Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Doroła Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Implementation of Data Mining on a Secure Cloud Computing over a Web API using Supervised Machine Learning Algorithm

Authors: Tosin Ige, Sikiru Adewale

PAGE 1 – 4

Paper 2: AI Powered Anti-Cyber Bullying System using Machine Learning Algorithm of Multinomial Naïve Bayes and Optimized Linear Support Vector Machine

Authors: Tosin Ige, Sikiru Adewale

PAGE 5 – 9

Paper 3: Replica Scheduling Strategy for Streaming Data Mining

Authors: Shufan Li, Siyuan Yu, Fang Xiao

PAGE 10 – 19

Paper 4: Use of Neural Networks in the Adaptive Testing System

Authors: Ekaterina Vitalevna Chumakova, Tatiana Alexandrovna Chernova, Yulia Aleksandrovna Belyaeva, Dmitry Gennadievich Korneev, Mikhail Samuilovich Gasparian

PAGE 20 – 27

Paper 5: Development of Ontology-based Domain Knowledge Model for IT Domain in e-Tutor Systems

Authors: Ghanim Hussein Ali Ahmed, Jawad Alshboul, Laszlo Kovacs

PAGE 28 – 34

Paper 6: The Design of Home Fire Monitoring System based on NB-IoT

Authors: Jun Wang, Ting Ke, Mengjie Hou, Gangyu Hu

PAGE 35 – 42

Paper 7: The Effect of Natural Language Processing on the Analysis of Unstructured Text: A Systematic Review

Authors: Walter Luis Roldan-Baluis, Noel Alcas Zapata, Maria Soledad Manaccasa Vasquez

PAGE 43 – 51

Paper 8: Hybrid Fault Diagnosis Method based on Wavelet Packet Energy Spectrum and SSA-SVM

Authors: Jinglei Qu, Bingxin Ma, Xiaojie Ma, Mengmeng Wang

PAGE 52 – 60

Paper 9: Multi-instance Finger Vein-based Authentication with Secured Templates

Authors: Swati K. Choudhary, Ameya K. Naik

PAGE 61 – 71

Paper 10: SHD-IoV: Secure Handover Decision in IoV

Authors: Hala E. I. Jubara

PAGE 72 – 80

Paper 11: The Impact of Security and Payment Method On Consumers' Perception of Marketplace in Saudi Arabia

Authors: Mdawi Alqahtani, Marwan Ali Albahar

PAGE 81 – 88

Paper 12: Individual Risk Classification of Crime Groups using Ensemble Classifier Method

Authors: Ardhito P. Anggana, Amalia Zahra

PAGE 89 – 98

Paper 13: Evaluating the Effectiveness and Usability of AR-based OSH Application: HazHunt

Authors: Ahmad A. Kamal, Syahrul N. Junaini, Abdul H. Hashim

PAGE 99 – 106

Paper 14: Efficacy of the Image Augmentation Method using CNN Transfer Learning in Identification of Timber Defect

Authors: Teo Hong Chun, Ummi Rabaah Hashim, Sabrina Ahmad, Lizawati Salahuddin, Ngo Hea Choon, Kasturi Kanchymalay

PAGE 107 – 114

Paper 15: Security Analysis on an Improved Anonymous Authentication Protocol for Wearable Health Monitoring Systems

Authors: Gayeong Eom, Haewon Byeon, Younsung Choi

PAGE 115 – 121

Paper 16: A Review on Bio-inspired Optimization Method for Supervised Feature Selection

Authors: Montha Petwan, Ku Ruhana Ku-Mahamud

PAGE 122 – 132

Paper 17: Implementation of a Data Protection Model dubbed Harricent_RSECC

Authors: Frimpong Twum, Vincent Amankona, Yaw Marfo Missah, Ussiph Najim, Michael Opoku

PAGE 133 – 145

Paper 18: Goal Question Metric as an Interdisciplinary Tool for Assessing Mobile Learning Application

Authors: Sim Yee Wai, Cheah WaiShiang, Piau Phang, Kai-Chee Lam, Eaqerzilla Phang, Nurfauzia binti Jali

PAGE 146 – 152

Paper 19: Spatial Feature Fusion for Biomedical Image Classification based on Ensemble Deep CNN and Transfer Learning

Authors: Sanskruti Patel, Rachana Patel, Nilay Ganatra, Atul Patel

PAGE 153 – 159

Paper 20: Effectivity Score of Simulation Tools towards Modelling Design in Internet-of-Things

Authors: Gauri Sameer Rapate, N C Naveen

PAGE 160 – 170

Paper 21: Analysis and Prediction of COVID-19 by using Recurrent LSTM Neural Network Model in Machine Learning

Authors: N. P. Dharani, Polaiah Bojja

PAGE 171 – 178

Paper 22: A Proposed Fraud Detection Model based on e-Payments Attributes a Case Study in Egyptian e-Payment Gateway

Authors: Mohamed Hassan Nasr, Mohamed Hassan Farrag, Mona Mohamed Nasr

PAGE 179 – 186

Paper 23: Improved ISODATA Clustering Method with Parameter Estimation based on Genetic Algorithm

Authors: Kohei Arai

PAGE 187 – 193

Paper 24: A Pre-trained Neural Network to Predict Alzheimer's Disease at an Early Stage

Authors: Ragavamsi Davuluri, Ragupathy Rengaswamy

PAGE 194 – 200

Paper 25: A k-interpolation Model Clustering Algorithm based on Kriging Method

Authors: Guoyan Chen, Yaping Qian

PAGE 201 – 207

Paper 26: A Food Waste Mobile Gamified Application Design Model using UX Agile Approach in Malaysia

Authors: Nooralisa Mohd Tuah, Siti Khadijah Abd. Ghani, Suryani Darham, Suaini Sura

PAGE 208 – 217

Paper 27: Entanglement Quantification and Classification: A Systematic Literature Review

Authors: Amirul Asyraf Zahir, Siti Munirah Mohd, Mohd Ilias M Shuhud, Bahari Idrus, Hishamuddin Zainuddin, Nurhidaya Mohamad Jan, Mohamed Ridza Wahiddin

PAGE 218 – 225

Paper 28: Effective Cross Synthesized Methodology for Movie Recommendation with Emotion Analysis through Ranking Score

Authors: R Lavanya, B Bharathi

PAGE 226 – 233

Paper 29: Supervisory Control and Data Acquisition System for Machines used for Thermal Processing of Materials

Authors: Diego Patino, Wilson Tafur Preciado, Albert Miyer Suarez Castrillon, Sir-Alexci Suarez Castrillon

PAGE 234 – 240

Paper 30: Modeling Wireless Mesh Networks for Load Management

Authors: Soma Pandey, Govind R. Kadambi

PAGE 241 – 251

Paper 31: A Model for Classification and Diagnosis of Skin Disease using Machine Learning and Image Processing Techniques

Authors: Shaden Abdulaziz AlDera, Mohamed Tahar Ben Othman

PAGE 252 – 259

Paper 32: A Hybrid Material Generation Algorithm with Probabilistic Neural Networks for Solving Classification Problems

Authors: Mohammad Wedyan, Omar Alshaweesh, Enas Ramadan, Ryan Alturki, Foziah Gazzawe, Mohammed J. Alghamdi

PAGE 260 – 266

Paper 33: IoT based Portable Weather Station for Irrigation Management using Real-Time Parameters

Authors: Geeta Ambildhuke, Barnali Gupta Banik

PAGE 267 – 278

Paper 34: E-Evaluation based on CSE-UCLA Model Refers to Glickman Pattern for Evaluating the Leadership Training Program

Authors: Ketut Rasmulyani, I Made Yudana, I Nyoman Natajaya, Dewa Gede Hendra Divayana

PAGE 279 – 294

Paper 35: Rule-based Text Extraction for Multimodal Knowledge Graph

Authors: Idza Aisara Norabid, Fariza Fauzi

PAGE 295 – 304

Paper 36: Soil Color as a Measurement for Estimation of Fertility using Deep Learning Techniques

Authors: N Lakshmi Kalyani, Kolla Bhanu Prakash

PAGE 305 – 310

Paper 37: A Survey on Genomic Dataset for Predicting the DNA Abnormalities Using MI

Authors: Siripuri Divya, Y. Bhavani, Thota Mahesh Kumar

PAGE 311 – 319

Paper 38: An Architecture of Domain Independent and Extensible Intelligent Tutoring System based on Concept Dependencies and Subject Paths

Authors: Sanjay Singh, Vikram Singh

PAGE 320 – 329

Paper 39: Secure Routing Protocol for Low Power and Lossy Networks Against Rank Attack: A Systematic Review

Authors: Laila Al-Qaisi, Suhaidi Hassan, Nur Haryani Binti Zakaria

PAGE 330 – 339

Paper 40: Validation of Evacuation Assessment Algorithm in Finding the Best Indoor Evacuation Model

Authors: Amir Haikal Abdul Halim, Khyrina Airin Fariza Abu Samah

PAGE 340 – 347

Paper 41: Effective Prediction of Software Defects using Random-tree Entropy based Feature Selection Framework

Authors: Abdulaziz Alhumam

PAGE 348 – 354

Abstract—Ever since the era of internet had ushered in cloud computing, there had been increase in the demand for the unlimited data available through cloud computing for data analysis, pattern recognition and technology advancement. With this also bring the problem of scalability, efficiency and security threat. This research paper focuses on how data can be dynamically mine in real time for pattern detection in a secure cloud computing environment using combination of decision tree algorithm and Random Forest over a restful Application Programming Interface (API). We are able to successfully implement data mining on cloud computing bypassing or avoiding direct interaction with data warehouse and without any terminal involve by using combination of IBM Cloud storage facility, Amazon Web Service, Application Programming Interface and Window service along with a decision tree and Random Forest algorithm for our classifier. We were able to successfully bypass direct connection with the data warehouse and cloud terminal with 94% accuracy in our model.

Keywords—Cloud computing; data warehouse; data mining; window service; Web API; machine learning algorithm; secure cloud computing

I. INTRODUCTION

As we all know that Knowledge discovery is the nontrivial extraction of implicit, previously unknown, and potentially useful information from data [1]. There is no doubt that the availability of billions of data in the cloud had open floodgates of opportunity in which model can be trained and learn by itself over time thereby enable machines and intelligent elements to make crucial and important decision without human intervention. As millions of data are constantly being stored and retrieve through cloud computing on daily bases. There is no doubt that data mining delivers a powerful competitive advantage [6] for any company or industry. With these also arises the challenge on how to make use of the unlimited data available through data mining on cloud computing, and how it can be done in a highly secure, scalable and efficient manner to combat several security threats associated with cloud computing.

In modern research and intelligent systems, the important of data can never be overemphasized across wide range of industries, especially when we consider the fact that the

traditional E-commerce businesses and industry were influenced by cloud computing in technical architecture, service modes and the industrial chain [4], economist needs to know how they can use readily available data in the cloud to predict consumers need and behavior, meteorologists need those data to make future weather forecast and predict or detect climatic change, government agency needs those data to make effective policy, police and intelligence agency needs data for background check and so on. All government and non-government parastatal depends on data from the cloud for one reason or the other. This further brings about the importance and urgency of mining data to detect previously unknown pattern in a scalable and efficient manner through cloud computing to address daily needs with the guarantee of maximum security, authorization and authentication which can be affected through a restful web API.

In this research, the use of constantly updating real time data and without any connection to the cloud data warehouse for maximal data protection and dynamic predictive pattern with high accuracy were implemented. To achieve this objective, an application Programming Interface (API) and Background window service was developed to detect and fetch new and updated records from data warehouse, transformed to json and written to a file on the cloud. This ensures maximum security to the data as there is no direct connection to the data warehouse where data are constantly being pulled from. We used IBM Cloud object storage facility to host our csv file while the data warehouse is also on the cloud but from another channel entirely. Then a restful web API service was developed using Django python framework which was deployed to Amazon Web Services (AWS). Since the newly created API will be constantly pulling data from the data warehouse and writing directly to into the CSV file which is on the IBM Cloud storage facility. The service can easily be overwhelmed, to prevent the service from being overwhelm, we developed a background service on a Microsoft console using Microsoft .NET Technology programming language.

Any record the web API misses or delayed in picking from the warehouse, the background service will pick it up. Hence, they complement each other and ensure efficiency so that the web API service is not overwhelmed. With this in place, there

is a constantly updated and up to date data on the CSV file hosted in the IBM cloud storage facility which is now serves as the primary source of data. This ensure accessibility to updated records at every stage of our data mining activities, as there is an existing restful API and background window service that fetches data from the warehouse to the hosted file in cloud environment from which data is being pulled from.

Combination of decision tree algorithm and Random Forest for classifier was implemented coupled with a graphic user interface (GUI) that automatically processed and displays newly discovered patterns in a graphical format on the screen at each and every update on new data.

There are four main objectives here which are:

- 1) Bypassing direct connection and retrieval from the data warehouse through a middle ware.
- 2) Real time access to dynamic data in an enabling cloud environment.
- 3) We want to shield the warehouse for maximum security and while also avoiding data lock.
- 4) Automation of the detection of any new pattern from the dataset and projection to the screen with graphical illustration and analysis.

To ensure successful accomplishment of the fourth objective, a scheduler called Python scheduling library was used so that the whole process is automatically initiated and repeated immediately a new pattern is detected.

II. BACKGROUND STUDY

The importance of cloud computing cannot be overemphasize as it includes; unlimited storage, provisioning and updating, guaranteed privacy more security [13]. Also, it is possible for users of cloud services to optimize server utilization, dynamic scalability, and minimize the development of new application life cycles [14]. In addition to the numerous benefits in cloud computing, there are also problems as a result of cloud outage since data storage is centralize in the cloud which can paralyze a company business [15], also attack on the integrated cloud environment can cause loss of data and finance for both the service providers and subscribers. There are also other risks associated with computing on cloud environment which includes the issues of threats to data security information confidentiality [5], and the possibility of information leakage and vulnerability [12].

In today's data mining, multiple data streams are generally complex than single data streams [2] considering the security architecture and cloud computing environment, the complexity increases when we consider the cost and benefit, reliability, cloud migration and inter clouding [3], While compute/storage scaling, data parallelism, virtualization, MapReduce, RIA, SaaS and Mashups are likewise also important in data mining [7] not all are always implemented. Although there had been improvement in the technology and services of the major Cloud Computing Platforms likes amazon Relational Database Service, Amazon Simple Queue Service, Amazon SimpleDB, Amazon Web Services, AppScale, Azure Services Platform, Caspio, CloudControl, Cordys Process Factory, Engine Yard, Force.com, FreedomBox, Google App Engine, Heroku, Hybrid

Web Cluster, OrangeScape, Platform as a service, Rackspace Cloud, Rollbase, Squarespace, Sun Cloud, Vertebra (cloud computing framework), Wolf Frameworks [8], some of the persistent problems associated with data mining on cloud computing are as a result of the existing method adopted in the industry and scientific world at large. Current cloud computation for data mining needed service provider to provide interface for user. The user does not need to bother about the infrastructure. It enables the retrieval of useful previously unknown data from integrated data warehouse, in such a way that users doesn't need to border about infrastructure, storage, or configuration and maintenance, the provider handles that. It is based on retrieving directly from the integrated data warehouse.

[5] discusses the importance of large item sets within a cluster and its implication for effectiveness, it doesn't address the several issues and vulnerabilities in cloud computing while [9] in his research work "Data mining in Cloud Computing", relies on extraction of previously unknown or meaningful pattern from unstructured or semi-structured data from the web sources; "The analysis steps in the Knowledge Discovery and Databases process" [11]. It listed three stages of research involving data warehouse which are staging, integration, and accessibility for the purpose of reporting and analysis in the Review of Data Mining Techniques in Cloud Computing Database by [10].

In addition to the problems associated with data mining on cloud computing in which majority of the problems are due to existing methods of data mining on cloud computing. The existing methods also creates a wide gap between data mining on cloud computing and application Programming Interface (API) which are yet to be closed. In the existing method we are yet to see an instance in which we call we only need to call an API endpoint, and then have everything done for us.

III. RESEARCH METHODOLOGY

Data used on this research work was obtained from social network on GitHub. To begin this research, four basic things were paramount;

- 1) Subscription to IBM Cloud Object Storage facility to host our CSV file.
- 2) Setting up a data warehouse on cloud from another channel different from IBM.
- 3) Development of a background window service using .NET Technology.
- 4) Implementation of a web service to be consumed in the cloud using python.
- 5) Scheduler using python scheduler library to trigger the web API at interval.

In order to prevent the web service from being overwhelm due to multiple calling of the endpoint at regular interval, we developed a background window service to support the restful API service. Both the web API and the window service are picking records from the integrated data warehouse and pushing to the CSV file on the IBM Object Cloud Storage facility. They automatically pick new records to the CSV, and if a record is modified, it will be picked and modified on the

CSV as well. The essence of the scheduler which was written in python is to be calling the web API at regular interval to check and push from the integrated data warehouse to the CSV file.

With the successful setting up of cloud environment and the necessary software programs being in fully execution, we proceeded by adopting the following data cleansing and preparation techniques;

Data cleaning: We use preprocessing and cleaning methods to remove incomplete data that might cause system failure and also affect output prediction. Rows containing missing values where completely removed. We also use different methods to identify and remove noisy data, outliers, and other factors which can influence the output result.

Data Reduction for Data Quality: In order to maintain data integrity, we needed to deal with all rows containing null value; hence we opted for python library tool called PyCaret. We have two options which are either to automatically fill all the null values or to remove any row(s) containing null values weighted. Having weighted the risk involves in both, we decided to remove any row with null or empty value from the data, and this was done using PyCaret python library.

Data Transformation: For us to make our data to acceptable format for easy data mining and pattern recognition, it needed to undergo some data transformation. To ensure data is fully transformed to acceptable format, we used Discretization, normalization, and data aggregation technique.

Data Mining: Having successfully set up our apparatus which includes IBM cloud object storage facility, running background window service, active web service, scheduler, and with the data being thoroughly pre-processed and transformed.

Unlike current data mining in cloud computing process in which, one needs to make direct connect to the data warehouse or directly call the csv file. We only called our restful API endpoint (Fig. 1) which was developed and hosted on the cloud.

This ensures a higher level of security and control over the data, the only thing that needed to be called is the endpoint of our API which automatically displays the data as seen in Fig. 1 displaying the first five (5) records in the data using python library in panda. (Fig. 2) shows the text representation of the selected features using decision tree algorithm.

```
In [3]: data = pd.read_csv('http://cs4430.meritgotech.com/customers/social')
data.head()

Out[3]:
```

	User ID	Gender	Age	EstimatedSalary	Purchased
0	15624510	Male	19	19000	0
1	15810944	Male	35	20000	0
2	15686575	Female	26	43000	0
3	15603246	Female	27	57000	0
4	15804002	Male	19	76000	0

Fig. 1. Preview of First Five Rows of Dataset.

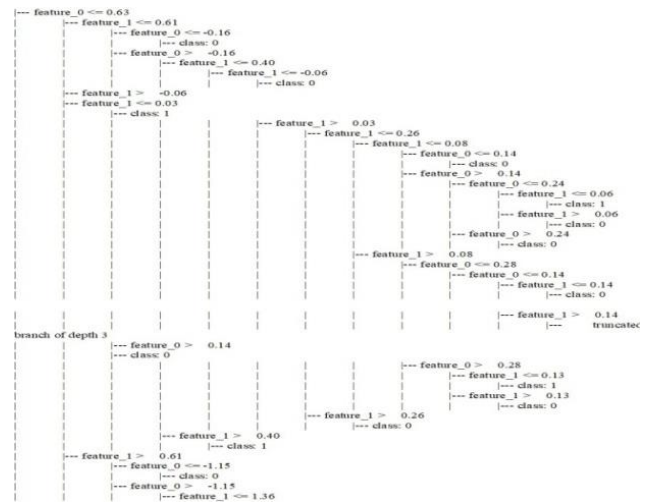

Fig. 2. Text Representation of the Features using Decision Tree.

Optimized Decision tree algorithm was used to train the model having slatted the data into two equal part, half of it to train the model and the remaining half for testing of the model as seen in (Fig. 3).

```
feature_cols = ['Age','EstimatedSalary']
X = data.iloc[:,[2,3]].values y = data.iloc[:,4].values
#split the dataset into training and test
X_train, X_test, y_train, y_test = train_test_split(X,y,test_size = 0.25, random_state= 0)
#perform feature scaling
from sklearn.preprocessing import StandardScaler sc_X = StandardScaler()
X_train = sc_X.fit_transform(X_train) X_test = sc_X.transform(X_test)
#fit the model in the decision tree classifier from sklearn.tree import DecisionTreeClassifier classifier = DecisionTreeClassifier()
classifier = classifier.fit(X_train,y_train)
```

Fig. 3. Code Snippet for Important Feature Selection and Training of Model.

We are able to obtain 90% accuracy on testing our model, after which we decide to optimize for more accuracy and better performance as seen in Fig. 4.

Fig. 4. Model Accuracy and Test Performance Evaluation.

We are able to obtain accuracy of 94% after which we decided to visualize the performance of the model.

We needed to know the level of fitting, because having an accuracy of 94% can be as a result of over fitting of the model with the training set of data, hence we decided to do two additional things. Firstly, we implemented Random Forest Algorithm for training the data again to check performance and then optimize, it gives an accuracy of 92%. Secondly, we fed another set of data in the format of the trained data but new to the model, the model performed very well with accuracy. So, we proceeded to measure the performance of the model using confusion matrix, classification report, and accuracy score which gives good indication of optimal performance. We are in

a dilemma either to ensure about 100% accuracy or over fitting because in supervise machine learning, high accuracy of almost 100% can be as a result of over fitting of the model which we want to avoid by possible means. So, since we are able to feed the model with new set of data which had not been previously fed to the model for which it performed very well with high rate of accuracy. So, we gave priority to avoid over fitting of the model than the accuracy of the model since high accuracy for supervised learning can be as a result of over fitting of the model for which the model becomes less accurate or behaved weird when fed with unfamiliar data. The validation report can be seen in Fig. 5.

```

```

Fig. 5. Validation, Cross Validation and the Estimation of Mean Square Error (MSE).

IV. CONCLUSION

In this applied research, we are able to achieve four goals:

- 1) Avoid direct interaction with integrated data warehouse.
- 2) We are able to access data in a secure cloud computing environment.
- 3) We are able to close the existing gap in data mining and web API, as all we needed to call is the endpoint of our web API. No need of terminal, or uniform resource locator (URL) of any csv is involved. It is simply over a web API.
- 4) As the patterns changes in the background, the algorithm automatically adjusts with accuracy of ninety-four (94) percent after optimization.

We are able to implement data mining in a secure cloud computing environment with accuracy of ninety-four (94) percent after optimization in our decision tree algorithm over web API. All that an AI engineer, data scientist, or machine learning engineer needs is just the endpoint of the API. This removes complexity while at the same time simplifying the whole process, it also add additional layer of security, and also remove unnecessary bottleneck as scientist and engineers will be able to concentrate more on optimizing their algorithm and model for optimal result since only API endpoint is what is needed to be called.

We hope that this will be de-facto standard in the data mining, machine learning, data science and other similar industry at large.

V. LIMITATION AND FUTURE RESEARCH WORK

This research work is based on the quantity of data available to us. Also, as Infrastructure As a Service Provider (IAAS), Software As a Service Provider (SAAS), and Platform As a Service Provider (PAAS) continually improves their service for more secured and enhanced cloud computing environment, over the times, this can affect the performance of the model and the overall architecture, also as more data becomes available, there is possibility of more false positive and this directly impacts the bias-variance tradeoff.

So, there is future research work of developing what we called intelligent model, model which can detect availability or changes in data, detect changes in the cloud computing environment and then re-trained and re-adjust itself over the time in line with those changes.

AI Powered Anti-Cyber Bullying System using Machine Learning Algorithm of Multinomial Naïve Bayes and Optimized Linear Support Vector Machine

Interception of Cyberbully Contents in a Messaging System by Machine Learning Algorithm

Abstract—“Unless and until our society recognizes cyber bullying for what it is, the suffering of thousands of silent victims will continue.” ~ Anna Maria Chavez. There had been series of research on cyber bullying which are unable to provide reliable solution to cyber bullying. In this research work, we were able to provide a permanent solution to this by developing a model capable of detecting and intercepting bullying incoming and outgoing messages with 92% accuracy. We also developed a chatbot automation messaging system to test our model leading to the development of Artificial Intelligence powered anti-cyber bullying system using machine learning algorithm of Multinomial Naïve Bayes (MNB) and optimized linear Support Vector Machine (SVM). Our model is able to detect and intercept bullying outgoing and incoming bullying messages and take immediate action.

Keywords—Cyberbullying; anti cyberbullying; machine learning; NLP; social media; multinomial Naïve Bayes; support vector machine

I. INTRODUCTION

Hatred, violence, and hostility in modern world can take several form [4],[5],[6],[2], one of which is cyber bullying using modern day technology medium. While the era of internet had brought in tremendous innovation and improvements to our daily activities and overall way of life, it had also opened floodgates for cyber bullying. Any devastating act in the mode of aggressive or abusive behavior toward people regarding digital interactions is cyber bullying [1] Fig. 1

The impact of social media like Instagram, Facebook, Twitter, WhatsApp, etc. on daily basis cannot be over emphasize as they had greatly influence modern way of communication As useful as social media is, it is a medium for promoting hatred, harassment, racism, etc. which is currently affecting millions of people across the globe.

Statistical record from 2019 Cyber bullying Data shows that 95% of teens in the U.S. are online, and the vast majority has access to internet on their mobile device, makes social media platform the most common medium for cyber bullying [11]. About 37% of young people between the ages of 12 and 17 have been bullied online. 30% have had it happen more than once [8],[9],[10]. The impact of cyber bullying is very visible in the world today as it had result in several hatred, trauma,

depression, and untimely death. Ryan Halligan (1989–2003), age 13, was an American student from Essex Junction, Vermont, who died by suicide at the age of 13 after allegedly being bullied by his classmates in person and online. While Jeff Weise (1988–2005), age 16, who was also an American high school student who committed the Red Lake shootings killing nine people and himself by suicide after being severally attack by cyber bullying Fig. 2.

There had been several measures and implementations put in place to prevent cyber bullying as a solution but none of them have actually solve cyber bully as the effect of cyber bullying is still obvious in our society.

Fig. 1. Statistical Analysis and Victim of Cyberbullying.

Fig. 2. Statistical Effects of Cyberbullying.

In this research work, Multinomial Naïve Bayes and Optimized Linear Support Vector Machine of machine learning algorithm was successfully used to implement an Artificial Intelligent Powered anti-cyber bullying system capable of detecting and intercepting online cyberbullying messages and filtered [3] them so that the intending recipient doesn't receive it. To ensure a better coverage across billions of device worldwide, we deployed our model and exposed it to a web application programming interface (API). The REST API was developed with Flask python framework, so the API load our deployed model, call it with parameterized input, and then indicated the status if it is cyberbullying or not using natural language processing capability of machine learning for detection and interception. All that any social media website like Facebook, Twitter, Instagram, LinkedIn, Snapchat, YouTube, WhatsApp, etc. needed to do is to integrate it on their platform by calling the API alone. With this implementation, the problem of cyber bullying had been laid to rest. In order to test our implementation in real time, we developed a chatbot automation messaging system, and then use it to consume our restful API service, we got an accuracy of 92% and the model was able to automatically detect and intercept any outgoing and incoming bullying message and then ensure that the intending receiver doesn't receive the message. We also estimate the time taken by the restful API service to detect, intercept, and process messages and discovered that it is negligible fraction of seconds which simply that our implementation can be implemented, deployed, and use in real time.

II. BACKGROUND STUDY

Over the years, there had been several efforts to address the issue of cyber bullying, but none had actually enforce the prevention which is why the rate of cyberbully had remain so high in our society. The authors in [14] from the MIT Media Lab, led by KarthikDinakar implemented an algorithm based on clustering and classification that is able to detect and categorize group of words in an online interaction [3]. The algorithm correctly categorizes contents in online interaction with high accuracy. It could not be used to combat cyber bullying both in real time. Several models and algorithm had been developed from various research labs, but none had been able to combat cyber bullying in real time. Logical probabilistic model of approach was used to develop a socio-linguistic model capable of detecting cybeybullying and the role play in the context of the conversation [15], Natural Language processing method of approach had been employed to identify cyber bullying on chat conversation [11], while Raisi uses Co-trained ensembles for weakly supervised bullying detection of embedded models used RNN and node2vec learners for detecting harassment and bullying from text base data [7].

As different research had been carried out from different research labs and centers, many of which involves the use of Different machine and deep learning techniques to catch word phrases and slangs like k Nearest Neighbor (kNN), Linear Regression (LR), Random Forests (RF), Logistic Regression (LogR), Boosting (Bos), Bagging (Bgg), Adaboost (ADB), Multiple Regression (MR), Maximum Entropy (MaxE), etc.

are being used for detection of cyberbullying on social media [12],[13].

Kainat et al, in 2021 proposed machine learning based algorithm which detects harassment actively and alert user to take action against it [13] But Kainat et al proposal is not feasible in real time and does not solve the problem of cyberbully due to the following reasons:

- 1) It does not intercept the incoming message: A real time anti cyberbully must intercept the incoming message before getting to the receiver.
- 2) The receiver have to take action to delete the content: If someone harasses me online, even though I delete the message, the fact that I already receive it will have psychological effect on me.
- 3) Reliance on csvfile from both sender and receiver which is not feasible due to cost and scalability.
- 4) No API exposure for wide coverage.

In this research work, we were able to implement anti-cyberbully system, which is able to automatically intercept an incoming message before getting to the receiver and take necessary action. Three major steps were involved:

- 1) We used Multinomial Naïve Bayes (MNB) and Optimized Linear Support vector Machine (svm) to train our model.
- 2) Deployed the model.
- 3) Build a Restful API service using Flask framework of Python.

III. RESEARCH METHODOLOGY

For this research, we used different sources of dataset collection which are related to cyber-bullying. The data is from different social media platforms like Kaggle, Twitter, Wikipedia Talk pages and YouTube. The data contain text and labeled as bullying or not. The data contains different types of cyber-bullying like racism, hate speech, aggression, insults and toxicity. Having set up our cloud environment and the necessary programs written, we proceeded by adopting the standard machine learning data cleansing and preparation techniques Fig. 3.

Data cleaning: We use preprocessing and cleaning methods to remove incomplete data that might cause system failure and also affect output prediction. Rows containing missing values where completely removed. We also use different methods to identify and remove noisy data, outliers, and other factors which can influence the output result.

Fig. 3. Data Preprocessing Steps.

Data Reduction for Data Quality: In order to maintain data integrity, we needed to deal with all rows containing null value; hence we opted for python library tool called PyCaret. We have two options which are either to automatically fill all the null values or to remove any row(s) containing null values weighted. Having weighted the risk involves in both, we decided to remove any row with null or empty value from the data, and this was done using PyCaret python library.

Data Transformation: For us to make our data to acceptable format for easy data mining and pattern recognition, it needed to undergo some data transformation. To ensure data is fully transformed to acceptable format, we used Discretization, normalization, and data aggregation technique.

Data Mining: Having successfully set up our apparatus which includes IBM cloud object storage facility, running background window service, active web service, scheduler, and with the data being thoroughly pre-processed and transformed.

Unlike current data mining in cloud computing process in which, one needs to make direct connect to the data warehouse or called the csv file. We only called our web API which was developed and hosted on the cloud as seen below;

Our Artificial intelligence powered anti-cyberbullying system is based on the system of intercepting an outgoing message from the sender. It automatically intercept an incoming message before getting to the receiver and validate the status whether it is bullying or non-bullying. If it is a bullying message, it is automatically blocked from getting to the receiver, and the status of the message will be displayed as 'not delivered' to the sender using a natural language processing mechanism of artificial intelligence. We use machine learning algorithm of Multinomial Naïve Bayes (MNB) and Linear Support Vector Machine (SVM) to train our model, and then expose it to a restful API for global coverage.

A. Implementation with Multinomial Naïve Bayes

Multinomial Naïve Bayes is based on the binomial distribution which is derived from series of combinatorial theorem (Fig. 4).

$$P(X_i|X_j) = P(X_i) \text{ for any distinct } X_i \text{ and } X_j \text{ as well as } P(X_i|X) = P(X_i) \text{ for any } X \subset X \setminus X_i.$$

Expansion and product simplification of the chain rule:

$$P(C_k, X_1, \dots, X_n) = P(C_k) \prod_{i=1}^n P(X_i|C_k)$$

In order to prevent the web service from being overwhelm due to multiple calling of the endpoint at regular interval, we developed a background window service to support the restful API service. Both the web API and the window service are picking records from the integrated data warehouse and pushing to the CSV file on the IBM Object Cloud Storage facility. They automatically pick new records to the CSV, and if a record is modified, it will be picked and modified on the CSV as well. The essence of the scheduler which was written in python is to be calling the web API at regular interval to check and push from the integrated data warehouse to the CSV file.

With the successful setting up of cloud environment and the necessary software programs being in fully execution, we

proceeded by adopting the following data cleansing and preparation techniques.

Data cleaning: We use preprocessing and cleaning methods to remove incomplete data that might cause system failure and also affect output prediction. Rows containing missing values where completely removed. We also use different methods to identify and remove noisy data, outliers, and other factors which can influence the output result.

Data Reduction for Data Quality: In order to maintain data integrity, we needed to deal with all rows containing null value; hence we opted for python library tool called PyCaret. We have two options which is either to automatically fill all the null values or to remove any row(s) containing null values weighted. Having weighted the risk involves in both, we decided to remove any row with null or empty value from the data, and this was done using PyCaret python library.

Data Transformation: For us to make our data to acceptable format for easy data mining and pattern recognition, it needed to undergo some data transformation. To ensure data is fully transformed to acceptable format, we used Discretization, normalization, and data aggregation technique.

B. Implementation with Linear Support Vector Machine

Similar to SVC with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and scale better over a large numbers of samples. This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme (Supervised learning, [online] [11]). We use the inbuilt C implementation which is based on random number generator to select best features so as to ensure low bias and high variance (Fig. 5).

C. Validation and Cross Validation

We obtain an accuracy of over 92% for both Multinomial Naïve Bayes and Linear support Vector Machine, But having such accuracy can be reason for over fitting a times. So we needed to see how the model will behave when fed or exposed to an unfamiliar data. Hence, we didn't jump to conclusion immediately; we decided to do validation and cross validation. We started our validation with confusion matrix and F1 score (Fig. 6).

Fig. 6. Validation Report.

With an accuracy of 96% and a very low mean square error (MSE), our model is certain to have low bias and high variance, hence, we proceeded to developing a restful API using Python's flask framework and then expose our model to the API to ensure the widest coverage. We developed a chatbot automation system and exposed it to our newly developed restful API service. The chatbot automation system has a graphical user interface (GUI) for human interaction.

Since, we have exposed our restful API to our model, the API is automatically called and it immediately intercepts both outgoing and incoming messages and categorizes them based on bullying and non-bullying. If the outgoing message falls into bullying, it automatically filtered it and ensures the receiver doesn't receive it. The sender too will see from the graphical interface that the message did not deliver. In this case, the bullying message does not reach the receiver (Fig. 7).

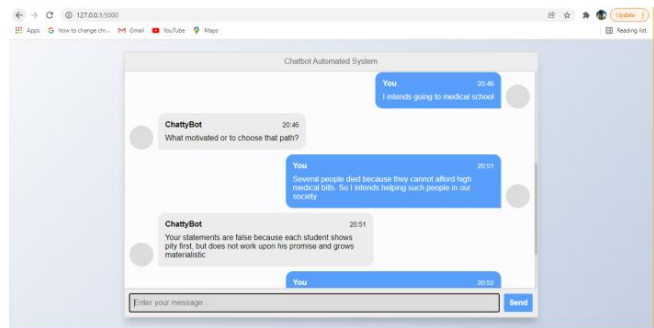

Fig. 7. Chat Messaging GUI.

D. Additional Observation and Time Delivery Comparison

Since, there is an Artificial Intelligence Powered backend implementation that intercepts all outgoing and incoming messages, we deem it necessary to estimate the time for the message to reach the receiver and vice versa since there is an additional backend process of interception. To do this we first removed the backend interception from the newly developed chatbot automation system, and then begin to interact by sending messages from the interface. We discovered that the messages were instantly delivered. Then we decided to re-introduce our restful API which will intercept all messages and feed our trained model, we monitor if for some time during message interaction from the surface. We find out the messages was also delivered on time if it is non-bullying, but if it is bullying the message is not delivered at all. Since, there is no apparent different in time taken when we removed the backend interception process and when we added. We came to conclusion that the extra time taken by the backend message interception process which determine whether the message should be sent to the receiver or not is fraction of a seconds which is negligible.

IV. CONCLUSION

With our research and implementation, we believed the problem of cyber bullying will be solved once and for all if our implementations can be integrated in all the online social media and messengers. Validation and cross validation of our results shows accuracy of 92%, with low bias and high variance and also a very low mean square error (MSE). Our implementation can be adopted and used on any real life social media or online messenger.

Our conclusion will be incomplete without mentioning the limitation of our developed model. The only limitation to our model is the data. The more the data used to train model, the more accuracy it will be.

The data used for this research is from different social media platforms like Kaggle, Twitter, Wikipedia Talk pages and YouTube. The data contain text and labeled as bullying or not. The data contains different types of cyber-bullying like racism, hate speech, aggression, insults and toxicity.

The greatest breakthrough in machine learning is going to be when a deployed model can automatically retrain itself by constantly getting live data from a source, train and update itself without any human effort. Since, model accuracy is somehow dependent with availability of data, and millions of new data are constantly being available in the cloud on daily bases after deploying our model. This will happen at some later time and we will be able to have a super model that is able to get live data, retrain, and redeployed itself on daily bases without human intervention.

Abstract—In a distributed storage and computing framework, traditional streaming data mining techniques are inefficient when processing massive amounts of data. In this paper, we take the copy in cloud storage as an allocatable resource for scheduling and propose a RepRM strategy to improve the efficiency of data mining and analysis. The key idea of this work is to take the data copy as the resource to be allocated, and use the backward inference method of dynamic programming to solve the data copy ratio, the optimal number of copies is obtained. Experiments and observations have proved that compared with the traditional scheduling method of Hadoop, after adopting the RepRM strategy scheduling, the memory resources of the homogeneous cluster are saved by about 40-50% during parallel mining of streaming data, and the throughput rate is increased by 20% to 30%.

Keywords—Streaming data mining; dynamic programming; replica scheduling strategy; cloud computing

I. INTRODUCTION

The continuous development of computer science has resulted in more and more tasks and data needed to be processed, and the computer processing capacity and processing speed have been difficult to meet the needs of users. As a product of virtual technology, cloud computing can process massive data and tasks. However, due to the huge amount of computing, the cloud platform needs to allocate the system resources to each task in the computing process reasonably. What's more, more and more streaming data are stored in the cloud, especially large data analysis systems store a great deal of data, such as data generated by sensors, generated by network management equipment, and generated by core switches, such as log data, audio and video data, etc. and these data are continuously generated in a data stream according to time. Consequently, an effective strategy to allocate the system resources to each task in the computing process is vital.

The mining of massive streaming data is applied to various fields and it produces valuable analytical results for it. Taking marketing as an example, by mining and analyzing the market behavior of a large number of user data, we can guide the further market working by getting the consumption habits of users. For example, according to the consumption situation of users' credit cards, we can directly know the main consumer needs, shopping interests and consumption concepts, which is very valuable information for marketing and product promotion, and is helpful to guide the next market planning.

Because massive streaming data has the characteristics of big data, and for the upper application of cloud storage, the processing and analysis of massive streaming data are very different from the previous processing. Taking data query and mining as examples, users need to query and analyze the accumulated data for a long time when analyzing the data, which has high requirements for the data searching and comparison performance in cloud storage, while the past data query only queries and compare for a certain data. So the traditional streaming data mining technology is inefficient when processing huge amounts of data. Uncontrollable and continuous surge of large volumes of data has exacerbated the trend of "the explosion of data and the lack of knowledge". At this time, the distributed computing platform has become a research hotspot as an effective means to solve the problems [1,2].

Take Hadoop as an example, the homogeneous or heterogeneous distributed computing platform built by it can meet the needs of large-scale data processing technology in scientific research, engineering and other fields, it has become one of the mainstream data processing frameworks of large Internet companies at home and abroad, such as the data processing applications of Yahoo, Twitter, and other companies. With the increasing scale of the Hadoop cluster and the increasing fields of use, the management and usage of resources are increasingly valued. Many researchers take YARN's resource scheduling algorithm as their research direction, through researching and designing reasonable resource allocation algorithms to achieve higher resource utilization. But among the numerous studies, according to the characteristics of streaming data, it is rare to design and implement the resource scheduling strategy of the data mining algorithm, so that the current mining model for streaming data in the cloud platform cannot effectively allocate the resources in the cluster, or complete the mining of streaming data efficiently.

In practical applications, most streaming data mining algorithms are aimed at a certain type of streaming data [3,5]. The operating parameters of the algorithm are determined in the program initialization stage and cannot be dynamically modified, which is called a "static algorithm" [4]. Although some algorithms can be regulated through parameter adjustment to adapt to the dynamic application environment, these dynamic algorithms are relatively rigid and have no learning and adaptive capabilities. For example, Franke pointed out that streaming data is usually a sequence of data objects with time as the latitude. Therefore, the execution process of

more streaming data mining algorithms is sorted according to the time when the data arrives sequentially, and a single linear scan method is used to analyze the data. Analyze and compare [4].

Alternatively, the relationship between steaming data and environmental differences has been considered by Knorr and other professors. Different environments can lead to differences in the expression form of streaming data, which can then lead to differences in data mining algorithms. For example, the resource allocation of a computer system is dynamic, and the data mining algorithms may allocate more or fewer resources (such as CUP, memory, etc.) because of the actual load situation of the computer system, and the number of resources will directly affect the response time and processing time of the streaming data mining algorithm. Therefore, an adaptive resource scheduling method is needed so that the resources can be adjusted according to the different streaming data.

The work done in this paper is as follows: First, verify the impact of replicas on the throughput of streaming data mining. After analyzing the relationship between the copy and the throughput rate of streaming data mining, the resource allocation model of streaming data mining is established. Secondly, according to the characteristics of streaming data, the resource scheduling model of the cloud platform incorporates the copy data resources and the resource (replica) scheduling model for the cluster. Once again, build a model to analyze and solve. Finally, based on the Hadoop big data platform, the scheduling model was implemented by improving the YARN component. What is more, in order to verify the effectiveness of the copy-based resource scheduling model, we use two types of test data sets and real network traffic data sets to test the improved resource scheduling strategy.

II. RELATED WORK

In order to propose an efficient resource scheduling model, we should consider the challenges which come from several aspects. Then we will investigate the recent research about these challenges as follow to build a proper model [6].

Dominant Resource Fairness (DRF) is a multi-resource allocation algorithm of max-min fairness [7]. The authors introduced that dominant share is the largest share of any resources that distribute to the user, and DRF conceived that the number of resources assigned to the user should be determined by its dominant share. After all, the purpose of DRF is to seek the maximum of the minimum share among all users. While DRF figured out the demand heterogeneity of multiple resources, however, DRF neglects the heterogeneity, it based on an assumption that computing resources are generally assumed to be isomorphic. In order to resolve more problems, many researchers have optimized and expanded DRF. DRFH [8] is a multi-resource allocation mechanism. For DRFH, the resources are pooled by a large number of heterogeneous servers; they are representing processing, memory, storage and so on. DRFH equalizes the global dominant share allocated to each user. However, it fails to consider users' placement constraints. PS-DSF [9], an extension of DRF is applicable for heterogeneous resource-

pools in the presence of placement constraints. Its solution is defining a virtual dominant share.

For further study, the current schedulers such as DRF which only for the fairness can't meet our needs, so professionals investigated other schedulers which consider the counterbalance between performance and fairness [6]. Gemini [10] considers two scheduling policies during runtime, the former maximizes the utilization of resources by balancing the remaining capacity of the resources of the node, while the latter is to fairly allocate resources to users in a system containing multiple types of resources. During the adjustment process, the strategy will be selected by estimating the loss of performance and fairness.

The cost of a great deal of energy consumption has taken up a considerable part of the total cost of the data center. When we not only need to reduce this part of the cost, but also meet the QoS requirements of users, it's been a main research topic of resource scheduling strategy. EFS [11] is an Energy-aware Fair Scheduling framework based on YARN, EFS uses dynamic node management. It can meet the users' QoS requirements and reduce the energy consumption, because of the energy-aware resources scheduling and the strategy of turning off the unused nodes for a specified duration. However, EFS does not consider the data distribution and replication dependencies.

In recent years, cloud storage systems have emerged as a promising technology for storing data blocks on various cloud servers [12], and replica is the basic means of tolerance and availability of the distributed systems, so the distribution of data copy is significant to the systems [13], many problems can be resolved by data replication algorithms. However, data replication also produces energy consumption and costs, so it is very important to reasonably schedule copy resources in resource scheduling, there are also many kinds of research about this topic.

In order to solve the problem about the placement of data replica, Cui et al. [14] build a tripartite graph-based model, and propose a genetic algorithm-based data replica placement strategy. The dynamic multi-objective optimized replica placement and migration strategies for SaaS applications in edge cloud are proposed by Chunlin et al. [15]. According to the result of the experiment, this strategy can improve the utilization rate of network resources. Huang and Wu [16] not only proposed an optimization model for data replication and placement problem, but also designed hybrid genetic algorithm based on data support degree to solve the model. The algorithm is found to have good performance by using real data set. Khojant et al. [17] proposed Predictive Frzyzy Replication (PFR). The new algorithm can replicate the historical usage of files, files size, the level of the sites and free available space for replication in advance and decide which replications should be deleted through forecasting of future demand and the relevant file of the replications to save cost. Salem et al. [18] created a new algorithm derived from a combination of ABC and Multi-Objective Optimization. The proposed MPABC algorithm enables fast access to the data and selects the best copy location closest to the user.

In these present studies, the purpose of most resource scheduling models is to allocate resources such as CPU, memory and bandwidth, they don't consider the data replica, CPU and memory simultaneously, unified scheduling. So we incorporate data copy as a scheduling resource when build a new resource scheduling model. And from the perspective of the whole process of data processing, the bottleneck of the big data processing performance in the distributed computing platform lies in the data transmission consumption, not the CPU computing power [19]. Therefore, an effective resource scheduling method is needed to select appropriate nodes for data processing, that is, considering the location of the current copy, data mining is performed on the node where the copy is located, so that the mining speed is greatly improved. Based on this, this article starts from the perspective of copy selection, takes the copy as a data resource and considers it as the computing resource at the same time, and uses the dynamic programming model to design the resource scheduling model of the big data platform to improve the data mining throughput rate of the cloud platform.

III. MATERIALS AND METHODS

A. Distributed Application and Copy Selection

In order to take Hadoop and OpenStack as examples, the copy in the cloud platform is generally set to 3, which means that the same data may only exist in a few nodes of the cloud platform. Therefore, when a distributed application applies for the use of resources such as CPU and memory, the positional relationship between the node where the resource is located and the copy is extremely important.

1) *Verification of the impact of replicas on distributed mining:* For the purpose of verifying and testing the impact on data copies on distributed mining, we use the KDD CUP 2000 data set for verification, and use Hadoop clusters and stand-alone machines to analyze and mine streaming data respectively. Table I shows that the Hadoop and single configuration used for the experiment. The experimental process is to extract NetFlow seven-tuples from KDD CUP 2000. What is more, The Hadoop test uses MapReduce to submit a task which is NetFlow analysis to Hadoop, and the stand-alone test uses the network interactive analysis tool set SILK for NetFlow seven-tuple analysis.

The results of the experiment are shown in Fig. 1. It can be found from the experiment that when the total amount of data is small (less than 400G), in contrast to the Hadoop distributed platform, in data analysis ability, a single machine has apparent advantages, which is just 70%. When the total amount of data is large (greater than 400G), the Hadoop distributed platform shows its advantages progressively. When the amount of data is 500G, the analysis time is only 84% of the single machine. But 5 servers make up this distributed platform, and the single platform uses just one server. It can be seen that using the single platform used in the experiment can process 400GB stream data within 15 minutes, which can meet the seven-tuple analysis of about 3.5Gpbs network traffic.

TABLE I. SERVER CONFIGURATION OF THE EXPERIMENT

Hadoop	Stand-alone
4 slave hosts: CPU: Two-way four-core 2.6G RAM: 48G Disk: 40TB	CPU: Two-way eight-core 2.6G RAM: 60G Disk: 20TB
1 master host: CPU: Two-way eight-core 2.6G RAM: 60G Disk: 20TB	

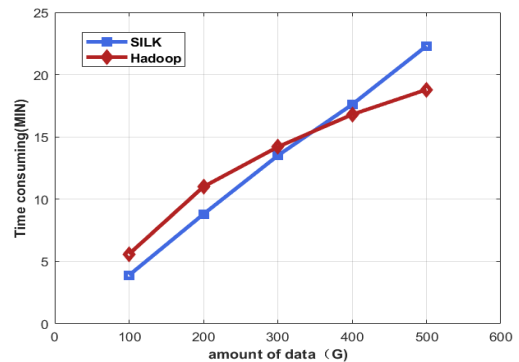

Fig. 1. Time Consuming (MIN).

In situation of a bit of data, the location of the replica in the Hadoop cloud platform will affect the throughput rate of the distributed platform for traffic analysis. Hadoop's three-copy strategy requires some computing nodes to wait for the completion of the network transmission of data, thus increasing the time consumption of network transmission; and the MapReduce task allocation mechanism has a certain time loss at the beginning and end of the task. Therefore, in the case of a relatively small amount of data, low throughput for traffic analysis on distributed platforms.

2) *The optimization problem of data copy in data mining:* Through the verification of 1), disposable resources such as replicas are important factors that apparently affect the capability of data mining algorithms. Both the results and throughput of data mining algorithms not only depend on the allocation of computing hardware resources such as CPU time and available memory, but are also closely related to the number of copies. In the case of a small number of copies and limited computing resources, there will be a disparity between data mining algorithm results and the optimal results.

The mining model can adjust itself by modifying its copy resources and computing resources, thereby increasing the throughput of the mining model. Therefore, to make the throughput of the mining algorithm higher, we need to adjust the computing resources's allocation and data resources. Especially for real-time streaming data mining, it is more necessary to dynamically adjust how computing resources and data resources are allocated, so that the real-time mining model is resource-adaptive [4].

Take the WEB server as an example, the WEB server needs to process a large number of incoming and outgoing data packets in the network in real-time. This is the typical stream of data. Within a period of time, the WEB server will receive data packets from the Internet and send a certain number of data packets to the Internet in chronological order. These data packets are usually organized in the form of IP data packets. Each IP data packet constitutes a stream data object, which together constitutes a data stream on the WEB server. When the network traffic is large enough, due to the limited resources of the host, online analysis, offline analysis, and initial filtering of stream data will all cause conflicts in resource usage.

For the contradiction between resources and speed, the solution is to effectively allocate limited data resources and computing resources [20, 21]. Taking the traditional mining model as an example, it will affect the four modules of the model: data filtering module, online mining module, offline mining module and resource detection module. Assuming that the process of processing a stream data object includes data online mining module, resource detection module, offline processing module and data filtering module, the total amount of available resources is R , of which data online mining module, resource detection module, offline processing module and the resources consumed by the data filtering module are R_1 , R_2 , R_3 and R_4 . Among these four modules, the online mining module and the data filtering module need to detect and process the data in real-time, so the resources consumed are increased or decreased at the same time; on the other hand, the offline mining module processes the data offline, the resources which are consumed do not increase or decrease at the same time as the first two. According to this situation, the resource consumption can be adjusted into three parts: the overall consumption R_1+R_4 of the online mining module and the data filtering module, and the consumption R_2 and R_3 of the resource detection module and the offline mining module. So when the total amount of resources R is certain, how to effectively allocate the resources of R_1+R_4 , R_2 and R_3 , so that the throughput rate of the online mining module, resource detection module, offline mining module and data filtering module can be increased to V_1 , V_2 , V_3 and V_4 , which maximizes the throughput rate, is a dynamic programming problem that optimizes resource allocation. To resolve this problem, the following modeling is required:

$$R = \sum_{i=1}^n R(p, z(p)) \quad (1)$$

In order to deal with the problem about dynamic programming, the resource allocation process is first divided into n different stages to allocate resources. In the p th stage, the p th module is allocated resources by the system. After the allocation is completed, the number of resources remaining in the system is $q(p+1)$. Then the system allocates the remaining resources $q(p+1)$ to the $p+1$, $p+2$, ..., n th modules. The optimal function value that can be obtained in the $p+1$ stage is set to $t(q(p+1), p+1)$, that is, under the premise of resource $q(p+1)$,

the final $p+1$ to n is completed. The maximum mining throughput rate that can be obtained by the allocation of each module.

Then, for dynamic programming problem, the basic equation is:

$$t(p, q(p)) = \max_{z(p) \in M(q(p))} \{R(p, z(p)) + t(q(p+1), p+1)\},$$

$$p = n-1, \dots, 1 \quad (2)$$

$$t(n, q(n)) = R(p, z(n))$$

The corresponding state transition equation is:

$$q(p+1) = q(p) - z(p) \quad (3)$$

For the resource optimization problem, according to Formula 2 and Formula 3, a related mathematical model is established. To solve the model, the optimal decision sequence $(z'(1), z'(2), \dots, z'(n))$ can be obtained through the inverse method, and then the maximum throughput rate $R(q(1))$ of the mining algorithm can be obtained. Specifically, in the data mining model, n is the 4 modules in the model, that is, $n=4$, and the total resource number S is the number of copies of the data resource.

In a distributed system, it is supposed that the resources of S units need to be allocated to n modules, where S represents the number of stream data objects that can be processed and is a positive integer. Assuming that the throughput of data mining can be increased to $R(k, z(k))$ after $z(k)$ resource units are allocated to the k th module, then the overall goal of resource allocation is to allocate S to each module. The resources of each unit finally make the total throughput of mining reach the highest, that is, the R value in Formula 1 reaches the maximum.

In this paper, we know that in the distributed framework, data mining is usually carried out in parallel, so it is usually multiple mining algorithms to mine massive data. Taking a typical parallel mining model as an example, suppose that there are S units of resources need to be allocated by distributed system to n parallel mining algorithms, and S is the number of data copies that can be allocated. Assuming that the throughput rate of data mining can be increased to $R(p, z(p))$ after allocating $z(p)$ units of resources to the p -th mining algorithm, then the overall goal of resource allocation is to be reasonable for the data mining algorithm to allocate S data copies, and finally maximize the mining throughput rate, in other words, the R value in Formula 1 reaches the maximum.

Similarly, in order to deal with the optimization problem, the allocation replica is grouped into n distinct phases in the resource allocation process in a distributed system. The p th algorithm is allocated data copy resources by the system in the p th stage. After the allocation is completed, the number of copies remaining in the system is $q(p+1)$. Similarly, the optimal function value that can be obtained in the $q(p+1)$ stage is set to $t(q(p+1), p+1)$. According to Formula 2 and the related theory of dynamic programming, the basic equation of the mathematical model can be determined at first:

$$t(p, q(p)) = \max_{z(p) \in M(q(p))} \{R(p, z(p)) + t(q(p+1), p+1)\},$$

$$p = n-1, \dots, 1$$

$$t(n, q(n)) = R(p, z(n)) \quad (4)$$

According to the above Formula 4, the state transition equation in the mathematical model can be determined as:

$$q(p+1) = q(p) - z(p) \quad (5)$$

According to the established mathematical model, the solution of this model can be used to obtain the optimal decision sequence $(z'(1), z'(2), \dots, z'(n))$ through the inverse method, so as to the mining throughput reaches the maximum value $R(q(1))$.

B. Replica Scheduling Strategy RepRM for Streaming Data

For big data systems (such as Hadoop systems), the distributed resource scheduling problem is an NP-hard problem. Mass flow data has a certain degree of no aftereffect, so the traditional scheduling algorithm can't allocate system resources well. In the whole process of mining algorithm operation, if adjustment of resources is a decision, the data mining between two decisions is a stage. Therefore, the resource allocation problem in distributed mining of streaming data is a dynamic programming problem. When performing distributed mining on streaming data, the resource allocation for it can be described as: how to allocate limited resources to multiple mining algorithms, so that the mining model can mine the streaming data to the greatest extent.

For various algorithms of parallel mining, take K-Means, KNN and Apriori algorithms as examples. It is assumed that each algorithm is performing streaming data mining, we need to consider how to build a model which can allocate limited resources to these algorithms to make the entire parallel mining model throughput rate be the largest. The problem comes down to how to allocate data copy resources to maximize the throughput of the parallel mining model, which is also a resource scheduling problem.

1) *Replica scheduling based on the copy*: Assuming that there are R assignable data copy resources in the distributed computing platform, n data mining algorithms are running on the platform at the same time, and the throughput of the algorithm in mining is related to the amount of replica resources put into use. Assuming that the i-th data mining algorithm are allocated by r_i data copy resources, and the throughput rate of the i-th mining algorithm is $f_i(r_i), i = 1, 2, 3, \dots, n$. At this time, the whole throughput rate of the platform's n algorithms on mining is $f_i(r_i), i = 1, 2, 3, \dots, n$.

Then the problem boils down to how to allocate R data copy resources: for n data mining algorithms, in order to maximize the total throughput rate, the total throughput rate reaches $g_n(r_n)$. The programming model is as below:

$$\text{Max} : Z = f_1(r_1) + f_2(r_2) + \dots + f_n(r_n)$$

$$\text{s.t.} \begin{cases} r_1 + r_2 + \dots + r_n = R \\ r_i \geq 0, i = 1, 2, \dots, n \end{cases} \quad (6)$$

This depends entirely on the throughput function $f_i(r_i)$ of each mining algorithm. When $f_i(r_i)$ is a linear function. It is a linear programming problem; when $f_i(r_i)$ is a non-linear function, it is a nonlinear programming problem. Especially when n is relatively large, the solution process is extremely troublesome. However, due to the inefficiency of massive data, the problem is to solve a parallel resource allocation model, which can be solved by using the inverse relationship of dynamic programming.

Let the state variable of the number of data replication resources allocated to algorithm k to algorithm n be s_k , and the decision variable u_k represents the number of data copy resources allocated to algorithm k. After the data copy resource allocation decision of algorithm k is completed, let the number of data copy resources obtained by algorithm k be r_k , that is, $u_k = r_k$ after the allocation is completed. At this time, the number of replica resources r_k allocated to algorithm k satisfies:

$$s_{k+1} = s_k - r_k \quad (7)$$

And because $u_k = r_k$, you can get:

$$s_{k+1} = s_k - r_k = s_k - u_k \quad (8)$$

The allowed decision set is:

$$D_k(s_k) = \{u_k \mid 0 \leq u_k = r_k \leq s_k\} \quad (9)$$

When the number of data copy resources of s_k is allocated to the k-th to n-th algorithms, the platform can get the maximum mining throughput rate of $g_k(s_k)$, and the inverse relationship of dynamic programming can be obtained:

$$\begin{cases} g_k(s_k) = \max_{0 \leq r_k \leq s_k} \{f_k(r_k) + g_{k+1}(s_k - r_k)\}, k = n-1, \dots, 1 \\ g_n(s_n) = \max_{r_n = s_n} f_n(r_n) \end{cases} \quad (10)$$

Using Formula 10, we can calculate one by one algorithm, and finally get $g_1(s_1)$.

2) *Replica scheduling model RepRM*: Distributable data copy resources and changes in data characteristics are two important factors that affect the throughput of data mining algorithms. In distributed streaming data mining, the available resources can be reasonably allocated to the mining model according to the number of copies and the characteristics of the streaming data, and the throughput rate of the model can be improved.

If only considered the computing resources, the CPU and memory contained in each server are almost the same, and the allocatable resources used by each node for streaming data mining are also almost the same. Then the problem can be simplified to the configuration of data copy resources. At this point, the problem turned into a resource allocation problem.

Take a Hadoop cluster as an example. The cluster is composed of R identical servers (for example, DELL 820), which are used for network traffic analysis and mining. When multiple different users submit n network traffic data mining algorithm requests, the mining throughput rate is $f_i(r_i), i=1,2,3,\dots,n$, and the inverse method can be used to solve the problem. Assume that in this example, the cluster is composed of 5 homogeneous servers. At present, the Apriori algorithm is already running for online mining of streaming data. At the same time, two users request to use the KNN algorithm and the K-Means algorithm for offline mining of streaming data. And according to the number of data copies allocated to the mining algorithm, the sampling size during mining is also inconsistent. The specific sampling size is shown in Table II.

TABLE II. DATA COPY RESOURCE ALLOCATION AND SAMPLING SIZE OF HOMOGENEOUS CLUSTER

Number of servers	0	1	2	3	4	5
K-Means	0 Gbps	3 Gbps	7 Gbps	9 Gbps	12 Gbps	13 Gbps
KNN	0 Gbps	5 Gbps	10 Gbps	11 Gbps	11 Gbps	11 Gbps
Apriori	0 Gbps	4 Gbps	6 Gbps	11 Gbps	12 Gbps	12 Gbps

At this time, according to Formula 10, the inverse method can be used to obtain the optimal solution, and the solution process is as follows.

Solution:

$$\begin{cases} g_k(s_k) = \max_{0 \leq r_k \leq s_k} \{f_k(r_k) + g_{k+1}(s_k - r_k)\}, k = n-1, \dots, 1 \\ g_n(s_n) = \max_{r_n = s_n} f_n(r_n) \end{cases} \quad (11)$$

Stage 3: When assigning s_3 data copies ($s_3=0,1,2,3,4,5$) to the Apriori algorithm, the sampling size is:

$$g_3(s_3) = \max_{r_3} [f_3(r_3)], r_3 = s_3 \quad (12)$$

Because only the Apriori algorithm is mining at this time, all data copies in the cluster can be allocated to it, so its sampling size is the maximum sampling size at this stage, as shown in Table III, in the table r_3^* means that $g_3(s_3)$ is the optimal decision at the maximum value.

Stage 2: Assuming that s_2 data copies ($s_2=0,1,2,3,4,5$) are allocated to the Apriori algorithm and the KNN algorithm, then for each s_2 value, the available sample size is:

$$g_2(s_2) = \max_{r_2} [f_2(r_2) + g_3(s_2 - r_2)], r_2 = 0,1,2,3,4,5 \quad (13)$$

TABLE III. RESOURCE DYNAMIC DECISION OF HOMOGENEOUS CLUSTER STAGE 3

r_3	$f_3(r_3)$						$g_3(s_3)$	r_3^*
	0	1	2	3	4	5		
0	0						0	0
1		4					4	1
2			6				6	2
3				11			11	3
4					12		12	4
5						12	12	5

Because r_2 data copies of the KNN algorithm are allocated, the mining throughput rate is $f_2(r_2)$, and the remaining $s_2 - r_2$ data copies are used in the Apriori algorithm, so the Apriori throughput rate is $g_3(s_2 - r_2)$. The sample size is $f_2(r_2) + g_3(s_2 - r_2)$ at this time. Therefore, it is necessary to select an appropriate value of r_2 to maximize the function. At this time, the numerical calculation table is shown in Table IV.

Stage 1: In order to obtain the maximum mining throughput rate, 5 data copies need to be allocated to the algorithms for calculation. Therefore, when $s_1=5$ data copies are allocated to the Apriori, KNN and K-Means algorithms, the mining throughput rate is:

$$g_1(5) = \max_{r_1} [f_1(r_1) + g_2(5 - r_1)], r_1 = 0,1,2,3,4,5 \quad (14)$$

At this time, the maximum value of this function is the maximum mining throughput rate. The specific numerical calculation table is shown in Table V.

According to the numerical calculation table, there are two executable solutions:

1) When $r_1^*=0$, look up Table V and Table IV to know that the allocation plan at this time is: $r_1=0, r_2=2$, and $r_3=3$.

TABLE IV. RESOURCE DYNAMIC DECISION OF HOMOGENEOUS CLUSTER STAGE 2

r_2	$f_2(r_2) + g_3(s_2 - r_2)$						$G_2(s_2)$	r_2
	0	1	2	3	4	5		
0	0						0	0
1	0+4	5+0					5	1
2	0+6	5+4	10+0				10	2
3	0+11	5+6	10+4	11+0			14	2
4	0+12	5+11	10+6	11+4	11+0		16	1,2
5	0+12	5+12	10+11	11+6	11+4	11+0	21	2

TABLE V. RESOURCE DYNAMIC DECISION OF HOMOGENEOUS CLUSTER STAGE 1

r_1	$f_1(r_1) + g_2(5 - r_1)$						$G_1(5)$	r_1
	0	1	2	3	4	5		
5	0+21	3+16	7+14	9+10	12+5	13+0	21	0,2

That is, the K-Means algorithm does not allocate data copies, the KNN algorithm allocates 2 data copies, and the Apriori algorithm allocates 3 data copies. At this time, the maximum throughput rate of the mining algorithm is 21Gbps.

2) When $r_1^* = 2$, look up Table V and Table IV to know that the allocation plan at this time is: $r_1=2, r_2=2$, and $r_3=1$.

That is, the K-Means algorithm allocates 2 data copies, the KNN algorithm allocates 2 data copies, and the Apriori algorithm allocates 1 data copy. At this time, the maximum throughput rate of the mining algorithm is 21Gbps.

IV. RESULT

A. Experiments and Observations

This article implements the RepRM model by revising the resource management and scheduling component (YARN) in Hadoop and modifying the Scheduler component in the Resource Manager module. By default, YARN only supports memory scheduling (such as Capacity strategy, Fair strategy). It uses "containers" to encapsulate memory and CPU. When tasks have resource requirements, they apply to YARN for the CPU and memory "containers" required by the task.

In the testing session, we conducted experiments and observations on the RepRM replica scheduling method. For the parallel streaming data mining model, we used KNN, K-Means and Apriori algorithms to simultaneously mine online. Then observe the differences between YARN's built-in Capacity strategy, Fair strategy and the improved RepRM strategy.

1) *Experimental environment*: In the experiment and observation, the Hadoop cluster used for testing is a 2U rack-mounted DELL PowerEdge FX2 server with a convergent architecture, which contains 4 nodes, and the operating system uses CentOS. The hardware configuration of each node is shown in Table VI. The experimental data includes two test data sets: the test data set generated by the IBM synthesizer and the WEB access traffic data.

a) *Experimental data set: IBM synthetic data*: The data set in this experiment is the T10-I5-D1000K data set produced by the IBM synthesizer [10], where T, I, and D mean the average length of the transaction, the average length of the pattern, and the number of transactions.

b) *Experimental data set: WEB access traffic*: The WEB access traffic used for testing was collected at the network exit of the library of Huazhong University of Science and Technology. The collection program is connected to the egress gateway through the bypass, and the program filters and saves the traffic of the WEB service.

c) *Evaluation index*: In the comparative experiment, YARN's built-in Capacity strategy, Fair strategy, and dynamic planning improved RepRM scheduling strategy are used for resource scheduling, and parallel data mining using K-Means, KNN, and Apriori algorithms. We observe the performance of RepRM from multiple angles: For the mining of test data sets, we compare the throughput and memory usage of parallel mining. By comparing the data obtained from these two sets of

experiments, we observe the different performance of the Capacity strategy, Fair strategy and RepRM strategy.

2) *Mining experiment of IBM synthetic data set*: In experiments based on data sets, we will pay attention to analyze the time complexity and space complexity of the algorithm. When comparing the two data, because the DARPA 99 data collective is at the GB level, and the T10-I5-D1000K is only at the MB level, in order to visualize it on the chart, we will use the test result value of the T10-I5-D1000K data set. It is 1000 times larger, so that it can be compared with the test results of the GB-level DARPA 99 data set.

In the time complexity test, the execution time of the mining model is compared. Fig. 2 shows the parallel mining results of the Capacity strategy, the Fair strategy and the RepRM strategy. It can be seen from Fig. 2 that the execution time of the RepRM strategy is lower than the Capacity strategy, what is more, it is also lower than the Fair strategy that Hadoop comes with. According to the data shown in the experimental results, compared with the Capacity strategy, the execution time of the RepRM strategy is about 70%, and compared with the Fair strategy, the execution time is about 65%. Therefore, the RepRM strategy increases the mining throughput rate by 25% compared with the Fair strategy and 30% compared with the Capacity strategy.

In the comparison of space complexity, the comparison is still based on the memory footprint of the algorithm. The specific data and comparison are shown in Fig. 3. The RepRM strategy has the least memory footprint, the Fair strategy has the middle memory footprint, and the Capacity strategy has the largest memory footprint. The experimental results show us the memory container consumption of the RepRM strategy is only 60%, and only about 53% compared to the Fair strategy.

TABLE VI. SERVER CONFIGURATION OF THE EXPERIMENT

Model	DELL FX2(Including 4 blade servers)
Master	128GBRAM/ 2TBDisk/Operating System CentOS 6.5
Slave1-Slave3	64GBRAM/ 2TBDisk/Operating System CentOS 6.5
Hadoop version	Cloudera 2.2
Network environment	1000M

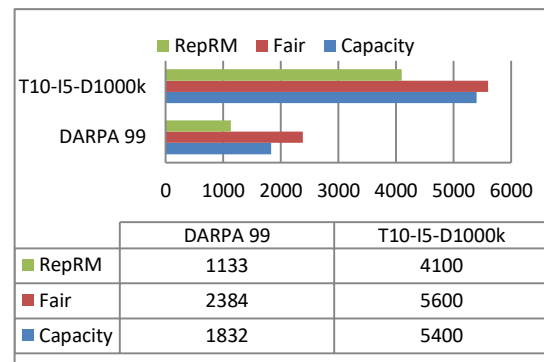

Fig. 2. Execution Time Comparison for the Three Strategies in the Parallel Model.

Fig. 3. Memory Footprint Comparison for the Three Strategies in the Parallel Model.

Through four sets of experimental data, it can be seen that the RepRM strategy improves the mining throughput rate by about 25-30% for the resource scheduling strategy that comes with YARN, and saves about 40% of resources in the consumption of memory containers. The reason is:

a) *RepRM strategy is resource-adaptive.* When the Capacity strategy and Fair strategy allocate tasks in Map-Reduce, they only allocate resources based on the existing remaining resources, rather than allocating tasks based on all running tasks. RepRM is based on the throughput of all tasks for dynamic scheduling and appropriate allocation of resources.

b) *YARN's own strategy does not consider the impact of copies on mining throughput.* For distributed mining under the condition of multiple copies, after the task is allocated by Map-Reduce, when there are more computing resources such as CPU and memory, it is necessary to wait for the network transmission of the copy. RepRM allocates computing resources based on the number of data copies, saving network transmission waiting time.

3) *Mining test of network traffic:* Before the start of the experiment, first, we use a data capture tool to capture and save the throughput network traffic from a certain WEB server within 240 hours; then we use the traffic replay toolkit to reproduce the saved traffic file; at the same time, the mining model in the cluster captures and mines traffic data, so that the stream data-parallel mining model can mine WEB traffic data.

Under normal circumstances, the traffic of the WEB server should be IP packets following HTTP, HTTPS and other protocols. If there is a network attack or intrusion (such as DDOS and TearDrop, etc.), the network traffic data in a certain period of time has certain abnormal characteristics, such as the statistical count of the source address in the seven-tuple. This abnormal characteristic is normal. There have a big difference in flow.

Due to the small traffic of the WEB server (KB-MB level), the simulation of a large traffic and large concurrent environment cannot be completed, so that the mining algorithm

does not consume all the resources that can be allocated. Therefore, in specific processing, by collecting network traffic data within 240 hours, and replaying the traffic to the network within a few hours, considering the carrying capacity of the cluster, the memory usage of the mining model in large-traffic and large-concurrency environment is usually relatively large. In order to avoid the emergence of a deadlock, the maximum memory that can be allocated by each scheduling strategy is limited to 20GB.

Fig. 4 records the value of the mining throughput rate under the Capacity strategy, Fair strategy and RepRM strategy scheduling of the parallel mining model at different flow rates. Fig. 5 records the value of the memory usage. In Fig. 4, when the network data flow rate is low, the Capacity strategy, the Fair strategy and the RepRM strategy can effectively mine the data. With the increase of network data traffic, the throughput rates of the three resource scheduling strategies have gradually increased. When the maximum allocable memory condition of 20G memory is reached, the maximum throughput rate of the Capacity strategy, the Fair strategy and the RepRM strategy is about 3Gbps, 4Gbps and 6Gbps, respectively.

Fig. 5 shows the memory occupancy of the parallel mining model under the Capacity strategy, Fair strategy and RepRM strategy scheduling under different network data flow rates. As shown in Fig. 5, when the network data flow rate is low, the memory footprint of the three resource scheduling strategies is roughly the same, and the value is relatively low. At the same time, it can be seen that the Capacity strategy and the Fair strategy are similar, and slightly larger than the memory occupied by the RepRM strategy. In addition, with the increase of traffic, the memory consumption of the three strategies has gradually increased. When the flow rate reaches 4Gbps, the Capacity strategy and the Fair strategy have exhausted 20G of memory, and when the flow rate reaches 7Gbps, the RepRM strategy has exhausted 20G of memory.

The RepRM resource scheduling strategy considers the location of the data copy in the memory allocation, which can better eliminate the network transmission time of the data copy, so that the mining model can effectively mine. Based on the experimental results in Fig. 4 and Fig. 5, compared to the Capacity strategy and the Fair strategy, RepRM's resource utilization for parallel data mining has increased by about 40%.

Fig. 4. The Effect of Flow Rate on Throughput.

Fig. 5. The Effect of Flow Rate on Memory Consumption.

Table VII shows the accuracy and window size of parallel mining when using the RepRM strategy to schedule resources under different traffic conditions. According to Table VII, when the traffic reaches 6Gbps, because the RepRM resource scheduling strategy has exhausted 20GB of available memory, the network data packet mining capability of the mining model cannot be increased anymore. After that the sampling frequency of the window can only be modified. Mining is carried out, but the sampling method of streaming data seriously affects the accuracy of mining, which makes the accuracy rate continue to decline.

TABLE VII. PARALLEL MINING EXPERIMENTS USING REPRM RESOURCE SCHEDULING

Model	DELL FX2(Including 4 blade servers)
Master	128GBRAM/ 2TBDisk/Operating System CentOS 6.5

V. CONCLUSION AND FUTURE WORK

For the mining of massive streams of data, resource allocation has always been a hot research topic. Researchers use various models to schedule CPU, memory, bandwidth, etc., in order to achieve ideal mining results. Especially when performing distributed mining of massive flow data, reasonable resource scheduling can achieve better mining results. However, most researchers did not consider the impact of the location of the data copy on the mining effect, and did not use the data copy as a resource for scheduling.

According to this, for distributed data mining, this paper takes the data copy in the cloud platform as a resource and incorporates it in the resource scheduling strategy for consideration, and realizes a copy-aware resource scheduling strategy RepRM. The RepRM strategy uses data copies as data resources, memory as computing resources, and uses a dynamic programming method to uniformly schedule data resources and computing resources, to improve the adaptability of the mining model to the data and computing resources in the cloud platform. In RepRM, data copies are regarded as resources that need to be allocated. At the same time, in order

to solve the problem of data copy ratio, this paper adopts the dynamic programming method to achieve the maximum mining throughput of the cluster.

Then, this paper conducts simulation tests on parallel mining of streaming data through experiments. The test results prove that the RepRM resource scheduling strategy proposed in this paper has obviously advantages compared to the original resource scheduling strategy of Hadoop itself. After the homogeneous cluster is scheduled through the RepRM strategy, memory resources are saved by about 40-50% during parallel mining of streaming data, and the throughput rate is increased by 20%-30%. After the heterogeneous cluster is scheduled through dynamic planning, the throughput of parallel mining of streaming data is increased by 30-40%, saving about 40% of memory resources.

We aim to extend the RepEM strategy to the use of heterogeneous clusters by taking both the data copy and memory resource as resources and use Lattice point method to solve the problem. What's more, we plan to add more kinds of datasets for further research.

Abstract—The paper examines the issues of the use of adaptive testing systems in terms of their incorporation in artificial neural network modules designed to solve the problem of choosing the next question, thereby forming an individual testing trajectory. The study presents an analysis of data affecting the quality of problem-solving, proposes a general modular structure of a system, and describes the main data flows at the input of an artificial neural network. The solution proposed for the problem of choosing the difficulty of the question is to use feedforward neural networks. Different architectures and parameters of training artificial neural networks (weight update mechanisms, loss functions, the number of training epochs, batch sizes) are compared. As an alternative, the option of using recurrent long-short term memory networks is considered.

Keywords—Adaptive testing system; artificial neural network; machine learning

I. INTRODUCTION

Adaptive testing is a technology of determining the level of knowledge of the tested subject, in which each upcoming question is automatically selected based on previous answers. The advantage of such testing, as seen by specialists, is the opportunity to determine the testee's level of knowledge more comprehensively and accurately. The problems of developing adaptive tests are topical not only as part of testing students, for example, for the purpose of developing individual learning trajectories, but also in other spheres that require assessment of the subject's competencies and personal intellectual and psychophysiological characteristics. Increasing interest in adaptive testing is demonstrated, for instance, by HR specialists in large companies concerned with recruiting new specialists and testing current employees.

At the heart of adaptive testing systems is an intelligent way to select questions individually for each test subject, based on the answers in all previous steps of the test. The degree of adaptation of the test depends on the number of parameters considered, such as the level of complexity and the number of tasks that are proposed to be completed [1]. Of the greatest interest for research are flexible adaptive systems that allow one to achieve a large variability of tests with high accuracy and reliability in determining the level of training and make the testing process itself look like an oral exam with a teacher. Therefore, the purpose of the study is to organize the process of intellectual choice of a topic (a thematic block of questions) and determine the complexity of the next

question, considering previous answers and the complexity of previously asked questions, as well as the connectivity of topics (blocks) and response time as a factor in guessing or searching for an answer in part of the adaptive testing system.

With the advancement of smart technologies, the development of new methods and the resolution of particular problems using computerized adaptive testing (CAT) is attracting ever-increasing interest from specialists.

At present, we can note three major directions of research, along which CAT methods are being developed:

- Item Response Theory (IRT). IRT is a set of related psychometric theories that serves as a foundation for subject assessment. At the basis of this theory lie mathematical models and logical functions characterizing the relationship between the subject's features (characteristics, knowledge) and the probability of correct answers.
- Bayesian Belief Network (BBN). BBN is a formal graphical language for representing and conveying decision scenarios that require reasoning under uncertainty.
- Artificial Neural Networks (ANNs). ANN is an information processing paradigm based on mechanisms similar to the operation of neurons in the human brain. An ANN is comprised of a certain number of interconnected nodes (neurons) that process information and transmit signals to other neurons based on the results of processing.

It can be stated that the majority of current theoretical and applied research in CAT concerns primarily the use of ANNs. In the field of testing, ANNs are most often proposed to be used as the final module for scoring. In several works [1-3], there were attempts to solve the problem of intellectual choice of a question in the form of determining the level of difficulty of the next question based on one previous one based on the correct or incorrect answer.

Currently, there are many different frameworks for creating ANNs, which makes this mechanism more accessible. However, creating and training a neural network that could offer a substantial advantage over traditional testing requires advanced theoretical knowledge and a fair number of experiments.

At present, researchers do not have a universal approach to creating neural networks for CAT. There arise questions related to the choice of the type and architecture of the network, as well as the number of training examples needed for an acceptable quality of recommendations generated by the network. Contemporary studies only offer general recommendations on these issues. For instance, Golovko and Krasnoproshin [2] suggest quite a large interval of the number of hidden layers.

It is also worth noting the lack of comprehensive works which, having an in-depth look at the entire process of creating a neural network, also describe the applied network learning technologies, which are an important element in ensuring the performance of an ANN.

Approaches to choosing the type of network also vary. Researchers employ both the "classical" feedforward neural networks, in which the signal goes sequentially from layer to layer [3, 4, 5], and recurrent neural networks, in which there is feedback between neurons, and the output signal can be transmitted to the input of the neurons of the previous layer [6]. What should be noted as interesting ideas published in a number of papers is the application of the methods of open systems in the creation of neural networks, in particular, the creation of ANN according to the modular principle [6].

II. METHODS

In the course of the study, the process of conducting a knowledge test in technical disciplines was analyzed from the point of view of its general organization and the identification of indicators that affect the course of testing. As disciplines, such disciplines as "Databases", "Informatics", and "Computer Graphics", read in different educational institutions for students of different courses and specialties, were chosen, and four teachers acted as experts.

At the initial stage, a classification of the tasks solved by the ANN within the process was carried out. Studies were carried out on the use of various types of networks for solving CAT problems, on the basis of which the types of network architectures for further research were determined. The place of the ANN in the overall structure of the adaptive testing system was determined. As a result, a general modular structure of the system was proposed and the main data flows entering the ANN input were described. To achieve the universality of the approach, i.e. regardless of the subject of the test, the choice of the next question was proposed to be carried out in two stages using two ANNs: to select a topic and select the level of difficulty of a question for a particular topic.

At the next stage, to solve the problem of determining the complexity of the question, a feed-forward network was considered. A comparison was made of various ANN architectures and training parameters (weight update algorithms, loss functions, number of training epochs, packet sizes).

In accordance with the results obtained at the previous stage, it was proposed to use six input neurons, which are fed with normalized average values of the correctness of answers to questions and their complexity, the number of questions

already asked, the average time of deviation from the expected response time, the assessment of the answer to the last question asked, and its complexity. At the output of the network there are five output neurons corresponding to the difficulty levels of the questions. Thus, for the simplest feed-forward network with one hidden layer of neurons, the 6-m-5 architecture was chosen and, in accordance with general heuristic recommendations, experiments were carried out for $m = 9, 12, 15, 18, 21$.

All results were obtained using the high-level Keras library, which allows you to quickly start at the initial stages of research and get the first results. SGD, Adam, NAdam and RMSprop implemented in Keras were compared as optimizers to achieve faster convergence. The loss function MSE (mean square error) was used together with the optimizer. Training was carried out on a training set of 1500 sets, which accounted for 80% of the general sample, 10% each were validation and test samples prepared by experts. Traditionally, training was carried out for a large number of epochs (50, 100, 20, 350, and 500), experimentally obtained graphs of accuracy versus the number of epochs for a different number of neurons in the hidden layer to determine the most appropriate architecture. The resulting graphs were constructed using cubic spline interpolation.

In order to determine the effect of the data packet size on the learning process for the 6-12-5 architecture, several experiments were carried out with packets of various sizes (5, 10, 15, 20, 25, 30, 50 and 100) and the optimal size for this task was determined.

Similar training experiments on the same general sample were carried out when switching to network architectures that included two and three hidden layers within 9-21 neurons.

At the final stage, as an alternative, the possibility of using a recurrent ANN LSTM (Long-Short Term Memory) network was considered. In accordance with the feature of this type of network, the number of input neurons was reduced to four, to which the question number, answer score, question complexity, and temporal deviation from the normal were applied. For training, the same tools and approaches were used as in training the feedforward network.

III. MODULAR STRUCTURE OF THE ADAPTIVE TESTING SYSTEM

The main objective solved by an adaptive testing system is the identification of a reliable "profile" of the examinee's knowledge in a particular area. In this case, adaptivity is understood not only as the intellectual selection of questions depending on the level of knowledge demonstrated by the subject, but also the extensibility and universality of the system as a whole [7, 8]. It is thereby clear that such a system has to be constructed by the modular principle, which will ultimately give the structure of the system greater flexibility and versatility.

Of particular interest is the smart selection of the next question. The approaches used in practice differ: assigning the subject an equal number of questions on all topics with different levels of complexity; giving the subject more questions on the topics they made mistakes in; or selecting the

questions using a clear preset algorithm [9-13]. In this case, these methods are difficult to regard as smart approaches.

In this paper, by the subject's profile of knowledge in the given area, we understand the level of mastery over the material in each considered topic. The level of mastery has to be determined in accordance with the difficulty of the assigned questions and the accuracy of the given answers. Therefore, all questions from the bank should not only belong to a certain topic but be characterized by a specific level of complexity.

Obtaining a reliable profile of knowledge through testing presupposes selecting the topic and complexity of the question to be assigned next, meaning that the question is selected for a specific subject in view of the number of questions assigned by topic, their association with one another, level of complexity, and the accuracy of answers given at the previous stages. This task is what an ANN is intended to solve.

The choice of the group of the next question is influenced by the following parameters, which serve as input data for the ANN:

- The topics of the question assigned previously;
- The number of the assigned questions (in each topic);
- The difficulty of the assigned questions (in each topic);
- The accuracy (grading) of the given answers (by the topics considering the levels of complexity);
- The relatedness of the topics to each other;
- Response time to the questions assigned previously.

Let us describe the form in which these data can be stored in the system. It is proposed to store a vector (an array with

the dimensionality equal to the number of questions assigned) of structures for each test taker containing:

- Question – topic, number, difficulty;
- Response time, or rather its positive or negative deviation from the expected norm, i.e. the time sufficient to read the question and give a meaningful answer;
- Grade – the degree of response accuracy (1 – correct, 0 – incorrect).

The relatedness of topics is set via the matrix $M[N, N]$ of coefficients varying in the range from 0 to 1, where 0 – the topics are completely unrelated, 1 – related to the highest degree. The coefficient at the intersection of the i -th row and the j -th column shows how related the i -th and the j -th topics are. The matrix is symmetric, with ones on the main diagonal, so the only really significant input values are $(N^2 - N)/2$.

With a large number of test questions (30-50), the number of input parameters is not only large but also constantly changes as new answers are given (growing in an arithmetic progression). This creates major challenges in determining the architecture of an ANN, as well as complicates the preparation of training and test data sets and the training process itself. In addition, the number of input parameters also changes when so does the number of questions in the test, which eliminates all possible universality.

To resolve this issue, we use two ANNs, one determining the topic of the next question and the other setting the difficulty level. To preserve the number of input parameters and make it constant, we integrate the ANNs with each other by means of algorithmic modules, which perform preliminary mathematical preparation of input values. The resulting general structure of the testing system, which has a hybrid architecture, is presented in Fig. 1.

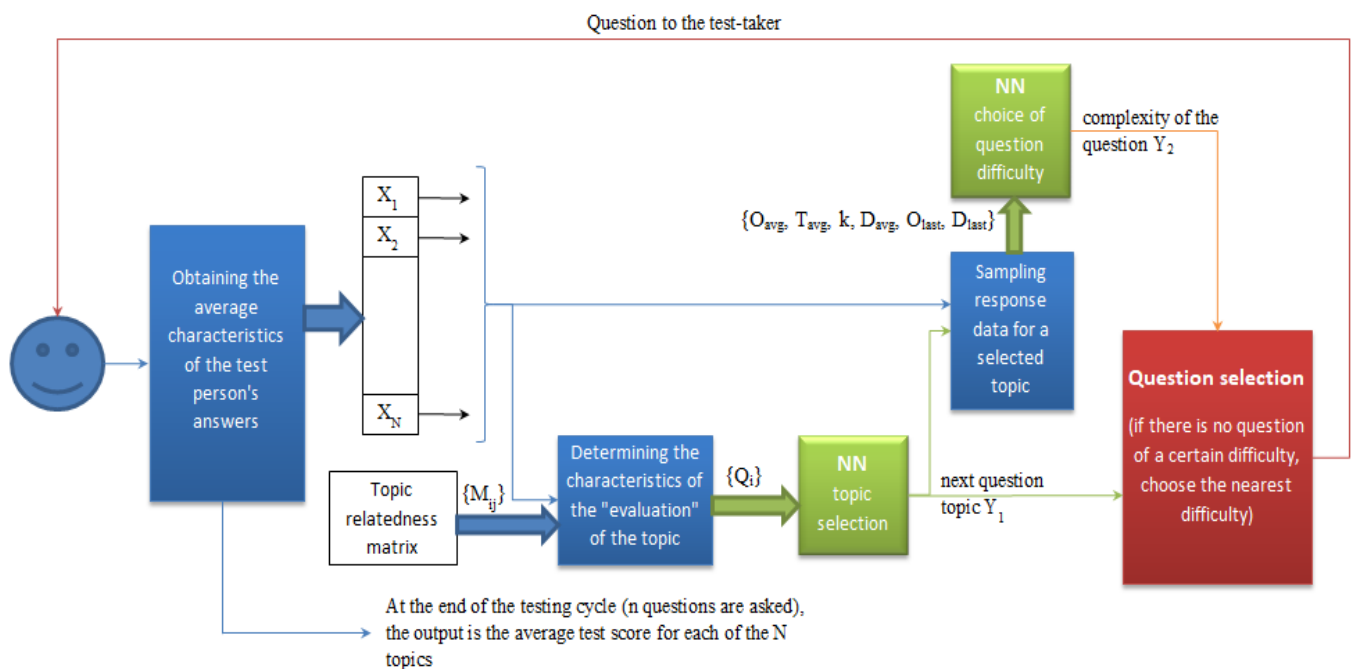

Fig. 1. General Scheme of Functioning of the Adaptive Testing System.

In the case of a feedforward neural network, consideration of all answers given to all of the questions is proposed to be performed by inputting in the networks the average parameters of answers for each topic $\{X_i\}$, for which purpose a respective module is included in the system. In the case of a recurrent ANN, the aforementioned module can be absent due to the capacity of the network itself to account for its previous states. In both cases, the number of inputs with a large number of topics is reduced insignificantly, but stays constant at all stages of testing for any number of questions. The efficiency of using particular types of ANNs is suggested to be assessed in further research.

The choice of the topic in the process of creating the individual testing trajectory needs to take into consideration both the subject's answers and the relatedness of the topics in order to, first, test proficiency in the material across different topics and, second, optimize the total number of questions asked in each topic. At the input of the topic selection ANN, it is proposed to put a vector of "assessment" coefficients of the topics $\{Q_i\}$, which are essentially derived by summing up the share of each answer minding the level of difficulty and relatedness of the topics. Mathematically, this can be expressed as the product of the topic connectivity matrix described earlier and the vector of averaged difficulty-weighted answers.

Once the topic is selected, the second ANN module should determine the difficulty of the upcoming question based on the averaged data for the already specified topic. The logic of decreasing or increasing the difficulty of questions is laid down during training based on the training sets provided by experts according to the given requirements.

As a result, the test taker receives a question selected from the question bank, the difficulty and topic of which are individually selected depending on the test taker's previous answers.

IV. NEURAL NETWORK MODULE FOR DETERMINING THE LEVEL OF DIFFICULTY OF A QUESTION

At the first stage, we design and train an ANN module responsible for selecting the difficulty level. Specification of the difficulty of the question after its topic is already selected largely decreases the number of input parameters that can affect the choice of the question. In this case, it is necessary to consider the parameters of the subject's answers only in one specific topic. For this very reason, this ANN module is preceded by the block of selection of the test taker's performance on a specific subject topic.

In the course of the study, the feasibility of using various ANN models was analyzed from the point of the correspondence of this task to the specific class of tasks solved by particular types of ANNs. This task, however, cannot be unequivocally attributed to a single type since, on the one hand, determining the difficulty of the next question is a classification task, i.e. determining the class of difficulty based on the subject's performance, while on the other, this task involves predicting the real level of knowledge based on the previous answers.

Although there are no specific architectures designed to solve classification tasks, the most commonly used type, in this case, is a multilayer feedforward neural network. For tasks based on sequences, a special type of ANN – a recurrent network – is used. It is impossible to determine in advance exactly which of the architectures is best suited for the task. Therefore, we focus on a more detailed study of two variants of networks, specifically:

- A feedforward neural network, in which all layers are connected with one another directly and sequentially – without feedback or delay lines.
- A recurrent Long-Short Term Memory (LSTM) network, which receives information from the previous passes, thereby being capable of learning long-term dependencies.

The well-known and obvious disadvantage of the latter is their high demands for hardware and resources, both in training (the training process takes a significant amount of time) and in startup.

Next, we will more closely consider the option of using a feedforward neural network. To account for all the previous answers on the topic, the number of which at a certain stage can be random, the input fed to the ANN should include the average values of the accuracy of the given answers and the difficulty of the questions, the number of questions already asked, as well as the average deviation from the expected answer time as a kind of indicator of guessing or searching for answers. In addition to the average values, which do not provide complete information for decision-making in this task even for a human, the network input also includes the mark for the last question answered and its complexity.

Thus, the input layer contains 6 neurons, the output layer – depending on the number of question difficulty levels. In our case, there are 5 neurons, which are aggregated into the last layer containing one neuron. For the final determination of the network architecture, it is necessary to determine the number of hidden layers and the number of neurons in them.

Following the recommendations of Golovko and Krasnoproshin [2], for a network with n-m-p architecture and training sample volume L, the number of neurons in the hidden layer should meet the following condition:

$$\log_2(p) < m < (L - p) / (n + p + 1) \quad (1)$$

Herein, the upper bound is derived from the condition that the training sample size exceeds the number of adjustable parameters. At the same time, there are heuristic rules according to which the size of the training sample must, at least, by an order of magnitude, exceed the number of adjustable parameters to obtain an error of 10%, and the number of hidden layer neurons must, at least, exceed the size of the input by 1.5-2 times [14].

If the use of a perceptron with one hidden layer fails to provide the required accuracy and generalizability of the network, then a neural network with more than one hidden layer is used. The optimal network architecture is also determined via genetic and evolutionary algorithms, which

have their own practical features and limitations. Therefore, at the first stage, we examine a network with architecture n-m-p, for which m and L should satisfy the conditions described earlier.

Since there are no exact methods for estimating the complexity of the problem to be solved and the learning algorithm, which are the determining factors for choosing the amount of data in machine learning, the sufficient amount of data cannot be determined in advance. On the basis of the above recommendations, it is possible to roughly estimate the required size of the general population of raw data and the number of neurons in a hidden layer. We will proceed from the fact that the minimum number of neurons in a hidden layer should be $m=9-12$, suggesting that the volume of the training sample should be, on the one hand, $L>110-150$, and on the other hand, $L\geq 1150-1500$, i.e. an order higher than the number of adjustable parameters for the given m. In the absence of other points of reference, the size of the training sample is set to be 1500 items. According to the generally accepted ratios, the training sample must be 80% of the general population, the verification (validation) sample – 10% (150 items), and the test (control) sample – 10% (150 observations). For the chosen training set, it is advisable to study a number of architectures for $m = 9, 12, 15, 18, 21$ neurons.

The requirements taken into account when preparing the samples are that they should contain a sufficient number of unique examples, should not contain duplicates, contradictions, omissions, and anomalous values, and that the numerical ratio of objects of different classes in each sample should be the same as in the initial general population [15].

In particular, the data structure is affected by the method of network learning. In our case, the “teacher – student” method is employed, as this method is the most commonly used for classification and prediction tasks. Training without a teacher is used in statistical and language models, as well as, for example, in the tasks of clustering and data compression, which does not correspond to the conditions of our task.

Two libraries (frameworks) are considered for the ANN modeling – Keras and PyTorch. These libraries differ in the levels of API and the ways of describing and running network training. Nevertheless, they produced similar results for the described network architecture and training on the same training sets. All the presented results are obtained with the Keras library, which makes it possible to easily create networks and simplify testing of training models, offering additional convenience in the initial stages of research and obtaining first results.

The quality of training of the model is determined not only by its structure and training set but a number of training parameters: the weight update algorithm (optimizer), the loss function, the number of training epochs, and batch size. Below we compare the most popular optimization methods, SGD, Adam, NAdam, and RMSprop, implemented in Keras to achieve faster convergence. The analysis shows that for the problem under study, the best results in terms of accuracy are demonstrated by Adam. The MSE loss function (root-mean-square error) is used for all optimizers.

Traditionally, training is performed for a large number of epochs, which is usually determined experimentally and is sufficient to obtain minimal error and high accuracy [16-18]. In this study, the training of networks with different numbers of hidden layer neurons is performed in the span of 50, 100, 200, 350, and 500 epochs. The results reveal dependencies of accuracy on the number of training epochs for networks with different numbers of neurons in the hidden layer, which are presented graphically below (Fig. 2).

The last noted parameter is the batch size (`batch_size`), i.e. the number of examples in the sample run through the network after which the weight coefficients are updated. Keras implements mini-batch gradient descent with the recommended batch size being 32. Meanwhile, the generalization ability can decline not only when the batch size, which is chosen experimentally, is reduced, but also when it is increased, which is due to the inner noise in the gradient estimation [19]. Several experiments with different batch sizes (5, 10, 15, 20, 25, 30, 50, and 100) are conducted for the 6-12-5 network, resulting in the best generalization ability obtained with a batch size of 50.

The network with the 6-15-5 architecture shows the best accuracy, the obtained learning curves are shown in the graph below (Fig. 3).

An increase of the number of neurons in the hidden layer, the number of hidden layers, and training epochs, as well as mixing the data and change of the learning rate, by means of Keras does not result in an increase in network performance, accuracy rates remain at an average level of 83-85%. The effect of retraining is also not observed. The conclusion from the conducted experiments is that to further improve the accuracy, the general sample of examples needs to be analyzed in terms of the completeness and complexity of the model.

Next, we examine a recurrent network with a similar number of neurons per layer [20, 21]. Proceeding from the fact that an LSTM network processes the temporal sequence of input data while preserving the internal state obtained when processing the previous items, it is not necessary to calculate averaged values to account for all previously received responses. The number of network inputs can be reduced to 4: question number, answer score, question difficulty, and response time deviation from normal. In general, the set of input parameters of the LSTM network will not differ from the previously considered case for the feedforward neural network.

The exception is the form in which training and test sets are presented, each of which, in fact, is a sequence of answers to the questions. In this case, the optimization methods and the functions of activation and evaluation of training results used for the LSTM network will be the same as for the feedforward neural network.

A number of experiments yield similar results (model accuracy of 95% and accuracy on the test sample of 80%) and learning curves, one of which is shown below (Fig. 4). The retraining effect is observed already at 100-150 epochs of training, indicating that the network remembers all the examples and its training requires large samples.

Fig. 2. Dependencies of Accuracy on the Number of Training Epochs for different Numbers of Neurons in the Hidden Layer.

Fig. 3. Learning Curves for Networks with 6-15-5 Architecture.

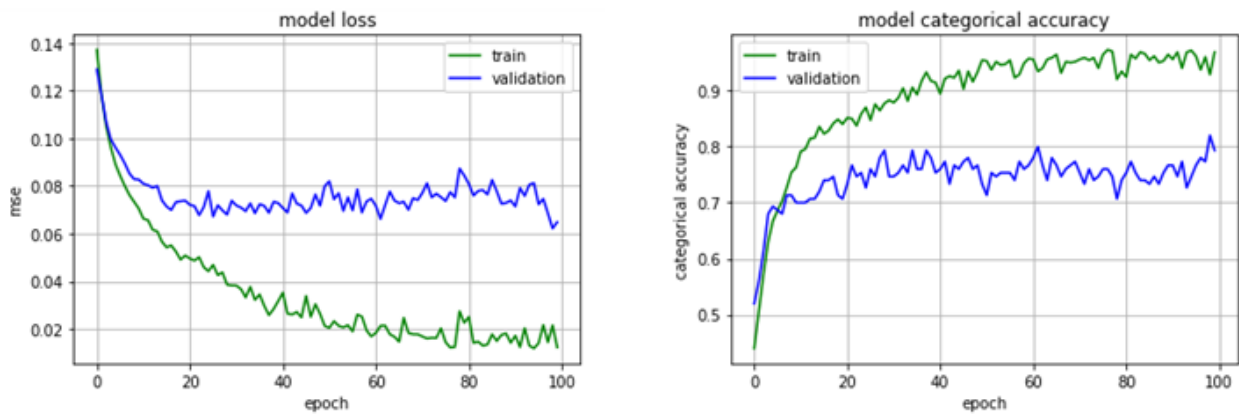

Fig. 4. LSTM Network Learning Curve.

It is not necessary to talk about the advantage of one of the types of networks (forward propagation networks and LSTM networks) for solving the problem of determining the next question in adaptive testing problems. Both types of networks require more detailed preparation of the training set. For direct propagation networks, this is primarily due to the complexity of the model, namely, the nature of the network input data – the averaged values of all previous answers. In this case, to complete the description of the model, more unique and consistent training and test cases are required. The form of the input data of the recurrent network is simpler, but the task of determining the complexity of the next answer based on all the previous ones remains, and, therefore, the training data must represent different testing trajectories at different stages. In addition, the number of adjustable parameters is several times greater than that of the direct distribution network, which also increases the requirements for the volume and quality of the training sample. Preliminary analysis of the training set revealed the presence of gaps in certain data ranges, as well as a certain uneven representation, which, if randomly mixed, can lead to learning failures.

V. DISCUSSION

In general, based on the study, we can conclude that the obtained accuracy of the direct propagation network of 83-85% is quite sufficient for its use in the adaptive testing system. A well-known and obvious disadvantage of using LSTMs is their demands on equipment and resources, both during training (the training process takes a significant time) and during startup, in our case, it is supplemented by increased requirements for the training set and, despite the obtained accuracy of 80%, puts questioning the expediency of further study of LSTM networks in solving this problem.

Using this solution to determine the level of complexity of the next question will consider all the answers given to the subjects, the levels of complexity of the questions, as well as the time of answers within each thematic block, and in the future and considering their thematic connection, in contrast to the previously proposed solutions, in which, only one previous test step is considered, and the accuracy for the recurrent network is 75%.

VI. CONCLUSION

The paper proposes a new structure for organizing an adaptive testing system based on the use of neural network modules, training of the neural network responsible for determining the level of complexity of the question asked is performed. The results obtained can be used in the construction of the second module of the ANN of the system, which is responsible for choosing a topic.

In addition to selecting the topic of the next question, an ANN can be entrusted with the task of moving to the next test stage (assigning the next question), i.e. deriving a reliable knowledge profile with an individual long test trajectory. The study of this possibility is interesting in terms of how optimal the number of given questions will be, whether the system will not go into infinite test mode, or the tests will be too short.

In addition, it is necessary to answer the question of the need to improve the efficiency of an already implemented

network, and, consequently, to conduct research on methods to improve the efficiency of networks, including finer tuning of parameters and learning algorithms, as well as architecture.

In general, the introduction of the proposed tools will allow organizing the process of adaptive testing, with an intelligent selection of questions depending on the demonstrated level of knowledge of the test person to form an individual testing trajectory in order to determine the reliable level of knowledge of the test subject for the optimal number of questions asked.

Development of Ontology-based Domain Knowledge Model for IT Domain in e-Tutor Systems

Ghanim Hussein Ali Ahmed, Jawad Alshboul, László Kovács

University of Miskolc, Faculty of Mechanical Engineering and Informatics, Miskolc, Hungary

Abstract—Ontology as a technology has been studied in many areas and is being used in several fields. A number of studies have utilized ontology to manage problems such as interoperability in teaching materials, modeling and enriching education resources, and personalizing learning content recommendations in the educational context. A possible reason for the lack of success may be that simply posting lecture notes on the internet does not provide enough learning and training. However, this situation can improve by using education software like an e-tutoring system. The e-tutor system has built-in modules to track students' performance and personalize learning according to an adaptation of students' learning styles, knowledge levels, and proper teaching techniques in e-learning systems. e-Tutor is an excellent area in the context of electronic instruction since it provides adequate aid for learners and becomes increasingly important for individual and collaborative learning. Thus, there has been significant interest in adopting e-tutoring to facilitate learning processes and enhance learners' performance. This paper represents a domain knowledge model for an e-tutoring system that enables knowledge to be stored in such a way separated from the domain of interest and assists in storing transfer and prerequisite knowledge relationships. This innovative technique is helpful for the students in improving their learning progress. This paper introduced a domain knowledge model for an e-tutor system to support the way of teaching and learning process. The model implementation is developed in Python and Owlready2. Two types of ontologies are provided: general concepts of the domain knowledge ontology and specific domain knowledge ontology. This solution represents the knowledge to be learned, delivers input to the expert model, and eventually provides specific feedback, selects problems, generates guidance, and supports the student model.

Keywords—e-learning; knowledge model; domain model; e-tutor system; SPARQL

I. INTRODUCTION

E-learning is a technique of learning and teaching utilizing Information and Communication Technology. It means that the growth of online learning is a collaborative task including several researchers in several disciplines such as educational design and learning material [1]. e-Learning system is frequently getting popular in the academic community due to the advantages of using it anywhere, and anytime [2]. However, it tends to be most commonly employed for web-based education to access online courses via the internet [2]. A possible reason for the lack of success may be that merely posting lecture notes on the internet does not provide enough learning and training [2]. This situation can be improved by using education software such as an e-tutoring system. The e-tutoring system includes built-in modules to monitor a learner's

performance and personalize education based on adaptation to learners' learning style, existing knowledge level, and suitable teaching approaches in e-learning systems. The e-tutoring framework usually applies to computer-based instruction. However, an e-tutoring system generally uses adaptive mechanisms and concepts to solve the current e-learning problems by applying artificial intelligence techniques.

Artificial Intelligence in Education (AIED) society frequently identifies the value of producing technologies with a global reach [3]. e-Tutor system is a computer application that uses artificial intelligence approaches to improve and personalize the teaching and learning processes. e-Tutoring differs from other e-learning systems because it uses a knowledge base to guide the pedagogical approach. It attempts to optimize the student's mastery of domain knowledge by generating new problems, concepts, and instruction feedback. e-Tutoring systems are computer-based teaching systems that regularly give students quick and personalized guidance or feedback without mediation from a personal teacher. e-Tutoring is an excellent subject in the context of e-learning. e-Learning environments are increasingly getting popular in different contexts in academies, universities, and vocational training [4]. Therefore, suitable support of learners is also getting great significance. Besides, collaborative learning is also growing, which puts greater demands on learners, especially when the collaboration is implemented and tailored to enhance learning and learning results [4].

The area of instruction is one of the first areas in which ontologies are applied in as a cognitive tool. For several considerations, this was a consequence to the extensive adoption of the constructivist paradigm of education and the general application of such knowledge technologies as concept maps, mind maps, and several more for learning goals [5]. Recently, scientists found that the benefits of using ontologies in the educational field have relative support for designing the coming e-learning environment. The term "ontology" comes from philosophy and it is defined as "a set of representational primitives with which to model a domain of knowledge or discourse" [6]. So, an ontology gives a specific view on some part of the world. While knowledge representation formalisms define how to represent concepts, ontologies identify the concepts to be described and are linked. Thus, ontology can be noticed as a well-established and widely agreed-upon system of concepts in a specific knowledge domain and their relationship. Specialized knowledge domain ontologies can be utilized as a semantic pillar for topics or repositories of teaching resources. By offering agreed-upon terminologies for the domain knowledge representation, ontologies would help

share, reuse, and exchange topic units. Ontologies also enable the availability of machine-readable web resources.

Most of the current solutions of e-tutor systems are designed and developed for a particular domain which means the provided solution will not be suitable for another knowledge domain. Therefore, these systems developed for isolated knowledge bases have some limitations and drawbacks for using local knowledge bases. These limitations refer to lack of standardization, limited knowledge base shareability, lack of flexibility, lack of reusability, and manual control. Due to these shortcomings, an ontology domain knowledge model is proposed to avoid the limitations and drawbacks of using local knowledge bases. To improve and increase the learning quality and process, a novel ontology domain knowledge model develops by defining a set of relationships that would be adequate and clear to represent all possible relationships for developing and building the ontology domain knowledge model. In the proposed ontology domain knowledge model, two types of domain ontologies were introduced: a) general concepts for domain knowledge model ontology and b) specific domain knowledge model ontology. The general concepts of the proposed ontology domain knowledge model deal with the domain knowledge model concepts and define the relationship related to these concepts. The ontology of a selected domain knowledge model deals with the selected subject area that can relate the selected subject domain to the general concepts for the domain knowledge model. It seems like individuals or instances for the general concepts of the domain knowledge model.

Another key issue in current systems is the limited concept level functionality. Many systems provide data-level features as they lack the information and engine to perform smart operations. The proposed ontology framework includes reasoning engines that can improve the adaptivity, customization of the e-tutor frameworks. In the proposed knowledge base, the schema can contain also rules as part of the background ontology. This approach supports a declarative description model instead of the procedural way; thus, it has an increased flexibility and coding efficiency.

This paper constructs a domain knowledge model for an e-tutor system which in turn would help enhancing teaching and learning process. Furthermore, the implementation of this model is described in Python, which can be applied in the future to support the problem-solving process.

This article is organized as follows. The introduction and methodology of designing the ontology are explained in the first and second sections. The third section displays the related work, the fourth section illustrates the proposed ontology of the domain knowledge model and explains the proposal model in detail, the fifth section presents a case study on ontology implementation using Python and Owlready2 module, the sixth section demonstrates the result and discussion, and the conclusion is in the seventh section.

II. METHODOLOGY

The primary goal of this work is to enhance the quality of the learning process by making it in a personalized way. The process design and development of ontology usually

encompasses several standard tasks. However, there is no dominating approach for constructing the ontologies. The main principle is to define the ontology concepts which are related to the objects and the relationships for the selected domain. The methodology for creating and building an ontology assumes defining the objectives and domain of applicability. Moreover, it must be identified in higher-level details: what is the purpose of designing the domain ontology, what are the types of questions that should be answered through it, how it will be utilized and supported for solving the problem for the selected domain. Several techniques for the design and development of ontology are given such as [7] and [8]. Though these methods are somewhat different and are influenced in varying ways by the technology used, the underlying processes of developing the domain ontology are similar. Therefore, the suggested ontology development process is composed of the following phases:

- Domain and purpose of the ontology.
- Discover if there are related ontologies.
- Enumerate important terms in the domain.
- Defining the key classes and their hierarchy.
- Identify the properties of classes.
- Facets attaching to properties.
- Creating class instances.

III. RELATED WORK

The technique known as e-tutoring system has been tracked by scholars in education, psychology, and artificial intelligence. The aim of e-tutoring system is to offer the advantages of one-to-one teaching. It allows students to train their skills by bringing out activities in greatly interactive learning platforms. e-Tutoring system is a computer application that uses artificial intelligence approaches to improve and personalize the teaching and learning processes [9]. e-Tutoring differs from other e-learning systems because it uses a knowledge base to guide the pedagogical approach. It attempts to optimize the student's mastery of domain knowledge by generating new problems, concepts, and instruction feedback. There are many e-tutoring systems meant and developed for learning and teaching reasons. These systems support learners to progress quickly and improve their self-confidence. SmartTutor is a web-based intelligent tutoring system developed to support teaching and students based on knowledge background, skills, and teaching techniques [10]. The remarkable aspect of SmartTutor is the incorporating of instructional and artificial intelligence (AI) methods in a unified intelligent e-tutoring system to give personalized help to learners based on the knowledge-level of individual learners [11]. e-Tutoring systems are developed to illustrate the essential knowledge on the subject, inform which kinds of knowledge can be used to solve problems in the given domain, generate and offer suitable task activity based on the recorded performance, and recommend the next suitable task for the learner to choose. Smart Tutor delivers the capability of a tutor to adjust to individual learners' requirements and skills [10]. e-Tutoring systems, also known as Intelligent Tutoring Systems

(ITS), became a reality in the mid-1970s and peaked at the end of the 1980s, when expert systems were in use [12]. During the nineties, most artificial intelligence and education investigations concentrated on intelligent learning environments more influenced by Computer-based learning, microworlds, and Computer-based training [13]. Of course, ITS study is still an active sub-field of research on adaptive learning. ITS systems were not cost-effective enough to survive in education and training. ITS got interested in the late 2010s, particularly since "statistical AI" based on neural networks and relevant methods allows extracting patterns from big data. These can be due to recommender systems that recommend learning analytic systems that detect learners' difficulties. ITS are adaptive systems that use intelligent technologies to tailor learning based on various characteristics of students, including their background knowledge, mood, and learning style. The e-tutoring system includes three kinds of knowledge to give students proper education, arranged into four separate system modules (as shown in Fig. 1).

Fig. 1. Traditional Components of an ITS [10].

The tutor model is a computer model that helps the system choose the appropriate explanation style for a particular learner based on the learner's history tracked by the learner model. This knowledge allows the e-tutoring system to check the student's responses and steps with an expert to assess what they know and do not know. The student model is the learner's knowledge-level while the student works on e-tutoring system. The model assesses student's behavior while working with the e-tutoring system to find their knowledge, cognitive skills, and reasoning abilities. The domain model is concerned with the knowledge associated with the problem considered for a specific domain, including the teaching materials and the meta-information about the topic to be taught. It depends on the learner model's diagnostic processes to determine what, when, and how to display information to a learner. The interface model is essential as a delivery mechanism and learning facility to help the learner complete the activity. It can also perform as an external representation of the expert and teaching models.

Researchers have investigated practices of knowledge representation such as semantic-based, rule-based, case-based, frame-based, Bayesian network, logic-based, and ontology-based. Rule-based models are also called Cognitive tutors. The rule-based models are built from cognitive task analysis, producing problem spaces or task models. These problem spaces or task models are constructed by observing the expert and novice users. Task models represent a set of production rules in which each rule represents an action corresponding to a task [14]. When a user tries to solve a given task, the user's reasoning ability is analyzed based on the rules applied by the

user, i.e., the user's solution is compared step-by-step to the solution given by the expert. Case-based is an artificial intelligence problem-solving method that records experience into cases and associates the current problem with an experience [15]. A logical representation language has some definite rules for dealing with propositions and reasoning for knowledge and representation. Logical representation entails deducing a conclusion from many circumstances. This representation establishes many fundamental communication principles. It is composed of well-defined syntax and semantics that facilitate sound inference. Each phrase can transform into a logical form through syntax and semantics. Frame-Based is one of the artificial intelligence techniques to structure the data, and it is used to separate information into substructures via the representation of stereotyped scenarios [16]. Frame-Based seems like a record form build-up of many characteristics and values used to describe an object in the real world. In addition, this object contains a collection of slots and their associated values. However, these slots come in a combination of shapes and sizes. Facets are the names and values assigned to slots. A Bayesian network is also referred to as a belief network or Bayes net. Bayesian network is probabilistic and graphical in a form of graph with directed acyclic devoid of loops and self-connections used for knowledge representation for an uncertain domain, with each node indicating a random variable [17]. Each edge denotes a conditional probability associated with the associated random variables. Semantic-based is a knowledge representation method that enables visualization of the knowledge via graphical networks [18]. This network incorporates nodes representing entities and arcs that reflect their relationships. Moreover, Semantic-based classify things in different ways and can also connect them in the style of a graph.

Ontologies, as semantic-based representation, have gained vital significance as one of the most commonly used techniques to describe and share knowledge in several disciplines such as E-learning systems, business modeling, software engineering, knowledge engineering [19].

Regarding the continuous development of new technology, it can change the way of teaching and learning. According to Fensel [20], the primary reason for the popularity of ontologies is due to providing "a shared and common understanding of a domain that can be communicated between people and application systems. Ontology can be constructed as a representation required for scale and variety in the design of educational frameworks. In the e-learning field, ontologies are employed in various applications extending from domain knowledge modules representation to automate generation and assessment of personalized learning materials. The concept of ontology is a useful technology that incorporates related resources, shares knowledge, and eliminates unnecessary data. Ontology is a fundamental description of the information in the world [21]. The ontology in computing refers to knowledge representation applying a collection of concepts and connections among them [22]. In the context of a targeted discipline, ontology is used to rationally reason and validate concepts in the semantic knowledge model. In theory, ontology is a "formal, explicit specification of a shared conceptualization" [23]. It offers a shared vocabulary that can

be employed to construct the domain knowledge model, involving objects, concepts, properties, and relationships.

A comparison was given utilizing some selected criteria according to the knowledge representation models employed in the present works for representing the domain knowledge module as a part of an E-tutor framework. The authors considered some criteria for comparing the representation model used with others in the literature. The suggested criteria covered a number of terminologies: standardability, reusability, flexibility, shareability, simplicity, and reasoning engine, as indicated in Table I.

TABLE I. COMPARISON OF THE MODELS

Models	Criteria					
	Standard ability	Reusability	Flexibility	Shareability	Simplicity	Reasoning engine
Semantic-based	√	√	×	√	×	√
Rule-based	√	√	×	×	×	√
Case-based	√	×	×	×	×	√
Frame-based	√	√	√	×	×	√
Bayesian network	√	×	×	×	×	√
Logic-based	√	×	×	√	×	√
Ontology-based	√	√	√	√	√	√

√ means feature is allowed, and × means feature not allowed.

IV. PROPOSED DOMAIN KNOWLEDGE MODEL FOR E-TUTOR FRAMEWORK

The domain model is the system's knowledge base, and it organizes the domain knowledge structure, its various key concepts, and the relationships between the concepts. This model essentially deals with the what-to-teach part of e-tutoring system [24]. The domain model is concerned with domain knowledge construction, organization, topics, and relationships [24]. Domain knowledge is a set of suggestions that identify all the vocabulary concepts to explain or solve problems. Domain knowledge is only declarative, and it does not tell how learners can use the domain knowledge model to solve a practical problem [25].

Based on the properties of the learning materials, two kinds of ontologies are employed, and these are general concepts domain knowledge ontology and specific domain knowledge ontology. These modules represent the knowledge to be learned, deliver input to the expert model, and eventually provide specific feedback, select problems, generate guidance, and support the student model.

A novel domain knowledge model was suggested based on the current research area, as shown in Fig. 2. This model is based on topics, concepts, attributes, tasks, competencies, assessment, and relations. In order to share and reuse the domain knowledge model in e-tutoring systems, ontologies are employed to organize and represent the domain knowledge

model. The benefit of this model is to personalize the materials for learners.

Based on the general concepts of the domain knowledge ontology shown in Fig. 2, topics, concepts, attributes, tasks, competencies, and assessment terms refer to the following:

- Topics can be utilized to present domain knowledge or a comprehensive overview of a subject or course.
- The concept identifies the sub-domain or unit of a subject or course.
- Competency is used to demonstrate the features and skills that allow and enhance the efficiency of student performance to gain new knowledge and understand specific topics.
- The task is used to demonstrate how a student can complete a task within a given period of time.
- The attribute represents a topic or domain attribute within a domain model.
- The assessment is used to present how the system can evaluate or assess the student activities required within a given period of time.

Fig. 3 displays the design of a specific domain knowledge ontology case study for IT domain in e-tutor system for the computer programming. Many types of relationships are used in the selected case study, such as specialization or generalization, association, and containment. A containment means that a specific topic within a domain contains different concepts (has-a). The specialization or generalization means that certain topics or domains have specific concepts (is-a). The association means that a specific topic or concepts associate with each other. Based on Fig. 2 and Fig. 3, the following shows a brief description of a subject:

- Topic: Control Structure.
- Concept: Loop, Sequence and Condition.
- Competency: understand, analyze, implement.
- Task: program, code review, project.
- Attribute: syntax, operators.
- Assessment: activities such as quizzes, tests.

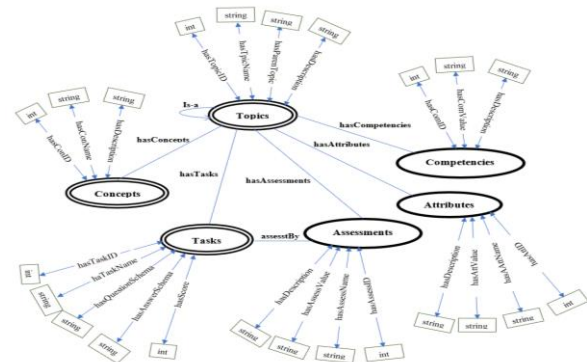

Fig. 2. The Proposed Ontology-based Model for Domain Knowledge.

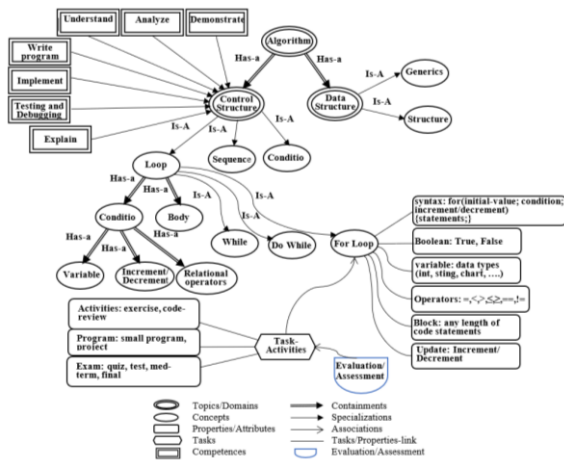

Fig. 3. Domain Knowledge Module Instances for e-tutoring Frameworks.

V. IMPLEMENTATION OF THE PROPOSED MODEL

Information science and technology provides many modules and packages for ontology construction and management. Python is one of the most popular languages adopted when implementing an ontology for the domain knowledge model. It is an interpreted, object-oriented, extensible programming language [23], which provides an excellent combination of clarity and versatility in different disciplines. The domain knowledge model, considered here, is “Basics of Computer Programming”, and the ontology created consisted of the “Algorithm in Computer Programming”. Fig. 4, 5, 6, 7, 8, 9, and 10 show the implementation of the proposed model using Python.

Fig. 4 displays a snippet of the domain knowledge components construction using Python and Owlready2 syntax "with ontology: ..." to indicate that the constructed ontology will receive the new RDF triples and the class keyword for declaring the components of the ontology. While Fig. 7 demonstrates the output of the ontology of the domain knowledge model components as a list of concepts. Fig. 5 displays a snippet of the object property related to the domain knowledge model in the format of domain and range. For example, "hasParts(Topics >> Concepts)" hasParts is the object property relationship that means each Topic may contain some Concept in this example, Topics is the domain of the relationship, and Concepts is the range of the relationship. Fig. 6 displays a snippet of the data property relationship related to the domain knowledge model in the structure of domain and range. Considering "topicName(Topics >> str, FunctionalProperty)," topicName declares the name of the Topics component, Topics are the domain, and str (means the topicName datatype is a string) is the range of the relationship. Fig. 8 presents how to insert the "While Loop" topic data as an instance related to the Topics component. Checking the consistency of the ontology using the Hermit reasoner, the most commonly used in ontology engineering applying sync_reasoner(), is shown in Fig. 9. Rule construction in SWRL layouts for inferring further knowledge can add to the created domain knowledge model of the selected ontology components using imp = Imp() and imp.set_as_rule() functions, as shown in Fig. 10.

```

Fig. 12. A SPARQL Query to Retrieve the Topic “While” and its Description.

VI. RESULT AND DISCUSSION

The most commonly utilized knowledge representations are semantic-based, rule-based, case-based, frame-based, Bayesian network, logic-based, and ontology-based [14], [15], [16], [17], [18] approaches. A comparison of knowledge representation forms is conducted according to some criteria or features covered: standardability, reusability, flexibility, shareability, simplicity, and reasoning engine. Ontologies, as knowledge-based representation, have gained vital significance as one of the most commonly used techniques to describe and share knowledge in several disciplines such as E-learning systems, business modeling, software engineering, knowledge engineering [19].

The semantic web is an extension of the World Wide Web, is crucial in the development of personalized learning in e-learning systems. Semantic web technologies such as RDF, XML, and ontologies can be used for knowledge representation and reasoning of the teaching materials. Ontologies, which can

be defined as a specification of a conceptualization, have the advantage of addressing the challenges of interoperability between educational repositories of various e-learning systems.

An ontology-based domain knowledge model has been proposed. In section 4, a theoretical model is described based on two kinds of ontologies. First, a general concepts domain knowledge ontology based on topics, concepts, attributes, tasks, competencies, assessment, and relations is presented in Fig. 2. Second, a specific domain knowledge ontology is designed as a case study for IT domain in programming using different types of relationships such as specialization or generalization, association, and containment as depicted in Fig. 3. In Section 4, an implementation of the ontology-based model is delivered using Python, Owlready2, and Protégé.

The current work deals with declarative knowledge that helps students understand all the vocabulary concepts in a specific subject. The future work suggests dealing with problem-solving process that works on procedural knowledge to help students in understanding how to use domain knowledge in solving a practical problem.

The proposed model is introduced to explain how the ontology domain knowledge model can be combined with an e-tutor system to improve the quality of intelligent problem-solving. Also, it will make it possible to reuse knowledge components and develop e-tutor system frameworks. Finally, a domain knowledge model for e-tutoring system, which can serve to enhance teaching and learning, is proposed. Furthermore, this model can avoid the issue currently exists in intelligent e-learning systems related to isolating knowledge bases. The majority of the domain knowledge models use an isolated knowledge base, and this local knowledge base can only provide limited knowledge background. The limitations of the isolated knowledge base are lack of standardability, reusability, flexibility, and limited knowledge. The solution can satisfy the characteristics of reusability, standardability, open knowledge, and flexibility.

By using ontology as a knowledge representation technique for building the domain knowledge model, the problem of isolated knowledge bases can be avoided. The developed ontology can be involved to manage adaptive intelligent e-learning frameworks in the future.

VII. CONCLUSION

An intelligent tutoring system or E-tutoring System is a type of educational system that uses artificial intelligence to reflect knowledge. The use of e-tutoring systems has become a key component of enhancing educational activities. In this paper, readers can see that e-tutoring is very significant in the context of the growing number of e-learning frameworks. An ontology-based knowledge model for IT domain has been developed for e-tutor system.

This paper constructs a domain knowledge model for an e-tutor system which in turn would help enhancing teaching and learning process. Furthermore, the implementation of this model is described in Python and Owlready2 module, which can be applied in the future to support the problem-solving process. Two types of ontologies are employed, and these are general concepts domain knowledge ontology and specific

domain knowledge ontology. These modules represent the knowledge to be learned, deliver input to the expert model, and eventually provide specific feedback, select problems, generate guidance, and support the student model.

The current work deals with declarative knowledge that helps students understand all the vocabulary concepts in a specific subject. The future work suggests dealing with problem-solving process that works on procedural knowledge to help students in understanding how to use domain knowledge in solving a practical problem.

ACKNOWLEDGMENT

The described study was carried out as part of the EFOP-3.6.1-16-00011 “Younger and Renewing University – Innovative Knowledge City – institutional development of the University of Miskolc aiming at intelligent specialization” project implemented in the framework of the Szechenyi 2020 program. The realization of this project is supported by the European Union, co-financed by the European Social Fund.

The Design of Home Fire Monitoring System based on NB-IoT

Jun Wang, Ting Ke, Mengjie Hou, Gangyu Hu
School of Mechanical and
Electrical Engineering
Jiangxi University of
Science and Technology
Ganzhou, China

Abstract—In the field of home fire monitoring, the currently relatively mature monitoring solutions include GPRS/GSM communication and Zigbee communication. The main disadvantage of GPRS wireless communication is high power consumption, and the disadvantage of Zigbee technology is that it needs to be combined with other communication technologies to realize remote monitoring. In addition, the above technical solutions all require self-built local or remote monitoring servers to save monitoring data. In view of the above problems, this system designs a home fire monitoring system based on NB-IoT technology and cloud platform. The system uses a single-chip STM32F103C8T6 as the core controller and contains a sensor data acquisition module and a narrowband IoT communication module. The data fusion of multi-sensor data is performed by BP neural network algorithm. On the basis of remote transmission, the system solves the problems of high power consumption, high cost and insufficient signal coverage of terminal hardware. The system can collect indoor environmental parameters and fire information in real time, and upload them to the cloud platform for storage. If abnormal data is detected, an early warning message will be issued. The feasibility of the system is verified, and the verification results show that the system works normally and the output is accurate, which meets the design requirements and can be widely used.

Keywords—NB-IoT; cloud platform; fire monitoring system; STM32F103C8T6; sensor; BP neural network

I. INTRODUCTION

Nowadays, high-tech electronic products are widely used in various families. However, because some people can't use these high-tech products reasonably, and even misoperation leads to adverse consequences, many abnormal situations or dangers occur. In addition, most families use natural gas, liquefied petroleum gas, etc. Some people forget to close the valve after use, causing gas leakage and other situations. Gas is a flammable and explosive gas, which is likely to cause fire or explosion accidents. Therefore, the indoor system needs to have the functions of gas detection and fire detection to ensure the safety of family environment. The establishment of family fire monitoring system has practical application value and social benefits [1].

In order to solve the above safety problems, a home fire monitoring system based on NB-IoT (Narrow Band Internet of Things) is designed. By using a variety of heterogeneous sensors (such as temperature and humidity sensors, smoke sensors, etc.) as the data acquisition module to collect indoor environmental information, the data is analyzed and processed

by the main controller to realize the functions of fire detection and gas leakage detection, so as to achieve the purpose of remote care of the home environment, ensure the safety of family life and property, and provide a safe and intelligent living environment for the family [2].

The core controller of the home fire monitoring system is a microprocessor STM32F103, which contains a sensor data acquisition module and a Narrowband IoT Communication Module composed of a home living room environment monitoring and fire monitoring system [3]. The system is based on the middle layer of the home fire monitoring system of Huawei's OceanConnect platform, and achieves the work of device data reporting and platform issuing commands [4]. The home fire monitoring platform realizes the remote monitoring of the home living environment. The validity of the fire detection algorithm is verified through experiments, and the test results are as expected; through the test of the terminal node, cloud platform and each functional module in the home fire monitoring platform, the feasibility of the function of the home fire monitoring system and the stability of data transmission are verified, which provides a reference for the practical application and promotion of the system.

II. RELATED WORK

FENG Hui et. al. [5] based on ZigBee technology, smoke, CO, temperature detection fusion were integrated, and community fire alarm system based on ZigBee is designed and implemented. QI Bin et. al. [6] used LoRa and GPRS separately for long-distance transmission of fire sensing information and fire alarm information. The combination of the two technologies meets the needs of wireless fire alarm system monitoring and alarming. ZHANG Zhi-hua et. al. [7] used probabilistic neural networks for information fusion of fire features, which can effectively perform fire identification and improve the accuracy of fire detection. XIE Rongquan et. al. [8] used the BP neural network algorithm to calculate and detect the developing rule and signal feature of the fire image. OKOKPUJIE K O et. al. [9] combined GPRS and single-chip microcomputer to build an automatic fire alarm system to realize remote fire monitoring.

Although Zigbee technology has flexible terminal nodes, easy deployment, and low power consumption, its application distance is limited. The disadvantages of GPRS/GSM wireless communication method are high power consumption, high operation and maintenance costs, low data transmission rate,

and the risk of withdrawing from the network with the rapid development of 5G technology in China. LoRa wireless communication technology needs to be combined with GPRS/GSM wireless communication method to achieve remote monitoring. In addition, the above technical solutions all require self-built local or remote monitoring servers to save monitoring data.

III. OVERALL SYSTEM ARCHITECTURE DESIGN

The system consists of sensing terminal, cloud platform and application layer. The sensing terminal mainly contains sensors, STM32 main control module, NB-IoT communication module and external control devices; the platform layer mainly contains IoT cloud platform; the application layer provides home fire monitoring application services to users, and the system architecture is shown in Fig. 1.

Fig. 1. Overall System Structure Diagram.

The sensing terminal collects indoor temperature and humidity, smoke concentration, harmful gases and other information, uploads alarm signals when abnormal conditions such as gas leakage and fire occur, sends the data to the cloud platform, and starts external control devices at the same time.

The IoT cloud platform is essentially a cloud server with functions of device management, data management, etc. It converts the format of upstream and downstream service data, connects NB-IoT terminal devices in the south direction, and connects the application layer in the north direction, decodes the south direction data for easy access by the perception layer subscription, and encodes the north direction commands for easy reception by the perception layer.

The northbound application is a human-computer interaction interface, which accesses data messages through a personal PC subscribed by the API interface and protocols opened by the IoT cloud platform, displays the home environment data status in real time, and includes alarm notification functions, and can issue commands to remotely control terminal devices when abnormal.

IV. TERMINAL HARDWARE DESIGN

The sensing terminal mainly consists of a variety of heterogeneous sensors, the main controller, NB-IoT module and other peripheral circuits, in which the sensors are mainly responsible for collecting indoor environmental data, the main control unit fuses, processes and controls the start and stop of the collected data, and establishes a connection with the cloud platform through the NB-IoT module networking, packages and uploads the data to the cloud platform, and receives commands from the cloud platform. The hardware block diagram of the system terminal is shown in Fig. 2.

Fig. 2. Terminal Hardware Block Diagram.

A. Environmental Parameter Acquisition Circuit

The system uses STM32F103C8T6 as the terminal main control chip, which has timer, UART, ADC, I/O and other modules inside, which fully meets the functional requirements of system hardware design. The temperature and humidity acquisition module DHT11 is used to monitor changes in temperature and humidity, the smoke sensor MQ-2 is used to detect gas leakage, and the carbon monoxide sensor 4CO-500 is used to detect CO concentration [10].

- 1) DHT11 chip adopts single bus data format. With high measurement accuracy and low power consumption, it only needs a single data pin port to complete I/O bidirectional transmission. Connect the I/O port PA7 of the STM32 microcontroller to the DATA pin of DHT11, and connect a pull-up resistor to the DATA pin to realize temperature and humidity acquisition.
- 2) The system uses MQ-2 smoke gas sensor to monitor the environment for gas leaks and fires, which is commonly used to detect smoke, liquefied gas, alcohol, methane and other gases, with the advantages of high sensitivity, wide detection range, high stability, long service life, etc. and is widely used in smart homes and other fields. The signal output by the two B pins of MQ-2 is a DC signal and changes with the smoke concentration. Connect the B pin to the PA0 of the STM32 microcontroller [11].
- 3) Carbon monoxide will be produced in the early stage of a fire. After carbon monoxide enters the human body, it will combine with hemoglobin in the blood, causing hypoxia in the body tissue, causing the human body to faint and suffocate to death. Therefore, it is very important to transmit the concentration of carbon monoxide to the fire control center in real time to guide fire rescue.

B. NB IOT Communication Module

The system selects the BC35-G wireless communication module to send data and receive commands, which is a multi-band NB-IoT wireless communication module with very low power consumption, high sensitivity and low cost. And it supports multiple network protocol stacks with significant advantages in positioning, power consumption, data transmission rate and other module performance and system security [12]. The SIM card adopts the special NB-IOT network card provided by China Telecom to store temporary data [13], user information and encryption key. The application circuit is shown in Fig. 3.

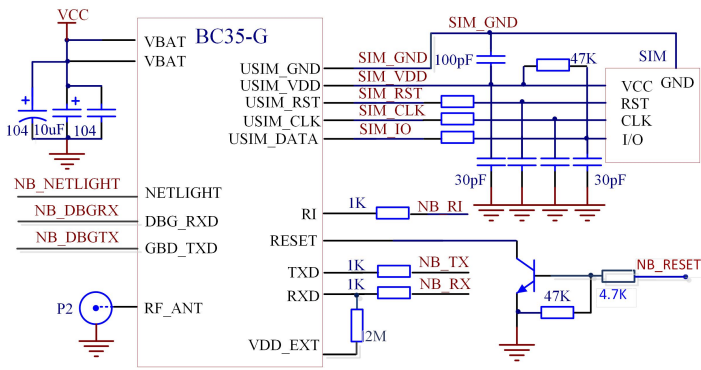

Fig. 3. Application Circuit.

C. Power Module Design

The external 3.7V lithium battery is chosen to power the whole hardware terminal, because the power supply voltage of each module is not consistent, the power supply voltage of the main control module is 3.3V, the power supply voltage of the data acquisition module is 5V, and the power supply voltage of the NB-IoT module is 3.7V. Therefore, the voltage needs to be converted into 3.3V and 5V to power the main control module and the data acquisition module respectively.

The lithium battery power supply module adopts the TP5410 chip for charging and boosting. The chip integrates the functions of charging and discharging, 5V constant voltage boosting, etc., and converts the lithium battery 3.7V voltage into 5V voltage through the boost converter. The circuit schematic diagram is shown in 3.3 shown. VUSB represents the voltage provided by the external device connected to the USB interface. The BAT pin is connected to a 3.7V lithium battery. The VOUT pin represents the circuit output voltage, which is converted to 5V by the booster.

RT8059 is selected as the 3.3V voltage regulator chip. This chip can effectively reduce the 5V voltage to 3.3V and conduct voltage stabilizing output. Its output current can reach 1 A. The power supply voltage regulator circuit is shown in Fig. 4.

Fig. 4. Power Supply Voltage Regulator Circuit.

V. TERMINAL SOFTWARE DESIGN

The role of the sensing terminal software is to realize the collection of environmental information, data processing and complete data reporting. The terminal device software execution process is shown in Fig. 5. After the terminal device is powered on, the hardware enters the initialization state. After the initialization is completed, the BC35-G module

connects the device to the network, and checks the network attachment status by calling the AT command. When the network attachment is successful, it connects to the cloud platform for data transmission services. After the NB network is successfully attached, the sensing terminal (southbound device) is connected to the IoT cloud platform. After the connection is successful, the CDP server is configured. At this time, the device is in the wake-up state and remains connected to the cloud platform, and the device can communicate with the specified application server. The sensing terminal first collects sensor data, fuses the data, determines whether there is a gas leak or a fire, if so, sends an alarm message, and then sends the data to the cloud platform [14]. The main controller encodes the acquired data according to the defined binary format, and constructs the fused data into CoAP packets and sends them to the cloud platform. The cloud platform parses the CoAP message, decodes it by calling the decode interface, and converts it into a unified json data format to complete the data reporting. When the cloud platform issues a command, it calls the encode interface to encode and convert it into a binary code stream to construct a CoAP message and send it to the sensing terminal. The main controller parses the command and returns a response to control the operation of related external devices.

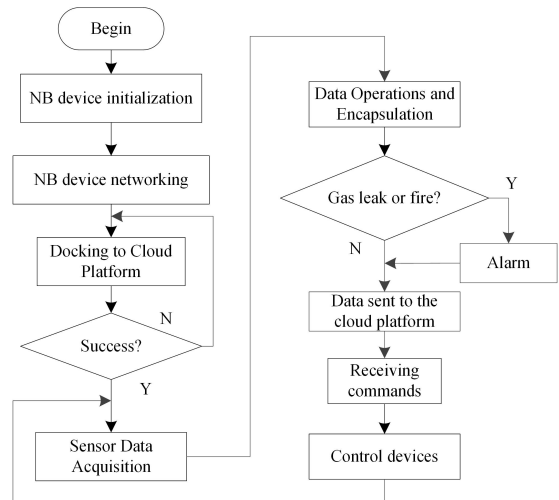

Fig. 5. End Device Software Execution Flow.

A. STM32 Project Configuration

The terminal software development uses the integrated development environment Keil uVision5. Since the STM32 requires a lot of initialization configuration during development, such as pin definition, clock configuration, etc. If the direct operation register development method is used, the process will be very cumbersome. In order to reduce the development time and energy, the STM32CubeMX software is used to configure the initialization code of the STM32 project in a graphical way. The generated STM32 initial project can be directly opened in Keil uVision5 and run.

Create a new project in STM32CubeMX, select the STM32F103C8 series MCU chip, configure the pin function according to the schematic diagram, and then configure the initialization parameters.

The main pin configuration functions are as follows:

- 1) PC14, PC15 pins: configured as RCC (clock system) clock source HSE (high-speed clock), and defined as Crystal/Ceramic Resonator (crystal/ceramic crystal) mode.
- 2) PD0, PD1 pins: configured as RCC clock source LSE (low speed clock), and defined as Disable mode.
- 3) PA13, PA14 pins: configured as program download pins and set to serial line mode.
- 4) PA2, PA3 pins: configured as USART2, which are serial communication pins between STM32 and NB-IoT module.
- 5) PB9, PB10 pins: configured as serial port USART1, the main function is to establish the communication serial port between STM32 and PC, and forward the communication content between NB-IoT module and STM32.
- 6) PA6 pin: configured as output pin GPIO_OUT to collect temperature and humidity values.
- 7) PA4 and PA5 pins: configured as analog-to-digital conversion pins ADC1_IN4 and ADC1_IN5, which are responsible for collecting smoke concentration and CO concentration respectively.

After the pin and initialization configuration is completed, the initialization project code is compiled and generated, which can be called directly when writing the program for each module.

B. Fire Discrimination Algorithm

The terminal nodes collect parameters such as temperature and humidity, smoke concentration, and CO concentration in real time, and then the collected data are homogenized and normalized, and then fuses the multi-sensor data through the BP neural network algorithm, and outputs it after decision analysis [15]. In the home environment, humidity has little effect on fire, so the effect of humidity is not considered in this paper for fire discrimination [16].

(1) Data preprocessing

Due to the existence of many interference noises in the external environment, the measured data are often inaccurate, which will cause great interference to the result judgment, and even misjudgment and omission may occur. In order to improve the accuracy of the data, the data needs to be preprocessed. Assuming that there are n different sensors in the system, their output vectors corresponding to the moment t can be summarized as $X(t) = (x_1(t), x_2(t), \dots, x_n(t))$, denoted:

$$\mu_i = \frac{1}{K} \sum_{i=1}^K x_i(t) \quad (1)$$

$$\sigma_i = \sqrt{\frac{1}{K} \sum_{i=1}^K (x_i(t) - \mu_i)^2} \quad (2)$$

$$f(x_i(t)) = \frac{1}{\sqrt{2\pi}\sigma_i} \exp\left(\frac{-(x_i(t) - \mu_i)^2}{2\sigma_i^2}\right), i \in [1, n] \quad (3)$$

where K is the number of sample data, is the sample arithmetic mean, and is the sample standard deviation. And from equations (1) to (2), it can be inferred that the homogenization formula of heterogeneous sensor data is:

$$y_i(t) = \frac{|f(x_i(t)) - f(\mu_i)|}{f(\mu_i)} = \left| \exp\left(\frac{-(x_i(t) - \mu_i)^2}{2\sigma_i^2}\right) - 1 \right| \quad (4)$$

Thus, the input vector can be transformed into: $Y(t) = (y_1(t), y_2(t), \dots, y_n(t))$. If some of the data fluctuate greatly during the measurement process, it may happen that the data with smaller values in the output data is assimilated by the data with larger values. To avoid this event, this paper uses the normalization method to compress the data after homogenizing the data. The normalization formula is shown in (5).

$$x_i'(t) = \frac{y_i(t) - y_{\min}}{y_{\max} - y_{\min}} \quad (5)$$

where $y_i(t)$ is the input vector after homogenization, $x_i'(t)$ is the normalized covariate value, y_{\max} is the maximum input value, and y_{\min} is the minimum input value.

(2) Fire Data Identification

In this paper, the BP neural network algorithm is used to fuse the preprocessed data. BP neural network consists of input layer, implicit layer and output layer, and the most rapid descent method is used to learn the rules, and the actual result output is made infinitely close to the desired output by continuously adjusting the threshold and weights, so as to finally achieve the purpose of learning training.

The number of neurons in the input layer of the BP neural network is influenced by the dimension of the input data, and the number of neurons in the output layer is determined by the specific application, while the selection of neuron nodes in the hidden layer is particularly important, and the appropriate selection number will directly affect the performance of the BP neural network, which usually uses equation (6) to select the neuron nodes in the hidden layer.

$$l = \sqrt{m + n} + a \quad (6)$$

where m is the number of input layers, n is the number of output layers, $a \in [1, 10]$.

In order to avoid the problem of solving linear indistinguishability brought by linear mapping, the S-type activation function $f(x) = 1/(1 + e^{-x})$ is used in the BP neural network in this paper.

In this paper, the three parameters of temperature, smoke concentration, and CO concentration are used as the input layer of the BP neural network. And the open fire probability, shaded combustion probability, and no fire probability are used as the

feature outputs according to the type of fire occurrence. The training output value is $[0, 1]$ between. The number of input and output neuron nodes is 3. According to formula (6), the number of hidden layer neuron nodes is set to 10, and the structure of BP neural network is shown in Fig. 6.

Fig. 6. Neural Network Structure.

The BP neural network structure is determined, and the network parameters are set:

Network inputs: $X_i = [x_1^i, x_2^i, x_3^i]$, group i temperature, CO concentration, smoke concentration;

Expected output: the expected output values of open fire probability, Smoldering fire probability and no fire probability in group i ;

Implicit layer input: $A_i = [a_1^i, a_2^i, a_3^i]$;

Implicit layer output: $B_i = [b_1^i, b_2^i, \dots, b_{10}^i]$;

Output layer input: $L_i = [l_1^i, l_2^i, \dots, l_{10}^i]$;

Output layer output: $C_i = [c_1^i, c_2^i, c_3^i]$, the actual output value of open fire probability, Smoldering fire probability and no fire probability in group i ;

The weight of the input layer and the implicit layer is w_{ij} , and the threshold is θ_j ; the weight of the hidden layer and the output layer is v_{jt} , and the threshold value is γ_t .

The network parameters are set and the feature-level fusion is performed. The core is iterative learning and training. The specific learning and training process is as follows:

- 1) Initialize the weights and thresholds, assign any real numbers within the interval $(-1, 1)$ of the weights and thresholds, and select the error function e , the calculation precision value ε and the limited number of learning times M .
- 2) Randomly select a group of samples k as input and target samples: the k th group of input $X_k = [x_1^k, x_2^k, x_3^k]$, the expected output $Y_k = [y_1^k, y_2^k, y_3^k]$.
- 3) Calculate the implicit layer inputs as:

$$A_i = \sum_{i=1}^3 (w_{ij}x_i - \theta_j) \quad (7)$$

The output is:

$$b_j = f(A_i) = \frac{1}{1 + e^{-A_i}}, j = 1, 2, \dots, 10 \quad (8)$$

- 4) Calculate the output layer input as:

$$L_j = \sum_{j=1}^{10} (v_{jt}b_j - \gamma_t) \quad (9)$$

The output is:

$$c_t = f(L_j) = \frac{1}{1 - e^{L_j}}, t = 1, 2, 3 \quad (10)$$

- 5) Calculate the unit error between the actual output and the expected output:

$$d_t^k = (y_t^k - c_t)c_t(1 - c_t), t = 1, 2, 3 \quad (11)$$

- 6) Calculate the error of each unit in the middle layer as:

$$e_j^k = \left(\sum_{t=1}^3 d_t^k v_{jt} \right) b_j(1 - b_j), j = 1, 2, \dots, 10 \quad (12)$$

- 7) Output layer weights and threshold correction:

$$v_{jt}(N + 1) = v_{jt}(N) + \alpha d_t b_j \quad (13)$$

$$\gamma_j(N + 1) = \gamma_j(N) + \alpha d_t \quad (14)$$

where, N is the learning rate, $\alpha \in (0, 1)$.

- 8) Implicit layer weights and thresholds:

$$w_{ij}(N + 1) = w_{ij}(N) + \alpha [(1 - \eta)e_j x_i^k + \eta e_j x_1^{k-1}] \quad (15)$$

$$\theta_j(N + 1) = \theta_j(N) + \alpha [(1 - \eta)e_j^k + \eta e_j^{k-1}] \quad (16)$$

- 9) Continuously update the replacement weights and thresholds, and perform iterative training until the error meets the preset accuracy or reaches the limit of the number of learning times, and then the training can be ended.

In order to verify the accuracy of the system fire detection algorithm, the system measurement data, SH3 polyurethane plastic fire and SH6 wood fire are selected to form the original samples, and a total of 70 sample data are formed. Part of the original data and expected output are shown in Table I.

Homogenize and normalize the original data according to equations (1) to (5), and the data will be limited to the $[0, 1]$ interval after normalization. The processed sample data are shown in Table II.

Using matlab simulation software to simulate the neural network, 60 groups of sample data are selected from the existing test data for network training, of which the number of learning times is 50, the learning rate is 0.1, and the number of neurons in the hidden layer is 10. The neural network error obtained by BP neural network algorithm is shown in Fig. 7. Where, the abscissa is the number of training times, and the ordinate is the neural network error [17].

9	0.33	0.63	0	0.05	0.1	0.85

Fig. 7. Neural Network Error.

When the error is less than 0.0001, the training of the BP neural network is completed. The preprocessed sample data in Table II are tested experimentally, and the sample data are input into the trained BP neural network to obtain the actual output values of several different fire probabilities. The test results are shown in Table III.

Through the above 9 sets of test data, it is known that the absolute error of open flame probability is 0-0.024, and the average absolute error is 0.00567; the absolute error of smoldering probability is 0.002-0.035, and the average absolute error is 0.01067; the absolute error of no fire probability is 0.010-0.091, and the average absolute error is 0.02056, it can be seen that the trained neural network conforms to the actual output. The fire detection algorithm can improve the measurement accuracy of the fire detection device in practical applications, and can better reduce the probability of false alarms and missed alarms.

VI. IOT PLATFORM DESIGN

The IoT platform used in this system is Huawei's Ocean-Connect platform, and the design process is as follows [18].

- 1) Create a home fire system product application, record the application ID and key;
- 2) Write a profile file to define the capabilities and characteristics of the NB device;
- 3) Design a codec plug-in, parse the reported data and encode the issued commands;
- 4) Register NB-IoT device, connect the device to the network. After the device is connected to the network, the platform can receive device data to realize the connection and management of the NB-IoT module and the OceanConnect platform;
- 5) Debug, create online debugging and testing equipment, and use application simulator and NB equipment simulator to simulate the process of data reporting and command issuance.

The device Profile file developed in this paper mainly defines four attributes, smoke (smoke), CO concentration (CO), temperature (temp), humidity (humi), and also adds the down command field, sets CmdValue as the exhaust fan on command. Cmdvalue = 1 means to turn on one exhaust fan, cmdvalue = 0 means to turn off the exhaust fan, and the attribute type is int; Set alarm as the alarm command, take 1 as the alarm and 0 as the off alarm [19].

NB-IoT devices generally have higher requirements for power saving and use binary format. However, the IoT platform communicates with the application side using JSON format. Therefore, coding plug-ins need to be developed for the IoT platform to call in order to complete the conversion between binary format and JSON format. When the terminal reports

temperature, humidity, CO, and smoke data messages, the message name and data type must match the definitions of the corresponding fields in the profile, that is, they are consistent [20].

After the design of the codec plug-in is completed, you can add a real device or a new virtual device for debugging. After the debugging is passed, you can develop Web applications. This system uses the OceanBooster platform to develop northbound applications. OceanBooster supports forms, text, buttons, background pictures, etc. When adding new menus, external links can be added, with the ability to analyze device statistics, one-click device commands can be issued, and supports docking to third-party systems to quickly build WEB-side applications. According to the NB-IoT device developed by the profile file and codec above, add device monitoring components, button components, switch components, device status trend components, etc., set the style and layout of each component, and connect the components with the products developed in the IoT platform, connect the attributes, services, and commands of the components correspondingly, and realize the uploading and sending of commands and data. The interface of the monitoring system is shown in Fig. 8. The current room temperature is 18°C, humidity is 71%, smoke concentration is 1%, and CO concentration is 0; the devices registered in the IoT platform can be selected to display the current status of each device, and the audible and visual alarms and exhaust fans can be manually controlled [21].

Fig. 8. Monitoring System Interface.

VII. CONCLUSION

By analyzing the functional requirements of the terminal system, the design scheme is determined, and the hardware

and software of the terminal system are designed. The system hardware terminal composed of STM32F103C8T6 as the main controller, each sensor data acquisition module, BC35-G wireless communication module and other peripheral circuits is designed. Through the design of the system terminal software, the sensor data acquisition module can collect the indoor environmental parameters (temperature and humidity, smoke concentration, etc.) of home living in real time, and after being processed by the STM32 main controller, the terminal data is sent to the IoT cloud platform by the BC35-G networking. And the threshold method is used to realize the indoor gas detection and alarm function. The three raw data of temperature, CO concentration and smoke concentration are processed by homogenization and normalization methods, and the BP neural network is applied to data fusion of the preprocessed data. Through continuous iterative learning and training, the probability of fire occurrence is obtained, and accurate fire detection is realized. The main work of the paper is as follows:

- 1) The system architecture design is completed and the NB-IoT home fire monitoring terminal hardware and software function programs are designed. The terminal node can collect indoor environment data (temperature and humidity, smoke concentration, etc.) and detect fire in living environment in real time while setting the threshold value through sensor data to achieve gas leak detection; Use data fusion technology to realize fire detection function; use NB-IoT wireless transmission technology to regularly upload data to the IoT platform, which has the characteristics of long-distance transmission and strong practicability.
- 2) Based on Huawei's OceanConnect platform, the NB-IoT intelligent gateway is built. By defining Profile files and developing and deploying codec plug-ins, the data conversion function is realized, providing a communication bridge between the system terminal and the application side. At the same time, the CoAP protocol is used as the communication protocol between the hardware terminal and the IoT platform, which further reduces the power consumption of the hardware terminal.

From the experimental results, the system meets the overall requirements of the design. The home fire monitoring system designed by using the emerging NB-IoT technology solves the problems of high cost, high power consumption and short transmission distance of traditional Internet of Things technology, and has high practical value; the fire detection algorithm and BP neural network are used to train the sample model,

which improves the accuracy of fire detection and reduces the misjudgment rate; the Huawei OceanConnect platform is used to manage data and equipment, and to process and store data at the same time, reducing application costs and improving overall system performance.

In the follow-up research, the training samples will be further enriched, the humidity data will be incorporated into the network structure, and the neural network algorithm will be optimized so that it can be applied to more complex fire environments such as public buildings; a mobile APP application will be designed, and the monitoring system of this paper will be connected to the fire protection big data application platform of the government to realize grading early warning of police situation and rapid linkage response. With the rapid development of computer technology and network technology, these ideas are expected to be realized as soon as possible.

The Effect of Natural Language Processing on the Analysis of Unstructured Text: A Systematic Review

Walter Luis Roldan-Baluis, Noel Alcas Zapata, Maria Soledad Mañaccasa Vásquez

Postgraduate School, Doctorate in Education
Cesar Vallejo University, Lima, Perú

Abstract—The analysis of the unstructured text has become a challenge for the community dedicated to natural language processing (NLP) and Machine Learning (ML). This paper aims to describe the potential of the most used NLP techniques and ML algorithms to address various problems afflicting our society. Several original articles were reviewed and published in SCOPUS during 2021. The applied approach was retrospective, transversal and descriptive. The data collected were entered into the SPSS statistical software v25 and among the findings, it was determined that the most used NLP technique was the Term frequency - Inverse document frequency (TF-IDF), while the most used supervised learning algorithm was the Support Vector Machines (SVM). Likewise, the predominant deep learning algorithm was Long Short-Term Memory (LSTM). This research aims to support experts and those starting in research to identify the most used algorithms of NLP and ML.

Keywords—Artificial intelligence; natural language processing; machine learning; unstructured text analysis

I. INTRODUCTION

The Internet has become an exclusive ally for any institution. According [1], there were more than 5'168,000,000 users worldwide, of which Asia accounts for 53.4%, and ranks first. Latin America and the Caribbean are positioned in ranks fourth with 9.6%. According to [2], in Spain the number of users reached 91% of the population. The author in [3] points out that there are currently more than 1'900,000,000 web pages. It also points out that 167 million videos are generated in a minute on the Tik Tok platform; likewise, Amazon customers invest USD 283,000 in e-commerce. It is concluded that in every second large amounts of data are produced in various formats such as images, audios, videos and texts.

The massive amount of data implies the need to automate human tasks through the fast advance of technological innovation. It can be used for decision making in an efficient and effective way. According to [4], such innovation includes Artificial Intelligence (AI). The author in [5] points out that AI trains computers to learn from experience and to do the work of human beings. This field has had an intensified growth due to the COVID-19 pandemic. In the research [6] states that AI surpasses the cognitive abilities of man. AI is an interdisciplinary field [7], of computing capable of solving problems of medicine, psychology, education, health, information technologies - TIC, among others.

On the Internet platform, there is a lot of traffic, users are producing a high volume of unstructured texts; it is difficult to determine which websites are visited by users. The author in

[8] propose a model made based on Natural Language Processing (NLP) techniques and neural networks to identify the websites visited by users by translating this problem into a text classification context. This solution is advantageous for the digital marketing because it allows the loyalty of users.

Social networks are platforms on which there are a high proliferation of comments, with absolute freedom and without restrictions from attacks, insults, discriminatory speeches, hatreds and other offensive terms. In the research work [9] proposes a text classification model to detect cyberbullying consisting of a neural network framework that examines the content of the text in order to analyze the effect of the extracted characteristics. The usefulness of this study lies in identifying solid mechanisms for the detection of cyberbullying.

Regarding the scope of the research, systematic review articles published in the SCOPUS Database, period 2021, were reviewed. For example, [10] submitted a systematic review article to provide evidence on the properties of text data used to train machine learning approaches and how they can be applied in clinical practice. In another review article, [11] highlighted the usefulness of NLP and Machine Learning (ML) to structure the comments of free texts issued by patients of health organizations. This led to identify that there is no systematic research that describes the frequency of the ML algorithms used in the various original articles. This work aims to fill this gap, being this the main motivation to carry out this research.

The objective of this study is to systematically review the bibliography of the application of natural language processing to analyze, interpret and classify the high production of unstructured texts produced in digital format. Also, to describe the frequency of ML algorithms such as supervised, unsupervised and deep learning. In this context, the aim is to answer the questions raised in Table I. Question one aims to identify NLP application fields. These features include text preprocessing techniques such as tokenization, etc. Question two describes the frequency of ML algorithms for data analysis. Finally, question three refers to the frequency of deep learning algorithms; this question has been given preference since algorithms are very specialized.

TABLE I. RESEARCH QUESTIONS

No.	Question
1	What are NLP and ML application fields?
2	What is the frequency of ML algorithms for text analysis?
3	What is the frequency of DL algorithms?

II. LITERATURE REVIEW

Natural Language Processing – NLP is a branch of artificial intelligence and a resource to carry out qualitative tasks of unstructured information, based on mathematical and statistical algorithms on large amounts of data. In this regard, [11] pointed out that the NLP is a computer analytical technique used to extract information from an unstructured text into a structured form, for which syntactic processing of a text is done; it also captures the meaning and identifies links based on semantic relationships. The author in [12] indicates that NLP is a technique of automatic extraction of information from different electronically written resources at the level of documents, words, grammar, meaning, and context. Likewise, [13] stated that the NLP is a key tool for information automation and extraction that can process large amounts of data and its application is useful for issuing reports from the radiology area of a hospital.

Machine Learning (ML) is used for creating models that allow computers to learn without being programmed. In this regard, [11] affirm that ML is a set of statistical algorithms that can train and test a group of data to detect patterns, predict feelings within a text. In the research [14] point out that ML is the process that detects and exploits patterns and trends that are "hidden" in the production of unstructured texts. The author in [15] indicate that ML is a set of machine learning algorithms built into machines to provide knowledge about processes quickly and efficiently. ML is classified into three fields, supervised learning (S), unsupervised learning (US), and reinforcement learning. The present work contemplates the use of algorithms of the first two fields mentioned.

Supervised learning uses algorithms that learn iteratively from data. They find hidden information by which computers learn. The author in [11] point out that algorithms try to predict and classify texts. For example, in the electronic documentation of a health service, the algorithms are able to identify the most common issues expressed by patients. Likewise, [16] points out that supervised ML divides the input data set into training and testing. The training data set has an output variable that must be predicted or classified.

Unsupervised learning uses algorithms to identify patterns and detect anomalies such as fraud, scam of potential users, among others. In this regard, [11] indicates that it is a technique that identifies models or patterns of behavior without the need to know the target attribute or objective that could be present in a text. In the research work [16] points out that the algorithms learn some characteristics from the data. One of the best-known models is the clustering.

The NLP is taking a lot of relevance in the sentiment analysis (SA), positive or negative, in the analysis of unstructured text; a source of application is the comments that are made on social networks. In that aspect, [17], making use of the tasks of NLP and ML methods, propose a model of word processing for SA that uses the comments made on Twitter. The first phase consists of collecting the text, cleaning it, preprocessing, extracting features from a text and then categorizing the data. The proposed corpus is multidisciplinary and can be used in the area of market analysis, customer behavior, survey analysis, and brand monitoring, among others.

This contribution is used as a basis for broadening the range of real applications.

The usefulness of NLP and ML has a high level of application in the medicine field. It can be applied to determine the misuse and abuse of prescription drugs in comments made on social networks. In this regard, [18] propose a model to detect self-reports of prescription drug abuse from Twitter. Using these public data, it develops a continuous monitoring system to classify the class of "abuse or misuse".

III. MATERIAL AND METHOD

A. Introduction

The PRISMA method is a structured tool with a systemic approach that helps to present the results of a research. According to [19], the Preferred Reporting Items for Systematic Reviews and Meta-Analyses – PRISMA 2020 is conceptualized as a series of recommendations that contribute to selecting, evaluating and synthesizing for better clarity and transparency of research. In fact, [20], [21] point out that the PRISMA declaration is an essential strategy for conducting good research and publishing the results. In the area of objectivity, this research has been divided into four phases, according to the process proposed by:

- 1) Retrieval of publications.
- 2) Review of titles and abstracts.
- 3) Revision of the full text.
- 4) System information collection.

With regard to the initial recovery phase, it is necessary to use a strategy that would allow efficient document searches. In this respect, [22] point out that the PICO strategy is relevant for raising research questions in order to optimize the placement of articles. The PICO system is an acronym and a component structure. According to [23], this format has four elements: problem, intervention, comparison and outcome. Table II shows the optimal search of documents, this strategy was adapted to the acronym PIO. In addition, the thesaurus Computer Classification System – ACM was used to identify the appropriate synonyms; the link is: <https://bit.ly/3dphAJP>.

From phase two: review, titles and abstracts; articles were located to be contrasted with the inclusion and exclusion criteria. Titles and abstracts were reviewed, then the method and results, in order to establish the search formula. The database consulted was Scopus, period 2021. In the third phase, the combination of keywords and synonyms was used with emphasis on the variables Natural Language Processing and text analysis. The logical operators AND and OR were used repeatedly until the appropriate formula was obtained. Table III shows the restricted query.

TABLE II. KEYWORDS AND SYNONYMS FOR THE PIO METHOD SEARCH

P	I	O
Natural Language Processing Natural language process Natural Language Text Computational linguistics Word processing NLP	text analysis text analytics text data	Corpus Classification

TABLE III. SEARCH CRITERIA FOR ORIGINAL SCIENTIFIC ARTICLES

Database	Search date	Search string
Scopus	December 15, 2021	OA(all) AND (TITLE-ABS("Natural Language Processing") OR TITLE-ABS("Natural Language Process") OR TITLE-ABS("Natural Language Text") OR TITLE-ABS("Computational linguistics") OR TITLE-ABS("Word processing") OR TITLE-ABS("NLP")) AND (TITLE-ABS("text analysis") OR TITLE-ABS("text analytics") OR TITLE-ABS("text data") OR TITLE-ABS("text classification") OR TITLE-ABS("Data extraction")) AND PUBYEAR > 2020 AND DOCTYPE(AR)

B. Selection of Criteria

Inclusion and exclusion criteria for the efficient search of research articles were identified in the PICO strategy. The query was held on December 19, 2021. The search was restricted since 2021 and 144 articles were located in Scopus database. To ensure the rigor and credibility of the selected articles, they were evaluated by extrapolating the criteria defined in Table IV.

TABLE IV. INCLUSION AND EXCLUSION CRITERIA USING THE PICOS MODEL

PICOS	Inclusion criteria	Exclusion criteria
Problem	Natural language processing – NLP in the text analysis	Natural language processing in formats other than texts (e.g., video, audio).
Intervention	NLP interventions in the data extraction and summaries of text analysis with free software (R language, Python)	NLP interventions in which actual text, using an NLP process, is not processed. Data extraction with licensed software. Chatbot.
Comparison	Comparison with other type of intervention such as the elaboration of the linguistic corpus.	Studies that have no other type of comparison.
Outcomes	Report on the impact of the intervention.	It does not contain a report on the impact of the intervention.
Study Type	Quantitative, qualitative, and mixed method studies of original articles.	Systematic review articles, meta-analysis, literature reviews, conferences, dissertations, protocol works, tutorials. Studies not conducted in English. Duplicate jobs and not available in full text.

IV. RESULTS

A. Search Results

A total of 144 articles were collected during the search process. 11 were deleted after reviewing the title and abstract (n=133) of each document. Then, the method and conclusions were reviewed with emphasis and those that did not meet the inclusion criteria were discarded (n=87). Finally, there were 46 potential articles for systematic review. Fig. 1 shows the flowchart of the search strategy.

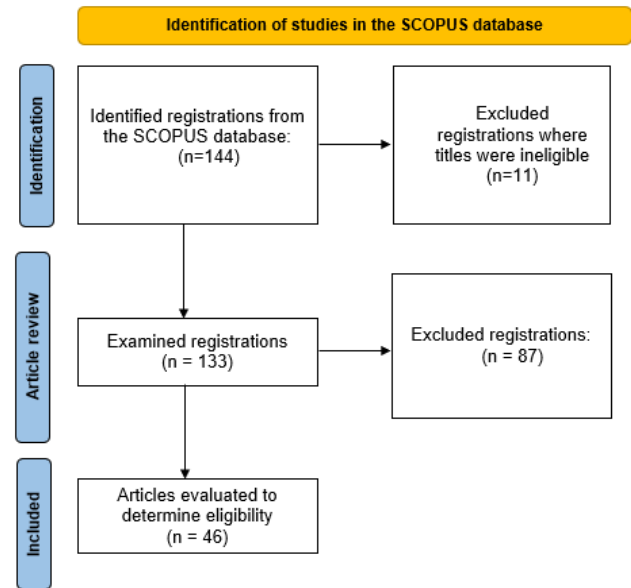

Fig. 1. Flowchart of the Literature Review Process.

B. Description of Included Studies

The application fields or sectors that have benefited from the NLP and ML application correspond to the domains such as aviation, medicine, cyberbullying, education, engineering, technology, among others. In this regard, the medical sector has benefited from 13 studies, 28.76%. The education system from 10 studies, 21.74%. The Technology field has seven articles, 15.22%, among others. Table V shows the details.

TABLE V. FIELDS OF APPLICATION AND FREQUENCY OF ARTICLES

Application field	Frequency	%	Author(s)
Aviation	1	2.17	[24]
Natural disaster relief	1	2.17	[25]
Cyberbullying	1	2.17	[9]

C. Frequency of NLP Algorithms

A number of NLP techniques were applied prior to the use of ML algorithms, and these NLP techniques are described in Appendix A. NLP techniques are associated with various algorithms, which are defined in Appendix B. After registering the data in the SPSS v25 statistical software, it has been discovered that the Term frequency - inverse document frequency (TF-IDF) algorithm was present in 22 articles, 47.82%. The Word2Vec algorithm was used 15 times, 32.60%. Glove algorithm at 14, 30.43%, while Bag of words (BoW) was used in 11 studies, 23.91%, and N-Gram was used in six articles, 13.04%.

On the other hand, seven studies, 15.21%, used three algorithms at the same time. Likewise, 12 articles, 26.09%, used two algorithms at the same time, while 26 articles used a single algorithm, 58.69%, in their research. The details of the NLP algorithms used are detailed in Appendix C.

D. Frequency of ML Algorithms

ML algorithms analyzed in this study are defined in Appendix D and grouped under supervised learning, unsupervised learning, and Deep Learning.

1) *Frequency of supervised learning algorithms (S)*: The Support Vector Machine (SVM) algorithm was used in 17 studies. The Naive Bayes (NB) algorithm was applied in 15 studies. The Random Forest (RF) algorithm has 10 studies. R has 9 studies. K-NN has 8 studies. RF has 5 studies. The Passive aggressive (PA) algorithm was used in two studies. The AdaBoost (ADA) algorithm has 1 study like Singular Value Decomposition (SVD) algorithm, Fig. 2 shows the details.

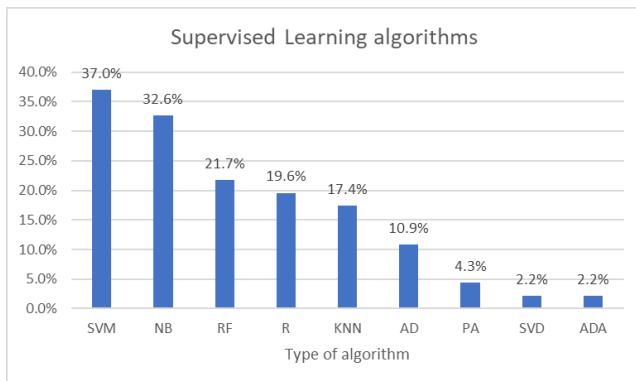

Fig. 2. Studies using S Algorithms.

2) *Frequency of unsupervised learning algorithms (US)*: The Latent Dirichlet Allocation (LDA) algorithm was used in three studies, 6.5%, while K-Means algorithm was used only in one study, 2.2%.

3) *Frequency of deep learning algorithms (DL)*: The Long Short Term Memory (LSTM) deep learning algorithm has 24 studies. Then, the Convolutional neural networks (CNN) algorithm has 12 studies. The Recurrent Neural Networks (RNN) algorithm has 9 studies. The Multilayer Perceptron (MLP) algorithm has 5 studies. The least used algorithms were

Gating Circulation Unit (GRU) algorithm with four studies and Artificial neural network (ANN) with two studies. Fig. 3 shows the details.

Fig. 3. Studies using DL Algorithms.

4) *Studies with hybrid algorithms, Supervised (S), Unsupervised (US) and Deep Learning (DL)*: Out of 46 articles, 10 (21.74%) use only S algorithms. In this regard, [24] and [52] use SVM. The author in [35] use NB algorithm. On the other hand, the study of [51] uses the LDA algorithm.

Three studies use S and US algorithms at the same time: [17] use two S algorithms: SVM, NB and 1 NS: K-Means. [67] use five S algorithms: SVM, NB, Regression (R), RF, KNN, and one US algorithm: LDA.

The author in [25] uses three algorithms: A supervised learning algorithm, the LDA, and two deep learning algorithms, GRU and CNN. Twenty-one studies, 45.65%, used only DL algorithms, in particular [8], [32], [48] y [68].

Eleven studies, 23.91%, used S and DL algorithms at the same time, in particular [9], [36], [38], [46], [47], [49], [53], [55], [57], [58] y [60].

The details of the ML algorithms used by the 46 studies can be found in Appendix C.

V. DISCUSSION

The popularity and proliferation of platforms working on the Internet such as web portals, social networks, and all digital media have created a massive social interaction between users, even more so because of the global COVID-19 pandemic that has led to the unprecedented increase in online learning and its consequent exponential production of unstructured texts. This phenomenon, according to [32], is allowing the increasing use of the NLP and ML field in text analysis for an efficient solution of real problems.

What are NLP and ML application fields?

It was discovered that sectors such as the health system, education, technology, engineering, software development, aviation, natural disasters relief, cyberbullying, construction, finance, marketing, politics, business organization, information security, psychology, and urban transport, benefit most. This reflects that NLP and ML can be applied to solve problems in any sector.

What is the frequency of ML algorithms for text analysis?

The analysis of the articles indicates that NLP preprocessing techniques such as tokenization, normalization, elimination of irrelevant words are necessary to apply ML algorithms, which allow having a positive impact to achieve the Garg & Sharma study objective [17]. TF-IDF, word2Vec, and Glove are among the most used NLP algorithms. The ML algorithms of supervised learning were: SVM, NB and RF. The least used algorithms were: PA, ADA and SVD. With respect to unsupervised learning algorithms, these were the least used. Only three studies used the LDA algorithm.

What is the frequency of DL algorithms?

With regard to Deep learning, the most used algorithm was LSTM with 22 articles, and the least used was ANN with only 2 articles. This approach becomes a primary tool for the NLP. However, it should be noted that ML algorithms can lead to error bias because it depends on the quality of data with which the research is carried out and especially on access to data since many institutions, unfortunately, restrict them, for example, hospitals [69].

Considering the works obtained, it can be said that the most used NLP technique was the TF-IDF. The most used supervised learning algorithm was the SVM, and with respect to neural networks or deep learning, it was the LSTM. On the other hand, according to [69], one of the main obstacles to applying the NLP and ML algorithms is access to data, representing a challenge for the AI community in reversing this situation.

VI. CONCLUSION

The most commonly used supervised learning algorithms for text analysis in the field of research are TF-IDF, word2Vec and Glove, while predominant deep learning algorithms are LSTM and ANN. In addition, this article complements the various studies regarding systematic reviews on NLP and ML, by describing the frequencies of influential algorithms and it is expected that this work will lead to further research to increase the cases of application of PLN and ML for the benefit of various fields such as health, education, transport, technology and others. Finally, it should be noted that improving the cognitive aspect of this science requires further research taking into account that the PLN and ML algorithms are universal, characteristic of mathematics and statistics.

APPENDIX A. NLP TECHNIQUES

Dimension	Definition
Word segmentation (Tokenize)	It is the process of converting paragraphs into inputs for the computer through a word list.
Data cleanup (Stop word)	It is the process of removing words that do not add exclusionary meaning to a sentence.
Lexicographic analysis with stemming	It is the process of converting each word of the sentence to its root form by removing or replacing suffixes.
Lexicographic analysis with lemmatization	It is a more accurate process than stemming and involves making an analysis of the vocabulary and its morphology to return to the basic form of the word.

APPENDIX B. NLP ALGORITHMS

Type	Algorithm	Definition
Basic mathematical functions	POS	It is the process of grammatical tagging or disambiguation of word categories.
	Name entity recognition (NER)	It is the process of "finding out" if a piece of data belongs to a person or business organization.
	N-gram	It is a sub-sequence of n items of a text data sequence. It is a probabilistic algorithm that allows making a statistical prediction of the next item of a sequence of a string of text data.
	Bag of words (BoW)	It is the process that allows the feature extraction from the text, determines the number of times that there is a word in the sentence.
Basic statistical algorithms	Term frequency - inverse document frequency (TF-IDF)	It is a statistical model that allows scoring the data to reflect their relevance in a given document.
	Text vectorization	It is the process which transforms the input of language into something that the computer can understand
	Statistical standardization	It is the process used to scale features of document data.

APPENDIX D. MACHINE LEARNING ALGORITHMS – ML

ML Type	Algorithm	Overview
Supervised learning	K-NN	It is an algorithm that can be used to classify new samples or to predict values by looking for the “most similar” data points (by proximity).
	Regression - R	It is the algorithm that determines the relationships between dependent and independent variables for prediction and prognosis.
	Decision tree - DT	It is an algorithm that uses the fork for every possible outcome of a decision.
	Support Vector Machines - SVM	It is an algorithm that seeks to find a hyperplane that best separates two different kinds of data points.

	Naive Bayes - NB	It is a classification algorithm based on Bayes' theorem and classifies each value as independent from any other. It uses probability to predict a class or category.
	Radom Forest - RF	It is the algorithm that represents a set of decision trees in which each tree trains with different data samples from the same problem.
	Passive aggressive – PA	It is an algorithm that is used for large-scale learning. Input data come in sequential order and the machine learning model is updated step by step.
	Singular Value Decomposition – SVD	It is the algorithm used to eliminate redundant data. It determines which values are important and removes those that are not.
	AdaBoost – ADA	It is an algorithm that can be used together with other learning algorithms to improve its performance.
Unsupervised learning	Cluster K-Media	It is an algorithm that trains and properly knows the data to find hidden groups.
	Latent Dirichlet Allocation – LDA	It is an algorithm and its objective is to find the topics to which a document belongs based on the words it contains.
Deep Learning	Convolutional neural networks -CNN	It is one of the variants of neural networks that is widely used in the computer vision field.
	Recurrent Neural Networks – RNN	It is an algorithm widely used in natural language processing. It is used to analyze time series data.
	Long Short Term Memory - LSTM	It is an algorithm that introduces loops in the network diagram to memorize previous states of variables to decide which one will be next.
	Artificial neural network - ANN	It is a group of multiple perceptrons/neurons in each layer.
	Multilayer Perceptron - MLP	It is a network class consisting of at least three layers of nodes: an input layer, a hidden layer, and an output layer.
	Gating Circulation Unit – GRU	It is an enhanced RNN.

Hybrid Fault Diagnosis Method based on Wavelet Packet Energy Spectrum and SSA-SVM

Abstract—As one of the important components of mechanical equipment, rolling bearing has been widely used, and its motion state affects the safety and performance of equipment. To enhance the fault feature information in the bearing signal and improve the classification accuracy of support vector machine, a hybrid fault diagnosis method based on wavelet packet energy spectrum and SSA-SVM is proposed. Firstly, the wavelet packet decomposition is used to decompose vibration signals to generate frequency band energy spectrum, and the bearing characteristic information is constructed from the energy spectrum to extract and enhance the bearing fault characteristic information. Secondly, the penalty and kernel parameters are optimized globally by sparrow search algorithm to improve the classification accuracy of support vector machine, and then construct the WPES-SSA-SVM model. Finally, the proposed model is used to diagnose and analyze the measured signals. Compared with BP, ELM and SVM, the effectiveness and superiority of the proposed method are verified.

Keywords—Wavelet packet energy spectrum; sparrow search optimization; support vector machine; rolling bearing

I. INTRODUCTION

With the deep integration of new generation information technology and manufacturing industry, the mechanical equipment is becoming more and more complex, accurate and intelligent. With the continuous operation of mechanical equipment, its running state and key parts will gradually degenerate, and the probability of failure and shutdown will gradually increase, which will affect the normal production and processing of enterprises. As one of the important components of machinery, rolling bearings are widely used because of their convenient use and maintenance, reliable operation and good starting performance [1]. Using the characteristics of bearings, the sliding friction between parts is transformed into rolling friction, which improves the production efficiency of the equipment. Once damaged, it will lead to problems in the operation of mechanical equipment, reduce the working efficiency, and even cause the functional failure of rotating machinery, resulting in serious economic losses and personal casualties[2-3]. Therefore, it is of great practical value to timely find and take corresponding measures for the faults of rolling bearings, and it has become a research hotspots in intelligent fault diagnosis.

In recent years, fault diagnosis methods for rolling bearings have been emerging and developing[4-7]. Fault diagnosis methods for rolling bearings have mushroomed and developed continuously. In general, the fault diagnosis

techniques of rolling bearings include: based on vibration signal[8], acoustic signal[9], electrical signal[10] and temperature signal[11]. Among them, vibration signal is more widely used, more intuitive and simple, because it can best represent the fault characteristic information in the process of bearing operation.

As the rapid and continuous development of machine learning and artificial intelligence, more and more researchers combine bearing fault diagnosis with it, and the intelligent fault diagnosis methods and systems are gradually improved. The common fault identification methods include deep learning (DL)[12], artificial neural network (ANN)[13], decision tree (DT)[14] and support vector machines (SVM)[15,16]. Literature [17] proposed the improved BP neural network algorithm Levenberg-Maquardt algorithm in order to improve the diagnostic efficiency of BP neural network. Literature [18] proposed a fault extraction method based on modified Fourier mode decomposition (MFMD) and multi-scale displacement entropy, and combined with BP neural network. Experiments show that this method has high recognition accuracy for different types of faults. In literature [19], wavelet packet energy and decision tree algorithm are combined to extract faults using wavelet packet energy, and then faults are identified and classified using decision tree model. In view of the low fault diagnosis rate of rolling bearings, the method of wavelet packet decomposition and gradient lifting decision tree (GBDT) was proposed in literature [20], and the extracted fault feature data set was input into the classification model of gradient lifting decision tree for fault diagnosis. In literature [21], scale invariant feature transform (SIFT) and kernel principal component analysis (KPCA) were used to extract faults, and SVM classifier was combined to achieve fault classification. Literature [22] applied SVM to fault state identification of rolling bearings and achieved good results. Literature [23] proposed a rolling bearing fault diagnosis method optimized by simplex evolutionary algorithm and SVM. Literature [24] diagnoses fault types by reducing high-dimensional data and using LSSVM.

At present, various intelligent optimization algorithms have emerged one after another, such as particle swarm optimization (PSO), whale optimization algorithm (WOA), ant colony optimization (ACO), genetic algorithm (GA), sparrow search algorithm (SSA), etc., and the combination and improvement of other algorithms have also achieved good results[25]. In reference [26], PSO was used to optimize SVM to realize the identification of multiple fault states of rolling

bearings. In [27], gray wolf optimization algorithm (GWO) was used to optimize the kernel function parameters of SVM globally, so as to achieve the best classification performance of SVM and improve the accuracy of classification recognition. Aiming at the influence of mixed noise of bearing vibration signals on useful information extraction, an optimization classifier based on multi-scale permutation entropy and cuckoo search algorithm (CS) was proposed in literature [28], which used CS to optimize the global optimal solution of SVM. Literature [29] proposed a method based on quantum behavior particle swarm optimization algorithm (QPSO), multi-scale displacement entropy and SVM to construct fault feature sets to realize fault identification of rolling bearings. Compared with single method for fault diagnosis, the combinatorial optimization methods have higher accuracy, but at the same time, different optimization methods have different problems, for example, BP model must be learned through a large amount of sample data, even if has been optimized the BP network parameters globally by optimization algorithm, the model is still not ideal in a small sample environment. SVM parameters can be optimized by PSO and other optimization algorithms to improve the classification accuracy, but this algorithm is prone to fall into local extremum. Therefore, combining the advantages of each algorithm and joint application to improve the effectiveness of rolling bearing status identification and fault diagnosis is the current research trend.

To improve the accuracy of bearing fault diagnosis, this paper firstly uses wavelet packet energy spectrum to extract energy spectrum feature vectors of bearing vibration signals, which are used as the input of SVM. Meanwhile, SSA algorithm is used to optimize the parameters of SVM globally, so as to build a hybrid model. The feasibility and effectiveness of the model are verified by experiments.

The rest parts of this paper are given as lists: Section 2 presents the preliminaries. Section 3 describes of the proposed method. Section 4 details the experimental setup. Section 5 analyzes and discusses the experimental results. Finally, Section 6 outlines the main conclusions.

II. PRELIMINARIES

A. Wavelet Packet Energy Spectrum

Wavelet packet decomposition can decompose signals into different frequency bands without leakage and overlap according to any time-frequency resolution. After wavelet packet transform, the information is intact and all frequencies are retained, which provides strong conditions for extracting the main information in the signal. This decomposition can be performed as many times as needed to obtain the desired frequency.

Fig. 1 shows the schematic diagram of orthogonal wavelet packet decomposition of a signal. The original signal was denoted as S_0 , and the two sub-bands S_{10} and S_{11} of layer 1 can be obtained after wavelet packet decomposition through filters H and G. Decompose the two sub-components of the first layer respectively to obtain the four sub-bands S_{20} , S_{21} , S_{22} and S_{23} of the second layer; By analogy, the sub-band of layer n can finally be obtained.

Fig. 1. Schematic Diagram of Wavelet Packet Decomposition.

As can be seen from Fig.1, wavelet packet decomposition decomposes the decomposed frequency band several times, and re-decomposes the high frequency part without subdivision in the wavelet decomposition. In addition, according to the characteristics of the signal to be decomposed, the corresponding sub-frequency band can be adaptively selected to match the frequency spectrum of the signal. After wavelet decomposition, all the characteristic information, including the low frequency part and the high frequency part, can be preserved, which provides strong support for the feature information extraction of the signal.

It can also be seen from Fig.1 that if there are too many decomposition layers, the dimension of the data to be processed will be increased and the unrestricted decomposition cannot continue. In practical application, it is necessary to select an appropriate decomposition level according to the actual situation.

Wavelet packet energy spectrum enhances the stability of wavelet packet decomposition coefficient by extracting the energy of sub-band to construct feature vector. The wavelet packet frequency band energy is defined as follows:

Using wavelet packet to decompose the original signal S_0 in n level, and $2n$ sub-frequency band can be decomposed. The energy calculation formula of sub-frequency band ni is Formula 1.

$$E(ni) = \sum f_{ni}^2 \quad (1)$$

where, f_{ni} is the coefficient of sub-frequency band ni , $ni = 1, 2, \dots, 2^n - 1$.

Therefore, the wavelet packet frequency band energy spectrum is defined as Formula 2.

$$En = [En_0, En_1, En_2, \dots, En_{2^n-1}] \quad (2)$$

B. Support Vector Machines

SVM is a machine learning algorithm based on statistical learning theory, which can successfully deal with many data mining problems such as pattern recognition, classification and regression analysis. It shows many unique advantages in solving small sample, nonlinear and high-dimensional pattern recognition problems, and overcomes the problems of dimension disaster and over-learning to a large extent.

Based on the theory of minimum construction risk, support vector machine maximizes the distance between the elements closest to the hyperplane and the hyperplane. Its core is to establish the best classification hyperplane, so as to improve the generalization processing ability of learning classification machine.

Taking binary classification as an example, its basic idea can be summarized as follows: first map the input vector to a high-dimensional feature space through some prior selected nonlinear mapping such as kernel function, and then seek the optimal classification hyperplane in the feature space, enables it to as much as possible to separate two classes of data points correctly, at the same time to separate two classes of data point furthest distance classification surface, as shown in Fig. 2.

Fig. 2. Classification Principle of SVM Method.

In Fig. 2, square and triangle represent two types of samples respectively. H is the optimal classification hyperplane; H_1 and H_2 are straight lines that pass through the boundary points of the two types of samples and are parallel to H , and the distance between them γ is the interval. The optimal classification line requires that the classification line can not only correctly classify the two categories, but also maximize the interval. The vector closest to the optimal classification hyperplane is called the support vector.

Assume the training sample set $\{x_i, y_i\}, i = 1, 2, \dots, m$; $x_i \in R^n, y_i \in \{-1, +1\}$, where x_i is the input index, y_i is the output index, m is the sample number, and n is the characteristic dimension of the sample. In the case of linear divisibility, there is a hyperplane that separates the two types of samples completely, as shown in Formula 3.

$$(\omega \cdot x) + b = 0 \quad (3)$$

where, $\omega = (\omega_1, \omega_2, \dots, \omega_n)$ is the weight vector of the training sample, which determines the direction of the hyperplane. x is the input vector; b is the distance between the hyperplane and the origin.

Solving the optimal classified hyperplane is to find the optimal ω and b , therefore, it can be summed up as the following quadratic programming problem:

$$\begin{cases} \min \frac{1}{2} \|\omega\|^2 \\ y_i = [(\omega \cdot x_i) + b]; i = 1, 2, \dots, m \end{cases} \quad (4)$$

In order to solve the quadratic programming problem of Formula 4, the Lagrange function \mathbf{a} is introduced and the duality principle is used to transform the original optimization problem into Formula 5:

$$\begin{cases} \max Q(\mathbf{a}) = \sum_{i=1}^m a_i - \frac{1}{2} \sum_{i=0}^m \sum_{j=0}^m a_i a_j y_i y_j x_i^T x_j \\ s. t. \sum_{i=1}^m a_i y_i = 0; a_i \geq 0; i = 1, 2, \dots, m \end{cases} \quad (5)$$

According to Formula 5, the optimal \mathbf{V} is $\mathbf{a}^* = (a_1^*, a_2^*, \dots, a_m^*)^T$. Thus, the optimal weight vector ω^* and the optimal value b can be calculated by Formula 6 and Formula 7.

$$\omega^* = \sum_{i=1}^m a_i^* y_i x_i \quad (6)$$

$$b^* = y_i - \sum_{j=1}^m a_j^* y_j x_j^T x_i \quad (7)$$

Then the optimal classification hyperplane is $(\omega^* \cdot x) + b^* = 0$, and the optimal classification function is obtained.

$$f(x) = \text{sgn}(\sum_{i=1}^m a_i^* y_i (x_i \cdot x_j) + b^*), x \in R^n \quad (8)$$

C. Sparrow Search Algorithm

SSA realizes optimization based on the idea that swarm organisms in nature can obtain a better living environment through mutual cooperation[30]. The bionic principle is as follows: in order to obtain abundant food, the sparrow population is divided into explorers and followers in the process of foraging. The explorer in the sparrow population who finds abundant food sources is responsible for providing the foraging area and the direction of food sources for the population, and the followers is responsible for finding more food according to the location provided by the explorer. At the same time, individual sparrows will also monitor the behavior of other individuals and compete for supplies with high-foraging peers. When the population is in danger, it will make anti predation behavior. The external sparrow will constantly adjust its position to move closer to an internal or adjacent partner to increase its own security. Therefore, the distribution of food in space can be regarded as the numerical value of function in three-dimensional space. The purpose of sparrow search is to find the global optimal value.

The specific implementation process of sparrow search algorithm is as follows. In the process of searching for food, the randomly generated position matrix X of n sparrows in the d dimensional space is shown as follows:

$$X = \begin{bmatrix} x_1^1 & x_1^2 & \dots & x_1^d \\ x_2^1 & x_2^2 & \dots & x_2^d \\ \vdots & \vdots & \ddots & \vdots \\ x_n^1 & x_n^2 & \dots & x_n^d \end{bmatrix} \quad (9)$$

where n represents the number of sparrows, d represents the dimension of the variable of the problem to be optimized, x_i^j ($i = 1, 2, \dots, n; j = 1, 2, \dots, d$) is the position of the j sparrow in i -dimensional space.

The fitness values are calculated and sorted to determine the finders and entrants, and 10% of randomly selected individuals are scouters. Obtain the current optimal sparrow individual position, and the best fitness value. For the first generation of sparrows, the initial optimal is obtained.

$$F = \begin{bmatrix} f([x_1^1 & x_1^2 & \dots & x_1^d]) \\ \vdots \\ f([x_n^1 & x_n^2 & \dots & x_n^d]) \end{bmatrix} \quad (10)$$

where f represents fitness values of individual sparrows.

In constant iterative optimization process, the explorers in the sparrow population have two main tasks: looking for food and guiding the movement of the population. When the scouters feel dangerous, will alert the populations and guide the followers to a safe area. The location of the explorers is updated as follows:

$$X_{ij}^{t+1} = \begin{cases} X_{ij}^t \cdot \exp\left(\frac{-i}{\alpha \cdot T}\right), & \text{if } R_2 < ST \\ X_{ij}^t + QL, & \text{if } R_2 \geq ST \end{cases} \quad (11)$$

where X_{ij}^t represents the position of the i -th sparrow in the j -th dimension of the t generation. α is a random number in the range of $[0,1]$; T represents the maximum number of iterations; Q is a random number that follows normal distribution; L represents a $1 \times d$ matrix where each element is 1; R_2 and ST represents the alarm value and alarm threshold respectively, $R_2 \in [0,1]$, $ST \in [0.5,1]$. When $R_2 < ST$ means that there are no predators around foraging at this time and the explorer can conduct extensive foraging operation. Conversely, it indicates that some sparrows in the group have found predators and send Danger Warnings to the rest, thus ensure that all sparrows can quickly move to a safe area to forage.

Followers search for food by monitoring and following the explorers with the highest fitness. According to the sorting principle, when $i > n/2$, the individual fitness value is low, and these followers need to search other locations to improve the individual fitness value. Conversely, the sparrow will randomly find a location near the current optimal location for feeding.

$$X_{ij}^{t+1} = \begin{cases} Q \cdot \exp\left(\frac{X_{worst}^t - X_{ij}^t}{i^2}\right), & \text{if } i > n/2 \\ X_p^{t+1} + |X_{ij}^t - X_p^{t+1}| \cdot A^+ \cdot L, & \text{if } i \leq n/2 \end{cases} \quad (12)$$

$$A^+ = A^T(AA^T)^{-1} \quad (13)$$

where X_{worst}^t represents the global worst position of the t -th iteration; X_p^{t+1} is the best position of the $t+1$ generation explorer. A is a $1 \times d$ dimensional matrix with each dimensional value randomly generated from 1 or -1.

Individual sparrows will move to the search circle or other companions when they encounter danger during the foraging process. The method of updating the position of individual sparrows in this process is shown in Formula (14).

$$X_{ij}^{t+1} = \begin{cases} X_{best}^t + \beta \cdot |X_{ij}^t - X_{best}^t|, & \text{if } f_i > f_g \\ X_{ij}^t + K \cdot \left(\frac{|X_{ij}^t - X_{worst}^t|}{(f_i - f_w) + \varepsilon}\right), & \text{if } f_i = f_g \end{cases} \quad (14)$$

where β is the step size control parameter, and it follows the normal distribution with mean value 0 and variance 1; K is the moving direction of the sparrow, and the value range is $[-1, 1]$; ε is the minimum constant to avoid zero denominator; X_{best}^t represents the current global optimal location; f_i represents the fitness value of sparrow i ; f_w and f_g represent the current worst and best fitness values, respectively.

III. PROPOSED MODEL

To improve the fault diagnosis accuracy of bearing vibration signals, a hybrid fault diagnosis model is constructed by using wavelet packet energy spectrum, SSA and SVM, which is named WPES-SSA-SVM. In order to accurately extract features, wavelet packet energy spectrum is used to extract feature information from vibration signals, and the energy of reconstructed signals are calculated through wavelet packet decomposition and reconstruction, and the feature vector is established. Then, SSA is used to optimize the penalty parameter c and kernel parameter g globally to improve the learning ability and generalization ability of SVM classifier. The model consists of data feature extraction, SSA optimization and SVM recognition. The functions of each part and the information transmission between them are shown in Fig. 3.

1) *Data feature extraction module*: Using wavelet packet decompose the bearing vibration signal, and the wavelet packet frequency band energy spectrum is generated according to the decomposition results. Taking the energy spectrum information as the fault diagnosis features, and divide it into training and test data set in proportion. Then, the training data is transmitted to the SSA optimization module, and the training and test data are transmitted to the SVM recognition module.

2) *SSA optimization module*: The SSA optimization module receives the training data from the data feature extraction module and the value range of penalty parameter c and kernel parameter g from the SVM recognition module respectively, uses SSA to find the best penalty parameter c and kernel parameter g , and returns them to the SVM recognition module.

3) *SVM recognition module*: The SVM recognition module first transmits the value range of penalty parameter c and kernel parameter g to the SSA optimization module for parameter optimization, then receives the optimized parameters, and carries out machine training using the training data received from the data feature extraction module. After that, the fault diagnosis on the test data is recognized to test the recognition effect.

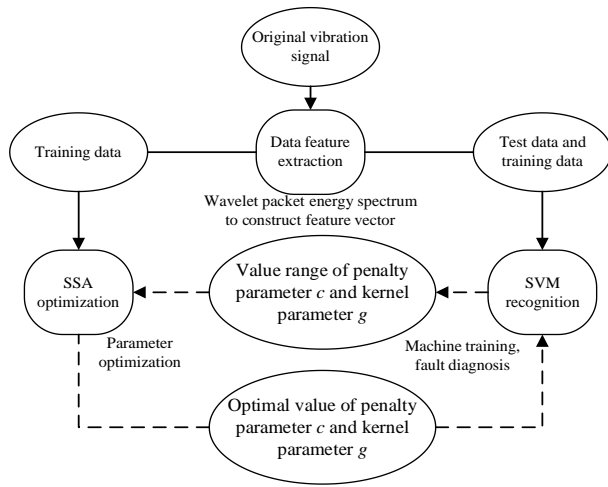

Fig. 3. Function and Information Transmission Path of each Module in WPES-SSA-SVM Model.

The algorithm of the model is divided into nine steps, and the flow chart is shown in Fig. 4.

Step 1: The original vibration signal is decomposed by wavelet packet, and the frequency band energy spectrum is calculated, and then the data is randomly divided into test data and training data in proportion.

Step 2: Select the kernel function to construct SVM, mainly including linear kernel function, RBF kernel function, polynomial kernel function and Sigmod kernel function, and set the value range of penalty parameter c and kernel parameter g .

Step 3: Initialize sparrow population. Set the population size $Size$, the maximum number of iterations T_{max} , the individual position X , where X is the multidimensional coordinate composed of penalty parameter c and kernel parameter g , the proportion E, F, S of explorers, followers and scouts, and the safety threshold ST .

Step 4: Using the classification accuracy as the fitness function value of SSA.

Step 5: Find the global optimal position. The fitness value f of individual position is obtained by using training data. The larger the value is, the better the position is, and the global optimal position is the position with the largest f . If multiple positions at the same f , the optimal position is the one with the smallest penalty parameter c .

Step 6: Update the population position and global optimal position.

Step 7: Iteration number condition judgment. If the current of iterations $t < T_{max}$, return Step 6 to continue running; Otherwise, execute Step 8.

Step 8: Using SSA optimization to get the best parameters, and the SVM is trained through the training data.

Step 9: Input the test data into SVM, output the calculated bearing fault label value, identify the fault type, and compare it with the real fault type label in the original data to verify the diagnosis effect.

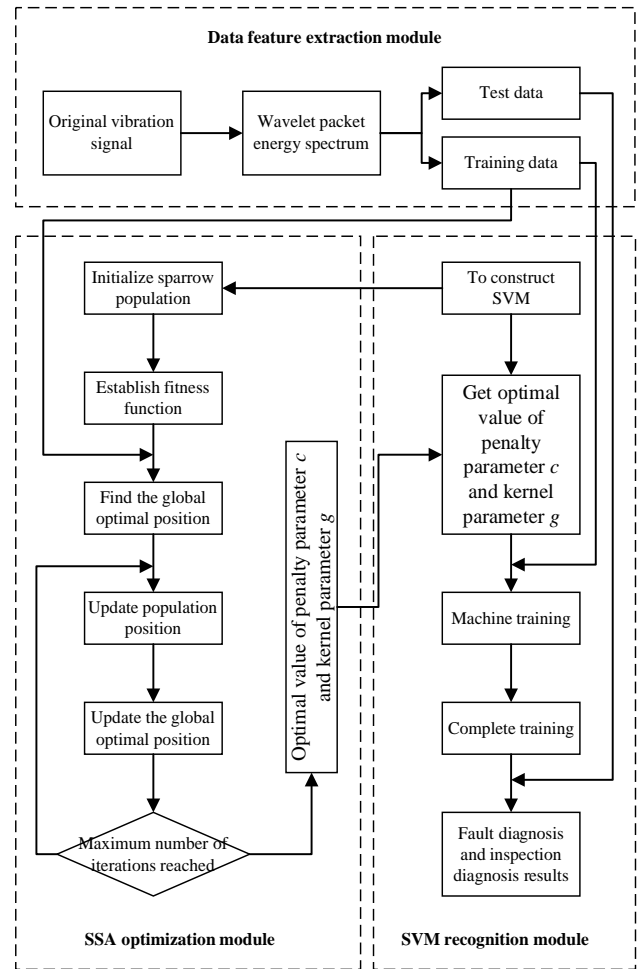

Fig. 4. Algorithm Flow Chart of WPES-SSA-SVM Model.

IV. EXPERIMENTATION

Feature extraction and fault diagnosis were performed using simulated fault data from the bearing experiment data provided by Case Western Reserve University (CWRU). The data set has been applied in many experimental studies and achieved good results. The time domain and wavelet packet characteristics of vibration signals are extracted from the official experimental data and fault diagnosis is carried out. The structure of the bearing test bench is shown in Fig. 5 [31].

Fig. 5. CWRU Bearing Test Bench.

The test bench is composed of three-phase induction motor, torque sensing device, electronic control unit, dynamometer and intermediate shaft. During the experiment, the motion state of the rolling bearing in the actual work is simulated. Single point defects with different widths such as 0.007, 0.014, 0.021, 0.028 and 0.040 inch are machined on different parts of the bearing by spark machining technology, so as to obtain the experimental data of different fault types, such as rolling element, inner race and outer race fault.

In this paper, the fault body diameter is 0.007 inch, the motor load horsepower is 1hp, the bearing model is SKF-6205-2RS-JEM, and the sampling frequency of acceleration sensor is 48KHz to collect the vibration signal data of normal bearing, inner race fault, outer race fault and rolling element fault at the driving end. Take 100 groups of data samples for each state, with a total of 400 groups of data samples. 100 samples are randomly divided into 70 training samples and 30 test samples after feature extraction by wavelet packet energy spectrum. The training samples are used to extract features for classification model training, and the test samples are used to test the effect of classification model. The parameters of rolling bearing are shown in Table I. The division and label setting of experimental data are shown in Table II.

TABLE I. ROLLING BEARING PARAMETERS

Type	Parameter
Bearing model	SKF-6205-2RS-JEM
Inner diameter	25.00mm
Outer diameter	52.00mm
Rolling elements number	9
Rolling element diameter	7.94mm
Pitch diameter	39.04mm
Contact angle	90°

TABLE II. STATISTICAL TABLE OF EXPERIMENTAL DATA

Bearing state	Fault body diameter	Number of samples	Label
Normal	0.007	100	1
Inner race fault	0.007	100	2
Outer race fault	0.007	100	3
Rolling element fault	0.007	100	4

V. RESULT AND DISCUSSION

The time domain waveform diagram can intuitively observe the waveform distribution and amplitude of the vibration signal in each state. The waveform will fluctuate with the fault location and size. The vibration signals of normal and different faults of bearings are shown in Fig. 6.

The wavelet packet decomposition with wavelet basis function as db3 is used to decompose the normal state, inner race, outer race and rolling element fault signals respectively, so as to obtain the decomposition coefficient and reconstruction coefficient, and then use the reconstruction

coefficient to reconstruct, finally obtain 8 sub-band energy, and the energy proportion of each frequency band is analyzed. Due to space limitation, this paper only lists the wavelet packet components of reconstructed nodes in normal state, as shown in Fig. 7. The energy proportion of 8 sub-bands in different states is shown in Fig. 8.

It can be clearly seen from Fig. 8 that there are differences in normalized amplitude of wavelet energy spectrum in different frequency bands after reconstruction of each node. Among them, the energy spectrum of sub-band 1 and 2 is relatively large in the four states, followed by the energy spectrum of sub-band 3 and 4, and the energy spectrum of sub-band 5, 6, 7 and 8 is relatively small, but there are slightly different in different states.

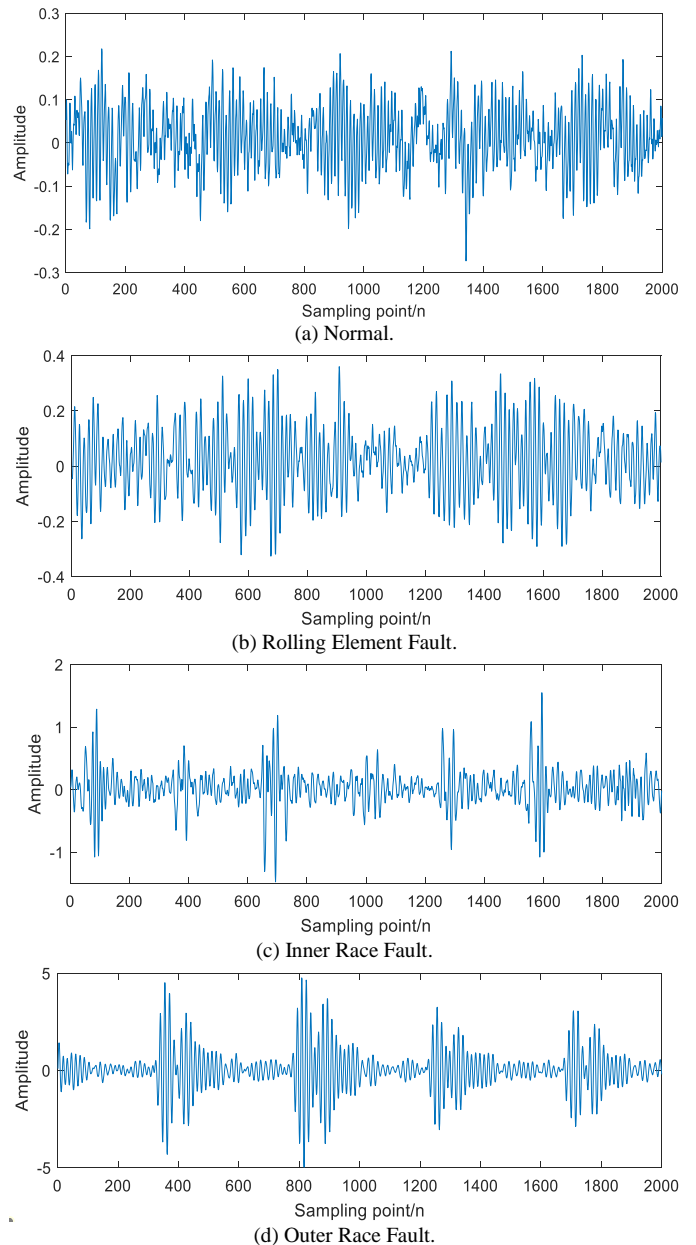

Fig. 6. Bearing Vibration Signal Diagram.

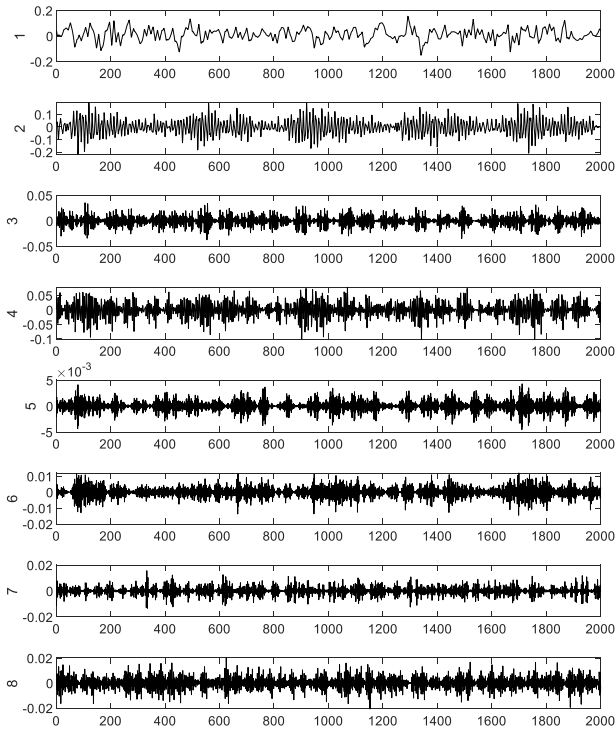

Fig. 7. Wavelet Packet Component of Normal Bearing Vibration Signal.

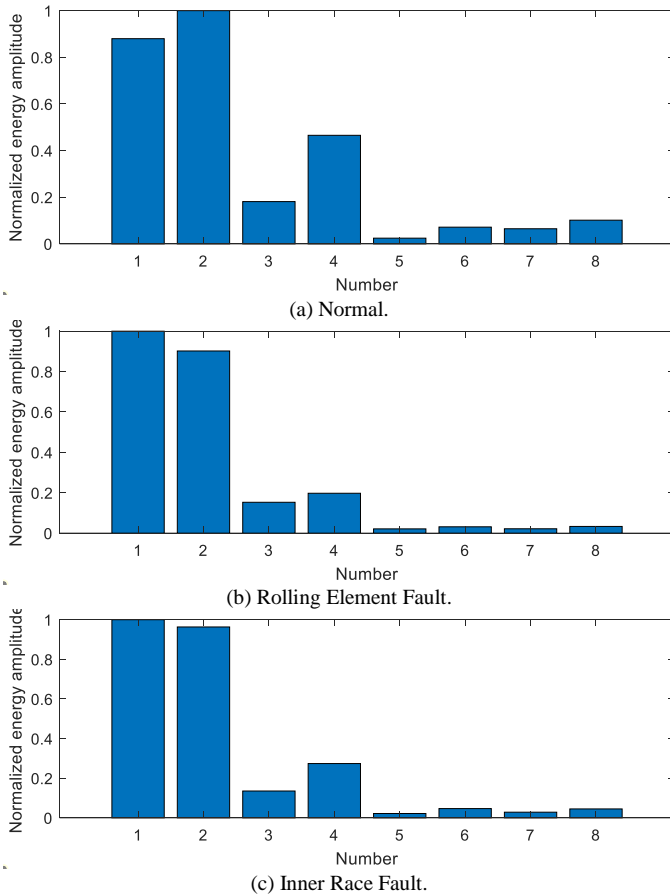

Fig. 8. Energy Spectrum of Wavelet Packet Frequency Band.

For example, when the bearing is in the normal state, the energy spectrum value of sub-band 4 is higher than that in the fault state. When the outer race fault occurs, the energy spectrum value of sub-band 1 is lower than that in other cases. In case of bearing inner race fault or rolling element fault, the energy spectrum graph is relatively close, but there is still a certain gap between the values of sub-band 4 and sub-band 6. The difference of wavelet packet energy spectrum graphics in different states reflects that the features extracted by wavelet packet transform are sensitive to the fault feature information of vibration signal. Therefore, the energy amplitude corresponding to each sub-band and the energy difference between frequency bands can be used to evaluate the different states of bearings.

To verify the feasibility and effectiveness of WPES-SSA-SVM, experiments were conducted on BP, ELM, SVM and WPES-SSA-SVM respectively. The diagnosis results are shown in Fig. 9, where 'o' stands for the fault category of the actual testing set, and '*' stands for the fault category predicted by the model.

From Fig. 9, the BP model misjudged 18 faults in total, including 5 rolling element faults misjudged into 3 inner race faults and 2 outer race faults, 8 inner race faults misjudged into 3 outer race faults and 4 rolling element faults and 1 normal, 5 outer race faults misjudged into 2 inner race faults, 2 rolling element faults and 1 normal, and the diagnostic accuracy is 85%. The ELM model misjudged a total of 16 faults, of which 4 rolling element faults were misjudged as 1 inner race fault and 3 outer race faults, 6 inner race faults were misjudged as 3 rolling element faults and 3 outer race faults, 6 outer race faults were misjudged as 1 rolling element fault and 5 inner race faults, and the diagnostic accuracy was 86.67%. There are 14 wrong judgments in SVM model, including 3 wrong judgments of rolling element fault, 2 wrong judgments of inner race and 9 wrong judgments of outer race. The diagnostic accuracy is 88.33%. WPES-SSA-SVM model misjudged 4 faults in total, including 1 rolling element fault misjudged as inner race fault, 2 inner race faults misjudged as outer race fault and 1 outer race fault misjudged as rolling element fault. The number of misjudged in the four states has been well improved. WPES-SSA-SVM model has the best diagnostic effect for ELM model, SVM model and BP model, and the diagnostic accuracy is 96.67%. The experimental results show that using wavelet packet energy spectrum for feature extraction and SSA to optimize SVM model can improve the performance of fault diagnosis, and has obvious advantages over other non-optimized models.

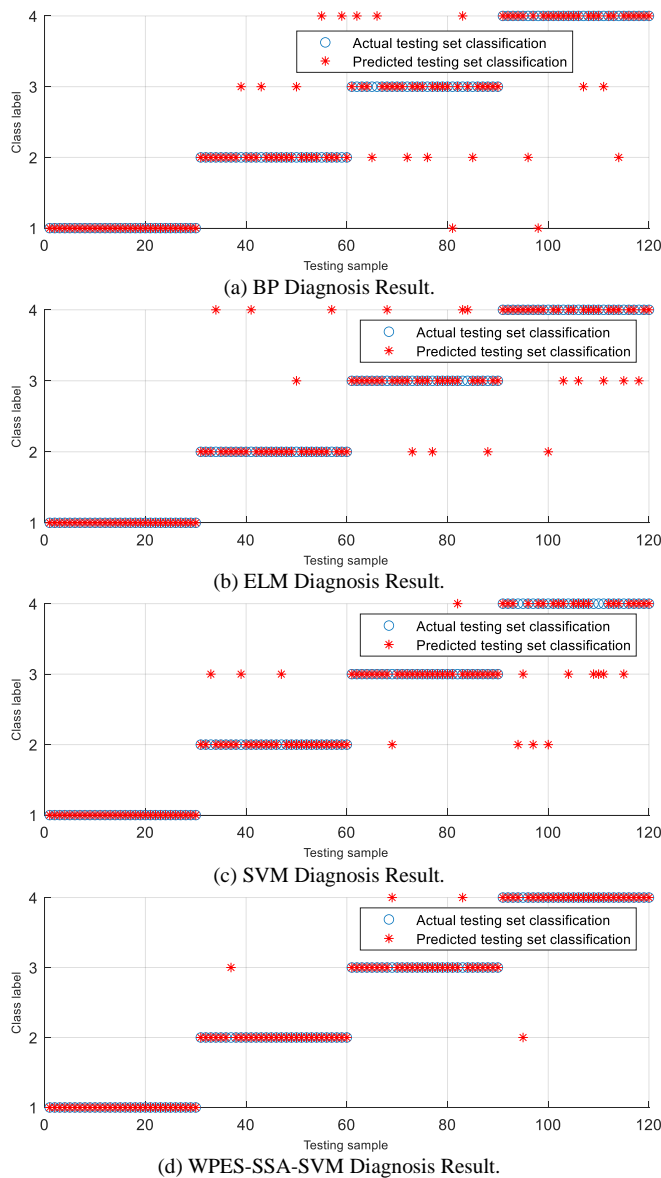

Fig. 9. Fault Diagnosis Results of Different Models.

VI. CONCLUSION

In this paper, we proposed a hybrid fault diagnosis method based on wavelet packet energy spectrum, SSA, and SVM in rolling bearing. Aiming at the difficulty of feature extraction of bearing vibration signals, wavelet packet decomposition was used to extract the wavelet packet features of vibration signals, and the energy spectrum of wavelet components is calculated and normalized to form the feature vector set, which fully contained the fault feature information of vibration signals. To improve the accuracy of fault diagnosis, the penalty parameter c and kernel parameter g of SVM are optimized by using the good global optimization ability of SSA, so as to build a hybrid fault diagnosis model WPES-SSA-SVM. To verify the classification performance of WPES-SSA-SVM, the CWRU bearing vibration data set is used to extract fault features and diagnose faults. The results show that compared with BP, ELM, and SVM, the proposed method can accurately extract the feature information from the

original vibration signals, and has higher diagnosis accuracy. SSA helps to optimize the parameters and improve the classification performance of SVM. In the future, we will use data from other industries and scenarios for diagnosis, and further investigate the improvement of model performance and diagnostic accuracy.

Abstract—The illegitimate access to biometric templates is one of the major issues to be handled for authentication systems. In this work, we propose to use two instances of finger vein images which inherits the advantages of a robust multi-modal biometric authentication system without needing different sensors. Two local texture feature extraction methods are experimented on standard finger-vein datasets. Fused discriminating features with reduced dimension lowers down the system computational cost. A cancelable template protection scheme as Gaussian Random Projection based Index-of-Max is then applied for embedding privacy and security to the templates. Foremost template protection properties like revocability, non-invertibility and unlinkability are observed to be significantly obeyed by the proposed system with considerable authentication performance. Recognition performance of the proposed methods are compared with some previously executed finger vein systems and observed to be less complex and overperforming on the combined basis of authentication and template protection. Thus, the proposed system utilizes multiple evidence and provides a balanced performance with respect to authentication, template protection and computational cost.

Keywords—Finger vein; multi-instance; authentication; cancelable; template protection

I. INTRODUCTION

Information Technology and Internet driven life has created the extreme need for securing the evidence related to personal identity. Biometrics based authentication systems put up some problems related to security and privacy of data [1], owing to which an efficient template protection scheme needs to be employed. The requirements regarding irreversibility, revocability, unlinkability and performance preservation should be satisfied by an effective template protection technique. To meet these requirements, various techniques have been investigated as bio-cryptosystems and cancelable biometrics. Among them, Cancelable biometrics is more appropriate technique to handle both, the security and privacy of templates by repeatedly deforming the template features using some transformation.

The design of transformation function should be extremely difficult to invert, enabling computational infeasibility to get the original features back from the transformed template. This characteristic prevents the privacy attack to get original data back. Renewability is another property that the designed transformation function should come up with. This enables generation of newly transformed template if the previously

enrolled template is compromised. Additionally, templates created by using different transformations should not match with each other applying diversity to the template protection technique. Furthermore, it should be challenging to differentiate between the templates established by same biometric information. This prevents cross matching of biometric data across various applications, obeying the unlinkability property. More importantly, when all the above-mentioned security and privacy preserving characteristics are considered to design a transformation function, it should not reduce the authentication level. The proposed framework applied the Gaussian Random Projection based Index of Max (GRP-IoM) hashing technique [2] on the real valued finger vein features to generate cancelable and highly non-invertible protected templates.

The proposed work is utilizing multiple instances of finger veins for authenticating people. Finger veins are innate, non-intrusive, and highly resistant to duplication and captured by small imaging sensor. Additionally, distinct patterns for twins [3] and liveness detection property are included in finger veins. Occasionally, finger vein images suffer from illuminations and blood fluctuations and becomes low contrast and unstable. Thus, to overcome this low-quality issue to some extent, combination of multiple instances of finger vein images will be beneficial minimizing the limitations of unimodal biometrics viz. non-universality, intra-class deviations, inter-class resemblance, scope for spoofing, etc. Thus, in this work, we propose fused-discriminant (FD) feature set extraction from two instances of finger vein images with two different local texture-based features. The feature extraction techniques experimented is Uniform Local Binary Pattern (ULBP) [4] and Local Hybrid Binary Gradient Contour (LHBGC) [5]. The texture features from the two finger vein instances are fused as well as reduced in size by maintaining their correlation within an individual and enhancing their discrimination between the individuals. This improves authentication performance and reduces computational intricacy transformation for template protection and matching. Thus, the key contributions of the proposed framework are outlined as follows:

- Generating highly irreversible, un-linkable and revocable templates by using fused-discriminant feature set.
- Person authentication is based on two separate identity proofs rather than single finger vein image to overcome the issues like low quality with lower computation cost.

- Two different texture-based features (ULBP and LHBGC) are experimented in their fused-discriminant forms for generating protected templates and preserving authentication performance, significantly.

This paper is organized as follows. Section II describes some of the previous work carried on, in the field of single and multi-instance finger vein authentication and a variety of template protection methods that has been practiced for the same. Section III provides description regarding the fundamental methods used in the proposed authentication system with template protection. Thereafter, in Section IV, details of implementation process for the proposed multi-instance finger vein-based authentication system and obtained experimental results for authentication and template protection are represented and analyzed. Validations of obtained authentication and time complexity results are shown by comparing with some earlier reviewed work. To conclude, Section V covers the overall contribution of the proposed authentication framework and its further scope.

II. RELATED WORK

Various approaches have been practiced for utilizing finger veins for authentication purpose. Handling the security issue of biometric templates with authentication is a great challenge. In Section II-A, different methodologies implemented for finger vein-based authentication are discussed. Further, Section II-B gives overview of various schemes practiced for protecting finger vein templates.

A. Finger Vein based Systems

There are line-based, point-based and texture-based features popularly used for vascular pattern finger vein regions. Line-based finger vein feature extraction is initiated by [3] in the form of Repeated Line Tracking (RLT) method through a line tracking algorithm. The author continued his research in [6] by extracting the center lines of the veins, calculating their local maximum curvatures. This method is found to be robust against variations in vein-widths. Later, [7] proposed Wide Line Detector (WLD) with comparatively faster vein pattern extraction but at the expense of degradation in authentication performance. In [8], Enhanced Maximum Curvature (EMC) method is used for feature extraction which identifies fine delineations in vein-patterns using Histogram of Oriented Gradients (HOG) but observed to be slower than WLD. Alternatively, some point-based feature extraction methods are also practiced as minutiae points in [9] or multiple key point sets from SIFT (Scale-invariant Feature Transform) in [10]. Ultimately, point based features also needs vein patterns involving computational cost for extracting vein pattern. In [11], special points as cross/end points of veins and connections between them are matched to reduce the finger vein matching time. The performance of this scheme is sensitive to Region of Interest (ROI) and used only good quality images for evaluation.

In texture-based approach, various classical and innovative methods for extracting texture information have been practiced. Most widespread method adept of extracting recognizable features from such images is Local Binary Pattern (LBP). This LBP method introduced by [12] is fast in which

texture features are obtained from gray level difference in neighborhood pixels. These classical LBP features are lengthy and observed to be very sensitive to image translations and rotations. To cope with this, there are various LBP variants proposed previously for finger veins and other biometrics [13]. In [14], t-norm based fusion of LBP feature scores belonging to two finger vein instances is implemented using hamming distance. Accurate authentication primarily depends on discriminability of features. Another variant of LBP as Local Hybrid Binary Gradient Contour (LHBGC) features [5] are shown to be more informative on finger veins compared to [13, 14]. This method computes local histograms to compute the frequencies of sign and magnitude components, locally in the image. Further, Uniform LBP (ULBP) texture feature extraction proposed by [4] is very much suitable to finger vein structure. As the vein will either lie inside or cross the neighborhood in vein-region, the resulting pattern will not have many distinguished bitwise transitions. Thus, these ULBP features which are more compact than LBP, covering majorly uniform patterns are suitable for finger vein. ULBP features preserving spatial information are found to have some degree of invariance to rotation, pose and illumination because of histogram computation over image partitions. Variety of feature extraction methods complementing with different classifiers have been practiced for finger vein images [15-20]. Some recent finger vein-based authentication implemented Machine Learning (ML) and Artificial Intelligence (AI) approach especially for identification, if huge data needs to be worked on. [21] utilized VGG-Net-16, which is composed of thirteen convolutional fully connected layer model finely tuned and pre-trained with two finger vein image difference. A deep learning-based technique is proposed by [22] to work on finger vein images of varying quality. This network comprised of four convolutional layers and is experimented on four different databases. Deep learning methods requires heavy processing configuration with huge amount of training data. Parameter tuning is another complex process to be handled in case of AI applications.

In this work, we offer to use two variants of LBP as Uniform LBP (ULBP) and Local Hybrid Binary Gradient Contour (LHBGC), considering their feature discriminability and suitability for finger veins. Additionally, LBP based methods are proven to be resistant to uneven shading and saturation from input imaging devices [23]. The proposed authentication is using ULBP and LHBGC features for multiple instances of finger vein, in their Fused-Discriminant form as FD-ULBP and FD-LHBGC respectively for reducing their dimensions and enhancing discriminability. These features are further transformed for template protection and their authentication performances are analyzed in transformed domain.

B. Finger Vein Template Protection

Severe security and privacy threats are faced by biometric templates stored in database, regarding unauthorized access, original feature breeding from coded template or from cross matching across applications. Bio-cryptosystems (BCS) and cancelable biometrics (CB) are the major template protection schemes employed to secure the templates. As the proposed framework is implementing CB for the previously mentioned

advantages, major emphasis is given on CB techniques. CB schemes are enormously practiced to secure various popular unibiometric traits as face [24], fingerprint [25] and iris [26]. CB techniques for different combinations of multi-biometric traits have also been practiced. Fusion of multiple traits at different levels are investigated in [27] for better performance. Feature level fusion [28] is advantageous over others, especially if template protection is needed as single fused protected template has to be handled. On the contrary, compatibility issues for features generated out of different biometric traits is highly challenging. When these fused-diverse features are transformed to form cancelable templates, preserving recognition performance is critical. A balanced solution to this is multi-instance biometrics offering multiple evidence-based authentications with compatible features and no extra sensor.

Focusing on CB for securing finger vein images [29] proposes a combined CB and BCS approach by applying cancelable bio-hashing method to finger vein image. Bio-hashing transforms finger vein Gabor features compacted by Linear Discriminant Analysis (LDA) into binary string. Then the Fuzzy Commitment Scheme (FCS) and Fuzzy vault is applied to binary string. In [30], a similar approach of random projection based cancelable transform is applied on Gabor features reduced by Principal Component Analysis (PCA) and then FCS is operated on the resulted binary feature set. L2-Norm is used to classify the transformed templates. [31] again offers a random projection based cancelable transformation of vein end and intersection points and classification is done using Deep Belief Network (DBN). This approach requires password and a huge dataset for training. In [32], Bloom filter template security is utilized for fingerprint, signature, and their fused features. As Bloom filter technique can be applied to fixed length binary features, some fingerprint-oriented methods like minutiae cylindrical code employed to finger vein [33] can be utilized for Bloom-filter based CB. [34] proposed CB for finger vein image through block-remapping and image-wrapping based transformation before feature extraction in image domain. Gabor features are used for verification and renewability evaluation. Block remapping in image domain is observed to provide better performance than wrapping which is also dependent on block size. Recently, [35] proposed CB method using on Index of Max [2] with alignment robust hashing (ARH). This work has also experimented with block-remapping and image wrapping but in feature domain to extract binary features. In [35], various binary feature extraction methods are experimented with three different types of CB techniques. ARH with Index of Max hashing works fine for alignment-free situations but inferior to image wrapping in feature domain with respect to authentication performance. Also, there is no clear empirical analysis of revocability for ARH-Index of Max hashing. AI-based methods like Convolution Neural Network (CNN) are very popular for identification but needs huge data volume. Also, as CNN is reversible in nature, the original raw features fed to CNN for classification can be inverted back. In [36], finger vein bio-hashed binary features are transformed into non-invertible and renewable code using Binary Decision Diagram (BDD). This protected code is fed to the Multi-Layer Extreme Machine

Learning for verification and identification which runs the system fast. Recently, [37] also implemented bio hashing for securing finger vein templates made out of deep features using multi-term loss function showing excellent verification outcome but have not investigated for template protection factors like unlinkability or irreversibility.

In this article, we propose to use Gaussian Random Projection-based Index of Max (GRP-IoM) hashing for non-linear mapping of real valued fused feature set from instances of finger vein to generate integer based protected templates. Authentication performances along with corresponding computational costs of the proposed framework with two different texture features are evaluated. Theoretical and empirical evaluation of non-invertibility, unlinkability and revocability for the protected finger vein templates is also provided.

III. PROPOSED METHODOLOGY

The proposed framework is for person authentication using cancelable transformation of multiple instances of finger veins. Particularly, vascular patterns composed of veins within the human physique are difficult to counterfeit, contactless and concurrently provides liveness detection. Multi-instance finger vein-based authentication system makes the overall recognition performance depend on a greater number of biometric facts. Cancelable and distorted versions of fused features from multiple finger veins creates a secure verification system based on intrinsic biometric trait. This ensures renewability/revocability of our permanent unique features which are quite un-linkable across various applications. Various methods involved in this combined approach of authentication and template protection are explained as follows:

A. Finger Vein Processing

Finger vein verification involves challenges as finger vein images suffer from illumination and blood fluctuation factors. Captured finger vein images with poor contrast and misalignment may deteriorate authentication performance. So, for reliable finger vein verification, proper pre-processing and feature extraction techniques are needed. Details of methods used in the proposed framework for finger vein pre-processing and feature extraction are explained below:

1) *Finger vein pre-processing*: Finger vein pre-processing involves Region of Interest (ROI) extraction with finger alignment and image enhancement. ROI is localized by firstly detecting finger outline by edge detection algorithm and fitting a center line into the finger. The finger is gradually rotated and shifted using this center line until it gets aligned in the middle of the image with horizontal posture. The rectangular ROI is extracted masking out the background portion. Further, adaptive histogram equalization technique is used on finger vein ROI images to improve the vein pattern visualization. The noise removal is done using Wiener filter. Fig. 1 shows the overall result images for finger vein pre-processing in a sequential manner. For further details on preprocessing please refer to [38].

Fig. 1. Finger Vein Pre-processing.

2) *Finger vein feature extraction*: In the proposed approach, texture features belonging to two finger vein instances are combined with enhanced discriminability and compaction and then used for person authentication. Further these fused feature set is transformed for generating cancelable protected templates to incorporate template security. Two types of texture-based features are experimented, namely histograms of Uniform Local Binary Pattern (ULBP) and Local Hybrid Binary Gradient Contour (LHBGC). Both features are variants of original LBP method which is computationally less complex and extracts fine scale textures [12].

The first method implemented for finger vein texture feature extraction is histogram of uniform LBP. Original LBP description of a pixel in its canonical form is simple and created by comparing the intensity of P neighboring pixels to the center pixel in some radius r . These P comparisons in clockwise or anticlockwise direction is interpreted as a binary vector. Binary 1 is taken if the center pixel intensity is less than neighboring pixel, otherwise binary 0 is taken. This $LBP_{P,r}$ feature extraction process replaces each pixel in original image to a binary pattern except border pixels which do not have all neighboring pixels. These feature vectors can be transformed into histogram with $2P$ bins as each conceivable LBP is assigned to an individual bin. Various combinations of r and P are practiced but the most popular combination is $P=8$ with $r=1$. Proposed framework is also using $P=8$ with $r=1$ focusing on histogram dimensionality for computation, memory consumption and minimal original information loss. Further, it has been observed that specific binary patterns count for fundamental texture properties known as “uniform” patterns [4]. These uniform LBP features are observed to carry gray scale invariance and rotation invariance, but additional computations for rotation invariance are not incorporated in the present work as alignment of finger vein pattern is implemented in pre-processing. LBP is termed as uniform if it consists of maximum two 1-0 or 0-1 switching, viewing the bit pattern in circular way. For example, the pattern 00000110 is uniform whilst 10100000 is not. It is noticed that uniform patterns accounted for approximately 90 percent of all patterns. Hence, least information was lost by handing over all non-uniform patterns to one non-uniform category. If practiced particularly for $P=8$, it is seen that just 58 of the 256 possible 8-bit strings are uniform, we can thus encode all 256, 8-bit local binary patterns using 59 (58 uniform and 1 non-uniform)

codewords. To indicate that uniform patterns are being used, $u2$ is added as superscript to the LBP operator to generate $LBP_{P,r}^{u2}$. Selecting the uniform patterns thus reduces the histogram length to 59 ($P*(P-1) + 3$) bins from 256 ($2P$) bins for $P=8$. Histograms of individual patterns show lower distinguishability as compared to that of uniform patterns accounting for the variations in their statistical properties.

Fig. 2 explains the overall process of uniform LBP feature extraction. Each input pre-processed image instance of finger vein is firstly split into N number of blocks. In the present work, each block is of size 8×8 with $P=8$ and $r=1$. Histograms were then computed for each block and the resulting histograms were then concatenated together to form one feature vector. Spatial information was implicitly encoded into this feature vector from the order in which the histograms were concatenated. Hence, after histograms of uniform LBP feature calculation the overall combined histogram feature length for the entire image is of length, $59 \times N$. These texture features for the two finger vein image instances are calculated and further processed for feature fusion with dimension reduction and template protection.

The second method experimented for feature extraction of finger vein images is Local Hybrid Binary Gradient Contour (LHBGC) [5], which is also an LBP variant. LHBGC features are considered for its property of extensive information content regarding finger vein authentication as compared to various other texture features. This method computes the local histograms counting for frequencies of sign and magnitude for finger vein images, locally. Firstly, the preprocessed image of finger vein is subjected to sign and magnitude component extraction followed by local histogram calculation. Fig. 3 shows sign and magnitude computation in 3×3 neighborhood periphery for an input image. Adjacent pixel intensities are compared in 3×3 neighborhood periphery and these distances, b_i for $i=0, 1, \dots, 7$ are calculated using Eq. (1) which are further break down into sign and magnitude components. Hence, sign ($[s0, s1, \dots, s7]$) and magnitude ($[m0, m1, \dots, m7]$) vectors are obtained by decomposing distances ($[b0, b1, \dots, b7]$) as shown in Eq. (2). The sign values are equivalent to basic Binary Gradient Contour codes and this binary code is further translated to decimal number. The magnitude component value for each 3×3 region is calculated by adding each of $[m0, m1, \dots, m7]$.

$$b_i = p_i - p_{(i+1) \bmod 8}, i = 0, 1, 2, \dots, 7 \quad (1)$$

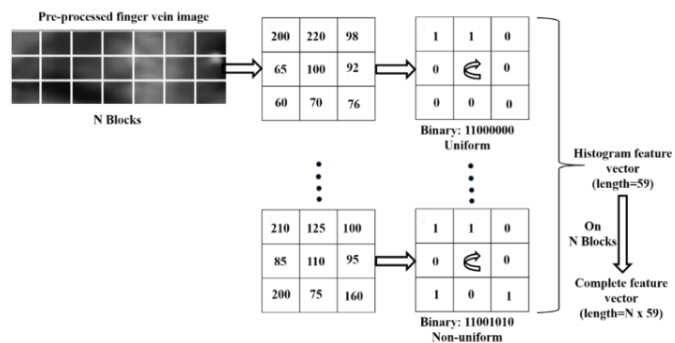

Fig. 2. Uniform Local Binary Pattern Histogram Feature Extraction Process.

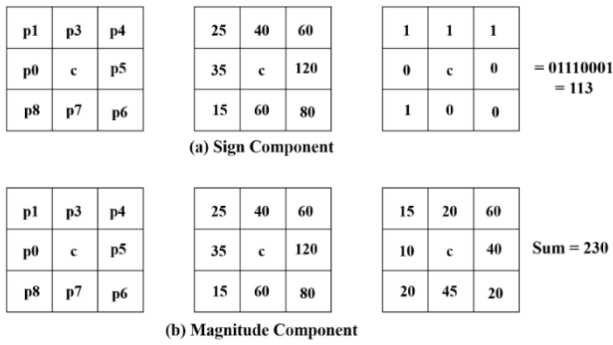

Fig. 3. Sign and Magnitude Component Calculation for Local Hybrid Binary Gradient Contour (LHBGC) Features.

where, $[p0, p1, \dots, p7]$ are the adjoining pixels along the periphery of 3×3 neighborhoods.

$$b_i = s_i * m_i \text{ and } \begin{cases} s_i \\ m_i = |b_i|, s_i = \begin{cases} 1, b_i \geq 0 \\ -1, b_i < 0 \end{cases} \end{cases} \quad (2)$$

The sign and magnitude components are distributed equally into number of cells for local histogram computation. For every single cell, a local histogram is computed, and the sign histogram bin is voted in a biased way by each pixel of the magnitude component in that cell based on the value present in the sign component. For further details on local histogram computation, please refer [5]. Various parameters involved in LHBGC feature extraction process are number of cells i.e., number of rows and columns with number of bins. The local histograms belonging to every cell are formed as vectors which are all concatenated to produce a combined feature vector for a finger vein image. This concatenated feature vector is of high dimension. Thus, further processing on this basic feature set is proposed for reducing feature dimensionality with enhanced feature discriminability.

3) *Finger vein feature fusion*: In the proposed approach, two texture-based features of finger vein image are experimented, namely ULBP and LHBGC as explained in the above section. The present work contributes for the effective person authentication using two instances of finger vein by fusing them into compact and informative feature set. Both ULBP and LHBGC histogram features are extracted from right index (RI) and right middle (RM) finger vein instances and fused using Discriminant Correlation Analysis (DCA) to form their fused-discriminant versions as FD-ULBP and FD-LHBGC. DCA reduces fused feature set dimensionality considerably (number of subjects present in training set), implemented by summing up the individual finger vein discriminant feature vectors. DCA is an effective tool for fusing features in pattern recognition. It is computationally efficient and applicable in real-time situations [39]. DCA obtains data from multiple feature sets and incorporates the class structure into canonical correlation analysis via transformations, thus taking into account the differences in the different classes while at the same time maximizing the pairwise correlations among the features in the two feature sets.

More details about how DCA works can be found in [39]. The proposed work contributes by authenticating person based on deformed version of compact and fused feature set for the two-finger vein instance evidence. The deformation of feature set is needed for template privacy and security.

B. Finger Vein Template Protection and Matching

Finger vein features are protected by creating their hashed codes using randomly generated projection matrices. These codes are observed as highly irreversible and revocable in nature. The overall process is known as Gaussian Random Projection-based Index of Max (GRP-IoM) and is proposed by [2] for uni-biometric fingerprint system. This hashing technique is implemented for multiple instances of finger vein images in the proposed system.

The fused feature set of multi-instance finger veins as $x \in R^d$ is projected onto a d -dimensional random Gaussian vectors as $k \in R^d$. The overall hashing process is operated as follows:

- 1) Generate q number of d -dimensional Gaussian random vectors as k_1, k_2, \dots, k_q and form a projection matrix, $W^i = [w^1, w^2, \dots, w^q]$.
- 2) Project input fused feature vector, x onto W^i and record index of maximum value from $\Phi_i(x) = \arg \max_{i=1,2,\dots,q} (W^i, x)$ as t .
- 3) Repeat steps 1 and 2, n number of times to obtain hashed feature set as $t = (t_1, t_2, \dots, t_n)$.

The IoM hashing basically obey the ranking based locality sensitive hashing that attempts to confirm that any two highly similar feature vectors result to greater probability of collision. On the other side, the dissimilar vectors result in smaller probability of collision. Assuming the collision probability of two hashed codes as enrolled template, $t^e = \{t_j^e | j=1, \dots, n\}$ and query template, $t^q = \{t_j^q | j=1, \dots, n\}$ is represented as $CP[t_j^e, t_j^q] = ss(t^e, t^q)$ for $j=1, 2, \dots, n$. Thus, the higher value of $ss(t^e, t^q)$ signifies high probability of collision. Computationally, $ss(t^e, t^q)$ is observed as the number of zeroes (collisions) counted in subtracting t^e and t^q , element-wise for n number of iterations which is considered as a template match score. In case of compromised template, IoM hashed code will be renewed by generating new random Gaussian matrices.

C. Multi-instance Finger Vein based Secured Authentication

The entire application of the proposed framework for multi-instance finger vein based biometric verification system with template protection is categorized into two major parts as enrollment and authentication. As shown in Fig. 4, enrolling an individual in the system involves finger vein pre-processing, feature extraction, feature fusion from multiple instances and creation of cancelable protected templates for secured authentication. Fig. 1 depicts pre-processing which involves alignment of individual finger vein images, ROI selection and image enhancement. Fig. 4 describes the overall enrolment and authentication process of right index and right middle finger vein images with feature extraction, feature fusion and cancelable protected templates.

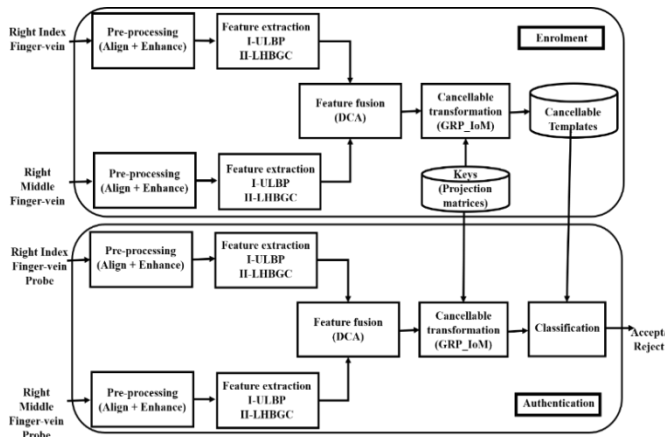

Fig. 4. Block Diagram of Proposed Multi-instance Finger Vein-based Authentication.

In the proposed work, two localized texture-based feature extraction methods are experimented on finger vein images to extract features namely, method-I, Local Hybrid Binary Gradient Contour (LHBGC) and method II, Uniform Local Binary Pattern (ULBP). Both, LHBGC and ULBP feature extraction techniques are explained in section III-A.2. Features extracted from multiple instances, particularly from right index (RI) and right middle (RM) finger vein images are then fused to create a combined feature set using Discriminant correlation analysis (DCA) [39]. DCA feature fusion is practiced with summation technique which also involves feature dimension reduction to significant extent. Thus, the fused-discriminant feature set for RI and RM finger vein instances as FD-LHBGC and FD-ULBP are ready for cancelable transformation meant for template protection.

Fused finger vein feature set is then converted to hashed code using Gaussian Random Projection based Index of Maximum (GRP-IoM) hashing technique [2]. This generic hashing scheme is highly irreversible and un-linkable cancelable transform. The irreversibility and un-linkability of the proposed template protection method on fused multi-instance finger vein feature set is shown in experimentation section. Finally, the cancelable protected templates are stored in database with their corresponding projection matrices (keys).

Authentication of a person also requires pre-processing, feature extraction and hashed code transforms to be generated in the same manner as that during enrolment. Classification of an identity is carried on using collision classifier as explained in Section III-B. Authentication and template protection evaluations for the proposed framework are demonstrated and analyzed in the experimentation section.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

Experiments have been conducted on the real multi-instance biometric datasets to evaluate the performance of the proposed multi-instance finger vein-based authentication methodology with respect to verification performance and template protection.

A. Database

Two openly available standard databases are used for evaluating the overall results of the proposed multi-instance finger vein-based verification system as SDUMLA-HMT and UTFVP. The SDUMLA-HMT (Shandong University Machine Learning and Applications) biometric database [40] consists of finger vein images for 106 individuals in addition to samples of additional biometric traits such as the face and iris. There are vein images of six fingers (three on each hand) and since vascular patterns differ on every finger of every hand, there are effectively $106 \times 6 = 636$ possible classes to identify. Furthermore, six images per class were captured resulting in a total of 3816 images. Each image is 320×240 pixels in dimension and stored in the uncompressed, bitmap file format. The UTFVP finger vascular pattern database [41] was produced by University of Twente, Nederland. It consists of 1440 images from 60 persons with 4 images per instance of 6 different fingers. The resolution of each image is 672×380 pixels stored in 8-bit gray scale PNG format.

B. Experimentation

We ensured that the data used to train the feature fusion process was never used to test it so that a true indication of its predictive accuracy could be obtained. For SDUMLA-HMT database, a total of 1272 images were used in carrying out the experiments. Individually for 106 subjects, four samples are used for training with DCA which executes feature fusion and dimension reduction and two samples for authentication testing. Combination of right middle (RM) and right index (RI) finger veins is considered for experimentation as it is the most popular and convenient choice for multi-instance system. Experimentation is carried on with total of 212 (106×2) genuine scores and 44520 ($(212-2) \times 212$) imposter scores for SDUMLA-HMT database. Similarly, in case of UTFVP database, total 480 finger vein images are used for experimentation. Training involved two samples per class and testing is done on other two samples for multiple instances. Experimentation is done on UTFVP with total of 120 (60×2) genuine and 14160 ($120 \times (120-2)$) imposter scores. All the experiments are implemented using MATLAB 2019a on a system i5-CPU with 2.5 GHz and 4 GB memory.

1) *Verification performance evaluation:* The verification performance of the proposed multi-instance finger vein authentication system is evaluated in terms of percentage equal error rate (EER). Fig. 5 shows Receiver Operating Characteristics (ROC) curves for the proposed verification systems, which also indicates the corresponding EER i.e., the error at where false acceptance rate (FAR) is equal to genuine acceptance rate (GAR). FAR, FRR (false rejection rate) and GAR are represented by following Eqs. (3-5).

$$FAR = \frac{\text{Number of falsely accepted imposters}}{\text{Total number of imposter trials}} \quad (3)$$

$$FRR = \frac{\text{Number of falsely rejected genuines}}{\text{Total number of genuine trials}} \quad (4)$$

$$GAR = 1 - FRR \quad (5)$$

Fig. 5. Receiver Operating Characteristic (ROC) Curves for Proposed Verification with (a) LHBGC and (b) ULBP Feature Extraction.

These ROC curves in Fig. 5 demonstrate that verification performance of the proposed multi-instance (RM+RI) finger vein system is much better with FD-ULBP features as compared to that of FD-LHBGC features. The proposed verification results in the form of EER with practiced feature extraction methods are depicted in Table I with the corresponding feature lengths for two different databases. Since the feature deformation method used for template protection is based on random projections, the EER is computed by considering the average of repeated twenty different randomly generated key-projections.

TABLE I. VERIFICATION PERFORMANCE OF THE PROPOSED SYSTEM

Method	Feature Extraction Method	Verification Performance (%EER) (95% confidence level)	
		Database	
		SDUMLA-HMT	UTFVP
I	FD-LHBGC ^a	4.2 ± 0.19	1.54 ± 0.11
II	FD-ULBP ^b	0.53 ± 0.161	0.00074 ± 0.00119

^aFused Discriminant-Local Histogram Binary Gradient Contour and ^bUniform Local Binary Pattern.

Thus, it is observed that FD-ULBP features are providing better and exceptional verification as compared to that of FD-LHBGC features regardless of change in database. Also, the proposed system is providing considerable verification with incredibly low feature length. This reduces the working plane complexity as well as memory requirement for template storage.

2) *Template protection evaluation:* In this section, privacy and security of templates are evaluated and analyzed for the proposed multi-instance finger vein authentication system. Privacy analysis implies the practical possibility for a template protection technique to tolerate any attack for regaining the intrinsic feature information. Whereas, to achieve considerable attack complexity against the unlawful access to the template protection system through counterfeit features is termed as template security. Particularly for Renewable biometrics, privacy analysis covers non-invertibility of

templates and Attacks via Record Multiplicity (ARM) whereas brute force attack analysis and ARM are included in security analysis. These individual investigations are described as follows:

a) *Privacy analysis:* Privacy analysis covers the assessment of non-invertibility/irreversibility and ARM for templates. Non-invertibility is the measure of computational toughness in retrieving the original feature set from the hashed coded stream with and/or without GRP-IoM method based random key matrices. Even if the number of random Gaussian vectors (q) for all the number of iterations (n) are known to the adversary, there is no clue available to recover the original real valued feature vector (x) from illegitimately obtained hashed coded templates. This is possible because there is no direct link between the projection matrices (token) and the original feature vector due to Index of Max (IoM) property of hashed code. In this case, to break the template privacy the adversary needs to predict the fused real valued features. Considering the worst scenario, let us assume that the maximum and minimum values of original features are known to the adversary for analyzing the guessing complexity. Considering an actual feature example with the minimum and maximum values for a fused feature set obtained for FD-ULBP features tested on SDUMLA-HMT finger vein instances as -0.3361 and 0.3622 , respectively. Suppose the adversary tries to guess from -0.3361 , -0.3360 , -0.3359 and so on, until the maximum 0.3622 . In this case, the total of 6983 options for predicting in the range of four decimal digit precision as in our execution, four decimal digits exactness is fixed. As guessing possibility of a single feature element is coming as $6983 (\approx 2^{13})$ attempts. Hence, the entire feature vector comprising of 105 elements needs around $2^{13 \times 105} = 2^{1365}$ trials. The guessing possibilities for the single and entire feature vector element for the proposed two feature types are shown in Table II. This guessing process is observed to be computationally infeasible. Moreover, the so called guessed feature set is not the original or raw finger vein features but the fused version of two finger vein instances which further adds on to the feature confidentiality.

TABLE II. GUESSING POSSIBILITY FOR SINGLE FUSED FEATURE AND COMPLETE FUSED FEATURE SET

Database (Feature Extraction)	Minimum value	Maximum value	Possibilities for single feature component	Total possibilities for complete feature set
SDUMLA-HMT (FD-ULBP)	-0.3361	0.3622	$6983 \approx 2^{13}$	$2^{13 \times 105} = 2^{1365}$
UTFVP (FD-ULBP)	-0.5243	0.5603	$10846 > 2^{13}$	$2^{13 \times 59} = 2^{767}$
SDUMLA-HMT (FD-LHBGC)	-0.0178	0.0239	$417 \approx 2^9$	$2^{9 \times 105} = 2^{945}$
UTFVP (FD-LHBGC)	-0.105	0.0198	$303 > 2^8$	$2^{8 \times 59} = 2^{472}$

ARM (Attacks via record multiplicity) is a kind of intrusion to template privacy which tries to reconstruct the original biometric data using numerous forfeited templates with or without parameters and information that linked to the algorithm. Specifically, ARM in IoM hashing is computationally tough for deducing the mathematical value as the saved templates are altered into rank space which are not correlated to the finger vein feature space. Thus, the ARM attack intricacy is the same as the non-invertibility attack possibility presented, formerly.

b) *Security analysis:* Security of biometric templates is in danger when threats like brute force attack or masquerade attack or pre-image attack. For GRP based template protection scheme, with $m=150$, $q=70$, guess intricacy for each entry is greater than 26 (70), as indices of hash code takes values between 1 and 70. Therefore, guess complexity for best performance obtained as for 150 (SDUMLA-HMT) and 300 (UTFVP) entries are greater than 2^{900} and 2^{1800} respectively. This is again computationally infeasible.

c) *Unlinkability analysis:* The unlinkability of the implemented multi-instance template protection scheme is validated by involving the pseudo-genuine scores. The pseudo-genuine scores are generated by matching different fused multi-instance finger vein hash codes of the same individual created by utilizing distinct key projection matrices. The pseudo-imposter scores are computed by matching hashed code templates of different individual created by using different key projection matrices, as explained in section IV-B.3.c With this perspective, the overlapping extent of pseudo-genuine and pseudo-imposter distributions indicates the indistinctive ability of the template generation from same or different users. The un-linkability level contributed by the implemented multi-instance finger vein-based authentication framework is indicated by the difficulty in discriminating these hash coded templates.

Fig. 6 and Fig. 7 demonstrate the distribution of pseudo-genuine and pseudo-imposter scores for both the proposed features as FD-ULBP and FD-LHBGC, experimented on SDUMLA-HMT and UTFVP databases. The pseudo-genuine and pseudo-imposter score plots are observed to be mainly overlapped for both the features. These results show that the IoM codes highly meet un-linkability property for the proposed multi-instance finger vein authentication.

Fig. 6. Un-linkability Analysis using Fused Discriminant Uniform Local Binary Pattern (FD-ULBP) Features on (a) SDUMLA-HMT and (b) UTFVP database.

Fig. 7. Unlinkability Analysis using Fused Discriminant Local Hybrid Binary Gradient Contour (FD-LHBGC) Features on (a) SDUMLA-HMT and (b) UTFVP Database.

d) *Revocability analysis:* Revocability or cancelability or renewability is determined by performing the experiments explained in [2]. This generates $105 \times (2 \times 106) = 22260$ and $59 \times (2 \times 60) = 7080$ pseudo-imposter scores for SDUMLA and UTFVP datasets, respectively. The distributions for genuine, imposter and pseudo-imposter scores are exhibited in Fig. 8 and Fig. 9 for both the FD-ULBP and FD-LHBGC features, respectively. It is noticed from Fig. 8 that the imposter and pseudo-imposter distributions for FD-ULBP features are largely overlapped. Fig. 9 implies that the pseudo imposter and imposter scores are not overlapping with each other for FD-LHBGC features, but the pseudo imposter distribution is still distinctive with genuine score distribution preserving differentiation between the two. This entails that even though the hashed codes belonging to the same source finger vein set are freshly created or renewed through newly generated random projection matrices, they are very much distinctive.

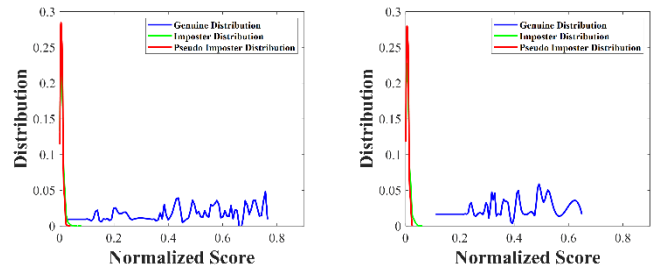

Fig. 8. Revocability Analysis using Fused Discriminant Uniform Local Binary Pattern (FD-ULBP) Features on (a) SDUMLA-HMT and (b) UTFVP Datasets.

Fig. 9. Revocability Analysis using Fused Discriminant Local Hybrid Binary Gradient Contour (FD-LHBGC) Features on (a) SDUMLA-HMT and (b) UTFVP Datasets.

3) *Validations*: Obtained results from the proposed authentication system are validated by comparing with that of other existing finger vein-based authentication systems. Validation is shown on comparisons to some of the similar existing finger vein systems based on their verification performance. Table III includes similar existing verification systems implemented with variety of feature extraction and classification methods. These systems contain methods utilizing single as well as multiple instances of finger veins. Performance comparison is shown on the viewpoints of authentication performance, number of evidence/instances used for authentication and template protection.

It has been observed from Table III that the proposed verification framework outperforms the shown similar work on the combined scale of verification performance and template protection. As some of the verification systems like [5] and [8] shows better verification but at the cost of unprotected templates. Moreover, the proposed system implemented the

verification utilizing two finger vein instances contributing to a greater number of evidence as identity proofs.

The verification performance combining with template protection property from Table III indicates that the proposed-I framework i.e., with Fused-Discriminant Uniform Local Binary Pattern (FD-ULBP) features performs better than Fused-Discriminant Local Histogram Binary Gradient Contour (FD-LHBGC) features as an overall authentication system with protected templates. Finger vein feature extraction and matching time contributes to the computation cost of the overall authentication system.

Moreover, if the system includes template protection and/or utilizing more than one instance of finger vein that again adds on the computational burden. Table IV shows the comparison of feature extraction and matching time of the proposed system with some of the similar popular methods practiced for finger vein authentication tested on a varied quality finger vein dataset, SDUMLA-HMT.

TABLE III. COMPARISON OF THE VERIFICATION PERFORMANCE OF THE PROPOSED SYSTEM WITH SIMILAR EXISTING VERIFICATION SYSTEMS

Ong et al. [9]	Minutiae	GA, k-modified Hausdorff dist.	---	---	---	0.7528	2	No
Proposed-I	FD-ULBP	Collision Probability	GRP-IoM	0.4609	6×10^{-4}	0.4615	2	Yes
Proposed-II	FD-LHBGC	Collision Probability	GRP-IoM	0.4545	6.23×10^{-4}	0.4551	2	Yes

It is observed from Table IV that both the proposed multi-instance finger vein authentications are outperforming with respect to some single or multi-instance state-of-the-art finger vein-based systems on the scale of computation time. In [5], LHBGC feature extraction time is calculated with the same parameter values (number of rows and columns) as that of the LHBGC based proposed-II system for fair comparison. Feature extraction time for the proposed methods involve pre-processing time, feature extraction time, fusion time, and template protection-based code generation time for two instances of finger vein images. Despite inclusion of template protection scheme, the proposed systems are showing significantly low values for feature extraction or template generation time. Moreover, matching time for the coded template is substantially less because of simple collision computations involved. Hence, the computational complexity of both the proposed protected systems is comparatively low with respect to the shown non-protected template-based finger vein systems.

Thus, the proposed methods of multi-instance finger vein systems provide considerable authentication accuracy with lower computation cost. The proposed frameworks also facilitate renewable templates in case of compromise with high irreversibility and unlinkability to produce template protection enabled authentication.

V. CONCLUSION

The proposed multi-instance finger vein-based biometric authentication system offers significant authentication performance. The proposed system used two local texture-based features which are computationally economical. Template protection is incorporated via. highly non-invertible and unlinkable, transform-based projection offering cancelable biometric templates. Proposed framework provides significant reduction in computational cost for feature extraction and

template matching, balanced with considerably outperforming authentication accuracy. Cancelable biometric template generation method as Gaussian Random Projection based Index-of-Max (GRP-IoM) is incorporated for template protection. The proposed Fused Discriminant-Uniform Local Binary Pattern (FD-ULBP) and Fused Discriminant-Local Hybrid Binary Gradient Contour (FD-LHBGC) feature based finger vein systems are observed to outperform some existing systems on the scale of verification performance. The proposed frameworks are experimented on two standard databases as SDUMLA-HMT and UTFVP. Moreover, FD-ULBP features are found to provide more significant results than FD-LHBGC for authentication and template protection.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude towards the authorities of K.J. Somaiya College of Engineering, Mumbai for providing continual support during this research work.

SHD-IoV: Secure Handover Decision in IoV

Hala E. I. Jubara

Department of Information System
Faculty of Computer and Information System
Jouf University, Sakakah, Aljouf, Saudi Arabia

Abstract—Internet of Vehicle (IoV) is the smartest thing being connected over the Internet. With continuously increasing urban population and swiftly growing of cities, causes moving vehicles with various speeds. These high speeds may increase the handover delay (HoD), accordingly causing an insecure connection due to the handover interruption. For instance, some of the network protocols try to overcome the problem without considering transport layer supports. This article proposes a dynamic HO algorithm with a cross-layer architecture called Secure Handover Decision (SHD) in IoV to assist the protocol layers aware of consecutive HOs of the vehicle. The results show that vehicle communication in IoV is more secure and lossless by reducing HoD in both sides of vehicle and network during fast movement.

Keywords—Internet of Vehicle (IoV); HO; L2; Stream Control Transmission Protocol (SCTP); Secure Handover Decision (SHD); security

I. INTRODUCTION

The need for mobile internet connectivity has increased as more users travel from place to place, for example, town to town over long distances. In a vehicular network, the user's vehicle connects to the internet through a fixed infrastructure installed on the side of a road for vehicle-to-infrastructure (V2I) communication. Another type of vehicle network communication is vehicle-to-vehicle (V2V) communication, which addresses the transmission of information among vehicles. However, this type of infrastructure contains gateways as well as BSs that offer services like the Internet of Vehicles (IoV) [29, 35, 36, 37, 38, 39]. In the IoV network, the vehicles are highly dynamic and can move at a high speed, which may cause a high handover (HO) rate leading to a communication delay or disruption (Fig. 1). Additionally, V2I communication is expected to meet many difficulties like poor channel quality plus connectivity because higher vehicle speeds lead to HO delay. Thus, there is a crucial need for efficient communication such as protocol or BS type communication that considers the specific characteristics of vehicular networks [4, 16, 17, 25, 26].

From the protocol side, most of the network layer (L3) protocols have a long HO delay, which affects the communication of the vehicles while moving. On the other hand, the current transport layer protocols suggested for better mobility can't address mobility alone because most of these ideas rely on the network layer mobility management necessities for the handover. Their proposal is purely to reduce the degradation in the performance of the transport layer caused by the handover. Several of these newly evolving protocols for L4 such as mobile Stream Control Transmission

Protocol (*mSCTP*), offer a basis for mobility support because they have multi-homing features that allow a mobile station to use a new IP address, while still assigning the previous IP address [5-9, 34].

In a data link layer (L2), an HO delay compromises the BS in completing the HO procedure with the next target BS (TBS) along the vehicle's path. Many network technologies such as cellular networks (GSM, 3G, 4G standard) [1, 23, 33] have been developed for broadband wireless access to meet the demand for high data rates in the wireless service. The most important improvement in this type of network for maintaining mobility is HO support. The HO is performed to maintain a continuous data-transmission service for all applications when the user is moving across the cell borders of the BSs. Three basic types of HO [3] have been defined for cellular networks: a hard handover (HHO), the macro-diversity handover (MDHO), and fast base station switching (FBSS). MDHO and FBSS are soft optional handovers, whereas HHO is a mandatory handover in WiMAX and LTE systems. HHO adopts a break-before-make method, where the user stops its radio link to the serving BS before establishing its radio link with the target BS [30, 32]. Because HHO is a simple method, it causes a long HO delay and disrupts service for certain applications, especially when the user is traveling at a high speed, such as traveling on a highway.

In a vehicular environment, as the vehicles are moving, the traffic generated by other background vehicles connected to the same BS decreases the available amount of bandwidth as the collision rates at the data link layer increase [31]. Under these network conditions, the HO may trigger repeatedly even for a static wireless station.

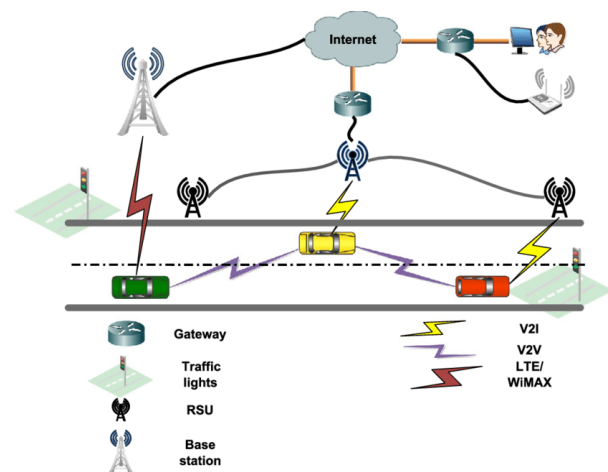

Fig. 1. IoV Networks Model.

This paper discusses a case in which a vehicle moves at a high speed from one BS to another in the IoV scenario, and it will cause long HO delays to the current Internet connection. To reduce this delay accordingly packet-loss rate during movements of the vehicle, an enhancement over the existing mSCTP protocol in L4 to support mobility has been proposed. This achieves through a cross-layer design of L2 and L4 to optimize the performance in terms of HO delay at L2, L4, and L3 consequently. The cross-layer design generates an L4 awareness regards to the vehicle movement using the radio signal strength indicator (RSSI) in L2 and utilizes the LM to track the vehicle movement with high speed along with the network.

The rest of this paper is organized as follows. An overview of the previous related studies is introduced in Section II in terms of mobility management of the protocol layers, vehicle, and cross-layer as well. The framework of vehicle mobility management to overcome the stated problem at high speed is discussed in Section III. Section IV presents the idea of the work of the smooth adaptive handover management for vehicle users. Then Section V shows the simulation test and Section VI details the results and analysis. Finally, Section VII provides some concluding remarks regarding this research.

II. RELATED WORK

A. Management of Mobility in different Protocol Layers

1) *Network layer mobility solutions:* The most common examples of network layer mobility solutions are Mobile IPv4 (MIPv4) and Mobile IPv6 (MIPv6) [4]. The Mobile IP permits transparent packet routing to the mobile user, as opposed to each node being allocated a permanent IP address that correlates to the home network. Furthermore, when a mobile user roams across several foreign subnets, each subnet receives a new IP address (Care-of-Address (CoA)). The mobile user then sends a binding update to its home agent (HA), which keeps track of the node CoA's current location and tunnels traffic from the mobile user to the mobile user. Routing optimization, hierarchical, and predictable algorithms have all been reported as breakthroughs for Mobile IP handover [5]. Furthermore, by tunneling traffic to the mobile user's AP, triangle routing is avoided [14].

The network is divided into domains by Hierarchical Mobile IPv6 (HMIPv6) [4], [8], each of which contains numerous access routers (AR) and a Mobility Anchor Point (MAP) that links the domain to the Internet. The MAP takes mobile user packets and tunnels them to the domain level CoA, as well as controlling the domain's mobility. This reduces changeover delay and loss by completing a micro-level address while still doing the macro-level handover, which has a large latency.

Fast MIPv6 (FMIPv6) [8] as a Fast Handover Protocol that uses L2 triggering for handover to improve speed and decrease packet loss. This is performed by announcing the existence of mobile users as well as the new AR's readiness to receive data from the new CoA. The necessity for collaboration between the user and for both prior and new AR, as well as the high unpredictability of packets arriving at the Aps is the system's

main drawbacks. In a comparison of several ways, FMIPv6 outperforms HMIPv6 in terms of handover delay and packet loss, however using both methods improves performance through each of them alone [4, 8, 15, 22].

2) *Transport layer mobility solutions:* the TCP and UDP protocols have been enhanced to provide mobility transport layer protocols, which are still the most commonly used on the Internet [1, 2, 11, 12, 21]. Another of these protocols is Stream Control Transmission Protocol (SCTP), which allows each endpoint of an association to utilize several IP addresses, allowing a mobile user to multi-home. The mobile Stream Control Transmission Protocol (mSCTP), which uses the SCTP IP address extension to allow an association's terminals to change their main IP address without breaking their current connection [21][24], is another innovation. Even while mSCTP can provide precise conditions for faultless handover when the main address must be changed, there is still an issue. Even while mSCTP can provide precise conditions for faultless handover when the main address must be changed, there is still an issue. A cross-layer design across several levels has been proposed in several studies [1, 2, 10] to improve the mobility of transport layer protocols such as SCTP and mSCTP. They were able to demonstrate that SCTP can give lower handover latency than mobile IP and a much reduced handover latency for several different types of handover in such studies.

3) *Cross-Layer mobility management for vehicle users:* Several solutions [11, 13, 14] that seek to promote smooth handover in high-speed users (e.g. cars) were explored. The authors of [11] utilize a system that forecasts vehicle motion to optimum performance in a high-speed environment, and they estimate that there will be no concerns as the length of connectivity increases. In the 802.21 method, the authors of [14] adopt a previous knowledge technique wherein network information is collected from both the mobile user and the network infrastructure in order to establish a connection with a new subnet ahead of time. A similar research [13] proposed lowering the effect of a service outage among high-speed users. This proposal offered a packet forwarding control which would select a point of agreement for forwarding packets in order to transmit them through a shorter path during a handover. The author in [14] proposes a network mobility protocol (NEMO) for usage in a vehicle networks (VANET) environment on a roadway. Despite the fact that each vehicle is traveling at a high rate and in a fixed direction in this case, vehicle-to-vehicle (V2V) connections might provide the vehicle with an IP address.

B. Cross-layer Mobility Solution

Various cross-layer efforts have been created in an attempt to reduce the HO delay. The author in [26] describes VSPLIT, transport layer performance improvement architecture for Internet-based Vehicle-to-Infrastructure (V2I) communications in vehicular networks based on TCP cross-layering and splitting methods. The primary goal of this strategy is to enhance TCP handover performance in 802.11 networks. The

VSPLIT-TCP cross-layer TCP protocol, which uses IEEE 802.21 Media Independent Handover (MIH) services to modify congestion control during the changeover by learning various network parameters after the handover. SHSBM, a Smooth Handover Scheme based on mSCTP, is proposed in the literature of [27]. To best support fast-moving users, SHSBM takes use of SIGMA [7, 10, 18, 19, 20, 21] and employs Buffer and Tunnel. They also provide two ways for dealing with the issue presented by the Buffer-scheme—sequence Out of Order. In comparison to SIGMA and Mobile IPv6 upgrades, performance criteria such as packet loss rate, throughput, and handover time were used to evaluate performance.

In their study, [28] provides a framework for linking vehicle networks to the IPv6-based Internet. This concept provides a road domain-based architecture to minimize the frequency of mobility handovers. In this study, they are developing a distributed address configuration mechanism for car networks. Using this method, a vehicle obtains a unique address from the nearest access point (AP), avoiding the detection of duplicate addresses. On the basis of this architecture, a routing mechanism based on geographical position is suggested. A car connects to the Internet by connecting to the nearest access point, and the routing algorithm has been applied to the link layer. During the mobility procedure, the vehicle's home address is always used to identify it, and no care-of address is necessary. As a result, packet loss due to a change in address is avoided. Additionally, packet loss is greatly reduced since a vehicle can receive data from the same AP during the mobility changeover phase. Their approach can minimize communication latency and packet loss, but IPv6 introduces a new delay that can affect upper-layer connectivity. They offer a cross-layer rapid handover strategy that communicates physical layer information with the link layer to decrease handover delays in automobile networks. The WiMAX mobile multi-hop relay mechanism, which allows inter-vehicle communications to connect to the Internet through a relay vehicle, provides the foundation for this technique. However, IP mobility is not included in the program. The need for flawless communication in high-speed settings is an appealing and difficult problem that necessitates accurate IoV in most modern networks [35, 36, 37]. While the majority of the preceding work focused on changeover for and moderate speeds, the requirement for smooth communication under high-speed situations is an appealing and demanding issue since most new networks require precisely IoV. In this situation, employing the lower layer's handovers and the transportation layer's communication layer will make handover awareness and avoid communication interruption, minimizing packet loss and, as a result, increasing network QoS.

III. VEHICLE MOBILITY MANAGEMENT FRAMEWORK

A. System Architecture

Any moving user traveling at varied speeds while communicating over the same network technology can use the SHD architecture. The vehicle and BS modules are the two most important modules in the design. A graphical representation of this is shown in Fig. 2. The vehicle module is in charge of protocol design and handles one SCTP relationship with a Domain Name Server (DNS) entity.

Fig. 2. Mobility Management's System Architecture.

The DNS entity, on the other hand, monitors and tracks the vehicle's mobility via the Dynamic Host Configuration Protocol (DHCP) server [6-9] (as shown in Fig. 5 and Fig. 7), which first monitors and tracks the vehicle's global movement by saving the current vehicle address in the server across networks to support L4 multi-homing. Second, the BS module controls the vehicle's HO using an adaptive algorithm in L2 that is dependent on factors like the received Signal to Noise Ratio (SNR), Received Signal Strength Indicator (RSSI), and vehicle speeds. The flow under this design begins when the vehicle initiates a handover to the TBS at a specified speed. Once the BS module has assessed speed and RSS/SNR, HO signals are delivered to the vehicle through the network. When the vehicle module gets the information marking the start of HO, cross-layer communications are sent. As a result, the SHD approach updates upper layers in response to the rapid change in speed.

B. Vehicle Mobility Management using Cross-Layer Design

The cross-layer design is suggested in this paper for managing transport layer mobility. The design proposes the mSCTP transport layer protocol, which is based on transport signaling messages and supports vehicle mobility handover over an IP network. As a result, the SHD's purpose is to ensure that any protocol may be used at any tier. In this case, the SHD's HO method permits information about the HO choice to be shared between layers. The next sections go over HOs at the L2, L3, and L4 levels in great depth.

1) *L2 HO Delay*: The WiMAX BS delay is employed to accomplish the HO operation at the datalink layer in this study. Signal strength is routinely measured in these types of BSs using parameters like the Received Signal Strength Indicator (RSSI) [34]. As a result, the HO is started as soon as the RSSI from the presently serving BS falls below a certain level. When the HO is necessary, this threshold is fixed (2dBm for traditional WiMAX) and is utilized to launch and execute it. When communication quality deteriorates, the vehicle's L2 looks for the best BS for HO and uses it as a TBS. We reduce the time here by restricting the number of scanning TBS to three (Fig.3, N=3).

The impact of an L2 delay on SHD performance may be split into two categories. The influence of the BS's HO process time is the first, while the vehicle speed is the second. L2 initiates a handover and the scanning procedure for the TBS begins if the SBS signal quality deteriorates, which takes roughly 15 ms for a high-speed vehicle [24]. Until the TBS completes the HO, communication is disabled. The whole

delay of L2 compromises the synchronization time (T_{sync}) between BSs and frame duration:

$$T_{L2} = T_{sync} + T_{frame} \quad (1)$$

Upon synchronization with the arriving downlink for other HO messages related to the BS HO, the downlink packet may be broadcast immediately (DAD procedure, tunneled packets, delay of each hop in a wired, resolution procedure, ranging process, re-authorization during HO, and re-registration). The L3 HO delay explains the role of L3 at the HO delay time.

2) *L3 HO Delay*: The network layer delay of handover is roughly 1 minute due to DAD and other HO messages on the network. L3 HO delay can be sent over a cross-layer of L2 and L4, allowing the delay to be linked solely to L2 and L4 HO. The issue is that the SCTP relies on the LM/DNS to keep track of the vehicle's current location when the IP domain changes. As shown in Fig. 4, it may be done during SCTP's HO, when the vehicle L4 updates the LM with the updated BS after HO. This enables real-time tracking of the new car. The performance of the L2 HO at various vehicle speeds, as well as the computations required for a successful HO to adjust L4 to each speed are discussed in the next section.

3) *L4 HO Delay*: The protocol detecting a HO causes L4 delay, which might last several seconds depending on the round-trip duration (approximately 10 ms) between the vehicle and the CN. This might lead to packet loss and, as a result, a decrease in throughput. The mSCTP, on the other hand, is utilized to facilitate multi-homing when going in a fast vehicle. The vehicle HO process is depicted in Fig. 3 from the time the vehicle gets the network's HO decision (SBS) until the time the dynamic HO is executed at L2.

To complete the HO between the vehicle and CN, the ASCONF SET PRIMARY/DEL IP messages that cause the HO delay at L4 are necessary. Because the connection latency for updating the LM has no influence on the SHD handover delay, the time necessary to update the LM of REG.REQ/RSP is disregarded. As a result, the L4 transfer's total interruption time is:

$$T_{L4} = T_{(ASCONF SET-PRIMARY/DEL-IP)} + RTT \quad (2)$$

4) *Adaptation between L2 and L4*: The vehicle adapts the L4 protocol SCTP and the vehicle speed at L2 using algorithms. At varying speeds, this technique dynamically manages the SCTP protocol's handover decision. It runs the vehicle's L2 protocol in order to make a HO decision based on the SBS's current signal quality, which is indicated by the RSSI in the MOB-NBR-ADV message. On the other hand, depending on this number, the HO execution produces the strongest TBS signal. Fig. 3 shows the flow of the HO algorithm. As shown in this picture, when a vehicle enters the HO region of the TBS, it receives a message about the availability and amount of TBSs. The algorithm leverages the vehicle speed supplied by the BS to make a dynamic HO choice when the vehicle signal strength begins to decline. To

relate the vehicle's speed to the HO choice, the computer use Equation 3.

$$Th_{HO} = Th_{loss} (1 + \log_2 (v+1)) \quad (3)$$

Furthermore, the adaptive method is based on the following conditions to avoid performing unnecessary actions such as lengthy HO delays or squandering network resources with unnecessary HOs, both of which can result in substantial system performance degradation:

$$RSSI_{SBS} < TH_{HO} \quad (4)$$

$$RSSI_{TBS} > Th_{loss} + \Delta D \quad (5)$$

When the RSSI falls below the TH_{HO} in Eq.4, the HO operation will start. In addition, in Eq.5, the HO is only done if another BS has an RSSI that is at least D greater than the Th_{loss} . These equations change the handover threshold (TH_{HO}) based on the current vehicle speed (v) and RSSI of the SBS, which have varying values at different points in the coverage area. To make the threshold dynamically adapt with speed, Eq.3 mentions the link between the TH_{HO} and the speed v . The communication's loss threshold (TH_{loss}) and the hysteresis value D govern the TBS. When the vehicle's speed rises, TH_{HO} rises as well, and the vehicle executes a straight handover to the following TBS to prevent a delay. TH_{HO} , on the other hand, uses Th_{loss} to achieve the lower limit when the speed is low. After that, the system compares TH_{HO} to the current RSSI (as in Eq.4 and Eq.5). The selection is made based on the vehicle's speed as well as the RSSI. As a result, two scenarios are examined for a HO operation. If TH_{HO} is bigger than RSSI (as in Eq.4), the HO operation is first carried out at the highest TBS signal intensity. Otherwise, the BS executes the HO by comparing the SNR with the neighboring BSs (NBSs). The second option is taken to minimize communication interruption due to fast changes in the received signal level caused by distortion or short-term shadowing of high-speed vehicles (Eq.5).

Due to the numerous HOs that occur at greater speeds, the adaptive HO algorithm's objective is to avoid a delay and packet loss during transmission. TH_{HO} and Th_{loss} are computed for each TBS at each handover (the method for initiating and performing a HO from the SBS to the TBS of vehicular users) (Eq.3). Because the HO delay is small, packet loss does not need a drop in the packet loss rate if the adaptive algorithm effectively controls the occurrence of a HO. Due to the additional latency, our approach employs an upgraded SCTP to decrease packet loss.

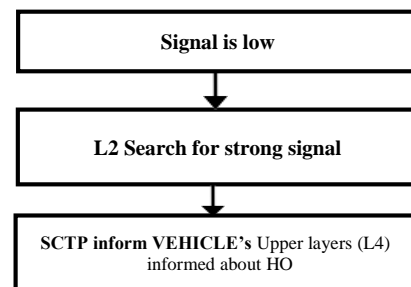

Fig. 3. Proposed Speed-Adaptive Algorithm.

IV. SECURE HANDOVER DECISION FOR VEHICLE USER

To assure the system's simplicity, adaptability, and efficiency while also achieving various aims, a cross-layer design of a SHD was carried out. Our solution, on the other hand, may be used to minimize HO in any protocol layer by changing user settings. As demonstrated in Fig. 4, the idea of a SHD-SCTP is that information may be transmitted across the vehicle's many protocol levels using primitives (short messages between layers) at L2, L3, and L4. A cross-layer design can help with mobility management by reducing HO delays and improving performance.

A. The Proposed Secure Handover Decision (SHD)

Each layer offers the higher layer with encapsulated services to use the information in that layer, focusing primarily on the L2 and L4 information exchanges (as in ISO protocol levels). This data is used to modify the L4 protocol architecture to changes in vehicle speed as follows:

The car is traveling at a rapid rate from the SBS to the TBS, and the signal strength of the SBS is deteriorating at this moment, resulting in communication deterioration. The car then enters the TBS through the handover area, and the TBS' signal strength begins to grow. L2 transmits a LinkStatusChange.end message to the upper layer network layer at this point (L3). When the vehicle arrives at the handover location and the connection with the SBS is lost, L2 uses LinkConnect.ind to send a message to L3 requesting the available number of TBSs. L2 has received a LinkUp.ind, indicating that the signal strength is growing, and a message from L3 alerting L2 that the network has been reached in the last phase of the handover, which is the conclusion of the handover. The flow of messages at the user side during handover is depicted in Fig. 4, which is a flow chart of the cross-layer design.

The L2 connections/disconnections are synchronized with the mSCTP flow thanks to the cross-layer SHD architecture. The TH_{HO} of active senders is set to a value that is determined by the vehicle's current speed and the TBS's updated RSSI. This is done right before the handover, when the car is removed from the SBS and no BS or mSCTP handover is required. BS signaling is used to get this information from the vehicle's BS. This improved handover decision can help real-time applications prevent packet loss or significant delays, while also increasing network efficiency and user fairness.

The mSCTP communications are unfair because to the various speeds of the vehicle nodes. Because quicker users have a larger number of handovers in the same amount of time as slower users, they often receive fewer throughputs. Furthermore, the standard TH_{HO} requires some time to reach the right functioning point before the handover, which takes longer when additional (slower) users are present in the HO region between two BSs. When a new connection to or disconnection from the BS occurs, the TH_{HO} can establish the correct HO choices for the SCTP flows. Because an SDH does not implement any L3 protocols to minimize the HO latency, this allows for a reduction in the disparity between fast and sluggish nodes.

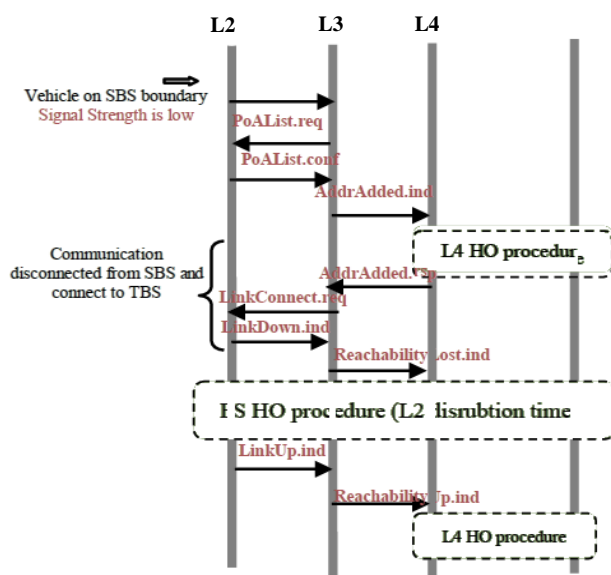

Fig. 4. Secure Handover Design.

B. Handover Procedure

A timing diagram depicting the cross-layer design is presented in Fig. 5. This design includes the two protocol levels' handover procedures (L2 and L4) as well as the cross-layer design's delay. The handover delay in L2 involves BS signaling messages between the SBS and the vehicle to begin (trigger) and conduct a typical HO procedure. The following communications come from the vehicle's L2 to the top levels, instructing them to begin the HO in L4.

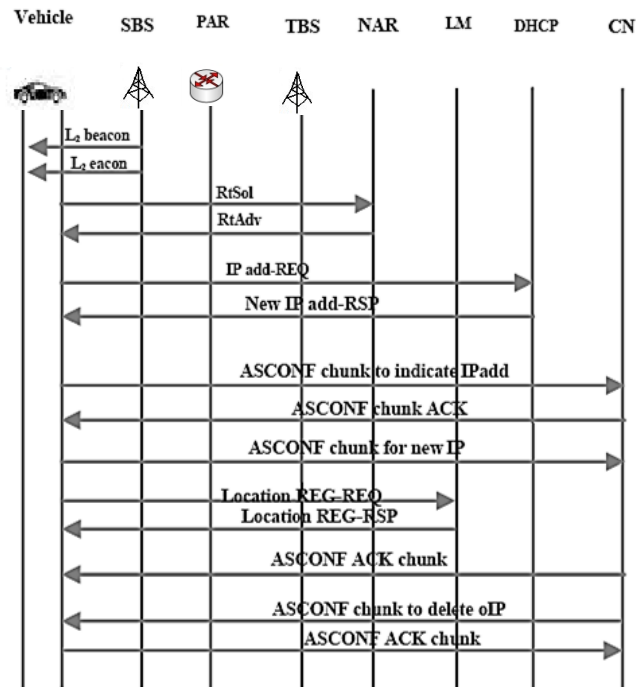

Fig. 5. Timing Diagram of the Proposed Idea Registration Request and Response (REG.REQ/RSP) is Minimal [20] and it is the Final Message in the HO Stages.

However, the majority of the L4 HO delay in this architecture is due to SCTP's set primary chunk as well as removing old IP (ASCONF SETPRIMARY/DEL-IP) handover messages, as well as the RTT of messages between the vehicle and CN (about 1–10 ms). This HO process is a conventional SCTP procedure with the addition of the LM/DNS server in the design. Because the handover delay is unaffected by the connection delay in updating the LM, the time for the location.

Finally, as shown in Fig. 5, the delay of our cross-layer design between L2 and L4 of the vehicle is around 34s, which is insignificant when compared to the L2 delay time. A cross-layer design's overall handover latency may be computed as follows:

$$(T_{HO}) = T_{L2} + T_{L4} (\text{ASCONF SET-PRIMARY/DEL-IP}) + \text{RTT} \quad (6)$$

The data connection layer delay is TL2, while the transport layer delay is TL4. We can eliminate the L3 duplicate address detection (DAD) delay, which is connected to the new address through the LM, and update the vehicle position at the TBS without an additional delay using this architecture. The LM can also be used to solve the problem of triangular packet routing between the CN and the vehicle. Because the CN continually delivers packets to the vehicle's current address across the LM, the mSCTP may work collaboratively with the LM to decrease the handover latency along with different layers. The interruption time from L2 is around 10 ms, which is minimal for L3. The HoD for this design is estimated from the vehicle to the CN. ASCONF to SET-PRIMARY/DEL-IP takes around 0.045 milliseconds in the L4 protocol, resulting in a total handover latency of about 20 milliseconds.

C. Design Goals

The following are the key objectives of this design:

1) As a mobile node, a vehicle must be connected to the network internationally. The SDH approach, on the other hand, accomplishes this purpose by employing a DNS server and an LM to track the vehicle's present location and forward packets quickly.

2) The whole vehicular network is utilized. This is a good goal for increasing mSCTP performance on the IoV network, since the protocol suffers from a large number of handovers. Our goal is to maximize the throughput of the SCTP flows before any losses or other delays occur. Between conflicting speeds and mSCTP flows, a fair handover choice is made. Handovers conducted by vehicle users traveling at various speeds might result in unfair behavior in the mSCTP. Users that stay connected to the same BS for a long time obtain better throughput in present mSCTP implementations because they experience fewer handovers. Furthermore, users who drive at fast speeds do not have enough time to receive a HO at the proper operating point. By swiftly tailoring T_{HO} to the vehicle speed and network circumstances (i.e., SNR), our handover technique can decrease changeover latency and interruption time, ensuring improved fairness between different vehicle speeds and competing SCTP flows.

V. SIMULATION TEST

A. Simulation Environment

The simulated architecture illustrates that the vehicle is traveling at high speeds along the highway (70–120 km/h) and is connected to the network through the IoV (Fig. 6). The coverage area of each BS that links automobiles to the Internet is about (1000 - 10000 m), with a 200-meter overlap between the two BSs. On the network side, the BSs are connected through the AR, with every two ARs connected to one MAP. This scenario creates an IoV communication by joining the network directly. The upper component of the network, as illustrated in the diagram, links the vehicle's present position and transmits traffic to it according to IoV services. The OMNET++ simulation was utilized to assess this architecture, together with MATLAB to compare network settings.

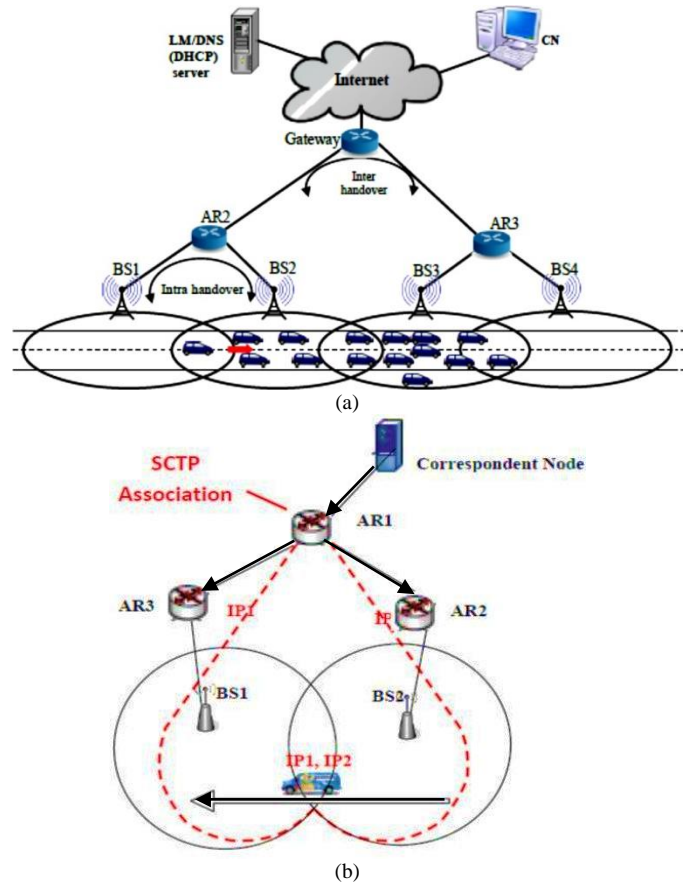

Fig. 6. Network Scenario. (a) One Vehicle Scenario. (b) Background Traffic Scenario.

The simulation performance compares two simulation models in the following way:

1) Scenario A: a single vehicle mobility management system (Fig. 6(a)). In the single vehicle instance, a vehicle drives in a straight path from the SBS to the TBS zone, with no traffic or network load. That is, the background traffic will have no effect on the car. In this instance, the handover may be limited to simply one vehicle.

2) Scenario B: Traffic mobility management in the background (Fig. 6(b)). The car is going ahead to the TBS with background traffic in the Background traffic mobility example. The HO happens when there are ten cars on the network, indicating that the vehicle is affected by the crowded network. In this situation, the car would be handed over after a longer period of time.

In order to detect and assess the performance of the proposed design and its impacts on the background traffic, we measured the HO latency and throughput for data transfer as a performance parameter of the system.

B. Background Traffic Implementation

Ten automobiles are deployed as background traffic inside the coverage area of the TBS on the network in this simulated scenario to assess the network's performance. Every vehicle travels at a different pace, and multiple of them communicate with their own networks, causing network congestion. This background traffic is created in two phases, each of which correlates to a different car count (up to ten). Each stage has different traffic levels, such as one car in the first and 10 vehicles in the second.

The background traffic conveyed to the SBS by other cars (Fig. 7(b)) raises the loss rates at L2 and hence limits the amount of available bandwidth. Even for static moving vehicles, this is a crucial element that impacts load variation and, as a result, activates the HO. The job of HO control in this situation is combined with the load-balancing service necessary to maintain an optimal decision point for deciding HO. This design evaluates performance in a variety of scenarios, such as background traffic.

Fig. 7. HO Delay Comparison.

VI. RESULTS AND ANALYSIS

A. Performance Evaluation

To assess this concept, SHD compares three mobility options in terms of scalability, as measured by the number of vehicles executing simultaneous handovers and vehicle speed. For scalability, two mobility scenarios were investigated, in which a single vehicle and ten vehicles, respectively, transit the overlapping region at varied speeds between 10 and 40 m/s. As demonstrated in the findings, this simulation can assess the

ability of each handover strategy to maintain a shorter HO latency in various vehicle mobility models with changing network characteristics. The following sections go over the performance in further depth.

1) *Handover evaluation:* First, when the triggering time of L2 is roughly 15ms for the BS, the total HO latency of the SHD design is compared to the other design advancements. This L2 HO latency is consistent with what is seen in networks for high-speed users. When the traveling speed is increased to 40 m/s, as shown in Fig. 8, the HO delay of SHD is clearly reduced. This is because while the car communicates with the CN via the old way, it may simultaneously do L2 triggering on the other user interface. As a result, as compared to the other design advancements, the impact of these latencies can be significantly reduced (SIGMA). Because there is insufficient time for a vehicle to prepare for a new course, the HO delay of the SIGMA upgrades is roughly 2.40–2.49 s, which is substantially greater than that of the SHD design.

The HoD between vehicles is around 20ms, depending on the RTT to CN. Fig. 8 and 9 illustrate a comparison between the proposed design and existing HoD designs, while Fig. 10 displays the HoD when the network load is high. Four different scenarios were evaluated to validate the concept, as illustrated in Fig. 9.

Fig. 8. Impact of an L2 HO Delay.

Fig. 9. Handover Delay with Background Traffic.

The first design employs the mSCTP to support a HO during a speed fluctuation; this design uses a cross-layer design to update L4 with current speed [1]. The second design (SIGMA) employs IP diversity in conjunction with SCTP to provide a multi-homing HO mechanism through the LM without the usage of L2 or a cross-layer [5-7]. The third design, SHD, is a cross-layer design between L2 and L4 enabling a speed-independent handover. However, the most recent design SHD uses an adaptive algorithm to create an ideal seamless HO during high-speed vehicle movement using a cooperative cross-layer mechanism between L2 and L4. The numbers show the outcomes of the tests.

2) *Throughput and packet loss*: For different vehicle speeds, communication time in one BS coverage region is around 67s, and HoD is about 25ms. This indicates that for high-speed automobiles with a repeating HO, the vehicle is unable to receive packets for 0.2 seconds before receiving packets for 66.8 seconds owing to the HO. As a result, in a highly dynamic handover situation, the throughput is much higher than earlier SCTP designs. Fig.10 compares the throughput of several designs versus the SHD design at high speeds using 10 automobiles as an example.

However, as shown in Fig. 10, mSCTP architecture operates effectively when at least one network is low loaded or has no load at all. For all BS load conditions, the throughput is optimal (4 Mbps), except when the BS is totally loaded (50–100s), in which case the throughput reduces to 2.5 Mbps. The same trend can be seen when looking at the packet loss in Fig. 11. Because the car is still connected to the same BS when the network is crowded and a speed-adaptive strategy is not used, the QoS suffers greatly. When background traffic decreases, the network becomes lightly burdened.

Otherwise, there is no load at all, and the maximum QoS improvement is determined, as shown in the Fig. 10 for the 100–150s interval. Table I concludes all the parameters for the three designs. At the end it is clear that the SHD has the outstanding in both cases with and without background.

Fig. 10. Throughput of the Background Traffic.

Fig. 11. Packet Losses for Two Cases.

TABLE I. HO DELAY, THROUGHPUT, LOSS, AND AVERAGE SNR, WHEN PERFORMING HANDOVER WITH HIGH SPEED OF 40M/S

Scheme	CL	HO delay	SNR (dB)	Throughput (Mbps)	Loss (Mbps)
SHD	1	0.07	64.3	11.8	0.04
	10	7.5	51.9	9.4	0.07
CLD	1	1.8	45.24	8.43	0.06
	10	5	35.33	7.1	0.1
SIGMA	1	2.4	33.76	5.8	0.12
	10	2	24.5	4.5	0.2

VII. CONCLUSION

Vehicles which normally move among cities at fast speeds have become basic computation in internet communication as IoV, thanks to the rapid growth of communication networks through the Internet. This sort of connection (IoV) may encounter a number of problems that degrade the quality of the Internet connection by lengthening the handover time (HoD). This work presents an approach that uses a cross-layer architecture SHD to dynamically lower the HoD in order to improve connection continuity while dealing with fast-moving data. The suggested architecture has reduced the delay by assisting L4 of the protocol for handover existence, allowing it to complete the handover in advance, resulting in even more secure and lossless vehicle communication. The numbers clearly indicate the improvements in throughput, latency, and packet loss.

Abstract—Digital transformation has been accelerated in recent years, and COVID-19 has resulted in a rise in overall internet spending. Businesses must take measures in order to ensure that customers have a safe and enjoyable online purchasing experience. In this paper, customers' security perceptions regarding the most popular e-commerce applications in Saudi Arabia are explored. Surveys were distributed online via Google Form to 200 participants in total as part of a cross-sectional research design using quantitative methodology. The main findings were related to confirming eight main hypotheses of the research that were related to testing if some factors were important to forming perceived trust by customers. Five factors (trust, security, reputation, benefits, and convenience) were found to have a positive effect, and the remaining three were not (familiarity, size, and usefulness). Finally, this study recommends various actions for practitioners and policymakers to take in order to improve customer perceptions of payment methods and security in Saudi Arabia.

Keywords—Payment security; digital strategy; digital transformation; user security

I. INTRODUCTION

E-commerce is a type of business transaction where goods and services are bought, sold, and given away over the internet. This includes both business-to-business (B2B) and business-to-consumer (B2C) deals. Consumer behavior has changed because of today's fast-paced market and the fierce competition between businesses [1]. Because of this, e-commerce has become a good choice for many businesses. Classified ads, C2C marketplaces, shopping malls, B2C stores, and social media-based online stores are all examples of e-commerce business models in Saudi Arabia, where people buy and sell things online. Because so many people in Saudi Arabia use mobile devices all the time, Noon is one of the best websites for shopping at e-commerce stores in the country [2, 3]. The Noon website sells merchandise. Noon's goal in Saudi Arabia is to provide a new shopping experience as well as simple sales, secure payment, and integrated logistics. As a result, it is critical for the application system to keep data secure and to have a method to ensure that the transaction records it generates are correct because it will be used to address many threats to the payment system [4]. Consumers must have faith in the security of personal data protection for online

remittances for this to happen. Increasingly, people are using smartphones and tablets to do things like make payments and transfer money because they are easy to use and easy to move around. Traditional financial transactions are thought to be more time-consuming and inefficient than mobile financial transactions [5,6].

Customers' perceptions of their personal information and the security of their financial transactions have shifted dramatically in recent years. Mobile applications with a good reputation for security and privacy are used to maintain security and privacy. Customers of mobile applications are concerned about malicious code and unauthorized access infiltrating their applications. They're also worried about others spying on their online activities and stealing their credit card information. Customers' willingness to buy and sell products through mobile commerce applications has been shown to be influenced by privacy and security concerns [6,7,8,9]. Customers are less likely to use an online platform if they are concerned about its security. To better engage with their customers, businesses must first understand how they perceive security and safety when they are online. Because social and cultural factors vary by country, it is critical to investigate customers' perceptions of online platform security and privacy across cultures [10,11]. User behavior shifts in the presence of cybersecurity threats, according to the Protection Motivation Theory (PMT), making it critical for social commerce platforms to protect their customers' personal information and data. As a result, we concentrate our research on customers in Saudi Arabia to investigate if the payment methods used have a positive impact on customer perceptions of security.

Saudi Arabia is widely regarded as a major online shopping market. People buy products using a variety of payment methods and applications all over the world. They are also concerned about the correlation between security, privacy, and payment methods [12, 13]. This motivates us to study the importance of security and privacy for Saudi buyers when it comes to mobile commerce. The objective of this study is to examine Saudi consumers' perspectives on security and privacy concerns when it comes to a popular e-commerce app, namely Noon in Saudi Arabia (KSA). This study used quantitative methodology to determine whether the payment methods that are used have a positive impact on customers' perceptions of

security. We used the most popular e-commerce website in Saudi Arabia, which is Noon. Multiple factors are made up of several sub-factors that helped us analyze the user experience of this e-commerce website. As a result, the main contribution of this research is to better understand customer perceptions of the payment methods and security in Saudi Arabia to improve customer perceptions that can be applied to other countries.

The rest of this paper is organized as follows. Section II presents recent related works on the impact of security and payment methods on consumers' perceptions. We present the problem formulation in Section III. Section IV introduces our proposed methodology in detail. Section V discusses the study setting and participants. Section VI presents the results and findings and some limitations. Finally, we conclude the paper and discuss some directions for future work in Section VII.

II. LITERATURE REVIEW

Numerous studies have shown that security and privacy are critical in mobile commerce applications. Customers are thus more likely to use mobile commerce applications that provide enhanced security and privacy. According to a study conducted in Indonesia by Hidayat et al. [14], trust is a critical factor for Indonesian customers when shopping online. Saprikis and Avlogiaris [15] conducted an empirical study to ascertain the factors that influence consumers' social media shopping behavior. The findings indicate that convenience, reward, and security all play a significant role in consumers' direct purchases via social applications (ICT facilitators of the UTAUT model). Customer satisfaction, according to Taherdoost and Madanian [16], is a critical factor in customer loyalty, which is why they validated an e-service satisfaction model in an e-commerce context. Customer satisfaction is determined to be most strongly influenced by trust, security, performance, and usability. According to Harris et al. [17], a variety of factors contribute to people installing and using mobile applications that violate their privacy and security. In their study, they discovered a correlation between customer trust and perceived security, indicating that customers who perceive more security have both increased trust and a lower perceived risk. According to Ghayoumi [18], m-commerce is also affected by six security factors. Integrity, non-repudiation, authentication, confidentiality, privacy, and availability are some of these factors. According to the study's researchers, security in m-commerce applications is contingent upon these factors. Mahmoud and colleagues [19] attempted to demonstrate the growing popularity of mobile commerce by highlighting the security risks associated with the use of modern devices and high-speed internet. While the study's primary objective was to make recommendations on how to address potential privacy and security concerns raised by the growing use of mobile commerce, it also examined user perceptions of trust in mobile commerce on three major websites: Amazon.com, AliBaba.com, and eBay. The study takes a deductive approach and employs only one method of research. Additionally, the data was analyzed using a 100-respondent random sample. Although an e-commerce environment is more private than a mobile commerce environment, the author asserts that trust in mobile commerce systems remains low due to the privacy and security paradigm. Additionally, this study demonstrates that there is considerable

room for improvement in terms of privacy and integrity, authentication, and security. According to Kumar and colleagues' research [20], while m-commerce applications are gaining popularity in India, users remain wary of them for a variety of reasons. Security and payment issues with these mobile commerce applications have been cited as significant factors. Consumers believe that mobile commerce applications are constantly vulnerable to hacking and phishing attacks and that they cannot trust any of them with their credit cards or even personal information. They are wary of using these apps because they lack trust in third-party websites to process their payments. Venkatesh et al. [21] also investigated customers' privacy concerns when making online purchases. It was discovered that among the recommendations included in the study were retailers' and other customers' preferences for products that were related to one another. According to a survey, online purchases are moderately influenced by recommendations and product-relatedness. Closely associated products with privacy enablers did not affect online purchase intentions. As Gurung et al. [22] discovered when they investigated online shoppers' security and privacy concerns. These concerns, they believe, influence customers' perceptions of risk. The relationship between privacy and security was also examined using organized conduct. The study's findings indicate that privacy and security concerns may influence risk assessment and awareness. Privacy and security concerns rank second, with trust ranking first. Additionally, individuals' mental states are affected by their perceptions of risk and trust. Ali et al. [23] also examined privacy to determine whether it could be used to deduce users' attitudes toward mobile app security. Värzaru et al. [24] used a reworked version of the technology acceptance model to deduce the factors influencing post-COVID behavioral intention and consumer satisfaction. According to the researchers, consumer intention was positively influenced by perceived usefulness and ease of use. D'Adamo and colleagues [7] discovered that in the post-pandemic era, European consumers are concerned about online security. According to the findings of this study, consumers in Europe have varying levels of concern about e-commerce security. According to Hussien et al. [25], customers and electronic marketplaces can benefit from agent software that provides client-side security to improve marketplace performance. For example, Chen et al. [26] proposed a forensic model that may aid in detecting abnormal system behavior. Numerous studies on e-commerce in Saudi Arabia have been conducted. Between 2013 and 2016, a long-term study by Miao & Tran [27] discovered a significant difference between SMEs' initial adoption of e-commerce and their intention to institutionalize it. Nachar [28] asserts that an e-commerce platform's ease of use and usefulness are statistically significant predictors of customers' willingness to shop online. According to Al-Empirical in Ayed's study [29], customer care, product selection, convenience, personality, and website customization all contribute to e-commerce customer loyalty. Saeed [30] conducted an empirical study of Saudi Arabian expats' adoption of e-commerce and discovered to enhance user interface usability, it is necessary to take cultural differences into account during the technical design stage. Alotaibi [31] found no significant differences in m-commerce customer loyalty by gender, age, or prior experience.

According to Razi et al. [32], participation in social commerce by students has a beneficial effect on purchase intentions and behavior.

According to a review of the literature, geographical and cultural factors influence users' attitudes toward online shopping. However, no comprehensive study of online customers has been conducted in Saudi Arabia. Due to the importance of user motivation and perception in technological adoption, there is a knowledge gap regarding how Saudi consumers perceive the security aspects of e-commerce applications.

III. PROBLEM FORMULATION

Certain studies focus exclusively on the relationship between factors influencing marketplace trust, and only infrequently do they examine the relationship between factors influencing payment system trust in developing countries. In the end, a study by Kim et al. [33] looks at whether trust is affected by factors like reputation, privacy, size, security, benefits, and convenience. It also looks at how this trust affects purchases made with EPS, credit cards, or cash on delivery (COD). It is regarded as user-friendly and useful. Security, usability, trustworthiness, interoperability, common issues, and extra services all affect how well electronic payment systems work. These six factors all affect how well electronic payment systems work. Mutual trust between merchants and customers is required when conducting online shopping, based on the six factors listed above. In [34], the author asserts that the value of security and trust cannot be overstated. Privacy refers to the right to keep one's personal information private. Additionally, privacy is defined as the capacity to manage personal information that is required and used by third parties [35]. If you want to buy something on the internet, you must be willing to give out your personal information before you do so [35]. When it comes to interpersonal relationships, humans prefer to maintain their privacy.

In e-commerce, privacy refers to how willing people are to give out personal information over the internet before they buy something [35]. The term "internet privacy" includes a lot of different things, like data, choices, and sharing with e-commerce service providers. As Belanger stated [36], consumers also want to know that the information they give is safe and lawful. The right to privacy of individuals is extremely well protected. When customers shop online, they provide sellers with extremely detailed information. Consumers who place a high value on privacy often give internet service providers inaccurate or incomplete information. It is possible to take advantage of the privacy settings on a website. In other words, the more confident a user is in a website's ability to protect their information, the greater their trust on the website.

A. Hypothesis

Trust is significantly influenced by people's perceptions of their reputation, privacy, size, security, benefits, website usability, and convenience.

- According to [33], a payment system's perceived user friendliness and usefulness is critical. Security, usability, trustworthiness, interoperability, common

issues, and additional services are all factors that have an impact on the performance of electronic payment systems. It's important to think about safety first. As shown by the preceding six factors, online shoppers and merchants need to put in a lot of work to build trust in one another.

1) *Perceived privacy has a positive effect on trust:*

According to the authors in [8], privacy is a method of protecting one's identity. The ability to retain one's personal information is defined as "privacy" in this definition. Also included in the definition of privacy is an individual's ability to control the extent to which their personal information is required and used by third parties [35]. Privacy online can be defined as consumers' willingness to share personal information before making a purchase [35]. Humans, like other people, have a standard for how much privacy they want. In e-commerce, privacy is defined as consumers' willingness to provide information via the internet before making a purchase [35]. Concerns about privacy on the internet include "spam," "data," "choices," and e-commerce service providers sharing information. Customers also want assurances that the information they provide will be restricted and regulated by the person concerned [36]. Everyone has a right to have their personal information kept private. Customers in the e-commerce industry are extremely picky about the information they divulge to merchants. Internet service providers are more likely to receive incomplete information from consumers who care about their privacy. When you give your personal information to a website, you run the risk of it being misused. The more trust is placed in an address's ability to protect personal information, the more confident that person is in that address's ability to protect that information.

2) *In general, security increases when people feel safe:*

Security is a significant control issue for businesses that conduct e-commerce. When consumers are involved in electronic transmission, data relating to e-commerce, such as buyer and seller data, must be kept confidential. Additionally, the transmitted data must be safeguarded against modification or alteration by anyone other than the sender [36]. According to [37], security can be defined broadly as the absence of danger. This understanding is comprehensive and encompasses an individual's sense of protection against both intentional and unintentional crimes, such as natural disasters. A security threat is defined as a situation, condition, or event that poses a risk of causing damage to data or networks, which can take the form of data destruction, leakage, alteration, or misuse. Consumer security concerns can be addressed in e-commerce using protection technology. When these technologies are used, they are classified as security features. According to [9], security can be classified into four categories based on security holes: physical security (physical security), personnel security (personnel security), data security (data security), and media and communication techniques (communications). Security in operations refers to the policies

and procedures that govern the establishment and management of security systems, as well as post-attack recovery procedures. The management of the online payment system's security can be viewed through the lens of risk management. Authors in [37] recommended employing the "Risk Management Model" when confronted with threats (managing threats). Risk consists of three components: assets, vulnerabilities, and threats. E-commerce network security that incorporates features such as guarantees, contracts, or other procedures ensures the existence and proper operation of payment security. Someone who has a high perception of structural assurance will fervently believe that internet technology (e.x. data encryption) protects in such a way that online transactions are safe. Consumers are protected from financial and personal loss through encryption, legal protection, and technological safeguards. In addition, the authors in [37] stated that security guarantees could be integrated into e-commerce sites through collaboration with third parties with a strong reputation in network security and who provide internet security assurance standards via web assurance seals. Consumers who feel secure in the online environment are more likely to trust websites that offer electronic commerce services than those who believe the internet is unsafe because they do not believe e-commerce sites offer adequate protection.

3) *Perceived benefits are considered when trust is enhanced:* According to [36,37], usefulness is the likelihood that a specific application will be used by potential users to make their work tasks easier. Results will be obtained more quickly and satisfactorily as a result of the product's simplified performance when used in conjunction with the new technology. Internet banking services can boost productivity by increasing people's perceptions of the benefits these services provide. Increased productivity, improved performance, and improved process efficiency can all be used to determine what people think about the benefits of technology.

4) *Consumer trust in a website is increased as a result of familiarity with it:* MAQABLEH et al. [39] study and observe consumer behavior and perceptions of security and trust in e-payment systems based on the proximity of the customer to the website. In addition, the authors in [39] identified a slew of determining factors. There was also a tendency to trust, as well as internet experience, personal innovation, and habit. Third-party involvement, payment system intention, enjoyment, risk aversion, and trustworthiness can all be found by looking at the variables that connect them. According to investigation made in [33], after a customer's first visit to a company's website, the level of consumer confidence in that company's website was measured. According to the findings of the investigation, consumers' perceptions of the company's reputation and willingness to improve products and services have a direct impact on consumer confidence. In addition to the other factors, it is thought that controls for usability, ease of use, and security have a big impact on trust.

5) *Perceived convenience has a positive effect on trust:* According to [37,38], ease of use can be defined as the extent to which a person believes that using technology will be free of effort on his or her part. As implied by the definition, ease of perception is a belief about the decision-making process that is experienced by the individual. Using an information system is more likely to occur if a consumer believes it is simple to use and understand. As identified by [36-37-38], the dimensions of perceived ease are as follows: ease of learning (easy to learn), ease of use (easy to use), clear and understandable (straightforward and easy to understand), and the ability to become skillful (becoming skilled).

6) *Perceived trust has a positive impact on purchase intention when EPS is employed:* Consumers' online behavior is heavily influenced by their level of trust in the companies they do business with, which is why trust is such an important consideration in electronic commerce. One's social standing rises as a result, and one can spend money in the market. According to [8-34-35-36], trust is based on the trustworthiness of the parties involved in the transaction, specifically electronic payments and cross-border trade. Trust in other parties and the use of regulatory control mechanisms were found to be the most important factors in determining the level of trust in transactions. Both variables have objective and subjective components. A lack of trust is a direct indicator of attitude and behavior because of the dynamic nature of cyberspace's high uncertainty and constant change. Trust can also be defined as a person's belief in the ability of others to be trusted, which is based on perceived integrity, benevolence, and competence. The most basic definition of trust is the belief that others will not take advantage of you and that the vendor will deliver on what they have promised. Online shopping relies heavily on trust, which is a significant factor in e-commerce. For e-commerce to work properly, trust and security are two of the most critical constructs, customers tend to have a higher level of trust in e-commerce websites with higher quality content. In a developing country, establishing trust in a new environment is a challenging task that is essential to influencing consumer attitudes [4,5,30,31,33].

7) *Perceived trust influences cash on delivery (or/and) credit card purchases:* Tsiakis and Sthephanides [40] argued that trust and security are two of the most important factors to consider when developing an electronic payment system. According to Kim et al. [33], user convenience and usefulness are important factors to consider when choosing a payment system for their needs. In fact, the ability to feel safe and confident in a company's products and services is critical to attracting and retaining customers.

IV. PROPOSED METHOD

This study's quantitative design collects data from a pool of participants one at a time. Customers of the Saudi Arabian online shopping platform Noon were chosen as the population and sample for this study based on the researchers' judgment of what they should buy. Hair et al. [41] stated that the number of samples in PLS-SEM research must be five times the number

of questions in the questionnaire. As a result, this study's questionnaires contain 5 x 40 questions, yielding a total of 200 respondents. The research questionnaire had closed questions with one of five measurement scales for each variable (Likert). This is done using Google Form and explains what will be done to respondents via social media such as WhatsApp, Instagram, and other social media.

The components of this study were adapted from Maqableh et al. [39] findings on trust behavior and online shopping payment methods for shoppers in Saudi Arabia. The Likert scale was used to measure all constructs in this study, with 1 representing "strongly disagree" and 5 representing "strongly agree." Table I summarizes the results of the fittest for the overall PLS-SEM model. With the Good of Model Fit (GOM) metric, the structural model testing phase can be done as follows:

TABLE I. MODEL FIT GOODNESS

Goodness Model of Fi	Original Value (Saturated Model)	Estimated Model	Note
d_ULS	4.23	9.378	Model Fit
SRMR	0.05	0.088	Model Fit
d_G	1.63	1.80	Model Fit

The Standardized Root Mean Square Residual (SRMR) graph illustrates the amount of error associated with predicting the independent variable's effect on the dependent variable in question. According to the definitions of d_ULS and d_G, a representative research model must have a value greater than 0.05 (if the 95 percent confidence interval is used) or greater than 0.01 for the study's smaller initial estimate (if using a 99

percent confidence interval). In other words, the research model's residual distribution is quite small. Validity is established when the square root of the average variance (AVE) value has a loading factor greater than 0.5, and reliability is established when the composite reliability value is greater than 0.7 or when Conbach's Alpha has a loading factor of 0.6.

V. STUDY SETTING AND PARTICIPANTS

Data points from the distribution of questionnaires were collected using Google's non-probability form method, and these data points can be used to generate additional research data. The following are the characteristics of the 200 participants in the survey (see Table II). Noon customers are predominantly female, with 80% of respondents to this study's questionnaire distribution reporting a shopping frequency of more than 19 times per month, according to the results of the study. Customers who are the most active on Noon fall into this category. Using a correlation coefficient, it was discovered that the effects of total reputation perception, privacy perception, scale perception, safeguard perception, perceived usefulness, user-friendly perception, and trust perception were all increased by 74.1%. In EPS, the variable assessing trust perception accounted for 42.4% of the total. Fixed trust perception of factual purchases made with credit cards accounted for 15% of the total, while variable trust perception of factual purchases made with cash-on-delivery accounted for another 24% of the total (see Table III). Finally, after figuring out the coefficients of determination for each parameter, we conduct the experiment to determine the validity of the hypothesis (Fig. 1).

TABLE II. DEMOGRAPHIC INFORMATION OF RESEARCH RESPONDENTS

Type of Characteristic	Characteristic	Total	Percentage
Sex	Male	40	20%
	Female	160	80%
Age	14 – 20 years old	102	51%
	21 – 30 years old	60	30%
	40 – 50 years old	18	9%
	> 50 years old	20	10%
Occupation	Students	100	59,27%
	Public Sector Employees	43	17,34%
	Private Sector Employees	40	18,95%
	Enterprise Employees	17	4,44%
Income	< RS 6,000	124	69,35%
	RS 7,000 – 12,000	50	20,16%
	RS 13,000 – 17,000	15	6,05%
	> RS 20,000	11	4,44%
Shopping Frequency	< 4 times	70	34,68%
	8 times	50	26,21%
	12 times	20	8,06%
	>19 times	60	31,05%
Shopping Cost	< RS 4,000	140	75,40%
	RS 5,000	48	19,76%
	RS 7,000	4	1,61%
	RS 15,000	8	3,23%

TABLE III. COEFFICIENT OF DETERMINATION

Model	R Square
Trust is significantly influenced by people's perceptions of their reputation, privacy	0.74
Purchase with the intention of utilizing EPS	0.428
Purchase made with credit card	0.015
Actual purchase made with on-delivery payment	0.024

Fig. 1. Coefficient of Determination (R-square).

VI. RESULT AND FINDINGS

These findings demonstrate that belief-formers have an impact on online shopping on the Noon application in Saudi Arabia, which is decided by factors such as safety, benefits, and convenience, all of which have a statistically significant impact. According to the authors in [12,33], high-quality e-commerce sites have a greater perception of trust from their customers, and the exceptional measures taken to earn the trust of customers will shape consumer attitudes in a developing country.

In this study, the researchers discovered that clients who shop online through the Noon application are more likely to purchase things from Noon when they pay with an electronic

funds transfer (EPS). According to the findings of Tsiakis and Sthephanides [40], credence and safeguard are the most important and vital components for electronic payment systems that are used as a tool in financial operations. Furthermore, according to the authors in [34], security and trust play crucial roles in recruiting and retaining customers. Also demonstrated in this study is that the perceived safety, benefits, and convenience of shopping online at Noon in Saudi Arabia have an impact on trust perception, and that using EPS is the most influential factor in trust perception when it comes to purchasing online. As a result, marketplace service providers such as Noon may be able to develop confidence by emphasizing the safety, benefits, and convenience of online shopping. In the long run, service providers may be able to design payment mechanisms that are compatible with EPS. The likelihood of consumers making purchases online at Noon will increase as their degree of confidence increases, as will the likelihood of consumers using EPS payment options (Fig. 2). The online services provided by Noon in Saudi Arabia will be directly recommended to clients who have expressed satisfaction with the company's trustworthiness, security, and convenience of payment (see Table IV).

Fig. 2. Influential Factor in Consumer Trust Perception Measurement.

TABLE IV. HYPOTHESIS TEST

Model	Original Sample	Mean of the ample	Standard Deviation	T-Value	P-Value	Note
Reputation, privacy, size, security, benefits, website usability, and convenience all influence trust.	0.155	0.151	0.070	2.224	0.021	significant
A favorable perception of the firm's size increases trust.	0.013	0.002	0.057	0.047	0.951	Not significant
People trust more when they feel safe.	0.411	0.452	0.057	7.749	0.000	significant
Perceived benefits increase trust.	0.112	0.165	0.055	2.560	0.015	significant
Familiarity increases consumer trust in a website.	0.030	0.020	0.083	0.363	0.711	Not significant
Convenience has a positive effect on trust.	0.156	0.182	0.081	2.227	0.039	significant
When EPS is used, perceived trust positively impacts purchase intention.	0.662	0.665	0.031	20.645	0.000	significant
Trust perception affects cash on delivery / credit card purchases	0.127	0.131	0.062	1.986	0.042	significant

VII. CONCLUSION

In recent years, digital transformation has accelerated, and COVID-19 has resulted in an increase in overall internet spending. Businesses must take precautions to ensure that their customers have a safe and enjoyable online shopping experience. This paper investigates customers' security perceptions of the most popular e-commerce applications in Saudi Arabia. As part of a cross-sectional research design employing quantitative methodology, surveys were distributed online via Google Form to a total of 200 participants. The main findings were related to confirming the research's eight main hypotheses, which were related to testing whether some factors were important in forming perceived trust by customers. Five factors were discovered to have a positive effect (trust, security, reputation, benefits, and convenience), while the remaining three did not (familiarity, size, and usefulness). Based on our findings, trust is a multidimensional construct comprised of reputation, privacy, size, benefits, security, benefits, familiarity with the web, and ease. As demonstrated by this result, the p-value does not apply to all indicators with a loading of less than 0.04 on the latent variable. This study suggests several actions that practitioners and policymakers can take to improve customer perceptions of payment methods and security in Saudi Arabia.

Individual Risk Classification of Crime Groups using Ensemble Classifier Method

Ardhito P. Anggana, Amalia Zahra

Computer Science Department, BINUS Graduate Program
Master of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480

Abstract—The most significant challenge for humanity worldwide to crime, especially terrorist attacks, should be considered. Determining the priority scale for anticipating individual terrorist groups is not easy and will significantly affect work activities and subsequent decision-making measures. Priority scale determination decisions should be made carefully so team members cannot choose the desired priority target. Determining the exact priority scale for a target can be influenced by several factors, such as desire factors and ability factors, using Dataset Intelligence. This research aims to find out the ability of each target and pattern to be carried out. Based on this problem, the study used the K-Nearest Neighbor (KNN), Naïve Bayes (NB), Decision Tree (DT), and Ensemble Bagging methods. Each of these algorithms has its characteristics; This classification technique can group priority targets according to their similarities, abilities, and desires. The value of each method used can be used as a reference to determine the correct group information for officers to determine the next steps. The study obtained a maximum accuracy of 70.25% using the Ensemble Bagging-Backward Elimination-K-Nearest Neighbor (KNN) classification method using 20 features. The results showed tests conducted and final analysis and conclusions based on accuracy and recall performance. The precision performance revealed that the Ensemble Bagged KNN, more precisely than KNN, Naïve Bayes, Decision Tree, and Bagging Naïve Bayes and Bagging Decision Tree. The KNN Bagging ensemble model can add accuracy, map individuals, and detect who should be intensely monitored based on predictive results.

Keywords—Priority scale; data mining; classification; ensemble classifier method

I. INTRODUCTION

The crime of terror is one of the most challenging threats to the global community. Its heterogeneous and complex nature has fostered an increasing interest in the scientific community, primarily to inform policy-oriented measures. The recent availability of large data sets, the diffusion of powerful machines, and advances in mathematical modeling techniques have contributed to the development of several approaches to the study of terrorism [1]. However, it is alarming that the sheer abundance of data makes it nearly impossible for authorities to examine every person, conversation thread, or social media post to classify whether they are linked to terrorism or contain elements of terrorist activity [2].

Forms of criminal acts spread in the corridors of terrorism can be intimidation and threats, murder, persecution, bombings, detonation, arson, kidnapping, hostage-taking, and piracy. The impact of these forms of terror is very diverse,

including the onset of panic, feelings of fear/intimidation, worry, loss of property, incision, and even death. Current hidden or missing link prediction models based on network analysis models rely on machine learning techniques to improve model performance in terms of prediction accuracy and computing power [3]. In addition, with the increasing use of computerized systems to track crimes, computer data analysts have begun helping law enforcement officers and analysts to speed up the crime resolution process [4].

Determining parameters is one of the most vital things in the division based on desire and ability factors to overcome how the data mining process can classify the individual risk of criminal groups to determine priority scales and predict the priority scale in each individual as well as how the comparison of trial results from the model used can predict the priority scale. Determining these parameters is not easy for indicated people and will affect the person's activities indicated and included in the subsequent investigation. Trend analysis is a challenging task because crime data relies heavily on timing. Any data collected around criminal behavior and crime types can repeatedly change during the investigation [5]. In this study, the priority scale in this grouping was divided into three priority scales. With the use of priority scales, we can find out the abilities and desires of the person, indicating whether to commit a criminal act or not.

This research will develop previous research [6]. It presents the best machine learning models that can be used on terrorism-related data to predict terrorist groups most accurately. The decision to take a subset of data analysis was to help overcome the limitations. However, this is still possible to collect, record, and process data using the Decision Tree, Naïve Bayes, K-Nearest Neighbour, and Ensemble Bagging approaches and use optimal classification in analyzing individual data. Datasets using intelligence data with data used amounted to 1088 data with 21 attributes. Of the 1088 data, are people indicated to be committing a crime of terror or related to the act. However, in this study, researchers wanted to determine which attributes affect and do not affect the process with the four algorithms mentioned earlier in the feature selection process. So that later it can be used to form a reliable model in knowing the patterns of individuals who have the possibility of entering the Green, yellow, and orange priority scale using the Ensemble Classifier Method Risk Classification Model [7] because it is theoretically and empirically proven to provide much better performance than Single Learner [8], [9]. This research is limited to RapidMiner as a tool, data using intelligence data, not doing the data imbalance data process.

II. THEORY

In this study, individual risk in the context of terrorism provides a unique opportunity to holistically consider risk factors rather than the individual critical factors often given in analysis [10]. Furthermore, understanding the modus operandi of each terrorist group provides a vast advantage to counter-terrorist institutions so that the necessary steps can be taken first to address the threat posed by those groups [6]. The machine learning approach can solve problems by finding a suitable algorithmic model and is better at generating predictive values from an input variable [7], and has four categories that are generally applied to the concept of data mining [11] is supervised learning, unsupervised learning, semi-supervised learning, and active learning.

In this study, the main categories of Machine Learning used utilizing existing data to perform classification [12]. Such models to perform introduction/classification/prediction is used in crime analysis [13]. When solving problems, no algorithm that provides the desired quality is proposed to use a composition or ensemble algorithm [14]. Data input for classification is a collection of records [15], where x is a set of attributes and y is a particular attribute. Classification models are helpful for descriptive encodings for distinguishing objects from different classes [16] and predictive modeling to predict class labels from unknown records [17]. Classification algorithms will produce patterns or rules that can be used to predict classes. Some of them are Naïve Bayes Classifier[18], Support Vector Machine (SVM), Decision Tree, K-Nearest Neighbor (KNN), and Random Forest Classifier.

The decision tree [14] is one of the exciting classification algorithms for taking measurements using a tree structure consisting of a collection of decision nodes connected by branches from the decision root to the leaf node to produce new decisions until they finally find the correct decision (leaf node) [19]. Data testing is conducted at each decision node[9] to separate datasets into subsets based on data homogeneity. Generally, the Decision Tree method used in modeling is Decision Tree CART. The CART algorithm [7] can build classification and regression modeling using the Gini Index [20] for the attribute selection process. Criteria determine the model of the decision tree formed, which is measured using the formula Entropy.

$$H = \sum P_k \log_2(P_k) \quad (1)$$

K-Nearest Neighbor (KNN), One classification method that can train the model without using parameters (non-parametric) [21] by classifying the object with the most vote values of each predefined object. The technique that can be used to measure the distance between two points or tuples of them is the Euclidean distance technique. Let us say point X is $X_1 = (x_1, x_2, \dots, x_n)$, Then point Y is $Y_1 = (y_1, y_2, \dots, y_n)$. Then the measurement formula used.

$$\text{dist} (d) = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \dots + (x_n - y_n)^2} \quad (2)$$

The Naive Bayes algorithm is a supervised learning approach used for classifying to predicting target variables. Generally, classification techniques predict labeled classes based on attributes by looking for significant correlations

between input and output variables. Naïve Bayes can be a simple probabilistic classifier that can build modeling on large datasets without estimating complex parameters [22]. The basic formula used in Bayes' theory.

$$P = \left(Y | X = \frac{P(Y) \times P(Y | X)}{P(X)} \right) \quad (3)$$

Ensemble Classifier Method is a diverse concept of modeling methods used to solve the problem of base learners by developing and combining a set of hypotheses to correct training data weaknesses using a single-learners approach [7]. This method is generally used in classification to build a model, including bagging, boosting, and stacking by reducing errors and optimizing accuracy results to be better than the base classifier itself [7]. The basic formula used in Ensemble Classifier's theory is.

$$F(x) = c_0 + \sum_{m=1}^M c_m T_m(x) \quad (4)$$

In this study, the algorithm used as a meta-classifier in the Ensemble Classification method is a Bagging algorithm. This simple ensemble meta-algorithm learning method helps reduce variance and improve the prediction and stability of feature selection [23]. By attaching each Ensemble basic learners to a subset of instances, by size n , tasted with repetition of instances n available. As a result, base learners will have a low statistical correlation, improving the Ensemble's predictive performance [24] and discarding error change segments [25] where individual algorithm errors are compensated reciprocally [26]. Furthermore, it is based on the idea of training multiple classifiers (primary) on the same sample, and the combination of its predictions conforms to some rules for new testing objects. Thus making it possible to collectively obtain more complex models than each model separately [14].

III. RELATED WORK

This research [1] uses the Global Terrorist Database (GTD) to learn to forecast the perpetrators of terrorist attacks and provided data on the types of attacks, targets, and weapons in addition to location, year, and other attributes using the Random Forest, Decision Tree and Gradient Boosting methods. Research [6] Presents the best machine learning models that can be used on terrorism-related data to predict the most accurate terrorist groups responsible for attacks based on historical data in India by modeling the behavior of terrorist groups using machine learning algorithms such as J48, IBK, Naive Bayes and Ensemble Voting approaches. In research [27], Create a framework for terrorist attacks that predicts the use of the Global Terrorism Database (GTD). The research approach assumes that textual features may influence the enhanced ability of classifiers to predict the types of terrorist attacks. Fitur text is extracted and represented using text representation techniques such as Term Frequency-Inverse Document Frequency (TF-IDF), Bag of Words (Bow), and Word Embedding (W2vec), Extracted later combined with data set features. The results showed that combining textual features with key features improved prediction accuracy significantly in research [28] using hypothesis tests and regression models. From a practice perspective, exploring the characteristics identified in patterns can lead to prevention strategies, such as changes in the physical or systemic environment. On research

[29] presents new insights into groups and target intruders using data mining algorithms by proposing a framework using historical data to train machine learning classifiers and predict intruder groups and attack types based on selected features using J48 and IBK algorithms. Research [30] uses terrorist event predictions from the Global Terrorism Database (GTD) with support vector machine (SVM), naive Bayes(NB), and linear regression(LR) techniques. Two feature selection methods, including Minimal-redundancy maximal-relevancy (mRMR) and maximum relevance (Max-Relevance), are used to improve classification accuracy. On research [31], Determine whether members of different organized crime groups cooperate using intelligence from the Canadian province of Alberta, which centers on criminals and criminal groups involved in different types of crimes in multiple locations. Bayesian techniques are used to extract multilevel network analytical frameworks and random graph models to uncover determinants of criminal collaboration between groups.

IV. RESEARCH METHOD

Over the past 20 years, terrorism has become a critical influencing factor in international politics and is now marked by increased terrorist attacks across international borders [30]. The increase in cases of terror crimes in the country itself is of particular concern to institutions, especially officers, because terror crimes affect the country's stability and harm the community. Therefore, to know the list of priority scales of targets under investigation should be seen from the reasons factors that indicate the priority scale of the list of supervised members and impact the amount of security stability and comfort of the entire community.

In this study, priority scale indicator predictions were designed using discrete methods described to define the target field by studying its features to identify problems [28] using a supervised learning approach [5]. The agreements to be used are supervised classification learning, including Machine Learning Decision Tree, KNN, Naïve Bayes, and Bagging, and building a predictive model from which results are interpreted [6].

Based on Fig. 1, the first stage is to determine the background and formulation of the problem to be raised using the study of the research literature that has been done to validate the urgency of the problem raised. The next step is from the background and formulation of the above problems and then re-conducted literature studies to determine the purpose of the research and the scope of the research and deepen the sentiment analysis model that will be offered as a solution. The next step is to collect the data used from the intelligence source of the investigation process, which is a collection of datasets from each terror target located in the West Java region obtained from the data collection process taken from Raw Data CDR, Raw Data Medsos, Raw Data Surveillance, Raw Data Funding, and Raw Data BAP. The dataset consists of 1088 data with 21 attributes. Crime datasets have inherent geographic features where all data in the dataset is not distributed randomly [5]. To divide by data dimensions, we analyzed the dataset to find multiple attributes by selecting the most promising feature attributes [27], [32], potentially

contributing to identifying the perpetrators [1]. From the attribute-giving techniques in this study, datasets are divided between desire patterns and abilities.

Fig. 1. The Flow of the Prediction System.

The desired stage pattern is based on the existence of intention and motivation, while the ability stage pattern consists of unique network patterns and patterns. It starts with the collection or retrieval of datasets, and then data is explored to determine inputs and outputs in dataset training and testing processes. The desire stage pattern is based on the existence of intention and motivation, while the ability stage pattern consists of unique patterns and network patterns. The attributes of these parameters are generated values from this priority scale which will be used as a result of research. The next step is to do data preparation which is done in several stages so that in the end, data can be used at the next stage. These stages include selecting and selecting data, transformation, and cleaning. The next step in building the classification will be through the stages that must be done in sequence and correctly. The steps are:

- Classification models are built for all three datasets using machine learning classification algorithms such as KNN, Naïve Bayes, and Decision Tree.
- Validation models are built for each algorithm to test base learner algorithms. The accuracy of the classifier can be further improved by using the Ensemble classifier.
- Validation models are built for each algorithm to test algorithms using Ensemble classification.
- The feature selection process aims to select subsets that can optically characterize the original data [30].

- In this study, classification algorithms were used to apply an ensemble approach and the use of attributes based on the best results of the Feature Selection process.
- Then the performance of the ensemble method is compared to the individual model.

After building a classification model, the stage that will be carried out in the evaluation stage. The stages are described below:

- Conducting a mode evaluation process using validation data tested with data testing then determines the value of Recall Rate, Precision Rate, and Accuracy Rate using confusion matrix measurement technique [27] where accuracy is single-handed, there is a significant difference between the number of Green, yellow and orange labels. Acquisition and accuracy can be used as criteria for classifier evaluation. This parameter is related to True Positive and False Positive (TP/FP), which refers to the number of positive predictions of right/wrong and True Negative and False Negative for the number of negative predictions of right/wrong (TN/FN). Confusion Matrix can measure machine learning performance in classification [11].
- Comparing the results with the other four methods (Decision Tree, KNN, Naïve Bayes, and Bagging).

A. Data Preparation

Data preparation will be done in several stages to obtain data used in the next stage eventually. These stages include Selection of data sampling, selection data, transformation, and cleaning with the priority scale sample dataset, and localized data system for pre-processed stages. Dataset used consists of 1088 Records with 23 Attributes. The primary purpose of the data is to find targets based on the risk of justice involvement in classification into three class groups, others referring to the green class, yellow class, and orange class. Then, perform pre-processed data and table determination. Separate data into training data and data testing 70:30 [7]. Use training data to train predictive models built on machine learning methods such as Decision Tree, Naïve Bayes, and K-Nearest Neighbour [19]. Finally, use data training to train validation models by performing k-fold cross validation processes [33] (k-fold =10) to get validation accuracy.

B. Model Development

Classification will go through the stages using machine learning classification algorithms such as KNN, Naïve Bayes, and Decision Tree. The Decision Tree Algorithm belongs to the family of trees used to generate decision trees. Naive Bayes is a probabilistic classifier belonging to the Bayes family. Furthermore, KNN is a lazy learning algorithm that implements the nearest K-neighbor algorithm. Validation models are built for each algorithm to test the base learner algorithm. The accuracy of the classifier can be further improved by using ensemble classifiers. Validation models are built for each algorithm to test the algorithm using Ensemble classification. The use of feature selection process because the feature aims to select a subset that can optically characterize

the original data [30]. Apply the ensemble approach and attributes based on the best results of the Feature Selection process. The three classification algorithms, KNN, Naïve Bayes, and Decision Tree, were given as inputs because the algorithm results had been analyzed earlier. Then the ensemble method performance was compared to the individual model.

Acquisition and accuracy can be used as criteria for classification evaluation. This parameter is associated with True Positive and False Positive (TP/FP), which refers to the number of true positive and false positive predictions, and True Negative and False Negative for true/false-negative predictions (TN/FN). Confusion Matrix can measure machine learning performance in classification [11]. Then the validation process is done using feature selection [33] to find which attributes can be used and which are not used by testing their accuracy. Furthermore, the determination of predictive accuracy values is based on the results of the cross-validation process. The results of the Feature Selection process determine the eight methods to be used based on the score used as which input can achieve the highest accuracy value and then compare the results with four other methods (Decision Tree, Naïve Bayes, K-Nearest Neighbour, and Bagging). Then the study concentrates on comparing predictive results to test data based on the results of feature training and then testing with data testing into the form of graphs or comparison tables.

The parameters and values of this priority scale results are then used as a dataset. Table I broadly describes the data obtained.

C. Confusion Matrix

For evaluation, we used the Confusion Matrix, as shown in Table II, to measure the accuracy of the classifier by calculating the ratio between the correctly predicted result and the number of samples. In this study, we will measure the level of accuracy, precision, and recall.

The explanations in Table II are:

- True Positive (TP) is the sum of one TRUE class that can be correctly predicted in the TRUE class.
- True Negative (TN) is the number of one FALSE class that can be predicted correctly in the FALSE class.
- False Positive (FP) is a condition where the TRUE class whose prediction is wrong in the FALSE class, while.
- False Negative (FN) is where the conditions in the FALSE class are predicted incorrectly in the TRUE class.
- The standard formula for calculating the degree of accuracy, precision, and recall is based on the confusion matrix as shown in Equations 1-3.

$$\text{Accuracy Rate} = \frac{(TP+TN)}{TP+TN+FP+FN} \quad (5)$$

$$\text{Precision Rate } (p) = \frac{TP}{(TP+FP)} \quad (6)$$

$$\text{Recall Rate } (r) = \frac{TP}{(TP+FN)} \quad (7)$$

TABLE I. RESEARCH DATASET

Type Variable	Variable	Description
Attribute	Mobile phone password	There is a password (No password=0, There is a password=1)
	Mobile phone encrypted	Mobile phone starts encrypted (Unencrypted=0, Encrypted=1)
	Mobile phone off/on	The mobile phone starts to die (Mobile phone off=0, Mobile on=1)
	Radical site access	Access radical sites (Not accessing radical sites =0, accessing radical sites =1)
	The meeting is getting more intense	Frequent meetings (Not attending meetings =0, Joining meetings =1)
	Get away from the network	Remove from the network / lone wolf (Not removing = 0, Removing yourself = 1)
	Counter Surveillance (SV)	Under surveillance (Unsupervised=0, Supervised =1)
	Purchase of Materials and Weapons	Making purchases of materials (Not Making illegal purchases =0, Buying illegal goods=1)
	Visiting the prison	Visiting the prison (Not visiting the prison =0, visiting the prison =1)
	Passport creation	Make a passport (Not make a passport =0, Create a passport =1)
	Withdrawal of large amounts of funds	Withdrawing vast amounts of funds (Not withdrawing funds =0, Withdrawing funds=1)
	Have the essential ability to make bombs	Has a bombing base (Has no base=0, Has a base=1)
	Personal funding capabilities	Have a permanent or non-permanent job (Unemployment=0, Work=1)
	Active Target Network	Active activities (Inactive=0, Active=1)
	Active Network Training activities	Frequent training activities (Not taking training =0, Taking training =1)
	Network Funding Capabilities	Frequently collecting network funds (Not raising funds=0, Raising funds =1)
	Permission from leader	Frequent visits to the leader of the organization (Never visited = 0, Visited = 1)
	Status background	Have a personal status background (Has no background=0, has background=1)
	Family background	Having the involvement of family members as network actors (Not having =0, Having=1)
	Label	Green
Orange		If there is a desire and no ability
Yellow		If there is no desire and there is the ability
ID	Initials Name	The name of each individual

TABLE II. CONFUSION MATRIX

Correct Classification	Classified as	
	Positive (+)	Negative (-)
Positive (+)	True Positive (TP)	False Negative (FN)
Negative (-)	False Positive (FP)	True Negative (TN)

V. RESULT AND DISCUSSION

In this study, we researchers will explain and discuss the study's results following the methods discussed in the previous chapter. The flow in this chapter will be presented in the flowchart:

Based on Fig. 2, an analysis of business needs will be carried out so that the data mining built can meet the needs of the company's goals. Unit XYZ is also unable to determine with certainty and estimate each target managed in developing the investigation process. In practice, it is often difficult to

determine the priority scale of each target. To ensure that priority scales can run effectively and efficiently, a strategy that considers the appropriate priority scale is needed to support the acceleration of handling the monitored targets. In this study, we used a dataset based on the investigation process taken from 2020 to 2021 for an investigation with Multivariate characteristics, with characteristic Attributes Polynomial and Integer, consisting of 3 Classes, 1088 Records, and 23 Attributes. Then the process using Retrieve Operator will upload an Object in the form of sample data from the Repository. After that, adding a Subprocess, this Operator that will combine other operators for the Preprocess stage will handle the Attributes of the data sample that the Retrieve Operator has loaded. The pre-processing stage is to convert nominal to numeric, normalize and replace missing values. Because there are still incorrect Attributes in writing, the MAP function maps a specific value of the selected attribute to be changed to a new value.

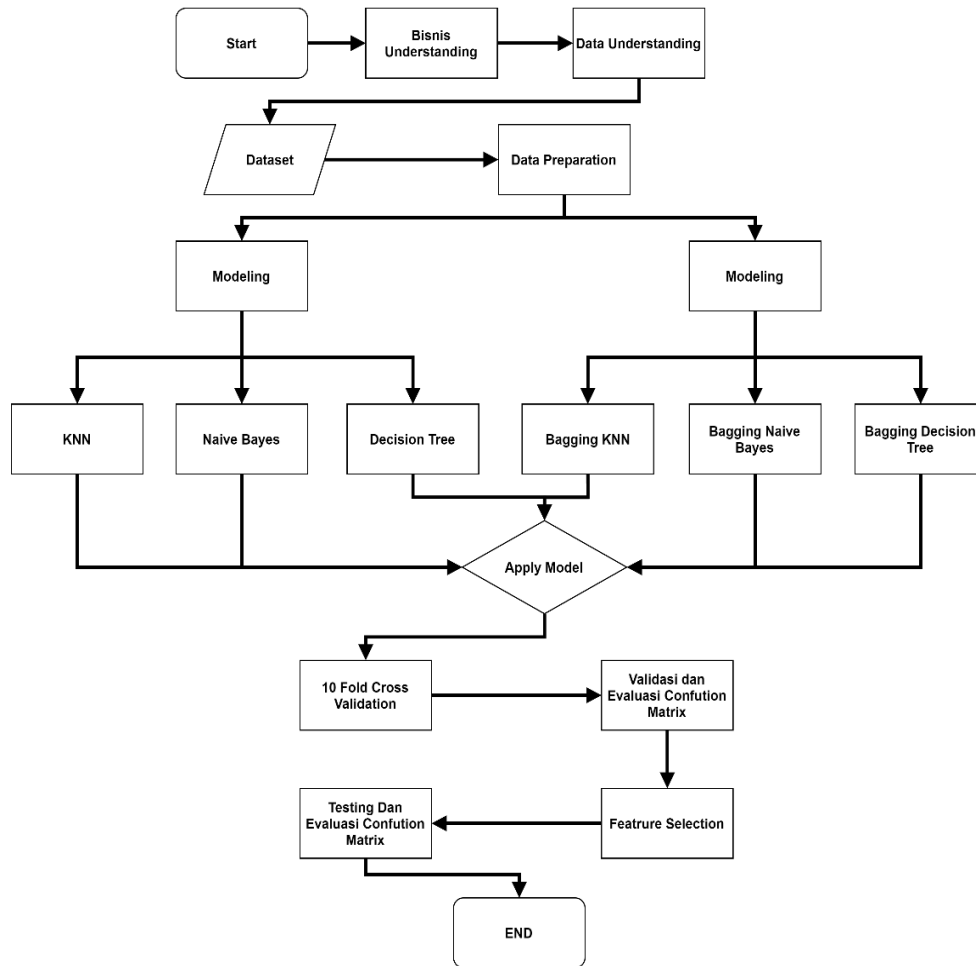

Fig. 2. Flowchart Result and Discussion.

Once the MAP process is complete, the next stage is Select Attributes. This Operator provides different filters to facilitate Attribute selection by selecting a subset of Attributes from Example Set and removing others. Only selected Attributes are sent to the output port. The rest was removed from Example Set. The next stage performs a Role Set to convert regular Attributes into Labels. This model calculation can be done by applying Set Role to turn the Priority Scale into a label. The next stage is to do the Split Data process based on the error score results. From this process, we are splitting the data 70:30. Next, separate the training data used to perform the validation test and the test data used to perform the test.

The Validation Test process tests several models using the Cross-Validation method. The accuracy of each model can be compared. The models tested were KNN, Naïve Bayes, and Decision Tree. The same Ensemble Bagging Model also uses three models to be tested: Bagging KNN, Bagging Naïve Bayes, and Bagging Decision Tree. The six models were chosen because they can process data available on RapidMiner. The validation testing process uses some training data. Validation accuracy results can be seen in Table III.

The next stage is the tuning process to get the best parameter value for feature selection and data mining. The feature selection results are carried out on the training data,

consisting of 21 input variables, using all the Attributes of the Dataset. The Feature Selection process uses the Forward Selection, Backward Elimination, and Optimize Selection parameters and produces two results from the Feature Selection process. The result of the first process is the feature selection process using single learner, KNN, Naïve Bayes, and Decision Tree. While the following result is the results of Feature Selection using the Bagging model that uses the Bagging KNN model, Bagging Naïve Bayes, and Bagging Decision Tree. Feature Selection results show that the Single Learner model obtained the highest result in the Decision Tree model using the Forward Selection-Decision Tree, getting 73.24% with 6 Attributes.

TABLE III. VALIDATION ACCURACY

Validation Model	Accuracy
KNN	71.26%
Naïve Bayes	65.88%
Decision Tree	70.35%
Bagging Decision Tree	69.68%
Bagging Naïve Bayes	66.01%
Bagging KNN	71.65%

Furthermore, the highest results in the Naïve Bayes model using Backward Elimination-Naïve Bayes get 71.79% with 13 Attributes. Moreover, lastly, the highest results obtained in the KNN model using Backward Elimination-KNN get 72.45% with 19 Attributes. The results of the Feature Selection get the result that bagging models obtained the highest results in bagging decision tree models using Forward Selection Bagging-Decision Tree get results 73.89% with 6 Attributes. Furthermore, the highest results were obtained in the Bagging Naïve Bayes model using Optimize Selection Bagging-Naïve Bayes got a result of 67.08% with 9 Attributes. Moreover, lastly, the highest results obtained in the Bagging KNN model using Backward Elimination Bagging KNN get 72.30% with 20 Attributes.

As shown in Table IV, the tuning process of the Single Learner model then produces the three best performance data, as seen below:

As shown in Table V, tuning the Bagging model produces the highest accuracy results for each model judging from the performance data for the following process. From the results of accuracy taken the best of each model as seen in Table V.

The processes presented in Fig. 3 are to conduct an Accuracy Testing process with Attributes based on the results of the Tuning process. The testing process uses models such as images with tuning parameters. The dataset used as input are divided into two separate parts.

The training process uses a dataset of 762 data with attributes that have been filtered according to the tuning process. The dataset used to produce the expected model is a dataset with 326 data and Attributes according to the tuning results in the testing process. In the testing model, there are two inputs, namely mods derived from the output of the training data model and Unl in the Apply Model, which comes from the output of the filter dataset and normalization. Accuracy Testing results have two results; the first is the process of Accuracy Testing using a single learner model that uses the Backward Elimination-KNN model using 19 Attributes, Backward Elimination-Naïve Bayes model uses 13 Attributes. The Forward Selection-Decision Tree model uses 6 Attributes. The following result is accuracy testing Ensemble Classifier using Bagging model that uses Bagging-Backward Elimination-KNN model using 20 Attributes, Bagging-Optimize Selection-Naïve Bayes model uses 9 Attributes, and Bagging-Forward Selection-Decision Tree model uses 6 Attributes. The Accuracy Testing results get results that for the Single Learner model obtained results for the KNN model using Backward Elimination get a result of 69.63%, with 19 Attributes.

Next is the Naïve Bayes model using Backward Elimination which produces 39.88% with 13 Attributes. Moreover, lastly, the Decision Tree model using Forward Selection gets 65.95% with 6 Attributes. The Accuracy Testing results get results that the Ensemble-Bagging model obtained results for the Bagging-KNN model using Backward Elimination get a result of 70.25% with 20 Attributes. Furthermore, the Naïve Bayes model using Optimize Selection results in 39.88% with 9 Attributes. Moreover, lastly, the

Decision Tree model using Forward Selection gets 68.10% with 6 Attributes.

The study used a data testing process tested using Feature Selection tuning validation data to see the accuracy of models in each class. By calculating the accuracy of some test data, the classification effectiveness can be known. This study uses 762 training data and 326 test data. The analysis compared and discussed three of the highest and different general classification performances, namely Backward Elimination K-Nearest Neighbor (KNN), Forward Selection Decision Tree (DT), and Elimination Naive Bayes (NB), as shown in Table VI and Table VII of the highest and other general classification Bagging performance bagging Backward Elimination K-Nearest Neighbor (KNN), Bagging Optimize Selection Naive Bayes (NB), and Bagging Forward Selection Decision Tree (DT).

TABLE IV. SUMMARY FEATURE SELECTION SINGLE LEARNER

Backward Elimination			
	KNN	Naïve Bayes	Decision Tree
accuracy	72.45%	71.79%	71.80%
Forward Selection			
	KNN	Naïve Bayes	Decision Tree
accuracy	72.44%	66.80%	73.24%
Optimize Selection			
	KNN	Naïve Bayes	Decision Tree
accuracy	71.51%	66.80%	72.56%

TABLE V. SUMMARY FEATURE SELECTION BAGGING MODEL

Backward Elimination Bagging			
	KNN	Naïve Bayes	Decision Tree
accuracy	72.30%	66.93%	72.06%
Forward Selection Bagging

TABLE VI. COMPARISON OF SINGLE LEARNER PREDICTION RESULTS

Predictive Actual	Backward Elimination KNN			Backward Elimination NB			Forward Selection DT		
	Green	Orange	Yellow	Green	Orange	Yellow	Green	Orange	Yellow
Green	1	0	0	0	0	0	1	0	0
Orange	0	60	27	1	130	193	0	66	45
Yellow	1	71	166	1	1	0	1	65	148
Total	2	131	193	2	131	193	2	131	193

TABLE VII. COMPARISON OF ENSEMBLE BAGGING PREDICTION RESULTS

Predictive Actual	Bagging Backward Elimination KNN			Bagging Optimize Selection NB			Bagging Forward Selection DT		
	Green	Orange	Yellow	Green	Orange	Yellow	Green	Orange	Yellow
Green	1	0	0	0	0	0	1	0	2
Orange	0	58	23	1	130	193	0	51	21
Yellow	1	73	170	1	1	0	1	80	170
Total	2	131	193	2	131	193	2	131	193

The first prediction modeling was done according to Table VI. It uses the Backward Elimination K-Nearest Neighbor method to predict an accuracy rate of 0.6963, the precision rate is 0.7957, and the recall rate is 0.6060. The following prediction model uses the Naïve Bayes Backward Elimination method and predicted accuracy of 0.3988; the precision rate was 0.1337, and the recall rate of prediction was 0.3308. The following prediction model used the Forward Selection Decision Tree method and obtained a prediction accuracy of 0.6595, the precision rate is 0.7621, and the recall rate of the prediction is 0.5902. For modeling, the second prediction is made according to Table VII. They are bagging the Backward Elimination K-Nearest Neighbor method that predicts an accuracy rate of 0.7025, the precision rate is 0.8043, and the recall rate is 0.6079. The following prediction model using the Bagging-Optimize Selection method Naïve Bayes obtained a prediction accuracy of 0.3988; the precision rate was 0.1337, and the recall rate of prediction was 0.3308. The following prediction model used the Bagging-Forward Selection Decision Tree method and obtained a prediction accuracy of 0.6810, the precision rate is 0.5730, and the recall rate of the prediction is 0.5900.

Of the several models tested, it is known that the one with the highest accuracy is Bagging-Backward Elimination-KNN, as seen in Table VIII.

Ensemble Bagging Classification Method to try to get better predictive accuracy. In this research, it is necessary to build a predictive model using Ensemble Bagging methods such as machine learning meta-algorithms to improve classification in terms of the stability and accuracy of classifications. It also reduces variance and helps avoid overfitting. The results were higher for Ensemble Bagging testing than testing using the single learner model. Of the several models tested, it is known that the one with the highest accuracy is Bagging-Backward Elimination-KNN, as seen in Fig. 4.

TABLE VIII. EVALUATION OF PREDICTION RESULTS

Classification Model	Accuracy	Precision	Recall
Backward Elimination-KNN	69.63%	79.57%	60.60%
Backward Elimination-Naïve Bayes	39.88%	13.37%	33.08%
Forward Selection-Decision Tree	65.95%	76.21%	59.02%
Bagging-Forward Selection-Decision Tree	68.10%	57.30%	59.00%
Bagging-Optimize Selection-Naïve Bayes	39.88%	13.37%	33.08%
Bagging-Backward Elimination-KNN	70.25%	80.43%	60.79%

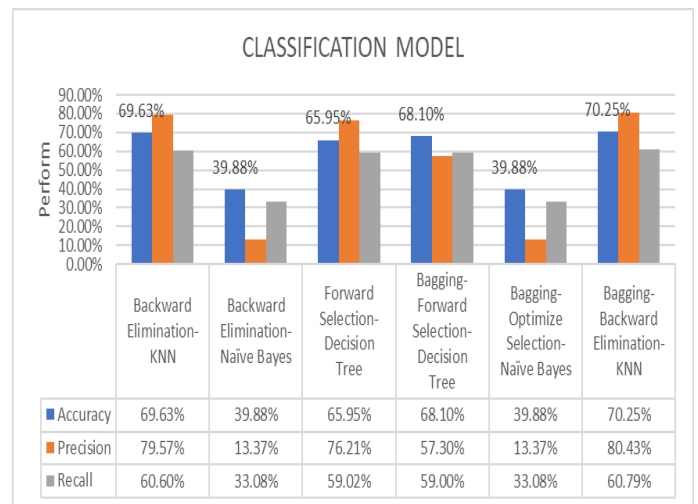

Fig. 4. Testing Performance.

VI. CONCLUSION

The experiments show how historical data or priority scale calculation patterns can be learned through data mining and generate new knowledge to predict future possibilities more accurately with other methods because the role of the priority scale is a picture of the consistency of individual targets in a behavior. The research shows that Bagging-KNN using Backward Elimination can be used, and the accuracy is 70.25%. Attributes that are considered to be no effect of Bagging KNN using Backward Elimination only one is There Is a Password. Influential attributes in determining the priority scale are Access to radical sites, Visiting prisons, Counter SV, Mobile Off, Permission from Amir, Active target network, Active Network training activities, Groups, Network Funding Capabilities, Personal funding capabilities, Family background, Background status, Removing from the network, Having basic bomb-making capabilities, Starting encrypted, Purchasing Materials and weapons, Making passports, Withdrawals in large numbers, increasingly intense Meetings and Territories. This research has discussed how historical data or priority scale calculation patterns can be learned through data mining and generate new knowledge to predict future possibilities more accurately with other methods. This study also compares the classification model of the previous ensemble research [6]. The Ensemble model is shown to improve the classification model with the research earlier model but uses an intelligence dataset instead of a dataset derived from GTD and uses the Ensemble method from previous studies using the J48, Naïve Bayes, IBK, and ensemble models using VOTE using the same model, only the VOTE Ensemble model use the same model. They are replaced using the Ensemble Bagging model. After implementing the research, it is known that the Bagging-KNN Ensemble Model using Backward Elimination can be used, and the accuracy reaches 70.25%. These results showed that the Ensemble model carried out against an existing model, Ensemble bagging KNN Backward Elimination, can increase the accuracy value by 0.62%.

Data mining with classification methods can predict the Priority Scale of each terrorist target. Using these prediction results, analysts can carry out an effective priority scale process in handling terrorism crimes so that the increase in cases of dissociation can be prevented and handled earlier. There are still many shortcomings in this study. For further work, we recommend increasing the number of variations of correlative features and large datasets so that it will help to improve the better performance of this study, namely external assessment features. In addition, more research is needed on feature selection grid methods so that each feature is more significant and very optimal for use in classification modeling.

Abstract—This study investigates the effectiveness and usability level of an augmented reality (AR) application called HazHunt to improve occupational safety and health (OSH) training. Previous research shows that AR has been growing in popularity as an innovative tool to enhance hazard identification courses. HazHunt, a marker-based AR app, was first developed using Vuforia software with OSH experts' guidance. Then, two online sessions of hazard identification course were conducted, where the experimental group's (EG) training was enhanced with the implementation of HazHunt. Analysis shows that the EG scores better (mean = 13.82, $s = 3.38$, $n = 22$) than the CG (mean = 13.41, $s = 2.15$, $n = 22$) in the post-quiz, but this difference is statistically non-significant, with $t(21) = 0.48$ and one-tail $p = 0.32$. Reduced Instructional Motivation Survey (RIMMS) shows that EG participants obtained higher confidence levels among the Attention, relevance, confidence, satisfaction (ARCS) factors in learning motivation. The System Usability Scale (SUS) score of HazHunt recorded the maximum count of 'Good' rating (mean = 78.41, $n = 8$). It is concluded that HazHunt has positive impacts on enhancing OSH training in terms of effectiveness and motivational impact. HazHunt also scored a high SUS score among the EG.

Keywords—OSH training; computer-aided training; online learning; marker-based AR; AR-based application; SUS score

I. INTRODUCTION

Augmented reality (AR) has been proven to play a vital role among the nine pillars of Industrial Revolution 4.0 (IR4) in enhancing occupational safety and health (OSH) activities [1]. Among the activities include rehabilitation [2] and the innovation of serious games for safety training [3]. Particularly, OSH training has evolved tremendously over the years, but most organizations still rely upon traditional way to impart the knowledge. Today, complex working infrastructure present more hazardous environment for the safety and well-being of workers. Thus, AR is a relevant tool that has the capacity to enhance conventional training, suitable for current trend.

The effectiveness of using AR in improving academic performances has been proven for many teaching-learning process [4]. AR have been one of the many popular technologies, used by various institutions as the attractive and interactive elements provide positive effects towards learning performances. However, the overall effectiveness of AR-based technology intervention for professional training was reported to have a small effect on the outcome [5]. Interestingly, AR improved the overall effectiveness of vocational training for a large size effect [6]. This indicates the potential of deploying

applications built with AR technology for OSH related training may produce better effects in achieving training outcomes as the first issue highlighted in this study.

Motivational impact is the second issue addressed when training is conducted conventionally [7]. Conventional training has seen a worse decline in providing sufficient motivational impact, especially in this pandemic era [8]. To overcome this, other IR4 technology such as virtual reality has been implemented for the sole purpose of boosting the motivation among learners [9]. In this study, the technological tool of interest, chosen to enhance motivation is AR [10], as AR is proven to be able to increase motivational impact as opposed to the conventional training delivery methodology [11].

Consequently, today's era perceived many information and communications technology (ICT) tools developed to be used in teaching-learning for various benefits, which requires the usability level of such tools to be properly examined [12], as the third issue for this study. In easy terms, usability level refers to the indicator on a specific user in a specific context, the ability to utilize the tool in achieving a goal effectively, efficiently, and satisfactorily. Simply developing a mobile app is insufficient to conclude its contribution towards the users in said fields, which is the reason to evaluate the usability level.

Therefore, based on the three issues elaborated, the following research questions are established:

- 1) What is the effect of implementing AR technology tool towards academic performances in OSH training?
- 2) What is the motivational impact of deploying the AR tool as a part of the OSH training?
- 3) What is the usability level of the developed AR tool?

II. BACKGROUND STUDY

Based on the research questions stated, there is a necessity to study several important areas. These important areas include the importance of conducting OSH training among organizational members in the organization, the effect as well as motivational impact of conducting training conventionally, and the relevant usage of AR as an innovative tool that had been reported to improvise the content delivery of OSH training in recent times.

A. Importance of OSH Training

In general, training is important because it is a precondition to ensure employees can perform their job effectively and

efficiently and, in the context of OSH, to ensure they can perform a job safely on top of being effective and efficient. To perform a job safely, the employees must equip themselves with sufficient, suitable OSH knowledge and skills, including the knowledge of hazards and how to identify them, the skills to assess risks related to the job, and the identification of suitable control measures reduce the risks.

Clarke & Flitcroft [13] studied the impact of training intervention over 24 months period on a sample of 10 companies and found that the interventions had a significant impact on company safety culture and productivity and even reduced workplace accidents by 22% on average. They also reported a significant increase in employee motivation and safety participation. The study demonstrated that training could be one of the important factors in creating a positive OSH culture within organizations.

In addition to the inherent characteristics of training that makes it important to have a safe workplace, the provision of training is also part of the organization's legal duty stipulated in many statutory laws around the world. For instance, in the United Kingdom, the Health and Safety at Work etc. Act (1974) [14] requires the employer to provide whatever training as is necessary to ensure, so far as is reasonably practicable, the health and safety at work of their employees. Iteration of similar requirements can also be found in the United States Occupational Safety and Health Act (1970) [15] and its Standards, Australia's Work Health & Safety Act (2011) [16], India's Occupational Safety, Health and Working Conditions Code (2020) [17], Canada Labour Code (1985) [18], Japanese Industrial Safety and Health Act (1972) [15], France's Code Du Travail (Labour Code, 2015) [19] and Germany's Arbeitsschutzgesetz (Occupational Health and Safety Act, 1996) [20].

The importance of OSH training is further compounded by the establishment of government-owned or government-linked OSH training centres such as OSHA Training Institute in the United States, OSH Training Centre of Hong Kong, The Occupational Safety Training Institute of Korea and Malaysian National Institute of Occupational Safety and Health, among others.

B. Effect and Motivation of Conventional OSH Training

Conventional OSH training commonly refers to a method of transferring OSH knowledge from the instructor (or trainer) to the training participants using a presentation-based lecture over one to several days' duration in a classroom setting. The variability of training delivery methods will depend on the syllabus, time allocation, the experience of instructors, the setting and location of the classroom and availability of training equipment and material. At its worst, conventional OSH training involves dry lectures coupled with PowerPoint printouts given as handouts and the use of unnecessarily long and unstimulating videos with content unrelated to the participant's learning needs [21]. Despite the many potential weaknesses and variability of conventional training, it remained popular as ever, as evidenced by the Association of Talent Development's State of The Industry report (2019) [22], citing 40% of an organization's hours were spent in a traditional classroom setting.

According to Casey, Turner, Hu & Bancroft [23], two important concepts that are relevant for OSH conventional training effectiveness are training engagement and training transfer. Training transfer is the application of learned skills, generalization to work scenarios and maintenance over time. A recent study by Aziz & Osman [24] highlighted that 98.3% of respondents used what they learned in training at their respective workplaces after training completion. The respondent of the study comprised of those who attended the Malaysian National Institute of Occupational Safety and Health (NIOSH) conventional OSH training courses.

On the other hand, training engagement involves the trainee's engagement with the training during its delivery. Safety training engagement, according to the authors, is the combination of optimal cognitive, emotional and behavioral activity that drives a trainee's motivation to learn. However, there is little research done to answer the question of how engagement can be increased and which elements of engagement are crucial within the context of different types of safety training [23].

C. AR as an Innovative Tool for OSH Training

The impact of AR technology has been studied in various industrial and educational settings, such as the real estate and construction industry [25]. While AR has been applied to several applications—OSH training is one novel application. For example, Kamal et al. found that the AR-based application has increased OSH training participants' active learning behavior, engagement, and interest [26]. It has also been established that AR can aid employees in identifying possible risks and correcting them before they cause actual damage. Sports, architecture, entertainment, and health training [27] have benefited from AR-based training. AR-based training is projected to grow in popularity and functionality greatly in the next years—aligned with the explosion of mobile technology [28].

In general, AR-based training provides several possible benefits and downsides. When developing or conducting a training programme, it is critical to consider these elements to ensure that everyone participating is optimally matched for the training opportunity. For example, Vignali et al. [29] developed Wearable Augmented Reality for Employee Safety in Manufacturing Systems (W-Artemys). They intended to provide new technology assistance for enhancing employee safety while performing machine operations using AR. Additionally, it is critical to assess the performance of AR-based training tools to ensure that workers retain and implement the material. If these goals are accomplished, AR-based training may be an effective method of equipping employees with the information and skills.

Immersive environments based on AR and VR have been effectively used to train personnel in many high-risk sectors [30]. Here AR may be a helpful tool for OSH training for various reasons. First, it can aid workers in comprehending complicated procedures. Second, it can serve as a visual depiction of potentially dangerous circumstances, reinforcing safety messaging. For example, Laciok et al. [31] designed a scenario for a work-related accident using the XVR software environment. Thirdly, it can assist employees in identifying

and resolving dangers prior to the occurrence of real damage. Fourth, AR may be utilized to deliver hands-on training tailored to specific industrial or safety needs.

However, the fundamental challenge is that applications of AR to OSH are still in their infancy [32]. For example, current AR-based training systems lack the scalability to support complicated training requirements. In addition, they may not give adequate augmented visuals to offer cognitive support or support for educational techniques. Verily, the influence of AR on OSH training is dependent on the way it is integrated into the curriculum. Aromaa et al. [33] stressed that there is a need for more interactive virtual and augmented OSH training material.

Therefore, there are a few possible ways to integrate AR into OSH training. This includes bringing a serious game and gamification approach to offer personalized learning interaction. For example, Holtkamp et al. [34] integrate AR and serious gaming to train workers wearing the right protective equipment and how to properly use ladders on their job site. In addition, more and more new AR-based instructional technique is required to motivate trainees and students alike to learn OHS [35].

However, assessing and evaluating the success of online training can be challenging. For example, some individuals may find AR-based OSH training to be tedious or ineffective. This may result in the loss of critical information or skills that employees require to do their jobs. If employees are disengaged with the training, they may be less likely to retain and implement the material. All these possible disadvantages may result in diminished learning and retention. To tackle these challenges, Tarallo et al. [36] created a mobile solution targeted at streamlining and speeding up the flow of training content concerning safety-related issues among safety managers, workers, and casual users.

These disadvantages may be offset by the benefits of AR-based training, such as its accessibility and ease of use [37]. In general, both online and enhanced OSH trainings are projected to gain popularity soon. The primary issue will be to ensure that these training alternatives are meaningful and available to workers in various scenarios and locales.

D. AR Enhanced OSH Training

Indeed, AR has the potential to improve OSH training outcomes by increasing trainee motivation. For example, Vigoroso et al. [38] prove that AR-based training games can boost training effectiveness. In their study, they proved that machine operators' abilities and safety understanding has also been enhanced. The learning process may be further sped up by incorporating learners. While AR has been implemented in a few sectors, it has yet to be implemented in OSH training.

Therefore, an enhanced OSH training is proposed by deploying an AR-based application called HazHunt. This enhanced training suggests the following hypotheses to be tested where the dependent variables are the effectiveness of implementing HazHunt in the enhanced OSH training, the impact of HazHunt towards learners' motivation, and the usability level of HazHunt application.

H₁: The implementation of HazHunt has a significant effect on trainees' learning effectiveness.

H₂: The enhanced training using HazHunt has a positive impact on the motivation of trainees.

H₃: The HazHunt app is perceived to have a high usability level by the trainees.

In conclusion, the following research objectives (RO) are established to test the hypotheses, then answer the research questions outlined, which are to:

RO1. Measure the effectiveness of deploying HazHunt on academic performances.

RO2. Evaluate the motivational impact of using HazHunt in the enhanced OSH training.

RO3. Measure the usability level of HazHunt.

III. METHODOLOGY

In overall, the aim of this study is to enhance the conventional OSH training by implementing AR technology. So, the AR-based application, HazHunt was firstly developed. Then, to achieve the three ROs, two sessions of short OSH training course was held. Department of Occupational Safety and Health (DOSH) officers were appointed as the trainers for the short courses. After the HazHunt prototype is developed, an advertisement targeting university staff and students is launched to find potential participants. Due to the pandemic, the courses had to be delivered online via Google Meet. Registered participants are separated into CG and EG. The first session is delivered conventionally to a control group (CG), followed by the second session to an experimental group (EG). HazHunt was deployed in the second session to EG. For the purpose of data collection, RO1 is measured with mechanical and chemical hazard identification post-quiz, RO2 is measured with Reduced Instructional Materials Motivation Survey (RIMMS), and RO3 is measured with System Usability Scale (SUS), developed by John Brooke [39].

A. Phase I: Development of HazHunt

HazHunt is a marker-based AR application. It is developed using Vuforia software, with the assistance of OSH expert. Fig. 1 shows the HazHunt main menu interface. HazHunt contains AR embedded hazard pictograms to be scanned with the app to access the elaborations and quizzes. Fig. 2 shows the pictogram buttons to access specific hazards. These pictograms are the AR markers to trigger the elaboration of each hazard type, consisting of a video and description. Fig. 3 is an example of HazHunt in action, used to trigger the "skull and crossbones" elaboration by scanning its pictogram.

B. Phase II: Short Courses for CG

In the first session, the participants selected as the CG attended the course by conventional training method (online) as in Fig. 4. By the end of the session, a question and answer (Q&A) slot was conducted as shown in Fig. 5. Later, participants answered the post-quiz and the RIMMS.

Fig. 1. HazHunt Main Menu.

Fig. 2. HazHunt Pictogram Buttons to Access the Specific Hazard.

Fig. 3. HazHunt: the Skull and Crossbones.

Fig. 4. The Presentation in the Short Course Session with the CG.

C. Phase III: HazHunt Implementation for EG

The group of participants selected as EG underwent the second session (online). The trainers involved were prepared with the knowledge and ability to use HazHunt. The usage of HazHunt was integrated into the training in delivering related content. Prior to the session, participants were provided with a

HazHunt apk file to be downloaded and installed on their smart devices. During the session, the trainers instructed the EG to scan the marker that appeared on the shared screen using HazHunt, as shown in Fig. 6. In addition to the learning materials, Fig. 7 shows the HazHunt quiz to enrich the training with AR contents. At the end of the session, the EG answered the post-quiz, the RIMMS and the SUS.

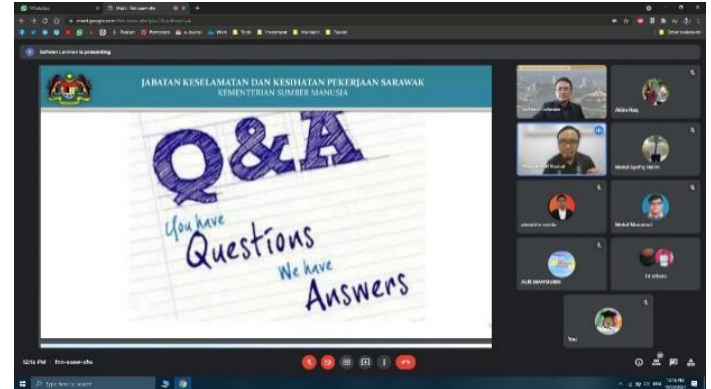

Fig. 5. Q&A Session in the Short Course Session with the CG.

Fig. 6. HazHunt was used in the Short Course with the EG.

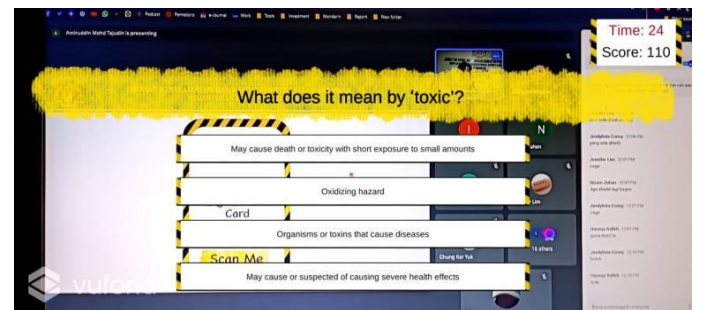

Fig. 7. The Quiz in HazHunt in the Short Course with the EG.

IV. RESULT

Courses were successfully conducted to both control groups (CG), and experimental groups (EG) involved 22 participants ($n = 22$) via Google Meet. Both courses were completed in October 2021.

A. Post-Quiz

The post-quiz consists of 18 questions derived from the topics covered in the course, which are corrosion, explosion, fire, general, health, oxidizer, and toxicity hazards. The post-quiz is analyzed to test the first hypothesis:

H₁: The implementation of HazHunt has a significant effect on trainees' learning effectiveness.

Table I shows the descriptive statistics of the post-quiz results from both groups. The post-quiz results of EG were hypothesized to be greater than CG's results. Based on the results, the EG has higher mean scores but also with higher standard deviation. This means the EG scores better than CG but vary larger among the participants, which shows that the HazHunt implementation does influence the learning effectiveness for the participants. This difference, however, was statistically non-significant, with $t(21) = 0.48$, $p = 0.32$ (one-tail), as can be observed from Table II.

B. RIMMS

The Reduced Instructional Motivation Survey (RIMMS) is a very useful tool to measure the learning motivations of the participants [40] to discern the differences between the CG and EG. The RIMMS is modified in conjunction with the training courses implementation. This survey is used to test the second hypothesis:

H₂: The enhanced training using HazHunt has a positive impact on the motivation of trainees.

Table III shows the descriptive statistics for CG, whereas Table IV shows the descriptive statistics for EG. The means from statements 1 to 3, statements 4 to 6, statements 7 to 9, and statements 10 to 12 contribute to the mean for attention, relevance, confidence, and satisfaction factors, respectively, as shown in Table V. Individually, the EG scores a higher mean in statements 2, 6, 7, and 11. However, EG participants only scored higher in the confidence factor in the ARCS model for learning motivation, collectively. Nonetheless, the enhanced training using HazHunt has a slightly higher positive impact on the participants' motivation to learn.

TABLE I. DESCRIPTIVE STATISTICS OF POST-QUIZ RESULTS

CG		EG	
Mean	13.41	Mean	13.82
Standard Deviation	2.15	Standard Deviation	3.38
N	22.00	N	22.00

TABLE II. THE T-TEST FOR THE TWO-SAMPLE ASSUMES UNEQUAL VARIANCES

Measures	EG	CG
Mean	13.82	13.41
N	22.00	22.00
Df	21.00	
t Stat	0.48	
p (T<=t) one-tail	0.32	
t Critical one-tail	1.69	

C. SUS Score

The SUS questionnaire is used to acquire the usability level [41] of HazHunt, distributed only to the participants in EG. The third hypothesis to be tested is:

H₃: The HazHunt app is perceived to have a high usability level by the trainees.

Table VI shows the descriptive statistics of the SUS scores for HazHunt. The scores range from 0 to 100, where HazHunt obtained a mean of 78.41 across 22 data collected, with the minimum and maximum scores being 62.50 and 95.00, respectively. According to the results shown in Table VII, the maximum scores with the count of 8 were recorded in the 'Good' rating, which means most of the scores were between 68 to 80.3 range. The second-highest scores count was recorded in 'Excellent' rating with the count of 10 participants to rate HazHunt above the 80.3 scores. None of the scores was equal to 68 under the 'Okay' and 'Poor' rating, but the 'Awful' rating consisted of 4 counts for the scores below 51. There might be several interpretations that can be perceived from these scores. However, factors non-related with HazHunt usability may have affected how participants provided the feedback in this questionnaire. Given that 81.8% (18 out of 22) participants provided above average for HazHunt SUS scores, HazHunt is perceived to have a high usability level.

TABLE III. DESCRIPTIVE STATISTICS OF RIMMS FOR CG

Statements	Mean	Standard Deviation
The quality of the slides helped to hold my attention.	4.58	0.50
The way the information is arranged on the slides helped keep my attention.	4.54	0.51

Excellent	8

V. DISCUSSION

The HazHunt app is developed in the hope of enhancing the benefits of OSH training by applying AR-based technology. The analysis is done in the previous section shows positive

results in terms of participants' feedback, but the differences are not huge or significant between CG and EG. However, there may be several inferences that can be made from the analysis done as follows.

A. Online Training Environment

Online learning decreases a certain amount of enthusiasm among participants [42]. Furthermore, an online learning environment could have required the participants to master the usage of various hardware and software to get the most out of the training learning outcome [43]. Online training delivery is supposed to encourage active learning as the participants need to adapt to technology simultaneously looking at the course contents [44]. However, those who lack experience in virtual learning might face various technical issues before and during the training [45]. Additionally, the lack of interaction may have caused the participants to experience the feeling of being alienated or isolated [46]. These could have led the EG participant's HazHunt-enhanced training experience to be affected negatively.

B. Technical Inconveniences

Another common factor that may lead to bad feedback is the occurrence of the technical inconvenience with participants being alone with no physical assistance could be provided, which includes when handling AR technology [47]. In addition, throughout the online learning session, connectivity issues also occurred among participants, which could disrupt the AR demonstration [48], causing a bad impression of the technology and HazHunt. As of date, HazHunt is only available for Android users, and some device or operating software-specific bugs may hinder certain participant learning processes [49]. Although only a small percentage, some users among the participants might have viewed AR as an entertainment tool and rather perceived the technology lack the suitability to be used as a part of professional training [50].

C. Teaching Presence

For some people, teaching presence is required to ensure that the learning process happens as certain participants feel the need to have the trainer be physically closed to assist them to grow as the course progresses [51]. It is true that online training may replace face to face sessions in the cognitive area. Still, it could not replace meaningful interaction between trainer to participants and among peers [52], which caused the HazHunt enhanced training was not able to empower participants significantly.

VI. CONCLUSION

The purpose of this study was to determine the efficacy and usefulness of HazHunt, an AR-based application that was developed to enhance conventional OSH training. The marker-based AR app was built with the assistance of OSH expert using Vuforia. The enhancement of OSH training using HazHunt has been demonstrated to have a good influence on trainees' learning process. Based on the findings, AR technology has a positive effect towards academic performances and motivational impact of OSH training. Furthermore, the AR tool is shown to have a good usability level among the trainees, making the enhanced OSH training to have a new and meaningful experience.

Abstract—This paper discusses the efficacy of the data augmentation method deployed in many Convolutional Neural Network (CNN) algorithms for determining timber defect in four timber species from Malaysia. A sequence of morphological transformation, involving x-reflection and rotation, was executed in the timber defect augmentation dataset for aiding CNN model training and generating the finest CNN models which offer the best classification performance in determining timber defect. For further assessing the CNN algorithms' classification performance, several deep learning hyperparameters were tried on the Merbau timber species by utilising epoch as well as learning rate. A comparison of the classification performance was then done between other timber classes, namely KSK, Meranti, and Rubberwood. According to the results, the ResNet50 algorithm, which has its basis in the transfer learning methodology, outclasses other CNN algorithms (ShuffleNet, AlexNet, MobileNetV2, NASNetMobile, and GoogLeNet) with the best classification accuracy of 94.59% using the data augmentation method. Furthermore, the outcomes indicate that utilising an augmentation methodology not just addresses the issue of a limited dataset but also enhances CNN classification output by 5.78% with the support of T-test that demonstrates a significant difference across all CNN algorithms except for Alexnet. Our study on hyperparameter optimisation by utilising learning rate as well as epoch is sufficient to infer that a greater number of epoch and learning rate does not deliver superior precision in CNN classification. The experimental findings suggest that the proposed methods improved CNN algorithms classification performance in identification of timber defect while tackling the imbalanced and limited dataset challenges.

Keywords—Convolutional neural network; deep learning; defect identification; image augmentation; transfer learning

I. INTRODUCTION

Of late, a multiple integration of the artificial intelligence algorithm and image processing approach has been studied for determining timber defects as the image segmentation methodology single-handedly cannot precisely categorise such defects. Even though many machine learning algorithms have shown considerable recognition rates for different kinds of timber defects [1][2][3], the present manual feature extraction procedure executed in machine learning is considered quite taxing due to its vulnerability to multiple feature attributes within the distinctive appearance of the timber. Therefore, the convolutional neural network (CNN) is deployed for

addressing the complex procedure of feature extraction in machine learning as deep learning algorithms not just offer superior classification performance but also provide an automatic feature extraction process which is tailored to the imminent problem during the training procedure. CNN is a deep learning algorithm which blends hierarchical and multilayer network architectures. Its distinctive architecture allows the algorithm to mine diverse abstract representations on the basis of a designated level of features while aiding CNN to imbibe the complex matter with an improved feature set [4]. CNN has exhibited its competence by outclassing traditional computer algorithms when it comes to object identification and image-based classification. Even though such computer algorithms have been utilised for scrutinising actual images in various fields since the 1970s, these pre-fabricated texture algorithms have to be built based on image domain specificities, which is a major issue [5]. CNN demonstrated its ability when DenseNet was able to attain a classification precision of 98.75% while [6] assessing the performance of four novel CNN architectures with pre-determined texturing techniques in the timber domain. Jung et al. [7] made a comparison of the performance of three CNN architecture depths by categorising into four kinds of defect classes. The outcomes indicated that deep CNN attained the best classification precision of 99.8% in determining timber defect, albeit with greater computational time because of the deeper network architecture. Although the precision of the architectures varies a bit, this shows that they are both viable solutions to the issues of timber classification.

Thus, the deep learning methodology presents a good ability for data mining and knowledge breakthrough in the domain of timber defect detection. However, one of the significant challenges in execution of deep learning is data disparity. On one hand, raw data is now more and more accessible; on the other hand, most datasets have unbalanced distributions with some object classes exhibiting plentiful representation and others possessing inadequate representations, like timber defects. Data disparity in deep learning could trigger inadvertent errors with possibly substantial consequences, particularly in classification tasks in which the lopsided distribution of class instances compels classification algorithms to trigger inductive bias with regards to the majority class. This causes a substandard classification performance because of lesser detection of the minority

samples [8][9]. For dealing with the challenges associated with imbalanced datasets, data augmentation was generally deployed to produce supplementary samples as shown by [10] in their study on imbalanced toxic comments classification by utilising deep learning as well as data augmentation. Moreover, Hu et al. [11] noted that deep learning approaches are not much deployed in the timber industry because of the inadequate quantity of defect datasets necessary for CNN training. Other aspects contributing to the dearth of timber defect images are the outlay incurred for gathering such images and the rigorous manual labelling procedure. One of the effectual techniques for utilising CNNs on minor datasets is espousing transfer learning that encompasses dropping a pre-trained CNN's classifier layer and adjusting it for the target dataset [12]. Thus, the transfer learning and data augmentation approaches might be the solution for addressing class disparity and limited-data problems in timber defect datasets.

This study advocated the use of deep learning approaches, in this case a Convolutional Neural Network (CNN) algorithm to address the complex procedure of feature extraction in machine learning as deep learning algorithms itself not only offer superior classification performance but also provide an automatic feature extraction process which is tailored to the imminent problem during the training procedure. In order to utilize the advantage and capabilities of CNN, both transfer learning and data augmentation technique are used to cater for imbalanced and limited size timber defect dataset. The data augmentation technique employed in this study would involve implementation of various morphological transformation during the image pre-processing process to increase the diversity of timber defect dataset, while the proposed transfer learning method will be applied to several CNN algorithms (ShuffleNet, AlexNet, MobileNetV2, ResNet50, NASNetMobile, and GoogLeNet) in search of highest CNN classification performance across the timber species via multiple combinations of learning rate and epoch parameters. In addition, both transfer learning and data augmentation technique proposed in this research is necessary to avoid overfitting during the training of deep learning algorithm and achieve greater accuracy for timber defect identification. Besides studying the efficacy of these two methodologies, this research assesses the performance of several CNN algorithms across the four timber classes from Malaysia.

II. METHODOLOGY

A. Overview of Approach

This portion elaborates the research approach devised to assess transfer learning and data augmentation efficacy based on numerous CNN algorithms to determine timber defects for

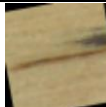

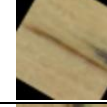

four species in Malaysia. The initial timber pictures are labelled and classified using species and timber defect categories. The timber defect dataset provided by the Universiti Teknikal Melaka Malaysia (UTeM) is used for this research [13]. Meranti, Rubberwood, Kembang Semangkuk (KSK), and Merbau species were used for this study. Data augmentation approaches were applied to the images representing timber defects to assess process efficacy for CNN classification. Original and enhanced images were sized using the inputs corresponding to the CNN techniques. Subsequently, ShuffleNet, AlexNet, MobileNetV2, ResNet50, NASNetMobile, and GoogLeNet were used for testing the transfer learning approach. The techniques were further assessed to determine hyperparameter configurations for optimal CNN classification effectiveness of timber defects. Lastly, the enhanced dataset was tested for classification efficacy using several deep learning hyperparameter settings for different timber specimens; data were gathered and assessed.

B. Data Augmentation

Data augmentation is regarded as the standard approach in deep learning, specifically when there are fewer data samples. The study considered the Meranti, Merbau, KSK, and Rubberwood timber species; experimental specimens were created using 1600 images representing timber defects. The dataset comprises eight timber defect categories (brown stain, blue stain, knot, borer holes, rot, bark pocket, wane, and split), along with one set of clear timber specimens. The dataset was enhanced using the augmentation technique that allowed data maximisation by processing original images. Several morphological changes (x-reflection and rotation) and different orientations of the original images were used to augment the dataset and enhance CNN timber defect detection accuracy. Researchers [14] assert that several morphological changes also reduce overfitting challenges associated with deep learning by allowing additional variations of the original information. Defect images were represented using 10-degree rotation versions to comprehensively depict defects as they appear on timber surfaces based on the direction of feeding. Image enhancement and other pre-processing approaches helped enhance the original dataset to ten times its initial size, i.e., comprising 16000 timber defect images. CNN architecture training and testing were based on the original and enhanced datasets. Table I presents some information concerning the morphological changes implemented during the image addition pre-processing steps to enhance dataset diversity.

- Rotation range 10–350°; rotates every image by 10°
- X – Reflection with 0°, 90°, 180° and 270° rotation

TABLE I. AUGMENTED SAMPLES USING MULTIPLE MORPHOLOGICAL TRANSFORMATION

Rotation	Image	Rotation	Image	Rotation	Image	Rotation	Image
Original		10°		20°		30°	
70°		90°		130°		180°	
210°		270°		310°		330°	
X-Reflection		X-Reflection 90°		X-Reflection 180°		X-Reflection 270°	

C. Transfer Learning using Convolutional Neural Network (CNN) Algorithms

Using transfer learning for CNN is an effective and practical approach to train deep learning models during labelled specimen scarcity. Transfer learning offers the versatility to change initially-trained systems and tune them using domain-based information. A model trained using a broader dataset is used, and specific weights are preferred over initial model training. Transfer learning acts as a potent approach for enhancing learning speed for image categorization and identification jobs. Higher speeds are possible because previous training jobs are employed, and knowledge is reused to enhance learning speed for new or relatively difficult data models [15]. Further, [16] established that transfer learning was usable for VGG16, AlexNet, and ResNet152 to identify timber defects. ResNet provided 80.6% accuracy when contrasted against the speedier R-CNN framework and other previously-trained transfer learning systems. Moreover, transfer learning is a vital approach to reduce overfitting when training deep learning models [17]. For CNN systems, transfer learning is implemented by assigning convolutional layer weights equal to the starting values for fresh classification problems than the complete network comprising fully-connected layers. Moreover, this approach is specifically beneficial to address the difficulty concerning learning classifiers where strong performance is required, but training samples are limited [18].

- AlexNet is among the initial noteworthy CNN system used for the ImageNet dataset to classify objects [19]. The system consists of five and three convolutional and fully-connected layers, 500,000 neurons, and 58 million parameters. A SoftMax classifier is used after the fully-connected layers; it outputs the likelihood values for a relevant class [16].
- ShuffleNet works under computational capability constraints, and this deep learning architecture is tuned for mobile devices. The system comprises convolutional and maximum pooling layers, 3 ShuffleUnit elements, global pooling, and fully-connected layers [20]. The model comprises point-by-

point pairing convolution and shuffles channels to maximise classification effectiveness while controlling the need for higher computational abilities [21].

- GoogLeNet is a differentiated neural network framework implementing a novel organisational system called “Inception Module”. This module implements several convolution operations along with filter concatenation for subsequent layers. Overall, the system comprises 27 layers (pooling layers included). There are 9 inception elements having maxpooling and convolution processes [22].
- ResNet50 is short for residual network (ResNet) and it comprises 50 layers. Contrasting to other CNN algorithms that amass manifold convolutional layers within their architectures, the ResNet50 architecture comprises diverse sets of identical layers and ascertains blocks which are utilised for signifying the usage of prior layers in the network [23]. Even though the network architecture is quite deeper, the quantity of parameters is quite smaller as against other equivalents [24].
- NASNetMobile is a neural architecture search net (NASNet) variation which emphasises on the mobile and embedded platforms. The architecture’s central structure utilises data-led and intelligent methodologies to construct network frameworks which are optimised through reinforcement learning. It generates a feature map by deploying repeated operations on either convolutional cells (reduction cell and normal cell) throughout the architecture [25]. The architecture comprises 12 cells having 5.3 million parameters [26].
- The MobileNetV2 architecture is enhanced for mobile computing. It decreases consumption of memory and delivers speed at a lower cost while removing overfitting on minor datasets [27]. The inverted residual and depth wise separable convolution are two of the main aspects in the MobileNetV2 architecture that comprises 32 entirely convolutional filters and 19 residual bottleneck layers [28]. MobileNetV2 has 3.47 million parameters [26].

In this research, transfer learning is implemented by altering the output class of both fully connected layer and classification layer of the CNN algorithms according to the number of classes in the timber defect dataset (9 classes). However, the other important CNN layer such as convolutional layer, activation function (ReLU), pooling layer are kept in their original algorithm architecture. Furthermore, all six CNN algorithms were fine-tuned to match the data in this article by retraining the weightage of each CNN layer. For model fine-tuning, each of the CNN algorithm was trained 48 times using different combinations of learning rate and epoch parameters across multiple timber species. While other training options such as stochastic gradient descent with momentum (SGDM) optimizer and batch size (10) were used and maintained throughout the training. Even though a decent predictive performance entails a huge number of annotated datasets, transfer learning is frequently utilised to adjust for data paucity. As per the observations by [29], the limited dataset will be sufficient for the remaining layers for learning the features in the pertinent domains, since the architecture had attained vital features like corners in their initial few layers. Thus, transfer learning has been seen to be a mostly effective technique for training neural networks having a limited dataset, and offers a significant promise in the domain of classifying timber defects.

D. Hyperparameter Optimization

Hyperparameter optimisation is a primary constituent essential in deep learning training for enhancing the CNN algorithms' performance. Even though the procedure is quite tough as well as time-consuming, the fine-tuning is necessary to warrant the high classification performance of these algorithms since these are the variables which the model is unable to learn independently. While there exist many proposals on automatic optimisation methods, each has its own merits and demerits when implemented for diverse kinds of problems [30]. Batch size, learning rate, and training epochs are few of the hyperparameters which are adjusted as per the intricacy of the problems or datasets because the model has to possess adequate capability for prediction tasks while evading over-fitting [31]. The learning rate is a vital hyperparameter in deep learning since it outlines the step size at every iteration for the objective function to congregate [32]. The learning rate is augmented by a superior learning rate; however, the gradient might fluctuate around a local minimum value or perhaps fail to congregate. A minor learning rate would congregate smoothly but with a substantial rise in model training time because of supplementary training epochs. Notably, in case the gradient is trapped at local minima, visible progress is achieved at the expense of computational outlay [33]. With a proper rate of learning, the objective function has to be able to congregate to a global minimum within a decent period of time. Conversely, the number of epochs can be ascertained by the size of the training set and has to be adjusted by progressively raising its value till validation precision starts to fall, signifying model overfitting. The deep learning model typically congregates in a few epochs and the following epochs might drive supplementary execution time as well as overfitting. This can be evaded through an early halting approach. This approach is a kind of regularisation wherein the model training is halted beforehand when the validation precision does not

enhance following a specific number of successive epochs. To sum up, ascertaining the apt hyperparameters is vital for warranting the utmost performance of learning algorithms, thus creating a model timber defect identification setup in this study. We adjust the learning rate (0.001 and 0.0001) and the quantity of training epochs (50, 100 and 200) to ascertain the top CNN classification performance for determining timber defect.

III. RESULT AND DISCUSSION

In this paper, multiple CNN classification performance was examined via analysis of the concerning classification accuracy measures. With the accuracy signifying the measure pertaining to true defects versus the predicted defects, this study focuses on highlighting the classification performance pertaining to the put forward augmentation method via comparison versus those six CNN algorithms. Again, comparison was performed for the detailed classification performance with regards to the put forward feature versus four Malaysia timber species, namely Merbau, Meranti, Rubberwood and KSK. By employing both epochs and learning rate, multiple tuning pertaining to both hyperparameters were evaluated to identify the best CNN training optimisation and determine timber defect. Table II displays the classification accuracy with regards to various CNN algorithms across both non-augmented and augmented timber defect dataset along with hyperparameter tuning. While the classification accuracy pertaining to both MobileNetV2 and ResNet50 was seen to enhance considerably, ResNet50 was introduced to show a better performance at 0.01 learning rate and 100 epochs. Thus, this signifies that the highest accuracy rate is displayed by 94.59% classification rate from augmented Rubberwood dataset versus other timber species as well as CNN algorithms. The greatest effect was cast by the augmented dataset with synthetic data on the Rubberwood dataset, wherein accuracy enhanced by almost 10.37% from 82.96% to 93.33%, while Merbau dataset displayed the lowest impact, displaying reduced accuracy to 86.74% from 89.63%. The highest classification accuracy of 94.07% was achieved via GoogLeNet employing 0.001 learning rate and 200 epochs in Meranti dataset. Based on the tables, it can be seen that augmented Rubberwood dataset distinctly had the highest accuracy enhancement at 11.11% from 81.48% to 92.59% with 0.001 learning rate and 50 epochs. Even though Merbau is regarded to be the most ineffective augmented dataset, which reduced the classification accuracy to 75.85% from 84.44%, the overall classification accuracy pertaining to GoogLeNet algorithm encompassing four different types of timber species was seen to rise by 3.18%. With regards to AlexNet, the highest classification performance was achieved at 92.81% by employing the Rubberwood dataset that had hyperparameters of 0.0001 learning rate and 50 epochs. Using data augmentation was seen to enhance the classification accuracy of the algorithm by 22.87%, i.e., from 68.69% to 91.56%. However, the augmentation technique also comes along with adverse impact, wherein the augmented dataset pertaining to the KSK species made the algorithm to overfit in the training. Even though our experiment results in AlexNet algorithm becoming overfit, the overall classification performance displayed that the accuracy with the augmentation technique was seen to enhance by 1.08%.

TABLE II. CLASSIFICATION PERFORMANCE OF CNN ALGORITHMS ACROSS TIMBER SPECIES WITH MULTIPLE HYPERPARAMETERS SETTINGS. THE HIGHEST CLASSIFICATION ACCURACY ACROSS TIMBER SPECIES IS INDICATED IN RED

In ShuffleNet, applying the augmentation technique in the Rubberwood dataset was seen to improve the accuracy by 13.48% with 0.0001 learning rate and 100 epochs, as displayed in Table II. However, ShuffleNet showed the highest classification performance with regards to the Rubberwood dataset (93.79%), wherein the overall accuracy increased by 4.11% across the timber species by employing data augmentation. Next, the best result of 94.3% was achieved via NASNetMobile by employing 0.001 learning rate and 100 epochs. With regards to the different epoch as well as learning rate combinations, the average classification accuracy can be enhanced by 5.78% by employing the algorithm across the timber species. Most of the defect datasets can achieve accuracy of greater than 94% in NASNetMobile aside from

Merbau dataset that can reach just 89.33%. In line with other data augmentation studies, few augmented datasets could cast an adverse impact on CNN classification performance, like Meranti augmented dataset, which can decrease the performance by 3.03%. With regards to the augmented Rubberwood dataset, MobileNetV2 displayed high classification accuracy enhancement of 12.96% employing 0.001 learning rate and 200 epochs. With the Rubberwood dataset (92.67%), the highest accuracy was displayed, specifying that the algorithm classification performance is enhanced by the augmentation method. After training with 0.0001 learning rate setting, the MobileNetV2 showed decrease in performance in Merbau augmented dataset, similar to the performance of AlexNet. In the Meranti dataset, a majority of performance accuracy degradation was observed from 91.11%

to 89.41% employing 0.0001 learning rate and 200 epochs. However, the overall algorithm performance employing the augmentation method demonstrated enhancement in classification accuracy by 3.63%.

Fig. 1 lists out the overall performance pertaining to multiple CNN algorithms employing both non-augmented and augmented timber defect datasets. These experiments demonstrated that with the help of the augmentation technique, the small dataset issue [34] can be addressed as well as the CNN classification results can be enhanced. Even though all the analysed models demonstrated enhancement in classification performance, the NASNetMobile model gave the best improvement (5.8%). By employing data augmentation, performance enhancement in the range of 1.08–5.78% was demonstrated across the CNN algorithms along with certain fine-tuning with regards to epoch as well as learning rate hyperparameters. Employing the augmentation technique with regards to timber defect identification also increased the average accuracy across the timber species i.e., from 87.78% to 91.84%. The ResNet50 was seen to function well across the

timber species giving an average accuracy of 91.84% along with high performance in terms of defect recognition, when compared with the results pertaining to other CNN algorithms in the timber defect dataset. Fig. 2 on the other hand, displays the validation loss curve of highest accuracy CNN models fine-tuned by two different hyperparameters (learning rate and epoch). Besides, it can be seen from the loss curve that ResNet50 can converge quickly compared to other CNN models. Referring to the t-test in Table III, the CNN classification performance in augmented dataset are significantly better compared to the original dataset with the results demonstrating statistically significant differences between the two datasets except for AlexNet. This evidently displays that the augmentation technique cannot be regarded as a domain specific technique and can be applied for other unexplored timber defect identification domain. Besides, CNN algorithms allow achieving high defect identification performance, which can be leveraged to develop automatic visual inspection system in real-world secondary wood industry processing facilities for optimisation of grading as well as cutting for timber.

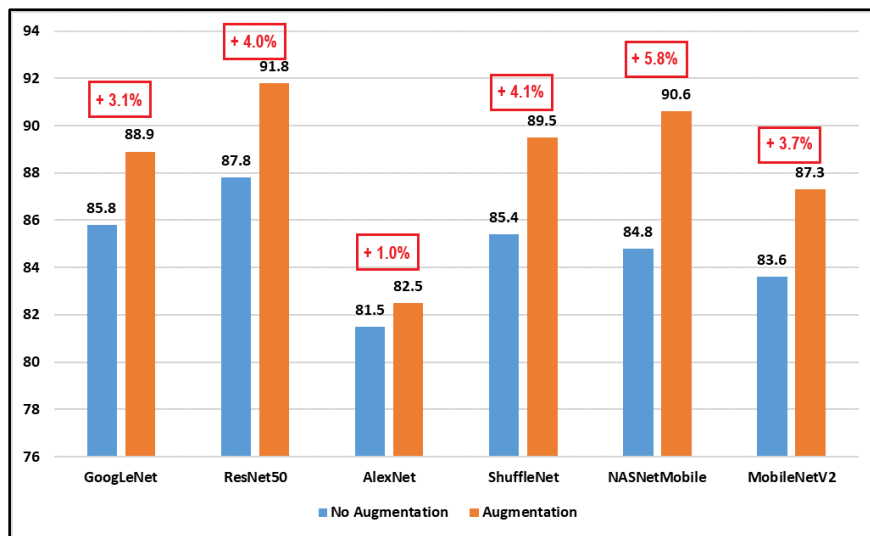

Fig. 1. Overall Performance of CNN Algorithms in both Augmented and Non-Augmented Timber Defect Dataset.

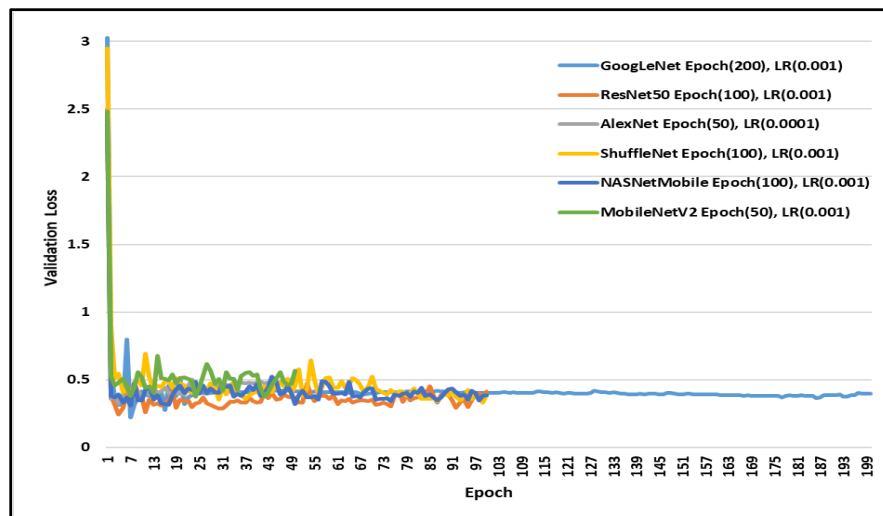

Fig. 2. Loss Curve of CNN Algorithms with Highest Classification Performance.

TABLE III. T-TEST RESULT ON AVERAGE CNN CLASSIFICATION PERFORMANCE IN BOTH AUGMENTED AND NON-AUGMENTED TIMBER DEFECT DATASET

CNN	Original Dataset (\bar{x})	Augmented Dataset (\bar{x})	Sig.	Result
ResNet50	87.78	91.84	.000	Significantly Different
GoogLeNet	85.77	88.95	.014	Significantly Different
AlexNet	81.47	82.55	.767	Significantly Similar
ShuffleNet	85.43	89.54	.001	Significantly Different
NASNetMobile	84.85	90.62	.000	Significantly Different
MobileNetV2	83.64	87.27	.015	Significantly Different

IV. CONCLUSION

This study is aimed at evaluating the effectiveness pertaining to data augmentation technique by using multiple CNN algorithms to identify timber defects across four timber species. The research employs CNN algorithms by implementing transfer learning on ResNet50, GoogLeNet, MobileNetV2, ShuffleNet, NASNetMobile and AlexNet. Evaluation of both data augmentation as well as transfer learning methods was done with various learning rate and epochs to identify the best CNN classification performance for timber species. The result showed data augmentation and transfer learning techniques can be effectively used for searching defect across timber species. The best accuracy could be achieved by employing the ResNet50 model (94.59%) along with optimisation of hyperparameters at learning rate 0.001 and 100 epochs. Our results demonstrate that the augmentation technique can deal with the limited dataset issue as well as enhance the average CNN classification performance by almost 5.78% with regards to the NASNetMobile model. Also, our research study has employed different combination of learning rate as well as epoch, suggesting that a higher number of learning rate and epoch does not necessarily give higher accuracy for CNN model classification. Besides, the research outcomes show that data augmentation as well as CNN algorithms methods with regards to timber defect identification can be used for cutting optimisation as well as industrial timber grading. Also, to further enhance the results, exploring of more complex data augmentation as well as transfer learning framework can be done. The method includes limitations with regards to the requirement of manually adjusting the orientation pertaining to the timber defect images to carry out data augmentation as well as manually label the images pertaining to training CNN algorithms, which may not be regarded as error-free. Future work may include using deep learning for analysis of various kinds of timber defects across different timber species.

Abstract—The wearable health monitoring system (WHMS) plays a significant role in medical experts collecting and using patient medical data. The WHMS is becoming more popular than in the past through mobile devices due to meaningful progress in wireless sensor networks. However, because the data about health used by the WHMS is related to privacy, it has to be protected from malicious access when wirelessly transmitted. Jiang et al. proposed a two-factor suitable for WHMSs using a fuzzy verifier. However, Jiaqing Mo et al. revealed that the protocol proposed by Jiang et al. had various security vulnerabilities and proposed an authentication protocol with improved security and guaranteed anonymity for WHMSs. In this paper, we analyse the authentication protocol proposed by Jiaqing Mo et al. and determine problems with the offline identification, password guessing attacks, operation process bit mismatch, no perfect forward secrecy, no mutual authentication and insider attacks.

Keywords—Authentication protocol; health status; physiological data; security analysis; WHMS

I. INTRODUCTION

Electronic health system keeps Wireless communication, authentication protocol, sensors using low-power, and security solution on authentication protocol [1-8] safe. Wireless sensor networks (WSNs), which play a significant role in e-health, detect, measure, collect or record patient information on a medical server for physician diagnosis. The wearable health monitoring system (WHMS) has received considerable attention regarding its movability, adaptability and operation cost [9, 10, 11, 12]. The WHMS detects, measures, and collects patient physiological data with the WSN inserted or embed within the patient's body. In addition, after monitoring the health status, information is transmitted through wireless channels to medical-related institutions to help manage it. Remote doctors can evaluate the health status through such data as the heart rate, blood pressure and body temperature.

The WHMS is simple and efficient for medical professionals, and patients receive many benefits from the WHMS. However, the detected data are transmitted over an unsafe wireless channel; thus, concerns exist regarding security and privacy problems. Therefore, a robust certified mechanism must be designed to protect the physiological data for patients whose security is critical. If an adversary modifies the data for

a patient, the doctor will misdiagnose the patient based on incorrect data. In addition, revealed data are highly likely to be used by malicious and illegal purposes. Medical personnel must authenticate that they are normal users before accessing patient's physiological data from the wearable sensor of the patient to prevent this. Even if the adversary eavesdropped on the message through the gateway of the WHMS, their identity and passwords must not be disclosed. A session key must be calculated between the sensor node and the medical personnel on the patient's body for future secure communication.

Kumar et al. [13] studied a user authentication protocol in 2012 to monitor patient physiological data in the medical WSN E-SAP and argued that the protocol was safe on the known attacks. But He et al. [14] and Khan and Kumari [15] found security vulnerabilities, such as lack of user anonymity and password guessing attack in the plans by Kumar et al. and presented improved versions. Li et al. and Wu et al., Mir et al. [16-18] individually found out that the plan by He et al. [14] has security problems, such as offline guessing attacks, denial-of-service (DoS) attacks, most attacks, and sensor node capture attacks. They proposed an enhanced version that is safer than the previous proposal to compensate for these loopholes. Das et al. [20] pointed out various security flaws such as lack of user anonymity, privileged insider attacks and sensor capture attacks in the protocol by Li et al. [21] and proposed an improved framework based on biometric recognition. Amin et al. [19] proposed a mutually authentication protocol providing user's anonymity in the WHMS and stated that the system was secure against already known various attacks. But Jiang et al. [22] revealed that the protocol has various vulnerabilities like as unsynchronised attacks, sensor key exposure and stolen mobile device attacks. Jiang et al. proposed an enhanced authentication protocol using smart card and password [22, 23]. Their protocol used square surplus, fuzzy validator [24] and timestamp mechanisms to ensure the plan by Amin et al. In addition, as a result of a security analysis, their plan achieved the desired security function.

Separately, Challa et al. [25] claimed an enhanced 3-factor (cryptography, smart card and biometric) authentication scheme for healthcare WSNs to enhance the scheme's security proposed by Liu and Chung [26]. However, this method, which requires the user to communicate directly with the remote sensor, greatly increases the sensor power consumption and

*Corresponding Author.

rapidly reduces its lifespan. Therefore, their systems cannot be applied to healthcare WSNs. Ali et al. [27] proposed a 3-factor protocol providing anonymity in the plan by Amin et al. [19] to frustrate security threats, such as user impersonation attacks, offline password guessing attacks and known session key temporary information attacks. Shen et al. [28] presented a multilayer authentication protocol using ECC in WBANs (wireless body area networks) to improve authentication's security and compute group key generation between sensors and mobile devices. Li et al. [29] proposed an efficient authentication scheme for a centralised WBAN organized two hops while maintaining anonymity and nonconnectedness in data transmission. And Shen et al. [30] proposed an ECC-based authentication protocol using public key signature scheme for WBAN. But according to [31, 32], their authentication scheme type with only two round messages is likely to fail in perfect forward secrecy.

Jiaqing Mo et al. analysed the protocol proposed by Jiang et al. [22] and discovered that Jiang et al.' protocol was not safe as their proven. Jiang et al.' scheme provides fuzzy verifiers to block offline password guessing attacks, their systems were still vulnerable to authoritative insider attacks, leading to user impersonation attacks. Unfortunately, the plan by Jiang et al. [22] is subject to KSSTI attacks; thus, their protocols are as vulnerable to sensor key disclosure as before. In addition, their protocols struggle with DoS attacks. In addition, Jiaqing Mo et al. implement an authentication scheme with improved security and guaranteed anonymity for WHMSs to solve this problem. However, in this paper, we analyse the authentication protocol proposed by Jiaqing Mo et al. and discovered problems with the offline identification, password guessing attacks, operation process bit mismatch, no perfect forward secrecy, no mutual authentication and insider attacks.

The rest of this paper is organised as follows. Section 2 describes the terms and adversary models used in this paper. Section 3 analyses the operation process of an authentication protocol with improved security and guaranteed anonymity for the WHMS proposed by Jiaqing Mo et al. Section 4 describes the vulnerabilities found by conducting a stability analysis on the protocol proposed by Jiaqing Mo et al. Finally, in Section 5, we conclude this paper.

II. RELATED RESEARCH

A. Summary of Symbol

Symbols used in the paper's operation process are shown in Table I.

B. Adversary Model

An adversary's capabilities are essential part of an adversary model. In this paper, it is assumed that the adversary has the following capabilities.

- An adversary can completely control open channels like as inserting, intercepting, eavesdropping, deleting, and modifying exchanged messages through open channels [33, 34].
- An adversary can find out all data (i.e. secret key and random number) stored in the mobile device when adversary acquire user's lost mobile device [35, 36].

- An adversary can estimate the ID_i and PW_i offline by listing pairs in Cartesian product $D_{ID} \times D_{PW}$ within polynomial time. Here, the D_{ID} represents identity space and D_{PW} is password space [31, 37].
- The secret key and random numbers party are suitably large so they overcome adversary from successfully guessing accurate data within polynomial time.
- The inside adversary may get a user's registration request message, and the insider may access the verification table [38, 39].

TABLE I. SUMMARY OF SYMBOL

Symbol	Meaning
U_i	Medical professional
ID_i	U_i 's identity
PW_i	U_i 's password
S_j	The j th sensor node
SID_j	S_j 's identity
GWN	Gateway
K	GWN's secret key
MD	The mobile device
R_1, R_2 and R_3	Random nonce produced by U_i , GWN, and S_j , respectively
\oplus	Bitwise XOR operation
\parallel	Concatenation
$h()$	One-way hash function

III. OPERATION PROCESS OF THE PROTOCOL PROPOSED BY JIAQING MO ET AL

Jiaqing Mo et al.'s proposed protocol consists of five stages: setting, medical expert registration, patient registration, login and authentication, and password change.

A. Setting Step

The registration center GWN selects two large primes p and q , computes $n = pq$, and maintains the private key (p, q) .

B. Medical Professional Registration Step

1) U_i inserts own ID_i and PW_i , a random-nonce r_i , and computes $HPW_i = h(r_i \oplus PW_i)$; then send $\{ID_i, HPW_i\}$ to gateway through a secure channel.

2) After receiving user's registration request, GWN selects $m \in [2^4, 2^8]$, a random-nonce R_i , computes $Reg_i = h(h(ID_i \parallel R_i \parallel HPW_i) \bmod m)$, $A_i = R_i \oplus HPW_i$, $B_i = h(ID_i \parallel R_i \parallel K)$, and $C_i = B_i \oplus h(ID_i \parallel R_i \parallel HPW_i)$. Reg_i is a fuzzy verifier. Thereafter, GWN transmits $\{Reg_i, A_i, C_i, m, n, h()\}$ to U_i using a secure channel.

3) When U_i receive GWN' message, U_i computes $A_i^* = A_i \oplus h(ID_i \parallel r_i)$, $D_i = r_i \oplus h(h(ID_i \parallel PW_i) \bmod m)$ and updates MD to $\{Reg_i, A_i^*, C_i, D_i, m, n, h()\}$.

C. Patient Registration Step

This step is almost identical to Jiang's plan [22].

- 1) The patient delivers the ID to the registration center.
- 2) Select the appropriate sensor kit from the registration center and assigns a professional.
- 3) The registration center calculates $SK_{GW-sj} = h(SID_j \parallel K)$ for S_j as a secret key between GWN and sensor node. And the registration center delivers the patient's significant information to the designated specialist.

D. The Login and Authentication Step

Through this step, this protocol will be able to provide mutual authentication and generate session keys between U_i and S_j for future communication.

1) U_i chooses own ID_i and PW_i , and MD calculates $r_i = D_i \oplus h(h(ID_i \parallel PW_i) \text{ mod } m)$, $HPW_i = h(r_i \oplus PW_i)$, $A_i = A_i^* \oplus h(ID_i \parallel r_i)$, $R_i^* = A_i \oplus HPW_i$, $Reg_i^* = h(h(ID_i \parallel R_i^* \parallel HPW_i^*) \text{ mod } m)$, and tests $Reg_i^* = Reg_i$. If false, MD selects a random number R_1 and calculates $B_i^* = C_i \oplus h(ID_i \parallel R_i \parallel HPW_i)$, $CID_i = (ID_i \parallel R_1 \parallel R_i^* \parallel SID_j)^2 \text{ mod } n$, $M_1 = h(ID_i \parallel B_i^* \parallel R_1 \parallel T_1)$, then transfers $msg_1 = \{CID_i, M_1, T_1\}$ to GWN. T_1 is the current timestamp.

2) After receiving the login request msg_1 , the GWN decrypts CID_i with (p, q) to obtain $(ID_i^*, R_i^*, R_1^*, T_1)$ and confirms the freshness of the timestamp T_1 . If the confirmation fails, GWN stops the session. Otherwise, GWN calculates $B_i' = h(ID_i \parallel R_i \parallel K)$ and $M_1^* = h(ID_i \parallel B_i' \parallel R_1 \parallel T_1)$ and then tests $M_1^* = M_1$. If inequality persists, GWN stops the procedure. Otherwise, GWN computes $SK_{GW-sj} = h(SID_j \parallel K)$, selects a random nonce R_2 , and computes $M_2 = h(ID_i^* \parallel R_1^* \parallel R_i)$, $M_3 = h(h(M_2 \parallel "1") \parallel SK_{GW-sj} \parallel R_2 \parallel T_2)$, $M_4 = M_2 \oplus h(SK_{GW-sj} \parallel T_2)$, and $M_5 = R_2 \oplus h(SK_{GW-sj} \parallel SID_j \parallel T_2)$. Finally, GWN sends $msg_2 = \{M_3, M_4, M_5, T_2\}$ to S_j .

3) When receiving msg_2 from GWN, firstly S_j checks the validity of T_2 . If it is not fresh, S_j stops next procedure. If it is fresh, S_j calculates $R_2' = M_5 \oplus (SK_{GW-sj} \parallel SID_j \parallel T_2)$ and $M_2 = M_4 \oplus h(SK_{GW-sj} \parallel T_2)$ and tests $M_3 = h(h(M_2 \parallel "1") \parallel SK_{GW-sj} \parallel R_2' \parallel T_2)$. If it is false, S_j terminates the session. Otherwise, S_j selects a random number R_3 and calculates $SK = h(M_2' \parallel R_2' \parallel R_3)$, $M_6 = h(SK \parallel R_3 \parallel SK_{GW-sj})$, and $M_7 = h(R_2' \parallel T_3) \oplus R_3$, where T_3 is the current timestamp. Then, S_j transfers $msg_3 = \{M_6, M_7, T_3\}$ to GWN.

4) When msg_3 is a received from S_j , the GWN confirms the validity of T_3 firstly. If timestamp is fresh, GWN terminates next procedure. Otherwise, GWN calculates $R_3' = M_7 \oplus h(R_2' \parallel T_3)$, $SK' = h(M_2 \parallel R_2 \parallel R_3')$, and $M_6' = h(SK' \parallel R_3' \parallel SK_{GW-sj})$ and examines whether $M_6' = M_6$ holds. If they are same, GWN computes $M_8 = R_2 \oplus h(ID_i^* \parallel R_1^*)$, $M_9 = R_3 \oplus h(ID_i^* \parallel R_2^*)$, and $M_{10} = h(ID_i^* \parallel SK' \parallel R_3 \parallel T_4)$ and transfers $msg_4 = \{M_8, M_9, M_{10}, T_4\}$ to U_i . Here, T_4 is the current timestamp.

5) U_i receives msg_4 from GWN and examines the timestamp T_4 . If timestamp is not fresh, U_i stops next procedure. Otherwise, U_i calculates $R_2' = M_8 \oplus h(ID_i \parallel R_1)$, $R_3' = M_9 \oplus h(ID_i \parallel R_2')$, and $SK^* = h(h(ID_i \parallel R_1 \parallel R_i') \parallel$

$R_2' \parallel R_3')$ and checks whether $M_{10} = h(ID_i \parallel SK^* \parallel R_3' \parallel T_4)$ holds. If they are not same, U_i terminates the current connection. If they are same, U_i can believe that both GWN and S_j are believable. Then U_i and S_j can proceed with secure communication in the future by using the session key. The login and authentication steps are summarized in Fig. 1.

IV. SECURITY ANALYSIS OF JIAQING MO ET AL'S PROTOCOL

This paper analyzed the operation process of Jiang et al.'s protocol and found various vulnerability as off-line ID, PW guessing attack, operation process bit mismatch, no perfect forward secrecy, no mutual authentication and insider attack.

A. Off-line ID, PW Guessing Attack

According to Jiaqing Mo et al.'s proposed protocol, when an adversary acquires a MD, the adversary can extract information stored in the MD and then find out the user's ID and PW. The information of $\{Reg_i, A_i, C_i, m, n, h()\}$ is sent to the MD through the GWN security channel. Thereafter, the MD calculates and updates $A_i^* = A_i \oplus h(ID_i \parallel r_i)$ and $D_i = r_i \oplus h(h(ID_i \parallel PW_i) \text{ mod } m)$. Finally, information of $\{Reg_i, A_i^*, C_i, D_i, m, n, h()\}$ is stored in the MD. Assuming that an adversary found out this through a physical analysis method, an ID and password can be derived through the formula of $Reg_i^* = h(h(ID_i \parallel R_i^* \parallel HPW_i^*) \text{ mod } m)$.

$$\begin{aligned}
 Reg_i^* &= h(h(ID_i \parallel R_i^* \parallel HPW_i^*) \text{ mod } m) \\
 &= h(h(ID_i \parallel A_i \oplus HPW_i^* \parallel h(r_i \oplus PW_i)) \text{ mod } m) \\
 &= h(h(ID_i \parallel A_i^* \oplus h(ID_i \parallel r_i) \oplus HPW_i^* \\
 &\quad \parallel h(r_i \oplus PW_i)) \text{ mod } m) \\
 &= h(h(ID_i \parallel A_i^* \oplus h(ID_i \parallel D_i \oplus h(h(ID_i \\
 &\quad \parallel PW_i) \text{ mod } m)) \oplus h(r_i \oplus PW_i) \\
 &\quad \parallel h(r_i \oplus PW_i)) \text{ mod } m) \\
 &= h(h(ID_i \parallel A_i^* \oplus h(ID_i \parallel D_i \oplus h(h(ID_i \\
 &\quad \parallel PW_i) \text{ mod } m)) \oplus h(D_i \oplus h(h(ID_i \\
 &\quad \parallel PW_i) \text{ mod } m) \oplus PW_i) \parallel h(D_i \oplus h(h(ID_i \\
 &\quad \parallel PW_i) \text{ mod } m) \oplus PW_i)) \text{ mod } m)
 \end{aligned}$$

Summarizing the above formula, the adversary will be aware of the information $\{A_i^*, D_i, m, h()\}$ except for the ID and PW. The adversary repeatedly performs verification while continuing to change until the user's ID and PW are found. Ultimately, the user's exact ID and PW can be found. The process of ID, PW guessing attack is summarized in Fig. 2.

B. Operation Process Bit Mismatch

In Jiaqing Mo et al.'s protocol, XOR operations are widely used, and XOR operations must have the same number of bits. However, in Jiaqing Mo et al.'s protocol, there may be a problem with the XOR operation because the number of bits does not match during the XOR operation. A hash function is a function that receives a message having an arbitrary length and outputs a hash value of a fixed length. Keys are used for cryptographic algorithms, but hash functions do not use keys, so the same output is always produced for the same input. The purpose of using these hash functions is to provide integrity to detect errors or alterations in messages.

$$HPW_i = h(r_i \oplus PW_i)$$

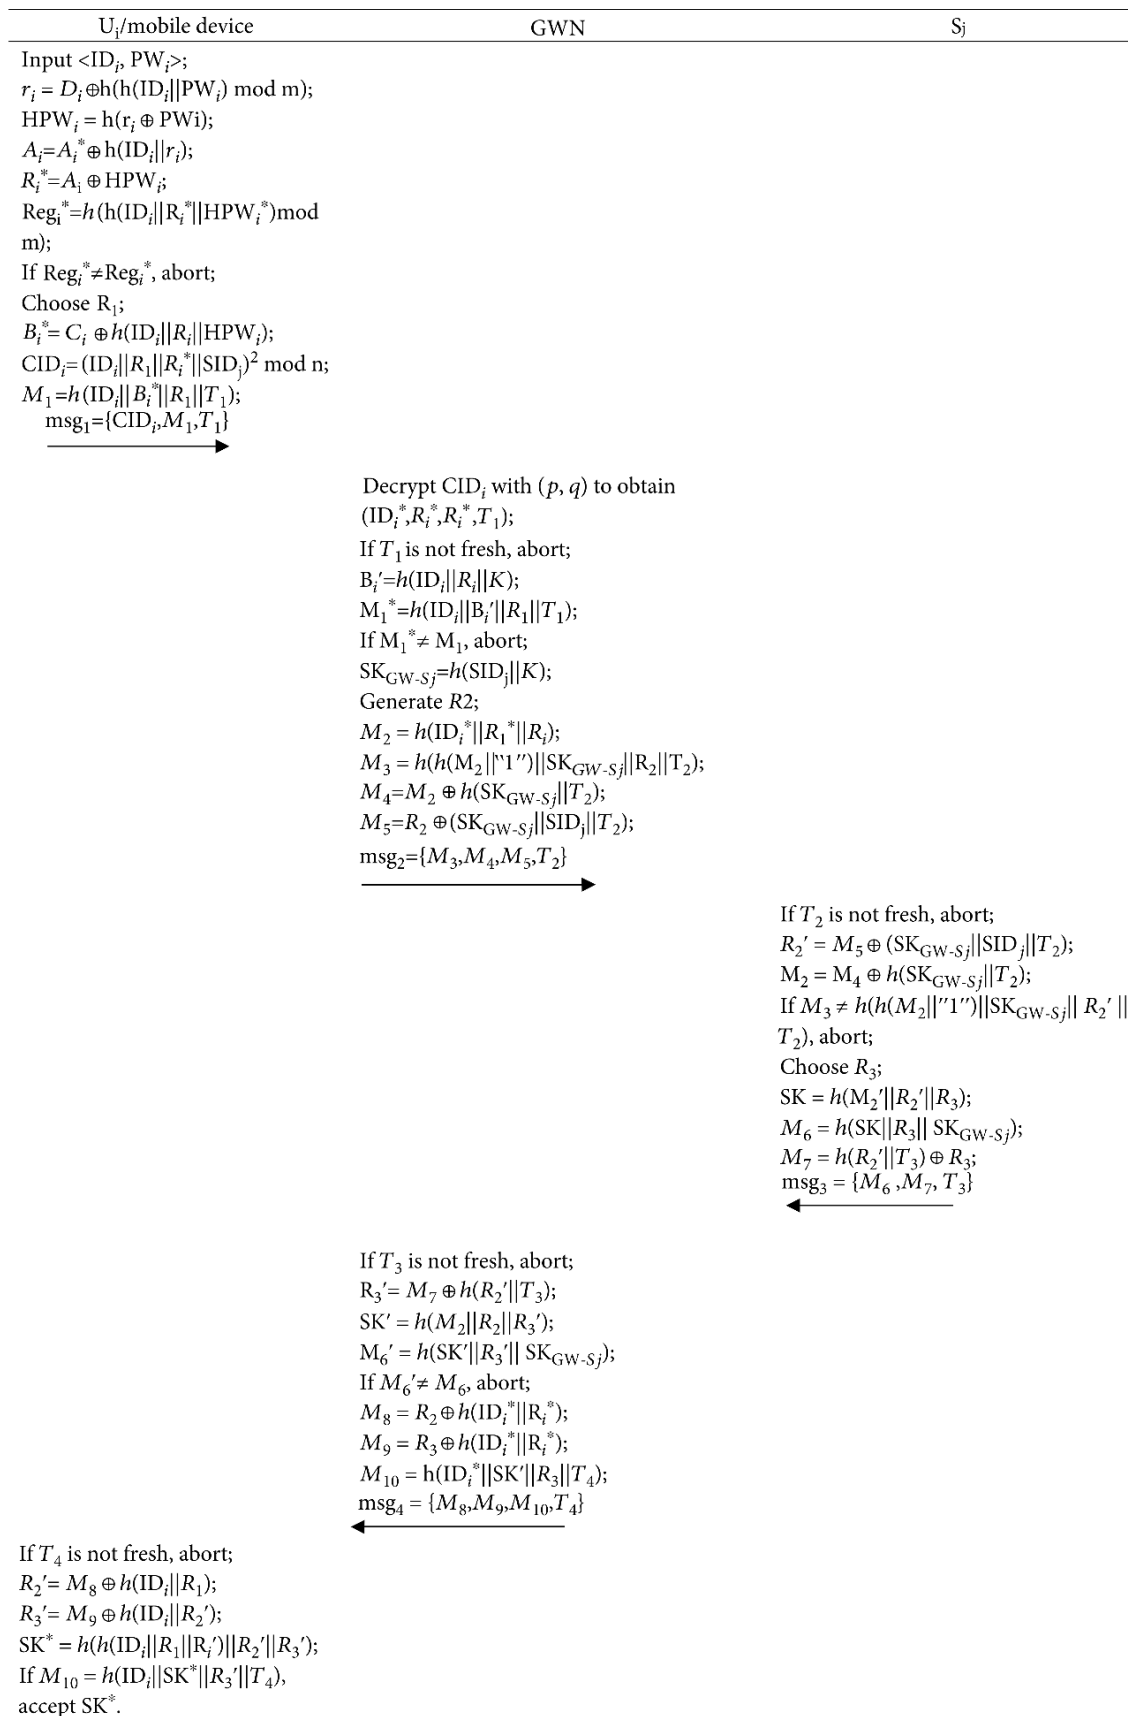

Fig. 1. The Login and Authentication Phase of Jiaqing Mo Et Al.'s Protocol.

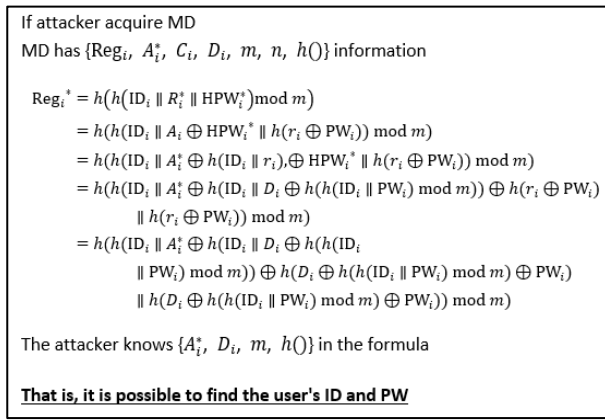

Fig. 2. Process of ID, PW Guessing Attack.

Random nonce values used in the formula usually use large random numbers of 128 bits or more, but the length of the password is very short compared to Random nonce. That is, the length of the random nonce and the length of the password cannot be the same. Therefore, there may be a problem with the XOR operation due to inconsistency in the number of bits in Jiaqing Mo et al.'s protocol.

C. No Perfect Forward Secrecy

The fact that the Perfect Forward Secrecy is met means that even if one of the important master keys in the protocol is exposed, the previous session key cannot be determined. However, in this protocol, the exposure of the (p, q) value, one of the unchanged long-term keys, does not meet the Perfect Forward Secrecy because it can identify not only future session keys but also previously used session keys. That is, assuming that the adversary has found out (p, q), it is possible to calculate the previous session key used between the mobile device and S_j.

1) The adversary has exposed (p, q) values and previous communication contents (CID_i of msg₁, M₈ and M₉ of msg₄) between the user and GWN and S_j. The adversary may decrypt the CID_i of the login request msg₁ as (p, q), and the adversary may find out ID_i^{*}, R_i^{*}, R₁^{*} and T₁.

2) In addition, the adversary may calculate R₂' using M₈, ID_i and R₁.

$$R_2' = M_8 \oplus h(\text{ID}_i \parallel R_1).$$

3) In addition, R₃' may be calculated using M₉, ID_i and R₂'.

$$R_3' = M_9 \oplus h(\text{ID}_i \parallel R_2').$$

4) Finally, the adversary may calculate the session key SK* by using the ID_i, R_i, R₁, R₂' and R₃' obtained so far.

$$\text{SK}^* = h(h(\text{ID}_i \parallel R_1 \parallel R_i') \parallel R_2' \parallel R_3').$$

Since long-term key (p, q) is a key that does not change after it is generated, it is a serious problem that the previous session key is exposed because it does not satisfy the Perfect Forward Secrecy when (p, q) is exposed.

D. No Mutual Authentication

Mutual authentication means that all components of the authentication protocol authenticate with each other. In the present protocol, U_i, GWN, S_j authenticates using M₁, M₃, M₆, M₁₀. Through four messages, mutual authentication between U_i and GWN and mutual authentication between GWN and S_j are provided, but there is a problem of not providing mutual authentication between U_i and S_j. The mutual authentication process is as follows.

1) GWN verifies the authentication of U_i using ID_i and M₁ = h(ID_i || B_i^{*} || R₁ || T₁) having the secret key K of GWN. When M₁ that U_i has is transmitted to GWN, GWN calculates B_i^{*} = h(ID_i || R_i || K) and M₁^{*} = h(ID_i || B_i^{*} || R₁ || T₁). When M₁ and M₁^{*} match, GWN authenticates that U_i is a normal user.

2) When the consistency is confirmed, S_j confirms the authentication of GWN using M₂ = h(ID_i^{*} || R₁^{*} || R_i) and SK_{GW-Sj} = h(SID_j || K). The authentication is confirmed by comparing M₃ = h(h(M₂ || "1") || SK_{GW-Sj} || R₂ || T₂) and h(h(M₂ || "1") || SK_{GW-Sj} || R₂' || T₂) having session key SK_{GW-Sj} of GWN and S_j.

3) When authentication is confirmed, GWN checks the consistency between M₆ = h(SK || R₃ || SK_{GW-Sj}) and M₆' = h(SK' || R₃' || SK_{GW-Sj}) to confirm the authentication of S_j.

4) Finally, if M₁₀ = h(ID_i^{*} || SK' || R₃ || T₄) matches h(ID_i || SK* || R₃' || T₄), U_i authenticates GWN.

GWN authenticates U_i through M₁, and S_j authenticates GWN through M₃. Through M₆, GWN authenticates S_j, and U_i authenticates GWN through M₁₀. That is, U_i and GWN, GWN and S_j are mutually authenticated, but in this protocol, mutual authentication between U_i and S_j is not provided. In order to create an authentication protocol with improved security, the authentication protocol will be safer only when U_i and S_j are also mutually authenticated. Fig. 3 describes in detail how the mutual authentication process is performed.

Fig. 3. Mutual Authentication Process.

E. Insider Attack

Even an insider of GWN should not be able to pretend to be a normal user by utilizing the information obtained in the process of verifying the user's authentication information in the MD authentication step. However, in the protocol proposed by Jiaqing Mo et al., there is a problem that insiders can disguise themselves as normal users using only {ID_i^{*}, R_i^{*}}. In this protocol, in the process of calculating the user's authentication information, an internal adversary can find out the user's {ID_i^{*}, R_i^{*}} information that authenticates with the GWN's secret key K. Based on this information, an internal adversary can

REFERENCES

succeed in authentication under the guise of a normal user, and a session key can also be calculated. Fig. 4 shows the protocol authentication process and the adversary calculating the session key.

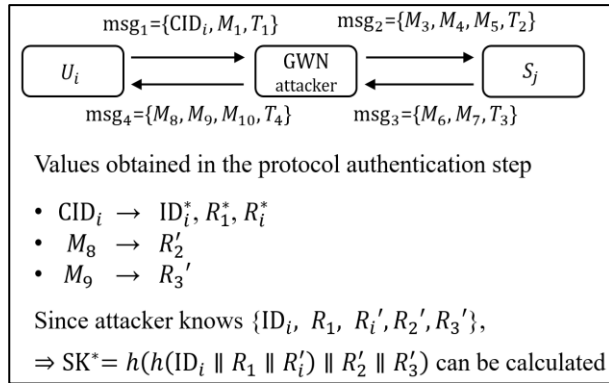

Fig. 4. The Adversary's Session Key Calculation Process.

Among msg₁ = {CID_i, M₁, T₁} transmitted to GWN by an insider, CID_i = (ID_i || R₁ || R_i^{*} || SID_j)² mod n may calculate using the unchanged values ID_i^{*} and R_i^{*} obtained by an insider adversary. In the case of M₁, B_i^{*} of M₁ = h(ID_i || B_i^{*} || R₁ || T₁) may be found using information of B_i['] = h(ID_i || R_i || K) known by an internal adversary. Since the T₁ value can also be generated by the internal adversary at the current time, M₁ can be calculated. This allows an internal adversary to succeed in authentication under the guise of a user with only the information received from GWN. An insider adversary who succeeds in logging in receives {M₈, M₉, M₁₀, T₄} information through msg₁, msg₂, msg₃, msg₄. The insider adversary must calculate information of R₂['] and R₃['] to compute the session key. Since the insider adversary has all the information in R₂['] = M₈ ⊕ h(ID_i || R₁), R₂['] may be calculated, and R₃['] = M₉ ⊕ h(ID_i || R₂[']) may be calculated using R₂[']. An insider adversary may calculate SK^{*} = h(h(ID_i || R₁ || R_i[']) || R₂['] || R₃[']) because it has all the information of {ID_i, R₁, R_i['], R₂['], R₃[']} necessary for calculating the session key. As a result, authentication can be successful under the guise of a normal user only with the information possessed by the insider adversary.

V. CONCLUSION

In this paper, a security analysis was conducted after explaining the operation process of an authentication protocol with improved security and guaranteed anonymity for the WHMS proposed by Jiaqing Mo et al. The protocols proposed by Jiaqing Mo et al. have vulnerabilities in offline identification, password guessing attacks, operation process bit mismatch, no perfect forward secrecy, no mutual authentication and insider attack problems.

Abstract—Feature selection is a technique that is commonly used to prepare particular significant features or produce understandable data for improving the task of classification. Bio-inspired optimization algorithms have been successfully used to perform feature selection techniques. The exploration and exploitation mechanism that is based on the inspiration of living things to find a food source and the biological evolution in nature. Nevertheless, irrelevant, noisy, and redundant features persist from the situation of fall into local optima in case of high dimensionality. Thus, this review is conducted to shed some light on techniques that have been used to overcome the problem. The taxonomy of bio-inspired algorithms is presented, along with its performances and limitations, followed by the techniques used in supervised feature selection in term of data perspectives and applications. This review paper has also included the analysis of supervised feature selection on large dataset which showed that recent studies focus on metaheuristic methods because of their promising results. In addition, a discussion of some open issues is presented for further research.

Keywords—Bio-inspired optimization; swarm intelligence; evolutionary algorithm; machine learning

I. INTRODUCTION

Application of science and engineering such as image classification, machine learning, text mining, image retrieval, intrusion detection, and biology analysis, containing huge number of features that are used for information processing and decision making [1],[2],[3],[4]. These applications must be approached carefully due to the abundance of data dimensions, described as the term of big data [5],[6]. Big data has well-known properties such as velocity, variety, value, volume, and veracity [7]. Memory space and costs will increase with escalated data volume. The variety of data makes data integration difficult due to data structured differently. The veracity is a noisy data and quality fluctuation of data when acquired from multi-sources [8],[9]. In solving this problem, irrelevant and redundant feature elements have to be eliminated from superfluous features leaving only data that represent the actual meaning of all features. This complication can be resolved by utilizing feature selection methods. Feature selection techniques are envisioned in the data-preprocessing stage to reduce the dimensionality by selecting the significant features from the original features in problem domain with higher performance of the task as well as speeding up the algorithm [10],[11],[12].

Filter methods such as the Fisher score [13] rank each feature independently under the Fisher criterion in a supervised model that successfully reduces the feature's size. However, this technique cannot determine the correlation among different features. The permutation of individual features does not necessarily and cannot achieve the desired feature set. Thus, the subset of feature is suboptimal [14]. Linear discriminant analysis is one traditional technique to enhance selected features by maximizing the proportion between the intraclass distribution and interclass distributions. Meanwhile, the inverse matrix calculation within-class distribution of linear discriminant analysis will be tolerated when dealing with a small number of labeled data [15]. Wrapper methods depend on a certain classification algorithm in evaluating the selected feature [16]. Hybrid methods attempt in incorporating the dominant characteristic of filter and wrapper models. The aim of filter phase is to reduce the feature dimensionality. The wrapper stage is then used to select the most optimal feature subset [17]. The author in [18] proposed a filter-wrapper algorithm which applied minimum redundancy maximum relevance algorithm to carry out a local search mechanism. Rough set theory and conditional entropy algorithm as filter method introduced in [19] were proposed in selecting the most significant features from a whole set as the initial population. The wrapper approach, which employs the k-nearest neighbor (KNN) algorithm, was then used as an evaluator of their quality of feature combination. The wrapper method can obtain a higher accuracy rate because they determine the correlations in each feature. In fact, the hybrid method achieves high accuracy with respect to the characteristic of wrapper and filter. However, wrappers are computationally more expensive, have less generalization than the filter and their performances are highly dependent on the particular classifier.

Searching and optimization methods are used to find the best solution of many classification problems. Recently, such techniques exhibit their capacity in dealing with Non-Polynomial (NP) hard problems. Finding the most significant features within reasonable amount of time is also considered as NP-hard problem [20], [21]. For example, there are N features containing in the dataset, 2N features are to be generated and evaluated, which will increase the computational cost, especially when each subset is executed by using the wrapper method. As a consequence finding the possible subsets using the exhaustive search or best-first search technique is not a great choice. Recently, an increasing number of optimization approaches have been focused in handling the issue of both

numerical and combinatorial optimization. Solutions have proposed optimal feature subsets and intensively developing based on a variety of metaheuristic methods. An optimization problem focuses on finding the optimal value which corresponds to the maximizing or minimizing one of its performance criteria, or multiple objectives have been proposed. Metaheuristics search strategy with a population-based approach has shown attractive competency in coping with the different character of optimization problem scenarios that can be used to handle the feature selection tasks [9],[22].

Metaheuristic optimization methods are getting inspiration evidentially from nature. Its mechanism and capabilities are extraordinarily magical and mysterious that researchers have focused on mapping the natural phenomenon onto intelligence algorithms. For example, finding the food source for the ant by using the shortest path through indirect communication with each other; interaction between organisms to fully matured human being; balancing the ecosystem; hunting movement and echolocation mechanism. Their abilities have been described to solve the complicated problem independently from elementary initial populations and parameters with little or no knowledge of the feature space. Thus, every feature and natural phenomenon used a suitable strategy in getting the best solution. This approach was able to find an optimal solution although simple optimization strategy has been used. One of the dominant categories of metaheuristics optimization methods is bio-inspired optimization. The bio-inspired optimization impersonates the various natural creatures behaviors like fishes, insects, bird swarms, terrestrial animals, reptiles, humans, and other phenomena [5]. The bio-inspired optimization family has emerged and applied in a proposal of feature selection applications, for instance, text mining, information retrieval, robotics, network security, biomedical engineering, power systems, business, agriculture and many more. Their behavior is a random decision that categorizes them as a randomized algorithm. Formulating a bio-inspired optimization algorithm involves modeling a proper problem representation, calculation the obtained solution efficiency through fitness evaluator and identifying operators to generate a new set of solutions [23]. Though, as previously stated, authors have divided a prevalent group in these approaches based on the evolutionary of biological paradigms.

Summarizations of feature selection algorithms have been performed by [11],[24],[25]. These studies have focused on the subset generation techniques in certain application, feature selection by using swarm-based algorithms together with particular classification and clustering tasks. However, a comprehensive overview of supervised feature subset selection based on bio-inspired optimization algorithms in obtaining the most optimal subset association with data perspectives and different applications was not performed. This paper proposes the bio-inspired optimization algorithm taxonomy according to natural biological inspiration as well as the areas in which these algorithms have been employed.

This paper is organized as follows: in Section 2, the description of the taxonomy of the bio-inspired optimization algorithms. The supervised feature selection using bio-inspired optimization algorithms is presented in Section 3. The analysis of technique for large datasets is introduced in Section 4 and

discussion of the supervised feature subsets selection using bio-inspired optimization algorithms are provided in Section 5. Finally, in Section 6, the conclusions are presented together with further research directions in supervised feature subset selection.

II. TAXONOMY OF BIO-INSPIRED OPTIMIZATION ALGORITHM

Bio-inspired optimization algorithms have been identified as an excellent approach and play an essential part in finding the best optimum solution in different problem domains. This type of algorithms imitated from the systematic behaviors of natural biological evolutionary such as mutation, selection along with distributed collective of living organisms, including birds, ants and wild animal. These algorithms exhibit high level of diversity, robustness, dynamic, simplicity, and fascinating phenomena as comparison with other existing methods. Studies in computer science area have been broadly used the various bio-inspired optimization algorithms in many kind of literature, like looking for the optimal solutions for hard and complexity problem domains [26],[27],[28]. The popular salient and accomplish classes or directions in bio-inspired optimization algorithms that mimic the biological collective behavior of animals, biophysical environment, and cooperation between species respectively [5],[29],[30]. This review paper aims to form the optimization algorithms category according to the area of such inspiration to perform a widespread view over the domain. This paper attempts to categorize the sources of bio-inspiration into swarm intelligence algorithms, evolutionary-based algorithms, and ecology-based algorithms [5],[31],[32]. Nature inspired algorithm consists of bio-inspired and physics-based algorithms. Swarm intelligence, evolutionary ecology-based algorithms are all bio-inspired algorithms. These algorithms are global optimization metaheuristics that search for solution in stochastic scheme within an appropriately runtime procedure. Generally, they start with initial solution and then generate the best solution in the next iteration. The important mechanism of metaheuristic algorithm is balancing between exploitation and exploration that may produce global optimal solution. Exploitation mechanism (intensification) contributes to the agent convergence in optimality. Exploration mechanism (diversification) prevents the loss of diversity which occurs when algorithm get trapped in local optima [33]. Bio-inspired algorithms help to tackle the global optimization problem for selecting feature subsets in the classification area by extracting and exploiting the collective local and global behavior schemes. Studies have now focused on increasing the performance of the search competency in the problem space and efficiently selecting a minimal and discriminating feature subset.

A. Swarm Intelligence Algorithm

Swarm intelligence is defined as an interactive system with the multi-agent. The system is the emergent of intelligent behavior collaborating with the collecting to complete the particular objective that cannot be completed by a single agent or acting alone [34],[35],[36]. Two expressive behaviors of swarm-based system consist of the self-organization and decentralization mechanism of animal living in nature. Self-organization can be identified as state transition rule and

stability through positive and negative feedback. Decentralization system can be described as the collaboration in groups through the state of environment to collect the communication. The examples of emergent swarm behavior in nature are bat echolocation, birds flocking, fish school, bee mating, mosquitoes host-seeking, cockroaches' infestation, ant foraging, sea creatures, and many others. Swarm intelligence approach has remarkable results in solving a wide range of NP-hard problems and really becomes nearly practical in the different real world problem domains. Furthermore, the number of possible solutions has gone up significantly in the problem that frequently leads to be indefinite. Swarm intelligence is used to solve real-world nonlinear problem applications considering many applications of sciences, engineering, data mining, machine learning, computational intelligence, business and marketing, bioinformatics, and industries. This paper emphasizes different swarm-based algorithms entirely starting from the behavioral and biological creatures perspective, which are specified in the life cycle of the insects, birds and animals (amphibians and mammals) [37].

According to [36],[38] used the term swarm intelligence to describe a system comprised of autonomous robots cooperating to fulfil the task under study. This mechanism only enables to handle with partial and noisy information about their environment, to force with uncertain situations, and to search solutions to complex problems. In this way, many existing theoretical frameworks and algorithms mimic the miracle ability of swarm behavior to deal with different scenario in feature selection problems. Among them, the well-known widespread used are ant colony optimization (ACO) [39], artificial bee colony (ABC) [40], particle swarm optimization (PSO) [41], cuckoo search (CS) [42] and firefly algorithm (FA) [43]. Another popular swarm intelligence technique is the monkey algorithm [44], wolf pack algorithm [45], bee collecting pollen algorithm [46], dolphin partner optimization [47], bat-inspired algorithm (BA) [48], and Hunting Search [49]. Salp swarm algorithm (SSA) has been extensively adapted bio-inspired algorithm on account of its advantage such as: (1) a novelty algorithm, (2) unsophisticated, (3) lesser parameters, and (4) low computation time [50]. Swarm-based approaches are less complex procedure with several parameters to strong solution as compared with evolutionary-based components such as selection, crossover, and mutation.

B. Evolutionary-based Algorithms

Evolutionary algorithm or evolutionary computation is a search method that simulates the biological perspective of generation stands on iterative framework of fittest population selection namely reproduction, mutation, recombination, and selection. This search has taken advantage of the assortment to find the suitable solution by using the historical data that leads to a better new solution. This algorithm simulates Charles Darwin's law of nature evolutionary of "survival of the fittest" in selection process in such environment. Evolutionary algorithms have been designed to search the optimal or near-optimal solution in various optimization frameworks whereas typical statistical techniques may produce ineffective results. The performance of evolutionary algorithms is generally depending on the evolutionary setting. For example, the methods for changing the values from reproduction and

mutation for creating the new populations may yield different optimization results and speeds of convergence. Some of the well-known evolutionary-based approaches are a genetic algorithm (GA), genetic programming (GP), evolution strategy (ES) [51], evolutionary algorithm, and artificial immune system.

C. Ecology-based Algorithm

Ecology-based algorithm has been presented for cooperative stochastic search algorithms. The algorithm mimics an ecosystem balancing on the earth. It relies on the population relationship of individuals in a particular ecosystem. Each population is related to adaptation or optimization strategy in the unit space. This algorithm, like other metaheuristic optimization algorithms such as ACO, ABC, GA, and others, seeks global optimization solutions [52]. The search performance of the individuals in each population are interpreted based on the exploration and exploitation mechanism, and the initial parameters [53]. The ecology-based algorithm is inspired by the ecological concepts of habitation, relationship and interaction, and inheritance ecologically. The examples of well-known ecology-based algorithms in the computer science are biogeography-based optimization, inspiration from the immigration scheme of species or animals to find new environment properly [54],[55]. Flower pollination algorithm (FPA) is presented by Yang [56]. The algorithm is inspired by flowers pollination process with biotic and abiotic pollination forms. Biotic pollination is typically linked with pollinators' livelihood such as birds, bees, bats or insects to transfer the pollen from one to another. Abiotic pollination is a process that depending on wind, rain or water. Biotic and pollination of a different plant are a process of global pollination performing by the Lévy distribution. Abiotic and self-pollination can be described as a local pollination procedure.

III. SUPERVISED FEATURE SELECTION METHOD

The classification task is associated with class labeled and can be classified into three frameworks: supervised [57], unsupervised [58], and semi-supervised [59]. Class labeled participation is based on supervised feature subset selection [60],[61]. On the contrary, unsupervised feature subset selection is a primary challenge due to the class is unlabeled. Meanwhile, semi-supervised feature subset selection approaches utilized both labeled and unlabeled classes [62].

Supervised feature selection has an intention on classification or regression problems. It determines the solution of feature subsets that aim to distinguish the instances from predicted categories or predicting the potential target. After splitting the feature subset selected by supervised feature selection into learning and testing sets, the learning set is learned and evaluated by certain classifiers or regression model. The relevance between feature and classes labels is evaluated via its correlation. Choosing a strategy with a filter method can be independent of the classifier algorithm. In contrast, the wrapper method can take the advantage of the classification or regression performance to evaluate the fitness of selected features from the original set or make utilization the intrinsic predictability of a classification algorithm in embedding feature selection algorithm into their specific

fundamental learning model called embedded method. Finally, the subset features with the unseen data in the test set are employed to label for the result of predefined class or regression target [25]. In the present paper, the proposed supervised feature subset selection methods in improving the classification performance are addressed.

A total of 46 publications on bio-inspired optimization algorithms focusing on supervised feature subset selection from 2018 to 2021 have been reviewed. The papers were obtained from Scopus database in December 2021. These papers might not provide the entire studies, but presents the trend in general. Table I displays the retrieval articles in two broad perspectives: static and dynamic data. The data perspectives are further categorized into two classes: using stand-alone metaheuristic or combination with other metaheuristics (hybridization). The most frequently used algorithms are swarm intelligence group, categorized as insect and reptiles like ACO, ABC and DA have been extremely applied to solve the supervised feature subset selection. In bird group of swarm intelligence, PSO, CS and harris hawk optimization (HHO) are used to combat feature selection problem. In Fig. 1, the overall number of those papers are also illustrated according to the year of publication. Research on swarm intelligence has significantly increased in 2019.

However, greater interest has shown on swarm-based algorithm such as PSO, ACO, ABC and FA as compared to evolutionary-based and ecology-based. This paper reveals that swarm-based algorithms have advantage in controlling their behavior autonomously, self-organization and adaptability [5],[34]. Moreover, the ecology-based algorithm has emerged as a new algorithm to show the performance for the supervised feature selection area. These algorithms with different evaluation methods (filter, wrapper, and hybrid) are described in this following subsection.

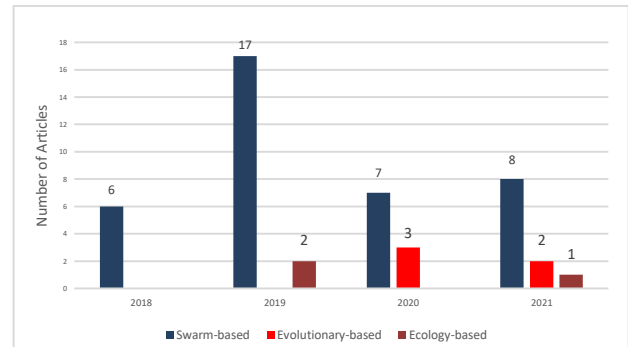

Fig. 1. Usage of the Bio-inspired Algorithm Applied in Supervised Feature Selection.

TABLE I. SUPERVISED FEATURE SELECTION ALGORITHM WITH DIFFERENT DATA PERSPECTIVES

Inspiration	Data perspective				Total
	Static data		Dynamic data		
	Stand alone	Hybridization	Stand alone	Hybridization

A. Filter Methods

Filter methods are generally less computational complexity than wrapper approaches. Filter methods evaluate characteristics of data based on some predefined criteria instead of using capability of certain learning algorithm. In this method, the evaluated features that have lower ranking criteria are filtered out. The filter method can be generally broken down into univariate and multivariate schemes. Individual features are ranked in univariate scheme, while the multivariate scheme ranked each feature simultaneously. Many studies have used different evaluation measure techniques to enhance the accomplishment of feature subset selection [25]. These techniques are relief algorithm [98], feature correlation [99], mutual information [100],[101], Fisher score [102] and principal component analysis (PCA) [103]. These techniques are not guided by a certain learning algorithm, such features could be deteriorated the decision making procedures. Requirement efficient metaheuristic methods can improve the performance when it carries on with large-scale feature space.

In [68], ten chaotic maps have been employed in searching process of the dragonfly algorithm (DA) for choosing the optimal extracted features for achieving convergence speed and efficiency of toxicity drug identification task. The selected features from chaotic DA were then fed into a support vector machine (SVM). The experiment indicated that Gauss chaotic map provide the best performance of DA. In [79] the population initialization in PSO is identified by assigning the Relief scores to distinguish ability of biological features. This technique examined the difference between selected sample as well as its homogeneous and heterogeneous neighbor sample. Then, the threshold selection is used to determine the number of features. The author in [78] carried out streaming features from big datasets through parallel processing with the MapReduce technique, dividing the incoming data into subsection. BA is applied in reduced data dimensionality. Then, the ensemble method with multi-layer perceptron artificial neural network classifier is employed to classify the selected significant features. The result of this work has

shortened the processing time but enhanced the accuracy. The author in [93] fused detection mechanism to scan the existing and incoming of feature drifts. The proposed multi-objective feature selection utilized measurement the quality of the solutions based on mutual information method and GA. The GA is started for evaluating the solutions based on merging population, sorting, and crowding distance mechanism. In addition, [28] proposed reducing the dimension of the binary search space of different scale datasets based on social spider algorithm (SSA), S-shaped and V-shaped transfer function are used to evaluate the binary search space. Each possible best solution is improved to the quality solution through crossover mechanism. The performance of this algorithm named BinSSA4 with crossover operator is superior in terms of fitness values, standard deviation values, number of the selected feature, and the accuracy. In application of network intrusion detection, [66] proposed the performance of ACO by enhancement the exploration process. The proposed algorithm keeps away from falling into a local optimum by designing fitness function, pheromone mitigation and increasing for some special trail.

B. Wrapper Approaches

A wrapper approaches is generally composed of two main steps: 1) explores for a potential feature subset and 2) measure the influential quality of selected features. The model iteratively generates both steps until the predefined stopping condition is met. The possible features are first generated as a feature subset, and then these features are evaluated to measure their quality based on a particular learning algorithm. In other words, the wrapper-based feature selection produces repeatedly until the desired accuracy rate is achieved or the desired minimum number of selected features is acquired and then returned as optimal selected features for a particular problem. However, the well-known impractical condition of wrapper methods is dealing with the high dimensionality of d features ($2d$) or the large scale of the search space. Additionally, this method will be met high complexity running time compared with the filter methods. However, there is a wealth of literatures on wrapper-based feature selection when handling high dimensionality datasets. In [63] the continuous version of original butterfly optimization algorithm (BOA) is performed by S-shaped and V-shaped activation function. The results shown that the S-shaped is able to boost the capacity of original BOA that can achieved better accuracy rate and number of selected features. The study of [69] proposed the grasshopper optimization algorithm (GOA) to obtain the most optimal solution by more repulsion in unexplored search space. Promising regions were exploited by intensity and length scale of attractive function. The literature supplemented the algorithm by using SVM during iterations to deal with unexplored feature space and duplicated features in the selected subset. In [64], the integration between ABC and gradient boosting decision tree algorithm is established to explore the best final result. The initial problem space is spanned based on gradient boosting decision tree to categorize the sample into positive or negative patterns. The performance of ABC algorithm can remove low correlation into reduced preliminary input of those decision algorithm. The study of [71] used differential evolution to perform the pheromone updating rule mechanism of max-min ant system (MMAS) by disrupting the

pheromone deposition over the features space and raising the behavior of ants in exploring for optimal feature subset for the benefit of classification task. The binary version of DA with dynamic behavior transfer functions, S-shaped and V-shaped are incorporated for beneficial better solution from unexplored regions [67]. Different chaotic map is experimented due to the problem of slow convergence speed and getting stuck in local optimum of SSA algorithm. The five chaotic variables are adapted for salp position. The results of this algorithm is compared with original SSA, GA and PSO that outperformed such algorithms [84]. Binary version of integrated grey wolf optimization algorithm (GWO) and PSO have been proposed in [81] to cope feature subset selection. This combining, the velocity and position have been controlled by weighting function to balance the diversification and intensification of proposed algorithm. KNN algorithm with euclidean distance measurement is employed in the wrapper-based method. Two binary forms of whale optimization algorithm (WOA) algorithm have been integrated with evolutionary operators to perform the exploration and exploitation mechanism in seeking the optimal selected feature for increasing classification targets. In the search process, the Tournament and Roulette Wheel Selection mechanisms are used. Crossover and mutation operators are applied to increase the exploitation mechanism of the WOA algorithm. The results showed that WOA with crossover and mutation outperformed GA, PSO and ant lion optimizer [33]. The study of [70] propose a binary FA with two objectives, accuracy rate and reduction rate to reduce the number of features. In this literature, the new formula is proposed by calculating the distance between two fireflies to enhance the quality of exploration and exploitation of search space. The results of algorithm outperformed the PSO. The discrete cosine transform (DCT) with fixed-size window technique was applied in [77] to exploit the current informative features of data streaming as a baseline. Then, the efficient feature subset produced from the PSO algorithm is fed into the KNN classification algorithm for decision processing. The experimental demonstrated the DCT without and with feature selection. The result show that the automatic feature selection process searches the best feature subset that can give higher performance. The combination metaheuristic approach is proposed by using GWO and WOA to enhance a wrapper-based feature subset selection technique. The hybridization is accomplished by improving the mechanism of both algorithms including immature convergence and stagnation to local optima [83]. As sine-cosine algorithm which can be supplemented the exploration stage, [74] combined this algorithm into HHO in exploration phase, as the result effectiveness in exploitation phase can get the quality information. Additionally, the delta factor is injected in exploitation phase. The results of this proposed outperform sine-cosine algorithm and original HHO algorithm for ten datasets out of sixteen in terms of fitness. In terms of accuracy, the proposed outperform other optimization method on eleven datasets out of sixteen. The author in [75] proposed the opposite point exploration and disruption operation due to problem of struggling in local optimization of CS algorithm, this prevents over random search of features. These enhancements improve the exploration phase and feature selection in complex data. The results show that this algorithm can find the maximizing the classification accuracy rate and

reducing the number of features; however, the computational time still increases. In the same manner, [86] has been adapted opposition-based learning (OBL) technique in slime mould algorithm (SMA) to overcome premature convergence and slow movement. Moreover, [89] presented the concept of OBL. The procedure is the WOA run first and at the same time during the run, population is changed by the OBL. To increase the accuracy and speed convergence, it is used as the initial population of FPA. The best feature set from transformed dataset is proposed in [85]. The continuous values are converted into binary search space using empirical threshold δ . This work shows very excellent results when combined with PCA and independent component analysis. As the results, feature selection method only reduces the unnecessary and unimportant features, not the correlated and higher-order dependencies among features. Due to the problem of CS that is over randomly causes blindly preservation the quality solution, the work of [76] applied chaotic map to enhance the exploration mechanism of CS. The proposed two-population elite preservation strategy can find the attractive one of each generation and preserve it. Levy flight is developed to update the position of a cuckoo, and the proposed uniform mutation strategy avoids the trouble that the search space is too large for the convergence of the algorithm due to Levy flight and improves the algorithm exploration ability. The author in [27] proposed binary PSO with FPA, PSO performs as a global search and FPA conducts a fine-tuned search. The study of [10] performed variant of PSO, competitive swarm optimizer with KNN to handle the large scale optimization problem.

Moreover, an ant colony-based approach has been presented to explore the suitable signals feature subset for application of power quality disturbances classification. S-transform fused with time-time transform is employed for detection and feature extraction. The proposed presented the results of classification with and without feature selection [65]. The author in [90] designed a OBL mechanism to both exploration and exploitation in differential evolution variant have been proposed in the application problem of engineering. The diversity measurement is designed to recognize the convergence behavior of OBL variants. Secondly, the explorative opposition and exploitative opposition are distinguished according to the convergence behavior of OBL variants. Finally, the protective mechanism is introduced to obtain a good ratio between exploration and exploitation for better performance without extra fitness evaluations. This literature carried out experiments on the IEEE Congress of Evolutionary Computation (CEC) 2017, CEC 2011 and CEC 2020 test suites that shows superior performance. The problem of over fitting classification in the swine breed has been solved in [95] by applying feature selection technique to reduce many large original features into the most significant porcine single nucleotide polymorphism. Binary FPA is combined with information gain along with the cut-off-point-finding threshold to identify a 0 or 1 value in feature vector and GA bit-flip mutation operator. The result of this study revealed that the proposed technique outperformed the PSO, CS and FA in terms of classification accuracy. The author in [91] proposed three-dimensional reduction of feature space mechanism under deletion conceptual the unimportant features utilizing the feedback information from evolution algorithm such as DE,

GA, PSO. The assistance of dimension reduction mechanism with evolutionary algorithm is effective way in finding a feature subset with higher classification accuracy and smaller number of features. The WOA with SVM is presented for the task of spam recognition in various languages. The model was proposed to perform automatic detection of arrival spams and gives an insight into the most influential features during the detection process [88]. A artificial fish swarm optimization algorithm with a crossover operation have modified for application of text categorization [1]. The method includes the best fish of swarm can be brought together to improve the capacity of local search. To reduce the run time complexity of ACO algorithm, the study of [21], the degree based graph representation of ACO algorithm for the field of speech processing domain have been proposed. The proposed method will have benefit over fully connected graph and contributed more flexibility on the problem space compared to binary connected graph representation.

In addition, FPA is used to propose the elimination of irrelevant features in biomedical data analysis [96]. The diversity of the population and search performance of the FPA algorithm have been increased by adopting the absolute balance group strategy and adaptive Gaussian mutation. The classification rate is evaluated by using KNN. The experimental result reveals that the proposed method outperforms other state-of-the-art methods. The author in [97] proposed hybrid version of biogeography-based optimization and GA in breast density classification. The authors of [73] combined ABC and CS for reduction the number of features to utilize the incoming anomalies detection in network. The binary pigeon inspired optimizer based on cosine similarity concept have been proposed to build optimal solution by calculating the velocity of the pigeons [3]. Another swarm algorithm for intrusion detection was proposed by [82]. The proposed algorithm utilized grey wolf optimization algorithm for selection the most optimal features by controlling the balancing between exploration and exploitation mechanism.

C. Hybrid Methods

Hybrid method aggregates the dominant of multiple feature selection approaches such as filter-wrapper. The principal intention is to increase the stability of the solution by combination salient of different available feature subset selection algorithms. For example, dealing with a small dataset with high dimensionality and dealing with a small combination on the training set will result in completely different solutions. By combining multiple selected features based on different approaches, the solutions are more straightforward, so the quality of the selected features can be preserved. In hybrid methods that is stimulated by the way of bio-inspired algorithm, [17] introduced the ranked informative features using filter method. Their quality obtained feature sets are then evaluated based on wrapper method. Improved memory to keep the best ant and normalized pheromone updating mechanism have also been proposed to enhance the feature selection. A logistic map sequence has been used to perform diversity in the problem space of PSO with a spiral-shaped mechanism integrated as an operation of local search around the known optimal solution boundary. The current position and flying velocity are incorporated with two dynamic correction

factors to improve the exploration and exploitation in the feature space [26]. In [87] applied the Pearson's correlation coefficient and correlation distance to adapt the weights of unrelated and consistent features based on filter manner. The random population WOA functions act as a wrapper algorithm. The results achieve the highest classification accuracy in all datasets, but not shortest length of feature set compared with other algorithms. In this manner, chaotic WOA is introduced [18]. Besides, [92] established integration the strengths of GA and PSO to conquer the tradeoff between exploitation and exploration procedure. The wrapper proposed utilizes artificial neural network to evaluate the fitness of feature set. This method applied the data which pull out from smaller datasets to reduce the processing time of subset selection on high volume datasets. Ant lion optimizer is integrated with hill-climbing technique to find the best solution in work of [19].

Furthermore, the feature selection for anomalies detection in the network has been proposed in [72] based on the FA. This literature employs mutation-based in filtering features and FA with wrapper-based methods for evaluating selected features to C4.5 and Bayesian Networks based classifiers. The author in [94] proposed filter-based, information gain metric and the sorting mechanism of evolutionary algorithm which is efficient multiobjective optimization algorithm. The dataset is the World Health Organization Director-General's speeches during the COVID-19 pandemic period and Stanford Sentiment Treebank. Due to the abundance of irrelevant and redundant data in microarray datasets, authors in [80] proposed information gain and krill herd algorithm to capture only the important features from the original datasets.

IV. ANALYSIS OF TECHNIQUE FOR HUGE DATASET

The goals of proficient data analysis rely on the providing a large amount of data and these purposes is indispensable to deal with analytics on huge datasets. Working toward data analysis, the facilitation of massive data preservation technologies, the revolution of digital technologies, where huge sizes of data are generated with ever-increasing volumes of transactions over time and diversity. The term "huge dataset" was motivated and officially reported in international conference [104]. One of distinctiveness of huge datasets is that the sample size is generated greater than petabytes level and moves very fast when used to describe a given sample. Recently, the modernizations of technologies and Smartphones have enabled users to use online media to communicate with others in a one-way or two-way manner. Some of examples of sources with huge datasets include Facebook, Twitter, blogs, flick, LinkedIn, Pinterest, sensing devices, and web-based email. Huge collections of these data platforms typically have complex structures which received from multiple sources. The information collected from this online source consists of different data formats such as text, image, videos, log, and so on. It is extremely challenging to obtain important hidden data from these social assemblages in an appropriate manner. The increasing rate of digital adoption has been observable since the initiation of the coronavirus, covid-19 pandemic since 2020. The rate of digital growth has increased dramatically, and more are expected in the second half of 2021 as shown in Fig. 2. It shows that the power of social media continues to drive activities to be connected all over the world, with an

increasing number of social media users worldwide, and an impressive step is rapidly approaching. Also, Facebook and Instagram have attained 5.1 billion users. Twitter generated 8 terabytes of data per day, or 80 million tweets per day [105], and Line and Whatsapp generates approximately 2.5 petabytes of data per hour.

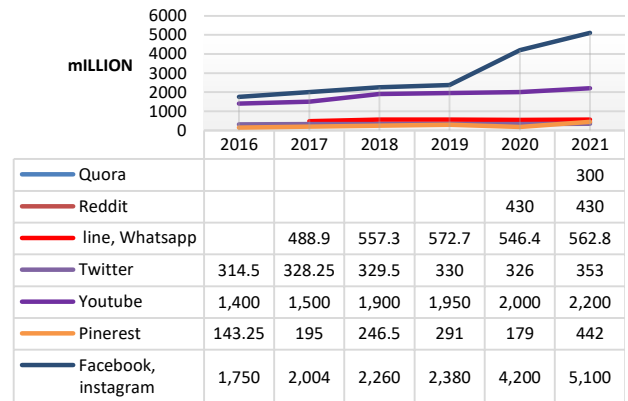

Fig. 2. The Rate of Data Generation in Digital World from 2016 to 2021.

An efficient way in extraction the important information can be measured by the complexity of computing methods and algorithms. Traditional methods and tools are used to operate small and structured data by trail-and-error. This endeavors analysis is not suitable when data sets are large and miscellaneous. This large dataset requires a large amount of memory to store and takes hours or days in the case of using traditional processing methods. At present, a superfluity of different improved techniques are being developed to treat with large amounts of unstructured data sets [106]. The nature of large amounts of data is adequate for learning models to be applied to real-world scenarios efficiently. In addition, the models can be enhanced to digest as much target discrimination as possible. Face forgery detection is an example of an application domain and technique that makes use of a large dataset, with data that is ten times larger than the previous forensic dataset. The increased data source is distorted through face swapping method for robustness the head poses variation due to videos on the internet usually have limitation gesture of head. The feature learning with dimensionality reduction via autoencoder is considered for forensics. The experiment was carried out with as many real-world perturbations as possible. The accuracy results remained low due to the poor quality of the learning set and augmentation method for face diversity [107]. Moreover, the novel chance constrained problem domain is formulated using a huge dataset. A weighted feature reduction operation is proposed to describe a relaxation problem of chance constrained problems. Also, a DE has been adapted and integrated with a pruning technique to force the relaxation concern of chance constrained [108].

In the natural language classification application domain, in [109] employed rule-based classification and Apriori algorithm because it cannot maintain the capability between accuracy and interpretability in the non-big data environment. This problem has been facilitated by proposing the probability integral transform theorem, rule induction and rule selection based on evolutionary optimization. The experimental results show that

fuzzy model-generated models are significantly simpler in terms of classification rate, complexity, and time consumption. A distributed fuzzy decision trees have been proposed due to the problem of time constraints and space requirements. This paper proposed using the MapReduce framework to partition large scale data into binary and multiple decision ways. The relevant features are derived by using information gain method, which will be used in the decision nodes. The author implemented the fuzzy decision tree learning scheme on the Apache Spark framework [110]. Among the given domains that use big data technologies is vehicular ad hoc network to handle their big size data. The author demonstrates a method that entail to detect accidental or irregularity on the way and estimate the distance and time spending on each route in the form of real time system, which allows the user to gain a database having the estimated time spending in all sections, this will serve the vehicles for the reasonable estimated time of attainment consistently throughout their travel and optimize the best route to reach the destination. The experiment reveals that this method effectively warns for crowded vehicles or portions the vehicle overwhelming in all roads, and it can also be used to save road safety [111]. Furthermore, human disease application used huge dataset to prevent the spread of infectious virus to human as the outbreak of covid-19 virus. The epidemic has forced everyone to stay and work at home that has affected on the people's mental health around the world. The global covid-19 pandemic requires a broader overview of data set to analyze the problem of human-to-human transmission of the virus across the country [112]. The covid-19 tracker with HPCC system is used to predict the future trend of the covid-19 outbreak, but this tool is limited in such a way that it cannot explain other factors that may influence trends such as mobility, local weather conditions, and so on. The smoothing filter of the covid-19 tracker is capable of eliminating irregular data transfers, but the system is still incomplete, with only a minor effect on the natural time vector. The automatically ingested data was pulled into the system for data cleaning and then extraction of the important data for subsequent analysis. The system will also be automatically executed when the new information enters to the system [113]. Additionally, human mobilities are extremely restricted affected by the covid-19 situation. Autonomous robot systems are becoming very important and can be conducted to replace human service work such as serving medicine to the infectious patients. The first large-scale elevator panel dataset has been made public in order to challenge the problem of inter-floor navigation. The deep learning based is used to recognize autonomous elevator operation. The performance of that model and dataset is compared to popular network such as ResNet, PSPNet and U-Net. The results of ResNet have the best performance when compared to the remaining networks [114].

V. DISCUSSION

The recent advance in feature selection algorithms have grown exponentially across a wide range of application domains. The most explored areas continue to be in fixed data or static such as bioinformatics and image processing. In addition, social media platforms such as Twitter, Facebook, blogs, and wikis are prevalent in streaming data or dynamic. Among the bio-inspired algorithms, the swarm-based

algorithms have been applied in many areas to produce excellent solutions for problems where the characteristic of the problem is NP-hard, which otherwise produce sub-optimum solutions and consume a lot of processing power. Due to the scalability and simplicity of SI-based algorithms, they have become the first choice in producing the outcomes for an optimization problem. The present researchers expect this review paper to provide other researchers working on different bio-inspired optimization algorithms to effectively and efficiently handle new challenges in supervised feature subset selection.

To this day, many valuable feature selection algorithms have been extensively developed for real-world application and theoretical analysis. However, the present researchers believe that more intelligent behavior from nature can be applied to improve the solutions in this field. There are several contributions and issues related to feature selection method. Firstly, according to the enormous increment in the volume of the data, the recent feature subset selection algorithms may be threatened especially in terms of scalability with online datasets. Secondly, the performance of supervised feature subset selection algorithms is commonly evaluated by the compromised accuracy. As a result, algorithms adaptation should be an essential concern when exploring new searching space and exploitation of the best solution that selected in each iteration to gain most optimal feature. It is determined as the affectability of a feature subset selection algorithm to feature combination during the training phase. Finally, in statistical feature selection algorithms, feature weighting techniques are frequently used to identify the number of selected features. In this method, the number of optimal selected features is discarded. Furthermore, a large number of selected features will jeopardize the learning performance due to the inclusion of noisy, irrelevant, and redundant features. By extension, it should not use a small number of feature subsets because some relevant features are excluded. In practice, many researchers have usually used a metaheuristic way to find and evaluate the candidate feature subset and feed the number of selected features that have the best classification accuracy, but the whole process suffers from computation time. The challenging problem in this domain is determining the optimal number of selected features. Furthermore, the present researchers believe that the selection of the evaluation criteria is also a crucial aspect which requires deeper investigation.

VI. CONCLUSION

Feature selection techniques aim to provide effective pre-processing of data in eliminating redundant and irrelevant features. It is a fundamental method in preparing the data which is clean and intelligible. It has been an interesting field of research work that has proven to be extremely useful in many application domains including image recognition, machine learning, web and text mining, pattern classification, and medical diagnosis in both offline and online platforms. The past few years the performance of many novel feature selection methods has augmented. This can be observed that, several optimization algorithms have been presented to solve problematic feature selection by optimization the value to gain the best suitable solution. Such algorithms that are inspired by the natural, biological and ecological behavior is to produce

good solutions. However, there are only several bio-inspired algorithms that have been proposed. This study has reviewed works on the enhancement of solving the feature selection problems. In addition, the authors have detailed the algorithms that are practical among which are wolf-based algorithms, salp, and biogeography algorithms. Highlights on each algorithm have been presented, followed by recent advances in the literature and problem domains for each. Nonetheless, it is important to highlight that these algorithms have yet to be demonstrated impressively in large-scale datasets such as streaming data and linked data. This brings up subsequent research application domain such as medical, the environment, and social science.

ACKNOWLEDGMENT

The authors would like to thank the Ministry of Higher Education Malaysia for funding this study under the Transdisciplinary Research Grant Scheme, TRGS/1/2018/UUM/02/3/3 (S/O code 14163).

Abstract—Every organization subsists on data, which is a quintessential resource. Quite a number of studies have been carried out relative to procedures that can be deployed to enhance data protection. However, available literature indicates most authors have focused on either encryption or encoding schemes to provide data security. The ability to integrate these techniques and leverage on their strengths to achieve a robust data protection is the pivot of this study. As a result, a data protection model, dubbed Harricent_RSECC has been designed and implemented to achieve the study's objective through the utilization of Elliptic Curve Cryptography (ECC) and Reed Solomon (RS) codes. The model consists of five components, namely: message identification, generator module, data encoding, data encryption and data signature. The result is the generation of the Reed Solomon codewords; cipher texts; and generated hash values which are utilized to detect and correct corrupt data; obfuscate data; and sign data respectively, during transmission or storage. The contribution of this paper is the ability to combine encoding and encryption schemes to enhance data protection to ensure confidentiality, authenticity, integrity, and non-repudiation.

Keywords—*Elliptic curve cryptography; encoding; encryption; Reed Solomon; security*

I. INTRODUCTION

A. Background of Study

The advent of computerized systems and networks has been beneficial to organizations and has subsequently enhanced their operations. This has resulted in the generation of larger quantum of data to augment the activities of these organizations. Data produced by these organizations are considered a major resource, therefore resulting in organizations adopting strategies that can protect this important resource from being misused. As a quintessential resource, comprehensive techniques are provided and instituted by these organizations frequently to offer protection to this data [1].

Though protective mechanisms are instituted, there is also an increase in threats to undermine organizations' operations. Notwithstanding, the insurgence of adversary's attacks have consistently hampered the functional activities of organizations over the past years and was colossal during the COVID-19 pandemic era. To ameliorate this insurgence, organizations started scrambling for solutions to protect their data. In this regard, researchers began to also seek for

solutions to mitigate this insurgence of threats and attacks through the development of robust techniques and methods to prevent loss of data and unauthorized access and modification. It is on the basis of the aforementioned, that it is always important for industry and researchers to stay a step ahead of attackers in the preservation of data in transit and storage, hence, the call for this research.

As several research have postulated, most security systems have focused on either using encoding or encryption strategies/techniques to guarantee the safety and accuracy of data [2]. Whereas the encoding schemes add extra bits to the original data to aid in error detection and correction, in order to maintain the integrity of messages. The encryption schemes, on the other hand, ensure messages transmitted or stored are obfuscated to prevent unauthorized access and modification in order to maintain the authenticity and confidentiality of messages.

Examples of data encoding and encryption schemes include Reed Solomon codes, Reed-Muller codes, checksum, and AES, RSA, ECC, Blowfish among others have emerged to offer protection to data [3]. The encoding and encryption schemes are aimed at preserving the confidentiality, authenticity, integrity and non-repudiation (CAIN) of data. The utilization of encoding scheme over encryption algorithms, even though, offers security but it is ineffective to provide optimal protection due to unauthorized access or alteration of data as a consequence of adversaries' activities. This illicit access and modification of the data by the attacker causes data compromise. Also, the utilization of encryption algorithms offer protection to data but it is inadequate as a result of inadvertent modification, loss of data or hardware failures. Data can be destroyed by hardware failures, untrusted communication channels or attackers when accessed. This also leads to data compromise and therefore requires the application of different security measures to offer optimal security.

This research therefore focuses on how to harness the strengths of encoding and encryption security techniques to achieve a robust data protection system.

B. Aim of Study

The study's aim is to implement a data protection model by integrating Elliptic Curve Cryptography (ECC) and Reed Solomon (RS) coding schemes.

*Corresponding Author.

To achieve the stated aim the following questions are raised:

- 1) Can ECC and RS codes be used to ensure secure data transmission and secure data storage?
- 2) Can a proposed Harricent_RSECC data protection model enhance data security by ensuring an uncompromised data transmission and data storage?
- 3) Will the implementation of the proposed Harricent_RSECC data protection model offers the required security to data?

II. ELLIPTIC CURVE CRYPTOGRAPHY (ECC)

Elliptic Curve Cryptography (ECC) is a contemporary group of public-key cryptosystems premised on the algebraic structures of elliptic curves over finite fields and the complexity of the Elliptic Curve Discrete Logarithm Problem (ECDLP).

An ECC curve can be illustrated as a curve that intersects two lines on a graph. This type of curve is determined by the properties of the mathematical group consisting of set of values for which operation on two of its members produces a third member [4] depicted in Fig. 1. Multiplying a point by a number on the curve produces an additional point on the curve, but finding what number has been used is very difficult, although parties involved know the original point and results. ECC uses elliptic curves in which elements of a finite field are all limited to variables and coefficients. The ECC is mathematically represented using the Weierstrass form of an elliptic curve denoted in (1) as follows $y^2 = x^3 + ax + b$ where $4a^3 + 27b^2 \neq 0$. Each "a" and "b" value has an elliptic curve that is different.

$$y^2 = x^3 + ax + b \quad (1)$$

Fig. 1. ECC Representation.

ECC constructs all of the substantial functionalities of asymmetric cryptosystem, including encryption, signatures, and key exchange. ECC cryptography is regarded as an effective modern replacement to the RSA cryptosystem since it utilizes smaller keys and signatures than RSA for the same level of security and offers extremely fast key generation, key agreement, and signatures.

A. ECC Keys, Algorithms, Curves and Key Length

In the ECC, the composition of private keys are generally numbers within a range of integers (usually 256-bit integers), thereby making it easier and faster for private key generation. The public key on the other hand is generated from points which lay on an elliptic curve, usually a pair of integer

coordinates (x, y). Ultimately, a shared key is a public key that is derived after multiplying the private key of the sender to the public key of the receiver and vice versa [5].

Besides, basing on the mathematical properties of elliptic curves over finite fields, the elliptical cryptography offers varied sets of algorithms. Three major categories of ECC algorithms are available consisting: signature algorithms such as elliptic curve digital signature algorithms, fast elliptic curve digital signature algorithms and Edwards digital signature algorithms; encryption algorithms for instance elliptic curve integrated encryption scheme and ElGamal Encryption using ECC (EECC); and lastly is the key agreement algorithms including elliptic curve Diffie Hellman X25519 and Fully Hashed Menezes-Qu-Vanstone (FHMV) [6].

Moreover, diverse sets of curves exist that elliptic curve crypto algorithms can utilize to achieve different purposes. Goals such as determining the level of cryptographic strength (security), the length of key and the performance are rational for implementing a different set of curves. Consequently, every curve consists of the following parameters (curve name; size of the field/key; the cryptographic strength – expressed as ratio of field size to 2; and the speed – also expressed as ratio of operations to seconds). Examples of ECC curves and their corresponding key sizes include “curve secp192r1 with 192-bit, curves secp256k1 and Curve25519 with 256-bit, curve P-521 with 521-bit among others” [6].

Therefore, it can be advanced that digital signature, encryption and key agreement algorithms utilizes any of the curves above for computations which heavily rely on the difficulty of ECDLP to provide adequate level of security to data while performing with minimal key length.

B. Key Benefits of Elliptic Curve Cryptography

The benefits of using elliptic curves stems from the fact that with shorter keys, equivalent levels of protection can be obtained compared with other algorithms. The ECC cryptosystem is useful in our contemporaries with massive upsurge in the development and usage of mobile devices. Thus, as the use of smartphones grows, more robust encryption is necessary for businesses to meet the increasing security requirements [7]. Some of the benefits are discussed below:

1) *Stronger keys:* ECC represents the latest encryption method, providing more security in elliptical curve cryptography. The underlying math problem of the ECC algorithm implies it is more difficult for hackers to crack compared to RSA and DSA, which makes the ECC algorithm more reliable than conventional methods for websites and infrastructure [8]. ECC algorithms rely on the difficulty of ECDLP to provide adequate level of security to data while utilizing minimal key length [5]. This invariably has improved performance and enhanced storage requirements.

2) *Short key size:* Comparably, Because ECC keys are substantially smaller than DSA/RSA keys; the size of the public and private keys in ECC is relatively short. As a result, the National Institute of Science and Technology (NIST) recommended that ECC can employ substantially lower

parameters for the same degree of security bits as RSA/DSA [9]. The choice for these algorithms is that elliptic cryptography uses lesser keys to achieve same security levels contrary to the other PKCs. For instance, the RSA/DSA technique requires a key length of 7680 bits to achieve 192 bits of security, whereas ECC requires a key size of 384 bits. Furthermore, the RSA/DSA algorithm requires a key size of 15360 bits to obtain 256 bits of data protection, whereas ECC requires a key length of 512 bits.

As a result, processing times are reduced while memory and bandwidth requirements are limited. ECC is especially suitable for applications with limited memory, bandwidth, and/or computing capability, and its use is expected to increase in this area.

III. REED SOLOMON (RS) CODING SCHEME

A. The Theory of Reed Solomon (RS) Coding

The RS code is a systematic, linear cyclic and non-binary block code. During RS coding, redundant symbols are created and appended to the symbols of the message by using a polynomial generator [10]. The position and magnitude of the error in the decoder are determined using the same polynomial generator [11]. The correction is then applied to the code received. RS coding is commonly used for error detection in a variety of communications and computer infrastructures, including storage, wireless or mobile communications, satellite communications, digital television, and high-speed modems [12].

RS codes were opted over other error detection and correction codes because of their faster decoding capabilities, i.e., their ability to detect and/or correct significant numbers of omitted or compromised data items; and the fact that they require the fewest additional error correcting codes bits for a known number of data bits [10]. Fig. 2 provides a framework representation of RS encoding/decoding process:

Reed-Solomon codes are by far the most extensively utilized for burst error correction [13]. The benefit of utilizing RS codes is that the likelihood of an error persisting in the decoded data is (generally) substantially lesser than if RS codes are not employed. Coding gain is a common term for this benefit. Because Reed Solomon code has a high coding rate, it is suited for a broad array of applications, comprising storage and transmission [12].

B. Properties of RS Code

RS code is specified as $RS(n, k)$ with s -bit symbols [10]. Given a symbol size s , the maximum codeword length (n) for a Reed-Solomon code is $n = 2^s - 1$. For instance, an 8-bit symbol will produce a maximum length of 255 bytes. This signifies that the encoder creates a n symbol codeword by adding parity symbols to k data symbols of s bits each. There is a total of $n - k$ parity symbols, each with s bits. A Reed-Solomon decoder can fix up to t symbols in a codeword that have errors, where $2t = n - k$. A typical Reed-Solomon codeword (known as a Systematic code because the data is not altered and the parity symbols are attached) is shown in Fig. 3 [14].

Fig. 2. Framework of RS Scheme.

Fig. 3. Reed Solomon Codeword Generation.

A code such as Fig. 3 can detect and correct up to $(n - k)/2$ or t symbol where each symbol represents an element within the finite fields $GF(2^m)$. This implies that any t symbols that may be corrupted can still be recovered from the original message [15].

An $RS(255, 223)$ with 8-bit symbols is an example. Each codeword is made up of 255 bytes, with 223 bytes of data and 32 bytes of parity. The following can be derived from the code:

$$n = 255; k = 223; s = 8; 2t = 32, t = 16$$

As a result, the decoder can automatically correct any 16 symbol errors in the codeword: that is, errors of up to 16 bytes can occur anywhere in the codeword.

In Fig. 4, the sender uses the RS encoder to encode the message in a codeword and transmits it through the communication channel. Channel noise and other disorders may disrupt the codeword and corrupt it. This corrupted codeword comes to the recipient end (decoder) and transfers the tested message to the receiver. If the error caused by the channel is larger than the decoder's error correction capability it may result in a decode failure. Decoding errors occur when a codeword has not been passed and a decoding error leads to an incorrect message [16].

The representation of an instance of an RS protected communication channel while transferring data is illustrated in Fig. 4.

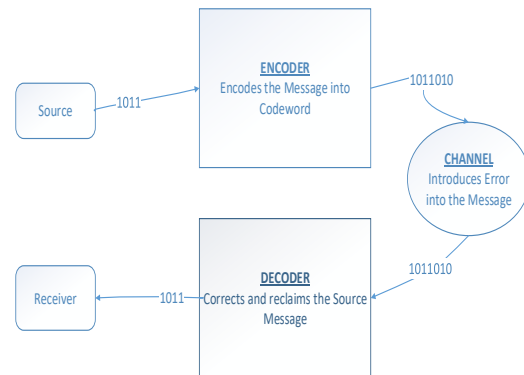

Fig. 4. Reed Solomon Protected Channel.

IV. REVIEW OF RELATED WORK

This section explores the extant works of ECC and RS. Elliptic curve cryptography (ECC) is by far the most effective public-key option for providing security services to devices with limited resources and it has been employed in a variety of business applications [5]. ECC, since its emergence has been considered the preferred option with notable efficiency for ensuring authenticity, encryption, signatures and key agreements [5]. To achieve these, He et al. deployed an ECC authentication model in a smart grid environment to obfuscate smart meter anonymity [17]. However, Sadhukhan et al pointed some security flaws in [17] such as internal and masquerading attacks [9]. Besides, by utilizing ECC and image steganography to maintain the legality and accuracy of medical health data, Eshraq et al.'s model obfuscated health data from being accessed by unauthorized access [18]. To ensure ECC's applicability in diverse contexts, the authors [19], [20], [21], [22] and [23] utilized ECC to achieve confidentiality, integrity, non-repudiation and authenticity levels of security.

On the contrary, the establishment of a reliable communication channel is very necessary as there exist security breaches within satellite or telephone channel which can compromise data security [10]. To overcome these security breaches many techniques of correcting errors have been introduced over time. One of such method is RS code which is a key non-binary BCH coding sub-class. These are useful cyclic codes utilized in detecting and correcting burst errors. RS codes have been prevalent due to its simplicity in encoding and well-structured decoding capabilities. In appraising the efficiency of RS codes, Wonshik & Jae-Yeon appraised the performance of RS(255, 239) in a smart transmission medium and an intelligent system [12]. The implementation of their system depicted RS code efficiency over a chaotic communication channel as the higher the codeword length, the greater the bit error rate improvements. Besides, Mounika [10] postulated that there exist security breaches on a satellite or telephone channel. Therefore, the establishment of a reliable communication channel is very necessary. To this end, [10] implemented a modified version RS codes for performing error corrections. Further, studies by [13] indicated that the decoding capabilities of RS codes have been efficient against deletion errors. And it was validated through the simulation results by [24] where the proposed RS decoder achieved a higher coding gain in contrast to algebraic decoding methods.

The identifiable gap is the ability to combine both techniques to achieve a robust security model and that's the goal of this study.

V. IMPLEMENTATION OF THE HARRICENT_RSECC MODEL

A. Conceptual Framework of an Efficient Data Security

Quite a number of studies have been carried out relative to mechanisms that can be deployed to enhance data protection. However, most of these studies have either focused on encryption or encoding schemes as postulated in [2]. The ability to integrate these two techniques and leverage on their strengths to achieve adequate data protection has been the

major concern in this study. To this end, the Harricent_RSECC data protection model has been designed and implemented to achieve the objective of this study through the utilization of Elliptic Curve Cryptography (ECC) and Reed Solomon (RS) codes. The prime goal for integrating ECC and RS is to achieve a fast, small, and portable cryptographic protocol, which would support elliptic curve digital signature generation and verification together with data reconstruction.

Fig. 5 shows the design of the Harricent_RSECC data protection paradigm, which integrates RS encoding and two variants of ECC to serve a purpose of improving data protection while achieving data integrity and confidentiality. Generally, the implementation of the model is achieved by the following steps.

B. Metrics used for Harricent_RSECC Data Protection Model

As a defensive system, it is always important to identify any messages or data received. Since messages come in different forms, understanding the different message types received play a crucial role when identifying the message/data received. The process for an unwanted message to be detected or identified is important to ensure the right defensive mechanisms are applied.

Having identified the type of message, a second defense module, the generator module, ensures proper defense by identifying which encoding level is crucial in identifying and correcting the right amount of errors that may occur in the system. This module also provides the chunking of data to ensure faster processing of the messages received.

Thereafter, messages received are transferred for security mechanisms to be applied to the message. The mechanisms are to encode, encrypt and sign the messages. These three effective security mechanisms will prevent unauthorized access to the message received.

As different attacks can be performed, each stage in the framework provides a defensive approach in protecting the message received.

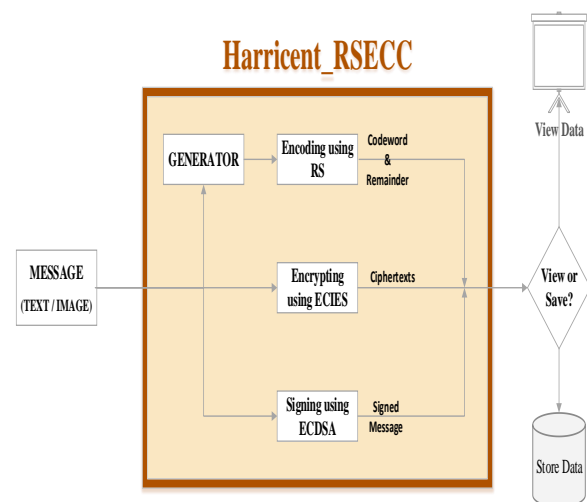

Fig. 5. Schematic Diagram of Harricent_RSECC Data Protection Model.

Therefore, the metrics that defined the functional requirements for Harricent_RSECC are:

- 1) The model must be able to identify the message type in order to perform the proper analysis. This maintains the scope of the study (text and images) prevent unclassified messages from being uploaded.
- 2) The model must be able to identify the message size/length in order to apply appropriate RS coder levels.
- 3) The model should be able to detect if a message has been compromised and correct eventually.
- 4) The model should be able to obfuscate the message and prevent unsolicited access and modification.
- 5) The model should be able to maintain the integrity of the message and associate messages transmitted or stored with the sender (i.e., ensuring non-repudiation).

The primary focus of this model is the ability for the system to identify a message type received, chunking of large messages for faster processing, obfuscation of the message, signing of the message, detection and correction of compromised messages. This work attempts to provide a protective mechanism which organizations can rely on to protect their resources.

C. Implementation of Harricent RSECC Components

From the design of the model, the following principal components are implemented: Message Identification, Generator Module, Encoding, Encryption, and Signature.

1) *Message identification*: A message is submitted by the user into the Harricent_RSECC model. This phase is to identify the type of message that is permissible to be uploaded into the model, be it a text or an image. This module consists of a rule-based component where rules are defined based on the list of file types and type of file uploaded or sent by the user.

For example, a typical rule might be `if(filetype==filetypeslist)` return true. The module identifies the message/data based on the type of file received/uploaded. The received message/data is processed and categorized to compute a value M_t based on two outputs, text (Dt) and Image (Di). Messages are identified based on $f(M_t)$ as follows:

$$f(M_t) = \begin{cases} D_t, & \text{if}(M_t = \text{filetypeslist}_t \wedge \text{filetype} = \text{filetypeslist}), \\ D_i, & \text{if}(M_t = \text{filetypeslist}_i \wedge \text{filetype} = \text{filetypeslist}). \end{cases}$$

If new message types are identified, there is the need for it to be added to the file type list to improve the efficiency of the system. If new message types are identified, there is the need for it to be added to the file type list to improve the efficiency of the system.

Files uploaded are checked by a function to prevent unclassified files from being uploaded.

```
#function file upload
```

```
if (filetype = ".txt" or filetype = ".doc" or filetype = ".docx" or  
filetype = ".png" or filetype = ".jpg" or filetype = ".jpeg" or  
filetype = ".gif");
```

```
upload file
```

```
else
```

```
print("file type not supported")
```

2) *The Generator Module (GM)*: This module prepares image and text files for the RS encoding scheme to be applied. It determines the length of message, chunks message based on encoder level and generates ASCII codes from message. The received message could be preprocessed by this module to determine the message's length. Message length, M_L , determination effectively enables how the message can be encoded. If a message, M , is presented as a number of characters w_1, w_2, \dots, w_n , then M_L is determined by w_n , where n is the last returning value, resulting in $M_L = n$. This module also takes into accounts the coder level during processing to determine the bits-type needed during encoding. The size of the bits-type is determined based on the message length M_L . The bits size, k , of a message is the bits-type to be used during RS encoding. Selection of the bits-type for a message is determined based on

$$f(M_k) = \begin{cases} 4bits, & \text{if}(M_L < \alpha), \\ 8bits, & \text{if}(M_L \geq \alpha) \end{cases}$$

where α is a pre-defined threshold value of thirteen characters.

The algorithm for determining the length of text messaging is presented below.

```
#def determine the length of message.
```

```
Take the length of message using the length library.
```

```
#def set bit size.
```

```
if messagelength < 13 and Bit_size=="8-bits":
```

```
Display a message that coder level must be either 'RS(15, 11)  
and RS(15, 9).
```

```
Set bit_size to 4-bits.
```

```
Else.
```

```
Pass
```

After the message length has been determined, a decision has to be made where the received message will be chunked (1) or not-chunked (0), utilizing the encoder level. The encoder level utilizes message length CML and codeword length CWL in its operation. All encoder levels are in the format: $CL(CW_L, CM_L)$, where CL is for coder level. Chunked messages M_c are determined based on.

$$f(M_c) = \begin{cases} 0, & \text{if}(M_L \leq CM_L), \\ 1, & \text{if}(M_L > CM_L) \end{cases}$$

The algorithm for chunking a message is presented below.

```
#code for chunking data.
```

```
#def chunkmydata(self, string, n):
```

```
chunks = [string[i:i + n] for i in range(0, len(string), n)].
```

```
return chunks.
```

The last operation of this module is the conversion of a message to its ASCII format. Each character (C) in the message is converted to its *ASCII code* (AC) (ie. $C_1 \Rightarrow AC_1, \dots, C_n \Rightarrow AC_n$).

The algorithm for messaging to their equivalent ASCII is presented below.

```
#def convert message length to ASCII codes.
```

```
letters = take the ordinal of the message characters to give  
their ASCII Codes.
```

3) *Data encoding*: This module utilizes the RS error correcting code to encode messages prepared from the GM to generate codeword. This is to guarantee that messages in transit or storage are devoid of corruption or contain errors by appending redundant data to it. The framework employed multiple encoder levels to encode. The RS code is built on finite fields, which have the feature that any computation on field elements always returns an element in the field-set [14].

To generate an RS codeword, a polynomial generator $g(x)$ is used with the following notations: information block $i(x)$, codeword $c(x)$ and a primitive element (α) of the field. A polynomial generator is illustrated in (2) below:

$$g(x) = (x - \alpha^i)(x - \alpha^{i+1}) \dots (x - \alpha^{i+2t}) \quad (2)$$

with the codeword generated as follows (3):

$$c(x) = g(x)i(x) \quad (3)$$

Following steps are employed in the generation of codewords and remainders:

a) An encoder level (RS) must be selected. To encode, Reed Solomon coder makes use of different encoder levels. Eight (8) RSCoder levels (RS) were selected ranging from (15, 9) to (255, 251) as follows:

```
RSCoder(15, 9), RSCoder(15, 11), RSCoder(53, 37),  
RSCoder(255, 223), RSCoder(255, 239), RSCoder(255, 251),  
RSCoder(255, 247), RSCoder(255, 191).
```

The above RS encoder levels determine the message (RS_M) and codeword (RS_C) lengths.

b) Message (M) length is determined based on the encoder level (RS) selected.

```
Message length = len(Message)
```

c) If message (M) length is less than or equal to the message (RS_M) length of the encoder, message (M) is encoded and a remainder (R) is generated.

d) A message (M) length that exceeds the encoder level message length (RS_M), message (M) is chunked based on the

message (RS_M) length of the encoder level using a chunk function explained above. Each chunked message is encoded and a remainder (R) generated for each.

```
Chunked Data = (M,  $RS_M$ ).
```

```
Chunked Data Length = len(Chunked Data).
```

```
If Message length >  $RS_M$ :
```

```
Chunked Data = (M,  $RS_M$ ).
```

```
codeword = rs4a.encode(Message).
```

```
remainder = codeword[-6:].
```

```
remainderhex = remainder.encode().hex().
```

4) *Data encryption*: The Encryption module provides obfuscation and protection of message/data. The framework used the ECIES to accomplish this. In an unsecured channel, ECIES will safeguard the contents from being read or altered with by unauthorized parties. During implementation, the ECIES combines the Secp256k1 curve with the Advanced Encryption Standard – 256 – Galois Counter Mode (AES-256-GCM) to offer the needed security. The AES-256-GCM algorithm is a symmetric encryption algorithm with a 256-bit key size [25]. To achieve ECIES encryption the following steps are followed:

a) *Generation of Key Pairs*: The first step in ECIES is to generate private (PRk) and public key (PUk) pairs. In the elliptic curve, private keys (PRk) that are generated are in integers and public keys (PUk) are points on the curve. Therefore, to encrypt file contents, the Harricent_RSECC model generated both public (PUk) and private keys (PRk). A private key (PRk) was created by obtaining 32 bytes from randomly generated numbers (R). A new private key (PRk) is generated if there is none; otherwise the private key already generated will be loaded. A private key (PRk) is just a sequence of raw bytes. To ensure better security, small numbers must not be chosen as private keys.

```
PRk = rand()
```

```
If PRk = NONE then
```

```
PRk = rand()
```

```
Else
```

```
PRk
```

Example: the limit of the integer number (N) as agreed by the communicating parties.

```
N =
```

```
10015792089237316195423125709850085568790718528137  
56427907490438260516314
```

```
PRk = random.randint(1, N)
```

```
PRk =
```

```
95193991353039061015378100235213857196721754949810  
9375643560636694135579
```

The public key, on the other hand, is determined by multiplying a point on the elliptic curve (G) and the private key (PRk).

$$PUk = PRk \times G$$

Therefore,

$$PUk = (PRk \times Gx) + (PRk \times Gy)$$

b) Generation of Shared Secret Keys: The second step of using the ECIES was to create a shared secret key by multiplying the private (PRk) and public (PUk) key using Elliptic Curve Diffie-Hellman (ECDH) algorithm. The ECDH algorithm is principally used to prevent eavesdropping by facilitating the exchange of the AES shared secret key. This shared key is a public key derived after multiplying the private key of the sender to the public key of the receiver and vice versa. Thus,

$$\text{Shared Secret key (S)} = PRk \times PU$$

c) Key Derivation Function (KDF) - AES Key and HMAC Key: The third step of the ECIES algorithm utilized the shared secret key to derive an Advanced Encryption Standard (AES) key and a Hash-Based Message Authentication Code (HMAC) key via a Key Derivation Function (KDF). The KDF component provides another layer of security to prevent man-in-the-middle attack which is a major issue in ECDH. The KDF ensures the hashing of the shared secret key (S) generated using SHA256 algorithm. The steps involved in implementing the key derivation function (KDF) are:

- i) Convert Shared key (S) to bytes
- ii) Using the SHA256 hash library, the bytes are hashed to produce a hash key (H).

The AES key derivation is based on the key length and the hash (shared) key (H). AES-256-GCM has the key length of 256 bits. To generate an AES key that was used for encryption, the hash (shared) key (H) length should be equal to 256 key bits length.

$$\text{AES Key Length} = 256 \text{ bits}$$

$$\text{AES Key} = H [: \text{AES Key Length}]$$

// AES key picks the first part of shared //key while the latter is for the HMAC key

More so, HMAC secret key utilized was also based on the key length and the hash (shared) key (H). HMAC's cryptographic strength depends on the size of its output as well as the size and quality of the key. HMAC-SHA256 operates on a bit size of 256. This size produces a sizable output and key. To generate HMAC secret key:

$$\text{HMAC Key Length} = 256 \text{ bits}$$

HMAC Secret Key = H [HMAC Key Length:] // HMAC key picks the later //part of the shared key

d) Message Encryption: The fourth step in adopting the ECIES is message encryption. To encrypt a message, a random initialization vector (IV) was created and XOR'd with the

message in addition to the AES key to generate a ciphertext. Initialization vector (IV) is an abbreviation of "nonce" which connotes the number used once. The randomly generated bits were based on the AES block size and the number of bits in the key length.

The generated IV is converted to bytes depending on the AES block size.

$IV = \text{random.getrandbits}(\text{AES block size} * \text{number of bits per byte})$.

$IV = IV. \text{to_bytes}(\text{AES block size})$.

$\text{Ciphertext (C)} = (IV \text{ XOR message, AES Key})$.

e) Hash-Based Message Authentication Code (HMAC): In the fifth step, HMAC was created to be used for initialization vector (IV) and Ciphertext (C). To create HMAC, two keys are generated from the HMAC Secret Key. The two keys are named, inner key (Ik) and Outer key (Ok). The first 256 hash (Fh) value is generated from the message and Ik. A second 256 hash value is generated from Fh and Ok. These keys are sent to the recipient for verification/decryption.

f) Transmitting PUK, IV, C and HMAC: The final step involves the sending of PUK, Initialization Vector (IV), Ciphertext (C) and Hash-Based Message Authentication Code (HMAC). The transmission is through a communication channel to the server facility for storage.

Encrypted data or ciphertext sent (C_s) is decrypted using the private key PR_k ,

$$\text{Message}_{\text{decrypted}} = (C_s, PR_k)$$

5) Data signature: This component uses Fast ECDSA to digitally sign files to uphold the integrity of the message. In comparison to other types of digital signatures, the Fast ECDSA technique is designed to conduct fast elliptic curve cryptography. In comparison to ECDSA, it takes very little time to perform its instructions. In the elliptic curve, private keys are integers, and public keys are points on the curve. To offer 128 bits of security, the curve adopted is P256/secp256r1. Creation curves are done using Weierstrass form: $y^2 = x^3 + ax + b(\text{mod } p)$.

The Fast ECDSA algorithm employed to digitally sign messages combines P256 / secp256r1 curve and SHA3_256. The curve is imported for use in this study as shown in the example below:

Example:

$$\text{curve} = \text{ec.SECP256R1}()$$

The following are the steps involved in the implementation of Fast ECDSA algorithm:

a) Generation of Key Pairs: Private (EPRk) and Public (EPUk) keys were generated to sign and verify messages by using P256 curve. Private (EPRk) keys are integers that were randomly generated and Public (EPUk) key were derived by multiplying the EPRk and a point on the curve (GE). Public

VI. DISCUSSION

The Harricent_RSECC data protection model provides data owners with the guarantee of data security in transit and storage while preserving data validity. It contributes to the field of security by incorporating encryption, encoding, and signature techniques to provide confidentiality, authenticity, integrity, and non-repudiation levels of security. Should an adversary intercept any of the ciphertexts, the model ensures data secrecy by utilizing ECIES to prevent unauthorized access and eavesdropping. The ECC key size for the Harricent_RSECC data protection model was 256. This provides a 128-bit security equivalent (RSA/DSA will use a key length of 3072). Furthermore, the model employs Fast ECDSA to digitally sign a message, ensuring its integrity and non-repudiation. Fast ECDSA generates hash values from the message which are used for signing the messages and verifying the authenticity of the ciphertexts. The model additionally leverages RS codes to identify and correct errors that arise in order to provide the capability of retrieving corrupted data files that occurred during transmission or storage, which further enhances data protection in transit or at storage.

The model affirms the studies conducted by [19], [20], [25], [26], [27], [21] that applied elliptic cryptographic algorithms to encrypt and decrypt the selected data and this guarantee the safety of private information, sensitive data, and can enhance the security of communication between computer systems. The Harricent_RSECC model through the use of Fast ECDSA validates the identity of the sender that transmitted the message which upholds the studies conducted by [19], [20] [28]. By employing Fast ECDSA, the content of the message cannot be altered without detection. This ensures the integrity of the message is maintained and, moreover, the signer cannot deny association with the signed content. Moreover, studies conducted by [13], [12], [10], [23] through the utilization of RS codes endorses the benefits of error detection and correction that may emerge.

A comparative discussion supported with existing literature is presented in this section. The security of the Harricent_RSECC data protection model was evaluated using five metrics: Message Identification, faster processing through chunking, obfuscation, detection and correction of compromised messages and signature of message. This is to ensure that the confidentiality, authenticity, integrity and non-repudiation (CAIN) levels of security are provided to the data. By obfuscating message, the confidentiality and authenticity of information stored on computer systems or transferred between its users across the internet is assured. By encoding and decoding the message, the integrity of the message is maintained through the addition of redundant data. By signing the message, the integrity and non-repudiation of the message is ensured. The selected metrics, as adduced in chapter 3, aids in appraising the security potentials of the system.

In analyzing the studies of [19] and [20], it was observed that their system partly used the message identification metric by concentrating on either text or image on separate studies. To ensure fast computational process, their studies utilized message groupings to chunk messages. However, their

adopted message groupings will slow the processing of messages as compared to the chunking component (generator module) in the Harricent_RSECC model. In our study, the GM chunks each message based on the RS coder level which leads to faster encoding processing. Even though, the authors utilized the ECC to obfuscate the messages, the two distinct studies lack the functionality of detecting and correcting of compromised messages in an event of error occurrence. More so, [19] and [20] studies failed to offer and maintain integrity of messages by not signing and associating messages transmitted or stored to the sender (i.e., ensuring non-repudiation); which have been ensured through fast ECDSA in Harricent_RSECC model.

In a related study, [23] developed a technology that allows messages to be hidden based on numerical ruler-bundle. It's worthy to note that message hiding is one of the reliable methods of preserving and ensuring the CAIN. Notably, [23]'s study partially made use of only one part of message identification (i.e., image) in comparison with Harricent_RSECC model. Analysis of [23]'s technology also reveals that the authors failed to decompose the information extracted from the image as their system read each stream of input sequence to determine its encoding alphabet; however, their technology hampers efficient computational processes. Their studies enable the hiding of an image inside another image in addition to noise tolerant codes. The model of noise-tolerant codes provided an opportunity to correct up to 25% of errors in the code word. Though, the technology has the capacity to detect and correct errors in comparison with Harricent_RSECC Model, but it lacks the capacity to ensure non-repudiation as their technology does not sign messages that are transmitted and stored.

Also, a study conducted by [21] concentrated on text messages the author's message identification at the exclusion of images. Besides, [21]'s study failed to highlight the imports of chunking which Harricent_RSECC model dwells because chunking is beneficial to ensuring faster computational processes. Like the Harricent_RSECC model, [21]'s model obfuscates the content of the message through the utilization of ECC. However, it lacks the ability to sign, detect and correct compromised messages; hence integrity and non-repudiation levels of security are not maintained.

More so, [22] designed a secure model for data protection in the cloud but the system lacks the ability to differentiate the types of data the study seeks to secure. Data identification is consequential in ensuring CAIN because each data has its own way of processing to offer the needed protection. Also, [22]'s model was not clear on how message chunking is being handled; however, much concentration was given to usability in the study. Whiles the latter is good, the former is equally important to ensure fast computation. More so, [22]'s model obfuscated messages, but the methods employed are AES and RSA, which in literature this study has adduced that the benefits ECC far outweighs RSA. Again, the [22]'s study indicated the concepts of non-repudiation and integrity but the methods in achieving those security metrics are not explicit. Lastly, their system lacks the ability to detect and correct compromised messages which inadvertently affect the integrity of the transmitted or stored data.

TABLE I. COMPARATIVE ANALYSIS OF SOME EXISTING WORK WITH HARRICENT_RSECC MODEL

Authors	MI		C	O	EDC	S
[19]		Image	Yes	Yes – ECC	No	No
[20]	Text		Yes	Yes - ECC	No	No
[21]	Text		No	Yes, ECC	Not	No
[22]	No message identification		Not clear	Yes, AES and RSA	No	Non repudiation and integrity are mentioned but method not clear
[23]		Image	No	Yes - numeric ruler bundle	Yes - numeric ruler bundle	No
Harricent_RSECC	Texts and Images		Yes	Yes - ECIES	Yes - RS	Yes – Fast ECDSA

Table I presents a comparative analysis of some existing work with Harricent_RSECC model in achieving secured system by basing on the stated metrics:

MI – Message Identification,

C – Chunking,

O – Obfuscation,

EDC – Error Detection and Correction,

S – Signature,

From the levels of security espoused, it can be asserted that it is only the Harricent_RSECC model that combines the functionalities of encrypting, encoding and signing to achieve confidentiality, authenticity, integrity, non-repudiation. Therefore, the Harricent_RSECC data protection framework offers the data owner the assurances of data protection in transit and storage, while maintaining the validity, integrity and confidentiality of the data. It is valid, therefore, to assert that Harricent_RSECC model is the efficient framework comparatively and offers protection to text and image datasets by using both ECC and RS encoding protocols.

To advance this section, the questions posited in section 1.3 are discussed.

A. Can RS and ECC be used to Ensure Secure Data Transmission and Secure Data Storage?

The characteristics of RS and ECC are advanced in Sections 2 and 3. To offer protection to data, several data encoding and encryption techniques have been proposed. In the case of the encryption, such schemes are utilized to obfuscate messages to prevent unauthorized access and modification to protect the validity and secrecy of messages transmitted/stored. While the encoding scheme adds extra bits to the original data to aid in error detection and correction in order to keep the messages from corruption or damage.

This study evaluates the RS encoding scheme and ECC encryption technique to create a data protection model. Data in transmission and/or storage are susceptible to attacks or security threats. Most security systems focus on either extra bit of data to messages or obfuscate the message. The utilization of one scheme over the other offers security but it is ineffective to provide optimal protection due to the inadvertent

loss of data as a consequence of adversary’s activities or hardware failures. Therefore, it is essential to combine both encoding and encryption strategies for ensuring effective data protection.

As a public key cryptography, ECC characteristically consists of a public key and a private key which augment the communication between the parties involved. As a result, ECC use significantly smaller parameters than RSA/DSA to achieve the same level of security.

B. Can a Proposed Harricent_RSECC Data Protection Model Enhance Data Security by Ensuring an Uncompromised Data Transmission and Data Storage?

The Harricent_RSECC model and implementation (shown in Fig. 8) achieved the study’s purpose of providing enhanced data confidentiality and integrity model by using Reed-Solomon encoding scheme and elliptic curve cryptography. This ensures that the data owner participates in the provision of security to the datasets before storing or outsourcing it to a storage infrastructure [21].

Firstly, from the implementation of the model, a message must be encrypted Using ECIES to inhibit unauthorized access and intrusions if any of the ciphertexts are intercepted. Secondly, prior to transmission, the message is signed by computing a hash value to enable the receiver to authenticate the validity and genuineness of the source message. This aids in detecting any compromises that ensued during transmission by untrusted channel or by an attacker.

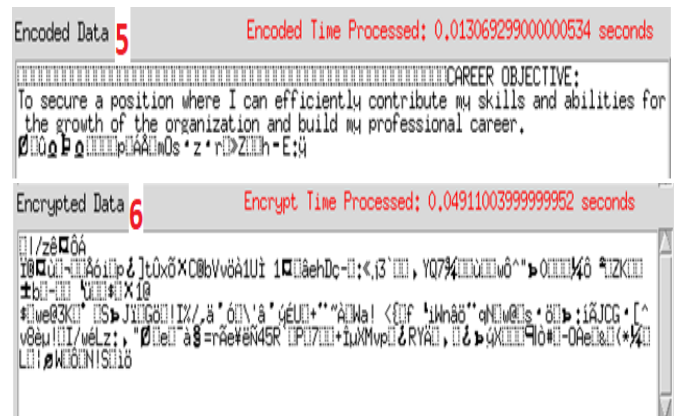

Fig. 8. A Snapshot of an Encoded and Encrypted Data.

Moreover, in the event of data compromise, the Reed Solomon scheme is utilized to decode and correct the corrupted message. Thus, at the receiving end, the receiver validates the validity and accuracy of the message by computing the hash value on the decrypted message to verify the authenticity of the message. The unmatched values computed from the verification algorithm would render the invalidity of the message.

C. Will the Implementation of the Hybrid Data Protection Scheme Offer Necessary Security to Text and Image Datasets?

The Harricent_RSECC data protection model is a robust model that offers higher security levels to texts and image datasets as it combines the strengths and efficiency of two outstanding data protection schemes. The implementation of the Harricent_RSECC data protection model offers necessary security to both image and text dataset including confidentiality, integrity and non-repudiation. From Appendix I, the Harricent_RSECC model provides confidentiality of the owner's data at the first level of security through encryption by using the ECIES. Again, at the second level of security, the ciphertexts are signed using the fast ECDSA to sign, authenticate and validate the source of the transmitted data. The Harricent_RSECC model provides protection from data loss or corruption using the Reed Solomon coding. Data integrity provided by both fast ECDSA and RS is achieved at the second and third level of the Harricent_RSECC model.

VII. CONCLUSION

In this paper, we appraise that data is vulnerable to attacks and security threats while in transit and/or storage. The study focused on integrating encoding and encryption schemes to offer optimal protection due to unintended data loss as a result of adversary actions or hardware failures. The study implemented a data security model, dubbed Harricent_RSECC data protection model, to improve CAIN of data by dwelling on five key metrics. Through data identification and classification process, the study was scoped with texts and images. The use of RS codes enabled the detection and correction of compromised messages so as to maintain the integrity of the message. To prevent man in the middle attack and message eavesdropping, the model obfuscated the message prior to transmission and storage. Consequently, the confidentiality and authenticity of the message guaranteed. Moreover, through message signing, the model achieved the security levels of integrity and non-repudiation.

VIII. FUTURE WORK

The future study will focus on improving the computational processes so that instead of three deliverables, authors may compress all output into one file. More so, study will expand the scope to cover other scope such audios and videos files.

Abstract—Assessing the mobile learning application among interdisciplinary researchers is a non-trivial task. Mandarin Learning App is a Mandarin 3D game tailor-made for students who choose PBC1033 Mandarin Language Level 1 as an elective course. It is an interdisciplinary project which it involves researchers from software engineering, computational science/mathematics and the Faculty of Language studies. In the project, the software engineer focuses on producing a quality application mostly through usability studies; the language teacher focuses on students' study performance upon using the Mandarin Learning App and the mathematician focuses on finding the statistical data dependency of collected data through the various statistical packages. Hence, we are facing issues like how to reach a consensus in working on assessing the Mandarin 3D games? How to enable the discussion among the researchers; how to consolidate the results so that we can understand? We introduce Goal Question Metric to tackle these issues. In this paper, we demonstrate how Goal Question Metric is used to form a holistic view of assessing requirements on mobile applications and guide the discussion and reach consensus in analyzing the results of the evaluation. The contribution of this paper is to introduce Goal Question Metric as an interdisciplinary tool while assessing the mobile learning application. With Goal Question Metric, we demonstrate how it can structure the assessment from a different viewpoint in a comprehensive and systematic manner; 1) better structure of the experiments, 2) able to reach consensus among researchers from different disciplines, 3) able to analyze the dependencies among various experiments and 4) able to find hidden results.

Keywords—Goal question metric; mobile application; evaluation; communication; interdisciplinary

I. INTRODUCTION

Language is very important for everyone to have connection and interaction with others either in verbal or nonverbal communication. UNIMAS has offered introductory Mandarin Language courses for students who wish to explore and learn Mandarin. Among them, the PBC0033 Mandarin Language Level 1 is offered as an elective course to students who do not have any basic knowledge of Mandarin. In this course, students start to learn and recognize the Chinese character; to pronounce the character together with pinyin and to write the character with the correct stroke. Based on our informal observation, students are interested to adopt mobile applications to learn Mandarin. Hence, we developed an in-house mobile application known as "Mandarin App", under an interdisciplinary project between researchers from software engineering, language teacher and mathematician.

In the project, the software engineer focuses on producing a quality application by evaluating the system mostly through usability studies. On the other hand, the language teacher focuses on students' study performance upon using the Mandarin Learning App and the mathematician focuses on finding the statistical dependency of collected data through the various statistical packages. Hence, we are facing issues like how to reach a consensus in working on assessing the Mandarin 3D games? How to enable the discussion among the researchers? How to understand the assessing mechanism in which some are too technical (e.g., statistical analysis) and how to consolidate the results so that we can understand? Hence, we are in the dilemma to reach a consensus when conducting the evaluation of the project.

We introduce Goal Question Metric (GQM) to tackle these issues. In this paper, we demonstrate how Goal Question Metric is used to form a holistic view of assessing requirements on mobile applications and guide the discussion and reach consensus in analyzing the results of the evaluation. The contribution of this paper is to introduce GQM as an interdisciplinary tool while assessing the mobile learning application. With GQM, we demonstrate how it can structure the assessment from a different viewpoint in a comprehensive and systematic manner. Section II presents the related works in using GQM to assess a system. Section III presents how GQM is used to assess a mobile application. Section IV presents the results derived from GQM measurement guidelines. The paper is concluded in Section V.

II. RELATED WORK

GQM is used to perform usability evaluation of real-time water quality monitoring mobile applications [1] and general mobile applications [2], [3], [4], [5], [6], [7], [8], [9]. It describes the data that we need to collect and how to interpret the data [10]. The GQM consists of goal, questions, and metrics. Several metrics are identified in user experiment measurements on mobile applications [11]. They are understandability, learnability, efficiency, effectiveness, operability, attractiveness, usability compliance, happiness, engagement, adoption, retention, task success, usability, satisfaction in use, safety, social presence, cross-platform interaction, algorithm diversity, user control, usage effort, outcome-related experience, review, connection, content, internet service, service availability, ease to use, utility, long term use, productivity, generalizability, pragmatic quality, hedonic quality, stimulation, emotion, psychology metric.

Other metrics are task completion, error rates, time to take the usage and subjective satisfaction like enjoyment, ease of use and safety [1]. Saleh et al. [12] classified the usability metrics into 7 criteria. They are satisfaction, efficiency, effectiveness, learnability, operability, universality, and user interface aesthetics. The satisfaction covers metrics of comfort, trust, pleasure, usefulness; the efficiency covers metrics like task efficiency, time efficiency, relative task time; effectiveness covers metrics of task completion, task effectiveness and effort frequency; the learnability covers metrics of time to learn, memorability, easy to understand error messages, completeness of user documentation, cognitive load; operability covers metrics of understandable, message clarify, operational consistency; universality covers metrics of cultural universality, standard compliance, accessibility; user interface aesthetics covers metric of customizability and attractive of the user interface.

The GQM is extensible to serve as a measurement guideline to measure mobile applications [1]. For example, [1] extend the GQM with guidelines to determine how a specific goal is reached. The guideline can drive the formation of questions for GQM. Meanwhile, the guideline will serve as expected answers for the metrics. For example, to achieve goal simplicity, a system should be easy to input the data, easy to install, easy to learn. Hence, the evaluator can form the questions like is it simple to key in data? How easy it is to install the application? etc. In addition, GQM [10] has been used in running a course activity to train the student's ability to understand its goal, refine its goal and design appropriate achievement metrics.

We extend the usage of GQM from usability evaluation into a wider assessment mechanism. Hence, GQM for mobile application evaluation should not only focus on usability study of mobile applications but it can also be used and support various experiments analysis. This is in line with the work [1] to extend the usage of GQM with guidelines. The guideline presents the expected answers for the metrics. On the other hand, [13] extended the GQM with instrument types and role mapping to relate the evaluation and analysis methods into metrics. Meanwhile, our work is related to [10] by treating GQM as a tool for stakeholders during the assessment of mobile learning application.

III. THE METHOD

This section presents the adoption of GQM as an interdisciplinary tool to assess mandarin learning app among different researchers.

GQM is known as Goal, Question, Metric [14]. The GQM model is represented as a hierarchical structure and covers three levels. They are conceptual level, operation level and quantitative level. The conceptual level defines the goal of the measurement. It represents the measurement from a high level of abstraction. The goal at this level covers the quality level of the system. Hereby, we treat is quality goal. The quality goal is to act as a non-functional goal and represents how a functional goal should have been achieved. The quality goal is the property of the system. Quality goals are non-functional goals (sometimes referred to as soft goals). The operation level defines a set of questions that will work towards the

assessment or achievement of a specific goal. The quantitative level defines a set of data that serves as the answers to the questions. The data can be objective or subjective depending on the measurement mechanisms (e.g. quantitative or qualitative assessment method).

The GQM processes cover the process to determine what to measure and determine how to measure. To determine what to measure, it involves processes to identifying entities, classifying entities to be examined and determine the relevant goals. Meanwhile, it is important to inquire about metrics and assign the metrics to determine how to measure.

In this section, we introduce how to adopt GQM as an interdisciplinary tool to assess mandarin learning apps among researchers from different disciplines.

The goal is the first step when working on the GQM model. The goal represents the objective or purpose of a system, and it is achievable [15]. Since GQM is used to measure the system, the goal must relate to what is the purposes to measure the entities regarding the issues been solved by whom. The goal is related to software quality characteristics as described in [1]. The goal here also refers to what do you want to know or learn from the system. The formation of the goal is based on the template given in [16]. According to [16], a goal is derived based on the elements like purpose, issues, object and viewpoint [16]. Goals need to be high level. We can derive the goals by referring to the documents' analysis, interviews [14] or existing usability models as listed in [1], [13], [12], [2], [17].

Questions are elicitation questions in achieving the goal as stated previously. The generation of the questions is based on the instrument decided and targets users.

Metrics are the measurement parameters in answering the questions towards achieving the goal. Metrics produces data. The data can be objective or subjective depending on the types of measurement mechanisms. For example, a quantitative analysis leads to objective data (e.g. number of satisfaction; the number of scores). Meanwhile, the qualitative analysis led to subjective data. Once, the GQM is formed, a goal-question-metrics refinement process takes place to enable the researchers to reformulate the goal, questions, and metrics on evaluating the mandarin learning app.

As mentioned before, this is an interdisciplinary project. The software engineer has the intention to develop a quality product and usability studies are among the famous technique for assessing it. On the other hand, language teacher is always focuses on study performance. This is done through pre-test and post-test. In addition, an empirical study is used to study the correlation of results regarding demographic and various post-survey as proposed by the mathematician. Hence, how to consolidate the different types of analysis and studies?

To evaluate the effectiveness of the games, several experiments are conducted. Data are collected by using both the written questionnaire surveys and interviews, a vocabulary pre-test and post-test (before-after), as well as game diaries. Collected data were analyzed with quantitative and qualitative methods. Specifically, exploratory factor analysis was performed to reexamine the grouping of variables in

questionnaire items to establish underlying dimensions that could explain its correlations.

All the experiments are conducted among 33 students from PBC0033, the batch year 2021 who answered the questionnaire and took the pre-test and post-test. As our sample size is very small, we only remove 3 respondents who rate their responses on Likert-type questionnaire items with the same answer always, resulting in a standard deviation lower than or equal to 0.385. Hence, the characteristics and demographics of our remaining 30 respondents are summarized in Table I.

TABLE I. RESPONDENT DEMOGRAPHICS AND CHARACTERISTICS

Demographic or characteristic	Frequency	Per cent
Gender:		
Male	5	16.5
Female	25	83.3
Ethnic:		
Bumiputera	28	93.3
Dusun	2	6.7
Age:		
21 - 22	20	66.7
23 - 24	8	26.7
25 - 26	2	0.6

Prior to the evaluation, the GQM is adopted and serve as a tool to drive the discussion among the researchers. Based on GQM, Table II shows the list of goals, questions, and metrics in related to our study. Meanwhile, Fig. 1 shows the GQM model in assessing the mobile learning App. It starts with a higher-level goal to ensure the effectiveness of learning through the mobile Mandarin App.

To achieve the main goal, there exists sub-goals of 'ensure engaging', 'ensure high performance', 'ensure likelihood', 'ensure secure learning', 'ensure privacy protection' and 'ensure cross culture learning'. The goals are derived from the Table I. To achieve the subgoals, several questions are generated and the answers from the questions will lead to the achievement of the sub-goals. In this case, the answer from "Do the students like to use the app to learn" will achieve the goal to ensure engaging; the answers from "are the games able to improve students' results" will achieve the goal of ensuring high performance; the answer from 'what are the factors that influence the adoption of games' will achieve three subgoals to ensure likelihood of the learning. In addition, we believe that the answers also lead to achievement of subgoals of namely ensure secure learning, ensure privacy protection, ensure cross culture learning after postmortem. The metrics that are corresponded to the questions are level of preference, level of self-learning, level of games challenges, level of critical thinking; number of pre-test level, number of post-test level, comparison of the results; number of dimensions, list of constructs; number of incidents and amount of lost. Finally, we have mapped the metrics to the testing instruments and the researchers that are handled or initiated by the researchers. The mapping of the metrics into instruments is presented in [13].

In sum, the GQM model can serve as a communication media to discuss among the researchers. Before this, we only identified three goals for the assessment. They are ensuring engaging, ensure high performance and ensure likelihood.

After the postmortem, three subgoals have been identified and three questions are derived. They are ensuring secure learning, ensure privacy protection and ensure cross culture learning although it does not cover in this evaluation. It shows how GQM model can be used to find the hidden evaluation elements during the discussion. In addition, the corresponding questions are 'Does the games secure?' 'Do the games able to protect privacy?' and 'Does the games able to promote cross culture learning?'

TABLE II. THE GQM LIST FOR THE STUDY

GQM		Item
Main Goal	Purpose	Improve Learning of mandarin through Mobile learning app Among students
	Issue	
	Object (process) Viewpoint	
Question		Does it an effective way to use mobile learning app?
Metric		Refer to the rest of the description.
Goal 1	Purpose	Ensure engaging in learning through mobile app among students
	Issue	
	Object (process) Viewpoint	
Question		Do the students like to use the app to learn Mandarin?
Metric		Level of preferences to use mobile games Level of self-learning Level of games challenges Level of critical thinking
Goal2	Purpose	Ensure high result performance by learning through mobile app among students
	Issue	
	Object (process) Viewpoint	
Question		Are the games able to improve student results?
Metric		Number of pre-test level Number of post-test level Comparison of the results
Goal3	Purpose	Ensure likelihood of student behaviour by learning through mobile app among students
	Issue	
	Object (process) Viewpoint	
Question		What are the factors that influences the adoption of games among students?
Metric		Number of grouping/ numbers of dimension List of constructs

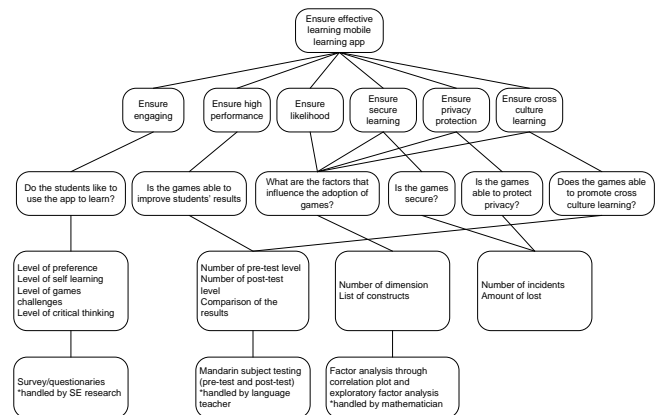

Fig. 1. GQM Model for the Project's Evaluation.

IV. THE RESULTS

A. Results for Goal 1

- Question: Is the games able to become a complemented tool on conventional Mandarin lesson?
- Answer: From the results, the mandarin learning app can serve as a complemented tool on conventional mandarin lesson.

Questionnaires are used as the method to achieve the goal. We have formulated the questionnaire based on the metrics given. The results from the usability study are shown in Fig. 2. The survey is designed based on five elements. They are students' motivation; students' attitudes with the games; students' cognitive development; games interface; students' expectation.

2. I prefer to answer questions using mobile games as compared to using books or paper. 33 responses

3. It is more flexible for me to determine my own learning time. 33 responses

5. These games challenge my understanding of the subject. 33 responses

1. These computer games help me to think critically. 33 responses

Fig. 2. Usability Study Results.

In sum, students are motivated to use the games in learning Mandarin. 65% of the students are interested to use the games in learning Mandarin instead of using books and paper. The games increase the student learning in which students can learn anytime and anyway (85%). The games can challenge the students to think critically and enhance problem solving in which 76% of respondents stated. Meanwhile, 87% of the

respondents agreed that the games can challenge the students' understanding of Mandarin. It has been reported that the games are interactive and interesting. 79% of the respondents agreed that the menus in the games are easy to understand. 64% of the respondents stated that the navigation and interaction are easy to use. The games are easy to function with a short time learning curve. 91% of the respondents stated that the multimedia elements in the games are interesting. 82% of the respondents show the interest to replicate the games mode in other level of Mandarin course. Although games are interesting, 50% of the respondents still prefer to have the traditional face to face class. This serves the objective on having the games as a complemented tool on conventional Mandarin lesson.

B. Results for Goal 2

- Question: Is the games able to improve student results?
- Answer: The post test results are more than pre- test results. Hence, the games can improve student results.

Fig. 3. Individual Pre-test and Post-test Score.

Pre-test and post-test are adopted in this study. We first give the individual pre-test and post-test scores in Fig. 3. Only slightly more than half of the students showed improvement in their test scores after going through mobile games enhanced learning. We then check the normality of the pre- and post-test scores by using Shapiro-Wilk test. Both the test scores are normally distributed as their p-values > 0.05. From their boxplots (see Fig. 4), we find that there is only a marginal improvement whereby the means of pre-test and post-test score are 14.4 and 15.4, respectively. Although the paired sample t-test supports that the true difference in means between pre- and post-test score is not equal to 0, if we plot the change scores (i.e. post-test minus pre-test scores) against pre-test scores, as shown in Fig. 5, a negative correlation can be observed. This implies that a common statistical phenomenon in repeated measurements, known as regression towards the mean (RTM) [20], can influence the findings from our pre- and post-test instruments. This RTM suggests that students with higher pre-test scores consistently make smaller improvement in post-test than students with lower pre-test scores.

As we are not able to use a randomized control group to deal with this RTM, we opt to assess the agreement between these two pre- and post-test measurements through Bland-Altman plot (see Fig. 6). The black line gives the mean of difference in score between pre- and post-test while the two blue dashed lines represents the 95% confidence interval limits of agreement for the mean of difference. In our example, the mean of difference is 0.96. This suggests that on average the post-test measures 0.96 score more than the pre-test as mean of difference (called bias) is non-zero. Besides, only two points appear to lie outside the limits of agreement indicating there is certain degree of agreement between the two tests.

Fig. 4. The Boxplots for Pre- and Post-test Score.

Fig. 5. Scatter Plot showing Change Score against Pre-test Score.

Fig. 6. Bland-Altman plot with the Representation of the Limits of Agreement (Dotted Line).

C. Results for Goal 3

- Question: What are the factors that influence the adoption of games among students?
- Answer: They are two major dimensions in making the mandarin learning app success among our students. The success of the mandarin learning app is due to high student motivation, high cognitive development from the games plays and the games meet the student expectation. Meanwhile, the games are user friendly.

A set of questionnaires with 5 constructs (motivation, attitudes, cognitive development, interface design and expectation) with 24 items and an open-ended question on student’s open comments about learning using the games is designed as shown in Table III. We present the correlation plot and exploratory factor analysis for questionnaire items in all 5 constructs to answer derived on this goal.

TABLE III. THE DETAILED OF QUESTIONNAIRE WITH 5 CONSTRUCTS

Section	Item	Question
Student’s motivation	A1	I think this gaming activity gives me lots of benefits.
	A2	I prefer to answer questions using mobile games as compared to using books or paper.
	A3	I am very interested in using games for learning new Mandarin words in the future.
	A4	Digital learning games do not bring additional value to Mandarin language learning
	A5	I prefer to do exercises in games rather than quizzes during class.
	A6	The usage of computer games makes this subject more interesting.
Student’s attitudes with the games	B1	With the games, I can learn better by myself.
	B2	I can learn better according to my own pace and sequence.
	B3	It is more flexible for me to determine my own learning time.
	B4	It is more flexible for me to choose my learning pace.
	B5	The content of the games matches my subject syllabus.
	B6	The element of multiplayer in games motivates me to study Mandarin characters.
	B7	The games do not affect my motivation to learn new words.
Students’ cognitive development	C1	These computer games help me to think critically.
	C2	Solving the given problems is very interesting.
	C3	It is worth using games for learning in future.
	C4	Looking for the answer to questions given is an encouraging activity.
	C5	These games challenge my understanding of the subject.
Game interface	D1	Menus available in the games are easy to understand.
	D2	Navigations and interactions are easy to use.
	D3	Multimedia elements in the games are interesting.
	D4	I just need a very short time to know how the game is functioning.
	D5	The use of colour and design layout in the games are interesting.
Students expectation	E1	I wish I have more opportunities to learn other Mandarin course using this game approach.
	E2	I prefer using games to learn Mandarin as compared to traditional methods in the class.
	E3	I would like to learn all computer subjects using educational games.
	E4	I wish this game will be available online for easy access.

We carried out the analysis using RStudio, specifically by using package ‘psych’ [18]. We first reverse the Likert score for variables A4 and B7 as they are negatively phrased items (hereinafter, the terms “variable” and “item” are used interchangeably). As Likert-scale questionnaires yield ordinal data, we measure the association of the ordinal variables in terms of polychoric correlation and estimate the internal

consistency for scales using ordinal alpha. The coefficient ordinal alpha gives 0.94 indicating a very good level of reliability. Furthermore, this alpha value does not increase a lot when any of the items is deleted. Therefore, all the items as given in Table III are considered for further analysis.

We explore the strength of the relationship between all variables by constructing correlation plot with package ‘corrplot’ [19], as shown in Fig. 7. The correlation is positive (resp. negative) when one variable increases as the other increases (resp. decreases). We find that the two negatively phrased items (i.e. A4 and B7) as well as item D4 have negative correlation with all other variables, suggesting that item D4 probably should be reversed. However, we chose not to reverse item D4 scoring as it showed that our respondents understood the questions correctly.

Fig. 7. Correlation Plot for all Likert-type Questionnaire Items.

We then employed multivariate statistical technique to further identify the possible latent relational structure among all the variables. Particularly, we performed exploratory factor analysis (EFA) to reexamine the grouping of variables and establish underlying dimensions that could explain the correlations, thereby allowing the formation and refinement of theory in the context of using mobile games to support Mandarin learning to a group of non-native learners. In other words, we tested the construct (i.e. factor) validity of the questionnaire with the factor analysis. The factors that explain the highest proportion of variance the variables share is expected to represent the underlying constructs [21].

To determine the suitability of our Likert-type questionnaire data for EFA, we perform Barlett’s test, and it returns p-value < 0.05 showing that the items correlate anyhow and EFA may be useful. Besides, the positive determinant of the correlation matrix suggests that EFA will probably run. We then determine the number of factors to retain by constructing the screen plot, as illustrated in Fig. 8. Together with parallel analysis, we take the number of factors as two for further analysis.

Fig. 8. The Screen Plot based on the Unreduced Correlation Matrix and Parallel Analysis.

We then carried out the exploratory factor analysis using maximum likelihood estimation procedure and its results are depicted in Fig. 9. Seventeen Likert-type items in the questionnaire make up the first factor and 9 items the second factor. Item E4 may be ignored as its load is lower than 0.3 for both factors. This implies that the measurement on students’ expectation is irrespective of whether the mobile game is available online or not. Also, from such a regrouping of variables, we could say that the correlations among all the variables might be categorized into two broad dimensions, in which the first dimension includes the students’ motivation, cognitive development and expectation whereas the second dimension mainly covers game interface. It is interesting to point out that variables related to students’ attitude with the mobile game are split into two dimensions, whereby items B1, B6 and B7 fall under first dimension while the remaining items B2 to B5 are in second dimension.

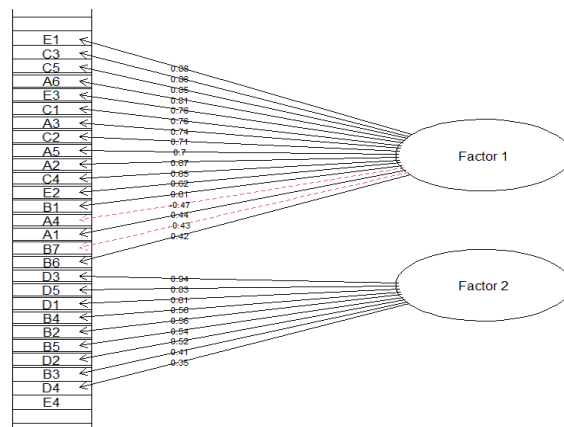

Fig. 9. Regrouping of Variables using Exploratory Factor Analysis.

V. CONCLUSION

This paper presents the adoption of GQM as an interdisciplinary tool to access the mobile mandarin app. With the GQM, we can summary the benefits of GQM as following. 1) Better structure of the experiments; 2) able to reach consensus among researchers from different disciplines; 3) able to analysis the dependencies among various experiments; 4) able to find hidden results. The GQM can structure the experiments and drive the communication among the researchers. It is also able to consolidate various experiments and preset the results in a more systematic manner as described in the previous section. In addition, the GQM can reduce the overlapping of method used, parameters and questions among different evaluation techniques that are used by the researchers. With GQM, we can discover the relationship across the experiments that are conducted by researchers. For example, the pre-test and post test results are able to continue study the cross culture learning among the students. The results can provide the answer to the question in achieving the goal of 'ensure cross culture learning'. On the other hand, the number of dimension and list of constructs can further be extended with factors like security and privacy to ensure the achievement of subgoals, 'ensure secure learning' and 'ensure privacy protection'. The contribution of this research is to demonstrate how GQM can be used as an interdisciplinary tool when assessing mobile learning application among researchers

from software engineering SE, language study, and mathematics. From the results, the mandarin learning app can serve as a complemented tool on conventional mandarin lesson. The post test results are more than pre- test results. Hence, the games can improve student results. They are two major dimensions in making the mandarin learning app success among our students. The success of the mandarin learning app is due to high student motivation, high cognitive development from the games plays and the games meet the student expectation. Meanwhile, the games are user friendly. In future, more works are required to investigate the adoption of others concept from agent models [22][23][24] into GQM. For example, to use HOMER questions in forming the questions is yet to explore.

Abstract—Biomedical imaging is a rapidly evolving field that covers different types of imaging techniques which are used for diagnostic and therapeutic purposes. It plays a vital role in diagnosis and treating health conditions of human body. Classification of different imaging modalities plays a vital role in terms of providing better care and treatment options to the patients. Advancements in technology open up the new doors for medical professionals and this involves deep learning methods for automatic image classification. Convolutional neural network (CNN) is a special class of deep learning that is applied to visual imagery. In this paper, a novel spatial feature fusion based deep CNN is proposed for classification of microscopic peripheral blood cell images. In this work, multiple transfer learning features are extracted through four pre-trained CNN architectures namely VGG19, ResNet50, MobileNetV2 and DenseNet169. These features are fused into a generalized feature space that increases the classification accuracy. The dataset considered for the experiment contains 17902 microscopic images that are categorized into 8 distinct classes. The result shows that the proposed CNN model with fusion of multiple transfer learning features outperforms the individual pre-trained CNN model. The proposed model achieved 96.10% accuracy, 96.55% F1-score, 96.40% Precision and 96.70% Recall values.

Keywords—Biomedical images; convolutional neural network; ensemble deep learning; feature fusion

I. INTRODUCTION

Biomedical imaging refers to capturing of an organ or tissue for diagnostic purpose. The field is very broad and rapidly evolving that covers different types of imaging modalities like ultrasound, magnetic resonance imaging (MRI), computerized tomography (CT), positron emission tomography (PET), etc. [1]. Biomedical and medical imaging plays a significant role in diagnosis and treating health conditions of human body. It helps to identify problematic health conditions in their early stages that certainly lead for providing better treatment to the patients [2]. The structural and functional changes in biological tissues of the human body normally cause the possible health problems. Biomedical imaging provides a way to view inside the human body that helps to reveal such changes [3].

Classification of different imaging modalities plays a vital role in terms of providing better care and treatment options to the patients. The traditional way to classify these different modalities of images is the naked eye classification that is

performed by medical professional or subject expert. This is the cumbersome and sometimes time-consuming method. Advancements in technology open up the new doors for medical professionals that involve computer-aided diagnosis (CAD) methods for automatic image classification [4]. The increasing advancement in the field of medical imaging technology, medical research and diagnosis become easy. Various types of imaging modalities and procedures are included in medical imaging technology that helps in diagnosis and treatment of the patients. Hence, it plays a dominant role in deciding the actions for the benefit of the patient's health.

In past few years, artificial intelligence (AI) brings a new way for analysing and interpreting data that also called predictive analysis that helps to identify the early signs of any of the health conditions [5]. Deep learning, an approach of AI, emerged as an outperformer in interpreting and analysing image data. Significant advancement has been made in the field of medical image diagnosis that improves disease diagnosis process significantly. Deep learning uses the architecture of artificial neural network that mimics the working of human brain. The complex computer vision tasks are effectively solved by the deep learning algorithms such as image recognition, classification and segmentation. The special class of deep learning algorithms is known as a convolutional neural network (CNN) is widely used to solve image classification problems and achieved a significant performance on benchmark datasets. The reason behind popularity of CNN is the large availabilities of datasets and support of powerful Graphics Processing Units (GPU) that makes the integration of deep learning methods with computer vision popular [6].

There are several distinct imaging modalities in which biomedical images are generated. They are different in shape and types. Due to the diverse data distribution patterns, it may happen that the same CNN model may show different performance on different datasets [7]. CNN models are sensitive to the particulars of the training data. This makes possible that each time they are trained; they may find a different set of weights. These different predictions generate high variance [8]. Moreover, these deep features face the problem of small intra-class variance and large inter-class variance [9].

To address the above issue, a novel spatial feature fusion-based approach for biomedical image classification based on ensemble Deep CNN and transfer learning is proposed. We

have used stacked generalization that is an ensemble learning method. We have used four benchmarked pre-trained CNN models as a deep feature extractor. Extracted features from different networks are merged using spatial feature fusion method. Finally, two FC (fully connected) layers with ReLU are used along with one FC layer with softmax activation function.

The major contributions of the paper include: (a) To propose an ensemble learning framework for creating a deep feature extractor that combines transfer learning features from more than one pre-trained CNN models (b) To apply a spatial feature fusion technique that creates a generalized feature space from extracted features (c) To proposed a deep CNN model that can be used for biomedical image classification with increased prediction accuracy.

II. RELATED WORK

Health care is one of the fastest growing sectors that is delivered by health experts. It is sometimes difficult to recognize disease patterns from huge number of medical images. The special classes of Artificial Intelligence (AI) are machine learning and deep learning algorithms. These algorithms give impressive results for classification of biomedical images. Image classification is considered as one of the computer visions tasks. Many researchers have been worked in biomedical classification that resulting several robust methods that can be categorized into two types; traditional digital image processing techniques and deep learning models. The traditional image processing methods involves manual feature extractions methods whereas deep learning models perform the feature extraction without manual intervention.

N. Sharma et al [10] used texture primitive features to perform segmentation along with classification of medical images. They have used artificial neural network (ANN) for designing the algorithm that performs segmentation and classification. The algorithm has been used for CT and MRI images of distinctive body parts like brain and liver. Ahmed M. Sayed [11] applied machine learning techniques for diagnosis of breast cancer from MRI images. The highest classification accuracy is 94/6% given by KNN. M. I. Daoud et al [12] proposed a fusion approach based on multiple ROI for classification of breast ultrasound image. GLCM texture features are extracted in each ROI that are further classified using binary SVM classifier. The dataset considered for the experiment contains 64 benign and 46 malignant tumor images. The proposed approach provides very promising results with 98.2%, 98.4%, and 97.8% values for accuracy, specificity, and sensitivity respectively. P. Chak et al [13] proposed an Artificial Neural Network (ANN) and SVM based approach to classify the kidney stone images. To extract the features from the CT images, GLCM method was used. The ANN approach gives 95% accuracy, whereas SVM approach gives 99% accuracy. P. Nanglia et al [14] proposed a hybrid algorithm for classification of lung cancer images. The dataset considered for

an experiment contains 500 images and the overall accuracy of the approach is 98.08%.

Deep learning is effectively applied for various domains, including satellite imaging, observation frameworks, mechanical and medical procedures, and precision agriculture. Several researchers have worked upon applying deep convolutional neural network for different medical applications. H. T. Nguyen et al [15] improved the prediction of disease using shallow CNN. They have applied data visualization techniques on Metagenomic data and achieved promising results. S. M. Anwar et al [16] proposed deep transfer learning and LDA (Linear Discriminant Analysis) based approach for classification of medical image modality. They have considered pre-trained ResNet-50 model to implement transfer learning approach along with LDA approach. For experiment, a benchmark ImageCLEF-2012 dataset was considered. The classification accuracy obtained is 87.91% that is significantly better as compared to the state-of-the-art approaches. C.-H. Chiang et al [17] applied CNN for automatic classification of medical image modality. They have considered multiple image modalities that include CT images of abdomen & brain and MRI images of brain and spine. The accuracy achieved for validation and test sets are greater than 99.5%. Moreover, the F1-score for each of the category is greater than 99%.

B. P. Battula and D. Balaganesh [18] propose a hybrid model for medical image classification based on CNN and Encoder. HIS2828 and ISIC2017 are the datasets considered for the experiment. The results show that the accuracy of the proposed model is better than the existing models. A. A. Goma et al [19] discussed about how CNN and GANs are used to improve early prediction of plant disease. They have considered a tomato plant images that are infected with Tomato Mosaic Virus for conducting an experiment. The proposed CNN provides 97% accuracy. S. Patel [20] classified bacterial colony images using Atrous convolution using transfer learning approach. The dataset considered for the experiment contains 660 bacterial colony images classified into 33 distinct classes. The proposed model replaces the standard convolution layer of the VGG-16 pre-trained model with the Atrous convolution. The training and validation accuracy obtained from the experiment are 95.06% and 93.38% respectively.

III. PROPOSED METHOD

In this research, we have proposed a novel spatial feature fusion based Deep CNN model for biomedical image classification. We have developed a feature fusion network using Ensemble deep CNN that leverages the power of state-of-the-art pre-trained CNNs. Ensemble learning is the technique that combines different individual CNN models in order to increase prediction accuracy through generalization [21]. As shown in Fig. 1, the proposed model has three stages, (a) deep feature extraction and feature maps (b) spatial feature fusion of deep transfer learning features and (c) classification.

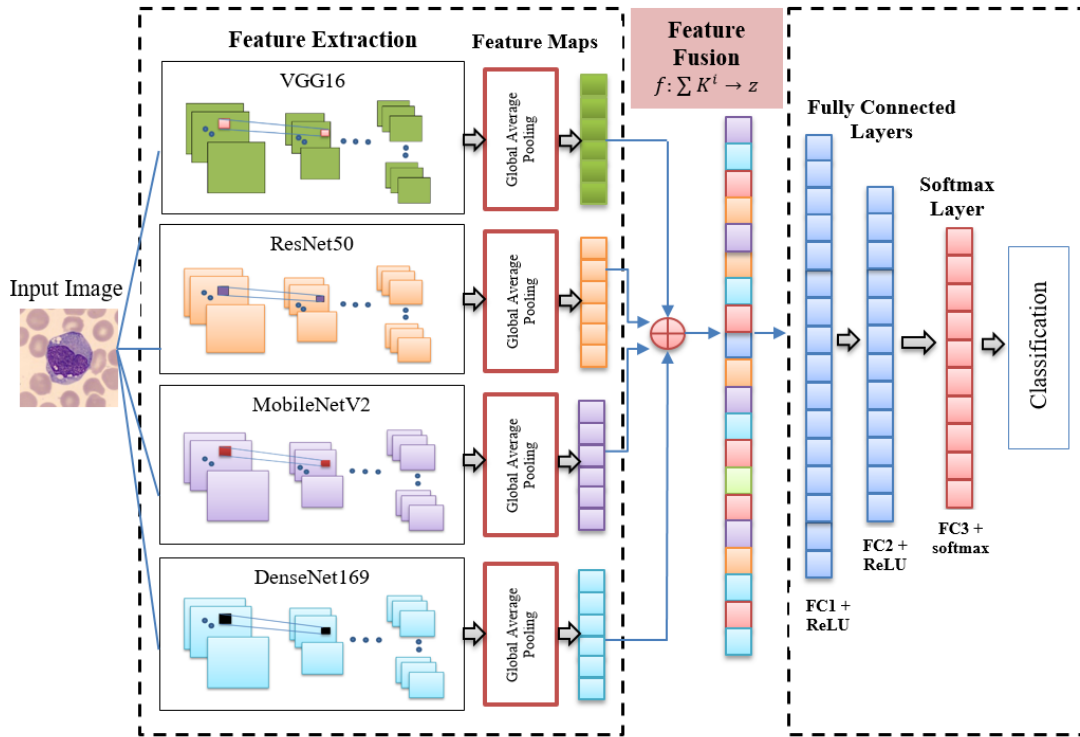

Fig. 1. Spatial Feature Fusion based Deep CNN Model using Ensemble Deep CNN and Transfer Learning.

A. Deep Feature Extraction and Feature Maps

Feature extraction and feature map generation is the crucial step for classification of images using deep learning networks. A deep learning network normally requires a large amount of resources and dataset to be trained for precise feature extraction. The common practice followed is to use the pre-trained model instead of building and training the CNN model scratch. There are several pre-trained CNN models already exist which are developed to solve a similar problem [22]. All modern pre-trained CNN models have emerged from the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) challenge [23]. The challenge is organized yearly from 2010 to 2017 that provides a platform for researchers to present their algorithms related to object localization and image classification tasks. The pre-trained models belong to ILSVRC are trained on ImageNet dataset that consists about 14 million images categorized in several classes. The pre-trained models used the concept of transfer learning, i.e. knowledge gained by solving one problem can be applied to solve similar related problems by using an already trained model to learn a different set of features. It eliminates the need of large amount of data with significant better performance along with reduced convergence time [24]. The commonly used pre-trained models are VGG16, VGG19, MobileNet, InceptionNet, ResNet, DenseNet, etc.

We have followed stacked generalization ensemble [25] approach to ensemble four pre-trained CNN models. For that, as the preliminary step, four benchmarked CNN models i.e. VGG19, ResNET50, MobileNet and DenseNet are considered as base models for the proposed novel model. We have reused these pre-trained networks with the parameter they have

learned on ImageNet dataset. Also, we have removed their final softmax classification layer as it contains 1000 neurons. We have frozen all the intermediate layers of base models to keep their original trained weights. After that, the global average pooling is applied for dimensionality reduction and an output feature vector is created for each of the base model.

B. Spatial Feature Fusion of Deep Transfer Learning Features

Fusing the features obtained from various pre-trained CNN models supported many applications to achieve better performance than the conventional approach of utilizing the single deep CNN network for the task of classification [26]. The classification approach presented in this paper maps the feature space obtained by various pre-trained CNN models like VGG16, ResNet50, MobileNetV2 and DenseNet169 to a generalized feature space [26]. The feature space generated by each feature extractor with different dimension is represented as:

$$f_i = \{F_i^{(m)}\}_{m=1}^j \quad (1)$$

Where $i=1, 2, \dots, N$ represents the number of images in the dataset and $m=1, 2, \dots, j$ represents the number of pre-trained CNN models used as feature extractors. The cumulative feature set for a particular image sample is defined as:

$$f_k = \{f_k^1, f_k^2, f_k^3, \dots, f_k^l\} \quad (2)$$

Where, f_k^i is representation of i th dimension feature in the given k th sample and $i, i \in [1, D]$ represents the individual feature dimension. Thus, features obtained by the particular

CNN model forms individual feature space [27]. This, individual feature space is defined as:

$$\psi = \{f_1, f_2, \dots, f_n\} \quad (3)$$

Where $f_i, i \in [1, n]$ is the feature set of individual sample and n represents the total number of samples in the dataset.

Feature fusion technique combines heterogeneous features obtained from various CNN models and utilize combined features for comprehensive processing for the cumulative decision-making. The feature fusion technique combines feature spaces obtained from individual CNNs and provide feature subspace, which is generalized than the original feature space. The feature fusion technique to create a generalized feature space is represented as:

$$f: (\psi_p, \psi_q, \psi_r, \psi_s) \rightarrow \psi \quad (4)$$

Where, f is future fusion function and ψ_p, ψ_q, ψ_r and ψ_s represents the feature spaces obtained by individual CNN model. The data imbalance and noise are the major limitations of the features obtained using individual CNNs. However, obtaining generalize feature vector by combining different feature spaces helps in selecting important features captured by different CNN models which leads to more accurate classification accuracy.

C. Spatial Feature Fusion

In this research, the spatial feature fusion algorithm fuses the feature maps obtained by four different deep pre-trained CNN models [28]. Hence, four pre-trained CNN models are connected with each other using feature fusion techniques and point of connection between four models is known as fusion point. The training of softmax classifier is the next step after the fusion point in order to achieve the result of the classification as represented in Fig. 1. The spatial feature fusion function represented as:

$$f: K^p + K^q + K^r + K^s \rightarrow z \quad (5)$$

Where, K^p, K^q, K^r and K^s presents the set of features extracted by feature extractor P, Q, R and S respectively. Here, z denotes the fusion space features' set and $K^p, K^q, K^r, K^s, z \in \psi^{LWD}$ where L states the length, W states the width and D states the channels of the feature set, respectively [28].

D. Classification

After feature extraction, it is required to classify the data into various classes. This can be achieved using fully connected layers. In the proposed model, the third stage is performing classification. We have obtained a final feature vector after performing spatial feature fusion. For classification, two FC layers with ReLU and one FC layer with softmax are added to the proposed network as depicted in Fig. 1. A Rectified Linear Unit (ReLU) is used as an activation function for the first two fully connected layers. As the network classifies the input image into eight distinct classes, the last fully connected layer is applied with the softmax activation function.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

The details regarding dataset, experimental setup and results are discussed in detail in this section. We have implemented the proposed ensemble CNN model using spatial feature fusion along with single model of VGG16, ResNet50, MobileNetV2 and DenseNet169.

A. Dataset

The experiment was performed on the microscopic images dataset that represents peripheral blood cell images [29]. The dataset contains 17902 microscopic jpg images with size of 360 X 363 pixels. The images are captured in the Core Laboratory at the Hospital Clinic of Barcelona. The images are taken using the analyzer CellaVision DM96. These all images are annotated by the clinical expert pathologists. The dataset contains very high-quality labelled images that can be used to train any algorithms belonging to machine learning and deep learning. The dataset categorized into eight distinct groups that are platelet, neutrophil, monocyte, lymphocyte, immature granulocytes, erythroblast, eosinophil and basophil. The dataset is specifically used for hematological diagnosis using computational tools. All the images of the dataset are acquired from the year 2015 to 2019 [30]. Fig. 2 represents the sample images from platelet, neutrophil and monocyte class.

The proportion of images in the dataset is represented in Fig. 3. As mentioned earlier there are 17902 microscopic images that categorized into 8 distinct classes.

From the dataset, 80% data are used for training and 20% data are used for validation.

Fig. 2. Sample Images of Platelet, Neutrophil and Monocyte Classes.

Fig. 3. Distribution of Microscopic Peripheral Blood Cell Dataset.

B. Environment Setup

The experiment is carried out on a workstation configured with an Intel® Core™ i7 8th generation processor, 32GB RAM, and NVIDIA Titan XP GPU with 64-bit Windows 10 operating system. To build the model for microscopic peripheral blood cell images classification, TensorFlow and Keras [31] API are used. TensorFlow is an open-source library and it provides many of the high-level and low-level APIs. Keras is one of the high-level API that built upon the TensorFlow library. It is a user-friendly and extensible library that makes the building of deep neural network fast. Keras offers various building blocks like activation functions, layers, optimizers, batch normalization etc. that are required to build a convolutional neural network. It provides the functionalities to run the CNN on a graphical processing unit (GPU) or tensor processing unit (TPU).

C. Network Training and Hyperparameter Tuning

One of the pre-requisite for any of the CNN model deployment is Training. One of the good practices is to use the pre-trained model instead of building and training the CNN model from scratch. Transfer learning is about re-using the pre-trained CNN model for solving a new problem [32]. All benchmark pre-trained CNN models are trained on the large dataset like ImageNet, PASCAL, COCO, etc. In this research, the weights along with learning of pre-trained model are transfer in the CNN model. Also, a fine-tuning process is performed by unfreezing the few of top layers to retrain them for classification purpose [33]. The dataset considered in the experiment is a small dataset as it contains 17902 images categorized into 8 distinct classes. Transfer learning and fine-tuning is performed by removing the last layer and introducing fully-connected softmax layer for the purpose of classification.

The basic building block of CNN model is artificial neural network. Thus, CNN models possess self-learning capability. For that, during training process, the weight of the network is adjusted in order to minimize the loss function [34]. There are set of parameters which controls the entire training process [35][36]. In this experiment, model specific hyperparameters are used. Table I summarizes the hyperparameters along with their optimized value.

TABLE I. OPTIMIZED VALUES FOR HYPERPARAMETERS

Hyperparameter (s)	Values
Number of Epochs	20
Learning rate	0.001
Batch size	32
Optimizer	SGD
Activation Function	ReLU / softmax
Dropout Rate	0.5

D. Evaluation Metrics

The benchmark evaluation metrics such as Precision, Recall, and F1-score are used to evaluate the performance of the proposed model. The equations used for the evaluation metrics are as per following.

$$\text{Precision}(r) = \frac{TP(r)}{TP(r)+FP(r)} \quad (6)$$

$$\text{Recall}(r) = \frac{TP(r)}{TP(r)+FN(r)} \quad (7)$$

$$F1 - \text{Score}(r) = \frac{2}{\frac{1}{\text{Recall}(r)} + \frac{1}{\text{Precision}(r)}} \quad (8)$$

Here, TP and FP are the true positive and true negatives, respectively. TN and FN are the true negatives and false negatives, respectively. To get the values of TP, TN, FP and FN, N X N confusion matrix is used, where N represents the number of classes available in the dataset [38]. The confusion matrix compares the actual values with the predicted values predicted by CNN model. It represents the values for TP, TN, FP and FN [37].

V. RESULT AND DISCUSSION

In this section, the performance of the proposed ensemble CNN model along with the performance of each individual CNN model i.e. VGG16, ResNet50, MobileNetV2 and DenseNet169 is discussed. To evaluate the performance of the model, two metric namely accuracy and loss are considered. The average accuracy and average loss for training and validation are measured. Accuracy is a metric used to measure the performance of a model. The accuracy is defined as:

$$\text{Accuracy} = \frac{TP+FN}{\text{Total no of samples}} \quad (9)$$

Where TP is the true positive and FN indicates false negatives [38].

Loss is defined as an error happened in prediction by a model. It is calculated by the difference between the value predicted by a CNN model and an actual value present in the dataset. While training the CNN model, the aim is to decrease the loss by optimizing the weights. Usually, two functions are used to measure a loss namely mean square error and cross-entropy. The cross-entropy is used to measure the loss and the formula is defined by the following equation [39].

$$\text{Cross - entropy} = - \sum_{i=1}^n \sum_{j=1}^n y_{i,j} \log(p_{i,j}) \quad (10)$$

Table II shows the values obtained for training and validation accuracy and loss respectively. It can be observed that the proposed CNN model achieved the highest accuracy i.e. 96.45% during training and 96.10% during validation. Moreover, it has the lowest loss i.e. 0.028 during training and 0.024 during validation. It shows that the proposed CNN model learns well as compare to the other models.

TABLE II. ACCURACY AND LOSS VALUES

Deep Learning Model	Training		Validation	
	Accuracy (%)	Loss	Accuracy (%)	Loss
Proposed CNN Model	96.45	0.028	96.10	0.024
DenseNet169	93.10	0.036	92.69	0.039
MobileNetV2	92.78	0.045	92.91	0.042
ResNet50	92.10	0.059	91.75	0.063
VGG16	87.56	0.097	86.80	0.089

Fig. 4. Accuracy and Loss for the Proposed CNN Model.

The proposed CNN model also converges adequately and it can be shown from Fig. 4. The figure represents the accuracy and loss curves obtained during training and validation. Fig. 4 shows that the curves for both; training and validation for accuracy are going parallel and close to each other. Moreover, the loss curves are also going parallel and close to each other. This shows that model is trained adequately without facing the issues of underfitting and overfitting.

Table III represents the values for the precision, recall and F1-score for the different models obtained during experiment.

The F1-score, Precision and Recall values for VGG16 are 87.30%, 87.45% and 87.15 respectively. For ResNet50, the values are 92.17%, 92.25% and 92.10% respectively. MobileNetV2 provides 92.76%, 92.75% and 92.82% for F1-score, Precision and Recall. DenseNet169 gives 93.02%, 92.90% and 93.15% for F1-score, Precision and Recall. However, the proposed CNN model outperforms all other individual pre-trained CNN models and provides the highest values i.e. 96.55%, 96.40% and 96.70% for F1-score, Precision and Recall respectively.

From the results, it can be concluded that the spatial feature fusion approach for classification of microscopic blood cell images provides better results with enhancement in learning ability. The generalized transfer learning feature space developed by deep feature extractor reduces the problem of bias and variance while increase the performance. Hence, the proposed CNN model has better performance than the individual pre-trained CNN models.

TABLE III. PRECISION, RECALL AND F1-SCORE VALUES

Deep Learning Model	F1-Score (%)	Precision (%)	Recall (%)
Proposed CNN Model	96.55	96.40	96.70
DenseNet169	93.02	92.90	93.15
MobileNetV2	92.76	92.75	92.82
ResNet50	92.17	92.25	92.10
VGG16	87.30	87.45	87.15

VI. CONCLUSION

Deep learning models provide promising results in biomedical image analysis. It brings a new way for analysing and interpreting data that helps to identify the early signs of health conditions. A spatial feature fusion approach for biomedical image classification based on ensemble deep CNN and transfer learning is proposed in this paper. For that, the generalized transfer learning feature space is developed and a spatial fusion is applied to merge the learned features of different pre-trained CNNs. The paper covers the details of implementation and evaluation of the most proposed CNN model for classifying microscopic peripheral blood cell images. The dataset contains 17902 images of blood cell that are categorized into 8 class labels. The experiment shows that the proposed ensemble CNN model outperforms individual pre-trained CNN model and provides better precision, recall and F1-score values.

Abstract—Simulation tools play an integral and significant role in studying the applicability and effectiveness of different algorithms for solving real-world problems cost-effectively. In the case of Internet-of-Things, the issues associated with real-world implementation are exponentially multi-fold. Although various simulators have facilitated the evolution of schemes to address the problems in IoT applications in the last few years, their applicability in the real world is highly questionable. Hence, this paper discusses the potential features of existing simulations (both commercial and research-based) and investigates features of different assessment environment tools to understand their current state. The paper further contributes toward a distinct research pattern. The core contribution of this manuscript is to review standard practices of using simulation tool along with different test environments. The paper also contributes towards exploring various prospects of unaddressed problems associated with a usage of existing simulation environment/tool for investigating the challenging and practical environment of an IoT ecosystem. The learning outcome of this study will assist the reader to make a decision towards adopting precise simulation tool for their work as well as it also highlights the need to perform more number of customization towards including the features that is found in research gap.

Keywords—Internet-of-things; real-world; application; simulation model; environment

I. INTRODUCTION

The process and various operation ranges involved in the real world are sometimes quite challenging to investigate and study, considering real-world entities. This problem can be solved by using simulation modeling to efficiently and safely perform the processes to offer solutions [1]. The implemented methods using different spectrums of the algorithm during the simulation study facilitate a simplified verification process over-controlled research environment [2]. This paper discusses the simulation perspective of studying various problems in Internet-of-Things (IoT), a network of different physical devices called things with distinct identifiers [3]. The dependable attributes for framing an IoT ecosystem are communication devices, sensors, processors, etc. [4]. An edge device or an IoT gateway node collects the sensory data shared via IoT devices and is forwarded to the cloud for storage or analysis [5]. However, implementing such a large ecosystem of an IoT is comprehensively a massive task as they are also associated with various implementation impediments, e.g., challenges of inappropriately aggregated data, processing of

unstructured data, ensuring coverage and connectivity of a large number of IoT device, ensuring power management for resource constraint sensors, challenges associated with data storage, integrating with all points of an IoT with appropriate software, proper identification of an IoT device with legitimate authentication, and compatibility issues of a large number of heterogeneous system in an IoT [6]. However, it should be noted that IoT is not only about sensory data collection [7], routing [8], and storage [9], but it is strongly related to potential data analytical operations, too [10]. At present, there are various schemes to ensure an effective operation of IoT communication in the majority of the perspective [11]-[14]; however, it is seen that the majority of such studies are carried out using a simulation-based approach while only a few proportions of work is carried out over real-time models and data. Both such schemes (real world and simulation-based) have their benefits and limitation. However, simulation-based studies are still more favorable toward cost-effective analysis, leading to much successful deployment in the real world. However, such a simulation-based approach should be deeply investigated to find out if they are really at par with solving impending problems in an IoT.

There is no doubt about the availability of a list of different simulators in current times for deploying novel logic for implementing an IoT. However, questions still arise about the taxonomies of such simulators, the discrete beneficial features towards cost-effective deployment, judging the applicability of simulation outcomes in the practical world, and finding the most adopted simulation tool in recent years. Finding answers to these questions will eventually guide better decision-making, either towards adoption or the evolution of new simulators in IoT. The prime motivation of the proposed study is to showcase the discussion on simulators with a higher and lower adoption rate in the last few years. Therefore, the *novelty* of the proposed study is towards assessing the functionalities and features of existing simulators towards investigating problems in IoT. Finally, the study also elaborates on the first and second levels of the research gap, unlike any existing research update. The contribution of the paper is as follows:

1) The paper offers a brief and compact insight towards the existing 5 standard simulation tools of an IoT exercised in commercial sector as well as 16 frequently adopted simulation tools practiced in research-based area.

2) The paper highlights essential characteristics of 6 standard environments adopted for assessing the protocols and algorithms meant for an IoT environment.

3) Existing trends of research work that is found towards developing simulation-environment is discussed in this paper that assists in highlighting the highly adopted simulation tool for studying IoT ecosystem.

4) The paper exclusively discussed elaborately about the research gap associated with the existing developments towards IoT simulation tool that offers critical information about unaddressed research problems.

The manuscript's organization is as follows: Section II discusses the existing simulation tools into practice, while Section III discusses the assessment environment offered by such simulation tools. Discussion of existing research trends towards using simulation tools is carried out in Section IV. In contrast, a meeting of the research gap is carried out in Section V. Finally; Section VI provides conclusive remarks and future work direction.

II. SIMULATION TOOLS FOR IOT

The simulation tools for assessing the performance of a newly developed logic for an IoT environment must adhere to standard vital parameters. With an expected budget of communication link above 164 dB and modulation method of either BPSK or QPSK for uplink transmission and QPSK for downlink transmission, the simulation for an IoT should be set up in FDD half-duplex mode. The simulation key parameter includes 64 kbps and 25 kbps of uplink and downlink data transmission with a latency of around 10 seconds. The most simulation also considers SC-FDMA for uplink transmission while OFDM for downlink transmission. The above mentioned are the prevalent values of critical parameters to be considered while carrying out a simulation study. This section further highlights the frequently used standard simulation tool in an IoT as follows:

A. Commercial Simulation Tool

These are the commercially used tools to assess the conditional logic, novel logic for communication in an IoT, and during prototyping of certain sense of implementation in an IoT.

1) *MIMIC simulation tool [15]*: This simulator manages various essential entities in an IoT environment, e.g., all the connected devices, sensors, and gateway nodes. The idea is to form a standard test assessment scenario of IoT capable of deploying and evaluating Industry 4.0, architectures with event-driven approaches, agriculture, factories, and smart cities.

2) *IoTNetSim tool [16]*: This simulation tool can manage different variants of the IoT network environment and structural information of the heterogeneous IoT nodes. The core idea is to facilitate a better form of modeling toward network connectivity concerning target application logic. The complete simulation process is carried out over three layers, viz. i) cloud layer, ii) edge layer, and iii) IoT layer. The *cloud*

layer is responsible for obtaining and managing the data processed by the edge layer, particularly in the data center of an IoT. The processed information is then forwarded to the sophisticated virtual machine via a specific set of the authenticated host. The *edge layer* is responsible for obtaining the data from the gateway node, followed by further processing the data to forward it to the devices that run under the supportability of the cloud layer. The *IoT layer* is responsible for deploying and generating the sensing devices to transmit the data to the link node. Further, this data is forwarded to the gateway node that can access and process this data to be forwarded to the edge layer in the form of aggregated information.

3) *Cooja simulation tool [17]*: This is a frequently used simulation tool mainly for sensory application. Due to this capability, it is also used for an IoT environment with the involvement of sensors. This simulation tool can evaluate sensors with intelligent capabilities, different communication technologies, and frequently used internet protocols in an IoT. This simulation tool uses Contiki mote to simulate the real-time assessment environment capabilities. Three forms of windows carry out the complete operation of this simulation tool, i.e., i) network window, ii) control window for simulation, and iii) note window. The *network window* can exhibit the environments of all mores and their respective radio traffic. It can also organize the physical elements associated with the sensor mote for a more in-depth and practical analysis of sensory devices in IoT. The *control window for simulation* is responsible for managing all the execution during simulation and simulation speed. Finally, the *note window* can store the execution logic and contains all the essential simulation points. It should be noted that the standard protocol of 6LoWPAN is adopted by this simulation tool. Apart from this, the standard protocol of IPv6 is also adopted by this tool concerning devices compliant with the family of IEEE 802.15.4 standards. This prime dependency of this simulation tool to develop an IoT environment are mainly two viz. i) Contiki operating system as a part of a software module and Tmote Sky as a part of the hardware module. Using both software and hardware module, this simulation tool can perform initialization of sync nodes and sensor nodes followed by establishing a reliable communication using standard protocols. Further, the sensor node is transmitted to the sink node from the transmitting node by this tool.

4) *IBM Bluemix [18]*: This is one of the famous commercial simulation tools for assessing the prototypes without dependencies on the physical device associated with an IoT platform. It is an IoT platform made to be functional in the IBM open cloud system so that the developer can easily access the proprietary software of IBM. This can significantly evaluate certain essential vital functions and security features associated with mobile and web applications. The continuous availability of cloud services offers the practical application and service manageability.

5) *SimpleIoTSimulator* [19]: This is one of the simplified forms of commercial simulator used to assess the environment for many IoT devices. It also offers much supportability of conventional IoT protocols, e.g., HTTPS, CoAP, and MQTT. This simulation tool facilitates different vendors to enhance product quality by formulating a better test environment. It offers supportability of both IPv6 and IPv4 sensors with operational supportability towards the constraint environment of an IoT.

B. Research-based Simulation Tool

There is a big difference between the simulation tool adoption for commercial practices and research-based studies. The commercial rules call for simulation tools with specific evaluation features; however, this is not the case with research-based simulation studies. Research work towards an IoT environment calls for including many features, conditional logic, and a flexible deployment environment to testify the targeted logic. Hence, simulation tools adopted for research-based work offer a more discrete set of operations with comprehensive functionalities. This section highlights the existing research-based simulation tools (Table I) as follows:

1) *ANSYS-IoT simulator* [20]: This form of simulation tool analyzes various forms of challenges in an IoT. The core usage of this simulation tool is mainly to assess the cumulative integrity of sensing devices with innovative capabilities deployed in an IoT environment. It is also used to assess longevity and energy consumption and enhance reliability, followed by validation.

2) *Bevywise simulation tool* [21]: This tool is specifically used for the scenario when fog computing is used in collaboration with an IoT environment. The tool facilitates the virtual clients by deploying the MQTT protocol on-premise. It also offers different variants of functional assessment over the cloud environment by enabling the deployment of many commodity servers. Particularly helpful for the industrial IoT environment, this simulation tool offers an end-to-end solution considering the constraints of the practical world of IoT implementation.

3) *IoTIFY* [22]: This tool offers a software backbone for operations associated with hardware modules of an IoT. This tool provides a precise building of a digital lab by harnessing a simplified construction of an analytical model and virtualization of an IoT device. IT can be used for analytical scaling, solutions for load testing, and building prototypes of an embedded system. It also assists in generating records and can well manage IoT devices used in a fog computing environment.

4) *EdgeCloudSim* [23]: This simulation tool caters to the demands of IoT operation dependent on computational queries of edge devices. It can carry out sophisticated calculations and evaluate its capacity to process the query and allocate necessary resources. This simulation tool is mainly meant for developers to assess the impact of their machine parameters on the communication and processing needs of an IoT node.

5) *MobIoTSim* [24]: The majority of the existing simulators of IoT demand higher resources to be used and are meant to be run on computing devices, e.g., desktops or laptops. This simulation tool is intended to simulate mobile-device built on the Android operating system.

6) *TOSSIM* [25]: This is another frequently used simulator by researchers who adopts sensor mote running on TinyOS. Hence, this tool can assess the smart sensory application running over an action-based operating environment.

7) *SWE Simulator* [26]: This simulation tool is mainly meant to assess the large-scale deployment scenario of IoT, including sensors. The tool also assists in effective cost control during implementation scenarios. It can also evaluate the presence of any risk factor and its possible influence. The simulation tool also uses observation services of sensors to develop topology and assess the performance of the assessment in an IoT.

8) *Atomiton* [27]: This is another simulator capable of simulating all the innovative sensory applications and involving different forms of actuators. Hence, this simulation tool assesses a specific state of the operating environment used for the complex operation of smart sensors in an IoT.

9) *QualNet* [28]: When the simulation study demands high-end accuracy, this is a preferred simulation tool for IoT applications. However, it should be noted that not all sensor devices are used for this form of simulation. Only the sensors compliant with specific families of IEEE 802.15.4 consider smart sensors. Although this is a commercial simulation tool, they are used extensively for research-based study. It also offers enriching interactivity owing to the improvised form of the Glomosim simulator.

10) *NS3 Simulator* [29]: This frequently used network simulator considers networks of the practical world scenario in IoT. The prime usage of this simulator is to assess the robustness of security features to resist various threats in the communication environment of an IoT. The tool offers the developer to use python and C++ for scripting while making use of the standard protocol of LTE, ZigBee, and 6LOWPAN. While working in an IoT environment, this tool adds three discrete types of devices, e.g., IoT node, blockchain, and Gateway. This simulation toolbox also assists in routing the class of all these entities in an IoT. The prime set of operations in an NS3 is to deploy the sensing IoT nodes, followed by applying standard protocol implementation of MQTT, HTTP, and CoAP. Finally, the data is forwarded to the sink.

11) *OMNet++* [30]: This simulation tool is popularly known for its discrete event simulation facilitation. A unique discrete simulation environment is constructed using enriched libraries from C++. Inspired by the Eclipse environment, this tool uses high-level language to develop more prominent components. It thereby forms an object-oriented model of simulation that could be used for different apps.

12) *SimIoT* [31]: This simulation tool can be used for any IoT system characterized by the static or dynamic attributes in a trial and error process. This mechanism is primarily meant

for managing the clouds environment system concerning its host of data centers. It assists in both method construction and the configuration of various entities.

13)CupCarbon [32]: This simulation tool is mainly used for assessing wireless sensor networks in their discrete form using multi-dimensional visualization features with multi-agents. Different forms of distributed algorithms can be validated using this simulation tool. It can also validate various iterative tasks over automation processes mainly meant for industrial applications. Further, it can also evaluate different forms of routing schemes, protocols, communication, and topologies in wireless networks involved in an IoT.

14)IoTSim [33]: This is another popular simulation tool used in IoT deployed alongside cloud environments. It can also be an extension of the popular cloud-based simulation CloudSim. One of the significant functions of this simulation tool is that it assists in processing big data that uses distributed software framework MapReduce. The process of identification,

as well as outcome analysis, is carried out using this simulation tool. It can be used for both research-based studies and industrial evaluation.

15)iFogSim [34]: This simulation is meant to carry out multiple levels of evaluation-based operation associated with different environment variants. It can simulate network connection, edge devices, fog data centers, IoT, etc. It can also be used for assessing another performance metric to be carried out over an IoT cloud environment. This simulation tool can also perform extensive assessments of various QoS metrics.

16)DPWSim [35]: This simulation tool profiles the devices synced with the web services associated with information exchanges, classification of services, and effective identification. This simulation tool is mainly used for explicit devices and applications related to the IoT to assess the dual form of operation, i.e., a function that enables hosting and processes that are being hosted. It also offers a better form of secure exchange of data

TABLE I. SUMMARY OF RESEARCH-BASED SIMULATION TOOL

III. ASSESSMENT ENVIRONMENT OF IOT

The previous section has elaborated on various existing simulation tools for evaluating various problems and their respective solution. It should be noted that the simulation tool facilitates the user to deploy their logic of implementation by reducing the same problem space of the IoT environment. It also enables various libraries to develop novel solutions. However, the simulation tool itself cannot be assumed to be 100% fulfilling the outcomes of the simulation study. For this purpose, there is a need for a legal assessment environment to be considered while carrying out the simulation study in IoT. Hence, the assessment environment provides a spectrum of IoT environments to analyze the solution model of researchers and assess troubleshoots, debugging, developing, and creating new logic, which is universally accepted. The prime advantage of considering a legal assessment environment is that it offers practical world usage of devices, interactions with the operating system, remote administration, and the capability to execute real-world devices/services/applications. Some of the standard assessment environments for simulating an IoT are JOSE [36], Smart Santander [37], FIESTA-IoT [38], FIT IoT-LAB [39], WHYNET [40], and MBTAAS [41] that are briefed as follows:

1) *JOSE* [36]: This assessment environment is meant for evaluating the devices or services associated with outdoor communication. It also offers many subject trials to facilitate resource computation, sensor network deployment, storage management, etc.

2) *Smart Santander* [37]: This is another standard assessment environment in an IoT that facilitates the adoption of many IoT devices along with small radio-based services and identification code deployment over both the static and mobility aspects of the nodes. This tool can evaluate traffic intensity mainly for the mobile environment in an IoT.

3) *FIESTA-IoT* [38]: This is one of the giant assessment environments considered during IoT simulation to offer its semantic and interoperable assessment feature. It integrates multiple numbers of another assessment environment in an IoT

to analyze the corpus of data. This large data further assists in facilitating webservices in live stream mode. The highly interconnected systems in this tool offer a significant ability to exchange information among various federated assessment environments in an IoT.

4) *FIT IoT-LAB* [39]: This form of assessment environment is made for performing experimentation on IoT on a huge scale. Various objects can be broadcasted and developed by this tool, considering many low-resource nodes for assessment. It also uses mobile robots to testify various upcoming innovative applications in IoT.

5) *WHYNET* [40]: Essentially meant for hybrid networks, this assessment tool is for performing realization of applications, protocols of WSN, heterogeneous networks, etc. Different forms of emulation and physical entities are carried out by this assessment tool using its single end interface itself. This environment can assess adaptive networks and large/small/medium scale networks in an IoT.

6) *MBTAAS* [41]: This tool is meant to offer assessment in the form of a service model. It also provides first-hand experience working over an IoT and getting acquainted with its functionality. The tool also provides various test-case formulations and solutions to multiple services to carry out an on-premise assessment of cloud-based IoT applications and services.

Table II summarizes the characteristics of the existing assessment environment of an IoT. One of the potential beneficial factors of using a standard assessment environment is that it enables all the entities and devices to carry out interactivity during testing that device. Hence, without constructing an actual physical device, adopting a standard assessment environment assists in truly justifying the effectiveness of its operation when exposed to a real-time environment. Although it is strongly advisable to use such a traditional assessment environment while carrying out a simulation study for an IoT, there are still various challenges. The primary difficulties are higher dependencies on assessment area, mobility of hubs, scaling operation, and repeatability.

TABLE II. SUMMARY OF EXISTING ASSESSMENT ENVIRONMENT

<i>Tool</i>	<i>Virtualization Support</i>	<i>Service domain</i>	<i>API integration</i>	<i>Built-in IoT Standards</i>	<i>A layer of IoT Architecture</i>	<i>Programming</i>	<i>scope</i>	<i>Type</i>

IV. EXISTING RESEARCH TRENDS

To understand the existing research trends, manuscripts published in the last six years have referred to the explicit usage of two different variants of simulation tools.

A. Adoption of Commercial Simulation Tools

There is a total of 256 manuscripts in IEEE Xplore digital library which has reportedly used commercial simulation tools, with 243 conference papers and 13 journal publication (Fig. 1).

They are mainly used to investigate problems associated with traffic management, object monitoring, indoor agriculture, security analysis, the discovery of resources, etc. Out of all this, some of the significant literature has been witnessed on IoTNetSim [16], Cooja [42]-[52], and IBM Bluemix [53]-[54] only. No significant modeling is being carried out towards using the MIMIC simulation tool and SimpleIoTSimulator. The advantage explored towards such adoption of commercial tools found are i) it offers a point-to-point exploration process for the target problem, ii) various prototyping using hardware are feasible to be investigated, iii) specific product or service-based analysis can be easily carried out. While the limitation found toward such adoption are i) it requires explicit skill to work on such tools, ii) various add-ons and software patches are required to be acquired to experience the full-fledged operation, iii) it doesn't offer extensible, cross-platform libraries for heterogeneous products/applications/services in IoT.

B. Adoption of Research-based Simulation Tools

One hundred seventy manuscripts are being reported to adopt research-based simulation tools, consisting of 126 conference papers and 44 journal papers (Fig. 2).

Fig. 1. Trends for Commercial on Simulation Tools.

Fig. 2. Trends for Research-based Simulation Tools.

This will eventually mean that the adoption of research-based simulation tools is a bit lesser than commercial simulation tools. It is also noted that the adoption of each tool is used to solve some common problems and specific problems. The common problems will include traffic monitoring and security analysis, while the specific problems investigated by these tools will be scheduling, data transmission, application-specific evaluation, etc. Some of the significant literatures that has reported towards using Ansys-IoT [55]-[57], Edge CloudSim [58][59], TOSSIM [60]-[62], QualNet [63], NS3 [64]-[74], OMNeT++ [75]-[83], iFogSim [84]-[96], and DPWSim [97][98]. The beneficial points of this adoption are: i) the majority is open-sourced, ii) user-friendly, iii) extensible environment for analysis, and iv) it doesn't require complex configuration or setup. While the limiting factors are: i) inbuilt methods and libraries are sometimes challenging to match with the problem space of analysis, ii) each simulator has distinct features and functionalities while migration or integration is sometimes not possible, and iii) quite specific to environmental usage in IoT.

V. LITERATURE REVIEW

From the prior section, it is noted that not all the simulation tools are widely used either in case of commercial or research-based practices. Cooja is highest used in commercial simulation while iFogSim is majorly used for research-based study. It should be noted that all simulators, in either of the

categories, have some common functionalities as well as some exclusive functionalities. The prime contribution of the manuscript is actually to judge the constraints as well as limiting factors associated with existing simulation tools. This is the core reason that the biometric analysis of this paper mainly consists of only studies that adopted 103 sources which has adopted simulation tools. The analysis of some of the recent work towards investigation IoT has also developed a computational framework on the basis of customized simulation study [99]-[103]. However, it is to be noted that adoption of simulation is one of the critical decision to be made by the researcher on the basis of the problems to be addressed in their model. An effective simulation tool should offer higher flexibility to assess the algorithm or protocol without much skill and re-engineering process. Unfortunately, this is not the case with existing studies as researchers tends to adopts frequently used standard simulation tools, which can cater up their investigation objectives. This is done by overlooking next sequence of investigation to be carried out in line of current research work. Apart from this, majority of existing simulation tool discussed in this paper doesn't offer much of customization privilege. Therefore, after reviewing the complete papers, this section discusses about the open-end issues in the form of contribution and thereby these findings are novel compared to any existing review work being carried out in current times.

A. Discussion of Research Gap

After reviewing the existing features of two variants of the simulation tool, standard assessment environment during simulation study, and research pattern, it is found that there are various contributory factors as well as open-end research issues. This section explicitly highlights the research gap in the first and second levels of research gap for better understanding.

1) *First level of investigation:* The first level of research gap will eventually mean all the open-end issues retrieved during the reviewing problem. IoT, which consists of highly interconnected devices in large numbers, consists of a multidisciplinary domain with multiple challenges that are quite difficult to assess. The existing simulation tools offer good privilege for investigating semantic queries, protocols, data transmission, routing, usability, privacy, and security considering various applications or services without considering scalability issues. At the moment of transition of problems associated with any factor from intra-net to inter-net, there is eventual evolution of scalability issues. Either commercial or research-based simulation tools cannot detect this. Although it is a well-known fact that repeatability of analysis is quite challenging in IoT, after knowing this fact, existing simulators don't offer much privilege toward addressing increasing heterogeneity of devices and information associated with it. Considering any use-cases of an IoT to be testified over current simulators, it is inevitable to assess multiple application domains (e.g., smart city, vehicular IoT, Industrial IoT, etc.). It will mean that such inclusion will extensively maximize the concurrency towards accessing the infrastructure. This is a computationally challenging task that is

not facilitated by any existing simulators, and developers are required to write a snippet or script for this. However, this doesn't solve the problem as the script written for one problem investigation may reasonably not be applicable when the problem space alters. The lack of formal assessment environment adoption is another justified reason for this. Well, adoption of all existing reported assessment environments cannot be always encouraged as they may vary too with the demands of simulation and the type of data being used. So, a more benchmark simulation environment is needed for an IoT. This eventually gives rise to multiple arenas of research questions, e.g.

- What strategy can be adopted for modeling heterogeneous IoT devices to facilitate concurrent operation?
- What mechanism can be adopted towards achieving granularity in investigation towards the inclusion of a massive number of IoT devices over dynamic topology?
- How to develop a cost-effective simulator which has an inclusion of the majority of privilege to investigate one single platform? Unless all these local issues are not addressed, existing simulators cannot be deemed entirely reliable.

2) *Second level of investigation:* The second level of research gap is the global level extracted from the first level as a local form. This research gap is the direct consequence of the first level gap analysis. Therefore, the following are the finalized version of the research gap.

a) From all the existing features available in simulators, one potential problem is that one simulator cannot be used to carry out an extensive investigation of the issues that are not supported by it. With concurrency towards accessing infrastructure, there are inevitable complexities associated with identifying the uncertain problems that stay low and hidden while contributing to declined or unpredictable outcomes. Hence, the primary research gap is existing simulators doesn't facilitate granular investigation to identify the attributes affecting the operation of IoT device/services.

b) A closer look at the local level of open-end issues in existing simulators are i) scalability, ii) device heterogeneity, iii) concurrency towards accessibility, etc. If all these problems are looked at deeply, it can be seen that the root cause of all of the issues is the lack of adoption of resource parametric modeling in the existing simulation tool. Current simulators can perform initialization of resource parameters while the developers must script the constraints associated with its usage. Such scripts are consistently required to be upgraded with the change of services or network operations. Hence, the secondary research gap is that existing simulators are not designed to practically consider the resource modelling of IoT devices and other devices in the process of simulation. The consequences of such modeling will lead to unrealistic data transmission simulation outcomes.

c) It is closely observed that security is a much more standard set of the problem being addressed by existing simulators. However, they do it by an available set of libraries and developers' written security scripts. Almost all these security approaches are based on cryptographic based. The prime reason is its dependency on using cloud or fog as an environment on top of IoT applications, which has higher supportability towards the conventional encryption-based operation. The beneficial point in this factor is that they are 100% stopping a specific set of attackers that is coded. The limiting factor is that they are entirely not applicable if the attacker changes its plan of attack.

d) Moreover, all the cryptographic algorithms are not resistive against all attacks; they have strengths and weaknesses. Another practical rationale is that adopting cryptographic measures will also induce a higher load toward low-powered IoT devices. Hence, the ternary research gap is that existing simulators don't address the IoT nodes' sustainability factor by frequently using cryptographic measures towards security.

B. Critical Discussion for Existing Study

From the outcome of this study, it is also found that majority of the simulation tools are part of discrete event simulators (NS3, OMNeT++, SimIoT, CupCarbon, iFogSim) which offers finite set of functionalities and demands API integration. It will eventually mean that customizing them for heterogeneous research problem will be a computationally expensive process. Apart from this, existing assessment tools are mainly meant to executing standard protocol for networking and not for data analytics, which require a dependency with different set of tools. The constraints found in existing simulation tool are also associated with accessibility towards single user for one project. This will eventually pose an impediment towards distributed investigation process by different user on same project at same time. Hence, the investigation process is time consuming and platform specifics too restricted to one user at a time. Another closer observation towards existing simulation tools highlights the inferior security features embedded in it. The enhancement towards security system is very few to find, where almost all the simulation tools either uses user-deployed security patches or uses third party script to introduce security features. This process is quite challenging to be customized for projects with multiple and heterogenous target of addressing problems in IoT. Hence, there is an emergent need to develop a simulation tool that offers cost effective and proper utilization of its features.

VI. CONCLUSION

This paper has discussed the scale of effectiveness of existing simulators. There are multiple simulators in practice; the discussion has been carried out concerning commercially used and research-based usage. The novelty of this manuscript is that i) it offers an informative and compact description of frequently used simulation tools in practice for an IoT, ii) It exhibits a unique and updated research trend towards IoT simulators adoption in the last six years, which is not reported

in any existing studies, and iii) it makes some interesting discoveries of limiting factors associated with the overall features of existing simulators. The above mentioned learning outcomes of proposed review work exactly matches with the core objectives of the paper associated with studying features as well as reviewing trends associated with simulation tools. The outcome of the paper also presents open-end research problem in the form of research gap discussion, thereby meeting the core study objective of this paper.

Hence, the future work will be carried out in the direction of addressing the finalized research gap as follows:

1) The primary research gap can be addressed by developing a novel computational model of a simulator to identify and construct a set of strategies that affect the accuracy of the simulation process. Discrete mathematical modeling can be carried out to address this gap.

2) The secondary research gap can be addressed by extending the first solution toward including various novel conditional logic. The development of such reasoning is accompanied by all the resource management attributes that affect IoT devices' sustainability factors during the simulation study. It will offer different reliable outcomes due to practical resource modeling during simulation.

3) The ternary research gap can be addressed by further developing another layer of security operation without using any form of encryption model or without using any existing techniques that are found to offer load towards low-powered IoT devices. Further novelty can testify to its resiliency towards maximum forms of reported threats in an IoT.

Abstract—As we all know that corona virus is announced as pandemic in the world by WHO. It is spreaded all over the world with few days of time. To control this spreading, every citizen maintains social distance and self preventive measures are the best strategies. As of now many researchers and scientists are continuing their research in finding out the exact vaccine. The machine learning model finds that the corona virus disease behaves in exponential manner. To abolish the consequence of this pandemic, an efficient step should be taken to analyze this disease. In this paper, a recurrent neural network model is chosen to predict the number of active cases in a particular state. To do this prediction of active cases, we need database. The database of COVID-19 is downloaded from KAGGLE website and is analyzed by applying recurrent LSTM neural network with univariant features to predict for the number of active cases of patients suffering from corona virus. The downloaded database is divided into training and testing the chosen neural network model. The model is trained with the training data set and tested with testing dataset to predict the number of active cases in a particular state here we have concentrated on Andhra Pradesh state.

Keywords—COVID-19; corona virus; KAGGLE; LSTM neural network; machine learning

I. INTRODUCTION

One of the journals Nature reported that these viruses are derived from unrecognized group called as corona virus and is identified by electron microscope. The full name of COVID-2019 is the Coronavirus disease of 2019, which has created panic in the whole world today. The total population of Andhra Pradesh in the year 2020 is 91,717,240 the people affected with the disease i.e., the confirmed cases are 4,45,139, the active cases of novel corona virus are 1,01,210 as of 2nd September, 2020 which has been taken from publicly available database [1]. All most all countries announced their states to lockdown in order to stop the travel of their citizens unnecessarily. Somehow the spreading of virus is controlled due to announcement of lockdown otherwise the spread of the disease is anonymous. Even though the economy of many countries was drastically dropped, the government announced lockdown. If anyone is found to be infected, she/he will be under quarantine for 14 days and treatment is given for

recovery. Base on the condition, it may cause death and many people gone to depression level. In India, the outburst of virus is disturbed the whole functioning life. At the starting stage, the cases are increased by transmission through local i.e., from person to person and later it is continued as the same [1]. The ways to detect corona virus by using rapid test kit, a portable device also detects virus in mucus membrane using a chip and a scanner and by taking a swab sample from patient's mouth or nose.

Till now there is no correct vaccine and anti-viral treatments are available and many medical organizations are trying hard to find out vaccine for COVID-19[2]. It is in our hands to save our lives from corona virus by providing personal protective equipments, masks and sanitization and maintaining social distance [3]. If we consider the present situation of COVID-19, the qualitative information is more prominent when compare with quantitative information. A best suited mathematical model is not able to predict the whole disease but, it may study the model to derive the nature of the disease. So, an appropriate machine learning/deep learning models are best suited to predict and study the nature and behavior of the whole disease shortly [4][5].

Artificial neural networks are very similar to our biological learning system that is interconnected with many several neurons in brain. ANN systems are provoked to confine this type of parallel computation based on distribution representations. To generate single valued output from real valued inputs, ANNs should be set up with a densely interconnected simple set of units. Here, interconnection is simply expressed as the means of processing the elements in neural network which are interconnected to one another [6]. So, the provision of all the elements and structure of connections are important in artificial neural network. Normally, we have three layers in ANN system. One is input layer where the inputs are feeding to the network and output layer, which generates outputs based on the inputs that we have provided to the system. The last and important layer is hidden layer where it acts as an interface between the input and the output layers. If we keep on increasing the hidden layers, the power required to process and computational speed can be increased and the entire system become complex.

Another class of ANN is recurrent neural network (RNN) [7]. The connections are formed between nodes and by a directed graph all along a series. This forms a dynamic behavior for a time series. These networks have feedback and form a closed loop. RNN also uses memory to process the series of inputs that we provided to the network. RNN have single layered recurrent network and multi layered recurrent network.

Fig. 1. Single Layered Recurrent Neural Network Model.

Fig. 1 is a network that represents a single layer network which provides a feedback connection in which each element of the node is given feedback to its own element or other element or can be to both.

Fig. 2. Multi Layered Recurrent Neural Network Model.

Here, in Fig. 2, the multilayered network is shown; the output of the element is directed to the other element of the same layer and to the previous layer which forms a multi RNN. Both the elements perform the same operation and the output depends on the previous calculations so here no need to have inputs at each step. The computations of the series are captured in the hidden layer.

II. RELATED WORK

Lin Jia et al. analyzed three different types of mathematical models namely Bertalanffy, Gompertz and Logistic models. They applied these three models for different regions and found different parameters. With these parameters, they found Logistic model gives the outer performance among all the three models [7]. Narinder Singh Punn developed mathematical models like SVR, DNN, RNN and PR to find the RMSE and concluded that PR model gives the less RMSE value when compare with other models [8]. Sarbjit Singh et al. developed a hybrid model which involves

the decomposition of dataset into series of components by applying discrete wavelet function and then these components are applied to a suitable model named as ARIMA model for prediction of death cases for next one month across five countries [9].

LinhaoZhong et al. proposed a mathematical model for early prediction of number of infected cases by using SIR model with minimum parameters like recovered rate and infectious rate. Since the number of cases are exponentially increasing manner, quarantine measures need to be followed strictly and must pay attention towards the medical service [10]. UtkucanSahin et al. presented a model to forecast the number of confirmed cases in UK, USA and Italy. The authors studied a nonlinear grey Bernoulli model, grey model and fractional nonlinear grey Bernoulli model to predict confirmed cases. In their study fractional nonlinear grey Bernoulli model offers the best performance of providing lowest MAPE, RMSE and R^2 values [11]. Lixiang Li et al. proposed suitable model to compare the official data and model predicted data and found the error is very small [12]. NaliniChintalapudi et al. presented a model using R statistics to forecast the registered and recovered cases [13]. Debanjan Parbat et. al. utilized SVR model for prediction of total number of recovered, death, confirmed cases and found the accuracy of the model along with MSE and RMSE [14]. SalihDjilaliet.al. presented a mathematical model to predict the spread of the disease transmission [15]. Patricia Melinet. al. proposed a neural network multi ensemble model with fuzzy response for the corona virus time series data to get valid and accurate predicted values [16]. Zlatan Car, Sandi BaressiSegota et al proposed a neural network model of multilayer perceptron to find R^2 values for recovered, confirmed and death cases [17].

III. DATASETS AND METHODOLOGY

A. Dataset Description

In this analysis, the COVID-19 data was downloaded from KAGGLE site. There are different source to get the data for analysis which includes: (1) john Hopkins (<https://corona.virus.jhu.edu/>); (2) KAGGLE (<https://www.kaggle.com/sudalairajkumar/covid19-in-india>); (3) CDC (<https://www.cdc.gov/library/researchguides/2019novelcoronavirus/researcharticles.html>); (4) data hub (<https://datahub.io/core/covid-19>); (5) Tableau (<https://www.tableau.com/covid-19-coronavirus-data-resources>) and soon. With these websites any researcher can download the datasets which is his/her interest and can do analysis. The data we have taken from 30 January, 2020 to 2 September 2020 which consists of confirmed, death, cured/migrated cases of all over India. But in this research article, we concentrated on only the state Andhra Pradesh. The dataset of daily reported cases are summarized in a table in the form of XLSX or CSV format with the parameters like confirmed, deaths, cured/migrated cases. These datasets are taken in this paper for analysis and prediction of active cases especially in Andhra Pradesh.

B. Methodology

The corona virus in India spreads due to local transmission from one person to other person easily at the earliest stage.

The expert person has to diagnose at the earliest stage and can control the spread of the disease. With the objective of forecasting the possibility of transmission among citizens, we developed a recurrent neural network model. This system model utilizes long short term memory (LSTM) cell [18]. To develop this, machine learning and deep learning library packages like pandas, numpy, matplotlib, seaborn, sklearn and math are imported into jupyter notebook to analyze confirmed, death cases and also to predict active cases of Andhra Pradesh (AP).

Fig. 3. Bar Plot of Top 5 States of Confirmed Cases.

The plot shown in Fig. 3 provides the information of confirmed cases where Maharashtra is in top position, Andhra Pradesh stood second position and fifth place is Uttar Pradesh. Similarly, if we consider top death cases, the below Fig. 4 shows the bar pot of states with top death cases.

Fig. 4. Bar Plot of States with Top Death Cases.

Now if we consider the total number of confirmed cases, death cases and active cases in Andhra Pradesh. Plot the line graph with the data available in CSV file, we get the graphs that was shown in Fig. 5, 6 and 7, respectively:

Fig. 5. Plot of Confirmed Cases in AP.

Fig. 6. Plot of Deaths Cases in AP.

Fig. 7. Plot of Active Cases in AP.

IV. IMPLEMENTATION OF ALGORITHM

A conventional neural network is having just a bunch of parallel layers which consists of nodes called as neurons. These neurons are interconnected to each other and forms layers from which data transmits from one layer to the next layer. This first layer is named as input layer, last layer is called as output layer and between layers are named as hidden layers [19]. A set of neural networks known as recurrent networks which deals with the time series data. These networks have memory to process the previous data that is transferred through the network. But the RNN experiences from short term memory. While computing gradients during back propagation, when the gradients become very small and they will not add up large amount of learning. Therefore RNN stops learning since they get very small gradients. Hence these RNN when it is seen in longer series networks won't learn much and thus have very short memory. To eliminate this short memory, LSTM should incorporate a mechanism inside the network known as gates and controls the stream of data that pass through the nodes and thus eliminates the short memory. The implementation of corona virus forecasting is based on the long short-term memory (LSTM) networks by taking one feature into account at a time [20] [21].

Fig. 8. LSTM Single Time Series Feature Model.

Fig. 8 represents an LSTM model which is a type of RNN and especially used to predict the time series patterns as well as classification problems. Since our dataset is time series, we have chosen this model for prediction. This model may take last 8 day's features and forecasts the figures for the 8th day. When the target value reaches, it stops and exists; it takes into account its predictions.

Fig. 9. LSTM Model with its Activation Function.

The LSTM model shown in Fig. 9 merges the forget gate and input gate into one gate. It also joins the cell state and hidden states. The number of nodes or neurons is chosen in trial and error method to give best results. The most common method is k-fold cross validation. The formula is expressed below to find number of nodes:

$$N_h = \frac{2}{3}(N_i + N_o) \quad (1)$$

Where N_i is the input neurons and N_o is the output neurons.

The outputs of the respective gates are given below:

$$\begin{aligned} Z_t &= \sigma(W_z \cdot [h_{t-1}, X_t]) \\ r_t &= \sigma(W_r \cdot [h_{t-1}, X_t]) \\ \tilde{h}_t &= \tanh(W \cdot [r_t * h_{t-1}, X_t]) \\ h_t &= (1 - z_t) * h_{t-1} + z_t * \tilde{h}_t \end{aligned} \quad (2)$$

1) Procedure of Neural Network1:

- a) Import required library packages.
- b) Read data which is saved in .csv format.
- c) Filter the data by choosing required state here Andhra Pradesh has been chosen.
- d) Line plot of confirmed cases of AP.
- e) Line plot of death cases.
- f) Divide the train, test data and also define number of epochs, batch size, number nodes, activation function and optimizer.
- g) Train the network model by using fit function and plot the graph of training and predicted values.
- h) Find out the performance metric like RMSE, MSE, MAE, SSE.

The loss of one layer in LSTM model is very high. To get best output, we need to add one more layer by adding nn2.add instruction.

2) Procedure of Neural Network Layer2

- a) Add the model as sequential.
- b) Add one more layer and one dense layer and repeat the compilation of nn2 to find the performance metrics.
- c) Here also all the metrics shows higher values.
- d) To reduce the metrics values, we have to convert the time series to stationary since the input we applied is dynamic time series and is not repeating.

3) Procedure to Find the Difference:

- a) Find the series of difference for the given time series as: $d_1 = L_1 - L_0, d_2 = L_2 - L_1, \dots, d_N = L_N - L_{N-1}$.
- b) From there, find $L_1 = L_0 + d_1, L_2 = L_1 + d_2, \dots, L_N = L_{N-1} + d_N$.
- c) Find cumulative series by finding $d_k = L_k - L_0, d_{k+1} = L_{k+1} - L_1, \dots, d_N = L_N - L_{N-k}$.
- d) Plot the graph of difference active cases.
- e) Again find the difference of difference of difference of active cases since, the difference we calculated in step 3 may be iterative.
- f) Compute the metrics of difference of difference of difference of active cases.
- g) Plot the graph of difference of difference of difference of active cases.

4) Procedure to Find the Scaling Transformation:

- a) First reduce the dataset into fixed interval.
- b) Use the activation function linear from 0 to 1 which eliminates negative values.
- c) Apply scaling transformation to the difference of active cases.
- d) Apply this value to third layer of LSTM model to train and to find performance metrics.
- e) Plot the actual series of active cases.

V. SIMULATION RESULTS

A. Performance Analysis

The performance parameters are analyzed to evaluate the neural network model called Mean Absolute Error, Mean Square Error, Root Mean Square Error and Sum of Squared Error and their definitions along with equations are shown below. The definitions of the performance metrics are shown along with equations [22]:

1) *Mean absolute error*: The ratio of sum of differences of all predicted values and tested values to the total length of tested values. The formula to compute MAE is given below [22] [23] [26]:

$$MAE = \frac{\sum_{N=1}^n |Actual - Predicted|}{N} \quad (3)$$

2) *Mean square error*: The mean of difference squared between the actual and predicted values. It is expressed as [22][24]:

$$MSE = \frac{\sum_{N=1}^n |Actual - Predicted|^2}{N} \quad (4)$$

3) *Root mean square error*: Root mean square error is used to compute the residual errors. These residual are measured by finding how the values are away from the line of regression. RMSE is the ratio of square root of summation of squared deviation of actual and predicted values to the number of actual values [25].

$$RMSE = \sqrt{\frac{\sum_{N=1}^n |Actual - Predicted|^2}{N}} \quad (5)$$

4) *Sum of square error*: It is defined as the sum of difference squared between all the actual and predicted values. The equation of sum of squared error is given by the formula [23]:

$$SSE = \sum_{N=1}^n |Actual - Predicted|^2 \quad (6)$$

The neural network model is trained with appropriate dataset to predict the active case in AP and computed the performance metrics.

B. Graphical Representation of Active Cases in Andhra Pradesh

Fig. 10 represents the data and predictions of active cases in AP.

Fig. 11 plots the data of predictions of active cases that was taken from second neural network model. Fig. 12 provides information of data after taking difference of active cases.

All the performance metric values are tabulated in Table I.

TABLE I. SUMMARY OF PERFORMANCE METRIC VALUES OF THE NEURAL NETWORK MODEL

S. No	Performance metrics	Values
One layer in LSTM model		
1.	Loss	49385091.59
2.	RMSE	3151.79
3.	MAE	1187.86
4.	SSE	1728478205.76
Second layer of NN		
6.	Loss	50219150.41
7.	RMSE	3178.29
8.	MAE	1197.85
9.	SSE	1757670264.37
Difference of active cases		
11.	Loss	18699324.54
12.	RMSE	1945.02
13.	MAE	730.94
14.	SSE	654476359.02
Third layer of NN (Scaling Transformation)		
16.	Loss	0.04
17.	RMSE	0.09
18.	MAE	0.03
19.	SSE	1.49

We tabulated the actual values and predicted values of active cases in Andhra Pradesh in Table II for the next 25 days.

TABLE II. ACTUAL AND PREDICTED VALUES OF ACTIVE CASES

S.No.	Actual Values	Predicted Values	S.No.	Actual Values	Predicted Values
1.	1	1	2.	1	1453

VI. CONCLUSION

Corona virus pandemic occurred in all over the world. By applying LSTM neural network model, we predicted the growth of active cases of Andhra Pradesh. If we observe the plot of actual series and predicted series, it is still showing exponential behavior. Every citizen need to follow preventive measures to avoid and controlling the spread of virus. This analysis shows the predicted values and performance metrics like MAE, MSE, RMSE and SSE values. Up on observation among all the mentioned metrics the third layer offers minimum error values with the LSTM model of 3 layers with 10 nodes. If we increase computing of difference between the active cases, we get the errors to minimum value.

VII. DATA AVAILABILITY

The data used to support the findings of this study are available from the corresponding author upon request.

VIII. FUNDING

This research has been no funds received for this research work.

IX. CONSENT

Informed consent was obtained from all individual participants included in the study.

X. CONFLICTS OF INTEREST

The authors declare that they have no conflicts of interest. Authors' Contributions All authors equally contributed to the study conception and design and implementation of the research, analysis and interpretation of results, and manuscript preparation.

ACKNOWLEDGMENT

The authors are thanks to Koneru Lakshmaiah Education Foundation, Guntur for providing the support and Characterization of completing this work.

AUTHORS' PROFILE

Mrs. N.P.Dharani received her M.Tech degree in Electronics and Communication Engineering with specialization of Digital Systems and Computer Electronics from Balaji Institute of Technology and Sciences, Warangal, affiliated to JNTUH, Hyderabad and received B.Tech degree in Electronics and Instrumentation Engineering from Sreenivasa Institute of Technology And Mngement Studies, Chittoor, affiliated to JNTUH, Hyderabad. She is pursuing Ph.D at K L E F Deemed to be University, Vaddeswaram, Guntur, Andhra Pradesh, India. Her area of research is Image/signal Processing, Prediction and Machine Learning/Deep Learning. She has published nine International journals and attended National and International Conferences. She is a life member of International Association of Engineers (IAENG).

POLAIAH BOJJA is presently working as Professor in department of Electronics and communication Engineering, K L E F Deemed to be University, Vaddeswaram, Guntur, Andhra Pradesh, India. He obtained B.Tech from JNTU, Hyderabad. M.Tech from Annamalai University, Tamil Nadu and Ph.D from JNTU Anantapuramu, Andhra Pradesh. He is a principal Investigator for the projects funded by AICTE, New Delhi and DeitY, New Delhi and Collaboration with C-DAC, Thiruvananthapuram. His overall teaching experience is 16 Years. He was published papers in International and National reputed journals with scopus/SCI Indexed and also overall presented conferences in National and International are more than 85. His research interests include Signal Processing and Embedded control systems and also Process Modelling, Optimization, Prediction, Adaptive Optimal Control, Automation, Machine Learning and Computing for Engg., applications. He is a Life Member's of International Society for Technology in Education (ISTE) and (Indian Science Congress Association (ISCA), Member of Automatic Dynamic Controller for systems (ADCS) and International Association of Engineers (IAENG). He has published two text book in Digital image Processing for Industrial Applications and twopatents. He acted as reviewer for many IEEE international conferences and also delivered keynote speech in various conferences and Organizations.

A Proposed Fraud Detection Model based on e-Payments Attributes a Case Study in Egyptian e-Payment Gateway

Abstract—As per Payfort's 2017 report, titled State of payments in the Arab world; Egypt had a 22% yearly increase in the overall volume of internet payments in 2016, which was assessed at \$6.2 billion. e-Payments are the major point of life nowadays in Egypt and the whole world; with tens of e-payments companies in Egypt and more than 5 million transactions done every day and 60 billion EGP volume of payments in 2018. Online and mobile fraud was estimated at \$10.7 billion in 2015, as per Juniper Research, and is expected to reach \$25.6 billion by the end of the decade. As the whole e-payments business is affected by fraud, e-payments firms and their consumers lose a lot of money. On the other hand, one of the most powerful techniques that could be used for fraud predictive is data mining techniques such as the decision tree. This paper introduces a prediction model for managing the risk of fraud in the Egyptian e-payment market that helps to reduce the loss of money. This model is developed using a real dataset from one of Egypt's top e-payment gateways based on the e-payment transaction attributes importance like transaction time, transaction amount, transaction limit, and transaction customer No. repetition limit. The importance of these attributes was determined using IBM SPSS modeler's decision tree and its predictors' importance. The model significantly assisted in the reduction of fraud cases by a very high rate, with an accuracy of 88.45% and a precision of 93.5% resulting in a savings of 101970.52 EGP out of 131297.83 EGP.

Keywords—Data mining; decision tree; e-payments; fraud detection; e-payment gateways; e-commerce

I. INTRODUCTION

Egypt scored the highest growth of online shopping in the Arab world with a 32% increase in the volume of e-payments. According to the internet, world stats report (2017) internet users in Egypt By the end of March 2017, Egypt had officially hit 36.5 percent of the population, half of whom use e-commerce services for everything from purchasing goods and services to paying bills. There are many definitions for e-payments, of which an e-payment system is a form of financial commitment that involves the buyer and the seller facilitated via the use of electronic communications [6]. Another definition defines e-payment as any form of fund transfer via the internet [6].

Using e-commerce; business payments have taken the form of exchanging money electronically and are called electronic payments [2]. Nowadays, most organizations, companies, and

government agencies have adopted electronic commerce to increase their productivity or efficiency in trading products or services in areas such as credit cards, telecommunication, healthcare insurance, automobile insurance, online auction, etc. [1]. The success of a particular electronic payment system is determined by how well it overcomes the practical and analytical hurdles that various online payment methods face.

These challenges include issues of laws and regulations (buyer and seller protection), technological capabilities of e-payment service providers, commercial relationships, and security considerations such as verification and authentication issues [2]. E-commerce systems are used by both legitimate users and fraudsters. Hence, they become more vulnerable to large-scale and systematic fraud. Internet Crime Complaint Centre (IC3) is a valuable resource for both victims of internet crime and law enforcement agencies in identifying, investigating, and prosecuting these crimes. In 2020, the IC3 gathered 15,421 Tech Support Fraud complaints from victims in 60 countries. The losses were over \$146 million, an increase of 171 percent over the previous year (IC3, 2020).

The Egyptian e-payments market is also affected by fraud crimes. Many customers have been defrauded in the Egyptian e-payments market by someone calling them and pretending to be from the e-payments company sales team, attempting to convince them to give their account details in order to receive a bonus. The motivation of this model is to protect and minimize the losses of customers who have been deceived.

One of the most important and rapidly growing payment methods in Egypt is e-payments gateway companies with more than 5 million transactions done every day. Those companies have more than 789 services that customers can use and about 294 thousand outlets spreading in all places in Egypt with 60 billion EGP volume of payments in 2018 and expectation to reach 90 billion in 2019. With high efficiency, ease, and speed, e-payment has become a significant facilitating engine in e-commerce through e-business success.

Hence, the paper is proposing a model for fraud detection in e-payments, especially in Egyptian e-payments companies and the proposed model will be applied to one of those companies. A decision tree, which is one of the most effective data mining techniques, was used to create the model depending on the importance of the e-payment transaction's attributes. The paper is organized into seven sections. The

second section presents definitions of e-payment gateway, decision tree, C5.0 algorithm, and related work. In Section 3 the methodology is presented. Section 4 shows the decision tree model and Section 5 presents results and discussion. Conclusion and future work are presented in Sections 6 and 7.

II. LITERATURE REVIEW

A. Background

This section explains the main points of the area being researched and gives an overview of these points. It starts with explaining what is e-payment gateway then give a brief about decision tree technique, C5.0 algorithm, Splitting criteria, and information gain metric.

1) *e-Payment gateway*: An electronic payment gateway system is a software service that connects with retailer and service provider networks and enables consumers to make payments through these [8]. e-Payment companies offer financial services to consumers and businesses through various channels and a large network of agents. These financial services include paying bills, paying vouchers, reservations, donations, and other services. e-Payment helps businesses to reach more customers, increase productivity, and help consumers to save time and pay for services at any time in a cheaper, easier, faster, and real-time way.

2) *Decision tree*: Decision tree is the most important and widely used categorization and forecasting approach. A decision tree is a tree structure that looks like a flowchart, with each internal node representing an attribute test, each branch reflecting the test's outcome, and each leaf node (terminal node) storing a class label[12]. By learning simple decision rules derived from data properties, a decision tree is used to develop a model that forecasts required variable values. ID3, C4.5, C5.0, and CART are only a few of the algorithms for learning decision trees from a given data set that have been presented. The C5.0 algorithm will be used in our model because of its accuracy and ease of implementation.

3) *C5.0 Algorithm*: One of the most well-known algorithms is C5.0. The C5.0 technique has become the best choice for generating decision trees since it works successfully for most kinds of challenges straight out of the box. The decision trees of the C5.0 algorithm work nearly as well as more difficult and complex machine learning approaches (such as Neural Networks and Support Vector Machines), but are significantly easier to understand and use.

4) *Splitting criteria*: Information Gain (Entropy) is the splitting criterion used by C5.0. The C5.0 model breaks the sample into fields based on whatever field provides the maximum information gain. Each sub-sample specified by the first split is split a second time, generally on a different field, and the technique is repeated until the subsamples cannot be split anymore. Lastly, the lowest-level splits are inspected again, and those that do not add significantly to the model's value are trimmed or removed.

5) *Information gain*: Information gain is a metric for how much data a feature offers about a class. It helps to specify the

order of attributes in the decision tree's nodes. The entropy of the dataset before and after a transformation is used to calculate information gain. The entropy of a sub split can be defined as a measure of its purity. Entropy is always between 0 and 1. Below is how the Information Entropy is calculated for a dataset with N classes.

$$E = - \sum_{i=1}^N p_i \log_2 p_i \quad (1)$$

Where p_i is the probability of randomly picking an element of class i (i.e. the proportion of the dataset made up of class i). Below is the formula of calculating Information Gain based on the calculated Entropy.

$$Gain = E_{parent} - E_{parent} \quad (2)$$

B. Related Work

Techniques for identifying fraud in e-payments are growing very quickly. Some of the popular techniques are rule-based systems, neural networks, Decision trees, machine learning business intelligence, hidden Markov Model, etc. As per lae Chouiekha and EL Hassane Ibn EL Haj [3], they have proposed a model to detect fraudsters in mobile communication using deep learning techniques. In order to forecast fraudulent events in a mobile environment, researchers compared the performance of convolution neural networks to that of classic machine learning algorithms.

Shirley Wong and Sitalakshmi Venkatraman [10] have proposed financial fraud detection and propose a forensic accounting framework using business intelligence. This framework presents a three-phase methodology for performing financial analysis, such as ratio analysis, for a business case scenario using unique knowledge discovery techniques. In contrast to traditional methods of vertical and horizontal analysis for the business case study, the framework's implementation practically demonstrates how the technologies and investigative methods of trend analysis could be used to investigate fraudulent financial reporting using their accounting data.

In another work, Roland Rieke, Maria Zhdanova, Jürgen Repp, and Romain Giot [9] developed a tool for runtime predictive security analysis that analyses process behavior in relation to transactions within a money transfer service and attempts to match it with the expected behavior provided by a process model. The tool analyzes deviations from the given behavior specification for anomalies that indicate a possible misuse of the service related to money laundering activities.

Memorie Mwanza [7] has proposed a model for detection of fraud on tax data for Zambia Revenue Authority using business intelligence model that implements data mining, outlier algorithms for fraud detection and is based on, Continuous Monitoring of Distance-Based and Distance-Based Outlier Queries was then designed and Hao ZHOU, Hong-feng CHAI and Maolin QIU [11] introduce machine learning algorithms to perform fraud detection of bankcard enrollment. They introduce several traditional machine-learning algorithms and finally choose the improved gradient boosting decision tree (GBDT) algorithm software library for use in a real system, namely, XGBoost also Shailesh S. Dhok, G. R.

Bamnote [4] model the sequence of operations in credit card transaction processing using a Hidden Markov Model (HMM) and show how it can be used for the detection of frauds. An HMM is initially trained on a cardholder's regular behavior. An incoming credit card transaction is considered fraudulent if the trained HMM does not accept it with an enough high probability. The hidden Markov Model aids in achieving high fraud coverage while minimizing false alarms.

With [5], two main techniques and using five classifiers, Sahu, Aanchal, G. M. Harshvardhan, and Mahendra Kumar created models to detect credit card fraud transactions. These two techniques are designed to address the problem of data imbalance which helps to detect fraud transaction.

III. METHODOLOGY

This section explains all the steps done to generate the model starting with describing the used data set, its preparation steps, and the used tools that helped build the model. The data set show available service categories and explains transaction details for the e-payment transaction done through the payments gateway.

A. Data Set

The data set contains real-life data of financial transactions of one of the top five e-payments companies in Egypt. Table I shows the services categories that e-payments companies in Egypt provide to their customers. There are governmental services such as electricity; gas and water there are mobile services for recharging and bill payment and many other services such as donation services, airline services DSL services, and many other services that any Egyptian consumer or corporates needs. Table II shows transaction details, some of those details are received by the system when the transaction is processed and some already exist related to the agent who made the transaction. The data set contains about 92718 records divided into two parts. Training data that contains 64903 transactions about (70%) and testing data set that contains 27814 transactions about (30%).

B. Data Preparation

As shown in Fig. 1 data preparation steps start with data gathering. The data was extracted directly and manually from the data source and exported to excel sheets then data cleaning and validation start by removing extraneous data and outliers, filling in missing values, conformed data into a specified pattern sensitive and private data was hidden, and removing error transactions. The next step was discovering and classifying the data. Data were classified and divided into months, weeks, and days for each agent's account based on three attributes (number of transactions, the amount, number of customer's number repeated).

Data analyzing was the final step. The data were divided into three groups based on the volume of transactions and the volume of their amounts in order to obtain better and more accurate results.

- Low volume rate group.
- Medium volume rate group.
- High volume rate group.

TABLE I. SERVICE CATEGORY

#	Service category	Description
1	Mobile recharge	Used for recharging mobile
2	Mobile bill payment	Paying for mobile monthly bills
3	Mobile e-voucher	Generate vouchers for recharging mobile phone
4	Donations	Donation to charities
5	Airlines	Reserving airlines tickets
6	Gas	Gas bills
7	Water	Water bills
8	Electricity	Electricity bills
9	DSL	DSL bills
10	Cinema tickets	Reserving tickets online
11	Games	Paying for online games

TABLE II. TRANSACTION DETAILS

#	Attribute	Description
1	Create Date/Time	Date and time for creating the transaction
2	Update Date/Time	Date and time for receiving a response from the service provider
3	Transaction ID	Unique transaction ID in the system
4	Provider	Service provider name
5	Service	Service name
6	Customer number	Identifier used by customer EX: Phone number for recharging mobile
7	Amount	The amount that should be paid
8	Total amount	The amount that should be paid + Service charge
9	Status	Status of transaction success or error
10	Provider Response Code	Code sent by the service provider in the response
11	Provider Transaction ID	Service provider unique transaction Id in
12	Transaction Initiator	Name of agent that made the transaction
13	Transaction Deduction From	Account number for the agent who made the transaction
14	Interface	Type of interface he used (mobile, web
15	Outlet	Name of the outlet
16	Area	Area of the outlet

Fig. 1. Data Set Preparation Steps.

TABLE III. DATA CATEGORIES SPECIFICATION

		Low Volume Rate	Medium Volume Rate	High Volume Rate
Transaction	Daily	50	100	300
	Weekly	300	1000	3000
	Monthly	1200	5000	10000
Amount	Daily	1200	2500	8000
	Weekly	5000	20000	80000
	Monthly	20000	100000	500000
Customer No.	Daily	3	6	10
	Weekly	15	30	50
	Monthly	50	100	100

As shown in Table III, each group contains the maximum daily transactions number allowed for the agent, the maximum weekly number, the maximum monthly number also the maximum daily, weekly and monthly amount, and the same for customer No. repeated times.

The data set was divided into six data sets based on the three groups that were received from the data analysis phase. Each group has two data sets one for training and one for testing. The training data set contains 70% of transactions and the testing data set contains 30% of transactions for each group as shown in Table IV.

TABLE IV. DATA SET VOLUME

	Low Volume Rate	Medium Volume Rate	High Volume Rate	Total
Training	42426	28242	22050	64903
Testing	12727	8472	6615	27814

IV. DECISION TREE MODEL

A. Tools used

IBM SPSS modeler was used to create the decision tree model. It is a data-mining tool that allows you to create

predictive models without programming. It helps you to specify groups, identify correlations between them and predicting events that will happen in the future. ASC5.0 is one of the decision tree algorithms included in IBM modeler, and it was used in the proposed model as shown in Fig. 2 due to its efficiency, as stated previously.

B. Splitting Criteria

As previously stated in the background section, C5.0 uses Information Gain (Entropy) as its splitting criteria. Fig. 3, Fig. 4, and Fig. 5 show the predictor importance for the e-payment transaction attributes for each group (low, medium, and high) as generated by IBM modeler. e-Payment transaction attributes are transaction allowed time, transaction (daily, weekly, monthly) allowed limit, transaction (daily, weekly, monthly) allowed amount, and transaction (daily, weekly, monthly) allowed customer number limit.

C. Resulting Decision Tree

The model will start by checking the transaction time if it is in the agent’s allowed time or not and if it is in the allowed time the model will go to the next step to check if the transaction exceeds the maximum monthly transaction number if it did not exceed the model will check for the weekly and after that the daily. The model will check for Amount and customer, No. repeated in the same way as the transaction number and if the transaction passed all the conditions it will be accepted. Fig. 6 shows the whole procedure of the resulting decision tree.

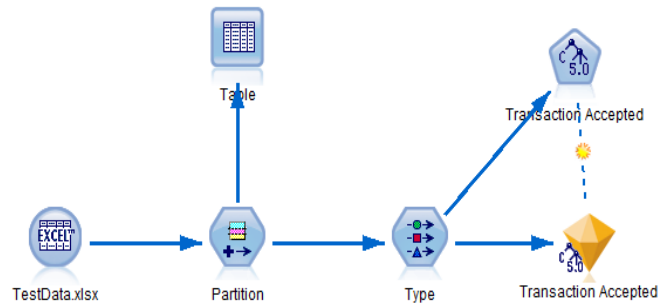

Fig. 2. IBM SPSS Decision Tree.

Fig. 3. Predictor Importance for Low Rate Group.

Fig. 4. Predictor Importance for Medium Rate Group.

Fig. 5. Predictor Importance for High Rate Group.

D. Decision Tree Derived Rules

R = Result for condition statement.

1 = True, 0 = False.

F(Mtrx) = Monthly transaction.

F(Mamut) = Monthly Amount.

F(Mcus.no) = Monthly Customer No.

F(Wtrx) = Weekly transaction.

F(Wamut) = Weekly Amount.

F(Wcus.no) = Weekly Customer No.

F(Dtrx) = Daily transaction.

F(Damut) = Daily Amount.

F(Dcus.no) = Daily Customer No.

1) Low volume rate group

$$R = f(Mtrx) \int_{0, > 1200}^{1, \leq 1200} R = f(Wtrx) \int_{0, > 300}^{1, \leq 300} R = f(Dtrx) \int_{0, > 50}^{1, \leq 50} \quad (3)$$

$$R = f(Mamut) \int_{0, > 20000}^{1, \leq 20000} R = f(Wamut) \int_{0, > 5000}^{1, \leq 5000} R = f(Damut) \int_{0, > 1200}^{1, \leq 1200} \quad (4)$$

$$R = f(Mcus.no) \int_{0, > 50}^{1, \leq 50} R = f(Wcus.no) \int_{0, > 15}^{1, \leq 15} R = f(Dcus.no) \int_{0, > 3}^{1, \leq 3} \quad (5)$$

2) Medium volume rate group

$$R = f(Mtrx) \int_{0, > 5000}^{1, \leq 5000} R = f(Wtrx) \int_{0, > 1000}^{1, \leq 1000} R = f(Dtrx) \int_{0, > 100}^{1, \leq 100} \quad (6)$$

$$R = f(Mamut) \int_{0, > 100000}^{1, \leq 100000} R = f(Wamut) \int_{0, > 20000}^{1, \leq 20000} R = f(Damut) \int_{0, > 2500}^{1, \leq 2500} \quad (7)$$

$$R = f(Mcus.no) \int_{0, > 100}^{1, \leq 100} R = f(Wcus.no) \int_{0, > 30}^{1, \leq 30} R = f(Dcus.no) \int_{0, > 6}^{1, \leq 6} \quad (8)$$

3) High volume rate group

$$R = f(Mtrx) \int_{0, > 10000}^{1, \leq 10000} R = f(Wtrx) \int_{0, > 3000}^{1, \leq 3000} R = f(Dtrx) \int_{0, > 300}^{1, \leq 300} \quad (9)$$

$$R = f(Mtrx) \int_{0, > 500000}^{1, \leq 500000} R = f(Wtrx) \int_{0, > 80000}^{1, \leq 80000} R = f(Dtrx) \int_{0, > 8000}^{1, \leq 8000} \quad (10)$$

$$R = f(Mtrx) \int_{0, > 100}^{1, \leq 100} R = f(Wtrx) \int_{0, > 50}^{1, \leq 50} R = f(Dtrx) \int_{0, > 10}^{1, \leq 10} \quad (11)$$

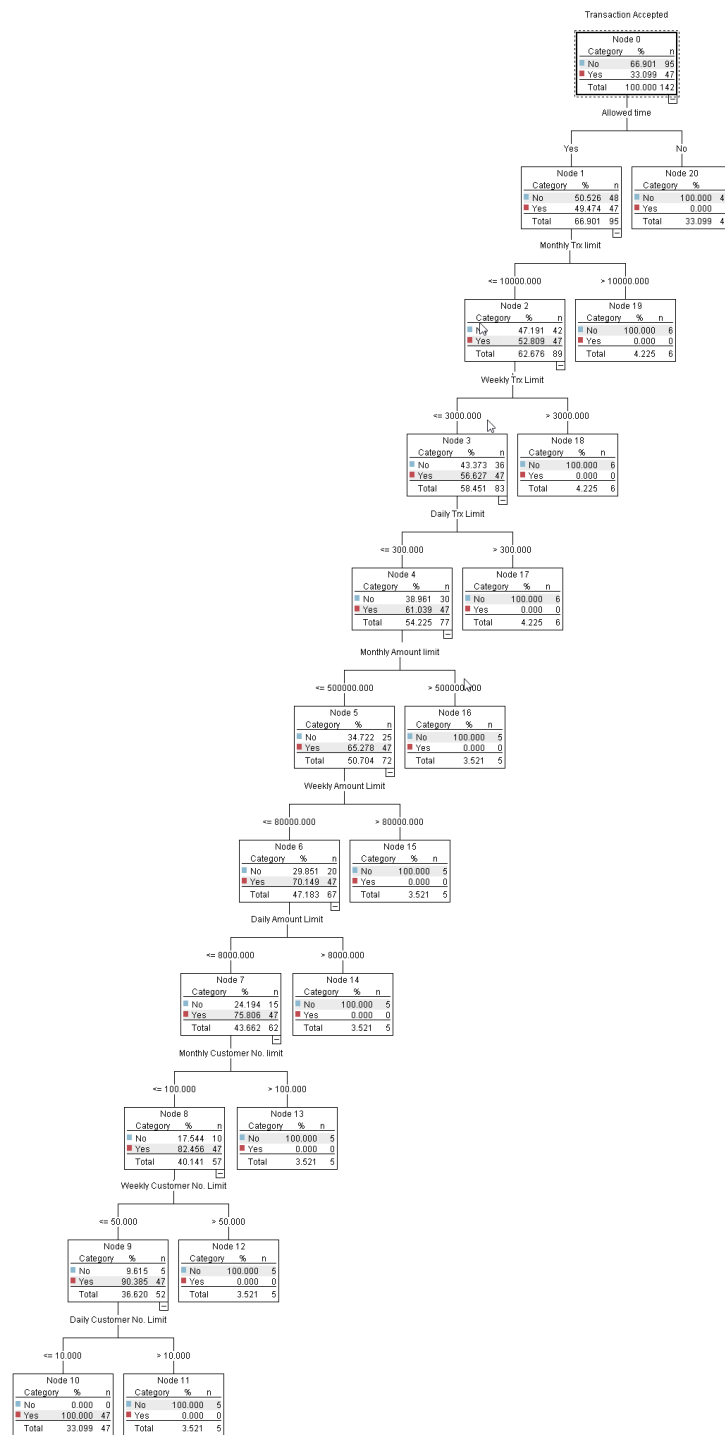

Fig. 6. Decision Tree Model for Low, Medium and High Volume Rate Groups.

V. RESULT AND DISCUSSION

A. Results and Findings

The model was implemented and a real data set that containing fraud transactions were used to test the implemented model. The used data set is a real dataset of a total of 1590 transactions with 590 fraud transactions totaling 131297.83 EGP in losses. With a total of 433 out of 590 fraud

transactions detected, the model was able to identify more than 73%. Out of a total of 131297.83 EGP, the model saved 77% of the total amount lost due to fraud, equating to 101970.52 EGP. The model significantly reduced fraud transactions, demonstrating the need to analyze and verify that all customer transactions are carried out by them, not only that they come from their account. The confusion matrix was used to calculate the accuracy, precision, and false alarm rate for the model as shown in Table V.

TABLE V. CONFUSION MATRIX DEFINITIONS

TP	True positive (number of transactions that were fraudulent and were also classified as fraudulent by the model)
TN	True negative (number of transactions that were legitimate and were also classified as legitimate)
FP	False positive (number of transactions that were legitimate but were wrongly classified as fraudulent transactions)
FN	F False negative (number of transactions that were fraudulent but were wrongly classified as legitimate transactions by the model)

Accuracy is the fraction of transactions that were correctly classified.

$$\text{Accuracy (ACC)/Detection rate} = (TN + TP) / (TP + FP + FN + TN)$$

Precision (also known as the detection rate), the number of transactions either genuine or fraudulent were correctly classified.

$$\text{Precision/Detection rate/Hit rate} = TP / TP + FP$$

False Alarm rate measures out of total instances classified as fraudulent or how many were wrongly classified.

$$\text{False Alarm Rate} = FP/FP+TN.$$

$$TP= 433 \quad TN= 1000 \quad FP= 30 \quad FN= 157.$$

$$\text{Accuracy (ACC)/Detection rate} = 1000 + 433 / (433 + 30 + 157 + 1000) = 88.45 \%$$

$$\text{Precision/Detection rate/Hit rate} = 433/433 + 30 = 93.5 \%F.$$

$$\text{False Alarm Rate} = 30/30+1000 = 2.9\%VI. \text{ Accuracy \& Precision \& False Alarm Rate.}$$

Accuracy	Precision	False Alarm Rate
88.45 %	93.5 %	2.9 %

B. Limitation of Work

One of the limitations that we faced is the lack of previous research studies on the topic of the Egyptian e-payment market and the absence of official statistics that help estimate the extent of the problem. As well as the difficulties we faced as a result of the payment companies' lack of cooperation and refusal to provide any numbers of fraud losses suffered by their customers.

VI. CONCLUSION

The paper introduces a fraud detection model using data mining. The model used the decision tree technique. The model is based on real data from one of the Egyptian e-payment gateways. With an accuracy of 88.45 percent, the suggested model helps in the detection of any up normal transactions that differ from the typical behavior of users' transactions. Fig. 7 shows that the model detected 433 fraud transactions out of 590, resulting in a savings of 101970.52 EGP out of 131297.83 EGP as shown in Fig. 8. Using this model, a secure payment environment will enhance user confidence and reduce money loss.

Fig. 7. Number of Fraud Transactions before and after using the Model.

Fig. 8. Total Amount Loss before and after using the Model.

VII. FUTURE WORK

This paper introduced a fraud detection model using the decision tree technique for a specific type of e-payment, which are e-payment companies that allow users to pay for services through their system. Through this research, several points have arisen that must be discussed in the future. One of these points is to implement the proposed model to other different e-payment types and analyze the results in order to improve the Another point is to apply this model using other data mining techniques and compare it to decision tree technique also applying this model in another e-payments fields for example credit card payments and mobile banking payments.

Improved ISODATA Clustering Method with Parameter Estimation based on Genetic Algorithm

Kohei Arai

Graduate School of Science and Engineering
Saga University, Saga City
Japan

Abstract—Improved ISODATA clustering method with merge and split parameters as well as initial cluster center determination with GA: Genetic Algorithm is proposed. Although ISODATA method is well-known clustering method, there is a problem that the iteration and clustering result is strongly depending on the initial parameters, especially the threshold for merge and split. Furthermore, it shows a relatively poor clustering performance in the case that the probability density function of data in concern cannot be expressed with convex function. To overcome this situation, GA is introduced for the determination of initial cluster center as well as the threshold of merge and split between constructing clusters. Through experiments with simulated data, the well-known the University of California, Irvine: UCI repository data for clustering performance evaluations and ASTER/VNIR: Advanced Spaceborne Thermal Emission and Reflection Radiometer / Visible and Near Infrared Radiometer onboard Terra satellite of imagery data, the proposed method is confirmed to be superior to the conventional ISODATA method.

Keywords—ISODATA clustering; nonlinear merge and split; concaveness of probability density function: PDF; remote sensing satellite imagery data; clustering; genetic algorithm: GA; nonlinear optimization

I. INTRODUCTION

Clustering methods can be broadly divided into hierarchical and non-hierarchical clustering methods [1], [2]. Typical non-hierarchical clustering methods are the k-means method¹ and the ISODATA method². In the k-means method, it is necessary to give the number of clusters and the initial cluster center in advance, and the calculation time and the obtained cluster shape will change depending on their settings. On the other hand, the ISODATA method can autonomously determine the effective number of clusters within a certain range of the set number of clusters.

The ISODATA method separates target data individuals into clusters based on the k-means method, and then divides and fuses the clusters according to a preset threshold value based on statistical indices within and between clusters, and rearranges the cluster individuals. This is a method of repeating this series of processing until the rearrangement end judgment criterion is satisfied. Therefore, although the ISODATA method has relatively high clustering accuracy, it takes a considerable amount of processing time to set these

parameters, and this determination can often be difficult. The final number of clusters, clustering accuracy and calculation time depends on these parameters. Especially in the case of clustering for multi-dimensional data such as satellite images, the number of parameters increases as the number of dimensions increases, so adjustment is extremely difficult.

Moreover, the k-means method and the ISODATA method implicitly assume that the probability density function of the target data is a convex function. That is, high clustering accuracy cannot be expected in the case of a distribution of a cluster that is a concave function in a multidimensional space.

This paper assumes that the target data is multidimensional like a satellite image, deals with the case where the probability density function of the cluster individual is concave, and improves the clustering accuracy by using the estimated optimal parameters. The author proposes a clustering method based on the ISODATA method. Genetic Algorithms (GA) [3], [4] were used for parameter optimization. There is the other alternative algorithm, sand cat swarm optimization (SCSO) [5], Grey Wolf Optimizer (GWO) algorithm [6], Moth-flame optimization algorithm [7], etc.

GA does not guarantee a global optimal solution, but it is a probabilistic optimization method that can estimate a suboptimal solution in a relatively short time [8], [9], [10]. It is effective for problems that have not been discovered and have such a large solution space that a full search is considered impossible [11], [12]. In this paper, the author first shows the effectiveness of the proposed method using simulation data in which the distribution of cluster individuals is a concave function.

The author also applied the UCI repository data set [13] and satellite image data, which are frequently used for comparative evaluation of clustering accuracy, to the proposed method and evaluated the clustering accuracy. The conventional ISODATA method and shape-independent clustering were used as the conventional clustering methods [14], [15]. It is reported here because the proposed method was superior to the conventional methods.

The following section describes related research works. Then the proposed method is described followed by experiment. After that, conclusion is described together with some discussions.

II. RELATED RESEARCH WORK

Influence due to geomorphology on context Genetic Algorithm: GA clustering is investigated [16]. On the other hand, learning processes of image clustering method with density maps derived from Self-Organizing Mapping (SOM) is also proposed [17].

Non-linear merge and split method for image clustering (closely related to the proposed method here) is proposed [18]. Meanwhile, revised pattern of moving variance for acceleration of automatic clustering is investigated [19].

Automatic detection method for clustered micro calcification in mammogram image based on statistical texture features is proposed [20]. On the other hand, comparative study between the proposed GA based ISODATA clustering and the conventional clustering methods are conducted [21].

Image clustering method based on density maps derived from Self Organizing Mapping: SOM is proposed [22]. Meanwhile, clustering method based on Messy Genetic Algorithm: GA for remote sensing satellite image clustering is proposed [23].

Visualization of learning process for back propagation Neural Network: NN clustering is proposed [24]. On the other hand, improvement of automated detection method for clustered micro calcification base on wavelet transformation and support vector machine is attempted [25].

Image clustering method based on Self-Organization Mapping: SOM derived density maps and its application for Landsat Thematic Mapper: TM image clustering is proposed [26]. Also, comparative study between the proposed shape independent clustering method and the conventional method (k-means and the others) is conducted [27].

Genetic Algorithm: GA utilizing image clustering with merge and split processes which allows minimizing Fisher distance between clusters is proposed [28]. Also, Fisher distance-based GA clustering taking into account overlapped space among probability density functions of clusters in feature space is proposed [29].

Initial centroid designation algorithm for k-means clustering is proposed [30]. Meanwhile, Pursuit Reinforcement Competitive Learning: PRCL based online clustering with tracking algorithm and its application to image retrieval is proposed [31].

III. PROPOSED METHOD

Clustering is a method of classifying target data by collecting similar items based on the similarity or dissimilarity between target data individuals and generating groups (clusters); also called analysis. The criteria for measuring how similar the target data individuals are similarity (dissimilarity) and dissimilarity. The degree of similarity is, for example, a measure indicating that the object is more similar as the value is larger, such as the correlation coefficient.

On the other hand, the dissimilarity, which is also called the dissociation degree, is a measure indicating that the larger the value, the less similar the objects. Generally, dissimilarity (distance) is often used. The similarity defined in clustering

has indices such as matching coefficient and similarity ratio, while there are many definitions of distance.

In this paper, we use local mean distance and similarity that can deal with the case where the probability density function of the target data individual is a concave function, and it is necessary for the ISODATA method by GA using the fitness function based on these. We propose a clustering method that determines the initial cluster centers as well as the thresholds for cluster partitioning and fusion.

A. Local Average Distance and Local Similarity

The author proposes the Moving Window method. Once the local range (Window) is determined, the local inter-individual distance and the similarity within the range are obtained. The Moving Window method is a method of finding the sum or average of local distances and similarities over the entire area by moving the local area little by little along each dimension (Fig. 1). In this research, the author uses a hypersphere as a window in multidimensional Euclidean space. In the figure, while moving in the local range of radius r , the distance between individuals within this range, or the sum and average of the similarities are obtained.

As shown in Eq. (1), the average value of the inter-individual distances within the local range is called the local average distance L .

$$L = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j=1, j \neq i}^n \delta_{i,j} \|l_i - l_j\| \quad (1)$$

where,

$$\delta_{i,j} = \begin{cases} 1, & \text{if } C_i = C_j \\ \frac{1}{2}, & \text{if } C_i \neq C_j \end{cases} \quad (2)$$

In addition, n is the number of individuals in the local range, l is the position vector of the individual, and C_k is the membership cluster of the individual of k . That is, the distance (norm) between individuals is the sum of all the distances between individuals in the local range considering 1 for the same cluster and half the weight for different classes.

Sum of local similarity is defined as follows:

The difference in distance between individuals belonging to the same cluster as the diameter within a certain local range is taken as the similarity, and the sum DS thereof is obtained as in the following formula.

Fig. 1. Moving Window Method.

$$DS = \sum_{i=1}^n \sum_{j=1, j \neq i}^n \delta_{i,j} (2r - ||l_i - l_j||) \quad (3)$$

where,

$$\delta_{i,j} = \begin{cases} 1, & \text{if } C_i = C_j \\ 0, & \text{if } C_i \neq C_j \end{cases} \quad (4)$$

B. Determine the Size and Weight of the Local Range

The local mean distance has a role to detect inter-cluster variance. Therefore, it is desirable that the local range, that is, the window size in the Moving Window method, can cover the inter-cluster dispersion. When the window size, that is, the radius of the hypersphere is gradually increased from the minimum distance between individuals, and the total sum of the local average distances is obtained, the local average distance has a peak when the inter-cluster dispersion is covered.

This peak is found and the radius of the hypersphere in its local range is used as the reference r_p . Experiments were performed using the simulation data shown in Fig. 2(a), (b), and (c) while changing the radius of the hypersphere. The results are summarized in Table I.

Looking at Table I, even if the radius of the hypersphere is made larger than the standard to some extent, it does not affect the clustering result, but below the standard value, it greatly affects the cluster result.

This can identify both cluster individuals if r is set so as to include the maximum inter-individual distance between different clusters, but if set shorter than this, that is, if the local range is set narrow, both cluster individuals are separated. It means that it will be difficult. Therefore, it is sufficient to set γ sufficiently long, but this is directly related to the increase in processing time (proportional to r^2), which is a problem.

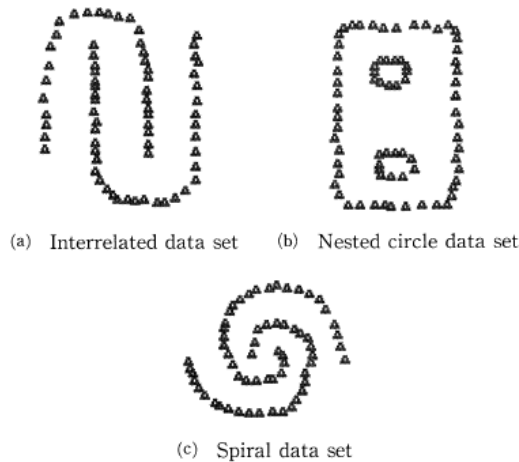

Fig. 2. 2D Simulation Data.

TABLE I. EFFECT OF WINDOW SIZE ON LOCAL AVERAGE DISTANCE

Error(%)	0.5rp	1.0rp	1.5rp	2.0rp
Interrelated	98.55	0.00	0.00	0.00
Nested circle	97.30	0.00	0.00	0.00
Spiral	96.77	96.77	0.00	0.00

Therefore, in this study, twice the reference value, $2r$, was taken as the radius of the hypersphere. On the other hand, the sum of local similarities is related to the distance between individuals within a cluster. The window size should be longer than the distance between all individuals in the cluster and their nearest neighbors, and smaller than the inter-cluster variance. When the window size is small, the clustering result has a large number of clusters due to the local average distance, and in an extreme case, all individuals themselves become clusters.

Therefore, the validity of the window size can be judged from the final number of clusters. Assuming that there is no isolated individual, it is appropriate that the window size, that is, the diameter of the hypersphere, is longer than the distance (d_{min}) between the individual farthest from other individuals and their nearest neighbors. First, clustering is performed by setting the radius of the hypersphere to d_{min} . Clustering is performed by increasing the radius of the hypersphere when the number of final clusters exceeds twice the expected number, or when isolated individuals appear. This process was repeated until the final number of clusters fell within twice the expected number.

It is important for the goodness of fit so that individuals whose distance is less than a certain threshold value belong to one cluster, that is, the sum DS of local similarities is maximized. This is equivalent to making the local average distance L as small as possible. From this point of view, it is better to make the weight M smaller, but the effective number of DS is finite, so the value of the weight must be set so that the effective value of M/L can influence the effective number of DS . Also, since maximizing DS is prioritized, it must be $M/L \ll DS$.

C. GA

1) *Real-Coded Genetic Algorithms (RCGA)*: GA is an optimization algorithm that refers to the evolution of living organisms. In GA, the solution of the problem is expressed as an individual, and each individual is composed of chromosomes. Individuals evolve by selective selection, crossover, and mutation, and search for optimal solutions. Early GAs performed crossovers and mutations with binary coded bit strings of variables. This ignores the continuity of variables.

On the other hand, a GA has been proposed which uses the numerical value itself and performs crossover and mutation considering the continuity of variables. This is called Real-Coded Genetic Algorithms (RCGA). RCGA does not use the bit string like the conventional GA but expresses the individual used for the search by converting it into a real vector.

Therefore, the conventional GA chromosomal locus composition replaces the bit string with a real vector. At this time, the multidimensional vector centered on the initial cluster is used as the real vector. In this research, the initial cluster center optimization is performed based on RCGA.

2) *Fitness function*: The author defines a fitness function that maximizes the ratio of the sum of inter-cluster variance to the sum of intra-cluster variance. As for the clustering result, the cluster is configured to be optimal when the probability density function of the target data individual can be regarded as a convex function. On the other hand, if the fitness functions are defined as in Eq. (5) using the sum of local similarities and the local average distance, an optimal cluster configuration is possible even in the case of a concave function distribution.

$$F = \frac{\sum DS + M}{\sum L} \quad (5)$$

where F is the goodness of fit and M is the weight. The local mean distance represents the intra-cluster variance in the local range. The smaller this value, the smaller is the intra-cluster variance. If all individuals in the local range belong to individual clusters, the local mean distance is the minimum.

When this value is used as the goodness of fit, the individuals within the range tend to belong to different clusters, and it is possible to perform clustering so that the individuals at both ends of the local area with large inter-individual variance belong to different clusters.

The sum of local similarities is related to the intra-cluster variance in the local range. The larger this value, the smaller the variance within the cluster in the local range. When all individuals in the local range belong to one cluster, the sum of local similarities becomes maximum. When this value is used as the goodness of fit, the number of clusters tends to decrease, and it is possible to perform clustering so that individuals with close distances belong to one cluster.

By using Eq. (5), it is possible to generate a fitness function that does not depend on the shape of the cluster by balancing the sum of the local average distance and the local similarity and considering the intra-cluster variance and inter-cluster variance at the same time.

3) *Crossover*: Since RCGA does not code, a crossover operator specialized for this is required. Typical examples of this include blend crossover (BLX- α) and unimodal normal distribution crossover (UNDX). BLX- α determines offspring as follows.

a) Let α , b be the two parents in the real-valued vector space.

b) Calculate the intersection $[A, B]$.

$$A = \min(a, b) - \alpha |a - b| \quad (6)$$

$$B = \max(a, b) + \alpha |a - b| \quad (7)$$

where α is a coefficient parameter.

c) Determine the offspring from the interval $[A, B]$ with uniform random numbers.

That is, in the conventional GA, unlike the crossover method in which some or all of the loci of chromosomes are replaced, the vector obtained by subtracting the coefficient times the inter-individual distance from the smaller individual vector to the larger individual vector is added. It is a method

of determining a crossing vector according to a uniform random number generated in the range up to it.

4) *Mutation method*: Mutations were given by normal distribution. That is, it is a method of changing the real number vector of an individual according to the normal distribution according to the probability of the mutation to be set.

5) *Selection method*: The selection method of RCGA is the tournament method, and the elite strategy to enhance the convergence performance of RCGA is adopted.

6) *RCGA Specific method and parameter setting*: RCGA is more efficient because there are many real-valued parameters in ISODATA method. In this study, RCGA is used to optimize the thresholds of initial cluster centers and division and fusion in the ISODATA method. The specific method is shown below.

- Set the number of RCGA populations to 30 and the number of generations to 300.
- Since RCGA is used, real coding is constructed by constructing a multidimensional vector from real values of each parameter and performing crossover and mutation on the vector.

The composition of the vector of chromosomes is as follows,

$$C(S, M, A_1, A_2, \dots, A_m) \quad (8)$$

where S is the division threshold, M is the fusion threshold, and A_m is the m -th coordinate of the initial cluster center.

In this way, the chromosome is defined by Eq. (8), and RCGA is performed to find the optimal thresholds for division and fusion of the initial cluster center and ISODATA.

- Set the tournament selection size to 3.
- Use the BLX- α method as the crossover method. The value of α is set to 0.5 and the crossover probability is set to 70%, in order to prevent falling into a local solution and also considering the speed of convergence.
- The mutation method uses the normal distribution mutation method and sets σ to 0.5. Here, if the mutation probability is set to 5% or less, the local solution is likely to fall, and if the mutation probability is increased, the efficiency of GA is deteriorated, so it is set to 5%.

In order to compare the clustering results, we perform clustering of 100 sets of initial cluster centers randomly determined by uniform random numbers and calculate the maximum likelihood result and average value. The author also does some hierarchical clustering.

D. Improved ISODATA

As mentioned above, the ISODATA method is a method in which target data individuals are divided by constructing cluster boundaries by the hyperplane (Voronoi division³) by

³ https://en.wikipedia.org/wiki/Voronoi_diagram

the k-means method. That is, the probability density function of the cluster is implicitly assumed to be a convex function, and if the probability density function of the target data individual is a concave function, accurate cluster division cannot be expected. When the probability density function is concave, the ISODATA method may be able to deal with the division and fusion process, but there is a possibility that clusters that are correctly classified by division and fusion once will be destroyed by rearrangement.

E. Reduction of Calculation Amount

In the proposed method, the initial cluster center is estimated in advance by the real-valued GA (RCGA), so that the clustering result can obtain an almost optimal cluster result without relying on the modification of the cluster center by repeating the ISODATA method. That is, the clustering result is hardly affected even if the number of iterations of the ISODATA method is reduced to some extent. In the experiment, the number of repetitions of the ISODATA method was set to 4.

In the Moving Window method, the computational complexity increases exponentially as the number of dimensions increases. In the proposed method, we decided to reduce the amount of calculation by moving each individual in order, rather than moving gradually along each dimension.

IV. EXPERIMENTS

A. Dataset of Data used

The UCI repository dataset is a data archive published by knowledge discovery researchers at the University of California, Irvine (University of California, Irvine). It can be accessed by anyone on the web page⁴. In this research, Iris, Wine, New thyroid, and Ruspini dataset of R, and fossil dataset of Chernoff are used for the experiment.

1) *Iris data set* The Iris data set is data of three types of iris flowers. The total number of individuals in the dataset is 150, including 50 individuals for each type. The data in this dataset is four-dimensional. They are the width and length of sepal, the width and length of petal, and the unit is cm. The Iris dataset is one of the best-known datasets for clustering.

2) *Wine dataset*: The Wine Dataset is the chemical analysis data for three Italian wines. The total number of individuals in the dataset is 178, and the number of individuals of each type is 59, 71, 48, respectively. The data in this dataset is 13 dimensions. There is a large difference in the range of data in each dimension. There are dimensions where all numbers are less than or equal to 1 and dimensions that include up to 1,000. Therefore, clustering Wine datasets is considered difficult. In this study, the normalized (Min: 0, Max: 1) Wine dataset was used.

3) *Ruspini data set*: The Ruspini Data Set is included in R and S-plus. It is four-dimensional data with four categories. The total number of individuals is 75, including 23, 20, 17, and 15 individuals.

4) *New thyroid data set*: The New thyroid data set is 5D data on infectious diseases in UCI. The total population is 215. The number of categories is 3, category 1 includes 150 individuals, category 2 includes 35, and category 3 includes 30.

5) *Fossil data set*: The fossil data set is 6-dimensional data on three types of limestone by Chernoff. The total number of individuals is 87, and each category includes 40,34,13 individuals.

These five datasets are standard datasets that are often used to compare clustering methods. Experiments were performed on these data sets. The results are summarized in Table II.

It can be seen from Table II that the error is 20.23% lower in the proposed method compared to the ISODATA method when the initial cluster centers are set randomly. It is also shown that the error of the proposed method is much smaller than that of the k-means method (ICCD) and the single linkage method.

B. Satellite Imagery Data used

Clustering was performed using a part (Fig. 3) near Kashima city in Japan extracted from satellite images of the Saga area taken by ASTER / VNIR: Visible and Near Infrared Radiometer on December 7, 2004. The sampling area shown in the figure was set, and 30 × 30 identical cluster image data individuals were set. Clusters of these individuals correspond to four cluster types: sea, plants, freshwater, and urban areas. The dimension of the image data individual is 3, and the maximum value of each dimension is 255. The image is shown in Fig. 4.

TABLE II. CLUSTERING ERROR OF THE FOUR CLUSTERING METHODS FOR FIVE DATASETS OF UCI REPOSITORY

Error (%)	Proposed	k-means	ISODATA	Single linkage
Iris	10.67	10.67	21.33	32.00
Wine	4.49	5.62	34.65	61.24
Ruspini	0.00	0.00	12.43	0.00
Fossil	4.60	4.60	34.42	13.79
New thyroid	13.02	13.95	31.63	29.77

Fig. 3. Satellite Images Around Kashima City, Saga Prefecture in Japan (Band: 1,2,3 N).

⁴ <http://mllearn.ics.uci.edu/MLRepository.html>

Fig. 4. Sampling Image Representing a Cluster.

The proposed method and the conventional ISODATA method are applied to the satellite image, and the cluster results are compared. In the conventional ISODATA method, the result based on the Ward method is used for the initial cluster center. The results are shown in Table III and Fig. 5. As shown in Fig. 5 of the clustered results of the proposed method and ISODATA, there are some clustering errors at the bottom right of the clustered result of ISODATA while there is no error for the proposed method.

As can be seen from this table, it is shown that the proposed method is also effective for satellite data in which the probability density function of the target data individual is a concave function. Also, from the center of the original image in Fig. 6(a), a part of $32 * 32$ pixels include the above four categories. Fig. 6(a) is extracted to perform clustering by the proposed method and the conventional ISODATA method. Applied and compared the cluster results. The results of clustering are shown in Fig. 6(b) and 6(c).

TABLE III. RESULTS OF EXPERIMENTS USING SATELLITE IMAGES

Method	Proposed	ISODATA
Error (%)	0.00	3.89
Elapsed time (s)	25567.445	1.134

Fig. 5. Clustered Results of Proposed Method and ISODATA.

Fig. 6. Original Satellite Image and the Clustered Results of the Conventional ISODATA and the Proposed Method.

In comparison with the ISODATA method, which does not form a cluster corresponding to this distribution, it can be seen that the proposed method forms an appropriate cluster.

It can be seen that the proposed method also gives better results for satellite image data than the conventional ISODATA method, especially for classification of fresh water.

V. CONCLUSION

From the results of clustering experiments using simulation, UCI repository dataset and ASTER / VNIR images, the proposed method was superior to the conventional method in all cases. It was found that the proposed method has a higher degree of separation than the conventional method even when the probability density function of the clustering target data individual is a concave function, and a good clustering result is obtained. Therefore, the proposed method overcomes the problem that accurate clustering cannot be expected when it is difficult to set the parameters of the ISODATA method (initial cluster center and threshold of division / fusion: split / merge) and when the probability density function of the ISODATA method is concave.

Although the calculation time of the proposed method is longer than that of the conventional method by the amount of parameter setting by the real-valued genetic algorithm, the cluster accuracy is significantly improved, and it is effective when the cluster accuracy is important.

VI. FUTURE RESEARCH WORKS

Further research works are required for validation of the proposed clustering method with the other satellite imagery data. Furthermore, the alternative optimization algorithms of

GA such as sand cat swarm optimization (SCSO), Grey Wolf Optimizer (GWO) algorithm, Moth-flame optimization algorithm, etc. have to be tried for the parameter selection of the proposed clustering based on the modified ISODATA clustering.

ACKNOWLEDGMENT

The author would like to thank Prof. Dr. Hiroshi Okumura and Prof. Dr. Osamu Fukuda of Saga University for their valuable comments and suggestions.

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 680 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>

A Pre-trained Neural Network to Predict Alzheimer's Disease at an Early Stage

Ragavamsi Davuluri, Ragupathy Rengaswamy

Department of Computer Science and Engineering
Annamalai University, Chidambaram, Tamil Nadu - 608001

Abstract—Alzheimer's disease (AD), which is a neuro associated disease, has become a common for past few years. In this competitive world, individual has to perform lot of multi tasking to prove their efficiency, in this process the neurons in the brain gets affected after a while i.e., "Alzheimer's Disease". Existing models to identify the disease at early stage has taken the individuals speech as input then they are converted into textual transcripts. These transcripts are analyzed using neural network approached by integrating them with NLP techniques. These techniques failed in designing the model which can process the long conversation text at faster rate and few models are unable to recognize the replacement of the unknown words during the translation process. The proposed system addresses these issues by converting the speech obtained into image format and then the output "Mel-spectrum" is passed as input to pre-trained VGG-16. This process has greatly reduced the pre-processing step and improved the efficiency of the system with less kernel size architecture. The speech to image translation mechanism has improved accuracy when compared to speech to text translators.

Keywords—Mel-spectrum; VGG-16; ADAM optimizer; softmax; flatten layers; ReLU

I. INTRODUCTION

Alzheimer's disease is a progressive brain disease that gradually deteriorates memory and thinking abilities, as well as the ability to do even the most fundamental tasks. The majority of people with late-onset type symptoms are in their mid-60s when they get the disease [6]. Early-onset Alzheimer's disease is extremely rare and occurs between the ages of 30 and 60. The most prevalent cause of dementia in elderly people is Alzheimer's disease [20]. Memory issues are usually one of the early signs of Alzheimer's disease, though the severity of the symptoms varies from person to person [7]. Other areas of thinking, such as finding the proper words, vision/spatial difficulties, and impaired reasoning or judgments, may also indicate Alzheimer's disease in its early stages. There is no cure or treatment for Alzheimer's disease that affects the disease process in the brain. Complications from severe loss of brain function, such as dehydration, malnutrition, or infection, result in death in advanced stages of the disease [13]. Alzheimer's disease can be detected using a machine learning approach, which involves the use of various machine learning algorithms [18]. Furthermore, the patient's severity level will be predicted in percentages, and the percentage levels will be divided into several categories. The importance of early detection in Alzheimer's disease management cannot be overstated [14]. Convolutional neural network (CNN) is one of the deep-

learning algorithms that have been used to detect structural brain alterations on magnetic resonance imaging (MRI) because of its high efficiency in automated feature learning [15]. Many additional deep learning methods are being utilized to diagnose Alzheimer's disease [17] and even pre-trained models can be used in the detection of Alzheimer's disease [19].

The proposed model uses the audio dataset to improve the accuracy of the model by analyzing the live streaming data in case of Alzheimer's disease prediction [8]. The model produces a spectrogram from audio files, which produces visualization of signal strength in the form of 2D graph. The model needs to do two pre-processing steps before converting it into image [23].

The audio data is stored in the digitized format. Any machine learning algorithm is difficult to work with this digital form. So machine needs sampling mechanism to convert the digital data into analog data [9]. Sampling technique transforms the signal with respect to time into numerical values by identifying the difference between two consecutive samples of audio segments [10].

The obtained sample may contain noisy values i.e., at few intervals the obtained time signals may have amplitude has zero, which represents the state of silence [21]. The model address this issue by performing quantization that helps them to replace silence with nearest precision value and then it normalizes the data to have values in between -1 to 1 [24].

The model needs frequencies to identify the voice modulation, so it applies Fourier transformations to convert the time signals into individual frequencies. The frequencies can be produced into two ways namely FFT & STFT. The model employs STFT because it can efficiently convert the 1-dimensional data into 2-dimensional data where horizontal axis represents time and vertical axis represents frequency [11]. In short note, the sound waves are segmented into smaller chunks and few of them might overlap. In the final stage, each frequency amplitude in decibels is stored as a "pixel" value of the image. This conversion process is known as "Mel Scale" [12]. These pixels need to be stored in the form of vectors. The spectrogram represented in Mel Scale is a Mel Spectrogram [22].

II. LITERATURE SURVEY

Rohanian et al. proposed Multi-modal fusion on sequential modeling using LSTM technique. These fusion models are good in handling the lexical information. Since this context

changes with time, the model uses gating concept. This receives inputs from two different models i.e., (audio and text) and combines them into single unit by eliminating the noises from the audio data acquired. All the higher layers utilize non-linear functions but the lower layers use linear functions. The non-linear is transformed into linear by attaching the carriers integrated with self repairing system. The model hyper tunes the LSTM to identify the error co-efficient at early stage [1].

Raghavendra et al. designed embedded techniques related to speech and fine tune those using BERT models. The model extracts the essential features by constructing the x-vectors, which is a deep neural vector. In the next step, Mel-frequency coefficient is computed by embedding all the global pooling layers. The encoder of the ResNet stores the signals in the encrypted format but at decoder side it implements a pre-trained VoxCeleb1. The performance of this model is estimated using the MMSE because most of the characteristics are relevant to prosody features. These features are hard to maintain, so BERT model using its self attention layer which converts the linguistics elements into embeddings [2].

Ning Wang et al. implemented Attention Network by collecting real time data from Google Speech Recognizer API. The model extracts four different features using four different networks. The model for extracting the frame level features of the linguistic, it implements VGG network because it is good in handling the embossed features. FREQ commands convert the received audio into transcript form. NLTK takes care of the converted text but the context of each sentence is extracted using the Universal Sentence Embedding technique [3]. The model implements dilated CNN layers instead of 2D-CNN layers because multi head component associated with the embedded layers can represent the encoded representation very efficiently [16].

Amish et al. designed a framework BERT integrated CNN to extract the embedding text associated with the context. The audio dataset is initially segmented into shorter clips and then Mel-spectrum is generated for those segments. The model utilized Fast Text-CNN to generate transcripts and clusters are formed based on the common word vectors. In this model, instead of encoding all the sentences, it encrypts only Out-of-Vocabulary words using sentence BERT technique. During the text processing phase, the probability of segment is compared against the probability of entire transcript and then combined to form a fusion. Finally, a concatenation embedding model is designed to treat the each text segments separately [4].

Zhaoci Liu et al. worked with bottle neck features generated from augment images. The model doesn't convert the audio signals into transcripts because the designed extractor creates temporary intermediate form of representation. The audio signals are divided into set of window frames, from which both local and global context information is extracted. This information is stored as a sequence in LSTM and attention pooling is applied to perform the classification. The validation of the model is performed using query system, which is designed as feed forward network with sigmoid activation function and the input is obtained in the form of key-value pair [5].

III. PROPOSED METHODOLOGY

Most of the researchers analyzed the Alzheimer's disease either from images or from the .csv file extracted from the images. Few researchers, which are stated in Table I, worked on predicting system using audio dataset, which is converted into textual format. The accessing and processing of text using NLP techniques takes a lot of time, which makes the system to take late decisions. This issue is resolved in this paper by transforming the speech into images and processing them using pre-trained model. The entire process is illustrated in Fig. 1.

TABLE I. IDENTIFICATION OF LIMITATIONS FROM EXISTING MODEL

S.No	Author	Algorithm	Merits	Demerits	Accuracy
1	Rohanian et al. [1]	Multi-modal fusion	The feed-forward helps the model to transfer the data quickly	The model can be extended by introducing the bio-markers	79.20
2	Raghavendra et al. [2]	BERT	Embedding BERT and X-vector has solved the modulation frequencies very effectively during speech recognition	Adaptable BERT integrated with LM interpolation will refine the predictions associated with target values	84.51
3	Ning Wang et al. [3]	Attention Network	Instead of single feature extraction, the model extracted multiple features from different sources. So, this model achieves less misclassification rate	The model doesn't apply any segmentation technique to process the speech with respect to time	80.28
4	Amish et al. [4]	Multi Modal Sequence	The FastText CNN has the capability to generate transcripts for unknown words also	The model has implemented late fusion technique to combine the text segments which consumes more memory to activate the cells	85.30
5	Zhaoci Liu et al. [5]	Masked data augmentation	Since the bottleneck features extracts the low level values, it requires less space and time to encrypt	Usage of query system for validating the model made the process complicated	82.59

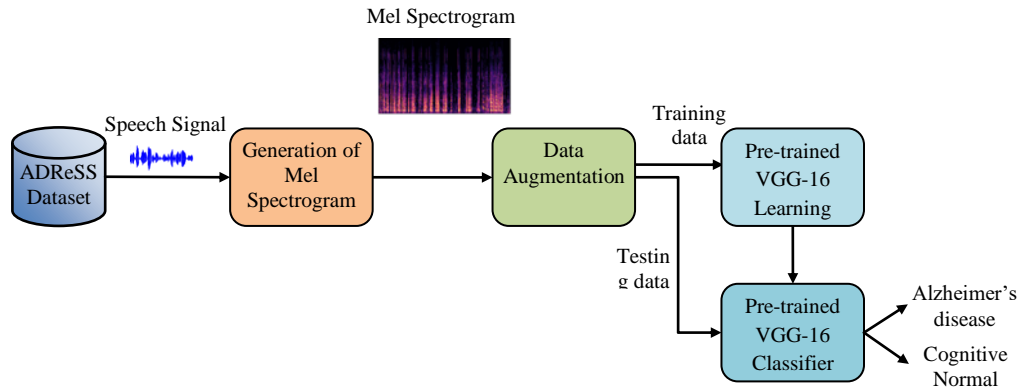

Fig. 1. Overall Architecture of Proposed System.

A. Conversion of Speech Signals to Mel-spectrum Images

The proposed research focused to analyze the disease from the speech, which are basically classified into Alzheimer’s disease (AD) and Cognitive normal (CN). Initially the model has constructed the Mel spectrogram from the speech files as represented in Fig. 2.

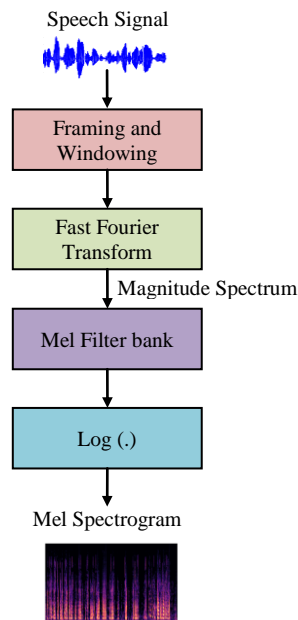

Fig. 2. Generation of Spectrogram Images from Audio Dataset.

The approach employs samples of air pressure over time to digitally represent a speech signal. The voice signal is transferred from the time domain to the frequency domain using the fast Fourier transform, and the system uses overlapping windowed portions of the speech stream. The technology converts the y-axis (frequency) to a log scale and the color dimension (amplitude) to decibels to create the

spectrogram. The y-axis (frequency) was mapped onto the Mel scale to generate the Mel spectrogram. The model applies a traditional Short Time Fourier Transformation (STFT); this is a very flexible class to represent time and frequency distribution from the processed speech signals. The identification of pitch variation is the major hyper tuning point. The computation is presented in equation (1).

$$STFT_m(input) = \sum_{n=-\infty}^{\infty} input_n * [H(n) - R_m] * e^{-j} \quad (1)$$

where, $input_n$ denotes input signal recognized at time ‘n’ $H(n)$ denotes N-length Hamming function applied on sliding window

R_m Represents hop size in between the m-size sliding window e^{-j} is a threshold multiplication function

Humans do not perceive frequencies on a linear scale, according to research. Lower frequency differences are easier to notice than higher frequency variances. Humans can readily distinguish between 500 and 1000 Hz, but we will struggle to distinguish between 10,000 and 10,500 Hz, despite the fact that the distance between the two pairs is same. As a result, we’ll utilize the Mel scale, which is a logarithmic scale based on the idea that equal lengths on the scale correspond to the same perceptual distance. Conversion from frequency (f) to Mel scale (m) is given in equation (2).

$$m = 2595 \cdot \log\left(1 + \frac{f}{500}\right) \quad (2)$$

A Mel Spectrogram is a spectrogram that converts frequencies to Mel scale. For the creation of log-Mel spectrograms, we chose 40 Mel filter banks. The availability of 40 Mel filter banks allows us to use pre-trained models such as VGG16 in the future. A Hamming window with a size of 2048 samples is used. With a hop-length of 1024 samples (the amount of samples between subsequent frames) and a sampling rate of 44.1 kHz. In the FFT calculation, the number of points is also 2048. The log-Mel spectrograms are separated into overlapping chunks of 100 frames each encompassing a length of 23ms to achieve this.

Algorithm for Construction of Mel Spectrum

```
Input: Audio Dataset with binary class labels, AD_Binary
Output: Mel-spectrum Generation
Begin
1. Set the path of the output folder to store the images of
spectrograms
2. ad_binary_labels←[“AD”, “CN”]
3. for i in ad_binary_labels: for j in path:
    a. audio_time_series,audio_sr←load(j,sr=None)
    // load the speech data in time series format with the
    specified sampling rate
    b. speech_frequency←stft(speech_time_series)
    c. speech_magintude, speech_phase ← magphase
    (speech_frequency)
    d. mel_scale_speech ← melspectrogram
    (S=speech_magintude,sr=speech_sr)
    e. mel_speech← amplitude_to_db
    (mel_scale_speech,ref=“minimum”)
    f. specshow(mel_speech,sr=speech_sr)
End
```

B. Disease Classification using VGG-16

The proposed system applies VGG-16 pre-trained model on generated spectrogram images to identify the disease. The model has chosen VGG network because of its simplicity nature even though it has huge parameter to hyper tune. The basic thumb rule for any deep learning algorithms is “More the training data more the accuracy”, but the training dataset has got fewer images from the speech signals. This issue is resolved by the model initially by applying basic image manipulation operations to increase the size of the generated spectrogram images as shown in Fig. 3.

The model has customized the few operations in the generator module to minimize the error rate. The basic customized operation is “pre-processing” unit because it denoises the images, which is a basic challenge faced by any of the computer vision applications. In this model, images are generated from the speech signals; therefore there are high chances to get noisy images due to sudden voice modulation from the external factors. The remaining customization operations are elaborated in Table II.

Fig. 3. Synthetic Data Created using the Image Data Generator Module.

The main advantages of the generator module lies in passing the multiple operations performed on the image are sent directly to the neural network instead of storing them in a temporary buffer or memory. Finally, the images are rescaled to 150 and divided them into 32 batch size. These synthesized images are passed as input to the VGG-16 neural network, whose task is achieved in two stages. In the first stage, it identifies the objects from the generated signals from the pre-defined classes available. In the second stage, the model contains 1000 class labels, so it has to classify the generated image from the customized class label. The model implemented its validation across Image Net dataset. The model implements only a kernel filter with size 3×3. The overall layers and their configurations for the VGG-16 are presented in Table III.

The entire architecture of the model is divided into 5 blocks of Ensemble 3-Dimensional CNN layers and 1 block of Fully Connected (or) Dense Layer. It takes standard input of size 224×224 with 3 dimensions. The first two blocks contains 2 layers of CNN with max pooling layer then remaining blocks contains 3 layers of CNN with max pooling. The final block contains two fully connected layers and one softmax layer.

TABLE II. DESCRIPTION OF IMAGE MANIPULATION CUSTOMIZATION OPERATIONS IN GENERATOR MODULE

S.No	Parameter Name	Description	Initialized Value
1	preprocessing_function	It removes the noise from generated images	Processed images from VGG16
2	Rotation_range	Some random images are rotated to 40 degrees angle	40
3	Width_shift	The images are translated 20% horizontally based on total width	0.2
4	Height_shift	The images are translated 20% vertically based on total height	0.2
5	Shear_range	It transforms the point to a particular	0.2
6	Zoom_range	The inside image contents are zoomed to 20%	0.2
7	Horizontal_flip	It randomly flips the half images of the dataset	True
8	Fill_mode	It fills the newly created pixels with nearest pixel values	Nearest

TABLE III. VGG-16 CONFIGURATION

S.No	Layer Name	Dimensions	Activation Function	Count
1	Convolution Layer	Initially it starts with 64 then it enhances up to 512	ReLU	13
2	Max Pooling Layer	From 75 × 75 × 64 to 4 × 4 × 512	-	5
3	Dense Layer	1×1×4096 is converted into 1×1×1000	ReLU	2

The customization of the pre-trained model is represented in the below section:

- 1) The model acquired the input images in the 2-Dimensional but VGG-16 requires in three dimensional. So it changes the input shape from 2-D to 3-D by passing additional parameters.
- 2) The model adjusted the weights of the neural network based on the "ImageNet" dataset.

3) The augment images have the shape of 150×150 but the VGG-16 accepts 224×224 . So, they include top attribute has assigned with false value.

4) In general VGG-16 requires softmax layer for multi classification but the model dataset has binary class labels. So, the model implements the softmax layer by flattening the layer. The overall architecture of VGG-16 is presented in Fig. 4.

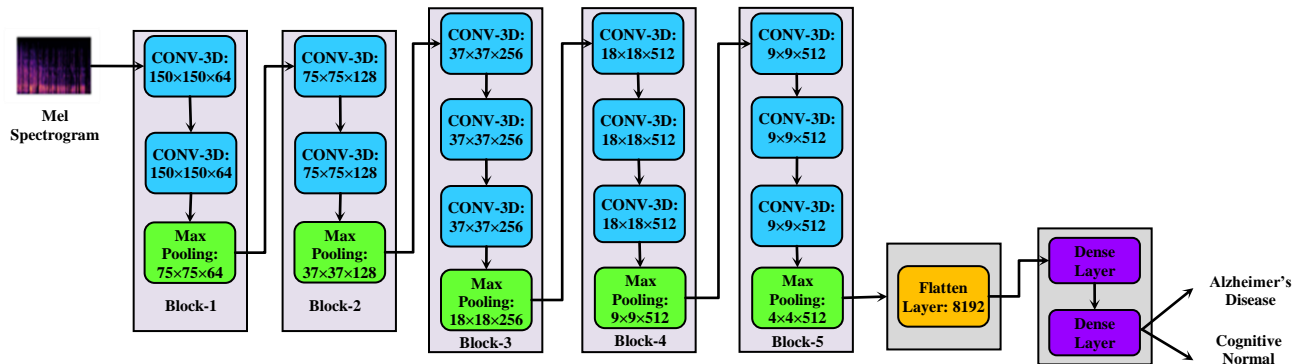

Fig. 4. Pre-trained Architecture of VGG-16.

IV. RESULT AND DISCUSSION

This model considers dataset from the publicly available repositories and uses Google Laboratory as the execution environment because the model needs GPU's to work with speech signals. The speech signals are labeled as "AD" and "CN". Alzheimer's is a group of neurodegenerative disorders characterized by a steady and long-term decline in cognitive function. Because age is the most important risk factor for AD, it affects the elderly the most. Because of the global severity of the situation, institutions and researchers are putting significant resources towards Alzheimer prevention and early detection, with an emphasis on disease progression. Cost-effective and scalable approaches for detecting Alzheimer disease in its most mild manifestations are needed. While several studies have investigated speech and language features for Alzheimer's disease and proposed various signal processing and machine learning methods for this task, the field still lacks balanced and standardized data sets on which these different approaches can be systematically compared. The ADReSS challenge dataset includes CN and AD patients' speech recordings, transcripts, and metadata (age, gender, and MMSE score). The dataset is balanced in terms of age, gender, and the number of CN vs. AD patients, with 78 patients in each class. The speech data is converted into Mel spectrograms. The outputs for the individual modules are represented in the below section.

Fig. 5(a) and 5(b) represents the generation of spectrogram from the speech signals for both the class labels. The graphs are represented by using the voice frequency obtained from the speech signals.

Fig. 6 represents the trainable and non-trainable parameters of VGG-16 by customizing the necessary parameters and

layers. In general, neural networks need more parameters to train the model but due to usage of pre-trained models, the trainable parameters got reduced.

Fig. 7 represents the training phase of the model in pre-defined Epochs values. With the increase of Epoch, there might be increase or decrease of the accuracy. So, the model saves the highest accuracy as the best model. It updates the checkpoints if and only if the model gets better accuracy than the previous value. The model wants to prove the state of accuracy by comparing the standard CNN with VGG-16 pre-trained model. So, it represented the initial output training results of CNN in Fig. 8.

Fig. 9 represents the accuracy values obtained by VGG-16 at different Epochs levels. From Fig. 10, the model can clearly state that the VGG-16 has performed very well than CNN by comparing from the initial Epochs.

V. CONCLUSION

In this paper, the model has recognized Alzheimer's disease at early stage effectively by creating the synthetic dataset of Mel spectrum images then these are acted as input for the ImageNet trained VGG-16 system. The model has opted pre-trained model instead of CNN because the dataset contains different modulation signals with noise. The design becomes complicated because to extract essential features from the

different modulations, more number of layers is required. It requires an efficient back propagation system to update the weights accurately. The numbers of trainable parameters are 8,53,145 in CNN where as the number of trainable parameters are 16,386 in proposed network. The misclassification rate and accuracy are also got affected because of the transfer learning process. As a conclusion remarks, it can be stated that variations in CNN model work well on the images because of its implicit feature extraction process.

A k -interpolation Model Clustering Algorithm based on Kriging Method

Guoyan Chen*, Yaping Qian
School of Mechanical Engineering
Jiangsu University of Technology, Changzhou, China

Abstract—In this work, a k -interpolation model clustering algorithm is proposed based on Kriging method, aim to partition data according to the relationship between the response of interest and input variables. Kriging method is used to describe the relationship between the response of interest and input variables. For each datum, the estimation errors of the interpolation models of the clusters are used to decide its assignment. An optimization strategy is proposed to obtain the final clustering results. The key factors of the proposed algorithm on its performance are studied through the synthetic and real-world datasets. The results show that the proposed algorithm is able to cluster the data according to the response of interest and input variables, and provides competitive clustering performance compared with the other clustering algorithms.

Keywords—Data clustering; Kriging method; k -means algorithm; interpolation model

I. INTRODUCTION

In recent years, massive data have been generated and recorded from real-world systems. The information mined from these data represents the characteristics of the real-world system, which can be used to analyze and improve the performance of the system. In most data mining tasks, it is necessary to build the performance prediction model first, aiming to accurately estimate the response of interest according to the input variables. However, the relationship between the response and input often changes greatly, which is difficult to evaluate through a unified prediction model [1-3]. Obviously, this issue can be solved by partitioning the data so that the data in the same part have a more similar relationship between response and input than the data from the other parts, and this work can be accomplished by data clustering.

Data clustering is a class of algorithms and techniques aiming to partition a dataset such that the data characteristics in the same cluster are more similar than the other clusters [4]. Many clustering algorithms have been proposed in the past decades, such as k -means algorithm, fuzzy c -means algorithm, Gaussian mixture model, and so on [5-6]. Since the k -means algorithm is easy to understand and implement, it has been widely used in many data mining tasks such as image recognition, modal analysis, and outlier detection. Shubair, and Al-Nassiri used the least square method to estimate the centers of clusters in k -means algorithm and applied the clustering algorithm in the preparation process of data streams [7]. Aldino et al. used k -means algorithm to group the corn-producing regions based on the collected data of corn crops to assist in the formulation of corn planting [8]. Yu et al. proposed multi-

layers framework to increase the performance of k -means algorithm on the dataset with outliers and noisy values [9]. In addition, genetic algorithm is used to obtain the optimal clustering results. Zhu et al. proposed a grid k -means algorithm to improve the clustering accuracy and stability and validated its performance on the dataset with the noise points [10]. Cuomo et al. used parallel techniques to reduce the computation cost of k -means algorithm for the large data analytic problem and provides solutions for the problems of GPU space limitation and host-device data transfer time [11]. k -means algorithm clusters data according to their spatial distance, resulting in it being difficult to ensure that the data in the same cluster have a similar or same relationship between the response of interest and input variables. Thus, it is necessary to develop a new clustering method under the framework of k -means algorithm.

In recent years, an interpolation model, Kriging method, has been widely used to model the relationship between the response and input variables of the measured data of the real-world systems. For example, Echard et al. assessed the failure probabilities of an engineering system using the importance sampling method and Kriging method, which has been successfully used in the reliability analysis of engineering systems [12]. Keshtegar et al. used Kriging method to estimate the solar radiation based on the meteorological data [13]. Wojciech proposed a digital terrain estimation method based on Kriging method, in which a neighbor points selection method is designed to accelerate the training speed Kriging method [14]. Belkhiri et al. estimate the groundwater quality for drinking purposes using Kriging method [15]. The results indicate that the Kriging model with electrical conductivity as co-variable produces the best performance compared with the other Kriging models. From the above works, it can be seen that Kriging method can effectively learn the relationship between the response of interest and input variables from the measured data. Thus, a k -interpolation model clustering algorithm is proposed based on Kriging method under the framework of k -means algorithm in this work, aims to partition data according to the relationship between the response of interest and input variables. Kriging method is used to evaluate the relationship between the response and input variables. For each datum, the estimation errors of the interpolation models of the clusters are used to decide its assignment. An optimization strategy is designed to obtain the clustering results. Finally, the performance of the proposed algorithm is validated through several synthetic and real-world datasets. The remainder of this work is organized as follows. The proposed algorithm

*Corresponding Author.

including the background of k-means algorithm and Kriging method is introduced in Section 2. The synthetic datasets and engineering datasets are used to test and compare the performance of the proposed algorithm with the conventional clustering algorithms in Sections 3 and 4. The conclusions are provided in Section 5.

II. LITERATURE REVIEW

In recent years, several data clustering algorithms have been proposed to partition data according to their relationship between the response of interest and input. Peng et al. [16] introduced ridge regression to evaluate the relationship of two-dimensional data in their clustering. Chen et al. [17] used the least square method to evaluate the features of data, and then applied fuzzy c-means algorithm to cluster them. However, only the linear relationship is considered in the above methods. To realize data clustering based on their nonlinear relationship between the response of interest and input, artificial neural networks and Gaussian process regression have been used to replace linear models. For example, Blažič et al. [18] used artificial neural networks to evaluate the nonlinear regression relationship to identify the state of engineering systems. Fuhg et al. [19] applied Gaussian process regression to evaluate the relationship among attributes to partition data according to their variation ranges. Fang et al. [20] used artificial neural networks to evaluate the relationship among data attributes to cluster the in-situ data of a tunnel boring machine.

III. PROPOSED METHOD

A. K-means Algorithm

k-means algorithm is developed in the area of signal processing, which aims to partition n data into k clusters in which each datum belongs to the cluster with the nearest mean (the prototype of the cluster). Generally, the clustering process of k-means algorithm can be subdivided into two stages: assignment step and update step as follows.

Assignment step: each datum is assigned to the cluster with the nearest prototype as follows

$$S_i^t = \{datum_p: \|d_{ip}\|^2 \leq \|d_{jp}\|^2 \forall j, 1 \leq j \leq k\} \quad (1)$$

where d represents the distance between the datum and the mean (Euclidean distance is usually used), and $datum_p$ is assigned to exactly one S_i^t .

Update step: the mean (prototype) of each cluster is recalculated as follows.

$$m_i^{t+1} = \frac{1}{|S_i^t|} \sum_{datum_j \in S_i^t} datum_j \quad (2)$$

The iterations are carried out until the assignments no longer change.

B. Kriging Method

In Kriging method (KRG), the following model is used to model the outputs at the samples:

$$Y(x) = f^T(x)\beta + Z(x) \quad (3)$$

where $Y(x)$ is the function of interest, $f = [f_1(x), f_2(x), \dots, f_m(x)]^T$ is the basis functions, and

$\beta = [\beta_1, \beta_2, \dots, \beta_m]^T$ is the corresponding coefficient vector. $Z(x)$ is a Gaussian stationary process with zero mean and covariance.

$$\text{Cov}(x_i, x_j) = \sigma^2 R(\theta, x_i, x_j) \quad i, j = 1, 2, \dots, n \quad (4)$$

where σ^2 is the process variance, $R(\theta, x_i, x_j)$ is the correlation function of the stochastic process, θ is the hyper-parameters of $R(\theta, x_i, x_j)$, and n is the sample number, The maximum likelihood method is used to optimize θ , where the likelihood function is expressed as follows:

$$L = (2\pi\sigma^2)^{-\frac{n}{2}} |R|^{-\frac{1}{2}} \exp \left[-\frac{1}{2\sigma^2} (Y - F\beta)^T R^{-1} (Y - F\beta) \right] \quad (5)$$

where R is the correlation matrix and F is a vector including the value of $f(x)$. β and σ^2 are estimated through the least-square method as follows.

$$\hat{\beta} = (F^T R^{-1} F)^{-1} F^T R^{-1} Y \quad (6)$$

$$\hat{\sigma}^2 = \frac{1}{n} (Y - F\hat{\beta})^T R^{-1} (Y - F\hat{\beta}) \quad (7)$$

By taking the logarithm of Eq. (5) with the imposed σ^2 value and multiplying by -1, the maximum problem to obtain the optimal θ is revised as

$$\text{minimize } \frac{1}{2} \ln(|R|) + \frac{n}{2} \ln(|\sigma^2|) \quad (8)$$

The prediction of Kriging method for a new sample x^* is

$$y(x^*) = f^T(x^*)\hat{\beta} + r^T R^{-1} (Y - F\hat{\beta}) \quad (9)$$

where $r = [R(\theta, x_1, x^*), R(\theta, x_2, x^*), \dots, R(\theta, x_n, x^*)]$.

C. The Proposed Algorithm

A k-interpolation model clustering algorithm is proposed based on Kriging method in this section. From Eq. (1), it can be known that the distance d should involve the relationship between the response of interest and input variables, if we want to cluster the data based on the relationship. In this work, Kriging method is used to evaluate the relationship, and the estimated response of each datum can be obtained as flows.

$$\widehat{y}_{p,i} = \text{KRG}(x_p)_i \quad (10)$$

where $\widehat{y}_{p,i}$ is the estimated response of k -th datum of i -th cluster, x_p is the vector of input variables. The distance d is defined as follows.

$$d_{ip} = |y_p - \widehat{y}_{p,i}| \quad (11)$$

Similar to k-means algorithm, the clustering process of the proposed algorithm (named k-IM) is summarized as follows.

Step 1. Set the clustering number c ;

Step 2. Generate the assignment of the data randomly;

Step 3. Construct KRG model of i -th cluster based on the data contained in the cluster;

Step 4. Using the obtained KRG models to get the responses of all the data and creating the responses matrix $Y_{n \times c}$;

Step 5. Assigning each datum to the cluster using Eq. (1) and Eq. (11).

Step 6. If any stop conditions are satisfied, the procedure is stopped, and the current assignment results are considered as the final clustering results, otherwise, return to Step 3.

Fig. 1. Flow-chart of the Proposed Algorithm.

IV. EXPERIMENTS ON SYNTHETIC DATASETS

In this section, the synthetic datasets are used to validate the proposed algorithm. For each dataset, the data of each cluster is generated first and combined as the final dataset. The Latin hypercube sampling method is used to generate the input variables, and then the corresponding responses are calculated through the setting relationship between the response and input variables. The naming of the dataset is based on its sample number and cluster number. For example, N400C2 means that the dataset has 400 samples and two clusters. The proposed algorithm is compared with three popular clustering methods, k -means algorithm (KM), fuzzy c -means algorithm (FCM), and Gaussian mixture model (GMM). The clustering performance is evaluated through the following indexes.

1) Misclassification rate (MS):

$$MS = \frac{N_{error}}{N_{total}} \quad (12)$$

where N_{error} is the number of misclassified data; N_{total} is the total number of data. The lower MS , the higher cluster validity.

2) Adjusted rand index (ARI) [21]: Given a set S of n elements, and two partitions of these elements, namely $X = \{X_1, X_2, \dots, X_s\}$ and $Y = \{Y_1, Y_2, \dots, Y_s\}$, the overlap between X and Y can be summarized in a contingency table $[n_{ij}]$ where each entry n_{ij} denotes the number of objects in common between X_i and Y_j : $n_{ij} = |X_i \cap Y_j|$ as shown in Table I. Adjusted rand index is defined as follows:

$$ARI = \frac{\sum_{i,j} \binom{n_{ij}}{2} - \left[\sum_i \binom{a_i}{2} \sum_j \binom{b_j}{2} \right] / \binom{n}{2}}{\frac{1}{2} \left[\sum_i \binom{a_i}{2} + \sum_j \binom{b_j}{2} \right] - \left[\sum_i \binom{a_i}{2} \sum_j \binom{b_j}{2} \right] / \binom{n}{2}} \quad (13)$$

The closer ARI to 1, the higher cluster validity.

TABLE I. CONTINGENCY TABLE

$X \setminus Y$	Y_1	Y_2	...	Y_s	Sums
X_1	n_{11}	n_{12}	...	n_{1s}	a_1
X_2	n_{21}	n_{22}	...	n_{2s}	a_2
...
X_s	n_{r1}	n_{r2}	...	n_{rs}	a_r
Sums	b_1	b_2		b_s	

3) Normalized mutual information (NMI) [22]:

$$NMI(X, Y) = \frac{I(X, Y)}{\sqrt{H(X)H(Y)}} \quad (14)$$

where $I(\cdot)$ is the mutual information metric and $H(\cdot)$ is the entropy metric. The closer NMI to 1, the higher cluster validity.

A. Effect of Sample Number

In this section, four synthetic datasets are used to study the effect of sample number on the performance of the k -IM algorithm. In each dataset, there are two clusters, and each cluster has the following relationship between the response and input.

$$\text{Cluster 1: } y = (6x - 2)^2 * \sin(12x - 4)$$

$$\text{Cluster 2: } y = 0.6(6x - 2)^2 * \sin(12x - 4) + 12(x - 0.5) + 6$$

where $x \in [0,1]$. For each synthetic dataset, one cluster has 150, 200, 250, 300 samples, respectively. Thus, the four synthetic datasets are denoted as N100A2C2, N200A2C2, N300A2C2, N400A2C2, respectively. The obtained N400A2C2 dataset is shown in Fig. 1. From Fig. 2, it can be seen that the samples of the two clusters are distributed similarly, but the relationship between the response of interest and input is different. The 30 times experiments are conducted for each dataset. The average experimental results are shown in Tables II to IV.

Fig. 2. N400C2 Dataset.

Fig. 3. Clustering Results Comparison of N400C2 Dataset.

From these tables, it can be seen that the k -IM algorithm produces much better results than the FCM, KM, and GMM

algorithms. The mean misclassification rate of the proposed algorithm is less than 0.03, which is much smaller than those of FCM, KM, and GMM, indicating the k -IM algorithm is able to accurately cluster the synthetic datasets. To further compare the performance of the clustering algorithms, the clustering results of N400C2 dataset of one experiment are shown in Fig. 3. From this figure, it can be seen that the proposed algorithm clusters the data based on the relationship between the output and input. The FCM and KM algorithms cluster the data according to their spatial distribution. It is noted that the GMM algorithm assigns most data to one cluster. The reason is mainly that it clusters data with the assumption that the data obey a Gaussian mixed distribution. The assumption cannot be stratified for N400A2C2 dataset. Thus, the clustering results of the GMM algorithm are much worse than the other algorithms. From the experimental results shown in Tables II to IV, it is observed that the sample number has an effect on the proposed algorithm. With the sample number increasing from 300 to 600, the MS of the proposed algorithm first decreases to 0.013 and then increases to 0.019. Similar results can be found in the indexes ARI and NMI. The reason is explained as follows. As the sample number increases, more samples can be utilized to construct the KRG models, which mean that the relationship between the output and input can be evaluated more accurately. The performance of the k -IM algorithm increases with the increase in the sample number. However, the KRG model tends to be overfitting when the sample number is too large. Thus, the performance of the k -IM algorithm decreases with the sample number increasing from 500 to 600. The proposed algorithm produces competitive clustering results for the datasets with different sample numbers tested in this section.

N500C2	0.923	0.216	0.085	0.063
N600C2	0.883	0.216	0.126	0.068

B. Effect of Cluster Number

Three datasets with different cluster numbers are used to test the effect of clustering number on the proposed algorithm, as shown in Table V. It is observed that the clusters of each dataset have similar but different relationships between the response and input variables. For each dataset, 30 times experiments are conducted. The average clustering results are shown in Fig. 4.

Fig. 4. Clustering Results of N400C2, N600C3 and N800C4 Datasets.

From Fig. 3, it is observed that the k-IM algorithm is still able to produce the best results among the tested four algorithms. The highest misclassification rate of the k-IM algorithm is around 0.10, which is much smaller than the conventional FCM, KM, and GMM algorithms. The index ARI of the k-IM algorithm is higher than 0.80 for all three datasets.

The index NMI is around 0.80, which is higher than the other clustering algorithms as well. It is noted that the misclassification rate of the GMM algorithm is higher than 0.50 for N600C3 and N800C4 datasets. The reason is that the GMM algorithm clusters almost all the data into one class, which means that most data are misclassified. Thus, the MS is higher than 0.50. With the cluster number increasing, the performance of the k-IM algorithm decreases, but it is still much better than the other popular clustering algorithms. The proposed algorithm can produce competitive clustering results when clustering the dataset with different cluster numbers tested in this section.

C. Effect of Noise

The measured data of real-world systems usually have noise. N400A2C2 dataset is used to test the performance of the k-IM algorithm on the noise. The synthetic datasets are generated as follows. For each cluster, the input variables are generated. The response is calculated according to the set function. For each datum, a random value is generated according to the set interval as shown in Table VI and added to the response. The average clustering results of 30 times experiments are shown in Tables VI to VIII.

TABLE V. EFFECT OF SAMPLE ON THE CLUSTERING PERFORMANCE (MS)

The performance of the k-IM algorithm is better than the other popular clustering algorithms even if the dataset has noise in the relationship between the response of interest and input variables. The MS of the k-IM algorithm is smaller than 0.05, which means that less than five percent of the data are misclassified. Similar results can be found in the experimental results of the performance index ARI and NMI. With the noise level increasing, the performance of the k-IM algorithm decreases. When the dataset has higher noise in the relationship between the response of interest and input variables, the Kriging method is more difficult to accurately evaluate the relationship. Thus, the performance of the proposed algorithm is worse when the noise level is higher. But, the MS of the k-IM algorithm is still smaller than 0.045. The k-IM algorithm can produce competitive clustering results for the datasets tested in this section.

V. EXPERIMENTS ON ENGINEERING DATASETS

In this section, three engineering datasets are used to further test the proposed algorithm. Since the classification information of the engineering datasets is unknown, the experiments are conducted as follows. For each engineering dataset, the dataset is first clustered into several subsets. For each subset, five cross-validation method is used to test whether the data in the same subset has a similar relationship between the response of interest and input variables. The subset is randomly divided into five parts, one part is selected as the testing data, and the remaining four parts are used as the training data. The experiments are conducted five times, and the average R-square of the five experiments is used to assess the consistency of the relationship of the subset. R-square is calculated as follows.

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (15)$$

where n is the number of the testing data, y_i is the real response, \hat{y}_i is the estimate response, and \bar{y} is the mean of the real responses. The closer R^2 to 1, the better performance.

A. Yacht Hydrodynamics Dataset

The yacht hydrodynamics dataset is first used. The dataset comes from a series of 308 experiments on the residuary resistance of sailing yachts [23]. Several input variables are considered, including the prismatic coefficient, longitudinal position of the center of buoyancy, length-displacement ratio, beam-draught ratio, length-beam ratio, and Froude number. The residuary resistance is evaluated through the per unit weight of displacement. The k-IM, FCM, KM, and GMM

algorithms are used to cluster the yacht hydrodynamics dataset into two subsets. And, five cross-validation methods are applied to each subset to test whether the data in the same subset has a similar relationship between the residuary resistance and input variables. The experiments are conducted 30 times, and the corresponding results are shown in Fig. 5. The average R^2 of the k-IM algorithm is higher than 0.98 for the obtained two clusters, which is much better than that of the FCM, KM, and GMM algorithms, indicating that the data of the same cluster obtained by the proposed algorithm have more similar relationship between the response of interest and input variables. The k-IM algorithm is able to cluster the yacht hydrodynamics dataset according to the relationship between the residuary resistance and input variables.

B. Bolt Tensioner Dataset

Bolt tensioner is a widely used tensioning tool in the assembly of large equipment such as nuclear power generators or the construction of large buildings [24]. It is an annular jack that rises up through hydraulic pressure. The bolt tensioner dataset recorded the data from 40 simulations, including the maximum stress at the piston of the bolt tension and the corresponding structural parameters with the same hydraulic pressure. In the experiment, the cluster number is set two as well, and the k-IM, FCM, KM and GMM algorithms are used to cluster the dataset. Based on the clustering results of each clustering algorithm, five cross-validation methods are to test whether the data in the same cluster has a similar relationship between the maximum stress and structural parameters. Fig. 5 shows the experimental results. It is noted that the GMM algorithm cannot provide clustering results since the covariance matrix is ill. From Fig. 6, it can be seen that the average R^2 s of the k-IM algorithm is the highest among the tested four clustering algorithms. The k-IM algorithm is able to cluster the bolt tensioner data such that the data in the same cluster have a similar relationship between the maximum stress and structural parameters.

Fig. 6. Experimental Results of Bolt Tensioner Dataset.

VI. CONCLUSION

In this work, we proposed a k -interpolation model clustering algorithm (named k -IM) to cluster data according to the relationship between the response of interest and input variables. In the proposed algorithm, Kriging method is used to construct the interpolation models. For each datum, the estimation errors of the interpolation models of the clusters are used to decide its assignment. An optimization strategy is designed to obtain the clustering results under the framework of k -means algorithm. The effect of the sample number, cluster number, and noise level on the k -IM algorithm is studied through several synthetic datasets. The results indicate that the k -IM algorithm in this paper can provide competitive clustering results. Two engineering datasets are further to test the performance of the k -IM algorithm as well, and the experimental results show that the k -IM algorithm is able to cluster the data such that the data in the same part have a similar relationship between the response of interest and input variables.

ACKNOWLEDGMENT

The authors would like to thank the editors' and reviewers' work on this paper.

Abstract—Food waste is a significant worldwide issue in landfill management. Due to improper implementation, technology applications related to food waste collection and its management system are still lacking in practice. The available applications have yet to address the issue of food waste management. Constructing an interactive mobile application is necessary for managing food waste collection for the decomposition process using Black Soldier Fly (BSF) treatment. Furthermore, as the mobile application requires participation from various user backgrounds, maintaining user involvement has become a priority. Gamification has emerged as one of the approaches that might favourably affect individual engagement behaviour. A comprehensive game element design is required where it focuses on how gamification can influence user engagement. This study aims to model the food waste gamified mobile application design to benefit Malaysia's decomposition ecosystem. It includes gamification, management features, and data visualization for reporting and will involve users from households, businesses, and the BSF farm. This paper presents the modelling process of a new mobile application design for this concept of study. The UX agile approach was used in gathering and designing the application requirements as it allows for active participation from all stakeholders. The result shows that the experts agree on the application design. This research will indirectly benefit the BSF industry in Malaysia, and it will have a significant impact on gamification, user experience, and food waste management in the direction of a sustainable environment.

Keywords—Avatar; food waste disposal; mobile apps; gamification; data visualization; black soldier fly

I. INTRODUCTION

Information system focuses on providing solutions to business processes for better operation management, information, and supporting the decision-making process. Recent technological advancements have transformed the way business processes are carried out. In this context of the study, the technology transformation includes the business process of collecting food waste from sources (households and businesses) and sending it to farms for treatment using black soldier fly (BSF). This treatment is one of the methods used to keep organic waste out of landfills [1]. With BSF as a treatment agent, food waste disposal is environmentally safe and cost-effective [1 – 2]. It is known that BSF decomposes food waste into animal feed and compost. Thus, the quality of food waste is critical for BSF production. As a result, food waste preparation should adhere to the guidelines provided. Therefore, food waste producers should be cultivated with proper, clean, and safe disposal. It is necessary to simplify the

procedure of food waste disposal for them to actively participate in keeping the surrounding environment safe [3]. This procedure could involve everything from waste preparation to waste collection and delivery to the farm for further processing.

As smartphones become more prevalent in daily life, using them to support food waste processes ranging from waste cultivation to collection will allow individuals and society to contribute to environmental sustainability. However, in order to contribute, they must be driven or motivated. Current food waste collection, disposal, and decomposition systems or mobile applications on the market are not related to collection, disposal, or decomposition. They are merely about raising awareness about food waste and recycling [3 – 5]. Although technology intervention in food waste operations may be attracting much attention worldwide, it is unlikely to be internalized for use by other landfills, particularly those commercially produced for the Malaysian market. This paper argues that it is deemed necessary to have an application that can stimulate community involvement and an application that can assist landfills in conducting their business operations, particularly in the case of the Malaysian context of studies. Gamification offers a game-like experience to a serious or monotonous type of work. This experience will make the users interact with the system not because they are forced to but because they want to use it and be a part of a fun and appealing system. As gamification aims to motivate users, its application may benefit food waste management. Furthermore, because the national aspiration is toward digitization, there seems to be a significant effort to improve the organization's information system management in all aspects of the operation.

This paper presents the development and modelling of a smart mobile gamified application for managing local food waste, a case study in the Malaysian context. Using BSF, the technology will support food waste requests and collection business processes for later decomposition arrangements. This technology is made available through mobile apps that include gamification, waste management features, and data visualization for reporting. The application can help to support the government effort to preserve the environment, especially the food waste disposal and ecosystem of BSF. For that purpose, the groundwork of the system application design and development are described, the results from the design usability testing are presented, and this design later be modelled as a guideline for similar system implementation. Given the current literature review, it shows that this research

would be a significant digital application if implemented in the context of Malaysia.

The following is how this paper is structured: First, as an introduction to the study, this paper reviews work related to food waste and BSF in Malaysia, food waste technology adaptation, and the use of gamification in the related application. Second, it describes the study's materials and methods. The description includes the development methodology, the mobile application's requirements and design, as well as design validation. The third section contains a discussion of the results of the design usability test. A model for such an application is created as a result of the design activities and is presented in section four. Finally, concluding remarks and recommendations for future work are presented in the final section.

II. RELATED WORK

A. The Model Development Process

Historically, most countries, developed or developing, have relied on landfills as final waste disposal sites [6 – 7]. Today, many developed countries have made other options within the waste hierarchy mandatory to reduce landfilling. Developing countries, particularly impoverished urban areas, rely on unsustainable solid waste management, primarily dumpsites. Over 90% of waste generated in low-income countries is either openly burned or disposed of in landfills [8]. Dumpsites receive all types of waste, including organic waste, and exposure to rainfall causes the production of leachate and methane. It contributes to the problem of climate change. Unknowingly, food waste is one of the wastes that has significantly contributed to the global dumpsite problem.

Malaysia had relatively high percentages of food waste from restaurants and households [3, 9]. According to Abd Ghafar [9], in 2017, restaurants contributed approximately 15,000 tonnes of food waste per day, with households contributing approximately USD 50 per month. In 2021, daily food waste will reach 38,000 tonnes, with household waste increasing by around USD 90 per month [10]. The local authorities are now dealing with a critical situation. One alternative to managing food waste is Black Soldier Fly (BSF). BSF will consume the food waste feed and compost the waste [1 – 2]. It is critical to preserve the ecosystem to create a sustainable environment. As a result, various approaches from various perspectives have been explored to support the effort. One of them is through the innovation of smart technology in assisting the food waste disposal processes for the benefit of BSF.

Food waste disposal management in the literature is centred on food recycling [3 – 4], landfill issues [4], and educational awareness [3, 5]. However, none of this is used commercially in Malaysia. Little is known about information technology that may impact food waste disposal processes and BSF production. High amounts of food waste are required to increase BSF production. Furthermore, the food waste disposal ecosystem should include households, retailers, agricultural industries, the local community, local governments, and the BSF industry. However, due to the limited venue or platform to contribute, communities may find the effort is not encouraged by the local

authority or another party. Thus, different individuals' behaviour and perceptions of the importance of beneficial food waste disposal emerge [11]. Besides, the community's awareness of the processes may not be widespread. As a result, there is a lack of involvement and motivation from the communities (restaurant, farm, household) [11 - 12]. In this view, communities may fail to see and realize the urgency to properly dispose of their food waste.

B. Technological Approach to Food Waste Management

Various alternatives should be developed to ensure a smooth domestic food waste disposal process, including food waste readiness, collection, sending to the appropriate farm (validated by local authorities), and verifying food waste disposal compliance. Research by Varhana, Faliasthiunus & Ulfah [13] has recently completed the development of a management system specifically for BSF. They created a traceable waste system that can track, control, and manage waste problems following their authority's policies. They used a waste bank, which served as a waste recipient, distributor, and manager. BSF would be able to generate a high economic value through the waste bank. However, since this application is primarily concerned with the management of BSF production, local communities, businesses, and government involvement may be given less emphasis. Other food waste mobile apps that have been developed are more focused on raising awareness [5], the Zero Food Waste Act [14], and ways to reduce food waste through donation [15]. In Jain et al. [5], gamification is used in a mobile application to encourage students to avoid making messes and wasting food and develop positive behaviour in maintaining a good environment. However, these current inventions do not include management of the food waste disposal process that involves societies for a sustainable environment. Some incentive that encourages them to be a part of the process should be designed and implemented to increase community participation.

Gamification is a practical approach to information management [16]. Gamification is expected to provide a fun and engaging environment for users to complete assigned tasks [16]. Ulla Santti et al. [17] investigated the use of gamification in encouraging users to process and sort their food waste. According to the study's findings, the gamified application can be effectively used to support a change in consumer behaviour, particularly in cultivating food recycling among young adults. Research by Ali & Ahmed [18] created a mobile geo-located system to locate and pattern user-reported food waste disposal. Gamification was used by the application to encourage user engagement with the application. Ali & Ahmed contend that increasing food waste awareness goes beyond food waste reduction. Users must be motivated to participate in the process. All available applications, such as those in [5, 17–18], are concerned with encouraging users to reduce food waste. In this regard, the gamification application differs from the proposed work for this research. However, the use of a motivating element to justify gamification is similar.

The local authority also requires an intelligent system to manage their waste administration better [9, 14]. In this view, a local authority may need a smart mobile application to cater to food waste movements. The application should involve the local communities, businesses, and BSF farms. An application

that allows them to actively monitor the production of BSF livestock from the collection of food waste seems demandable. Such application will indirectly help to improve the production of BSF livestock.

III. MATERIALS AND METHODS

This section describes the modelling and verification process of developing the proposed mobile application. The description includes the methodology used in the study, the detailed modelling processes involved, and the materials used in the study. The requirement analysis and application design activities in modelling the interactive application for managing household food waste for BSF in Malaysia are presented in detail.

A. Agile UX Methodology

The modelling and verification of the mobile application development follow the agile UX methodology. The methodology was chosen due to the nature of the work that requires active involvement from a system developer, project management, and other system stakeholders. Obtaining collective opinions and approval will be difficult if meetings do not exist or are held infrequently [19]. The study by Akhbar et al. [20] shows that software companies in Malaysia have been opting to adopt an agile approach in their software development projects. This adoption is due to the company's agreement to support the global software development projects, outsourcing the tasks to other offshore companies. The approach seems to have encouraged the collaboration of ideas, staff skills, and company resources between the local and offshore companies. Besides, agile implementation in the context of IS projects in Malaysia was a successful approach in delivering a rapid system implementation [21].

The agile UX development lifecycle is a method variation that builds on the Scrum framework [22]. It is organized into two tracks; the agile team and the UX team. The hybrid methodology consists of several phases that are interconnected between the agile team and UX team during the requirements, design, and testing phases. This development lifecycle follows the agile UX framework proposed by Kieffer, A., Ghouti, A., & Macq, B. [19], as illustrated in Fig. 1.

The requirement analysis and designs of the application will be the core and critical elements for this context of the study. Because the process involves the developer, designer, researcher, and potential users (e.g., admin farm, household, restaurant, local authority representation), all stakeholders will validate the requirements, design, and feedback.

Fig. 1. Agile UX Development Lifecycle. Note. This Model was Adopted from Kieffer et al. [19].

B. Agile UX phases

Based on the methodology in Fig. 1, the application of each phase in this study is described as follows:

1) *Product vision*: This phase addresses the users and technical requirements. The UX team conducts user requirements, while the agile team obtains technical requirements. The UX team used personas (user stories) and task analysis to analyze the stakeholder's requirements. Meanwhile, technical requirements are gathered based on system development, team, and deployment requirements. The application's specific features are obtained at the end of this phase. Activities for user requirements are explained in the next section, requirement analysis.

2) *Product co-creation*: The team will design the application user interfaces and create a high-fidelity prototype for each feature during this phase. The designs are the initial features that have been proposed. The team will improve these designs regularly through the sprint activities. This phase also involves two groups, one from the agile team and one from the UX team. The agile team will create a product backlog for each feature and update it as the feature progresses for each sprint.

Meanwhile, the UX team will validate the design by conducting usability testing on each design and prototype. They will then decide what design changes are required in the next sprint. The sprint iterated until each design feature was released. Once released, the high-fidelity prototype will be transferred to development for final product deployment. This phase's research activity is to report on the study's initial design and design verification sections.

3) *Product enhancement*: The agile team will concentrate on product enhancement, investigate the errors, and correct them as necessary. Meanwhile, the UX team will reanalyze key user feedback and confirm the current designs. In addition, the analysis will feed requirements into other features in an indirect manner.

C. Requirement Analysis

1) *Scrum meeting*: Two scrum meetings were conducted to determine the system's requirements. The first meeting is for the initial user story and requirement, and the second is to confirm the stories and requirements. The official meeting was conducted online due to the different geo-location and limitations during the pandemic situation. The session involves developers, a system consultant, the system owner, and a system user. Non-official meetings were also held, which were conducted via phone calls and group messages. The consensus of each member on the required features is gathered and synchronized with the user stories. The requirements were later transferred to the initial designs.

2) *Personas*: A user story is essential for understanding the roles involved in the system application and which features should be designed according to the roles. It aids in

clarifying the system's scope and clearly defining users' roles in the system. In this study, the system has three main user stories. The story is as follows.

- **Collector (rider):** A collector is a rider who collects waste from a pickup location and transports it to a designated landfill site. They must apply to be a collector in the application and wait for the admin approval. They will be issued a collector's ID once they have been approved. The application will be using Google Maps to show the location with a tracking destination to assist a rider in picking up the waste. Collectors need to scan a QR code at the pickup and sending locations and confirm the pickup items. Riders must log in to their page to see their dashboard on completed tasks, new collection tasks, uncompleted tasks, history tasks, and revenue collected from the tasks. The rider will be able to update their profile and see their achievements through the gamification elements on their page.
- **Household or restaurant:** A household/restaurant manager ensures that food waste is ready for collection. They must bag the waste according to the instructions and then be prepared with the description, number of bags, and total weight to be entered into the application. In the application, they can find instructions and information on what is and is not collectable food waste. The household must book the available date and time for collection in the application. Aside from that, they will be able to view the entire collection history and the following scheduled collection. The application also allows for scheduling and cancellation. Households can view their accomplishments and contributions to an eco-friendly environment on their profile page.
- **System Admin:** An administrator is a person in charge of the system. The administrator will be able to manage the users. After checking and verifying user profiles, they will manually assign the system's users' roles (collector, household, and restaurant). In addition to auto collection allocation, the admin will be able to assign a collector to collect waste manually. Admin can view and report on all transactions. The admin is also the person in charge of approving waste deliveries and processing payments to the collector.

D. Initial System Design

1) *Application function flow:* Following the requirement, the user story is used to define the system flow. There are three flows in total: 1) food waste pick up collection flow (Fig. 2a), 2) household/restaurant request for collection (Fig. 2b), and 3) Admin manage the system (Fig. 2c).

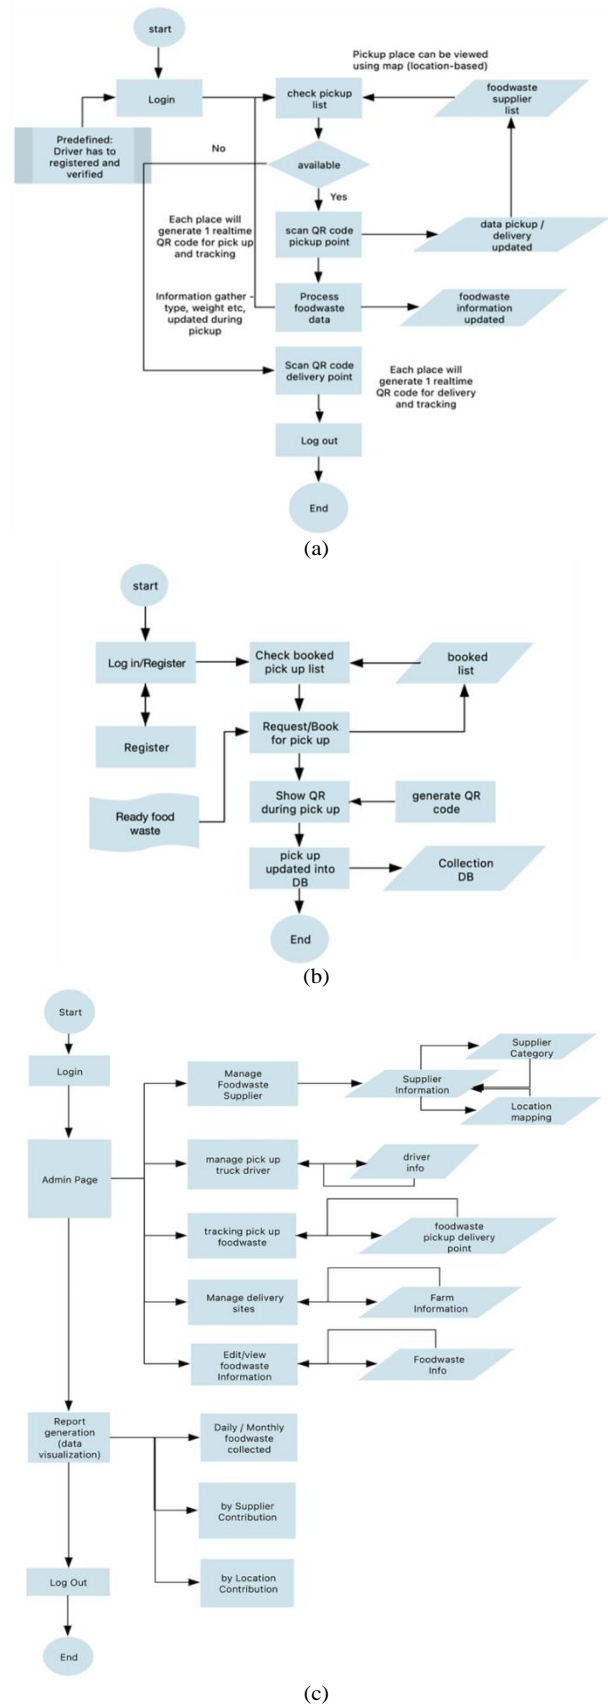

Fig. 2. (a) Food Waste Collection Flow Chart, (b) Requesting for Collection Flow Chart, (c) Admin Site Flow Chart.

2) *Application design:* The Figma application was used to create the high-fidelity prototype. Using Figma, it is possible to quickly visualize and present the application to users during the design sprints. The design comprises three main parts in line with the user story. The design includes the screen for signing up and login (see Fig. 3), the main screen for a collector - dashboard of a collection task, transaction history, maps direction for collection, user's profile – with gamification element, and QR code generation (Fig. 4a and 4b). It also includes the main screen for household and restaurant - collector profiles with gamification, transaction history, rewards, and QR code generation (Fig. 5a and 5b).

The gamification (as in Fig. 6a) included points, ranking, level, and rewards. Riders will be awarded points based on the total number of kilometres collected. When they reach specific points, such as 1km to 10,000km, they will advance to the intermediate level, 10,001km–50,000km, and 50,001km and above, they will go to the advanced level. The landfill's administrator can adjust the level. The rank element is determined by the rider's income from the collection. Each rider can convert their points into physical rewards based on the redemption offer made by the participating party.

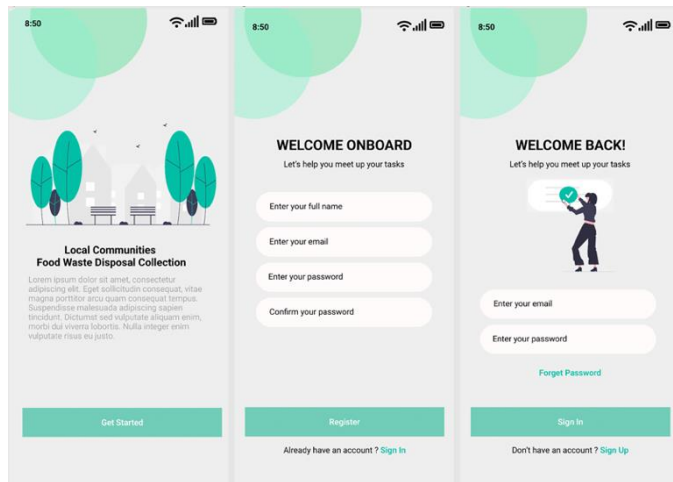

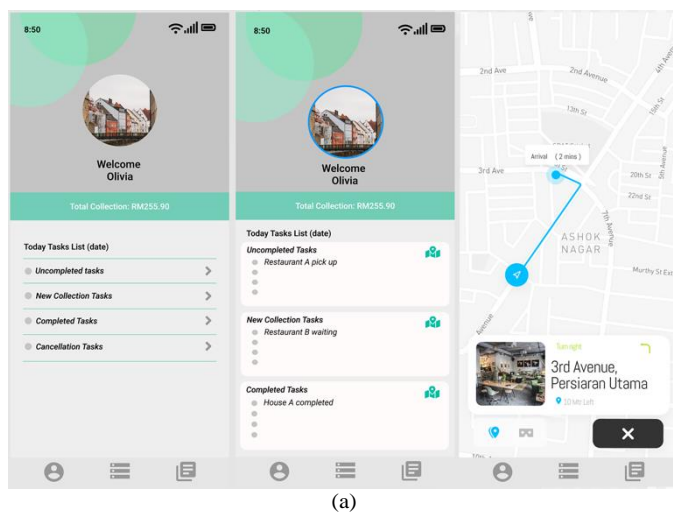

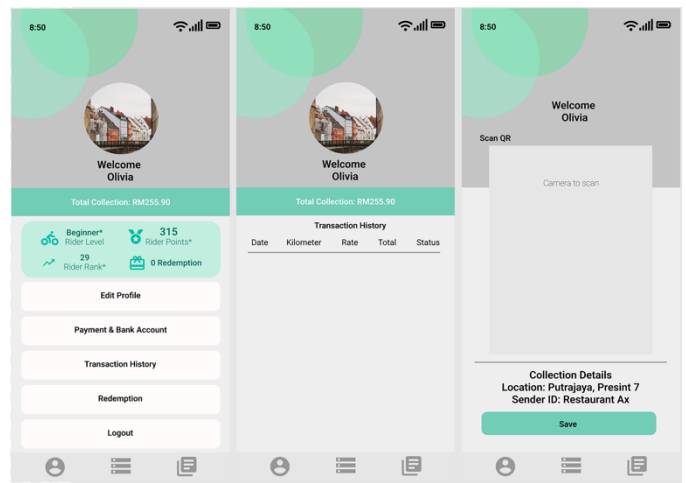

Fig. 3. The Main Screen, Sign Up and Login Screen.

(b)

Fig. 4. (a) Collector's Screen – Dashboard, Task and Direction, (b) Collector's Screen – Profile and Transaction History.

(a)

(b)

Fig. 5. (a) Household/Restaurant Screen – Dashboard and Request, (b) Household/Restaurant Screen – Rewards and Profile.

Gamification elements in the restaurant or household function include points, ranking, level, and rewards (Fig. 6b). Like the rider, restaurants/households will be rewarded with

points based on the amount of waste they send to landfills. When they reach a certain kilogram weight, for example, between 1kg and 1,000kg, their level is changed to the keeper. If the total weight is between 1,001kg and 5,000kg, their level changes to a saviour, and if the total weighs more than 5,001kg, their level changes to a knight. The rank is determined by the total number of kg contributed. The points accumulated can be redeemed based on the redemption offer.

E. Design Validation

The designs were validated in the second phase of the Agile UX method. The validation was carried out to ensure that the design applications complied with the requirements and specifications of the users. Six participants were recruited for this purpose to provide feedback on the application's flow and their designs. The process was repeated several times until the final design was reached. The study was carried out via an online sprint meeting. Participants were asked to review the design, flow, and expected applicability when thoroughly applied.

1) *Participant and research design:* The selection of participants is based on their roles in the system and their responsibility in the system development. Generally, the roles involve collector, food waste supplier – households/restaurants, system owner, system developer, designer, and system consultant. These participants were also the key users of the system. In this manner, they were involved from the requirement phase to the design phase. They are also classified as someone being technologically savvy, as their daily activities involve the use of online systems and applications. The same participants were involved in assessing the proposed systems model design against design specification and system usability – ease of use in completing a specified task, consistency and standard design, and its practicality in implementation. The demographic of the participants is summarised in Table I.

TABLE I. PARTICIPANT'S DEMOGRAPHIC

Demographic	No
Gender	
Female	4
Male	2
Age	
25 - 29	1
30 - 34	0
35 - 39	1
40 - 44	4
Type of Users	
Key users (Non-system developers)	4
Non-key users (System developers)	2
Field of Expertise	
Key User	2
UX/UI researcher and developer	2
Landfill and dumpsites	2

2) *Application verification:* Before the study began, the researcher formally emailed each sprint meeting's invitation to the participants. The email was sent to obtain their consent and provide detailed information about the study. Following their consent, the online meeting details were emailed to them for confirmation. The meeting begins with a presentation of the system (status and features), usability testing, and a comments and discussion session. The session will typically last 30-45 minutes.

A list of tasks based on the system flow and design is provided for usability testing. The tasks are listed in the following Table II. For this testing, two materials were used – 1) the list of tasks to obtain usability problems raised during each sprint session, and 2) the types of user error measurement usability metric adopted from Kieffer et al. [19] (as shown in Table III) to indicate any usability problem found during the test.

TABLE II. LIST OF TASKS FOR USABILITY TESTING

Sprint (S)	Tasks	
Sprint 0:	T1	Sign up, log in, forget password
	T2	View all collection tasks
	T3	Select new task collection and view map for direction
	T4	Request collection (Restaurant)
Sprint 1:	T5	Edit profile, change a picture, edit payment bank info (both collectors and restaurant)
	T6	View transaction history and collection status (both collectors and restaurant)
	T7	Redemption function (both collectors and restaurant)
Sprint 2:	T8	QR code generation and scanning (both collectors and restaurants)
	T9	Review gamification elements (both collectors and restaurants)
	T10	Main menu review (both collectors and restaurant)

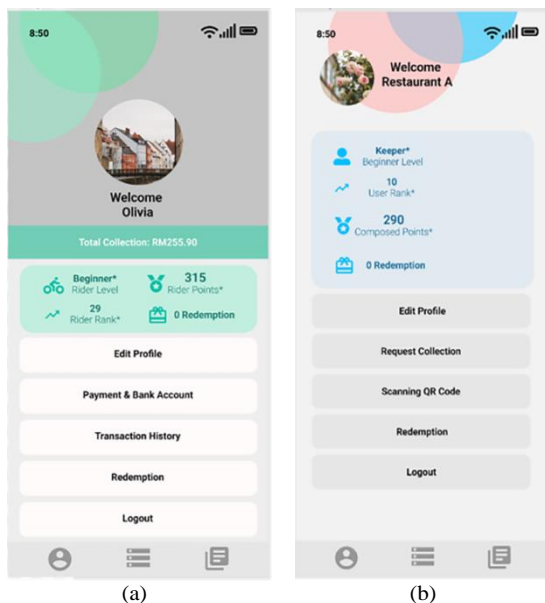

Fig. 6. (a) Rider's Gamification.(b) Household/Restaurant Gamification.

TABLE III. TYPE OF USER ERROR

Code	Type of Error
UE1	Behaviours that prevent task completion
UE2	Mistaken believes that a task is completed when it is not (or vice versa)
UE3	Misinterpretation of the content
UE4	Oversight of something that should be noticed
UE5	Expression of frustration by the participant
UE6	Participants remark about the possibility of improvement

During the online sprint meeting, participants will personally conduct the test of the design prototype according to the given tasks. Then, participants will note the types of errors they discovered for each system design prototype. For each error discovered, the severity of the error (low, medium, high) will be noted to determine what actions should be taken. Once finished, they will send back the error list to the researcher.

IV. RESULT AND DISCUSSION

1) *Usability testing*: Table IV summarizes the indications of usability errors. The authors discovered that participants misinterpreted the content of a few tasks: task 3, task 8, and task 9. One task (task 5) was mistakenly thought to be completed, while another task (tasks 5&9) was suggested for improvement. Overall, the errors were rated as having a low risk of seriousness. The low risk indicates that the issues raised are not likely to cause task failure, but they may have a minor impact on system efficiency or user satisfaction. Thus, feedback from participants was gathered through comments and discussion sessions for detailed explanation and to work out the proposed solution.

TABLE IV. SYSTEM DESIGN USABILITY ERRORS

Sprints	Sp0				Sp1			Sp2

UE5										
UE6					☑ P4/ P5/ P6				☑ P1/ P6	
Severity					Low			Low	Low	

*P – Participant Code, T – Task Code, UE – Usability Error Code, Sp – Sprint code

2) *Design feedback*: Table V summarises the experts' feedback based on the remarks and discussion session at the sprints meeting session. The summary is divided into four sections: challenges, improvements, questions to consider, and interesting implemented features. The main areas that need more attention, according to the feedback, are the collection operation, the payment process for collectors, and features for providing feedback on waste quality. As a result, the following actions were put in place.

- Collection operation: using a dynamic QR code, food waste collection at pickups and sending locations could be improved. A dynamic QR code will change over time, making it easier to capture time accurately. As a result, the payment process can be calculated based on the recorded time.
- Payment procedure: the discussion in this section resulted in a manual operation for paying the collectors' commission on waste delivery. The delivery fee will be calculated based on the delivery rate per kilometre and the weight of the waste. The landfill will make weekly payments to collectors. All payment transactions will be recorded; only payment transfers will occur outside the system.
- Providing feedback: it is crucial to rate the collected waste as the land site needs to produce a high quality of decomposed for BSF. Preparation of food waste has to follow the given guideline to avoid receiving food waste that does not meet the standard, and landfills must rate the waste. Any non-compliance should result in negative feedback, and the household or restaurant will be barred from sending waste for an extended period.

The collectors and household/restaurant modules were prioritized following the sprint design meeting. The justification for this was that the functionalities were directly related to the collections processes, which are the application's key features for the key users. After considering all the feedback from the sessions, a series of design concepts were created later to demonstrate the workflow development process.

3) *Implementation of agile UX approach*: Sprint activities are remarkably beneficial in improving the system's designs and functionality when using an Agile UX approach. On the other hand, the concepts can be easily moulded because they are all aimed at the same goal. During the sprints, participants with varying expertise and skill sets contributed a wide variety of ideas and criticism. Nonetheless, at the end of each sprint session, all participants reached an agreement.

TABLE V. FEEDBACK COLLECTED FROM SPRINT ACTIVITIES

Challenges	Viewpoints and Improvements
<ul style="list-style-type: none"> - Getting households to use the apps, generate the QR code, and use the code every time collectors collect waste may be difficult for some users who experience difficulties with mobile technology. - How can landfills managers ensure that households and restaurants provide high-quality Waste for BSF and improved decomposition? - Paying collectors via the system immediately after completing a delivery is more efficient than a manual payment. However, it may be difficult for the landfill manager to control the quality of the waste while also managing a fair collection assignment for all collectors. - Gamification in a mobile application required some time to see the effect on collector motivation and behaviour. 	<ul style="list-style-type: none"> - Reminders and notifications should be used when collectors reach their destination (pick up and send locations). - Payment workflows should be improved. - Gamification features should be explained in detail once all data has been integrated. - Data visualization on the collector's dashboard could assist them in effectively synchronizing their work. - Could external devices such as scanners be incorporated in determining the waste quality? - The app's purpose is to make waste collection and distribution easier. It has made a gig platform job opportunity available to local communities. - A reward is an interesting method to appreciate user involvement - Sprint activities gradually demonstrate the system from concept idea to design step-by-step.
Questions to Ponder	Interesting Features
<ul style="list-style-type: none"> - Local community involvement in catchment teaches good waste management ethics and environmental care surroundings. How do you ensure the information provided and feedback to them is actionable? - Is it possible to shorten the work and process of decomposition by using mobile apps? 	<ul style="list-style-type: none"> - Gamification elements are used to encourage users to participate in collecting and delivering food waste. - The designs are acceptable, and the concepts are considered to make sense as they adequately address the requirements. - Feedback and ratings would be relatively beneficial in nurturing households and restaurants in providing quality food waste.

Generally, communication and collaboration are the main challenges a company faces in Malaysia when using a UX approach [21, 23]. The programmers faced various challenges regarding the technical aspects, particularly those concerning application design and development. The challenges elicited when connecting the system's requirements and designs between the end-users, the software developers, and the software vendor. The developers and user experience practitioners can become frustrated, particularly when openness to sharing the system problems and solutions is limited to the knowledge or skills of developers and practitioners [24]. In such cases, it would expose their inability to solve problems during the development process. Developers might also experience high pressure in providing seamless progress [21]. However, this situation could be because of several independent factors implemented in various ways. For example, a collaboration between developers of different level of skills level to complete a successful system, input from ethnic diversity provides a different insight into the system implementation, and different levels of technology-savvy

among users help to train users to be more competent. Project progress sharing will make the project more visible and transparent. We argue that this variety should provide the team with more valuable input to the projects, mainly in the case of the Malaysian context. These situations have encouraged collaboration, allowing further exploration of the team's creativity. Looking on the positive side, the team could alleviate the challenges with careful team design and well-planned work.

As UX and agile approaches are heavily involved with users in every phase of system development thus, regardless of individual limitations, cooperation from each member is imperative towards achieving the project's aim. The authors anticipated that using an agile UX approach would produce a great system preferred by the users.

V. SYSTEM DESIGN MODEL

The system requirements and designs are reviewed before encapsulating them in a design model specifically for developing such applications for managing local food waste. The model consists of the required components to improve BSF decomposition in the Malaysian context. This model should be used as a guideline when creating similar applications or applying the development approach to software applications.

The model was created to reflect the application's features, purposes, the environment in which it will be used, and its requirements. The applications' core ideas were extracted and summarized from requirements activities to designs and testing into a model. As a result, the model comprises five distinct components, as illustrated in Fig. 7. For each of the components in the model:

- Motivation: As the goal of the apps was to have an interactive application that can support food waste management processes and get local communities involved, motivation elements and a rewards system should be used to connect all the components in the model.
- Stakeholder: The involvement of stakeholders is critical because they must understand their responsibilities and act accordingly.
- Systematic and user friendly: A standard system application should be designed with a user-friendly feature, and the system should be implemented systematically across all aspects of the application. This includes a map showing the collection route and a map that can track collector movement, data visualization to show the waste collection activities and disposal, the payment process, and the rewards system.
- Job opportunity: From the application development process, the application should be able to provide users with job opportunities or, at the very least, a side income opportunity. Collectors are also known as riders, and providing a gig job has become a popular trend in the global economy.

- Eco-friendly approach: The applications should promote an environmentally sustainable attitude by raising awareness of safe and proper food waste disposal practices. This strategy will both educate and develop communities indirectly.

The project management team can better plan for system design and development with this model. The proposed system design concept was generally well welcomed. The participants expressed their excitement to see the result of food waste collection operations after the system was fully implemented.

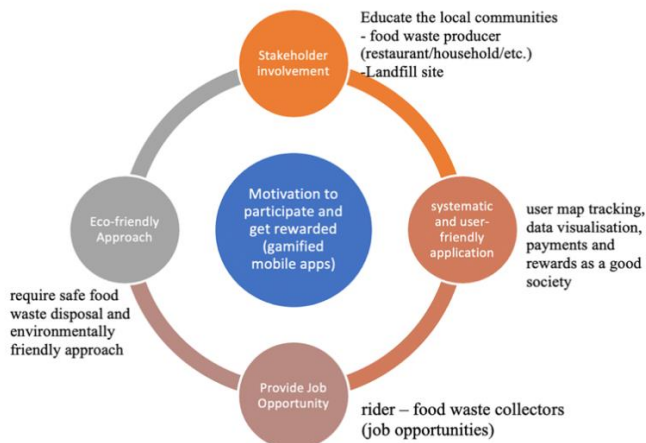

Fig. 7. The Mobile Apps Model for Food Waste.

VI. CONCLUSION

Proper food waste disposal utilizing BSF is one way to support the goal of having and keeping a clean and safe environment. The usage of an assistive tool, such as a gamified mobile application for food waste management, is thought to be necessary to ease the disposal processes. This method would require the involvement of the surrounding communities in order for everyone to contribute to a safe environment. Also, by providing this type of application, communities will be able to learn and adapt to proper and safe food waste disposal in their regular lifestyle. However, waste preparation must meet the stated criteria to maintain decomposition quality. It will also assist local governments in monitoring food waste compliance using the application.

This study describes the process of developing a mobile-based application for managing food waste, focusing on the preparation and collection processes. This study's work was based on the Agile UX methodology, particularly its adoption in the Malaysian context of information system development. In the entire process, two teams are involved: agile and UX. The developed design was subjected to usability testing to ensure that the design and requirements were in sync. Feedback on the process flow and its designs aided in achieving the system's goal. The system model was developed as a guideline when developing a similar application resulting from the design process. Overall, the application designs and features were agreed upon for implementation.

Of course, this study has several limitations. One of them was locating and assigning a time for a sprint meeting to all participants. However, an online meeting appears to be more

convenient for all parties due to the pandemic. It seems to be more effective in moving from one sprint to another. Then, because working from home has become the new norm, various distractions to complete the work sometimes require time extension, dragging the project timeline. However, the authors believe this is a low-risk situation that can be managed until the project is completed. In future work, the researcher will conduct acceptance testing and assess the effectiveness of the application in the actual environment with the actual users. A study on how the application could affect the BSF industry in a bigger picture, i.e., production and business, should also be conducted. At present, the study's findings indicate that the proposed system design and model are feasible and would contribute positively to food waste and the BSF ecosystem.

ACKNOWLEDGMENT

The authors would like to thank the University Malaysia Sabah for the financial support and opportunities in conducting the research, and the participants who participated in completing this study.

Abstract—Quantum entanglement is one of the essences of quantum mechanics and quantum information theory. It is a physical phenomenon in which entangled particles remain correlated with each other regardless of the distance between them. Quantum entanglement plays a significant role in areas such as quantum computing, quantum cryptography, and quantum teleportation. Quantifying entanglement is important for determining the depth of the entanglement level and has an impact on quantum information tasks performance. Entanglement classification is critical in quantum information theory for determining the class of states in a quantum system. The entanglement classification of two qubits as separable or entangled has been established. The classification of multiqubit entanglement is more challenging, especially in higher-qubit systems. The goal of this study is to identify different established measurements for entanglement quantification and entanglement classification methods through a systematic literature review. Indexed articles between 2017 and 2021 were selected as secondary resources from several sources based on specific keywords. This study presents a conceptual framework of entanglement quantification and classification based on previous studies.

Keywords—Entanglement quantification; quantum entanglement; entanglement classification; quantum measurement

I. INTRODUCTION

Quantum entanglement is one of the most studied features in quantum mechanics that is critical to quantum information processing [1] in areas such as quantum teleportation, quantum cryptography, and quantum computing. In quantum computing, quantum entanglement plays a vital role in demonstrating the superiority of a quantum computer over its classical counterpart [2]. Although interest in quantum entanglement has grown over the years, knowledge of the

phenomenon is still limited, especially in higher-dimensional systems [3].

Entanglement quantification is a process of determining the level of entanglement and the intactness of a system and characterizing it. It is a fundamental problem in quantum information theory, especially in multipartite settings where the complexity increases with the number of subsystems involved [3, 4]. Some known entanglement quantification measurements are concurrence [5], Schmidt decomposition [6], negativity [7], and entanglement of formation [8].

The most well-known protocols in entanglement classification are local unitary (LU), local operations and classical communication (LOCC), and stochastic local operations and classical communication (SLOCC). The process of entanglement classification is an open problem in quantum information theory. Entanglement classification is established as either separable or entangled in a two-qubit system. The classification becomes more complex as the number of qubits in the system grows. For example, the classification in a three-qubit system is one separable, three biseparable, and two genuinely entangled states (GHZ and W) under SLOCC [9]. The classification for n -qubit ≥ 4 is understudied and it is even more complicated due to the infinite number of classes under SLOCC [10-12].

Entanglement classification is used to categorize the class for complex structures starting from $n = 3$ qubits. It will be complemented with quantification because the measure that has been by quantification determines the degree of entanglement of each state.

This study followed a set of guidelines to identify existing entanglement quantification and classification methods, and propose a framework for the methods. The paper is organized

*Corresponding Author.

as follows. The research methodology is detailed in Section II. Section III covers the results and discussions. Section IV concludes the study.

II. METHODOLOGY

This section discusses the publication standard used in this study, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). The following topics are thoroughly discussed: (1) PRISMA review protocol, (2) research question formulation, (3) systematic searching strategy, (4) quality appraisal, and (5) data extraction and analysis.

A. PRISMA Review Protocol

PRISMA [13] was used as the review protocol in this systematic literature review. This review protocol served as a guideline for conducting a systematic literature review by formulating research questions, identifying the inclusion and exclusion criteria in a systematic searching strategy, conducting a quality appraisal of selected articles, and critical data extraction and analysis over a specified period. The scope of this study is entanglement quantification and classification.

B. Research Question Formulation

The systematic literature review is guided by the research questions developed during the preliminary phase. The following research questions were formulated in accordance with the research objective of presenting a conceptual framework of entanglement quantification and classification: (1) What are the established methods of entanglement quantification? (2) What are the established methods for classifying quantum entanglement? (3) What is the preferred alternative method of entanglement quantification and classification?

C. Systematic Searching Strategy

The systematic searching strategy of this study consists of three steps: identification, screening, and eligibility.

1) *Identification*: Identification is an important process as it determines which articles are relevant to the review. The articles for the study were primarily drawn from the databases of two powerful multidisciplinary search engines, Scopus and Web of Science (WOS), as well as an additional database, Google Scholar. A comprehensive search was conducted using the field tags “TITLE-ABS-Key” (title, abstract, and keywords) in Scopus and “TS” (topic) in WOS with the keywords entanglement quantification, quantum entanglement, entanglement classification, and quantum measurement.

The search strings were created to search for related articles in both databases. The searches were conducted from November to December 2021 (see Table I). A manual search was conducted using Google Scholar, with handpicked related articles derived from the same keywords as in Scopus and WOS. Based on the systematic searching of Scopus and WOS, a total of 13,659 potential related articles were identified and 1,934 articles were downloaded. Additionally, 8 articles were selected from Google Scholar for further analysis. The search results from Scopus and WOS are displayed in Fig. 1.

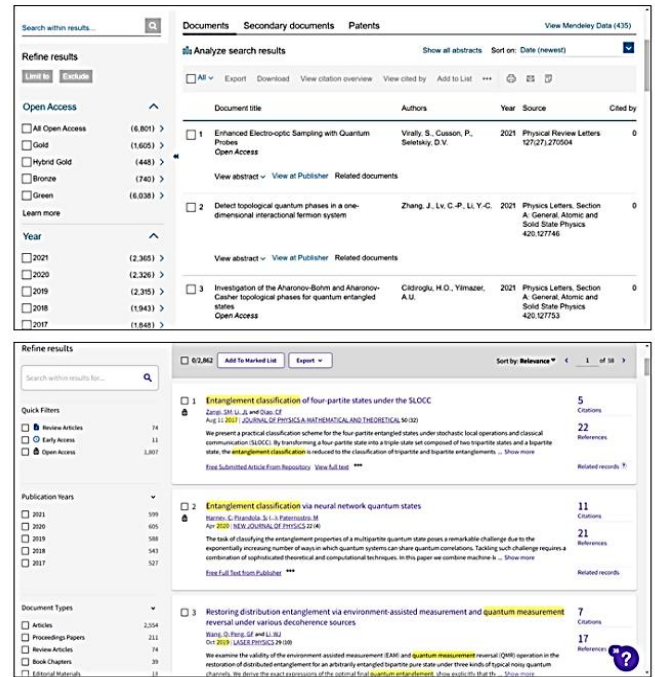

Fig. 1. Search Results in Scopus and WOS.

2) *Screening*: This systematic literature review examined indexed articles on entanglement quantification and classification published between 2017 and 2021. The five-year period was chosen because of the maturity of the subject [14]. 1,847 of the total 1,942 downloaded articles were excluded due to duplication by title review and abstract review. During the screening stage, the remaining 95 articles were validated to ensure they met the inclusion and exclusion criteria. The inclusion and exclusion criteria are the subject matter, literature type, language of the article, and year of publication (see Table II). Articles that are unrelated to entanglement quantification and classification were excluded from this study. As a precaution against misunderstanding and mistranslation, only articles written in English were considered. After this stage, 62 articles met the inclusion and exclusion criteria.

TABLE I. SYSTEMATIC REVIEW PROCESS SEARCH STRING

Database	Search string
Scopus	TITLE-ABS-KEY (“entanglement quantification” OR “quantum entanglement” OR “entanglement classification” OR “quantum measurement”)
WOS	TS= (“entanglement quantification” OR “quantum entanglement” OR “entanglement classification” OR “quantum measurement”)

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Inclusion	Exclusion
Articles on the subject matter of “entanglement quantification” and “entanglement classification”	Articles written in languages other than English
Indexed journal articles	Articles published before 2017

3) *Eligibility*: In the third stage of the systematic searching strategy, the remaining 62 articles from the screening stage were reviewed again for suitability for this study. After a thorough examination, 27 articles were removed since their research direction or theme did not focus on entanglement quantification and classification. The remaining 35 articles were then prepared for a quality appraisal (see Fig. 3).

D. Quality Appraisal

The 35 selected articles were sent to an expert in the field for quality appraisal to ensure that only high-quality articles were used in the review. According to [15], the remaining articles should be ranked as high, moderate, or low quality, with only high and moderate-quality articles being included in the review. To meet the quality standard, the expert concentrated on specific elements such as the theme, objective, and results of the articles. Following the appraisal, the expert determined that all 35 articles were suitable for the review.

E. Data Extraction and Analysis

In-depth analysis was used to extract relevant data from the articles by first analyzing the abstract, then the discussion and conclusion, and finally the body for any other relevant

information. The extracted data were tabulated in Microsoft Word. The articles were divided into five categories based on the year they were published (see Fig. 2). There are 8 articles published in 2017, 8 articles in 2018, 3 articles in 2019, 5 articles in 2020, and 11 articles in 2021.

The main themes in the articles from the extracted data are entanglement quantification and entanglement classification. In the following section, we will go over a few of the methods that were discovered.

Fig. 2. Articles Group by Year Published.

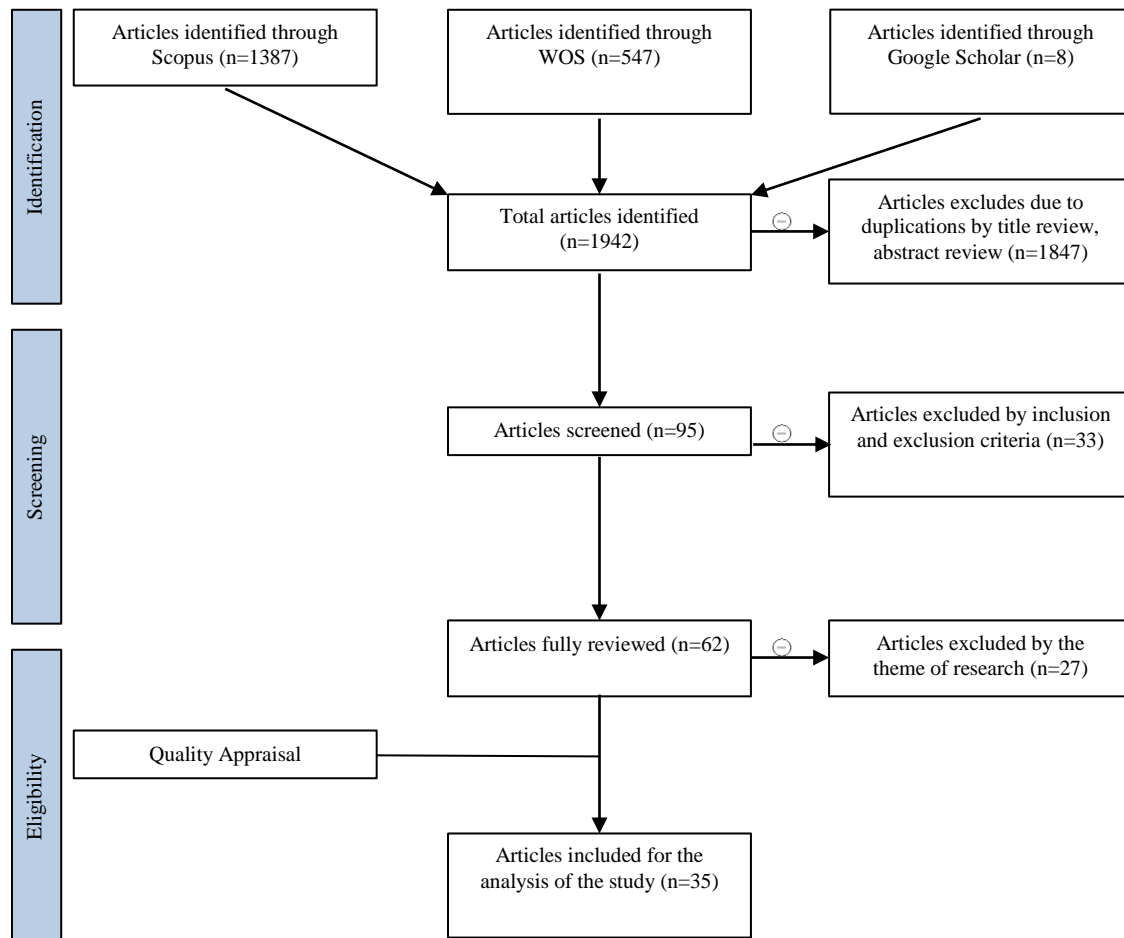

Fig. 3. Article Selection Process.

III. RESULT

This section discusses the identified themes, entanglement quantification, and entanglement classification in previous studies (see Table III and Table IV). A proposed conceptual framework of entanglement quantification and classification has been developed and is presented as a reference for future work (see Fig. 6).

A. Entanglement Quantification and Entanglement Classification Methods

There are 19 entanglement quantification methods established from previous studies, as shown in Table III. Some of these methods are compounded (additional variables or adaptation) such as base or compounded concurrence [4, 5, 8, 16-19], base or compounded negativity [4, 7, 8, 19], base or compounded entanglement of formation [4, 5, 8, 20], base or compounded convex-roof measures [6, 8, 21], base or compounded tangle [4, 5, 17], base or compounded entanglement witness [22, 23], relative entropy of entanglement [20, 21], and Schmidt decomposition [6, 20]. Other established entanglement quantification methods are: (1) Tsallis-q entanglement measure, (2) k-entanglement measure, (3) entanglement of assistance, (4) supervised machine learning, (5) linear entropy of entanglement, (6) an extension of an entanglement measure for the mixed state from the measure of a pure state, (7) global nonselective projective measurement, (8) Gramian operators, (9) exact PPT entanglement cost, (10) operational entanglement monotone approach, and (11) entanglement of formation.

These methods were grouped into the following clusters: Cluster 1: Concurrence; Cluster 2: negativity; Cluster 3: Entanglement of formation; Cluster 4: Convex-roof measures; Cluster 5: Tangle; Cluster 6: Entanglement witness; Cluster 7: Relative entropy of entanglement; and Cluster 8: Schmidt decomposition. Fig. 4 depicts the clusters of entanglement quantification methods. Concurrence is the most commonly used entanglement quantification method, followed by negativity. Base or compounded concurrence and negativity are widely regarded as simple and direct measures of entanglement compared to other listed methods in this research.

Fig. 4. Entanglement Quantification Methods Cluster.

Table IV lists 25 published entanglement classification methods. The protocols used in the studies were emphasized instead of the methods. The LU, LOCC, and SLOCC protocols were identified in the articles. As shown in Fig. 5, it was found that SLOCC is the most utilized protocol. This may be due to the fluidity of the SLOCC protocols in classifying entanglement. The protocols were classified into three clusters, as depicted in Fig. 5.

B. Conceptual framework of entanglement quantification and classification

Methods for quantifying and classifying entanglement established in previous studies were thoroughly examined to comprehend the essence of both concepts. The purpose of this research is to develop a conceptual framework of entanglement quantification and classification in bipartite and multipartite systems. The framework was developed following the specifications established in previous studies on the

quantum qubit system and state for entanglement quantification, as well as entanglement classification protocols.

Fig. 5. Entanglement Classification Protocols Clusters.

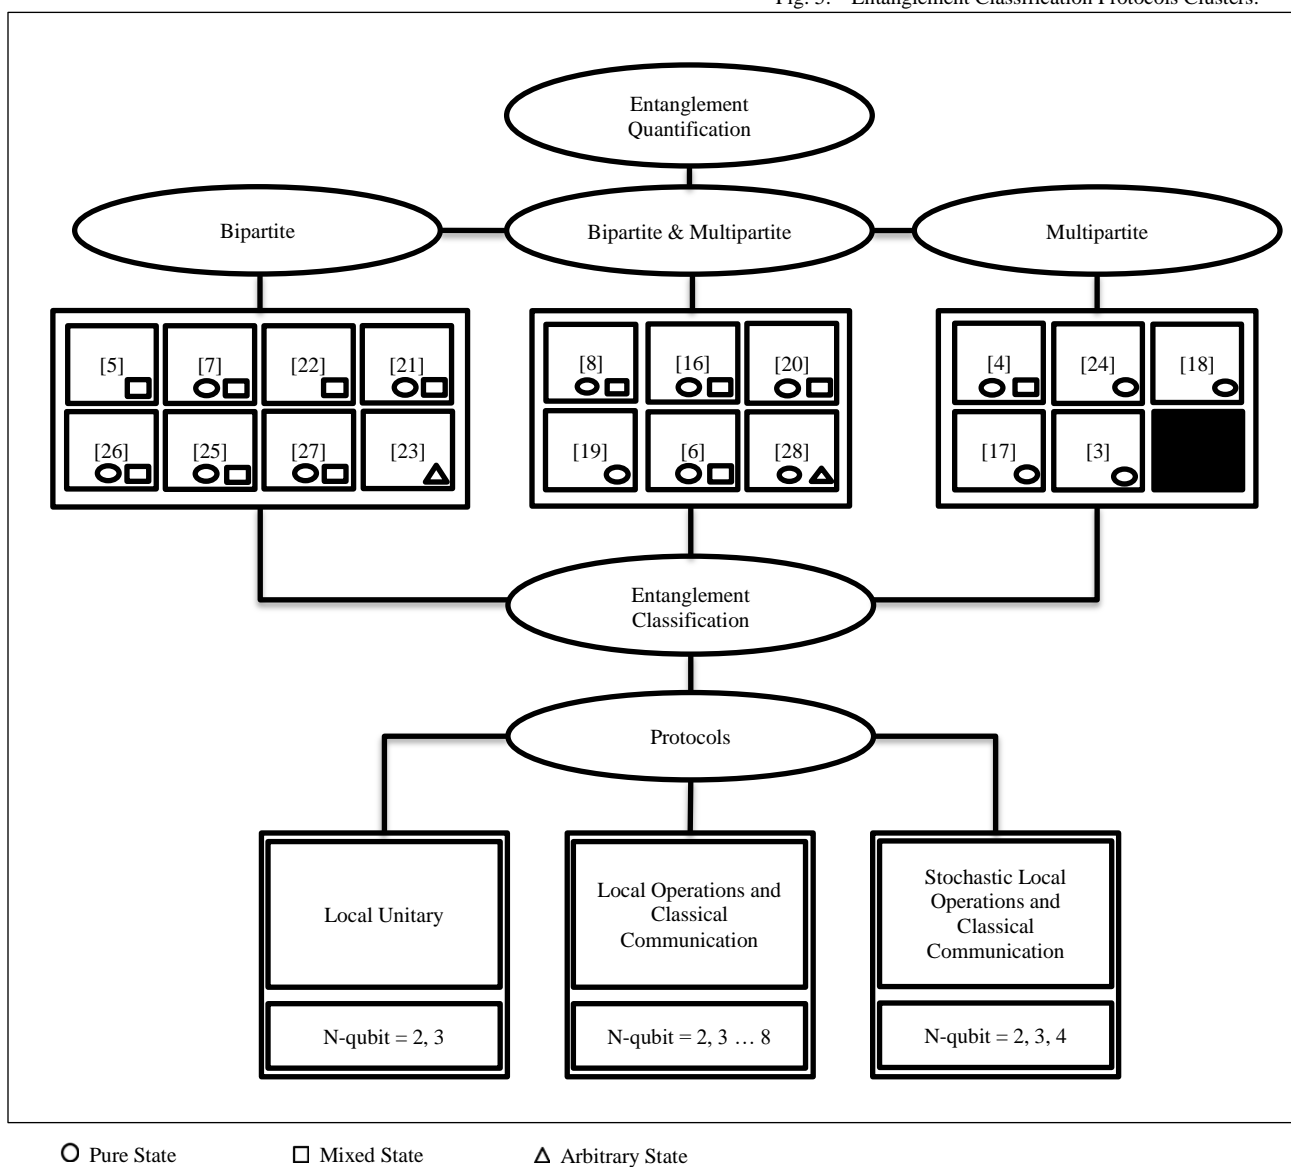

Fig. 6. Proposed Conceptual Framework of Entanglement Quantification and Classification.

IV. CONCLUSION

Even though significant progress has been achieved, entanglement quantification and classification remains a challenging and open problem in quantum information processing, especially in mixed quantum state and when there are many particles (qubits) involved, i.e., n -qubit ≥ 4 .

This study presents several established methods for quantifying and classifying entanglement that have been identified in previous studies. In addition, a conceptual framework of entanglement quantification and classification in bipartite and multipartite systems was developed and presented as a guidance or reference for future work based on one's specific requirements, namely measurement methods, qubit system, quantum state and protocols.

The understanding of the entanglement measures and classification is still considered insufficient. Therefore, further study on entanglement quantification and classification methods based on the proposed conceptual framework is needed to produce a universal quantification measurement and precise classes or families for classification in a higher-qubit and higher-dimensional system.

Abstract—Providing accurate movie recommendations to a user with limited computing capability is a challenging task. A hybrid system offers a good trade-off between the accuracy and computations needed for such recommendations. Collaborative Filtering and Content-Based Filtering are two of the most widely employed methods of computing such recommendations. In this work, a high-efficient hybrid recommendation algorithm is proposed, which deems users' contour attributes to screen them into various groups and recommends movie to a user based on rating given by other similar users. Compared to traditional clustering-based CF recommendation schemes, our technique can effectively decrease the time complexity, whereas attaining remarkable recommendation output. This approach mitigates the shortcomings of the individual methods, while maintaining the advantages. This allows the system to be highly reactive to new viewer inputs without sacrificing on the quality of the recommendations themselves. Building on other hybrids of a similar kind, our proposed system aims to reduce the complexity and features needed for calculation while maintaining good accuracy and further enhanced by utilizing Sentiment Analysis to rank the movies and take user reviews into consideration, which traditional hybrids do not take into account. Then analysis was performed on the data set and the results show that the proposed recommendation system outperforms other traditional approaches.

I. INTRODUCTION

Watching movies is one of the most popular forms of media entertainment. Viewers are incredibly engrossed and invested in the culture of motion films. Recent advancements in technology have enabled the widespread streaming of movies on demand [1]. This, in turn, has added to the popularity and ease of access to movies. There are thousands of movies for one to choose from. These movies are not only segregated by their genre, cast, production teams, direction, and numerous other factors. This makes it particularly difficult to pick a single movie to watch first. Everyone's preference of movies is also subjective and one may not enjoy a movie that another person loves. This creates an ambiguity as it is complex to determine what features the most impactful when are looking for a new movie to watch [2]. Movie recommender systems help combat this by providing recommendations based

on what the user may have already watched by suggesting similar movies. It attempts to figure out what movie a viewer is likely to rate among the highest.

Recommending a movie is not a straightforward task. This is particularly challenging also as the preferences of viewers may be very different. This leads to there being a distribution of niches that are not uniform to be immediately apparent [3]. Consequently, a movie that is not conventionally popular may be preferable to some viewer simply based on their subjective view towards movies in general. This can be tackled effectively by taking into account a large variety of movies and a large amount of them so as to encompass the likes and dislikes of users of all categories [4]. A robust recommender must be able to recommend movies that are more relevant to the user themselves as shown in Fig. 1.

Many techniques have been used to make recommenders effective in this regard and perform well with large data [5]. Recommender systems are a set of algorithms aimed at emulating information processing systems where the end goal is to suggest relevant items to users, items being movies that users watch. The various classification of recommender system is given in Fig. 2. Content Based methods also offer a way to deal with the issue of limited rating data [6]. Content Based methods work by taking into consideration the similarity between the movies themselves. This similarity could be between various aspects of the movies such as the genre, cast and other related data [7].

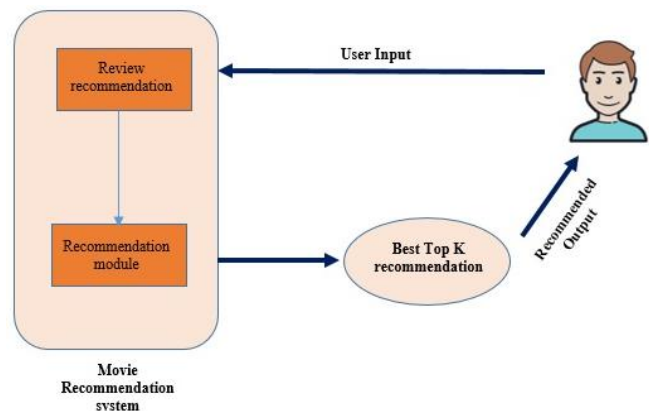

Fig. 1. Schematic of Recommendation System.

Fig. 2. General Classification of Recommendation System.

A problem that arises with the content-based system is an uncertainty if the system can take the user's behavior towards one genre or source and apply that preference shown to all the other content present in the system. If the engine simply keeps suggesting content similar to what the user is already watching, its value goes down quite a bit in some sectors of recommendation. The Collaborative Filtering approach recommends items by creating a profile for users [8]. The similarity between the profiles is based on the movies rated. If the user rates certain movies high then the algorithm would look for other users who have also rated the same movie highly or in the range of the rating by the user to whom it is to give recommendations. It then predicts what rating the user would give to a movie that they have not seen based on how they have rated the movies they have already seen. Therefore, Collaborative Filtering works well where there is history available for the user ratings on other movies [9]. This however is also a drawback as new users do not have many ratings and this poses a problem for Collaborative Filtering [10]. Based on the advantages, a hybrid system seems to be the most promising approach to mitigate the drawbacks of these common systems and to bring forth their advantages [11]. There are many ways in which Hybrid models can be used: by extrapolating separate content-based recommendation list and collaborative-based recommendation list of predictions and unifying them as one single list; using collaborative-based methods as a primary approach and enhancing them by adding content-based capabilities; using content-based methods as a primary approach and enhancing them by adding collaborative-based capabilities; combining the capabilities and features of both models and creating one single model. This paper is structured as follows: Section 1 emphasis the introduction. Section 2 emphasis the related study and the narrative of the objective. The procedures and resources are discoursed in Section 3 and their exploration and clarifications are exposed in Section 4. The conclusion was clarified in Section 5.

The rest of the paper flows as literature survey in Section II, Section III explain the methodology and implementation process of recommendation system, Section IV describes the comparison and analysis of various recommendation techniques, and Sections V and VI briefs the conclusion and future work.

II. RELATED WORK

Collaborative Filtering algorithm generates a user profile based on the ratings the viewer has given to other movies. If two users have rated similar kind of movies highly, this means that there is a good chance they may prefer similar movies. If the other viewer has already rated other movies, it allows the system to predict if the target viewer will enjoy it or not. This

is the basic premise of how a Collaborative Filtering system would recommend a movie [12]. Collaborative Filtering has been widely employed in many ways, and a lot of academic work has revolved around combining other techniques to boost the performance of such a method. One of the main issues when it comes to Collaborative Filtering is that the computations needed are heavy. Thus in most cases, it has trouble when trying to scale the data up [5]. The method uses Self-Organizing Map Neural Networks [13] to carry out Collaborative Filtering. This method offers a good alternative as the Self Organizing Map Neural Network is not very computationally heavy. While this method worked well for the data, the data itself only comprised of a few dozen movies and about a hundred and seventy users. This makes it hard to judge if the effectiveness of this technique will remain high when faced with a larger dataset, or one with more features.

This multilayer perceptron neural network system works by utilizing the reduction in error in prediction by subjecting the training data to go through multiple passes of a neural network [14]. This method is promising as it does not need to have a deep network for classification. This is particularly effective for polar sentiment data, which will be the focus of the proposed system. This is because for binary classification, a very deep neural network may in fact introduce overfitting to the data. Overfitting occurs when the data trains too well for the test set. This may result in the model performing really well for the trained data but not for the actual target or testing data itself. A shallow network also allows for faster inference time. A personalized Recommendation approach [15] grounded on Three Social Influences, Personal interest means user-item relationship and interpersonal influence and interpersonal interest similarity means user-user relationship of social networks. Probabilistic matrix Factorization makes experiments on the datasets, namely, MovieLens and yelp [16]. Tactically this removes the tricky cold start and data sparsity.

A recommendation system for real estate websites [17] is that it helps consumers in acquiring new properties or homes. Recommendation system is proven by merging case based reasoning (CBR) and Ontology. Former systems supports single characteristic exploration systems but this system support multivalued search system. Sentiment Analysis can also be used along with Collaborative Filtering for better and more inclusive results. The system [18] was trained on data where all the users had given a large number of ratings. This brings into question how well the system would perform where the ratings are limited. Also, the similarities between other features of the movies, such as genre, were not considered in the study.

The author in [19] used a Diverse Collaborative Prediction to combine Collaborative Filtering with Content-Based filtering. This system gave better results than just the individual techniques did, however this method does not consider reviews either. The author in [20] employed an Item-Based Collaborative Filtering model with a Content Based one. The predictions are reached by the TF-IDF method with the nearest neighbor predictions. The MovieLens and Film Trust datasets were used for training and testing this system. The author in [21] used a cosine similarity matrix that showed better

accuracy than that of the other systems, but it also did not take written reviews into consideration.

Another study [22] showed that the Singular Value Decomposition worked well for recommendations. These studies support that the TF-IDF and SVD methods take a lot of heavy computation, but they give some of the most accurate results for recommendations. The author in [23] focused on the hybrid recommendation model which encouraged the user's social data, reviews, and ratings available.

This model of recommendation consists of six processes, review transformation, the feature generation, community prediction, model training, feature blending, and prediction and the last one, evaluation criteria for ontology based recommendations. This [24,27] mainly focuses on a system which helps to provide details analysis about the items which are arranged by the wishes of the similar users. The recommendation system with the proper recommendation for this research will be used in suggesting the item selection system by making a recommendation system with the help of an item-based collaborative filtering methodology. Based on the literature, the associated research challenges are observed.

- Data sparsity may happen due to user/rating matrix is sparse and it is hard to find the users who have rated the same item.
- The existing recommendation technique requires enormous processing time and mostly user is prohibited in getting accurate recommendations that are similar to their profile.

Subsequently it is fortified about the essential for the proposed research to enhance the movie recommendation process competently. The associated objectives are proposed in this research work so as to address few issues in recommendation technique. The contribution of the research comprises.

- To provide enhanced movie recommendation system for the users through an improved hybrid recommendation algorithm combination of user-based CF (UBCF) and item-based CF(BCF) in the context of SVD dimension reduction to improve the speed and quality of recommendation.
- To providing content related to the collection of relevant and irrelevant items for users of online service providers and to recommend movies to users based on user / item base movie ratings.

To enhance the recommendation accuracy in hybrid recommendation system through optimized sentiment analysis for providing more diverse recommendations by satisfying the requirements recommendation features.

III. METHODOLOGY

A. User-Based Collaborative Filtering

User-Based Collaborative Filtering is a technique for predicting which products a user would enjoy based on the ratings provided to that item by other users who share the target user's tastes [1]. Collaborative filtering is used by many

websites to develop their recommendation systems. Steps for Collaborative Filtering with Users: Step 1: Identifying users who are similar to the target user U. The algorithm may be used to calculate similarity between any two users 'a' and 'b'. Step 2: Estimate of an item's missing rating done as follows: Now, the target user may be quite similar to certain people while being very different from others [13, 26]. The proposed system employs a combination of Collaborative Filtering and Content Based Recommendations, further enhanced using Sentiment Analysis to rank the movies.

The movielens dataset is hired in our research paper and collected from the GroupLens [25,28], which contains 20 million ratings for around 27000 different movie titles and has a user ID, movie ID, rating, and timestamp. The Characterization of the movie's content information includes over 54058 records and includes movie ID, title, genre, director, actor, and more. The graph in Fig. 3 represents the relation between categories and the movies rated accordingly.

The data contains a huge amount of reviews. This helps retain most of the movies while reducing the number of users by about a third and represented using a seaborn graph as given in Fig. 4. This can be important in the order that we are able to see the link between a movie's specific rating and therefore how much the movie got. Therefore, we must set a threshold for a minimum number of ratings while constructing a system that recommends. So, to create this new column we use the utility of pandas' groupby. We groupby the title columns, so use the calculation method to calculate the number of ratings each movie received as shown in Fig. 5. The tags for all the movies are combined with the genre to generate a larger metadata for the movies as shown in Fig. 6. This metadata can be used to perform a Content Based approach. The goal is to keep the number of features as low as possible without compromising on the accuracy of the results.

An added benefit of keeping the features lower is that it is less complex when it comes to calculation. A lighter model will help improve the inference time.

We create the value of movie data 'rating' using movie title and calculate rating count in 'title' by applying threshold and get the result.

Fig. 6. Movies with Genres and Tags.

B. Filtering based on Content

The data is sampled to take a large chunk to make a training set on which the SVD loss will be trained. The movie genres are combined with tags to create the metadata of the movies. This metadata will be used to generate a Content Based Recommendation model. A segment of the data is segregated where it contains the user ID, the movie ID and the rating that the user gave to the movie as shown in Fig. 7.

Title	Rating	Rating count
Toy Story(1995)	1.750000	3
Jumanji (1995)	3.84333	2
Grumpier Old Men (1995)	2.00000	2
Waiting to Exhale (1995)	0.60000	1

Black Butler: Book of the Atlantic (2017)	3.50000	1
No Game No Life: Zero (2017)	5.00000	3
Flint (2017)	3.050632	4
Bungo Stray Dogs: Dead Apple (2018)	2.25000	24
Andrew Dice Clay: Dice Rules (1991)	3.75000	2

Fig. 7. Number of Rating of Movies after Threshold.

This data will be utilized to build the Collaborative model of the hybrid. Additionally, the movie ID and the genres as well as the tags related to the movie are segregated for building the content matrix for the hybrid system. A pass of Singular Value Decomposition is performed in order to flatten the matrix dimensions even further by introducing factorization. This also gives an idea of the variance, which indicates that the first 25 components in the ratings explain the majority of the variance.

This allows us to be even more selective for the data. SVD [22] was chosen as the preferred decomposition method as it gives reliable results and there is some flexibility on how many folds of data we can choose to train on. Furthermore, by our previous review it has been established that it is a good way to ensure high precision.

This adds up in the end when the actual recommendations are generated. Furthermore, TF-IDF is utilized to empower the hybrid recommendation module. This works well with the SVD used earlier.

IV. COMPARISON AND ANALYSIS OF VARIOUS RECOMMENDATION APPROACHES

The Hybrid Recommender System is built with two main components, the Collaborative matrix and the Content matrix. First, the matrix of movies and their ratings are transformed into a feature matrix as given in Fig. 8. This matrix contains the movies against the users and the data contained is the rating given by the user. This featurization is done by utilization of Term Frequency-Inverse Document Frequency. This creates a large number of features, but decomposition will allow these features to be lessened, ultimately bringing down the complexity of the calculations needed. When Singular Value

Decomposition (SVD) is used on this matrix it reduces the features hundredfold. Moreover, analysis after SVD revealed that most of the variance in the data comes from about the first 125 features, which limits the features even further.

Fig. 8. Feature Matrix with Movies and Ratings.

The algorithm for Hybrid SVD is proposed and it is given with detailed procedure as shown in Fig. 9 for utilizing the concept of standard SVD and enhanced further to acquire the hybrid enhanced method for obtaining low computation time for recommendation procedure.

A. Comparison on Traditional Approach

Root-Mean-Square-Error (RMSE) between real ratings and predictions is a widely used measurement. The lower the RMSE, the more accurately the recommendation algorithm predicts user ratings. To get the initial phase of results on a smaller scale of dataset we decided to use Root Mean Square Error method to find out relevant recommendations as required by the user. Root Mean Square Error [26] method is frequently used method to calculate the difference between the observed measure and the predicted measure. This measurement is usually done using a mathematical formula which is as follows in (1):

where,

n = total number of values present.

p = predicted value.

o = observed value.

i = the value at given position.

So, using this formula and the data from the datasets, recommendations of movies were obtained at initial stage. Here, we used unsupervised learning to classify the data according to our needs from the dataset.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (P_i - O_i)^2}{n}} \quad (1)$$

We gave some input factors as to get the relevant recommendations.

Algorithm: The HybridSVD-based dimension reduction algorithm

Input: Matrix P

Output: Correlation matrix Q,P,T

1. P is factored into three matrices $Q_1 P_1 T_1$;
2. Reduce the $n \times n$ matrix P_1 to have only k largest diagonal values and obtain a matrix $P_i, i < n$.
3. The matrices Q_1 and T_1 are reduced accordingly, then the reconstructed matrix $S_k = QP_kT$ is the closest rank-n matrix to S, $S_k \approx S$;
4. Calculate the square root of P to be $P^{1/2}$ and calculate the two correlation matrices $QP^{1/2}, P^{1/2}T$.
5. Fill in the unrated data and smooth the matrix. Replace all missing values with the corresponding column average and subtract the corresponding row average from every matrix entry.
6. Calculate the SVD of S according to steps 3 and obtain the matrix Q,P,T.
7. Calculate the user correlation matrix $QP^{1/2}(m,k)$, denoted by U, and the item correlation matrix $P^{1/2}T(k,n)$, denoted by I.
8. For the matrix U(m,k), clustering method is used to obtain the similar rating user-modes and obtain the user-based commendation set P_u .
9. For the matrix I(k, m), a set of top-K similar items towards item i_j will be generated according clustering algorithm. Calculate the prediction for user on page u_a and obtain the item-based commendation set P_i .
10. Sort P_u and P_i by predicted rating and obtain the commendation set P.

Fig. 9. Hybrid SVD Algorithm.

In the experiment, comparing with the traditional UBCF, IBCF algorithm, we can learn that the HybridSVD algorithm can consistently get a lower RMSE and provide better quality of predictions as represented in Fig. 10. The density of a rating matrix can have a significant impact on the performance of collaborative filtering.

Fig. 10. Comparison of Customary and the HybridSVD Algorithm.

Fig. 11. Traditional vs Hybrid with Sparse Data.

In Fig. 11, we analyze how RMSE evolves with the density of rating matrix. The results indicate that the hybrid approaches consistently improves the recommendation performance regardless of sparsity of test users or items.

B. Sentiment Analysis for Ranking Calculation

The Sentiment Analysis [27] is done over the Large Movie Reviews Dataset. The reviews are categorized in a polar way, so 1 is for a positive review and 0 for a negative. The method used for prediction in the proposed system is a multilayer Perceptron model [14]. Such a model has shown to be effective in predicting sentiment. For each user, the interest movie ratings are used as dimensions to create a vector. The similarity between any two users is determined by the cosine of the angle between the vectors of those two users using the formula as given in (2).

$$\text{Similarity} = \cos \theta = \frac{A \cdot B}{||A|| \times ||B||} \quad (2)$$

For instance, interest movie ratings of two users are {3.5, 1.0, 4.0} and {2.0, 4.0, 0} respectively. The cosine of the angle between two vectors is calculated as 0.84624085163. This implies that the two users are approximately 84% similar to each other with respect to their interests.

Likewise, the calculation is performed for all users with respect to each other and a similarity matrix is generated. The comparison of different scores for movies based on different filtering approaches is given in Table I.

C. Rating Calculation

The rating calculation for the predicted system with sentiment score is calculated as given by (3). These values are linked with the movie titles and averaged according to the titles as shown in Fig. 12. This allows it to be merged with the data used for the hybrid recommendation. This however also reduces the number of movies drastically as the recommendations available are limited.

$$\text{Rating}_{\text{Sentiment}} = \frac{\sum_1^n s_{m,n}}{n} \quad (3)$$

The predictions generated are averaged to reach a general predicted number for the particular title. Finally, the recommendations from the hybrid system are used to predict the top k movies that would be the most relevant according to

the system. These recommendations also have the predicted ratings attached to the movie titles for each user. These ratings are generated by the similarity matrix between the hybrid recommender.

To reduce the time needed to calculate the final recommendations, the proposed system simply takes these movies and then calculates a final ranking for each movie. The rating from Sentiment is reached by averaging over the number of ratings (n) for the movie across the movie title (m) as given in (4). For instance, a user has selected his interest genre as humour. The similarity points of all opted movies in particular genre, say {10,9,9,8,9}, are listed. The mode is calculated as 9. So, the domain score is 9.

TABLE I. COMPARISON OF SIMILARITY SCORES

Title	CBF	CF	HYBRID SVD

94	Andrew Dice Clay: Dice Rules (1991)	0.535082

Fig. 12. Predicted Sentiment Score based on user Tags.

The process is repeated for all the preferred interests. Using the scores of the interest domains, rather than the raw input of all users alone, can give us a better similarity and the overall precision shall be increased to a certain extent. This final ranking is reached by adding the averaged sentiment score with the predicted ranking. This allows taking into account the sentiment rating without having to compare it with a huge number of movies. In this way, the impact of the sentiment analysis is still relevant but keeps the sorting of the movies from the larger dataset largely dependent on the output from the hybrid recommendations module. For testing the accuracy of the system, the metrics of precision and recall have been used.

For testing the accuracy of the system, the metrics of precision and recall have been used. These have been used by many other works to indicate how accurate the system is. Precision is the ratio between the True Positives (TP) and the total positives predicted by the system. Recall is the ratio between the True Positives and the total TP with False Negatives (FN). So, Precision gives a measure of how accurate the actual predictions are, while recall gives an idea of how many of the predications are actually being considered. F-Measure gives a great idea of accuracy. For F-Measure to be high, both precision and recall have to be high. Precision, recall and F-Measure all have values between 0 and 1. Equation 1 gives the equation for precision, recall and F-Measure [28]. Fig. 13 shows the performance of the proposed system based on accuracy for validation sets containing 1 million review ratings. Both the Precision and Recall are above 0.7 and this causes the average F-Measure to be 0.93, which is highly competitive with other similar systems as can be seen by the study. Table II shows the performance of the proposed system on different number of ratings.

As the results show the best F-Measure comes from the lower amount of ratings. As the number of ratings increases, precision is seen to increase, while recall gets lower. This causes a lower average F-Measure.

However, the accuracy is still very high. As we can see from the measures, the hybrid system itself takes a lot of time to compute the recommendations. However, the addition of the Sentiment Analysis adds very little time to the overall merged system. So, it is still keeping the time relatively low than if the Sentiment Analysis was used with the total system instead.

We conclude from these experiments that the proposed hybrid algorithm is effective at improving the quality of recommendations and accuracy of the proposed technique improved with sentiment score added.

TABLE II. PERFORMANCE MEASURES FOR DIFFERENT RATING COUNTS

Ratings Count	F-Measure	Recall	Precision
20	0.9304	0.791	0.877
40	0.9334	0.728	0.861
60	0.9147	0.719	0.852
80	0.8012	0.7021	0.811

Fig. 13. Predicted Accuracy based on Sentiment Score.

V. CONCLUSION

In this paper a number of studies on recommendation were analyzed and a hybrid recommender system is proposed which works with a Sentiment Analysis model to filter the final results. This system focuses on keeping the computations lesser while still incorporating review data into the recommendations, which contains critical information about the opinions of the viewers. Hybrid SVD is used to generate effective movie recommendations, while a multilayer perceptron is used for Sentiment Analysis to optimize the accuracy level higher. The system performs competitively with other methods, while also incorporating written reviews. For future work, this proposed system might be tested further with a more comprehensive data, for generating recommendations.

VI. FUTURE WORK

The limitation of our work is, we did not have the sentiment score merged with movie dataset. In future research work, we are interested in analyzing the various techniques of sentiment analysis with the respect to the different types of recommendation techniques.

Abstract—A supervisory control and data acquisition (SCADA) system has been developed for three machines used for the thermal processing of materials: a hot wire cutter, an induction heater and a welding test stand. The cutter uses a transformer with adjustable voltage between 20 V and 32 V, and current of 8 A, measuring the temperature of the wire with thermal expansion. The heater uses a 24 V, 15 A sources, and a type K thermocouple embedded in the sample in order to measure temperature. In welding, a temperature control system was implemented for the sample using type K thermocouple and a cooling fan using a 12 V and 20 A sources. The SCADA system consists of a PLC and a PC with a graphical interface which serves to select the process to be worked on as it displays the thermal history of the monitored object. The supervisory system uses a PC with a 32-bit Windows 7 operating system and an OPC software package running on the academic LabVIEW platform. It was designed to use a single human-machine interface for different thermal processes. This paper describes the important components of the system, including its architecture, software development and performance testing.

Keywords—Automatic control of thermal processes; programmable logic controllers; monitoring and supervision in automatic control systems; machine components; Sensors and virtual instruments for control

I. INTRODUCTION

The thermal processing of materials requires keeping track of the measurement of temperatures and their behavior over time, in order to record the thermal history and understand the physical phenomena inherent to each process.

The hot wire cutting machine uses a chrome-nickel alloyed wire between 0.5 and 1 mm in diameter, heated under the Joule effect [1] produced by a source of electrical energy that allows the current to circulate through the wire. When adjusting the operating parameters of the machine, it is always necessary to specify the temperature of the wire and the speed with which the cut must be executed [2]. In addition, the wire must be kept tensed in order to cut certain materials such as foams and Styrofoam [3].

In the case of welding processes, the thermal information of the sample is useful, as it is welded to describe the process phenomena from the point of view of its technology, metallurgy and heat transfer, as required in the development of welding procedures [4]. The measurement of temperatures below the weld bead and its location with respect to the bead is

useful to use a computer program [5], [6], which predicts the temperature distribution of the welded sample. In the particular case of welding materials sensitive to high temperatures, such as manganese-alloyed steels, it is necessary to keep the temperature of the sample below 250°C so as to keep the material from cracking. Fans can be used to cool the sample before continuing to make new welding deposits [7].

The induction heating machine is used for treating ferrous materials with heat [8]. In this case study, small cylindrical samples were heated in order to obtain their heating, maintenance, and cooling cycles. The thermal history experienced by the treated material is of vital importance to learning the behavior and mechanical properties that it will present when used.

In order to be able to interact with the thermal processing machines located in the same laboratory space, a Supervisory Control and Data Acquisition (SCADA) system that supervises and controls the variables present is required. This is achieved with the use of a graphical interface platform such as Labview from National Instruments, and the STEP 7 Micro WIN application for programming the Programmable Logic Controller (PLC) [9]. Other applications have been used for data acquisition in the laboratory and for the control of variables [10]–[13], as is intended with thermal processing machines. No sophisticated temperature control systems were developed [14]–[16], but results were achieved without signal interference.

In this paper, three machines were connected to the SCADA system and, consequently, threads were developed in the PLC to use a single graphical interface from a personal computer (PC). A “Human Machine Interface” (HMI) was designed with control panels for each machine, which can be selected by the user to operate the machines independently.

To describe the SCADA system proposed, the hardware implementations are presented, while the interface developed and the logic applied for the three machines are explained. The three machines used operate independently. These are: the hot wire cutting machine, the induction heating machine and the welding test machine. The rest of the sections in this paper are organized as follows: The next section illustrates the Hardware and Logical interface of the supervisory system. The results are comprehensively presented and discussed in section Results and Discussion.

II. METHODOLOGY

To describe the SCADA system proposed, the hardware implementations are presented, while the interface developed and the logic applied for the three machines are explained. The three machines used operate independently. These are: the hot wire cutting machine, the induction heating machine and the welding test machine.

A. Hardware for the Supervisory System

The system architecture is made up of an HMI interface in charge of supervising the thermal variables of the materials treated and inserting the initial parameters for its execution and a PLC connected to each machine. The PLC is an S7-200 from Amsamotion that has 14 digital inputs and ten digital outputs.

In the cutting machine, PLC controls the movement of the motor and regulates the voltage of the wire, taking the readings of the current and expansion of the wire (Fig. 1). This information is sent to the HMI interface so that the operator can see the thermal behavior of the machine.

The PLC can only apply ON/OFF logic to control the coil in the induction heating machine since it works with a fixed voltage of 24 V (Fig. 2). This machine's interface only shows the temperature of the sample throughout its thermal cycle, that is, the temperature and the time it takes to reach its maximum point and the time it takes to reach ambient temperature.

In the welding machine, the preheating temperature and the temperature at the welding point are monitored (Fig. 3). The functions of the interface for this machine is to set the desired preheat temperature and display the data from the two temperature sensors. This is achieved through two thermocouples connected from the PLC. Additionally, a fan used to cool the sample is directly connected.

Fig. 1. Structure of the SCADA System on the Hot Wire Cutting Machine.

Fig. 2. Structure of the SCADA System in the Induction Heating Machine.

Fig. 3. Structure of the SCADA System in the Welding Machine.

Because the machines are linked to the same PLC, a bar with eight switches was implemented to connect the five sensors (Fig. 4).

It is thus possible to use all five sensors with only two analog inputs. However, only one machine's sensors can be used at a time.

For the operation of the Brushless motor, it was necessary to add a controller that allows manipulating the direction of the motor's rotation and varying the speed. Likewise, to determine the motor's position, Hall Effect sensors were connected to the input pins of the PLC to determine the exact position of the motor's rotor.

For the hot wire cutting machine, a linear expansion sensor and a current sensor are connected to the PLC, manipulated by means of pulse width modulation (PWM). Likewise, the Q0.2 output is connected to an electrical circuit that allows the average voltage flowing through the wire to vary.

Induction heating is commanded by pin Q0.4, which turns the coil on and off. In addition, a type K thermocouple connected to pins 5 and 6 of the switch bar is used, which is in turn connected to the analog input +A of the PLC [17].

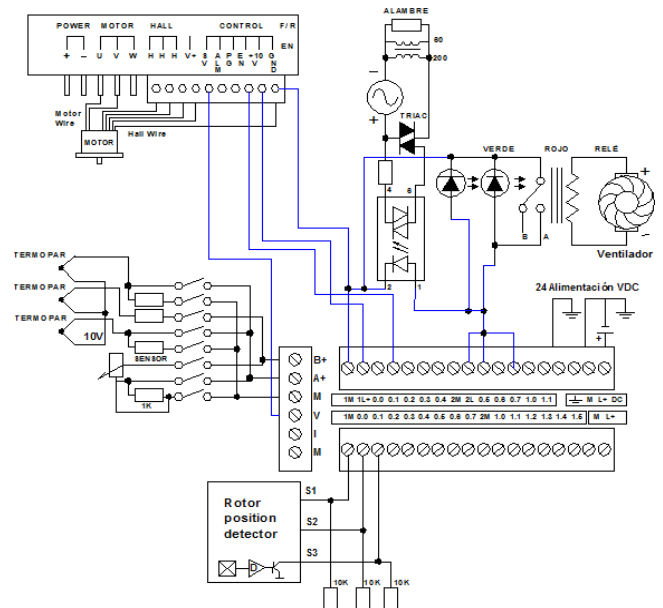

Fig. 4. Structure of the SCADA System in the Induction Heating Machine.

Finally, the pins used for controlling and monitoring the welding machine are Q0.6 and Q0.7, indicating the welding application or the halt of the process. Likewise, pin Q0.8 is responsible for activating or deactivating the fan.

B. Logical Interface of the Supervisory System

For the development of the HMI interface, the LabVIEW computational tool is used. Four virtual instruments (VIs) were implemented: one main instrument (Fig. 5) and three additional ones.

The interface of the hot wire cutting machine (Fig. 6) specifies the configuration of the wire according to its type and dimensions, the maximum current values, temperature, and expansion, in addition to the length of the wire and its electrical resistance. Next, the operating parameters are regulated, namely the voltage of the source and the cutting speed.

A graph is displayed for the current flowing through the wire and another for the temperature measured through the thermal expansion of the wire.

In the interface of the induction heating machine (Fig. 7), the preheat temperature of the workpiece is set. Initially, the sample is heated until it stabilizes at an initial temperature. A ramp then raises the temperature from the initial to the final temperature. In addition, the conditions of the sample are specified, namely initial temperature, length and speed of advance to indicate movement in one direction, in the opposite direction or in alternating direction.

Fig. 5. Main Interface.

Fig. 6. Hot Wire Cutting Machine Interface.

Fig. 7. Induction Heating Machine Interface.

The temperature that the sample finally reaches is graphically represented to observe the thermal history of the material.

For the interface of the welding testing machine (Fig. 8), the expected preheating and maximum temperatures must be entered, as well as the welding speed for the movement of the sample with respect to the electrode both in forward or reverse directions.

The two thermocouples installed in the sample measure the temperatures below the welding bead and their temperature. These are displayed graphically on the screen and the data is processed for analysis of thermal cycles in welding.

Regarding the software, in addition to the VIs for the interfaces, an automation was designed in the control algorithm for the PLC with the functionalities of the three machines. The PLC programming language used was Ladder, along with the LabVIEW "Object Linking and Embedding for Process Control" (OPC) module for communication between PC, PLC and sensors.

Fig. 8. Weld Testing Machine Interface.

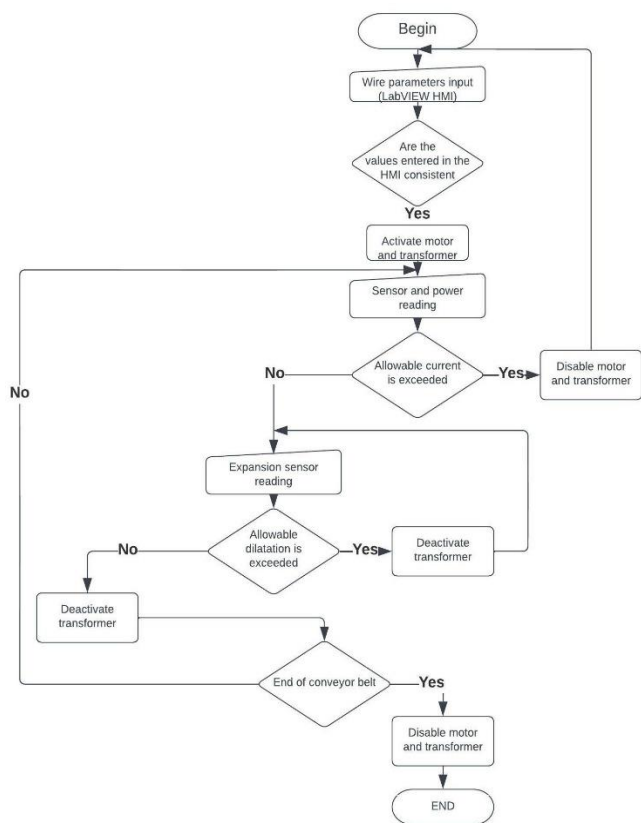

Fig. 9. Flow Chart for Hot Wire Cutting Machine.

The logic of the hot wire cutting machine (Fig. 9) consists of checking the coherence of the entered values, checking the allowed current and the expansion, and finally deactivates the motor and the transformer.

The operating logic for the induction thermal processing machine (Fig. 10) verifies the preheating of the sample and on the other hand the parameters, so as to visualize the temperature ramp with respect to time.

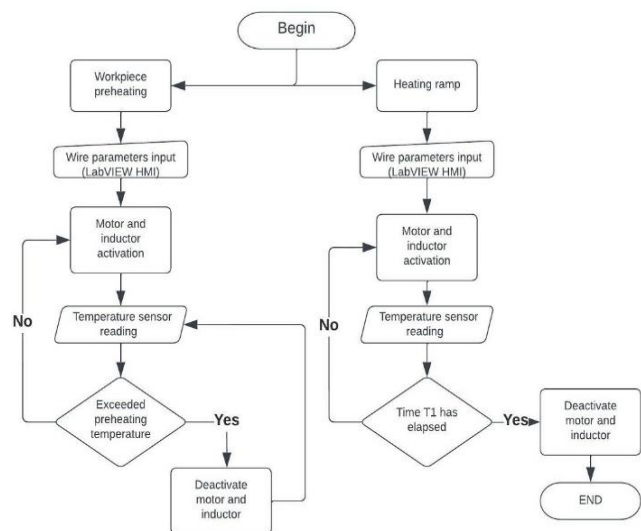

Fig. 10. Flow Chart of Induction Heating Machine.

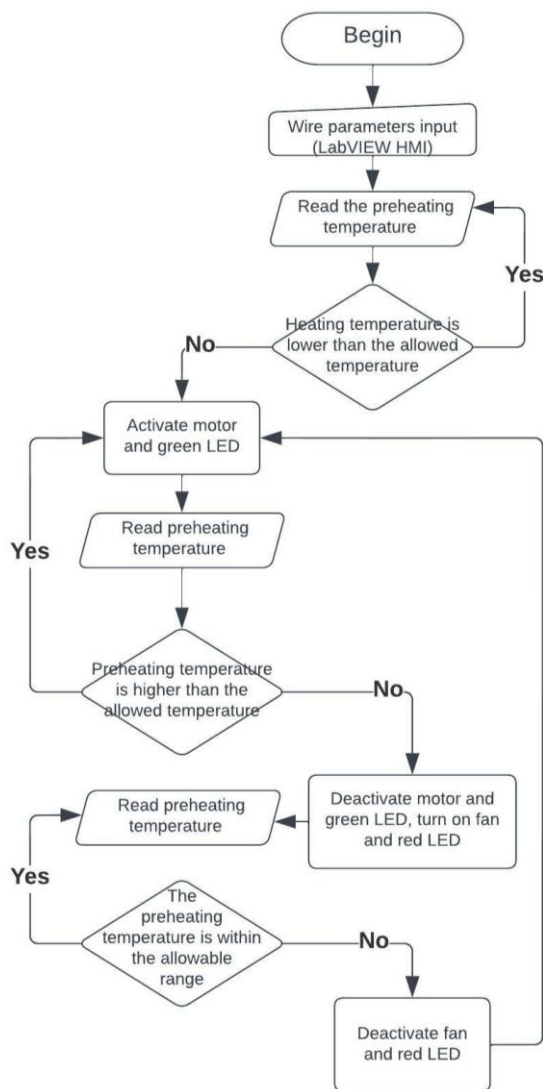

Fig. 11. Flow Chart of the Welding Testing Machine.

The logical process required to work the welding machine (Fig. 11) begins by specifying the preheating temperature of the sample to be welded, delimiting the allowed range. If the temperature is below the range, a red light will go on, indicating that welding cannot start. If the temperature is above the allowed range, it means that the welding must stop and a fan must be activated to cool the welded sample.

III. RESULT AND DISCUSSION

Based on the mechanical design of the machines and the manufacture and installation of components previously carried out by the company Ingeniería Brasilerio Colombiana SAS, the automation of the thermal processes was carried out using the SCADA system. First, a transformer with variable voltage between 18 V to 30 V of alternating current (AC) was designed and installed, controlled from the PLC by means of an Optotriac used as an interface between the controller and the power Triac of the transformer, in order to vary the voltages. The maximum amperage reached was 9A. Fig. 12 shows the implementation of the hot wire cutting machine.

Fig. 12. Implementation of the Hot Wire Cutting Machine.

Then, a KTR-type displacement sensor was implemented. Since it is welded to the counterweight that tenses the wire, it manages to measure the linear expansion caused by its heating. This sensor measures from 0 cm to 2.5 cm, and has a maximum error of 0.02 mm. Measuring the linear thermal expansion of the wire when heated allowed making an indirect measurement of temperature using (1).

$$T_f = T_o + (L_f - L_o) / \alpha L_o \quad (1)$$

Where, L_f and L_o are the final and initial lengths of the wire; T_f and T_o are the final and initial temperatures of the wire; and α is the coefficient of thermal expansion obtained from the wire manufacturer.

In addition to those with variable voltage, tests were carried out using a transformer with a fixed voltage of 20 V. This was done to determine the reliability of the SCADA system function and to compare its accuracy. In this way, it was possible to determine the feasibility of using PWM to manipulate the output and obtain different voltages to heat the wire. Table I shows the comparison between the two voltage sources. A wire with a diameter of 0.7 mm was used for this, varying between three different lengths (800 mm, 900 mm and 1000 mm), as shown. To obtain an acceptable margin of error, three iterations were performed for each length value, with a total of 9 samples for each source.

TABLE I. HOT WIRE TESTS

Length (mm)	Variable source		Fixed source	
	T_{\max} (°C)	I (A)	T_{\max} (°C)	I (A)
800	788	8.7	779	8.6
800	791	8.7	780	8.6
800	790	8.7	784	8.6
900	651	8.2	642	8.15
900	654	8.2	640	8.15
900	649	8.2	640	8.15
1000	583	8	576	8
1000	585	8	578	8
1000	580	8	576	8

When comparing the temperatures measured with each source, a maximum error of 5 °C can be seen. With this error in mind, the use of the sensor can be considered as a good alternative to measure the temperature indirectly in the wire. It is also possible to validate that the results obtained with variable tension are consistent with those obtained with fixed tension.

In the tests with the induction heating machine, an Adeeing Flyback heating plate of 1000 W and 20 A was used for low voltage induction ZVS between 12 V and 48 V. The power supply is carried out with a 24V DC switched source with 15A DC current. The steel sample to be heated must dimensionally comply with a 1/3 ratio between diameter and length [18] for effective induction in thermal processing. Thus, the sample was 15 mm in diameter and 45 mm in length. Simulation tools can also be used to determine the parameters of the induction coil [19]. Fig. 13 shows how the test body reached the bright cherry red required to treat steel with heat. The temperature in these conditions must exceed 700°C up to a maximum of 1100°C. The measurement made with the thermocouple verified that the temperature reached in the process exceeded 700°C. The design of the coil was beneficial for this positive result: it was made of 6 mm diameter copper tubing, obtaining a 7-turn cylindrical shape with an internal diameter of 35 mm and a height of 50 mm. In another phase, the programming of a heating ramp from an initial temperature to a final temperature was tested. This was done by configuring the ignition time of the coil with an ON/OFF control commanded from LabVIEW.

In order to determine the best location of the thermocouple tip with respect to the center of the coil, four tests were performed at distances of 0, 5, 10 and 15 mm.

The thermocouple placed in the middle of the inductor presents a high interference (green line in Fig. 14) due to the magnetic field generated by the coil. When the thermocouple is withdrawn 15 mm, the interference disappears (blue line in Fig. 14). This was confirmed by previous experiments [20].

Finally, the implementation in the welding testing machine was carried out. In it, a car powered by a Brushless motor, previously used in the cutting machine, a press was adapted to hold the sample to be welded. Two K-type thermocouples were inserted into a steel plate to monitor temperatures. For each thermocouple, a transmitter that amplifies and filters the temperature signal to take it to the PLC was used. From the HMI interface, the motor was activated to move along the car with the sample at the welding speed when the electric arc was ignited (Fig. 15).

Fig. 13. Induction Heating Test.

Fig. 14. Preheat Temperature at Different Distances from the Coil Center.

Fig. 15. Implementation in the Welding Testing Machine.

Two lights (one red and one green) are placed on the machine to indicate when the temperature to start welding is reached, which turns on the green light. The red pilot lights up when the sample reaches the maximum temperature previously specified on the HMI. When this happens, a fan that accelerates the cooling of the sample is activated to continue the welding operations.

Additionally, a 12 V and 20 A switching power supply was used to start the fan. The location of the thermocouple tip with respect to the heat source (the electric arc) is also important in order to avoid interference in the signal due to the magnetic field of the welding current, as happens when the thermocouple is moved between 5 and 10 mm away (Fig. 16). A way to measure the temperature in welded plates is thus indicated in comparison with modern techniques [21] and analytical methods [22].

Fig. 16. Temperature at Different Distances from the Weld Bead.

IV. CONCLUSION

In the hot wire cutting machine, the electronic circuit composed of Triac and with the help of the PWM signals generated by the PLC maintains coherence with the linearity of only a maximum error of 1.4%, which allows smooth variations in the voltage, continuously and safely.

In the induction heating machine, it is possible to bring the steel to the temperature necessary for the quenching heat treatment. It is also possible to locate the thermocouple inside the sample, eliminating interference in the signal with a delay of no more than 40 seconds, which could be reduced by increasing the power of the inductor.

In welding, it is important to regulate the advancement speeds of the cord, as well as the measurement of the thermal cycles experienced in the welded area, which was fully accomplished thanks to the implemented automation. To correctly locate a thermocouple on the welded plate, it must be drilled so that when inserting the thermocouple it is spaced between 5 and 10 mm from the center of the weld bead. An online application should be developed to allow remote management outside the laboratory in future work.

ACKNOWLEDGMENT

We thank the company Ingeniería Brasileiro Colombiana SAS for facilitating the laboratory testing infrastructure as well as the thermal processing machines which allowed carrying out this project. We also express our appreciation towards the Francisco de Paula Santander University and the University of Pamplona for their professional and technical support.

Modeling Wireless Mesh Networks for Load Management

Soma Pandey¹, Govind R. Kadambi²

Faculty of Engineering and Technology, Ramaiah University of Applied Sciences, Bangalore, India

Abstract—Developing a simulation model for multi-hop multi-gateway wireless mesh networks (WMNs) is a challenging task. In this paper, a multi-hop multi-gateway WMN simulation model is developed in a step-by-step approach. This paper presents a MATLAB Simulink-based simulation model of Wireless Mesh Network (WMN) designed for easy optimization of layer 2. The proposed model is of special utility for the simulation of scheduling of GateWay (GW) and packet within a multi-hop multi gateway wireless network. The simulation model provides the flexibility of controlling the flow of packets through the networks. Load management among the GWs of WMN is performed in a distributed manner wherein the nodes based on their local knowledge of neighborhood beacons optimize their path to a GW. This paper presents a centralized Load Management Scheme (LMS). The LMS is based on the formation of Gateway Service Sets (GSS). The GSS is formed on basis of equal load distribution among the GWs. The proposed LMS is then analyzed for throughput improvement by leveraging the MATLAB Simulink model developed in the paper. A throughput improvement of almost 600% and a 40% reduction in packet loss was observed through simulations thus indicating the efficacy of the proposed LMS. The uniqueness of the simulation model presented in this paper are its scalability and flexibility in terms of network topology parameters.

Keywords—MATLAB; Simulink; multi-hop; wireless mesh network (WMN); gateway; simulation model; load management

I. INTRODUCTION

Nearly always good research methodology is supposed to culminate with performance analysis and simulation study. Research in wireless networks carries no exception. In this paper, a system model is presented to simulate the WMNs. The model is designed in a manner such that it supports the flexibility to increase or decrease the number of GateWays (GWs) within the mesh as well as supports the increase and decrease in the number of hops for a particular router. This results in providing a very simple lightweight model for the optimization of layer 2. This model can be applied easily for GW scheduling in a very quick and efficient manner.

Designing a multi-hop multi gateway WMN model is a tough challenge. In such a mesh network there are multiple parameters to be handled. A very popular example is the IEEE 802.11s mesh architecture [1]. Another example is the Zigbee mesh architecture [2]. In a mesh architecture, the model has to be developed in such a way that the simulations can be performed on a wide variety of scenarios. Specifically, the model should be able to generate scenarios wherein the number of gateways can be varied. At the same time, the model should also have the capability to increase/decrease the number of

Mesh Routers (MRs). The model should also be able to depict the three-level hierarchy of a WMN as presented in Fig. 1 and Fig. 2 of this paper. In this paper, a WMN model is developed which comprises all the aforesaid properties efficiently. Such a model can be used by researchers to apply their solutions easily. The contribution of this paper is to provide a platform and insight which can be used by the scientific community to build their WMN models in a better and more efficient manner using Simulink.

In this paper, a load management technique is applied to reduce congestion in GWs of WMN. In multi-GW WMNs, there is no mechanism available to schedule a fixed set of MRs to GWs. This causes either contention or congestion of GW [3,4]. In this paper, a GW scheduling technique is applied by creating a fixed Gateway Service Set (GSS). GSS is defined as assigning an equal number of MRs to each GW. This will result in avoidance of delay due to repeated computation of nearest GW by MRs. This will also reduce GW congestion by avoiding unfair allocation of MRs to GWs. Such an LMS is then used to analyze the performance of load sharing in various scenarios of WMN. The pertinent point is that the simulations to analyze the proposed LMS could be performed with ease due to the flexibility provided by the proposed simulation model.

II. LITERATURE REVIEW

Most of the research about WMNs generally opts for the ns2 [5] simulator which is an unlicensed open-source simulator. Among the licensed simulators, the top choices are Qualnet and Simulink [9]. Simulations are of two types – Discrete events and continuous ones. Discrete event simulations are suitable for models where parameters do not change until the occurrence of some event. Continuous event simulations are suitable for models where parameters change continuously and do not require the occurrence of any event for the occurrence of change [6]. In [7], the authors have defined and compared different types of simulation models based on event and time. A characteristic feature of a good model is its scalability. The model of WMN should allow flexibility in changing the network topology quickly and easily. An analysis of different types of network simulators is presented in [8].

The model of a WMN comprises three types of nodes – GWs, MRs, and End Nodes/client nodes. GWs provide Internet access to MRs and end nodes. There can be multiple GWs that connect the network to the Internet. The difference between MRs and End nodes is that MRs can redirect traffic to GWs, whereas End nodes just connect to the nearest available MR. Unlike MRs, the End nodes cannot connect to a far-off node

that is out of communication range of a GW. Most of the WMNs follow the generic architecture recommended by the IEEE 802.11s standard [1].

An abundance of literature is available on wireless network simulations using Simulink [9,10,19]. But in most of these papers, the researchers are unable to consider multi-hop multi-gateway WMNs such that the number of GWs is more than 5 and the number of routers more than 20. In [9], the authors have simulated multi-gateway mesh networks. Although the authors of [9] analyze multi-GW association in WMNs, the simulation model comprised only two GWs and 14 MRs. The authors in [10] have simulated WMN with 100 MRs but have not considered more than one GW. This limits their analysis to WMNs with only a single GW. In [11], the authors have used the ns2 simulator to simulate a network with 50 nodes but with only a single GW. The authors in [12] have considered WMN with up to 5 GWs and 50 MRs. But the topology of WMN has not been modified throughout the simulation process.

In this paper, a step-by-step process is presented to develop a WMN on Simulink. Thereafter, the model is used to analyze the performance of the WMN when there is an increase in the number of GWs and MRs systematically. In the process, there is an attempt to achieve a balanced approach for ensuring a fair allocation of MRs among multiple GWs. Therefore, to each GW an equal number of MRs is assigned. The uniqueness of the model presented in this paper is that it is scalable and flexible in terms of network topology parameters. In this model, very easily the number of MRs can be increased and decreased. The same applies to GWs wherein the number of GWs can be increased and decreased with ease.

Finally, this model is applied to analyze a fair GW scheduling technique. This paper proposes to allocate a fixed set of MRs to a GW thus forming a GSS. The GWs are deployed such that each GW receives an equal number of MRs which is in its wireless coverage area. These MRs assigned to a GW might be directly within its communication range or through another MR as mesh topology [1]. This will result in the mitigation of delay in the computation of the path to a GW. Since most of the traffic is to or from the Internet, GWs become a major source of traffic within WMN. This results in congestion of the wireless links to GWs and congestion due to queuing delays in GWs. This occurs since some GWs might have a larger number of MRs associated with them compared to some other GWs in WMN, which might be idle due to no traffic through them. In [13], the authors have identified that the available capacity of a GW reduces by $O(1/n)$ where n is the number of users. The presence of many users results in GW bottleneck and was termed as a 'bottleneck collision domain' in [13]. In [14,16] the authors have attempted mitigation of GW bottleneck with a proposal of performing cooperative caching among the MRs to avoid packet loss. Most of the load balancing techniques focuses on route optimizations. Since most of the time routes are formed on basis of the information about the neighborhood of a node, these are not very optimal techniques. It is also observed by [15] that such techniques consume network resources and bandwidth due to repeated attempts for route requests and route response packets. A very recent paper in this direction is by [17]. In this paper, the authors have attempted to balance load by optimizing the

Adhoc On-Demand Distance Vector (AODV) Routing Protocol. AODV is a very popular routing protocol in WMNs. This is because most of the optimization techniques in WMN are derived from the adaptations of MANET technologies. In the case of MANETS, assigning a fixed service set to GW is not possible due to peer-to-peer routing. But in the case of WMNs, especially IEEE802.11s WMNs, such an assignment is possible because WMNs are a hybrid of fixed and mobile infrastructure. Therefore, this paper proposes a mechanism in which each GW can be assigned its own GSS thereby reducing the network traffic for route determination. This technique also results in a fast and efficient delivery mechanism because the MRs do not have to keep computing the shortest path to a GW when there are multiple GWs in the vicinity. In [18] the authors have performed a detailed survey and have concluded that the WMNs are here to stay for a long time. In [18] the authors also note that the WMN model should become more and more flexible in a manner that allows for the nodes to move from one gateway to another seamlessly. This paper attempts to provide such flexibility while performing the load sharing among gateways through a fair assignment of MRs to GWs.

III. NETWORK ARCHITECTURE OF WMN

Fig. 1 presents a conventional WMN with three levels of nodes. For more details on WMN and its architecture one may refer to [19] in which authors have explained in detail different types of WMNs based on various IEEE standards. At the first level is the GW node which connects to the Internet. In IEEE802.11s standard [1], it is called the Mesh Portal Point (MPP). But in this paper, a more generic term called the GW node is used. The GW node is connected to many routers which are called the Mesh Points (MPs) in IEEE 802.11s. But to keep the term generic, it is called the Mesh Router (MR). Finally, the end nodes are the client devices, for example, a laptop, smartphone, or a sensor. These are called the Mesh Clients in IEEE 802.11s. In this paper, they are referred to as End nodes.

The WMN architecture in Fig. 1 is extended further to a real-world scenario in Fig. 2. The difference between Fig. 1 and Fig. 2 is that in Fig. 1 none of the GWs have a fixed Gateway Service Set (GSS) whereas in Fig. 2 each GW has been assigned a fixed number of MRs.

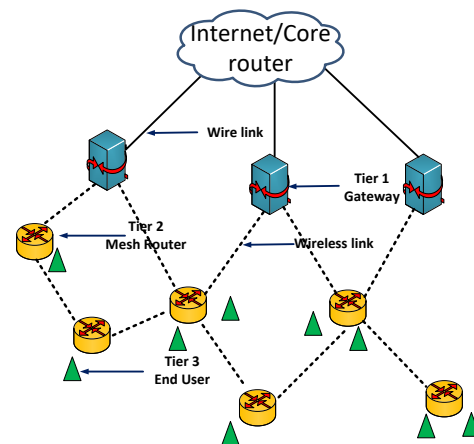

Fig. 1. Three Tier WMN Architecture.

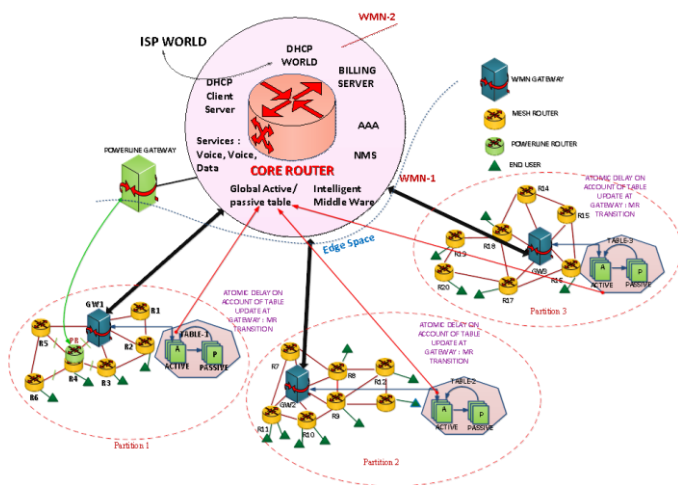

Fig. 2. Schematic of a Real-World WMN Scenario.

In Fig. 2, the MRs and the GWs are connected through wireless links and there are wired connections between the GWs and the core router. Each GW locally maintains an Active Passive Routing (APR) table which is explained later in this section. It is important to note that there might be many WMNs connected and served by the same Internet Service Provider (ISP). To illustrate this, there are two labels indicating WMN-1 and WMN-2 in Fig. 2. Both the WMNs are shown connected to the same ISP and core router. Fig. 2 depicts a dashed line that separates the ISP space and the edge space. The edge space marks the beginning of the WMN space or the Local Area Network (LAN) space.

The next section presents how this model can be used to implement fair scheduling of GWs within a WMN. The proposed scheduling of GWs through the judicious management of the routing table is called Load Management Scheme (LMS). The usage of the term LMS is justified because the scheduling of GWs aims at the reduction of processing load on GWs. A particular GW can hand off its extra load to a neighboring GW by simply changing the MR entry from active to passive, in its routing table. At the same time, the GW receiving the load will change the entry of the MR from passive to active. Therefore, by managing and changing the routing table, a fair allocation of GW to MRs can be maintained.

IV. COMPONENTS OF WMN

The core router is a router that connects the edge network to the Internet. The major functionality of the core router is to streamline the Internet traffic as per the bandwidth demand without a loss in performance [16]. In this paper, the core router is entrusted with the main functionality of meeting the bandwidth demand at the edge routers (GWs in this case). Fig. 2 depicts the Core Router sub-block. The major components of a core router are Internet Service Provider (ISP), Core Router, Authentication, Authorization, and Accounting (AAA) server, Billing server, Network Management System (NMS) Server, Voice, and Video data services, DHCP Server, Global Active/Passive Routing (APR) Table and Intelligent Middle Ware (IMW).

Although the APR Table and IMW may not be a part of the core router in conventional WMN, the proposed LMS requires this additional software to be installed at the core router. The IMW and its components are discussed in more detail in a later section. The components of Edge Space define the components of WMN and are described next.

A. GW

This is the connection point to provide Internet connectivity through the Core router. The GW is connected to the core router through a wired medium or high bandwidth.

B. MRs

The GW is associated with a set of MRs labeled from R_1 to R_6 . Each MR has a wireless connection to either another MR or the GW. An MR is connected to another MR or GW if they are within transmission range of each other. If an MR is not in the transmission range of the GW, it can still reach the GW through multiple hops by using another MR which is within the transmission range of GW. An MR is not allowed to send a packet to GWs other than its associated GW even if there are other GWs that are in its transmission range. The MR-GW association is decided through the APR table depicted alongside each GW in Fig. 2.

C. Local APR Table

This is the most important data structure of the proposed LMS residing at the GW. This table facilitates mapping the GSSs of WMN. Each GW has two main columns in its APR table namely, the active column and the passive column. The active column contains the list of all those MRs that are associated with the GW whereas the passive column keeps the list of all those MRs that are in the transmission range of the GW but are not associated with it. While configuring the WMN, the GW routing table is configured such that the GSSs obtained from the Greedy Graph Partitioning Algorithm (GGPA) are mapped onto the routing table of each GW. This means all those MRs that belong to a GSS are made active in the routing table of GW.

Table I is the routing table of the GW belonging to GSS 1 depicted as partition 1 in Fig. 2. In Table I, the active column contains MRs labeled $R_1, R_2, R_3, R_4, R_5,$ and R_6 . The MRs labeled R_7 and R_{11} are associated with GW_2 as shown in Fig. 2. But because they are within the transmission range of GW_1, R_7 and R_{11} are listed under the passive column of Table I.

TABLE I. APR TABLE FOR GSS 1 (PARTITION 1 IN FIG. 2)

Active	Passive

R_5	
R_6	

When a GW gets overloaded, some MRs must be offloaded to a neighbor GW. This process becomes remarkably simple with the proposed APR table of the GW. If GW2 becomes overloaded, then it can offload MRs labeled R7 and R11 to GW1 by changing the APR table entry of GW1 and GW2.

TABLE II. APR TABLE OF GW OF GSS1 AFTER RECEIVING MRs FROM GSS 2 FOR LOAD SHARING

Active	Passive
R ₁	
R ₂	
R ₃	
R ₄	
R ₅	
R ₆	
R ₇	
R ₁₁	

Initially, the APR table of GW1 appears like Table I and after offloading of MRs labeled R7 and R11 to GW1, the modified APR of GW2 is depicted in Table II. Interestingly, the transition process at the core router involves only updating the entry of the APR table of receiving and sending GWs.

D. The Intelligent Middle Ware

The core router shown in Fig. 2 executes an IMW explained in this section. The IMW residing on the Core router of Fig. 2 has two modules namely load monitoring and load sharing. The load monitoring module periodically estimates the load demand of each GW. Based on this estimation, the module decides whether the load on GW is excess or not. The basis of this calculation is based on comparing load demand to the capacity of GW. A discussion on computing the capacity of GW is presented in [16,20]. If the load demand exceeds the capacity of GW, then a particular GW is overloaded. Demand at each GW is computed by the load monitoring module by recording the number of MRs connected through the GW and the applications that they are executing.

The load sharing module has two components to support load sharing with neighboring GWs. Load sharing with wireless GWs is invoked when the load monitoring module raises an overload alert. The load sharing module checks the stability condition (whether any neighboring GW is having less load and is willing to receive MRs from the overloaded GW). If the stability condition is satisfied, then from an overloaded GW, an MR with a high bandwidth demand is shifted to a neighboring GW with a nominal load. Accordingly, the APR tables are updated.

V. SIMULATION MODEL OF THE PROPOSED LMS OF WMN

Since this research is focused on routing optimization for load balancing, this study requires simulation to be built around the multi-hop routing mechanism of mesh. In this paper, the Simulink blocks are developed to suit the requirement of IEEE 802.11s MAC which is the main module of interest to this paper. To develop this model, the network architecture evolved in the previous section is used. The

coming sections explore this process and after the explanation of the individual blocks, the complete integrated model is presented. Fig. 3 represents the sub-blocks required for the implementation of the proposed LMS. The simulation model has the following four major modules namely Packet Generator, Core router, MR Mobility, and MPP GW.

Fig. 3. Simulation Models of Sub Blocks for LMS.

These blocks follow the network architecture depicted in Fig. 2. It can be recalled that in the network architecture of Fig. 2, the core router routes packets to the respective GWs. Thereafter the GWs forward the packets to the destined MR through multiple hops. Finally, the destined MR forwards the packet to the client/customer device. The simulation model uses a packet generator to generate traffic and this traffic constitutes the input to the core router. Each packet has a destined MR identified by an IP address. The core router module maintains a global APR table for each of the GWs of WMN.

The MR-mobility module simulates the transition of MRs from one GW to another. Since the MR transition effect percolates to the core router, this block is kept located between the GW and the core router block in the hierarchy. For this, the MR mobility block receives signals from the GW about the completion of the transition. It must then send a signal to the core router to resume packet flow from the packet generators, in case the MR transition is complete. The core router in turn issues a signal to the packet generator to resume packet generation.

The MPP GW module defines the operations of GW. The GW model also has a sub-model that simulates the end-user/customer device which operates on the normal IEEE 802.11x [21] standard. This simulation also comprises the client hand-off/handover process between two MRs. A detailed discussion of the layout of each block is presented in the coming sub-sections. The block layout is followed by a screenshot of the actual Simulink model used in the simulation. More details on the process of designing the Simulink block are presented in [22].

A. Packet Generator Module

A packet generator is modeled as a random packet generator that generates packets with labels for specific GWs. The packet generator has five major blocks as depicted in Fig. 4, namely, Set Attribute, Free running counter, Time based entity generator, Repeating Sequence Stair, and FIFO Queue.

Fig. 4. Block Hierarchy of the Packet Generator Model.

Set attribute block gets packet generated. The free-running counter block is for data generation. Repeating sequence block is to define the length of the data block. Time-based entity generator defines the rate at which packets are generated. Finally, packets are delivered to the core router through the FIFO queue. A screenshot of the final packet generator Simulink block comprising these sub-blocks is shown in Fig. 5. The output of the packet generator is fed to the core router. This module is explained in the next subsection.

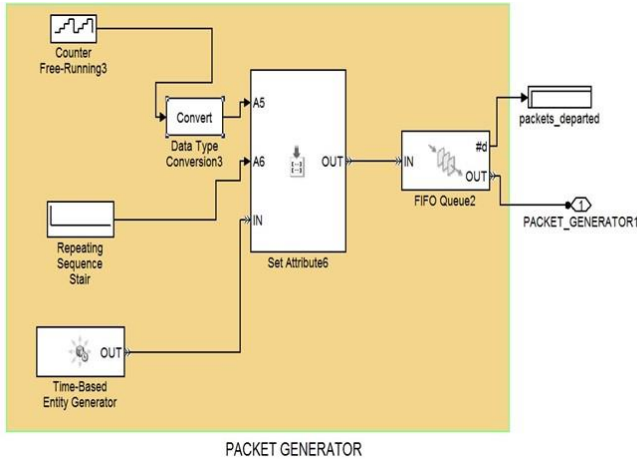

Fig. 5. Simulink Model of Packet Generator.

B. Core Router Module

The function of a core router is to route the packet coming from the packet generator to respective GWs. From its global APR table, the IMW checks for the destination MR and the GW associated with the destination MR. Then the packet is routed to the associated GW of destination MR. The core router has six major blocks as depicted in Fig. 6.

Fig. 6. Hierarchy of the Core Router Block.

- 1) *GW server* receives packets from respective ‘packet generators’ which are to be fed to ‘path selector’.
- 2) A *reverse traffic block* is used to model traffic from GWs and MRs to the core router.
- 3) *Path selector* sorts all the GW packets along with power line packets and reverses traffic packets.
- 4) *The service time function* computes the time taken for path selection (routing) to respective GWs. The referred service time is computed by dividing the length of the packet by the capacity of the core router. For example, if the length of the packet is 512 bits and the capacity of the core router is assumed to be 100 Mbps, then the service time for each packet is 512 ns.
- 5) *Core GW server* serves each packet in-service time defined by the service time function. The health of the core router is monitored in the “core GW server” by analyzing

Channel Utilization, Average delay, Number of packets departed, Number of packets dropped, Average wait time, and packet delay.

6) *Output switch* sends packets to their destined GWs: The functionality of the Core router block along with these components is depicted through a Simulink model shown in Fig. 7.

Fig. 7. Simulink Model of Core Router.

C. MR-Mobility Module

MR Mobility module simulates the MR hand-off and hand-over from one MR to another MR just like client mobility in an IEEE 802.11x network. When an MC moves out of an MR access area, the MR hands over the MC traffic to the MR which is accessible to the MC. This delay is added to the total packet response time. A Simulink model of MR mobility is shown in Fig. 8. It can be observed that the MR mobility module has two major blocks.

- MR delay model.
- GW Channel model.

Fig. 8. Functional Blocks of MR Mobility Model.

1) *MR delay model*: The MR delay block simulates delay due to the transfer of MR from one GW table to another. This is an atomic process involving a delay in updating the global APR table at the core router and the local APR tables at the sending and receiving GW involved in MR transition. This block consists of a packet generator sub-block as shown in Fig. 9.

Fig. 9. Sub-blocks of the MR Delay Block.

The packet generator block induces reverse traffic from the GW towards the core router. In this paper, the word ‘traffic’ indicates the traffic from the Internet (packet generator) to the MRs whereas ‘reverse traffic’ is defined as packets from the

MR towards the Internet. This reverse packet, when generated by the packet generator module of the MR delay block, indicates invoking of load sharing. When the reverse traffic packet reaches the main packet generator module through the core router, it blocks the packet generator till the time the MR transition takes place (delay in updating the local and global APR table). Once the MR transition is over, another reverse packet is generated from the MR delay block towards the core router and the packet generator resumes the forward traffic. Fig. 10 depicts the MR delay block comprising the packet generator sub-block.

Fig. 10. Simulink Model of MR Delay Block of MR Mobility Module.

The packets generated by the MR delay block are forwarded to the ‘GW Channel Model’, explained in the next section, which incurs channel processing delay.

2) *GW channel model of the MR mobility block*: The GW Channel block of the MR mobility module models the channel between the GW and Core router. The sub-blocks of the channel model are depicted in Fig. 11.

Fig. 11. Sub Blocks Comprising the Channel Model Block.

a) *Path selector*: This module is used to receive packets from the core router (in case of forwarding traffic) and MR delay block (in case of reverse traffic).

b) *Signal latch*: Path selector uses ‘Probabilistic signal latch model’ to select packets.

c) *Attribute*: The service time in processing packets in a single server is calculated by the ‘Attribute Function’ block.

d) *Packet sink*: The data packets are routed to the respective GW or core router in case of backward traffic using the ‘Packet sink’ block.

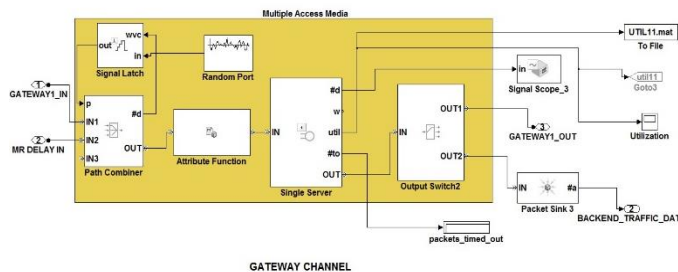

Fig. 12. Simulink Model of GW Channel Block of the MR Mobility Module.

e) *Output switch*: The packets are sorted by ‘Output switch’ which checks the packet header and routes the packets to the respective destination GW or routes the packet back to the core router if it is a backward packet requesting a traffic block. Fig. 12 depicts the final Simulink block of the channel model representing all the above-listed sub-blocks.

3) *The final MR mobility Simulink block*: The final MR mobility Simulink block comprising its major sub-blocks the MR delay block of Fig. 10 and channel model of Fig. 12 is shown in Fig. 13.

Fig. 13. Simulink Model of MR Mobility Module.

D. GW Module

The GW module segregates and routes the packet destined to a particular MR. The structure of the GW module is depicted in Fig. 14.

Fig. 14. Hierarchy of the GW Model.

As depicted in Fig. 14, the GW Model has two major blocks:

- MPP GW
- MR Multi-Hop (Multi-Hop of MR)

1) *MPP-GW sub block of the GW*: MPP-GW model further comprises the sub-blocks shown in Fig. 15.

Fig. 15. Sub Blocks of the MPP-GW Block.

This block has four major sub-blocks:

a) *Wireless GW*: This model has a ‘set attribute’ block that receives packets from the core router and forwards them at a pre-defined data rate (bandwidth) to the channel model through the ‘FIFO queue’ block.

b) *Power Line GW*: The power line GW gets the packets directly from the core router. It uses the same ‘set attribute’ block to define the data rate. The ‘FIFO queue’

block gets input about the MRs chosen to transit to the power line. This block is attached to the core router and it routes the traffic from the core to the MRs specifically attached to the power line. The MRs attached to the power line GW can be identified using the global APR table at the core router.

c) *Mesh Client Mobility delay*: This block has two parts. One part simulates the end-user device, and the other part simulates the mobility of the client. The end-user device acts as either a source or a sink for the traffic flow. Therefore, the end-user device is modeled as having two parts- the packet generator part which is the source, and the sink which consumes the packets which are received through its connected MR. The mobility of the client is modeled by introducing a handoff-handover delay whenever the mobile client moves from one MR transmission range to another.

d) *MR Channel model*: This model simulates the channel between the GW and the MRs. The channel model is responsible to induce the client's mobility delay. This is the delay involved in hand-off and hand-over when an end-user moves from one MR to another MR. This is different from the MR mobility delay which involves delay incurred during the transition of MRs for load sharing.

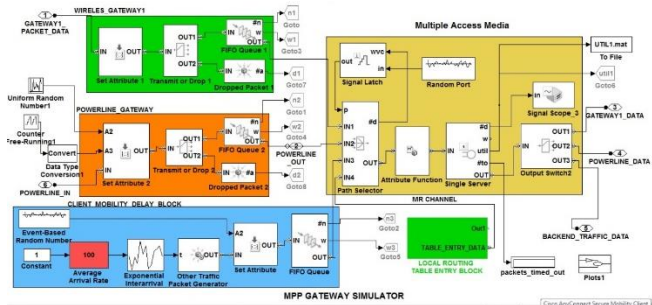

Fig. 16. MPP-GW Simulation Sub Block of the GW Simulator Block.

The sub-blocks listed in Fig. 15 are shown in the final Simulink block of the MPP-GW model block in Fig. 16.

2) *Multi-Hop MR of GW*: The ‘multi-hop MR’ sub-block receives packets from the MPP-GW block and records variation in-service time due to the increasing number of hops. This block consists of two sub-blocks as depicted in Fig. 17.

Fig. 17. Sub Blocks of the Multi-hop MR Block.

These blocks are:

a) *Get attribute*: It refers to MR where it receives service time from the respective GW. The service time of the packet will be almost doubled for every hop.

b) *Backend traffic delay*: This block simulates the processing delay incurred by the mesh management traffic. Although this traffic does not contain the actual data packets, mesh management packets are also important. The Simulink block of multi-hop MR simulation is shown in Fig. 18 which depicts the ‘get attribute’ and ‘delay’ sub-blocks listed in Fig. 17.

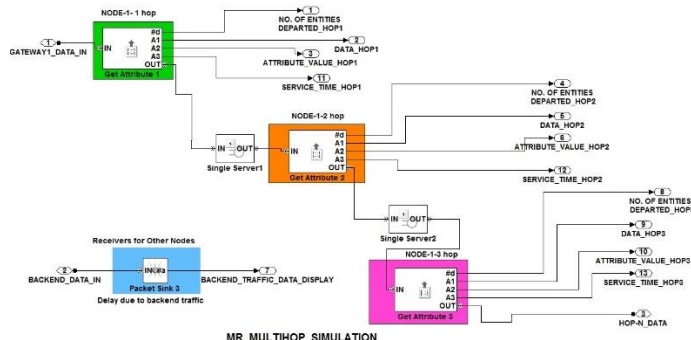

Fig. 18. Multi-hop Simulation Sub Block of the GW Simulation Block.

3) *Display block*: Since this is the final and the last block of the simulation model, it displays parameters such as ‘number of packets departed’, ‘Average waiting time’, and ‘service time’.

E. Final GW Simulation Block

Fig. 19 depicts the final GW simulation block comprising the MPP-GW and the MR multi-hop simulation blocks.

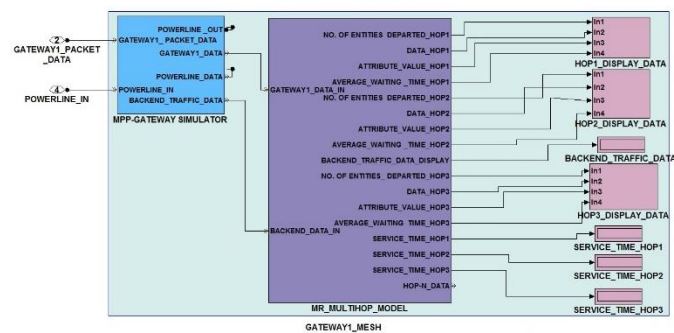

Fig. 19. GW Simulation Block.

F. System-Level Simulation Block

The system-level simulation model is shown in Fig. 20. This model depicts the packets generator module, the core router module, the MR mobility module, and finally the GW module. The process flow can be mapped onto the final simulation model in Fig. 20. This model will be used in the next section to derive various performance results and to investigate the various system parameters. The framework of this model follows the schematic architecture proposed in the network architecture diagram in Fig. 2. The next section presents the results obtained through the system-level simulation block of LMS shown in Fig. 20.

Fig. 20. System-Level Simulation Block of LMS.

VI. ASSUMPTIONS AND PARAMETERS FOR MATLAB MODEL

In the previous sections, a simulation model of the proposed LMS was developed using MATLAB, and Simulink blocks. This model is used to analyze the performance of the proposed LMS. Various test cases for performance analysis are created to compare the performance of the WMN with the proposed LMS and the conventional WMNs with no load management feature. Throughout the simulation process, the simulation parameters are chosen as per Table III.

The traffic flow is assumed to be Markov distributed. The core router is assumed to be connected through a high-speed wire link. Therefore, its capacity is 100 Mbps which is the usual capacity of a high-speed fiber backhaul. The communication range of 250 m and carrier sensing range of 550 m is the most used value in the simulation of the IEEE 802.11 standard. This assumption is based on the ns2[5] and Qualnet’s physical layer adaptation of the IEEE 802.11 standard and 914 MHz Lucent WaveLAN DSSS wireless card [23].

TABLE III. SIMULATION PARAMETERS

Parameter	Value
Number of GWs	1 - 15
Number of MR	Varying (100 – 300)
Maximum number of Mesh Clients	250
Mean Packet arrival rate	0.01s (100 packet/s)
Mean hop delay	0.01s
Flow rate	Markov Model
Packet Size	64 bytes
Core router capacity	100Mbps
GW Capacity	2 Mbps
Transmission range of MR & GW	250m
Carrier sensing range	550m

Initially, a formulation is derived to compute the throughput from the simulation results. Thereafter this formulation is applied to obtain the throughput in the following section. First, a simple WMN is simulated without load management or GW scheduling. The throughput of this WMN is recorded. Thereafter the GW scheduling is performed, and the throughput is computed again. The performance of a conventional WMN is compared with a WMN with GW scheduling on basis of throughput, packet delay, and packet dropped parameters.

VII. ANALYSIS OF THE THROUGHPUT OF A WMN WITH THE PROPOSED LMS

This section investigates the throughput of WMN after applying each step of the proposed LMS. To compare the performance, it is necessary to create two WMN models namely Conventional WMN without LMS and WMN with proposed LMS. It can be observed that both these models can be derived from the system-level simulation model in Fig. 20 by making slight modifications in the IMW block.

A. Creation of a Simulation Model for Conventional WMN without LMS

To create a model of such a WMN, the simulation model of Fig. 20 is modified slightly. The IMW block as well as the Global APR table as explained in previous sections is disabled. The MRs are assigned to the GWs randomly and the respective APR tables of GWs are created accordingly. Thereafter, there is neither load monitoring nor load adjustments throughout the simulation period. This is the closest approximation to the conventional model of WMN without LMS.

B. Creation of Simulation Model of Load Management with Load Sharing

To obtain this model, the IMW block is modified such that all the blocks are enabled, and load monitoring is performed. Whenever the steady-state load condition is violated, the WMN performs load-sharing as explained in the IMW earlier. Since one of the major comparison parameters is the system throughput performance, the next subsection explains how throughput is calculated from the system utilization graph obtained through the simulation.

C. Process of Throughput Computation from the System Utilization Graph

This section explains how the throughput is calculated using the system utilization graph obtained from the MATLAB simulation. The system utilization graph is a part of the results displayed by the display block of the System-level simulation model in Fig. 20. It represents the average channel utilization of the entire WMN. The throughput computation is based on the following system parameters.

Core router bandwidth = 100 Mbps.

GW bandwidth = 2 Mbps.

Packet size=512 bits.

The throughput is determined using the relation.

$$\text{Throughput} = \text{Bandwidth} * \text{Utilization}.$$

D. Throughput Analysis with Load Sharing

This section presents the analysis of a WMN having the capability of load sharing incorporated in it. For uniformity and ease of comparison, the same scenarios of the previous section are reconsidered. For the simulation, the maximum capacity of GWs is assumed to be 2 Mbps. The first simulation on a WMN with load-sharing features pertains to the studies on the variation of throughput as a function of the number of MRs. As can be seen from the results of Fig. 21, initially the throughput improves with the increase in the number of MRs. The improved throughput is due to the fair scheduling of WMN. Regarding the throughput performance, it is interesting to note that the performance profiles exhibit a steep rise and slow decay characteristics.

It is worth mentioning here that a very similar trend was observed in [24] when they performed a similar study on fifth-generation cellular networks. It was observed by them that increasing the number of devices resulted in a decrease in data rates. They concluded that until better technology is devised, this decrease is bound to continue. This indicates that when a WMN gets congested and when all its GWs are utilized to their full potential, the throughput shall begin to drop. The relationship between the capacity of a WMN and the capacity of GW can be written as:

$$\text{The capacity of a WMN} = (\text{Capacity of GWs}) \times (\text{Number of GWs}).$$

E. Comparison of a Conventional WMN and a WMN with Proposed LMS

This section compares the throughput obtained in a conventional WMN without LMS with the throughput obtained in a WMN with the proposed LMS feature. The simulations have been performed keeping the total number of MRs fixed to 100 in each of the WMN scenarios but the number of GWs has been varied. This helps to study the effect of increasing the number of GWs on the throughput of WMN, keeping the number of MRs constant.

Fig. 21. Throughput of WMN with a Fixed Number of GWs and a Varying Number of MRs.

The results in Fig. 22 depict a continuous increase in the throughput after the application of the proposed LMS. The percentage increase in throughput of a WMN with 5GW 100MR after load sharing is 869%. In the case of a WMN with 10 GW 100 MR, the percentage increase is 893% after load sharing. For a WMN with 15GW 100 MR, the percentage increase in throughput is 1000% after load sharing!!!

The only difference in the simulation scenario between the Fig. 22 and Fig. 23 is the change in the total number of MRs to 200. Additionally, Fig. 23 also compares the throughput of a WMN obtained with a total number of 5 GW and 100 MRs.

The results of Fig. 23 reveal that a WMN with the same number of GWs but with a relatively larger total number of MRs exhibits better throughput performance. The throughput improvement of a WMN with 15GW 200MR is 1036% after load sharing. For a WMN with 10GW 200MR, the throughput improvement is 811% after load sharing. For a WMN with 15GW 200MR, the throughput improvement is 102.7% after load sharing. It can be noticed that if the number of MRs is fixed and only the number of GWs is increased, the gain in throughput is not as significant after performing load sharing. This is because when the number of GWs is increased but the number of MRs is fixed, then the GSS of every GW gets a lesser number of MRs. This results in a smaller number of MRs per GW and thus implying a relatively lesser gain in throughput.

Fig. 22. Throughput Improvement of 100 MR WMN with Varying Number of GWs.

Fig. 23. Throughput Performance of LMS for Different WMN Scenarios.

The next section compares the parameter of packet drop before and after applying load sharing.

F. Analysis of Packet Loss

Since the proposed LMS relieves the congestion of GWs, it results in a reduced packet loss thereby leading to overall improved performance of a WMN. For the simulation, a WMN of 100 MRs is considered. Fig. 24 presents a comparative summary of the results obtained for the packet loss parameter. For the simulation results showed in Fig. 24, the total number of MRs remains constant at 100 while the number of GWs is varied from 5 to 15. The results of Fig. 24 depict an average 40% reduction in the packets dropped after applying the proposed LMS. This confirms the progressive improvement attributed to each constituent process of the proposed LMS thereby demonstrating the best performance.

Fig. 24. Comparison of Packets Dropped With and Without LMS.

VIII. CONCLUSIONS AND FUTURE WORK

This paper has demonstrated the step-by-step process in the development of a simulation model of WMN using Simulink. The proposed simulation model was used to analyze the performance of the LMS proposed in this paper. It was found that there was an average 600% increase in the throughput of WMN after applying the LMS. The model also depicts a reduction of 40% in the number of packets dropped. The model is designed to facilitate the flexibility to increase or decrease the number of GWs within the mesh to support the increase and decrease in the number of hops for a particular router. The presented model will be helpful for researchers to analyze proposed techniques that involve many variations in the topology of WMN. The proposed model is also useful for the simulation of scheduling of Gateway and packet within a multi-hop multi gateway wireless network. This paper discusses the MATLAB model of conventional WMN and the implementation of the Load Management Scheme (LMS) on it. Using the proposed model, this paper has presented a comparative analysis of the throughput performance of WMN with and without the LMS. The uniqueness of the model presented in this paper is that it is scalable and flexible in terms of network topology parameters.

Abstract—Skin diseases are a global health problem that is difficult to diagnose sometimes due to the disease's complexity, and the time-consuming effort. In addition to the fact that skin diseases affect human health, it also affects the psycho-social life if not diagnosed and controlled early. The enhancement of images processing techniques and machine learning leads to an effective and fast diagnosis that help detect the skin disease early. This paper presents a model that takes an image of the skin affected by a disease and diagnose acne, cherry angioma, melanoma, and psoriasis. The proposed model is composed of five steps, i.e., image acquisition, preprocessing, segmentation, feature extraction, and classification. In addition to using the machine learning algorithms for evaluating the model, i.e., Support Vector Machine (SVM), Random Forest (RF), and K-Nearest Neighbor (K-NN) classifiers, and achieved 90.7%, 84.2%, and 67.1%, respectively. Also, the SVM classifier result of the proposed model was compared with other papers, and mostly the proposed model's result is better. In contrast, one paper achieved an accuracy of 100%.

Keywords—Skin disease; image processing; classification; machine learning; diagnosis; SVM; RF; K-NN; acne; cherry angioma; melanoma; psoriasis

I. INTRODUCTION

Nowadays, imaging is used in medical science extensively, so before any surgery or treatment decision a preliminary knowledge can be determined, and diagnosis can be done. For this, imaging in medicine has become a tool to start most of the disease treatment cycle, starting from detection passing through evaluation, and ending with the treatment decision. Skin disease is one of these medical areas where images play a role in detecting, diagnosing, and treating the disease [1]. In recent years, skin diseases have increased and begun to be a global health problem [2]. Those who suffer from skin diseases without disease diagnosis may diminish their life quality and have a negatively psycho-social impact [3].

In fact, skin diseases are difficult to diagnose due to the complexity of human skin. Also, the lack of expertise may lead to misdiagnosis or overdue diagnoses. Diagnosis of skin diseases at the health center may take a long time and require domain expertise, which causes physical and financial costs. On the other side, machine learning and image processing

techniques can help achieve high accuracy in skin diagnosing at the initial stage. Images processing plays an effective role in diagnosis the skin diseases with the help of libraries such as OpenCV, Scikit-Image, and NumPy. Afterward, machine learning algorithms such as SVM, RF, and K-NN are used for the classification task. Combining these techniques will save time and reach a quicker and more trusted diagnostic than typical procedures like patch tests and biopsy [4]. Due to the limitation of the existing models that diagnose different skin diseases, this proposed model studied four skin diseases. This research work aims to build a model that provides an easy, fast and efficient solution for skin disease diagnosis, i.e., acne, cherry angioma, melanoma, and psoriasis, using image processing and machine learning techniques.

The building of the proposed model passes through multi-steps of image processing including, acquiring images, preprocessing images, i.e., resizing images, color transformation, de-noising, and normalization, segmentation, and feature extraction. In the end, train the model with traditional machine learning algorithms, e.g., SVM, RF, and K-NN. Several papers conducted on this paper's topic had been focused on the use of machine learning and image processing to classify skin cancer. Thus, this paper proposed a model to diagnose other common diseases in addition to skin cancer. Furthermore, the proposed model tested cherry angioma disease, which is very rarely tested in the previous research.

This paper is organized into the following sections: Section 2 reviews the previous work, Section 3 presents the methodology, Section 4 shows the obtained results, and Section 5 is the conclusion of this work.

II. PREVIOUS WORK

Many researchers have proposed a model that combines image processing and machine learning algorithms techniques to classify and diagnose several skin diseases.

Hameed, Shabut, and Hossain [5] implemented a system that classifies healthy, acne, eczema, psoriasis, benign, and melanoma (malignant) skin diseases. The system was built based on image processing techniques. To enhance images, the authors used an algorithm called Dull Razor to remove hair from skin images and then applied the Gaussian filter to

smooth it. After that, in the segmentation task, they firstly discarded any non-skin area, then applied Otsu's thresholding on the area of skin in order to segment the disease lesion. Moreover, they used color spaces like red, green, and blue (RGB), hue, saturation, and value (HSV), luma, blue, and red (YCbCr) which means separate brightness i.e. luma from color, and grayscale to extract color features. Also, they used neighborhood gray-tone difference matrix (NGTDM) and Gray Level Co-occurrence Matrix (GLCM) techniques to extract the texture features. In the end, they classified the diseases using SVM and obtained an accuracy of 83%.

Additionally, Sinthura S. et al. [6] propose a method to detect skin diseases. Their method indicates using the adaptive filter to remove the noises, then converting it to grayscale color. Besides, they used Otsu's thresholding technique to segment the disease lesion. Furthermore, they used GLCM to extract the texture features. Finally, to validate their proposal, they used the SVM classifier and achieved an accuracy of 89%. In image classification-based color, the researchers in [7] train a model for detecting and classifying various skin diseases using the K-NN classifier. They use color models to extract features, including the HSV and the lightness, red/green, and blue/yellow (L^*a^*b) color models. Their results showed that the HSV color model is more efficient with 91.80% accuracy than the L^*a^*b color model with 81.60% accuracy. Moreover, Ahmed, Ema, and Islam [8] propose a new automated system using the Transductive SVM (TSVM) to classify 24 types of skin disease. The proposed system uses a hybrid genetic algorithm to segment the image. Also, they used ant colony optimization (ACO-GA) and GLCM to extract its features. Their work achieved 95% accuracy.

A method was carried out to apply pre-trained Convolutional Neural Networks (CNN) to extract features for skin diseases. The paper by ALenezi [9] proposes a system using the pre-trained CNN AlexNet to extract skin disease features and SVM to classify the diseases. The system was built with a dataset of 80 images of these skin types; melanoma, psoriasis, eczema, and healthy skin. Her system was tested on 20 images and achieved an accuracy of 100%. The same method used by researchers [10] present an intelligent expert system for classifying 9144 skin lesions, i.e., acne, eczema, benign or malignant (melanoma), and healthy skin images. For extracting the lesion's features, they used a pre-trained CNN model AlexNet. Their system result achieved an accuracy of 86.21% by using the SVM classifier, where divided dataset in the ratio 70:30 for train and test set.

Another study by Hajgude et al. [11] proposes a solution to detect 408 images of eczema, impetigo, melanoma skin diseases, and a class named other images. They build the model using these techniques: median filter to remove the noises, the Otsu method to segment lesions, 2D Wavelet transform to extract features like entropy and standard deviation, and GLCM to extract texture features like contrast and correlation. They used SVM and CNN classifiers to classify the diseases and obtained an accuracy of 90.7% and 99.1%, respectively. Authors in [12] describe the CNN classifier and the major libraries for image processing. Then, they use CNN to classify and diagnose skin disease with an accuracy of 70%, even though using a large dataset may

increase accuracy by more than 90%. Authors in [13] propose a web system to diagnose skin diseases in Ghana (Africa). Their study includes a CNN to classify 254 images of diseases, i.e., atopic dermatitis, acne vulgaris, and scabies. In the end, they reached an accuracy for each disease of 88%, 85%, and 84.7%, respectively. The proposed system just takes 0.0001 seconds to diagnose, which may expedite more patients' diagnoses than a diagnosis in the clinic.

Most of the previous studies prove the efficacy of using SVM and CNN. Furthermore, the studies evinced the image processing plays a key role in helping to classify various skin diseases. Moreover, increasing the number of images may positively affect the classification due to the increased training model.

III. METHODOLOGY

This paper demonstrates the classification of several types of skin disease to diagnose the lesions such as acne, cherry angioma, melanoma, and psoriasis. Accordingly, the processes involved in identifying these skin diseases are preprocessing, segmentation, feature extraction, and classification. The following points show the datasets used and explain the proposed and techniques of this work.

A. Dataset

Due to the privacy of medical records, collecting images is a challenging task. Therefore, the images gathered from available resources: the dermnet NZ [14] and atlas dermatologico [15]. In this work, the dataset consists of 377 images of four different disease classes: acne, cherry angioma, melanoma, and psoriasis. Fig. 1 shows a sample of each class. Table I lists the number of images of each class.

1) *Diseases definition:* In the following, a brief definition of each disease studied in this work, as mentioned in the dermnet NZ website [14].

a) *Acne:* It is a common chronic disorder, often confined to the face, but it may happen in the chest, back, and neck. Acne may occur in children and adults of all ages. However, acne is caused due to a combination of several factors such as familial tendency, acne bacteria, and hormones. Acne could be characterized as blackheads and whiteheads.

b) *Cherry angioma:* The reason of cherry angioma is unknown. It is very prevalent in males and females of any age, while it markedly increases in people from about the age of 40. However, cherry angioma may be in red or purple, or blue color. Also, it could be scattered overall body surface parts.

c) *Melanoma:* It is the gravest form of skin cancer. It happened due to the uncontrolled growth of melanocytes (pigment cells). Melanoma may occur at any age but is very rare in children. However, the features of melanoma could be having several colors like blue, brown, red, etc.

d) *Psoriasis:* It is a chronic inflammation of a skin condition. It affects males and females at any age. It is characterized by symmetrically distributed, red color, scaly plaques with well-defined edges.

Fig. 1. Dataset Samples

TABLE I. DATASET DISTRIBUTION

Disease	Dataset	Total
Acne	Dermnet NZ dataset, Atlas dermatologico	80
Cherry angioma	Dermnet NZ dataset	37
Melanoma	Dermnet NZ dataset, Atlas dermatologico	80
Psoriasis	Dermnet NZ dataset, Atlas dermatologico	180
Total		377

B. Proposed Methodology

This section presents the processes of this proposed model and the techniques used. The architecture of this model is shown in Fig. 2. The procedure of the proposed model is described in the following points:

- Import the train set images and process it through: preprocessing the images, then segmenting the lesion from the remaining normal skin, and after that extracting its features.
- Import the test set images and process them in the same way as step 1.
- The features that extract from the train set images are stored in a knowledge base.
- Compare the features that extract from the test set image with the feature stored in the knowledge base.
- Classify images using machine learning algorithms i.e., SVM, RF, K-NN.
- Diagnosis of the disease.
- When the user uploads an image, it is will pass through the same processing of the test set image.

1) *Image processing*: Image processing is a technique that manipulates and analyzes an image received from a camera or sensors. Therefore, the image processing's main objective is to enhance the image's quality and extract its information in order to be more interpretable by a human or machine perception. Nowadays, many image processing techniques are incorporated as they turn out to be strong computational methodologies and strong potential to be effective in healthcare and all fields [16]. In the following, describe the image processing techniques used in this work.

a) *Preprocessing*: The first step in processing the skin disease images is preprocessing in order to enhance images. In this work, firstly, all the images were resized to 250X250.

After that, due to the noises in skin images, a de-noising technique called a median filter was applied. The median filter is the most filter the researcher used according to the advantage of preserving the edges of the image [17]. Further, the color images converted to a grayscale color model for segmentation and feature extraction tasks. Finally, the images pixels' values normalized between 1 and 0. In Fig. 3, column A shows the original images with a size of 250X250. Next, column B shows the images after applying the median filter. Also, column C shows images converted to grayscale.

b) *Segmentation*: The segmentation task is a process of partitioning the lesion region from the skin. This segment gains based on similarity or difference of pixels properties like color, sharpness, brightness, or intensity of an image [18][19]. Based on this work, it's a challenging task due to the several diseases the proposed test. Also, the key problem is the entire lesion's color may be similar, and the lesion's boundaries may be fuzzy, besides the complexity of the skin itself. To address this problem, the Otsu's thresholding is used to create a mask (binary image), then applied it to the grayscale image. Some of the results are shown in Fig. 3. Column D shows the binary masks, and column E shows the final segmentation results.

- Otsu's: Otsu's is the most popular threshold segmentation technique, and it is applied to a grayscale image. Unlike the manual threshold, it automatically compares the minimize weighted within gray classes variance to find the optimal threshold value. Since the threshold value was determined, the lesion can be segmented from the normal skin region [20][21].

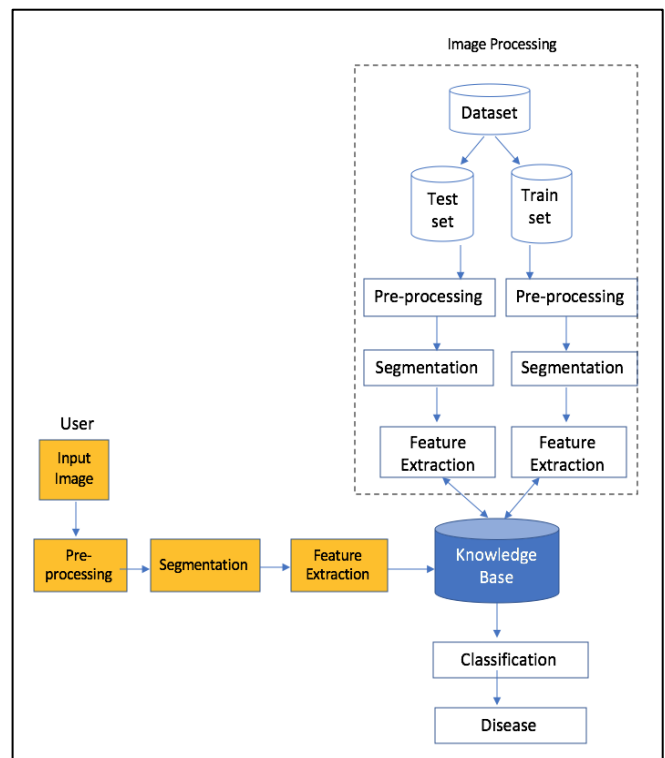

Fig. 2. Model Architecture.

Fig. 3. Samples Results of Images Processing Techniques.

c) *Feature Extraction*: Feature extraction is a technique that plays a significant role in image processing. It is used the image or the segmented lesion to extract the characteristics' features that represent the information of that image for classification tasks. However, texture feature is a type of feature that can be used in recognition of an image by describing the visual image's surface. Textures are complex patterns composed of many characteristics, including size, color, brightness, slope, etc. [22]. In this work, feature extraction is performed using Gabor and Entropy techniques to extract texture features and the Sobel technique for edge

features. All the feature extraction techniques' parameters used in this proposed model are listed in Table II.

- **Gabor**: Gabor filter is a linear filter used to extract texture features. It is the most commonly used in image processing and image texture analysis [23]. Essentially, Gabor is a band-pass that extracts patterns in a signal at specific frequencies [24].
- **Entropy**: It measures the expectation of the quantity of information in the grayscale image. It calculates the center pixel of all the neighboring pixels in the kernel's window [25].
- **Sobel**: Sobel is a filter used to detect the image's edge features. It has the power on processing with more minor time consumption, less in loss of edge, and strongly resists the noise [26]. In this work, the Sobel is applied that utilized two kernels to obtain the horizontal(Gx) and vertical(Gy) approximation of the derivation of the grayscale skin diseases images. These kernels were convolved to overlay the image's pixels.

2) *Classification*: The classification task classifies data into distinct known classes using machine learning algorithms to predict the disease. Once features are extracted, it is given as input to the classifier model. When the model is accurate, it is used to classify new images that are a member of the trained disease classes. The proposed model used the traditional well-known classifiers to conduct the experiments, i.e., SVM, RF, and K-NN.

TABLE II. THE PARAMETERS OF FEATURE EXTRACTION TECHNIQUES

Feature Extraction Technique	Formula	Parameters	Value
Gabor	$G(x, y, \lambda, \theta, \phi, \sigma, \gamma) = \exp\left(-\frac{(x^2 + \gamma^2 y^2)}{2\sigma^2}\right) \cos(2\pi \frac{x}{\lambda} + \phi)$, where $x = x \cos \theta + y \sin \theta$ $y = -x \sin \theta + y \cos \theta$	λ : wavelength of the cosine multiplier. θ : Frequency of alternations in degrees. ϕ : Phase offset of the sinusoidal function. σ : Sigma / standard deviation of the Gaussian envelope. γ : Spatial aspect ratio and specifies the ellipticity of the support of Gabor function.	$\pi/4 = 3.14/4$ $4 * \pi = 4 * 3.14$ 0 1 and 3 0.5
Entropy	$H(X) = - \sum_{i=1}^n P(x_i) \log_b P(x_i)$, where $\log_b = 2$	Kernel	3X3
Sobel	$G_{x,y} = \sqrt{G_x^2 + G_y^2}$	Two Kernels: Gx and Gy	3X3 and 3X3

IV. EXPERIMENTAL RESULTS

This section shows the evaluated experiments to measure the performance of this model. The proposed model's experiments were implemented using the python language in Spyder environment from anaconda, along with several libraries, i.e., Scikit-learn to perform machine learning algorithms, OpenCV, Glob, and Os to perform image processing, Skimage to perform filters, and Matplot for the visualization.

A. Evaluation Measure

The model performance was analysis with several measures. These measures are formulated as in (1), (2), (3), and (4):

$$\text{Accuracy} = (TP + TN) / (TP+FP+TN+FN) \quad (1)$$

$$\text{Precision} = TP / (TP+FP) \quad (2)$$

$$\text{Recall} = TP / (TP+FN) \quad (3)$$

$$\text{F1-score} = 2 * (\text{precision} * \text{recall} / (\text{precision} + \text{recall})) \quad (4)$$

Where TP is true positive, TN is a true negative, FP is false positive, and FN is a false negative.

B. Splitting Dataset and Classifiers Parameters Results

To detect the behavior of machine learning algorithms, it needs to test the model on data that is not used in the training process. Toward this, the dataset splits into two sets: training set and testing set. Table III lists three experiments of splitting and lists the accuracy results of each classifier.

TABLE III. THE SPLITTING DATASET WITH TRAIN AND TEST RESULTS

Splitting	#images	Classifiers	Parameters	Training	Testing
Train: 70% Test: 30%		SVM	Kernal = 'rbf' n_estimators=50 n_neighbors=5	92.3%	78%
	Train: 263	RF		100%	73.6%
	Test: 114	K-NN		73.7%	67.5%
Train: 75% Test: 25%	Train: 282	SVM	Kernal = 'rbf' n_estimators=50 n_neighbors=5	91.4%	77.8%
	Test: 95	RF		100%	74.7%
		K-NN		72.6	68%
Train: 80% Test: 20%		SVM	Kernal = 'rbf' n_estimators=50 n_neighbors=5	91%	90.7%
	Train: 301	RF		100%	84.2%
	Test: 76	K-NN		73%	67.1%

TABLE IV. CLASSIFIERS PARAMETERS AND THEIR RESULTS

Classifiers	Parameters	Values	Accuracy
SVM	Kernel Regularization(C) Degree	'linear', 'rbf', 'poly', 'sigmoid' 1.0 3	'Linear': 81.5% 'rbf': 90.7% 'poly': 71% 'sigmoid': 63%
RF	n_estimators	30,40,50,60	30: 73.6% 40:80% 50: 84.2% 60: 82.8%
K-NN	n_neighbors	3,4,5	3: 64% 4: 63% 5: 67.1%

Each ML classifier has several possible values of each corresponding parameter that value may affect on accuracy result. However, the value that obtains the highest accuracy result will be used in the proposed model. The possible parameters and their values are illustrated with the accuracy results in Table IV. All these experiments were tested on the dataset that split into 80% for training and 20% for testing.

C. Classifiers Performance Matrix

This section shows the confusion matrix of each classifier. It is represented in a table style to describe the model's classifier performance. However, it presents the prediction results on the test set data. The matrix size is based on the number of classes; in this case, the matrix size is 4X4. The rows indicate the true class, while the columns indicate the prediction for each class. While The diagonal of the matrix points to the number of images that are correctly classified. Fig. 4 displays the confusion matrices of the classifiers of SVM, RF, and K-NN as shown in A, B, and C, respectively. For example, in SVM, a total of 16 acne images, it classified 14 images correctly and 2 images were misclassified as psoriasis.

From these confusion matrices, could measure the accuracy, precision, recall, and F1-score of each disease with each classifier as shown in Table V. Among the three classifiers, SVM is superior performance on the accuracy rate of cherry angioma, melanoma, and psoriasis. While acne obtained the highest accuracy rate using the RF classifier. In contrast, K-NN has the worst results accuracy in all these diseases.

D. Classification Experiment

The proposed model was validated using SVM, RF, and K-NN classifiers with the evaluation measures, i.e., accuracy, precision, recall, and f1-score. Table VI lists all measurement results of each classifier. It is observed that the SVM has superiority in classifying skin diseases over others in accuracy, precision, recall, and f1-score of 90.7%, 91%, 90.8%, and 90.8%, respectively. At the same time, the K-NN has obtained the worst results.

E. Comparison Results

To our knowledge, there are no study experiments on the same diseases of this work. Also, due to different and unavailable datasets, the proposed model was compared with the research that tested some of the diseases studied in this work. Table VII details the comparison research [5], [6], [9], and [10] toward their studied diseases and the image processing techniques they used.

Basically, many techniques are available for image processing and classification tasks, and it used in several skin diseases classification research. Among that, the comparison research in Table VII are probably the most papers close to the techniques used and to the diseases tested in this work.

In the comparison papers, they present in two ways of image processing: manual and automatic. In manual image processing, researchers [5], [6] follow the same processing steps with different preprocessing filters techniques; Dull Razor with Gaussian in [5], and Median in [6]. Further, they used the same segmentation technique, i.e., Otsu's. Another essential point, studies have shown that extraction techniques play a key role in extracting the appropriate features for the

classification task. For that, [5] extract the texture features using GLCM and NGTDM, and extract color features using color spaces. Similarly, researchers [6] extract texture features using GLCM. On the other hand, both researchers [9] and [10] utilized the automatic image processing by CNN with a pre-train AlexNet.

Therefore, Table VIII lists the SVM classifier accuracy of this proposed model with the comparison research model's accuracy that used the same classifier, i.e., SVM, and different image processing methods. All these papers showed a promising high accuracy rate in diagnosing diseases above

83%. However, it was observed the proposed model is higher than [5], [6], and [10] with 90.7% accuracy.

Thus, probably the proposed model's performance is better since this proposed model used multi techniques to extract a combination of features, i.e., Gabor and Entropy for texture features and Sobel for edge features. In contrast, the paper [9] is superior to the proposed model with 100% accuracy. Despite the fact, that they trained the model on 80 images, while the proposed model was trained on 301 images. Also, the proposed model tested cherry angioma disease, whereas the other studies did not test it.

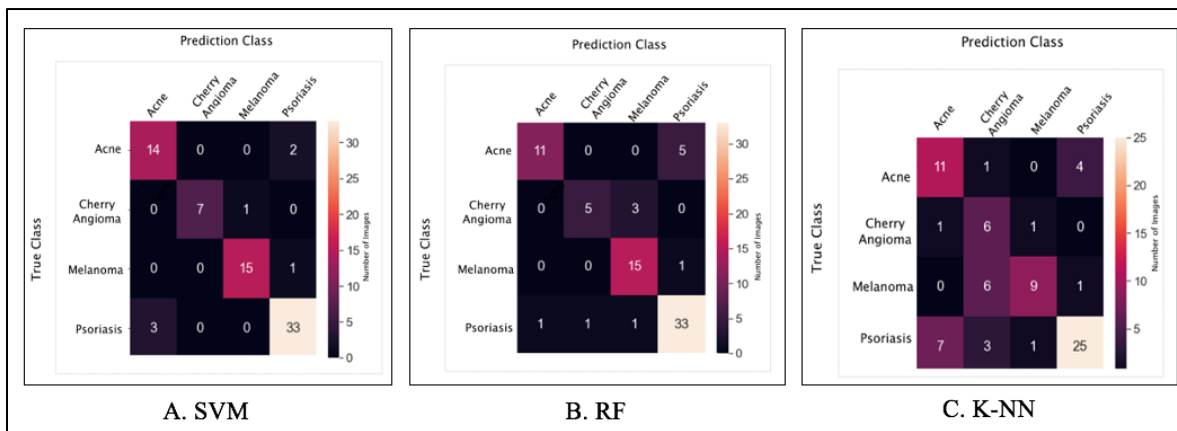

Fig. 4. The Confusion Matrices OF SVM, RF, AND K-NN Classifiers.

TABLE V. DISEASE CLASSIFICATION RATE

		Accuracy	Precision	Recall	F1-score
SVM	Acne	82%	82%	88%	85%
	Cherry Angioma	100%	100%	88%	93%
	Melanoma	94%	94%	94%	94%
	Psoriasis	92%	92%	92%	92%
RF	Acne	92%	92%	69%	79%
	Cherry Angioma	83%	83%	62%	71%
	Melanoma	79%	79%	94%	86%
	Psoriasis	85%	85%	92%	88%
K-NN	Acne	58%	58%	75%	60%
	Cherry Angioma	38%	38%	75%	52%
	Melanoma	82%	82%	56%	67%
	Psoriasis	83%	83%	61%	71%

TABLE VI. CLASSIFIERS RESULTS

Classifier	Accuracy	Precision	Recall	F1-Score
SVM	90.7%	91%	90.8%	90.8%
RF	84.2%	84.8%	84.2%	83.8%
K-NN	67.1%	72.8%	67.1%	68.4%

Hameed N et al. [10]	86.21%
Proposed Model	90.7%

The main problem encountered in developing the proposed model was the few of availability of the image of the diseases tested. In addition, the few papers that study various types of skin diseases. May training more images increase the accuracy and make the model more accurate to diagnose new images, as well as selecting appropriate techniques to extract useful features.

V. CONCLUSION

This paper proposed a model that provides the classification of different types of skin diseases: acne, cherry angioma, melanoma, and psoriasis. According to the previous works in this area, there is a scarcity in the studies on these diseases as most research focuses on skin cancer. This model was conducted through image processing techniques and machine learning algorithms on a total of 377 images. The dataset is divided into 301 images for the train set and 76 images for the test set. Firstly, the processing techniques are applied to images in several steps: preprocessing including resizing images, removing the noise using the median filter and converting the image to grayscale, then separating the infected area using Otsu's, and extracting its features using Gabor, Entropy, and Sobel. Secondly, the model was evaluated using SVM, KNN, and RF classifiers in terms of accuracy, precision, recall, and f1-score. However, the proposed model results show that the SVM accomplished higher accuracy with 90.7% than RF and K-NN. At the same time, RF and K-NN achieved 84.2% and 67.1% accuracy, respectively. The result of the proposed model using the SVM classifier achieved better accuracy than the comparison research' accuracy. In contrast, one paper outperformed the proposed model's accuracy. Since it was not possible to collect a skin disease dataset locally, finding a public source with multi images of diseases was the biggest challenge during this work. This model can accomplish higher accuracy by using more dataset images. Moreover, programmers can utilize the model to develop a smartphone application to diagnose these skin diseases easily and early.

Abstract—Classification is based on machine learning, in which each element in a set of data is classified into one of a predetermined set of groups. In data mining, an artificial neural network (ANN) is the most significant methodology because of the exact results obtained through this algorithm and applied in solving many classification problems. ANN consists of a group of types of feed-forward networks, feed-back network, RBF networks, and the probabilistic neural networks (PNN). For classification issues, the PNN is frequently utilized. The primary goals of this research are to fine-tune the weights of neural networks to enhance the classification accuracy. To accomplish this goal, the Material Generation Algorithm (MGA) was investigated with PNN in a hybrid model. Newly, the hybridization of algorithms is ubiquitous and it has led to the development of unique procedures that outperform those that use a single algorithm. Several distinct classification tasks are used to test the efficiency of the suggested (MGA-PNN) approach. The MGA algorithm's efficiency is evaluated using the PNN training outcomes generated, and its outcomes are compared to that of other optimization strategies. By 11 benchmark datasets, the suggested algorithm's performance in terms of classification accuracy is evaluated. The outcomes display that the MGA outperforms the biogeography based optimization, firefly method in terms of classification accuracy.

Keywords—Artificial neural network (ANN); material generation algorithm (MGA); classification; probabilistic neural networks (PNN)

I. INTRODUCTION

Recently, our ability to collect data has greatly improved [1]. Millions of databases have been utilized in a variety of applications, including marketing campaigns, company management, scientific endeavors, and several others [2]. The availability of sophisticated and affordable database systems has resulted in a growing growth in the number of such databases [2, 3]. There is a great need to resort to intelligent approaches to get knowledge from processed data. As a result, data mining has become a popular research field [4, 5]. Classification is a supervised machine learning problem in which a collection of training data is used to map input data into one of several predetermined categories [5, 6]. Any classification algorithm's purpose is to create a technique

which can reliably predict the category of unobserved examples [7]. Classification has numerous uses in a range of areas, including document organization, medical diagnosis, and many more. Many classification techniques and models have been devised and used as a result of this, including radial basis function (RBF) network [8], naive Bayes (NB) classifier [9], support vector machines (SVMs) [10], and K-nearest neighbours (KNN) algorithm [11] and several others.

To solve classification difficulties, ANNs have been frequently used [12]. There are several different kinds of ANNs [13] as modular neural networks, RBF networks, feed-forward neural networks, learning vector quantization neural networks, and several others. Not only do the aforementioned ANNs differ in terms of how they apply to learning, but also in terms of their control method and topology [14].

The PNN is considered a feed-forward neural network that can be used to predict challenges and solve classification. The gradient steepest descent approach, a common optimization technique, is used in the PNN technique to minimize errors between the predicted and actual output functions by allowing the network to modify the weights of the network [15].

The goal of merging metaheuristic algorithms and NN to build classification tools like the PNN is to improve effectiveness and efficiency while also allowing for more accurate and faster solutions of complex problems.

The problem statement was specified by one basic research question: Can the searchability of the Material Generation Algorithm have the ability to choose the best weights so we can get the best accuracy?

Metaheuristics are split into two kinds: population-based and single-based. Genetic algorithm (GA) [16], particle swarm optimization (PSO) [17], water evaporation optimization (WEO) [18], differential evolution (DE) [19], firefly algorithm (FA) [20], artificial bee colony (ABC) [21] and several others are population-based metaheuristics. Local search (LS) [22], tabu search [23] and simulated annealing (SA) [24] are examples of single-based metaheuristics.

The Material Generation Algorithm (MGA) was investigated and utilized in this research to enhance the efficiency of the PNN in solving the classification problem [25]. The PNN was utilized to generate some preliminary solutions that were generated at random and the MGA was utilized to tune the weights of the PNN.

The study is divided as follows. Section II is showed a background and literature review for the MGA. In Section III, the background on big data and its issues is presented. The PNN approach is described in detail in Section IV, while the MGA is described in detail in Section V. The proposed methodology is then detailed in Section VI. In Section VII, the outcomes are presented. Finally, in Section VIII, the conclusion is offered.

II. BACKGROUND AND LITERATURE: MATERIAL GENERATION ALGORITHM (MGA)

The author in [25] suggested that MGA be used to solve engineering challenges in the best possible design. The MGA has identified some of the advanced and fundamental parts of materials chemistry as inspirational concepts, notably the formation of chemical molecules and chemical reactions in the production of new materials. This research demonstrates that the MGA is able to produce highly competitive, if not exceptional, outcomes that outperform other metaheuristics.

The author in [26] presented the optimal design of truss structures using the MGA. For statistical purposes, many optimization runs are carried out. The results showed that the MGA may produce extremely acceptable, resulting in the smallest potential weight compared with the outcomes of a number of metaheuristic methods.

The author in [27] optimized the moulding parameters of resin reinforced sand mould cores using a hybrid Taguchi-WASPAS- MGA to get the optimum outcomes.

The author in [28] used sunflower optimization algorithm and MGA for efficient generation and analysis of materials and equipment of mechanical reducer for the material handling industry. The results showed that the technique is precise in providing better output.

III. BIG DATA: OPPORTUNITIES AND CHALLENGES

The existence of trillions of records that have been produced by millions of people and kept in a variety of online sites suggests the concept of big data [28]. Scientists can use the big data to address issues with small data samples by giving adequate test data to evaluate models, better handling noisy train data, avoiding overfitting models to train data and loosening theoretical model assumptions. In Big Data, there are challenges, like capturing, transferring, storing, cleaning, analyzing, filtering, searching, sharing, securing, and visualizing data [29]. Different research communities have been battling to produce a dynamic, fast, new, and user-friendly Big Data technology [28], which contribute to solving many problems related to data and how to retrieve it.

IV. PROBABILISTIC NEURAL NETWORK (PNN)

The PNN was proposed for the first time in[30]. The training of a PNN does not entail using heuristic searches to

find the best smoothing factor, as this is an optimization problem [31]. A four-layered feed-forward network is formed: (a) input layer, (b) hidden layer, (c) summation layer, (d) output layer, using a statistical algorithm. Fig. 1 illustrates the architecture of a typical PNN. Each input neuron acts as a unique characteristic from the train and test datasets [32]. The PNN network's four levels are detailed below:

- Input layer: Each indicator variable is represented by a neuron. The categorical factors are made up of N-1 neurons, with N being the number of categories. By subtracting the middle value, the input neuron is expected to normalize the value range. It then divides it into quartile range values.
- Hidden layer: Each occurrence in the training dataset is represented by a single neuron. Each training sample has one unit which creates a product of the input vector x and the weight vector wi, zi = x.wi, and then runs the nonlinear procedure:

$$\exp \left[\left(\frac{(w_i - x)^T \cdot (-w_i - x)}{(2\alpha^2)} \right) \right] \quad (1)$$

- Pattern/summation layer: A single pattern neuron is available for each class of objective criteria. The weight value that emerges from the hidden neurons is given to the pattern neurons that match with the hidden neurons. Each training group's objective class is stored alongside each hidden neuron. which combines the contributions for each type of input and provides the output of a network as a probabilistic vector:

$$\Sigma_i \left[\left(\frac{(-w_i - x) \cdot (w_i - x)^T}{(2\alpha^2)} \right) \right] \quad (2)$$

- Output / Decision layer: creates binary classes that correspond to the decision classes Ω_s and Ω_r , $s \neq r$, $s, r = 1, 2, \dots, q$ relies on the following criteria of classification.

$$\Sigma_i \left[\left(\frac{(w_i - x)^T \cdot (-w_i - x)}{(2\alpha^2)} \right) \right] > \Sigma_j \left[\left(\frac{(w_j - x)^T \cdot (-w_j - x)}{(2\alpha^2)} \right) \right] \quad (3)$$

There is just one weight for these nodes, C, the number of training samples in each class and the prior membership probabilities, C, given by the cost parameter:

$$C = \frac{h_s l_s}{h_r l_r} \cdot \frac{n_r}{n_s} \quad (4)$$

Fig. 1. Probabilistic Neural Network Structure.

V. MATERIAL GENERATION ALGORITHM (MGA)

In the year 2021, MGA is a bioinspired algorithm inspired by material chemistry[25]. To construct and formulate a well-defined mathematical model for the new method, the basic principles of chemical compounds, reactions, and stability are used. MGA determines a number of materials (Mat) made of several periodic table elements (PTEs), based on the fact that such natural evolution technique create a preset population of solution candidates that are evolved by random changes and selection. A materials numbers are examined as solution candidates (Mat_n) in this algorithm, each of which is made up of some constituents that are represented as decision variables (PTE_jⁱ). The following is the mathematical representation of these two components:

$$\text{Mat} = \begin{bmatrix} \text{Mat}_1 \\ \text{Mat}_2 \\ \vdots \\ \text{Mat}_i \\ \vdots \\ \text{Mat}_n \end{bmatrix} = \begin{bmatrix} \text{PTE}_1^1 & \text{PTE}_1^2 & \dots & \text{PTE}_1^j & \dots & \text{PTE}_1^d \\ \text{PTE}_2^1 & \text{PTE}_2^2 & \dots & \text{PTE}_2^j & \dots & \text{PTE}_2^d \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ \text{PTE}_i^1 & \text{PTE}_i^2 & \dots & \text{PTE}_i^j & \dots & \text{PTE}_i^d \\ \vdots & \vdots & \dots & \vdots & \ddots & \vdots \\ \text{PTE}_n^1 & \text{PTE}_n^2 & \dots & \text{PTE}_n^j & \dots & \text{PTE}_n^d \end{bmatrix}, \quad \begin{cases} i=1,2,\dots,n. \\ j=1,2,\dots,d. \end{cases} \quad (5)$$

There are two variables in the mathematical equations where d denotes the number of items (decision variables) in each subject (the candidate solutions) and n denotes the total number of items considered.

PTE_jⁱ is determined at random in the first step of the optimization procedure, whereas the decision variable boundaries are defined based on the problem under consideration. The initial placements of PTEs in the search space are set at random:

$$\text{PTE}_j^i(0) = \text{Unif}(0,1) \cdot (\text{PTE}_{i,\max}^j - \text{PTE}_{i,\min}^j) + \text{PTE}_{i,\min}^j, \quad \begin{cases} i=1,2,\dots,n. \\ j=1,2,\dots,d. \end{cases} \quad (6)$$

Where PTE_jⁱ(0) is the beginning value of the jth element in the ith material; PTE_{i,min}^j and PTE_{i,max}^j are the minimum and maximum permissible values for the jth decision variable of the ith solution candidate, respectively; and Uni f(0, 1) is a random number in the [0, 1] range.

To mathematically simulate chemical compounds, all PTEs are considered to be in the ground state, which can be externally activated by magnetic areas, photon or light absorption, and interactions with other colliding entities or particles in the case of ions or other individual electrons. Elements have a tendency to gain, lose, or even share electrons with other PTEs due to their varied stabilities, resulting in ionic or covalent compounds. Using the initial Mat in equation (5), d random PTEs are chosen to model the ionic and covalent compounds. The probability theory is used to model the operations of sharing electrons, gaining, and losing for the selected PTEs. To achieve this goal, for each PTE, a continuous probability distribution is used to configure a

chemical molecule, which is then regarded a new PTE, as follows:

$$\text{PTE}_{\text{new}}^k = \text{PTE}_{r_1}^{r_2} \pm e^-, \quad k=1,2,\dots,d \quad (7)$$

R2 and r1 are random integers uniformly distributed in the intervals [1, d] and [1, n], respectively; PTE_{r₁}^{r₂} is from the Mat that was chosen at random; e- is the probabilistic component for simulating electron loss, gain, and sharing in the mathematical model represented with a normal Gaussian distribution; and PTE_{new}^k new is the new material. PTEs are used to construct a new material (Mat_{new1}), which is being added as a new solution filter to the list of the raw material (Mat):

$$\text{Mat}_{\text{new1}} = [\text{PTE}_{\text{new}}^1 \text{PTE}_{\text{new}}^2 \dots \text{PTE}_{\text{new}}^k \dots \text{PTE}_{\text{new}}^d], \quad k=1,2,\dots,d \quad (8)$$

The candidates for the overall solution are then integrated and displayed as follows:

$$\text{Mat} = \begin{bmatrix} \text{Mat}_1 \\ \text{Mat}_2 \\ \vdots \\ \text{Mat}_i \\ \vdots \\ \text{Mat}_n \\ \text{Mat}_{\text{new1}} \end{bmatrix} = \begin{bmatrix} \text{PTE}_1^1 & \text{PTE}_1^2 & \dots & \text{PTE}_1^j & \dots & \text{PTE}_1^d \\ \text{PTE}_2^1 & \text{PTE}_2^2 & \dots & \text{PTE}_2^j & \dots & \text{PTE}_2^d \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ \text{PTE}_i^1 & \text{PTE}_i^2 & \dots & \text{PTE}_i^j & \dots & \text{PTE}_i^d \\ \vdots & \vdots & \dots & \vdots & \ddots & \vdots \\ \text{PTE}_n^1 & \text{PTE}_n^2 & \dots & \text{PTE}_n^j & \dots & \text{PTE}_n^d \\ \text{PTE}_{\text{new1}}^1 & \text{PTE}_{\text{new1}}^2 & \dots & \text{PTE}_{\text{new1}}^k & \dots & \text{PTE}_{\text{new1}}^d \end{bmatrix}, \quad \begin{cases} i=1,2,\dots,n. \\ j=1,2,\dots,d. \\ k=1,2,\dots,d. \end{cases} \quad (9)$$

Fig. 2 depicts the structure of the mentioned method for configuring new materials based on chemical components (covalent and ionic).

Fig. 2. The Random Periodic Table Elements (PTE) Selection and Creation of New Materials are Depicted Schematically.

The following is the probability of selecting a new element (PTE_{new}^k) in relation to the randomly picked first element (PTE_{r₁}^{r₂}):

$$f(\text{PTE}_{\text{new}}^k | \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \cdot e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad k=1,2,\dots,d \quad (10)$$

The symbol for the standard deviation in the previous equation is σ; the symbol for the variance is σ²; μ is the

median, expectation of the distribution or mean, which corresponds to the randomly chosen PTE ($PTE_{r_1}^2$); and e is the natural logarithm's Napierian base or natural base.

Chemical reactions are a type of manufacturing method in which various chemical changes are decided for producing products with altered characteristics that are even distinct from the initial reaction mixture. To simulate the procedure of manufacturing new materials mathematically using the reaction mixture idea, an integer random number (l) is determined depend on the materials in the first Mat that are examined for participation in a reaction mixture. After that, to decide the placements of the picked materials in the initial Mat , l integer random numbers (m_j) are created. As a result, new solutions are created that are linear combinations of the previous ones. Fig. 3 depicts a schematic illustration of the given procedure, with the following mathematical representation:

$$Mat_{new2} = \frac{\sum_{m=1}^l (p_m \cdot Mat_{m_j})}{\sum_{m=1}^l (p_m)}, j=1,2,\dots,l \quad (11)$$

The Mat_m is the m th randomly chosen material from the first Mat , Mat_{new2} is the new material created by the chemical reaction idea and p_m is the normal Gaussian distribution for the m th material participation factor.

Fig. 3. A Diagram of the Random Material Selection Method for Developing New Materials.

VI. METHODOLOGY PROPOSED: MGA WITH PNN

The MGA was utilized in this research to determine the best weights to employ with the PNN algorithm. To address the classification issues, it suggested the MGA–PNN, a new hybrid method. As shown in Fig. 4, the method begins with the PNN producing the initial weights randomly. Following that, the input values are multiplied by the matching weights w_{ij} , which are based on the PNN model's values.

The proposed MGA–PNN structure is shown in Fig. 5. It is divided into two sections: the first is the PNN, which makes utilize the training data. The data that has been tested is then classified. The accuracy is calculated using equation (12). The MGA is then used to fine-tune the PNN weights. The new data will then be tested for accuracy. This method is continued until the end criteria have been fulfilled.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (12)$$

The object is categorized as TN if both the expected and actual labels are negative. The class is categorized as TP if both the expected and actual labels of the object are positive. Further, the class is categorized as FP, when the anticipated class is positive, but the actual label is negative. The

anticipated class is negative, but the actual label is positive, therefore it's categorized as FN. See Table I [33].

For evaluating the proposed MGA-PNN performance, three additional performance measurements were calculated: The rate of error was found (equation (13)), specificity (equation (14)), sensitivity (equation (15)) and G-mean (equation (16)).

$$Error\ Rate = 1 - \frac{TP+TN}{TP+TN+FP+FN} \quad (13)$$

$$Specificity = \frac{TN}{FP+TN} \quad (14)$$

$$Sensitivity = \frac{TP}{FN+TP} \quad (15)$$

$$G\text{-mean} = \sqrt{(Sensitivity \times Specificity)} \quad (16)$$

Fig. 4. Representation of Initial Weights.

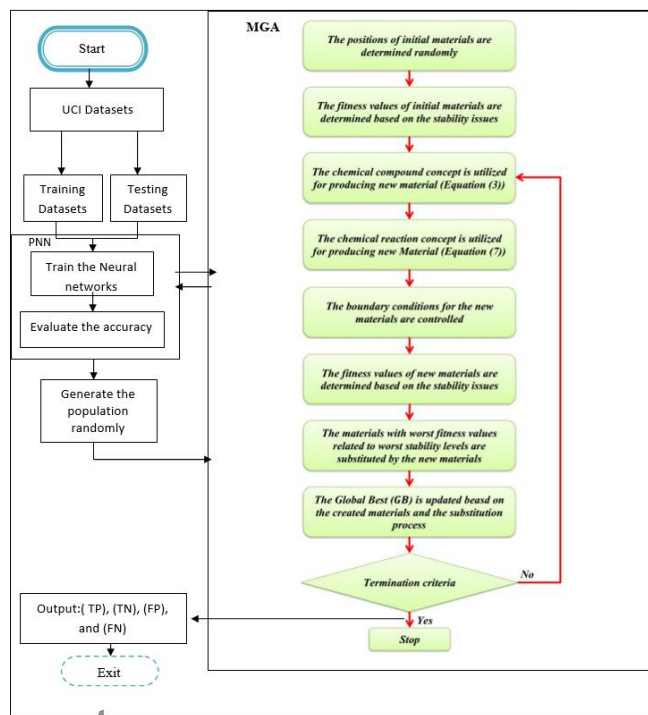

Fig. 5. Flowchart of MGA-PNN Technique.

TABLE I. CROSS-MATRIX CLASSIFICATION

	Positive	Negative
Positive	TP	FN
Negative	FP	TN

VII. EXPERIMENTS AND RESULTS

The efficiency of the MGA-PNN approach is measured in this research using 11 benchmark UCI datasets. We will compare the outcomes of proposed method (MGA-PNN) with PNN, biogeography-based optimization (BBO) and firefly algorithm (FA).

A. Description of the Dataset

These studies are based on a set of a datasets, which may be found at [7]. The previous link provides the size of the testing and training sets. The split was made using a basic train/test split algorithm with a training size is equal to 0.7 and a testing size is equal to 0.3.

B. The Categorization Quality Evaluation Results

Experiments are run on a Windows 10 professional PC with MATLAB R2015b and 16 GB RAM with an Intel ®

Xeon ®CPU ES-1630 v3 @3.70 GHz computer. Table II displays the settings for the input parameters.

The recommended method's rating quality is determined by their ability to improve the desired solution. Table III compares the performance of the proposed MGA technique with PNN, FA [34] and BBO in terms of ratio G-mean, error rate (%), specificity, accuracy and sensitivity.

TABLE II. INPUT PARAMETER SETTING

The outcomes showed that the proposed algorithm is superior in 9 out of 11 datasets over the rest of the algorithms in Table III. The original PNN achieved 65.1% accuracy in the PIMA Indian diabetes (PID) dataset, while the proposed MGA-PNN attained 82.8 percent accuracy. All the best outcomes showed in bold. The suggested technique has strong exploitation capabilities and can come up with superior solutions because a large number of candidates are grouped around the best solution. On almost all datasets, the suggested MGA outperforms the original PNN approach in terms of error rate, sensitivity, specificity and accuracy.

The MGA's performance was further validated by examining whether it differed statistically from the FA. For classification accuracy, a t-test with a significance interval of 95 percent ($\alpha = 0.05$) was used. Table IV displays the suggested approach's standard deviations and accuracy means. The performance of the MGA is clearly superior to that of the FA, as all of the P-values are less than 0.01.

TABLE IV. THE P-VALUES FOR MGA ACCURACY WITH FA AND T-TEST ACCURACY

Dataset		Mean	Std.Deviation	Std.Error Mean	P-Value

VIII. CONCLUSION

The major goal of this study was to propose a new strategy for determining high-quality answers to categorization problems. The Material Generation Algorithm is a population-based metaheuristic that MGA is a bioinspired algorithm inspired by material chemistry. Therefore, the weight values of

the PNN can be optimized by MGA. When a huge search space is being examined, the MGA's superior exploitation and exploration capabilities allow it to achieve better results than FA and BBO. The MGA was utilized to tune the weight of the PNN in this study. To attain the research's targets, the results of this strategy rely on PNN and MGA was used to compare with the results original PNN's classification accuracy, FA-PNN and BBO-PNN. The MGA, which optimized the PNN weights, was used to improve the initial solutions, which were created randomly using the PNN. According to experimental results utilizing 11 benchmark datasets, the suggested MGA with PNN outperformed the original PNN, FA-PNN and BBO-PNN on 9 out of 11 benchmark datasets. This leads us to the fact that MGA can be implemented in additional real and high dimensional datasets to investigate their behavior under different situations in terms of trait numbers. As a result, we'll be focusing our efforts on this topic in the future.

IX. DISCUSSION

This study is considered one of the most important studies in the world of Data Mining. As our use of the method of merging with the metaphysical algorithms, especially with the MGA, and comparing its results with the results of 3 other studies (PNN, FA and BBO) that gives clear evidence of its importance in terms of increasing classification accuracy. As this study only used one algorithm to combine it with PNN, I believe that merging more than one of the high-specification meta-historical algorithms with PNN leads to an improvement and a significant increase in accuracy, and this is our destination in the work of these studies in the future.

IoT based Portable Weather Station for Irrigation Management using Real-Time Parameters

Geeta Ambildhuke, Barnali Gupta Banik

Department of Computer Science & Engineering

Koneru Lakshmaiah Education Foundation

Deemed to be University, Hyderabad Telangana-500075, India

Abstract—Rainfall in India is very unpredictable and is characterised by monsoon gaps. Rainfall prediction is very crucial for irrigation management to enhance farm productivity.. This article presents a portable rainfall prediction device which can be carried to fields. In the field by sensing the current atmospheric parameters like temperature, humidity, atmospheric pressure along with the current status of the sky to know the types of clouds present and gives the chances of rainfall. It is a novel approach in terms of portability of the device and it will give the prediction based on current information at a particular location by combining the predictions from the model of image processing of the clouds using deep learning and the currently sensed weather parameters are processed using machine learning without using WIFI or internet connection by providing Edge analytics where the data processing, rainfall prediction, and decision making is carried out locally on the device without any backend servers or cloud platform which will be very useful for the people like farmers who don't have accessibility to internet in villages. The farmers can decide before every irrigation schedule, based on the prediction to what extent the crops can be irrigated. If chances of rain are very low 90% irrigation can be carried out, If chances of rain are predicted as low to medium then 40 to 60% irrigation can be done and if the prediction says medium to heavy rainfall then no irrigation is recommended.

Keywords—Deep learning; edge analytics; internet of things; machine learning; irrigation management; precision agriculture; rainfall prediction

I. INTRODUCTION

The agriculture industry is the backbone of the Indian economy, accounting for roughly 15% of national GDP and about half of India's population is entirely or partially reliant on agriculture and related activities for their living. India is one of the top 15 agricultural commodity exporters in the world. India is also facing an exponential population growth that demands a great need for food in the future. Traditional agricultural practices, on the other hand, must be modified with the help of technology to meet the increasing demand for good quality food to meet the future need of the population. Agriculture development will benefit not just farmers, but also a huge portion of the people living in rural areas that are actively involved in agriculture or indirectly tied to agriculture as consumers. More efficient production methods would produce a more conjugative environment in the country for the overall development of the economy and greater agricultural income. Small and marginal farmers will be empowered via education, reforms, and development,

resulting in better, more efficient, and stronger Indian agriculture. New production and marketing models, as well as raising awareness and providing education to farmers in villages, will aid in the sector's development and, more crucially, improve the economic situation of impoverished farmers [1].

Precision agriculture is the most promising approach to farm management in today's era, as it uses technology Internet of Things (IoT) to monitor the spatial and temporal parameters of the field and ensures that input resources such as water, fertilizers, pesticides, and other chemicals are applied to the crops at the right time, in the right place, and the right amount. Traditional agricultural surveillance tactics were modified by IoT-based agriculture applications, which quickly provided quantitative data with great temporal and spatial resolution. Ecological data is collected in real-time from the surroundings of the agriculture field using various sensors installed in the fields, which will be communicated and analyzed to determine various problems. This collected data is analyzed and processed to extract the proper information and is utilized to decide on various tasks performed in the field to automate the agriculture process to overcome certain difficulties. Multidisciplinary methods that combine remote sensing, modelling, and deep learning techniques can aid in the improvement of agricultural operations and, as a result, crop output [2].

Collecting data manually from a big field is challenging, and it results in fluctuation when compared to inaccurate field measurements. Wireless sensor networks (WSN) help in integrating various sensors in the field for the collection of different parameters from the field and environment. Various farm monitoring applications like crop selection according to the soil in the farm, soil monitoring to make zones with similarity to promote multi cropping and to assist farmers with various decision making like when and in what amount of fertilizer to be used, when to irrigate the crop, early disease predictions etc. are possible due to several emerging technologies like WSN, Deep learning, Machine learning, IoT etc.

Agriculture utilizes 85 percent of the world's available freshwater resources, and this fraction is progressively rising in parallel with population expansion and rising food demand. As a result, there is a need to develop more efficient methods to ensure that water resources are properly utilized in irrigation. New innovative plans in this direction are needed in

research to boost productivity and water management through novel irrigation techniques [3].

Proper irrigation aids in the growth of crops, landscape maintenance, and revegetation of disturbed soils. In addition to frost protection, weed suppression in grain fields, and soil consolidation prevention, irrigation plays important role in healthy crop cultivation. Irrigation management is required even in places with abundant rainfall to boost farm productivity. Monsoon gaps are a feature of Indian rainfall. As a result, sometimes it won't rain for two or more weeks during the rainy season, causing agricultural damage in the absence of irrigation.

In the near future, proper integration of advanced agricultural practices based on various technologies and adaptation by rural communities should be secured. Climate change will have extensive consequences in the next decades. As a result, laws, and practices must be devised to protect farming communities, particularly small landholders, from the immediate losses caused by extreme events [4].

The most important reasons for India's need for perfect irrigation are:

- Chaotic nature of climate.
- Uneven Rainfall Distribution.
- Optimized use of water resources to meet crop needs and soil requirements.
- To maximize crop production.
- To manage supplement supply even in areas with abundant rainfall.

Irrigation scheduling is managed by rainfall forecast based on weather conditions, which determines the amount of water to be supplied by irrigation to maintain the threshold value of water (moisture) required by the crop at any given time.

Automatic irrigation scheduling systems have replaced manual irrigation based on soil water monitoring. While implementing, the plant evapotranspiration was taken into account, which was based on many climatic characteristics such as humidity, wind speed, solar radiation, and even crop aspects such as stage of growth, plant density, soil attributes, and pest.

Weather forecasting does an excellent job of providing people with early warnings and alerts about severe climate change events, however, due to a lack of infrastructure, people in remote regions such as villages do not receive information on time due to the absence of internet, and forecasting is not very accurate for any given location. As a result, this portable device may be taken anywhere and used to anticipate the state of rainfall by sensing current atmospheric characteristics and present sky status to identify clouds related to rainfall.

Most of the farmers are living in rural areas and are not able to access the internet and weather forecasting applications at remote locations like fields. This article presents a portable weather station that uses a novel approach that predicts the intensity of rainfall as No Rain to very Low Rain, Low to Medium Rain or, Medium to high Rain based on the combined

approach of identifying types of clouds present in the sky and some important weather parameters such as temperature, humidity, and atmospheric pressure using affordable sensors that are within the reach of farmers and will work independently of WIFI or internet.

This device consists of Raspberry pi with an integrated camera for taking digital images of the sky to know the type of clouds present in the sky along with some atmospheric parameter sensors like DHT11 sensor, BMP 180 etc. to sense temperature, humidity, and atmospheric pressure and will give the prediction on rainfall by both approach from cloud status and sensed atmospheric parameters. Improvement in crop production and planning by using local climate prediction without the internet can definitely help an individual farmer to increase his yield by managing the irrigation cycle by avoiding irrigating the crop with extra water or less water.

A. Novelty

The proposed work is distinguished from previous work by its multi-modal integration of two separate techniques. The majority of previous research has proposed solutions in irrigation management by providing automatic irrigation based on either atmospheric parameters collected from nearby weather stations / using sensors or only by capturing sky images, but the proposed system takes advantage of both approaches where real-time atmospheric parameters on the fields are sensed using sensors and the sky image at that location is captured to provide better rainfall predictions without using WIFI or internet so that it can be used by farmers or people at remote locations. Due to the global shortage of clean water resources, it is critical that they be utilised to their full capacity, which may be accomplished by utilising water resources wisely and paying equal attention to irrigation water management. This device will help farmers to take decision before every irrigation scheduled cycle to what extent the field should be irrigated by predicting the intensity of rainfall as low, medium or high.

The rest of the article is arranged as follows: Section 2 describes relevant work, Section 3 discusses the proposed system in detail, Section 4 discusses methods and methodology, Section 5 discusses findings, and Section 6 discusses conclusion and future work.

II. RELATED WORK

Weather conditions play an important role in both irrigation requirements and crop performance. Researchers used various weather parameters and different technologies and algorithms to predict the weather to know the status of climate to control the use of water in Irrigation.

The evapotranspiration of water in the soil is affected by temperature and humidity. The thermic level of the atmosphere is described as air temperature, which is generally measured in Celsius, Fahrenheit, or Kelvin degrees. It is the most closely observed weather metric. The presence of water vapour in the air is known as humidity. The proportion of water vapour in the air is expressed in percentage (%). The other major parameters considered by the researchers are luminosity and is defined as the brightness or intensity of light. Lux is the unit of measurement. It causes more water

loss from the soil as the temperature rises with the direct solar radiation. The most important parameter is the rainfall or amount of precipitation that influences whether or not irrigation is necessary as well as the amount of water to be used if irrigation is required. The author in [5] presents a detailed survey on the IoT systems and recent sensors used in an automatic smart irrigation system in Precision Agriculture and discussed various weather monitoring parameters, sensors, soil characteristics. The author in [6] proposed an automated irrigation system which starts the motor and water is supplied only if the level of soil moisture goes below the threshold and the amount of water supply is managed by considering the weather parameters temperature and humidity sensed by the sensor to predict the type of climate as sunny (no rain), cloudy (rain chances <50%) or rainy (rain chances>50%). In [7] to add intelligence to the existing idea of automatic irrigation systems, an autonomous irrigation system is proposed that employs machine learning and predictive algorithms to predict the status of rainfall using historical climate data for the amount of water to be used by calculating the time of motor to be ON based on the soil moisture value for each zone separately. Work proposed in [8] is the development of an efficient IoT architecture that monitors soil, microclimate, and water parameters, as well as performing proper irrigation management based on challenges studied in irrigated farmland of Ethiopia, Kenya, and South Africa. For educated decision making and effective operation of the irrigation management system, indigenous agricultural and expert knowledge, local climate information, particular features of crop and soil are provided to the system. Broadband connection and cloud services are either unavailable or too costly in Sub-Saharan Africa. To overcome these constraints, data processing, network administration, irrigation choices, and farmer communication are all done locally, with no back-end servers involved. In the article [9] the technique was evaluated using five crops at four European sites with varying weather circumstances to optimize irrigation water consumption by taking into consideration soil water availability, local weather predictions, crop physiological condition, and water demands in real-time. Main observations are the major effect of inaccurate predictions of the forecast, unless the target yield was excessively high, was that the target yield was not attained, but the irrigation schedule stayed near to optimum, according to the data. In other words, while the actual yield did not match the objective, just a little amount of irrigation

water was lost. In [10] author proposed an idea to automate the irrigation process to manage the motor's pumping by taking into account the soil moisture content and rainfall forecast. Soil moisture data is continuously sensed using a soil moisture sensor and is sent to raspberry pi and depends upon the value a rainfall prediction is obtained from Openweather API to decide on irrigating the field or not and the Android Application is used to track the complete irrigation process for the agricultural field. The article [11] effectively shows a simple, low-cost, and somewhat accurate system for monitoring current meteorological conditions and forecasting rain. This system has a significant benefit over comparable Arduino-based weather monitoring systems in that it also provides rain probability at the current moment using weather parameters namely temperature, humidity, light intensity, and wind conditions. The goal of this study [12] was to provide a way for a reliable irrigation system based on a suitable rainfall forecast algorithm. The new approach, which is Romyan's method is introduced to calculate water requirement for crops, as well as the time necessary for the motor to be turned on. The author in [13] presents a technique for high-accuracy rainfall forecasting that combines two types of data i.e., cloud imaging data and humidity as an atmospheric parameter in numerical form. Convolution Neural Network is used for image recognition by extracting important features using ResNet. In this research, a novel network is built that combines the cloud picture with other meteorological information and creates the result, to forecast rainfall with greater accuracy than the existing ResNet image recognition alone.

A comparison of the existing and proposed work based on the parameters and technology along with methods and methodologies used are shown in Table I. The comparative analysis of the previous research work has revealed that most of the models used either atmospheric parameters or cloud images for the prediction of rainfall and only one paper proposed a system using a combined approach but using only one parameter as humidity. However, after researching existing systems it is clear that the combined approach of two modalities to predict rainfall gives more clarity and would be very useful. In this regard, the system proposed uses a multisource data approach that combines predictions from digital cloud images and atmospheric parameters to provide an improved rainfall prediction system.

TABLE I. COMPARISON OF THE PROPOSED SYSTEM WITH EXISTING SYSTEMS

Model	Atmospheric Parameters used	Source of weather data	Sky status	Methodology used	Output
[6]	temperature and humidity sensors	Sensor deployed in the field	No	Controllers, sensors, and algorithm	Climate predicted as sunny, cloudy, or rainy
[11]	temperature, humidity, light intensity, and wind conditions	Sensors	No	Matlab, Arduino IDE	Automatic Irrigation using soil moisture and rainfall prediction
[8]	Soil and microclimate parameters	sensors	No	IoT, GPRS/GSM communication	autonomous actuations for smart irrigation management
[14]	Temperature, humidity, pressure, and uv_index	Sensors	No	algorithms like SVM, KNN, ANN, etc. explored	Gives rainfall prediction for the next four days
[13]	Humidity	Sensors	yes	CNN, RESNET, and Neural network	rainfall forecasting with cloud imaging data and humidity
<i>Proposed System</i>	<i>Temperature, Humidity, and pressure</i>	<i>Sensors</i>	<i>yes</i>	<i>Transfer learning, IoT, Machine learning</i>	<i>Rainfall intensity as No rain, Low rain, and High rain</i>

The suggested system addresses the optimal integration of different sensing modalities as well as their practical execution. Additionally, machine learning approaches and deep learning architectures are applied to the different inputs and the final decision is provided by combining the output from both approaches to predict rainfall and gives an appropriate decision on the amount of irrigation to be done. In comparison to current procedures, the suggested approach has presented a technology-based solution that would be beneficial to the agricultural and scientific communities in terms of its portability and use of edge analytics where input is processed and output is given at the device level only without cloud platforms, internet or WiFi.

III. PROPOSED SYSTEM

The study of clouds and their characteristics is crucial for a wide range of applications. It's been utilized to produce precise weather forecasts via nowcasting. There exist many clouds in the sky but only a few clouds are responsible for rain. Identification of rainclouds can be done using image classification with the help of deep learning on a ground-based image cloud dataset. To make the predictions more accurate the atmospheric parameters like temperature, humidity, atmospheric pressure is taken into account which can be easily sensed by the sensors and are affordable. The results from both approaches are combined and the final output is given as the prediction on the rainfall as No rain, Low to Medium rain, or heavy rain as shown in Fig. 1 as a multi-modal proposed system on basis of which many agriculture-related activities can be carried out like managing irrigation by taking in account the status and intensity of rainfall.

A. Components used

1) **BMP180:** BMP180 is a barometric sensor with an I2C ("Wire") interface, used to measure pressure surrounding it and altitude. It is also used to measure temperature. It works on push sensor BMP180 and can measure the pressure in the range of 300 to 1100 hPa with relative pressure error to 0.12 hPa (1m height). The BMP180 outputs absolute pressure in pascals (Pa). By observing variations in pressure short-term weather changes can be predicted. Dropping pressure, for example, frequently indicates the arrival of rain or a storm (a low-pressure system is moving in). When the pressure rises, it usually signals that clear weather is on the way (a high-pressure system is moving through).

2) **DHT11** sensor is a basic and commonly used to record temperature and humidity from the atmosphere in the digital form. This sensor utilizes a thermistor and a capacitive humidity sensor to detect the surrounding air. To monitor humidity and temperature instantly, it may be simply interfaced with any microcontroller such as Arduino, Raspberry Pi, and so on.

3) **Raspberry Pi 4:** Raspberry Pi 4 is the latest model and is a tiny processor or a controller with great processing power integrated with Broadcom 2711, 64-bit quad-core Cortex-A72 processor and is available with 1 GB, 2 GB, or 4 GB RAM. It features a true gigabit Ethernet port, 2 x USB 3.0 "Super-Speed" ports which can be used to attach mouse and keyboard. It comes as a size of the credit card so is portable and easy to carry. New version comes with a combination of small footprint, low-power drop, customization and amazing community support and the pi can be used in several.

4) **USB camera:** Logitech HD webcam c270 has a USB interface that makes it easy to connect and has 3-megapixel image resolution along with superb color-rich imaging even in ultra-low light with HD support.

5) **OLED Display Screen:** To display the output as the atmospheric parameters along with the status of rainfall and the decision based on the rainfall is displayed on an OLED display screen. The OLED display screen is very thin and light-weighted with a size of 0.96 inches comes with a resolution of 128X64. It has 4 pins named VCC: 3.3-5V GND: Ground SCL: Serial Clock SDA: Serial Data to carry out I2C communication.

6) **Basic Shield:** Basic Shield is a component provided with 8 LED's, 2 push buttons and is very popular for interfacing electronics components like a push button, potentiometer, LDR, buzzer, etc. and can be easily connected with 5 V/3.3 V microcontrollers.

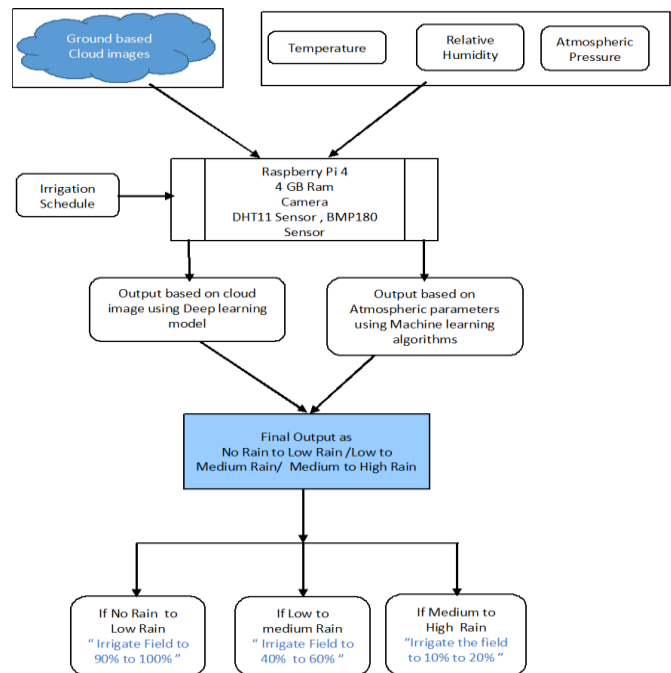

Fig. 1. Proposed System.

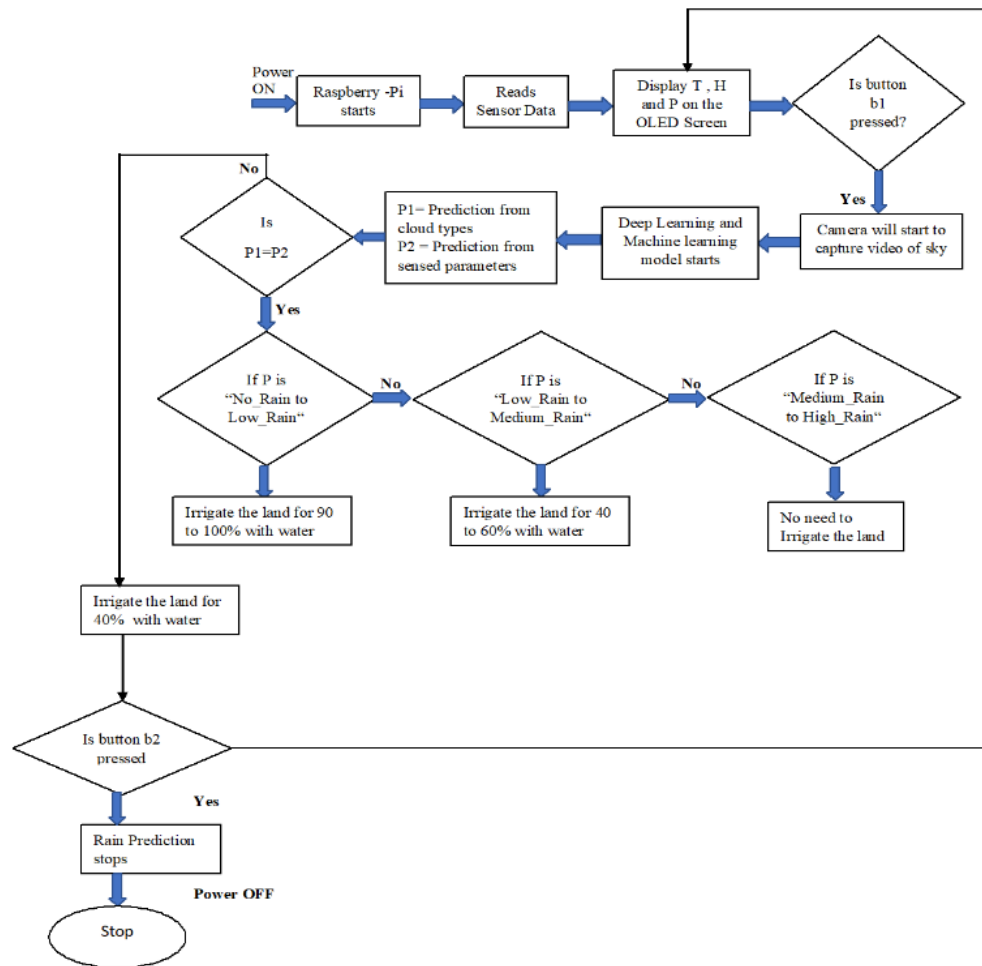

Fig. 2. Working Flow of the Device.

B. Working Principle of the Device

The Device consists of Raspberry Pi 4 Model B and components DHT 11, BMP 180, OLED display screen, USB camera, and Basic-Shield are connected to the respective pins. Power is provided to Raspberry Pi using a power bank with a C-Type cable to make the device portable. The work is shown in Fig. 2. Sensors sense the atmospheric parameters like temperature denoted by T, Humidity denoted by H, and Pressure is denoted by P. Once power is supplied to the device the code snippet for collecting sensor data will start and will get displayed on the screen after regular intervals. To start the Rain prediction push-button b1 needs to press. Once b1 is pressed camera will start and the video will be captured, so the camera should be faced towards the sky to get the proper input, which is fed as input to deep learning model at the same time machine learning code will also be executed by giving values T, H, and P as input parameters.

IV. METHODS AND TECHNOLOGY

A. Irrigation Scheduling

Irrigation scheduling is critical for ensuring that crops receive the right quantity of water at the right time to

minimize crop water stress and optimize output [15]. Water stress can affect vegetable crops in two ways: when there is a lack of water (drought stress) or when there is an abundance of water (water stress) caused due to waterlogging or soil water saturation. A water deficit occurs when water is supplied at the wrong time or insufficiently, reducing the amount of water available to plants in the soil. Long durations of irrigation or high-water application rates can produce excess soil moisture, wasting water and causing nutrient loss. Crop water stress can also have an impact on crop management. Wilting occurs when soil moisture falls below a certain level, preventing plants from drawing water into their roots. Furthermore, in low moisture circumstances, any moisture-activated herbicides and nutrients would not be efficiently used by plants. Presently, many different approaches are adopted for irrigation scheduling as listed in Table II to optimize the water application to crops. These methods are ranked according to the level of management required for water application [16]. Irrigation scheduling is different for a different crop at every growth stage and must be followed to optimize the crop yield and the use of water.

TABLE II. IRRIGATION SCHEDULING METHODS

Rank	Method	Type of water management
0	The "Irrigate whenever" method	Water is applied without scheduling
1	"Feel and appearance" method	The irrigation manager decides the amount of water to be applied and when by observing the soil sample and assessment is done by comparing it with the soil reference images.
2	Systematic method	Regardless of considering weather or soil water conditions, the application of water is done based on the amount or time.
3	Crop water demand method	The amount of water applied is determined by the crop's evapotranspiration (ETc). This strategy involves calendar-based scheduling based on prior seasons and should take into account rainy days.
4	Soil water status method	Water is supplied to the crop root system based on soil moisture levels, usually by giving a proportion of soil accessible water. Rainfall occurrences should be taken into consideration with this technique.
5	Water budgeting method	Water application is dependent on crop evapotranspiration, soil moisture content at the root level, and water budgeting.

The first method is completely traditional and requires human interventions and results in lots of water wastage in terms of irrigation as management was not done properly and no parameters are considered. The second and third methods considered soil parameters and timings as well as an amount for application of water which reduced the water wastage but may result in water stress as no weather conditions are considered. The last three methods are improved and make use of technology by considering various parameters like soil moisture content and rainfall events to plan the irrigation scheduling thus optimizing the use of water resources. From the above table, we can see that Irrigation scheduling is very important to optimize the water application thus by improving the yields and rainfall is one such important factor that must be taken into account to protect the crop from the application of excess water thus improving the Irrigation Management system.

B. Internet of Things (IoT)

Every element of traditional farming processes may be substantially altered by incorporating the newest sensor and IoT technology into agricultural practices. Currently, Wireless sensors and the Internet of Things (IoT) are being integrated into smart agriculture and are capable of taking agriculture sector to next level. Soil, humidity, wetness, light, air temperature, CO2, solar energy sensors, and a variety of other IoT sensors are all employed in agriculture. Sensors, which are placed across the fields, on smart agriculture vehicles, in IoT-based monitoring systems, and weather stations, collect data in real-time and give farmers visibility and control over their activities. Fig. 3 shows the basic architecture of IoT.

Fig. 3. A Basic Architecture of IoT.

IoT architecture consists of various hardware components like sensors as per the requirement to sense the data from surroundings which requires software and various communication technologies to exchange the data among the devices and finally, the data sensed by the interrelated devices

gets stored on the cloud for further analysis and various application are developed to convert this data into important information required for many useful or decision-making activities.

The information about IoT technology stack that contains companies and produce different level IoT boards or controllers, then come communication technologies NB-IoT, LoRaWAN, ZigBee, Bluetooth, etc. supported by many Communication protocols such as MQTT, CoAP, AMQP, and many more as shown in Fig. 4.

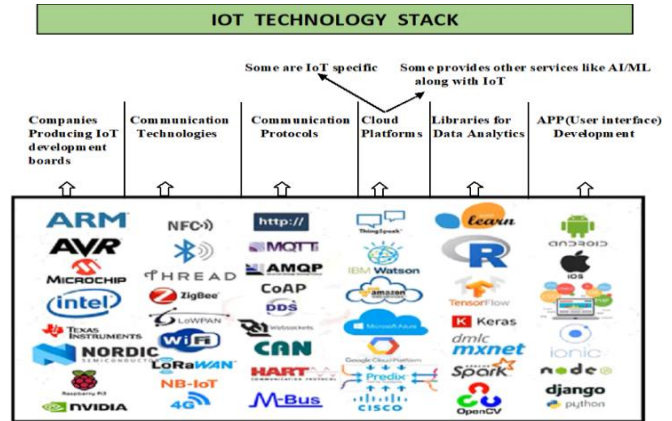

Fig. 4. IoT Components and Technologies.

Today we have clouds like Thingspeak, IBM Watson specifically for IoT along with general-purpose cloud platforms (AWS Amazon, Google, Cisco). Once the data is stored it is analyzed with analytical tools like keras, Tensorflow, OpenCV is libraries with very powerful functions and finally, the information retrieved after analysis of data is used for various applications.

C. Edge Analytics

Sensors are used to collect data from the environment or surroundings and Actuators are the devices that will take action based on the output of processed data. If the Analytics is performed at the device level that concept is called Edge Analytics. Only data for storage is sent to the cloud. If analytics is done in the cloud, then it is called cloud analytics. This experiment used DHT11 and bmp180 sensors to sense temperature, Relative humidity, and atmospheric pressure, and the data is fed to a machine learning algorithm (pickle file) to

get the status of rainfall based on these real-time parameters. Along with it, raspberry pi is integrated with a digital camera to capture the image of the sky at that location, and the image is given as the input to the deep learning model (.h5 file) to get the status of rainfall based on the types of clouds present in the sky at that time. The processing is done in Raspberry pi and the predictions are displayed on the screen attached to it. This proposed device uses Edge analytics to give output as the processing is done at device level and does not depend on WIFI or internet. The cloud can be used to just store the data collected by the sensor only when Wi-Fi is available. The cost of data storage and management is reduced using edge analytics. It also saves operational costs, bandwidth requirements, and time spent on data analysis. Despite the widespread use of internet-connected gadgets, connection problems persist due to the unavailability of the internet or limited network access. Edge analytics guards against possible network failures by ensuring that applications aren't hampered by internet issues or limited network access [17]. This is especially beneficial in rural regions (remote locations) or when trying to save communication expenses with costly technologies like cellular.

D. Deep Learning

Clouds are crucial in climate forecasting. Rainfall forecasting is also heavily influenced by the state and kinds of clouds in the sky. CNN model is used with transfer learning to classify clouds based on their features like texture, color, etc. to know the type of cloud and rainfall can be predicted using the precipitation associated with that cloud. Ground-based cloud images are readily available compared to satellite cloud images and provides information about the local atmosphere by analyzing bottom-level features of clouds like cloud height, cloud type, and cloud cover [18]. Rain clouds are mainly classified as Cirrus, Stratus, and Cumulus [19] and the main clouds are shown in Fig. 5.

The proposed device is provided with 8 megapixels digital camera integrated into Raspberry-pi to capture live sky images at any location by clicking a button on the device to activate the device. A cloud image is given as input to the convolution neural network (CNN) and the SoftMax activation function is used to classify the cloud into No Rain to very Low Rain, Low to Medium rain, or Medium to High Rain based on the amount of precipitation associated with each cloud. According to the Precipitation and the amount of Rainfall as shown in Table III, all cloud images are classified into three classes or groups.

The operation of the deep learning model as shown in Fig. 6 where the weights of the pretrained model are downloaded first, followed by freezing of all the layers except the top layer, which is used for classification in the fresh dataset, and finally the training of the model. All of the layers are unfrozen for fine-tuning, and the model is trained on a new dataset with a very low learning rate. Once trained, the model was able to accurately predict the outcome. All three pretrained models, VGG16, Inception-V3, and Xception, follow

the identical flow and concluded with The Xception model gives better accuracy to predict Rainfall based on cloud images taken from the ground, giving output whether Rain or little Rain or medium Rain or high Rain as compared to VGG 16 and Inception-V3. Rain Prediction using deep learning on ground-based cloud images using transfer learning, is presented in [20].

E. Machine Learning

To support the rain prediction model based on cloud images, atmospheric parameters are also considered which also plays vital role in determining the rainfall. Temperature, humidity, and pressure in the atmosphere fluctuate rapidly, causing instability in the atmosphere, which can result in rain, storms, and even lightning and thunder. The most significant elements in predicting precipitation are temperature and humidity [21]. Air pressure, dewpoint temperature (or relative humidity), wind speed, and cloud cover are four more meteorological factors that are substantially connected to rainfall [22]. But as the device is portable so only the most important variables are chosen for the experiments which are temperature, relative humidity, and air pressure that can be sensed with affordable sensors and are sufficient to predict the status of the rainfall.

Fig. 5. Types of Clouds.

TABLE III. CLOUDS CLASSIFICATION BASED ON ASSOCIATED PRECIPITATION

Cloud	Associated Precipitation	Class
Cirrus Cirrostratus Cirrocumulus Altostratus	None None None None	No Rain to Very Low Rain
Altostratus Stratus Stratocumulus Nimbostratus	Produces light showers or sprinkles, drizzle or Bring a light or moderate Rainfall of long duration	Low to Medium Rain
Cumulus Cumulonimbus	Showers or snow Heavy Rain with lightning, hail, or snow	Medium to Heavy Rain

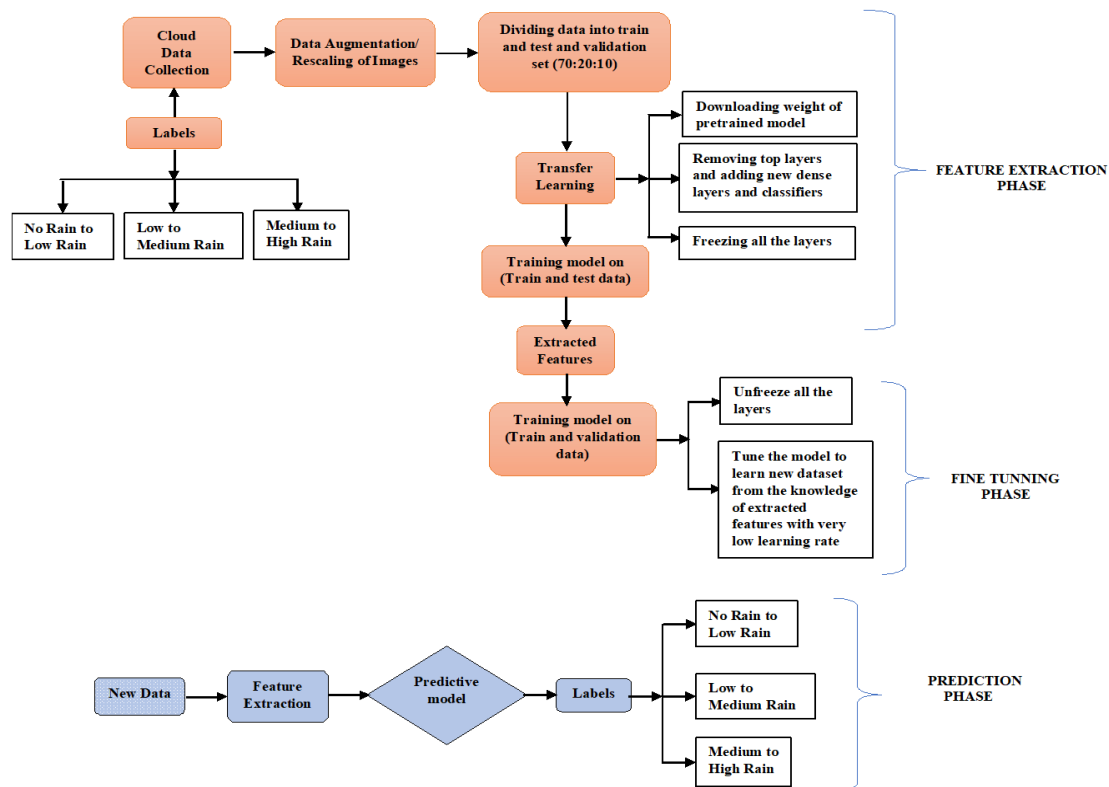

Fig. 6. Working of Deep Learning Model.

Rainfall intensity is classified according to the rate of precipitation, which depends on the considered time. The following categories are used to classify rainfall intensity [23]:

- Low rain — when the precipitation rate is < 2.5 mm (0.098 in) per hour
- Medium rain — when the precipitation rate is between 2.5 mm (0.098 in) and 7.6 mm (0.30 in) or 10 mm (0.39 in) per hour
- High rain — when the precipitation rate is > 7.6 mm (0.30 in) per hour, or between 10 mm (0.39 in) and 50 mm (2.0 in) per hour
- Very High rain — when the precipitation rate is > 50 mm (2.0 in) per hour

Here also the data is classified in the same categories as in cloud dataset as No Rain to Very Low Rain, Low to Medium Rain, and Medium to Heavy Rain based on the precipitation rate.

The data is collected for the city of Hyderabad, Telangana, from Nasa Power Data viewer for Daily data, which contains various climatic parameters, but only the most significant ones are picked, and the data is collected over a 40-year period from 1981 to May 2021. Because there are an average of 64-65 rainy days each year, collecting sufficient data over a long period of time is required. The dataset contains many attributes (columns), but for this experiment, the independent variables are Temperature, Relative Humidity, and Pressure,

and the dependent variable is Condition, which is labelled in three categories based on precipitation: No rain to very low rain, Low to medium rain, and Medium to high rain. Various steps carried out to train the model from collecting dataset to cleaning of the dataset, balancing the dataset, feature extraction, and then partitioning of the dataset into train and test sets as shown in Fig. 7. After that various classification models are applied on the training set to train the model on selected parameters then the performance is analyzed by calculating the accuracy based on the predictions from the test dataset.

It has been observed, that among all individual machine learning models RandomForest and KNN gave a good prediction as compared to others. Logistic regression and SVM also performed well while predicting the values but Decision Tree and Naïve Byes performance was poor in estimating the predictions compared to other models as shown in Fig. 8. For evaluating the machine learning models a very effective technique called K-FOLD CROSS VALIDATION is used where the model is tested on part of the dataset which was not used for training. In this experiment, value of k is set to 5 in the K-fold cross-validation technique to check the accuracy attained by various models used. Although predictions from stacking Ensemble are better than voting, the calculation time is three times that of individual machine learning models. As a result, the RandomForest classifier was chosen to implement in hardware since it is faster and has similar accuracy to Stacking Ensemble.

Fig. 7. Machine Learning Model for Rain Prediction based on Atmospheric Parameters.

Fig. 8. Accuracy Obtained by Different Classifiers and Ensemble.

F. Device Setup

All the components are connected to Raspberry Pi as shown in Fig. 9. The screen displayed the currently sensed parameter values when the power is given to the device.

No internet or WIFI module is used in this device and the power can be given by the power bank to make the portable device so that it can be carried to any location. Logitech USB Camera is used to capture the video of the sky which will be divided into continuous image frames and given as input to the Deep learning model to get the rainfall prediction based on the clouds present in the sky. Data sensed by the DHT11 sensor and BMP180 i.e. temperature, humidity, and pressure is given as input to the machine learning model. The predicted rainfall from both the models is displayed on the OLED screen and

the final decision for the amount of irrigation is also displayed on the screen. Based on the output the motor can be switched ON to irrigate the land for the appropriate amount of water based on the decision given. The instrument is tested and found to give very correct predictions based on both approaches. This rainfall system would be very much useful in many agricultural events where the rainfall prediction needs to be considered. Prediction is given based on two different models where atmospheric parameters and clouds both are considered. The most important is this device works without the internet only power is needed. The device can also be used only to monitor individual atmospheric parameters temperature, humidity, or pressure which can be used to make a decision on food storage, or crop harvesting.

Fig. 9. Device Setup.

G. Tools and Libraries used

To execute the Deep learning model Debian GNU/Linux (64 bit) aarch 64(beta version) is installed which is a free and open-source operating. Debian GNU/Linux is a unique software distribution that combines Debian's philosophy and methodology with GNU tools, the Linux kernel, and other key free software to make aarch 64. Because of its technical brilliance and profound dedication to the requirements and aspirations of the Linux community, Debian is especially popular among expert users. The Deep Learning model and machine learning models were trained on python 3 so all the supporting libraries with the required versions Keras – 2.4.3,

Tensor Flow-2.4.0-rc2, Scikitlearn-0.20.2, and OpenCV -4.5.3 are installed.

V. RESULT

Some of the screenshots of output are shown in Fig. 10. Here in the display screen T denotes Temperature, H denotes Humidity and P denotes Pressure sensed by the sensor and are displayed as soon as Raspberry Pi starts. The Value of T, H, and P keeps on displaying on the screen. When button b1 is pressed its status changed from 1 to 0 and the rain prediction model starts by starting the camera to capture the sky image and is given as input to the deep learning and T, H, and P values are passed to the machine learning model. P1 denotes output from deep learning (i.e. from clouds) and P2 denotes output from machine learning (i.e. from Parameters).

The device is tested in the open space in residential area by powering it with the USB power bank as the Raspberry Pi requires a 5volt input voltage, which is provided via the USB type-C connection. The input voltage should actually be a little higher than 5 volts. Because power losses occur in the connectors and wires of the circuit's transmission, 5.1–5.2 Volts would be optimum. The results obtained as the intensity of rainfall were compared with the open weather API for the same day and time and found that the device prediction gives 70-75% accurate results which will be really helpful in many areas that require instant information on the rain at particular location and time. The device must be operated in open space and camera should be kept facing towards the sky to capture the cloud images. Device can be used as many times by rotating the facing of camera to capture sky in all directions.

Fig. 10. Final Output at Different Stages.

VI. CONCLUSION AND FUTURE SCOPE

In this era of technology people like farmers must be able to use various technologies to increase their decision-making in various agriculture processes like the timing of irrigation, spraying of pesticides, use of fertilizers in the right amount, and at right time needed by the crops. But there are some limitations as unavailability of WIFI, No Internet, lack of knowledge while using the technologies. This IoT based portable device is a small effort for people like farmers, transporters where rain prediction is of utmost use for decision making and the main advantage of this device is that it will be operated without the internet and will give the prediction by sensing the atmospheric parameters and sky status at the current location. Compared to the previous devices this proposed system gives rainfall prediction based on atmospheric parameters along with present cloud/sky status specific to that location, hence is very useful in agriculture for monitoring the weather status without the use of any internet and the device require very low power which can be given by a power bank using USB-C Type cable to a raspberry pi.

Farmers cultivating crops under irrigation can benefit from climate prediction of precipitation and temperature at various stages of the growing season. These forecasts enable farmers to better manage the timing of water application and apply the appropriate amount of water to maximize crop production. This device can also be used to monitor individual parameters as per the requirement like temperature, humidity, or atmospheric pressure. The device works in two modes for monitoring individual parameters and gives rain prediction only after pressing the push button. Rain prediction is given by combining output from machine learning by giving atmospheric parameters as input and deep learning by taking sky image as input. For a deep learning model Xception model gives better accuracy of around 80% as compared to VGG16 and Inception V3. Whereas for the Machine learning approach among all individual machine learning models RandomForest and KNN gave a good prediction as compared to others. Logistic regression and SVM also performed well while predicting the values but Decision Tree and Naïve Byes performance was poor in estimating the predictions compared to other models. The device is handy and requires human intervention for pressing the button to get the rainfall prediction as per the requirement. Before reaching the final decision of irrigating the land the device can be used after every 1 or 2 hours to monitor the changes in the atmosphere. The sensed data can be stored in excel in Raspberry-pi and whenever a WIFI is available the data can be stored on the cloud for future use.

For future work, the GSM module can be integrated to operate the device automatically at regular intervals and the prediction can be sent to the farmer's mobile and also the motor can be switched ON/OFF as per the suggestion based on the rainfall prediction. Water wastage may be greatly reduced by including a smart irrigation system, which can reduce water consumption by 20%. The integration of smart technology, such as machine learning, IoT, the web, and the mobile framework, has been a major driver in achieving sustainable precision irrigation. Some of the study's findings

show that sustainable precision irrigation management can help farmers achieve food security and avoid water constraint.

Abstract—This study aimed to describe the implementation of the level III leadership training program at the human resource development agency. The evaluation process used the CSE-UCLA model that was divided into: (1) components of system assessment, (2) program planning, (3) program implementation, (4) program improvement, and (5) program certification. This study involved 100 participants from the human resource development agency as institutional leaders, heads of divisions and heads of sub-sectors, lecturers/Widyaiswara, implementers/committees, superiors of alumni/mentors, and leadership training participants. Data was collected through questionnaires, interviews, observation, and documentation. The data were analyzed by quantitative descriptive analysis and verified by the Glickman quadrant, while the weaknesses found in the evaluation used qualitative descriptive analysis. The results showed that the level of effectiveness in terms of system assessment component included good criteria with a percentage of 82.4%, program planning component included good criteria (86.4%), program implementation component included good criteria (82.8%), and program improvement component included good criteria (83.2%). Lastly, the program certification component included good criteria (83%). The implementation of this Leadership Training Program is a strategy in developing SCA competencies, both managerial competencies, technical competencies, and socio-cultural competencies, to create a world-class bureaucracy in 2025 through independent learning and learning through coaching and mentoring.

Keywords—E-evaluation; leadership training; evaluation of educational programs; CSE-UCLA; human resource development agency

I. INTRODUCTION

Leadership is a performance that is carried out by someone in a group in order to move and influence others in developing human resources through education[1]. Leaders must have good decision-making skills in carrying out responsibilities for all processes, from procurement to evaluating work programs and the workforce[2]. However, in reality, there are still institutional leaders who are not fully able to manage themselves to change their mindset according to leadership concepts and competencies[3]. The facts show that the quality of the relationship between leaders and subordinates is still less harmonious and relevant[4],[5]. Some of the results of previous studies show an effect of increasing employee performance by transformational leadership, but some cases of

efforts to get transformational leaders are less open and competitive [6].

One of the essential efforts to continuously improve the quality of human resources for the apparatus is through education and training. Efforts to develop human resources are dealing with the facts on the ground that the implementation of education and training experiences several problems and obstacles[7]. The training's less than optimal implementation is due to the quality of the staff, facilities, and curriculum substance[8]. This problem is far from the ideal condition that the implementation of leadership training produces training participants' outputs who can demonstrate adaptive leadership competence (adaptive leadership) in developing innovations[9],[10]. In addition, the implementation and development of competency certification in education and training has not yet reached the target and has not been optimal, so the provision of innovation in the implementation of education and training does not continue and even stops [11],[12].

The determination of the innovation program needs to be regulated in the short, medium, and long term with specific, measurable, achievable, realistic time limit criteria[13],[14]. The implemented programs in accordance with the provisions need to be evaluated for the process and post-training. Evaluation applied in education and training named program evaluation. Evaluation of education and training programs is an activity carried out by an evaluator to collect and analyze complete and accurate information about the object/program/service/particular policy being studied [15],[16]. The education and training evaluation results can be used as recommendations in making decisions[17]. The implementation of education and training is able to ensure the formation of leader characters who have operational insight to build good governance. The evaluation results of the implementation of the training show that the old pattern was limited to equipping participants with the competencies needed to become visionary leaders [18],[19]. The problem of cost is also becoming an issue in implementing education and training. Therefore, post-training evaluation can be a policy solution regarding comparing the results and benefits of training with the costs incurred [20]. The post-training evaluation that have been carried out so far have not had a comprehensive normative standard and involve all stakeholders, so the recommendations obtained from the

*Corresponding Author

evaluation of the education and training carried out have not been optimal. In addition, the strengths and weaknesses in the implementation of education and training are not studied in depth [21].

The introduction of this study has explained the problems and constraints as part of a development and coaching system implemented by the education and training institution. The implementation of education and training must be implemented and developed in-depth to equip the state apparatus with good leadership [22]. This study examines scientifically through the CSE-UCLA (Center for the Study of Evaluation-University of California in Los Angeles) model. The CSE-UCLA model was chosen because it is very suitable and has advantages in the form of program implementation stages that can introduce the existence of the program being evaluated and the sustainability of the impact of an educational program[23]. The suitability of expectations and optimal implementation of the model will be known through a follow-up evaluation process [24]. This research is evaluative, which aims to determine the effectiveness of the leadership training program in terms of system assessment, program planning, program implementation, program improvement, and program certification in implementing programs in human resource institutions.

This study will observe the internal aspects of the education and training organization and its relation to implementing the education and training program that still needs to be improved. This study will observe the internal aspects of the education and training organization and its relation to implementing the training program, which still needs to be improved according to the objectives. The purpose of training in this research is to increase knowledge, skills, and attitudes in order to be able to carry out the duties of the level III leadership positions professionally based on the personality and ethics of civil servants according to the agency's needs. The fundamental objective of education and training in this research is through operational policies, which stipulate that the human resource development agency is a regional apparatus that carries out the functions of supporting government affairs in education and training. The training program's success is known through post-training evaluations to measure the level of success of the training process in an objective, reliable and valid manner, which is carried out after the training process is complete. The training program evaluation in this study used an e-evaluation based on the CSE-UCLA model, referring to the Glickman pattern for evaluating the leadership training program at the human resources development agency.

The research questions are (1) how is the effectiveness of implementing the leadership training program in terms of the system assessment aspect, namely the legal basis, the organization's vision and mission, regulations for the implementation of leadership training, local government support, and stakeholder support?; (2) how is the effectiveness of the implementation of the leadership training program in terms of program planning aspects, namely the management of the implementation of leadership training in terms of the ability of teachers/widyaswara, committee readiness, facilities and infrastructures, and budget?; (3) how is the effectiveness

of the implementation of the leadership training program in terms of program implementation aspects, namely the achievement of innovation, the factors driving and inhibiting alumni innovation, and the impact of innovation on the organization?; (4) how is the effectiveness of the implementation of the leadership training program in terms of the program improvement aspect, namely the participants' reactions to the abilities of the teachers/widyaiswara, committee, materials, schedules, and training programs, as well as the behavior of participants after returning to their work units?; (5) how is the effectiveness of implementing the leadership training program in terms of the program certification aspect, namely the adaptive leadership competence of alumni?

II. LITERATURE REVIEW

A. System Assessment of Leadership Training

The analysis of training needs is an ongoing process of collecting data to determine education and training needs[25],[26]. Education and training can be developed to help organizations achieve goals based on the results of a needs analysis so that they are the basis for program success[27]. This analysis begins with a training needs assessment (needs assessment) which aims to collect information on the training program's needs[28]. The results of the analysis of training needs are helpful as a basis for making a decision and providing solutions, instructions on what to do, how to implement, and what results are obtained[29]. The accuracy will significantly influence the leadership development program in preparing the curriculum, materials, methods, and learning evaluation systems that will be carried out[30]. The evaluation that will be carried out is expected to provide information about the value and benefits of the objectives to be achieved, design, implementation, and impact to help make decisions, accountability, and increase understanding of the existing phenomena[31].

B. Program Planning of Leadership Training

One of the main activities in implementing education and training is to design the program (designing and constructing the education and training). Design (design) is a planning process that describes a sequence of activities (systematics) regarding a program[32]. The design and construction of the education and training program are planning the sequence of activities for the education and training aspect, which is a unanimous unity of the program[33]. There are three essential elements in each education and training design that need to be considered to improve activities for each individual, namely: 1) purpose (what must be achieved); 2) method (how to achieve the goal); 3) format (under what circumstances the determination of the existing design is to be achieved)[34]. Planning is the initial activity of management functions. Planning is the most crucial stage of a management function, especially in dealing with a dynamically changing external environment[35]. Strategic planning is the first step that agencies must take in order to be able to respond to the demands of the local, national and global strategic environment. The realization of the strategic plan is carried out through the selection of targets and priority programs that must be implemented so that the vision and mission are in line

with the potential, opportunities, and constraints faced in efforts to increase performance accountability[36].

C. Program Implementation of Leadership Training

Leadership Education and Training is training that provides insight, knowledge, expertise, skills, attitudes, and behavior in the field of apparatus leadership to achieve leadership competency requirements in certain structural levels[37]. Leadership training is carried out to achieve the leadership competency requirements of government officials following the level of structural positions[38]. The competencies built-in leadership training are operational and tactical leadership competencies indicated by the ability to develop character and integrity behavior, develop activity plans, describe the agency's vision and mission, collaborate internally and externally, innovate, and optimize internal and external potentials. External to the organization[39]. These competencies can be achieved by designing a curriculum structure that includes five stages of learning, including 1) Diagnostic Stage of Organizational Change Needs; 2) Taking Ownership Stage; 3) Designing Change and Team Building Phase; 4) Leadership Laboratory Stage; and 5) Evaluation Phase[40].

D. Program Improvement of Leadership Training

Leadership behavior is an exciting study because it opens up great opportunities for everyone to become a leader. The study of the behavior and type of a leader for government organizations is growing and is supported by a government organizational model that is increasingly leading to a corporate organizational model[41]. The demand for leaders to constantly bring new things to the organization is hope for every individual[42]. Leaders of change who become the jargon in the new pattern of leadership training are not only an expression but in the new pattern of training. Each participant is expected to be able to present projects that can bring about change in the workplace[43]. Organizational leadership can be enriched through education and training, not solely on The grand man theory[42].

E. Program Certification of Leadership Training

Training is essentially aimed at developing human resource competencies. These competencies are developed through a conducive learning process during the training program[44]. The output of the training program is expected to support adaptive leadership competencies, the concept of innovation, and organizational performance[45]. Adaptive leadership means leadership that quickly adapts to changes and new circumstances[46]. The need for adaptive leaders is due to complex challenges and not enough operational improvisation to meet challenges[47]. Strategic organizational changes are needed to display satisfactory organizational performance[48]. The state civil apparatus must create work productivity to achieve public services that lead to good governance and clean governance[49],[50]. Improving service quality can be achieved by recognizing the conditions and challenges faced[51]. Resolution of organizational problems can be achieved with the principles of accountability and innovation[52].

F. CSE-UCLA Evaluation Model

Each education and training institution must have the competence or ability to build human resources for the apparatus, which is realized through implementing the education and training administration system by paying attention to quality, namely input, process, and output[53]. Sustainability of expenditure is the final result of the training not ending. Education and training institutions must monitor alumni performance in the form of follow-up evaluations (post-training) to determine the effectiveness of competencies in their work units[54]. CSE-UCLA is an evaluation model that has five evaluation aspects, namely system assessment, program planning, program implementation, program improvement, and program certification[55]. The CSE-UCLA model can evaluate service programs that help human life, such as educational learning programs, banks, cooperatives, e-government, e-learning[56]. A system assessment is an evaluation that provides information about the state or position of the system[57]. Program planning is an evaluation that helps select specific programs that may be successful in meeting program needs[58]. Program Implementation is an evaluation that provides whether the program has been introduced to specific groups as planned[59]. Program Improvement is an evaluation that allows the organization to achieve specific achievements[60]. A program certification provides information about the value or use of the program [61].

III. METHOD

The implementation of this research was carried out at the Human Resources Development Agency in the Province of Bali. This research is evaluative research that aims to determine the effectiveness of the leadership training program in terms of system assessment, program planning, program implementation, program improvement, and program certification in program implementation. An explanation of the sample, evaluation model design, data collection, and analysis can be presented in this section.

A. Sample

The distribution of the population in this study is in Table I.

TABLE I. DISTRIBUTION OF THE RESEARCH POPULATION

No.	Population Source	Total (Person)
1	Head of Institution	1
2	Head and Head of Subdivision	15
3	Alumni/Mentor Supervisor	34
4	Level III Leadership Training Alumni from 5 (five) batches	147
5	Lecturer/Widyaiswara	15
6	Committee	10
Total		222

The sampling technique used in this study is a purposive random sampling technique. The considerations used in this purposive sampling are (a) the training participants are in direct contact with the committee and education staff (widyaiswara) every day during the training; (b) In carrying out their duties, the training participants also interact with the committee, widyaiswara and mentors/superiors of the training participants; (c) After sampling, the samples with the following composition were obtained in Table II.

TABLE II. RESEARCH SAMPLE

No.	Population Source	Total (Person)
1	Head of Institution	1
2	Head and Head of Subdivision	15
3	Lecturer/Widyaiswara	15
4	Executor/committee	10
5	Alumni/Mentor Supervisor	25
6	Level III leadership training participants	34
Total		100

B. Evaluation Model Design

The variables involved in this program evaluation research are the effectiveness of the leadership training program implementation as measured by the components of the system assessment, program planning, program implementation, program improvement, and program certification to measure the adaptive leadership competencies of alumni. The component of the evaluation aspect is in Table III.

TABLE III. DESIGN OF THE CSE-UCLA MODEL ON EVALUATION OF THE IMPLEMENTATION OF THE LEADERSHIP TRAINING PROGRAM

Component	Evaluation Aspect
A(System Assessment)	1. Organizational Vision and Mission and Objectives of the Implementation of Leadership training (<i>Diklatpim</i>) 2. Legal basis 3. Support from local government and stakeholders
B(Program Planning)	Readiness/ability: 1. Lecturer/Widyaiswara 2. Committee 3. Infrastructures 4. Budget
C(Program Implementation)	1. Implementation of Leadership in implementing innovation 2. Factors driving and inhibiting alumni innovation
D(Program Improvement)	1. Participants' reactions to the ability of training staff/widyaiswara, committee, infrastructure 2. Behavior of participants after returning to the work unit
E(Program Certification)	1. Adaptive leadership competence 2. Impact of organizational innovation

C. Data Collection

The instrument used is a questionnaire. Correct and representative conclusions are generated from informations that were obtained correctly, validly, and reliably. Researchers used four methods to seek information from primary and secondary data sources: education and training managers (institutional leaders, heads of divisions, sub-sectors, and teaching staff/widyaiswara) and alumni of Leadership Training. Researchers use triangulation and reference materials. Through triangulation, researchers have checked the findings of the data by comparing it with various data sources and methods as well as time. The triangulation used in this research is source triangulation and method triangulation, and time triangulation. The data used in this study is primary data which is the answers of various research respondents, namely women and men, different ages, education levels, ranks, and positions. Data collection was carried out from May to September 2021. The questionnaires were distributed through the Google form considering that when the research was implemented PPKM level.4 COVID 19 in Bali Province (Governor Regulation No.12/2021).

The data obtained in this study is numerical data through a questionnaire compiled using a Likert Scale model to measure respondents' opinions, attitudes, and perceptions regarding the effectiveness of the implementation of Leadership Training. The scoring format using a Likert scale model is in Table IV.

Data collection through questionnaires is equipped with a grid of instruments to guide the making of questionnaires, namely a questionnaire for teachers/widyaiswara, questionnaires for participants/training alumni, interview grids (leader, head/head of sub field of mentor, widyaiswara, committee and training, and education alumni), observation grids and evaluation documentation of the leadership training program implementation. Technical data collection can be demonstrated by going through the flow or framework in Fig. 1.

The mechanisms for calculating content validity using the Gregory Formula are:

- 1) Assessment of the instrument per item by using a scale, a scale of 1 – 4.
- 2) The scale is grouped. For example, a score of 1-2 is grouped to be less relevant, a score of 3-4 is grouped to be very relevant.
- 3) The results of the experts are tabulated in the form of a matrix.

TABLE IV. SCORE FORMAT IN LIKERT SCALE

Positive Statement (+)		Negative Statement (-)	
Score.1	Strongly Disagree	Score.1	Strongly Agree
Score.2	Disagree	Score.2	Agree
Score.3	Neutral/Sufficiently Agree	Score.3	Neutral/Sufficiently Agree
Score.4	Agree	Score.4	Disagree
Score.5	Strongly Agree	Score.5	Strongly Disagree

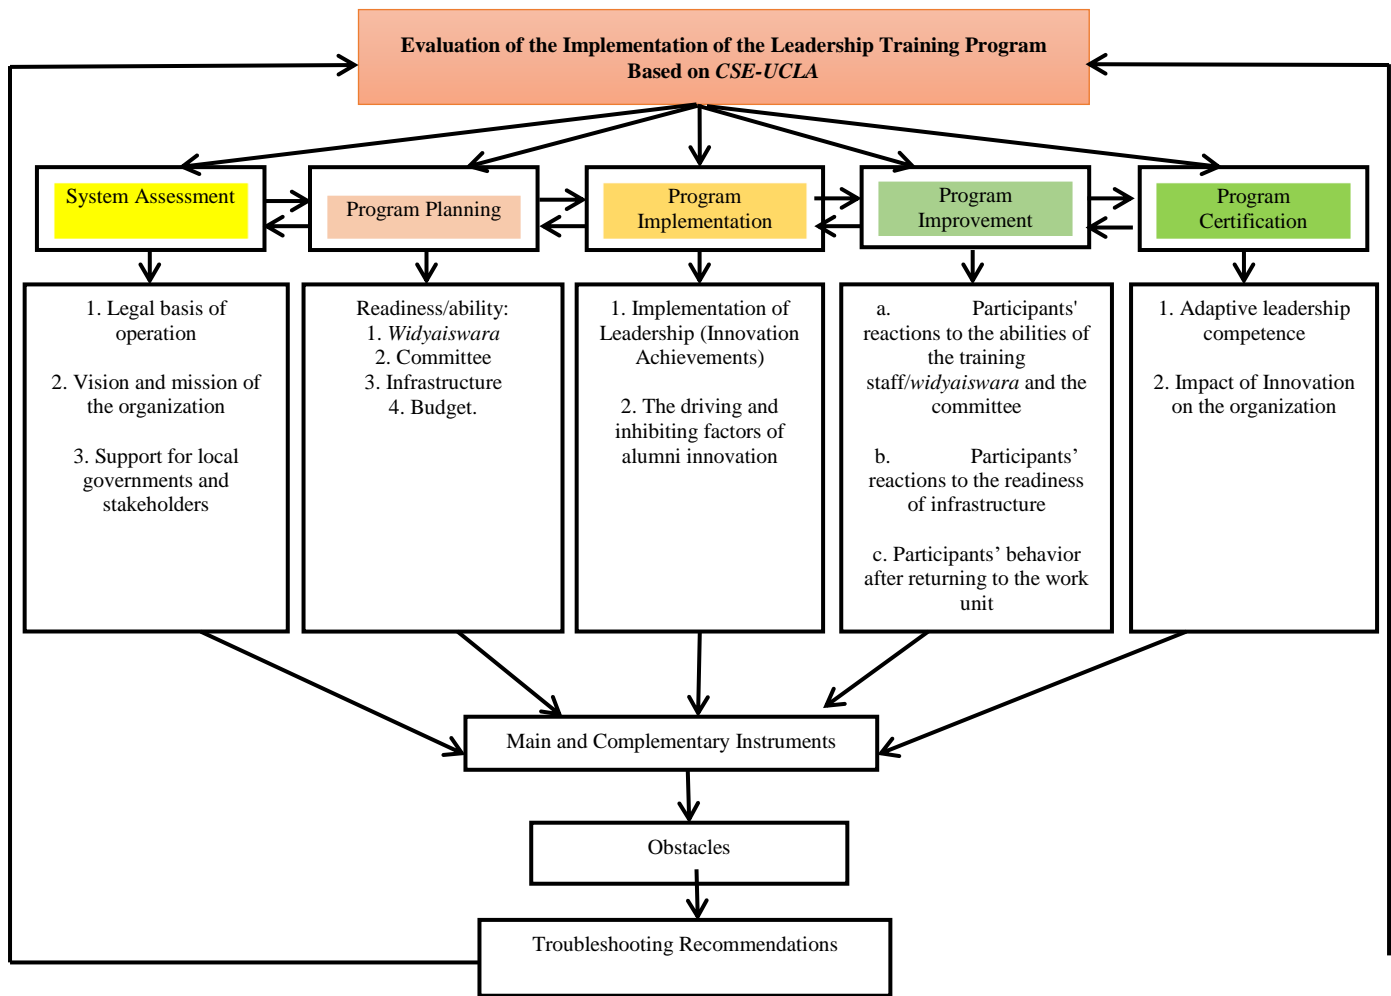

Fig. 1. Mechanism of Data Collection Evaluation of the Implementation of the CSE-UCLA-based Leadership Training Program.

4) Cross tabulation is made.

5) Content validity is calculated using the formula:

$$\text{Content validity} = \frac{D}{A+B+C+D} \quad (1)$$

Notes:

A = Disagreement between the two raters

B and C = Differences in views between raters

D = Valid agreement between the two raters

Content validity ≥ 0.60 is said to have good content validity and the test can be used in research.

For reliability, the formula used is Cronbach's Alpha as:

$$r_{11} = \left[\frac{k}{(k-1)} \right] \left(1 - \sum \frac{\sigma_b^2}{\sigma_t^2} \right) \quad (2)$$

Notes:

r_{11} = reliability,

k = number of questions,

2 = number of item variants,

t^2 = total variance.

Instrument reliability in its interpretation uses the interpretation of the correlation coefficients found to be large or small so that it can be guided by the provisions listed in the Table V [62].

By using this formula, the results of the empirical validity and reliability test are in Table VI. Based on the Table VI, it appears that the value of $r_{\text{count}} > r_{\text{critical}}$ for $n = 30 = 0.361$. Thus, all questionnaire items for the training and education alumni participants were declared valid and suitable to measure research variables. The questionnaire reliability coefficient for the training alumni participants was 0.949, with a very strong category based on the reliability calculation.

TABLE V. INSTRUMENTS' RELIABILITY

The value of r	Interpretation
0.00 – 0.199	Very low
0.20 – 0.399	Low
0.40 – 0.599	Moderate
0.60 – 0.799	Strong
0.80 – 1.000	Very strong

TABLE VI. VALIDITY AND RELIABILITY OF QUESTIONNAIRES OF THE TRAINING ALUMNI

Item Number	r _{count}	r _{critical} (n=30)	Conclusion	Reliability
1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43.	0.566; 0.571; 0.624; 0.381; 0.677; 0.626; 0.585; 0.605; 0.574; 0.659; 0.552; 0.600; 0.501; 0.589; 0.409; 0.546; 0.624; 0.381; 0.677; 0.534; 0.585; 0.605; 0.574; 0.659; 0.552; 0.614; 0.572; 0.531; 0.504; 0.749; 0.547; 0.562; 0.659; 0.529; 0.410; 0.520; 0.494; 0.481; 0.504; 0.545; 0.572; 0.562; 0.659.	0.361	Valid	0.949

Based on the Table VII, it appears that the value of $r_{count} > r_{critical}$ for $n = 30 = 0.361$. Thus, all questionnaire items for education and training teachers were declared valid and suitable to measure research variables. Based on the reliability calculation, the questionnaire reliability coefficient for education and training teachers is 0.938, with a very strong category.

TABLE VII. VALIDITY AND RELIABILITY OF THE EDUCATION AND TRAINING TEACHER QUESTIONNAIRES

Item Number	r _{count}	r _{critical} (n=30)	Conclusion	Reliability
1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45.	0.593; 0.530; 0.641; 0.503; 0.517; 0.478; 0.539; 0.641; 0.503; 0.430; 0.594; 0.527; 0.487; 0.612; 0.449; 0.663; 0.673; 0.424; 0.480; 0.497; 0.401; 0.646; 0.488; 0.405; 0.641; 0.503; 0.430; 0.594; 0.527; 0.487; 0.612; 0.449; 0.603; 0.673; 0.442; 0.394; 0.556; 0.521; 0.400; 0.401; 0.401; 0.646; 0.488; 0.552; 0.442.	0.361	Valid	0.938

D. Data Analysis Techniques

The data analysis techniques were carried out by

- 1) Distributing a questionnaire in terms of tangibles, reliability, responsiveness, assurance, and empathy;
- 2) Interviews with respondents to find out information about the leadership training program and synchronize the results of the questionnaires from the subjects studied, including the administrators of the educators themselves and the educators;
- 3) Observations are carried out to find out whether the implementation of the training seen from the observed aspects have been supported by authentic documents which are the legal basis for post-training implementation and to determine the effectiveness of the leadership training program in terms of aspects of system assessment, program planning, program implementation, program improvement, and program certification in the implementation of leadership training;
- 4) Documentation is related to the object of research and the program implementation.

Data analysis on the five CSE-UCLA Aspects was carried out quantitatively and qualitatively. Analysis of data on the evaluation of the implementation of the Leadership Training program in terms of the Aspects of the system assessment program planning, program implementation, program improvement, program certification using quantitative descriptive analysis measuring tools. For the constraints found in implementing this program using a qualitative descriptive analysis, primary and secondary data analysis was carried out in the data analysis stage. Primary data analysis includes:

Calculates the average score obtained in each evaluation and converts it into classifications and categories using a five scale based on the ideal mean (Mi) and ideal standard deviation (SDi), with the formula:

$$M_i = \frac{1}{2} (\text{ideal maximum value} + \text{ideal minimum value}) \quad (3)$$

$$SD_i = \frac{1}{6} (\text{ideal maximum value} - \text{ideal minimum value}) \quad (4)$$

The categorization of scores was determined by the three categories in Table VIII.

TABLE VIII. CATEGORIZATION OF SCORES IN THREE CATEGORIES USING IDEAL VALUES

Score categorization	Information
$(M_i) < \bar{X} \leq (M_i + 1.5SD_i)$	High
$(M_i - 1.5SD_i) < \bar{X} \leq (M_i)$	Enough
$\bar{X} \leq (M_i - 1.5SD_i)$	Less

Calculate the score obtained into the standard score (z score) with the formula.

$$z = \frac{x - \bar{X}}{SD} \quad (5)$$

z = Standard score

- X = raw score obtained by respondents
- \bar{X} = mean/mean
- SD = standard deviation/standard deviation

Change the standard Z-score into a T-Score with the formula:

$$T\text{-score} = (Z\text{-score} * 10) + 50 \quad (6)$$

Notes:

$T \geq 50$ Aspect value is high which is symbolized by H (Height)

$T < 50$ Aspect value is low which is symbolized by L (Low)

If 50 is a constant number which is the average limit of the normal curve that moves from 20 to 80 with six standard deviation values where one standard deviation of the value is 10.

Interpreting the T-Score of each Aspect into the Glickman Quadrant implementation level category is shown in Table IX.

TABLE IX. EFFECTIVENESS OF IMPLEMENTING A PROGRAM IN ALL ASPECTS OF CSE-UCLA FOLLOWING THE GLICKMAN PATTERN

Effective					Excellence				
A	B	C	D	E	A	B	C	D	E
H	H	H	H	L	H	H	H	H	H
H	H	H	L	H					
H	H	L	H	H					
H	L	H	H	H					
L	H	H	H	H					
Poor					Less				
A	B	C	D	E	A	B	C	D	E
L	L	L	L	L	H	L	L	L	L
					L	H	L	L	L
					L	L	H	L	L
					L	L	L	H	L
					L	L	L	L	H
					H	L	L	L	L
					L	L	H	L	L
					L	H	H	H	L
					L	H	L	H	H
					H	H	L	L	H
					L	H	L	H	L
					L	L	H	L	H
					H	L	H	L	L

To determine the effectiveness of a program or activity, the following classification is determined[63]:

Notes:

Excellence: If all five Aspects/variables are of high value (H)

Effective: If four of the five Aspects/variables are of high value (H)

Less : If one or two of the five Aspects/variables are of high value (H)

Poor : If all five Aspects/variables are low value (L)

Secondary data analysis includes: confirming the results of tabulation of primary data with data obtained through triangulation data collection techniques, namely interviews, observations, and cross-check documentation of the tabulation of the data obtained. They discussed and concluded things that resulted in an overview of the effectiveness of the implementation of the Level III Leadership Training program at BPSDM Bali Province in terms of the Aspects of the System Assessment, Program Planning, Program Implementation, Program Improvement, and Program Certification.

The data analyzed qualitatively include data obtained from interviews and observations or document studies. Furthermore, the validity of the data can also be checked. The data analysis technique, according to Sugiyono, follows the steps: data reduction, data display/data presentation, conclusion/verification[62]. Qualitative data validity test in qualitative research includes credibility, transferability, dependability, and confirmability tests.

IV. RESULT

Measurement of success is based on the interpretation of measurement behaviour that can describe the degree of quality and quantity and the existence of program implementation. However, the measurement results cannot be used as a reference for decision-making from quality and quantity if they do not have a comparison with a reference or comparison material. This research produces information about the effectiveness of the leadership training program in terms of system assessment, program planning, program implementation, program improvement, and program certification in program implementation.

A. Quantitative

Description of the quality of Leadership Training and Education data from the assessment of Teachers/Widyaiswara is shown in Table X. It can be concluded that it is univariate (analysis used on one variable to know and identify the characteristics of the variable). The tendency of scores in the description of the leadership training program is based on the data description and ideal score criteria. The determination of the ideal score criteria uses the ideal mean (Mi) and the ideal standard deviation (SDi) as a comparison to determine the score seen from the A-B-C-D-E (AP4) aspect. Table X, in general (average) the quality of the leadership training program on the AP4 aspect of the teacher/Widyaiswara assessment is good, namely 83.48%.

TABLE X. DESCRIPTION OF THE QUALITY SCORE OF LEADERSHIP TRAINING ON THE AP4 ASPECT OF THE TEACHER/WIDYAISWARA ASSESSMENT

The Calculation Results		Aspect					Implementation(AP4)
		A	B	C	D	E	
1	$\sum X$	61.87	64.9	62.11	62.5	62.25	312.96
2	N	15	15	15	15	15	15
3	M	4.12	4.32	4.14	4.16	4.15	-

8	Max	5	5	5	5	5	-
9	Min	2	2	1	3	3	-
10	Category	Good	Excellence	Excellence	Enough	Enough	

Data analysis using the Glickman Formula about the quality of the leadership training program obtained in this study was transformed into a T-score. Based on the data described on the quality of implementing the leadership training program for teachers/widyaiswara in terms of the CSE – UCLA Evaluation Model, it is summarized in the following Table XI. The quality of the Leadership Training Program Implementation for Teachers/Widyaiswara is categorized as Effective.

Quality results of implementation of leadership training programs for teachers/widyaiswara in view from the CSE-UCLA evaluation model using the Glickman formula can be seen visually in Fig. 2.

Description of leadership training quality data from the assessment of training alumni participants can be seen in Table XII. In general (on average), the quality of the leadership training program on the AP4 aspect of the assessment of the training alumni participants is very good, namely 90.72%.

TABLE XI. SUMMARY OF QUALITY RESULTS THE IMPLEMENTATION OF LEADERSHIP TRAINING PROGRAMS FOR TEACHERS/WIDYAISWARA IN VIEW FROM THE CSE-UCLA EVALUATION MODEL

Aspect		Frequency			Information
		High	Low	Results	
1	<i>A(System Assessment)</i>	5	10	Low	L
2	<i>B (Program Planning)</i>	8	7	High	H
3	<i>C(Program Implementation)</i>	8	7	High	H

Based on the Table XIII, the quality of the leadership training program implementation for alumni training participants is categorized as Effective.

TABLE XIII. SUMMARY OF QUALITY RESULTS OF LEADERSHIP TRAINING PROGRAM IMPLEMENTATION FOR ALUMNI TRAINING PARTICIPANTS VIEWED FROM THE CSE-UCLA EVALUATION MODEL

Aspect	Frequency			Information
	High	Low	Results	
1 A(System Assessment)	32	18	High	H
2 B (Program Planning)	29	21	High	H
3 C(Program Implementation)	24	26	Low	L
4 D(Program Improvement)	35	15	High	H
5 E(Program Certification)	33	17	High	H

Notes:
L:Low
H:High

B. Qualitative

Description of Leadership Training quality data from the evaluation of the Committee, Teachers/Widyaiswara and alumni are presented in every aspect.

1) *Implementation effectiveness of leadership training program on the system assessment aspect:* I Nyoman Mariada said that the Human Resources Development Agency (BPSDM) of the Province of Bali as the center of excellence in developing the competence of SCA in the Province of Bali in supporting motto of Bali Government “Nangun Sat Kerthi Loka Bali” through a universally planned development pattern. The vision, mission and goals of BPSDM Bali support

the creation of the sanctity and harmony of Bali’s nature and its contents, to realize a prosperous and happy Balinese life with Trisakti Bung Karno principles (political sovereignty, economically dedicated, and culturally personal) through patterned development, comprehensive, planned, directed and integrated within the framework of the Unitary State of the Republic of Indonesia based on the values of Pancasila.

“The objective of *BPSDM* is to create professional and competent apparatus resources as stated in the strategic plan. The goal of this is to produce change leaders who are able to analyze and solve problems in their institutions in the form of innovations/change projects.”

Interview with Widyaiswara, I Made Sedana Yoga

“As a teacher, he is not directly involved in formulating and disseminating the vision, mission and objectives of the leadership training program implementation, but in general it is quite good. We strongly support this vision and mission and the programs it supports. So even though we are not directly involved in its formulation, we can see and judge, so far it has been a visionary.”

Interview with Widyaiswara, Dewa Ketut Winanda

Administratively, participants who wish to participate in leadership training at least have sat at the administrator level or supervisor level planned for promotion to administrator. They must also pass the selection and meet the portfolio and maximum age requirements. If this administrative selection passes, we can continue to participate and we will provide guidance according to the rules.”

Interview with Widyaiswara, I Made Gede Partha Kesuma

Administration standards are set as requirements and based on regulations from the center. The aim is to ensure that participants who take part in the training are individuals who have qualified and are able to become leaders for their respective institutions. Based on the results of interviews from several respondents from *widyaiswara* at *BPSDM* Bali, it can be seen that in organizing a program, an institution must have a clear vision, mission and goals.

2) *Implementation effectiveness of the leadership training program on the program planning aspect:* Widyaiswara’s readiness to teach is one of the keys to the success of implementing Leadership Training level III at the Bali Province BPSDM, so that the institution strives to continue to improve the competence and readiness of *widyaiswara* to be able to control and bring education and training towards the vision, mission and goals of the institution. As an effort to improve the competence of *widyaiswara*, BPSDM Bali Province must take an evaluation step to find out how the *widyaiswara*’s ability when teaching.

“For the purposes of improving the competence of *widyaiswara*, we routinely carry out performance evaluations during teaching. The main source on which we base our evaluation is using a questionnaire from the training participants. From the questionnaire, we will do a mapping in each aspect. Because from the questionnaire the answers are

usually mixed and subjective, we cannot immediately conclude from the results of the questionnaire, but also with other analyzes and considerations. Anyway, until later, we will generalize what needs to be evaluated.”

Interview with the Head of Sub Division of Core Technical Competency Development for Administration, Ni Ketut Suwardhyaksadewi

Facilities and infrastructure for the implementation of Level III Leadership Training at the Bali Province BPSDM have been well prepared before the program runs. So far, the Bali Province BPSDM has succeeded in facilitating all the needs of the Leadership Training and ensuring that both widyaiswara and training participants receive proper and functioning teaching and learning facilities.

“We can make sure that the infrastructure here is adequate and complete for the continuity of the education and training. And this is proven by the Pim III Education and Training having the A accreditation predicate, where one of the assessments to get A Accreditation is the availability of training infrastructure according to standards. So we are also grateful with all these facilities, we have succeeded in maintaining the quality standards of the education and training, we are also sure that from here the vision, mission and goals of the institution can be realized.”

Interview with Head of Sub Division of Learning Resources Management and Cooperation, Ni Putu Massuli Adi

3) *Implementation effectiveness of leadership training program on program implementation aspect:* The output of the implementation of leadership training is innovation in the form of change projects. The sustainability of the change (innovation) project for training participants is very important because there are still several milestones or goals in the change project that have not been achieved. This failure can usually be analyzed through the identification of the inhibiting factors.

“Actually, we already have innovation ideas for our institution. After participating in the training, we can also be strengthened about these innovations. However, conditions in the field sometimes hinder its realization, as in our opinion the most hindering is the hectic volume of work, even when on campus you still have to do office work, plus the number of staff is very minimal.”

Interview with Alumni of Training Participants, I Made Toya Arnawa

After the implementation of the Leadership Training, participants received reinforcement to implement change (innovation) projects at their respective home institutions. However, conditions in the field often create obstacles that complicate the realization of innovation in institutions. This is also similar to what was conveyed by other alumni of the training participants.

“After the training, we are enthusiastic to innovate, as if we have a lot of innovations that we can apply in institutions. We also get good ideas from mentors and widyaiswara. It’s

great if they are implemented. But indeed when we meet the facts on the ground, there are some obstacles. What we feel the most here is the lack of support, especially the support from the community.”

Interview with Alumni Training Participants, Ni Nyoman Sri Rahayu

The change (innovation) project is carried out in the institution under the guidance of a mentor. Mentors are direct supervisors of participants who have competence in providing support, guidance and input to participants to carry out change projects. During the formulation and implementation of the change project, the training participants must coordinate regularly with their respective mentors so that the innovations carried out are on target according to the initial design.

“The presence of a mentor here is very important, because sometimes we like to improvise when we innovate. Trying outside of the previous plan, so if it is not coordinated with the mentor, it may not be right on target. So we do continue to coordinate, discuss the concepts and technicalities, if there are obstacles, what are the solutions. Coordination with our mentor is quite good but the problem is that he has retired from duty but his successor is also very supportive until we can continue the realization of my change project.”

Interview with Alumni Training Participants, Ni Nyoman Sri Rahayu

4) *Implementation effectiveness of leadership training program on program improvement aspect:* Widyaiswara has been prepared by the institution to be able to teach the material in depth with a fun andragogy method. Mastery of the material from widyaiswara becomes one of the modalities of the successful implementation of Leadership Training. This widyaiswara readiness was also felt by other alumni of the training participants.

“There are some who have good quality both in terms of mastery of the material and the ability to distribute it to participants. Some may master the material, but for me it is not suitable in delivery so that it becomes less enthusiastic. But those whose names are teachers already understand that they have their own teaching styles. It may be suitable for me but not necessarily for others. But if you want to be objective in terms of mastery of the material, the widyaiswara at BPSDM have mastered it very well, so we can take a lot of knowledge.”

Interview with Alumni of Training Participants, I Made Toya Arnawa

The effectiveness of the implementation of the Level III Leadership Training program at BPSDM Bali Province in terms of the aspect of the program improvement can also be seen from the behavior of participants after returning to the work unit. Training can be said to be successful if it is able to provide positive changes to the training participants, both academically and non-academically.

“It is undeniable that we have gained a lot of knowledge from this leadership training. We share this knowledge with our colleagues at the institution, so that the benefits are not

only for us, but also for many people. On the other hand, what we get from the training we convey so that they understand and help carry out their duties responsibly. Because if we already know, then we can start and invite others. That's the principle."

Interview with Alumni Training Participants, Ni Wayan Vijayanthi Sari

Training participants gain new knowledge and experience to form problem-solving skills. Experience is gained mainly through change projects that bring participants face to face with various impediments to the implementation of ideas that need to be resolved. This is in accordance with the objectives of the innovation program (change project), where prospective change leaders (leadership training participants) at various levels are required to be able to identify and solve technical and adaptive problems.

"Personally, I feel that after participating in the leadership training, we know better how to deal with and overcome the problems that exist in the institution. After completing the training, the ability to solve problems faced in the work unit is more structured. We have the knowledge to be more observant to see what is behind the problem. Previously, we only knew that there was a problem, but we didn't really know what caused the problem, so it couldn't be solved. With this training, we can better understand how to deal with it all."

Interview with Alumni Training Participants, Ni Nyoman Sri Rahayu

5) *Implementation effectiveness of leadership training program on program certification aspect:* The results of this data analysis are also supported by interviews with alumni of the training participants regarding the participants' adaptive leadership competencies and the impact of organizational innovation after participating in the Leadership Training program. The main goal of Leadership Training is to produce visionary, innovative and creative leaders. These competencies are part of the character of adaptive leaders (adaptive leadership). Adaptive leadership after attending Leadership Training can be seen from the aspect of innovation replication and the ability to encourage the growth of a culture of innovation in the employees/staff of the training participants.

"Innovation replication that can be applied in work units by training participants will definitely be implemented. We learn a lot from mentors, as well as from other friends. There we observe the ideas that arise, if there are any that fit or approach the needs of the organization/work unit. Because innovation must look at the problems that exist in the organizational unit, so we don't just formulate the innovation. There are many considerations, and mentors are always accompanied."

Interview with Alumni Training Participants, Ni Nyoman Sri Rahayu

The increased performance of the Leadership Training participants is the result of an understanding of the main tasks and functions, as well as the inculcation of an attitude of

integrity from students. Leadership Training in addition to providing knowledge and experience, also fosters the fundamental values of a leader who has great responsibility in moving the wheels of the organization.

"The most important impact after participating in this leadership training is actually an increase in performance. Because performance is measurable in nature, before and after participating in the training, it can definitely be assessed if it is a performance problem. Frankly, our performance has increased, but whether it is significant or not, it goes back to the acceptance of each participant. But generally it increases. Because of that, we focus on receiving knowledge, we are given skills, experience. It all goes to the end of the performance improvement. Alumni performance is further improved because they get new knowledge during training that can be applied in work units."

Interview with Alumni Training Participants, Ni Nyoman Sri Rahayu

V. DISCUSSION

Based on data analyzed using system assessment aspects, program planning, program implementation, program improvement, and program certification, the implementation of the program from the teacher/widyaiswara assessment and alumni assessment is good. In the following, each aspect of AP4 is described and explained.

A. System Assessment

Aspects of the system assessment in Table X (assessment of teachers/widyaiswara) obtained 82.4% in the good category and the mean value of 4.12 in the good category. The data in Table XI (alumni assessment) scores 91.8% in the very good category, and the mean is 4.59 in the very good category. The concept of leadership is generally interpreted as a critical aspect in determining the success of an organization because leadership plays an essential role in the management of employees. The organization helps to maximize their efficiency (producing the most output with the minor input) and effectiveness to achieve their organizational goals[64]. The quality of the education and training program implementation is viewed from the vision and mission of the organization. The quality supported The objectives of implementing the education and training, the legal basis, and support from the local government and stakeholders. The vision, mission, and objectives of the leadership training program are following the direction of the institution's ideals and qualitative data analysis. Guided by a clear vision and mission and measurable goals, leadership training can run in a structured and systematic way for good development[28]. The widyaiswara interview on aspects of the system assessment shows that the compatibility between the vision, mission, and program objectives is structured based on the sanctity and harmony of nature, which creates a prosperous life. The formation of the vision, mission, and objectives is expected to produce good quality leaders and training programs. Therefore, the suitability of the leadership training's vision, mission, and objectives with the interview results of the training shows success for the further development of the training.

B. Program Planning

The aspect of program planning in Table X (assessment of teachers/widyaiswara) scores 86.4% in the very good category, and the mean is 4.32 in the very good category. For the data in Table XI (alumni assessment), the score is 89.6% in the very good category, and the mean is 4.48 in the very good category. Leadership training aims to develop apparatus resources regarding administrative skills, management (leadership), and leadership competencies[65]. The quality of the training program implementation is from the aspect of the planning program, the readiness/ability of the widyaiswara, the readiness/ability of the committee, the readiness of infrastructure, and budget readiness. The results of the qualitative data analysis show that the organizational structure of the Bali BPSDM has been structured and systematic. All teachers/widyaiswara have competence and quality in teaching. The facilities and infrastructure for implementing the Leadership Training of the Bali Province Human Resources Development Agency have been prepared well before the program runs. Level III Leadership Training and Education of the Bali Province Human Resources Development Agency also received an A accreditation rating, indicating that the implementation of the Level III Leadership Training Program, especially in the program planning component, has been running effectively[66]. The results of interviews with the head of the sub-sector on program planning indicate that forming an organizational structure in structured and systematic leadership training can help carry out organizational functions properly. Structured and systematic conditions make an enormous scope of work divided into small ones. The suitability of the institution's role with minor aspects will focus on performance. It can support the implementation of the vision, mission, and goals according to the aspect or field of expertise. This success and effectiveness make an excellent forum for implementing leadership training.

C. Program Implementation

Aspects of program implementation in Table X (assessment of teachers/widyaiswara) scored 82.8% in the very good category, and the mean value was 4.14 in the good category. For the data in Table XI (alumni assessment), the score is 88.8% in the very good category, and the mean is 4.44 in the very good category. The education and training program's quality support implementing innovation and the factors driving and inhibiting alumni innovation[67]. Qualitative data regarding the project also support the results of this data analysis. Changes (innovations) that can be implemented after attending the training Sustainability of innovation/alumni change projects can be used as a benchmark for improving agencies' performance in organizational units. The performance has succeeded in facilitating and guiding training participants to implement change projects at their respective home institutions. The realization of the change project encourages these new ideas to be realized[68]. The results of interviews with alumni of training participants on the program implementation aspect show that the implementation of sustainable innovation/projects is carried out in each institution because of the incompatibility of the education system, training implementation. This discrepancy is in implementing projects

that do not run optimally, such as doing office assignments during teaching activities on campus and coupled with minimal staff. The implementation of innovation development in each institution becomes an effective way. Implementing innovation development at each institution will not succeed optimally without guidance. In implementing this training, a mentor or mentor is presented from the participant's direct supervisor who has competence in providing support, guidance, and input in terms of innovation/project changes. The mentor system will support the effective implementation of the training following the expected goals.

D. Program Improvement

The aspect of the program improvement in Table X (assessment of teachers/widyaiswara) obtained a score of 83.2% in the good category and a mean value of 4.16 in the good category. For the data in Table XI (alumni assessment), the score is 92% in the very good category, and the mean is 4.6 in the very good category. The quality of the training program implementation gets from participants' reactions to the abilities of teachers/widyaiswara and committees, participants' reactions to the readiness of infrastructure, and participant behavior after returning to the work unit. Qualitative data analysis also shows that training participants gain new knowledge, experience, and skills to transform into adaptive leaders. This training program can support sustainability in developing new technologies and innovations[69]. These results indicate that the Level III Leadership Training of the Bali Province Human Resources Development Agency regarding the program improvement components has been running effectively. Aspects of program improvement can identify the causes of problems and formulate solutions to be said to be effective[70]. The results of interviews with alumni of the training participants on the aspect of the program improvement. The interview indicates that the accuracy of the objectives of the training and the process of developing the participants' leadership competencies is not always successful because the system has been structured. The aim of the training will show its success in the competencies possessed by each participant who has different thoughts and abilities. The training and education executive committee has prepared the program very well. The established program is to develop a coordination system for each participant to build good knowledge related to administrative and technical processes and infrastructure. Therefore, through a coordination system such as asking questions related to the development of education and training between participants, it makes it easy for participants to develop leadership competencies.

E. Program Certification

Aspects of the program certification in Table X (assessment of teachers/widyaiswara) obtained 83% with a fairly good category and a mean value of 4.15 in a good category. For the data in Table XI (alumni assessment), the score is 91.4% in the very good category, and the mean is 4.57 in the very good category. The quality of the implementation of the training program is viewed from the aspect of the adaptive leadership competency program certification and the impact of organizational innovation. The education and training evaluation results will be significant and influential

feedback in improving the quality of education and training and maintaining the sustainability of the education and training organization. The product of a training process is in the form of outputs or alumni of training participants, while further product benefits are in the form of outcome, namely how the influence of training on motivation which in turn has an impact on the actual performance of a training participant in its implementation[71]. Qualitative data analysis also shows a positive change in the behavior of the participants and an increase in the performance of the training so that in terms of the program certification component, the Level III Leadership Training and Development Agency of the Bali Province Human Resources Development Agency has been running effectively. This program can direct the leadership system to experience the development of organizational innovation[72]. The results of interviews with alumni of training participants on aspects of program improvement show that the program certification makes training participants have leadership competencies and has a good impact on organizational innovation. This success is the primary goal of implementing training that follows the character part of an adaptive leader. It can be said that the training participants who have carried out the training in a gradual and structured manner can encourage the growth of a culture of innovation in the employees/staff of the training participants. The education and training program, in general, has succeeded in encouraging training participants to play a role in cultivating innovation in their respective work units.

The results of research on all aspects of the system assessment, program planning, program implementation, program improvement, and program certification show that the implementation of leadership training can support the formation of the character of professional and integrity bureaucrats. Thus, training alumni can internalize the fundamental values of state civil apparatus SCA and the growth of high public ethics and do not stop at building competencies as has been going on so far but can produce leaders and change agents. The novelty of this program is that the development of Management knowledge with the CORPU (Corporate University) approach is a strategy in developing SCA competencies. Managerial competencies, technical competencies, and socio-cultural competencies to realize SMART SCA 2024 and world-class bureaucracy 2025 through independent learning and learning through coaching and mentoring. The CSE-UCLA model used in this study is considered to evaluate leadership training education programs[73]. The CSE-UCLA evaluation model has advantages that other evaluation models do not have, namely the program implementation stage, which can introduce the existence of the program being evaluated and the sustainability of the impact of an educational program[74]. This program can encourage training participants to innovate and is expected to transmit culture to innovate in their work environment.

VI. CONCLUSION

Based on the research findings and the results of data analysis, conclusions can be drawn about the effectiveness of the implementation of the leadership training program in terms of the components of the system assessment, program

planning, program implementation, program improvement, and program certification. The components in the entire system reach a minimum of good categories according to the assessment of the widyaswara and training alumni participants. The system assessment is running effectively with the support of the organization's vision and mission, the objectives of the education and training implementation, the legal basis, the support of the local government and stakeholders. Program planning is running effectively with structured and systematic support for widyaswara competencies, facilities, and infrastructure for the implementation of leadership training well prepared before the program runs. Program implementation runs effectively with the support of leadership implementation in carrying out innovations and the driving factors for the sustainability of alumni innovation. The program improvement is running effectively with the result that the training participants gain a lot of new knowledge, experience, and skills to transform into adaptive leadership in developing innovations.

VII. RECOMMENDATION

This research can provide recommendations for human resource development agencies to be responsible for preparing widyaiswara and leadership training program committees to have academic qualifications, competencies, and certifications to participate in the training program. Acceleration needs to be done to include managers who have not received MOT (Management of Training) training so that the quality of training management can be improved and the knowledge and skills of managers can be better. The purpose of organizing leadership training is to provide knowledge, skills, and attitudes in apparatus leadership. The human resource development agency needs to improve the development of knowledge management and the learning process by all organization members in identifying, creating, and distributing knowledge. The education and training program can be an alternative to encourage improvement in the implementation of the integrity zone and efforts to accelerate towards a corruption-free area. The CSE-UCLA model in this study has the advantage of measuring various aspects of the effectiveness of achieving the goals of the Level III Leadership Training Program. CSE-UCLA is related to the success of the decision-making process, and stages of the activities carried out. Furthermore, the CSE-UCLA evaluation model has advantages that other evaluation models do not have, namely the Implementation program stage, which can introduce the existence of the program being evaluated and the sustainability of the impact of a Leadership Training Program.

VIII. LIMITATIONS

In the context of management training, this research aims to evaluate the implementation and achievement of the goals and objectives of the Level III Leadership Training program. This research is needed in order to improve the quality of the implementation of the Level III Leadership Training program at BPSDM Bali Province. Implementation of evaluation through a series of interrelated processes to collect, analyze and report data is the focus of this research. The scope of the research is limited to research on the results of the implementation of the Level III leadership training program

with the sub-focus setting on five Aspects of the CSE-UCLA model at the Level III Leadership Training in 2019. The implementation of the CSE-UCLA Model in this training has limited program success, namely widyaiswara as a measure of success. The evaluator's task is more challenging, and he must be sensitive and have much dialogue. The evaluator became a living instrument before the evaluation criteria and tools were developed.

Rule-based Text Extraction for Multimodal Knowledge Graph

Idza Aisara Norabid, Fariza Fauzi
Faculty of Information Science and Technology
Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia

Abstract—Textual information is widely integrated in visual tasks such as object/scene detection and image annotation. However, the textual information is not fully exploited, overlooking the wide background knowledge available for Web images. This work proposes a multimodal knowledge graph (KG) to represent the knowledge extracted from unstructured Web image surrounding text and to integrate the relationship between image and text entities. Existing multimodal KG works have mainly focused on advanced visual processes for extracting entities and relations from images, and only employed standard text processing techniques such as tokenization, stop word removal, and part-of-speech (POS) tagging to capture nouns only or basic subject-verb-object from text in the semantic enrichment process. Adversely, neglecting other rich information in the text. Thus, the proposed approach attempts to address this as an automatic relation extraction (RE) problem to extract all possible triples from the text information from simple to complex sentences, in constructing the multimodal KG which eventually can be used as a training seed for visual tasks. A linguistic analysis is performed on a set of Web news articles consisting of news images and their related text. The dependency relations and POS information obtained are used to formulate a set of domain-agnostic entity-relation extraction rules. A triple extractor incorporating these rules, is developed to extract the triples from a news articles dataset and construct the proposed MKG. The Precision and Recall metrics are used to evaluate the extractor's performance. The evaluation results show that the proposed approach can extract entities and relations in the dataset with the precision score of 0.90 and recall score of 0.60. While the results are promising, the extraction rules can still be improved to capture all the knowledge.

Keywords—Relation extraction; knowledge graph; multimodal knowledge graph; dependency relations; object/scene detection

I. INTRODUCTION

The web consists of valuable images with surrounding textual information (also referred to as contextual information) that have been used in various computer vision tasks such as object/scene detection, image annotation, image clustering, image understanding, etc. This information is in which the surrounding texts are related to the image, rich in high-level semantic concepts and contains both direct and indirect information about the image [1-2].

While contextual information has been long used to improve computer vision task performance, there is still opportunity for improvement. According to [3], there is a gap between textual and visual analysis for image understanding. Existing algorithms, such as deep neural networks, mainly

focus on specific features in the image itself, typically ignoring the extensive background knowledge of the real world [4] that can be found in the contextual information.

In [3], [5] and [6], both visual and text are merged in the analysis for object detection and image retrieval, but these works focused more on the visual part rather than the text. The descriptions used are obtained from expert, hence, the image-text correlation is very high, however annotations from experts have the disadvantage of being time consuming and also expensive.

Many textual descriptions contain extensive background knowledge especially in news articles and blogs. The news carries variety of domain such as sport, education, entertainment and more. This implies that the knowledge is not restricted to a single area, but rather covers a broad range of topics. Hollink et al. [7] also states that news articles have a natural relationship between text and images. Works of [7] and [8] have proven the importance of images to be in their natural textual context, where they created corpus from online news articles. Typically, a news article will include a headline, the article and an image (or more) that is relevant to the news. Also, the image comes with a description (i.e., caption), where the description serves as context for the image and provides knowledge about it. By simply looking at the image, one may not fully comprehend the scene depicted. The thorough explanation of the scene is given in the description as well as in the headline and article, as illustrated in Fig. 1. Compared to manual captions from MSCOCO dataset in Fig. 2, the texts in these news articles are rich with high-level knowledge (abstract rather than object-level semantics), relevant to the article images, and readily available.

Fig. 2. A Sample Image and its Captions from MSCOCO.

If the background knowledge in the Web news articles can be acquired in a structured manner, then a knowledge base can be generated, which can then be applied in visual tasks. Pan et al. [9] worked on methods that can improve the task of question answering (QA) and similarly, Wu et al. [10] proposed method to improve performance for answering visual questions. Both studies prove that it is important to incorporate external knowledge into machines to propose how humans handle such tasks. However, this vast knowledge that relates to the images is in the unstructured textual form. Thus, the suitable technique for extracting knowledge in a more structured way from large amounts of text and images and for describing the diversity of entities and concepts that exist in the real-world is required.

Li et al. [11] propose knowledge graph to learn knowledge for social image understanding. Knowledge graphs (KG) have long been used to represent knowledge and real-world events as graphs with nodes (entities), edges (relations) and labels. A KG is a data structure capable of capturing real-world concepts/entities and their relationships from unstructured text, transforming them into a structured graph. It reveals relationships between entities found in the text. Two entities and the relation between them are called triple (i.e., the basic building block for KG).

Gong and Wang [12] have produced a KG in their work where the graph is a multimodal KG (i.e., a KG consisting of text and images). The method used still has room for improvement as it only captures nouns or noun phrases, ignoring other rich information such as the verbs or the adjectives that explain about the image, hence, not fully utilizing the vast image background knowledge that can be acquired from the unstructured text.

To build a KG from text, the task of relation extraction (RE) is applied to extract the relationship. The development of this relation extraction algorithm has several techniques. The two general categories are rule-based and machine learning-based [13]. Rule-based relation extraction is performed by using linguistic knowledge and domain knowledge to build pattern based on words, parts of speech (part-of-speech) or semantics in collaboration with domain experts and then the

relationship is extracted according to the set of rules. Several works have used this approach in achieving their objectives [14,15,16].

Next, machine learning-based relation extraction methods use large amounts of labeled data for training and have shown good results in some instances [13]. There are also several open-source information extraction systems that use this approach such as NELL [17] and OLLIE [18]. However, problems can arise, such as lack of training data and poor generalized performance. Thus, a rule-based relation extraction is the best option for extracting relationships as it does not require prior training data and the set rules will extract a more overall result.

In conclusion, the issues discovered are that unstructured background knowledge (text) needs to be organized in a structured way while still maintaining the natural image-text relationship found in news articles. Second, the use of simple text (nouns) in the construction of multimodal knowledge graphs causes the overlook of other rich information available from the text. Therefore, the aim of this work is to build a multimodal knowledge graph by using the images accompanied by textual information in news articles, as well as linguistic-based relation extraction techniques to overcome the stated problems.

This paper contributes to the development of a set of rules for extracting entities and relationships from text and image in news articles. The rules are based on linguistic analysis of simple to complex sentences, factoring in the image from the news article. Grammar dependency relationships are utilized as they are syntactic rather than semantic, and thus, not restricted to any domain, and relationship between words is preserved as well. In addition, two new rules are introduced to preserve the inherent relation between the news image and text. A triple extractor is implemented using these rules. The resultant extracted triples are then used to construct a multimodal KG that represents the news image and its background knowledge, where the main entities and their relationships are clearly illustrated.

This paper is divided into several sections. Section 2 highlights issues related to multimodal KG and current linguistic-based relation extraction techniques. Section 3 discusses in depth the proposed framework to build the multimodal KG automatically from a corpus of news articles. The framework consists of three main phases: Phase 1: Pre-process datasets, Phase 2: Extract entities and relationships, and Phase 3: Build a multimodal KG. The triple extractor which produced the multimodal KG that describes the relationship between texts and images is evaluated based on precision and recall metrics and the findings are shown and discussed in Section 4 and finally, Section 5 concludes this paper.

II. RELATED WORK

This section provides an overview of KG and multimodal KG, with a focus on how text are processed and used in building multimodal KG as well as relation extraction (RE) techniques specifically the rule-based approach and dependency relationships.

A. Multimodal Knowledge Graphs (KG)

A knowledge graph (KG) is a directed labelled graph consisting of nodes and edges. Nodes are real-world concepts and apart from text, images can also be used as nodes. Edge connects a pair of nodes and shows the relationship between nodes [19]. Nodes can also be known as entities and the edges that connect these two entities are known as relations or relationships. Two entities and the relation between them are referred to as a triple, which are the basic building block for KG. Many existing KGs have been built such as Google Knowledge Graph, DBPedia, Wordnet, ConceptNet. These existing graphs have been used in many real-world applications including computer vision tasks such as object detection, visual question answering tasks, image classification and more.

Wu et al. [20] have built a KG from text in news articles. Since this work focuses on summarize output, the resulting graph is a summary KG even though the original input is a long sentence. The essence of the sentence has been captured; however, it may not capture other information found in a long sentence. For example, given the following two sentences:

“Two more young black men join in the beating, which is caught on cameras.”

“Two men who are young black and join fight.”

The first sentence is the original long input sentence which is summarized to the second shorter input text. Triples from the summarized sentences are used to build the KG. Hence, in the example, the output does not capture the phrase “caught on cameras” which can also be the entity and relation for another triple. In another example, “Alice and Bob took the train to visit the zoo. They saw a baby giraffe, a lion, and a flock of colorful tropical birds.” is summarized to “Alice and Bob visited the zoo and saw animals and birds”. The words in bold in the original longer sentence are the text that are dropped and summed up as “animals and birds”. These nouns can be important entities in computer vision tasks and the adjectives of the entities can be used to describe them. To obtain the main gist of a piece of information, the summarized sentences are sufficient, and the additional information may seem trivial. However, this trivial information can be considered particularly useful in object detection tasks even if it is only some descriptive text for certain entities.

Gong et al. [21] have produced multimodal learning approach for information extraction in which entities involve not only text but can include images or audio and relationships that connect entities either within or across modalities. The authors state that multimodal information such as text, pictures or audio are usually interrelated and complement to each other. Text and image modalities are focused due to the high availability of information.

Likewise, Gong and Wang [12] propose a multimodal learning algorithm to integrate textual information into visual knowledge extraction. While they have linked both the visual and textual parts in their proposed multimodal information extraction method, only nouns and noun phrases are used to tag image (or object in the image) with the “has-tag” relationship linking the image (or image object) to the image tags (i.e. the nouns or noun phrases), leaving out other rich information

available from text, for example, in the sentence “A girl is playing with a sleeping dog in a room”, the bold text “playing” and “sleeping” which give the actions for the nouns “girl” and “dog”, respectively, are not captured.

Attribute is generally used to describe an object. According to [22], attributes allow to describe, compare and categorize objects easily. Researchers such as [23] and [24] have proven that with the addition of these attribute, there have been and improvement in the visual tasks. Hence, the present multimodal KGs can still be further improved by filling in more information that is available from text into multimodal KG.

B. Relation Extraction (RE)

As mentioned in Section 1, to build a KG from text, it is very important to understand the text before extracting the relationship. Thus, leading to the task of relation extraction (RE). RE is a major sub-task of information extraction [25] and is also utilized for the detection and classification of semantic relationships between entity pairs [26].

Among the techniques in RE, [14] is one of the works that used a rule-based approach. The authors used this approach for mapping a predicate of a triple to an identical predicate in a KG. However, the generated rules cannot cover all possible patterns in open domain because of the sparsity of unstructured text. Similarly, in [15] use a rule-based approach but with the addition of a similarity-based approach to achieve their objective. In which, the resulting rules are able to cover all possible patterns which result in more complete triples.

In [16] has conducted a study to build an open information extraction system for Indonesian language with rule-based approach. This author has proven that by only using rule-based still can formulate a generalized rule that can capture triples in a wide, open domain. Thus, this work is referenced in terms of the method used to extract relationships between entities. They use part of speech (POS) tagging such as noun, verb, etc. and dependency relationships to extract relationships. The authors concluded that the method used was to identify the relationship based on the VERB POS tag in the extraction of the single verbs. Moreover, the ADVMOD (adverbial modifier) dependency relationship was used alongside VERB POS to obtain a more complete relationship. Extracting entities for both subject and object produced a complete triple. However, the author does not consider the syntactic relationship that exists between the texts which describes a word i.e., an adjective to a noun. By taking in consideration this type of relation, most of the relationships that exist between texts will be captured.

Overall, the reviewed RE methods perform well for simple sentences but poorly for complex sentences. This study attempts to consider adverbial phrases with the extraction of verbs and prepositions in addition to the extraction of single verbs and utilizes the adjectival modifier (AMOD) dependency relation where this relationship describes the nature of an entity; therefore, leveraging on the available text resources.

C. Dependency Relationships

The dependency-based parser labels the relationship that is dependent on the key word in order to get a sense of the

predicate-argument relationship [27]. The task of the dependency parser is to take the input text and apply the proper set of dependency relationships to it [28]. A dependency parser helps to create a dependency tree, which is a tree model based on dependency relationships, by parsing words or sentences.

TABLE I. RELATIONS IN CLAUSE PREDICATE CATEGORY

Clause Predicate	Description
Nsubj	Nominal subject
Nsubjpass	Passive nominal
Csubj	Clausal subject
Csubjpass	Clausal passive subject
Dobj	Direct object
Iobj	Indirect object
Ccomp	Clausal complement
Xcomp	Open clausal complement

TABLE II. RELATIONS IN NOUN DEPENDENTS (MODIFIER) CATEGORY

Noun Dependents	Description
Amod	Adjectival modifier
Advmod	Adverbial modifier
Nmod	Nominal modifier
Nummod	Numeric modifier
Appos	Appositional modifier
Det	Determiner
Compound	Compound

Based on Universal Dependencies (UD) [29], there are 42 relationships that can be grouped into nine categories: (1) clausal predicates, (2) Non-core dependents of clausal predicates, (3) clausal dependents, (4) Noun dependents,

(5) Coordination, (6) Compounding and unanalyzed, (7) Case-marking, prepositions, possessive, (8) Loose joining relations dan (9) others. According to [27], frequently used relationships focused on only two of the nine UD categories. The two categories are clausal predicates and noun dependents (modifiers). Table I and Table II are the examples of the list of universal dependency relationships that have existed. Some of these relationships, mainly subject (nsubj, nsubjpass, csubj, csubjpass), object (dobj and iobj), modifiers (amod, advmod) and compound relations, will be investigated in the analysis process of defining the rules.

III. PROPOSED METHOD

In this section, a detailed explanation of the framework for building a multimodal KG is given. The framework for this study has three main phases. Phase 1: pre-process dataset, Phase 2: extract entities and relationships and Phase 3: build a multimodal KG. Fig. 3 shows the flow of how a multimodal KG is built from a news article.

This study contributes to the extraction of entities and relationships from real-world sentences found in news articles that can be simple short sentences up to long and complex sentences. Simple sentence is the article headline, mainly a short sentence that only have one verb per sentence while complex sentence is the caption which is a long sentence that can consist of multiple verbs in a sentence. This study aims to extract the relationship between two entities or known as triple from the text. The dependency relationship technique is applied to maintain the relationship of each word. Linguistic analysis is performed on each sentence to obtain grammatical dependencies, where a set of dependency relationships will be identified. This is an initial step to detect consistent pattern to formulate relation extraction rules. Once the rules set have been formulated, this set will be used to extract triples of the text. Finally, the extracted triple is used to construct a multimodal KG.

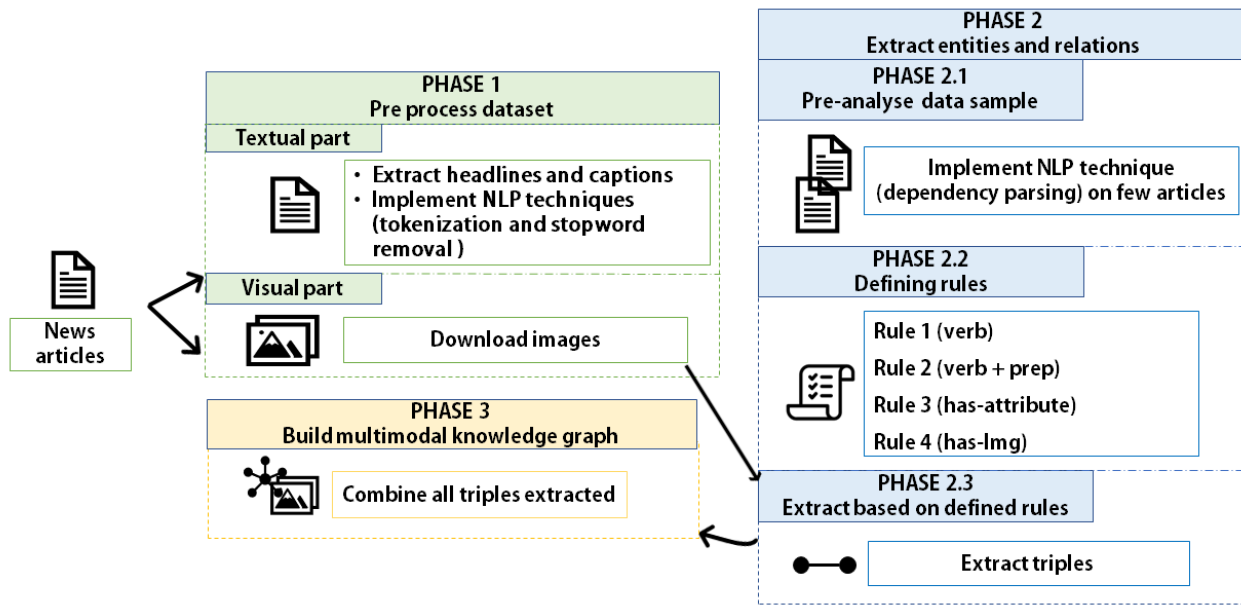

Fig. 3. Framework for Building a Multimodal KG.

A. Phase 1 (Pre-process Dataset)

Starting with the first phase, the Phase 1 input is a collection of online news articles. Each article consists of an image and a text article. Here, the focus is on the image and the descriptive text that accompanies the image. Therefore, this study only considers article titles, captions and images. The text source is derived from the title and caption of the image while the visual source is from the article image.

A web news article consisting of news text and images related to the news. News articles need to be cleaned and filtered because news articles have a lot of information gathered (headlines, captions, date published and more). However, in this study, only a small portion of this rich information will be used. This is because the title and caption are sufficient to describe the image. NLP techniques such as tokenization and stop word removal will be applied to titles and captions. Both techniques will be modified so that the output produced is consistent with the study.

To briefly described, tokens can be formed in individual words or phrases but usually, one word is detected as one token. Even so, in some cases, there are words that cannot be considered a token. Tokenization is customized in a way that can combine several words as a single token. This customization will collect all words that have a hyphen (-) and combine them into one token. The next pre-processing step is stopword removal. The original stopword list should not be used in this study. Words such as prepositions (at, in, of, etc.) can be used as examples of why the original list cannot be used. This is because words prepositional words will be used later to extract relationships. Thus, the stopword list will be self-determined to suit this study. Specifically, words like 'left, right, above, center, below'. These words are generally used in the caption to describe the position of a particular object in an image and are removed because it affects the performance of dependency-based parser which makes it less accurate.

For the visual part, each news article usually has an image to support the news. Each of these images will be downloaded via URL. It is then stored to be paired with the has-Image relationship which will be explained further in phase 2.2. This is to indicate that the caption is related to the image.

In conclusion, the output from this phase is the extracted text referring to the title and caption, and the image that has been downloaded. Finally, the dataset, D, represents the set of the entire news article.

$$D = \{T, V\} \quad (1)$$

where T and V are equivalent to the text and visual parts, respectively. For the set, T, consisting of h and c. h represents the title while c represents the caption.

$$\{h, c\} = T \quad (2)$$

For set V, which consists of only one element, img, which is the downloaded image.

$$\{img\} = V \quad (3)$$

B. Phase 2 (Dependency-based Entity Relation Extraction)

The next phase is an extension of the textual part which is extracting entities and relationships. It will be divided into three sub-phases namely Phase 2.1: pre-analyse data, Phase 2.2: defining rules and Phase 2.3: extract based on the defined rules. Briefly, in Phase 2.1, several articles consisting of simple and complex sentences were selected and parsed through a grammatical parser. In Phase 2.2, the output of the grammar parser which is the dependency tree of each article will be analysed. This is an initial step to detect consistent pattern to formulate relation extraction rules. Once the rules have been determined, the triples (entities and relationships) will be extracted in Phase 2.3. Also, the downloaded images earlier on will be used as one of the entities for the triple set. Typically, a sentence with only a single verb consists of one triple. However, in some cases, there can be one sentence consisting of several triples. For instance, long sentences that have multiple verbs will produce more than one set of triples.

1) *Phase 2.1 (pre-analyse data: dependency parsing analysis)*: In this sub-phase, the pre-analysis is carried out to identify rules for entity extraction. 10 sentences (headlines and captions) are randomly selected from several news articles together with the accompanying images and are analyzed manually which information supposed to be extracted. Then, it is parsed through a parser to show its grammatical structure (POS tag, dependency relations) to detect a pattern. The 10 sentences consist of five simple sentences and five complex sentences. Five more sentences are analyzed to ensure that no new patterns emerge. Hence, these 10 sentences are sufficient for the pre-analysis because of the nature of English sentences to have a similar grammar pattern, thus the result will be much alike.

Firstly, the set of sentences are manually examined where words that describe an image are identified and marked in yellow as shown in the Fig. 4 and 5. These marked words are considered as information that should be extracted. The sentences are put through a grammar dependency parser to obtain the parse tree structure, list of dependency relations and POS tag. Each word that has been marked is viewed in its grammatical structure that is the dependency relationship and POS tag as shown in Fig. 6. Based on the grammatical outputs produced, there are several dependency relationships that are often present on the marked words. The Visitation: Glasgow City Council pay family over Nazi-looted artwork. The crew of an Emirates Airline Boeing 777 prepares for passengers ahead of a demonstration flight in Dubai in 2007. Emirates announced plans Thursday to begin flying a Dubai to Panama City route on a 777, which will be the longest in the world.

Table III shows the frequently found dependency relations together with their explanations by [30,31].

Fig. 4. Example of Simple Sentence.

Fig. 5. Example of Complex Sentence.

Fig. 6. Example of Dependency Tree.

TABLE III. TYPES OF DEPENDENCY RELATIONSHIPS

Dependency Relationships	Description
ROOT	the main topic (verb) for the sentence
Compound	nouns that modify the head of a noun phrase
Nsubj	nominal subject (noun phrase)
Dobj	direct object
Pobj	prepositional object
amod	adjective phrases that change the meaning of a noun phrase
Prep	prepositional phrases that modify the main meaning

According to [27], frequently used relationships are focused on two categories of relationships as mentioned in the previous section which is the clause predicate (Table I) and Noun Dependent (Table II). In Table III, these are the list of consistent relationships generated by the parser which fall into both of those relationship categories. The relationships are Compound, Nsubj, Dobj and amod. The prep relationship needs to be considered in order to capture the verb as a whole. Pobj in turn connects object entities to prep relationships.

According to [31], ROOT is a special label in the dependency tree that is usually on the main verb of a sentence. For some cases, if a phrase is processed or in other words is not a full sentence, ROOT is assigned to the noun of the head of the phrase. It can be observed that ROOT can be either a verb or a noun, in some sentences; and when the ROOT relation and POS noun are found in a sentence, the noun entity is highly related to the image, or to a particular entity in the image.

Hence, this is used to specify a new relation between the text (noun entity) and image (i.e., a text-visual relationship).

Apart from the dependency relationship is the POS tagging. This is the process of labelling punctuation in a language based on class classification. In other words, POS tagging indicate parts of speech to each word such as nouns, verbs, adjectives and more. Table IV shows the most common labels found on words that have been identified by the parser.

Having observed and analyzed the output of dependency relationships and POS tagging for these data samples, Tables III and IV are consistent patterns generated by the parser of the marked text. All these dependency relations and POS tag are used as the basis for the entity and relations extraction rules.

TABLE IV. POS TAG LABEL

POS tag	Description
ADP	Preposition
ADJ	Adjective
DET	Determiner
NOUN	Noun
PROPN	Proper nouns
VERB	Verb

Based on the output in Fig. 6, basically for a relationship between texts, the text to be captured as a relationship has a POS tag labelled VERB and the entity has a POS tag labelled NOUN or PROPN. But the proposed method will also use the dependency relationship that has been generated by the

dependency parser to extract the entities more accurately. The pattern for entity extraction based on dependency relationships is that text labeled Nsubj, Dobj or Pobj will be captured as an entity. The dependency relationship derived from the dependency tree also denotes a word that is either a subject or an object.

To extract the overall relation of the verb, the text having the 'prep' dependency relationship was also combined with the main verb. With this, making the extracted relationship was more ideal. Furthermore, texts describing an entity are extracted based on 'amod' dependency relationships making full use of all naturally occurring relationships between texts. In contrast to the text-image relationship, this relationship is pre-defined and uses the ROOT label to extract the appropriate entity.

Consistent pattern of dependency relationships and POS tag are used as the basis for rules for extracting entities and relationships. Also, relationships will be categorized into two namely 1) text-text and 2) text-visual. Category 1 is an extracted relationship that exists naturally between texts, for example, verb-based relationships, verb-based relationships and prepositions and relationships based on 'amod' dependency relationships but are named as has-Attribute while Category 2 is a relationship set to link text with images.

Once the entity and relation are successfully extracted completely, then the triple, R that is completely extracted will be produced and the relation (h), subject (s), and object (o) are arranged in the following order.

$$R = \{h, s, o\} \tag{4}$$

2) Phase 2.2 (Defining rules): As noted earlier, this study focuses on rule-based relation extraction and covers not only text-text relationships but also text-visual relationships. In this subphase, four types of rules are set for extracting relationships as shown in Fig. 7. Therefore, the development of the rules is explained in more detail. After the analysis in

Phase 2.1 is performed, the following rules are defined for extracting the relationship:

- Rule 1 (based on verb relationships).
- Rule 2 (based on verb + preposition relationship).
- Rule 3 (based on has-Attribute relationship).
- Rule 4 (based on has-Image relationship).

For Rule 1, the relation is captured first before the entity, so the first step is to identify the verb. The token having the ROOT dependency label and verb POS tag (VERB) will be captured as its relation. Next is to find subjects and objects as entities.

As for Rule 2, in addition to the verb itself, the relationship of verb + preposition is also considered in this study; similar to Rule 1, but with the addition of a prep dependency relationship as in Fig. 7.

Next, this Rule 3 is based on an amod-dependency relationship renamed as 'has-Attribute' relationship to indicate the characteristics of a particular word, which is mostly taken from an adjective word. Other than the previous rule, this Rule 3 will identify the object first by identifying the word with the amod dependence.

Since the has-Image relationship has been predefined so Rule 4 is defined to extract the entities for the relationship that link the image and text. Thus, it represents a text-visual relationship.

3) Phase 2.3 (Extract based on rules): Once the rules are determined, then the relations and entities will be extracted according to the rules as described in Phase 2.2. The processed data will go through an algorithm and a triple list will be generated. It will be arranged according to the respective articles. In this way it is clearer that there are some sentences that have more than one triple especially complex sentence.

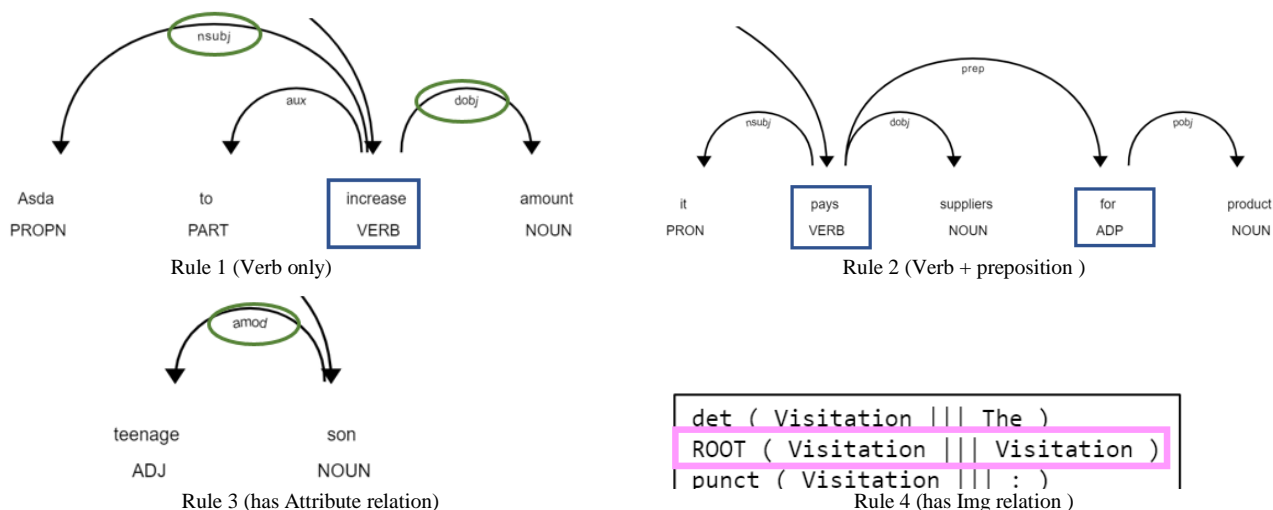

Fig. 7. List of Rules.

C. Phase 3 (Build a Multimodal KG)

In this phase, the relationship of texts and text-visual will be described. The extracted triples will be combined and produce a multimodal knowledge graph which can be formulated as follows. G represents a multimodal knowledge graph for an article that contains a combination of several subgraphs or triples, R_n where n is the total number of triples extracted.

$$G = \{R_1, R_2, \dots R_n\} \quad (5)$$

The multimodal KG can be visualized as in Fig. 8 where the graph has two different types of modalities namely text and image. From the graph, there are other subgraphs. A subgraph produced represents a triple.

Fig. 8. Multimodal Knowledge Graph.

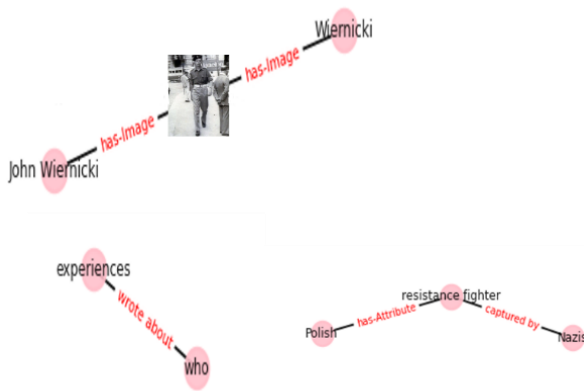

Fig. 9. Hanging Sub-graph.

However, after the experiment was done it was found that there was a subgraph that hung alone as in the following example of Fig. 9. For human-like mindset, it can be concluded that the hanging subgraph still has some relation with the image. This relationship can be labelled as an indirect relationship. Thus, the addition of the rule (Rule 5) for the indirect relations will be applied to the subgraph. This relationship will be called has-Bg-Kg where Bg represents Background while Kg represents Knowledge. This relationship indicates that the subgraph describes the background knowledge of an image in addition to creating a stronger relationship between other subgraphs and also the image-text relationship.

IV. EXPERIMENT AND DISCUSSION

A. Experimental Setup

In this study, the dataset used in this experiment is a sub-dataset from ION Corpus (Hollink et al., 2016) consisting of 60 news articles published on five newspaper websites, collected from August 2014 and August 2015. This dataset contains a collection of sentences with different difficulty level such as simple sentence which mainly the headline of a news article and the complex/long sentence which are the captions from the images.

The original news articles had to be cleaned for having a lot of information collected (title, caption, date of publication and more). The data that has been extracted from news articles primarily are headlines and captions. These text needs to go through a process of tokenization and stopword removal. The library that will be used for the NLP techniques implemented in this experiment is the Spacy Library. Both processes need to be modified as needed to produce a suitable output.

With the result from the pre-processing phase of the dataset, the texts will go through the dependency parser and a dependency tree will be produced as. Several sentences will be expressed as a dependency tree as an initial step in making rules for the rule-based relation extraction. A total of 60 articles were used to extract relationships and entities to produce triples.

To evaluate the quality and quantity of the generated triples for the multimodal KG, the evaluation is performed by manually extracting triples from the 60 articles. These sentences from the articles are examined for relevant triples and then compared to the triples extracted by the algorithm.

B. Comparison

This section will discuss the comparisons between the two methods from other works such as Gong & Wang [12] and Romadhony et al. [16]. Table V shows the summary of both the comparisons. Gong & Wang's method [12] will be compared to the way they extract only nouns to link between text as well as visuals. Romadhony et al.'s method [16] extracts the relationships that can be found from the text itself. The rules they set are from the verb and also the ADVMOD dependency relationship where it changes the predicate or verb.

TABLE V. SUMMARY OF COMPARISON

Proposed method	Gong & Wang [12]	Romadhony et al. [16]
Extract from verb and also consider preposition	only extract nouns	Extract from the verb and the ADVMOD dependency relationship
Additional attribute relationship	-	-
Has relation between image and text but also extract mostly information available	Has link between text as well as visuals but only simple text	Only extract the relationships that can be found from the text

The proposed method is an improvement of the following two works. This is because, for the method of Romadhony et al. [16], the authors focus to texts only. For [12], the method used only focuses on the image-text relationship which indirectly ignores other information that can be obtained from the text. This proposed method not only succeeds in extracting the relationship of texts, but also the relationship of image-texts also makes it very full of information to be filled in the multimodal KG to be built.

In addition, the proposed method can also produce triples of a long and complex sentence. The has-Attribute relationship makes the extracted relationship more adequate and less neglect of information from the text. This is because all the information that can be extracted from the text can be used to the fullest.

$$P = \frac{X \text{ correctly extracted triples by algorithm}}{\text{Total triples extracted by algorithm}} \quad (5)$$

$$R = \frac{X \text{ correctly extracted by algorithm}}{\text{Total relevant triples in the corpus}} \quad (6)$$

This proposed method is evaluated with the formula precision (P) and recall (R). Based on Table VI, here we can see that P = 0.90 and R = 0.60 for this study is the highest when compared to the other two methods. Thus, it can be concluded that this proposed method succeeds in extracting more triples and importantly accurate triples. The value of accuracy (P) here is high because among the 209 triples produced, there are 190 triples produced correctly. However, the recovery value (R) has only a value of 0.6 where only 190 triples are produced out of 319 triples that are theoretically capable of being produced.

TABLE VI. PRECISION AND RECALL SCORE

Total/ Method	Proposed method	(Gong & Wang, 2017)	(Romadhony et al., 2018)
Triples should be extracted (319)	The triple is extracted by the algorithm	209	71
	Triple the extracted accurately	190	60
	Precision score (P)	0.90	0.85
	Recall score (R)	0.60	0.20

This proposed method is highly dependent on parser dependency performance making it a challenge because when the performance of this parser is low as it affects the results. Generally, parser performance deteriorates with complex sentences. Another issue faced with complex sentences is the longer the sentence, the more clauses it contains, making it harder to trace back to the subject (entity) in the main clause, which resulted in the extraction of some incomplete triplets with insufficient entities, as described in the previous paragraph. Another reason for the incomplete triplets is because of co-referencing (pronouns) problem. If co-referencing resolution is performed and parser performance for complex sentences can be improved, then the value of R can also be increased.

V. CONCLUSION

The proposed multimodal KG has successfully extracted the Web image background knowledge from unstructured texts and organized in a structured graph while still maintaining the image-text relationship. A set of rules based on repeated patterns of dependency relations and POS information, can correctly extract from simple to complex sentences regardless of the domain (sport, education, world, etc.). Two additional rules are included to take into consideration the inherent correlation between the Web image with the news headline and image caption. Hence, capturing the background knowledge for Web images that are much needed by researchers in the computer vision field. This multimodal KG can be used as training data for machine learning approaches such as graph embeddings.

Soil Color as a Measurement for Estimation of Fertility using Deep Learning Techniques

N Lakshmi Kalyani, Kolla Bhanu Prakash

Department of CSE, Koneru Lakshmaiah Education Foundation
Guntur (DST), Andhra Pradesh, India

Abstract—Soil Behavior helps the farmer predict performance for growing crops, nutrient movement, and determine soil limitations. The traditional methods for soil classification in the laboratory require time and human resources and are expensive. This analysis examines the possibility of image recognition by artificial intelligence, with a machine learning technique called deep learning, to develop the cases that use artificial intelligence. This study performed deep learning with a model using a neural network. Neural Networks has used to evaluate relationships between the parameters of the three-dimensional coordinates resulting in soil classification and parameters. So Artificial Neural Networks (ANN) can be an effective tool for soil classification. This paper focused on AI techniques used to predict the soil type, advice the crop to yield, and discuss the transformed learning and benefits.

Keywords—Artificial neural networks; deep learning; soil classification; soil nutrients; data augmentation; transform learning

I. INTRODUCTION

Agriculture stands very quintessential in society. Agriculture is a source of livelihood in most parts of the world. Agricultural produce is of great importance. But in recent years, the farm produce is gradually decreasing. Soil plays a crucial role in agriculture. Soil consists of nutrients that the plants use to grow. There exist various kinds of soils available, and each has different effects. Crop's productivity was mainly based on the type of soil [1]. The possible way to improve productivity is that choose the right crop for the right land type. Soil needs to be investigated primarily before classifying them into distinctive groups. Based on these soil groups and the geographical conditions, one can decide which crop is best suited and is beneficial. The traditional methods are Costly, lengthy process and also time-consuming.

Consequently, there is a necessity for new technologies and methods to enhance the existing system to get faster and better results. Soil texture is due to the percentage of silt, clay, and sand present in it, and change in the fraction may result in different colors due to interaction among soil characteristics. Classification has a significant influence in agriculture for estimating yielding crops, and soil classification will define the relation between soil samples and other natural substances present. Convolutional Neural Network (CNN) is the branch of Deep learning and enables the machine to exhibit self-learning, to show the intelligence to predict by analyzing the input [3]. The essential point here is the privilege of the computer to learn automatically without human interaction.

Soil is the source of the minerals, liquids organisms that produce the foundation for the plant, and classification plays a major role in managing a crop, increasing soil primarily before classifying them into distinctive groups. Based on these soil groups and the geographical conditions, one can decide which crop is best suited and is beneficial [4]. The traditional methods are Costly, lengthy process and also time-consuming.

This research aims to benefit the former in identifying the red soil, and it analyzes the different soil patterns using CNN and recommends particular crops in that soil. And also help the researcher in soil science. The general purpose of this research is to compare the different soils and identify the red soil. The consequence of this may have numerous advantages to agriculture, soil management, and the environment.

II. LITERATURE SURVEY

In this section, we summarized various works related to machine learning, image processing, and classification models from different papers seen in Table I.

The least median squares regression techniques produce more reliable results than the classical linear regression technique from the set of characteristics [2].

SVM classifier can work efficiently with high level of accuracy. MATLAB software has proved an efficient tool for design and development of classifier and can be used for further development of independent interface for on-site real time soil classification [5].

Time-honored methods of soil assortments are standard penetration test (SPT), cone penetration test (CPT), pressure meter test (PMT), and vane shear test (VST), time-consuming and needed for accurate results. Soil classification can be automated using artificial neural network techniques [6].

Mrs.Saranaya and Ms.A.Mythili researched to analyze the soil types so that it is helpful to farmers to choose a crop that to be cultivated. They have considered the SVM algorithm and chemical effects of soil like pH, salinity, organic matter, potassium, sulphur, zinc, Boron, calcium, Magnesium, Copper, Iron, and Manganese [7].

Classification of soil and quality prediction using a software-enabled solution using machine learning algorithms including decision tree, by considering soil chemical parameters [8].

TABLE I. VARIOUS MODELS USED FOR SOIL CLASSIFICATION

S.No.	Title	Techniques
1	Soil classification and crop suggestion using machine learning	Naive Bayes, J48, JRip algorithms
2	An Intelligent Model for Indian Soil Classification using various Machine Learning Techniques	The Pre-processed images are feature extracted, and the data extracted is used to train the SVM classifier.
3	Recent Trends Of Machine Learning In Soil Classification	Various emerging machine learning algorithms like SVM's, KNN, ANN, DT(decision tress) were discussed.
4	Soil Classification and Crop Suggestion using Machine Learning	Bagging Classifier, SVMachine, and KNN for classification of soil and crop recommendation.
5	Machine Learning in Soil Classification and Crop Detection	Image acquisition, Pre-processing, KNN, Feature extraction, SVM classifier.
6	Prediction Of Soil Quality Using Machine Leaning Techniques	Decision Tree and Random forest algorithms
7	Artificial intelligence system for supporting soil classification	Neural network models are used, CNN, steepest descent method.
8	Soil Classification & Characterization Using Image Processing	Technically proposed system has been based on HSV, Enhancement algorithm, and SVM classification algorithm.
9	Soil Physical Properties	Stokes regulation, bulk density, particle density, mass flow
10	Chemical properties of soils	Different types of chemical organic molecules.
11	Nutrients Detection in the Soil: Review Paper	Soil Nutrient detection, Reflectance sensing, Electro chemical sensing, Electro Conductivity sensing.
12	Soil Classification Methodology: Critical Analysis	Classification Methods, Inventory Methods.
13	Soil Data Analysis Using Classification Techniques and Soil Attribute Prediction	Data mining, classification, regression, soil testing, agriculture , WEKA Tool.
14	Soil Classification & Characterization Using Image Processing	Classification of soil by image processing using SVM technique, Machine Learning.
15	Soil Classification using Machine Learning Methods and Crop Suggestion Based on Soil Series	Classification of soil by image processing using SVM technique based on colour, energy, HSV of soil.
16	Determination of Soil Nutrients and pH level using Image Processing and Artificial Neural Network	Rapid soil Testing, Soil Test kit, Artificial Neural Networks, Image processing are used.
17	Soil Quality Measurement using Image Processing and Internet of Things	IOT and image processing to measure pH, moisture present, Soil Nutrients. Raspberry-Pi and camera are used.
18	Analysis of Soil Behaviour and Prediction of Crop Yield using Data Mining Approach	Naive Bayes and K- Nearest Neighbour methods are used.

Prediction soil type was performed by deep learning model using neural network. Research carried out for three classes of soil, specifically for clay, sand, and gravel, an AI model, was constructed that was keen efficient homogeneity of the images utilized and the research has shown that this AI model can be applied to conceive judgments on soil classification [9].

The SVM classifier was found to outperform over all other techniques. Maximum Likelihood classification, sub-pixel classification, and ANN classification were chosen as image classification techniques from various methods [11].

Soil classification and segmentations are necessitated, along with soil nutrients to recommend crops and fertilizers to use. Non-specialists farmers can understand features easily [10].

Researcher T.Abimala proposed a model to predict the variety of soil applying image processing techniques. Classification of soil is by the processing of soil image color and texture patterns [12].

Soil Characteristics have a notable impact on the response of soil in the field of agricultural uses. Soil aeration depends on the soil texture, is a static property of soil quality. Plants' growth depends on soil quality and temperature [13]. Weathering processes may create porous media at the land surface. The correlation between soil and bio-indication may not be strong enough to bring out such suitable changes. Soluble elements are purged into the lower layers of soils where they accumulate. Insoluble chemical elements remain in the upper layers of the soil [14].

Soil nutrients and pH define through image processing and ANN [15]. The process of soil classification systems based solely on grain diameter is capable of misunderstanding because the physical properties of outstanding soil elements depend on many factors other than grain size [16]. There is also the quantity of water (humidity) which is also a non-negligible factor. It is the newest and most used because it is the improved form of all others [17].

The least median squares regression can predict soil is identified to generate abler results than the classical linear regression by analyzing soil sample and cropping pattern [18].

Image processing using SVM techniques classify the soil based on color, energy, and HSV [19]. The researcher recommended a suitable crop for a particular soil by analyzing the PH value, moisture level, and nutrients collected using sensors with IoT technology. Here former need to have a piece of knowledge on hardware [20].

Experimental study says yield prediction is possible with AI Techniques. ANN attained more accuracy than RF, MLR, and NB Techniques [21]. Categorization of soil could be done using Data mining techniques like K-Nearest neighbors and naive Bayes as low, medium, and high. It helps to choose suitable land for more profitable crop production [22]. SVM, principal component analysis can be added further.

The CNN-based regression model is developed based on the characteristics of the TIR images, with required generality and performance. This model, in comparison with DNN, gives

promising accuracy. Remote digital imaging using a drone is advantageous than data acquired using satellite [23].

There are non-exhaustive methods utilizing image processing, machine learning, and deep learning in previous research work related to soil classification [24]. And many researchers focused on traditional methods, image processing, computer vision techniques, and computer-based applications. This paper proposed advanced soil classification techniques using machine learning and deep learning. The primary purpose of soil category is to forerun behavior, determine the uses, assess their productivity, and extrapolate analysis to predict nutrients.

This paper discusses the architecture of the proposed system, methodology, results, concluding remarks, and future scope.

III. METHODOLOGY

In Telangana, 48% of the land covered red soil and types of red soil and color and causes listed in Table II.

Some of these soils look reddish due to the wide diffusion of iron in crystalline and metamorphic rocks, and some are yellow due to diffusion occurring in a hydrated form. Soil is the foothold for plants' roots and holds the necessary nutrients for plants to grow. It filters rainwater and regulates the discharge of excess rainwater, preventing flooding, and it is capable of storing large amounts of organic carbon. All these depend on the characteristics of the soil. The primary skill to succeeding in farming here understands soil type and giving the most fitting plants for that soil [14].

Soil classification could be made as per engineering properties, and it could be free from trouble-free from field survey and the usually, engineers classify soils as per soil characteristics. Classification would commence from the soil image. Convolution Neural Network is an incredible image recognition invention and is a sub-class of deep learning neural networks. CNN generally used to analyze images and image classification.

CNN Architecture Fig. 1 has four layers listed as follow:

- Convolution layers.
- ReLu layers.
- Pooling layers.
- Fully connected layers.

TABLE II. RED SOIL CLASSIFICATION

S.No	Soil Type	Colour	Chemical
1	Red Clay Soil	Red	Iron oxide
2	Red loam soil	Red	Potash
3	Red Laterite Soil	Red	Iron and Aluminium
4	Red –Yellow soil	Red-Yellow	Ferric hydroxide
5	Red Sandy soils	Red	Iron
6	Red Gravel Soil	Red	Iron

A. Convolution Layer

- Convolutional layers: these layers apply a convolution operation to the input image and pass the information on to the next layer.
- Pooling Layer: The next layer is the pooling layer, where outputs combined as cluster of neurons into a single layer. And the next layers are fully connected layers, in which all neurons connect to each neuron in the next layer.

B. Relu

Proposed CNN Model and trained it on a Soil image dataset. The results observed that performance was minimal. Training a model with millions of images takes days to achieve high performance in real-world applications. An alternative is to use a pre-trained model, and it would retain on our dataset as transform learning.

In this Model, an image was directly given to the algorithm, which will classify the given image as either red soil or not, as shown in Fig. 1 and the detailed flow explained in Fig. 2.

C. Pre-Processing

A smoothing (low pass) filter has been used to eliminate high-frequency noise and artifacts from the picture. Smoothing filters employ a moving window operator that adjusts the value of one pixel of an image at a time based on a function of a local area of pixels. As the operator advances over the picture, all of the pixels are affected. As a consequence, the smoothing filter progressively enhances the image over time by eliminating imperfections.

D. Feature Extraction

The feature extraction stage is the essential phase in the process. It encompasses all of the characteristics that are needed to classify the soil type, such as texture, color, and intensity was extracted. As a result, a metric known as color moments was employed to distinguish photographs based on their color characteristics.

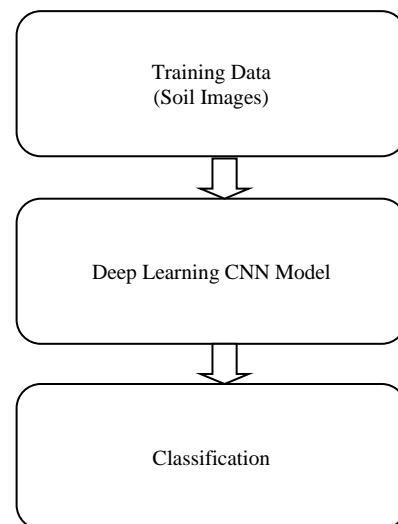

Fig. 1. Abstract Level Soil Classification Architecture.

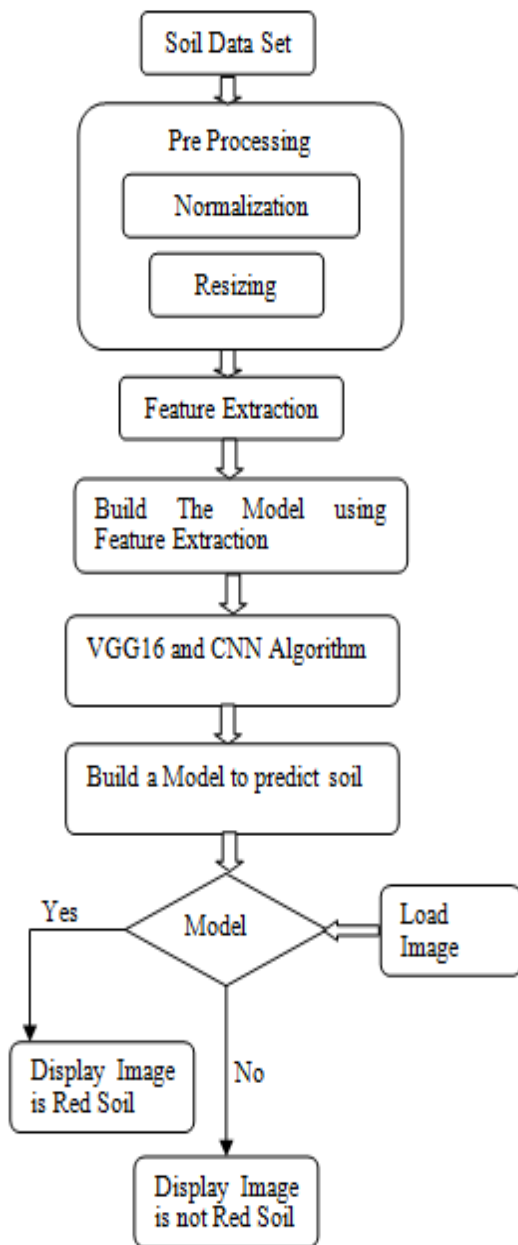

Fig. 2. Detailed Soil Classification Architecture.

E. CNN Classification Model

CNN or ConvNet are deep neural networks used for image recognition, object detection, and classification. Image classification is the process of deciding which class (or combination of categories) best describes an input image. In CNN, we take a picture as an input, assign weight to the image's various aspects/features, and differentiate one from the other. CNN requires much less pre-processing than other classification techniques.

F. Softmax

Softmax is an intriguing activation function since it maps our output to the [0, 1] range and maps each output so that the entire sum equals one. Softmax's output is a probability distribution as a result as shown in Fig. 3.

Fig. 3. Soil Classification with CNN.

In-Training the Model, all the images are converted into arrays and stored in Data Variable. Each image is given labels for the detection and stored in Variable Labels.

After preprocessing the steps to be done to build the model Average pooling is applied to down sample the input dimension, Height, and width by taking average value over a window of size 4x4 for each input channel. Strides shift the window along each dimension.

Flatten transforms the pooled feature pictures into a single column, then sent to the fully linked layer. Dense added the fully connected layer to the convolution neural network, and dropout is a strategy for preventing over fitting in a model. Once the model has fitted with the Layers, the trainable parameters have been set.

Fig. 4 shows how many total parameters are there and how many are available for the training.

Fig. 4. Listing of Parameters in Training.

IV. RESULT

Every step picks images from the training set at random. Then, each step finds its bottlenecks from the collection. And ultimately, each step puts the images into the final layer to get predictions. Then, the forecasts are equated alongside the actual labels to inform the final layer's weights using the back-propagation procedure.

Each step shows the level of training accuracy and validation accuracy Fig. 5. Training accuracy was the prediction of training images that were classified correctly. Quality of the model measured by validation accuracy and to what extent it guess depending on data it has not seen before. Suppose 86% percentage on the training set and 85% on the validation set. You can expect your model to perform with 85% accuracy on new data.

From Fig. 6 Prediction Accuracy into a percentile, the accuracy of the prediction soil image classifier is 91%.

This model could test using User Interface (UI). Once the model was ready, we developed a web application using the Flask framework. Here users can upload images to predict soil type.

V. CONCLUSION

The proposed model categorizes soil using CNN successfully identified the Red soil and tested in the field got 91 percent accurate results. And can estimate the soil's fertility by predicting significant nutrients for specific soil. Introducing cutting-edge technologies in Agriculture can improve the yield by applying adequate application fertilizers, and with an improved dataset, also get 99 percent accurate predictions.

Abstract—Genomic data is used in bioinformatics for collecting, storing and processing the genomes of living things. In order to process the genetic information, machine learning algorithms plays a vital role in building a computational model by using the statistical theory. This paper helps the researchers, who are doing research with the DNA dataset by applying the machine learning logics. Feature scaling machine learning techniques helps in predicting the sequence of genome for extrachromosomal amplification and predicting the tumor intensity in the human gene. Identification of unconventional chromosome in the DNA sequence minimizes the structural risk. In this paper, researchers can get clear insight on classification, sequence prediction, fuzzy relationship and SNP on genome dataset. The performance of various existing models is measured using the performance metrics and the accuracy.

Keywords—Genomic data; deoxyribonucleic acid (DNA); machine learning algorithms; single nucleotide polymorphism (SNPs)

I. INTRODUCTION

Deoxyribonucleic acid (DNA) is the combination of different nitrogenous bases, phosphate molecule and sugar molecules which are combined to form nucleic acid. These nucleic acid molecules consist of genetic information that are used for transmitting organic material from parent to child. All the combinations in the nucleic acid of a cell are arranged in a sequence to form a DNA structure. DNA are mainly responsible for storing genetic information and also for producing the proteins in human body through transcription and translation process. DNA are in double helix structure, present in eukaryotic and prokaryotic cells.

Deoxyribonucleic acid (DNA) is located in each and every cell nucleus of human body containing the genetic information. The cell nucleobases of DNA consist of four nitrogen nucleotides namely adenine represented as A, cytosine represented as C, guanine represented as G and thymine represented as T formed using the nitrogen bond as represented in the Fig. 1. DNA of a cell nucleus consist of chromosomes. There are 3-billion pair of chromosome sets termed as genome. Genome consist of 46 chromosomes in the DNA sequence grouped to 23 pairs.

DNA can be divided into four different categories based on the structure as A-form, B-form, C-form and Z-form DNA. The base pairs which are not in perpendicular to the helix axis are defined as the A-form DNA, these protect the human body in the extreme desiccation effect of bacteria. The

base pairs which are perpendicular to the helix axis form are defined as the B-form DNA, these are responsible for gene expression, mutation under normal conditions. The zig-zag form of base pairs to the helix axis are defined as Z-form DNA, these are responsible for gene regulation. The base pairs which are in the form of non-integral helix structure are defined as the C-form DNA, these are responsible for cloning the eukaryotic genes.

DNA consisting of 3 billion base pairs carrying information from one gene to another gene are created and replicated based on the human genetics and the life-style. The DNA arranges the base pairs in a chain sequence to perform transcription and translation process to produce protein in mRNA to develop the human body. These proteins are used as energy to do large amount of work by our body. The DNA structure is divided into two halves or two single strands. The strands in DNA are thin molecules wrapped to form a helix structure, these are composed of blocks or nucleotides. Human genome is around 98% similar to chimpanzees and 75% similar to mouse.

Fig. 1. Deoxyribonucleic Acid [23].

A. DNA-Sequence-Classification

DNA can be classified based on various standards like structure, number of base pairs, location, coiling patterns, nucleotide sequences, number of strands, coding and non-coding. DNA sequence-classification is performed based on the nucleotide combinations in the sequence. The four nucleotides A, T, C and G forms a series in the nucleic acid of the cell. The process of identifying the nucleotide sequence in the DNA are used to determine the order of nucleic acid sequence. DNA sequences are classified to get the information related to the evolution of various species, living organisms and their transformations, medical-diagnoses, forensic

investigations and organism identification. The nucleotide canonical DNA structure using the computer terminology can be classified for various predictions like disease risk, next generation sequence, cancer research, birth defect screening, food importing/exporting control, paternity testing, drug target and gene therapy.

The process in which the information from the DNA is carried out to the RNA molecules are called as transcription. Transcription process is carried out in three different stages in the gene expression, enzymes that perform transcription in copying the DNA strand from the DNA [24] sequence in eukaryotes cell is called RNA polymerases. The single stranded DNA correlation with the complementary strand RNA is performed using the RNA polymerases by adding the new-nucleotides. The first step in the gene transcription is initiation of promoters for binding the RNA polymerase with the DNA sequence molecules in each gene. The second step is elongation process where the RNA molecule builds the complementary nucleotides chain in the template strand. Termination is the final step in the transcription where the sequence mechanism is formed as hairpin RNA molecule.

The process in which the information from the termination of RNA molecule is translated to the ribosome to produce proteins is called translation process. In the translation process the genetic code from the RNA molecule is converted to the amino acid 20-letter code to produce the protein blocks.

The translation in the ribosome is performed in three different stages. The first step of gene translation is initiation, where the small-ribosomal-subunit binds the information from the transcription and codons initializes the methionine code & AUG to transfer the information. The second step of translation is elongation where the codon continues to increase the chain by adding the corresponding amino-acid using the peptide bond. The final step in the translation process is the termination where the proteins are produced by completely binding the codons from the RNA molecule.

Fig. 2 displays the transcription control flow and the translation process, in converting the DNA information to produce the proteins. Transcription synthesis of single stranded RNA from a double stranded DNA template is used to produce messenger RNA. Translation is the first stage of protein biosynthesis from RNA in the gene expression.

B. DNA Methylation

DNA Methylation is the process in which the methylation activity in the DNA segment is changed without changing the original gene sequence. Methylation is a process where the methyl groups are attached to the DNA molecule to repress-gene. DNA methylation occurs during the epigenetic event. The covalent modification of DNA methylation results in three types of methylated bases called C5-methylcytosine(5mC), N4-methylcytosine(4mC), N6-methyladenine(6mA). The DNA methylation is important for transcriptional-gene-silencing, genomic imprinting, maintaining the genome stability, embryonic development and X-chromosome inactivation's.

Fig. 2. DNA Transcription and Translation.

Fig. 3. DNA Methylation.

Fig. 3 is the chemical modification of the cytosine, where by addition of a methyl group to the number 5 carbon of the cytosine is converted to 5-methylcytosine which is followed by the guanine dinucleotide CpGs process.

C. DNA Damage

DNA damage is the process of alteration in the DNA structure resulting in the chemical abnormalities. DNA damage are mainly caused due to the change in the environmental factors and the metabolic process inside the cell. The main source of the DNA damage is endogenous damage with in the cell and exogenous damage caused by the external agents like X-rays, UV-rays. The DNA damage can be classified into three different types based on the alteration in the genetic material as single-base-alteration, two-base-alteration and chain-breaks-and-cross-linkages. The abnormality in single base of the DNA is caused by depurination, alkylation, deamination and base-analog formation. The two base alteration is caused by UV induced dimer formation in the thymine and bifunctional-alkylating agent. The chain-breaks-and-cross-linkages are caused by ionizing radiation, oxidative-free-radical-formation, radioactive disintegration, cross linking-between bases in same or opposite strand, cross linking between DNA and protein molecules. The Fig. 4 represents the DNA damage caused during the cellular alteration. Agents damaging the DNA [22] are radiations caused due to highly reactive oxygen radicals, ultraviolet rays and ionizing radiations, chemicals in the environment like aromatic hydrocarbons and aflatoxins.

Fig. 4. DNA Damage [26].

DNA repair can be performed by the cell in two ways, direct-damage-reversal and excision of DNA damage. In direct-damage-reversal initially the single polypeptide with the enzymatic properties binds the chain and restores using DNA photolyases and alkyl transferases. In the excision of DNA damage, it solves the excised free bases generated by altering the bases to deoxyribose-phosphate by initializing the DNA glycosylases called base-excision-repair. Nucleotide-excision-repair mechanism is used to replace the DNA damage in 30 bases. Mismatch repair mechanism allows the enzymes to identify the strand and replace them with normal cellular enzymes corresponding to the base-pair-rules, strand break repairs, single-strand breaks and double-strand break damages. The diseases caused due to the defect in the DNA repair system are ataxia telangiectasia, bloom syndrome, Cockayne's syndrome, progeria syndrome, rothmund-thomson syndrome, trichothiodystrophy, Werner syndrome, xeroderma pigmentosum and hereditary non polyposis colon cancer.

Fig. 5 represents the Nucleotide-excision-repair mechanism is used to replace the DNA damage in 30 bases.

D. Mitochondrial DNA

Mitochondrial DNA is responsible for the cellular-metabolism, oxidative-stress-control and apoptosis. Mitochondria is also known as the power-houses of DNA cell, it is inherited from the mother's ovum. It consists of 13 coding genes and the 24 non-coding gene of length 16,569 bp in the human body. Mitochondria uses the oxygen and sugars to create energy of the main cell. The mitochondria mainly designed with 22tRNA and rRNA coding genes to control replication and transcription process in the cell. It is in circular structure with several copies of single mtDNA-molecules present freely in the nuclear envelope.

Fig.6 Mitochondrial organelles structure are found in the cell cytoplasm as represented in Fig. 6 which consist of some of components like 2 membranes called inner membrane and outer membrane protecting the cellular matrix.

E. DNA Mutation

The heritable change in the arrangements of genetic material chromosomes position is termed as mutation or DNA mutation. Mutations are occurred in gametes and causes permanent change in the genetic sequence of nucleotide

forming new amino acid. The gene mutation rate is 1 or 2 new mutations in 1000000 genes during the DNA copy. Mutations are unpredictable and can be of many forms like gene mutation or point mutation and chromosome-mutation. These mutations are caused due to change in the complete chromosomes structure, chromosomes count and single pair of chromosome's structure. Some of the forms of mutations are due to the addition of extra nucleotide that causes gene mutation and addition of extra chromosome that causes chromosome mutation. Deletion of nucleotide chain from the gene sequence causes gene mutation and chromosomes are lost in the gene sequence causing chromosome mutation. Duplication of nucleotide chain is repeated in gene mutation and chromosomes are repeated in chromosome mutation. In inversion nucleotide sequence are detached from the gene sequence causing gene mutation and deleted chromosomes rejoining the chain in the inverse position causing chromosomes mutation.

Fig. 7 represents different mutations caused in the DNA. The first sequence in the Fig. 7 represents the normal gene sequence consisting of cytosine, thymine, adenine and guanine. The insertion of new guanine in the sequence at the second position results in the mutation. The deletion of adenine in the 3rd position of the sequence, duplication of cytosine and thymine, inversion of the 2nd and 3rd position of the sequence causes DNA mutation.

Fig. 5. DNA Repair [25].

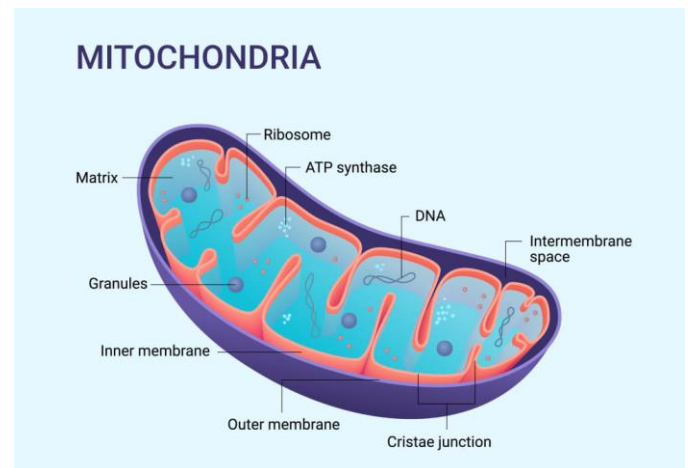

Fig. 6. Mitochondria.

Fig. 7. DNA Mutation.

II. BACKGROUND AND MOTIVATION

Deoxyribonucleic-acid composed of 46 chromosome's carries genetic information from parents to children in homo sapiens. Chromosomes are made up of different groups of purine-pyrimidine bases, phosphate and sugar attached to the one carbon of deoxyribose's forming as adenine represented as A, cytosine represented as C, guanine represented as G and thymine represented as the T formed using the nitrogen bond. Human genome is used for scientific research for understanding the physical gene sequence and base pairs functioning. DNA research for analyzing and classification of human genome to predict the accuracy of disease effecting a person through machine learning approaches became enormous in the present-day. Research in DNA is unearthing the evolution of human in the nature by mapping the gene based on the physical features. DNA classification of chromosomes can be used for predicting numerous inheritance mutations and DNA damages. Human-Genome-Project which was started in 1990 and continued till 2003 worked on the base's sequences in the gene sections of 3 billion long with an average size of 3000 bases. Human-genome-project work done by scientist all over the world improved the medical field, microbial genome research, forensics, disease risk assessment and human evolution. DNA abnormalities can lay a step forward for predicting the multifactorial inheritance risk in effecting children from parents.

III. RELATED WORK

The classification of eukaryotic genome linear DNA chromosomes on extrachromosomal DNA by Zhenyu liao et al., in 2020 [1] provided a circular structure of the extra chromosomes which were found outside of the eukaryotic-genome. The authors had classified the unconventional chromosomes for identifying the cancer tumor miscellaneous behavior in the gene. The extrachromosomal were classified based of the spectrum of microscopy technology for detecting the progression of tumor. According to the authors research the extrachromosomal DNA is mainly characterized into four types based on the size of the chromosomes, frequency in the tumor cells and functionality. The progression in the tumor were relatedly close to two gene amplification in the chromosome segmentation which increases the intensity in the

tumor cells. The authors discussed about the drugs that resist to the tumor cells and formulated the extrachromosomal cycle and its proliferation in the genome. The extrachromosomal DNA formulation gives the complete information regarding the circular chromosome amplification and its translocation of tumor cells. The super resolution of the next generation genome sequencing for different elements of the extrachromosomal DNA tumor identification and amplification were resolved using gene editing tools.

Receiver-operating-Characteristic-curve was achieved by Leif E.Peterson et al.,[2] for cancer microarray DNA using different Machine-learning classifiers, feature-scaling and fuzzification for the 9 cancer microarray datasets. The sample size is initially considered for obtaining the AUC values for the fuzzy set and the crisp set based on the statistics to recommend the factor which is influencing the AUC percentage value. The inferential hypothesis test is used for predicting the effect on the AUC value. The feature-scaling of the dataset is performed using the t-test suboptimal ranking for N inputs. The fuzzy logics were used to get the real gene expressed in the cancer microarray dataset. Machine learning logics were used to find the regression and classification of the cancer microarray datasets using certain formulas for supervised classification. The authors had compared the results of both the fuzzy and crisp accuracy of the 9 datasets in the graphical representation and the cancer microarray are categorized based on the classification of the data. The AUC fitting for the cancer datasets for the least and the highest correlations are obtained based on the feature-scaling and fuzzification performance.

Stephen winters-hilt et al.,[3] had developed a new computational method for Single-Molecular DNA Classification to enhance the accuracy of hairpin DNA using single species data in silico. This computation method was named as Watson-crick-basepairs. The authors in this model, performed the SVM multiclass architecture to analyze the state of DNA molecule and also its transitions in the molecular structure with respect to the kernels. The Hidden-Markov-model parameters are also used for denoising and feature-vectors in the molecule. The model performance is measured for a single DNA molecule using the performance metrics in the biophysical analysis. Nanopores are generally used to measure the DNA molecules for each and every basepairs, the feature extractions are performed from multiclass scalability trends to analyze the sequential data of basepairs. SVM provides the optimized hyperplane which separates the hyperplane into clusters for mapping of feature-vector to discriminate the structural risk in DNA hairpin in the experimental procedure. This model achieved a highest accuracy of 99.6% in less than six seconds.

A new method for handling classification problem in the DNA coding was proposed by Ting-Cheng et al., in 2015 [4] as variable-coded-hierarchical-fuzzy-classification-model (VCHFM). The supervised learning method is used as an interface for fuzzy system and the DNA coding. This model works on four main principles. The first main principle of VCHFM is automatic fuzzy rules generation for numeric data and feature-extraction. The second principle works on the DNA computation functions. The third principle works on the

optimization of the chaotic particle that regulates the weight grade of the inference node in DNA. The final principle works on classification functions and the multi-objective-fitness optimization function. This model is highly capable of reducing the overlapping problem and dimensionality reduction problem that affects the classification. VCHFM obtained a benchmark result in best classification rate with a smaller number of fuzzy rules.

Umit Atila et al., in 2020 [5] had classified DNA damage problem using convolutional neural network using the comet images of the grayscale DNA. The authors had worked on the quantification of the images and the identification of the damage comet object in the DNA. They divided the entire DNA into four categories namely healthy, poorly defective, defective and very defective based on this the images were classified in the neural network. Comet-assay-experiment was conducted to obtain the images of 170*170-pixel resolution images for four categories labeled as G0, G1, G2 & G3. Authors had achieved a highest accuracy of 96.1% in predicting the damage DNA using convolutional neural network.

R. Touati et al., in 2021[6] provide a detail description on converting the DNA sequences into the chaos-game representation using the FCGR images. Authors had initially considered the helitron-family FCGR images for feature extraction in the automated system to develop the DNA sequences of helitron-family. The authors also applied the machine learning methods for classifying the images of DNA using SVM, PTDNN and Random-forest algorithms. SVM is used to minimize the structural risk in the DNA by dividing it into different clusters in the hyperplane. Pre-trained deep neural network is used for classifying the DNA images using the softmax activation function on the 2D images to classify the images. Random forest techniques like bagging are used for detecting the different variation of DNA images. The accuracy of classification of the DNA with all the three machine learning approaches were analyzed.

L. Liu et al., [7] provided the detailed description of the cancer plasma cell detection from the methylation sequence and its classification. Authors had developed a comprehensive-methylation-sequence by targeting a single plasma and identified the presence of cancer. The molecular testing method is used for classification of the cell-free DNA in the cancer gene to detect the defected plasma.

Sergio Bittanti Simone Garatti Diego Liberati[8] had provided a detailed description of the degeneration effect in the various types of cancer using unsupervised clustering. Author had classified leukemia and paradigmatic using data mining techniques. To analyze the data the authors had used the microarray technology for training the gene expressed data and for performing unsupervised clustering for diagnostic of DNA. Using this approach authors are capable to classify the data without any pathological information.

SNP-Single nucleotide polymorphism impact on DNA is classified by the Jard H. de Vries et al., 2021[9] which is used to solve the investigation of a murder case from the genomic data. The SNPs are generally used for obtaining the DNA quality & quantity, in the crime case by applying the global-

screening-array to the sample. The impact of SNPs is used to classify the kinship, based on the positive and negative values of kinship-classification the murder case is solved.

Jun Hu et al., in 2020 [10] provided information related to the protein sequence analysis from DNA-binding using the computational methods. Authors had worked on the target DNA-binding protein by applying four feature extraction operations. The base features of the DNA are extracted using the Amino-Acid-Composition, Pseudo-position-specific-scoring-matrix, pseudo-predicted-relative-solvent-accessibility and pseudo-predicted-probabilities-DNA-binding-sites. They had combined both the base features and their weights to determine the original-super-feature to perform the machine-learning algorithms. Authors had used statistical predictors to improve the accuracy of the DNA-Binding-protein, dataset analysis, feature extraction, multi-view-features and feature selection to identify the DNA-sequence. The results of applied feature selections are measured using the performance metric like ROC, accuracy and CBR ranking.

The cancer classification based on the DNA-mutation patterns were performed by the Lei Wu et al., in 2020 [11]. The amplifications in the tumor cells are identified in the DNA-sequence using the Surface-Enhanced-Raman-Spectroscopy (SERS). The authors had created a free amplification SERS sensor to integrate it into microfluidic-chip with in the DNA-nucleotide mixture for demonstrating the melanoma-cell lines and colorectal cancer. The SERS classification of cancer types using the profiling mutation in the DNA patterns had achieved a benchmark accuracy of above 90%.

The classification of DNA-microarray using advanced algorithms was discussed by Beatriz A. Garro et al., in 2016 [12] for synthesis of mRNA molecules. The authors had diagnosed various diseases to identify the tumor and detect its amplification in the cells. The new algorithms using artificial-neural-network to solve the classification problem in the DNA groups associated for a particular disease in gene expression. The computational models used by the authors to classify are artificial-neural-network, multilayer-perceptron, radial-basis-functions and support-vector-machine. In the feature selection process, the authors had evaluated the accuracy of the model by using four different datasets for a particular disease using ABC algorithm.

Firoz khan et al., in 2020 [13] provided the information related to the digital DNA-sequencing to detect the ransomware using various machine-learning approaches. Software used to implement digital DNA-sequencing is ransomware, it is one of the classes of malicious software which is used to predict various attacks over the internet. Author had developed appropriate ransomware attack flow with machine-learning algorithms called DNAact-Ran (engine) methodology to predict the DNA-sequence. The DNAact-Ran engine is evaluated using the machine-learning performance metrics for analyzing the accuracy and engine effectiveness on real-time dataset.

The DNA-Binding model EL_LSTM was proposed by Jiyun Zhou et al., in 2020 [14] for residue relationship prediction. In this novel approach the authors had mainly

concentrated on the two concepts initially finding the pairwise relationship with long-short-term-memory bigram model and secondly solving the data-imbalance problem in DNA-binding. The authors considered four datasets namely PDNA-224, DBP-123, HOLO-83 and TS-61. The residue data instances are calculated using the sequence length and sub sequence length of the chain with protein sequence. Using the LSTM method, the experiment was conducted and the performance of each and every residue data instances are evaluated for neural-network, random forest, support vector machine and LSTM and accuracies of all algorithms are analyzed for all the four datasets.

Wunsch algorithm was proposed by Amr Ezz El-Din Rashed et al., in 2021 [15]. Biological-sequence-alignment-algorithm problems were addressed by authors using the Wunsch algorithm. In this model the DNA-sequence is considered as the input to the parallel workflow model, all the input sequences are performed with the machine learning models to decode the sequences label and to obtain the results. The traditional sequential model discussed in this paper are based on the sequential workflow consisting of input sequence, initialization of matrix, matrix score, traceback of matrix score and results generation. The Wunsch algorithm is capable of computing and converting the DNA-sequence from alphabet to the decimal or binary representation. The proposed model achieved a benchmark accuracy of 99.70% to prevent overfitting problem in the DNA-sequence.

Transcription-factor-binding was implemented using convolutional-neural-network by Qinhu Zhang et al., in 2021[16] for understanding the various DNA cellular-functions and binding mechanisms.

Erfan Aref-Eshghi et al., in 2018 [17] provided a detail description on monotonous debate between histone adjustment DNA methylation proposes that the ailment might be anticipated to show DNA-methylation impressions that ponder those primitive error related with chromatin myopathies. Here we study 14 mendelian states that show from direct disordering or indirect disordering of the proteins. To recognize Genomic regions, bear methylation. Switch, a jolt courser approach is used by the jolt courser package. Ten-fold cross checking of this representation showed an accuracy of 99.6%. If exactly detected the class of the 141 pompous subject that are used in training with other samples obtainable from alike conditions & other diseases are being reviewed for discovery of epi-signatures.

Antonino Fiannaca et al., in 2015 [18] suggested adjustment free procedure for DNA barcode categorization that is established on both a phantom representation and a neural-gas-network (NGN), for unsupervised-clustering. Best results can be acquired using adjustment -free approaches established on phantom sequence representation. The main aim of the suggested process that is pondered an addition of our earlier work is the categorization of an unrevealed DNA sequence utilizing the frequency of a little set of k-mers. Here other classifiers reached almost (99%-100%) accuracy, but CT method reached 97%. The efficiency decays to approximately 95% at the family, species, and genus level with suggested method 98-96% accuracy is achieved when for analysing full-

length sequences the score decays to 99-97% compared with suggested method.

Sara Alghunam et.,al. in 2019 [19] report on machine-learning that can be used for categorization, handling each dataset individually and connecting them. Micro-array is one of the fastest growing technologies in genetic research. When SVM and logistics were used they showed 50% and 45% respectively after feature selection process is applied, they showed 75% and 63% respectively. Spark & Weka libraries - when analysed spark libraries showed high accuracy and SVM (in Weka) has exceeded the other classifiers. Comparisons showed that GE data exceed DM, and SVM has given 99.68% efficiency.

Wenbin Liu et al., in 2020 [20] proposed a new miscellaneous learning review on ASM-SNP data (bi-polar disorder & schizophrenia). The recognized genetic differences in ASM-SNP data are key to disclose the underneath process of mental problems. Here the authors labelled the immediate confront via the latest miscellaneous learning and machine learning. New SNP (feature-selection) and continuous pathway-selection was examined and various miscellaneous learning meths included kernel-PCA, LLE...etc. The comparison from constitution clustering and imaging suggested that the misclassification between schizophrenia & Bi-polar disorder could be unavoidable for physicians. They achieved highest performance when using t-SNE and needed only 20% SNPs (Top-ranked) to achieve the best diagnosis.

Giulio Pavesi et al., [21] investigating whether practical details about genes can be predicted by using details obtained from their sequences combined with gene expression data. The SVM plays a crucial role in responding to the main request emerged from the work. To evaluate the categorization execution of SVMs authors worked on various holdout mechanism. They cautiously reviewed the election bias issue. For every training set obtained from proponent a subgroup of motifs outcome calculated by weeder. In specific, regarding one cluster, the genes percentage in test sets ranged from 68% to 70%. Experimentation as well case studies such as these may assist to shack more light on the present problem which remains amongst the most pertinent and calculated in bioinformatics and molecular-biology.

DNA functionality method that used the p53 malfunctioning in identifying the diseases [27] was proposed by Mikael S.Lindstrom et al., in 2022. The recognition of p53 worked was focused from many years with the enhancement in the biomedicine. Malfunctions associated with each disease can be identified using the clear insights of p53 malignancies. Authors used p53 for treating the cancer patients based of the DNA replicas. The fundamental procedure used for treating the cancer patients are p53-centeres multifaceted pathways and ribosome-biogenesis (RiBi). Author using the DNA replica and RiBi methods proposed a new approach which firstly deals with p53 canonical interaction and their regulation in post-translation of the target. Secondly, the response in DNA speed in performing replication with the p53 cellular genomic association with targeted cancer cells are given brief description. Emerging of p53 in replication stress (RS) are highlighted from the emerge of p53 to the key role in DNA

link replication. In addition, the tantalizing crosstalk in identifying the mediated monitoring between DNA replication and cell nucleolar RiBi are analyzed. Cancer diseases are outlined using the IRBC and the RiBi pathway tumorigenesis identification using the p53 malfunctioning in human. The p53 role in identifying the DNA replication and ribosome-biogenesis in cell homeostasis provided a clear vulnerability in identifying the cancer elucidation.

Prognostic investigation on DNA [28] methylation to identify the subtypes of tumors are proposed by Christopher et al., in 2022. Aberrant analyses of human DNA methyl patterns helped in identifying the subtypes of cancer diseases based on the response and outcomes. Authors used osteosarcoma malignancy procedure to perform chemotherapy using DNA methylation analyses. Authors worked on predicting the patient tumor with the help of the genomic methylation to identify the situation in the early stages. The patient response behavior to surgical reactions is also predicted using the hypomethylation procedure which derived high perfect outcomes. Downstream analysis for identifying the methylation patterns were performed in an experimental analysis using three datasets to derive site-specific methyl patterns. The experimental analysis was associated with the clinical human genomic outcomes.

Impact of mitochondrial DNA (mtDNA) in human brain postmortem detailed description was provided by Alba Valiente-palleja et al., in 2022. The authors [29] investigation pm mitochondrial DNA reveals the facts on the heterogeneous disorder genes that synthesize the phosphorylation oxidative systems. Neuropsychiatric symptoms are used for understanding the disorders of the human brain functioning. authors provided an empirical study on human brain tissues to alert the ageing process investigation in unequivocally diseases. The experimental analysis of this procedure on testing with various samples resulted a benchmark outcome in identifying the disorder using the mtDNA for finding the contradictory cells in human brain

IV. ML APPROACHES

In order to process the genetic information, machine learning algorithms plays a vital role in building a computational model by using the statistical theory. Table 1 describes the accuracy of various machine learning algorithms applied on different genome datasets. It helps the researchers in analyzing the DNA and its replications to various diseases and ML helps to identify the abnormalities in using the experimental procedure and optimization techniques to derive the accurate outcomes.

TABLE I. ACCURACY OF VARIOUS MACHINE LEARNING ALGORITHMS APPLIED ON DIFFERENT GENOME DATASETS

DATASET	ALGORITHM	ACCURACY
Helitrons database	Pre-Trained Deep Neural Network (PTDNN) classifier	72.6%
Helitrons database	Support vector machine (SVM)	68.7%
Helitrons database	Random forest (RF)	91%
TF Binding Datasets	Deeper CNN	

UCI Pima Indians Diabetes	Fuzzy rule-based classification	73.70%
Glass	Fuzzy rule-based classification	60.04%
Wisconsin Breast Cancer,	Fuzzy rule-based classification	91.21%
Wine	fuzzy if-then rules.	99%
Iris datasets	Fuzzy rule-based classification	96.67%
PDB database	SVM-REF+CBR; without feature extraction	78.85
PDB database	SVM-REF+CBR; with feature extraction	79.71
Multiple datasets	Needleman–Wunsch (NW) algorithm	85.9
WDBC directory	Sequential minimal optimisation (SMO),k-nearest neighbour(KNN),and decision tree(BF-tree)	96.19%
WDBC directory	Hybrid of k-means and SVM	97.38%
The gene expression omnibus(GEO)	novel graph-based semi supervised learning algorithm	24.9%
National center of biotechnology information (NCBIGEO)	SVM and logistic regression	>75%
Orange laboratories	SVM and logistic regression on sparks	75%
Epsilon dataset and GECCO dataset	SVM logistic regression, and Naive Bayes on spark	>75%
NCBI GEO	SVM	<70%
PDNA-224	EL_LSTM	82.59
DBP-123	EL_LSTM	81.44
PDNA-224	LSTM	78.36
DBP-123	LSTM	80.51
PDNA-224	NN	72.34
PDNA-224	Rf	75.27
PDNA-224	SVM	74.98
PDNA-224	LSTM	78.36
DBP-123	NN	76.36
DBP-123	Rf	77.29
DBP-123	SVM	78.34
DBP-123	LSTM	80.51
Ransomware	Multi-Objective Grey Wolf Optimization (MOGWO)	78.5%
Ransomware	Binary Cuckoo Search (BCS) algorithms.	83.2%
ALL-AML	MLP	1.0000
ALL-AML	SVM	1.0000
ALL-AML	SVM	1.0000
ALL-AML	KNN	0.9736
ALL-AML	SMV	0.9583
ALL-AML	KNN	0.9412
BREAST	SVM	1.0000
BREAST	SVM	0.9470

BREAST	J48	0.9381
BREAST	SMV	0.8421
PROSTATE	MLP	1.000
PROSTATE	SVM	0.9804
PROSTATE	SMV	0.9706
PROSTATE	LDA	0.9550
PROSTATE	LDA	0.9118
BOLD database	SVM	64.8%
Comet assay database	CNN	96.1%.

V. CURRENT CHALLENGES

The researchers, who are doing research with the DNA dataset by applying the machine learning logics can work on this current challenges.

- Improvements in the medical field.
- SNP for forensic investigation.
- DNA samples for identifying the human genetics.
- Inheritance disease identification.
- DNA damage in the gene sequence.
- DNA sequencing accuracy enhancement.
- DNA degradation.
- DNA analysis for body fragmentation.
- DNA mutation identification.
- DNA affect in health development.
- DNA profiling.
- DNA analysis with the high-end technologies.

VI. CONCLUSION

This paper helps the researcher those who are doing research with the DNA dataset to choose the appropriate machine learning logics depending on the model accuracy. They are given scope for predicting the sequence in the genome for extrachromosomal amplification identification using the feature scaling. By applying machine learning techniques in the unconventional chromosome can minimize the structural risk. DNA mutations can also be predicted using the genome data analysis using the statistical theory. Experimentation as well case studies shown in this paper may assist to shack more light on the present challenges.

An Architecture of Domain Independent and Extensible Intelligent Tutoring System based on Concept Dependencies and Subject Paths

Sanjay Singh, Vikram Singh

Department of Computer Science and Engineering
Chaudhary Devi Lal University, Sirsa, India

Abstract—Intelligent Tutoring Systems (ITS) seek to provide personalized tutoring to learners, but are often domain specific, and lack extensibility. When featuring extensibility and domain independence, it is a challenge to provide appropriate level of personalization for every learner. In this paper, an architecture of a system that features domain-independence and extensibility with personalization and automatic course improvements without requiring persistent subject expert intervention has been proposed. The proposed architecture utilizes the notion of concept dependencies and the ability to sequence inter-dependent concepts intelligently into subject paths that enable automated tutoring as well as effective course customization per learner. It features a separate interface for subject experts through which they do not require ITS building knowledge to fulfil their appropriately assigned tasks assisted intelligently by the system, and an API based interface layer that supports today's mobile requirements for better engagement.

Keywords—Personalized tutoring; intelligent tutoring system; adaptive learning

I. INTRODUCTION

Since centuries, students have been taught in classrooms, where there is one teacher and multiple students. A more personalized tuition may involve a teacher personally tutoring a single student. Ever since computers were invented, there has been a considerable effort at using them to mimic the teaching capabilities of a human teacher. Facilitating the job of teaching through the use of any electronic technology falls under the huge umbrella of e-learning, which is a far-reaching discipline that covers the analysis of all conjunctions of technology and education. A more appropriate definition by researchers in [1] states “Educational technology is the study and ethical practice of facilitating learning and improving performance by creating, using, and managing appropriate technological processes and resources”.

Since a human teacher, besides barely delivering a classroom lecture, performs considerable communication with the students and adjusts their teaching in response to the students' learning progress, researchers have been aiming to bring the exact qualities into e-learning systems to provide better tutoring. The most important and in-fact the ideal characteristic for an intelligent tutor is the ability of this communication [2]. The years around the 1960s and 1970s saw many new Computer-Assisted Instruction (CAI) projects funded by big names such as IBM and HP, that looked at

tutoring through a behaviorist perspective based on Skinner's theories [3]. While the CAIs were attracting interests, the researchers in [4] introduced Intelligent Tutoring Systems (ITS) and shed light on the idea that computers could act as a teacher rather than barely a tool. These systems realize established teaching-learning processes by way of AI (Artificial Intelligence) with an intention of delivering learner-adapted tutoring without any direct mediation of a human teacher. Intelligent tutoring systems combine AI, education theories, and psychological models of the student and the expert [5]. Thus, building truly intelligent tutoring systems requires experts from the AI community, psychology community and education community to come together. In a nutshell, an ITS aims to put AI technologies to use for the delivery of a teaching, which would have been branded as “Good Teaching” if it were delivered by a human teacher [6]. Many of the works have employed ethnographic and design research methods [7] to study the scenarios in which the teachers and learners actually use the ITSs, many a times disclosing unexpected needs that they met, failed to meet or even create in some cases.

Present day ITSs try to mimic the role of a teaching assistant, by trying to automate pedagogical functions such as problem generation and selection. Many recent works have focused on how ITSs can supplement the duties of an existing human teacher [8] in a classroom or a peer [9] in other social contexts. The field of intelligent tutoring systems have evolved into various sub-areas, like Dialogue Based Tutoring Systems [10] which provide tutoring to the student using natural language dialogue, Cognitive Tutors [11] which utilize a cognitive model (an approximation of animal cognitive processes) to provide feedback during the learning process, tutoring systems for Intelligent Computer Assisted Language Learning, etc.

The task of individualized one-to-one tutoring can be made more efficient if the tutoring machine is portable, leading us to the field of mobile learning, which allows a student to carry the tutor with them wherever they go. According to [12] M-learning is “learning across multiple contexts, through social and content interactions, using personal electronic devices”. The researchers in [13] suggest that mobile technology combined with network technology can connect formal learning to informal learning. Formal learning refers to the education delivered in a traditional classroom environment by trained teachers and informal learning is any type of learning

which is not formal. Mobile learning has the strength of being portable, which leads to more responsiveness and the ability to provide instant feedback. The work of [14] observed that mobile learning can increase exam scores from the 50th to the 70th percentile and reduce the dropout rate by 22 percent in technical fields. Mobile learning is also relatively cheaper because the cost of mobile devices is relatively lesser than that of laptops and personal computers.

Intelligent tutoring systems are expensive to develop, are often built for a specific domain of study, and the domain knowledge contained in them is limited because it is usually only fed-in at the time of development of the system. This paper proposes a framework for developing a domain independent and extensible system, that does not require persistent availability of subject experts, and the following sections discuss the related work, the proposed system's architecture with description of its components and modules, and an evaluation of the modules of the system.

II. RELATED WORK

The architecture of an ITS has greatly varied throughout the years in the works of various researchers but the core idea has remained the same – it can employ any architecture provided that it delivers intelligent tutoring, even though the original discussions on the architecture of an ITS describe these four crucial modules: The Student Model, The Domain Model, The Tutor (pedagogical) Model and The Interface Model [15–17]. The domain model, which can also be referred to as the knowledge model is the part of the system that contains the concepts, rules and problem-solving strategies of the domain to be learned. It helps fulfilling certain roles such as – being a source of knowledge, being a standard for evaluating learner's performance, etc. The student model is generally built on top of the domain model, as an overlay. It is often referred to as the core component of any ITS, as it deals closely with the learner's cognitive and affective states and their evolution as the learning process advances. The tutor (or pedagogical) model connects with the domain and student model of the system and makes decisions about the tutoring actions and strategies. This model is responsible for guiding the learner through the overall learning process making sure the learner does not deviate from the particular tutoring strategy adopted by the system. The interface model “integrates three types of information that are needed in carrying out a dialogue: knowledge about patterns of interpretation (to understand a speaker) and action (to generate utterances) within dialogues; domain knowledge needed for communicating content; and knowledge needed for communicating intent”

It is in-fact extremely rare to find two different scratch ITSs with the same architecture. The word Scratch ITS refers to all those ITSs that have been built from the ground up and have not been authored using some ITS building framework. Out of these, there have been ITSs based on three-model, four-model and other varieties of architecture.

A three-model architecture is based upon the declaration of three major core components – domain knowledge, student knowledge and tutoring knowledge. Researchers in [18] have proposed an ITS with the expert domain model, tutoring model and student knowledge model being the three major

components. The expert domain model and the student knowledge model guide the procedures in the tutoring model by providing the necessary information. The tutoring model is the most well-defined part of this architecture and it has various sub-components for curriculum planning, tutorial intervention and lesson planning. Another important three-model architecture is in the work of [19]. It also comprises of a domain model, a tutoring model and a student model but the difference between this architecture and the previous one is that it also incorporates an additional process – an overall system control process to co-ordinate the three models. This architecture also extends the lesson planning and dynamic adaptation concepts from the previous architecture to facilitate multiple tutoring strategies and information representations.

The three-model architectures made way for the classical standard four-model architectures. These architectures contain the three core components discussed in the previous architectures and add a fourth – the user interface component. A typical example for the four-model ITS architecture would be the work in [20] that has a knowledge base, a student model, a pedagogical model and a user interface. This architecture embodies cognitive and meta-cognitive processes in the student model and contains domain dependent tutoring rules in the pedagogical model. The key difference between this architecture and the architectures discussed in the previous section is that this architecture regards the user interface as an integral and internal component of the system whereas the previous section regarded this as a component external to the whole ITS system. This inclusion is helpful in that it concretizes the fact that a user-interface has a huge impact on the overall tutoring process, hence more efforts in user-interface design and development have become a concerning part of the overall ITS development process.

There are some architectures that take a deviance from the three-model and four-model architectures discussed. The idea of an intelligent learning environment has been promoted in MATHEMA [21] a multi-agent architecture which incorporates the notion of a human expert society (HES), a micro-society of artificial tutoring agents (MARTA) and external human motivators. This architecture surrounds the constituents of the classical architectures, although through a distinctive representation. The domain model is implanted within HES and MARTA, the user interface component is represented as interface agent, the role and functions of the tutoring model are dispensed among MARTA, and the human learner is not represented as a student model component as in other architectures, it is instead represented as a component of the learning environment itself. This architecture is suggested for well-structured, formal and specific knowledge domains.

There has been very limited work that has been done in the direction of domain independent ITSs, for they require considerable effort in representing each domain fairly. The researchers in [22] put forward ASSISTment builder tool that allows easy creation of ITSs that mimic cognitive tutors but the ITSs made with this are limited in that they only work for a single problem. These tutors provide a simple cognitive model based upon a state-graph tailored to a specific problem. Other aspects that have been rarely touched are extensibility – the ability to considerably extend the knowledge contained in the

system even after the system has been deployed. AutoTutor [23] is an intelligent tutoring system that helps students learn science, technology, and other technical subject matters by holding conversations with the student in natural language. Being able to extend the domain knowledge easily without requiring expert ITS development knowledge and doing that on-the-fly still remains a challenge. Another challenge is portability – for having a greater amount of time of the day with the learner, which brings various opportunities for better tutoring motivation. For solving all these challenges and more, in the following section, an architecture that ensures domain independence, extensibility, and portability, while ensuring personalization and adaptivity has been proposed.

III. CAPTAIN: MODULES, ARCHITECTURE AND WORKFLOW

This paper proposes Computer Assisted Personal Tutor with Adaptive INstruction (CAPTAIN) - a domain-independent ITS based upon concept dependencies and subject paths. It features extensibility – through automatic data generation, learner submitted questions and impersistent expert intervention, and portability – through an API based interface model that allows both desktop and mobile clients to interact with the ITS.

Its main strength is being able to expand its knowledge, improve itself, and be adaptable to any study area. It is based on five-module architecture and the modules have further specifications for sub-components as illustrated in detail in Fig. 1.

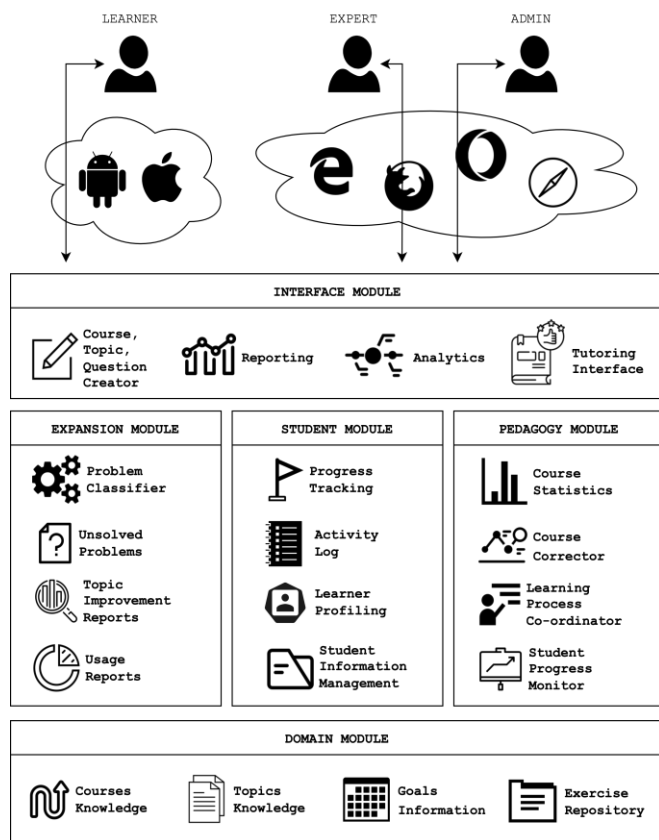

Fig. 1. Architecture Diagram of the System.

The domain module stores the domain knowledge. The architecture is not designed for any specific study domain, so the domain module is capable of storing knowledge about almost any subject area that can be represented through storing and linking modular topics, courses and study paths, along with exercises represented as questions and activities, and information about goals that drive the study paths and the whole tutoring flow.

The pedagogy module is made up of different components that share the common goal of assisting the tutoring process. It is responsible for using learner activity data for improving the quality of the courses that have been crafted by subject experts through its course corrector component, as well as coordinating the learning process and monitoring the progress of the learner.

The student module deals with storing and managing all the information about the learner. It deals with learner profiling – customizing the course according to the knowledge level of the learner in the course, and also deals with tracking the progress and logging the activities of the learner which are in turn used to by various other components of the system.

The expansion module is responsible for the ever-growing nature of the system. It has the problem classifier which maps the user submitted problems to their closest subject area for effective resolution by the appropriate subject expert, or prompts for creation of new topics if there aren't any appropriate ones available. It also provides the subject experts with topic improvement reports and information about how the courses are performing as well as the unsolved problems. It also provides the administrators the comprehensive usage reports of the system.

The interface module is responsible for facilitating the interaction between the learner and the system through mobile based platforms, and between the subject expert and the system as well as between the administrators/management and the system through the web-based platforms.

The system is designed and developed and has been deployed as three interconnected components – a backend server based on Django (python) that uses PostgreSQL as the database engine and serves a RESTful API, a web-app primarily for subject experts and administrators based on React JS, and a mobile app for the learners based on React Native.

In the following sections the key parts of the proposed architecture are explained in detail.

A. Basis

At the core of the system, the smallest and most re-usable atomic unit of information that exists to teach a fine-grained concept or skill has been termed a topic. Any subject area that is intended to be tutored must be fed into the system by subject experts in the form of small topics. The subject experts are expected to create topics that consist of that atomic bit of information which is content in itself.

The amount of information on a concept which is small enough that it is always expected to be studied together in one go, and that dividing which further will not make enough sense as there will always be another bit of information that always needs to be studied along with it. This makes the topics re-

usable and they can be used again and again in different courses, which in turn can be re-used in different study paths. As depicted in Fig. 2, in the proposed architecture, a topic is made up of any sequence of theory activities and question activities, along with an evaluation activity.

As it stated above that a topic needs to be fine grained, it may naturally require prior knowledge of zero or more other topics, which is necessary to represent complex concepts as simple learnable units. Topics are related with other topics via the ‘requires’ relation. This relationship can be realized via a graph, more precisely through a Directed Acyclic Graph representing topics as nodes and a topic’s requirements as an edge from the topic’s node to its required topic’s node as illustrated in Fig. 3.

Since specifying a topic as a requirement for another topic is susceptible to possible creation of cyclic requirements (a situation in which topic A requires topic B and, directly or indirectly, topic B requires topic A), a measure has been implemented to prevent generation of cycles at the point where the subject expert adds a topic as a requirement for a topic.

Studying individual topics is good, but to study a subject or a large topic, one has to study a large number of topics in a certain sequence. This feature has been termed as a **course**, which is crafted by a subject expert by linking a set of topics together in a particular sequence so as to fulfill the aim of tutoring a subject or a large or complex topic. Since a topic may require prior knowledge of other topics, this puts some constraints on the sequencing of topics in a course, because a topic’s required topics must only be sequenced before the topic. Also, how many of the topics’ required topics will be included in the course is another decision the subject expert makes. If a course contains topics whose pre-required topics are not a part of the course, they become the requirements of the course itself, as illustrated in Fig. 4, with reference to the topic relationships illustrated in Fig. 3, as topics 9 and 7 require topic 2 and topics 10 and 7 require topic 6 but topic 2 and 6 are not part of the course, they become the requirements of the course, rest all other topics’ requirements are being satisfied within the course.

Fig. 2. Structure of a Topic in the System.

Fig. 3. Topic Relationships Illustrated through a DAG.

Fig. 4. Illustration of the Structure of a Course.

A course is also designed with such a level of granularity that it is independent in itself in teaching a subject or a large topic, and in this sense, it becomes a re-usable unit that can be studied by learners who have different goals but they are to study certain courses, in a certain sequence to achieve their specific goal. This level of sequencing has been termed a study path, which is an ordered collection of courses intended to prepare the learner for a specific goal, and this is the largest learnable unit in the system, and the least re-usable one.

In the system a goal refers to any concrete motive or objective for studying. The best example of a goal is any national level exam that is to be conducted, and there are many students that need to prepare for it. Goals are added by system administrators, the subject experts then create the study paths for them by re-using the courses in the system or by creating new courses, by in-turn re-using the topics in the system or by creating new topics, while mapping dependency relations to other topics if necessary. Fig. 5 illustrates the operation from the learner’s goal selection to the system’s tutoring process.

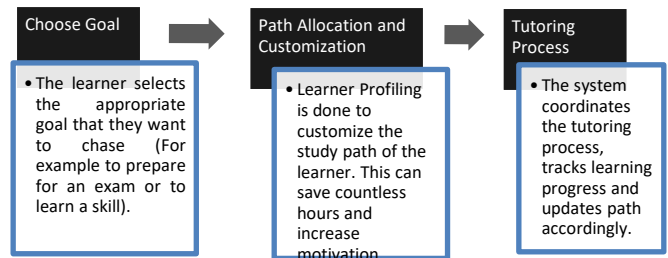

Fig. 5. Flow from Goal Selection to Tutoring.

B. Extensibility

The limited domain knowledge contained in a system can be extended from two ends. One of these is when the subject experts manually feed new domain knowledge into the system using the appropriate interface. This has a limitation – it is slow and it only expands the system in the direction which is determined by what the subject experts think should be and should not be a part of the system. Another way to truly steer the direction of expansion of the system towards what the learners of the system actually need is by allowing the learners to submit new questions.

In the proposed architecture, the new questions submitted by any learner are mapped on to the topics that currently exist in the system, and if there are no appropriate topics that fully relate to the questions, the architecture prompts the subject expert to create new topics that map with the question more appropriately. This leads to two outcomes, the first one being improvement and expansion of already existing topics, which is in turn going to help other learners as well. The second one being creation of new topics, which will eventually lead to generation of new courses, and new courses lead to new

subject paths that lead to new goals that increase the overall reach and usability of the system. Fig. 6 depicts the overall process of expansion.

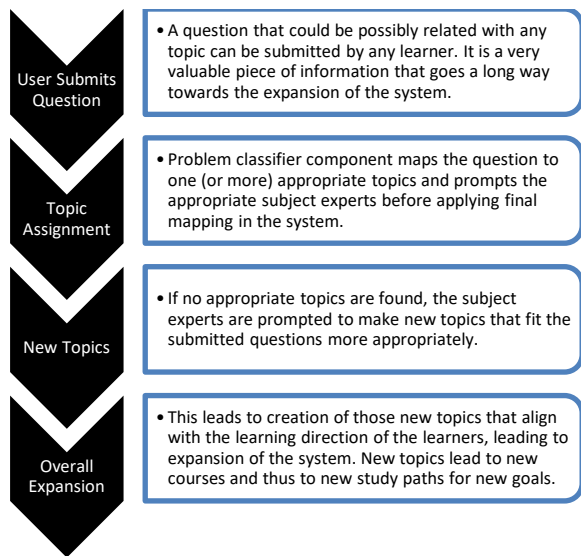

Fig. 6. Flow of System Expansion.

There is a mapping between questions and topics, that a question could be linked to one or more topics. The task of mapping a submitted question/problem to a topic is achieved using the problem classifier component of the system, which is an integral contributor towards the extensibility of the system.

1) *Problem classifier:* The ability of a learner to ask questions to a subject expert for an effective resolution is, at its core, one of the most fundamental activities involved in any learning process. In fact, a good question, combined with its solution will continue to help future learners who want to learn the subject, who can learn a lot by reading other people's questions and their solutions. For this, and many other reasons, in an e-learning environment that deals with questions, it becomes very helpful to classify the questions according to subject areas for an organized study. This problem of question classification falls under the umbrella of a domain of research called text classification.

Text classification deals with utilizing machine learning techniques to assign a class/label to any input text. It has been used widely to classify product reviews by corporations that want to understand the sentiment of their customers, or many specific cases such as to predict the ideological direction of court cases [24], or to classify fake news or hoax, which have become the most prevalent cybercrime in today's day and age that have immeasurable harms [25] or to identify a person's distinctive habits and behaviors through personality classification [26]. Various papers resolve the issue of programmed text classification proposing various strategies and arrangements. Extensive thorough reviews also exist that document text classification in detail [27-30].

When the data-set consists of user-submitted short questions with a vastly disproportionate number of questions in different subjects, the overall classification becomes a

challenge. Researchers in [31] have proposed a general-purpose approach to assigning user-submitted questions their appropriate topic labels, without any extra vocabulary information related to the subjects. Several grid hyperparameter-searched iterations of Generalized Linear Model, Deep Learning (ANN), Gradient Boosting Model, Extreme Gradient Boosting Model (XGBoost), Distributed Random Forests and Extremely Randomized Trees were trained and evaluated, and it was found that out of these, XGBoost performs the best with a small and imbalanced dataset of very short text documents. To further improve the classification performance, a general-purpose approach to handle the unbalanced classes was used utilizing class weights.

C. Personalization

Personalization is the gist of intelligent tutoring. There is no point in calling a system intelligent unless it has some sort of personalization or adaptivity in it. In the context of ITSs, personalization and adaptivity can be practiced at various stages, but the most common one of these is the customization of the course a learner is taking according to the knowledge levels of the learner. This level of adaptivity is helpful at various aspects, one of which is it shortens the overall duration of the course. It is also helpful for uplifting the motivation of the learner to study because if the system presents those topics to the learner which they already know, it can lead to loss of interest, possibly leading to the learner leaving the course in between.

It is particularly challenging to implement course personalization in a system that features extensibility, as the system is going to require personalization in the courses of various varied domains that are going to be created automatically (or subject expert assisted) in the future and do not exist at the time the system was built.

1) *Learner profiling:* To achieve personalization and adaptivity in a system, sufficiently granularized domain knowledge is needed which can be broken-down or combined in multiple ways. This is best achieved when a limited piece of domain knowledge about a certain subject or a fixed number of subjects is structured into the domain model of the system in any rule-based analogy, as utilized by researchers in various domain-specific ITSs discussed in the previous sections. It is easy to form specific strategies to estimate the knowledge level of a specific subject, but to achieve learner profiling in a general-purpose system that supports all types of textual subjects is a challenge that researchers in the field of intelligent tutoring have been trying to solve since decades.

Researchers in [32] have proposed a learner profiling algorithm which is able to adapt any general-purpose course that the learner wants to take, to the knowledge level of the learner, in a very short time quantum, improving the motivation of the learner, shortening the total amount of time needed to complete the course tremendously and hence the overall learning process. The amount of time saved for the learner depends upon the number of topics detected to be known and the individual lengths of those topics. The algorithm requires topic inter-dependency information, which is typically provided by subject experts while drafting the

course. In addition to this, data of responses of past students that undertook the same course is used to improve the topic interdependency information – taking a safer approach for a general-purpose tutoring system when there is a possibility that the subject expert might not be able to map accurate relationships between topics perfectly. These two help the minimal learner profiling algorithm build the learner’s knowledge profile as illustrated in Fig. 7 and it does that in the minimum amount of time possible.

Fig. 7. The Proposed Model for Learner Profiling.

As there is no way to actually look inside the brain of the learner and check the neural connections to determine whether the learner knows the topic or not, the actual accuracy of predicting the knowledge level of the student with respect to a specific topic depends upon the quality of the assessment activity of the topic and the honesty of the learner’s responses. If the quality of the assessment activities is assumed to be perfect the algorithm guarantees accurate adaptation of the course to the learner in the minimum possible time.

D. Course Improvements

A system that allows extensibility and teaches any types of courses to all types of learners without need of persistent intervention from a subject expert, it is necessary to have a mechanism that improves the domain knowledge and course information in the system. In the proposed architecture course improvement is achieved through two means as discussed in the following sections.

1) *Automatic course improvement*: The subject expert specifies the dependencies between topics and creates relationships mappings illustrating which topic depends upon which zero or more topics. These dependencies assist the overall instruction procedure for the learner, but the actual degree of dependencies between the topics is further refined using the data obtained from the initial learner profiling algorithm as covered in the work of [32]. This improves the overall mappings between topics, thus creating even better tutoring procedures and experiences for future students.

2) *Collaborative course Improvement*: This is achieved through manual intervention by the learners. The learner – the ultimate end-users of the system can also, collaboratively,

seed course improvements for everyone. Since the expansion in the system happens dynamically, at any point can have gaps and/or faults in any grain of knowledge anywhere from a simple question to a topic to a course to an entire goal. The learners can report errors or gaps in any grain of the system, and it is prompted to the appropriate subject expert. Since every grain of knowledge is interconnected deeply with all the other parts of the system, improvements in any tiny fragment leads towards refinement of the entire system.

IV. EVALUATION

For the evaluation of the effectiveness of the proposed framework, the components that make up the framework were evaluated thoroughly. The said evaluations have been stated in this section grouped under the respective modules they serve.

A. Expansion Module

In the implementation of the system for the evaluation of the module which is responsible for the ever-growing nature of the system, majorly because of the problem classifier component, a dataset of 6925 problems made up of short text documents from 13 different topics as illustrated in Fig. 8 was taken.

Fig. 8. Problem Dataset Distribution.

The system trained and evaluated around 20 industry standard classification algorithms on the dataset, the four best performing ones of which are shown in Fig. 9 with their per-class error distributions.

Fig. 9. Per Class Error.

Fig. 10. Classification Error and Log Loss of Question Classifier.

Out of these algorithms XGBoost had the minimum per class error and was chosen as the algorithm of choice for the problem classifier component in the implementation of the system. The classification error and log loss of the algorithm are illustrated in Fig. 10. The figure illustrates the changes in classification error and log loss with respect to the number of trees in the iteration of the algorithm for training as well as validation data.

This problem of imbalanced classes refers to the situation that all the subjects have not been represented equally. More precisely, there is a huge disproportionality between classes, with certain subjects having more than 800 samples and some not even having 80 samples. The problem of imbalanced classes has been greatly explored in excellent reviews in [33], [34]. Class weights were calculated from the dataset distribution frequency and the model was retrained with the best hyperparameters found by the previous search. As a result, the F1 score as well as precision and recall values improved as seen in Table I.

In the quest of proposing a general-purpose approach to assigning user-submitted questions their appropriate subject

labels, without any extra vocabulary information related to the subjects, several grid hyperparameter-searched iterations of Generalized Linear Model, Deep Learning (ANN), Gradient Boosting Model, Extreme Gradient Boosting Model (XGBoost), Distributed Random Forests and Extremely Randomized Trees were trained and evaluated, and it was found that out of these, XGBoost performs the best with a small and imbalanced dataset of very short text documents.

TABLE I. CLASSIFICATION REPORT FOR XGBOOST

Class	After Class Weights			Support
	Precision	Recall	F1-Score	
Artificial Intelligence	0.29	0.14	0.19	14
Computer Networks	0.87	0.83	0.85	168
Digital Logic	0.79	0.86	0.83	143
Algorithms	0.72	0.72	0.72	109
Computer Organization	0.73	0.79	0.76	112

To further improve the classification performance, a general-purpose approach to handle the unbalanced classes was used utilizing class weights. The overall average performance of XGBoost on the validation data has been shown in Table II.

The workflow also same training can be repeated when implementing the system for any other subject domain. Through the ability of problem classification, the system is able to classify new and unseen learner submitted problem to their appropriate topics, and if there aren't any appropriate topics, the system allows the subject experts on the backend to create new more appropriate topics for the problem at hand, resulting in the expansion of the system.

B. Pedagogy Module and Student Module

Based on the topic relationships illustrated in Fig. 3, learner response data was collected from 60 learners assessed over 10 topics and using the algorithm proposed in [32] the precision of the relative prediction of knowledge of other topics when knowledge of one topic is given was calculated as illustrated in Table III. The intensity of the shade in each cell denotes the magnitude of the precision.

TABLE II. PERFORMANCE METRICS OF XGBOOST ON THE CLASSIFICATION OF VALIDATION DATA

The improvements in the course suggested by the course corrector component through the use of the prediction precision table are illustrated in Fig. 11. After manually choosing a threshold value of 0.8 and combining it with the prediction precision information calculated before (as shown in Table III), the course corrector component predicted the relative dependencies between topics, mapped over the topic relationships specified in Fig. 3. In the figure, the dotted lines show new suggested dependencies and the numbers written on the arrows suggest the predicted strength of the dependency. This way the component can be used for learner-response-data-driven course improvements.

The learner profiling algorithm uses the topic dependencies fed in by the subject experts, and possibly improved by the course corrector component, and combine it with the past learner response data to achieve learner profiling with the minimum possible number of assessment activities based on a controllable parameter that has been called the trust threshold. Fig. 12 illustrates the various assessment sequences generated by the algorithm with respect to the value of the trust threshold parameter.

So, through the use of a non-subject-specific arbitrary topic relationship structure and hierarchy and past learner response data, the system is able to generate assessment sequences of varying lengths and complexities. This show that the framework can perform course customization through learner profiling on any course that is made up of a sequence of inter-dependent topics, be it of any subject.

C. Domain Module and Interface Module

The domain model realized the entire course, topic, goal and exercise information the system revolves around as entities and the relationships mapped among them. In the current implementation of the system the domain model was implemented using the popular open-source object-relational database system PostgreSQL. The following describe the highlights of the implementation of the architecture of the domain module in the system:

- It realizes the building blocks that the framework is based around adequately.
- It can represent all expected data over time.

- The model ensures that it avoids repetitive storage of the same information.
- The model ensures the maintenance of data integrity over time.
- It is clean, consistent and easy to understand.
- The model provides efficient access to data.

The interface module is able to successfully control access to the data is through the use of token-based authentication mechanisms. The module, apart from giving access to appropriate interfaces to appropriate users and learners, ensures the proper functioning of various other modules through various integrity checks in place. For illustration, in the creation of courses that do not possess cyclic dependencies between topics, because a topic A requiring prior knowledge of a topic B while simultaneously topic B requires prior knowledge of topic A is a problem, and it can inhibit the proper functioning of the pedagogy and student module. The rest of the evaluation of the interface module has been avoided for the sake of brevity.

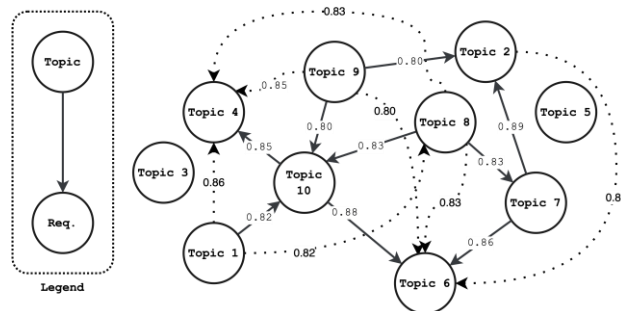

Fig. 11. Topic Relationships Calculated by Course Corrector Component.

V. CONCLUSION

In this paper, an architecture for a domain-independent intelligent tutoring system that features extensibility, personalization and automatic course improvements has been described. It features an interface module that provides separate interfaces for learners and subject experts. The architecture allows expansion of the system without requiring persistent intervention or any knowledge of building ITSs from the subject experts and portable (mobile) interfaces for learners for better learning, motivation and engagement. This provides countless avenues for cost-effective tutoring.

The proposals for future work would be to add support in the architecture that allows the ability of creation of new portable modules that could be built by anyone using a possibly defined format, and added to the system to incorporate various features into any part of the system. An example would be a module that replaces the pedagogy algorithms, or a module that utilizes neural networks for a part of the system, etc. Also proposed is the ability to integrate with other apps, since this architecture has an interface module that works through APIs, the possibility of what can be achieved after integration with other apps and platforms would be exciting to explore.

Secure Routing Protocol for Low Power and Lossy Networks Against Rank Attack: A Systematic Review

Laila Al-Qaisi, Suhaidi Hassan, Nur Haryani Binti Zakaria
InterNetWorks Research Lab, School of Computing
Universiti Utara Malaysia, Kedah Darul Aman, Malaysia

Abstract—The Internet of Things (IoT) is witnessing massive widespread along in almost all aspects of life. IoT is defined as a network of interconnected devices applied in various environments including smart cities, transportation, health, industries, military, and agriculture. Its main purpose is to simplify the exchange and collect data from and to deployment environments. Due to their small size and cost-effectiveness, Wireless Sensor Networks (WSN) form one of the core technologies deployed in IoT. Yet, things interconnected with each other and exchanging data are prone to different kinds of security attacks. As a result, it is possible to compromise data while transmitted from source to destination through nodes. Routing Protocol for Low Power and Lossy Networks (RPL) offers only slight protection against routing attacks, but having a network with limited energy sources, processors, and memory, besides being deployed in unattended nature and hostile environment requires more scalable security measures. This paper focuses on investigating the problem of security provisioning in RPL. As such, a Systematic Literature Review (SLR) of security mechanisms proposed for RPL will be discussed. An extensive search was conducted on various online databases, then findings were filtered by reviewing abstracts, introduction, and conclusion. Finally, a summary of recent research work is presented. This work is important to highlight various aspects of securing RPL and get an initial insight for studying them.

Keywords—Wireless sensor networks; internet of things (IoT); routing security; RPL; objective function

I. INTRODUCTION

Internet of Things (IoT) emergence was led by the assistance of existing wireless communications along with Radio-Frequency Identification (RFID), Wireless Sensor Network (WSN) technologies besides new emerging technologies such as Information-Centric Network (ICN) and Named Data Networks (NDN) [1]. So, data is easily transmitted between various devices and associative things regardless of time and place through network standards and protocols. Every device and thing in IoT is assigned a unique Internet Protocol (IP) address, by which they can sense and collect data from the deployment environment for both processing and decision making. IoT is contributing significantly to various domains like smart cities, building, healthcare, and agriculture and has a vital impact on improving people's daily life [2].

IoT architecture is presented in the literature as mentioned by [3]–[5] consisting of three main layers, namely, perception, network, and application layers. As a hot research topic, many

researchers found the three layers architecture very basic and is suitable for defining the main terminology of IoT and cannot be used for research that digs into further components of IoT. This is when the five layers architecture was introduced as [3] explained, it included processing and business as additional layers. Fig. 1 shows both three- and five-layers architecture.

The network layer is responsible for communication and information exchange employing techniques, standards, and protocols to simplify the task such as Internet Protocol Version 4 (IPv4), Internet Protocol Version 6 (IPv6), Constrained Application Protocol (CoAP), Wireless Personal Area Network (WPAN), IPv6 over Low Power Wireless Personal Area Network (6LoWPAN), User Datagram Protocol (UDP) and Transmission Control Protocol (TCP). Securing data transmitted between the perception layer and the application layer is facilitated by the network layer as well [6].

The Routing Protocol for Low-Power and Lossy Networks (RPL) was developed by the Internet Engineering Task Force (IETF) to fit into Wireless Sensor Networks (WSNs) and the Internet of Things (IoT) domains. As a simple networking protocol, RPL was designed as an interoperable protocol that handles resource-constrained devices connected via multi-hop networks. It enables efficient use of smart devices' energy along with the establishment of flexible topology and routing of data [7].

Nevertheless, the RPL protocol since its inception suffers from a lack of security measures at the network layer as stated by [8]. RPL and its improved versions suffer from a severe performance gap towards network attacks especially ranking attacks [9]. Securing IoT routing should be studied considering WSN features as they are inherited into the IoT environment [10]. Moreover, other metrics in RPL should be taken into consideration such as power consumption as a major challenge facing IoT and controls network lifetime [11].

Cryptography, Intrusion Detection Systems (IDS), Intrusion Prevention Systems (IPS), authentication, trust-based mitigation techniques, and much more, have all been introduced to solve security vulnerabilities in LLNs [12]. In the application, transport, network, and physical levels, IoT devices and traditional PCs share some similar protocols. The biggest impediment to LLN devices implementing existing security methods at IoT interfaces is their limited computational and energy resources [13]. LLN devices produce massive amounts of data, but they lack the resources to store and process it.

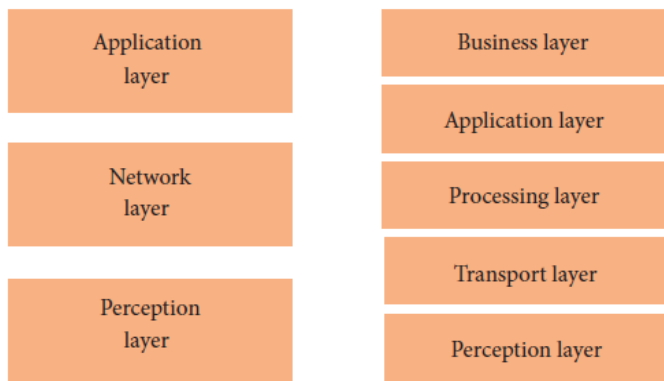

Fig. 1. IoT Architectures [3].

Since in IoT, RPL plays a vital and broad role in service providing, it's a clear target for attackers and a crucial candidate for defense as well. To overcome security issues and challenges in RPL routing, further research is required as per [14], and how intrusions on RPL can be detected is one facet of defense that must now be examined. As a result, this forms a starting point to investigate, propose, and implement mitigation mechanisms for network layer attacks [15].

The main goal of this study is to show the impact that rank attacks (RA) can have on RPL networks. Also, to study and compare the available research that support RPL security and counter the effect of these attacks in terms of the security techniques utilized and their performance. To point up the flaws in the available solutions suggested by existing studies. To suggest some potential methods to address the existing flaws and increase RPL security in IoT networks by limiting the effects of RA. Also, discuss some open challenges in this study area that require more attention.

This paper presents an SLR of security mechanisms proposed for RPL RA specifically being one of the most destructive attacks targeting RPL topology. Starting with RPL in-depth explanation. Followed by a discussion on RPL attacks along with a suitable taxonomy. A focus on rank attacks is presented afterward. Finally, a summary of the selected studies is presented. The remainder of this paper is organized as follows: Section 2 defines and explains preliminaries. Then, Section 3 identifies and explains the following SLR methodology. Section 4 discusses the results found thoroughly. Finally, Section 5 summarizes selected research papers and therefore compares the approaches used by the researchers.

II. PRELIMINARIES

A. Routing Protocol for Low-Power and Lossy Networks (RPL)

Since Low-Power and Lossy Networks (LLN) consist of highly constrained devices in terms of memory, processing capabilities, and energy resources, RPL was designed as an IPV6 distance vector protocol to support communication among LLN devices such IoT. It was mentioned by [16] and [17] that such networks suffer from low data and packet delivery rates along with lossy connection which RPL was designed to be flexible enough for network conditions'

adaptation and provide suitable alternative routes when default ones are not available for any reason at any time.

RPL can be defined as a proactive routing protocol that relies on the distance between nodes and sink node to form a topology. The following explanation of the RPL hierarchy is based on [18]–[21]:

1) *Hierarchy*: Using the distance vector procedure RPL exploits Directed Acyclic Graphs (DAG) mechanism to construct a structure tree or DODAG (Destination Oriented Directed acyclic graph) that controls available nodes' connections with each other. This will enable multi-hop communication via the closest nodes.

RPL methods for establishing connections include point-to-point (P2P), point-to-multipoint (P2MP), and multipoint-to-multipoint (MP2P) communications. While types of nodes for constructing topology are, the source that are responsible nodes for gathering information, leaf nodes that do not perform any task and sink nodes which are the most significant with capabilities of energy and processing to compile whole network information. Hence, two major terms are required here, Control Messages (CM) by which connections are initiated and maintained along with topology formation, and Objective Functions (OF) for routing decision making through the network.

Four types of CM are used to exchange information between nodes in RPL:

- DODAG Information Solicitation (DIS): it is used to request passing the DIO to network neighbors.
- DODAG Information Object (DIO): Stores pertinent information needed to build upward DODAGs route such as RPLInstanceID, configuration parameters, candidate parent information, DODAG maintenance, and more.
- Destination Advertisement Object (DAO): sends information to register every node visited on the downward route.
- Destination Advertisement Object Acknowledgement (DAO-ACK): confirms safe receipt of sent DAO message to the sender node.

2) *Objective function (OF)*: OF was described as the basic element that is handling several vital definitions;(1) computing link cost, (2) parent node selection (when, who, and how many candidates), and (3) computing rank cost, fourth: advertising path cost. There are two defaults OF with RPL, MRHOF (Minimum Rank with Hysteresis Objective Function) and OF0 (Objective Function Zero), and the following are their definitions as per [22]–[24]:

- OF0: This OF adds a specifically predefined value to the previous rank. It takes hop count as a routing metric and selects the best parent node from available candidates based on that. While building the DODAG, nodes should consider hop count to get the shortest path for reaching the grounded root. The rank increases

while going down from root to candidate nodes. However, reliance on node metrics will cause poor link quality. Also, selecting the shortest path in terms of minimum hop count may lead to more retransmissions along with increased packet loss if the path was unreliable. Additionally, this same shortest path may cause more node failure which will definitely decrease network lifetime.

- MRHOF: This OF was designed to overcome the shortcoming of OF0 which depends on a single node metric to compute rank and choose the best parent node. It relies on the expected transmission count (ETX) as a dynamic link metric to stabilize the rank. Still, it chooses the lowest-cost path and avoids network churn overflow using two mechanisms. First, choose a low-rank path, and second hysteresis mechanism ensures changing rank to a lower one only if there exists a rank that is less than the current one. Literature has two main implementations of MRHOF, one that relies on ETX and the other relies on energy.

3) *Routing metrics*: Routing metrics are essential to evaluate path cost and then choose the lowest cost path. There are too many implementations in literature for OF, some take a single metric to calculate rank, while others consider more than one metric. As a matter of fact, metrics can be categorized based on their characteristics into node and link, dynamic and static, quality and quantity routing nodes [25]. Both routing metrics and constraints are used to form a criterion to choose the optimal path. Yet, the main difference between them is that constraint is used to restrict options such as avoiding unreliable links, while metrics define a certain level of reliability to include links that give the optimal path. As a result, both metrics and constraints are used and deployed as per RPL implementation requirements [26]. Moreover, dynamicity is a vital characteristic of metrics, since RPL operating environment is rapidly changing which results in instability of both node and link metrics [27].

The following list summarizes metrics of both link and nodes (refer to Fig. 2):

- Link metrics:

a) *RSSI and LQI*: main radio link estimators are the Received Signal Strength Indicator (RSSI) and the Link Quality Indicator (LQI). The former indicates the level of power received by an antenna that is a high level of RSSI means a stronger radio signal which indicates a closer destination. While the latter measures the quality of the link using a range of values between 0 to 7.

b) *ETX*: Expected Transmission Count indicates the reliability of the network and gives the required number of transmissions for receiving acknowledgment from the destination.

- Node metrics:

a) *Energy*: represents the energy consumed by nodes through network operations.

b) *Hop count*: it is a measure of path link that is used extensively in wireless networks and the main drawback is to get the shortest path with the lowest hop count regardless of link quality.

c) *End-to-end delay*: a vital metric for building route in RPL and it indicates the needed time to deliver packets to the sink from sender nodes.

B. RPL Attacks Classification

RPL is vulnerable to various kinds of attacks and does not have a solid security measure that can prevent such attacks [28]. There are several taxonomies proposed for attacks targeting RPL in different studies, such as Almusaylim et al. [17] in which three main types of attacks were explained namely; against resources that consume nodes resources, topology in which try to cause damage in the construction process and traffic which aim at capturing as much traffic as possible. Also, Avila et al. [10] categorized attacks into passive and active attacks, where passive attacks aim to gather information after accessing the system and comprise confidentiality, and active ones sabotage the system by data alteration, disabling nodes, or giving access to unauthorized users. An interesting categorization was presented by Raouf et al. [29], in which attacks were classified based on their origin into RPL Specific and WSN inherited as Fig. 3 shows.

Fig. 2. Routing Metrics.

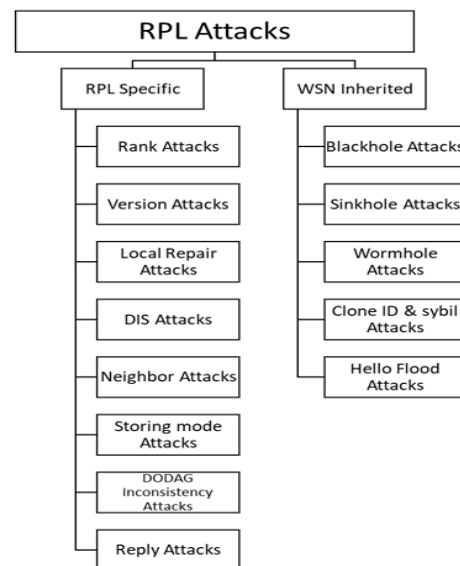

Fig. 3. RPL Attacks.

III. METHODOLOGY

This study employed the systematic literature review guidelines and standards proposed by Kitchenham [30]. This consists of a set of well-defined stages conducted in line with a predefined protocol. SLR consists of three phases: planning, conducting, and reporting the reviews according to Shaffril et al. [31]. These phases consist of the following processes: (1) identifying RQs; (2) developing a review protocol; (3) determining both exclusion and inclusion criteria; (4) selecting search strategy and study process; (5) quality assessment (QA); and (6) extracting and synthesizing data.

A. Identifying Research Questions (RQs) Text

To achieve the main objectives of this study, primary studies should be assessed and reviewed thoroughly. As a result, the following research questions are proposed based on Population, Intervention, Comparison, Outcomes, and Context (PICOC) as per [30]:

- RQ1: What is the impact of the rank attack and to which extent do they damage the network?
- RQ2: What are the proposed approaches that monitor the network to handle attacks targeting RPL?
- RQ3: What are the technical performance metrics of the research in this field?
- RQ4: What are the advantages and disadvantages of each proposed approach?

B. Developing a Review Protocol

A vital step that makes SLR different from traditional methods of reviewing the literature. Because it decreases study bias as discussed by Shaffril et al. [32]. The review protocol categorizes review background, search strategy, development of RQs, extraction of data, criteria for study selection, and data synthesis.

C. Search Strategy

The search strategy started with choosing E-digital libraries and online databases as the following list shows, taking into consideration selecting only high-impact-factor publications:

- IEEE Explore
- ACM Digital Library
- Science Direct
- Scopus
- Wiley Online Library

Afterward, the search string is required to conduct an in-depth search through selected E-digital libraries. The following steps were applied to define the used search string as per [30]:

- Define major keywords depending on identified research questions.
- Consider linguistic synonyms, alternatives, and interchangeable terms for each keyword.
- Use conjunction operators (AND, OR) when needed to produce the full search string.

As a result, keywords included for the search were “IoT” OR “Internet of Things” AND “RPL” OR “Routing Protocol for Low-Power and Lossy Networks” AND “rank attack detection” OR “mitigation”. All available papers relating to specified keywords 2022 were collected from digital libraries.

Afterward, a manual search was applied to the results of the automatic search by filtering each paper's title, abstract and content. This is to ensure that the selected paper supports answering the defined QAs and Fig. 4 illustrates the overall search phases.

D. Inclusion and Exclusion Criteria

Search results are filtered in terms of the following inclusion and exclusion criteria:

- Inclusion Criteria:

- a) Written in English language.
- b) The study's domain is RPL and responds to previously stated RQs.
- c) Published in journal or conference.
- d) Published date: 2017-2022.

- Exclusion Criteria:

- a) Duplicates.
- b) Unavailable full text.
- c) Do not meet the inclusion criteria.

Afterward, a manual filtration process was conducted by reviewing the title, abstract, and conclusion to get papers that meet the set criteria of found papers. This eliminated the number of found papers from 1061 to 9 only, given that only papers published between 2017 to 2022 and studied RA in RPL only.

E. Applying Quality Assessment (QA)

The related studies' quality was assessed using QA as recommended by Kitchenham [30]. All found studies were assessed concerning every single research question. QA criteria used for the assessment process were as follows:

- QA1: Is the topic addressed in the paper related to securing RPL?
- QA2: Is there any mechanism proposed to detect rank attack detection in RPL?
- QA3: Is there a sufficient explanation of the background in which the study was performed?
- QA4: Is there a clear declaration concerning methods used to validate the applied mechanism?

The reliability of articles and studies found was tested through the four QA criteria and has three categories low, medium, and high as by Shaffril et al. [31] and [32]. Each QA had a score of 2 points and each paper that meets the defined QA earns a score of 2, 1 is earned when the paper partially meets the QA criteria and 0 when it does not satisfy the QA criteria at all. Papers scored more than 5 are discussed in the next section and are categorized based on the technique used and Table II summarizes the findings sorted by year of publication.

Fig. 4. Systematic Literature Review (SLR).

F. Data Extraction and Synthesis

For accurate data extraction and synthesis, a form was developed to conduct this step. Details of each study related to the reference, year of publication, methodology, and comments were extracted. A tabular form was used to register this information about each study. Table I illustrates the details registered for each paper.

TABLE I. TABLE TYPE STYLES

Extracted Data	Description
Study ID	paper DOI
Year	Publication Date
Type	Journal or conference
Methodology	e.g., trust, cryptography, IDS
Performance Measure	e.g., ACC, PR, RE

IV. RESULTS

This section discusses rank attacks against RPL and analyzes the application of detection and mitigation techniques towards it. The methods analyzed herein are ones that were proposed to secure RPL against RA. The goal is to present their performance in terms of the chosen performance metrics which will be discussed here as well.

A. Rank Attack (RA) (RQ1)

This attack aims at attracting network traffic to a specified node. Ul Hassan et al. [34] defined RA as an attack that occurs when the malicious node sends information of a lower range, to be closer than others to the root. This scenario will have a consequence that makes malicious nodes able to capture as much traffic as possible. Hashemi and Aliee [35] mentioned that RA is considered the most destructive attack among other types, this is because it intentionally aims at downgrading the network performance by tampering with the rank. By which a rank is decreased to make the malicious node closer to the

chosen parent, so a massive amount of passing packets through it may be manipulated.

RA workflow starts when a malicious node sends a fake rank through an RPL control message or advertises a fake route across the root node to mislead close nodes to make them transmit packets through it [36]. In other words, RA exposes ranks of child nodes in the RPL network topology, then modifies the way of processing DIO messages by neighboring nodes. The worst part will occur when a malicious node with a fake rank is chosen as the preferred parent node while operating, which will result in creating more traffic for data packets to go through the malicious node as un-optimized routing occurs due to network topology OF is not completely achieved as discussed [37].

Mishra and Pandya [38] added another scenario for rank attacks by which an attacker node advertises a better routing metric to other neighboring nodes although it's fake, it misleads network flow to be passing through it. Besides, this may lead to significant increasing latency and decreasing throughput in the network. Fig. 5 illustrates an example of RA.

RA may affect the network and causes several issues as discussed by Nandhini and Mehtre [39]: first, form an unoptimized route. The second is unrecognized loop formation. Third, RPL network topology never uses the optimized route. Fourth, the decreased packet delivery ratio affects the delay increase. Fifth, network topology changes rapidly causing DIO messages number to increase. Some network restricted resource properties would be affected such as energy consumption, throughput, latency, and data rate.

As a result, RPL security forms a major concern that should be considered and further investigated, especially when RA is the topic. This is because routed data shouldn't be accessed by a third party or attacker.

B. RPL Rank Attack (RA) Countermeasures (RQ2)

Many papers categorized countermeasures deployed to secure RPL against attacks, Raoof et al. [29] classified detection and mitigation mechanisms into Acknowledgment-based which depends on sending and receiving acknowledgment messages to prevent any suspicious alteration, and Trust-based depending on the node to monitor neighboring nodes by rating them and consider a ratio to accept, Location-based considering physical location of nodes and Statistical/Mathematical-based by which a mathematical calculation is considered to detect attacks.

Further classification is presented by Verma and Ranga [37] added to the above mentioned, Intrusion Detection Systems (IDS) that consists of signature-based IDS, anomaly-based IDS, and specification-based IDS. It is defined by [40] as, a complete system that may be deployed either in a stand-alone computer system or a network. Its main role is to monitor activities and analyze them to specify any incident which targets security policies integrity, availability, or confidentiality and report it as unauthorized or malicious activity.

Muzammal et al. [41] also mentioned IDS as a significant method that is used to mitigate attacks of RPL in addition to all previously stated ones. Besides many alterations to OF by combining various previously explained link and nodes metrics with adopting additional methods such as fuzzy logic.

Moreover, Tasneem and Wahid [42] classified proposed defense methods for RPL into reactive approaches that include cryptography-based, trust-based, and threshold-based methods, and proactive approaches which consist of time-based and energy-based methods.

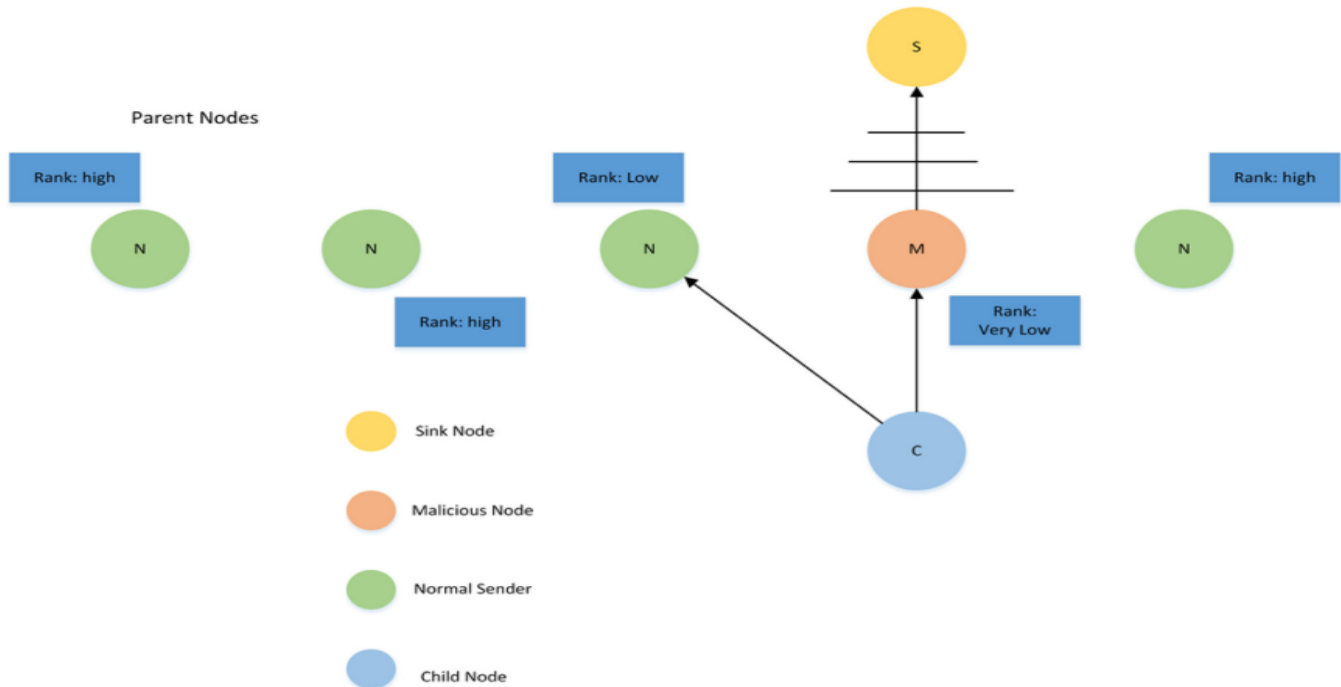

Fig. 5. RA Example, [33].

Finally, countermeasures proposed for RPL against RA were classified by Almusaylim et al. [17] into modification techniques by which some alterations may be applied to a certain component of RPL such as DODAG, OF, or ranking policies and IDS.

C. Performance Metrics (RQ3)

Various metrics were used for measuring the performance of the proposed methods. Yet, many studies like [7], [9], and [14] mentioned using node and link metrics discussed previously such as power consumption, ETX, and PDR. In addition, accuracy metrics including True Positive Rate (TPR), False Positive Rate (FPR), and Detection Rate (DR) were mentioned to be used as well, and below are their formulas as per [43]–[47]:

- Detection Rate (DR): Refers to the ability of the model to rank patterns, and its ability to select a threshold in the ranking used to classify patterns as normal if above the threshold and abnormal if below. It is calculated using Equation 1 below:

$$DR = \frac{TPR}{TPR+FNR} * 100\% \quad (1)$$

where All = TPR + TNR + FPR + FNR

- TPR: Also called sensitivity and it measures the truly predicted positive and were correctly identified. It is calculated as in Equation 3:

$$TPR = \frac{TPR}{TPR+FNR} * 100\% \quad (2)$$

Where FNR is calculated as follows:

$$FNR = \frac{TPR+TNR}{TPR+FPR} * 100\% \quad (3)$$

- FPR: Refers to the probability of a False Alarm. That is, the percentage of actual abnormal flows predicted as normal flows and it is calculated as in Equation 4:

$$FPR = \frac{FPR}{FPR+TNR} * 100\% \quad (4)$$

Where TNR is calculated as follows:

$$TNR = \frac{TNR}{FPR+TNR} * 100\% \quad (5)$$

D. Summary of Shortlisted Studies (RQ4)

This section discusses thoroughly found nine studies that proposed techniques to detect and mitigate RA targeting RPL and strictly meet the criteria defined in the SLR methodology section along with a summary presented in Table II.

A Secure RPL Routing Protocol (SRPL-RP) for rank and version number attacks was proposed by Almusaylim et al. [48] in which a timestamp is added to ensure the legitimacy of sending nodes. A monitoring table is included through the process of constructing DODAG which collects all information about existing nodes. A blacklist and alert tables were added to simplify the procedures of mitigating and isolating both types of studied attacks. Several conditions were added to control the current rank of nodes and parent nodes to maintain a safe network. Simulations were conducted using the Cooja simulator and results showed that the proposed SRPL-RP had a

higher PDR and a lower control message value compared to methods previously proposed in literature along with 95% accuracy in all kinds of tested network topologies.

Shafique et al. [49] proposed a novel sink-based IDS (SBIDS) by which a timespan is added to the DAO message for ensuring its freshness. Then several detection steps are followed to detect any violence in rank, especially a rule that compares node current rank (NCR) to node parent rank NPR. Simulations were conducted using the Cooja simulator and performance metrics were percentage of accuracy, TP, TN, FP, FN, and confidence interval (CI) under mobility conditions. Results showed that SBIDS had 100% detection accuracy under normal circumstances, yet it decreased with the number of nodes with mobility increased.

TABLE II. FINAL SELECTED PAPERS FOR SECURING RPL AGAINST RA

Ref	Paper Information			
	Year	Type	Methodology	Performance Measure
Almusaylim et al. [48]	2020	Journal	SRPL-RP based on rank strategy	PDR, Acc
Shafique et al. [49]	2018	Journal	Sink-based IDS (SBIDS)	Acc, TPR, TNR, FPR, FNR, and confidence interval (CI)
Boudouaia et al. [50]	2021	Journal	Rank property + DIO messages with 2 rank thresholds	DR, average network hops, and global energy consumption.
Nair and BJ [51]	2021	Conference	SCF and Dijkstra's algorithm	Throughput and PDR
Karmakar, Sengupta and Bit [52]	2021	Conference	DODAG modification with adding Authentication Code (HMAC-LOCHA)	DR, FPR, FNR, and energy consumption
Zarzoor [53]	2021	Journal	Layering mechanism	Latency, energy consumption, and DR
Stephen and Arockiam [54]	2018	Conference	Node energy based E2V architecture with IDS	Network convergence delay, energy consumption, and attacker identification delay
Seth et al. [55]	2020	Conference	Round trip time (RTT) based detection and isolation mechanism	Acc
Althubaity, Gong, and Raymond [56]	2020	Conference	Specification-based IDS (FORCE)	DR and overheads incurred on the nodes' resources

Boudouaia et al. [50] proposed a security scheme that uses a rank property to choose a preferred parent in RPL topology, so any malicious behavior in terms of rank may be detected. Afterward, when the DIO message arrives two values will be calculated to indicate the minimum rank threshold and maximum rank threshold depending on the neighboring rank. As a result, nodes that do not match threshold criteria are blacklisted and the selection process will be held upon legitimate nodes only. Experiments were done using the cooja simulator, 4 scenarios, and performance evaluations were conducted in terms of successful detection rate, the average network hops, and the global energy consumption.

Another solution was proposed by Nair and BJ [51] in which both spatial correlation function (SCF) and Dijkstra's algorithm were applied to select the preferred parent nodes using proactive routing in terms of throughput and energy as selection parameters. For experiments, the NS-2 simulator was used, and performance evaluation was based on throughput and PDR.

An interesting study by Karmakar, Sengupta, and Bit [52] combined several methods to secure RPL against RA. First, the algorithm forming DODAG was modified to be able to detect RA during building and maintaining the topology. Second, two modules were added, distributed at all nodes, and centralized at the sink node. Third, the DAO control message was modified to lower overhead levels and a lightweight Message Authentication Code (HMAC-LOCHA) was used to verify exchanged message's integrity and authenticity. Cooja simulator was used to conduct experiments and multiple test case scenarios were applied. detection accuracy, false positive/negative rate, and energy consumption.

Zaroor [53] proposed a security mechanism that relies on the layering principle. It consists of three main phases: first, nodes are categorized into layers. Second, calculate the trust value for the path. Third, detect and mitigate the RA. For implementation Cooja simulator was used and performance evaluation was conducted based on latency, nodes' energy consumption, and accuracy of malicious node detection.

A further three-phase mechanism called E2V was proposed by Stephen and Arockiam [54] which starts with rank calculation, substantiation, and elimination. Where the malicious node is detected at the substantiation phase by the defined IDS. Then, in the elimination phase, malicious nodes will be eliminated by either local repair or global repair. The Cooja simulator is used for implementation purposes and evaluation in terms of network parameters such as network convergence delay, energy consumption, and attacker identification delay.

Seth et al. [55] used round trip time (RTT) to detect verify and isolate malicious nodes from the network in RPL. Cooja simulator was used for implementation and performance was evaluated in terms of accuracy where the proposed scheme was found to be better than previous ones.

Althubaity, Gong, and Raymond [56] proposed a fully distributed specification-based IDS (FORCE). The type of node forms a significant issue for FORCE, yet it was designed so that every single node can analyze and receive control

messages and in case of any attack detection an alert will be generated directly. Evaluation metrics used were detection rates and overheads incurred on the nodes' resources and experiments were conducted using the Cooja simulator.

V. DISCUSSION

The main goal of this part is to understand the obstacles and current research for detecting RA in RPL routing protocols, as well as several flaws that require more research. RPL routing protocols provide for more efficient use of smart devices, resources, and data routing. Because of the characteristics that distinguish this network from others, developing secure routing algorithms for IoT networks is a difficult task. Secure routing techniques for IoT devices have received a lot of attention in recent years. However, they all rely on traditional cryptographic operations, which deplete device resources and have a significant impact on the performance of limited IoT devices. They are vulnerable to a wide range of security threats. The absence of infrastructure, inconsistent links, resource limits, poor physical security, and changing topology of PRLs make them vulnerable to attacks and difficult to defend against.

A. Limitations

Based on reviewed studies it was found that current security features of RPL may be defined but not actually used either in real applications or in research as they are marked as optional features. This puts security as a significant concern of RPL especially since it's being deployed and used widely in IoT environments which are witnessing massive growth globally.

As RPL is vulnerable to several attacks, RA is one of the major attacks that were found to compromise RPL, yet a lower amount of research conducted to specifically target it. Also, these studies had several shortcomings which should be addressed to overcome their consequences.

As a result, it was found from this review: that first, most studies considered either selection or mitigation, but only a few of them investigated both schemes. Second, mainly one type of network topology was selected to test and measure the performance of the proposed scheme. Third, most research studies tend to evaluate their proposed schemes by taking small IoT Networks (<100 nodes) which are considered impractical because the impact of network size on both attacks and security mechanisms remains unknown. Fourth, many schemes encountered an increased number of control messages for acknowledgment purposes which may cause both complexities and increased overhead and are considered inefficient.

B. Comparison

Based on provided review and summery in Table II, it can be concluded that most chosen metrics for performance evaluation were DR and energy consumption as in [50], [52], [53] and [56]. As DR indicated to which extent the proposed mechanism was able to detect threats and energy consumption represented a measure of keeping devices resources available. IDS was chosen as a detection solution in three papers [49], [54] and [56], while the rest choose to modify the main protocol policies and add certain solutions to improve its

security measures. None of found studies tented to combine IDS with protocol policy improvements. Also, none of them included integration with other recently hot fields such as fuzzy logic as a solution.

Studies discussed securing RPL against RA were 5 conference papers to 4 journal papers within period 2017 to 2022, which means this kind of attacks require more powerful solutions are to be proposed in order to provide efficient solution.

Finally, experiments of all founded papers showed that the Cooja simulator usage is dominant in RPL studies where all of them implemented proposed solutions using it.

VI. CONCLUSION

This paper studied applied methods for RA detection in RPL thoroughly to address limitations in this field. An SLR was conducted to determine the required studies to be conducted for improving security measures deployed in this regard. Definitions of required terms starting from IoT, RPL architecture, and security attacks, to detection and mitigation techniques, are presented to help researchers have a brief explanation of them. Also, a summary of recent studies is presented. It was found that many of the currently applied mechanisms in literature have weak points, cryptographic-based methods may provide security, but it definitely consumes nodes' restricted resources. While trust-based may solve the resource restrictions, it may cause other issues regarding network performance such as latency. IDS, it's considered the most effective solution among all proposed ones, but it requires collaboration, and many aspects in this regard should be taken into consideration such as placement. Finally, a hybrid IDS is highly recommended as a solution for securing RPL as it is used by IoT and keeping it safe will definitely be reflected in the overall IoT environment.

VII. FUTURE WORK

Future research aims at extending this review to examine and build better detection and mitigation measures for RPL. This will primarily be addressing RPL rank vulnerabilities.

ACKNOWLEDGMENT

This research was supported by the Ministry of Higher Education (MoHE) of Malaysia through The Fundamental Research Grant Scheme (FRGS/1/2020/ICT07/UUM/01/1).

Abstract—This paper proposed an indoor evacuation assessment algorithm. Indoor evacuation wayfinding to the nearest exit becomes more difficult due to the intricacy of the inside layout and the involvement of numerous people. Thus, evacuation models were developed by researchers to assist evacuees in safely exiting a building. Unfortunately, building owners are unsure which evacuation model is best for their high-rise buildings. Therefore, we proposed an assessment algorithm to help the owners assess the best evacuation model. This research uses floor plan levels 13 and 14 of Yayasan Melaka's, an office building, to simulate the evacuation. Ten simulation studies for each level are created. The proposed assessment algorithm focuses on three Microscopic evacuation models; agent-based, cellular automata, and social force. Hence, three simulation software were used to represent the mentioned evacuation model: Pathfinder, PedGo, and AnyLogic. K-Mean is then used to cluster the simulation time results. Elbow, Silhouette and V-measure techniques were applied to produce accurate results of the K-Mean. We compiled and analyzed the results from ten simulation studies for each level. The validation was done by comparing the final results. It shows that 70% of the lowest time taken is from Pathfinder, 30% from PedGo, and 0% from AnyLogic. Based on the result, it is proven that the proposed assessment algorithm can provide the best indoor evacuation model followed the attributes set for the building.

Keywords—Assessment algorithm; evacuation model; indoor evacuation; k-mean; validation

I. INTRODUCTION

Evacuation is the organized, regulated, and supervised retreat, dispersal, or withdrawal of individuals from places of risk or hazard and their reception and treatment in secure environments [1]. Despite the limited space available in urban regions, the population of large and medium-sized cities worldwide continues to grow. As a result of the requirement to deal with this development, high-rise buildings have popped up fastly [2]. Thus, fires in high-rise buildings have become more prevalent in recent decades as high-rise structures significantly affect the skylines of major cities [3]. Therefore, proper emergency evacuation in any high-rise structure is critical.

According to the Fire & Rescue Service Department and the Occupational, Health and Safety Environment, the evacuation method by occupants in one building should be able to escape the building 3 minutes after the emergency alarm goes off. Building evacuation must be evaluated for time optimization to avoid human casualties [4]. Evacuees with a misperception of the building environment may display significant rounding or even be trapped, resulting in a

significantly longer evacuation time. According to Ventura [1], people usually take a path of self-estimated speedy escape depending on their current condition. In addition, panic and stamping can lead to several people departing in an emergency. The architecture of escape routes from structures, human psychology and behaviour, and various social and behavioural patterns can significantly influence evacuation performance, resulting in a trapped situation [5]. For instance, a case in Gujarat, India, sacrificed 20 students in a fire because no safety equipment was installed in the building, and there were no escape routes [6]. Another example of disaster is the World Trade Centre (WTC) Twin Towers terrorist attack on September 11, 2001, where 3000 innocent people died [7]. Thus, a high-rise building must have an evacuation strategy to allow evacuees to evacuate the building safely.

Jiang et al. [8] stated there are three types of evacuation models which is microscopic, macroscopic, and mesoscopic. Individuals' geographical and chronological activities are frequently defined by microscopic models [9]. The continuum model, often known as the macroscopic model, integrates variables and monitors characteristics [10]. Finally, mesoscopic models, which focus on groups but offer more specific information about each pedestrian, considered the individuals but not individuals' interactions. The goal is to keep some control over the individual while moving the group as a whole and avoiding local interactions [11]. As a result, mesoscopic is not taken into account in this study. Shi et al. [12] claimed that microscopic and macroscopic models are often used in evacuation evaluations to illustrate pedestrian traffic. Macroscopic models, which reflect overall population movement, do not typically characterize individuals.

On the other hand, microscopic models focus on the smallest of individuals' details. Microscopic models have been employed extensively in recent years [13] in various crowd simulation studies to understand better crowd behaviour in emergency scenarios [14]. For microscopic models, researchers have mostly employed these three models: Agent-based model (ABM), cellular automata (CA), and social force model (SFM) [15]. Thus, the microscopic model is the best among the three types of evacuation models for the indoor evacuation model.

Therefore, this research proposes an intelligent indoor evacuation assessment algorithm for critical incidents. The assessment algorithm can help select the best evacuation model for the chosen building. The best model selection is crucial since it depends on the environment and the building's needs. It also includes the evacuees' ability to evacuate safely and quickly. This paper's organization begins with a brief

introduction in Section 1. Section 2 explains the related work and is followed by the research methodology in Section 3. Section 4 elaborates on the results and discussion on optimal k number, v-measure score, intracluster distance, and chosen lowest time taken results. Finally, Section 5 concludes the study and briefly mentions future enhancement.

II. RELATED WORK AND TECHNIQUES

This section describes the related works in clustering algorithms and techniques related to the study.

A. Related Work

The related works involved in this research include the K-Mean algorithm and finding the optimal k number. In general, the K-mean approach is dependent on the value of k , which must always be provided before any clustering analysis can be performed. Clustering with various k values will provide diverse outcomes [16]. The algorithm in clustering can be a feature, as an example in Fig. 1. Training examples are shown as dots and cluster centroids as crosses, (a) original dataset, (b) random initial cluster centroids, and (c-f) illustration of running two iterations of K-Means.

The closest cluster centroid is allocated to each training sample in each loop. It is demonstrated by “painting” the training samples with the same colour as the cluster centroid to which they have been allocated. Then, for each cluster, the mean of the points assigned to it is shifted from the centroid to the mean of the points assigned to it.

Fig. 1. Clustering example of K-Mean.

The process typically finishes when the centroids stabilize, or the points cease migrating to other groups. However, this depends on the type of grouped data, and the objective function used to quantify proximity. Because K-Mean might have difficulties with local optimum solutions, a proper initialization has proved to be an effective strategy to avoid being caught in the incorrect local optimal solutions [17]. Fig. 2 shows the K-Mean pseudocode [18]. The clustering aims to improve the objective feature (f) by measuring the range between entities and clusters (the most used measurement is the standard Euclidean Distance) as in (1) [19]:

$$f = \sum_{i=1}^K \sum_{j=1}^N \|x_j - C_i\|^2 \quad j \in G_i \quad (1)$$

where K is the number of clusters, N is the number of objects, x_j is the coordinate of object j , C_i is the coordinate of

the cluster i and G_i is the group of objects that belong to cluster i . The algorithm shifts the cluster in space to reduce the square distances within the cluster. The positions of all objects belonging to each cluster are recalculated by averaging. Calculation of the center uses as in (2):

$$C_i = \frac{1}{|G_i|} \sum_{j=1}^N X_j \quad j \in G_i \quad (2)$$

where $|G_i|$ is the number of objects in the cluster i . The algorithm begins with a random set of the C_i cluster’s initial K center points ($i = 1, \dots, K$), which are the present centroids.

<p>Input: K_y: the number of clusters D_y: a data set containing n object</p> <p>Output: A set of K_y clusters</p> <p>Algorithm:</p> <ol style="list-style-type: none"> 1. Input the data set and value of K_y. 2. If $K_y = 1$ then Exit. 3. Else 4. Choose k objects from D randomly as the initial cluster centers. 5. For every data point in the cluster, j reissue and define every object into the cluster where the object matches, based on the object’s mean value. 6. Update cluster means; after that, for each cluster, calculate the object’s mean value. 7. Repeat from step 4 until no data point was assigned; otherwise, stop. <p>The satisfying criteria can be either number of iteration or the change of position of the centroid in consecutive iterations.</p>

Fig. 2. Pseudocode of K-Mean.

Finding the best k number for the cluster is crucial because K-Mean requires a suitable initialization of the k number for clusters to avoid getting trapped at an incorrect local optimal solution. Running the algorithm numerous times and selecting the appropriate number of clusters based on a few validity criteria or automatically identifying them using practical ways or standards is a fundamental way to decide the number of clusters. The process may also change and tweak the cluster centers several times [20]. Several frameworks and techniques have been thoroughly investigated and developed in the past to provide cluster quality measures that indicate if a particular clustering is suitable. There are three ways to verify the clusters, which are called cluster validity index (CVI). These include external, internal, and relative validity indices [21].

More than one index should be used to obtain outstanding and accurate findings [22]. A few methods for determining the best k number have been considered for this study. Two commonly used approaches, the Elbow method and the Silhouette method, are investigated in this study to aid in the manual selection of the number of displayed clusters [23]. Internal validity indexes are used in both methods to assess the correctness of a clustering algorithm [24]. Another technique examined for this study is the V-measure, based on an external validity index. External validity indices such as V-measure are commonly used to determine the best clustering result for a dataset since they know the ‘real’ number of clusters in advance [25], particularly the number of clusters recommended by Elbow and Silhouette techniques for this study. Table I briefly describes the methods used to find the optimal k number for K-Mean.

TABLE I. METHODS TO FIND OPTIMAL *K* NUMBER

Methods	Description	CVI Type
Elbow	The consistency of the optimal number of clusters was visually checked by comparing the difference in each cluster's square error sum (SSE). The best figure is the most significant variation in elbow angle [25].	Internal
Silhouette	Uses a silhouette coefficient that combines separation and coherence. The larger the Silhouette coefficient, the better the cluster [24].	Internal
V-Measure Score	If items in clusters have independent labels, the V-measure is a handy tool for evaluating them. The degree of homogeneity of labels in clusters may be used to measure the quality of clustering objectively [20].	External

B. Related Techniques

The related technique used in this research is the indoor evacuation assessment algorithm based on our previous research [26][27]. Fig. 3 shows the detailed flow of the developed indoor evacuation assessment algorithm. The design and development are separated into six sections in general: 1) determine attributes, 2) run the simulation, 3) identify the best *k* number, 4) evaluate cluster performance, 5) compute intracluster distance, and 6) select the best evacuation model.

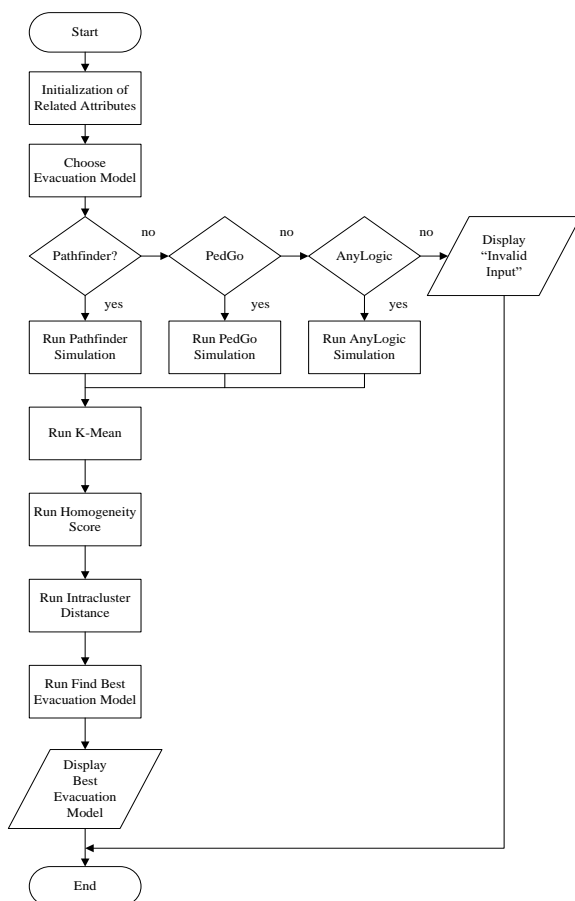

Fig. 3. Overview of Indoor Evacuation Assessment Algorithm.

The attributes involved consist of seven: 1) number of agents, 2) agents' behaviour, 3) room size, 4) number of doors,

5) number of staircases, 6) blockage status, and 7) number of exits. Once entering attribute values, they are used in the selected evacuation simulation software. Three simulation software programs calculate how long the agents will take to evacuate the building. The simulation software involved is Pathfinder, PedGo, and AnyLogic. The K-Mean clustering technique is used once the findings are generated. Several actions are conducted at this point in order to obtain correct findings. The processes involve determining the optimal *k* number, confirming it with the V-measure score, and determining the lowest intracluster distance between clusters to find the lowest time taken. Finally, the assessment algorithm presents the most effective evacuation model.

III. METHODS

This section divides the research methodology into two phases: 1) drawing and mapping floor plans; and 2) simulation studies.

A. Drawing and Mapping Floor Plans

The floor plan of the chosen building is drawn and mapped in the simulation software. The high-rise building used for this research is Yayasan Melaka's building. The chosen floors are levels 13 and 14, which level 14 being the highest level. Yayasan Melaka is a large office with several rooms and barriers that might make evacuation difficult. This construction is a high-rise skyscraper with two access paths on each floor. Staircases are said to be an escape route. Elevators and windows are not permitted to be utilized as exits since elevators are outlawed, and the building's height renders window escape difficult.

The simulation software used to produce time taken results is Pathfinder, PedGo, and AnyLogic. The simulation software represents the evacuation model chosen, ABM, CA, and SFM, respectively. The drawing and mapping of the floor plan are based on the simulation studies created. A few ground rules were observed during the mapping process because each simulation software's functional capabilities vary; such criteria are observed. Two rules are: 1) for each simulation, the paths are set in stone and 2) the agents are positioned in the same room for each simulation software.

As a result, particular simulations require manually mapping the agents' path from the beginning point to the endpoint so that they can travel during the experiment. Fair simulations are ensured by placing agents in the same rooms for each simulation software. The procedures required to map the layouts in each simulation program differ from one another when it comes to mapping.

B. Simulation Studies

The assessment algorithm aims to find the most suitable evacuation model for the given structure. The evacuation simulations were used to apply simulation findings for the research purposes for the assessment process. These simulation studies are implemented in Pathfinder, PedGo, and AnyLogic simulation software. For each level 13 and level 14, ten simulation studies highlight the seven simulation attributes. Level 13 simulation studies are shown in Table II, while level 14 simulation studies are shown in Table III.

TABLE II. SIMULATIONS STUDIES FOR LEVEL 13

Simulation Study	Number of agents	Agents' behaviour	Room size, ft^2	Number of doors	Number of staircases	Blockage condition	Number of exits
SS13-1	50	Group	1.5E	13	26	Yes	2
SS13-2	50	Scattered	1.5E	13	26	Yes	2
SS13-3	100	Group	1.5E	16	26	Yes	1
SS13-4	100	Scattered	1.5E	16	26	Yes	1
SS13-5	150	Group	1.5E	21	26	No	2
SS13-6	150	Scattered	1.5E	21	26	No	2
SS13-7	200	Group	1.5E	20	26	No	1
SS13-8	200	Scattered	1.5E	20	26	No	1
SS13-9	250	Group	1.5E	22	26	Yes	2
SS13-10	250	Scattered	1.5E	22	26	Yes	2

TABLE III. SIMULATIONS STUDIES FOR LEVEL 14

Simulation Study	Number of agents	Agents' behaviour	Room size, ft^2	Number of doors	Number of staircases	Blockage condition	Number of exits
SS14-1	50	Group	1.5E	13	28	Yes	2
SS14-2	50	Scattered	1.5E	13	28	Yes	2
SS14-3	100	Group	1.5E	14	28	Yes	1
SS14-4	100	Scattered	1.5E	14	28	Yes	1
SS14-5	150	Group	1.5E	20	28	No	2
SS14-6	150	Scattered	1.5E	20	28	No	2
SS14-7	200	Group	1.5E	21	28	No	1
SS14-8	200	Scattered	1.5E	21	28	No	1
SS14-9	250	Group	1.5E	22	28	Yes	2
SS14-10	250	Scattered	1.5E	22	28	Yes	2

The values are chosen depending on the building's appropriateness. The number of agents begins at 50 and rises by 50 in each iteration until the total number of agents reaches 250. A group or scattered behaviour distinguishes the agent. The room size is based on the original layout set and is set at $1.5E ft^2$. The number of doors is determined by the total number of doors utilized by the agents, and the number of staircases can either be two or four, depending on the structure. This research uses the time taken for agents to escape using stairs of 0.44m/s for the mean overall movement speed [28], and the length of the stairs is 7384mm from up to down [29]. The requirement for a blockage is assessed, and the number of exits is set to one or two.

IV. RESULT AND DISCUSSION

A. Optimal k number Results

When using K-Mean clustering algorithms, determining the appropriate k number is crucial. The best k number for K-Mean is found using the Elbow and Silhouette approaches. The Elbow and Silhouette method findings and the Silhouette analysis are included in the results. The graph depicts the outcomes of finding the best k number. The elbow point in the graph for the Elbow technique reveals that the point is the ideal k number for determining the optimal k number based on the graphs. The optimum k for the Silhouette technique is the point with the highest silhouette score. The result of visualization

graphs depends on the simulation study; thus, we only show the result for SS13-1 since inserting all the results will take too many pages. Fig. 4 depicts the Elbow method's result where the elbow point can be seen as either 3 or 4. 4 is chosen to be the elbow point. Fig. 5 shows the Silhouette method's result where the highest silhouette score shown is 2. Silhouette analysis in Fig. 6 shows the silhouette plot of the clusters and the visualization of the clustered data. The dotted red line in the silhouette plot of the clusters shows the optimal silhouette coefficient value. Table IV shows the k number results suggested by both Elbow and Silhouette methods for level 13, and Table V shows the k number suggested by both Elbow and Silhouette methods for level 14.

Fig. 4. Elbow method result for SS13-1

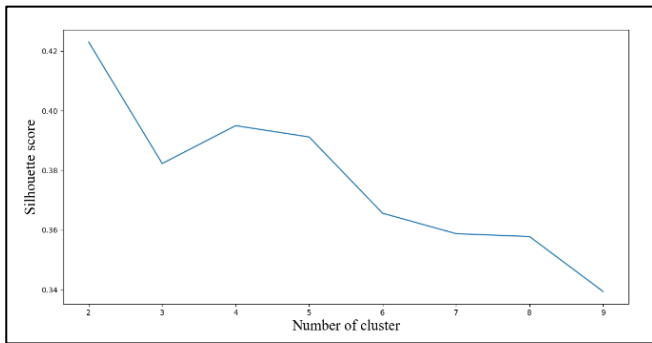

Fig. 5. Silhouette Method Result for SS13-1.

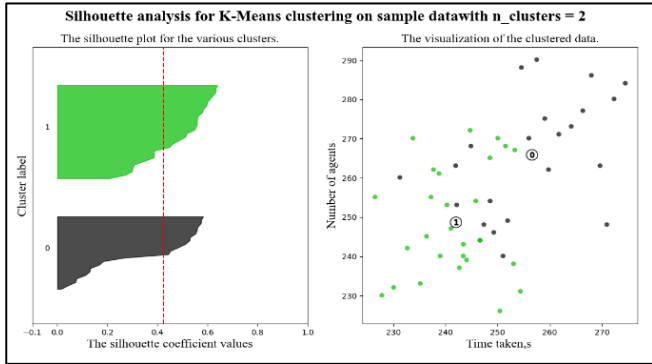

Fig. 6. Silhouette Analysis for SS13-1.

B. V-measure Score Results

The V-measure score is then used to validate the suggested optimal k number. It will compare the Elbow and Silhouette methods outcomes. If one of the scores is higher than the other, the Elbow or Silhouette approach with the highest score is picked. Table VI shows the V-measure score results based on the k number results suggested by Elbow and Silhouette methods for level 13. Table VII shows the V-measure score

results based on the k number results suggested by Elbow and Silhouette methods for level 14. The chosen k number is also shown in the tables.

C. Intracluster Distance Results

The result of time taken from each simulation research is incorporated in K-Mean using the Elbow and Silhouette techniques to discover the optimal *k* number and the V-measure score to decide which optimal *k* number is superior when both approaches are compared. The intracluster distance may then be computed for each cluster in each simulated experiment. The intracluster distance is calculated using Rapidminer. Table VIII shows each simulation study's lowest intracluster distance results for level 13, and Table IX shows each simulation study's lowest intracluster distance results for level 14. The chosen cluster is also shown in the tables.

TABLE VIII. INTRACLUSTER DISTANCE RESULTS FOR LEVEL 13

Simulation Study	Lowest Intracluster Distance	Chosen Cluster
SS13-1	-251.299	3
SS13-2	-181.858	3
SS13-3	-1726.339	3
SS13-4	-1847.029	0
SS13-5	-1265.699	0
SS13-6	-1399.664	0
SS13-7	-3823.050	0
SS13-8	-3723.412	1
SS13-9	-5497.067	2
SS13-10	-4800.702	1

D. Chosen Lowest Time Taken Results

The intracluster distance aids in determining which cluster is ideal for finding the quickest evacuation time. The evacuation model implemented in the chosen building is determined by the lowest time chosen from the three simulation software findings based on each simulation study by level. The simulation software's time-based findings are incorporated into the assessment algorithm, which is then examined and contrasted. For level 13, Table X provides the lowest time taken findings from the selected clusters based on each simulation study and its accompanying simulation software. For level 14, Table XI provides the shortest time taken findings from the selected clusters based on each simulation study and its accompanying simulation software.

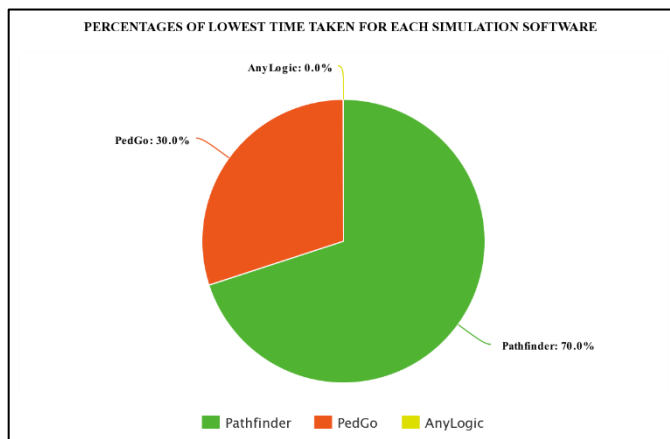

Fig. 7. Piechart of Lowest Time Taken for each Simulation.

As a reminder, the building's architecture determines the appropriateness of existing evacuation models. Different types of evacuation models are suitable for different high-rise structures. Based on the distributed result for each level, Fig. 7 depicts a piechart of the percentages of the lowest time taken for each simulation software. Pathfinder accounts for 70% of the lowest time taken, PedGo for 30%, and AnyLogic for 0%. As a result, it can be determined that ABM is the optimal evacuation model for Yayasan Melaka's building.

V. CONCLUSION

Many developed evacuation models now focus on investigating various evacuation behaviours and times. As a result, the characteristics of the models differ, making it difficult for users to choose a suitable evacuation model. Thus, we presented the indoor evacuation algorithm for high-rise buildings and assessed the proposed solution. Methods and specific attributes for each simulation software were identified, and we managed to compare and analyze the results. It helps to prove how well the assessment algorithm can assess the evacuation model. The result of the lowest time taken has been validated to determine the best evacuation model. Since this study uses a single case study for the simulation and assessment, thus, for future recommendations, the developed assessment algorithm is advised to be evaluated using various high-rise buildings and expand the research by examining the

complete building plan. It is fascinating to compare and contrast because each layout, structure, construction, and fire-resistant capability has its degree of difficulty.

Effective Prediction of Software Defects using Random-tree Entropy based Feature Selection Framework

Abdulaziz Alhumam

Department of Computer Science
College of Computer Sciences and Information Technology
King Faisal University, Al-Ahsa, Saudi Arabia

Abstract—Software systems have grown in size and complexity. These characteristics increase the difficulty of preventing software errors. As a result, forecasting the frequency of software module failures is critical to a developer's efficiency. Many methods for defect detection and correcting problems exist. Hence, Machine Learning (ML) classification performance has to be greatly improved. Thus, in this study, a novel approach is proposed for predicting the number of software defects based on relevant variables using ML. First, feature entropy on each raw features is performed and then identifying the un-pruned random feature. Then is selected the relevant feature through the identical existence among the entropy and un-pruned feature. And finally, the software defect dataset of National Aeronautics and Space Administration (NASA) PC-1 is sent to an ML-based model to estimate the number of faults. Initial PC-1 dataset comprises 37 raw features from this only 8 critical characteristics are utilized to enhance the ML model. A random tree feature selection strategy is shown to be accurate and potentially outperform existing methods in the experimental results. The proposed method considerably outperformed the performance of current ML models by obtaining the accuracy of 97.76% in Random Forest (RF) model.

Keywords—Software defect prediction; machine learning; classification; feature entropy

I. INTRODUCTION

In the recent years, the researcher tried to find different techniques and tools in taming the quality, dependability, and reliability of the software systems [1]. A software defect can cause minor inconvenience or catastrophic failure. Pre-deployment fault prediction for testing is supported by recent research in software fault prediction (SFP). Object-oriented programming is harder than procedural programming due to inheritance. By identifying faulty software modules before to the start of the testing process, software defect prediction can help enhance software quality and testing efficiency. These findings aid software engineers in allocating scarce resources to more prone-to-failure modules. Complex software application can deliver high efficient, accurate and powerful work to modern organizations [2]. Software defect prediction (SDP) has grown in popularity during the previous two decades. The results of the SDP assist in allocating resources for software testing. However, defect prediction is often employed for activities with a high degree of precision. It is

difficult to ensure resource allocation prior to software testing or without prior execution data. Machine learning is used to identify problematic modules, as it reveals hidden patterns in software properties [3]. The feature selection activity removes non-classification features with low performance [4]. The variant selection activity selects the best versions of classification methods for their ensemble [5].

A data collection method based on regular expressions and bug-code linking [6] is proposed. In terms of accuracy and consistency, our strategy outperforms other commonly used data collection methods and their publicly available datasets [7]. Around 65 publicly available base datasets containing Chidamber and Kemerer (CK) and other inheritance indicators were used to determine the effect of inheritance on SFP [8]. They investigate the degree to which an inheritance metric accurately predicts software fault proneness. Additionally, they choose CK measures and inheritance metrics for predicting software problems. In SFP experiments, metrics such as exclusive usage and inheritance viability are analyzed [9]. They combed publicly available inheritance metrics data sets and discovered approximately 40 that contained inheritance metrics. Their initial cleanup included nine metrics relating to inheritance.

They preprocessed selected data sets and then merged them using all possible inheritance metrics combinations. The study [10] examined defect prediction datasets. There is no memory data management strategy proposed, nor is a mechanism for defect detection proposed. The proposed technique for defect prediction keeps track of the error rate performance. The defect prediction detector initiates the generation of defects, warning, and control flags. The proposed technique outperforms the conventional technique (p-value 0.05) and within-group comparisons yield statistically significant effect sizes. We observe that increasing the error rate results in DP, which results in suboptimal prediction performance. To overcome the difficulties associated with zero value thresholds, a spectral classifier based on the median absolute deviation threshold was developed [11]. Rather than using a measure of central tendency, this method makes use of the dispersion of eigenvector values. The report's baseline technique is a zero-value threshold spectral classifier, and the entity class is predicted using a heuristic technique.

The highest co-entropy criteria [12] successfully handle the non-Gaussian noise for SDP. A new classifier is created after instance filtering, feature selection, and reduction. It also finds a non-normal distribution for the 21 most significant software indicators. The hybrid feature selection (HFS) [13] is divided into two stages and it clusters features first using hierarchical agglomerative clustering and then eliminates un-normalized and duplicate features using two wrapper methods. Three distinct classifiers with four performance metrics were evaluated empirically on 11 well-studied NASA programs such as accuracy, precision, recall, and F-measure.

II. RELATED WORK

To predict defects on NASA datasets, decision tree (DT), random forest (RF), Naive Bayes (NB), multi-layer perceptron (MLP), radial basis function (RBF), support vector machine (SVM), and k-nearest neighbour classifiers are used [14]. Precision, Recall, F-Measure, Accuracy, Matthew Correlation co-efficient, and ROC Area are used to evaluate classification performance. A two-stage data pre-processing method for software failure prediction models and semi-supervised deep fuzzy C-mean clustering feature extraction is presented [15]. The main goal is to optimise intra-cluster class and feature using deep multi-clusters of unlabelled and labelled data sets. A new strategy called conditional domain adversarial adaptation (CDAA) [16] can help with a variety of SDP problems. The CDAA has a generator, discriminator, and classifier. This is how the generator learns to move between spaces. The discriminator learns to spot the generator's bogus instances. The classifier learns to classify occurrences appropriately. In our CDAA, both classifier and discriminator loss functions propagate to generator. The enhanced wrapper feature selection (EWFS) [17] method selects features in stages while keeping previous choices in mind. This feature selection improves subset assessment while maintaining model performance. On software defect datasets of various granularities, the DT and NB classifiers were used to evaluate EWFS. This feature selection outperformed existing metaheuristics and sequential search-based WFS techniques in the experiments.

For feature exploration and categorization, neural forest (NF) [18] combines deep neural network with decision forest. After the neural network, a decision forest is connected to perform classification and guide feature representation learning. For efficient defect prediction, NF combines NN and decision forests, and the performance of this hybrid method is examined [19]. The hybrid approach [20] improved classification accuracy compared to existing methods. This method investigates the relationship between defect density, velocity, and introduction time. An integrated machine learning approach is used in ten PROMISE data sets with 22838 instances.

To see how FRFS (filter-based ranking feature selection) [21] methods affect software defect using feature selection methods that are too computationally costly. Empirically, they

look at three large-scale web applications. Then they build SVP models using a random forest classifier and seven FRFS methods. To address the prediction model's low classification rates, a hybrid strategy called DELT (diverse ensemble learning technique) [22] is presented. Unlabelled test modules are predicted by majority voting. The DPAHM (Defect Prediction based association hierarchy method) [23] is used to allocate resources for coarse-level activities. FAHP (Fuzzy Analytical Hierarchy Process) is a prevalent multi-criteria decision-making method [24]. Conversely, this evaluation methodology employs a wide range of performance indicators. They may now trust study findings more, avoid misleading conclusions and set realistic restrictions. They employed 11 defect classifiers and 22 prominent performance measurements. The study used KNIME data mining and 12 NASA MDP software defect data sets.

With KMFOS, the class imbalance problem is solved [25]. KMFOS creates additional faulty instances by interpolating between two clusters. They would then spread out in the flawed dataset space. To reduce the noise, CLNI uses cluster-based oversampling. To develop an HDP model, a structured unsupervised deep domain adaptation is applied [26]. They start by combining data from both source and target projects into one statistic. The authors then develop an SNN (simple neural network) model to manage the various and class-imbalanced difficulties in SDP. The hybrid defect prediction model [27] uses the cross-entropy loss function as the classification loss function to reduce distribution mismatch. A heterogeneous defect prediction approach [28], [29] addresses the issue of extreme class imbalance in real-world software datasets. Minority samples in defect data are balanced using the Majority technique based on Mahalanobis distance in the first step. Ensemble learning and joint similarity measurement are used in the second stage to identify the most relevant and representative features across the source and target projects. At last, knowledge transmission from source to target project inside Grassmann manifold space.

The PROMISE Source Code (PSC) dataset was created to expand the CNN research's initial PSC dataset [30]. Our study used 30-repetition holdout and 10-fold cross-validation. An improved CNN model was then proposed and compared to previous CNN findings and an empirical study. It is used to identify contributing elements and independent variables [31]. Defect-free modules have their bugs replaced by a negative number, while faulty modules have their bugs left alone. Negate the false values of defect-free modules while increasing the false values of defective modules. In the next step, algorithms from NASA, SoftLab, and Promise are used. RKEE [32] is preceded by feature selection and rough set-based KNN noise filtering. Remove redundant features first using the feature ranking algorithm. A rough-KNN noise filter removes noisy samples from both minority and majority classes in the second stage. Both the minority and majority classes deal with ambiguity and overlap. NASA and Eclipse data sets have been used to test our technique.

There are considerable discrepancies in data sharing between the source and destination projects, which leads to inconsistencies in metrics. First, we present a clustering-based metric matching approach. An extract multi-granularity metric feature vector unifies the metric dimension while keeping maximum information. A strategy for predicting cross-project defects [33]. That is, it converts the project's original feature space into a manifold space, then uses that manifold space to train a superior naive Bayes prediction model. FSLBDA (few-shot learning based balanced distribution adaptation) technique [34] for unique defect prediction. Under-sampling can correct class imbalance in defect datasets, but reduces the size of training datasets. They remove redundant measurements from severe gradient boosting datasets. Dual innovative approaches [35] for learning from imbalanced data sets to improve minority class forecasting accuracy. These strategies try to distinguish between oversampling and misclassification costs. Experiment findings showed that identifying problematic modules accurately reduced detection system costs by G-mean and AUC. Instance weight is determined by information gravity among source and destination domains, whereas feature load is determined by high correlation with the learning goal, low correlation with other features, and low domain difference. Using 25 real-world datasets, the suggested methodology outperforms existing CPDP (cross project defect prediction) approaches [36]. The suggested approach builds a better CPDP model by allocating weights based on the varying contribution of characteristics and cases to the predictor.

III. PROPOSED METHOD

This section summarizes the software defect classification framework, as well as the significance of each feature. There are a total of 37 software defect attributes in total, with 8 significant features chosen for model performance evaluation. The proposed framework's system block diagram is shown in Fig. 1. NASA software defect datasets must be analyzed using machine learning models. The model is trained using six classification methods in this experiment: DT, EB, RF, SVM, LM, and NN. The experiments are carried out with the help of the R programming language, which trains models to classify software defects. The RF random tree and DT entropy have used feature values for each measurement and measurement class as inputs.

A. Dataset Description

The publicly available NASA Defect Dataset of PC1 was used in this study which is presented in Table I. In the dataset, there are 759 samples and 37 features, respectively. Lines of code, normalised cyclomatic complexity, cyclomatic density, essential complexity, maintenance severity, halstead content, halstead difficulty, parameter count, and other metrics are included in the data as presented in the Table II.

B. Algorithm

The algorithm was input with different dataset of different raw features along with m sample, the different models were trained with, and the performance model was observed for True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) for the model performance evaluation. The steps were followed for each feature with various entropy features using recursive partitioning and with different decision criteria.

-
- Input dataset with n raw features $F_r = \{f_1, f_2, f_3, \dots, f_n\}$ and m samples.

IV. RESULT AND DISCUSSION

In this section, the summary of the experimental results obtained by various machine-learning models are presented. These experiments are conducted on the dataset NASA PC1 Dataset. The results obtained from various ML models are shown in Table III. In the next stage, the ML method on the dataset with all the features of confusion matrix calculated and shown in Fig. 2. The accuracy and precision are also calculated and are shown in Fig. 2 and Fig. 3. The Sensitivity and Specificity are also calculated the results are shown in Fig. 4.

Fig. 7. Accuracy and Precision of ML Models with Significant Features.

Although this result is obtained by using with only 8 features out of 37 features, the proposed approach time consuming due to the large number of parameters in features

selection. Since the proposed model utilizes only important features and avoid features which are not have high impact. Machine Learning models are used in to find out optimal feature selection and significant result improvement achieved by using Random Forest method in selection process.

The results revealed that our proposed method performed better than existing methods without significant features. The machine learning models with all features accuracy results obtained 97.50 % by using Random Forest method. The same dataset with significant features results in accuracy improvement 97.76 is achieved. Six distinct models are investigated for software defect data classification with selected features. As a result, the results of all six classification methods are compared using the outputs of the suggested feature ranking algorithms as input. The experimental results in Table IV shows that the suggested feature with an RF model have the greatest accuracy scores of all six features.

V. CONCLUSION

Software defect prediction method plays important role and important to prevent and predict the bugs in the software in early stages are very difficult and challenging. However, this work using machine learning models perform evaluation of defect prediction with all features used in NASA dataset. The Machine learning models like DT, EB, RF, SVM, LM, and NN are used. The evaluation process carried out using with significant features and all features. The experimental results analyzed and summarized based on confusion matrix, accuracy, precision, sensitivity and specificity. The accuracy is plays major role and error rate also evaluated by using random forest the results are improved. The comparison results with all features and significant features used with ML models shows improvements. As future work, many more ML models and performs comparison among them to make more optimal results.

Abstract—The vibrational energy harvesting has been essentially applied to power up low-power electronics, microsystems, and wireless sensors especially in the areas of Internet of Things (IoT) devices. This paper investigates the prospect of incorporating nonlinearity in a unimorph piezoelectric cantilever beam with a tip magnet placed under a harmonic base excitation in IoT enabled environment. An empirical and theoretical analysis on the impact of various parameters such as spacing distance between magnets, presence of magnetic tip mass and positioning of vibrational source on the frequency response output was performed. It was observed that the largest spectrum of frequency can be produced when at the lowest resonant frequency of the cantilever. The positioning of vibrational source deeply impacts the hysteresis region and frequency range in realizing broadband energy harvesting. The inclusiveness of vibration source on both the cantilever beam as well as the external magnets impacts the energy harvester in terms of frequency range and the minimal distance for bistable condition.

Keywords—Energy harvesting; nonlinear dynamics; piezoelectric; vibration; broadband frequency

I. INTRODUCTION

The innovations in low power electronics for Internet of Things (IoT) in a variety of capacities ranging from health facilities, smart homes, and security surveillance has been extensively researched in the literatures [1, 2]. These low power sensors and devices traditionally function using batteries that have a limited lifespan. As the demand of sustainability in IoT devices increases, the need to recharge or replace these conventional batteries are essential to ensure the system is fully operational thoroughly [3]. The application of piezoelectric cantilever effect in transforming surrounding mechanical vibration energy to operational electrical energy has gained significant research interest progressively over the years. The vibrational energy harvesting has been applied widely to supply electrical energy to power up low-power electronics, microsystems, and wireless sensors [4-6]. It has also been regarded as an alternative source to chemical batteries that are relatively small and have restricted life duration. Piezoelectric energy harvesters are usually integrated in areas where the usage of batteries is unfeasible and inappropriate. The most commonly deliberated vibration-to-electrical energy conversion mechanism in the literature is modeled using either electromagnetic, electrostatic, magnetostrictive, triboelectric or piezoelectric energy mechanism [7-9].

The single cantilever piezoelectric energy harvester (PEH) that was projected irrespective of load as a linear resonator does not provide efficient operating frequency as it characteristically suffers from a constricted operating frequency range [10]. The simplicity in incorporating piezoelectric harvesters has encouraged in-depth research to increase its performance and extending its operational frequency spectrum. Since piezoelectric energy harvester is a resonant-based model, one of the requirements to obtain maximum electrical power output is to ensure that the excitation frequency of the ambient surroundings matches to the resonant frequency of the harvester [11, 12]. A minor frequency disparity or deviations from the harvester resonant frequency will significantly reduce the harvested power as the imparted stress-strain effect in the piezoelectric mechanism has been affected accordingly. Unfortunately, in real world circumstances, the frequency spectrum of the vibrational energy in ambient environment changes dynamically and can be unpredictable over time [13]. In order to mitigate this issue, evolutions in design and parameters of the piezoelectric energy harvesting system has been expanded in several aspects such as altering design configurations [14, 15], manipulating mechanical nonlinearities [16, 17], and improving electronic circuitry [18, 19] with intentions to increase the spectrum of operational frequency and thus its power output. These innovations have seen viable success in its intended purpose to provide better solutions for vibrational energy harvesters [20].

In view of the design aspects discussed in the literatures, most of the methodology focuses on either tuning the resonant frequency or broadening the operational frequency spectrum of the energy harvester [21, 22]. For techniques involving active resonant frequency tuning, the resultant development of the energy harvester may not be practicable as the tuning of the actuators actually consume more power than the device can harvest [23, 24]. In passive resonant tuning, the increase usage of sensors and actuators indirectly create an upsurge in cost and intricacy of the system [25]. Current research for increasing the bandwidth of the operating frequency has developed positive prospective in recent years in terms of extending range of frequencies to be processed [26-29]. This innovative strategy allows the energy harvester to response to several vibration frequency excitations at the same time. There is no tuning mechanism involved; however, there may be a decrease of maximum power harvested at the instance. The strategies involved in widening the operational frequency spectrum includes designing an array of piezoelectric cantilevers as generators [30], introducing mechanical stopper to limit the

This work is sponsored by the Ministry of Higher Education Malaysia under Fundamental Research Grant scheme (FRGS/1/2020/TK0/MMU/03/13)

harvester amplitude [31], and accustoming nonlinearities into the harvester system through bistable configurations [32, 33]. Many researchers have enthusiastically expanded the bistable configurations which comprises of two stable equilibria energy states created by the exploitations of magnetic field force [34, 35]. Further exploration in the effect of restoring force by magnets and its nonlinearity may create the opportunity to extend the bandwidth of operating frequency in the energy harvesting system. With these motivations, the empirical study in this research paper thus focuses on widening the operational frequency spectrum through exploitations of magnetic field. In the literatures, most researchers study the impact of permanent magnets when only the piezoelectric cantilever was placed under seismic vibration while the external magnets were assumed to be static [36-39]. Some researchers also studied the impact of permanent magnets when both the piezoelectric cantilever beam and external magnet are placed under the same vibration. As the beam and its external magnet of the piezoelectric energy harvester are usually designed inclusively and placed together on the same vibrating platform, both the beam and external magnets will experience the same vibration and will counteract during vibration. Thus, the need to analyse and model a nonlinear energy harvesting system based on the positioning of vibration source is essential for further improvement of broadband energy harvesting.

In this paper, the noteworthy impact in terms of resonant frequency and the voltage output of the piezoelectric energy harvesting system as the relative distance between two fixed magnets in repulsion mode varies horizontally was investigated. The proposed model is designed by incorporating magnets as mass on the single unimorph piezoelectric cantilever beam and inducing the effects of magnetic field force to control the stress-strain effect in the cantilever beam. This paper discusses an experimental analysis on the effect of using magnets and its variations in spacing range towards the bandwidth of frequency spectrum for a wideband bistable energy harvesting system. Furthermore, the influence of positioning the vibration source on either the cantilever beam or both the beam and external magnets are compared to analyse its effect on the resonance frequency and voltage output of the energy harvester. A comparison in term of resonance frequency, output voltage and its spectrum of frequency between both scenarios will be done accordingly.

This paper is organized as follows. Firstly, the research methodology and its concept in using the magnets as load for the piezoelectric cantilever are described in Section 2. Furthermore, Section 3 presents the consequence of extending the horizontal displacement between the two magnets on the piezoelectric resonant frequency. In Section 4, further investigation is done to observe the consequential outcome of spacing distance between magnets on the performance of the harvester. Lastly, a summary of the overall research results in the paper is established and elaborated in the final section.

II. THEORETICAL ANALYSIS

A. Modeling and Design Analysis

The design of the bistable piezoelectric energy harvesting system involves a unimorph piezoelectric cantilever beam and two magnets that will be applied as mass and also for its

repulsive-attractive mechanism. The piezoelectric cantilever is setup by clamping one of its end firmly onto the vibration shaker with the aim to decrease the effect of gravity. At the other free end of the cantilever beam, a magnetic mass that weighs approximately 0.75 gram will be fixed to the piezoelectric cantilever to behave as a mass as well as to be responsible for providing the magnetic force restoration for the system. Subsequently, an additional alike magnetic mass is secured in a fixed location but is positioned in reverse polarity compared with the magnetic mass on the cantilever free end. During the experiment, the magnet in the fixed position will be displaced along the x -axis accordingly to provide displacement, d . The setup of these magnets will provide a variation of repulsive magnetic force strength as the distance between both magnets adjusted accordingly. The controllable vibration shaker functions to provide a transverse harmonic displacement for the piezoelectric cantilever throughout the experiment. In this paper, a comparison will be done to observe the impact of the magnets on the resonance frequency and voltage output when the vibration source is placed differently as illustrated in Fig. 1. In Fig. 1(a), the piezoelectric cantilever beam is placed on the vibration shaker and the magnetic mass is fixed to a stationary structure, namely piezoelectric beam with stationary magnet (PSM) system. While in Fig. 1(b), both the piezoelectric cantilever beam and the fixed magnet will be placed under the same vibration source applying the same base excitations, namely piezoelectric cantilever under the same vibration (PVM) system.

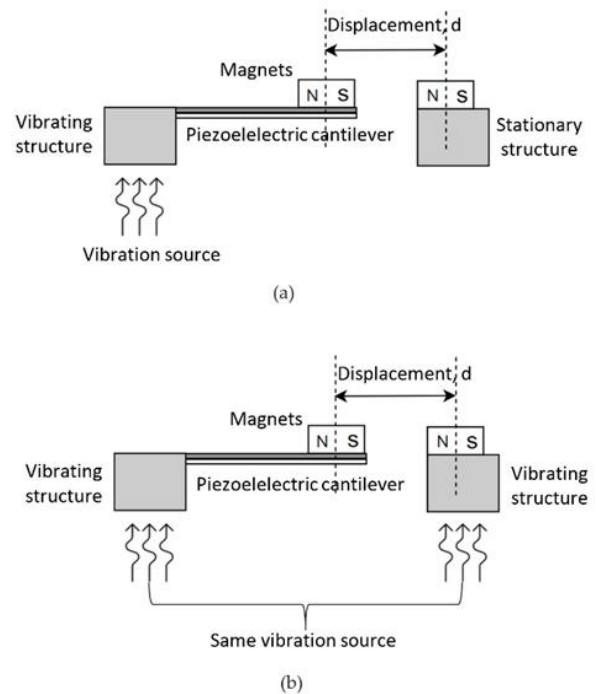

Fig. 1. Setup of Piezoelectric Energy Harvester for (a) PSM (b) PVM.

In electromechanical modeling, a linear resonant piezoelectric harvester can be represented based on Euler-Bernoulli beam equation. In Fig. 1, if the magnets are taken out and replaced with a similar sized mass, the piezoelectric harvester becomes a linear system that can be described using the governing electromechanical model, as in (1) and (2).

$$M\dot{x}'(t) + Cx'(t) + Kx(t) - \theta v(t) = F(t) \quad (1)$$

$$C_p \dot{v}(t) + \frac{v(t)}{R} + \theta \dot{x}(t) = 0 \quad (2)$$

Where M and C denotes the total mass and damping experienced by the energy harvester respectively. K and θ characterize the effective stiffness and the equivalent linear piezoelectric electromechanical coupling coefficient. C_p characterizes the corresponding capacitance of the piezoelectric substance and $v(t)$ denotes the voltage across the external load resistance, R . The vertical tip displacement of the mass is represented by $x(t)$ while $F(t)$ is force mechanically induced by the surrounding vibration excitation [40-42].

When the proof mass of the energy harvester is interchanged with magnets and arranged in repulsive mode, a magnetic repulsive force, F_m exists between the magnets and eventually changes the linear system defined by (1) and (2) to be magnetically coupled non-linear piezoelectric harvester. The non-linear energy harvesting system can then be described, as in (3) and (4).

$$M\ddot{x}(t) + C\dot{x}(t) + Kx(t) - \theta v(t) = F(t) + F_m \quad (3)$$

$$C_p \dot{v}(t) + \frac{v(t)}{R} + \theta \dot{x}(t) = 0 \quad (4)$$

Where the nonlinear magnetic force, F_m can be articulated as the polynomial equation of.

$$F_m = \mu x(t) + \lambda x^3(t) \quad (5)$$

B. Effect of Distance on Interaction between Magnets

Since the stiffness of the piezoelectric cantilever beam is dependent on the magnetic force in the system, the position and distance between magnets will also be one of the factors that will determine the energy harvester performance. In order to create bistability, two magnets are placed in opposite polarity with a specific distance, d along the x -axis of the beam as illustrated in Fig. 2. Due to the magnetic repulsive force, F_m amid the magnets, the actual bending of the beam tip can be characterized as the vertical displacement, h of the tip mass.

Theoretically, a magnetic repulsive force, F_m exists between the magnets and its magnitude will decrease as the distance, d between the magnet increases. In order to observe the impact of this repulsive force on the system, a simplified lumped parameter model is used to represent the physical system as well as to approximate the effect of distance to the respective force as shown in Fig. 3.

Fig. 2. A Piezoelectric System with Adjustable Distance between Magnets.

Fig. 3. A Simplified Lumped Parameter Model for the Piezoelectric System.

The total mass, m of the energy harvester system is determined by the effective mass of the first flexural mode of the beam plus the magnetic mass, while the effective spring stiffness, k denotes the elastic response of the piezoelectric cantilever beam [40]. The repulsive force, F_m is assumed to have a constant magnitude for a given value of distance, d provided that the angle θ is reasonably small. Thus, as the mass on the cantilever tip moves, the repulsive force, F_m changes in the direction by an angle α . Since the longitudinal stiffness of the piezoelectric cantilever is assumed to be adequately high, the horizontal component of the repulsive force, F_m will be balanced off. The vertical component of the repulsive force, F_{mv} which affects the stiffness and motion of the energy harvester can be described as.

$$F_{mv} = F_m \sin \alpha \quad (6)$$

The distance, d between the magnets and its relation to the vertical mass displacement, h can be written as.

$$h = d \tan \alpha \quad (7)$$

Consequently, the resultant relationship between the distance, d and the vertical constituent of the repulsive force, F_{mv} can be further deduced as.

$$F_{mv} = F_m \sin \alpha = F_m \frac{h}{\sqrt{d^2 + h^2}} \quad (8)$$

Applying Taylor series expansion around $x=0$ up to the third term, the vertical force, F_{mv} can be represented as.

$$F_{mv} \cong \frac{F_m}{d} x - \frac{F_m}{2d^3} x^3 \quad (9)$$

It is noted that the vertical force, F_{mv} is a nonlinear third order polynomial function which matches the assumption earlier for magnetic response cantilever system. From the derived equations, it is observed that as the distance, d increases, the vertical force, F_{mv} will decrease accordingly. Since the repulsive force, F_m is also a function of distance, d , this simply indicates that as the relative distance between the magnets decreases, the resultant magnetic force applied on the cantilever system increases and hence the potential energy of the energy harvesting system will change accordingly.

As the mass, m being repositioned from its equilibrium point, the total force, F_{total} acting on the mass, m as shown in

Fig.3 will be the summation of the spring restoring force, F_s and the counter-restoring vertical force, F_{mv} that is described as.

$$F_{total} = F_s + F_{mv} = -k_{beam}x + \frac{F_m}{d}x - \frac{F_m}{2d^3}x^3 \quad (10)$$

The potential energy, $E(x)$ of the energy harvesting system is then deduced as.

$$E(x) = - \int F_{total} dx = \frac{1}{2} \left(k_{beam} - \frac{F_m}{d} \right) x^2 + \frac{F_m}{8d^3} x^4 \quad (11)$$

As the distance between the magnets increases, it is perceived that the repulsive magnetic force, F_m will also be reduced significantly and when it decreases until zero, the energy harvesting system will become a linear system. Fig. 4 shows the graph for potential energy, $E(x)$ of the energy harvesting system for diverse values of repulsive magnetic force per distance.

When the repulsive magnetic force per distance is less than or equal to the cantilever beam stiffness, k_{beam} , the potential energy, $E(x)$ of the energy harvester will have only one stable equilibrium position at its origin. In this circumstance, the system is said to be working under monostable condition and is still characterized under linear system. As the repulsive magnetic force per distance increases and exceeds the cantilever beam stiffness, k_{beam} , the potential energy, $E(x)$ will exhibit a bistable behavior whereby a symmetric double well with an unstable equilibrium position at the origin and two stable equilibrium positions exist within the energy harvester. When the system is working under bistable condition, the cantilever beam will oscillate within the stable equilibrium positions in each energy well as it will interchange from one equilibrium state to another when the external vibration energy is sufficiently high.

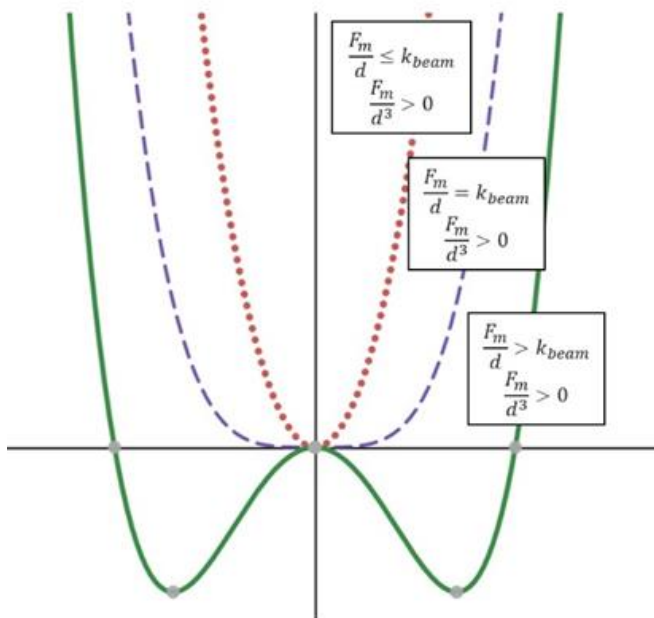

Fig. 4. Potential Energy, $E(x)$ for Monostable and Bistable Conditions.

The change in the potential energy of the cantilever beam basically results in a monostable or bistable characteristics in the energy harvesting system allowing the system to work differently based on the diverse requirements in the vibration environment. If the system is working under bistable behavior, the cantilever beam is able to switch between two equilibrium states, thus expanding the possibility of harvesting energy in a wider spectrum of vibrational frequency. Therefore, in order to achieve bistability in the system, the distance between the magnets should be sufficiently low enough to achieve the condition where the repulsive magnetic force per distance exceeds the stiffness of the cantilever beam, k_{beam} .

C. Effect of Magnetic Stiffness on Resonance Frequency

For a linear piezoelectric harvester with effective mass, m , the resonant frequency of the linear energy harvesting system can be described as.

$$\omega_{beam} = \sqrt{\frac{k_{beam}}{m}} \quad (12)$$

When the tip mass is replaced with a magnet and the energy harvesting system is deliberated as presented in Fig. 1, the resultant magnetic force will vary the stiffness of the cantilever beam, k_{beam} resulting in a change of resonance frequency. Consequently, the resonance frequency of the energy harvester will now be dependent on the stiffness linked to the magnetic force as well as the rigidity of the cantilever beam. The effective stiffness and the weight of the magnet will essentially determine the resonant frequency of the energy harvesting system. In order to parametrically model the influence of the magnetic strength and spectrum on the stiffness of the cantilever beam, a lumped parameter model was proposed to characterize the nonlinear system.

Fig. 5 illustrates the lumped parameter model of the nonlinear energy harvesting system as a consequence of additional stiffness acquainted with the repulsive magnetic force. The resultant force contributed by the repulsive magnetic force is demonstrated as a variable spring where the stiffness of the spring is subjected to the variation of the magnetic force with respect to the relative distance between both of the magnets.

As a result, the total effective stiffness and its resonant frequency of the energy harvester can be further deduced as

$$K_{eff} = K_{beam} + K_{magnet} \quad (13)$$

$$\omega_{eff} = \sqrt{\frac{K_{eff}}{m_{eff}}} \quad (14)$$

Fig. 5. Lumped Parameter Model for Nonlinear Energy Harvesting System.

Theoretically, as the magnetic force on the beam increases, the stress/strain imposed on the cantilever beam will also increase accordingly. Consequently, the resonance frequency will also change depending on the attractive or repulsive mode of the magnets and the resultant stiffness at the mass tip of the cantilever. It should be noted that stress induced by the magnets should not be larger than the yield stress of the beam for repulsive magnetic mode. By deducing the equations, one can tune the desired resonant frequency, ω_{tuned} from the original beam frequency, ω_{beam} of the energy harvester by determining the appropriate magnetic stiffness using the equation.

$$K_{magnet} = m_{eff}\omega_{tuned}^2 - K_{beam} = m_{eff}(\omega_{tuned}^2 - \omega_{beam}^2) \quad (15)$$

III. RESULT AND DISCUSSION

A. Design of Experiment

To assess the feasibility of the nonlinear energy harvester, a prototype of the system was built and verified in the laboratory. Fig. 6 shows the apparatus and design of the experimental structure for the energy harvesting system. The vibration shaker was used to produce the controllable vibration base excitation to the whole system throughout the experiment. A piezoelectric strip with dimensions of 1.25 x 0.5 x 0.02 inch, weighing 1.372 gram was used as the cantilever beam in the system. Fig. 7 illustrates the dimension of the piezoelectric cantilever applied throughout the experiment. A permanent magnet weighing 0.75 gram was secured at the free end tip of the cantilever beam while another magnet with opposing polarity was fixed on an external stationary structure with the purpose to adjust the distance between the magnets. The magnets were arranged in repulsive mode and were displaced in the direction of x -axis.

The empirical study of the bistable energy harvesting system was divided into two classifications. The initial part of the experiment comprises of analysis on the effect of the spacing displacement, d between two of the repulsive magnets on the resonant frequency of the system. In the subsequent experiment, the performance in terms of voltage output of the piezoelectric energy harvester was further examined according to the variety of the relative distance between the two repulsive magnets. Through the variation of distance between the magnetic mass, the stiffness of the cantilever beam can be regulated to obtain the desired frequency range. As the relative displacement between both of the repulsive magnets decreases, the stationary location of the cantilever beam changes accordingly. The variation of stationary point is reliant on the extent of hardening influence on the piezoelectric cantilever as the relative displacement between the two repulsive magnets changes.

Furthermore, as discussed in the previous sections, both of these experiments were done under two different circumstances scenarios. One of the scenarios involves pairing of the static magnetic mass under stationary condition while another scenario involves pairing of the static magnetic mass under similar vibration source, as depicted in Fig. 1. The frequency response curve for both scenarios was investigated respectively. The impact of spacing displacement on the magnetic force that affects the bistability of the energy harvesting system was also observed accordingly.

Fig. 6. Design of Experiment Apparatus of the Piezoelectric Energy Harvester.

Fig. 7. Dimension of the Piezoelectric Cantilever Beam (a) Top View (b) Side View.

Fig. 8. Top View of Experiment Apparatus of the Piezoelectric Energy Harvester with Displacement in x -axis.

Fig. 8 illustrates the top view of the apparatus setup with horizontal spacing displacement in x -axis between the two magnets. For this setup, the energy harvester involves pairing of the static magnetic mass under stationary condition. During the experiment, the static magnet was adjusted and move away from the piezoelectric cantilever beam to observe the impact of magnetic force on the system. The spacing displacement between the magnets was measured from the center of the respective repulsive magnets.

B. Effect of Spacing Displacement on Resonant Frequency

An analysis on the effect of applying magnetic forces in the adjustment of the resonance frequency of the energy harvesting system has been investigated as follows. In the first part of the experiment, the fixed magnet is placed under stationary condition to observe the influence on the resonant frequency of the energy harvester as presented in Fig. 1(a). The static magnet is then displaced along the x -axis, making sure there is no displacement in the y -axis and z -axis between the two repulsive magnets in the system. The deviations of the resonant frequency as a function of spacing distance for PSM system is then plotted as presented in Fig. 9(a). Based on the observation, as the magnets were moved closer to each other from large distances, the system tends to behave as monostable linear system with decreasing resonance frequency until it reaches the condition where the repulsive magnetic force per distance, exceeds the stiffness of the cantilever beam, k_{beam} . Subsequent to this condition, when the magnets are pushed further and are sufficiently close, the resonant frequency tend to increase drastically creating bistability condition for the system. In this circumstance, the system has the ability to interchange between two equilibrium states and the fluctuation of the tip displacement can surge substantially if the base excitation level is increased sufficiently.

Further analysis on the PSM system results shows that for spacing displacement above 8 mm as in region IV, the resonant frequency of the energy harvesting system tends to stabilize, indicating the waning of repulsive force by the magnets. As the relative displacement between the magnets decreases, the resonant frequency of the system seems to decrease accordingly, as shown in region III. It is also observed that for displacement ranges between 3 mm and 4 mm (region II), there is a sharp decrease of resonant frequency up to its minimum frequency of 114 Hz. It is then followed by a sharp increase of resonant frequency (region I) as we decrease the spacing displacement, placing the magnets into stronger repulsive mode. As the strength of the repulsive magnet force increases, the piezoelectric cantilever beam responded accordingly through the change in its static position and bending effect, subsequently triggering a drastic adjustment in the resonant frequency response. At this point, the energy harvester will be working under bistable condition. Thus, the resultant analysis displays that in order to ensure that the energy harvesting system is working under bistable mode; the minimum requirement for the distance between the repulsive magnets is less than 3 mm.

In the second part of the experiment, the fixed magnet is placed under the same vibration source as the piezoelectric cantilever beam to observe the effect on its resonant frequency as demonstrated in Fig. 1(b). Fig. 9(b) illustrates the variations of the resonant frequency when the spacing distance between two magnets is altered accordingly under the common vibration source for PVM system. It is observed that a similar pattern of resonant frequency is obtained in comparison with the PSM system. However, the change of resonant frequency may not be as abrupt compared to the static magnetic mass

under stationary condition. Based on the analysis, the resonant frequency of the system stabilizes as the distance between both magnets increases above 6mm, as shown in region III. As we move the magnets to closer to each other, the resonant frequency of the PVM system decreases gradually for distances between 4 mm to 6 mm (region II). In this setup, the energy harvesting system began to function as a bistable system for magnetic distances below 4 mm (Region I).

For the significance of this investigation, it is perceived that the repulsive influence between the magnets tend to stabilize only at displacement beyond 6 mm for the energy harvesting system. For relatively smaller distance of the spacing displacement, the increase of hardening influence between the magnets causes further bending effect on the cantilever and thus creates bistability of the resonant frequency in the system. In comparison between both of the systems, the PVM system seems to provide more feasible design for the energy harvester and it was able to achieve its bistability mode for larger threshold distance between magnets. This proves that the design of the nonlinear energy harvester should include the effect of vibration source on both the piezoelectric cantilever beam as well as the fixed magnet on the external structure.

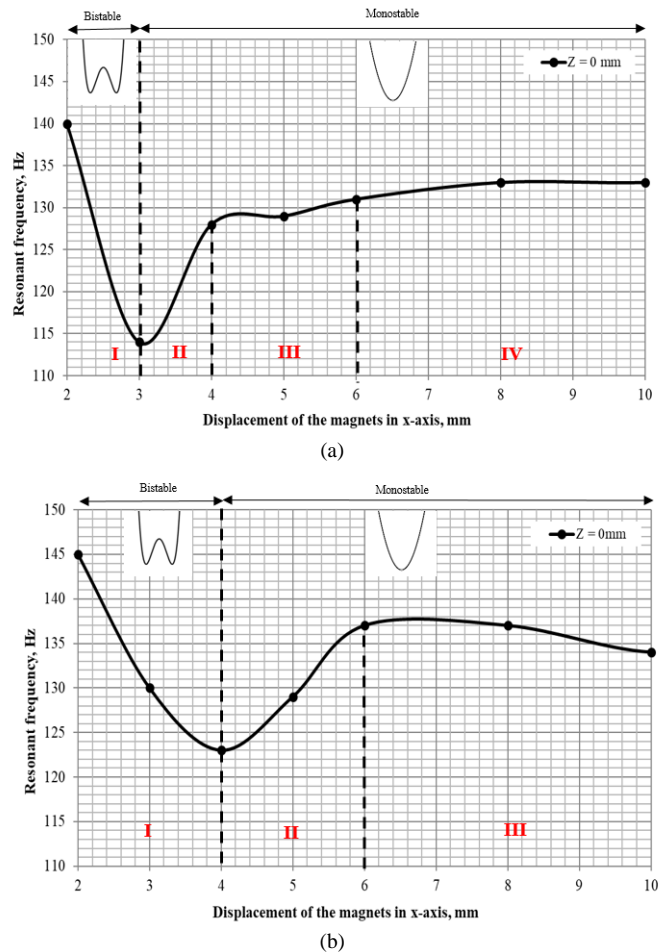

Fig. 9. Resonant Frequency of the Energy Harvester for different the Spacing Displacement, d for Static Magnetic Mass under (a) PSM (b) PVM.

Furthermore, the resultant graph for both experiments are also consistent with the theoretical expectations, endorsing that the cantilever beam leaps between two stable states for sufficiently close magnetic distance and adequate base excitation as demonstrated in Fig. 4. This change in resonance frequency due to the spacing displacement of the magnets was also found to have similar pattern as other researchers' work [43, 44]. However, in comparison with the other researchers' work, it was found that the addition of vibration source on the external magnet increases the region of bistability for the energy harvester. The resonance frequency of piezoelectric cantilever for the energy harvester with same vibration source also increases in comparison with the stationary magnet due to the impact of vibration on the coupling between the magnets.

These findings are substantially vital during the design considerations for vibration energy harvester and notable for researchers in this field of research.

C. Effect of Spacing Displacement on Output Voltage

A similar setup as presented in Fig. 1 was applied to measure and verify the performance of the nonlinear energy harvester in terms of open-circuit output voltage. The energy harvester was excited by a controllable vibration shaker with mechanical vibrations and placed accordingly using both scenarios as discussed in Section II. The excitation level of the shaker is set sufficiently low to prevent initiation of bistable mode as the distance between the magnets becomes substantially close. Consequently, the energy harvester was held to oscillate at only one interwell equilibrium state throughout the experiment. The function generator and amplifier was used to regulate the vibration shaker in tuning the resonance frequency for each cantilever beams. The output electrical responses were observed using the oscilloscope and its frequency response curve are plotted accordingly.

The resultant graph will also include the voltage output of the linear system with proof mass for comparison purposes. Fig. 10 illustrates the frequency response output of the open-circuit root mean square (rms) voltage generated by the energy harvester for a variation of relative displacement between the magnets for the PSM and PVM system. The differences in the output voltage were compared to observe the impact of magnetic force and location of vibration source on the cantilever beam. Based on our observation, the results showed that the relative displacement between the two magnets significantly affects the level of the harvested voltage. It is also eminent that the positioning of the vibration source on the piezoelectric cantilever and/or permanent magnets impacts the frequency response curves especially in terms broadening the frequency range of the energy harvester.

Fig. 10 shows that the relative distance between the two magnets significantly affects the level of the harvested voltage. It is also observed that by changing the relative displacement, the energy harvesting system has the competence to harvest vibrational energy in a wider spectrum of operating frequency. For the spacing displacement of $d=2\text{mm}$ as presented in Fig. 10(a) and Fig. 10(b), since the magnets were placed essentially close to each other, both of the PSM and PVM systems are now under bistable conditions. At this point, the magnetic field strength applied on the system was very high and the nonlinear

characteristics will be substantially visible as the excitation level of the vibration source increases. However, the effect of magnet on the piezoelectric cantilever causes the output voltage to drop significantly lower than its other counterparts. The resultant bandwidth for both of the system is also lower and does not provide a good model for broadband energy harvesting.

For the spacing displacement of $d=3\text{mm}$ as shown in Fig. 10(a), the PSM system was operating at its lowest resonance frequency as discussed in the previous section. In this case, both PSM and PVM systems are still operating in bistable conditions. However, the PSM system tends to exhibit broader frequency range as compared to the linear system and its other counterparts. Similarly, at the spacing displacement of $d=4\text{mm}$ for PVM system as shown in Fig. 10(b), where PVM was also operating at its lowest resonance frequency, the output voltage and its bandwidth are significantly higher than its counterparts of different spacing distances. In other words, in designing a bistable system, the optimal spacing distance to be chosen is when the resonant frequency of the cantilever beam is at its lowest point. The magnets were displaced further at spacing distance of 5 mm and above. The frequency response curves in Fig. 10(a) show that the output voltage of the PSM system decreases and remain fluctuating around the similar output voltage accordingly. Similarly, at Fig. 10(b), the output voltage remains constantly the same for spacing distance of 6mm and above.

(a)

(b)

Fig. 10. Output Voltage of the Energy Harvester for different the Spacing Displacement, d for Static Magnetic Mass under (a) PSM (b) PVM.

These outputs indicate that both the PSM and PVM system were not affected significantly by the repulsive force of the magnets and thus regardless of the position of the vibration source, both system exhibits similar frequency response curve. However, it is noticeable that the output voltage for both PSM and PVM system is slightly lower in comparison with the linear system with proof mass and yet it has similar spectrum of frequency range in the frequency response curves.

As can be perceived from the experimental figures, with the decrease of spacing distance between the magnets, the impact of magnetic force intensifies and thus increases the hardening response of the piezoelectric cantilever. This notion of experiment indicated the ability of the energy harvesting system to shift from linear to nonlinear system gradually using permanent magnets. The results also showed that the position of vibration source affects the resonance frequency as well as the operating frequency of the energy harvesting system. Note that as the spacing distance was decreased to its minimal length, the frequency response did not provide the best bandwidth for PVM system. This indicates that as the magnetic force increases, the increased hardening response in the piezoelectric cantilever can cause reduction in bandwidth and eventually may not provide the widest possible range of operating frequency to harvest the vibrational energy. Thus, it is essential to note that the relative distance between two repulsive magnets as well as the positioning of vibration source can directly affect the resonant frequency and the operational range of frequency spectrum of the energy harvester.

IV. CONCLUSION

In this paper, the concept of bistable piezoelectric energy harvesting system by exploiting the effect of magnetic force was presented. Detailed investigation on the effect of the horizontal spacing distance between two magnets of repulsive mode in a piezoelectric energy harvester has also been deliberated. The impact of positioning the vibration source on either the piezoelectric cantilever beam only or both the piezoelectric cantilever beam and external magnets was compared in terms of resonance frequency and bandwidth of the operating frequency for broadband energy harvesting. It is shown that the model is feasible and applicable in harvesting energy in a wider band of frequency spectrum from ambient mechanical vibrations. Likewise, it is also established that the fundamental resonant frequency of the cantilever beam has significant dependence on the variations of relative distance between the magnets as well as the positioning of vibration source on the external magnets.

This paper shows that the piezoelectric energy harvester can be envisioned to accomplish wideband frequency energy harvesting by selecting the optimal spacing distance between two repulsive magnets. Alteration of spacing displacement can also be used to adjust the resonant frequency of the harvester for matching of surroundings excitation frequency in the environment.

V. FUTURE WORK

As a continuation of this research, further work on the impact of different sizes and locations of the magnets on the cantilever beam can be considered. The size of the magnets

may impart a different magnetic force towards the stress and strain of the cantilever beams and is therefore noteworthy for future work considerations. Furthermore, multiple piezoelectric beams with magnets and different configurations can also be worked upon for further considerations in increasing the bandwidth of the vibration energy harvesting system.

ACKNOWLEDGMENT

The authors would like to express gratitude and sincere appreciation to the Ministry of Higher Education of Malaysia for the financial support through Fundamental Research Grant Scheme (FRGS/1/2020/TK0/MMU/03/13). The authors would also like to acknowledge the Faculty of Engineering and Technology, Multimedia University and Faculty of Electronic and Computer Engineering, Universiti Teknikal Malaysia Melaka for the support given in conducting this research.

Abstract—The Covid-19 pandemic has affected all aspects of human life and has even forced humans to shift their life habits, including in the world of education. The learning model must shift from the traditional face-to-face pattern to a modern face-to-face pattern or an asynchronous pattern with information technology-based applications. Blended learning is one of the appropriate solutions to adjust the limited face-to-face learning conditions. Blended learning can be done, for example, by scheduling learning by dividing the number of participants by 50% and entering on a scheduled basis. However, the problem is that the time and effort used are less efficient. Blended learning can also be done by conducting learning simultaneously with 50% of students in class and the remaining 50% through conferences. This concept will streamline the time and effort used. However, the problem is that there is a gap in the learning experience between students in class and students who do learning via conference. This innovative blended learning system framework is proposed to overcome these problems. The system built seeks to present an online learning experience atmosphere so that it is expected to be able to resemble an offline learning atmosphere. We created a system using camera technology and object detection that will track the movement of the teacher so that the teacher can move freely in the room without having to be stuck in front of the computer holding the conference. The algorithms used are MobileNet Single Shot Detector and Centroid Tracking. This research produces an accurate model for detecting teacher movement at a distance of 2, 4, and 6 meters with a camera installation height of 1.5 and 3 meters.

Keywords—Smart blended learning; mobilenet; single shot detector; convolutional neural network; centroid tracking

I. INTRODUCTION

Blended learning has been applied in higher education for several years, but there is still limited research on what affects student satisfaction in blended learning environments in higher education [1]. The implementation of blended learning at a university is evaluated by measuring student satisfaction in face-to-face sessions, independent study sessions using online learning, and the overall learning experience in a Blended Learning environment.

There are two main areas related to the blended learning environment. The first is a blend of traditional classroom learning and e-learning, and the second is synchronous and asynchronous e-learning technology [2]. This first area is the

best-known form of combination seen in the amalgamation of theory and practice of instructor and student-centered learning. The second type of blended learning is the blend of technologies that give students access to synchronous and asynchronous communication and information. This is especially useful when considering the number of external students outside of campus studying at the tertiary level and the associated geographic and access issues and creating an environment accommodating cross-cultural learners.

Along with the development of artificial intelligence technology, various technologies are born to assist humans in completing a task or activity. The technology in question is capable of performing actions like a human. An example is computer intelligence replacing the human sense of sight, usually known as computer vision [3]. By utilizing camera functions supported by object detection algorithms, today's computers can intelligently carry out surveillance automatically like a human's vision.

On the one hand, the current Covid-19 pandemic requires physical interaction restrictions to prevent virus transmission [4]. These restrictions have brought significant changes in various fields, especially in education, namely the limited offline learning activities that are shifted to semi-online and even full-online learning to avoid interactions that can spread virus transmission.

One of the benefits of blended learning is that learning becomes more flexible because its implementation is not limited by distance and time. Online learning from home and offline learning in the classroom can be carried out simultaneously [5]–[9]. However, there are shortcomings, namely the limited space for teachers and students in learning activities. There is a gap between the learning experience in offline classes and online learning conditions. Therefore, a system can be developed to overcome this gap by utilizing computer vision technology, especially object detection technology. The system in question is a system that can use a camera to detect objects on the teacher so that the teacher has free space to explain like in an offline class, and the teacher's position will still focus on video because of the combination of objects detection algorithms and tracking algorithms. The benefit for students is to present a learning experience that tries to approach conditions like in an offline class.

II. LITERATURE STUDY

Object tracking is essential in computer vision and widely used in human-computer interaction, surveillance, and medical imaging. In its simplest form, tracking can be defined as estimating the trajectory of an object in the image plane as it moves around the frame [10]. Object tracking has attracted significant attention because it can perform a wide range of processes, including intelligence in video surveillance, machine and human interfaces, and the field of robotics [11]. However, designing an excellent visual tracking method is still an open issue. Challenges in visual tracking problems include varying shapes and appearances of objects, occlusion, lighting changes, irregular scenes, etc.

The object tracking process consists of two stages in analyzing the video, namely detecting objects and tracking the movement of objects from frame to frame [12]. One of the tracking algorithms that can be used is the centroid tracking algorithm. The centroid tracking algorithm works by taking into account the center point (centroid) of an object in tracking [13]. Therefore, the tracking process in the centroid tracking algorithm is very dependent on the accuracy of the object detection or identification algorithm. The tracking process will be challenging if the object detection algorithm has minimal accuracy and takes a long time. An object tracking task requires an object detection process that can work in real-time and has good accuracy to avoid decision errors.

Research on object identification using a neural network has been carried out by Girshick by proposing the R-CNN architecture [14]. The results obtained are 66% accuracy with 47 seconds per image detection time. The long detection time is due to the algorithm classifying as many as two thousand proposal regions for each image. Furthermore, Girshick optimized the study [14] and proposed the Fast R-CNN architecture [15]. This algorithm can shorten the detection time to 25 times faster than R-CNN and produces an accuracy of 66.9%. The increase in detection speed occurs because the CNN process was initially carried out amounted to about two thousand times be reduced to only one time. The detection time per image only takes 2 seconds.

Research by Ren et al. [16] proposed an architecture called Faster R-CNN. The idea of Faster R-CNN is to replace the selective search algorithm to generate proposal regions used in research [14], [15], becoming a Region Proposal Network (RPN). The detection time per image can reach 0.2 seconds with an accuracy of 66.9%.

Li et al. [17] carried out subsequent research to test the performance of an architecture called MobileNet SSD. The test results show that the accuracy can reach 95% with a detection time of 0.12 seconds. MobileNet SSD combines MobileNet architecture and Single Shot Multibox Detector (SSD) that uses depthwise and pointwise convolution, reducing computation significantly [18]. MobileNet SSD can provide faster object detection performance compared to Faster R-CNN.

Rahman et al. [13] conducted research on object detection in the form of vehicles to find out which vehicles are against

the current or in the opposite direction. The movement of objects is known to use the YOLO detection method and centroid tracking. Centroid tracking works well on single class objects, but if applied to multiclass objects; it allows the identity of object tracking to be exchanged. The results of this study can track vehicles against the direction of the current, which is tested on a 1280x720 video.

Distance learning is usually carried out via video conferencing. In general, video conferencing use technology assistance such as WebRTC [19]. This technology allows video, audio, or other data to be transferred to the student in real-time. In blended learning, the problem is that the video source that is usually used is placed in a static position in front of the teacher so that the teacher can only stand in front of the video source camera. In our proposed research, object detection and tracking technology are implemented with the aim that the teacher's camera can be placed far from the teacher to shoot a wide area in the classroom so that wherever the teacher moves, the video will still focus on the teacher in the center of the video.

III. METHODS

Data collection is the first step in the research process—image data is produced by splitting test and training data. The test data is organized around a single object class: humans. The previously provided test data is fed into the pre-processed data. The data is pre-processed to create a more optimum feature extraction. The next step is to extract the features to obtain a value utilized as input in the following stage. MobileNet SSD is the object detection algorithm. The outcomes of the architectural trials are analyzed, and the best accuracy is chosen for use as training for future test data. As for the test data, pre-processed data is carried out, and then we proceeded with feature extraction and final testing. Workflow can be seen in Fig. 1.

A. Data Acquisition Stage

The data used as input is a real-time video recording. Aside from video recordings, the dataset was derived from open-source internet sources, specifically Open Images and YouTube videos containing things to be detected, specifically human objects.

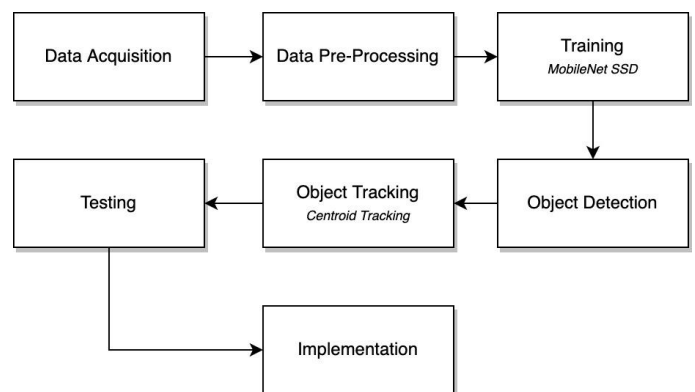

Fig. 1. Research Methodology.

B. Data Pre-processing Stage

After the input dataset was collected, the annotation process was carried out. Annotation is the process of creating labels by providing a bounding box along with the object class name in each image. In this study, the annotations were stored in a file containing information about the object class, each bounding box's coordinates, and its label. Details of the number of datasets are:

- The dataset is an image of a human class object.
- We amassed about 330 data, consisting of 227 training data and 33 test data.
- The number of annotations on the training data is 1,307, while the number of annotations on the test data is 83.

C. Training Stage

Object recognition training is carried out using an annotated image dataset. Then a convolution process is performed using the MobileNet SSD architecture to train the model weights to accurately categorize objects visible on the video camera. In the training stage, iteration was determined by a threshold indication, which takes the form of a loss function value, as seen in Fig. 2. The lower the loss value, the better the developed object detection model.

The SSD MobileNet architecture combines the MobileNet architecture as the base network and the SSD architecture as the detecting network.

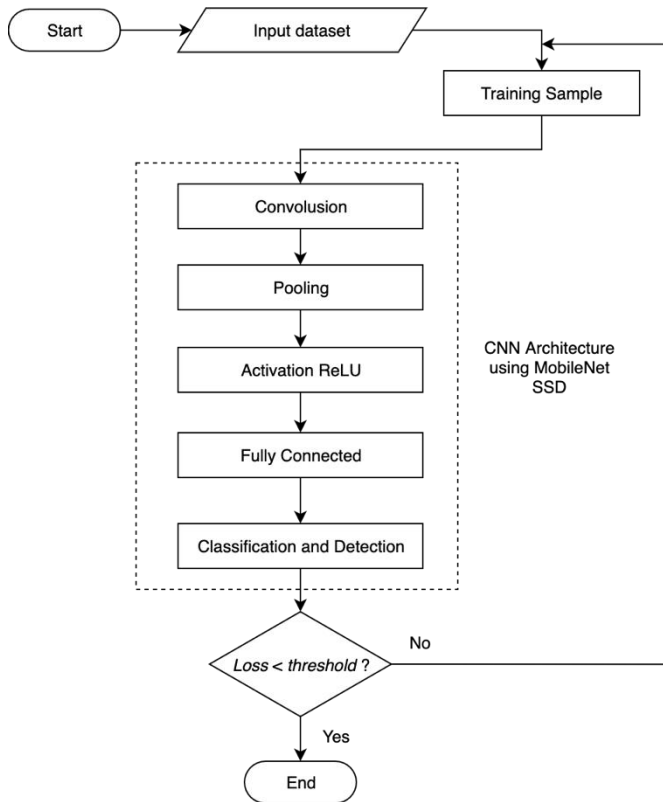

Fig. 2. Block Diagram of Training Process.

Table I depicts MobileNet's standard architecture. Column *n* specifies the number of layers, column *c* specifies the output size, and column *s* specifies the stride [20]. Before average pooling, the MobileNet architecture employs all layers, and the SSD architecture replaces the layers in the typical pooling and fully connected network.

TABLE I. MOBILENET ARCHITECTURE

Input	Operator	t	c	n	s
$224^2 \times 3$	conv2d	-	32	1	2
$112^2 \times 32$	bottleneck	1	16	1	1
$112^2 \times 16$	bottleneck	6	24	2	2
$56^2 \times 24$	bottleneck	6	32	3	2
$28^2 \times 32$	bottleneck	6	64	4	2
$14^2 \times 64$	bottleneck	6	96	3	1
$14^2 \times 96$	bottleneck	6	160	3	2
$7^2 \times 160$	bottleneck	6	320	1	1
$7^2 \times 320$	conv2d 1x1	-	1280	1	1
$7^2 \times 1280$	avgpool 7x7	-	-	1	-
$1 \times 1 \times 1280$	conv2d 1x1	-	k	-	-

A multiscale feature map layer is employed in SSD design, which indicates that various feature map sizes are used. In general, the feature map sizes on SSDs are 512, 256, 256, and 128 [21]. Modifications were performed in this study by adding a 64 feature map, resulting in the SSD network configuration being 512, 256, 256, 128, and 64. The addition of this feature map seeks to evaluate the model's effectiveness in recognizing items of smaller size.

D. Object Detection

After the training stage is completed, the model can be used to identify the trained objects. Fig. 3 depicts the steps of object identification.

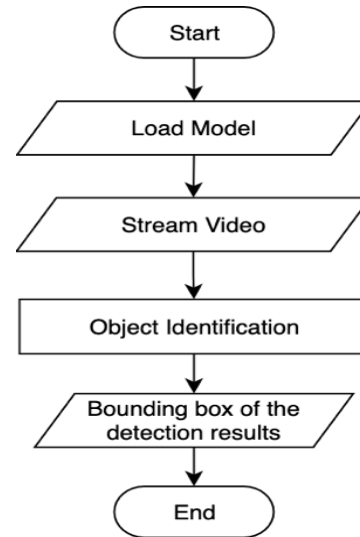

Fig. 3. Block Diagram of Object Identification Process.

E. Object Tracking

Object tracking is used to identify the detecting object so that its movement in a movie can be monitored from frame to frame. The object tracking algorithm used in this work is a centroid tracking approach, although it has been changed to improve performance. Tracking workflow can be seen in Fig. 4. The centroid tracking algorithm is based on the Euclidean distance between the existing centroid object and the new centroid object between frames in a video. The following are the suggested tracking steps:

- Determine the centroid at each of the bounding box locations.
- Calculate the Euclidean distance between the new and old bounding boxes.
- Update the coordinates (x, y) based on the object and class category.
- If a new detection occurs, the new object is added to the new track.
- If the tracking object has been lost, it is removed by setting a threshold for the next N frames.

The centroid tracking approach can perform effectively if the object detection model delivers correct results. The object detection model may not be accurate in the object detection process. Therefore, there is the possibility of mistakes in the form of objects that are not identified or detected but are less accurate. For example, one object is detected as two or more objects. The Non-Maximum Suppression (NMS) method is used in this work to suggest an additional way of post-process detection. NMS works to solve the problem of overlapping bounding boxes from detection results. Incorporating this process will aid the detection process in determining if the bounding box above another bounding box is still the same object or a distinct object [22]. The following are suggested steps from NMS:

- Step 2 should be repeated for each separate object class.
- Take the last index from the index list's enclosing box and add the index value to the specified index list.
- Find the greatest coordinate (x, y) for the bounding box's start and the smallest coordinate (x, y) for the bounding box's end.
- Determine the bounding box's width and height.
- Determine the overlap ratio.
- Remove from the index list any indexes with overlapping threshold values.

F. Testing Stage

The tracking performance testing procedure steps are carried out by applying detection and tracking algorithms on image and video testing with a variety of tests, including camera distance and height testing, frame rates at various video resolutions, and object closures. The F1 score from the confusion matrix is used to calculate performance.

Fig. 4. Block Diagram of Tracking Object Process.

G. Implementation

Following the completion of the testing stages and the development of a good model for detecting human class objects, in this case, the instructor, the implementation is carried out in the classroom.

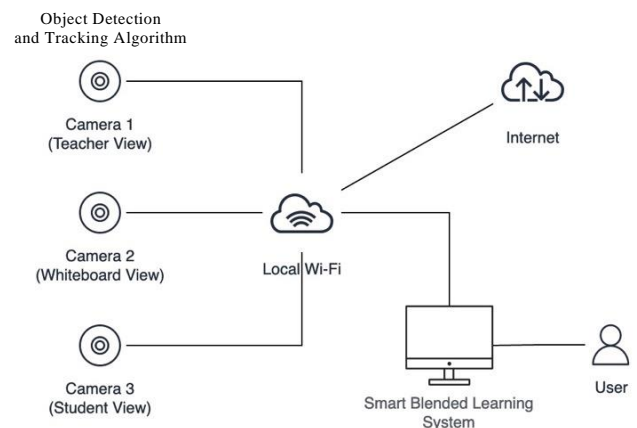

Fig. 5. The Architecture of the Smart Blended Learning System.

The MobileNet SSD object detection algorithm and centroid tracking are only applied to camera 1, pointing to the teacher, as shown in Fig. 5. The algorithm will monitor and zoom in on the teacher, ensuring that the video results in the video conference constantly center on the teacher.

IV. RESULT AND DISCUSSION

The F1 score test is used to evaluate the performance of the object detection algorithm by taking precision and recall into account. In 5,079 steps, the human object class is trained according to the results in Fig. 6. The resulting mAP value is obtained by employing transfer learning techniques, which allow the trained model to converge faster because the initialization of weights in the convolution process does not begin at random but rather uses the weights value of the model that has been trained on a large dataset with a variety of objects. This transfer learning technique enables the model to understand the pattern of each object class being taught more quickly.

Fig. 6. Mean Average Precision.

The transfer learning technique allows the trained model to converge faster since the initialization of weights in the convolution process does not begin at random but instead employs the weights values of the previously trained model on big datasets with various objects. This transfer learning strategy enables the model to recognize the pattern of the object class being learned more quickly. Fig. 7 depicts the statistics of the loss value produced in each iteration.

Because this study focuses on predicting the positive class rather than the negative class, average precision and recall data are employed; suppose we have a total of 10,000 pieces of data. However, only 40 data points have positive labels, while 9,960 data are classified as negative. By predicting all negative classifications, the algorithm can achieve an accuracy of more than 99 percent with this data composition. The resulting model is less efficient if it can only be accurate in the negative class. Metric precision and recollection are required to address this difficulty. The mAP value varies from 0 to 1, with 0 being the lowest and 1 being the highest. The trained model's final mAP value on box detection performance for the human class is 0.1926.

The loss value is calculated from step to step till the training procedure is terminated. Losses are calculated in three ways: classification loss, localization loss, and regularization loss. Classification loss displays the error value for the object class's classification results. Localization loss is a number that expresses the error in determining the position of an object's bounding box during the inference process. Meanwhile, regularization loss is a process that adjusts or reduces the coefficient to zero, which is vital for assisting the trained network is converging more quickly. Based on Fig. 7, the last classification loss value is 6.02, the last localization loss value is 2.15, the last regularization loss value is 0.346, and if they are added together, the total loss is 8.516. The smaller the loss value, the better the performance of the resulting model.

Furthermore, the model's capacity to detect distance and camera height is tested to see how well the model performs, which will subsequently be utilized to detect things for teachers with varied detection distances and camera installation heights. The distances tested in this test are 2 meters, 4 meters, 6 meters, 8 meters, and 10 meters. While the camera tested has a height of 1.5 meters and 3 meters. Fig. 8 depicts an example of a test with varying distances.

The model testing results with varied distances and camera heights are shown in Table II. The dataset utilized was gathered independently by photographing human things at various distances and heights. The test results utilizing a camera location at the height of 1.5 meters revealed that the model could recognize human objects at detection distances of 2, 4, and 6 meters, as indicated by an F1 score of 1. It was discovered that the model's capacity to identify human objects is good at distances of 2, 4, and 6 meters while at a camera height of 3 meters. Object identification performance decreased significantly at a distance of 10 meters with an F1 score of 0.28.

Fig. 7. Statistics and Loss Function Values.

Fig. 8. Detection Results at Different Distances.

TABLE II. F1-MEASURE FOR DIFFERENT DISTANCES AND HEIGHTS OF CAMERA

No	Object Class	Height	Distance				
			2 m	4 m	6 m	8 m	10 m
1	Person	1.5 m	1	1	1	0.75	0.75
		3 m	0.92	1	0.8	0.76	0.28

This study adds new parameters to the detector network layer, specifically a new feature map with a depth of 64 at the network layer's end. The feature map is made smaller than the previous layer, which has a depth of 128. The addition of this layer attempts to provide the trained model the ability to distinguish smaller or farther away objects. The test results following the addition revealed that the detection results were steadier from a distance of 2 meters to 6 meters. However, at a distance of 8 and 10 meters, the accuracy value fell dramatically. Measurement results with varying distances are carried out in a room with sufficient light intensity, and limited lighting sources can affect the results of object detection in the system.

This study success performs object detection and tracking technology to shoot a wide area in the classroom so that wherever the teacher moves, the video will still focus on the teacher in the center of the video. It will provide space for teachers to teach and move freely in the classroom.

V. CONCLUSION AND FUTURE WORK

We created a learning system solution in the form of a smart blended learning system based on a video camera in this framework by adding object detection and tracking. This solution has made online and offline learning more participatory for teachers and students.

So far, we've successfully implemented and piloted a smart blended learning system in a real-world classroom setting. A static camera is utilized in this video. Our next main project will involve the usage of a dynamic camera with a pan and tilt mechanism.

The design and implementation of our smart blended learning system framework are still ongoing, emphasizing the difficulties that continue to emerge and must be addressed to achieve a smart blended learning system framework in a global formulation.

ACKNOWLEDGMENT

The authors are grateful to the Indonesian Ministry of Education, Culture, Research, and Technology for funding this research through the Higher Education Leading Applied Research (Kementerian Pendidikan, Kebudayaan, Riset dan Teknologi or PTUPT) scheme in 2021. We are obliged to Universitas Negeri Makassar (UNM) to provide the facilities and equipment needed for this research to be carried out.

El Jadida, Morocco

Abstract—Internet of Things (IoT) technology makes all areas of human life more comfortable. The development of farms through the use of IoT positively influences agricultural production not only by strengthening it, but also by making it more profitable and reducing the cost of production. The goal of this paper is to offer a new IoT-based smart agriculture system that helps farmers get real-time data such as (temperature, humidity, soil moisture) for effective environmental monitoring that will allow them to increase overall yield and product quality. The farm monitoring system proposed in this paper is based on the ESP32 microcontroller with a set of sensors. This new model produces a real-time data feed that can be viewed online via a mobile app. The proposed new system uses solar energy with battery as an energy source.

Keywords—IoT; smart agriculture; new model; solar panel; esp32; mobile app

I. INTRODUCTION

Agriculture has always played a very important role for the human being and for the economies of countries, indeed countries that have experienced significant economic growth have experienced a significant increase in the agricultural sector, agriculture is not only an important factor of economic growth but also a heritage, a way of life, a cultural identity of a country. The use of the Internet of Things in agriculture makes it possible to put technology at the service of the development of agriculture and also to help the farmer to:

- Make very important decisions at the right times.
- Save energy and time.
- Deal with the lack of information.
- Increase agricultural production.
- Allow the farmer to develop and develop his agricultural production.
- Increase the participation of agriculture in job creation.
- Ensure our country's needs for agricultural products.

The organization of the article is as follows, in Section II (Literature Survey): we collected the work carried out in the field of smart agriculture, Section III (discussions and results): we treated and analyzed the work done and proposed improvements in this area, Section IV (the new model): we proposed our new intelligent farm system, and Section V (Conclusion and outlook).

II. LITERATURE SURVEY

To study the use of IOT in the agricultural field, it is essential to make a literary study on the current state, projects and studies that have been carried out in this field, this step is important to be able to have visibility on the current state and on the difficulties encountered, it will allow us to make proposals for improvement in this area.

A. Data Collection

To carry out our literary study we focused our research work on three databases ACM Library, Science Direct and IEEE. The Pattern used is IOT and agriculture during the last four years (2018-2022) this has allowed us to have 29 publications on the different methods and procedures of use of the IOT in the agricultural field as well as the advantages, disadvantages, and prospects for improvement in this field, Table I below summarizes the research approach.

TABLE I. ARTICLES

Database	Search pattern	Years of publication	Number of articles
ACM Library	IOT and agriculture	(2018-2022)	8
Science Direct	IOT and agriculture	(2018-2022)	10
IEEE	IOT and agriculture	(2018-2022)	12

TABLE II. DATA COLLECTION (SMART AGRICULTURE)

Year / Author	Sous-domain	Challenges	Data / Sensors	Technologies
Hsiao-Tzu (2018) [1]	✓ Agriculture monitoring	✓ Monitor the condition of agricultural land	✓ Temperature ✓ Humidity ✓ CO2	✓ Wi-Fi ✓ Node MCU ✓ Rasepberr y ✓ Web technology

B. Data Processing

The processing and analysis of the work carried out in this area will allow us to compare the following attributes: data collected, technologies used, challenges of the current approach. Table II shows this comparison. During our analysis, we excluded the number of sensors, the amount of data collected, the underlying technologies, the topology of the sensors and other intermediate gateways were not included as this does not add value to our research work.

III. DISCUSSIONS AND RESULTS

A. Data Analysis

The analysis of the data gave us the opportunity to have quantitative and qualitative data on the use of IOT in the agricultural field, our analysis focuses on the agricultural field and the types of data collected, the technologies used and the areas of application. The objective of this analysis is to increase productivity and efficiency while saving natural and human resources in the agricultural sector.

B. Agricultural Domains

We have grouped the articles and classified them by agricultural field, as shown in Table III below. This ranking gave us four agricultural sub-domains, following the results obtained we deduced that smart irrigation is the most treated agricultural field with a percentage of 40%.

TABLE III. AGRICULTURAL SUB-DOMAINS

Agricole domain	Percentage (%)
Smart irrigation	(40%)
Agriculture monitoring	(33%)
Smart farming	(17%)
Greenhouse agriculture	(10%)

C. Data Collected

Data collection is part of the objectives of the IOT, so it is necessary to collect a large amount of data to give accurate results, to follow up on our analysis it was deduced that many articles are focused on temperature (31%) and soil moisture (28%), and humidity (25%). Other data were also collected but with a small percentage. Table IV shows the results.

TABLE IV. DATA (SENSORS)

Data collected	Percentage (%)
Temperature	(31%)
Soil Moisture	(28%)
Humidity	(25%)
Light	(5%)
Ph	(4%)
Water level	(4%)
CO2	(3%)

D. Technologies used

The grouping of technologies used in the articles covered tells us that cloud technology is identified as the most used technology (23%), followed by Arduino and Mobile technologies (16%). Followed by WIFI (15%), followed by Nodmcu (12%) and followed by Raspeberry (11%) other technologies were also used but with a small percentage. Table V shows the results.

TABLE V. TECHNOLOGY

Technology	Percentage (%)
Cloud technology (23%)	(23%)
Wifi (15%)	(15%)
Arduino (16%)	(16%)
Mobile technology (16%)	(16%)
Nodmcu (12%)	(12%)
Raspeberry (11%)	(11%)
Web technology (2%)	(2%)

E. Results

In this paper, we were able to study the use of IOT in the agricultural field, this allowed us to identify important attributes to analyze it, for this we gathered and analyzed recent scientific data, this survey was a way to have the list of the most studied sub-areas: Smart irrigation, Agriculture Monitoring, Smart farming, Greenhouse Agriculture.

Smart irrigation is the most studied agricultural sub-field in recent years, as most countries focus mainly on the use of water resources due to its lack. Smart irrigation has become an essential means that positively influence the agricultural field and its production, current efforts focus on the management of water resources this has given great value to irrigation management to increase the quality and quantity of agricultural products.

The second sub-area is forecast agriculture because the demand for products is constantly increasing so it is essential to opt for a forward-looking management of agricultural production. This makes it possible to review any risk that can block the objectives of farmers and makes it possible to ensure a quality and increase in agricultural production and also saves resources. Based on our analysis, it was found that ambient temperature followed by soil moisture and moisture are among the most commonly measured data. According to the results of our study, it was found that the use of the Internet of Things in agriculture can be used effectively to increase agricultural production to meet the growing needs of the population.

The majority of research focuses on water management by monitoring environmental parameters such as temperature, humidity and soil moisture. Many results have emphasized the importance of the proper management of water resources, saving human and material resources.

Innovation in the IT field makes it possible to cover all agricultural areas to allow an important development. IoT has solved many problems related to agriculture and farming, but several limitations are to be taken into consideration such as the lack of interoperability and compatibility of devices, the problems of network flexibility when several devices connect, and the lifetime of the sensor are some of the limitations to be solved in future research.

Food production is a great challenge for all economies around the world due to the rapid and constant evolution of the world's population, especially with climate change and labour shortages. Currently, current research focuses on robotics to solve these problems. Many researchers and companies have focused on robotics and artificial intelligence (AI) to reduce the amount of herbicide used by farmers.

Following the analysis of the data collected, it was found that the IOT is in great demand to develop the agricultural field, several researches have been carried out in relation to this subject, the articles that we studied in this report have not taken into consideration the sources of energy to power the IOT equipment and the security of agricultural fields against intrusions, thus the majority of articles use Arduino technology for the interconnection of IOT equipment, which is why we will propose a new model that will take into account the energy

source, uses an interconnection technology with low energy consumption and secures agricultural fields against intrusions.

IV. NEW MODEL

A. Solution

After the in-depth study of the work done in this area, we found that agriculture is one of the main areas that use IoT. Several IoT components have already been put in place to serve the agricultural field to monitor soil conditions such as temperature, moisture, soil moisture and soil ph.

We also found that most authors propose solutions provided by wires or batteries such as power sources, the things that make powering objects a real challenge for several reasons, the most important of which are:

- The area of agricultural land is large, which increases the cost of installing electrical cables. The installed cables remain subject to damage that can be caused by agricultural vehicles, insects, and water, as the cables are underground.
- The difficulties of maintenance and repair in case of failure because the cables are underground it is necessary at each failure to remove them to repair them.
- Battery life remains limited and varies from a few hours to several years.
- The power of objects by alkaline batteries has major disadvantages. These batteries have a limited amount of energy.
- The cost of purchasing and replacing the batteries of the objects.

We offer a solution that offers an improvement of existing solutions. Our model is highly customizable and provides a data analysis solution that enables large-scale data processing on real-time observation streams. Our new model uses solar energy with battery as a power source, the ESP32 microcontroller as a low-energy interconnection technology [30] and a motion detector to protect our agricultural field from intrusions.

B. Components

1) *Ph: Sensor:* The PH sensor is a sensor that allows determining the acidity of the soil between 0 and 14 at a temperature between 0 and 60 ° C, this acidity varies depending on the availability of nutrients in water / soil. The detection of PH is therefore essential to understand how to fertilize it properly in order to prepare a good environment for agricultural production. Fig. 1 shows the ph sensor.

2) *Temperature and humidity sensor:* The DHT11 sensor is a low-cost basic digital temperature and humidity sensor. Capable of measuring temperatures from 0 to 50°C with an accuracy of 2°C and relative humidity levels from 20 to 80% with an accuracy of 5%. A measurement can be made every second. Fig. 2 shows the DHT11 sensor.

Fig. 1. Ph Sensor.

Fig. 2. Temperature and Humidity Sensor.

3) *PIR Sensor*: The passive infrared sensor is used for intrusion detection in agricultural fields and helps farmers detect movements (of animals and humans) in their agricultural fields. Fig. 3 shows the PIR sensor.

Fig. 3. PIR Sensor.

4) *Soil Moisture Sensor*: This sensor, as shown in Fig. 4, measures soil moisture due to changes in the electrical conductivity of the earth (soil resistance increases with drought). A digital output with an adjustable threshold is used to trigger an alarm or sprinkler pump. A second analog output accurately tracks fluctuations in soil moisture. When the sensor fork is planted vertically in the ground (agricultural fields, garden, etc.). The electrical resistance between the two electrodes is measured.

Fig. 4. Soil Moisture Sensor.

5) *ESP32 Microcontroller*: The ESP32, illustrated in Fig. 5 designed and produced by the company Espressif, it integrates functions dedicated to the Internet of Things and more particularly wireless communications and Bluetooth and lora for a reduced cost. It is the best choice for smart cities, smart farms, and smart homes.

Fig. 5. Esp32.

6) *Solar panel*: Solar panels, shown in Fig. 6, are the devices used to absorb the sun's rays and convert them into electricity. In our case we will use solar panels to power our IoT devices.

Fig. 6. Solar Panel.

7) *Lithium Batteries*: In our case we will use the lithium battery illustrated in Fig. 7, to have the possibility of setting up an autonomous network equipped with a battery capable of storing energy during the day and provides electricity during the night.

Fig. 7. Batteries.

8) *Top-up card for power bank*: In our case we will use the charge card, illustrated in Fig. 8, to build a power bank from lithium battery cells to charge all IOT devices compatible with 5V.

Fig. 8. Power Bank.

C. System Description

To achieve a high-quality yield, we will build a new smart farm monitoring system powered by solar energy. The proposed solution consists of two parts, a hardware part and a logicielle. la hardware part consists of a transmitter node that contains the pH, soil moisture, temperature, humidity, and motion sensor connected to ESP32 and a solar panel and battery to supply our system with electrical energy. The software part consists of a mobile application that allows farmers to monitor their agricultural environment as long as it

is connected to the internet. The method of data acquisition is illustrated in Fig. 9. The pH, soil moisture, temperature, humidity, and motion sensors send digital data to the ESP32. This data will be transmitted to the cloud server via WIFI communication. When there is incoming data on the cloud server, farmers can monitor their farming environment via a mobile app.

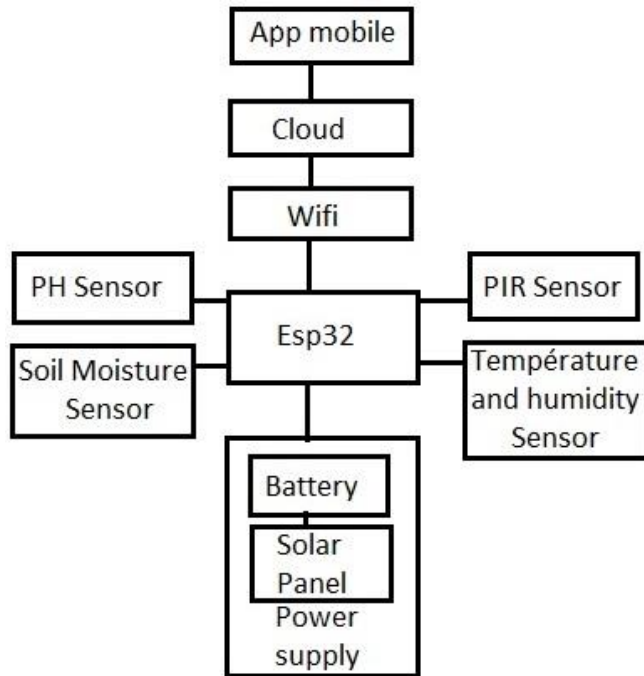

Fig. 9. New System.

D. Tools and Libraries used

In this paper we used several software and libraries to implement our new farm monitoring system:

1) *Arduino*: The Arduino integrated development environment is a cross-platform application for Windows, Macos, and Linux that is written in C and C++ functions. It is used to write and download programs to Arduino-compatible boards. The EDI source code is released under the GNU General Public License, version 2. The IDE environment contains mainly two basic parts: the editor and the compiler where the old one is used to write the required code and later is used to compile and download the code in the given Arduino module.

2) *Libraries*: The Arduino IDE can be extended using libraries, just like most programming platforms. Libraries offer additional features, such as working with hardware or manipulating data. The standard libraries used are described below.

a) *DHT.h*: To read the data from the DHT sensor, we will use Adafruit's DHT.h library. To use this library, we must also install the Adafruit Unified Sensor library.

b) *WiFi.h*: This library allows our esp32 card to connect to the Wi-Fi network to start sending and receiving data.

3) *Algorithms and flowchart*: This section presents the algorithms and flowchart of the overall process of our new Smart Farm System:

a) *Algorithms*: Generic process algorithm for temperature, humidity, soil moisture and pH sensors.

STEP 1: start the process;

STEP 2: connected to wifi;

STEP 3: read temperature, humidity, soil and ph;

STEP 4: get temperature, humidity, soil and ph values from analog pins;

STEP 5: send data to cloud;

STEP 6: delay to 10 seconds;

STEP 7: repeat step 4, 5 & 6 until the process end;

STEP 8: end;

b) *Flowchart*: Generic process flowchart for pir sensor motion sensor (Fig. 10).

Fig. 10. Flowchart (Pir Sensor).

E. Mobile Application

In creating our app, we used the blynk platform that supports Android. It works with several types of microcontrollers such as Arduino, Raspberry and ESP32. It consists of three main components:

- The blynk app that allows you to control a device and view data.
- The blynk server, which is a cloud service responsible for all communications between objects and the smartphone.
- Blynk libraries, which include various widgets such as control buttons, display formats, and notifications.

When creating our application, as shown in Fig. 11, we tried to make it very simple, with a single interface that shows the main information collected by our ESP32. This application immediately requests real-time information from the cloud to display it.

Fig. 11. Mobile App.

F. System Test

We tested the consumption of the solar power of our new model for seven days. Using the display screen of our new model shown in Fig. 12, we noticed that with the equipment used for four days, the consumption of our battery does not exceed 26%.

Fig. 12. Test.

V. CONCLUSION AND PERSPECTIVES

In this article, a new smart farm monitoring model was realized. To propose this model, we started by studying the work already done in the field of smart agriculture, the analysis of the data allowed us to raise three major questions: The energy sources to power the equipment, the technologies used to interconnect these objects and the security of agricultural fields against intrusions. The tests we carried out for our new agricultural field monitoring system were positive, using new devices and sensors for example (PIR sensor).

The prospects of our project are to test our new model in a large agricultural field to study the autonomy of the batteries connected to the solar panels and propose improvements to our new system.

Abstract—Crypto ransomware is malware that locks its victim's file for ransom using an encryption algorithm. Its popularity has risen at an alarming rate among the cyber community due to several successful worldwide attacks. The encryption employed had caused irreversible damage to the victim's digital files, even when the victim chose to pay the ransom. As a result, cybercriminals have found ransomware a lucrative and profitable cyber-extortion approach. The increasing computing power, memory, cryptography, and digital currency advancement have caused ransomware attacks. It spreads through phishing emails, encrypting sensitive data, and causing harm to the designated client. Most research in ransomware detection focuses on detecting during the encryption and post-attack phase. However, the damage done by crypto-ransomware is almost impossible to reverse, and there is a need for an early detection mechanism. For early detection of crypto-ransomware, behavior-based detection techniques are the most effective. This work describes RENTAKA, a framework based on machine learning for the early detection of crypto-ransomware. The features extracted are based on the phases of the ransomware lifecycle. This experiment included five widely used machine learning classifiers: Naïve Bayes, kNN, Support Vector Machines, Random Forest, and J48. This study proposed a pre-encryption detection framework for crypto-ransomware using a machine learning approach. Based on our experiments, support vector machines (SVM) performed with the best accuracy and TPR, 97.05% and 0.995, respectively.

Keywords—Ransomware; crypto-ransomware; ransomware early detection; pre-encryption; pre-attack; ransomware lifecycle

I. INTRODUCTION

Ransomware is a relatively new type of malware that targets users in an attempt to extort money. Ransomware is malware that encrypts or locks files on an infected computer and demands payment to unlock and decrypt the files. Ransomware was a relatively new intrusion attack that used encryption to extort money from its victim. The victim must follow the ransom note's instructions to pay the ransom in Bitcoin to decrypt and recover the original files. The attacker frequently uses Bitcoin due to its anonymity, as its identity is difficult to trace. On the other hand, paying the ransom does not guarantee that the victim will receive the decryption key necessary to recover the files [1], [2].

Ransomware employs a variety of attack vectors, including social engineering, spam email, botnets, detection evasion, and self-propagation via vulnerabilities. After successfully infecting the victim's machines, it will lock files and directories and encrypt files with the following extensions: .docx, .xlsx, .odt, .zip, .pdf and .jpg. As a result, the victim cannot access their files or computer until the attacker receives the ransom payment within a specified time [3], [4].

Ransomware attacks have grown in sophistication, posing a significant threat to education, health, business, and government organizations. Cybercriminals created hundreds of ransomware variants as a result of lucrative incentives. As a result, ransomware has recently dominated the cyberthreat landscape. Individuals, businesses, government agencies, universities, and hospitals, are targeted by ransomware attacks. For instance, in 2017, the Wannacry ransomware infected over 300,000 victims in 150 countries via the Shadow Brokers APT EternalBlue exploit. Petya ransomware was the first targeted ransomware attack, with most infections occurring in Ukraine. However, Petya has spread to over 60 countries. As a result, ransomware attacks continue to dominate the cyber security world, with an expected dramatic increase in targeted attacks. Due to the exponential growth of ransomware attacks, it is necessary to focus on this type of threat. Exploit kits, cryptocurrency, and ransomware-as-a-service (RaaS) are the primary factors accelerating the global crypto-ransomware outbreak. With RaaS, even inexperienced attackers can launch a crypto-ransomware attack against any organization [4]–[7].

The rest of the paper is organized as follows. Sections II, III and IV discussed this research's motivations, scope, and objectives. Finally, Sections V and VI discussed the research contributions and design. Section VII provided the literature review for this study. Section VIII described the dataset used in this work. Section IX described the framework design and development. Next, Section X described the testing and validation done in this study. Finally, Section I concluded the research and explained the possible future work for this research.

II. MOTIVATION

The crypto-ransomware attack is irreversible, and it is almost impossible to recover the files. Therefore, there is a need to identify it before it attacks the system and files. Crypto-

ransomware poses a significant threat, with new varieties and families being regularly discovered on the internet and the dark web. Furthermore, due to the encryption mechanisms utilized by these outbreaks, recovering from ransomware attacks is challenging [8]–[10]. In addition to the costs of downtime and the money that individuals and businesses may be compelled to pay as ransom, victims may suffer other consequences such as data loss, reputation loss, and even death [8], [11], [12].

III. RESEARCH SCOPE

This research is implemented only for the crypto-ransomware attack. However, this malware category is still persistent and creates massive damage in many crucial sectors [13], [14]. Furthermore, this research focused on crypto-ransomware targeting the Windows operating system since this platform is the most exciting target for the crypto-ransomware operators [15]–[17]. Besides that, most crypto-ransomware targets regular and average computer users, and most of them are running the Windows operating system [18]. The Windows operating system was chosen because it is the most frequently used platform in computer systems and is targeted by most ransomware attacks. The research will focus on crypto-ransomware that uses an encryption algorithm to encrypt its victim's data and files. Crypto-ransomware was chosen because the damage caused by this type of ransomware is often severe and irreversible [19], [20].

IV. RESEARCH OBJECTIVES

The first objective is to investigate ransomware behavior via Windows API calls. API is the set of instructions that every program uses to communicate with the operating system. Therefore, it is critical to analyze the ransomware's API to understand the ransomware's behavior better. The second goal is to develop an early detection framework for crypto-ransomware attacks. This is to mitigate the ransomware attack's damage. The third objective of this research is to create a dataset to identify crypto-ransomware in its early stages. This dataset contains critical data from the initial stages of a crypto-ransomware attack. The dataset will be used to train and test the machine learning classifier. Furthermore, this dataset can be used for future research in ransomware early detection.

V. RESEARCH CONTRIBUTIONS

In meeting the above objectives, this research has provided the following contributions. The first contribution is discovering important behaviors of crypto-ransomware attacks with the analysis of API produced. The second contribution is developing the RENTAKA framework to detect crypto-ransomware before triggering the mass unauthorized file encryption. The third contribution is an algorithm for determining the pre-encryption boundary and assists in extracting the required features. The fourth contribution is the crypto-ransomware early-stage behavior dataset that can aid future research using a machine learning approach. This research also filled the gap from previous research in focusing on the pre-encryption stage of the crypto-ransomware attack, which is a critical point; recovery is impossible after encryption happens. In addition, this research also provided a unique solution by combining the signature matching approach

and machine learning approach, which provided two levers of detection that can complement each other. Listed below are the contributions of this research:

- Identification of crypto-ransomware behavior during the early stages.
- Proposed a framework for crypto-ransomware early using a machine learning approach.
- Proposed an algorithm for pre-encryption features.
- Crypto-ransomware behavior dataset.

VI. RESEARCH DESIGN

The framework within which a researcher chooses the research methods and techniques is the research design. The design enables researchers to focus on appropriate research methods for the subject matter and establish a foundation for success in their studies. Therefore, this study is divided into four phases, as depicted in Fig. 1:

Fig. 1. Research Design.

VII. PHASE 1: LITERATURE REVIEW

A. Ransomware

Locker and crypto-ransomware are the two types of ransomware. The Locker ransomware merely affects the user interface, leaving the system and files intact. The Locker ransomware encrypts files and disables operating system features, including desktop apps and input/output utilities. Meanwhile, cryptographic ransomware, often known as crypto-ransomware, tries to extract money from victims by encrypting their files [21].

Crypto-ransomware encrypts user-related files using the cryptography features in the host operating system. The consequences of such ransomware are reversible only through the cryptographic keys possessed by a distant adversary, which sets it apart from other types of malware. Files that have been encrypted are renamed and given new extensions. Some of the most common ransomware encrypted file extensions are ".ccc", ".cerber", ".cerber2", ".cerber3", ".crypt", ".cryptolocker", ".cryptowall", ".ecc", ".ezz", ".locky", ".micro", ".zepto", and ".encrypted". It substitutes a fresh wallpaper with a ransom note for the original desktop background. Cryptolocker,

CryptoDefense, KeRanger, ZCryptor, Crysis, zCrypt, Locky, and WannaCry are just a few examples of crypto-ransomware [5], [8], [22].

The availability of development toolkits and the ease with which ransomware assaults can be traced from victims to attackers are the key factors driving the surge in ransomware attacks today. Before a ransomware attack can occur, it must first get access to the victim's computer [23]–[25].

Ransomware is commonly distributed using spear-phishing and exploit kits. Spear-phishing is a sophisticated email assault designed to deceive people or corporations into accessing a malicious website infected with malware. These emails frequently include attention-getting content from reputable sites to attract recipients to click on the offered link. Furthermore, it is common for an attacker to employ a series of commands or code to exploit the capabilities of a susceptible program. Finally, exploit kits, which can be used manually or automatically, assist hackers in finding flaws in software that would otherwise be impenetrable [26]–[28].

Ransomware has developed throughout time. Its many variations are being produced daily. As a result, there are a lot of ransomware families and their variants. Various obfuscation tactics are used for creating new versions, including garbage code insertion, variable renaming polymorphism, metamorphism, and packing [29].

Crypto-ransomware is malware that encrypts a victim's data and holds it hostage in exchange for money. Cybercriminals collect the ransom in the form of cryptocurrency, typically Bitcoins, to hide their identity. There are two types of ransomware: locker and crypto-ransomware. Crypto-ransomware is more common and offers a more significant threat than locker ransomware [30], [31].

WannaCry, Cryptolocker, Cryptowall, and Locky are examples of ransomware that have progressed from low-impact assaults like PC-Cyborg (also known as AIDS) to high-impact attacks like WannaCry, Cryptolocker, Cryptowall, and Locky. In addition, the number of ransomware variations has been rising since 2012. For example, ransomware variations increased from one to 193 between 2012 and 2016. As a result, ransomware became a significant threat to cybersecurity during this period. In addition, ransomware-as-a-Service (RaaS) families like Cryptolocker, CryptoWall, Locky, and TeslaCrypt also appeared in 2017, causing significant financial losses worldwide [32].

Crypto-ransomware assaults have become increasingly prevalent, allowing attackers to make millions of dollars per month. Around 180 million non-technical individuals were victimized by ransomware in 2017. In 2018, there were approximately 850 million ransomware assaults. In 2019 and 2020, ransomware is expected to have caused around \$11.5 billion and \$20 billion in global damage, respectively.

B. *Crypto-ransomware Lifecycle*

- **Deployment:** The crypto-ransomware must be able to install itself on the targeted system successfully. Phishing emails are the most typical way for ransomware to propagate. Cybercriminals use social

engineering techniques to persuade people to believe the email message and open the malicious file attached to it. Social engineering approaches include executables with appealing icons, Microsoft Office macros, and phishing files. Furthermore, ransomware spreads using malicious websites or exploit kits like Angler and Magnitude.

- **Installation:** The infection begins after a malicious payload successfully lands on the victim's platform. The malicious components are built using scripts, procedures, batch files, and other resources. Ransomware will make configuration changes to a Windows-based system, such as establishing unique registry keys in the registry to ensure harmful malware runs every time the computer reboots. Payload persistence, restricted system restoration, stealth mode, environment mapping, and privilege escalation are all features of more complex crypto-ransomware.
- **Command and Control:** After the ransomware has been installed, it begins interacting with its command and control server. This server provides ransomware with further instructions and a public encryption key. Next, the crypto-ransomware will try to connect to its C&C server, which the ransomware operator controls. Once the link has been established, it will provide information about the victim's computing platform and the encryption key.
- **Destruction:** The encryption stage begins after establishing effective contact with the targeted computer. The files are encrypted once the ransomware gets the encryption code and the location of the victim files. The encrypted files are renamed with a different extension when the original files are erased. Some ransomware variations add their name to any file as an extension. A list of the files that will be encrypted is included in the ransomware payload. Essential files like "WINDOWS," "Application Data," and "Temp" are excluded to keep the Windows operating system functioning. By erasing the volume shadow copies, ransomware prohibits the user from restoring them. Instead, it uses administrator rights to erase shadow copies of the Windows drive using the cmd.exe command.
- **Extortion:** The ultimate stage of a crypto-ransomware assault is extortion. Once the data have been fully encrypted, the next step is to inform them and persuade them to pay the suggested ransom. At this point, a windows pop-up or a desktop wallpaper with the ransom note appears on the screen. The directions on proceeding with the ransom payment are included in the ransom note. All ransomware has a different look and various texts in the ransom note. Finally, the crypto-ransomware final stage shows an extortion message demanding a ransom in exchange for the decryption key. Fig. 2 shows the steps in the crypto-ransomware lifecycle.

Fig. 2. Crypto-ransomware Lifecycle.

C. Early Detection

Crypto-ransomware is a type of malware that is relatively new. To our knowledge, only a few studies have been conducted on early detection. However, the emerging threat of crypto-ransomware piqued the interest of numerous researchers worldwide, who sought to develop a method for detecting it. Additionally, due to crypto-encryption ransomware's capability, this distinct characteristic can be used as a critical indicator for its early detection during the pre-encryption stage.

Crypto-ransomware pre-encryption detection detects it even before the encryption process begins. Due to the critical nature of detecting crypto-ransomware early in the attack lifecycle, several studies on pre-encryption detection of crypto-ransomware have been proposed.

It is more difficult to detect in the pre-encryption phase due to a lack of evidence that crypto-ransomware is present. Simultaneously, no unauthorised encryption activity occurs. The benefits of successfully detecting a crypto-ransomware infection at this level are that no files are lost and the ransomware is prevented from infecting additional hosts or networks.

In the case of crypto-ransomware, detecting it during the pre-encryption stage is very valuable. Due to the irreversible and irrecoverable nature of a crypto-ransomware attack, it is critical to detect it early, even before it begins encrypting the files. Several studies have proposed methods for detecting crypto-ransomware infections before encryption. Pre-encryption detection occurred before the start of file encryption activity. Detection is critical at this stage to prevent any files from being encrypted. The benefits of detecting crypto-ransomware activity at this level are incredibly beneficial for an organization's file, system, and network security. Apart from preventing any files from being encrypted, detection at this stage may alert system administrators to the infection as soon as possible, allowing security precautions to be taken in time.

Additionally, this proactive measure can help prevent the spread of crypto-ransomware to other endpoints or networks. Finally, detection enables system owners and administrators to

respond to an attack as soon as possible before significant damage is caused.

The basic steps in most crypto-ransomware lifecycle, as shown in Fig. 2 are further grouped into three sub-phases of attack: Pre-encryption, encryption, and Post-encryption. These sub-phases are depicted in Fig. 3.

- Pre-encryption – because any crypto-ransomware objective is to encrypt files in bulk, it is frequently designed to avoid detection by making a series of pre-attack API requests. Fig. 4 shows a list of activities during this stage.
- Encryption – at this attack level, unauthorized mass file encryption is taking place.
- Post-encryption – this is where the extortion takes place, by strategically notice the victim of the fate of the encrypted files and luring the system owner to execute the ransom payment.

Crypto-ransomware is a dreaded type of malware that has gained notoriety because of its fatal and irreversible effects on its victims. Due to the irreversible damage caused by ransomware, it is critical to notice these assaults quickly. The following is a list of the reasons why early detection of crypto-ransomware is critical:

- To avoid file loss and the need to pay the ransom (Kok et al., 2019).
- To detect ransomware attacks as early as possible to prevent data loss and stop ransomware self-propagation (Roy & Chen, 2019).
- Early detection can help users protect confidentiality and availability while limiting the probability of an attack and minimizing losses (Moussaileb, 2018).
- The value of detecting cryptographic ransomware is at the pre-encryption stage. It is useless after the encryption activity is completed because data loss has already happened.
- The damage done by crypto-ransomware is irreversible (Al-Rimy & Maarof, 2018).

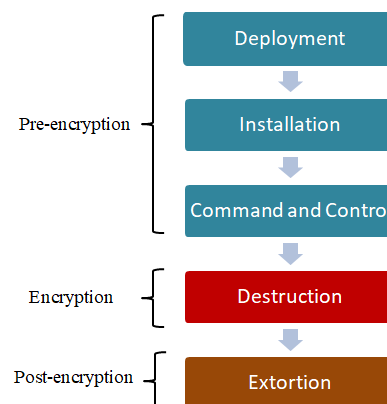

Fig. 3. Pre-encryption, Encryption and Post-encryption Stages.

Fig. 4. Activities of a Crypto-ransomware during the Early Stage.

D. Related Work

Early detection and prediction are advantageous for varieties of malware where recovery is difficult and costly. Crypto-ransomware, for example, encrypts user files and withholds the decryption key until the perpetrators are paid a ransom. Unfortunately, as the frequency of crypto-ransomware attacks has grown in recent years, so has the research community’s attention to this issue. As a result, few studies examining various threat detection strategies have been conducted. Table I provided a summary of the related works.

EldeRan is a machine learning framework for detecting ransomware early in its lifecycle. As far as this research is concerned, it is the first of its kind in ransomware early detection. The framework looked at dynamic analysis data from ransomware samples. It also keeps track of events throughout the ransomware’s installation phase to capture ransomware features. As a result, EldeRan can operate without requiring advanced access to a ransomware family. The first restriction is that it is difficult to analyze and identify crypto-ransomware samples that have been silent for a long time or are waiting for a user-initiated trigger action [33].

As a ransomware early detection framework, the Pre-encryption Detection Algorithm, or PED A, was proposed [34]. The framework has two phases: PED A-Phase-I and PED A-Phase-2. API calls were collected after examining the samples for 30 seconds in the Cuckoo sandbox. PED A-Phase-I will use the learning algorithm (LA) to collect and analyze the Windows API calls generated by a suspicious sample. The LA can then assess whether the suspicious program was ransomware or not using API pattern recognition. This method ensures the most thorough identification of known and unknown ransomware, but it may lead to many false positives. PED A implemented a signature database for the samples and placed it in the Phase-II signature repository if the prediction was for ransomware.

Meanwhile, in PED A-Phase-II, the signature repository uses the signature matching method to detect ransomware at a far earlier level, namely the pre-execution step. Yet this approach only detects known ransomware, though it is proven accurate and quick despite its rigidity. PED A’s two phases resulted in two layers of early ransomware detection, guaranteeing that the victim’s data was not lost. This technique, however, was unable to detect ransomware that employed its encryption code and inherited the disadvantages of a signature-based approach [24].

For the early detection of crypto-ransomware, Alqah tani introduced the CRED framework [35]. Their study focuses on the flaws in currently existing ransomware early detection tools. They also presented a model capable of accurately

characterizing the attack lifecycle’s pre-encryption phase. This strategy is superior because it can overcome data insufficiency gathered during the pre-encryption phase by giving enough time before stopping data collection and using two categories of data: process-centric and data-centric. However, they did not present experimental data to indicate that their approach is superior to others because their study is preliminary.

A group of researchers used file system data to detect ransomware, including whether the contents appear to have been encrypted and the number of modifications made to the file type. As a result, the researchers recognized all 492 ransomware strains tested and prevented, with less than 33% of user data destroyed in each case [36].

TABLE I. DIFFERENCES OF CURRENT PRE-ENCRYPTION DETECTION FRAMEWORK

Framework	Elderan	PEDA	CRED
Pre-encryption boundary identification	Dynamic analysis runtime limited to first 20 seconds.	Identify first occurrence of CryptoAPI.	Using temporally correlated IRP-API based pre-encryption delineation method
Features	30967 features. (API, registry key operations, file operations, dropped files, embedded strings)	232 API calls	API calls and IRP
Dataset	RISS	RISS	Process-centric Data-centric

E. Challenges in Pre-encryption Detection

Crypto-ransomware operations are often disguised as legal user actions, mainly when crypto-ransomware does not require special rights and depends on cryptographic functionality similar to benign applications. Because most crypto-ransomware either implements cryptography or uses existing libraries, this is the case. Apart from that, all they have to do is read and write files.

Detecting ransomware is a race between the bad guys and the creators. New countermeasures push ransomware creators to improve their ransomware, resulting in new countermeasures. For ransomware scenarios, it may, for example, act more like legitimate software or a human user.

There are few strong evidence indicators during the early stages of a crypto-ransomware attack. For example, there is no evidence that many files were encrypted during these early stages. Furthermore, no encryption action is taking place. Strange file extensions, unauthorized changes to the desktop wallpaper, the appearance of a ransom letter, increased CPU utilization, or system slowdown are not visible symptoms of ransomware infection. As a result, the evidence available during the early stages of the investigation is inadequate to evaluate whether the described behaviors are crypto-ransomware-like. It’s impossible to tell whether the listed current activity belongs to a benign program or a crypto-ransomware because there was no significant unintended encryption activity during the early phases [20], [34], [37].

There are few significant indicators during the early phases of a crypto-ransomware assault. The fundamental reason is that

there is no indication of illicit file encryption during the early stages [38], [39]. Furthermore, there is no encryption operation in progress. Strange file extensions, unauthorized desktop wallpaper changes, the appearance of a ransom letter, increased CPU use, and system slowdown are not indicative of a ransomware infestation. As a result, the information supplied at the investigation's outset is insufficient to determine whether the described actions are crypto-ransomware-like. Determine whether the related current activity is owned by benign software or crypto-ransomware due to the lack of significant illegal encryption activity in the early stages. The data on the victim's PC is encrypted using a robust encryption method in any crypto-ransomware attack.

VIII. PHASE 2: DATASET

The dataset was from the Resilient Information System Security (RISS) research group from Imperial College London in 2016. This dataset was selected because it has API data for ten ransomware families and a good selection of goodware. The dataset was created using a dynamic analysis approach for 582 samples of ransomware and 942 samples of benign program. The data are captured in five main categories with 30,067 features. API calls have 232 features. Two groups of researchers used this dataset for works on crypto-ransomware early detection frameworks [33], [34].

As far as this research is concerned, the dataset on crypto-ransomware behavior is still lacking. However, the RISS dataset is by far the best dataset available for ransomware behavior, and this is shown by the works done by Elderan and PEDDA [33], [34]. Tables II and III provided some information about the RISS dataset used in this study.

TABLE II. RANSOMWARE FAMILIES IN RISS DATASET

No.	Sample name	Count
1	Critroni	50
2	Cryptlocker	107
3	Cryptowall	46
4	Kollah	25
5	Kovter	64
6	Locker	97
7	Matsnu	59
8	Pgpocoder	4
9	Reveton	90
10	Teslacrypt	6
11	Trojan-ransom	34

TABLE III. CATEGORIES OF DATA IN RISS DATASET

Category	Count
API	232
Registration key	346
Dropped file	6622
Files and directory operation	7500
Embedded string	16267
Total	30967

These researchers successfully used the RISS dataset from different institutions and produced acceptable results. Another dataset is from The Zoo malware repository, which provides ransomware binaries that can be downloaded and analyzed into dynamic analysis sandboxes such as Cuckoo Sandbox.

IX. PHASE 3: FRAMEWORK DEVELOPMENT

Given the size and variety of threats we face today, having solutions to detect unknown crypto-ransomware attacks before unauthorized mass file encryption takes place seems necessary. In addition, it is essential to protect user data from any variants of crypto-ransomware attacks with zero data loss.

Monitoring API calls made by crypto-ransomware makes it possible to design an early detection framework to halt crypto-ransomware attacks, including those using sophisticated encryption capabilities.

We proposed a pre-encryption detection framework for crypto-ransomware using a machine learning approach, RENTAKA, to protect user data from being encrypted. The framework is depicted in Fig. 5. Based on detailed investigations of most cases, ransomware-specific events and processes are heavily related to Application Programming Interface (API) calls for the Windows platform. User-level malware like ransomware requires the invocation of system calls to interact with the operating system (OS) to execute its malicious actions. Application Programming Interface (API) calls are the functions that a program utilizes in its execution. In other words, API calls are a set of routines provided by the OS for building applications in which each API call performs a specific task. The API calls is extracted through dynamic analysis after executing the ransomware sample in a sandbox environment. We demonstrate that our proposed solution can detect crypto-ransomware in the pre-attack stage and achieve zero data loss against current ransomware families. Furthermore, as shown in Table IV, we also proposed an algorithm to extract the data related to the pre-encryption stages.

TABLE IV. PSEUDOCODE FOR PRE-ENCRYPTION BOUNDARY ALGORITHM

1. Sample executes in sandbox
2. Run dynamic analysis
3. Extract the behavioral log
4. Locate APIstat cluster
5. Find encryption API
 - a. If found encryption API, flag it as "ENC"
 - b. Extract all API before the ENC flag
 - c. Store in a file
 - d. Kill sample execution, repeat with next sample

Fig. 5. The Proposed RENTAKA Framework.

X. PHASE 4: TEST AND VALIDATE

The proposed model is tested and validated on a real-world corpus of ransomware samples. The results show that API call features accurately distinguish between ransomware binaries and benign ones. Furthermore, the relevant feature selection process can improve the model building time without compromising the accuracy of the malware detection system.

This study experimented with 80 features using five different classification algorithms: Random Forest, Naïve Bayes, SVM, kNN, and J48. Based on our experiments, support vector machines (SVMs) performed with the best accuracy and TPR, 97.05% and 0.995, respectively. The second-best result is the Random Forest classifier, with 96.39% accuracy. Finally, J48 performs with the lowest accuracy, which is 94.75%. The overall results from our experiments are listed in Table V.

TABLE V. RESULTS FROM MACHINE LEARNING CLASSIFIERS

Classifier	Accuracy	TPR	FPR
Random Forest	96.3934%	0.984	0.071
Naïve Bayes	80.9836%	0.781	0.142
SVM	97.0492%	0.995	0.071
kNN	96.0656%	0.979	0.071
J48	94.7541%	0.979	0.106

XI. CONCLUSION AND FUTURE WORK

This paper discussed the ransomware categories, attack lifecycle, analysis approaches, detection techniques, and related works in its detection. This paper also provided the challenges of crypto-ransomware early detection. We proposed a ransomware detection scheme using a machine learning classifier. Based on our experiments, support vector machine (SVM), one of the supervised machine learning algorithms, performed the best accuracy and TPR. Crypto-ransomware attacks are very dynamic, and it is moving toward becoming a kind of targeted attack. Therefore, early detection systems with machine learning-based classification algorithms are needed to mitigate crypto-ransomware attacks. For future work, we will test with more extensive samples and improve the pre-encryption boundary algorithm. The encryption boundary identification algorithm is a crucial part of this research. It defines the number of features to be used for building the machine learning model.

Non-contact Facial based Vital Sign Estimation using Convolutional Neural Network Approach

Nor Surayahani Suriani, Nur Syahida Shahdan, Nan Md. Sahar, Nik Shahidah Afifi Md. Taujuddin
Dept. of Electronics Engineering, Universiti Tun Hussein Onn Malaysia
Batu Pahat, Johor, Malaysia

Abstract—A rapid heart rate may indicate early diagnosis of heart disease, which could result in abrupt mortality if a heart attack occurs while exercising. A fatal incident is usually precipitated by a heart attack while strenuously exercising. This paper proposed invasive health monitoring through remote photoplethysmography (rPPG) analysis captured by RGB video camera to measure a wide range of biological data. A non-contact facial-based vital signs prediction can facilitate checking pulse rate and respiration rate regularly. Several studies have been conducted on evaluating rPPG signals under a variety of static conditions and little head movement, including different skin tones, angles of the camera, and distance from the camera. A study of heart rate (HR) and breathing rate (BR) data from facial videos for fitness applications were presented in this paper. Most studies still do not have a way to measure vital sign estimation especially for physical activity application from facial videos. The face detector was applied based on three regions of interest on facial landmarks for vital sign estimation. Then, the rPPG method with convolutional neural network (CNN) is presented to construct a spatio-temporal mapping of essential characteristics and estimate the vital sign from a sequence of facial images of people after doing various types of exercises. This will allow people to keep track of their health while exercising and creating a tailored training program based on their physiological preferences. The absolute error (AE) between the estimated HR and the reference HR from all experiments is 2.16 ± 2.2 beats/min. While the AE for the estimated BR from the references BR are 1.53 ± 2.3 beats/min.

Keywords—rPPG; remote heart rate estimation; respiration rate; fitness

I. INTRODUCTION

HR and BR are key health indicators for monitoring heart and lung function, especially during this critical COVID-19 pandemic period. Monitoring post-COVID-19 patients' physical activity responses helps in the recovery process. To monitor vital indicators including respiration rate, oxygen saturation, and heart rate, contactless measurement is critical. Infections, fever, asthma, and breathing issues are all signs of a higher HR. Pneumonia or lung illness might create an unstable BR. BR can be influenced by a variety of circumstances, including exercise, emotions, and injuries. Shortness of breath and cough was noted by nearly 10% and 25% of COVID-19 patients, respectively [1].

Our research goal is to assess the efficacy of our prototype of health monitoring status, which will include a built-in camera for non-contact vital sign estimation. The aim of this study presented in this article shows the potential of

estimating HR and BR from facial video streams. We also intended to validate the performance of our prototype so that it could be integrated with the CNN model as a comprehensive non-invasive system to aid in the creation of our healthcare system. The proposed work demonstrates the efficacy of a CNN-based model for post-exercise datasets. The dataset was created to expand the application of our prototype health monitoring system.

Remote photoplethysmography (rPPG) approaches use a webcam or a mobile camera to determine an individual's heartbeat from pixel variation in human skin surface induced by cardiac activity. The principle that blood absorbs more light than other surrounding tissue is used to investigate variations in blood volume transmission on the skin surface using an optics-based rPPG approach. In general, the rPPG procedure entails detecting and tracking the individuals' skin colour changes. Heart rate, heart rate variability, and respiration rate were evaluated using the tracking signals.

Several studies have reported that the potential of rPPG in heart rate estimation is quite promising. Reflected light and movement interferences, however, continue to cause significant challenges. Furthermore, rather than BR, rPPG signals are frequently applied to measure HR. This is because rPPG's frequency properties may not be reliable in estimating respiratory rate. Traditional rPPG approaches have some drawbacks because they rely on assumptions like simplified noise reduction and a skin optical reflection model. Furthermore, remote rPPG approaches will produce unstable results in real-world circumstances where patients are in motion. Deep learning breakthroughs have considerably enhanced the performance of rPPG approaches [2].

This paper describes how to use spatial-temporal facial features mapping to train the CNN model and estimate the rPPG matrix vector on the network's final layers. The single vector represents the rPPG signal, which will be processed further to estimate the HR and BR. Compared to previous work [11-13] and [16], our method addresses the efficacy of vital sign estimation from facial video for fitness or involving physical activity. Our proposed method also addresses the challenges to improve the system robustness. As a result, the following are the paper's contributions:

- 1) Limit the facial regions to only the forehead, cheeks, and nose to form spatial-temporal features for the CNN model to increase the reliable information for blood variation on face. Our approach improves the signal-to-noise ratio (SNR) for a better signal quality assessment of physiological signals.

2) Calculate HR and BR from the estimated rPPG signal, which is the CNN output. Our approach is in line with deep learning research community where many CNN frameworks have been successfully developed for detection and estimation. Further signal processing algorithms are proposed to estimate the HR and BR from the estimated rPPG signals.

3) For post-exercises with more variable heart rates, we use the rPPG signal to estimate HR and BR using CNN. From the best of our knowledge, very little study includes non-contact facial of different conditions performing several physical exercises especially for fitness development application.

The remainder of this paper is structured as follows. Section 2 provides a synopsis of related work areas. Section 3 describes how to use CNN architecture to effectively estimate rPPG and measure HR and BR after subjects perform several physical exercises. Section 4 goes over the experimental setup and metrics for evaluating performance. Section 5 summarises the findings and discusses potential future work.

II. RELATED WORK

Previously, pulse oximetry was used to obtain non-invasive vital sign estimates by evaluating the PPG signal at different wavelengths. While non-invasive rPPG signal monitoring with a video camera is a viable technique for vital signs monitoring without even any electrodes or sensors directly contacting patients. The most of of rPPG estimation research was conducted under different illumination conditions, head movements, colour skin variations, and camera distance. All of these constraints were established using traditional methods. Deep learning has recently received a lot of attention.

A. Conventional Methods

The rPPG's early work is entirely based on a signal processing approach. To generate colour signals, skin detection is applied to a selected RoI and the average is tracked over time. The green channel of rPPG signals produced the strongest signal, which roughly corresponds to an oxyhemoglobin absorption peak. After that, the Blind Source Separation (BSS) technique is used to separate the rPPG signals from the noise [3].

The HR could be extracted using the Fast Fourier Transform (FFT), which also indicates the respiratory rate based on the RoI of the entire face. The independent component analysis (ICA) method predicts HR based on the largest spectral peak between 0.75 and 4Hz. Poh et al. [4] used viola-jones face detection to determine the mean intensity of the red (R), green (G), and blue (B) colour channels. Then, ICA was used to demix the pulse signal from the raw RGB signals. To handle skin-tone mismatch and subject motions, combined RGB channels must be normalized. Cheng et al. [5] use independent vector analysis to separate the facial components from the background regions in order to address illumination artefacts. Wang et al. [6] proposed modified projection orthogonal to the skin tone to extract pulse. Haan et al. [7] proposed CHROM method where the RGB channels were projected into the chrominance subspace to eliminate

motion components. Chen Lin et al. [8] proposed motion index method to develop a real-time contactless pulse rate status monitoring of head motion modelling using trajectories of tracked feature points. The BR in [9] was calculated using heart rate variability (HRV). Band-pass filtering and spectral analysis can be used to extract changes in the rPPG waveform. Similarly, in [10], the FFT is used to estimate HR from the rPPG signal, and motion analysis is used to estimate BR.

B. Deep Learning Methods

HR convolutional neural network (HR-CNN) detects regions of interest (RoI) in a pretrained Convolutional Neural Network (CNN) model, extracts de-noised signals, and predicts HR using an estimator. Spetlik et al. [11] proposed end-to-end HR estimation with a single scalar value of predicted HR as the output network. Qui et al. [12] created an EVM-CNN architecture that includes face detection, feature extraction, and estimation. The RoI defined the central part of the human face and formed spatial decomposition and temporal filtering based on 68 landmarks. The CNN was used to estimate HR based on these feature images. Chen and Mcduff [13] addressed subject motion issues using DeepPhys, a deep convolutional network. To estimate the HR signal, the network learns spatial masks and extracts features from blood volume pulse (BVP) data. Yu et al. [8] used deep spatiotemporal networks to reconstruct rPPG signals from raw facial videos as well. The measured rPPG signal has peaks that correspond to the R peak of ground truth electrocardiogram (ECG) signals. The other CNN model for HR estimation developed in [14] is trained using transfer learning on images constructed from synthetic rPPG signals. The synthetic rPPG signals are generated by interpolating BVP or ECG signals.

Another paper in [15] developed and trained a 2D CNN for skin segmentation on both skin and non-skin region samples. The detected skin region was then subjected to conventional rPPG algorithms (ICA and PCA) for HR estimation. Furthermore, the RoI colour information was extracted using the Generative Adversarial Network (GAN) architecture [16]. This method was used to create a high-quality noiseless rPPG signal in order to improve HR accuracy performance.

The research in [17] combines 2D CNN with Residual Neural Network (RNN) models such as Long Short-Term Memory (LSTM) to compare the performance with other HR-CNN models. The facial input was fed into a 2D CNN, which then extracted spatial features from RGB frames of video. In the context of temporal domain, RNN was used to form spatial features. Other than that, the Siamese-rPPG algorithm is based on Siamese 3D CNN [18]. The proposed framework is intended to overcome a variety of noises on various facial appearances. For a better pulse pixels extraction, the forehead and cheek regions were chosen as the RoI to extract significant rPPG information. The predicted rPPG signals were produced by fusion branches at the intermediate layer with two 1D convolutional layers, and average pooling layer. Table I shows the summary of related works using CNN for HR estimation based on facial videos. Most of the outcome was tested on public standard datasets like PURE, MAHNOB and COHFACE.

TABLE I. SUMMARY OF RELATED WORKS USING CNN

Ref.	Methods	MAE	RMSE
11	HR-CNN	10.09	13.14
12	EVM-CNN	6.85	6.95
13	DeepPhysPCA	2.35	4.50
16	Deep-HR	3.41	0.027

Instead of proposing a new framework to improve estimation performance through the use of deep learning-based methods, more understanding of CNN-based methods is required to clarify how it works with rPPG technology. Some research has also been conducted on the constraint and sensitivity of CNN-based networks in rPPG technology. According to the paper in [19], CNN for rPPG signal extraction is a learning-based information related to PPG signals, and the training is easily affected by the delay between the video data and the ground truth data. The CNN-based methods have some limitations, such as a limited number of frames. Some frameworks are not ideal for long-term signal estimation, possibly because they are only supporting for a specific dataset.

This paper addresses HR and BR estimation using the CNN method for subjects after they have completed a series of physical exercises in order to gain more valuable insights into the effectiveness of deep learning approaches in HR and BR prediction. Based on region-based skin detection, the recorded facial videos will be fed into CNN to create a spatio-temporal map of skin region. HR and BR are expected to be estimated using the spatiotemporal map. The comparison is made with ground truth data collected by contact-based HR and BR monitoring as presented in [20].

III. METHODOLOGY

This section will go into detail about several steps, such as preprocessing facial videos to extract skin regions and training spatio-temporal networks for rPPG estimation. Further investigation is required to calculate the HR and BR from our recorded dataset.

A. Preprocessing

The steps for preprocessing are as shown in Fig. 1. First, we convert the RGB input image to grayscale colour. Then, using Haar cascade for face detection, find the RoI in the input videos. The RoI of the face is divided into four sections: the Forehead, Eyes, Cheeks (including the Nose and Mouth), and Chin. The splitting steps are used to obtain local face features which capable to form sufficient RoI within the face area [22]. In Fig. 2, only two selected regions, the Forehead (RoI1) and both Cheeks and Nose (RoI2), serve as image training sequences for the CNN model. According to [23, 24], these areas typically contain more BVP information with the highest absorption region and are less affected by non-rigid motion such as smiling or eye blinking.

Fig. 1. Region based Skin Detection on Forehead, Cheeks, and Nose Areas.

Fig. 2. The Overall Architecture from Region-based Skin Detection as an Input to the CNN and Spatio Temporal Convolutional Blocks. The Output is Single Scalar Vector of Predicted rPPG Signal.

B. Convolutional Neural Network

CNN was used specifically used to extract and estimate the single scalar vector of HR prediction. The CNN network is made up of multiple layers. Table II depicts the nine-layer CNN model structure. The first layer is a convolution kernel with a size of 5×5 and a stride of 1, which produces 64 feature maps. To reduce noise in extraction, the pool layer of the second layer used to perform maximum down-sampling of 2×2 . The next three layers are a spatio-temporal convolutional block with a 10×10 kernel in the convolution layer and a 2×2 kernel in the max-pooling layer. The high-level image features are generated by 200 feature maps. The next convolution layer has 500 feature maps, a kernel size of 4, and an average pooling layer with a 7×7 kernel. Convolution process, stride size, and pooling filter are used to minimise information loss while maintaining accurate physiological features for rPPG estimation.

The predicted rPPG signals are indicated by the output of spatio-temporal CNN from a single scalar vector. Each sample image was normalised to a size of 64×64 , with additional padding. Padding is required for all convolutions to maintain a consistent size. The non-activation ReLU function was used with a learning rate of 0.0005, a batch size of 200, and a training time period of 30.

C. Interbeat Interval

As shown in Fig. 3, peak detection is used to locate individual beats in the extracted rPPG signal. As a result, the inter-beat-interval (IBIs) is extracted from the rPPG signal. The IBIs are correspond to the time intervals between consecutive beats. Then, filters applied to the extracted IBIs to remove false positive/negative peak detections.

TABLE II. NETWORK ARCHITECTURE

CNN Layer	Layer Type	No. of Feature Map	Input Size
Layer 1	Conv.	20	64 x 64
Layer 2	mPool	20	32 x 32
Layer 3	ST Conv Block	200	16 x 16
Layer 4	ST Conv Block	200	8 x 8
Layer 5	ST Conv Block	200	8 x 8
Layer 6	ST Conv Block	200	4 x 4
Layer 7	ReLU	500	4 x 4
Layer 8	AvrgPool	16	1 x 1
Layer 9	Conv.	1	1 x 1

Fig. 3. Peak Detection of rPPG Signal.

D. Heart Rate Calculation

For valid peaks, the absolute IBI sequential difference should be less than 0.5 seconds. The HR is calculated by averaging all IBI over a time window and computing the inverse signals [21]. The IBI series is calculated as $IBI_{t_n} = t_n - t_{n-1}$ where t_n is the time of n -th detected peak. To simplify, $HR = 1/\overline{IBI}$ where \overline{IBI} is the mean of all inter-beat intervals within the time window. So, multiplying the HR in beats-per-minute by 60 yields the HR in beats-per-minute. For further analysis, the heart rate data is saved in a .csv file.

E. Respiration Rate Calculation

The normal respiration rate while people at resting condition is 12 to 20 beats per minute (bpm) [25]. Less than and more than this range are considered unstable respiration rates, indicating a slower (13bpm) or faster (>20bpm) breathing rate. Peak detection of the rPPG signal was used to estimate the BR using a time-domain technique. The duration of BR is defined as the time lag between the first and last detected peak. As a result, using spectral analysis on the estimated HR signal, the BR can be estimated. The power spectral density (PSD) was calculated, and the highest frequency amplitude within a plausible frequency range was chosen to represent the respiratory signal. The plausible respiratory frequency range was set from 0.1Hz to 0.4Hz.

F. Performance Metric Evaluation

The metrics evaluation used root mean square error (RMSE) and mean absolute error (MAE) to quantify the performance of proposed methods between predicted HR and BR rate and the ground truth. The fit standard error, or RMSE, was used to evaluate the best fitting of both estimated and ground truth data. As a result, as the RMSE decreases, so does the goodness of fit. The following equations were used to calculate the RMSE and MAE:

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N |R_i - P_i|} \quad (1)$$

$$MAE = \frac{1}{N} |R_i - P_i| \quad (2)$$

Where R_i and P_i denote as the ground truth and predicted HR and BR, respectively. While N is the total number of heartbeats and respiration rate per minute.

IV. RESULT AND DISCUSSION

A. Datasets

This work used a self-collected dataset of 80 videos, as described in [20]. A total of 20 subjects with frontal view of face videos and 4 videos from each participant were obtained. All subjects are in good health and have signed a consent form to participate in the study. The video was shot under visible lighting with a webcam and a smartphone camera. Subjects perform three different conditions: 1) relaxed mode, (2) after a walking exercise, and (iii) after going up and down stairs. After each exercise, subjects were asked to sit still, and their facial expressions were recorded. The ground truth of each subject's HR and BR were taken within 60 seconds, with the pulse sensor and pulse oximeter collecting the data and

feeding it to the Arduino microcontroller for data evaluation. The final heartbeat values were displayed on the LCD screen.

Fig. 4 shows the schematic design of the prototype to collect the benchmark value of the HR and BR. The development and testing of this prototype has been done using standard PM100 pulse oximeter model. This prototype of self-collected facial dataset will be tested with another state-of-the-art algorithm to extract the rPPG signal using CNN-based model. The CNN network was implemented using Phyton with Tensor Flow and Keras framework within Colab notebook. The proposed work is validated with our self-collection post-exercise dataset which contains facial videos of different lighting conditions and taken from smartphone or webcam. We have produced three different set of exercise mode to evaluate the proposed framework efficiency. At the same time, validate the effectiveness of our health monitoring prototype. We observed that the dataset which consists varying pose of less motion yields better accuracy in terms of HR and BR estimation. Motion artefacts and lighting variations also causing lots of noise in the extracted rPPG signal. Hence, the number of false positive or negative peak detections will increase.

B. Heart Rate Analysis

The simulation work was done in order to compare the measured HR to the predicted HR. The comparisons for the rest and post-exercise conditions are shown in the following figures. The efficacy of the proposed RoI was experimentally validated using the extracted rPPG signal for both HR and BR estimation. Fig. 5 depicts a comparison of measured and estimated HR when the subject is at rest. The estimated HR falls within the normal range of 60 to 100bpm. Fig. 6 and 7 depict a sample of the subject after exercises, which are walking and staircase exercises. The difference between measured and estimated HR for post-exercise falls within a range of more than 80 bpm. According to our observations, the estimated HR based on the CNN model agrees well with the measured HR from the prototype developed in our previous work. Our proposed method accurately calculates the changes in estimated HR from rest to post exercise.

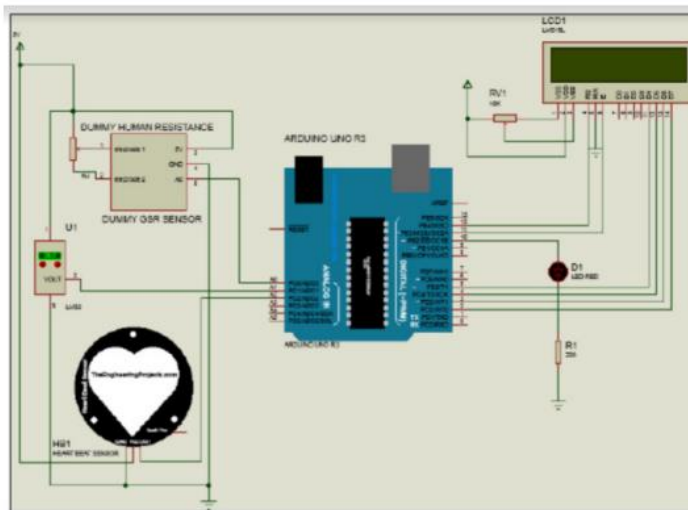

Fig. 4. The Schematic Design of the Health Monitoring Prototype [20].

Fig. 5. Measured Heart Rate against the Estimated Heart Rate while Subjects Resting Conditions.

Fig. 6. Measured Heart Rate against the Estimated Heart Rate for Subject after Walking Exercise.

Fig. 7. Measured Heart Rate against the Estimated Heart Rate for Subject after Stairs Exercise.

From the results in Table III, the RMSE and MAE are derived from the average measured of the actual HR and predicted HR for all subjects for several types of exercises. The average of actual HR for resting, walking and after stairs exercise are 87.75, 89.8 and 95.3, respectively. The MAE for our proposed method using our self-collected physical exercise dataset is very good, falling within the 2.16 ± 2.2 beats/min range. To evaluate our dataset using our proposed method, we compared it to other state-of-the-art methods based on CHROM, ICA, PCA and HR-CNN. Our proposed

method outperforms the traditional CHROM, ICA and PCA methods with low MAE and RMSE. We conclude that CNN based methods are more accurate and present relevant beats from the pulse rate series for HR estimation. We demonstrate the similar process for BR performance.

TABLE III. HR ANALYSIS BASED ON AVERAGED MEASURE, RMSE AND MAE

Method	Exercise	Predicted _{avg} HR	RMSE	MAE
CHROM[7]	Rest	75.97	11.47	5.4
	Walk	78.98	10.92	7.64
	Stairs	69.6	21.19	9.48
ICA[15]	Rest	75.2	5.22	0.97
	Walk	67.65	12.67	8.21
	Stairs	68.8	14.94	10.05
PCA[15]	Rest	85.43	9.72	3.9
	Walk	77.88	2.17	1.14
	Stairs	79.03	7.44	7.98
HR-CNN[11]	Rest	83.05	2.52	2.80
	Walk	80.65	2.55	2.91
	Stairs	88.37	2.37	2.15
Proposed Method	Rest	87.47	1.92	1.72
	Walk	80.48	2.37	2.96
	Stairs	86.1	2.64	1.8
	Overall		2.31	2.16

C. Breathing Rate Analysis

Fig. 8 depicts a comparison of measured and estimated BR when the subject is at rest. The estimated BR falls within the normal range of 15 to 20bpm. Fig. 9 and 10 show a sample of the subject after exercises, which are walking and stairwell exercises. The difference between measured and estimated BR for post-exercise falls within a range of more than 20 bpm. The curves are simulated from the extracted rPPG signals within a constant distance from the camera. ow SNR. Rapid changes of breathing rate can be detected from resting position and stairs exercise. This is accomplished by selecting the peak in the spectrum that provides the highest SNR for the pulse signal.

Fig. 8. Measured Heart Rate against the Estimated Heart Rate while Subjects at Resting Conditions.

Fig. 9. Measured Heart Rate against the Estimated Heart Rate for Subject after Walking Exercise.

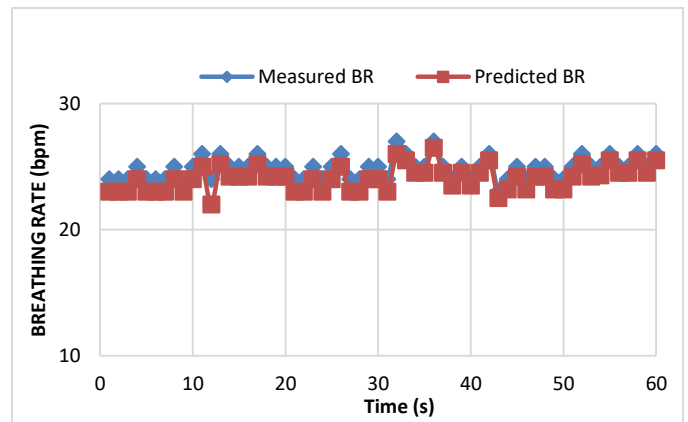

Fig. 10. Measured Heart Rate against the Estimated Heart Rate for Subject after Stairs Exercise.

Table IV derived the RMSE and MAE from the average measured of the actual BR and predicted BR for all subjects for several types of exercises. The average of actual BR for resting, walking and after stairs exercise are 19.9, 20.5 and 24.8, respectively. The MAE for our proposed method of estimating BR is between 2.16 and 2.2 beats/min. We demonstrated the effectiveness of BR peak finding interpolation and reported an acceptable MAE of less than 2 bpm. The method is compared to various state-of-the-art methods (CHROM, PCA, and ICA) and an HR-CNN-based method. For our specific post-exercise dataset, our proposed technique produced valuable findings. Although the use of the CNN framework in our suggested method does not compete with other deep learning methods, it is sufficient to examine the practicality of our prototype as a non-invasive health assessment system.

The results presented for HR and BR estimation show a high level of agreement between calculated and ground truth measurements. Based on the HR and BR analysis in Table III and Table IV, the CHROM method has the highest RMSE and MAE. CHROM is typically used to remove noise caused by light reflection via colour difference channel normalisation. For the purposes of comparison, both the ICA and PCA methods are types of BSS techniques in which independent signal sources are filtered from a mixed signal. Both ICA and

PCA improved the RMSE and MAE in this simulation work. Most rPPG research studies have a very limited post-exercise dataset. Despite the fact that several deep learning methods have been implemented in the facial-based rPPG dataset, our results validated on this self-collected post-exercise dataset are comparable to other state-of-the-art algorithm.

Based on the experimental results and performance evaluation, the proposed RoI of facial regions is effective for CNN model in forming spatio-temporal features for rPPGg signal estimation. A low percentage of MAE and RMSE indicates that the RoI selection is significant in improving the SNR for better signal quality assessment. We can assume that the majority of significant pulse pixels are located on forehead and cheeks. In practice, the most significant impediment to accurate HR and BR analysis is false peak detection. The signal was interpolated at 256 Hz to sharpen the peaks and manage the latency. Beat-to-beat pulse rate values were computed from the interbeat intervals. When calculating the interval between beats, a false peak detection appears as an incorrect beat and causes a major error in the HR and BR analysis of a healthy person. Removing unnecessary peaks may also have an impact on HR and BR estimation.

However, there are few limitations included in our study. The HR and BR estimation from the extracted rPPG signal requires further evaluation using CNN. The end-to-end approach of CNN model will be efficiently incorporated into our model's future development. Due to the limitations of the dataset used for this study, we will increase the duration of exercise and the recorded time to produce more variation in the HR and BR signal patterns. In the future, we will use adaptive RoI detection to improve the efficacy of our region-based skin detection model.

TABLE IV. BR ANALYSIS BASED ON AVERAGED MEASURE, RMSE AND MAE

Method	Exercise	Predicted _{avg} BR	RMSE	MAE
CHROM[7]	Rest	17.28	14.98	4.46
	Walk	17.85	7.99	3.46
	Stairs	22.30	13.77	2.38
ICA[15]	Rest	18.28	2.16	1.01
	Walk	18.85	3.17	1.01
	Stairs	23.3	2.95	3.93
PCA[15]	Rest	18.73	4.08	2.97
	Walk	19.30	5.09	2.97
	Stairs	23.75	2.87	1.89
HR-CNN[11]	Rest	18.52	2.53	1.89
	Walk	20.25	1.94	1.85
	Stairs	25.61	1.52	1.51
Proposed Method	Rest	19.03	2.93	0.89
	Walk	19.60	0.94	1.89
	Stairs	24.05	1.72	1.81
	Overall		1.86	1.53

VI. CONCLUSION AND FUTURE WORK

We may conclude that the results are promising enough to support the effectiveness of the CNN model in extracting relevant pulse pixels for further analysis. For HR estimation, our methods achieved an average RMSE of 2.31 and MAE of 2.16. The overall BR estimation had an average RMSE of 1.86 and an MAE of 1.53. Our methods perform well in a variety of post-exercise facial video streams under controlled lighting conditions, whether utilizing a camera or a smartphone.

In the future, an end-to-end CNN approach will be established using this dataset for simulating HR and BR estimation. This system can be upgraded to detect sudden changes in heart rate and breathing patterns. Furthermore, this system made use of a partial face region, which was expected to contribute the most blood variation. The system will be improved in real-time scenario especially when subject performing head movements.

Other factors under consideration for future research include increase the number of hidden layers in the CNN framework and optimizing the network design to achieve more promising outcomes. The number of layers, number of filters per convolutional layer, and number of neurons per dense layer could all have a significant impact and provide an automatic method of determining the best network architecture. Further investigation can be performed such as improving the CNN framework and comparing the influence of colour channel performance, particularly in terms of rPPG signal accuracy and artifact removal.

A Survey on MCT vs. DCT: Who is the Winner in COVID-19

Omar Khattab

Department of Computer Science and Engineering
Kuwait College of Science and Technology (KCST), Doha, Kuwait

Abstract—Coronavirus disease (COVID-19) is a contagious disease appeared in late 2019 and caused by a virus called SARS-CoV-2. It is a pandemic spreading across the whole world and impacts millions of people and sadly causes death. There are two main Contact Tracing Methods (CTMs) to limit and slow down any chance of transmission of it: Manual Contact Tracing (MCT) and Digital Contact Tracing (DCT). The MCT abides by the guide to World Health Organization's guidance (WHO) on COVID-19 in terms of properly applying social distancing, wearing masks, washing hands, using sanitizers, etc. while the DCT abides by the digital contact tracing applications developed by several countries. This survey is mainly focused on these CTMs and the recent proposed solutions in this field, in order to highlight their drawbacks that negatively impact on both of satisfaction and feasibility in using them. The findings in the survey will be beneficial to understand the effectiveness of CTMs and current proposed solutions, in order to develop a comprehensive smart tracking system able to cooperatively contribute with both of MCT and DCT in extremely detecting, preventing, and slowing down the spread of COVID-19 or even any other similar pandemics in the future.

Keywords—COVID-19; coronavirus disease; manual contact tracing; digital contact tracing

I. INTRODUCTION

Coronavirus disease (COVID-19) has been emerged for the first time in Wuhan [1-9], where the first reported cases were found in Huanan seafood market [10-12]. It has been reported by the World Health Organization (WHO) that there are 318,648,834 confirmed cases of COVID-19, including 5,518,343 deaths [13]. To slowing the spread of COVID-19 and protect family and community, Contact Tracing Methods (CTMs): Manual Contact Tracing (MCT) and Digital Contact Tracing (DCT) play a vital role in this respect, The MCT is a manual method [14-20] strives to [21]:

- 1) Support COVID-19 patients to stay home and self-isolate.
- 2) Alert and help people who have been in close contact with COVID-19 patients.
- 3) Follow-up them in testing, quarantine, and wearing a mask properly.

The DCT is a dynamic method [22-34] based on smartphones' applications which strives in tracking people diagnosed with COVID-19 to notify mobile users whether they

have been exposed to the virus or not. The DCT utilize several technologies to collect data [35]: cell tower location data, Quick Response (QR) code, credit card/public transit card, videos surveillance, Global Positioning System (GPS), and Bluetooth.

There are three main approaches to store users' sensitive data [36]: Centralized Approach (CA) where the data is stored on centralized servers, Decentralized Approach (DA) where the data is stored on individual mobiles, and Hybrid Approach (HA) which is combination between CA and DA. The DA aims to protect users' sensitive data where a central server plays a small role in this respect by keeping very little data [37]. The CA is more efficient [37] and more secure compared with the DA, while it is considered a single point of failure [38].

To the best of our knowledge, existing related works have not fully considered CTMs and recent proposed solutions. Therefore, this paper thoroughly surveys both of CTMs and recent proposed solutions to highlight their drawbacks that negatively impact on both of satisfaction and feasibility in using them. The rest of the paper is organized as follows: In Section II, an overview of CTMs and proposed solutions is presented: DCT and MCT. In Section III, a comprehensive comparison of CTMs and proposed solutions is presented: MCT vs. DCT, DCT approaches, and DCT proposed solutions. In Section IV, a discussion is presented. Finally, a conclusion is given in Section V.

II. OVERVIEW OF CTMS AND PROPOSED SOLUTIONS

To provide a comprehensive comparison of CTMs, this section presents lots of vital recent related works either theoretical or practical: surveys, overviews, and proposed solutions for DCT and MCT.

A. DCT

In [22], the authors have introduced a Self-Sovereign Identity (SSI) model based blockchain to address the following issues in DCT applications: privacy leakage, efficiency, and energy consumption. The effectiveness of the proposed solution has been validated by theoretical analysis.

In [27], the authors have proposed a blockchain enabled privacy preserving contact tracing scheme: BeepTrace. Numerical analysis has shown higher security and privacy, battery friendly, and globally accessible.

In [34], a framework of a blockchain, Artificial Intelligence (AI) and Internet of Things (IoT) based system for the detection of COVID-19 and distancing has been proposed. It has aimed to offer real time data sharing, security, and transparency. However, no implementation or testing provided about the framework.

In [35], an overview of several DCT applications has been conducted. It has been concluded that the DCT have had the following issues: limited Internet access in poor countries, people without smartphones, lack of signal, transparency, privacy and security.

In [39], a cross national online survey has been conducted in the UK, Republic of Ireland, and the US, in order to discover public attitudes and the acceptability of DCT. It has been concluded that that trust and privacy have been the main concerns for the adoption of DCT.

In [40], 41 countries and 23 US states have developed a total of 64 DCT applications, where they have sampled eight applications in European countries between British Isles, and mainland Europe equitably. Using various analysis (e.g., quantitative analysis and qualitative coding), it has been concluded that the DCT has required updating regularly due to governmental policies and guidelines, there have been issues in the devices, applications and their features, high battery consumption, usability should be enhanced, and users have been generally unhappy with the applications.

In [41], a detailed analysis of DCT applications for 32 countries has been presented. The proposed architecture using blockchain Hyperledger Fabric (HF) has addressed the following inherent issues related to contact tracing: security, privacy, authentication, access control, flexibility, scalability, interoperability, and efficiency.

In [42], the authors have proposed COVERT blockchain HF for COVID-19 contact tracing with keeping user's privacy. The results have proved its scalability, robustness, and efficiency in protecting privacy leakage.

In [43], the authors have proposed a blockchain platform for contact tracing with keeping user's privacy, using a Generative Adversarial Network (GAN) application. It has shown that the privacy has been addressed by iterative deleting older data from the database.

In [44], the authors have proposed a prototype of blockchain and SSI-based digital contact tracing platform, using Mystiko blockchain cluster. A performance evaluation of the platform has been conducted, where it has shown addressing issues in security, privacy, scalability, and transaction throughput features.

In [45], the authors have proposed a framework used off-chain scaling mechanism of Interplanetary File System (IPFS) for contact tracing. There a performance evaluation using Ethereum application has been conducted of the framework in terms of security, privacy, and scalability.

In [46], the authors have proposed and implemented a blockchain based system called COVID-19 Contact Tracing System (CCTS), to verify, track and detect new cases of

COVID-19, using Ethereum application. However, user's privacy and accuracy in detecting contacts of COVID-19 have not been investigated.

The DCT provides several features: accurate, fast, and low cost [47].

B. MCT

It is a traditional contact tracing method manually managed by health care providers to identify the contacts of infected individuals, interview, alert them to quarantine, and to seek a test [47]. However, the MCT has become difficult to be used due to rapid spread of COVID-19 [48], as it has been some drawbacks: relying on human memory, taking time [49], requiring trained human resources [47], [50], inefficient [51], costly, highly error prone, and not scalable [14].

The recent studies in [52] and [53] shows that the combination of MCT and DCT is more efficient for contact tracing.

III. COMPARISON OF CTMS AND PROPOSED SOLUTIONS

In Section II, plenty of recent related works have been considered: surveys, overviews, and proposed solutions of CTMs. To provide a comprehensive comparison of CTMs, in this Section, three types of comparisons are presented: MCT vs. DCT, DCT approaches, and DCT proposed solutions.

A. MCT vs. DCT

Ten factors are considered to distinguish between CTMs (MCT and DCT): time, efficiency, accuracy, cost, diagnosis, failure, scalability, reliability, dependency, and investigation. This is shown in Table I. In this competition, the DCT obviously has a full advantage over the MCT.

B. DCT Approaches

Five factors are considered to distinguish between the DCT approaches (CA, DA, and HA): data storage location, efficiency, privacy, security, and point of failure. This is shown in Table II. In this competition, the HA obviously has dominant features over the CA and DA.

TABLE I. MCT vs. DCT

Comparison	DCT	MCT
Time	Less	More
Efficiency	More	Less
Accuracy	More	Less
Cost	Less	More
Diagnosis	Fast	Slow
Failure	Low	High
Scalability	High	Low
Reliability	High	Low
Dependency	Technology	Human memory
Investigation	GPS, QR code, Bluetooth cell tower location data, credit card/public transit card, videos surveillance	Self-assessment survey

TABLE II. DCT APPROACHES

Comparison	CA	DA	HA
Data storage location	Server (S)	Mobile (M)	S & M
Efficiency	High	Low	Average
Privacy	Low	High	Average
Security	High	Low	Average
Point of failure	High	Low	Average

TABLE III. DCT PROPOSED SOLUTIONS

Paper	Year	Type of Research	Implementation	Concern	Addressing	Solution
[22]	2021	Theoretical	Analysis	n/a	Privacy, efficiency, energy consumption	SSI model based blockchain
[27]	2021	Theoretical	Analysis	n/a	Security, privacy, battery friendly, globally accessible	BeepTrace based blockchain
[34]	2021	Theoretical	n/a	Not developed	Real time data sharing, security, transparency	Framework based blockchain, AI and IoT
[35]	2020	Theoretical	Overview	Limited Internet access, people without smartphones, lack of signal, transparency, privacy, security	n/a	n/a
[39]	2021	Theoretical	Survey	Trust and privacy	n/a	n/a
[40]	2021	Theoretical	Analysis	Updating DCT regularly, issues in the devices, applications and their features, battery consumption, usability, user satisfaction	n/a	n/a
[41]	2021	Practical	HF	-	Security, privacy, authentication, access control, flexibility, scalability, interoperability, efficiency	Architecture based blockchain
[42]	2021	Practical	HF	-	Scalability, robustness, privacy	COVERT based blockchain
[43]	2021	Practical	GAN	-	Privacy	Platform based blockchain
[44]	2021	Practical	Mystiko	-	Security, privacy, scalability, transaction throughput features	SSI model based blockchain
[45]	2021	Practical	Ethereum	-	Security, privacy, scalability	Framework based blockchain and IPFS
[46]	2021	Practical	Ethereum	Privacy, accuracy	Verify, track, detect new cases of COVID-19	CCTS based blockchain

C. DCT Proposed Solutions

Five factors are considered to distinguish between the DCT proposed solutions [22, 27, 34, 35, 39-46]: type of research, implementation, concern, addressing, and solution. This is shown in Table III.

As for the type of research, it can be seen that the related works have been equitably conducted between theoretical and practical research works. This is shown in Fig. 1.

Fig. 1. Type of Research for DCT Proposed Solutions.

For the implementation, three related works are used analysis, followed by HF and Ethereum with two research works each; lastly, overview, survey, GAN, and Mystiko. This is shown in Fig. 2.

Fig. 2. Implementation for DCT Proposed Solutions.

In terms of the concern, fifteen common issues are arisen and divided into two main categories: IT's issues and user's issues. This is shown in Fig. 3.

In the addressing, eighteen common issues are arisen. It has been noticed that all the addressed issues are related to IT issues. This is shown in Fig. 4.

Finally, the most DCT proposed solutions based on the blockchain, as shown in Fig. 5.

Fig. 3. Concern for DCT Proposed Solutions.

Addressing

Fig. 4. Addressing for DCT Proposed Solutions.

Solution

Fig. 5. DCT Proposed Solutions

IV. DISCUSSION

In Section III, a comparison of CTMs has been conducted, where three types of comparisons have been presented: MCT vs. DCT, DCT approaches, and DCT proposed solutions.

For MCT vs. DCT, the DCT has shown a full advantage over the MCT in terms of time, efficiency, accuracy, cost, diagnosis, failure, scalability, reliability, dependency, and investigation, as shown in Table I.

For DCT approaches, the HA has shown dominant features over the CA and DA in terms of data storage location, efficiency, privacy, security, and point of failure, as shown in Table II.

For DCT proposed solutions, twelve research works have been conducted [22, 27, 34, 35, 39-46]. It has been noticed that all these works have been confined in introducing, enhancing or proposing DCT applications related to IT issues and user issues, as shown in Table III.

Therefore, in addition to the combination between DCT (HA approach) and MCT, it would be more effective to propose, implement and, distribute a comprehensive smart tracking system located in public places, universities, schools, hospitals, banks, airports etc. This obviously will extremely limit and slow down any chance of transmission of COVID-19 or even any other similar pandemics in the future. This is shown in Fig. 6.

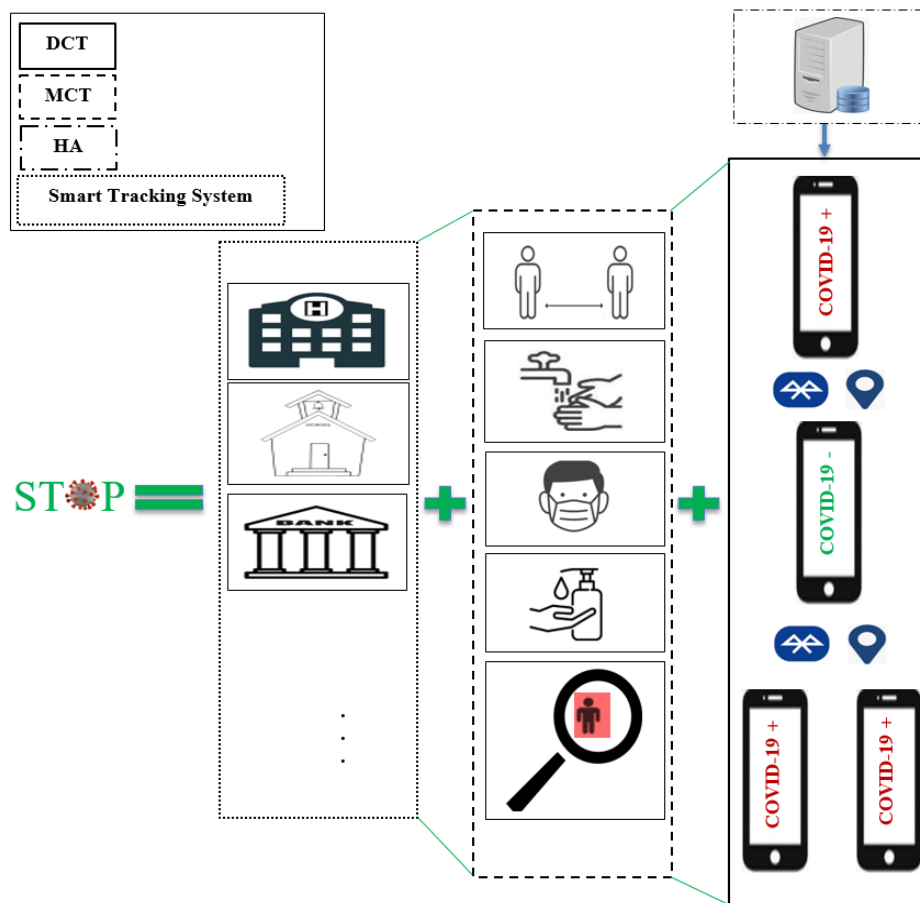

Fig. 6. Comprehensive CTM.

V. CONCLUSION

In this paper, the CTMs and the recent proposed solutions for COVID-19 have been surveyed thoroughly, where a fair comparison has been presented: MCT vs. DCT, DCT approaches, and DCT proposed solutions. For DCT proposed solutions, twelve research works have been conducted. It has been concluded that all these works have been confined in introducing, enhancing or proposing DCT applications related to IT issues and user issues.

Therefore, the competition in this paper has shown the importance of using both of MCT and DCT (HA approach), and come up with a comprehensive smart tracking system able to cooperatively contribute with them in extremely detecting, preventing, and slowing down the spread of COVID-19 or any other similar pandemics in the future.

Abstract—The interaction between academic community members in universities is fundamental in facilitating the learning management process and workflow, thereby necessitating a communication tool system that is unrestricted by time and place. Social customer relationship management as a communication tool through social media is also essential. Therefore, this research employed a mixed-method exploratory design to evaluate 2421 subjects determined based on a proportional random sampling technique from the academic community of universities in four cities in Indonesia. The data collection method used an online interview questionnaire, and the coding techniques, namely open, axial, and selective coding, as well as the value stream analysis, were used. This research found that Social Customer Relationship Management (SCRM) can be a communication tool between the academic communities in higher education. This tool can be exploited by utilizing effective social media platforms, namely Instagram, Facebook, WhatsApp, and YouTube, integrated and connected as a center for information retrieval.

Keywords—Social customer relationship management; communication tools; social media; academic client and communities

I. INTRODUCTION

The implementation of the academic community in a good university is influenced by communication from social media or Social Customer Relationship Management (SCRM) to create a committed and mutually beneficial two-way relationship between customers and the academic community. Because social media has great potential to facilitate closeness between the academic community, allows interaction with many people and customers due to the sophistication of internet-based communication that is increasingly easy and directed, facilitates interaction between users who gain value, and social media is becoming ubiquitous and essential, but this can limit the word-of-mouth interaction of marketers.

Social media that is used as a communication tool has two benefits in human life, the benefits of light and dark sides. Research conducted by Sands et al. (2019) [1] reveals the two sides of social media as a strategy for users. First, social media has a dark side: the identified risks are social media risks for individuals, communities, and organizations. Presence and

Identity load on the same factor. Presence represents concerns about the privacy of the user's presence and activity, whereas Identity reflects concerns about other people or social media entities knowing too much about the user. Apart from that, the bright side of social media is sharing, conversation, relationships, groups, reputation, and personal.

The existence of a debate between SCRM and social media, with the existence of social media, can help communication between the academic community and the students of the University. However, there are technical barriers to social media caused by the lack of facilities and the critical role in the communication process. The research from Jędrzejczyk [2], a weakness in secondary school activities is the absence of a school development strategy that will set guidelines for creating a positive image of the school through the use of social media. The school does not have an active standard-setting on social media. Their activity is limited in terms of monitoring content about them.

As Hujran et al. researched [3], social media platforms have changed how the public sector relates and interacts with its citizens. Indeed, social media offers various benefits to the public sector. However, the use of social media cannot be separated from the risk. Risks that may arise from using social media platforms in the public sector include privacy, security, and lack of control over communication channels.

The academic community in a university consists of lecturers, students, and all campus management bodies, and its involvement, along with the alumni as a supporting group, largely determines the success of a university. Students are the foundation for future environmental protection and the essence of citizens [4]. Therefore, implementers, processes, management, budgets, facilities, infrastructure, testing, evaluation, and related results are necessary to realize good academic quality. Nasution [5] stated that academic quality and resources can be measured based on scientific papers published internationally and globally and indexed by legitimate and recognized databases.

Meanwhile, a lecturer gives class lessons, provides guidance, and updates teaching materials according to scientific developments, thereby allowing students who

eventually become alumni to experience these processes for a particular time. Besides participating in classroom teaching and learning, students must do appropriate scientific work at the end of their studies. Based on their scholarship level and is either a Bachelor's, Master's, or Doctoral program, this work must ensure that the students understand and practice scientific principles and ethics [5].

According to the ASEAN Economic Community (MEA), graduation competencies must be considered to ensure comparability with university alumni domestically and abroad [5]. The ability to compete with local or international alumni depends on the execution of the student's educational process, from teaching to writing scientific papers, and supervisors without this competency will potentially produce incompetent graduates. Hence, members of the academic community, particularly lecturers or teaching staff, must become independent in conducting scientific publications internationally.

Generally, implementing a good university is inseparable from the communication process, which occasionally faces obstacles or difficulties. The term 'communication' comes from the Latin word 'communis,' which means creating togetherness or building friendship between two or more people [6]. According to Harold D. Lasswell, it is a process of delivering messages from a communicator to the communicant through the media to produce specific effects [7].

Communication is a prerequisite of human life and necessary for forming humans, groups, and organizations. Fajar [8] also stated that it aims to change behavior, opinions, attitudes, and social change. However, the university communication process occasionally experiences three main obstacles or difficulties, namely technical, semantic and behavioral barriers that need to be resolved. Technical barriers are caused by several factors, such as the lack of facilities and the necessary roles in the communication process. Social media tools that continue to develop in this field only focus on academic progress and social learning aspects of a vital tool in higher education [9]. Information can be delivered quickly with technology [10], as the sophistication of increasingly accessible and undirected internet-based communication facilitates interaction between users who gain value [11].

Social media became ubiquitous and essential [12] and eliminated the limited word-of-mouth interaction of marketers [13], thereby connecting and empowering customers alongside challenging the implementation of business on the internet. Bala et al. [14] also stated that it serves as a tool for users to interact and exchange information through online communities. Implementing CRM in a college environment includes a student-centered focus, improved customer data and process management, and increased student loyalty, retention, and satisfaction with college programs and services [15]. Social media has great potential to facilitate closeness between academic communities and customers [16] and enables interaction with many people [17]. One of which is a social media-based platform; every university has a different perception of social media-based platforms [18]. A new practice, Social Customer Relationship Management (SCRM), combines the two main concepts between social media or Web

2.0 and Traditional CRM [18], [19]. Faase et al. [20] also concurred that social CRM uses Web 2.0 services to create a committed and mutually beneficial two-way relationship between customers and the academic community.

The transformation of traditional methods into social CRM can accommodate communication between academic community members to achieve common goals. It can enable an organization or community to have real-time conversations with customers, monitor their expressions, and facilitate constructive dialogues [21]. Hence, this strategy is indispensable as a new business approach that can expand the capabilities of today's traditional CRM.

Attaining exemplary university achievements depends on the communication between lecturers, students, education staff, alumni, and other employees who can develop a creative and dynamic spirit [22]. It can trigger an increase in more meaningful interactive relationships and improve aspects of the traditional and social CRM [23]. Online communication can be seen from a person's personality; for example, extroverts convey happiness, optimism, and passion, especially about those that fascinate them. This story will appeal to people with high Openness to experience because these people are curious, open to unusual ideas, and responsive to new things [24]. Social CRM is also regarded as a customer relationship management process that provides communication through social media sites, such as Facebook, Instagram, WhatsApp, and Twitter [25].

According to the rationale above, this research aims to create the basic concept of developing Social Customer Relationship Management (SCRM) as a communication tool through social media for academic communities at universities. Social media is a platform for people to discuss their issues and opinions. Therefore, the process is a breakthrough to improve business achievement through the five domains involved, namely online community building, proactive management of interactions in social communities, online community as a method of customer engagement, the utilization of social media in CRM systems, and collection, as well as the integration and utilization of customer information [26]. According to the rationale above, this research aims to create the basic concept of developing Social Customer Relationship Management (SCRM) as a communication tool through social media for academic communities at universities. Social media is a platform for people to discuss their issues and opinions.

Before knowing the aspects of social media, people must know what social media is? Social media are computer tools that allow people to share or exchange information, ideas, images, videos, and even more with each other through a particular network. This paper covers all aspects of social media with its positive and negative effects. Focus is on particular fields like business, education, society, and youth. This paper describes how these media will broadly affect society [27]. The growing popularity of social media compelled marketers to think about this media and traditional functional marketing areas. Social media is based primarily on the internet or cellular phone based applications and tools to share information. Many social media users are more than some countries' populations today. The impact of social media

on marketing can be judged by comparing marketing before and after the introduction of social media and the type of technologies used in social media [28]. The authors also propose a hypothesis in this study, i.e., “can the social media be used as a communication tool for the academic community in Universities.”

II. BACKGROUND

The Theme of social customer relationship management has been widely studied. From the results of the author's search through the connected paper's platform related to articles on social customer relationship management, the graphic results are obtained as follows in Fig. 1.

Fig. 1. Social Customer Relationship Management Research Theme Distribution.

Source : <https://bit.ly/3lwcRtR>

From the search results, the theme of social customer relationship (SCRM) has become a research theme that is quite interested in the modern era. Before the SCRM theme emerged, the theme related to Customer Relationship Management had been studied by several previous researchers starting around the years 2010-2014, until entering 2015 the new SCRM theme emerged. However, research related to SCRM only emerged around 2015 when research conducted by Marolt [29] titled “Social CRM Adoption and its Impact on Performance Outcomes:a Literature Review” was published journal *Organizacija* Vol 48 No 4 2015.

Entering 2015 to 2021, the theme of SCRM is increasingly emerging, which can be used as a basis for related research. The author highlights the development of SCRM research themes related to communication in an organization. Research conducted by Dewanarain [30] highlights that using SCRM as a communication tool in hotels can use social media tools for customer relationship management to increase business profitability. In addition, research conducted by Al-Azzam [31] reviews the context of SCRM aimed at improving customer relationships and making customers more engaged.

Research conducted by Arora concludes that a properly implemented SCRM will result in Customer Loyalty, Customer

Retention, and Customer Satisfaction [32]. Dewanarain et al. revealed that social customer relationship management activities could trigger service process innovation in their research, leading to customer engagement with hotel brands [33].

From several previous studies related to the SCRM theme, researchers have tried to link SCRM with customer communication. However, there has been no research that tries to link SCRM as a communication tool for the academic community in higher education through social media. So that the novelty in this research is the development of previous research with the theme of SCRM as a communication tool using social media, so this research is worth doing.

III. LITERATURE REVIEW

Customer relationship management is a strategic business approach underpinned by relationship marketing theory. It is defined as a “process of acquiring, retaining, and partnering with selective customers to create superior value for the company and the customer” [34]. In 2008, CRM underwent a significant shift from a strategy that focused solely on customer transactions to one that integrates customer interactions [35]. Marketers can extract first-hand information about customers, which companies then use to achieve greater effectiveness in delivering customer value [15], [17]. Consequently, CRM was renamed social customer relationship management or CRM 2.0 [35].

Paul Greenberg defined social customer relationship management (SCRM) as a “business strategy of engaging customers through social media with the goal of building trust and brand loyalty” [36]. The introduction of social media has been very disruptive to the customer–marketer relationship; this has raised some speculations about applying traditional CRM models and theoretical concepts [37]. As pointed out by Vivek et al. (2012) and Berthon, Pitt, Plangger, and Shapiro (2012), the traditional approach entailed the firm producing value for customers. However, one of the significant effects garnered by social media is the involvement of customers in the process of value co-creation, either through reviews or in the form of user-generated content [38], [39].

Potential CRM must be applied in the e-learning domain. In this regard, the use of CRM systems is to maximize the value offered by e-learning institutions to students, thereby focusing on managing the institution–student relationship and supporting collaborative relationships with and between scholars and student workgroups [21]. CRM is a business strategy that involves customers and builds trust and brand loyalty [22]. It is defined as a philosophy and strategy where technology platforms, social media, and business rules create an open, transparent, and collaborative environment with customers to satisfy one's needs, thereby achieving mutual benefits [17]. According to Deepa & Deshmukh [23] and Greenberg [17], social CRM is an amalgamation of social media technologies, such as Facebook, Twitter, LinkedIn, YouTube, Pinterest, and other well-known applications, connecting marketers and customers using two-way interaction.

Clear business goals are inseparable from challenges that can undermine the main objective. Any technology operated on

the internet will have significant vulnerabilities regarding data security, legal risks, privacy, and even reputation. Therefore, convincing customers to engage and convert them into business promoters will be more beneficial. It allows the business world to interact effectively with customers, reducing risks and improving all aspects of customer relationships [24].

The growth of social media has significant consequences for the business. Social media have brought in a value-creation environment and information-rich and empowered customers [40]. User-generated content can influence other customers' decisions considerably[41]. Put, social networking sites (SNSs) are changing business activities. They change and reverse how consumers gather information in the decision-making process [42]. Social networking tools give firms a way to track customer feedback but also to proactively respond to customer satisfaction [43], [44].

An example of SCRM in action is seen when airlines provide customers with flight information updates using Twitter or answer customer questions via a Facebook page or when large computer manufacturers like Dell leverage SCRM to drive sales promotions. Thus, social CRM can help companies create a positive customer experience that will help develop customer loyalty and advocacy. Customers will see themselves as partners and feel that they share in the company's success. In the world of higher education, SCRM can give universities the chance to better connect with students who are accustomed to using social platforms since they are primarily from the millennial generation and grew up in the era of web 2.0 [45].

As higher education flocks to marketing, SCRM becomes an acronym rolling to the tongues of these marketing staffers. The lifetime of a university constituent is just as important and essential as that of a product consumer. At its simplest, the high-level goals of SCRM in corporations are to find new customers and maintain existing ones so they can repeat their purchases. Similar goals can be drawn in higher education: to find new students, research funders, faculty, etc., along with retaining them for an extended period of time. Retention in a higher education institution is more of being entrenched in a constituent's life and, hopefully, their legacy [9].

The use of SCRM allows the university to conduct frequent surveys to measure the students' satisfaction, allowing the university to react immediately to student demands – increasing student retention, which is of significant financial value to HEI management [46]. Thus, effective adoption and use of SCRM are of increasing importance to the running of the university [47].

IV. MATERIALS AND METHODS

This study employed a mixed-method exploratory design of qualitative research in the first stage and continued quantitative research, which develops qualitative data. Qualitative research, namely the method, can be understood as a research procedure, and qualitative research, namely the method, can be understood as a research procedure that utilizes descriptive data in the form of written or spoken words from people and actors who can be observed. Qualitative research is conducted to explain and

analyze phenomena, events, social dynamics, attitudes, beliefs, and perceptions of a person or group towards something.

Thus, qualitative research begins by developing basic assumptions and rules of thought that will be used in the research. Qualitative data, including audio recordings and transcripts of in-depth or semi-structured interviews and structured interview questionnaires, contained substantial open-ended comments, including a large number of responses to open-ended comment items [28]. This study employed a mixed-method exploratory design of qualitative research in the first stage and continued quantitative research, which develops qualitative data. The exploratory method is a research method that tends to be carried out to study a problem that has not been clearly defined and provides a good understanding of the research problem. This research method generates ideas or hypotheses for further quantitative research [48].

Qualitative research is a type of research that explores and understands the meaning of several individuals or groups of people originating from social problems. Quantitative research is a type of research that connects variables by requiring researchers to explain how variables affect other variables [49] and the respondents were members of university academic communities, particularly students, lecturers, education staff, and alumni, spread across four provinces in Indonesia, namely South Sumatra, Lampung, Bengkulu, Bangka Belitung. The problem in this research is how to promote higher education to the point where it reaches the intended target, namely students who will enter college through social media. In this study, it can be concluded that this research uses qualitative research methods and then continues with quantitative research, aiming that SCRM in universities can be used as a communication tool for the academic community. The following is a description of the flow in this research in Fig. 2.

Fig. 2. Research Flow.

The respondents were determined through John Creswell's technique [50], which suggested 350 subjects for survey research using a proportional random sampling method. Then, the data were collected through an online interview questionnaire on the Google Form platform. It was arranged based on open and closed interview techniques, which respectively allowed the expression of respondents through individual response sentences and provided answers to be chosen [50]. A structured interview guide was used separately from the research questions in this study because this study used two methods at once. Thus, structured interview guides were used in a qualitative setting, while mixed questions were used in a quantitative setting.

This research also employed a coding technique consisting of open, axial, and selective coding stages. Open coding is a process of breaking down data, studying it one by one, comparing, and conceptualizing data. So the goal at this stage is to name and categorize phenomena through data scrutiny. Axial coding is a procedure where data is put back in a new way after open coding by making connections between categories. Selective coding is selecting core categories,
