knowledge, experience, and intuition. This method can provide an opportunity for everyone to make decisions on various types of problems [23].

IV. Research Result and Discussion

A. The Weighting of Characteristics and Sub-characteristics of ISO 25010:2011

Determination of the characteristics and sub-characteristic weights of the ISO 25010:2011 quality model was carried out to measure the quality of the Halodoc software. Determination of this weight is done before evaluating the quality of the software. This Weighting method is based on previous research [24]. Weight determination will be carried out on 8 characteristics and 29 sub-characteristics of the ISO 25010:2011 quality model. Determination of the weights will use software assistance, namely Web-based AHP with the link address: https://bpmsg.com/ahp/ahp-calc.php.

B. The weighting of Characteristic of ISO 25010:2011

The results of determining the weight characteristics of the ISO 25010:2011 quality model obtained a weight of 8 characteristics as shown in Fig. 2.

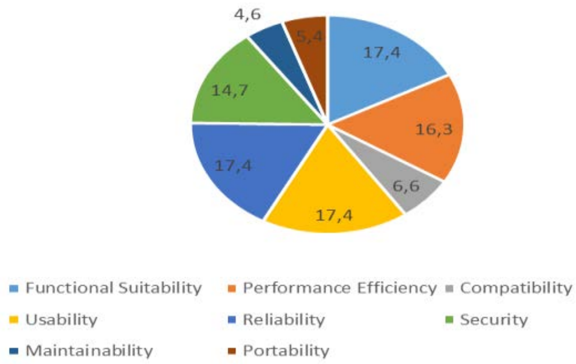

Fig. 2. Result of Weighting Characteristics of ISO 25010:2011.

Characteristics of Functional Suitability, Usability, and Reliability each get a weight of 17.4%. Characteristic of Performance Efficiency gets a weight of 16.3%. Security characteristic gets a weight of 14.7%. Compatibility characteristic gets a weight of 6.6%. Portability characteristic gets a weight of 5.4% and Maintainability gets a weight of 4.6%.

After determining the weight of each characteristic, the determination of the weight of the sub-characteristics will be carried out on each characteristic of Functional Suitability, Performance Efficiency, Compatibility, Reliability, Security, Maintainability, and Portability. This journal will write 4 characteristics tests that will be used for weight determination and application testing. Those characteristics are Performance Efficiency, Reliability, Security, and Usability.

1) The weighting of performance efficiency: Three sub-characteristics that will be included are Resource Utilization, Time Behavior, and Capacity. The next step is to determine the priority of the three sub-characteristics.

The sub-characteristics of Resource Utilization and Time Behavior have the same important priority so that they get priority 1. It's because Time Behavior is used to examine the processing time when performing a function and Resource Utilization is used to determine the number of hardware resources used to carry out the function.

The Time Behavior sub-characteristic has a higher priority than Capacity with a priority of 5, which is of medium importance. It's because Time Behavior is used to examine the processing time when performing a function while Capacity is used to determine the maximum amount of hardware resources used to carry out the function.

The Resource Utilization sub-characteristic has a higher priority than Capacity and gets priority 3, which is slightly more important. This is because Resource Utilization is used to find out the number of hardware resources used to carry out functions while Capacity is used to find out the maximum number of hardware resources used by the software.

The result of determining the priority of sub-characteristics can be seen in Fig. 3. Time Behaviour gets a weight 48.1%, Resource Utilization gets 40.5%, and Capacity gets 11.4%.

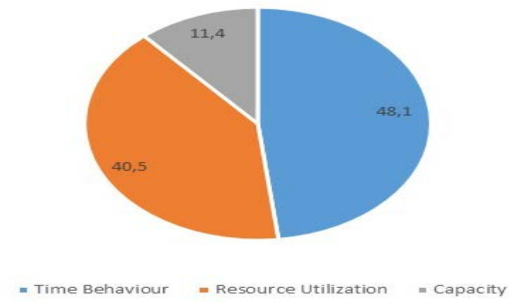

Fig. 3. Performance Efficiency Weighting Result.

2) The weighting of reliability: The four sub-characteristics that have been included are Availability, Maturity, Recoverability, and Fault Tolerance. The next step is to determine the priority of the four sub-characteristics.

The Maturity and Fault Tolerance sub-characteristic is slightly more important than the Availability and Recoverability sub-characteristics. This gives Maturity and Fault Tolerance priority 3. This is because Maturity is used to determine software maturity in various conditions and Fault Tolerance is used to determine whether the software can run properly even if an error occurs while Availability is a sub-characteristic that serves to test software availability and Recoverability is used to determine whether the software can recover data and systems as desired if a failure occurs.

The sub-characteristics of Maturity and Fault Tolerance have the same level of importance so that they get priority 1, which is equally important. This is because Maturity is used to determine the maturity of the software under various conditions and Fault Tolerance is used to determine whether the software can run properly even if an error occurs.

The sub-characteristics of Availability and Recoverability have the same level of importance so that they get priority 1, which is equally important. This is because Availability is a sub-characteristic that serves to test the availability of software and Recoverability is used to find out whether the software can recover data and systems as desired if a failure occurs.

The result of determining the priority of sub-characteristics can be seen in Fig. 4. Maturity gets a weight 37.5%, Availability gets 12.5%, Fault Tolerance gets 37.5%, and Recoverability gets 12.5%.

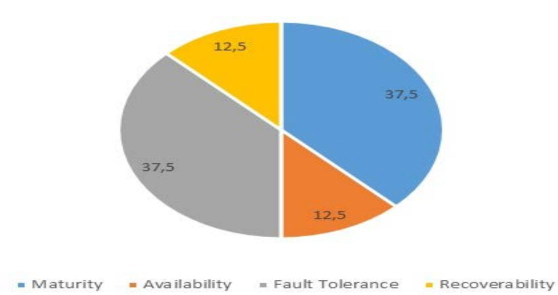

Fig. 4. Reliability Weighting Result.

3) The weighting of security: The five sub-characteristics included are Integrity, Non-repudiation, Confidentiality Authenticity, and Accountability. The next step is to determine the priority of the five sub-characteristics.

The sub-characteristics of Confidentiality, Integrity, Authenticity have the same level of importance so each of them get priority 1, that means is equally important. This is because the Confidentiality sub-characteristic ensures that application data can only be modified and accessed by authorized parties. Integrity ensures the prevention of alteration or deletion of information by unauthorized parties, and Authenticity ensures that the identity of the subject can be proven as stated by the subject.

The Confidentiality sub-characteristic is slightly more important than the Non-repudiation and Accountability sub-characteristic so it get priority 3 that means it is slightly more important. This is because the Confidentiality sub-characteristic ensures that application data can only be modified and accessed by authorized parties. While non-repudiation is used to determine the extent to which events or actions can be proven to have occurred and Accountability is used to know that the actions of an entity can be traced to that entity in a unique way.

The Integrity sub-characteristic is slightly more important than the Non-repudiation and Accountability sub-characteristic with priority 3. This is because Integrity ensures the prevention of changes or deletion of information by unauthorized parties while Non-repudiation is used to determine the extent to which events or actions can be proven to have occurred and Accountability is used to know that the actions of an entity can be traced to that entity in a unique way.

The Authenticity sub-characteristic is slightly more important than the Non-repudiation and Accountability sub-characteristic with priority 3. This is because Authenticity ensures that the identity of the subject can be proven as stated by the subject whereas Non-repudiation is used to determine the extent to which events or actions can be proven to have occurred and Accountability is used to know that the actions of an entity can be traced to that entity in a unique way.

Non-repudiation sub-characteristics with Accountability have the same level of importance so they have priority 1. This is because these two sub-characteristics have the same two objectives, namely to prove and record activities that have been carried out so that they can be proven.

The result of determining the priority of sub-characteristics can be seen in Fig. 5. The Confidentiality gets a weight 27.3%, Integrity also gets 27.3%, Non-repudiation gets 9.1%, Accountability get 9.1%, and Authenticity get 27.3%.

4) The weighting of usability: Six sub-characteristics of Usability are Learnability, Appropriateness Recognizability, User Error Protection Operability, Accessibility, and User Interface Aesthetics. These six sub-characteristics will be included then be prioritized.

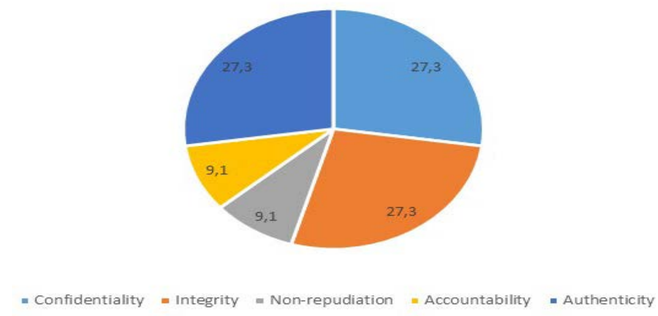

Fig. 5. Security Weighting Result.

The Learnability and Operability sub-characteristic are more important than the Appropriateness Recognizability sub-characteristic so Learnability and Operability obtain priority 3, slightly more important. Learnability test software can be learned easily or not and Operability tests whether the software is easy to operate or use by users while Appropriateness Recognizability is used to test the extent to which users can recognize whether a software fits their needs.

User Error Protection sub-characteristics and User Interface Aesthetics with Appropriateness Recognizability sub-characteristics obtain priority 1 which means the same importance. User Error Protection tests whether the software can protect users from making mistakes, User Interface Aesthetics tests whether the software interface allows pleasant and satisfying interactions for users, and Appropriateness Recognizability is used to test the extent to which users can identify whether a software fits their needs.

The Appropriateness Recognizability, Learnability, and Operability sub-characteristic are more important than the Accessibility sub-characteristic with priority 3. Appropriateness Recognizability is used to test the extent to which users can recognize whether a software fits their needs, Learnability tests software that can be learned easily or not, and Operability sub-characteristics test whether the software is easy to operate or use by the user while Accessibility tests whether the software can be accessed or not by the user.

Learnability sub-characteristics with Operability sub-characteristics obtain priority 1 which means the same importance. Learnability sub-characteristics test the software can be learned easily or not and Operability sub-characteristics test whether the software is easy to operate or use by users.

Learnability sub-characteristics with User Error Protection and User Interface Aesthetics sub-characteristics get priority 1 which means the same importance. The Learnability sub-characteristics tests whether the software can be learned easily or not, the User Error Protection Sub-characteristics tests whether the software can protect users from making mistakes, and User Interface Aesthetics Sub-characteristics test whether the software interface allows pleasant and satisfying interactions for users.

Operability sub-characteristics with User Error Protection and User Interface Aesthetics sub-characteristics get priority 1 which means the same importance. The Operability sub-characteristics test whether the software is easy to operate or use by the user, the User Error Protection sub-characteristics test whether the software can protect users from making errors and User Interface Aesthetics sub-characteristics test whether the software interface allows pleasant and satisfying interactions for users.

User Error Protection sub-characteristics with User Interface Aesthetics sub-characteristics obtain priority 1 which means the same importance. The User Error Protection sub-characteristic tests whether the software can protect users from making mistakes and the User Interface Aesthetics sub-characteristic tests whether the software interface allows for a pleasant and satisfying interaction for the user.

The User Error Protection sub-characteristic is more important than the Accessibility sub-characteristic with priority 3, a little more important. The User Error Protection sub-characteristic tests whether the software can protect users from making mistakes while Accessibility tests whether the software can be accessed by the user.

Sub-characteristic User Interface Aesthetics with sub-characteristic Accessibility get priority 1 which means the same importance. Sub-characteristics of User Interface Aesthetics test whether the software interface allows pleasant and satisfying interactions for users and Accessibility tests whether the software can be accessed or not by the user.

The result of determining the priority of sub-characteristics can be seen in Fig. 6. The Appropriateness Recognizability gets a weight 13.5%, Learnability and Operability each get 22.4%, User Error Protection gets 18,2 %, User Interface Aesthetics gets 15.8%, and Accessibility gets 7.7%.

C. Testing Halodoc Application

This section will describe the testing for Halodoc Application. Type of testing will be used depend of the sub-characteristic. Some of the test will be using software for testing.

1) Performance efficiency characteristic test: Time Behavior testing for Halodoc application will use Black-Box testing. This test is carried out with the aim of knowing how long the response and process time can reach the requirements when carrying out the function. This test is carried out using web-based testing software, namely testproject.io.

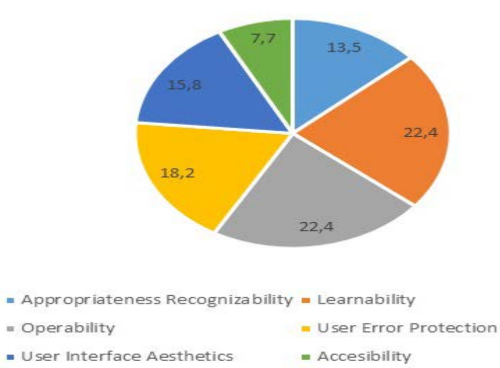

Fig. 6. Usability Weighting Result.

Resource Utilization testing will use Black-Box testing. This test is carried out with the aim of knowing the extent to which the amount and type of resources are used by the software when carrying out its functions in order to meet the requirements. The test for checking RAM allocation for the application will use Apptim Software.

Capacity testing will use Black-Box testing. This test is carried out with the aim of knowing the extent to which the maximum limit of a product or system parameter meets the requirements. The test for checking maximum RAM usage for the application will use Apptim Software.

Fig. 7 will show the score for each sub-characteristics of Performance Efficiency. The total score of Performance Efficiency characteristic will be calculated based on the accumulation sub-characteristics score. This result can be seen in Table I.

2) Reliability characteristic test: Maturity test for the Halodoc application will use stress testing. This test is carried out with the aim of knowing how much the software can meet the requirements for reliability in normal operation. This test is carried out using the Monkey feature on the Android SDK. Monkey can be used to stress testing applications by entering random but repetitive commands.

Availability test for Halodoc application will use stress testing. This test is carried out with the aim of knowing the extent to which the product can operate and can be accessed when needed for use. This test is done by accessing the website version of the Halodoc application using the Jmeter tool to create 100 virtual users. The website version was chosen to facilitate testing with Jmeter and because of the Availability characteristic; it aims to find out if the application can be accessed when needed.

Recoverability test will use Black-Box testing. This test is conducted with the aim of knowing in the event of a failure or breakdown, the system or application can recover the affected data directly and reestablish the desired system state.

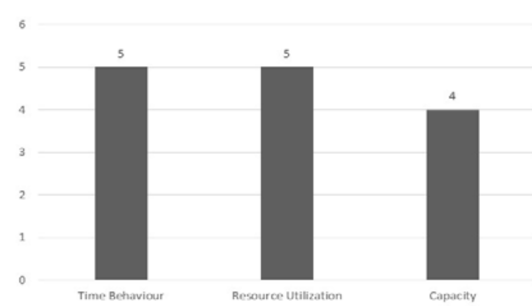

Fig. 7. Performance Efficiency Sub-characteristics Score.

TABLE I. PERFORMANCE EFFICIENCY TEST RESULT

No.	Sub-Characteristics	Weight	Score	Total Score
1	Time Behaviour	48.1%	5	48.1% * 5 = 2.405
2	Resource Utilization	40.5%	5	40.5% * 5 = 2.025
3	Capacity	11.4%	4	11.4% * 4 = 0.456
Total Score of Performance Efficiency				4.886

Fault Tolerance test will use stress testing for Halodoc application testing. This test is carried out with the aim of knowing the extent to which the system or application can operate properly despite software or hardware errors.

Fig. 8 will show the score for each sub-characteristics of Reliability. Total score of Reliability characteristic will be calculated based on accumulation sub-characteristics score. This result can be seen in Table II.

3) Security characteristic test: Confidentiality test will use Black-box testing. This test is carried out with the aim of knowing how the system or application can ensure that data can only be accessed by those authorized. In this test case, it is done by logging into the Halodoc application.

Integrity test for the Halodoc application will use Black-Box testing. This test is carried out with the aim of determining if a system or application can prevent modification of computer programs or data and prevents unauthorized access. In this case, testing will be carried out to change user profile information and modify the Halodoc program.

Non-Repudiation test will use the observation method. This test is carried out with the aim of knowing the extent to which an action or event can be proven to have occurred so that the event or action cannot be denied in the future. The test is carried out by observing the logs or history in the Halodoc application.

Accountability test will use the observation method. This test is carried out with the aim of knowing the ability of the software to distinguish the original user or not. Testing is done by observing user activities when logging into the application.

Fig. 9 will show the score for each sub-characteristics of Security. Total score of Security characteristic will be calculated based on accumulation sub-characteristics score. This result can be seen in Table III.

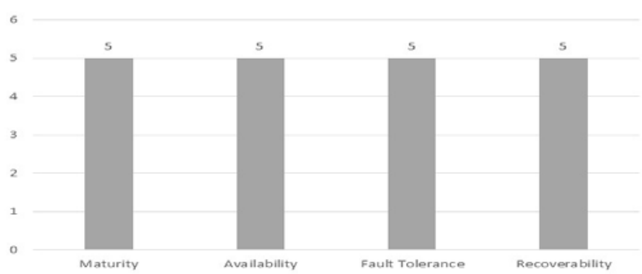

Fig. 8. Reliability Sub-characteristics Score.

TABLE II. RELIABILITY TEST RESULT

No.	Sub-Characteristics	Weight	Score	Total Score
1	Maturity	37.5%	5	37.5% * 5 = 1.875
2	Avalability	12.5%	5	12.5% * 5 = 0.625
3	Recoverability	12.5%	5	12.5% * 5= 0.625
4	Fault Tolerance	37.5	5	37.5% * 5 = 1.875
Total Score of Reliability				5

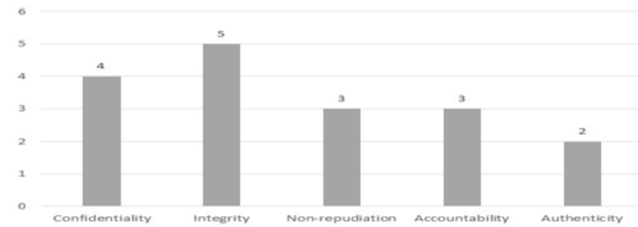

Fig. 9. Security Sub-characteristics Score.

TABLE III. SECURITY TEST RESULT

No.	Sub-Characteristics	Weight	Score	Total Score
1	Confidentiality	27.3%	4	27.3% * 4 = 1.092
2	Integrity	27.3%	5	27.3% * 5 = 1.365
3	Non-repudiation	9.1%	3	9.1% * 3 = 0.273
4	Accountability	9.1%	3	9.1% * 3 = 0.273
5	Authenticity	27.3%	2	27.3% * 2 = 0.546
Total Score of Security				3.549

4) Usability characteristic test: Usability characteristic testing for the Halodoc application will use 6 sub-characteristics. The sub-characteristics are Operability, Appropriateness Recognizability, User Error Protection, Learnability, Accessibility, and User Interface Aesthetics. The questionnaire that will be used in this test is based on J.R. Lewis Usability Questionnaire that has been modified by previous research [24]. Testing these characteristics will use a questionnaire distributed to respondents who use the Halodoc application. The results of the questionnaire test will then pass the validity and reliability testing using the IBM SPSS version 20 program.

Research sample selection will use the random sampling technique. The sampling method used refers to the solving approach. The result is 100 samples required for usability testing. The questionnaire will be distributed to 100 people who have used the Halodoc application.

The data from the questionnaire that has been collected will then be tested for validity and reliability. The results of the validity test can be said to be valid if the value obtained exceeds the value of the r table with sample (N) = 100 at a significance of 5% with an r value of 0.197. The questionnaire each question passes this validity question. The next step is to test the Reliability of the questionnaire. Reliability testing is carried out after the validity test results get valid results. This step is done after testing the validity of using SPSS Tools. The result can be seen in Fig. 10.

The results of the reliability test obtained the value of Cronbach Alpha of 0.931. If you look at Table IV, the reliability test results get the Very High category. This means the questionnaire that has been filled out by the respondent is reliable.

Case Processing Summary

		N	%
Cases	Valid	100	100.0
	Excluded[a]	0	.0
	Total	100	100.0

Reliability Statistics

Cronbach's Alpha	N of Items
.931	17

Fig. 10. Usability Questionnaire Reliability Test Result.

TABLE IV. RELIABILITY INDEX CRITERIA

No.	Interval	Criteria
1	0.000 - 0.200	Very Low
2	0.201 - 0.400	Low
3	0.401 - 0.600	Enough
4	0.601 - 0.800	High
5	0.801 - 1.000	Very High

Appropriateness Recognizability is done to find out how much users can recognize whether a product fits their needs. The sub-characteristic of Appropriateness Recognizability has 3 questions out of 17 questionnaire questions asked to respondents with a total of 300 votes. From Fig. 11, the Appropriateness Recognizability sub-characteristic gets the most votes for Agree with 152 votes out of 300 votes.

Learnability is carried out to determine if the software is easy to learn by users. Learnability sub-characteristics have 3 questions out of 17 questionnaire questions asked to respondents with a total of 300 votes. From Fig. 11, the Learnability sub-characteristic gets the most votes for Agree with 133 votes out of 300 votes.

Operability is carried out to determine if the software is easy to control and use by users. Operability sub-characteristics has 3 questions out of 17 questionnaire questions asked to respondents with a total of 300 votes. From Fig. 11, the Operability sub-characteristic gets the most votes for Agree with 137 votes out of 300 votes.

User Error Protection is carried out to determine if the system protects users from making mistakes. User Error Protection sub-characteristics has 2 questions out of 17 questionnaire questions asked to respondents with a total of 200 votes. From Fig. 11 can be seen that the User Error Protection sub-characteristic gets the most votes for Agree with 80 votes out of 200 votes.

Aesthetic User Interface is carried out to determine if the user interface allows pleasant and satisfying interactions for users. User Interface Aesthetic sub-characteristics has 4 questions out of 17 questionnaire questions asked to respondents with a total of 400 votes. Fig. 11 shows that the Aesthetic User Interface sub-characteristic gets the most votes for Agree with 191 votes out of 400 votes.

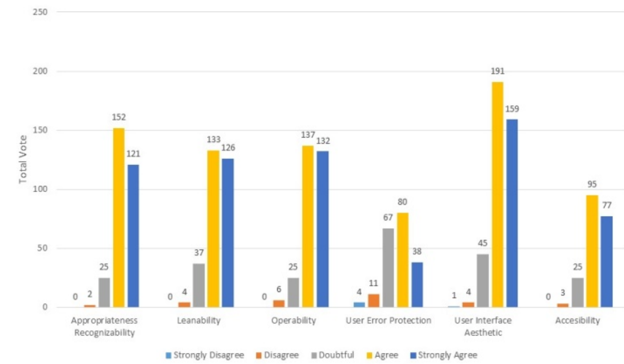

Fig. 11. Usability Sub-Characteristics Votes.

Accessibility is carried out to determine if the software is easily accessed by users. Accessibility sub-characteristics have 2 questions out of 17 questionnaire questions asked to respondents with a total of 200 votes. From Fig. 11, the Aesthetic User Interface sub-characteristic gets the most votes for Agree with 191 votes out of 200 votes.

Total score of Security characteristic will be calculated based on accumulation sub-characteristics score. This result can be seen in Table V.

TABLE V. USABILITY TEST RESULT

No.	Sub-Characteristics	Weight	Score	Total Score
1	Appropriateness Recognizability	13.5%	4	13.5% * 4 = 0.54
2	Learnability	22.4%	4	22.4% * 4 = 0.896
3	Operability	22.4%	4	22.4% * 4 = 0.896
4	User Error Protection	18.2%	4	18.2% * 4 = 0.728
5	User Interface Aesthetic	15.8%	4	15.8% * 4 = 0.632
6	Accesibility	7.7%	4	7.7% * 4 = 0.308
Total Score of Usability				4

D. Halodoc Application Total Result

The testing and assessment of the characteristics of the ISO 25010:2011 on the Halodoc application have been carried out. The value of each characteristic can be seen in Fig. 12.

The next step is to calculate the total value for the Halodoc application. Table VI shows the calculation of the total value obtained by the Halodoc application by combining the 8 characteristics of the ISO 25010:2011 model.

The quality test assessment of the software, namely Halodoc, uses the ISO 25010:2011 method with 8 characteristics and 29 sub-characteristics, the assessment is carried out using various testing models such as Black-Box testing, stress testing, observation, and questionnaires distributed to 100 respondents. The Halodoc application gets a score of 4,515 out of a total score of 5. This score is good for Halodoc software because it is only less than 0.5 points adrift to get the maximum score.

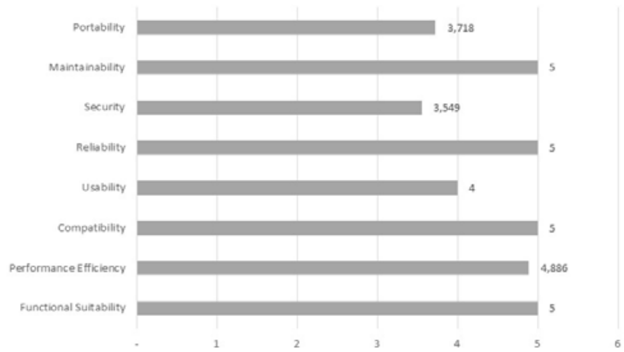

Fig. 12. ISO 25010:2011 Characteristics Score.

From Fig. 12 can be seen that the Security and Portability Characteristic result is enough but need improvement. Performance Efficiency and Usability already get a good result but still, it can be improved.

TABLE VI. TOTAL SCORE OF HALODOC APPLICATION

No.	Sub-Characteristics	Weight	Score	Total Score
1	Functional Suitability	17.4%	5	17.4% * 5 = 0.87
2	Performance Efficiency	16.3%	4.886	16.3% * 4.886 = 0.796
3	Compatibility	6.6%	5	6.6% * 5 = 0.33
4	Usability	17.4%	4	17.4% * 4 = 0.696
5	Reliablity	17.4%	5	17.4% * 5 = 0.87
6	Security	14.7%	3.549	14.7% * 3.549 = 0.522
7	Maintainability	4.6%	5	4.6% * 5 = 0.23
8	Portability	5.4%	3.718	5.4% * 3.718 = 0.201
Halodoc Application Total Score				4.515

V. CONCLUSION AND SUGGESTION

A. Conclusion

Halodoc application testing using the ISO 25010:2011 model has been successfully carried out. Characteristics of Functional Suitability, Performance Efficiency, Compatibility, Usability, Reliability, Security, Portability, and Maintainability with 29 sub-characteristics used to assess Halodoc applications. Tests are carried out using several testing methods ranging from Black-Box testing to testing the characteristics of Functional Suitability, Performance Efficiency, Compatibility, Security, Portability, and Maintainability. Stress testing is also carried out to test the characteristics of Reliability. The questionnaire method was used for usability testing which was distributed to 100 respondents using the Halodoc application.

Characteristics of Functional Suitability, Compatibility, Reliability, and Maintainability managed to get the best score, namely, 5. The Usability and Performance Efficiency Characteristics managed to get scores of 4 for Usability and 4.886 for Performance Efficiency. This characteristic has received good values but can still be improved. Characteristics of Portability and Security get a value of 3.718 and 3.549 respectively. The total score obtained is 4.515 from a total value of 5 for the Halodoc application. This value indicates that the Halodoc application has good software quality, although some characteristics still need development and improvement. The results of this test can be taken into consideration for Halodoc application developers to correct deficiencies and improve what is already good.

B. Suggestion

Testing the quality of the Halodoc application using the ISO 25010:2011 method can still be developed again. The use of tools or tools for testing can be added again. Such as tools for testing the characteristics of Reliability, Security, and Portability. The testing method used can also be added, such as the penetration testing method for security characteristics. Sub-characteristics that were not used in this study can also be added for further research. This can be done so that the shortcomings that occur in the application can be known in detail.

A. *List of Question in Usability Questionnaire*

TABLE VIII. USABILITY QUESTIONS

No.	*Sub-characteristic*	Question
1	Appropriateness Recognizability	Overall I am satisfied using the Halodoc application?
2	Appropriateness Recognizability	How to use the Halodoc application is very simple?
3	Appropriateness Recognizability	The information obtained is very easy to understand?
4	Learnability	I feel very fast in getting health information on this application?
5	Learnability	I find it very easy to learn the Halodoc application?
6	Learnability	The information provided by the Halodoc application is very clear?
7	Operability	Can I get health information quickly using the Halodoc application?
8	Operability	Is it easy to get information about health on the Halodoc application?
9	Operability	The information I get on the Halodoc application helps to get the health information I want to know?
10	User Error Protection	If an error occurs, the application informs the error that occurred?
11	User Error Protection	Whenever I make a mistake, can I recover quickly?
12	User Interface Aesthetic	Am I comfortable using the Halodoc application?
13	User Interface Aesthetic	The layout in the Halodoc application display is very clear?
14	User Interface Aesthetic	Halodoc application display is very easy?
15	User Interface Aesthetic	I like the look of apps like Halodoc?
16	Accessibility	The ability of the application to complete all the functions in it make me satisfied?
17	Accessibility	Overall I am satisfied with the Halodoc application?

The Novel CPW 2.4 GHz Antenna with Parallel Hybrid Electromagnetic Solar for IoT Energy Harvesting and Wireless Sensors

Irfan Mujahidin[1]*, Akio Kitagawa[2]
Micro Electronics Research Laboratory (MeRL), Kanazawa University, Kanazawa, Ishikawa, Japan

***Abstract*—The design and implementation's novelty simultaneously utilizes the antenna's frequency, polarization, and feed structure to maximize the harvested RF energy and become a microstrip communication circuit for wireless sensor or communication systems in IoT devices. In addition, the optimization of the parallel circuit configuration has a voltage doubler model with an integrated parallel system and thin-film solar cells. Implementation of the antenna structure has two-line feeds in one antenna. Usage both feeds have the same function as CPW circular polarization. Another advantage is that there is no miss-configuration when installing the port exchanges when using both output ports simultaneously. The 2-port antenna has an area of 1/2 per port (where accessible wavelengths work well at the 2.4 GHz frequency). It has been shown to achieve a relatively narrow bandwidth of 86.5 percent covering WiFi frequency band networks and IoT communications. It does not require additional filters and analog matching circuits that cause power loss in the transmission process in parallel voltage doubler circuits. Integrating a reflector on the CPW antenna with two ports for placement of thin-film solar cells provides antenna gain of up to 8.2 dB. It provides a wide beam range with directional radiation. Using a multi-stage parallel to increase voltage output and integrated with a thin-film solar cell converter proves efficient in the 2.4 GHz frequency band. When the transmission power density is -16.15 dBm with a tolerance of 0.023, the novel energy harvester configuration circuit can produce an output voltage of 54 mV dc without adding solar cell energy. And Integrated thin-film solar cell a light beam of 300 lux in the radiation beam area of -16.15 dBm, the energy obtained has a value of 1,74467V. It also shows that the implementation of this configuration can produce an optimal dc output voltage in the actual indoor and outdoor ambient settings. The optimization of antenna implementation and the communication process with Multiple signal classifications improves the configuration of antennas that are close to each other and have identical phase outputs. It is instrumental and efficient when applied to IoT devices.**

Keywords*—*Double CPW antenna; energy harvesting; wireless sensors; IoT communications

I. Introduction

Most mobile-based device implementations connect wireless sensor networks, actuators in implementing Internet-of-Things (IoT) communication, manufacturing processes, health care, and transportation. However, the challenges of powering these devices require battery usage, recharging, and power support across multiple sensors. However, it still requires conventional charging, and battery replacement is becoming very expensive and unsustainable[1][2]. Using energy harvesters to collect energy from environmental sources outside of IoT devices is the most feasible solution. Energy harvesting such as solar, thermal, vibration, piezoelectric, magnetic, and RF are just forms of exploration in collecting energy sources. Film Solar cells with integrated ambient RF or electromagnetic energy collection have better performance than single-source harvesting, based on the principle of using an integrated antenna to harvest energy in the environment and harvesting embedded solar energy indoors or outdoors[3][4]. It can be scaled to multiple nodes either in parallel or partially having high functionality. The technology related to electromagnetic energy harvesting is a wireless power transmission process in which the emitted electromagnetic energy comes from a specific source to be harvested. In addition, the harvesting of electromagnetic energy can be done by collecting sources of electromagnetic radiation present, such as in WLAN systems or other wireless networks, whose use is legally free[5][6]. Harvesting ambient RF energy to support independent IoT devices is becoming practical, increasing devices becoming wireless RF sources.

Most previous research on antennas as electromagnetic energy harvesters only considers partial antenna designs in the one-time harvesting process. They have not utilized antennas as a dual function domain and linear antenna integration. For example, a recent paper presents High-Efficiency Rectenna Broadband for Energy Harvesting RF environment [7]. It only has the function of harvesting single polarized and electromagnetic energy for single antenna use. Consequently, it is essential to use multi-function and optimization of parallel antennas and have directional radiation coverage and power gain to optimize the collection of RF energy in the environment. Antennas with multi-polarization properties can maximize the available RF energy so that absorption from the transmission with random polarization can be well in the IoT device communication system. The configuration has the aim of collecting polarized varying ambient RF energy while minimizing polarization mismatch. It has an alternative to collect ambient RF energy integrated antenna as optimization needs to combine thin-film solar cells [8].

This study proposes a single narrow band electromagnetic environmental energy harvesting device that functions as an electromagnetic energy harvester and wireless sensor[9], especially in IoT devices at the WiFi frequency (2.36-2.44 GHz) integrated with reflectors embedded with The thin-solar cells. Then optimized with parallel configurations to address

*Corresponding Author

the challenges of charging and replacing batteries in IoT devices. Some of our work is: 1) exploiting the antenna function and spatial domain simultaneously, as well as adjusting the polarization to optimize the function as support for sensors or wireless IoT communication and RF energy harvesting, 2) proposing an integrated CPW antenna with a reflector as placement of thin-film solar cells as a canopy on the back of the antenna with the schematic in Fig. 1, 3) provides a design for a compact high gain. To ensure that the dc output voltage can reach 1.2V -1.7V when integrated. [10][4] Provide a comparison of our technology with previous work in outdoor and indoor environments.

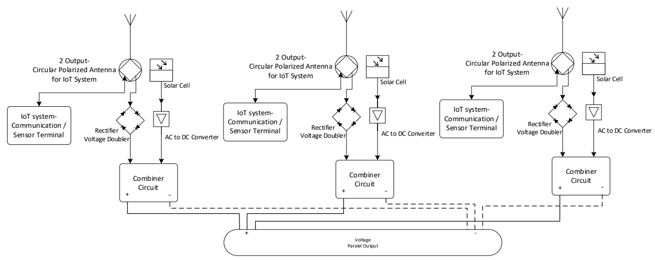

Fig. 1. Schematic of CPW 2.4 GHz Antenna with Parallel Hybrid Electromagnetic Solar for Energy Conversion Systems.

II. Parallel Hybrid Electromagnetic Circuit

A new 2.4 GHz rectenna was developed and exhibited with optimal configuration dimensions and structures to maximize IoT communication for wireless sensor and voltage. A line of 3 microstrips connects the antenna and the rectifier; Integrating Base Element on FR4 epoxy white paper with a rhombus-shaped slot. Integration is also done on the patch antenna with a radiator in the form of a double patch.

A. Paralel multi Stage Voltage Doubler Paralel Circuit

The rectifier circuit determines the effectiveness of the AC-to-DC Electromagnetic conversion; therefore, this circuit is an essential part of the Hybrid Solar Electromagnetic circuit. The requirements of a suitable rectifier are low power application, high sensitivity, and high voltage handling capability [11]. A rectifier configuration typically consists of an ideal 50-ohm connection for maximum voltage level delivery, a rectifier component (diode) for AC-to-DC Electromagnetic conversion) [12][13]. The only use of power forward in a rectifier circuit is a standard single series diode. The RF power of the antenna is reduced as it passes through the stripline and diode circuits, so direct current is created from the remaining energy.

Due to low power density and unmet circuit bias criteria, single series diode arrays (as opposed to single shunt array diodes) are inefficient for ambient electromagnetic energy collection. In addition, the breakdown voltage of a single diode rectifier is limited, limiting the power handling capacity of the circuit. As a result, as shown in Fig. 2, a rectifier with a voltage multiplier is shown, which implements a modified diode arrangement on a single shunt. The waveform is rectified half-cycle at the positive pole by the diode circuit D1, through the power supply voltage collection at the voltage C1. After the shunt diode D2 rectifies the negative half-cycle of the waveform, the power absorption is at C2. The power voltage C2 can be transferred to C1 in a single series diode arrangement producing a certain energy level around C1 from an almost simultaneous peak voltage considering the values of RJ, CJ, and Rs on the diode.

As the breakdown voltage of the rectifier increases, the power level of the empirical peak conversion voltage of the rectifier also increases. Furthermore, a partial rectification of the D2 waveform produces a bias voltage of D1 and reduces the input electromagnetic power level (thus increasing the power voltage level sensitivity). The voltage multiplier rectifier was selected for the rectenna design using a bridge type to optimize the voltage output and its architecture in Fig. 4. There are two diodes in each of the two branches.

Some of the results of the previous diode can generate a bias connection of each diode. Use settings that lower the total electromagnetic power consumption. The maximum power level can increase power sensitivity using the half-wave rectifier technique and power level capacity optimization. The choice of the diode is crucial because it can be a significant source of charge voltage and affect circuit performance. Low power input signals (forward bias voltage: 20–100 mV at 0.1 mA) requiring a low bias voltage are ideal for low power applications; diode for parallel selection circuit using Schottky SMS7630.

Another part involved in this circuit is the point of the nonpolar capacitor. The capacitor used in this circuit is a type of Tantalum SMD with a working frequency greater than 2.4 GHz, making it easier to optimize both physically and in terms of calculations. At the same time, optimization [14] on the input impedance of the CMOS circuit chip with a voltage multiplier, where the measurement is challenging and has a reasonably complex stage. To optimize the voltage output in the circuit design, the capacitor on the circuit will cross the load. The output voltage determines the value of the transient response speed for DC leveling.

TABLE I. HYBRID ELECTROMAGNETIC SOLAR CIRCUIT - 3 STAGE PARALLEL VOLTAGE DOUBLER STRUCTURE PARAMETERS

No.	Component	Label	Value and Material
1	*Non Polar SMD Stage Capacitor*	*C1, C3, C5, C8, C12, C16, C10, C14, C18*	100uF - Tantalum
2		*C2, C4, C6, C9, C13, C17, C11, C15, C19*	10nF - Tantalum
3	*Stage SMD Diode*	D1-D19	RB551VM-30
4	*Solar Cell Thin Film*	*hl1*	1 mm - Copper
5	*Circuit Dimension*	*Wu,Lu*	55.5 mm, 72 mm
6	*Copper Conductor*	*hl2*	0.035 mm - Copper
7	*Substrate Semiconductor*	*h*	1.6 mm - Phenolic white paper (FR-4)

The most dominant simulation instrument is the Advanced Design System (ADS) software for the configuration and design in Fig. 3. Based on the simulation analysis, the 3-parallel voltage multiplier stage is most suitable for this implementation. For implementing the Rectenna Circuit using the KiCAD software next, the building blocks of printed circuit boards are Basic Epoxy Fiberglass (FR4) (PCB). Table I lists the components in the circuit. Circuit elements consist of active and passive components. Connections to PCBs and other modules using 50 ohm SMA connectors are given special attention because they are related to matching.

B. Microstrip CPW Antenna

Due to the variability of electromagnetic environmental signals, antennas for RF or electromagnetic energy harvesting usually have special requirements. The need for broad direct rays and circularly polarized antennas require an antenna capable of receiving input waves with varying polarization and phase changes. In addition, in antenna performance, it is crucial to consider the quality of the standing wave ratio because hybrid circuits can apply higher working frequency signals and determine conversion at DC voltage levels. The desired frequency band range is 2.3–2.5 GHz. The conventional method for the standing wave ratio is to utilize a bandpass filter between the antennas of a hybrid circuit rectifier to pass another standing wave on a less clear broadband signal in previous studies[15][16]. However, rejecting broadband signals is much more complex than rejecting narrowband signals, so the proposed antenna uses narrowband. Broadband filters can increase the physical size of the rectenna and large insertion loss voltages [17][18]. As a result, the strategy in this research is to connect a narrowband antenna with a half AC to DC converter integrated with solar cells to get them working frequency focus. The reference antenna (initial setpoint) consists of a planar double pole with two pairs[19]; after optimization and striping the lines, cut square-shaped slots on each pole area to modify the surface, which is 95mm long and 99mm wide.

Furthermore, the second harmonic impedance must be reduced or increased by changing the impedance on the smith chart of the square-shaped slot. The plane of the micro-ground strip antenna, which is orthogonally and behind the microstrip feed line antenna, has two line feeds on it. Ansys HFSS software uses the FEM method to construct microstrip antennas. After calculation and optimization, the high-order parameters are omitted, and the ideal performance of the proposed antenna is shown in Fig. 5.

The partially independent antennae is a narrow band dual-line L feed patch probe antenna, and the 2-port antenna structure is constructed using two antenna elements. Each 2-port antenna configuration has a thin-film solar cell integrated with a reflector to increase gain and optimize radiation. The antenna implementation has microstrip lines printed on the rear, while the 45-degree line feed curve and rectangular cutouts edge are etched on the front. Feed ports 1 and 2 are also shown in Fig. 5. The antenna section comprises a small feed-in with a square cut slot antenna with the exact specifications as a CPW antenna at 2.4 GHz. The length and width of the slot are approximately half a wavelength by design. The optimized ground width in a typical slot mode is a quarter of a wavelength. In optimizing the frequency shift and the patch polarization filter, the slots are optimized into square pieces, and the soil in the area around the square is reduced to a certain extent. The 45-degree line feed antenna works in one wavelength perimeter mode.

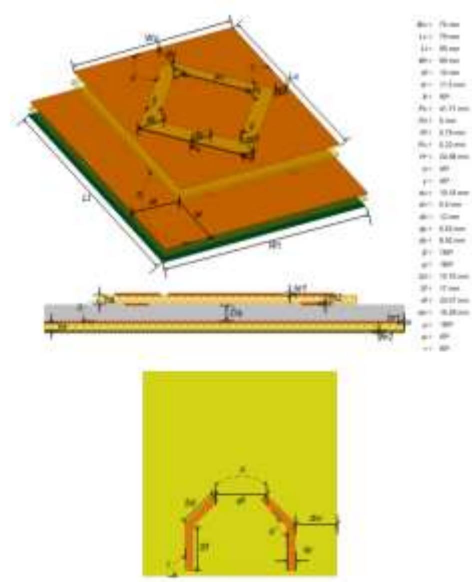

Fig. 5. Structure of Implementation of Double Port CPW Antenna.

To other advantages, the proposed antenna design can adjust the center frequency of the two-port S parameter almost independently under the matching conditions. To tunning it by varying the square side of the ground plane (Prd) in Fig. 6 with length Prd = Pr-de, where de is the diagonal edge at the end ground. As illustrated in Fig. 4, the initial simulation of varying Prd = {29mm, ... ,33 mm} refers to Fig. 5, while the value of Pr without is adopted for the initial antenna prototype before the optimization.

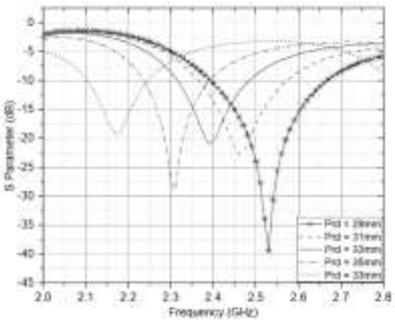

Fig. 6. Tuning Matching Antenna Frequency based on Prd Variation.

However, the frequency adjustment needs to be optimized again by increasing the accuracy of the center value. The optimization with varying dimensions of edge slot on the length square side of the ground. It is interdependent between the horizontal edge Pu and the vertical edge Pt with a symmetrical value resulting from optimizing circular polarization. Figure 5 illustrates with a dimensional accuracy value of up to 0.01mm to obtain frequency accuracy in the variation of dimensions Pu={5.14mm,…., 5.26 mm} and Pt = {5.70,…..,5.82}, with Pr and Pu values resulting from the final optimization of the antenna, which has been independently combined with other antenna parameters in Fig. 7.

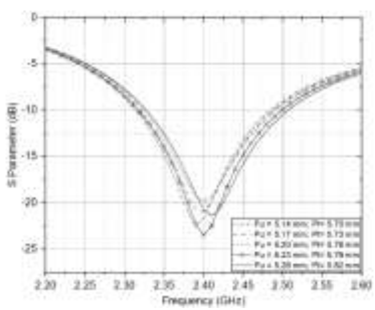

Fig. 7. Increasing the Accuracy of the S parameter Focus Value based on the Edge Ground Dimension Optimization.

The substrate, reflector, and conductor on the patch antenna using a CPW polarized SMA-probe in a narrow band are directly a 1.6 mm thick phenolic patch positioned above the ground and supported by a substrate on a white paper dielectric constant of 4.2. The materials parameters are shown in Table II.

We used a thick air substrate to optimize distance with the integrated thin-film solar cell to increase the radiation gain and beamwidth between the patch and the reflector. The proposed 2-port antenna has an average antenna area of 1:2 per port. It represents a compact multiport antenna design with an open-space wavelength at 2.4 GHz. Therefore, our basis for calculating the average antenna area per port on the design in free space wavelengths: 1) the primary substrates of the proposed patch antenna are fr4 and antenna; 2) the multiport antenna design is compact, expressing the Freespace wavelength because the nearest antenna port is often connected by air with the requirement with layered material.

TABLE II. MATERIALS STRUCTURE OF THE ANTENNA CONFIGURATION

No.	Parameters	Values	Materials
1	*ha*	1.6 mm	Copper

6	*hr*	1.6 mm	Copper
7	*hr1*	0.035 mm	Copper
8	*hr2*	0.035 mm	Phenolic white paper (FR-4)

III. PERFORMANCE AND ANALYSIS

A. Double port CPW Antenna Performance

Based on measurements, Fig. 8 shows the value of the reflection coefficient with the representation of the S parameter at each port of the antenna. The analysis is carried out first on the narrowband reflection coefficient. The rectangular graph shows a frequency shift between |S11|. Measurements and 0.1 GHz range. Port 1 has a bandwidth of -15 dB of 192 MHz (2.353-2.545 GHz), while Port 2 has a -15 dB of 161 MHz (2.36-2.521 GHz) bandwidth. From 2.453 to 2.821 GHz, bandwidth still below -15 dB has a bandwidth of 148 MHz (78 percent) overlap. Overall, the reflection coefficient with the representation of the S parameter value of -15 dB and the spectrum power level test of the antenna can work at a frequency of 2.4GHZ, which is shown in Figure 13. The spectrum reception and S Parameters, the antenna based on regulation, can work well for IoT and Energy harvesting applications.

Another performance advantage of the dual-port mode is represented in Fig. 8. Optimizing the microstrip antenna using a reflector integrated with a thin-film solar cell can generate the power gain value in the 2.3–2.5 GHz free IoT communication band with a significant advantage of 8.2 dB at 2.4GHz. The overall gain level is between 8 and 8.6 dB, which is higher than a standard microstrip antenna with an average of 3dB. Optimization of the distance and dimensions of the reflector, which integrates with the thin-film solar cell on the 180-degree position antenna, makes the power signal collection on the radiation element not distorted. Due to the demands of optimal IoT communication, it utilizes circular polarized antennas. It can receive and transmit vertical, horizontal, and other than the two electromagnetic waveforms, so necessary to obtain an axial ratio value below 3dB. Fig. 9 shows the comparison of values between horizontally polarized transmission waves and vertically, expressed by the value of the axial ratio below about 3dB of variation as a representation of circular polarization[16]. Thus the optimization resulting in CPW or total circular polarization is obtained from a symmetrical base plane with electromagnetic filter effect radiation on the slot on-ground configuration.

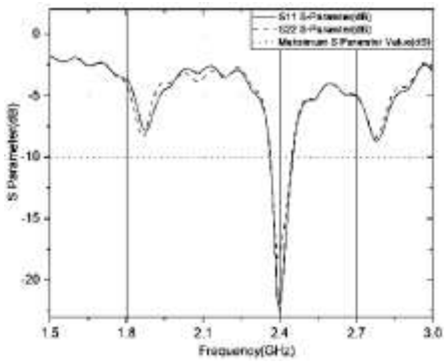

Fig. 8. S Parameters of CPW Dual-Port Microstrip Antenna.

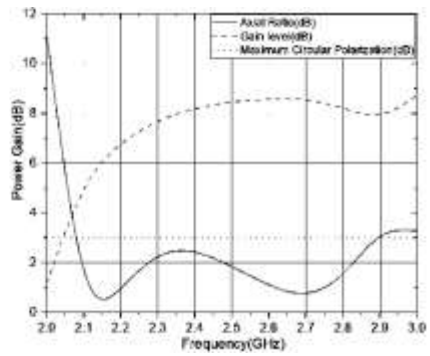

Fig. 9. Gain and Axial Ratio CPW Dual-Port Microstrip Antenna.

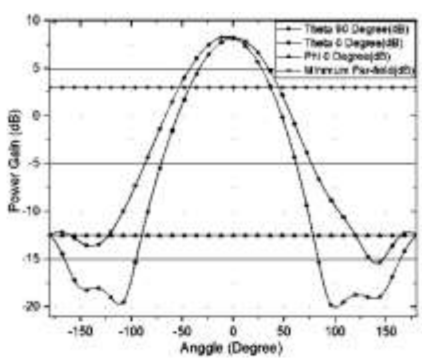

Fig. 10. Radiation Pattern of CPW Dual-Port Microstrip Antenna-Rectangular Plot.

Fig. 10 represents the performance analysis of the antenna implementation based on the typical radiation pattern at an operating frequency of 2.4 GHz inside and on the surface. The performance analysis results match the statistical value of the power distribution level in the direction of the intended device quite well. The radiation pattern is transformed at the position θ with an angle of 90 degrees and θ at 0 degrees. The reference antenna position faces the Z ordinate with a condition of 0 degrees. Hence, Z ordinate radiation the antenna has one lobe with the most significant power level value. It has a minimal sidelobe value on the radiation viewing angle transformation at ϕ on 0 degrees so that the polarization of the Antenna is Directional. To simplify the implementation of the rectenna in the analysis using Fig. 11 using polar coordinates to describe the degree of exposure of the area. The directional radiation pattern of the antenna indicates that the antenna can be used as an access point in IoT applications to generate energy and communicate directly. The optimization on the square ground plane of the dual-port antenna allows simultaneous vertical and horizontal polarization. The proposed antenna has the following advantages: small overall size, optimal bandwidth, and not cross-polarization.

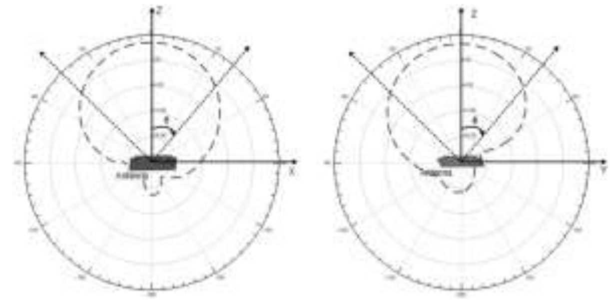

Fig. 11. Radiation Pattern CPW Dual-Port Microstrip Antenna-Polar Plot.

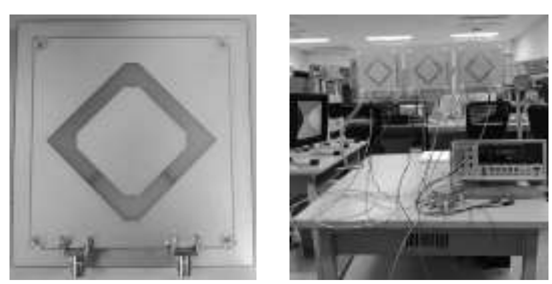
B. *Performance Electromagnetic-Solar with Parallel CPW antenna Circuit Integrated*

In the parallel circuit performance test, the receiving antenna is connected to the rectifier circuit via an SMA connection with a characteristic impedance of 50 ohms. The produced rectenna was tested in the laboratory, as illustrated in Fig. 12. The performance of the rectifier circuit as determined by the AC-DC voltage conversion value and the output frequency is illustrated in Fig. 13 and 14, respectively, used the same experimental data collection technique with different configurations of performance measurements as in Fig. 12(b).

The rectifier circuit, Receiver antenna, and thin film can be directly connected because the dual output feed antenna and the input port of the rectifier circuit have the same impedance as the output port. In addition, the circuit configuration has a compact implementation for other ports as the IoT communication feed line. However, to make measurements more movable in the laboratory using a coaxial cable with an adjustable impedance. The results of the performance measurements of the rectenna are in Fig. 12(b). a signal generator connected to the SHRP RZ1AT4A antenna as a microstrip antenna used in industry is the signal source to spread electromagnetic waves in the laboratory area. Then the antenna absorption value is expressed by testing the spectrum in Fig. 13, which works well at a frequency of 2.4 GHz, which consists of -16.15 dBm, -23.66 dBm, and -33.89 dBm, because testing the signal spectrum is also very important when used in the communication process on IoT devices.



(a) (b)

Fig. 12. (a) Antenna Implementation and (b) Configuration Circuit Testing.

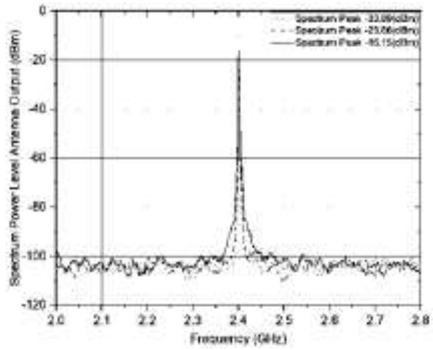


Fig. 13. Antenna Spectrum Test at a Frequency of 2.4 GHz.

The absorbed energy is amplified using a voltage doubler with a parallel and simultaneous configuration with a maximum absorption rate of -16.15 dBm antenna and a frequency range of 2.0 GHz to 2.8 GHz. At the primary working frequency of 2.4 GHz, the transmitting antenna is a beam with a power level of 20 dB.

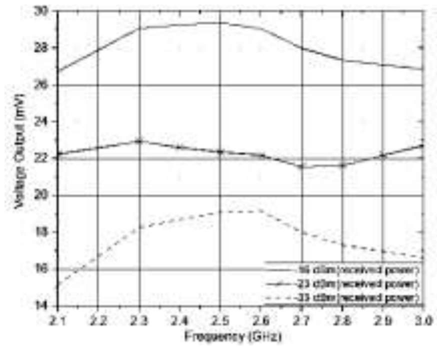
At the input power of -16.15 dBm, the output voltage with an electromagnetic field source in the single rectenna circuit configuration with 3 stage doubler has a value of 29.3 mV. The parallel circuit configuration has a value of 52 mV, as shown in Fig. 14. Fig. 14 shows that the increase is quite significant if the configuration is optimized to be parallel with the analysis of equation 1, which shows an efficient circuit performance, where the value of R_{iL} is the value of the resistance of the circuit. $V_{Pcircuit}$ is the output voltage of the rectifier circuit, R_0 is the internal resistance of the transmission medium, μ is the characteristic coefficient of the circuit voltage quantity with a value of 0.6, and n_P is the number of parallel lines sources in the circuit.

$$V_{Pcircuit} = \mu \boldsymbol{n_p} \frac{n_0 \boldsymbol{V_0}}{n_0 \boldsymbol{R_0} + \boldsymbol{R_{iL}}} \boldsymbol{R_{iL}} \tag{1}$$

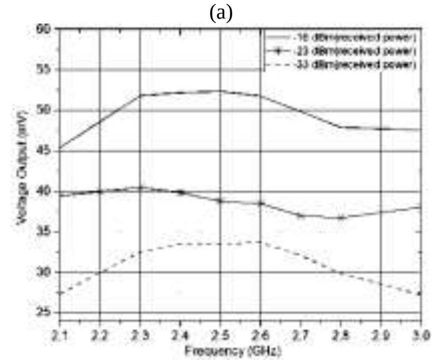
Fig. 16 shows the performance of the Parallel 3 Stage Voltage Doubler Circuit. It generates an output voltage and AC voltage conversion from the rectenna with variations in the power level collected at the same value on two 2.4GHz ports based on the variable transmit power source, namely, the RF source and light intensity. First, the circuit performance test is comprehensively tested with various light conditions in Fig. 15.

When the light intensity received by the thin-film solar cell increases, the output voltage increases whether used in single or parallel configurations. The output voltage in the configuration proposed in this study, a parallel configuration with the integration of thin-film solar cells, has an output voltage of 1.74467V with a light-emitting source of 300 lux in Fig. 16. The parallel circuit has the advantage of increasing the voltage up to 80% compared with a single [20] configuration. In addition, integration with solar cells can also increase the power up to 25 times if only relying on electromagnetic sources [21]. In this case, the electromagnetic source is inferior, according to the source in the IoT device.

The optimization of the design and implementation significantly improves compared to previous studies [22][10]. This Reference only relied on a single configuration and one particular application. The increase in the voltage value in the circuit test on the independent variable shows that it can work well, both from one energy source and two sources of energy.



(a)



(b)

Fig. 14. Antenna Output Voltage in an (a) Single and (b) Parallel Three-Stage-Voltage Doubler Circuit.

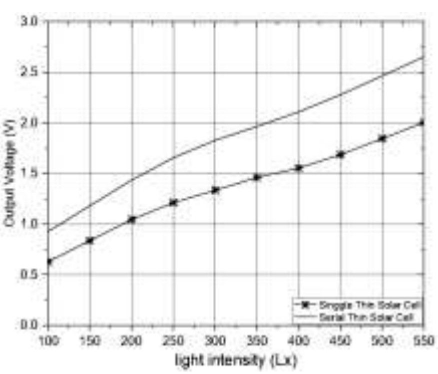


Fig. 15. AC to DC Conversion Test on Solar Cell Film.

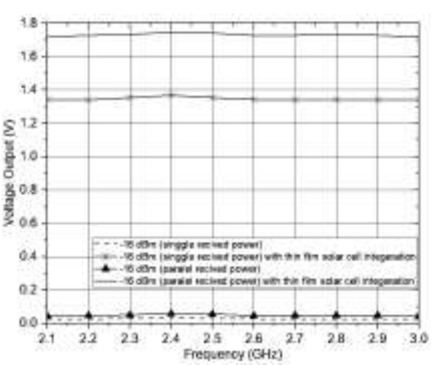

Fig. 16. Performance of Integrated Parallel Rectenna-thin Film Solar Cell Output Voltage.

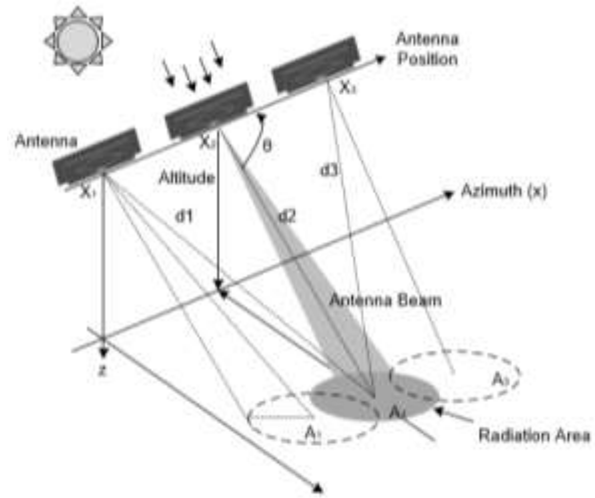

Fig. 17. Overall Implementation Analysis of the Integrated Rectenna-thin Film Solar Cell Prototype.

Fig. 17 shows the overall implementation analysis scheme of the prototype that has been tested in the laboratory. Implementing energy harvesting with the integration of thin-film solar cells is estimated as exposure to sunlight, 100 lux when cloudy to 1000 lux maximum. This range is following the performance test of the lowest voltage limit on the prototype for implementation. In addition, the implementation of the energy harvesting and communication process must adjust the radiation angle based on Fig. 10 and 11 of the antenna element radiation patterns. The optimum main lobe value at the antenna altitude is θ of 48 degrees, with overlapping antenna beam coverage areas. However, the antenna has almost the same phase in IoT communication and has a close position [23]. Therefore, it is necessary to analyze the signal with high accuracy to determine the number and direction of arrival of the antenna signal by using multiple signal classification analysis for Linear Array elements assuming the antenna's position with the number of transmitting sample signals analysis 1000 times and four source antennas, one antenna as a reference. Azimuth antenna on identical antenna elements based on Fig. 5, then the array manifold a(θ) is determined:

$$\mathrm{a}(\boldsymbol{\theta}) = \begin{bmatrix} 1 \\ e^{j2\pi d_1 \sin\theta_1/0.0125} \\ e^{j2\pi d_2 \sin\theta_2/0.0125} \\ e^{j2\pi d_3 \sin\theta_3/0.0125} \end{bmatrix}$$

Where d is the distance from a common reference point in the array and the azimuth coordinate antenna $\boldsymbol{\theta}$ that the direction measured from the perpendicular to the array, so if applied to multiple antennas with the transmission on communication devices with **F** is the amplitude at the 2.4GHz frequency of the antenna devices.

$$\begin{bmatrix} \mathbf{X_1} \\ \mathbf{X_2} \\ \mathbf{X_3} \\ \mathbf{X_4} \end{bmatrix} = [\mathrm{a}(\theta_1) \quad \mathrm{a}(\theta_2) \quad \mathrm{a}(\theta_3) \quad \mathrm{a}(\theta_4)] \begin{bmatrix} \mathbf{F}_1 e^{j15.085\times10^9 t} \\ \mathbf{F}_2 e^{j15.085\times10^9 t} \\ \mathbf{F}_3 e^{j15.085\times10^9 t} \\ \mathbf{F}_4 e^{j15.085\times10^9 t} \end{bmatrix}$$

Signal transmit of device source with random amplitude on covariance matrix:

$$\boldsymbol{s} = \begin{bmatrix} -0.2523 - 4.0111i & -3.0320 + 0.3830i & \dots & -1.3591 + 2.3441e-13i \\ 0.4964 + 7.8909i & 2.6104 - 0.3297i & \dots & 0.4605 - 7.9429e-14i \\ -0.2283 - 3.6299i & 1.6989 - 0.2146i & \dots & 1.9914 - 3.4346e-13i \\ -0.4224 - 6.7140i & 2.4543 - 0.3100i & \dots & 2.1928 - 3.7827e-13i \end{bmatrix}$$

With resultant steering vector between incoming signals$\mathbf{F}_1 e^{j15.085\times10^9 t}$ and **A** is steering matrix $\mathrm{a}(\boldsymbol{\theta})$, than $\mathrm{a}(\boldsymbol{\theta})$ *is* $\chi = \mathbf{A}\times\mathbf{s}$ dan χ^* ensemble average so $\overline{\chi_1\chi_1^*}$, $\overline{\chi_2\chi_2^*}$, $\overline{\chi_3\chi_3^*}$, $\overline{\chi_4\chi_4^*}$ Autocorrelation with the Rss. Then Rss autocorrelation input signal itself and the other cross-correlation value on the signal on the assumption of the signal plane then the covariance matrix for the incoming signal:

$$\overline{\chi\chi^*} = \begin{bmatrix} \overline{\boldsymbol{\chi_1\chi_1^*}} & \overline{\chi_1\chi_2^*} & \overline{\chi_1\chi_3^*} & \overline{\chi_1\chi_4^*} \\ \overline{\chi_2\chi_1^*} & \overline{\boldsymbol{\chi_2\chi_2^*}} & \overline{\chi_2\chi_3^*} & \overline{\chi_2\chi_4^*} \\ \overline{\chi_3\chi_1^*} & \overline{\chi_3\chi_2^*} & \overline{\boldsymbol{\chi_3\chi_3^*}} & \overline{\chi_3\chi_4^*} \\ \overline{\chi_4\chi_1^*} & \overline{\chi_4\chi_2^*} & \overline{\chi_4\chi_3^*} & \overline{\boldsymbol{\chi_4\chi_4^*}} \end{bmatrix} = \mathbf{A}\,\mathbf{R}\mathrm{ss}\,\mathbf{A}^* + \textit{power noise}$$

Then, extract the signal information using the Eigenvector of **A Rss A*** and the Eigenvector of noise power to generate the signal eigenvalues and the noise eigenvalues. We can describe the value noise subspace from the ***D*** matrix for the eigenvalue.

$$\boldsymbol{D} = \begin{bmatrix} 8.8141e-05 & 0 & 0 & 0 & 0 \\ 0 & 9.7605e-05 & 0 & 0 & 0 \\ 0 & 0 & 1.010e-04 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \dots & 1.4814 \end{bmatrix} \approx \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \dots & 1 \end{bmatrix}$$

Then describe each **Rank** on the signal eigenvalues and eigen noise = **Ei** to determine the trash hold value of the signal. From this treatment, we can obtain a spectrum picture of each signal using the multiple signal classification equations 2.

$$P = \frac{1}{\mathrm{a}^*(\boldsymbol{\theta})\cdot \mathbf{E}_i \cdot \mathbf{E}_i^* \cdot \mathrm{a}(\boldsymbol{\theta})} \qquad (2)$$

The spectrum generated can be analyzed of each incoming signal spectrum result and the angle of origin signal even though the phase is almost identical, and the position is close to each other seen in Fig. 18. The spectrum shows a signal from the antenna with a directional arrival angle of $1/\mathrm{Norm}^2$ on each power signal. Information appears at 61, 92, 125, and 180 degrees for the analysis sample. Thus, the analysis can provide an efficient solution to the proposed configuration using a liner position antenna with circular antenna specifications when working as an IoT communication for wireless sensors antenna and energy harvester.

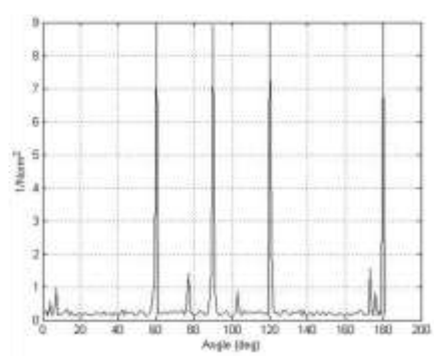

Fig. 18. Spectrum Analysis of Incoming Signals on Multiple Antennas.

IV. Conclusion

This article is based on performance tests and a new analysis of IoT Energy Harvesting and Wireless Sensors using 2.4 GHz CPW Antenna with Parallel Hybrid Electromagnetic Solar. A 2.4 GHz CPW rectangular dual-port antenna with IoT Wearable broadband, direction power beamwidth, and high gain is used as the receiving antenna. The proposed configuration includes a 2.4 GHz CPW rectangular dual-port antenna rectifier circuit based on IoT communication and the concept of parallel voltage doubling with an integrated thin-film solar cell. The performance of the microstrip antenna input and output of the S parameters of network feed with S11 -18.02 and dB S21 -24.7 dB, gain value of 11dbi, and axial ratio value of 2.46. According to these tests, the configuration of the rectifier and antenna circuits has a very narrow operating frequency range. And can be used effectively in any direction based on the radiation polarization. In addition, the integrated Rectenna has a compact design and is easy to apply. In the energy harvester performance test at the input power of -16.15 dBm, the output voltage with an electromagnetic field source, the single rectenna circuit configuration with 3 stage doublers has a value of 29.3 mV, and the parallel circuit configuration has a value of 52 mV. In addition, the output voltage in the configuration proposed in this study, which is a parallel configuration with the integration of thin-film solar cells, has an output voltage of 1.74467V. This configuration has the advantage of increasing the voltage up to 80% compared to the single configuration. In addition, integration with solar cells can also increase the temperature up to 25 times if only relying on electromagnetic sources. Based on the implementation analysis, the configuration energy harvester with thin-film solar cell integration can work up to at least 100 lux exposures to sunlight. And the electromagnetic transmission area will work optimally at an angle of 48 degrees based on the radiation pattern, and the prototype of IoT communication analysis can be implemented. Multiple signal classification for Linear Array for circular polarization antenna with high accuracy to determine the spectrum of each incoming signal and the angle of origin of the signal even with almost the identical phase. In progress, the development of this prototype is to become more compact and work on the working frequency of other IoT devices so that there are more options to be implemented.

Smart Air Pollution Monitoring System with Smog Prediction Model using Machine Learning

Salman Ahmad Siddiqui*, Neda Fatima, Anwar Ahmad
Department of Electronics and Communication Engineering
Jamia Millia Islamia, New Delhi, India

***Abstract*—Air Pollution is a harsh reality of today's times. With rapid industrialization and urbanization, the polluting gases emitted by the burning of fossil fuels in industries, factories and vehicles, cities around the world have become "gas chambers". Unfortunately, New Delhi too happens to be among the most polluted cities in the world. The present paper designs and demonstrates an IoT(Internet of Things) based smart air pollution monitoring system that could be installed at various junctions and high traffic zones in urban metropolis and megalopolis to monitor pollution locally. It is designed in a novelistic way that not just monitors air pollution by taking varied inputs from various sensors (temperature, humidity, smoke, Carbon monoxide, gas) and but also presents it on a smart mirror. Its unique feature is the demonstration of a smog prediction model by determining PM10 (Particulate Matter 10) concentration using the most efficient machine learning model after an extensive comparison by taking into account environmental conditions. This data generated can also be sent as a feedback to the traffic department to avoid incessant rush and to maintain uniform flow of traffic and also to environmental agencies to keep pollution levels under check.**

Keywords—Air pollution; IoT; machine learning; smart mirror; temperature and humidity sensor

I. Introduction

Air pollution is one of the most significant causes of deaths worldwide. It claims seven million lives a year, mostly premature, and is a major driver of fatal non-communicable diseases like lung cancer, bronchitis asthma, heart attacks etc. [1]. It is a potential cause for allergies and causes irritation to the eyes, throat and skin. It also adversely affects climate change and a major cause for global warming that is responsible for drastic climatic catastrophes in the world. With rapid industrialization, urbanization, emergence of huge metropolises and megalopolises, pollution is ever increasing in the cities with cities in India especially Delhi NCR consistently featuring in the top most polluted cities of the world. The problem is further exacerbated in the winter season when the temperature, humidity and prevailing wind conditions provide favorable conditions for development of smog like conditions in most parts of North, North West and West India.

Air pollution is measured as the concentration of various gases in parts per million or ppm. Pollutants are of two kinds: primary and secondary pollutants. Primary pollutants are those which are released directly into the atmosphere in the form smoke from the industries and factories or exhausts from vehicles. Primary pollutants include ammonia, sulfur dioxide, carbon monoxide and nitrogen dioxide. Secondary pollutants are those which are comparatively harmless in the atmosphere, however, turn into toxic pollutants on reaction with atmospheric conditions. Some types of secondary pollutants are ground-level ozone, acid rain and nutrient enrichment compounds.

Multiple ways have been devised to measure air pollution. Currently, it is monitored with the help of Air Quality Index(AQI) that defines the air quality in terms of ranges of pollutants in air in parts per million. AQI can be considered as a yardstick that runs from 0 to 500. The higher is the AQI value, the greater is the level of air pollution and the greater is the health concern. The following Table I demonstrates the air quality suitability with the corresponding range of pollutant concentration.

In line with this system of measurement of Air pollution, the present paper implements an IoT based Smart Air pollution monitoring system that depicts the localized air pollution levels along with temperature and humidity levels on Smart Mirror. It also employs the most efficient Machine learning model for Smog Prediction and this predictive analysis can serve as a feedback to the traffic department to forecast possible traffic jams and environmental agencies to keep the pollution levels in check.

The paper has been logically arranged in different sections. Section II describes the previous literature in this theme with their relevant shortcomings that led to the improvement in this project. Section III describes the methodology of the system in detail with special emphasis on the different machine learning algorithms employed in the system. Section IV presents the results obtained and its extensive analysis describing the resolution of the most efficient algorithm and the consequent results obtained. Section V discusses the advantages of the developed system and discusses about its real time deployment. Finally, the paper sums up with a futuristic conclusion and applications in Section VI.

TABLE I. AIR QUALITY INDEX

Range (PPM)	Status
0-50	Good
51-100	Moderate
101-150	Unhealthy for sensitive groups
151-200	Unhealthy
201-300	Very unhealthy
301 and above	Hazardous

*Corresponding Author

II. Review of Literature

The section describes the different works in the broad thematic area of research. While many types of research have been carried out in this broad area, they suffer from some inadequacies and limitations. For instance, paper [2] proposes and develops an IoT based Air Quality Monitoring System for Smart Cities using Raspberry Pi. However, it does not calibrate the sensors which results in drastic difference in values as opposed to the values yielded in Air Quality Index (AQI). While the calibration of sensors is employed in [3], it only utilizes one sensor i.e. MQ135 gas sensor thus excluding an important primary pollutant Carbon Monoxide from its scope of study. The paper [4] also suffers from similar limitation though it has employed humidity and temperature sensor that was not utilized in [3].

Application of neural network has a restrictive scope, for instance, the study demonstrated in [5] is a predictive analysis through neural network to demonstrate the harmful effects of air pollution on the human body and larger scope of the environment is not covered. In paper [11] application of artificial neural network for predicting air pollution levels has been presented whereas paper [6] employs an algorithm uses RFID technology to track down vehicles that cause vehicular pollution with higher emissions and reports them to environmental agencies. Thus, a thorough comparative modeling has not been performed. Further, the system in [7] demonstrates a crude set up to display air pollution however its accuracy is compromised to balance the cost of the set up.

With quite a few papers in the area of monitoring, the paper [8] uses a remote server to store data related to air pollution levels. In [9], combinations of wireless sensor networks and electrochemical toxic gas sensors with RFID (Radio Frequency Identification) tagging have been utilized to understand the pollution levels in vehicular emissions. The study proposed in [10] uses seismic sensor to predict earthquakes and light and humidity to analyze the location weather conditions. Thus, these researches are limited to the ‘monitoring’ aspect of air pollution.

Predictive analysis through machine learning has been demonstrated in some of the researches that have been surveyed. In [12], the prediction of air pollution is restricted to the supervised learning algorithms. In [13], the authors have utilized deep learning but with a highly imbalanced dataset and have predicted generic air pollution that too with a lower accuracy without confirmation with a real time dataset. In [14] and [15], the research is limited to different variants of Long Short Term Memory (LSTM) models for Air quality prediction in Delhi and South Korea respectively than the system proposed in this paper of specific smog prediction. A hybrid model was tested for monitoring air pollution at Iran’s combined cycle power plant in paper [16]. In [17], a single machine learning model SVM (Support Vector Machine) has been employed to detect air quality in California with an already available dataset from the internet. While an improved weighted LSTM model has been utilized in [18], significant resources have been utilized for real world application and the performance parameters such as speed and machine cycles have been compromised for accuracy. Finally in [19], AdaBoost machine learning has been employed in Taiwan to monitor air quality.

The present paper hones upon the existing research and addresses the shortcomings of the previous research such as lack of sensor calibration, limited number of sensors, incomplete datasets, compromised accuracy of predictive modeling, lack of comparative analysis of predictive modeling, compromised speed and machine cycles and inefficiency of resources. The paper presents a comprehensive approach that monitors air pollution on a real time basis, by utilizing input data from a variety of sensors to cover all possible sources of air pollution. It translates the data through calibration of sensors and averaging the value of sensors for ambient air quality index. Finally, it displays the Air pollution data along with smog levels on a Smart Mirror that can be employed at various junctions and high traffic zones in the city. Taking this data as input as well as dataset from Internet, the most efficient trained machine learning model is employed for Smog prediction. Furthermore, based on the data presented, corrective measures can be taken by traffic department environmental agencies to improve air quality and reduce air pollution.

III. Methodology

The system has been designed as a multi input multi output system. The sensory data from variety of sensors employed are fed into the microcontroller which monitor the localized atmosphere and generate a dataset that is displayed on the dynamic Smart Screen i.e. Magic Mirror. The dataset acts as an input for the Smog Prediction Model that employs the most efficient Machine learning model for the predictive analysis.

As demonstrated in the block diagram in Fig. 1, the present paper utilizes Arduino Uno R3 employing ATMega328P as microcontroller for implementation of the system. Arduino is an interactive open source platform characterized by low cost and flexible hardware and software. Arduino Uno R3 is the reference model and widely used. It has ATmega328 microcontroller chip (8- bit) at 16 MHz, with 14 digital I/O pins and 6 analog input pins. It is usually powered through USB connection but can also be powered by DC power socket from batteries.

The inputs to the Arduino are fed from the various sensors to determine the local environmental conditions. The most important sensor is the MQ135 Gas sensor. It can sense Ammonia (NH_3), Nitrous Oxides (NOx), alcohol, Benzene, smoke, CO_2 and some other gases. It gives the output in the form of voltage levels.

Since carbon monoxide is a significant primary air pollutant and MQ135 has the limitation of not measuring CO data, MQ7 carbon monoxide sensor has also been employed. This further hones the air pollution data received by Arduino Uno and can establish better results. The MQ-7 sensor can measure CO concentrations ranging from 20 to 2000ppm. It possesses faster response time and a high sensitivity. The sensor's output is an analog resistance.

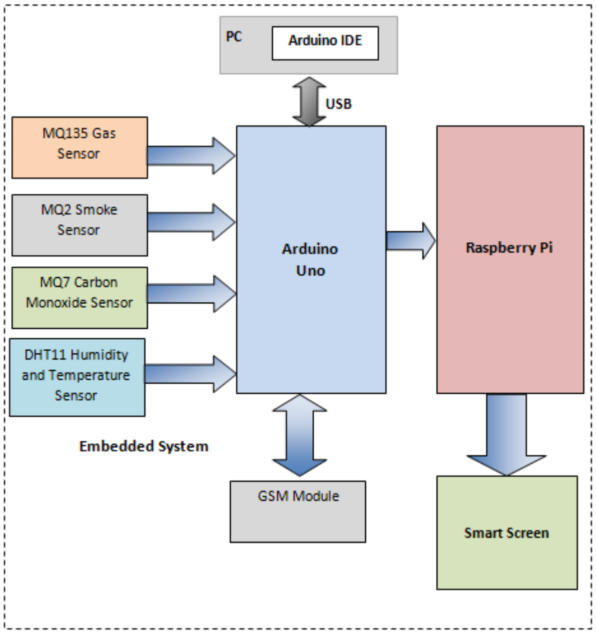

Fig. 1. Block Illustration of the Technique.

In high traffic zones such as highways, merging freeways and cross junctions, pollution probability is higher. This increases the probability of presence of smoke at the location. To measure the concentration of smoke in the location, MQ2 Smoke sensor has been utilized. The MQ2 gas sensor is an electronic sensor which is used to detect ambient gas concentrations such as smoke, LPG, propane, methane, hydrogen, alcohol and carbon monoxide in the range of 200-10000ppm. The gas sensor MQ2 is often referred to as a chemical resistor. It includes a sensing material whose resistance changes when the gas is in contact.

Finally, DHT 11 Humidity and Temperature sensor have been utilized to analyze the localized humidity and temperature conditions respectively. A requirement of digital temperature and humidity sensor that is simple and ultra-low-cost is fulfilled by the DHT11. A thermistor and a capacitive humidity sensor is used to test the air quality of surroundings and the result provided by the data pin in form of digital signal. It requires a careful timing in order to collect information but it's fairly easy to use.

The data from MQ7, MQ2 Smoke Sensor and DHT11 Humidity and Temperature Sensor is used to determine the smog levels in the location. Smog usually appears as haze in the air due to the mixture of smoke, gases, and particles. Smog formation is the result of the combination of stable atmospheric conditions, due to inversion, nitrogen oxides, and organic compounds reaction resulting in ozone and related compound and different kind of air pollution and the emissions from increasing number of cars. The most important step in this system design is the calibration of MQ135, MQ2 and MQ7 Gas sensor with respect to fresh air and then development of an equation that transforms output sensor voltage into corresponding PPM levels. For this, the average analog readings of the resistance from the sensor and converting it to the voltage are taken.

The data from Arduino R3 is fed into Raspberry Pi 3. The Raspberry Pi 3 is a Pi series development board that can be viewed as a single computer board. It works with the LINUX Operating System. It has a fast processing speed, and uses wireless Local Area Network (LAN) and Bluetooth and can set up a WIFI hotspot to connect to the internet. It has a dedicated Liquid Crystal Display (LCD) display port. All the above data are displayed on the smart screen/magic mirror specially designed for the same. Smart screen though previously developed multiple times provides basic facilities like displaying clock, news, weather using APIs. The proposed screen is especially designed to provide serial communication between Arduino and Raspberry Pi Screen.

Fig. 2 represents the schematic diagram of the air pollution monitoring system developed. It shows the pin connections and the schematic of the functioning of the system.

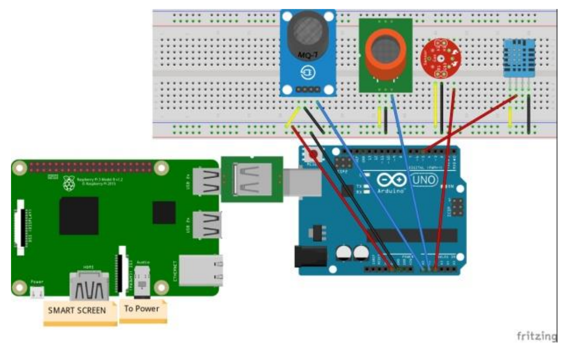

Fig. 2. Schematic Diagram.

A. Equations

The sensor gives raw value and it needs to be converted into PPM. The relation for the same is obtained from the (Rs/Ro) versus PPM graph as shown in Fig. 3. The resistance of these sensors changes in response to the concentration of gases, viz. value of resistance decreases in response to increase in gas concentration; taking MQ135 sensor graph as reference for calculation.

Ro is the value of resistance in fresh air and the value of Rs is the value of resistance at various Gas concentrations. After preheating the sensor, the important step is to calibrate the sensor in fresh air to find Ro; from circuit diagram in Fig. 4 of MQ135, applying Ohm's law.

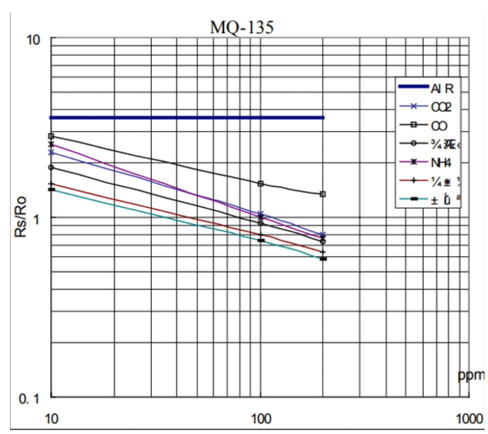

Fig. 3. Graph showing Rs/Ro Ratio for MQ-135 Sensor.

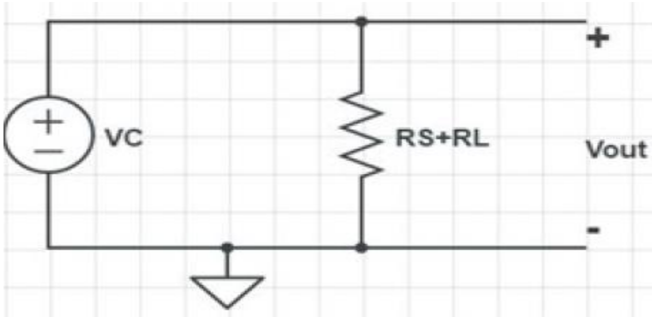

Fig. 4. Internal Circuit of MQ135.

$$V_{R_l} = \left[\frac{V_c}{R_s + R_l}\right] * R_L$$

$$V_{R_l} = \left[\frac{V_c * R_L}{R_s + R_l}\right] \quad (1)$$

$$V_{R_l} * (R_s + R_s) = V_c * R_L$$

$$(V_{R_l} * R_s) + (V_{R_l} * R_l) = V_c * R_L$$

$$(V_{R_l} * R_s) = (V_c * R_L) - (V_{R_l} * R_l)$$

$$R_s = \frac{(V_c * R_L) - (V_{R_l} * R_l)}{V_{R_l}}$$

$$R_s = \frac{(V_c * R_L)}{V_{R_l}} - R_l \quad (2)$$

Thus, the final equation in (2) is used to determine Rs.

From the graph above in Fig. 3, the resistance ratio Rs/Ro for fresh air is constant i.e. 3.6. To calculate Ro, Rs is to be found in fresh air, which is done by averaging the sensor raw reading and converting the same in volts and then using this volts value in equation (2) to obtain Rs, which is then used to find the Ro using Rs/Ro ratio of fresh air.

Now this Ro is used to find Ratio in presence of gas concentration. Using the Resistance ratio value in presence of gas, equivalent value of PPM for that particular gas can be determined from the graph.

To determine PPM from graph using resistance ratio, equation of line was applied on this log graph:

$$log_{10} y = m * log_{10} x + b \quad (3)$$

To find the slope, two points were selected from the graph. The points (200, 2.6) are and (10000, 0.75) from the LPG line. The formula becomes:

$$m = \frac{log y - \log(y_0)}{log x - \log(x_0)} \quad (4)$$

After solving (3) and (4), the values obtained were m= -0.318 and b= 1.13. Thus, the gas concentration using any ratio can be found using:

$$lo\ g(x) = \frac{lo\ g(y) - b}{m} \quad (5)$$

B. Smart Mirror

This paper presents the design and development of a smart mirror for displaying the air pollution based on Arduino sensor output. It provides a novel approach for establishing transmission between Arduino sensors and the Pi based Smart mirror which is based on node.js languages. The configuration file of the mirror was modified to incorporate the necessary parameters (port address, list of sensors and their output format) to make Arduino sensors value visible on magic mirror. The sensors value from Arduino is sent via serial communication in a standard format (understandable by mirror).

The mirror provides a natural means of interaction through which the commuters can control their movement based on the prevailing environmental condition in that area. The data displayed gives the real time conditions. The module for displaying the output is developed keeping in mind all the requirements. Fig. 5 shows the proposed Smart Mirror.

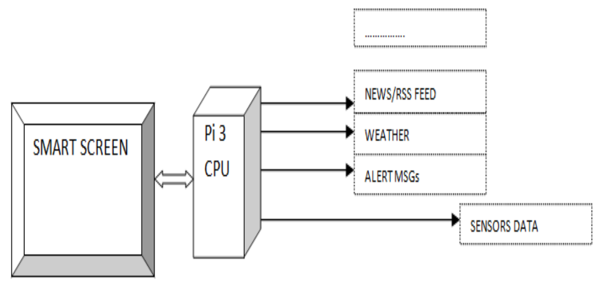

Fig. 5. Schematic Diagram of Smart Mirror.

C. Smog Prediction Model

Smog is one the important cause of severe air pollution. It is formed as a result of combination of smoke, fog and water vapor. Sudden appearance of smog and/or fog on the highway more often than not causes serious and sometimes fatal accidents. It can also aggravate health problems including problems with breathing and sleeping, as well as it can adversely damage the surrounding flora and fauna.

Smog Prediction analysis has been performed by testing and comparing six different Machine leaning models. In the first model, a general learning framework based on an ensemble strategy and artificial neural networks (ANNs) has been employed. Thus, ANN has been trained to predict the PM 10 concentrations which is the main cause of the occurrence of smog phenomena. For the neural network presented, carbon monoxide, temperature, relative humidity, PM concentration of previous day and smoke were fed as an input and the target is the present day PM10 concentration.

Various types of neural network architectures with varied number of hidden nodes were formed and tested to get the best network for each measurement station. Among the different types of ANN, feed forward network is employed. It is a type of artificial neural network in which nodes' connections do not form a loop. As a result, it differs from its descendant, recurrent neural networks. The information in this network flows exclusively in one direction: forward, from the input nodes to the output nodes, passing through any hidden nodes (if any). Multi-layer perceptron (a class of feed forward ANN) as shown in Fig. 6 demonstrated the best result.

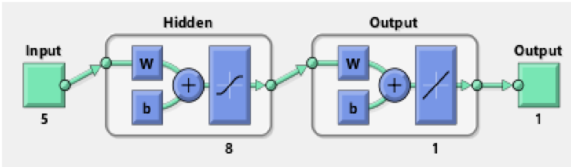

Fig. 6. Artificial Neural Network Trained using MATLAB.

The next modeling was performed using Support Vector Regression. It is a supervised learning algorithm that is used to predict discrete values. Support Vector Regression uses the same principle as the support vector machine (SVMs). The basic idea behind SVR is to find the best fit line. SVR was tested with different kernel functions. The function of kernel is to take data as input and transform it into the required form.

Linear Regression Algorithm was also trained and tested for the same dataset to determine accuracy and other comparison parameter. It is a supervised machine learning algorithm that carries out a regression task. Based on independent variables, regression models a goal prediction value.

An AdaBoost regressor was performed on the given dataset. It is a meta-estimator that starts by fitting a regressor on the original dataset, and then fits new copies of the regressor on the same dataset, but with the weights of instances modified based on the current prediction's error.

Stacking regression was also trained for this dataset. It is a technique for creating linear combinations of various predictors in order to enhance prediction accuracy. Under non-negativity restrictions, cross-validation data and least squares are used. It consists in stacking the output of individual estimator and use a regressor to compute the final prediction. Stacking allows using the strength of each individual estimator (base estimator) by using their output as input of a final estimator. RigdeCV and linear SVR was the base estimator for stacking regression and random forest was the final estimator.

Furthermore, Random Forest Regression, a supervised learning approach for regression was also trained and tested for predictive modeling with hyper parameter tuning. Hyper parameter tuning implies varying the hyper parameter (number of trees and number of features) selected with criterion parameter as “gini” and then “entropy”. Random Forest Regression uses the ensemble learning method that combines predictions from several machine learning algorithms to get a more accurate prediction than a single model. The algorithm has been demonstrated in Fig. 7.

Certain parameters were compared to be able to predict the most efficient model. The comparison of the model was performed using accuracy, Root Mean Square Error (RMSE) and correlation coefficient as shown in Table IV.

Accuracy is the measurement used to determine which model is best at identifying relationships and patterns between variables in a dataset based on the input, or training, data. Mean Square Error (MSE) is one of the simplest metrics used in regression. It is defined as the sum of the squares of the difference of the actual value to the predicted value or it is average squared errors of the prediction made. RMSE is defined as Square root of Mean square error. The square root minimizes the errors and RMSE is used instead of MSE as MSE does not give an accurate picture when data is noisy. Higher the value of RMSE lesser the accuracy of Supervised Learning methods, lower the value of RMSE higher the accuracy. For two variables, the Correlation Coefficient compares the distance of each data point from the variable mean and uses this to tell us how closely the relationship between the variables can be fit to an imaginary line drawn through the data.

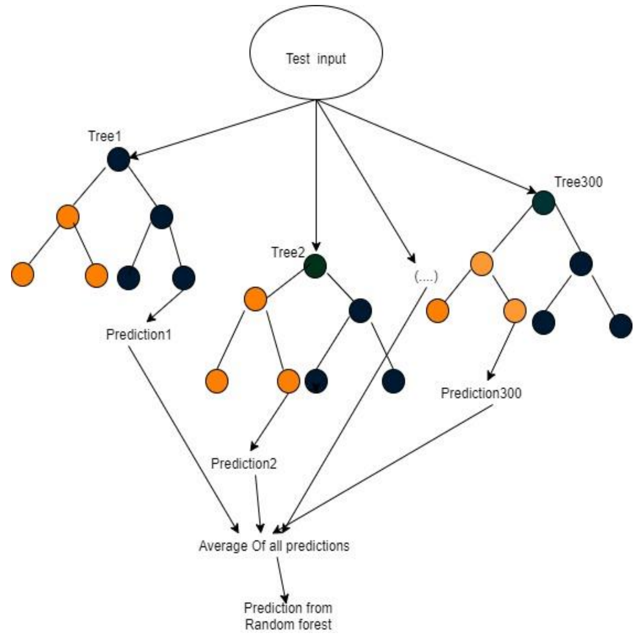

Fig. 7. Random Forest Algorithm.

The dataset was split as 75% training subset, and 25 % testing subset. The dataset comprises of around 400 values collected in the interval of three months by taking measurements at different durations of the day for temperature, humidity, Carbon monoxide, smoke, PM10 (previous day) and PM (current day). The use of sensors for temperature, relative humidity, carbon monoxide concentration and smoke with PM10 concentration of previous day obtained from the official site using Python command ensures the real time prediction of smog and utility of the deployed system after network has been trained. This ensures the continuous working of the system.

Huge amount of data is being generated continuously on the social web in the form of air quality and weather forecast. Thus, to improve our machine learning models prediction further Big data analytics can be employed which will improve the prediction done by trained models using physical sensor by utilizing social web data like weather tweets, geographic information, meteorological records and air quality records.

IV. Results

A. Sensors Measurement

1) After calibrations, Sensors were installed in an open terrace in the industrial area of Delhi NCR with reading taken at every 3 hours interval during the day as depicted in Fig. 8.

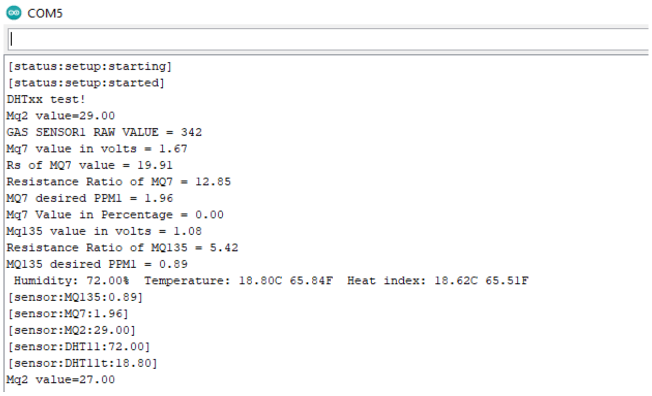

Fig. 8. Sensor Measurement.

2) *The readings from DHT and CO* sensor were compared with values measured by standard real time AQI values and are tabulated in Table II.

3) *The readings from MQ135* sensor were compared with Air quality monitor AM7000 and smoke sensor were compared with the standard values and tabulated in Table III.

4) *The RMSE value for temperature* is 0.644759 and for humidity is 0.953065. The RMSE value for CO is 0.5420.

5) The RMSE values for MQ135 sensor and Smoke is 0.8524 and 1.23051 respectively.

6) *Lower values of RMSE* obtained imply improved accuracy of Pollution monitoring than the previous research associated with monitoring.

TABLE II. COMPARISON OF MEASURED AND ACTUAL PARAMETERS

$Temp_M$ (°C)	$Temp_A$ (°C)	$Humidity_M$ (%)	$Humidity_A$ (%)	CO_M (ppm)	CO_A (ppm)
22.0	21.3	34.1	35.4	2.6	2.1
23.3	22.8	32.2	32.9	2	1.72
23.9	24.5	30.0	31.3	2.2	2.09
24.4	23.6	28.9	27.9	2.2	2.6
24.4	24.6	29.4	29.1	1.6	2.1
23.8	24.5	31.3	30.6	1.2	1.51
..	..	..	..	..	..
17.8	18.6	42.9	42.2	1.2	2.3

TABLE III. COMPARISON OF MEASURED AND ACTUAL PARAMETERS CO2 AND SMOKE SENSORS

$CO2_M$ (ppm)	$CO2_A$ (ppm)	Smoke $Sensor_M$ (ppm)	Smoke $Sensor_A$ (ppm)
2.1	2.96	54.05	52.8
2.82	3.42	65.7	64.1
6.9	8.5	58.45	56.3
15.4	15.1	57.2	56.9
12.5	11.9	53.8	53.4
..	..	..	..
4.9	4.4	55	55.3

B. Model Training and Comparison

1) *Six different machine* learning models were trained and tested viz. MATLAB ANN, Support vector regression, linear regression classifier, random forest regression, Adaboost regression and Stacking regression for predicting the PM10 concentration based on fed input.

2) *The following graph* in Fig. 10 shows the test value (PM10) result and actual values (PM10) for ANN and the result is considerably accurate.

3) *ANN is a statistical* model and the choice of ANN architecture, including the number and type of neurons, and the selection of a learning algorithm is very important to improve the accuracy.

4) *The ANN model* was trained multiple times with different number of hidden layers to determine the best suited number of hidden layers as shown in Fig. 7. The best suited was hidden layer with 8 nodes.

5) *The correlation between* actual PM10 values and test values came out to be 0.76 which is normal.

6) *While linear regression* is simple to implement but the values obtained were worst amongst all the models tested though better than ANN. It was fitted to reach the best accuracy of 76.42%, the least among all.

7) *The linear kernel* is shown to be the best input transformation technique for SVR.

8) *Stacking regressor performed* with mediocre accuracy among the others.

9) *For random forest*, the best results were obtained for 300 number of trees (accuracy 78.97 and RMSE 24.65), however, in comparison of all parameter values, Adaboost regression proved most efficient.

10) *Accuracy for Adaboost* reaches 98.24% which is highest among all the models as presented in Table IV.

11) *Thus, Adaboost Regression* was finally selected for Smog Prediction Model.

12) *Parameters such as correlation and RMSE* as shown in Fig. 9, 11, 12, 13, 14, 15 between measured and actual data for all models.

13) *As demonstrated*, multiple algorithms have been tested before determining the best and most efficient algorithm for Smog Prediction.

TABLE IV. COMPARISON OF MODELS

Model	Accuracy	RMSE	Correlation
Linear Regression	76.42	50.69	0.906964
ANN (MATLAB)	58.156	66.41	0.765523
SVR	80.9	33.28	0.914284
Random Forest Regressor (300 Trees)	78.97	24.65	0.917268
Adaboost Regression	98.24518	12.37	0.991843
Stacking Regression	88.18798	31.3603	0.942327

14)A differential factor not found in the previous research was that the models have been developed in a robust manner for which each model was re-built 25 times using different random subsets of training and testing samples keeping the splitting proportion constant.

C. Magic Mirror

1) Fig. 17 shows the dynamic magic mirror screen output.

2) Fig. 16 shows the sensors output from Arduino and this output are taken as input to trained model for predicting smog.

3) Environmental conditions viz. sensors' output are displayed on the specially designed Magic Mirror/ Smart Mirror using Raspberry Pi and the same screen can be installed in the traffic vicinity or the traffic junctions in the metropolis/megalopolis for the common people to have 24 hours pollution and smog monitoring.

4) To make the demonstrated smart screen more attractive, additional features on the screen apart from air pollution data have also been incorporated like showing News, Calendar, and the Weather forecast of Delhi region as shown in Fig. 17.

5) Alert messages for maintaining social distancing and wearing mask for corona and air pollution has also been incorporated.

Fig. 16. Sensor Output on Magic Mirror Screen.

Fig. 17. Magic Mirror Display.

V. Discussion

The novelty of the system is the Smog Prediction model presented based on PM10 concentrations which is trained using Machine learning model. The system is based on constantly updated data and the finally displayed in a dynamic and interactive Smart Mirror. The machine learning model employed has been selected after extensive testing of six models with different parameters and the chosen model has the maximum efficiency and maximum stability. The dataset utilized is dynamic from both real time measurement as well as the internet.

The system presents an improved and calibrated approach towards data analysis by the sensor inputs and corrects PPM calculations thus making it accurate and ready to display in accordance with standard air quality index measurements. These values along with the obtained previous day PM10 values are fed as an input to the trained model to predict the formation of smog. Based on this analysis, SMS alerts can be sent by triggering communication with SIM800l using Python script when smog is detected to the designated traffic official to divert the traffic, especially at crowded junctions.

Thus, the system overcomes the limitations of the previous research by adopting sensor calibration, increasing number of sensors, varied datasets, improving accuracy of predictive modeling, presenting comprehensive comparative analysis of predictive modeling and implementing efficient use of resources.

The system is designed to be flexible and can be altered easily by adding new sensors. The system generates awareness among the masses and the government about air pollution and provides data to localized tackling of air pollution. A small compact kit can also be developed for indoor air pollution monitoring whereas for outdoors the entire kit would suffice for accurate results.

VI. Conclusion

The paper successfully implements a Smart IoT based Air pollution monitoring system that employs advanced machine learning models to implement a novel system with SMOG prediction modeling that helps in improving the health of the people and their environment by making them aware of their surroundings. The data is projected on a Dynamic smart screen/ Magic Mirror that can be displayed at various traffic junctions for general awareness. Also, the data and further graphical representations obtained can help the traffic department and environmental agencies to take corrective actions regarding the pollution levels as and when it is updated. This set up can further aid the local municipalities to take corrective steps and solve this rabid problem in a democratically decentralized manner.

An efficient, viable and affordable implementation of the system is presented that is functioning in real time conditions in New Delhi's environment. The System has been made flexible and to further hone the results of smog detection, ozone layer status sensor can also be utilized. PM 2.5 laser dust sensor can also be utilized; however, it may take up the cost of the system. For the purpose of forecasting air pollution on a large scale, large-scale node location and data collection can be expected in the future.

***Abstract*—The increasing security concerns in Internet-of-Things (IoT) have led the researchers to evolve up with multiple levels of the research-based solution towards identifying and protecting the lethal threats. After reviewing the existing literature, it is found that existing approaches are highly specific toward stopping threats via predefined threat information. Hence, the proposed system introduces a new computational model capable of building up a flexible validation model for evaluating the legitimacy of the IoT nodes. The proposed system develops an algorithm that uses a simplified generation of secret keys, performs encryption, and generates validation tokens to ensure a higher degree of privacy and data integrity. The proposed model also contributes towards a unique energy allocation approach to ensure better energy conservation while performing security operations. The simulated study outcome shows better security and data transmission performance compared to the existing scheme.**

***Keywords*—Internet of things; security; validation; privacy; integrity; attacks**

I. Introduction

Internet of Things (IoT) offers more extensive coverage of different connected physical objects or machines, which are also known as things linked to a broader version of the network, i.e.,the internet [1]. Such physical objects are contributed by various technologies, software, hardware, actuators, and sensors, mainly with the objective of data transmission over the internet [2]. Data plays a significant role in IoT as this concept has evolved by integrating multiple technologies, e.g., automation, control system, wireless sensor network, ubiquitous computing, analytics, artificial intelligence [3]. This concept mainly targetsdeveloping a smart city by enabling more extensive connections of multiple and different types of machines. This causes a severe and increasing threat to security and privacy issues. There are various security concerns in the IoT environment connected explicitly with IoT devices and exchanged data. The first problem is its existing protection mechanism based on weaker password forms typically hard-coded and embedded within the device [4]. The second practical problem is associated with insufficient compliance of IoT devices manufacturers, which leads to insecure transfer and storage of data, usage of older operating environment and software, absence of robust updating mechanism, issues related to hardware, and hard-coded password. The next problem is related to a significantly lesser extent of awareness within the users, making the user morevulnerable in threat detection. Problems also exist due to the usage of insecure firmware. Due to this issue, the system suffers from brief downtime when the data is stored outside the cloud environment by the IoT device while performing updating operations. The existing physical devices are not secured from the external threat, which is not defined by the firewall system. Moreover, it is not feasible to imply a sophisticated security protocol running within the smart appliances or IoT devices due to their limitation of resource constraints and processing capability constraints. The usage of botnets by the attacker can significantly affect many IoT devices connected. Hence, during Distributed Denial-of-Service attacks in IoT, many connected appliances can be adversely affected. Apart from this, eavesdropping, industrial espionage, hijacking are some of the potential threats in IoT that have not yet met the robust security solution. There are various dedicated research-based solutions to deal with security concerns in IoT [5]-[9]. The conventional security solution of an IoT depends on Secure Socket Layer, Transport layer security, Datagram Transport Layer Solution, Quick UDP internet connection, secure MQTT, IP Sec [10].

Therefore, the research problem of proposed study is to address the limitation of conventional security scheme that may offer resistance but fails to offer full-proof validation of intention of any threat in large scale deployment over IoT. This problem is computationally challenging to implement whereas there is an increasing evolution of network devices as well as smart appliance for accessing services over IoT. Hence, this acts as motivating factor towards security for IoT devices.Therefore, this manuscript offers a solution to this issue by presenting a unique and lightweight validation scheme designed, unlike any existing approach. The prime objective of the proposed solution is to develop a computational framework that can perform secure validation towards securing all forms of IoT devices.The proposed model can identify the malicious intention of IoT nodes and offers a simplified encryption mechanism to mitigate the undefined threat in IoT. The paper also contributes to a novel energy computation scheme that compliments secure validation. The organization of the proposed paper is as follows: Section II discusses different taxonomies of existing security validation in IoT, followed by outlining research problems in Section III. Section IV discusses proposed research methodology while algorithm design is discussed in Section V. Section VI presents discussion while Result evaluation is illustrated in Section VII, while conclusive remarks are stated in Section VIII.

II. Related Work

At present, various schemes contribute towards security validation associated with identifying IoT devices while performing data forwarding.

- Blockchain-based Approaches: Blockchain is increasingly used in the majority of existing security approaches. The work presented by Hosen et al. [11] used context-aware blockchain validation. The approach also uses a software-defined network in the form of middleware to better control security operations in IoT. Banerjee et al. [12] have developed a blockchain-based authentication mechanism considering the key agreement protocol. The model is used in an implantable device that makes secure communication with the servers in the cloud. Blockchain is also reported to carry out authentication of cross-domain in IoT, as witnessed in the work of Ali et al. [13]. The researcher has presented a decentralized scheme for delegating permission and offer control over the structure of IoT. Further, the scheme also facilitates validating the local blockchain using the proof-of-Authentication and Integrity mechanism.

- Key Management-based Approaches: This is the most frequently used security scheme in IoT, where the emphasis is all about generation, storage, updating of secret keys among IoT devices. The computational model presented by Wang et al. [14] has presented a validation scheme for certificates used in IoT nodes. The prime idea is to assess the trust factor of IoT nodes. Xia et al. [15] have used a chaotic map to develop a key management scheme for authentication. The validation is carried out using informal security analysis along with the real-or-random model. Park et al. [16] have emphasized developing independent verification systems to offer untraceability and anonymity.

Further, the study has also used Burrows-Abadi-Needham logic to establish a secure bridge for mutual authentication servers and IoT devices. Shim et al. [17] have presented a study to assess a validation scheme towards anonymity issues in IoT. This security scheme is focused on the certificate's signature scheme to resist attacks towards secret keys and public keys. Another key-based protocol for validation is constructed by Saleem et al. [18], mainly targeting secure communication among cloud servers, roadside units, fog servers, and vehicles. Mahmood et al. [19] have developed key management based on distributed multiparty to carry out a compelling validation of nodes in IoT. The technique makes use of a chaotic map along with an on-way hashing approach for securing keying operation among all the core nodes and trusted servers. Public-key encryption and its different variant are witnessed to cover the IoT devices from most known threats. Such adoption of logic was reported in He and Zeadally [20],where elliptical curve encryption is used while validating RFID devices in IoT. The study outcome has found its security suitability on healthcare applications mainly. The work discussed by Yang et al. [21] has emphasized achieving forward secrecy in order to protect the session keys. For this purpose, a dynamic session key is presented,strengthening the credential management system in industrial-based IoTwithout any dependencies towards using primitives of public-key encryption.

- Policy-based Authentication:This scheme constructs a predefined policy to resist security threats. The security model of Banerjee et al. [22] has used a hashfunction with a defined security policy for offering validation for the regular/malicious IoT nodes. The study has also used a logical operator (bitwise exclusive OR) andan unclonable security function to compliment the device security. A similar approach of validation was also presented by Yanambaka et al. [23]. Existing studies have reported the usage of the message authentication scheme in order to construct a security policy in order to stop forgeability attacks in IoT. The model developed by Li et al. [24] has used identity-based encryption using signatures to strengthen privacy in IoT communication.

- Trust-based Security: These schemes are mainly meant for trust computation for ensuring the validation of IoT nodes. Rani et al. [25] have used game theory in order to evaluate trust in IoT. The work of Azad et al. [26] has used homomorphic encryption for securing the trust score in a decentralized manner. Xia et al. [27] have implemented a scheme for storage security using the trust factor to control accessibility. Almogren et al. [28] have used fuzzy logic for resisting Sybil attack and thereby developed a trust management scheme. The existing system has also witnessed other trust-related schemes by Truong et al.[29], Awan et al.[30], Fang et al.[31], Awan et al. [32], Wang et al. [33], Han et al. [34], etc.

- Unique Approaches: The work carried out by Amato et al. [35] has presented a unique technique based on workflow languages as well as semantics used for validating the inbuilt security characteristic of IoT devices. Another unique approach is presented by Ko etal. [36], where a validation scheme is designed using a tree that connects with variable security services with signature. The model assists the user in carrying out validation of the genuine sources anda relationship with the server. The existing system has also witnessed usinga cross-layer-based approach to offer an authentication scheme in IoT. The study carried out by Lee et al. [37] is mainly towards validation of user over physical layer as well as implementing encryption for large scale IoT deployment. The study makes use of the physical attributes in order to carry out preemptive-based authentication. Another unique approach witnessed in security validation in IoT is based on a group-based scheme, as witnessed in Aydin et al. [38]. The study has mainly targeted to resist man-in-middle attacks and replay attacks.The protocol also emphasized energy saving while carrying out group-based validation of many IoT nodes in a decentralized scheme.

The prominent research gap is existing approaches doesn’t offer lightweight encryption supportive of decentralized environment in IoTwith biased attacker identification policy. The next section outlines the problems associated with existing approaches and their methods towards validation.

III. Limitation / Research Problem

From the prior section, it has been seen that there are various approaches towards secure validation of an IoT device. After analyzing existing literature, apart from a valuable perspective in its security method and outcomes, there are also exploratory studies towards the limiting factors. This section outlines the limiting factors associated with the existing scheme as follows:

- Issues of decentralization: To offer more security coverage to large-scale IoT deployment, it is necessary to ensure the security scheme is decentralized. However, existing blockchain and key agreement-based schemes using a trust are more on a centralized security scheme and very much less towards decentralized implications. However, some work has used decentralized schemes, emphasizing delay control is not witnessed in existing schemes.

- Usage of Sophisticated Encryption: The encryption scheme is majority iterative and uses complex mathematical operations to ensure a better trapdoor function. However, the existing usage of encryption is quite voluminous, which will introduce a computational burden while trying to transmit data over the dense and more extensive network in IoT. Apart from this, sophisticated encryption will also saturate the resources to a higher level, and it is unlikely for the resource-constrained IoT nodes to sustain a more extended data transmission period.

- Unstructured Communication Scheme:The majority of existing secure data transmission scheme in IoT permits the data being captured from IoT nodes and directly forward to the gateway node. Such schemes offer higher resource fluctuation and challenge to control threats in case of multiple attackers in IoT. The impact of threat also becomes maximum. Such schemes cannot offer resistance from distributed denial of service attacks and man-in-middle attacks for large-scale deployment in IoT.

- Biased Identification Policies: Existing schemes are developed considering apriori information about attackers. Even the assessment is carried out using the same attackers. Such schemes will offer protection only from a predefined set of attackers and will never be able to identify if the attacker changes its strategy differing from what is coded within the firmware of the IoT nodes. A malicious node eventually does not attack when introduced in the environment; hence, existing security validation techniques will fail to identify dynamic attackers. The key management techniques are developed on an equal basis where there are fewer options for offering multi-stage encryption with a lightweight operation.

Apart from the above-stated problems, the existing scheme is not meant to cover up a set of integrated IoT attacks over a large scale. Apart from this, there is less consideration of resources used during validation during secure transmission. Therefore, the problem statement is "Developing a secure validation approach considering dynamic attack balancing with resource demands is challenging computational task in IoT." The next section outlines the solution towards this problem.

IV. Research Methodology

The proposed methodology addresses the limitation of existing approaches presented in prior section. The issues of decentralization is solved by presenting a lightweight encryption operation supportive of decentralized environment in IoT. The limitation of usage of sophisticated encryption is solved by parallel assessment of energy along with generation of secret key. The problem of unstructured communication scheme is addressed by developing a specific topology of an IoT which organization device and its respective communication with a gateway node. The problem of biased identification policies is addressed by performing secure modelling of local and global IoT. Local IoT would mean a network with a single application, while global IoT would mean forming a centralized network with multiple (and diverse) applications. Therefore, the proposed system uses a domain-based communication system where the domain will refer to a particular local IoT device where a heterogeneous domain performs its communication via a gateway node. Initially, simple modelling is being carried out by defining actors in local IoT (datacenter, target IoT, sensors) and global IoT (network of all the datacenters). A novel authentication mechanism is presented among all the possible actorsresiding within the local and global IoT domain by incorporating challenge and response-based approaches. A sophisticated validation module will be designed to validate the legitimacy of the requestor node. The research methodology adopted is analytical-based, as shown in Fig. 1.

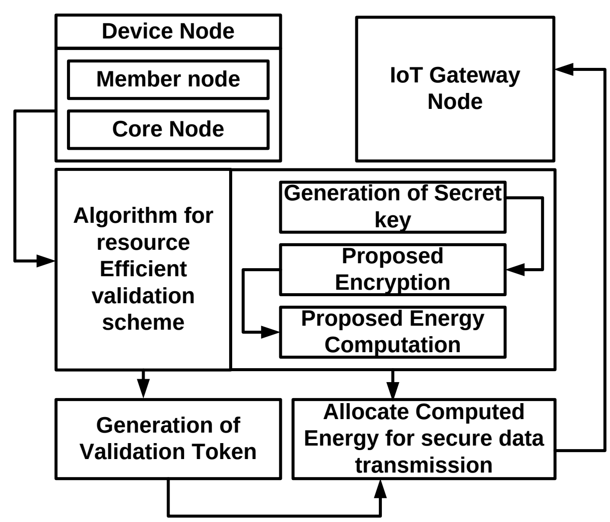

Fig. 1. Tentative Research Methodologies for Phase-II.

The proposed system will formulate an algorithm for ensuring both forward and backward secrecy to safeguard the presented authentication framework for any possible threats. The system will use cipher-text-based encryption and novel energy computation to strengthen the authentication mechanism with lower resource consumption. The novelty of this model is its validation process which is meant to mitigate dynamic threats in large-scale IoT more effectively and in a decentralized manner to offer more security coverage. The next section discusses algorithm design and implementation towards the model.

V. Algorithm Design

The primary concern of the proposed system is to construct a unique validation scheme that could be used for assessing the authenticity of the IoT nodes. Owing to the last deployment scenario in an IoT, it is required to ensure that this scheme should also be resourced efficiently, balancing with the security demands. The proposed algorithm performs this dual-task in combining the security features with resource efficiency features. The steps of the proposed algorithm are as follows:

Algorithm for Resource-Efficient Validation Scheme

Input: n, A, s, e, p
Output: v_{tok}, E
Start
1. init n, A, s, e, p
2. **For** i=1:n
3. $n_{mem} \leftarrow$ msk
4. $[d, e, n] \leftarrow f_1(\text{msk}, \text{NP})$
5. $n_{core}=A_{ix}(G_i(r<T_i))$
6. $[v, ix] \leftarrow \arg_{min}(\text{dist})$
7. $[v_{tok}] \leftarrow f_2(\text{msg}, enc_i, n_i)$
8. $E_{tx}=f_3(\text{dist}, \text{PL*cm})$
9. $E(n_{core}(i)] \leftarrow E(n_{core}(i))-E_{tx}$
10. **End**

End

The algorithm takes the input of n (IoT nodes), A (simulation area), s (gateway node), e (initialized Energy), p (probability of core IoT node) that upon processing yields and outcome of v_{tok} (generation of validation token) and E (computed Energy). The proposed algorithm initializes a master key *msk* and allocates it to a structured memory system n_{mem} of a node (Line-3). The next essential step of the proposed algorithm is to apply a customized function f_1(x), responsible for carrying out a secret key generation. The internal steps of f_1(x) are as follows: The function takes the input of master key *msk*, and nearest prime number *NP* and it generates three attributes memory structure of decryption *d*, memory structure of encryption *e*, and IoT nodes *n* (Line-4). Following are further steps:

- The IoT nodes *n* is computed by-product of master key *msk* and nearest prime number *NP*.
- An internal security attribute is constructed Φ, computed as Φ=(msk-1)(NP-1).
- The greatest common divisor is computed concerning random numbers for *NP* and obtained internal security attribute Φ.
- The value of this scheme is obtained by applying the modulus of the product of *d* and *e* and Φ.

The obtained information of attributes *d*, *e*, and *n* are further updated in the memory systems, accessed by legitimate IoT devices on a memory-sharing basis. In order to offer better control of the communication in large-scale IoT device deployment, the proposed system introduces a threshold-based provisioning scheme for the selection of core IoT nodes n_{core}(Line-5). The proposed mathematical expression of this threshold is as follow:

$$T = \frac{p}{\Delta p}.\Delta E \quad (1)$$

In the above expression (1), three dependable parameters are used in computation, i.e., p, Δp, and ΔE. The first variable,*p*, represents the probability that one of the IoT devices will be provisioned as a core IoT node authorized to forward the data to the gateway node. The second variable Δp represents $(1-p(|1/p|)).E/E_{init}$, where E and E_{init} represent total and initialized Energy, respectively. The selection of core IoT node n_{core} is selected considering matrix A_{ix} which retains all active nodes with E more than zero and any candidate IoT node randomly selected number less than T_i (Line-5). It should be noted that the variables T and T_i are different as the former is represented by mathematical expression (1) while the latter is represented as $T_i=E(G_i)$. It will mean that T_i is the threshold considered for all the randomly selected candidate nodes G_i which has sufficient residual Energy. The next task is to compute the distance *dist* between all the candidate IoT devices with the core IoT device (Line-6). The proposed system computes the minimum distance and obtains its value *v* and coordinates *ix* (Line-6). The variable *ix* is further used for updating the core IoT device. The next part of the algorithmic step is to perform encryption using an explicit function f_2(x). Following are the internal operation of this encryption function:

- The function f_2(x) takes the input of message *msg*, encryption attribute enc_i, and IoT device $n_{i,}$ which yields an outcome of validation token v_{tok} (Line-7).
- The first step is to compare the length of the message *msg* with the unit value. If it is found more than the unit value, then the size of the message is reduced to 32 bit.
- A simplified encoding is carried out for the encrypted attributed enc_i by converting decimal to binarized value.
- The function further compares the value of obtained encoded value from the prior step with the unit value. If the size of the encoded value is found more than the unit value, then it further put forward a condition where the value of the encoded attribute is equated to the unit value. The coefficient c is computed as,

$$c = |(c^2, n) * msg, n|, \text{ c=1} \quad (2)$$

$$c = |(c^2, n)| \quad (3)$$

The expression (2) is implemented if the encoded value is equal to the unit value, while expression (3) is implemented if the encoded value equals zero. The outcome, by either condition, generates coefficient c, which is a validation token vtok (Line-7). This completes the operation of the proposed encryption.After the encryption is carried out, the next emphasis is given to control the energy dissipation. The proposed system implements the final function f_3(x), which mainly targets to reduce the dissipated Energy while forwarded the encrypted data from the core IoT nodes to the gateway node (Line-8). Following are the internal steps being carried out towards energy control function f_3(x):

- This function takes the input of distance *dist*, length of data *PL*, and domain member *cm*. The proposed system considers domain-based communication where the domain represents a group of similar IoT devices. Each domain consists of two categories of nodes, i.e., domain member *cm* and core node n_{core}. The elementary information is captured by domain member *cm* and is then routed to core node n_{core} while the core node n_{core} forwards all the data collected to the gateway node. The proposed model implements a standard energy computation of hierarchical communication scheme [39] for computing transmittance energy.
- The energy model used in this part of the implementation emphasizes the distance attribute. The core idea is to ensure that the distance between two communicating nodes is kept as minimal as possible. A higher distance will eventually lead to excessive energy drainage. Hence, a greedy approach is applied to ensure that nodes with minimum distance criteria perform data transmission to the gateway node.
- While performing the energy computation, the energy control function f_3(x) considers practical energy factors, e.g.,Energy required for antenna to carry out transmission within an IoT device, Energy required to amplify the signal, length of data to be transmitted, and distance. Further, the function initializes the Energy required to transmit validation token v_{tok}. This operation can be carried out for both active and passive modes of validation.
- The active mode of validation is when the validation is required instantaneously by the user, while the passive mode of validation is when the validation of the security token can be done later. The difference is that an active mode of validation is carried out before the data is transmitted, while a passive mode of validation is carried out when the data starts receiving at different network elements in an IoT environment. The active mode of validation can be carried out in case of a known attack, while the passive validation model can be carried out if the attacker strategy is unknown to the user. In both cases, safety is ensured. Therefore, the total energy consumption will bea summation of Energy required in performing either mode of validation of v_{tok}.

After the cumulative energy E is computed, the proposed system performs a reduction of Energy. This is carried out by obtaining the appropriate Energy obtained by subtracting the total Energy of the core IoT device with allocated transmitted Energy (Line-9). Unlike any existing energy modelling, the novelty factor is thatthe proposed system does not allocate static Energy, but it computes the exact necessary Energy and allocates it after performing the encryption steps. The next section discusses the discussion followed by results evaluation.

VI. Discussion

At present, there are scattered and multi-variants forms of security approaches to ensure that accessibility towards the IoT device is always carried out in secured manner. There are reported claims of benefits observed in existing approaches too in this regards on the basis of reviews carried out in Section II. However, a closer look into the review of literature shows that there is no potential connectivity among the existing techniques, which will mean that hybridization of multiple techniques are extremely challenging with existing approaches. The prime reason behind this is the dependencies of research environment, specification of implementation, and applicability are highly narrowed scope. Hence, there is no scope of integrating conventional security approaches towards assessing the legitimacy of the devices. This calls for evolution of the novel idea presented in this paper, where the idea is to address the identified research problem / limitation outlined in Section III.

A closer look into existing approaches shows that they are yet not much supportive of decentralized environment. This problem is directly addressed by implementing a key generation approach discussed in Section V considering completely distributed communication among IoT nodes in the form of cluster. Unlike any conventional IoT system, where there are only two roles of nodes i.e. IoT node and IoT gateway node, the proposed system offers two more distinct roles i.e. member node and core node, which is designed from the operational features of sensor network in IoT environment. The benefit of this scheme will be i) highly supported of decentralized environment considering local and global IoT system, ii) highly structured communication among different roles of device nodes and IoT gateway node, iii) conservation of energy due to structured communication system. Apart from this, the security strength of proposed system is further leveraged by inclusion of validation token which ensures the legitimacy of the node to participate in data communication process.Another interesting contribution of proposed methodology that separates it from existing approaches are its formulation of validation technique and all its attributes involved in it. Majority of the attributes used in the formulation of algorithm discussed in Section V i.e. distance, nodes, master key, message, encryption attribute, etc. are readily available from neighborhood node or hop table. No extensive computation is required to assess the validation token except few conditional checks being carried out. This significant reduces the computational burden and make the system highly scalable in peak traffic load in IoT for secure validation. Result evaluation is discussed next.

VII. Evaluation

This section illustrates the outcome obtained by implementing the secured validation in IoT. It is to be noted that the proposed system introduces a flexible validation scheme contributing towards secure communication in IoT.

A. Simulation Parameters

The proposed system is scripted in MATLAB on a regular 64-bit machine with a Core i5 processor. The study is evaluated considering 100-500 IoT devices deployed in an arbitrary position in a simulation area of 1000 x 1000 m^2 considering the variable location of the gateway node. The initialized Energy of IoT nodes is considered 10 Joule with a 5% probability score for a member IoT node to become the core access node in IoT. The proposed study also consider variable energy attributes, e.g., theEnergy utilized for data transmission by IoT nodes as 5nj/bits, Energy required to amplify signals by wireless IoT nodes as 100 pJ/bit for every squared meter of simulation area,Energy utilized for generating and assessing validation token as 80 μJ/validation tokens, Energy required for assessing validation token in active mode as 13μJ/validation tokens, Energy required for assessing validation token in passive mode as 5μJ/validation tokens, the size of the data packet is 1000 bytes. The consideration of the values has been considered according to the standard ranges observed from existing literature and standard secured hierarchical protocols.

B. Simulation Environment

The first step of the implementation is to deploy a generalized IoT environment consisting of member IoT devices, core IoT devices, and a gateway node. A domain-specific communication is carried out where the member IoT nodes forward the data to core IoT nodes which further aggregates the data and forward it to either gateway node directly or forward to its nearest neighboring core node. The direct transmission to the gateway node is carried out if the distance between the core node and gateway resides in the proximity of each other. Otherwise, multi-hop transmission is carried out via other core nodes to the gateway node. Assuming the presence of attackers, the analysis is carried out as the proposed system is designed to resist any form of key-based and routing intrusion associated with identity-based theft attacks in the IoT environment. The communication is permitted to continue for 7000 simulation rounds till all the IoT nodes are depleted of their Energy.

C. Performance Evaluation

For an effective benchmarking system, the proposed system consider the existing system of the secured hierarchical protocol [39], which acts as baseline security of IoT device. The prime justification of adopting this existing system for benchmarking is as follows: i) sensors and actuators are an integral part of an IoT environment in the form of IoT devices compliant with security protocols applied for sensory application. Hence, secure hierarchical protocols [39] offer a balance between security and energy efficiency, which suits the proposed objectives too, ii) it offers a standard mathematical formulation to compute Energy considering various energyattributes. In order to facilitate equivalent testbeds, similar energy parameters are also selected to carry out the proposed implementation. This will offer a fair outcome in a similar test environment for both proposed and existing systems. For more granular analysis, the proposed system is assessed for both its active and passive state of verification of validation tokens. The performance parameters selected for the analysis are rounds required to complete validation, number of sustained nodes, delay, throughput, resource, fluctuation, and overall energy depletion.

D. Impact of the Proposed System on Transmission

This section discusses the simulation outcome involved for each performance parameter.

1) Validation round: The first performance parameter to assess is validation rounds, computed by observing the total number of rounds required for both proposed and existing systems to complete the validation.
